**Materials/methods:** We performed a systematic review and meta-analysis to evaluate the proportion of patients receiving antibiotics in outpatient primary care across LMICs. PubMed, Embase, Global Health and the Cochrane Library were searched for relevant publications from Jan 1, 2010 to Apr 4, 2019. Cross-sectional studies conducted in LMICs reporting data on medicine use in primary care were eligible. We used random-effects meta-analysis with Freeman-Tukey transformation to calculate pooled prevalence estimates of antibiotic prescribing and conducted several subgroup analyses. To evaluate between-study heterogeneity we calculated the I² statistic, generated prediction intervals and used random-effects meta-regression. The WHO AWaRe [Access–Watch–Reserve] framework was adopted to classify antibiotics according to their potential for selecting resistance. An existing risk-of-bias assessment tool for prevalence studies was adapted for use in our review.

**Results:** We included 41 studies conducted across 22 LMICs that reported the proportion of drug prescriptions containing antibiotics or the number of patients receiving antibiotics [the latter resulted comparable to the former as all patients received a drug prescription]. Most studies were performed in the public sector and in urban areas, and 83% used records abstraction to capture prescription details. The pooled prevalence proportion of antibiotic prescription was 51% [95% CI: 50-52], with a prediction interval ranging from 44 to 58%. Estimates were consistent across studies, and – in studies including all-comers in outpatient care - almost always exceeded the WHO recommended threshold of 30% antibiotic usage. Fourteen studies provided details on individual antibiotics: Access-group antibiotics usually represented >60% of the total, and Watch-group antibiotics [i.e. with high resistance potential] were extensively employed in Mexico [90.3%], China [78.4%] and Pakistan [47.8%].

**Conclusions:** Antibiotics are largely prescribed in outpatient primary care across LMICs. Although we would benefit from better quality data on inappropriate antibiotic use, urgent action is needed to improve prescription practices, starting from the integration of the WHO treatment recommendations and the AWaRe classification into national guidelines.

Abstract 2717

**Diversity of methicillin-resistant staphylococci among wild Iberian hares: detection of mecA-methicillin-resistant staphylococci strains**

Vanessa Silva*, José Eduardo Pereira1, Luís Maltez1, Euguénia Ferreira2, Vera Manageiro3,4, Manuela Caniça2, Jose Luís Capelo5, Gilberto Igrejas1, Patricia Poeta1

1University of Trás-os-Montes and Alto Douro, Vila Real, Portugal, 2National Health Institute Dr. Ricardo Jorge, Lisboa, Portugal, 3National Reference Laboratory of Antibiotic Resistances and Healthcare Associated Infections, Department of Infectious Diseases, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal, 4Centre for the Studies of Animal Science, Institute of Agrarian and Agri-Food Sciences and Technologies, University of Porto, Porto, Portugal, 5Universidade NOVA de Lisboa, Lisboa, Portugal

**Background:** Information on the incidence of MRSA in the environment and, in particular, in wild animals, is scarce. The presence of MRSA strains in wild animals, including game species, may represent a serious threat to human and animal health. The Iberian hare is one of the most emblematic game species of Portugal and equally important in an ecological context, as they also feed various species of animal predators. In this study, we investigated the prevalence of methicillin-resistant staphylococci (MRS) in wild hares (*Lepus granatensis*), focusing particularly on MRSA strains.

**Materials/methods:** Samples from 83 wild hares were collected during the hunting season from September to December 2018. Isolation of MRS was accomplish using ORSAB medium with 2mg/L of oxacillin. The susceptibility of the isolates was tested against 14 antimicrobial agents. The presence of resistance and virulence genes was studied by PCR. *S. aureus* strains were further characterized by MLST, *agr*, *spa* and SCCmec typing.

**Results:** From the 83 wild hares analyzed, 15 MRS were isolated. More than half of the staphylococci species were identified as *S. sciuri* (*n*=8), followed by *S. aureus* (MRSA) (*n*=3), *S. vitulinus* (*n*=2), *S. lentus* (*n*=1) and *S. cohnii* subsp. *urealyticus* (*n*=1). All strains harbored the *mecA* gene responsible for the methicillin resistance. MRS isolates were coagulase negative and showed low levels of resistance. Three MRSA isolates were found, one of which had a multidrug resistance profile with resistances to β-lactams, aminoglycosides, macrolides and lincosamides. All MRSA strains were ascribed to ST2855, t1190 and SCCmec type III.

**Conclusions:** Although MRSA carriage rate was relatively low (3.6%), this frequency may be considered relevant since Iberian hares are wild free-living animals which are not treated with antibiotics and are on the bottom of the food-chain. Therefore, MRSA carriage by these animals may be explained by the uptake of these strains or resistance determinants from the natural environment. The potential of MRSA strains to survive in different ecological niches and colonize different hosts, in particular wild animals and game species, is considered an important emerging threat and ongoing MRSA surveillance in wildlife is becoming essential.

Resolution of discrepant results observed during the clinical evaluation of investigational use only prototype of the BIOFIRE FILMARRAY Blood Culture Identification 2 (BCID2) panel

Kerrin Koch1, Iryna Kavetska1, Tanner Robinson1, Jeremiah Antosch1, Jessica Stone1, Kristen Holmberg1, Yang Lu1, Jake Peterson1, Zhenmei Lu1, Margarita Rogatcheva1, Usha Spaulding*1

1BioFire Diagnostics, LLC, Salt Lake City, United States

Abstract third-party references: BioFire Diagnostics, LLC

Background: The BioFire® FilmArray® Blood Culture Identification 2 Panel is a rapid diagnostic test that provides results for 7 fungal and 26 bacterial bloodstream pathogens as well as 10 bacteria-associated antimicrobial resistance (AMR) genes from positive blood culture (PBC) samples. A multi-center prospective clinical evaluation using an investigational-use-only (IUO) version of the Panel yielded an overall sensitivity of 99.2% and specificity of 99.6% for pathogen identification. All BCID2 Panel organism assay results that were discordant with the reference method were investigated.

Materials/methods: At 7 US and 2 EU sites, 1074 residual PBC were enrolled prospectively. The reference method for evaluation of the BCID2 Panel organism assay performance was microbial culture performed at clinical sites as part of routine patient care. All false positive (FP) and false negative (FN) results were investigated using alternate PCR assays and confirmed by sequencing.

Results: Overall, 74 discordant results involving 16 bacterial and 3 fungal assays were investigated. In all 54 FP cases, 18 from polymicrobial samples, the presence of the detected analyte in the PBC was confirmed by sequencing. Of the 20 FN results, 7 were attributed to isolate misidentification by the clinical laboratory; these were resolved as true negative results by sequencing. Low analyte level (below the assay’s limit-of-detection) was determined to be the root cause of 9 FN results; 8 of which were encountered in PBC samples identified as polymicrobial by the reference method. Currently, 4 FN cases remain unresolved. Notably, 38/74 (51.3%) discrepancies needing investigation involved Staphylococcus epidermidis. In 26/29 FP cases, S. epidermidis was not recovered by culture but was sequenced from the PBC. Nine discrepancies (6 FN, 3 FP) were caused by incorrect identification of the Staphylococcus species recovered by the clinical laboratory. Low analyte titers in polymicrobial PBC was responsible for the remaining 3 FN results.

Conclusions: With 61/74 discordant results resolved favorably, the BCID2 Panel would have yielded an overall success rate of 99.8%. Therefore, the BCID2 Panel is expected to provide highly accurate identification of causative agents of bloodstream infections.

Data presented are from assays that have not been cleared or approved for diagnostic use.

1Sorbonne Université, INSERM, Institut Pierre Louis d’Épidémiologie et de Santé Publique (iPLESP), AP-HP Pitié Salpêtrière Hospital, Department of Virology, Paris, France, 2CHU Gabriel Toure, Département de Gynécologie-Obstétrique, Bamako, Mali, 3CERKES, Kenedougou Solidarité, Sikasso, Mali, 4CHU Gabriel Toure, Département de Biologie Médicale, Bamako, Mali, 5Université des Sciences Techniques et des Sciences Techniques de Bamako, USTTB, Centre de Recherche et de Formation sur le VIH et la Tuberculose SEREFO, Bamako, Mali, 6University of Paris, IAME & St Louis Hospital, Department of Bacteriology, Associated Lab of the National Reference Center for bacterial STIs, Paris, France, 7CHU de Bordeaux and Univ. Bordeaux, Department of Bacteriology, National Reference Center for bacterial STIs, Bordeaux, France, 8Fondation GSK France, Marly le Roi, France, 9Hopital Régional de Tombouctou, Tombouctou, Mali, 10CHU Gabriel Toure, Département de Pédiatrie, Bamako, Mali, 11Northwestern University, Institute for Global Health, Illinois, United States

Background: Sexually transmitted infections (STIs) in Africa remain a public health concern and little studies have been conducted to assess their prevalences in Mali. We performed a cross-sectional study including women from Sikasso, Mali, to assess viral human papillomavirus [HPV], herpes simplex virus [HSV-1 and 2], bacterial STIs [Chlamydia trachomatis [CT], Mycoplasma genitalium [MG], Neisseria gonorrhoeae [NG]] and Trichomonas vaginalis [TV] prevalences and risk factors associated with.

Materials/methods: Women HIV-infected (n=44) or HIV-uninfected (n=96) and screened for STIs in Kenedougou Solidarité community health center were included. For each one, liquid-based cytology and serum were collected. Socio-demographic data including age, marital status, marital age, education level and contraception were collected. HPV-testing was performed with the AnyplexII HPV28 (Seegene), HSV-1/2-serology and DNA genital detection with LIAISON® HSV-1 IgG/HSV-2 IgG (DiaSorin) and artus® HSV-1/2 RG PCR kit (Qiagen), respectively, and STI screening with Allplex STI Essential kit (Seegene).

Results: Median [IQR] age of women included was 37 [29-44] years and the majority (78%) was married with a marital median age of 19 [17-22] years. Forty-one (35%) were polygamous, 111 (77%) did not use contraception and 113 (78%) reached primary school or less. Overall, high-risk HPV (hrHPV) prevalence was 63%. Each woman harbored in median 1 [0-2] different hrHPV. HPV31 was the most prevalent (28%) followed by HPV56 (25%) and HPV52 (n=26, 18%). HPV16 and HPV18 prevalence was respectively 9.7% and 7.6%. Prevalence of HSV-1 and HSV-2 was respectively 92% and 46%, and of other STIs as follow: CT: 4.2%, MG: 9%, NG: 1.4% and TV: 6.9%. Among HSV-seropositive patients, 7 [15%] were positive for HSV2-DNA but none for HSV1-DNA in the genital tract. Among parameters analyzed, prevalence of hrHPV and HSV-2 infection were higher among HIV-infected women (77% versus 55%, p=0.012 and 84% versus 32%, p<0.001, respectively). HSV-2 infection was also higher among patients with hrHPV infection (56% versus 37%, p=0.05) and HIV-prevalence tended to increase with decreasing education level (p=0.055).

Conclusions: Some STIs are more prevalent in HIV-infected women, as previously reported. However, both viral and bacterial STIs were frequent and improvement of systematic screening and treatment are needed in Mali.

Abstract 2724

Phenotypic testing of ceftriaxone susceptibility on the Pheno system in characterised Enterobacterales

Amira Bhalodi*1, Nico Magnano1, Romney Humphries3

1Accelerate Diagnostics, Inc., Tucson, United States

Background: Various methods to detect extended-spectrum beta-lactamase (ESBL) Enterobacterales are utilized by clinical laboratories. However, both CLSI and EUCAST support the use of current breakpoints for cephalosporins and aztreonam in lieu of ESBL testing as MIC is understood to be the in vitro predictor of clinical treatment outcomes for Enterobacterales. Despite in vitro activity, clinical data suggest the use of beta lactam/beta lactamase inhibitor combinations for bloodstream infections due to ceftriaxone (CRO) non-susceptible (NS) isolates as less favorable than definitive carbapenem therapy. Earlier detection of these organisms can help guide antibiotic therapy. The objective of this study was to compare the performance of the Accelerate PhenoTest™ (AXDX) CRO susceptibility to reference broth microdilution (BMD) for beta-lactamase producing Escherichia coli, Klebsiella pneumoniae, and Proteus mirabilis.

Materials/methods: 37 characterized E. coli, K. pneumoniae, and Proteus mirabilis isolates obtained from ARLG Virtual Biorepository, CDC Antibiotic Resistance Isolate Bank, and Accelerate Diagnostics frozen clinical isolate collection were utilized. Clinical and Laboratory Standards Institute (CLSI) broth microdilution (BMD) in triplicate was performed on each isolate as the reference method. The CLSI ESBL confirmatory disk test utilizing cefotaxime, cefotaxime plus clavulanate, ceftazidime, and ceftazidime plus clavulanate (BD Diagnostics Systems, Sparks, MD) was also performed in triplicate. Species identification and AST was also performed on the AXDX according to the manufacturer’s instructions. CLSI 2019 breakpoints were used to assess interpretation.

Results: In a collection of primarily CRO resistant isolates (29/37, 78%) overall CRO categorical agreement (CA) of AXDX was 97.3% (36/37) compared with reference BMD due to 1 minor error. The CLSI ESBL disk test resulted in 1 false negative (ESBL + AmpC) and 1 false positive (original-spectrum beta lactamase (OSBL)) (Table 1).

<table>
<thead>
<tr>
<th></th>
<th>AXDX CRO CA (%)</th>
<th>BMD CRO NS</th>
<th>ESBL Disk Test</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESBL±AmpC (n=23)</td>
<td>95.6%</td>
<td>23/23</td>
<td>22/23 positive</td>
</tr>
<tr>
<td>OSBL+AmpC (n=6)</td>
<td>100%</td>
<td>6/6</td>
<td>0/6 positive</td>
</tr>
<tr>
<td>OSBL (n=8)</td>
<td>100%</td>
<td>0/8</td>
<td>1/8 positive</td>
</tr>
</tbody>
</table>

Conclusions: AXDX provided accurate detection of CRO susceptibility across a collection of isolates with various genotypes. ESBL production is highly correlated to CRO non-susceptibility. Therefore, earlier phenotypic detection of CRO susceptibility may help expedite the optimization of antibiotic therapy.

In vitro activity of lefamulin against isolates commonly causing community-acquired pneumonia collected during the SENTRY surveillance programme 2015–2019 in Europe

Susanne Paukner1, Steven F Gelone2, Sj Ryan Arends3, Helio S. Sader3

1Nabriva Therapeutics GmbH, Vienna, Austria, 2Nabriva Therapeutics US, Inc., King of Prussia, United States, 3JMI Laboratories, North Liberty, United States

Abstract third-party references: Funded by Nabriva Therapeutics

Background: Lefamulin, the first-in-class systemic pleuromutilin antibacterial, has been recently (August 2019) approved in the United States for use as an intravenous (IV), oral, or IV-to-oral switch monotherapy in adults with community-acquired bacterial pneumonia. We evaluated the in vitro activity of lefamulin and comparators against typical CAP pathogens collected in Europe in 2015–2019.

Materials/methods: Overall, 7560 clinical isolates (1/patient) were collected in Europe [41 sites, 19 countries] in 2015–2019, from patients with community-acquired respiratory tract infections or hospitalized with pneumonia (74.8%), bloodstream infections (15.1%), skin/soft tissue infections (8.5%), and other infections (1.7%). MICs were determined using reference (CLSI) broth microdilution methods; susceptibility was determined applying EUCAST (2019) breakpoints, and, for lefamulin, FDA interpretive criteria [https://www.fda.gov/drugs/development-resources/antibacterial-susceptibility-test-interpretive-criteria].

Results: Lefamulin demonstrated potent antibacterial activity against all tested pathogens and was unaffected by resistance to other antibacterial classes (Table). While 99.9% of Streptococcus pneumoniae isolates were susceptible to lefamulin (MIC50/90 of 0.06/0.12 mg/L, susceptible breakpoint of ≤0.5 mg/L), susceptibility rates of other antibacterials commonly used to treat CAP were lower (penicillin, 71.8%; azithromycin, 76.3%; tetracycline, 78.4%; and moxifloxacin, 98.4%), though rather consistent over time. Similarly, 99.5% of Staphylococcus aureus isolates were susceptible to lefamulin (MIC50/90, 0.06/0.12 mg/L, susceptible breakpoint [methicillin-susceptible S. aureus] of ≤0.25 mg/L), whereas susceptibility rates for the comparators were lower for S. aureus overall and particularly for methicillin-resistant S. aureus [% in brackets]: 73.3% [40.7%] for azithromycin, 96.9% [84.9%] for cefaroline, 82.2% [29.5%] for moxifloxacin, and 96.1% [92.7%] for doxycycline. Haemophilus influenzae (17.2% β-lactamase positive) and Haemophilus parainfluenzae isolates were largely susceptible to all comparators except trimethoprim-sulfamethoxazole (64.6% and 78.8% susceptible, respectively). Applying the susceptible breakpoint of ≤2 mg/L, 99.6% of H. influenzae isolates were susceptible to lefamulin (MIC50, 0.5/1 mg/L). Moraxella catarrhalis isolates were susceptible to all comparators and inhibited by lefamulin concentrations of ≤0.12 mg/L [MIC50/90 of 0.06/0.12 mg/L].

Conclusions: Lefamulin demonstrated potent in vitro activity against bacterial pathogens that commonly cause CAP and were isolated in Europe over the last 5 years. This activity was unaffected by resistance to other antibiotic classes and particularly those commonly used to treat CAP, including macrolides, β-lactams, fluoroquinolones, and tetracyclines.

Identification and clinical significance of Mycobacterium avium complex isolates in a university hospital in a 13-year period

Fanourios Kontos*,1, Georgios Skyllas2, Ioanna Kouva1, Ioanna Korbila2, Effrosyni D. Manali2, Anastasia Antoniadou3, Spyridon Papiris2, Spyros Pournaras1

1Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, , Athens, Greece, 2"Attikon" University Hospital, Athens Medical School, National and Kapodistrian University of Athens, Athens, Greece, 3Attikon University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Mycobacterium avium complex (MAC) includes a group of mycobacterial pathogens most commonly isolated from respiratory samples. MAC infection can also result in lymphadenitis and disseminated disease in both immunocompromised and immunocompetent patients. This retrospective study assessed the microbiological characteristics, the clinical relevance and the experience of molecular identification of MAC isolates recovered from patients in Attikon University Hospital, Athens Greece over the 13-year period December 2006 to November 2019.

Materials/methods: We studied 83 MAC single-patient isolates that were identified with the Genotype CM and Genotype NTM-DR assays (Hain-Lifescience). Sequencing analysis of 16S rDNA (1500-bp) and hsp65 (440-bp) genes was performed when necessary. The criteria from the American Thoracic Society/Infectious Disease Society of America (ATS/IDSA 2007) were applied to determine the clinical relevance of recovered isolates.

Results: Thirty-five strains identified as M. avium, 41 as M. intracellulare [32 as M. intracellulare subsp intracellulare and 9 as M. intracellulare subsp. chimaera], and 5 as M. marseillense. The CM and NTM-DR assays identified correctly all M. avium and M. intracellulare strains, while misidentified all M. marseillense strains as M. intracellulare. On the other hand, NTM-DR assay identified correctly all 9 M. intracellulare subsp. chimaera strains. Of the 83 MAC strains, 70 [84.3%] were recovered from respiratory specimens: 25 [71.4%] M. avium, all 41 M. intracellulare, and 4 [44.4%] M. marseillense and 13 [15.7%] MAC strains from extrapulmonary specimens: 12 M. avium and 1 M. marseillense. Of the 70 MAC strains recovered from respiratory specimens, 41 [58.6%] were considered as clinically significant according to the ATS/IDSA criteria: 17 M. avium, 3 M. marseillense, 16 M. intracellulare subsp intracellulare and 5 M. intracellulare subsp. chimaera. For 19 of them [46.3%], smears were positive for acid-fast bacilli. The remaining 29 MAC strains were not considered as clinically significant, probably representing contamination. All 13 MAC strains that were recovered from extra-pulmonary specimens were considered as clinically significant: 4 patients suffered from skin and soft tissue infection and 9 patients from AIDS and disseminated infection.

Conclusions: Of the 83 recovered MAC stains, 54 [65.1%] were linked with human disease. Our findings suggest that the combined use of molecular commercial identification tests with sequencing analysis improves the ability to correctly identify the recovered MAC strains.

In vitro activity of imipenem/relebactam against Klebsiella pneumoniae and Pseudomonas aeruginosa isolates from patients with respiratory tract infections in the Asia/Pacific region: SMART 2015-2018

Sibylle Lob1, Krystyna Kazmierczak*1, Wei-Ting Chen2, Yi Vonn Khoo1, Kanchan Balwani3, Katherine Young4, Mary Motyl5, Dan Sahm1

1IHMA, Schaumburg, United States, 2MSD, Taiwan, Taipei, Taiwan, 3MSD, Malaysia, Petaling Jaya, Malaysia, 4MSD, Singapore, Singapore, 5Merck & Co., Inc., Kenilworth, United States

Background: Relebactam (REL) inhibits class A and C β-lactamases and was approved in the USA in combination with imipenem (IMI) and cilastatin for treatment of complicated intraabdominal and urinary infections. We evaluated the activity of IMI/REL against isolates collected < and ≥48 hours post-admission for the SMART surveillance program in Asia/Pacific from patients with lower respiratory tract infections (LRTI).

Materials/methods: In 2015-2018, 57 clinical laboratories in Australia, Hong Kong, India, South Korea, Malaysia, New Zealand, Philippines, Taiwan, Thailand, and Vietnam each collected up to 100 consecutive gram-negative pathogens from LRTI. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints, except for IMI/REL for which FDA breakpoints were used. Isolates testing with IMI MIC ≥2 mg/L (K. pneumoniae, KP) or ≥4 mg/L (P. aeruginosa, PA) were screened for β-lactamase genes.

Results: The 5 most common species collected were PA (n=3550, 29.1% of all collected), KP (n=31 20, 25.6%), A. baumannii (n=1356, 11.1%), E. coli (n=1140, 9.4%), and S. maltophilia (n=490, 4.0%). The table shows the activity of IMI/REL and comparators against KP and PA stratified by length of hospital stay at time of specimen collection.

N/A, not applicable

Among IMI-resistant KP collected < and ≥48 hours post-admission (n=138), 50.7% carried metallo-β-lactamases (MBL), 39.1% KPC, 6.5% OXA-48-like carbapenemases, 2.2% AmpC extended-spectrum β-lactamases (ESBL), and in 1.4% no acquired β-lactamases were detected. 37% of IMI-resistant KP were IMI/REL-susceptible (n=52), of which 98.1% carried KPC and 1.9% only AmpC. Among all IMI-resistant PA (n=603), 13.5% carried MBL, 2.2% carried only ESBL, 0.7% GES-carbapenemases, and in 83.7% no acquired β-lactamases were detected. 64.0% of IMI-resistant PA were IMI/REL-susceptible (n=386), of which 1.0% carried only ESBL and in 99.0% no acquired β-lactamases were detected.

Conclusions: KP and PA were the two most common species in this collection of LRTI isolates from Asia/Pacific. IMI/REL maintained activity against ≥90% of isolates collected ≥48 hours post-admission, which generally showed lower susceptibility to the tested agents. Only amikacin and colistin showed comparable or higher activity. IMI/REL could provide an important treatment option for patients with LRTI in the Asia/Pacific region.

Background: It is expected that new antiretroviral regimens reduce drug resistance in treated subjects, even if this hypothesis remains to be evaluated in recent years. Resistance and its correlates were studied in treatment failing patients in a comprehensive database over the 2009-2018 period.

Materials/methods: We analyzed 3,094 HIV-1 pol sequences and 1,058 integrase sequences from subjects enrolled in 21 Centers of the Italian ARCA database. Patients were included when they had viremia > 50 copies/mL and received a resistance genotypic test on plasma after at least 24 weeks of treatment. Mutations were identified through International AIDS Society 2019 drug resistance mutations lists and the Stanford HIVdb algorithm. Five periods of study were evaluated, one for each biennium. Trends and correlates of resistance were analyzed by Cochran-Armitage, Chi squared tests and logistic regression models.

Results: Males were 63.2%; non-B subtypes increased from 13.1% to 23.8% from the first to the last biennium (p<.001). Resistance to NRTIs, NNRTIs and PIs declined, from 61.7% to 43.5% (p<.001), from 44.7% to 40.4% (p=.024) and from 36.4% to 30% (p=.001), respectively. INSTI resistance declined from 31% to 20.8% (p=.002), when Stanford HIVdb was adopted for moderate or high grade resistance. A reduction was observed for many RT and PR mutations, such as TAMs, M184V, K103N, M46I, I47V, I54L/M, L76V, V82A/T/L, I84V and L90M, while a significant increase was found for Y181C. In the integrase region we observed the decrease of G140S, T149C, D148H and the increase of S147G and Q148R. In the multivariate analysis, the risk of resistance was not influenced by epidemiological correlates such as subtype, while it decreased significantly over time (OR per 1 biennium higher 1.13, 95% CI 1.10-1.15) and it was associated with previous antiretroviral treatments (OR per 1 more previous antiretroviral line 0.77, 95% CI 0.70-0.85).

Conclusions: A stable reduction of acquired resistance was observed over the last decade, suggesting that new antiretroviral regimens and standards provide a higher genetic barrier, with better maintenance of treatment options. Nonetheless, some concerns remain for patients who failed several previous regimens, reinforcing the need for surveillance of resistance in subjects experiencing virological failures.

Abstract 2731

Assessment of quantitative composition of Bacteroides fragilis in children with coeliac disease at the time of diagnosis and after a six-month period of diet

Agnieszka Krawczyk*1, Dominika Salamon1, Kinga Kowalska-Duplaga1, Zofia Grzenda-Adamek1, Agnieszka Koziół-Kozakowska2, Krzysztof Fyderek2, Tomasz Gosiewski2

1Jagiellonian University Medical College, Division of Molecular Medical Microbiology, Department of Microbiology, Faculty of Medicine, Krakow, Poland, 2Jagiellonian University Medical College, Department of Pediatrics, Gastroenterology and Nutrition, Faculty of Medicine, Krakow, Poland

Abstract third-party references: Supported by National Science Centre in Poland grant no.2017/26/E/NZ5/00266

Background: The genetic background (DQ2 or DQ8 haplotypes encoding specific antigens in the HLA region) is necessary to induce symptoms of celiac disease (CD), however, a triggering factor is required. Recently, an important role in CD etiology has been attributed to intestinal dysbiosis. It is supposed that some microorganisms occurring in patients’ intestines, may interact with gluten, producing highly immunogenic peptides activating the immune response which triggers CD symptoms. Bacteroides fragilis belongs to the gut microbiota but in case of failure of host defense mechanism or intestinal dysbiosis this commensal microorganism may turn into pathogenic inhabitant. The potential pathogenicity of B.fragilis is related to the expression of a variety of virulence factors, including proteolytic and other hydrolytic enzymes. Perhaps, changes in number of B.fragilis and associated virulence factors may contribute to initiating CD. The aim of this study was assessment of quantitative composition of B.fragilis in children with CD at the time of diagnosis and after a six-month period of diet compared to the healthy group.

Materials/methods: The materials were stool samples taken from children hospitalized in the years 2018-2019 in University Children’s Hospital of Cracow, Poland:

I. with CD at the moment of diagnosis (n=32)
II. with CD 6 months after diagnosis (n=14)
III. healthy, being a control group (n=23)

The bacterial DNA was isolated from the samples. Amplification by the quantitative polymerase chain reaction (qPCR) was used to determine the number of B.fragilis in the group’s I-III.

Results: In group I, number of B.fragilis was significantly higher (1.77x10^9 CFU/g) compared to the control (3.64x10^8 CFU/g, p=0.014). In group II number of B.fragilis decreased (1.15x10^9) but observed changes were not statistically significant (p>0.05).

Conclusions: Obtained results showed that patients with CD at the moment of diagnosis were characterized by increased colonization of B.fragilis. Perhaps in the case of people who have genetic predisposition for the development of CD these bacteria may contribute to the induction of inflammation, which may be confirmed by reducing their number after a period of gluten-free diet.

**Abstract 2733**

**In vitro activity of imipenem/relebactam against Gram-negative organisms collected from patients in Colombia: SMART 2015-2018**

Sibylle Lob1, Krystyna Kazmierczak1, Jacqueline Pavia2, Katherine Young3, Mary Motyl1, Dan Sahm1

1IHMA, Schaumburg, United States, 2MSD, Colombia, Bogotá, Colombia, 3Merck & Co., Inc., Kenilworth, United States

**Background:** Relebactam (REL) inhibits class A and C β-lactamases and was approved in the USA in combination with imipenem (IMI) and cilastatin for the treatment of complicated intraabdominal and urinary tract infections. We evaluated the activity of IMI/REL against non-Morganellaceae Enterobacterales (NME) and Pseudomonas aeruginosa isolates collected as part of the SMART surveillance program in Colombia.

**Materials/methods:** In 2015-2018, 7 clinical laboratories in Colombia each collected up to 250 consecutive aerobic or facultative gram-negative pathogens from various infection sources. MICs were determined using CLSI broth microdilution and interpreted with CLSI breakpoints. US FDA breakpoints (≤1/4 mg/L, susceptible; 2/4 mg/L, intermediate; ≥4/4 mg/L, resistant) were applied to IMI/REL. Multidrug-resistance (MDR) was defined as nonsusceptibility (intermediate or resistant MIC) to ≥3 of the following sentinel drugs: amikacin, aztreonam, cefepime, ceftazidime (NME only), ciprofloxacin, colistin, imipenem, and piperacillin-tazobactam. Isolates testing with IMI MIC ≥2 mg/L (NME) or ≥4 mg/L (P. aeruginosa) were screened for β-lactamase genes (excluding NME from one site in Colombia).

**Results:** The susceptibility to IMI/REL and comparators of all NME, all P. aeruginosa, and resistant phenotypes is shown in the table.

</table>

IMI, imipenem; REL, relebactam; FEP, cefepime; CAZ, ceftazidime; ATM, aztreonam; P/T, piperacillin-tazobactam; CIP, ciprofloxacin; AMK, amikacin; CST, colistin; NS, nonsusceptible; MDR, multidrug-resistant.

Among all collected NME, 8.4% were KPC-positive and 0.6% were metallo-β-lactamase (MBL)-positive. Among 47 characterized IMI/REL-nonsusceptible NME, 27.7% carried MBL, 12.8% were KPC-positive and MBL-negative, 2.1% carried only an acquired AmpC, and in 57.4% of isolates no acquired β-lactamases were detected. Among all collected P. aeruginosa, 9.1% were KPC-positive and 4.8% were MBL-positive; among 68 characterized IMI/REL-nonsusceptible P. aeruginosa, 29.4% carried MBL, 38.2% were KPC-positive and MBL-negative, and in 32.4% no acquired β-lactamases were detected.

**Conclusions:** Among isolates collected in Colombia, IMI/REL was active against >97% of NME and >83% of P. aeruginosa, 11-23 and 9-20 percentage points, respectively, higher than tested comparator β-lactams. IMI/REL maintained activity against >82% of NME and >43% of P. aeruginosa isolates that were nonsusceptible to individual β-lactams or MDR. IMI/REL could provide an important treatment option for patients in Colombia with infections due to resistant gram-negative organisms.

Abstract 2735

5-year Surveillance of Lefamulin against Gram-positive Cocci Collected from Acute Bacterial Skin and Skin-Structure Infections (ABSSSI) and Bloodstream Infections (BSI) in Europe (SENTRY 2015–2019)

Susanne Paukner*1, Steven P Gelone2, Sj Ryan Arends3, Helio S. Sader4

1Nabriva Therapeutics GmbH, Vienna, Austria, 2Nabriva Therapeutics US, Inc., King of Prussia, United States, 3JMI Laboratories, North Liberty, United States

Abstract third-party references: Funded by Nabriva Therapeutics

Background: Lefamulin, a novel pleuromutilin antimicrobial, has been approved in the United States for the intravenous (IV) and oral treatment of community-acquired pneumonia in adults. In a phase 2 clinical trial in ABSSSI, lefamulin (150 mg IV) demonstrated clinical efficacy comparable to that of vancomycin (1000 mg IV). This study investigated the in vitro activity of lefamulin and comparators against bacterial pathogens collected from ABSSSI and BSI in Europe during 2015–2019.

Materials/methods: 2116 unique bacterial isolates were collected in Europe (19 countries, 40 sites) in 2015–2019, from patients with ABSSSI (64%) and BSI (35%). Lefamulin and comparators were susceptibility tested by reference CLSI broth microdilution, and MIC values were interpreted per EUCAST (2019) criteria.

Results: Lefamulin demonstrated potent antibacterial activity against staphylococci and β-hemolytic and viridans group streptococci (Table). Among Staphylococcus aureus isolates, 20.6% were methicillin-resistant S. aureus (MRSA), which showed particularly high resistance rates to fluoroquinolones (moxifloxacin, 68.7%) and macrolides (erythromycin, 53.2%). Lefamulin inhibited 99.5% and 98.6% of S. aureus and MRSA isolates, respectively, at 0.25 mg/L (MIC50/90 of 0.06/0.12 mg/L). Coagulase-negative staphylococci (CoNS) showed high resistance rates to macrolides (erythromycin, 55.7%), fluoroquinolones (moxifloxacin, 50.5%), aminoglycosides (gentamicin, 45.3%), and oxacillin (68.0%) but were largely susceptible (>90%) to tetracyclines, oxazolidinones, and lipo- and glycopeptides. Lefamulin displayed an MIC50/90 of 0.06/0.12 mg/L against CoNS overall and of 0.06/0.5 mg/L against S. epidermidis specifically. Lefamulin also demonstrated potent activity against β-hemolytic streptococci (MIC50/90 of 0.03/0.06 mg/L), including group A, B, C, and G isolates; β-hemolytic streptococci were largely susceptible to all tested comparators except erythromycin [21.3% resistant] and clindamycin [12.5% resistant]. Among viridans group streptococci, lefamulin showed an MIC50/90 of 0.06/0.25 mg/L, against all species except S. gallolyticus, against which lefamulin displayed an MIC50/90 of 2/4 mg/L. Overall, susceptibility/resistance rates for comparators were generally consistent over time.

Conclusions: Lefamulin demonstrated potent in vitro activity against this contemporary European collection of Gram-positive cocci gathered from ABSSSI and BSI, and lefamulin activity was unaffected by resistance to other antibiotic classes. These data support the continued development of lefamulin for the treatment of ABSSSI and further exploration of lefamulin activity in BSI.

Abstract 2736

Diagnostic utility of stool polymerase chain reaction in enteric fever: experience from a high-incidence London hospital

Desmond Hsu*, Simon Tiberi1, Ruaridh Buchanan1, Caryn Rosmarin1

1Royal London Hospital, Barts Health NHS Trust, London, United Kingdom

Background: Enteric fever is a systemic illness that is most commonly caused by Salmonella enterica serovars Typhi and Paratyphi A. A barrier to prompt treatment is the lack of reliable diagnostic tests. Blood culture remains the most commonly utilized diagnostic modality, but only identifies 60-80% of cases. The increasing availability of stool PCR testing presents an additional technique that has potential to improve the diagnostic yield. We report on the sensitivity and utility of stool culture and PCR in a retrospective cohort of subjects with microbiologically confirmed enteric fever presenting to local healthcare services.

Materials/methods: Data were collected from electronic laboratory records to include: all positive blood and stool cultures where enteric fever-causing Salmonella species were isolated between July 2017 – September 2019; and all positive stool PCR results for Salmonella species DNA between January 2019 (when PCR was introduced) and September 2019.

Results: In total, 57 subjects met the Public Health England definition of a ‘Probable case’ of enteric fever; compatible clinical history in a returned traveller with microbiological confirmation by either blood or stool testing. Fifty-four subjects underwent blood culture testing, 23 had stool culture, and 17 had stool PCR testing. Using pooled positive results as a gold standard, the sensitivities of the individual diagnostic techniques were calculated (Table).

<table>
<thead>
<tr>
<th>No. positive/ No. tested</th>

<tr>
<td>Stool culture</td>
<td>18/23</td>
<td>0.78</td>
</tr>
</tbody>
</table>

Table. Sensitivity of blood culture, stool PCR and stool culture in microbiologically confirmed cases of enteric fever

Only 13 (23%) of the 57 patients who met the case definition had samples taken for concomitant blood culture and stool PCR tests. Of these 13; 9 patients (69%) were positive in both blood culture and stool PCR, 2 (15%) had positive blood cultures with negative stool PCR, and 2 (15%) had positive stool PCR with negative blood cultures.

Conclusions: Results from this retrospective cohort suggest that the inclusion of stool PCR as part of routine diagnostics in those presenting with suspected enteric fever is a useful adjunct to identify cases that may be missed using blood culture alone.

Abstract 2739

Antimicrobial susceptibility and carbapenem co-resistance among piperacillin/tazobactam-resistant Pseudomonas aeruginosa: SMART Asia/Pacific 2016-2018

Sibylle Lob1, Krystyna Kazmierczak*1, Wei-Ting Chen2, Kanchan Balwani3, Tsz Kin Khan4, Katherine Young2, Mary Motyl2, Dan Sahm1

1IHMA, Schaumburg, United States, 2MSD, Taiwan, Taipei, Taiwan, 3MSD, Singapore, Singapore, Singapore, 4MSD, Hong Kong, Hong Kong, Hong Kong, 5Merck & Co., Inc., Kenilworth, United States

Background: Ceftolozane/tazobactam (C/T) is an antipseudomonal cephalosporin combined with a β-lactamase inhibitor. C/T has been approved by the FDA and EMA for complicated urinary tract infections, complicated intraabdominal infections, and hospital-acquired and ventilator-associated bacterial pneumonia. Using isolates collected in Asia/Pacific as part of the SMART surveillance program, we evaluated the activity of C/T and comparators against piperacillin/tazobactam-resistant (P/T-R) P. aeruginosa.

Materials/methods: In 2016-2018, 56 clinical laboratories in Australia, Hong Kong, India, South Korea, Malaysia, New Zealand, Philippines, Singapore, Taiwan, Thailand, and Vietnam each collected up to 250 consecutive aerobic or facultative gram-negative pathogens from various infection sources, for a total of 25,927 isolates including 4,362 P. aeruginosa. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints. P. aeruginosa isolates (excluding those collected in India) testing with C/T MIC ≥8 mg/L or imipenem MIC ≥4 mg/L were screened by PCR and sequenced for genes encoding β-lactamases.

Results: Of the 4,362 P. aeruginosa isolates, 28.9% were P/T-R, ranging from 11.8% in New Zealand to 53.0% in India; 12.5% were resistant to both piperacillin/tazobactam and meropenem (P/T-R+MEM-R), ranging from 2.3% in New Zealand to 41.8% in Vietnam. The table shows the activity of C/T and comparators against P/T-R and P/T-R+MEM-R P. aeruginosa isolates.

The activity of C/T against P/T-R P. aeruginosa ranged from 22% observed for isolates collected in India and Vietnam to >84% in Australia, South Korea, New Zealand, and Taiwan. Against P/T-R+MEM-R P. aeruginosa, susceptibility ranged from 8% in India to 78% in New Zealand. Of the 545 P/T-R+MEM-R isolates, 392 were molecularly characterised: 36.2% carried metallo-β-lactamases (MBLs), 3.1% GES-carbapenemases, 0.3% KPCs, 3.3% only extended-spectrum β-lactamases (ESBLs), and in 57.1% no acquired β-lactamases were detected.

Conclusions: Overall, C/T maintained activity against 65% of P/T-R P. aeruginosa collected in Asia/Pacific (24% higher than meropenem) and against 34% of P/T-R+MEM-R isolates, with substantial variability observed across countries; only amikacin, and colistin showed comparable or higher activity. C/T could provide an important treatment option for patients with infections caused by antimicrobial-resistant P. aeruginosa.

Selective decontamination of the digestive tract prevents postoperative pneumonia and anastomotic leakage after esophagectomy

Robin Janssen*, Frans Van Workum2, Nikolaj Baranov2, Harmen Blok1, Jaap Ten Oever4, Eva Kolwijck3, Alma Tostmann5, Camiel Rosman2, Jeroen Schouten1

1Radboud University Medical Center, Department of Intensive Care Medicine, Nijmegen, Netherlands, 2Radboud University Medical Center, Department of Surgery, Nijmegen, Netherlands, 3Radboud University Nijmegen, Nijmegen, Netherlands, 4Radboud University Medical Center, Department of Internal Medicine, Nijmegen, Netherlands, 5Radboud University Medical Center, Department of Medical Microbiology, Nijmegen, Netherlands

Background: Postoperative infectious complications occur frequently after esophagectomy. The use of selective decontamination of the digestive tract (SDD) might reduce postoperative infections in patients undergoing esophagectomy. The aim of this study was to evaluate the effectiveness of SDD in preventing infectious complications and anastomotic leakage after esophagectomy for cancer.

Materials/methods: A retrospective cohort study was conducted in patients undergoing elective Ivor Lewis totally minimally invasive esophagectomy in four Dutch hospitals between 2012 and 2018. Two hospitals used SDD perioperatively (start 3 days before and stop 3 days after esophagectomy) and two did not. SDD consisted of oral paste and suspension, containing amphotericin B, colistin and tobramycin. Outcomes of patients receiving SDD perioperatively were compared to those not receiving SDD. Primary outcome was 30-day postoperative infectious complication rate (more specifically; pneumonia, mediastinitis/empyema and surgical-site infections [SSI]). Secondary outcome was anastomotic leakage. Univariate and multivariate logistic regression were used to determine the effect of SDD on postoperative infectious complications and anastomotic leakage.

Results: In total, 496 patients were included (179 received SDD perioperatively). Postoperative infectious complications were observed in 214 (43.1%) patients. Pneumonia occurred in 30.2% of the patients, SSI in 5.0% and anastomotic leakage in 16.5%. One-year survival was significantly lower in patients with infectious complications compared to those without a postoperative infection (40.1% vs. 59.9%, p=0.006). Univariate analysis showed that patients who received SDD were less likely to develop postoperative infections overall (36.9% vs. 46.7%, p=0.034), pneumonia (20.1% vs. 36.0%, p<0.001) and anastomotic leakage (10.6% vs. 19.9%, p=0.008), but surgical-site infections occurred more frequently (8.9% vs. 2.8%, p=0.003) in the SDD group. In multivariate analysis, SDD showed to be an independent protective factor for postoperative pneumonia (OR 0.41, 95% CI 0.24-0.69, p=0.001) and anastomotic leakage (OR 0.46, 95% CI 0.26-0.84, p=0.011).

Conclusions: SDD seems to be an effective strategy to prevent pneumonia and anastomotic leakage after elective esophagectomy for cancer.

Abstract 2741

**In vitro activity of imipenem/relebactam against Klebsiella pneumoniae and Pseudomonas aeruginosa isolates from Patients in intensive care unit and non-intensive care unit wards in the Philippines: SMART 2016-2018**

Sibylle Lob1, Krystyna Kazmierczak2*, Wei-Ting Chen2, Gillian Abello1, Maria Villanueva1, Katherine Young4, Mary Motyl4, Dan Sahm4

1IHMA, Schaumburg, United States, 2MSD, Taiwan, Taipei, Taiwan, 3MSD, Philippines, Makati, Philippines, 4Merck & Co., Inc., Kenilworth, United States

**Background:** Relebactam (REL) inhibits class A and C β-lactamases and was approved in the USA in combination with imipenem (IMI) and cilastatin for the treatment of complicated intraabdominal and urinary infections. We evaluated the activity of IMI/REL against isolates collected as part of the SMART surveillance program in the Philippines from patients in ICU and non-ICU hospital wards.

**Materials/methods:** In 2016-2018, 4 clinical laboratories in the Philippines each collected up to 250 consecutive gram-negative pathogens from various infection sources. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints, except IMI/REL for which FDA breakpoints were applied. Isolates testing with IMI MIC ≥2 mg/L (Enterobacterales) or ≥4 mg/L (P. aeruginosa, PA) were screened for β-lactamase genes.

**Results:** 299 K. pneumoniae (KP) and 143 PA isolates (48.5% and 65.7%, respectively, from lower respiratory tract infections; 28.1% and 19.6% from intraabdominal infections; 17.1% and 10.5% from urinary tract infections; 17.1% and 10.5% from bloodstream infections; and 1.0 and 0.7% from unspecified sources) were collected in ICU and non-ICU wards. The table shows the activity of IMI/REL and comparators against KP and PA stratified by ward type.

Among IMI-resistant KP (n=22), 13 isolates carried metallo-β-lactamases (MBLs), 7 KPCs, 1 AmpC, and in 1 isolate no acquired β-lactamases were detected. Seven IMI-resistant KP isolates (31.8%) were IMI/REL-susceptible and all carried KPC. Among IMI-resistant PA (n=25), 6 isolates carried MBLs, 1 carried only an extended-spectrum β-lactamase (ESBL), and in 18 isolates no acquired β-lactamases were detected. Twelve IMI-resistant PA isolates (48.0%) were IMI/REL-susceptible; of these, 1 carried only an ESBL and in 11 isolates no acquired β-lactamases were detected.

**Conclusions:** Antimicrobial susceptibility of PA was lower among isolates from ICU than non-ICU wards, while the pattern was less clear for KP. Even among ICU isolates, IMI/REL maintained activity against 94% of KP and 86% of PA, 6-37 percentage points higher than the other tested β-lactams. Only amikacin and colistin showed comparable or higher activity. IMI/REL can provide an important treatment option for patients in the Philippines, including those in ICUs.

Abstract 2744

**Seroprevalence of anti-HCV antibodies in the Bulgarian population**

Desislava Velcheva¹, Anelia Gotseva*, Georgi Popov³

¹MDL Cibalab, Sofia, Bulgaria, ²Laboratory of Virology, Uni Hospital, Panagyurishte, Bulgaria, ³Military Medical Academy, Department of Infectious Diseases, Sofia, Bulgaria

**Background:** Hepatitis C virus (HCV) is among the leading etiological causes for the development of chronic liver disease globally. Chronic HCV infection often flows asymptomatic and is defined as a risk factor for the development of liver cirrhosis and primary hepatocellular carcinoma (HCC). Modern laboratory diagnostics of HCV is based on immunological and molecular-biological methods. The incidence of HCV, both in the overall population and among risk groups, is assessed by establishing the presence of anti-HCV antibodies. The quantification of HCV RNA is a major marker for post-therapeutic monitoring and demonstration of current infection with the virus. The purpose of the study is to provide up-to-date data on the seroprevalence of the antibodies among the Bulgarian population. There is also a high focus on the modern possibilities of diagnostics HCV infection with the application of automated serological methods (CLIA, ECLIA, ELFA), immunoassay tests (recomLine HCV IgG) and molecular analyses (RT/real-time qPCR).

**Materials/methods:** For the period from 01.01.2017 – 31.10.2019, a total of 54,185 serum / plasma samples were tested for the detection of anti HCV antibodies in individuals over a large scale of age range (4 months - 88 years). The positive and equivocal results of the screening studies were confirmed by immunoblot. HCV RNA determination by RT / real-time qPCR was performed in 119 subjects.

**Results:** A reactive (positive) results for anti HCV antibodies were obtained in 941 (1.7%) of the subjects, respectively, 53,826 (98.3%) were seronegative. The highest segment is infection in the groups 31-40 years and over 61 years. Out of the 119 subjects tested with RT / real-time qPCR, HCV RNA was demonstrated in 36 (30.2%). A higher proportion of anti HCV seropositivity was observed in hemodialysis patients who were identified as a risk contingent.

**Conclusions:** Data for Bulgaria indicate 1.7% seroprevalence of HCV. Serological screening for anti HCV antibodies among the general population and high-risk groups is important for early detection of infected asymptomatic individuals, as well as for limiting the spread of infection and preventing its adverse effects on human health.

The accuracy of β-D-glucan and Aspergillus DNA detection by PCR in serum and bronchoalveolar lavage fluid for the diagnosis of pulmonary aspergillosis in critically ill patients with suspected ventilator associated pneumonia

Laura Loughlin*, Thomas Hellyer, P Lewis White, Danny Mcauley, Raquel Posso, Malcolm Richardson, David W. Denning, John Simpson, Ronan Mcmullan

1Queen’s University Belfast, Belfast, United Kingdom, 2Newcastle University, Institute of cellular medicine, Newcastle, United Kingdom, 3University Hospital Wales, Cardiff, United Kingdom, 4Queen’s University Belfast, Belfast, United Kingdom, 5Manchester University, Manchester, United Kingdom

Abstract: Invasive aspergillosis is the most frequently missed infective diagnosis in critically ill patients, demonstrated by autopsy studies. Diagnosis is particularly challenging in this patient group because of limited access to validated diagnostic tests. The aim of this study was to estimate the diagnostic accuracy of three index tests: (i) β-D-glucan [BDG] in serum; Aspergillus DNA detection by PCR in (ii) bronchoalveolar lavage fluid (BALF) and; (iii) serum.

Materials/methods: Two prospective UK studies recruited 360 critically ill adults with new or worsening alveolar shadowing on chest X-ray and clinical/haematological parameters supporting suspected ventilator-associated pneumonia (VAP). All patients underwent standardised bronchoalveolar lavage and were eligible for inclusion in the present study if sufficient volumes of stored serum and BALF were available for mycological testing. Index test results were compared to a reference standard constructed for this population which defined probable Aspergillus infection using clinical, radiological and mycological criteria. Mycological criteria comprised one or more of: positive histology or microscopy; positive BALF culture; galactomannan optical index ≥1 in BALF or ≥0.5 in serum.

Results: Of 194 patients eligible for inclusion, 24 (12.4%) fulfilled the reference standard definition of Aspergillus infection. The table shows key diagnostic accuracy characteristics of the index tests. The most sensitive single test was BDG (41.7%), while the most specific was serum PCR (86.9%). For confirmation of aspergillosis, BDG plus serum PCR had highest positive predictive value (PPV) at 60% (95%CI, 20.9-89.5). For exclusion, combining negative BDG and BALF PCR, had highest negative predictive value (NPV) at 90.6% (95%CI, 85.6-94.1), providing only a small advantage over each test used alone.

Conclusions: While acknowledging limitations arising from an imperfect reference standard, our data demonstrate possible roles for BDG and BALF/serum PCR in this patient group. Serum BDG may be a favourable non-invasive test for disease exclusion.

Abstract 2746

A Peptoniphilus species nova closest to P. harei from human clinical materials but which was misidentified by Bruker Biotyper as P. indolicus

Kathy Bernard¹, Deborah Wiebe¹, Alida Veloo*,³, Arianne Ebbinge³

¹National Microbiology Laboratory, Special Bacteriology Unit, Winnipeg, Canada, ¹National Microbiology Laboratory, Special Bacteriology Unit, Winnipeg, Canada, ¹University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: Clinical isolates of a strictly anaerobic Gram-positive anaerobic coccus (GPAC) referred to reference centres in Canada and the Netherlands and indistinguishable by 16S rRNA gene sequencing (16S), have been characterized and found to possibly represent a novel Peptoniphilus species, closest to P. harei. We present features of this taxon group, derived from human clinical materials.

Materials/methods: Nearly full 16S rRNA gene sequencing, MALDI-TOF MS analyses (Bruker with Biotyper ver 7854/8468) and standard phenotypic assays, including ATB 32A, were done. Some strains have also had cellular fatty acid composition (CFAs) or grew well enough for antimicrobial susceptibility testing (AST) by broth microdilution (BMD) or by Etest

Results: Eight Canadian isolates and four Dutch isolates, recovered from various human clinical materials, were found to be closest (99.3%-99.9% similarity) to each other but f98.6% to P. harei DSM10020T accession no. NR_026358. All isolates were strictly anaerobic, non-reactive to most substrates and indol positive. CFAs were consistent with the genus. AST suggested that strains were largely susceptible to common antibiotics. Interestingly, P. harei-like strains tested by MALDI-TOF Biotyper ver 7854/8468 gave rise to high scores [2.28-2.38] towards MSPs identified as P. indolicus (identifiers ENR_0001, ENR_0003, ENR_0423, ENR_0430) as well as MSPs shown as P. harei (08_570 IBS, and 06_622IBS) [scores 2.12-2.17] but scores of <1.6 towards P. harei DSM10020T. By 16S, both P. harei like and P. harei sensu stricto had <96.9% identity with P. indolicus ATCC 29427T (accession no. NR_115509).

Conclusions: These data suggest that a new Peptoniphilus species closest to P harei, recovered from human clinical specimens exists. Next steps include characterization of the isolates by whole genome sequencing, preparing a sp nov description and arrange for corrections to Bruker Biotyper ver 8468. Furthermore, the prevalence of this new species in clinical specimens will be assessed.

Presenter email address: a.c.m.veloo@umcg.nl
Background: Rift Valley fever is an arboviral infection endemic to most of sub-Saharan Africa and the Arabian Peninsula. It is a climate-related zoonotic infection characterized by high rates of abortion and mortality in pregnant ruminants. However, there is limited data on its effects in pregnant women. Here, we summarize and critically appraise evidence on the effects of Rift Valley fever (RVF) in pregnant women.

Materials/methods: An exhaustive search of clinical trial registries and bibliographic databases from their respective dates of inception to September 30, 2019, was conducted using a combination of MeSH terms and keywords depending on the level of term indexation for the database. There were no language or study design restrictions. Individual patient data were extracted to generate odds ratios or proportions depending on available information. Statistical analyses were conducted in R and a gap analysis performed.

Results: Our comprehensive review yielded four studies reporting 51 pregnant women infected with RVF. The relative risk of foetal loss due to maternal RVF was estimated at 4.47 (95% C.I. 1.34 to 14.91, I²=76.02%, P=0.04). However, the summary estimate is not precise given the wide confidence interval and the high amount of between-study heterogeneity. Additionally, past infection is a likely confounder given that one study assessed women over a two-year period and it is unclear if all foetal losses were a result of acute infection. The formal gap analysis shows there is very little data on the maternal effects of RVF or the management of pregnant patients with RVF.

Conclusions: The currently available evidence suggests that similar to reports in ruminants, infection with RVF virus may be associated with a substantial risk of foetal loss in pregnant women. With a more than four-fold increased risk of foetal loss in positive pregnant patients, there is a need to prioritize pregnant women as a sub-group of special interest for RVF research. Well-conducted prospective studies estimating the true incidence of adverse pregnancy outcomes in pregnant women with RVF are needed.

PROSPERO protocol number CRD42018097022

Can adjuvanted influenza vaccine given as standard of care reduce the risk for influenza outbreaks in nursing homes: evidence from a cluster-randomized trial of 823 nursing homes

Kevin Mcconeghy1,2, H. Edward Davidson3, Lisa Han4, Elie Saade4,5, David Canaday4,5, Vince Mor1,6, Stefan Gravenstein2,6,7

1Brown University School of Public Health, Health Services Policy and Practice, Providence, United States; 2Providence VA Medical Center, Center of Innovation in Long-term Services and Support, Providence, United States; 3Insight Therapeutics, LLC, Norfolk, United States; 4Case Western Reserve University, Cleveland, United States; 5University Hospitals Cleveland Medical Center, Cleveland, United States; 6Brown University School of Public Health, Center for Gerontology and Healthcare Research, Providence, United States; 7Warren Alpert Medical School of Brown University, Providence, United States

Abstract third-party references: ClinicalTrials.Gov NCT02882100, Funding via investigator-initiated grant by Seqirus.

Background: Nursing home (NH) influenza outbreaks pose a serious threat to their frail residents and occur even in vaccinated populations. More immunogenic influenza vaccines may offer an advantage to preventing outbreaks over non-adjuvanted trivalent influenza vaccines (TIV). We conducted a large pragmatic cluster randomized controlled trial to evaluate the effectiveness of an adjuvanted TIV (aTIV) vs. TIV with a secondary outcome of NH influenza outbreaks.

Materials/methods: 823 U.S. NHs with at least 50 long-stay residents aged ≥ 65 years were cluster randomized to either the aTIV or TIV for the 2016-17 influenza season (November-May). We employed a hierarchical Bayesian analysis with weakly informative priors to evaluate the impact of the intent-to-treat vaccine assignment on the number of facilities reporting outbreaks from November-March. We collected monthly outbreak data according to standard CDC definitions (2 or more cases of flu-like illness in 72 hours or 1 laboratory-confirmed influenza case and 1 other ill resident). We adjusted for facility-level vaccination rates and resident characteristics in the final model. All analyses were performed using STAN (v2.19) and R statistical software (v3.5.3).

Results: Of 823 randomized NHs, 777 [aTIV, n=387; TIV, n=390] reported on influenza outbreaks. Facilities were similar across most covariates, except race/ethnicity. TIV homes had more African-Americans (13.7 vs. 18%). Mean outbreaks/NH/month was 0.37. Of 295 outbreaks, 133 (0.34 per facility-month) vs. 162 (0.41) occurred in aTIV vs TIV facilities, respectively. The unadjusted analysis estimated relative reduction (RR) in outbreaks as 0.82, 95% credible interval: 0.65, 1.04 [Prob. RR<1, 94.6%]. Analyses adjusted for race/ethnicity, age 85 and older, staff and resident influenza and pneumococcal vaccination rate, estimated a RR 0.78, 95% CI: 0.63, 0.99 [Prob. RR<1, 97.8%].

Conclusions: Secondary findings from a cluster-randomized pragmatic nursing home trial observed ~20% fewer influenza outbreaks with aTIV vs. TIV, a finding not previously demonstrated in any experimental setting.

Figure 1. Plot of influenza outbreaks over time. % ILI - Percentage of outpatient visits with diagnosis of influenza-like illness [Centers for Disease Control and Prevention Surveillance Data]. aTIV - Adjuvanted Trivalent Influenza Vaccine [n=387]. TIV - non-adjuvanted trivalent influenza vaccine [n=390].

Abstract 2751

**EUCIC survey on influenza vaccination among infection control team: Action speaks louder than words**
Șiran Keske1, Nico T. Mutters2*, Constantinos Tsioutis3, Önder Ergönül4

1American Hospital, Istanbul, Turkey, 2University Medical Center Freiburg, Freiburg im Breisgau, Germany, 3European University Cyprus, Egkomi, Cyprus, 4Koç University Hospital, Istanbul, Turkey

**Abstract third-party references:** The EUCIC Influenza Survey Investigator Group, The European Committee on Infection Control (EUCIC)

**Background:** Varying rates of annual influenza vaccination of healthcare professionals (HCPs) are observed, depending on local policies, as well as HCP knowledge and perceptions. One of the tasks of the hospital infection control team (ICT) is to ensure that HCPs are vaccinated for influenza. We aimed to describe the opinions of ICT about influenza vaccine and related factors across different countries.

**Materials/methods:** A multilingual survey was performed between May 17, 2019 and July 15, 2019 targeting the opinions and practices of ICTs regarding the 2018-2019 influenza season. The participants were reached via ESCMID and EUCIC newsletters, social media, national societies’ newsletters, national scientific associations. An online survey consisting of 23 items covering potential factors that may have influenced their decision to receive or refuse the vaccine, was administered. This anonymous and voluntary survey was a collaborative study conducted by EUCIC.

**Results:** In total, 899 participants from 56 countries were enrolled. Overall reported vaccination rate was 76%, with highest rates in Finland, Portugal, Norway and Israel (100%), and lowest rates in Turkey (39%) and Italy (68%). Influenza vaccination rate was 86% among physicians and 52% among IC nurses. Personal influenza vaccine experience (49%) and scientific authorities (48%) were the most significant factors that affected participants’ vaccination decision. Regarding the 2018-19 season, self-protection (84%) and protecting patients (74%) were the most common motivators for vaccination, whereas not being in a high-risk group (32%) and inconvenience (25%) were the most common reasons for not having been vaccinated. In multivariate analysis, Turkey (OR: 0.41, 95% CI: 0.22-0.77, p=0.006) and infection control nurses (OR:0.43, 95% CI: 0.24-0.80, p=0.007) were significantly associated with not having been vaccinated, whereas vaccination of head of infection control committee (OR: 16.04, 95% CI: 8.4-30.8, p<0.001) and free vaccine (OR: 7.56, 95% CI: 2.1-27.4, p=0.02) were the strongest predictors of having been vaccinated for influenza during 2018-19.

**Conclusions:** In this multinational study, we detected that being IC nurse, leader’s vaccination status and cost of vaccine significantly affected influenza vaccination behavior of ICT. These factors should be taken into account to plan future activities aiming to increase HCPs’ influenza vaccination coverage.

Abstract 2752

Antimicrobial activity of aztreonam-avibactam and comparator agents tested against contemporary (2019) clinical Enterobacterales isolates

Hello S. Sader*, 1, Cecilia Carvalhaes 1, Sj Ryan Arends 1, Rodrigo E. Mendes 1, Mariana Castanheira 1

1JMI Laboratories, North Liberty, United States

Abstract third-party references: This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services preparing this abstract.

Background: Aztreonam (ATM) is a monobactam stable to hydrolysis by metallo-β-lactamases (MBL), and avibactam (AVI) is a non-β-lactam β-lactamase inhibitor that inhibits Ambler class A, C, and some class D enzymes (e.g., ESBL, KPC, and AmpC). ATM-AVI is under clinical development for treatment of serious infections caused by Gram-negative bacteria, including MBL-producers.

Materials/methods: A total of 5,671 Enterobacterales (ENT) were consecutively collected from 47 medical centres located in Western Europe (W-EU; 22 centres in 9 countries), Eastern Europe (E-EU; 10 centres in 7 countries), Asia-Pacific region (APAC; 10 centres in 6 countries), and Latin America (LATAM; 5 centres in 4 countries), and tested for susceptibility by reference broth microdilution methods in a central monitoring laboratory (JMI Laboratories). MIC results were interpreted per EUCAST criteria. Isolates were mainly from bloodstream infections (30%), urinary tract infections (24%), and pneumonia (20%).

Results: Overall, 99.8% of isolates were inhibited at ATM-AVI MIC of ≤4 mg/L (MIC50/90, ≤0.03/0.12 mg/L), including all (100.0%) carbapenem-resistant (CRE; n=133; MIC50/90, 0.25/0.5 mg/L) and 99.1% of multidrug-resistant isolates (MDR; n=1,058; MIC50/90, 0.06/0.25 mg/L). Isolates with ATM-AVI MIC >4 mg/L (n=10) were detected in only 4 countries (Australia [2], Poland [1], Thailand [2], and Turkey [5]), and included 7 E. coli, 2 E. cloacae, and 1 K. pneumoniae. Highest ATM-AVI MIC value was only 2 mg/L in W-EU and LATAM (Table). The most active comparators were meropenem (92.2-98.9% susceptible [S], 97.1% overall), tigecycline (94.9-96.4% per US-FDA criteria; 95.6% overall), and amikacin (88.1-97.7%; 95.3% overall). Susceptibility rates for ceftriaxone, levofloxacin, and gentamicin were highest in W-EU (80.5%, 79.7%, and 89.9%, respectively) and lowest in LATAM (48.8%, 52.5%, and 63.0%, respectively), whereas susceptibility rates from piperacillin-tazobactam and meropenem were highest in W-EU (85.2% and 98.9%, respectively) and lowest in E-EU (66.4% and 92.2%, respectively). CRE rates were 1.0%, 6.0%, 2.9%, and 2.0% in W-EU, E-EU, APAC, and LATAM, respectively (2.3% overall).

Conclusions: ATM-AVI demonstrated potent activity against a large collection of contemporary (2019) Enterobacterales isolates from Europe, APAC, and LATAM, including CRE and MDR isolates. Resistance rates for comparator agents were generally higher in E-EU and LATAM compared to W-EU and APAC.

Background: The aim of this study was to evaluate the risk factors for candidemia in patients with liver cirrhosis

Materials/methods: This was a multicenter case-control-control (1:2:2) study performed in four Italian tertiary centres from 2006 to 2015. Cases were patients developing candidemia. For every case of candidemia, four controls divided in two groups were selected and matched according to age, sex and model for end stage liver disease (MELD) calculated at hospital admission. Controls were defined as follows: controls A were patients undergoing blood cultures for suspected infection yielding isolation of a bacterial pathogen; controls B were patients undergoing blood cultures for suspected infection yielding negative results.

Results: During the study period 90 patients with candidemia, 180 patients with bacteremia (control A) and 180 patients with culture-negative infection (control B) were included. The mean (±SD) age of 60 (±11 years) and a prevalence of 63% of male gender. Chronic viral hepatitis (59%) was the main cause of liver cirrhosis followed by alcoholic abuse (36%). The median (IQR) MELD score at hospital admission was 17 (13-23) points. Of the 90 patients with candidemia, Candida albicans was the main isolated species (64%) followed by Candida parapsilosis (14%) and Candida glabrata (9%). Septic shock was diagnosed in 24% and acute-on-chronic liver failure (ACLF) in 56% of cases.

At multivariate analysis assessed by means of multinomial conditional regression models, factors independently associated with candidemia were previous (<30 days) ACLF [OR 2.22 [95%CI 1.09-4.54]], previous (<30 days) gastrointestinal endoscopy [OR 2.22 [95%CI 1.09-4.54]], previous (<30 days) intravenous antibiotic treatment for at least 7 days [OR 3.99 [95% CI 1.28-12.44]], presence of central venous catheter (CVC) [OR 3.75 [95% CI 1.85-12.44]] and total parenteral nutrition [OR 3.79 [95% CI 1.59-8.78]] at infection onset. Conversely, rifaximin treatment was associated with lower rate of candidemia [OR 0.38 [95% CI 0.19-0.77]].

Conclusions: We identified previous antibiotic use, gastrointestinal endoscopy or ACLF and presence of CVC especially for parenteral nutrition as independent factors associated to candidemia. Surprisingly, chronic rifaximin use was a protective factor.

Abstract 2762

CTX-M type extended-spectrum beta-lactamase in Serratia marcescens in Japan

Hiroaki Baba*1,2, Hajime Kanamori1,2, Yuki Suzuki3, Shiro Endo4, Hisakazu Yano3, Mitsuo Kaku5

1Department of Infectious Diseases, Internal Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan, 2Department of Intelligent Network for Infection Control, Tohoku University Graduate School of Medicine, Sendai, Japan, 3Department of Microbiology and Infectious Diseases, Nara Medical University, Kashihara, Japan, 4Department of Intelligent Network for Infection Control, Tohoku University Graduate School of Medicine, Sendai, Japan, 5Division of Infectious Diseases and Infection Control, Tohoku Medical and Pharmaceutical University Hospital, Sendai, Japan

Background: Extended-spectrum β-lactamases (ESBLs) producing bacteria are increasing worldwide. Screening criteria for detection of ESBLs, however, are not standardized for AmpC-producing Enterobacteriaceae including Serratia marcescens, thereby masking the presence of ESBLs in AmpC-producing Enterobacteriaceae. We investigated the prevalence of ESBLs in clinical isolates of third-generation cephalosporin-resistant S. marcescens in Japan with phenotypic detection tests.

Materials/methods: We studied a total of 300 clinical isolates of S. marcescens that presented resistant to at least one of following 3 antimicrobial agents, cefotaxime, ceftazidime, and cefmetazole, collected throughout Japan between April and June 2017. Production of ESBL and AmpC were assessed by the Mastdiscs™ ID AmpC and ESBL ID Set and the boronic acid test. PCR screening for blaCTX-M, blaSHV, blaTEM, and blaOXA was performed on isolates that were phenotypically confirmed to be ESBL producers.

Results: Among the 300 isolates, 7 (2%) were both ESBL and AmpC-positive, 9 (3%) were ESBL-positive-AmpC-negative, 178 (59%) were ESBL-negative-AmpC-positive, 48 (16%) were both ESBL and AmpC-negative, and 58 (19%) isolates were “not applicable” by Mastdiscs™ ID (Figure). Among these 16 ESBL-positive isolates, 3, 4, 2, 9, 3, and 2 were possessed blaCTX-M-1G, blaCTX-M-2G, blaCTX-M-9G, blaSHV, blaTEM, and blaOXA respectively, and one isolate was PCR-negative. In addition to all he ESBL-positive isolates, one ESBL-negative and one “not applicable” isolates met the criteria for ESBL production in the boronic acid test. blaSHV was detected in the “not applicable” isolate.

Conclusions: Our data suggests that blaCTX-M groups of ESBLs are spreading among clinical isolates of third cephalosporin-resistant S. marcescens in Japan. Detection of ESBLs among clinical S. marcescens encourage clinicians to select more appropriate antibiotics.

Figure. Results of Mastdiscs™ ID AmpC and ESBL ID Set and PCR-screening among isolates of Serratia marcescens

Background: Treatment of brain abscess relies primarily upon expert opinion and may differ within and between countries.

Materials/methods: Using an internet-based questionnaire, we conducted an international, multi-centre survey of real-life treatment of community-acquired BA in France, Sweden, Australia, and Denmark. Study participants were also asked to prioritise future randomised controlled trials (RCTs) on brain abscess treatment from 1 (High priority) to 6 (Low priority). Switch to oral therapy before completion of four weeks of intravenous (IV) antibiotics for brain abscess was categorised as ‘early transition to oral antibiotics’.

Results: During November 2019, 270 infectious diseases specialists (43% female) participated in the survey from France (39%), Sweden (32%), Australia (20%), and Denmark (9%). Respondents worked primarily at university hospitals (67%) with >600 beds (50%) and an on-site neurosurgical department (60%). National guidelines for treatment of BA were available in France, Sweden, and Australia.

Preferred empiric antibiotic regimen were cefotaxime (148/235, 63%) or ceftriaxone (53/235, 23%) combined with metronidazole for varying durations according to neurosurgical treatment (Figure). Routine treatment with follow-up oral antibiotics after completion of a standard IV regimen (i.e. 4-8 weeks) was used by 105/226 (46%) respondents, while early (i.e. <4 weeks) transition to oral antibiotics was used by 114/231 (49%).

Favoured oral antibiotics for brain abscess (n=143; several answers possible per respondent) included trimethoprim-sulfamethoxazole (41%), amoxicillin and metronidazole (37%), clindamycin (29%), moxifloxacin (25%), and linezolid (17%). Median prioritisation scores (n=221) with interquartile ranges for future RCTs on BA treatment were: Early transition to oral antibiotics = 1 (1-2), duration of therapy = 1 (1-2), comparison of different antibiotic regimens = 3 (2-4), use of adjunctive dexamethasone = 3 (2-4), neurological aspiration versus excision = 3 (2-4), use of prophylactic anti-epileptic drugs = 3 (2-5), and intracavitary antibiotic instillation and continuous drainage versus standard therapy = 4 (3-5). Willingness to include patients into RCTs was high for early transition to oral antibiotics 198/220 (90%) and duration of therapy 207/220 (94%).

Conclusions: Duration of intravenous antibiotic treatment and use of early transition to oral antibiotics varies substantially among specialists. RCTs are needed to better define optimal treatment of brain abscess.

Efficacy of fosfomycin-trometamol versus fluoroquinolone single-dose as prophylaxis for trans-rectal ultrasound-guided prostate biopsy

Tristan Delory*, Annabelle Goujon1, Alexandra Masson-Lecomte1, Pauline Arias1, Eva Mayet1, Touratier Sophie1, Beatrice Bercot1, Jean-Michel Molina1, Pierre Mongiat-Artus1, Matthieu Lafaurie1

1Saint-Louis Hospital, AP-HP, Paris, France

Background: Antibiotic prophylaxis is essential to prevent post-TURBP urinary tract infection (UTI). Fluoroquinolones (FQ), single-dose, are the recommended prophylaxis in France. Rectal carriage of FQ-resistant bacteria is associated with an increased risk of post-TURBP UTI. We aimed to estimate if Fosfomycin-trometamol (FT) could be an alternative prophylaxis of UTI in TURBP.

Materials/methods: Preliminary report of a monocentric, prospective observational cohort study, including all consecutive patients receiving single-dose FQ (FQ-arm) or single-dose FT (FT-arm) according to physician choice for TURBP. Primary endpoint was the occurrence of post-TURBP UTI. Secondary endpoints were post-TURBP antibiotic intake and hospitalization. Relative-Risk (RR) and corresponding 95% Confidence-Intervals (95%CI) were measured using logistic regression.

Results: 222 men were enrolled from April 2017 to June 2019, 141 (64%) received FQ and 81 (36%) FT. Of which, 100 (45%) had a history of prostate biopsy. Median age was 67.6-years [IQR 61.4-66.8], Charlson score 3 [IQR 3-5], and prostate volume 45 grams [35-62]. 123 (55%) had traveled abroad within 12 months, and 69/221 (31%) had received antibiotics within 6 months. 8 (4%) reported having UTI in the past 3 months. Single-dose FQ-prophylaxis was ciprofloxacin in 128 (58%) patients, ofloxacin in 7 (3%) and levofloxacin in 6 (3%). Time between prophylaxis intake and prostate-biopsy was 2.5 hours [2.1-2.9]. Two-hundred and two (91%) had two visits, with a median time between biopsy and post-biopsy visit of 29-days [22-36]. A total of 197 (89%) patients were evaluable for primary and secondary endpoints. Overall, 24 (12%) had a post-TURBP UTI: 17/116 (15%) in FQ-arm versus 7/81 (9%) in FT-arm (p=0.295). After adjustment on Charlson' score and intake of antibiotics in the previous 6 months, no statistically significant difference was measured between FQ and FT-arms (aRR=0.55 [95%CI 0.21-1.44], p-value=0.222). For secondary endpoints, 14/116 (12%) received antibiotics after TURBP in FQ-arm versus 7/81 (9%) in FT-arm (RR=0.70 [95%CI 0.27-1.82], p-value=0.462); and 13/116 (11%) were hospitalized after TURBP in FQ-arm – 9 related to UTI – versus 3/81 (4%) in FT-arm – 1 related to UTI (RR=0.30 [95%CI 0.08-1.11], p-value=0.071). The rate of adverse events was similar between FQ and FT-arms (RR=0.3 [95%CI 0.1-1.1], p-value=0.071).

Conclusions: Rates of post-TURBP UTI were similar following FT or FQ prophylaxis. A randomized comparison of the two strategies is warranted to establish FT as a potential alternative to FQ.

Classifying the *Mycobacterium tuberculosis* complex into the main phylogenetics lineages (Seville, Spain, 2015-2019): is something changing?

Veronica Gonzalez Galan¹, María José Torres Sanchez², Luque Rafael¹, Navarro Veronica¹, Medina Gallardo Juan Francisco¹, Raquel Valencia³, Briones Eduardo⁴, Javier Aznar*³

¹Hospital Universitario Virgen del Rocío/IBIS/CSIC/US, Sevilla, Spain, ²universidad de Sevilla, Sevilla, Spain, ¹Hospital Universitario Virgen del Rocío/IBIS/CSIC/US, Sevilla, Spain, ³Unidad de Salud Pública Sevilla, Distrito Sevilla, SAS, Sevilla, Spain

**Background:** Genotyping *Mycobacterium tuberculosis* complex (MTBC) strains plays an increasing role for understanding the epidemiology of tuberculosis. Some lineages have been associated with a wide geographic distribution, such as the MTBC lineage L4, which is the most predominant around the world. However, other lineages are restricted to certain areas. We used complementary genotyping methods to classify strains from Seville (southern Spain) into the six main human-associated lineages and sub-lineages of MTBC.

**Materials/methods:** The molecular typing was performed by applying the 43-spacer spoligotyping following standard protocols and SNP-typing was performed by a Taqman real-time PCR according to Stucki et al, 2012 protocols. All the 462 MTBC strains used in this study were from clinical samples from an ongoing molecular epidemiology study on tuberculosis in University hospital Virgen del Rocío, Seville, Spain since 2015.

**Results:** We studied 370 out of 462 strains (80.08%), classifying 91% strains into the main phylogenetic lineages. The typing results are shown in table 1. The most frequent lineage detected was L4 corresponding to 95% (n = 355) of all MTBC strains, followed by East Asian L2 with 1.62% (n = 6). L5 and L6 were the less frequent lineages with 2 and 4 cases, respectively. The most frequent sub-lineages identified were L4.1.2 (Haarlem family) with 23.24% (n = 6) and also we found 4 cases (1.08%) the emerging Uganda genotype of MTBC.

**Table 1. MTBC lineage 2015-2019.**

</tbody>
</table>

**Conclusions:** This results shows the MTBC diversity circulating in Seville. Throughout the five years of study we have found strains belonging to 6 different lineages. Lineage 4 being the most prevalent (until November 2019). However, the lineages founded, that are limited to specific geographical areas such as the African continent and Asia make us aware of new patterns of tuberculosis transmission in our area.

Ozenoxacin, a topical fluoroquinolone, demonstrates activity versus methicillin-susceptible and methicillin-resistant Staphylococcus aureus, and Streptococcus pyogenes wound isolates including fluoroquinolone-, fusidic acid- and mupirocin-resistant strains

Philippe Lagacé-Wiens*1,2, Heather Adam3, Melanie Baxter2, James Karlowsky1,2, George Zhanel2

1Saint Boniface Hospital, Shared Health, Winnipeg, Canada, 2University Of Manitoba, Winnipeg, Canada, 3Health Sciences Centre Winnipeg, Shared Health, Winnipeg, Canada

Background: Ozenoxacin (OZE) is a novel fluoroquinolone used topically for the treatment of impetigo formulated as a 1% w/w cream (10 mg/g). The purpose of the study was to assess the in-vitro activity of OZE and comparator agents against wound isolates obtained from the Canadian Antimicrobial Resistance Alliance-CARA/Health Canada partnered national surveillance study CANWARD.

Materials/methods: 751 wound isolates from CANWARD 2007-2018 were selected including 422 MSSA, 283 MRSA, and 46 Streptococcus pyogenes. Antimicrobial susceptibility testing was performed using CLSI methods (M07, 11th edition, 2018). MICs were interpreted using CLSI M100 (2018) criteria, except where indicated in the table.

Results: The activity of ozenoxacin versus various resistance phenotypes of MSSA, MRSA and S. pyogenes is depicted in the table below.

* EUCAST breakpoint (MIC >1 mg/L)
** median MIC

Conclusions: Ozenoxacin MIC90 values are low (≤ 1 mg/L) for all species and resistant subgroups of MRSA, MSSA and S. pyogenes tested, including strains with elevated MIC to fluoroquinolones, macrolides, clarithromycin, fusidic acid and mupirocin. Ozenoxacin is very active (MIC90 ≤ 0.12 mg/L, MICmax = 0.5 mg/L) against all MRSA strains tested.

Measles outbreak in Catania: a retrospective study and clinical revision

Alessio Pampaloni1*, Laura Todaro2, Federica Cosentino1, Maria Elena Locatelli1, Andrea Marino1, Vittoria Moscatt1, Daniele Scuderi1, Vincenzo Boscia1, Maria Gussio1, Gaetano Lupo1, Anna Onorante1, Aldo Zagami1, Benedetto Maurizio Celesia1, Bruno Cacopardo1

1ARNAS Garibaldi Hospital, Catania, Italy, 2University of Catania, Catania, Italy

**Background:** Measles is a highly contagious air-born exanthematous disease caused by **measles morbillivirus**. Despite the introduction of recommended vaccination since the early 1990s in Italy, measles outbreaks keep occurring due to a suboptimal vaccination coverage.

**Materials/methods:** In our study we described retrospectively the latest measles outbreak in Catania occurred in 2018. First we looked to all clinical records with discharge diagnosis of measles in Garibaldi Hospital. Then we collected epidemiological and clinical characteristics of patients hospitalized in the Infectious Disease Department during the period from January to December 2018.

**Results:** 199 cases were reported in the study period. 68(34.2%) were discharged from the Emergency Department with symptomatic treatment, 18(9%) were admitted in Pneumatology department, 5(2.5%) were recovered in ICU, of whom 3(1.5%) died for severe measles pneumonia. 108(54.3%) were admitted in Infectious Disease Department: 58(53.7%) were men, median age was 27 (IQR 21-31), 106(98.1%) were not vaccinated. Median days of hospitalization were 7 (IQR 6-9), median days of fever (including days before the hospitalization) were 9 (IQR 8-12). In their clinical history 92 patients (85.1%, p<0.001) had diarrhea as a prodromal symptom. Organ impairment is summarized in Table 1, 17 patients (16%) had multi-organ impairment. Leukopenia (WBC <4000/mmc) was found in 46 patients (43%, p=0.03), and thrombocytopenia (PLT<150.000/mmc) in 68 patients (63.5%, p=0.02). Antibiotic therapy was administered to 88 patients (81.5%), 33 multi-antimicrobial therapy, 55 mono-antimicrobial therapy; amoxicillin/clavulanic acid was the most administered (77 patients). Antibiotic therapy has not reported reduction in terms of days of fever and it prolonged days of hospitalization (p=0.027). Nevertheless no fatalities occurred.

**Conclusions:** Measles still represent a pernicious condition for community. Our study demonstrates the necessity of both high level awareness in health care personnel and approved clinical management algorithms to face any possible future measles outbreaks. Last but not least, vaccination coverage must be improved to prevent future outbreaks.

Comparison of intermittent versus continuous infusion vancomycin therapy for severe patients in intensive care unit

Carolina Yamada¹, João P. Telles*¹,², Dayana Santos¹, Juliette Cieslinski¹, Victoria Stadler Tasca Ribeiro¹, Juliano Gasparetto¹, Felipe Tuon¹

¹Pontifical Catholic University of Paraná, Curitiba Campus, Laboratory of Emerging Infectious Diseases - Department of Medicine, Curitiba, Brazil, ²A.C. Camargo Cancer Center, Department of Infectious Disease, São Paulo, Brazil

Background: Patients admitted to intensive care unit (ICU) are under risk for infection by methicillin-resistant Staphylococcus aureus (MRSA). Vancomycin continues to be an important therapeutic option for MRSA treatment. Serum trough level target (15-25 μg/mL) may be achieved by continuous infusion (CI) or intermittent infusion (II), but with different delay. Aim of this study was to compare pharmacokinetic characteristics between II and CI vancomycin for critically-ill patients admitted to intensive care units.

Materials/methods: II of vancomycin was administered for 60 minutes and prescribed as a loading dose of 30 mg/kg and continued with 15mg/kg q12h. CI was prescribed as a loading dose of 30mg/kg followed by 30mg/kg on constant infusion pump. Blood samples from vancomycin II group were collected 1h before third dose, 1h, 8h and 24h after third dose infusion. Blood samples from vancomycin continuous infusion group were collected 1h after loading dose, 12h, 24h, 36h and 48h after continuous infusion initiation. Mann-Whitney or Student’s t-test and Chi-square or Fisher’s exact test were used. Statistical significance was considered if \( P < 0.05 \).

Results: Twenty-three patients were included. Eleven on CI group and twelve on II group. CI and II groups median age were 49 years. Median APACHE-II score [IQR] were 15 [14-18.5] in CI group and 17 [10-21] in II group. Site of infections were pulmonary (n=12), central nervous system (n=4), skin and soft tissue (n=3), abdominal (n=2) and catheter-related (n=2). Death rate was 36% (n=4) in CI group and 31% (n=4) in II group. Median serum concentration on CI group at H1, H12 and 24-hour were 23.9 μg/mL [9.5-38], 19.6 μg/mL [14.4-23.7] and 23.59 μg/mL [14.52-28.97], respectively. Median serum concentrations on II group at 23-hour and 25-hour were 12.30 μg/mL [7.275-18.125] and 17.58 μg/mL [12.5-22.5], respectively. Median AUC[23-48h] from II group was 357.2 mg.h/L and from CI group was 530.2 mg.h/L (p=0.559) (Figure).

Conclusions: Vancomycin CI reached steady state earlier, which guarantee therapeutic levels from the first day and makes it possible to manage therapeutic drug monitoring faster.

Figure. Serum level of vancomycin in critically-ill patients treated with continuous (n=11) and intermittent (n=12) infusion of intravenous vancomycin.

**Infectious complications of patients with breast cancer treated with palbociclib: unexpected serious and opportunistic infections**

Martín Luck*, Patricia Costantini1, Gabriela Zapata2, Patricia Garcia1, Adriana Sorge1, Mara Vallejos1, Vanessa Lopez2, Andrea Aguilar2, Javier Serer1, Mariana Savignano2, Gustavo Roganovich2, Laura Albi2, Marcelo Bronzi3, Diana Bucher3, Valeria Caceres2

1Universidad de Buenos Aires, Instituto de Oncología Angel H. Roffo [Infectious Diseases Department], Buenos Aires, Argentina, 2Universidad de Buenos Aires, Instituto de Oncología Angel H. Roffo [Unit of Breast and Gynecologist Tumors Oncology Department], Buenos Aires, Argentina, 3Universidad de Buenos Aires, Instituto de Oncología Angel H. Roffo [Microbiology Department], Buenos Aires, Argentina

**Background:** An increasing number of patients with solid tumours receive target or biologic therapy due to its efficacy and safety compared with standard chemotherapy. Palbociclib is a cyclin-dependent kinase CDK4 and CDK6 inhibitor approved for the treatment of HER-2 negative metastatic breast cancer. The most common adverse event is neutropenia, but febrile neutropenia is infrequent (1,8%). In Phase II and III trials, 34 to 59% incidence of infectious complications has been reported with no mortality or opportunistic infections. The objective of this study is to describe the characteristics of infectious complications in patients receiving Palbociclib.

**Materials/methods:** Prospective, observational and descriptive study of moderate or severe infectious complications that required infectious disease consultation and/or hospital admission in women with metastatic breast cancer that received Palbociclib from March 2016 until March 2019.

**Results:** 130 patients received Palbociclib. 95/130 (73%) received Palbociclib/Letrozol and 35/130 (27%) Palbociclib/Fulvestrant. Clinical characteristics are shown in the table. 21/130 patients (16%) had 30 episodes of moderate or severe infection, 60% of them during the first 4 cycles of Palbociclib. Out of thirty episodes, two had less than 500 neutrophils/mm$^3$, and 12 less than 800 lymphocytes/mm$^3$. 13/30 episodes were microbiologically and 17 clinically documented infections. Sources of infection were skin and soft tissue (35%), respiratory (30%), Herpes simplex and Zoster (16%), urinary tract infections (5,5%) and others (13,5%). Among microbiological documented infections, 83% were bacterial and 17% fungal. Several opportunistic infections were identified: 3 Varicella zoster virus, 2 Aspergillus spp, 1 Nocardia spp, 1 Roseomania gilardii. In 14 episodes, admission was required, 4 in the ICU. Four patients died.

<table>

</tr>
</tbody>
</table>

**Conclusions:** 16% of 130 patients had at least one episode of moderate/severe infection, of which 46% required admission. Most of them in non-neutropenic patients. Four patients died.

Opportunistic infections not previously described were documented in patients that received no other immunosupression. More prospective studies are required for a proper characterization of infectious complications associated with Palbociclib.

Amikacin probability of target attainment in critically ill oncological patients: results from a prospective observational cohort.

Olivia Borges1, Karen Migotto1, Juliana Valeria Souza Framil2, Michel Leandro Campos3, Pedro Caruso4, João P. Telles2*, Ivan Leonardo França Jr1

1A.C.Camargo Cancer Center, São Paulo, Brazil, 2A.C.Camargo Cancer Center, Department of Infectious Disease, São Paulo, Brazil, 3Federal University of Mato Grosso, Health Science Institute, Sinop, Brazil, 4A.C.Camargo Cancer Center, Department of Intensive Care, São Paulo, Brazil

Background: Aminoglycosides are major therapeutic options against resistant gram-negative bacilli (GNB). Once important variability in pharmacokinetic/pharmacodynamics parameters between populations is observed, probability of target attainment (PTA) from general populations may not be used to critically-ill oncological patients. The aim of this study was to evaluate PTA from extended interval amikacin regimen in oncological patients admitted to intensive care unit (ICU).

Materials/methods: This was an observational prospective cohort study from a brazilian cancer center. Patients with amikacin prescription, admitted to ICU, > 18 years, and diagnosed with oncological disease were included. Amikacin infusion occurred during 30 minutes and blood samples were collected until 30 minutes from infusion end (Cmax) and on day-after (Cmin) to every infused dose. According protocol, PD target was a ratio of 10 between Cmax and minimal inhibitory concentration (MIC). Clinical and laboratorial data were collected. Monte Carlo simulation was conducted to predict PTA in > 90% of patients using MICs 2, 4 and 8 mg/L. Elimination rate constants and volumes of distribution were calculated assuming a one-compartment model pharmacokinetics.

Results: Fifteen patients were included. Each patient provided between one and four pairs of concentrations (Cmax-Cmin). Ten (66%) patients were male, median age was 66 [28-74], median weight was 74.4 Kg [69-83] and septic shock was diagnosed in 7 (47%). Median albumin plasma level was 1.9g/dL [1.5-2.1] and Creatinine Clearance (ClCr) was 64 ml/min [28-150]. Median amikacin first dose and Cmax were 18mg/Kg [14-28] and 46.8 mg/L [34.9-63.8], respectively. Median elimination rate constant (kel) was 0.085 [0.05-0.10] and volume of distribution (Vd) was 0.36 L/Kg [0.30-0.44]. PTA in all included patients using MIC of 2, 4 and 8 were 8.66, 17.32 and 34.63mg/Kg, respectively (Figure). Furthermore, considering only patients with ClCr < 60ml/min, PTA using MIC of 2, 4 and 8 were 7.32, 14.65 and 29.29mg/Kg, respectively.

Conclusions: Amikacin higher doses than 15-25mg/kg on critically-ill oncological patients are needed to achieve PD considering MIC of 8mg/L regardless of ClCr. More studies are needed to understand inter-individual variability of amikacin parameters among oncological patients.

Figure. Amikacin PTA from critically-ill oncological patients using MICs of 2, 4 and 8mg/L.

Presenter email address:jpmarochi@hotmail.com
Background: Carbapenem-resistant Enterobacteriaceae (CRE) infectious disease became a notifiable disease since 2014 under the infectious diseases control law of Japan. In addition, in March 2017, a national pathogen surveillance for isolates obtained from reported CRE cases was launched to reveal the molecular epidemiology of CRE infections.

Materials/methods: Isolates, mainly from reported cases of CRE infection, were collected and sent to local public health laboratories. CRE was defined as Enterobacteriaceae resistant to meropenem (minimum inhibitory concentration [MIC] ≥ 2 µg/mL), or to both imipenem (MIC ≥ 2 µg/mL) and cefmetazole (MIC ≥ 64 µg/mL). All isolates were subjected to the disk diffusion test to screen for β-lactamase production according to the provided standardized testing protocol. All isolates were also tested for the four major carbapenemase genes (bla<sub>IMP</sub>, bla<sub>NDM</sub>, bla<sub>KPC</sub>, and bla<sub>OXA-48-like</sub>) by the PCR.

Results: Since the beginning of CRE pathogen surveillance, PCR results for 2587 isolates have been reported. The most prevalent was Klebsiella aerogenes (918, 35.5%), followed by Enterobacter cloacae (730, 28.2%), Klebsiella pneumoniae (275, 10.6%), and Escherichia coli (247, 9.5%). Among those isolates, 540 (20.9%) were carbapenemase gene-positive Enterobacteriaceae (CPE). K. aerogenes was the most prevalent species among tested CRE isolates. However, only three (0.3%) isolates were CPE compared to 537 (32.2%) for non-K. aerogenes isolates. Among CPE isolates, the most prevalent carbapenemase gene was bla<sub>IMP</sub> (488 isolates, 90.4%), which is a known domestic gene in Japan. Among the isolates harboring bla<sub>IMP</sub>, E. cloacae (157, 32.2%) was most prevalent species, followed by K. pneumoniae (123, 25.2%) and E. coli (114, 23.4%). There were 39, 13, and four isolates with bla<sub>NDM</sub>, bla<sub>KPC</sub>, and bla<sub>OXA-48-like</sub>, respectively. About 70% of these non-bla<sub>IMP</sub> CPE isolates were obtained from patients with no or an unknown linkage with travel to foreign countries. The remainder of the isolates had epidemiological linkages with mainly foreign Asian countries such as Vietnam, China, and India.

Conclusions: The national pathogen surveillance system revealed that bla<sub>IMP</sub>-positive E. cloacae was most common among CPE isolates in Japan. Increasing reports of bla<sub>NDM</sub>-positive isolates from cases without international travel may reflect sustained local transmission from imported cases.

**Background:** Tissues from cadaveric donors can be applied in several clinical condition, however, despite rigorous microbiological and viral screening of tissues donors, transmission of infectious diseases has been reported, such as hepatitis C virus (HCV). Moreover, cadaveric blood may be affected by inhibition phenomena after death. The aim of this study was to evaluate the performance, specificity, sensitivity, and accuracy of different commercial molecular tests for the detection and quantification of HCV in peripheral blood samples from cadaveric donors through artificial contamination.

**Materials/methods:** All the 20 cadaveric samples were obtained after donator or family consent term concordance. The samples were tested by spiking 1,000 IU/mL (3.00 log) of lyophilized standards of HCV 14/150 (NIBSC/WHO/2016). Samples were analyzed by XPERT HCV Viral (Cepheid), COBAS® TaqMan® HCV Test, v2.0 (Roche), and artus® HCV RG RT-PCR Kit (Qiagen). Student’s T-test and p value concordance and sensitivity, specificity and accuracy were calculated.

**Results:** Cepheid's kit could quantify all 20 cadaveric donor samples with a mean quantification of 2.50 log (SD 0.17) and 343.35 IU/ml (SD 134.36), 100% accuracy, 100% specificity and 100% sensitivity. Roche's kit showed a mean quantification of 2.62 log (SD 0.30) and 501.11 IU/ml (SD 308.96) for cadaveric donor samples, however, 2 out of 20 samples showed no detection of virus and 2 out 20 samples showed an invalid result. Moreover, 2 out 5 negative controls showed an invalid result, demonstrating 60% specificity, 80% sensitivity and 76% accuracy. For Qiagen's kit, the spiked samples showed that 8 were invalid and 12 did not have virus detected, while the negative controls showed that 4 were invalid and 1 did not have virus detected, demonstrating that the test had 0% accuracy, 20% specificity and 0% sensitivity (Figure 1).

**Conclusions:** The evaluation and comparison of different kits and brands showed a wide variability in cadaveric samples. Qiagen's kit did not present satisfactory results, while Roche and Cepheid kits can be applied for tissue donors screening for HCV with more than 1,000 IU/ml.

**Figure 1.** Boxplot indicating HCV [IU/ml] mean detection and SD among the brands for cadaveric donor samples by Student’s T-test.

Evaluation of biofilm formation and removal efficacy of three medical-device detergents by bacterial and yeast species

Kuenyoul Park*, Kyu-Hwa Hur¹, Heungsup Sung¹, Mi-Na Kim¹

¹Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Biofilm formation is a major risk upon the reuse of chronic devices and physical cleaning is essential before disinfection. This study was performed to evaluate the efficacy of enzymatic and non-enzymatic detergents against biofilms formed by various bacterial and yeast species.

Materials/methods: Biofilm removal by two enzymatic agents, Empower™ and Cidezyme™, and a non-enzymatic detergent, Matrix mint™, was tested in comparison to chlorine bleach and distilled water (DW). Staphylococcus aureus RN9120 (SA9120), Enterococcus faecalis clinical isolate (CI), Escherichia coli ATCC35218 and CI, Klebsiella pneumoniae CI, Pseudomonas aeruginosa ATCC27853, Candida albicans ATCC14053, Candida auris CI, and Trichosporon asahii CI were used for the test, with S. aureus RN6607 (SA6607) as the biofilm-negative control. After 72-hour incubation of the test organisms in tryptic soy broth (TSB) and 96-well polystyrene plates, a residual biofilm mass was measured by crystal violet staining after rinsing with the detergents with or without incubation for 30 minutes at room temperature (RT) and 37°C.

Results: All strains showed significant biofilm formation with a mean optical density at 620 nm (OD₆₂₀) ranging from 0.61 to 1.44, while SA6607 did not (OD₆₂₀: 0.10). SA9120 fully produced biofilms only when 4% NaCl was added to TSB. Compared to DW, Empower™ and Cidezyme™ significantly reduced (>50% of OD₆₂₀ at 37°C) biofilm masses for all strains except E. faecalis, T. asahii, and C. auris. Matrix mint™ did not reduce biofilms significantly at any condition.

Conclusions: Biofilm formation and detergent efficacy vary according to the bacterial and yeast species. Especially, E. faecalis, C. auris, and T. asahii biofilm were resistant to detergent treatment under all conditions.

Abstract 2791

First epidemiological report on colistin- and carbapenem-resistant Enterobacteriaceae isolates obtained from selected tertiary hospitals in south-eastern Nigeria

Uchenna Ijioku Ugah*, 1 Theophilus Kachi Udeani2

1 Alex Ekwueme Federal University Ndufu-Alake Ikwo, Department of Microbiology, Faculty of Sciences, Alex Ekwueme Federal University Ndufu-Alake, Ikwo, Nigeria, 2 University of Nigeria Enugu Campus, Department of Medical Laboratory Science, Faculty of Health Sciences and Technology, Enugu, Nigeria

Background: Colistin is the last line of treatment reserved for Enterobacteriaceae isolates that have become resistant to drugs including the cephalosporins and carbapenems. However, there have been reports of high prevalence of carbapenem resistance in other regions of Nigeria. This study aimed at determining the occurrence of carbapenem and colistin resistant Enterobacteriaceae in clinical isolates obtained from tertiary hospitals in South-Eastern Nigeria. One tertiary hospital was selected from each of the five states that make up the region.

Materials/methods: A total of 400 Enterobacteriaceae isolates obtained from the medical microbiology laboratories were used for this study. The total number of isolates obtained from each hospital was 77, 103, 116, 52 and 52 from FMC Umuahia, AEFUTHA, ESUTH, ISUTH and COOUTH respectively. Colistin resistance was detected using broth microdilution method. Four tubes were used having concentrations of 2µg/ml, 4µg/ml, 6µg/ml and 8µg/ml of colistin sulphate (Oxoid, Batch number 2372007). Resistance to carbapenem was detected using disk diffusion method with disks containing 10µg each of ertapenem, imipenem, meropenem and doripenem. Results were interpreted based on CLSI and EUCAST version 8.1 guidelines. An isolate was recorded as being carbapenem resistant if it showed resistance to all the carbapenems tested. Data was analyzed using SPSS version 20.0

Results: Overall, colistin resistance was detected in 103 (25.75%) isolates while carbapenem resistance was observed in 117 (29.25%) isolates in tertiary hospitals in South-eastern Nigeria. From each of the states, colistin resistance was observed in 16 (20.78%), 29 (28.16%), 38 (32.76%), 11 (21.15%) and 9 (17.31%) from isolates obtained from FMC Umuahia, AEFUTHA, ESUTH, ISUTH and COOUTH respectively. Also, carbapenem resistance detected in isolates obtained from these hospitals were; 19 (24.68%), 30 (29.13%), 39 (33.62%), 15 (28.85%) and 14 (26.92%) respectively.

Conclusions: There was a high rate of colistin and carbapenem resistance in all the tertiary hospitals in South-eastern Nigeria and these calls for strict infection control measures to prevent further decline. This is because colistin resistance when fully established may result in situations worse than the era before the discovery of antibiotics.

Abstract 2792

Empowering nurses to assess patient-reported antibiotic allergies: a pilot implementation study of a validated antibiotic allergy assessment tool

Misha Devchand1,2, Emma Cohen1, Steven Walker1,2, Kyra Chua1, Natasha Holmes1, Susan E Bury1, Kent Garrett1, Jason Trubiano1,3,4

1Austin Hospital, Heidelberg, Australia, 2Monash University Parkville Campus, Parkville, Australia, 3Peter MacCallum Cancer Centre, Melbourne, Australia, 4University of Melbourne, Parkville, Australia

Abstract third-party references: Austin Health

Background: Up to 23% of patients with cancer report an antibiotic allergy. A documented antibiotic allergy has significant impacts on morbidity, mortality and medication safety. However, 50% of documented penicillin allergies are low-risk and potentially amenable to direct de-labelling or removal following oral provocation. The aim of this study was to evaluate the feasibility of implementing a nurse-led antibiotic allergy assessment tool (AAAT) at point-of-care.

Materials/methods: Two weeks prior to implementation of the AAAT, an education package, comprising of two 20-minute face-face education sessions, was delivered to hematology nurses at Austin Health (Melbourne, Australia). The haematology ward implemented the AAAT on the 01/04/19 and nurses were encouraged to integrate the AAAT into their routine admission procedure. The results following this intervention were audited from 01/04/19 to 31/10/19. Completeness of antibiotic allergy documentation pre/post allergy assessment, referral of low-risk allergies to the antibiotic allergy service, and number of allergies de-labelled by the antibiotic allergy service was collected for patients (≥18 years) admitted to the ward with a reported antibiotic allergy. An independent AMS pharmacist evaluated the accuracy of the antibiotic allergy assessments by reviewing blinded nurse completed AAATs.

Results: 57 patients were included in the 6-month audit. During this period a total of 80.7% (46/57) patients had an allergy assessment undertaken by nurses using the AAAT. At the time of admission 69.6% (32/46) of patients identified had allergies with complete documentation (substance, reaction type and severity), which increased to 84.8% (39/46, p = 0.14) when the same patients were assessed by nurses using the AAAT. Of the antibiotic allergy assessments completed by nurses, 93.5% (43/46) were concordant with the assessment by the independent AMS pharmacist. 52.2% (24/46) of patients had allergies that were assessed as low-risk, of which 87.5% (21/24) were referred to the antibiotic allergy service. Of the 24 patients that were referred to the antibiotic allergy service with low-risk allergies 41.7% (10/24) had their allergy de-labelled.

Conclusions: This audit highlights the value of empowering nurses to accurately assess antibiotic allergies at point-of-care using a validated tool. The AAAT improved antibiotic allergy documentation which is central to modern AMS activity.

Abstract 2797

**Intravenous administration of personalised cocktail of bacteriophages as salvage therapy in combination with ceftazidime/avibactam in patients with relapsing *Pseudomonas aeruginosa* bacteraemia associated with intravascular implants: lesson to be learned from two cases**

Tristan Ferry\(^1\), Anne Conrad\(^1\), Claude-Alexandre Gustave\(^1\), Camille Kolenda\(^1\), Fadi Farhat\(^1\), Mélanie Catroux\(^3\), France Cazenave-Roblot\(^1\), Claire Triffault-Filillet\(^1\), Cindy Fevre\(^4\), Charlotte Petitjean\(^1\), Christian Chidiac\(^1\), Jérome Josse\(^1\), Gilles Leboucher\(^1\), Frédéric Laurent\(^1\)

\(^1\)Hospices Civils De Lyon - HCl, Lyon, France, \(^2\)Claude Bernard University Lyon 1, Centre International de Recherche en Infectiologie, Villeurbanne, France, \(^3\)Poitiers University Hospital, Poitiers, France, \(^4\)Pherecydes Pharma, Romainville, France

**Background:** Lytic bacteriophages trigger bacterial lysis through their multiplication in an exponential and self-sustained reaction. They have a high therapeutic potential in patients with implant-associated infection, as they have a synergistic activity with antibiotics on biofilm-embedded bacteria.

**Materials/methods:** We managed 2 patients (64, 67 yo) with relapsing *P. aeruginosa* bacteremia associated with intravascular implants (prosthetic aortic valve, coil infection following bronchial artery embolization) for whom surgery was impossible or at risk of death. Both of them experienced >6 relapses in the previous year. After discussion with the French health authority, 3 bacteriophages produced following Good Manufacturing Practice (GMP) guidelines were selected by Pherecydes based on their activity (Panel A). Hospital pharmacist mixed each phage (1 ml of 1x10\(^{10}\) PFU/ml) extemporaneously as "magistral" preparation (final dilution 1x10\(^{8}\) PFU/mL). Bacteriophages quantification before and after the mix and in the blood of the first patient were performed to determine the optimal way of preparation and administration. Phages were administered every 2 or 3 days, during 10 to 21 days in combination with cedtazidime/avibactam prescribed during 6 weeks, if possible in combination with another active drug (fosfomycin or colistin).

**Results:** Phages were administered to the first patient during a 6 hours infusion with an electronic pump. Depending on the filter used, we observed a decrease of the titer in the final solution: no bacteriophages were detected in the line, as well as in the patient’s blood. As this patient experienced a relapse, direct (5 min) intravenous injections of phages were then performed, after using the adequate filter. One bacteriophage was detected in the patient’s blood. Blood cultures became negative. A new prosthetic valve exchange was done, and postoperative cultures were now negative (panel B). The second patient also received direct IV injections following the same process, and blood cultures remained negative during the three months follow-up.

**Conclusions:** The type of filter used for the magistral preparation and the duration of the perfusion influenced the phage titer, as the titer in the patient’s blood. Personalized GMP bacteriophage therapy has the potential to be used as salvage therapy of *P. aeruginosa* intravascular implant infections.

A Prospective randomised controlled trial comparing the effectiveness of smartphone video directly-observed therapy (VDOT) versus in-person DOT in newly-diagnosed pulmonary tuberculosis patients

Thanawin Saewong*, Warangkana Keeratichananont

1Songklanagarind hospital, Prince of Songkla University, Hatyai, Thailand, 1Songklanagarind hospital, Prince of Songkla University, Hatyai, Thailand

Background: In-person directly observed treatment (DOT) has been the standard of care in tuberculosis for improved drugs adherence. But it is still inconvenient for patients and service providers. Video directly observed therapy (VDOT) has been conditionally recommended as an alternative to DOT. But the evidence was graded weak due to few randomized controlled trials available and more recently, smartphone apps have been developed that enable video clips to be recorded and forwarded for later viewing smartphone (VDOT). The objective is to compare treatment successful and drugs adherence rate between smartphone VDOT versus in-person DOT

Materials/methods: A prospective randomized controlled study was conducted in newly diagnosed pulmonary tuberculosis patients in Songklanakarind Hospital. We randomly assigned participants to either smartphone VDOT (daily remote observation using LINE app) or in-person DOT until treatment completion. In VDOT group, patients were trained to record and send videos of every dose ingested 7 days per week using a smartphone app. Authorized doctor or trained treatment observer view these videos through a password-protected application. In-person DOT, we designed for use family-based DOT technique. Treatment successful and drugs adherence rate between groups were compared. Measurement of satisfaction by using patient satisfactory score.

Results: Sixty-one patients were enrolled. We randomly assigned 30 patients to smartphone VDOT and 31 patients to family-based DOT. There were no significant differences in baseline characteristics between the two groups. In the ITT analysis for the patients who already treatment completion, Anti TB drugs adherence rate was higher in VDOT group 98% compared to 78% in family-based DOT group, \( p = 0.046 \). Treatment successful rate with smartphone VDOT group was similar to family-based DOT group 100% vs. 89%, \( p = 0.089 \). And this study found, smartphone VDOT was feasible and acceptable for patients with pulmonary tuberculosis, mean satisfactory score 10 vs. 8.5 for family-based DOT \( p=0.048 \).

Conclusions: Smartphone VDOT was feasible, acceptable and enhance high treatment successful rate, with higher anti TB drugs adherence rate when compared with family-based DOT.

Abstract 2801

Human parechoviruses infections in northern of Spain, 2016-2019
Ana Navascués Ortega1, Aitziber Aguinaga Perez2, María Cabrerizo3, María Eugenia Portillo4, Carmen Ezpeleta Baquedano5

1Complejo Hospitalario de Navarra, Pamplona, Spain, 2Complejo Hospitalario de Navarra, Pamplona, Spain, 3Instituto de Salud Carlos III, National Centre for Microbiology (CNM), Enterovirus and Parechovirus Laboratory, Madrid, Spain, 4Complejo Hospitalario de Navarra, Pamplona, Spain, 5Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Human parechoviruses (HPeV) are RNA viruses which belong to the family Picornaviridae and 19 genotypes are described currently. HPeV cause gastrointestinal, respiratory diseases, fever and also serious diseases such meningitis, encephalitis and sepsis-like illness. Infections are prevalent in young children, mainly in patients under three months of age. The aim of this study is to review clinical presentation, epidemiology and characteristics of HPeV cases detected from June 2016 to July 2019 in Navarra.

Materials/methods: The retrospective study included 478 clinical samples (CSF and/or blood) from 442 patients hospitalized in Navarra (650,000 citizens) from June 2016 to July 2019. HPeV were detected using a commercial PCR, Progenie Molecular). Genotyping was performed in the CNM.

Results: HPeV were detected in 8 (1.6%) samples from 5 patients: 3 were positive in CSF and blood samples and 2 only in blood. Three cases were detected in 2017 and 2 in 2019. Median age was 21 days (interquartile range IQR: 28.5-12.5 days). Three were male. Genotypes identified were HPeV3 in 4 cases and HPeV4 in one. Clinical diagnosis of the HPeV-infected patients was febrile illness or neonatal sepsis. Symptoms were: fever (5/5), irritability (4/5), rash (3/5), gastrointestinal illness (3/5), mild respiratory illness (2/5), vomiting (0/5), neurological disorders (0/5). In 4 cases, CSF biochemistry was: median white cells 2.5 leucocytes/mm3 (IQR: 0.25-4), median red blood cells 192 hematies/mm3 (IQR: 1.-1595), median glucose 51mg/dL (46.75-71.75), median protein 46.5g/L (38-50.95). There were not any neurological sequels (0/5). The study of stools was performed in 2 of the patients and in both HPeV was detected.

Conclusions: All HPeV cases were children under three months of age with febrile illness or neonatal sepsis. HPeV infections are characterized by no pleocytosis and normal glucose and proteins levels. It is important to include HPeV detection in the routine diagnosis of infections in young children with febrile illness or neonatal sepsis, being CSF or blood the most suitable samples for it. Stools are not invasive samples which could be useful

Presenter email address: me.portillo.bordonabe@navarra.es
Evaluation of the RIDA GENE CAP Bac real-time PCR assay for diagnosis of community-acquired pneumonia from human bronchoalveolar lavage (BAL)

Andreas Hiergeist, Silvia Foerster, Andreas Simons, Udo Reischl

1microBIOMix GmbH, Regensburg, Germany, 2Universitätsklinikum Regensburg, Institute of Clinical Microbiology, Regensburg, Germany, 3R-Biopharm, Darmstadt, Germany

Background: Community acquired pneumonia (CAP) is the most frequently registered infectious disease worldwide and the most frequent fatal infectious disease in Western nations. The most common atypical CAP bacteria are Chlamydophila pneumoniae, Legionella spp. and Mycoplasma pneumoniae. This study aimed to evaluate the performance of the RIDA®GENE CAP Bac multiplex real-time PCR assay or the direct qualitative detection of Chlamydophila pneumoniae, Legionella pneumophila and Mycoplasma pneumoniae in human bronchoalveolar lavage (BAL).

Materials/methods: The RIDA®GENE CAP Bac is a qualitative multiplex real-time PCR assay targeting the 16S-rRNA for Chlamydophila pneumonia, 16s-rRNA for Legionella pneumophila and the IGS for Mycoplasma pneumoniae with fluorogenic target-specific hydrolysis probes. Evaluation of the RIDA®GENE CAP Bac assay was performed retrospectively on 282 extracted BAL leftover specimens against an routine DIN EN ISO 15189 accredited in-house real-time PCR assay on the Lightcycler 480II (Roche). DNA extraction was performed on the MagNA Pure 96 (Roche) according to laboratory SOP. In addition, also the reactivity with Legionella pneumophila (serogroup 1-14, w/o serogroup 11) from culture material was evaluated.

Results: Of the 282 samples, 17 samples were excluded as the RIDA®GENE CAP Bac assay classified them as invalid. Compared to the in-house real-time PCR as gold standard the sensitivity, specificity, PPV and NPV of the RIDA®GENE CAP Bac assay were 100%, 100%, 100% and 100 % for Chlamydophila pneumonia, 100%, 97.7%, 90.9% and 100 % for Legionella pneumophila, and 100%, 100%, 100% and 100 % for Mycoplasma pneumonia, respectively. All cultured Legionella pneumophila serogroups were detected correctly.

Conclusions: The RIDA®GENE RIDA®GENE CAP Bac multiplex real-time PCR assay showed an excellence performance in terms of sensitive and specific for the differentiation and diagnosis of Chlamydophila pneumoniae, Legionella spp. and Mycoplasma pneumoniae from human bronchoalveolar lavage (BAL).

Abstract 2809

Nation-wide survey of catheter-related bloodstream infections in medical, surgical and intensive care settings, 2019

Marie Decalonne1, Florent Goube1, Rémi Gimenes1, Agnès Petiteau1, Anne Berger-Carbonne2, Stephane Le Vu2, Nathalie Laure Van Der Mee-Marquet*3

1CHRU Hôpitaux De Tours, Tours, France, 2Direction Maladies Infectieuses, Unité Infections associées aux soins et Résistance aux Antibiotiques, Saint-Maurice, France, 3CHRU Hôpitaux De Tours, Hôpital Bretonneau, Tours, France

Abstract third-party references: SPIADI network

Background: Prevention of intravascular catheter-related bloodstream infections (CRBSIs) is a public health issue. In this context, a nation-wide network, named SPIADI (Surveillance and Prevention of Invasive Devices Associated Infections) gathers the French infection control teams who develop in their hospitals a 3-pronged strategy combining CRBSI-monitoring, field observation, and education of the healthcare-workers responsible for insertion and use of catheters along the patient course.

Materials/methods: A nation-wide 3-month survey of CRBSIs was conducted (January-April 2019) to provide a baseline description of CRBSI events in both ICU and non-ICU French hospital settings, to identify potential interventions. We used a unit-based protocol close to ECDC-HAI-Net-ICU protocol 1.02. Briefly, for all nosocomial BSIs, the variables studied included patient age and sex, place of acquisition, portal of entry, and for CRBSI, insertion site and time between insertion and first signs of BSI.

Results:

- 1001 participating hospitals (including 64% of the 529 French tertiary-hospitals, 54% of the 570 acute-care clinics, 89% of the 18 oncology specialized-hospitals), covering 129477 beds (including 60% of the 6313 French ICU-beds), 13390393 patient-days (PD) and 701277 dialysis-sessions.
- 9381 nosocomial BSIs detected, including 3292 CRBSIs (31%); higher prevalence for dialysis-units (71%), cancerology (56%), hematology (36%) and ICUs (33%).
- CRBSI acquisition into hospitals (87%) or following home-care or inner-city-medical-care (13%); into ICUs (21%).
- CRBSI associated with implantable-venous-access-port (ivap) (33%), central-venous-catheter (cvc) (24%), peripheral-inserted-central-venous-catheter (picc) (14%) and short-peripheral-venous-catheter (PVC) (15%).
- Predominance of S.aureus (21%), CoNS (28%) and Enterobacteriaceae (19%); multidrug-resistant bacteria/fungi in 9% of CRBSI (15% in ICUs).
- 36% ivap-RBSI associated with staphylococci and arising >4 weeks after insertion, suggesting no strict asepsis during catheter use.
- 25% cvc-RBSI associated with staphylococci and arising <7 days after insertion, suggesting inadequate skin antisepsis during catheter insertion;
- time between PVC-insertion and first signs of BSI >7 days in 20% of S.aureus-pvcRBSIs, suggesting long-term use of PVCs.
- Clusters of P.aeruginosa, K.pneumoniae- and Enterobacter-CRBSI in ICU and hematology-oncology wards, suggesting environmental contamination.

Conclusions: The description of CRBSIs currently detected in intensive care, medical and surgical settings, provides multiple opportunities for improvement, and allows defining SPIADI-network priorities for 2020: [1] local observation of catheter insertion and use to detect the likely gaps between practice and guidelines, and [2] an awareness-building activity on the epidemic risk associated with sinks colonized by Enterobacteriaceae into ICUs.

Presenter email address: n.vandermee@chu-tours.fr
Background: Epstein–Barr virus (EBV) is a human lymphotropic herpesvirus that is carried in a latent, essentially non-pathogenic state by 80–90% of all humans. EBV is associated with a variety of lymphomas/leukemias, and other malignancies. Instead of performing a tissue biopsy of the primary tumor, EBV viral load quantification has played a more important role in the diagnosis and management of EBV-associated diseases in immunocompromised patients.

The CE-IVD marked AltoStar® Automation System AM16 [AAS] was launched by altona Diagnostics GmbH, Germany in April 2018. This flexible system automates the entire workflow from sample preparation to analysis. The purpose of this study was to evaluate the performance of the AAS relative to our current method for quantitative EBV PCR.

Materials/methods: A total of 124 samples (121 patients’ EDTA whole blood [WB] samples and 3 proficiency samples from the College of American Pathologists [CAP]) were tested in parallel using the RealStar EBV assay on the Biomerieux EasyMag/Bio-Rad CFS96 Deep Well® Real-Time System (EasyMag/CFX96) and the AltoStar EBV assay on the AM16/Bio-Rad CPX96 Deep Well® Real-Time system (AM16/CFX96). Samples with discordant results were reviewed and retested on both systems.

Results: Overall, the AM16/CFX96 system agreed well with the established EasyMag/CFX96 System.

Correlation study using EDTA WB demonstrated that the EBV viral load obtained using the AM16/CFX96 system was 0.65log10 higher than the one obtained using the EasyMag/CFX96 system.

The Limit of Detection (LoD) using the AM16/CFX96 system was 4.80E+02 IU/mL for EBV WB samples. The study of the linear range for EBV using the AM16/CFX96 system yielded a lower limit of quantification (LLoQ) of 1.5E+3 IU/mL. The coefficient of variation (%CV) of high positive control and low positive control with the AM16/CFX96 system were less than 5% and 10%, respectively.

The AM16/CFX96 significantly reduced the turn of time (TAT) for EBV WB testing by 50 per cent using AM16/CFX96.

Conclusions: With the limited number of samples we tested, the AM16/CFX96 system had a comparable lab performance to the EasyMag/CFX96 system. In addition, it improved workflow and productivity. Further evaluation using samples other than whole blood are needed.

Abstract 2819

**Types of carbapenemases produced by Gram-negative bacteria detected isolated in cancer hospital in 2017-2019**

Victoria Aginova¹, Natalia Dmitrieva², Petukhova Irina²,2, Zlata Grigoryevskaya², Nataliya S. Bagirova², Svetlana Dyakova², Inna Tereshchenko², Irina Klyuchnikova²

¹College of medicine, Moscow, Russian Federation, ²NN Blakhin National Medical Research Center of Oncology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

**Background:** Gram-negative microorganisms producing carbapenemase are particularly dangerous in the event of infectious complications of cancer

**Materials/methods:** 161 strains of carbapenem-resistant (Car-R) gram-negative bacteria isolated from various biomaterials in 2017-2019 were studied jointly with the Research Institute of Antimicrobial Chemotherapy (Smolensk, Russia). Microorganisms were identified using MS MALDI-ToF. Carbapenem resistance was determined using Vitek 2 and WalkAway analyzers. Genes encoding carbapenemases were detected by PCR real-time. *P. aeruginosa* isolates were tested for metal-β-lactamases (MBL), including VIM, IMP and NDM. *A. baumannii* isolates were tested for the abovementioned MBLs and for OXA carbapenemases (OXA-23, -24/40, -51, -58). *K. pneumoniae* were tested for MBLs and OXA-48 and KPC - carbapenemases.

**Results:** *K. pneumoniae* accounted for 10.0% of all microorganisms isolated in 2017-2019 (2017 - 10.8%, 2018 - 9.2%, 2019 - 10.0%), *A. baumannii* accounted for 5.5% (5.1%, 5.9% and 5.0%, respectively) and *P. aeruginosa* – for 7.1% (6.7%, 7.6%, 7.1%, respectively). 161 Car-R isolates of gram-negative bacteria (123 in 2017-2018 and 38 in 2019) included 48 isolates of *A. baumannii* (29.8%), 38 isolates of *P. aeruginosa* (23.6%) and 47 isolates of *K. pneumoniae* (29.1%). The remaining Car-R isolates (17.5%) comprised single strains of various enterobacteria and were not taken into account in a further study. 94.7% of *A. baumannii* isolates were producers of OXA-23 type carbapenemases (97.1% in 2017-2018 and 92.3% in 2019), 88.2% of *K. pneumoniae* isolates produced OXA-48 type carbapenemases (86.5% in 2017-2018 and 90.0% in 2019), KPC-carbapenemases (2.1%) and metal-β-lactamases NDM-type (2.1%). 44.2% of *P. aeruginosa* isolates produced VIM-type MBL (46.7% in 2017-2018 and 41.7% in 2019) (p> 0.05).

**Conclusions:** no significant difference in species composition and types of carbapenemases, produced by *A. baumannii, K. pneumoniae* and *P. aeruginosa* in 2017-2019, was seen. Car-R *K. pneumoniae* mostly (88.2%) produced OXA-48 carbapenemases. *A. baumannii* mostly (94.7%) produced OXA-23. *P. aeruginosa* frequently produced MBL (44.2%, type VIM). Production of MBL (NDM type) by *K. pneumoniae* was low (2.1%). The determination of the types of carbapenemases in cancer patients with nosocomial infections is extremely valuable, as it allows to determine strategy and tactics of antibiotic therapy in a particular hospital.

Molecular epidemiology of vancomycin-resistant enterococcus in parts of China
Hongli Sun*, Liu Chang, Yingchun Xu

*Peking Union Medical College Hospital (PUMCH), Department of Clinical Laboratory, Beijing, China, Beijing Huaxin Hospital, the First Hospital of Tsinghua University, Department of Clinical Laboratory, Beijing, China

Background: Enterococcus is conditional pathogens that are associated with nosocomial infections, often causing bloodstream and urinary tract infections. Vancomycin-resistant Enterococci (VRE) mostly is Enterococcus faecium carrying vanA type in China, but vanM type was reported in several hospitals in Shanghai, China. Most VRE strains in hospitals are clonal complex 17 (CC17). This study retrospectively studied the molecular epidemiology of VRE in multiple centers in China from 2006 to Oct 2019 to understand the epidemiological characteristics.

Materials/methods: A collection of 245 VRE (240 VREfm and 5 VREFs strains) strains from 16 hospitals of China were selected in this study. MICs of antibiotics were determined by using a microdilution broth method. Vancomycin resistance and virulence genes were detected by PCR. The clonal dissemination and genetic relationship of strains were analyzed by PFGE and MLST. 25 VREfm isolates from blood were analyzed by WGS, and vancomycin resistance and virulence genes were further identified. The phylogenetic tree conducted by wgSNP and cgMLST was used to presume the genetic relationship of Enterococcus faecium.

Results: No tetracycline, daptomycin and linezolid non-sensitive VRE isolates were found, but the increased trends for daptomycin MICs were observed. 93.3% (224/240) of the strains carried vanA, while the strains carrying vanA and vanM accounted for 6.3% (15/240), which were all from Beijing. Up to 82.9% (199/240) and 55.4% (133/240) of the strains carried esp and hyl, respectively. The majority of ST types of VREfm strains belonged to ST78 (45.8%, 110/240), which grouped into CC17. The results of PFGE showed a highly diverse genetic background. The results of cgMLST and wgSNP were more consistent.

Conclusions: VRE in China is still dominated by vanA-VanA type. Daptomycin and linezolid still have good activities for VRE in vitro, but the increased trends for MICs for daptomycin were observed. The dominant clone of VRE in China was ST78-CC17. Based on wgSNP typing, a few VREfm strains were epidemic in the same ward or among different wards in the same hospital, and even in different hospitals and cities, sometimes caused outbreaks.

No negative conversion at follow-up blood culture (FUBC) is significant predictors of early [1-week] mortality in carbapenem-resistant Enterobacteriaceae or vancomycin-resistant enterococci bacteraemia patient: univariate and multivariate analysis

Shi Hyejin*1, Hyeah Choi1, Yong Kyun Cho1, Joong Sik Eom1

1Gil Hospital, division of infectious disease, internal medicine department, incheon, South Korea

Background: In bacteremia patients, initial mortality is important. The aim of this study is to find some initial parameters that can predict early [1 week] mortality in carbapenem-resistant Enterobacteriaceae (CRE) or vancomycin-resistant Enterococci (VRE) bacteremia patients.

Materials/methods: From January 1, 2015 through June 30, 2019, we collected CRE and VRE true bacteremia patient in a tertiary hospital, South Korea. Baseline characteristics, initial laboratory data, vital signs, PITT bacteremia score, and early [1 week] mortality were collected. Patients were divided into alive or death group by their survival or death 1 week after initial bacteremia onset. Univariate and multivariate analysis was done.

Results: Total 171 patients was included, 121 were survived and 50 were dead at 1 week after bacteremia onset. There were no differences in baseline characteristics between two groups. In univariate analysis, respiratory-derived, Central line associated blood stream infection, whether follow-up blood culture (FUBC) negative conversion, initial hypotension, and initial C-reactive protein ≥15 mg/dL were related with early mortality of CRE or VRE bacteremia. In multivariate analysis, only no negative conversion in FUBC had statistically significant association with early mortality (OR 1.762, 95% CI=5.726-54.244)

Conclusions: There were several indicators that predicts early mortality in CRE or VRE bacteremia. Only negative conversion of FUBC were statistically significant predictors of early mortality in multivariate analysis.

Abstract 2828

**Accuracy of predicting early mortality of severity indicators among carbapenem-resistant Enterobacteriaceae or vancomycin-resistant enterococci bacteraemia patient: univariate and multivariate analysis**

Shi Hyejin*1, Hyeah Choi1, Yong Kyun Cho1, Joong Sik Eom1
1Gil Hospital, Infectious disease, Incheon, South Korea

**Background:** The desire to predict patient outcome is existed traditionally. It’s more concerning among the severe cases like carbapenem-resistant Enterobacteriaceae (CRE) and vancomycin-resistant Enterococci (VRE) bacteremia. The aim of this study is to evaluate specific severity index that correlates with early mortality in CRE and VRE bacteremia patients.

**Materials/methods:** From January 1, 2015 through June 30, 2019, we collected CRE and VRE true bacteremia patient in gil medical center, single tertiary hospital in incheon, South korea. Patients were divided into alive group versus death group, by their survival or death after 1weeks of initial bacteremia onset. To evaluate severity, acute physiology and chronic health evaluation [APACHE]-IV score, APACHE-mortality rate, sequential organ failure assessment (SOFA) score, PITT bacteremia score, systemic inflammatory response syndrome (SIRS) score, and Charlson-comorbidity index was calculated for each of the patient. Univariate and multivariate analysis was done by SPSS 24.

**Results:** Total 171 patients was included. 100 of the patient had CRE bacteremia and 71 of the patients had VRE bacteremia. 73 patients are alive (alive group) and 98 patients were dead (death group). At univariate analysis, all index except Charlson-comorbidity index had statistically significant association with early-mortality of CRE and VRE bacteremic patients. In multivariate analysis, only PITT bacteremia score was statistically significant to early mortality of CRE and VRE bacteremia patient. The odds ratio was 1.329 (95% CI 1.049-1.684).

**Conclusions:** Among severity indexes, only PITT bacteremia score has statistically significant relationships with early mortality of CRE and VRE bacteremia.

Factors associated with the recurrence of Clostridiodes difficile infection in a university hospital

Jorge Rodriguez Prida, Sagrario Maria Santos Seoane, Marta Izquierdo, Pedro De La Iglesia, Ana Perez-Garcia, Cristina Helguera, Candela Menendez, Alicia Garcia, Jose A Boga, Joaquin Moris, Azucena Rodriguez-Guardado*

1Hospital Universitario de Cabueñes, Gijon, Spain, 2Hospital Universitario Central de Asturias, Oviedo, Spain, 3Fundación Hospital de Aviles, Aviles, Spain, 4Hospital de Jarrio, Coaña, Spain

Background: Around 25% of patients with Clostridium difficile infection (CDI) suffer a recurrence of the disease after finishing the treatment. We describe the factors associated with the recurrence of CDI in a university hospital.

Materials/methods: We performed a retrospective study of all patients older than 18 years with CDI between 2017-2018 in University Hospital of Cabueñes, Spain. C. difficile was detected in stool samples by detection of GDH antigen and toxins A and B using an immunoassay (C. Diff Quick Check Complete, Alere). Those samples with GDH (+)/Toxins (-) were analyzed with the PCR-based assay GenomEra CDX System (ABACUS Diagnostica) to detect gen tcdB. Qualitative variables were compared using the Chi2 test or the Fisher exact test. For quantitative variables, the Student t test or the Mann-Whitney U test were used. Significance was designated at p<0.05.

Results: 60 patients (52.5% females, mean age: 71 years, mean stay before the infection: 6 days) were included. The most frequent underlying diseases were diabetes (23.7%), respiratory diseases (18.6%), inflammatory bowel diseases (12%), neoplasms (13.6%), and hematologic disease (12%). 90% of patients received omeprazole and 91.5% antibiotics. Sixteen (26.7%) patients had a recurrence in five for one second time, seven had three episodes, one four episodes and two five episodes. The first line treatment was metronidazole in 49 patients and vancomycin in the rest. Recurrences were treated first with vancomycin and the rest with fidaxomicin (three cases). Two cases treated with fidaxomicin didn't cure and the patients went under fecal transplant. Omeprazole was retired in 35.4% of patients and antibiotherapy in 81.6% without relation with the apparition of relapses. Six patients died due to the infection. There is not significantly differences in sex, age, or underlying diseases between relapses or not. Toxin was negative more frequent in relapses group (58.3% p=0.055) but multivariable not confirmed this association.

Conclusions: Relapses are frequent in Clostridium difficile infection without relation with sex, age or underlying disease. It is necessary more studied about the virulence factors of the CD and his relationship with human gut microbiota.

Abstract 2841

**Bacterial contamination of collagen membranes in dental surgery**

Aleksandr Rachkov*¹, Tatsiana Shevela¹

¹Belarusian state medical university, Minsk, Belarus

**Background:** Wide using of barrier membranes in dental and maxillofacial surgery is due to the predictability of treatment and the simplicity of the protocol. Resorption of collagen membranes occurs primarily under the action of collagenases and proteases. These enzymes are produced, including parodontopathogenic bacteria, for example, Porphyromonas gingivalis, Actinobacillus actinomycetemcomitans and Treponema denticola. Inflammation and contamination by microorganisms accelerate the splitting of membranes and can lead to the development of postoperative complications, up to the loss of bone tissue volume and the need for repeated operations.

**Materials/methods:** Twenty patients underwent surgery for chronic apical periodontitis (10 patients), radicular cysts (6 patients), third molar retention (4 patients). During the operation from the biotopes of the surgical intervention area, smears were taken for subsequent polymerase chain reaction diagnostics. Determination of DNA of parodontopathogenic and conditionally pathogenic microflora was carried out to 14 species of microorganisms. After filling with a blood clot sockets of extracted teeth and bone cavities after cystectomy, they were covered with barrier membranes made of type II collagen. Re-sampling of material for polymerase chain reaction diagnostics was carried out on the 7th day using a mandrel needle. The needle was inserted under the barrier membrane and the contents of the wound were aspirated with a syringe.

**Results:** The biotopes composition of surgical area in day of surgery is represented by the following species: Porphyromonas gingivalis (6 patients), Streptococcus spp. (5 patients), Bacteroides forsythus (2 patients), Klebsiella spp. (4 patients), Helicobacter pylori (2 patients), Treponema denticola (2 patients), Actinobacillus actinomycetemcomitans (3 patients). On day 7 only 3 microorganism’s DNA was determined: Streptococcus spp. (5 patients), Treponema denticola (2 patients), Actinobacillus actinomycetemcomitans (3 patients) in patients who were carriers before the operation. These bacteria have sizes from 0.4 to 1.5 μm, while others, not detected after surgical accommodation, are 3 to 6 μm.

**Conclusions:** Investigation of barrier membranes microstructure is of clinical importance and requires further analysis, data on microbial contamination of membranes and their permeability by microorganisms will help prevent wound infection.

Cerebrospinal fluid metabolomics profile in herpes virus type 1 encephalitis

Andrea Mastrangelo*1, Diego Franciotta2, Giulia Maria Scotti3, Leonid Gorelik4, Richard W. Price5, Caccia Roberta6, Turrini Filippo1, Marco Morelli3, Adriano Lazzarin1, Antonella Castagna6, Paola Cinque6

1Vita-Salute San Raffaele University, Milano, Italy, 2Neurological Institute Foundation Casimiro Mondino, Pavia, Italy, 3Vita-Salute San Raffaele University, Center for Omics Sciences, Milano, Italy, 4Fortress Biotech, Waltham, MA, United States, 5University of California, San Francisco, San Francisco, United States, 6San Raffaele Hospital, Milano, Italy

Background: Metabolomics may identify disease-specific variations in small molecules (metabolites), thus enabling pathogenesis insights and providing new potential biomarkers. We exploited this technique to detect differences in cerebrospinal fluid (CSF) metabolomic spectra in patients with acute Herpes Virus type-1 (HSV-1) encephalitis.

Materials/methods: We analyzed CSF samples from 11 patients with HSV-E and, as controls, from 9 HIV-negative patients with progressive multifocal leukoencephalopathy (PML), 17 patients with inflammatory or non-inflammatory non-infectious neurological diseases (NID) and 20 healthy subjects (HC). Analysis was performed at Metabolon (Durham, NC) using both liquid and gas chromatography/mass spectrometry. Molecules were identified by comparison to library entries or purified standards, and peak areas values were log-transformed and normalized by median. Metabolites associated with p<0.05 and q<0.1 in the ANOVA model were considered significant. Tukey’s test was run to identify differences in groups pairwise comparisons. Unsupervised hierarchical cluster analysis (HCA) based on significant metabolites by ANOVA was used to inspect the natural structure of correlation between samples and normalized metabolite concentrations were represented in a heat-map. HSV-1 viral load was quantified by real-time PCR and correlated with peak area values using Spearman’s test.

Results: HSV-E, PML and NID were comparable for age and gender (median age 61 years, 40% males); HC were younger (median age 46) and predominantly men (90%). 25 metabolites were differentially expressed among the four groups, and the majority belonged to kynurenine/tryptophan, mitochondrial function and oxidative stress pathways. HSV-E clustered separately from NID, HC and PML, which in turn tended to cluster together, as shown in Figure 1 (where each column identifies a patient: above by HCA and below by heat map). Kynurenine, 2-hydroxybuthyrate, cytidine and 3-dehydrocarnitine distinguished HSV-E from all the other groups, whereas kynurenine, isocitrate and ascorbate differentiated either HSV-E or PML from NID. Among these molecules, kynurenine correlated with CSF HSV-1 viral load (Spearman r= 0.67, p 0.02).

Conclusions: Our study shows specific metabolic CSF alterations in HSV-E, when compared to PML, NID and HC, and found kynurenine to be significantly associated with HSV-1 viral load. This approach seems promising for the identification of biomarkers and therapeutic targets for HSV-E.

Abstract 2847

Can we use sepsis scores to predict bacteraemia in the elderly?
Sathyavani Subbarao*1, Suhasini Subba Rao2, Michael Andrews1, Yasmin Milner1, Caoimhe Nicfhogartaigh3

1Barts Health NHS Trust, London, United Kingdom, 2Texas A&M University, College Station, United States, 3Barts Health NHS Trust, London, United Kingdom

Background: Community-acquired Escherichia coli and Klebsiella sp. bacteraemia are associated with high mortality rates in the elderly. Sepsis scoring systems may be useful tools to predict bacteraemic cases and facilitate early broad-spectrum antibiotic therapy but need validation in this population. Unnecessary broad-spectrum antibiotic therapy in this age-group can have significant adverse effects including emergence of resistance. This study aimed to test a range of scoring systems and their ability to predict Gram-negative bacteraemia in elderly patients presenting to the emergency department.

Materials/methods: Blood cultures of patients over 65 years admitted to a London hospital between September 2017 and January 2019 were retrospectively reviewed (n=2588). We selected E. coli or Klebsiella sp. Bacteraemia (“GNR”, n=185) and negative cultures (n=2403). A comparison of Systemic Inflammatory Response Syndrome (SIRS), qSOFA, National Early Warning Score (NEWS), National Early Warning Score 2 (NEWS2) and modified Pitt score was carried out on a random selection of 51 cases from each group. “R” was used for statistical analysis.

Results: T-tests demonstrated differences in scores between GNR and negative cultures among all systems: Pitt (p=0.0026), NEWS (p=0.033), NEWS2 (p=0.0076), qSOFA (p=0.033) and SIRS (p=0.043). Based on these results we analysed the conditional probabilities of bacteraemia given the grouped NEWS2 scores (table 1) and compared them to the baseline probability (0.062). We observe a far greater incidence rate of bacteraemia amongst patients with NEWS2 > 9 (100%) scores compared to the baseline probability (6.2%), suggesting that patients with NEWS2 scores > 9 have a high positive predictive value for bacteraemia.

Table 1. Probability of bacteraemia for NEWS2 score range.

![Table 1](image)

Conclusions: All scoring systems showed significant differences for GNR bacteraemia and negative patients. The greatest difference was seen with NEWS2, suggesting this could be used as a more accurate predictor of Gram-negative bacteraemia and support use of broad-spectrum antibiotic therapy in this group. Further validation is being carried out on a larger dataset to determine the optimal cut-off score with greatest sensitivity and specificity. Despite current literature demonstrating that the sensitivity of established scoring systems is sub-optimal in the elderly, we have encouraging data suggesting a role for using NEWS2 as a predictor of bacteraemia in elderly patients.

Improvement of infection rates and hand hygiene adherence in pre-post comparison after introduction of an infection-prevention-measures-bundle implemented by an infection prevention link physician

Meike Neuwirth1,2*, Frauke Mattner1,2, Regine Galante1, Ina-Kathrin Dombrowski1, Robin Otchwemah1,2,3

1Cologne Merheim Medical Centre, University Hospital Witten/Herdecke Cologne, Institute for Hygiene, Cologne, Germany, 2Witten/Herdecke University, Department of Hygiene and Environmental Medicine, Cologne, Germany, 3Cologne Merheim Medical Centre, University Hospital Witten/Herdecke Cologne, Department of Trauma and Orthopaedic Surgery, Cologne, Germany

Abstract third-party references: German Federal Ministry of Health

Background: In the project "HygArzt", the effects of an infection-prevention-measures-bundle (IPM) implemented by an infection prevention link physician (PLP), who mediates between infection control- and clinical departments in Germany, in trauma surgery/orthopedics on the nosocomial infections (NI) rates (NIR) and epically on surgical site infections (SSI), were investigated.

Materials/methods: A pre-/post- intervention study design was used. Trauma surgery and orthopedic patients on normal wards were included. As intervention a bundle was implemented, which consisted of: decolonization of patients before surgery, standardized wound care, usage of remanent disinfectants for skin preparation in the operating theatre and prophylactic closed incision negative pressure wound therapy for high-risk wounds. To identify NI, clinical signs of infection were recorded according to KISS and CDC definitions. Additionally, an active surveillance, including attendance to morning rounds was performed. In addition to the NI, process parameters such as general hand hygiene adherence (HHA) and dressing change HHA were investigated.

Results: During the pre-phase (1141 surgeries) 61 NIs were recorded (NIR 5.3% [CI 95% 4.0; 6.6]) including 44 SSIs [rate 3.1% [CI 95% 1.5; 3.2]]. In the post-phase (1546 surgeries) 35 NIs were recorded (NIR 2.3% [CI 95% 1.1; 2.7]) including 26 SSIs [rate 1.7% [CI 95% 1.1; 2.3]]. The post-phase showed significant lower relative risks for NIs (RR=0.43 [CI 95% 0.28; 0.64], p<0.001) and SSIs (RR=0.44 [CI 95% 0.27; 0.70], p<0.001) compared to the pre-phase. The general HHA was significantly increased (3453 observations in pre- and 3686 observations in post-phase). The most significantly increase in adherence was observed “before aseptic procedure” (pre: 34%, post: 79%; p<0.001) and “before touching a patient” (pre: 37%, post: 77%; p<0.001) in all type of indications (“after body fluid exposure risk” (pre: 79%, post: 95%; p<0.001), “after touching a patient” (pre: 66%, post: 99%; p<0.001), “after touching patient surrounding” (pre: 71%, post: 90%; p<0.001)) was a significant HHA increase in the post-phase. HHA during dressing change was also significantly increased.

Conclusions: NI and SSI rates could be reduced by an infection control-bundle in orthopedic/trauma patients implemented by a PLP. The trainings of the PLP improved the HHA.

Optimal treatment duration of *Pseudomonas aeruginosa* Infections in allogeneic haematopoietic cell transplant recipients

Flaminia Olearo*, Ilona Kronig1, Nicolas Mueller1, Urs Schanz1, Nina Khanna1, Jakob Passweg2, Michael Medinger1, Stavroula Masoundi Levrat1, Yves Chalandon1, Christian Van Delden1, Dionysios Neofytos1

1University Hospital of Geneva, Geneva, Switzerland, 2University Hospital of Zurich, Zurich, Switzerland, 3University Hospital of Basel, Basel, Switzerland

**Background:** There are limited data on appropriate treatment durations of *Pseudomonas aeruginosa* (PA) infections, including PA-bloodstream infections (PA-BSI) and pneumonia (PA-PNA), in allogeneic hematopoietic cell transplant recipients (allo-HCTr).

**Materials/methods:** We conducted a retrospective study using the Swiss Transplant Cohort Study from 2011 to 2018. Allo-HCTr with PA-BSI and PA-PNA, and available follow-up data for ≥365-days post-infection were included. The objectives were to describe incidences and treatments of primary and recurrent PA-infections.

**Results:** Fifty-four patients with primary PA-infection were identified among 1299 allo-HCTr, with a cumulative incidence of 3.8% (incidence rate 0.025/1000-person-years; Figure 1a). Twenty-two (40.7%), 23/54 (42.6%), and 9/54 (16.7%) patients were diagnosed with PA-BSI, PA-PNA and concomitant PA-BSI+PNA, respectively. Median time to primary PA-infection was 274.5 (interquartile ratio, IQR: 105-707) days post-HCT. Most of available PA-isolates (30/48, 62.6%) were susceptible to all antibiotic-classes tested. 81.5% (44/54) of patients received a monotherapy during the course of treatment. Median duration of antibiotic treatment for primary PA-infection was 16.5 (IQR: 13-29) days. Seventeen of 46 (36.9%) patients with available data developed a recurrent PA-infection (cumulative incidence: 35.1%; Figure 1b) at a median of 28 days (IQR: 13-38) after primary PA-infection. Recurrent PA-infections were observed equally among patients with primary PA-BSI (6/22, 30%), PA-PNA (9/23, 47.4%) and PA-BSI+PNA (2/9, 22.2%; P-value: 0.48; Figure 1c). Fourteen of 17 (82.4%) patients had one and 3/17 (17.6%) patients had >1 recurrent PA-infections. Patients with recurrent PA-infection were more likely to have received shorter treatment courses for their primary infection (median: 13 days, IQR: 11-16) compared to those without recurrence (median: 25, IQR: 14-31; P-value: 0.005). Recurrent infection was observed in 8/31 (25.1%) and 9/15 (60%) patients who received treatment for ≥14 and <14 days, respectively (P-value: 0.02). Similarly, recurrent infection was observed in 3/20 (15%) and in 14/26 (53.8%) patients who received treatment for ≥21 and <21 days, respectively (P-value: 0.007). Treatment of the primary PA-infection for ≥21 days (OR: 0.15, 95%CI 0.03-0.64, P-value: 0.005) was the only protective factor identified against recurrent PA-infection.

**Conclusions:** Incidence of primary PA-infection was low in allo-HCTr. However, we report a high rate of recurrent PA-infections with almost 1 in 3 allo-HCTr developing a recurrence after prior PA-infection. Longer treatment courses appeared to be protective for PA-infection recurrence.
Abstracts 2020

Figure 1. In this figure the incidence rates of primary PA infections (1a), recurrent PA infections overall (1b) and by type of recurrent PA infections (1c) are presented.

Abstract 2858

Global prevalence estimates of syphilis among men who have sex with men: a systematic review and meta-analysis

Motouki Tsuboi*, Jayne Evans1, Elia Davies1, Jane Rowley2, Tim Clayton1, Melanie Taylor1, David Mabey1, R. Matthew Chico2

1London School of Hygiene and Tropical Medicine, London, United Kingdom, 2None, London, United Kingdom, 3World Health Organization Headquarters, Geneva, Switzerland

Background: Men who have sex with men (MSM) represent an important population at high-risk of syphilis. Recent resurgence of syphilis in some countries has been observed exclusively in this population. Despite the importance of MSM to syphilis control and elimination efforts, there have been no systematic reviews and meta-analyses to produce pooled prevalence estimates at the global level.

Materials/methods: We searched MEDLINE, EMBASE, LILACS, and AIM databases for studies reporting syphilis prevalence among MSM that were conducted between January 2000 and April 2019. Studies included had reported syphilis as diagnosed by at least one biological assay. Point prevalence estimates were corrected using the sensitivity and specificity of diagnostic assays. We adopted random effects models to produce pooled prevalence estimates by the eight regions of the Sustainable Development Goals (SDG). We also conducted sensitivity analyses based on quality assessments of included studies.

Results: Of 3,995 records screened, we identified 177 eligible studies from 46 countries (Figure). Overall, the pooled prevalence estimate of syphilis in MSM was 8.6% [95%CI 8.1-9.2] based on 47,256 positive tests among 547,112 individuals. Pooled prevalence was 9.6% [95%CI: 8.6-10.6] (N=84 studies) across studies from 2000 to 2009, and 7.8% [95%CI: 7.2-8.5] among studies between 2010 and 2019 (N=93 studies). The lowest regional prevalence estimate was 1.2% in both Australia and New Zealand and sub-Saharan Africa [95%CI: 0.3-2.7 and 0.4-2.3, respectively], whereas the highest was 11.0% in Northern Africa and Western Asia [95%CI: 8.9-13.6]. Subgroup analyses revealed some evidence of differences among SDG regions, study periods, income levels, legality of same-sex acts, sub-population groups of MSM, and sampling methods. Sensitivity analyses detected no apparent difference between overall pooled prevalence estimates calculated with or without studies that were at high-risk of bias [8.6% [95%CI 8.1-9.2] vs. 8.7 [95%CI: 8.1-9.3], respectively].

Conclusions: The global syphilis prevalence estimate among MSM is substantially higher than that of the general population. To achieve the targets for the 2030 set in the World Health Organization Global Health Sector Strategy for reduction of syphilis among the general population, rapid scale-up of evidence-based interventions is needed to interrupt the recent resurgence of syphilis among MSM.
**Abstract 2861**

**MERS-related Coronavirus screening and trends in returning travellers**  
Benjamin Canning¹,², Clare Overton-Lewis¹, Helen Kirk-Granger¹, Husam Osman¹, Michael Kidd¹, Sowsan Atabani¹

¹Heartlands Hospital, Public health laboratory Birmingham, Birmingham, United Kingdom, ²Heartlands Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

**Background:** Middle East respiratory syndrome coronavirus (MERS-CoV) is an imported zoonotic infection of camels that causes respiratory illness, with a substantial mortality rate and a high economic impact in healthcare-related transmissions. Public Health England (PHE) Birmingham Laboratory is one of only two UK centres that provide screening for MERS-CoV. Respiratory samples were audited from travellers returning 2016-2019.

**Materials/methods:** Respiratory specimens from patients fulfilling the PHE screening criteria (www.gov.uk) were tested for MERS-CoV and a panel of respiratory viruses, and correlated with sample type, geographical risk, and symptoms.

**Results:** 601 patient samples were received over 46 months. Camel exposure was documented in 24 patients. MERS-CoV was identified in a single patient with geographical risk factors, not associated with pilgrimage. This patient was simultaneously infected with rhinovirus and adenovirus at presentation. Referrals for testing doubled in the months following this case, indicating a heightened awareness of the virus.

Other viral causes were identified in 237 patients (39.6%). Of these, rhinoviruses were the greatest cause of infection, detected in 67 patients (28.2%), followed by influenza viruses (Influenza A H1pdm09 in 35 (14.8%), A H3 in 51 (21.5%) and Influenza B in 14 (5.9%)). 37 patients had more than one virus detected. A bacterial cause was reported in 11 patients. The advance of the Hajj through the solar year (from mid-September 2016 to mid-August 2019) revealed a decline in influenza (25% in 2016 to 19.3% in 2019) and an increase in rhinovirus (17.9% in 2016 to 31.6% in 2019).

Among 160 patients from whom both upper (URT) and lower respiratory tract (LRT) samples were received, 58 (36%) were discordant. Rhinovirus and influenza were more likely detected in LRT samples.

**Conclusions:** Despite a large number of patients having a clinical picture consistent with MERS-CoV and epidemiological risk factors, MERS-CoV was only identified in one patient, with rapid infection control procedures preventing spread. Whilst MERS-CoV remains a substantial public health risk, clinicians in Europe managing suspected cases are more likely to encounter patients with rhinovirus or influenza virus and should initiate early appropriate management, including good infection control. The advisability of providing LRT samples is emphasised.

Identification, genotyping and antimicrobial susceptibility testing of Brucella spp. isolated from livestock in Egypt

Waleed Abdelwahab*

1Ministry for Agriculture and Land Reclamation – Agriculture Research Center (ARC), Central Laboratory for Evaluation of Veterinary Biologics, Abbasaia (CLEVB), Cairo, Egypt

Background: Brucellosis is a highly contagious zoonosis worldwide with economic and public health impacts. The aim of the present study was to identify Brucella (B.) spp. isolated from animal populations located in different districts of Egypt and to determine their antimicrobial resistance.

Materials/methods: In total, 34 suspected Brucella isolates were recovered from lymph nodes, milk, and fetal abomasal contents of infected cattle, buffaloes, sheep, and goats from nine districts in Egypt. The isolates were identified by microbiological methods and matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS). Differentiation and genotyping were confirmed using multiplex PCR for B. abortus, Brucella melitensis, Brucella ovis, and Brucella suis (AMOS) and Bruce-ladder PCR. Antimicrobial susceptibility testing against clinically used antimicrobial agents (chloramphenicol, ciprofloxacin, erythromycin, gentamicin, imipenem, rifampicin, streptomycin, and tetracycline) was performed using E-Test. The antimicrobial resistance-associated genes and mutations in Brucella isolates were confirmed using molecular tools.

Results: In total, 29 Brucella isolates (eight B. abortus biovar 1 and 2 B. melitensis biovar 3) were identified and typed. The resistance of B. melitensis to ciprofloxacin, erythromycin, imipenem, rifampicin, and streptomycin were 76.2%, 19.0%, 76.2%, 66.7%, and 4.8%, respectively. Whereas, 25.0%, 87.5%, 25.0%, and 37.5% of B. abortus were resistant to ciprofloxacin, erythromycin, imipenem, and rifampicin, respectively. Mutations in the rpoB gene associated with rifampicin resistance were identified in all phenotypically resistant isolates. Mutations in gyrA and gyrB genes associated with ciprofloxacin resistance were identified in four phenotypically resistant isolates of B. melitensis.

Conclusions: This is the first study highlighting the antimicrobial resistance in Brucella isolated from different animal species in Egypt. Mutations detected in genes associated with antimicrobial resistance unravel the molecular mechanisms of resistance in Brucella isolates from Egypt. The mutations in the rpoB gene in phenotypically resistant B. abortus isolates in this study were reported for the first time in Egypt.

Abstract 2863

Clinical efficiency of anti-\textit{Blastocystis} therapy in ulcerative colitis patients
Abdurakhim Toychiev*, Svetlana Osipova

\textsuperscript{1}Research institute of epidemiology, microbiology and infectious diseases, Tashkent, Uzbekistan

\textbf{Background:} Ulcerative colitis (UC) is an inflammatory bowel disease with chronic and recurrent course. High prevalence of \textit{Blastocystis} sp. was revealed in the structure of intestinal protists in UC patients, and protozoa could be a contributing cause of UC. The aim of the study is to estimate the influence of \textit{Blastocystis} sp. on the course of UC.

\textbf{Materials/methods:} The prospective, interventional, randomized, double-blinded clinical study was performed. UC patients with severe form were selected according to Mayo Clinic score consisting of 4 items: stool frequency, rectal bleeding, findings of flexible proctosigmoidoscopy and patient’s functional assessment. 20 (1\textsuperscript{st} group), 25 (2\textsuperscript{nd} group) and 22 (3\textsuperscript{rd} group) UC patients with \textit{Blastocystis} infection were treated with nitazoxanide (1.0 g/day), mesalazine (1.5-2 g/day) and combination of nitazoxanide (1.0 g/day) and mesalazine (≥1.5-2 g/day) for 14 consecutive days, respectively. Parasitological (triple coprocscopy), clinical and endoscopic examination was conducted before therapy, immediately and in 6 and 12 weeks after therapy completing.

\textbf{Results:} After completion of the therapy with nitazoxanide and combination of nitazoxanide with mesalazine elimination of \textit{Blastocystis} sp. among UC patients was observed in 100% cases. However, in 6 weeks after the course of therapy with nitazoxanide low intensity of \textit{Blastocystis} sp. was detected in 5.0±4.8% of UC patients. In 12 weeks after the course of therapy low intensity of \textit{Blastocystis} sp. was detected in 10±6.7% and 18.2±8.2% of UC patients obtained nitazoxanide and combination of nitazoxanide and mesalazine, respectively. Any significant changes in prevalence and intensity of \textit{Blastocystis} sp. were not found in UC patients of the 2\textsuperscript{nd} group after therapy completing and in 6 and 12 weeks after the course of therapy. Despite a limited amount of participants under study after therapy a positive clinical response, clinical remission and mucosal healing were revealed in all groups. During all period of follow-up the best response to the therapy, especially mucosal healing was detected among UC patients obtained combination of nitazoxanide with mesalazine.

\textbf{Conclusions:} Diagnosis of \textit{Blastocystis} sp. and anti-\textit{Blastocystis} therapy should be introduced in the complex examination and therapy of UC.

\textbf{Presenter email address:} abdurahim1988@gmail.com
A machine learning model for evaluating Chagas disease screening in immigrant populations

Juan Luis Fernandez-Martinez1, Jose A Boga2, Luis Casado3, Enrique De Andres-Galiana1, Jonathan Fernandez-Suarez2, Mercedes Rodriguez-Perez2, Fernando Vazquez2, Alicia Garcia4, Candela Menendez5, Azucena Rodriguez-Guardado6

1University of Oviedo, Oviedo, Spain, 2Hospital Universitario Central de Asturias, Oviedo, Spain, 3Hospital la Cruz Roja, Gijon, Spain, 4Hospital de Jarrio, Coaña, Spain, 5Fundación Hospital de Aviles, Aviles, Spain, 6Hospital Universitario de Cabueñes, Gijon, Spain

Background: The migration of people from endemic areas for Chagas disease is a growing reality in Europe making. This study presents a mathematical model based on machine learning methodologies to evaluate the burden of Chagas disease and contribute to the design of screening programs in this population.

Materials/methods: A retrospective cross-sectional screening program of Chagas disease was conducted in all immigrant patients from endemic areas attended the Tropical Medicine Unit of the Hospital Universitario Central de Asturias. The ID-Chagas antibody test [particle gel immunoassay (]) was used as a screening assay. All positive samples were confirmed by determination of anti-T. cruzi antibodies by indirect immunofluorescent antibody test and by polymerase chain reaction (PCR). A mathematical model based on machine learning methodologies was designed to establish the set of most discriminatory prognostic variables to predict the appearance of the Chagas disease in the immigrant population.

Results: We analyzed 346 patients (66.2% female, mean age: 36 years; Time in Spain: 5.5 years). The screening was positive in 39 patients (11.2%); 78.4% of them female; mean age: 40 years; Time in Spain: 4.7 years. No patients were diagnosed during the first year in Spain. The countries of origin were Bolivia (82%), Brazil (8%), Paraguay and Argentina (5.5% each). In univariable an multivariable analysis a positive screening was significantly associated with coming from Bolivia [P < 0.0001; OR 29.7600; [11.088-79.870]. The estimated probability of having Chagas disease is 0.0388, and therefore an average of 26 screenings is needed to detect the first Chagas case. Chagas is predicted with an accuracy of 92.88%. Taking as reference the population from the endemic zone resident in Spain as of January 1, 2019, according to the mathematical model, it is expected that they reside in the country 42,904 persons with Chagas disease.

Conclusions: Our estimates of the population at risk show the existence of 42,904 probable infected by T. cruzi, with only 26 screens needed to find a positive patient. Current screening based on screening in pregnant women and their children should become universal for all immigrants from the endemic area.

Abstract 2867

**Evaluation of endoperoxides and tetrahydropyrans as potential anti-leishmanial drugs**

Margherita Ortalli¹, Stefania Varani*², Giorgia Cimato³, Ruben Veronesi³, Marco Lombardo¹, Claudio Trombini³, Magda Monari¹, Arianna Quintavalla³

¹St. Orsola Malpighi University Hospital, Unit of Microbiology, Regional Reference Center for Microbiological Emergencies, Bologna, Italy, ²University of Bologna, Dept. of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy, ³University of Bologna, Department of Chemistry, Bologna, Italy

**Background:** Human leishmaniasis is a neglected disease, for which the drug arsenal is limited. Thus, the development of new molecules against leishmaniasis is a priority. In this context, natural products may serve as structural template for drug discovery, for example, natural endoperoxides, including artemisinin and its semi-synthetic derivatives, have shown anti-leishmanial activity. In the present study, a series of endoperoxides were synthesized together with their corresponding tetrahydropyrans, which bear the same substitution pattern of endoperoxides, but lack the peroxide bridge. These new compounds were tested to assess their in vitro anti-leishmanial potential and the mechanism of action of the most effective ones was investigated.

**Materials/methods:** Synthesis of endoperoxides and tetrahydropyrans was achieved through an efficient and low cost approach. Drug susceptibility assays were performed on promastigotes and amastigotes of *Leishmania donovani*, while cytotoxicity of the compounds was analyzed on mammalian cells. The role of iron in the anti-leishmanial bioactivity of the compounds was tested as well as generation of reactive oxygen species (ROS) in untreated and treated promastigotes. Distribution of the compounds within the parasite was analyzed by confocal microscopy.

**Results:** Screening on *L. donovani* promastigotes and amastigotes revealed that 3 endoperoxides and 3 corresponding tetrahydropyrans exhibited good inhibitory activity. These promising compounds were further investigated for their mechanism of action against *L. donovani*: the presence of iron chelator desferrioxamine did not affect the anti-leishmanial bioactivity of the compounds, suggesting that iron does not play a crucial role in the activation of the selected molecules. Compound-treated parasites showed an increase in the intracellular ROS levels, indicating the development of a moderate oxidative stress upon treatment. Further, studies on confocal microscopy were performed on fluorescent–labeled compounds: tetrahydropyrans mainly accumulated in the parasite cytoplasm, while endoperoxides also localized in the nucleus.

**Conclusions:** Six compounds proved to be significantly active against *L. donovani* promastigotes and amastigotes, with low cytotoxic effects towards mammalian cells. The preliminary data about the mechanism of action of these molecules suggest that peroxide function is not a crucial pharmacophoric requirement for the anti-leishmanial bioactivity.

**Difficult-to-treat mucocutaneous leishmaniasis in an elderly Italian traveller returning from Argentina resolved with combination treatment**

Gregorio Basile, Glauco Cristofaro, Luca Giovanni Locatello, Iacopo Vellere, Matteo Piccica, Silvia Bresci, Giandomenico Maggiore, Oreste Gallo, Stefania Fallani, Andrea Novelli, Giovanni Gaiera, Trentina DI Muccio, Marina Gramiccia, Luigi Gradoni, Alessandro Bartolini, Lorenzo Zammarchi

1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 2Careggi University and Hospital, Infectious and Tropical Diseases Unit, Florence, Italy, 3Careggi University Hospital,, Otorhinolaryngology Unit, Florence, Italy, 4University of Florence, Department of Health Sciences, Clinical Pharmacology and Oncology Section, Florence, Italy, 5Vita-Salute San Raffaele University,, Clinic of Infectious Diseases,, Milan, Italy, 6Istituto Superiore di Sanità, Unit of Vector-borne Diseases, Department of Infectious Diseases, Rome, Italy, 7Careggi University Hospital, Referral Center for Tropical Diseases of Tuscany, Infectious and Tropical Diseases Unit, Florence, Italy

**Background:** Mucocutaneous leishmaniasis (MCL) is a complication of tegumentary leishmaniasis causing potentially life-threatening lesions in the ear, nose and throat [ENT] district, most commonly due to *Leishmania (Viannia) braziliensis*. We report a case of relapsing MCL in an elderly Italian traveler returning from Argentina.

**Materials/methods:** Case-report of relapsing mucocutaneous leishmaniasis.

**Results:** A 65-year-old Italian male patient with chronic kidney disease (CKD) (eGFR 33.3 mL/min), arterial hypertension, prostatic hypertrophy, diabetes mellitus was referred from another center for relapsing MCL causing severe dyspnea, dysphonia, and nasal ulceration. Three years earlier, after a travel to Argentina, he developed a chronic cutaneous ulcer in the right leg which healed slowly and was followed by the appearance of nose ulceration and ENT symptoms. By that time the patient underwent ENT examination revealing severe edema and erythema of nasopharynx and larynx (Figure). A nasopharyngeal biopsy revealed a lymphoplasmacytic inflammation and presence of *Leishmania* amastigotes, subsequently identified as *L. (V.) braziliensis*. Despite receiving 4 courses of liposomal amphotericine B (L-AmB) (3mg/kg day 1-5, 10) and two courses of miltefosine (50mg tid for 28 days) in a two-years period, the symptoms relapsed few months after the end of each course. We decided to start treatment with intravenous pentamidine 4mg/kg on alternate days for 10 doses followed by one dose per week for additional 7 doses, intralosomal meglumine antimoniate on the nasal lesion once per week for 6 doses, oral azoles for three months, and aerosolized L-AmB on alternate days for three months. Few reversible side effects were observed and the treatment led to regression of mucosal lesions (Figure) and respiratory symptoms.

**Conclusions:** This case highlights the difficulties in managing a life-threatening refractory case of MCL in a patient with multiple comorbidities. Even though parenteral antimonial derivatives are traditionally considered the first choice for treatment of MCL, they are relatively contraindicated in case of CKD, as dose adjustment in case of impaired renal function is unknown, and the use of alternative drugs is recommended. This case was resolved with a combination treatment, including aerosolized L-AmB that, to the best of our knowledge, was never used before for MCL.

Abstract 2875

**Quinacrine is effective for treatment of resistant giardiasis**

Karin Andersson Ydsten*1, Urban Hellgren1,2, Hilmir Ásgeirsson1,2

1Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, 2Unit of Infectious Diseases, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden

**Background:** Nitroimidazole-refractory (i.e. metronidazole, tinidazole) giardiasis is an increasing problem worldwide, especially on the Indian subcontinent. There is limited evidence for alternative treatment. The old drug quinacrine has been increasingly used with promising results. The aim of this study was to assess the efficacy of quinacrine in a larger patient material.

**Materials/methods:** All verified cases of giardiasis at the Department of Infectious Diseases, Karolinska University Hospital, Sweden, during 2008-2017, were retrospectively identified. Nitroimidazole-refractory giardiasis was defined as parasitologically confirmed treatment failure (positive stool microscopy or PCR [BD MAXTM Enteric Parasite Panel; Franklin Lakes, NJ, USA]) after at least two treatment courses with nitroimidazoles. Information on patients’ demographics, travel/migration history, diagnostics, treatment and outcome were collected from medical records.

**Results:** Of 159 patients with intestinal giardiasis 67 (42%) cases of nitroimidazole-refractory giardiasis were identified. Forty-eight (72%) had acquired the infection on the Indian subcontinent, and the most common reason for travel was tourism (80%). The median age was 35 years (3-73) and 29 (43%) were females. No cases of HIV or IgA deficiency were identified. Of the 67 nitroimidazole-refractory cases 33 were treated with quinacrine as monotherapy (100mg t.i.d. for 5-7 days) while three patients received combination treatment with quinacrine and metronidazole. Other drugs used were albendazole, paromomycin, nitazoxanide, or combinations of these medications. Of 36 quinacrine treated cases 33 had follow-up stool samples (31 had two or more samples, two had a single sample). In all but one (32/33) all follow-up samples were negative (97% parasite efficacy). One patient was PCR positive and symptomatic after treatment (but microscopy negative), but was finally cured after receiving quinacrine in combination with paromomycin. The overall parasite efficacy in those not treated with quinacrine was 59%. One patient reported possible side effects to quinacrine (headache, nausea, dizziness), but all patients completed the full treatment course.

**Conclusions:** Quinacrine is an effective alternative for nitroimidazole-refractory giardiasis with a good tolerability.

**Presenter email address:** karin.andersson-ydsten@sll.se
Characterisation of methicillin-resistant Staphylococcus aureus strains isolated from purulent subcutaneous lesions of food-producing rabbits

Vanessa Silva*, Paula Gómez2, Telma Sousa1, Adriana Oliveira Da Silva1, José Eduardo Pereira1, Carolina Sabença1, Madalena Vieira-Pinto1, Carmen Torres2, Jose Luis Capelo3, Gilberto Igrejas1, Patricia Poeta1

1University of Trás-os-Montes and Alto Douro, Vila Real, Portugal, 2University of La Rioja, Logroño, Spain, 3Faculdade de Ciências e Tecnologia da Universidade Nova de Lisboa, Caparica, Portugal

Background: Rabbit meat is highly consumed in Portugal. Lesions detected during the post-mortem examination, in particular purulent infections such as abscesses, may lead to rejection of the carcass resulting in high economic losses. Furthermore, cross-contamination may occur leading to the dissemination of the pathogen. Staphylococcus aureus are mostly associated with this type of infections and are considered one of the main pathogens causing food poisoning worldwide due to its ubiquity and its ability to form enterotoxins in food, responsible for causing human disease. Therefore, we aimed to investigate the prevalence and antibiotic resistance profiles of MRSA strains isolated from purulent lesions of food-producing rabbits.

Materials/methods: Samples from purulent lesions of 66 rabbits (Oryctolagus cuniculus) were collected during a period of 4 months in a slaughterhouse in Portugal. Samples were seeded onto ORSAB plates with 2mg/L of oxacillin for MRSA isolation. Susceptibility to antibiotics was tested by the Kirby-Bauer disk diffusion method against 14 antimicrobial agents. The presence of resistance genes, virulence factors and the immune evasion cluster system were studied by PCR. All isolates were characterized by agr and spa typing.

Results: The presence of mecA-positive MRSA was detected in 16 (24.2%) animals of the 66 analyzed. All strains displayed a multidrug-resistant phenotype and all presented resistance to penicillin, erythromycin and clindamycin. Ten isolates showed resistance to tetracycline and harbored the tet(K) gene. Resistance to aminoglycosides was also detected, being 7 isolates resistant to gentamycin, tobramycin and kanamycin, and all harbored the aac(6')-Ie-aph(2'')-Ia gene. The IEC genes were detected in 3 isolates. All strains were positive for agr type III. Isolates were assigned to 7 different spa types (t1190, t2802, t002, t1094, t084, t032 and t1491) which were grouped into 5 clonal complexes, of which CC97 was the most prevalent.

Conclusions: This study revealed the presence of MRSA strains in food-producing rabbits at slaughterhouse level with multidrug resistance phenotypes. This may represent serious food safety and public health concerns since cross-contamination may occur leading to the spread of MRSA and, eventually, the possibility of ingestion of contaminated meat.

Abstract 2879

**Rapid antiretroviral therapy initiation in the era before universal treatment, Croatia, 2005 to 2014**

Nikolina Bogdanic*, Liam Bendig2, Lukas Davorka3,4, Šime Zekan4,5, Josip Begovac4,5

1University Hospital for Infectious Diseases, Zagreb Croatia, Zagreb, Croatia, 2Medical Scholars Program, AU/UGA Medical Partnership, Athens, GA, USA, Athens, Georgia, United States, 3University Hospital for Infectious Diseases, Zagreb Croatia, Zagreb, Croatia, 4University of Zagreb School of Medicine, Croatia, Zagreb, Croatia, 5University Hospital for Infectious Diseases, Zagreb Croatia, Zagreb, Croatia

Abstract third-party references: University Hospital for Infectious Diseases, Zagreb Croatia

**Background:** Croatia has a centralized system of HIV care and all patients are treated at the University Hospital for Infectious Diseases (UHID) in Zagreb. The aim of our study was to examine factors related to rapid ART initiation among persons who entered HIV care in Croatia from 2005 to 2014.

**Materials/methods:** Included into the study were Croatian citizens/residents ≥18 years who entered HIV care and started ART at UHID. Excluded were pregnant women and those who were in care elsewhere before entering care at UHID. The follow-up ended on Dec/31/2017 (earlier if died, moved or lost to follow-up). The time from HIV diagnosis to ART initiation was categorized: up to 30 days (“rapid”), from 31 days to one year (“intermediate”), and more than one year (“delayed”). We conducted quantile regression analysis to study factors related to the time from confirmed HIV-diagnosis to ART initiation with gap in care (>1 year without follow-up) considered the major predictor variable.

**Results:** 628 patients were included into the study with a total of 4333.0 (median per-person, 6.7 [Q1 -Q3: 4.3-9.5]) years of follow-up. 91.9% (577/628) were men; median age was 36.1 (Q1 -Q3: 29.6-43.8) years. The median time from HIV-diagnosis to ART initiation was 31 days (Q1 -Q3: 0.3-17.7 months). Rapid ART initiation was observed in 49.8% (313/628) patients, 21.7% (136/628) and 28.5% (179/628) had intermediate and delayed initiation, respectively. On regression analysis, calendar year of entry into care, and markers of more advanced HIV disease (higher viral load, lower CD4 cell count and clinical AIDS) were significantly associated with earlier ART initiation. A gap in care before ART initiation was significantly associated with later ART initiation at all quantiles. Gap after ART, gender, transmission risk [MSM vs not MSM], age and place of residence [Zagreb vs outside Zagreb] did not have a significant impact on time to ART initiation.

**Conclusions:** A significant proportion of patients started ART early in Croatia in the period 2005–2014. Early ART initiation was not associated with a subsequent gap in care whereas longer waiting for ART initiation was associated with a gap in care before ART initiation.

**Presenter email address:** nikolinabogdanic@gmail.com
Nonsteroidal anti-inflammatory drugs as a promising alternative to antibiotics to combat methicillin-resistant Staphylococcus aureus biofilms

Vanessa Silva*, José Eduardo Pereira†, Luís Maltez†, Jose Luis Capelo‡, Gilberto Igrejas†, Patricia Poeta‡

†University of Trás-os-Montes and Alto Douro, Vila Real, Portugal, ‡Universidade NOVA de Lisboa, Lisbon, Portugal

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) are a diverse group of drugs that have anti-inflammatory, antipyretic and analgesic effects which are frequently associated with bacterial infections. Nevertheless, available information on the antibacterial action of NSAIDs are scarce. Currently, few antibiotics are available to treat infections caused by multidrug-resistant bacteria, in particular, methicillin-resistant Staphylococcus aureus (MRSA), thus, alternative approaches to controlling bacterial infections are urgently required. The main goals of this study were to determine the minimum inhibitory concentration (MIC) and the activity of NSAIDs on the control of biofilms of MRSA strains.

Materials/methods: MICs were determined by the broth microdilution method using 2 NSAIDs used in human medicine, namely naproxen and diclofenac, against 8 multidrug-resistant MRSA strains isolated from infected diabetic foot ulcers. The antibiofilm activities were determined by the microtiter biofilm assay. In order to assess the NSAIDs ability to control adhered cells and 24h old biofilms, bacterial suspension was added to 96-well microtiter plates and incubated for 2h and 24h, respectively. After the incubation period, the plates were washed, each NSAIDs solution to a final concentration at MIC and 5xMIC and fresh medium were added. The plates were incubated for 24h after which the biofilm biomass was measured.

Results: MICs of naproxen and diclofenac ranged from 1000 to 2000 µg/ml and 500 to 1500 µg/ml, respectively. Diclofenac showed a higher potential to remove adhered cells than naproxen (41.9% and 37.7%, respectively). Naproxen showed moderate ability to remove adhered cells at MIC; nevertheless, 5xMIC showed inferior values of adhered cells removal. On the opposite, a higher biomass removal was detected at 5xMIC of diclofenac than at the MIC values. Regarding the biomass removal of 24h old biofilms, naproxen showed better results with biomass elimination reaching 22% in comparison to diclofenac with a maximum removal of 17%.

Conclusions: Both naproxen and diclofenac showed efficacy against MRSA strains. Diclofenac showed a higher potential to remove adhered cells whereas naproxen had better efficacy in biomass removal of 24h old biofilms. Therefore, these non-antibiotic drugs may be used as an alternative to antibiotics since they may act through different mechanisms from those of antibiotics.

Presenter email address: nessita.silva@hotmail.com
Background: Respiratory syncytial virus (RSV) is a well-known pediatric pathogen, but lately it has been increasingly recognized as a prominent pathogen in adults. However, the role of RSV in the elderly population (>65 years) during the influenza season has not been sufficiently assessed.

Materials/methods: This study was performed during the influenza season, from September 2017 to April 2018 in a tertiary Spanish hospital. The study population included only patients older than 65 years with either community-acquired or hospital/healthcare-associated influenza-like illness, according to the European Centre for Disease Prevention and Control criteria. Samples were analyzed using a rapid molecular assay (Xpert® Flu/RSV). RSV-positive patients were compared with a randomly age-stratified influenza positive control group. We compared Influenza and RSV infected populations regarding outcome, days of antibiotic use, length of stay, ICU admission and use of specific antiviral treatment.

Results: Of the 4009 samples processed during the study period, 2441 (60.9%) of the samples corresponded to adults > 65 years old and 842 (34.5%) had a positive result as follows: 394 (16%) Flu A; 289 (12%) Flu B and 159 (6.5%) RSV. When RSV-positive and influenza-positive patients were compared, RSV-positive patients presented with more comorbidities as expressed by Charlson index (6.08 vs 5.40; p = 0.005), and their disease was more frequently healthcare-related (44/159, 27.7% vs 23/159, 14.5%; p =0.006). They also had significantly less antivirals prescribed (2/159, 1.25% vs 119/159, 75%; P < 0.001). Admission rates were similar among RSV and influenza patients (128/159; 80.5% for RSV and 129/159, 81.1% for influenza), but median length of stay was slightly higher among influenza patients (11.2 days vs 8.6 p=0.1). Admission to ICU was required only in 3 RSV patients and 5 flu patients. Mortality was also higher in RSV-positive patients (20/159, 12.5% vs 12/59, 7.5%; P = 0.5).

Conclusions: RSV is a major cause of moderate-to-severe influenza-like illness, with a high mortality, probably related to the lack of specific treatment for this population. More studies regarding efficacy of oral antiviral agents for elderly RSV infected patients must be developed.

Abstract 2888

Interest of rapid detection of emerging extensively drug-resistant bacteria by PCR associated with temporary dedicated team for high-risk patients

Marie-Pierre Otto1, Chrystelle Darles1, Julie Plantamura1, Patricia Rossi2, Marion Walker2, Emmanuel Sennavoine3, Benoit Ducret3, Yves Auroy3, Frédéric Janvier*1;4

1Hospital Instruction Of Armées Sainte-Anne, Microbiologie et hygiène hospitalière, Toulon, France, 2Hospital Instruction Of Armées Sainte-Anne, Hygiène hospitalière, Toulon, France, 3Hospital Instruction Of Armées Sainte-Anne, Toulon, France, 4Val-de-Grâce School, Paris, France

Background: Management of "high-risk patients" for carbapenemase-producing Enterobacteriaceae (CPE) or vancomycin-resistant enterococci (VRE) is based on a rapid search and isolate strategy. In order to avoid contact cases, French recommendation suggests a dedicated team at hospital admission. This recommendation is difficult to apply and maintain until the results of the cultures (48h). Here, we report the results of a new management strategy combining early detection with PCR and dedicated team during few hours.

Materials/methods: Repatriated patients, contact patients or previously known CPE/VRE carriers were targeted as being "high-risk" patients for CPE/VRE carriage.

In order to control the spread of CPE/VRE and facilitate the implementation of control measures for these patients, we proposed to medical wards a strategy combining :
- isolation in a single room, contact precautions and dedicated team at admission
- patient rectal screening with culture and Xpert® Carba-R v2 and Xpert® VanA/VanB 24H a day.

In case of PCR negativity, dedicated team was stopped and standard contact precautions maintained until culture results. If PCR was positive, the dedicated team was maintained or a high level of contact precautions implemented in case of understaffed.

Results: Between july 2018 and august 2019, 189 rectal screening were performed. Among them, 26 PCR were prescribed at admission.

Nine of the 26 PCR were positive [34,6%] with 5 OXA-48, 1 NDM, 2 OXA-48+NDM, 1 false positive with VanB. Four patients benefited of dedicated team during hospitalization [no contact case] and 4 patients of high contact precautions level without dedicated team, generating 108 contact cases and no secondary case.

Analysis of the 189 prescriptions reveals that 15 other patients could have benefited from a PCR. Six CPE [40%] were isolated in culture generating 131 contact cases and 2 secondary cases.

Conclusions: Combination of rapid molecular screening of CPE/VRE 24 h a day and dedicated team pending PCR's results allows adhesion of the caregivers to heavy complementary measures. This strategy avoids late discoveries of CPE/VRE, limits the number of secondary cases [0/108 vs 2/131 contacts] and reduces costs related to the dedicated teams [4 hours vs 48 hours for 17 negative patients].

Abstract 2889

Antimicrobial therapy with aminoglycoside or meropenem in the intensive care unit for hospital-associated infections and risk factors for acute kidney injury

Raphael Pitta1, Juliano Gasparetto1, Thyago De Moraes1, João P. Telles1,2*, Felipe Tuon1

1Pontifical Catholic University of Paraná, Curitiba Campus, Laboratory of Emerging Infectious Disease - Department of Medicine, Curitiba, Brazil, 2A.C. Camargo Cancer Center, Department of Infectious Disease, Curitiba, Brazil

Background: Aminoglycosides were discovered more than 75 years ago and remain an interesting and effective class of antibiotics used in the context of multidrug resistance. Nevertheless, there have historically been concerns of acute kidney injury (AKI) with the use of aminoglycosides. The present study aimed to compare the AKI incidence and mortality rate between critically-ill patients treated with aminoglycoside or meropenem in the intensive care unit setting using a propensity score matching approach.

Materials/methods: This cross-sectional study was conducted at two university hospitals from January 2011 to October 2017. At both centers, amikacin was prescribed at 15 mg/kg daily infused over 30 minutes, while gentamycin was prescribed at 3 mg/kg daily and meropenem with a minimum dose of 1,000 mg q8h infused over 3 hours after the loading dose regimen. Clinical and laboratorial data were evaluated to exclude potential confounders and to calculate the Charlson index. AKI was classified according to the Acute Kidney Injury Network criteria. All tests were two-tailed, and a p value ≤0.05 was considered significant in the univariate and multivariate analyses.

Results: We included 494 patients, 95 and 399 of whom used meropenem or aminoglycoside, respectively. Patients in the subgroup that used meropenem were matched with controls (aminoglycoside). Among the 494 patients, 120 developed any grade of AKI (24.2%). After propensity score matching, there were no significant differences in AKI incidence and mortality rate between the aminoglycoside and meropenem groups (p=0.324 and 0.464, respectively). Association between use of nephrotoxic drugs and AKI development demonstrated statistical significance only for vancomycin (p=0.002) and loop diuretics (p=0.033).

Conclusions: Patients on the aminoglycoside regimen neither presented a higher AKI incidence nor mortality rate when compared with those on the meropenem regimen. Aminoglycosides may be a safe option for the treatment of critically-ill patients on carbapenem sparing antimicrobial stewardship programs.

**Debridement And Implant Retention (DAIR) with local administration of personalised cocktail of bacteriophages (PhagoDAIR) followed by suppressive antibiotic therapy as salvage therapy in patients with relapsing prosthetic knee infection (PKI)**

Tristan Ferry\(^{1,2}\), Camille Kolenda\(^{1,2}\), Batailler Cecile\(^{1}\), Claude-Alexandre Gustave\(^{1,2}\), Sébastien Lustig\(^{1,2}\), Cindy Fevre\(^{1}\), Charlotte Petjeian\(^{1}\), Christain Chidiac\(^{1}\), Leboucher Gilles\(^{1}\), Frédéric Laurent\(^{1,2}\)

\(^{1}\)Hospices Civils De Lyon - Hcl, Lyon, France, \(^{2}\)Claude Bernard University Lyon 1, Centre International de Recherche en Infectiologie, Villeurbanne, France, \(^{3}\)Pherecydes Pharma, Romainville, France

**Abstract third-party references:** Lyon BJI study group

**Background:** Lytic bacteriophages trigger bacterial lysis through their multiplication in an exponential and self-sustained reaction. They have a high potential in patients with prosthetic joint infection, as they have a synergistic anti-biofilm activity with antibiotics. In elderly patients with chronic PKI, suppressive antibiotic therapy is sometimes used after performing an open “DAIR” procedure, but the rate of success is only approximately 60%. Arthroscopic DAIR is considered to be not appropriated, as this procedure is associated with a higher failure rate.

**Materials/methods:** We proposed in “CRIOAc Lyon” to perform DAIR with local administration of a personalized cocktail of anti-*S. aureus* or anti-*P. aeruginosa* bacteriophages [PhagoDAIR] followed by suppressive antibiotic therapy in patients with relapsing PKI in therapeutic dead-end (for whom revision or transfemoral amputation was not feasible) (panel A). Each case was discussed with ANSM, the French health authority. Bacteriophages, produced according Good Manufacturing Practice (GMP) guidelines, were finally selected from the Pherecydes library depending on the phagogram (panel B). Hospital pharmacist mixed each phage (1 ml of 1x10\(^{10}\) PFU/ml) extemporaneously as “magistral” preparation (final dilution 1x10\(^{8}\) PFU/mL).

**Results:** Four patients (64, 81, 84, 89 yo) were treated with the PhagoDAIR procedure. All of them had relapsing PKI due to methicillin-susceptible *S. aureus* (2 patients), *S. lugdunensis* (1 patient) and *P. aeruginosa* (1 patient). Arthroscopic DAIR was performed in 2 patients (arthrotomy not feasible) (panel C), open DAIR was performed in the 2 others, with soft tissue flap in one of them. Patients were initially treated with antibiotics in combination during 6 to 12 weeks, followed by suppressive anti-biotherapy (cephalexin for staphylococci PKI, ciprofloxacin for *P. aeruginosa* PKI). During a follow-up of 6, 7, 12 and 24 months, respectively, the outcome was favorable with considerable improvement of the function for all patients and disappearance of signs of infection (panel D) [video available].

**Conclusions:** Personalized GMP bacteriophage therapy has the potential to be used as salvage therapy during DAIR in patients with relapsing *S. aureus*, *S. lugdunensis* and *P. aeruginosa* PKI, to improve the efficacy of suppressive antibiotics, and to avoid considerable loss of function.
Detection of microorganisms in sonicated titanium screw model after in vitro biofilm production using culture, MALDI-TOF MS and qPCR

Juliette Cieslinski¹, Victoria Stadler Tasca Ribeiro¹, Leticia Kraft¹, Paula Suss¹, Edvaldo Rosa¹, Luis Gustavo Morello¹, Marcelo Pillonetto¹, João P. Telles*¹², Felipe Tuon¹

¹Pontifical Catholic University of Paraná, Curitiba Campus, Laboratory of Emerging Infectious Disease - Department of Medicine, Curitiba, Brazil, ²Pontifical Catholic University of Paraná, Curitiba Campus, Xenobiotics Research Unit, School of Life Sciences, Curitiba, Brazil, ³Carlos Chagas Institute - Fiocruz, Laboratory for Applied Science and Technology in Health, Curitiba, Brazil, ⁴Pontifical Catholic University of Paraná, Curitiba Campus, Curitiba, Brazil, ⁵A.C.Camargo Cancer Center, Department of Infectious Disease, São Paulo, Brazil

Background: Sonication can increase the sensitivity of prosthetic device cultures, since it can disrupt the bacterial biofilm associated with infections. Molecular investigation of sonicated fluid has been described, aiming to improve the sensitivity of the diagnosis. The aim of this study was to evaluate the sonication technique with a plastic bag and the effect of refrigeration on microorganism detection with conventional culturing, MALDI-TOF MS (mass spectrometry) and qPCR (real-time PCR) assay on an orthopedic screw model.

Materials/methods: Biofilms of Staphylococcus aureus, Pseudomonas aeruginosa, and Candida albicans were produced on orthopedic screws, which were stored under different conditions and temperatures before sonication. After sonication, MALDI-TOF MS, qPCR and culture protocols were performed using the sonicated fluid for detecting the microorganisms involved in the biofilm. The results were analyzed by non-parametric Mann Whitney test and difference was significant when p <0.05.

Results: The bacterial bioburden decreased by approximately 1log after the refrigeration period, in the screws containing P. aeruginosa and S. aureus biofilms. All the microorganisms involved in the screw biofilms were detected with MALDI-TOF and qPCR. In culture, reduction was significant in the groups with P. aeruginosa stored in plastic bags, where the count in the immediate group was 9x10⁷ CFU/mL and the count in the post-refrigeration group was 2x10⁶ CFU/mL (p <0.05). S. aureus colony counts reduced from 4x10⁸ CFU/mL in the immediate SP to 1x10⁷ CFU/mL in post-refrigeration SP (p <0.05) (Figure 1).

Conclusions: Significant reductions in CFU counts occurred only in groups stored in the plastic bag, indicating that changes in temperature and humidity may favor cell death. Microbial identification by MALDI-TOF in sonicated fluid is feasible, provided that the sample has enough bioburden. With qPCR, there were no differences between the detection in the screws processed immediately or after refrigeration. It is necessary to consider whether the refrigeration period would affect microbial recovery in an explanted prosthesis.

Figure 1. (A) Distribution of S. aureus samples after different processing conditions; (B) Distribution of P. aeruginosa samples after different processing conditions; (C) Distribution of C. albicans samples after different processing conditions. RC: Rigid recipient, PB: Plastic bag.

Abstract 2897

**Changes in the characteristic of the population with chronic hepatitis C receiving treatment with direct acting antivirals in a referral centre during the post-interferon era**

Andrea Lombardi*1,2, Kesav Aditya Vijayagopal3, Margherita Sambo2, Patrizia Legnazzi2, Paolo Sacchi1, Valentina Zuccaro2, Renato Maserati1, Roberto Gulminetti1, Layla Pagnucco1, Giuseppe Michelone1,2, Domenico Zananaboni1, Serena Ludovisi1, Raffaele Bruno1,4

1Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases I, Pavia, Italy, 2Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases II and Immunology, Pavia, Italy, 3Fondazione I.R.C.C.S. Policlinico San Matteo, Farmacology, Pavia, Italy, 4The University of Pavia, Clinical, Surgical, Diagnostics and Pediatric Sciences, Pavia, Italy

**Background:** Treatment of chronic hepatitis C (CHC) has been revolutionized since the widespread availability of direct acting antivirals (DAAs) in 2015. These regimens allow now the eradication of hepatitis C virus (HCV) in the majority of those treated. However, the characteristics of treated patients are changing, and it is difficult to forecast the future needs in term of treatment number and characteristics.

**Materials/methods:** We retrospectively collected the demographic and clinical characteristic of all those treated with DAAs from 01/01/2015 to 30/10/2019 in a referral centre in Northern Italy and we stratified these characteristics according to the year of treatment.

**Results:** Overall, 2569 patients were treated: 230 (9%) in 2015, 261 (10.2%) in 2016, 660 (25.7%) in 2017, 988 (38.5%) in 2018 and 430 (16.7%) in 2019. Male were the majority until 2018 when female surpassed them (P=0.01). Cirrhotics were the majority until 2017, when DAAs treatment was granted to all those infected, then non-cirrhotic largely exceeded them (P=0.01). The fraction of foreigners almost doubled from 2015 to 2019 (4.3% vs 8.1%, P=0.04). The sustained virologic response rates steadily increased during the study period, from 93% in 2015 to 96.9% in 2018 (P=0.01). Interestingly, also the median age at treatment progressively increased during the study period, from 59.8 in 2015 to 62.2 in 2019 (P=0.04). Finally, the prevalence of HIV-infected patients reached the top in 2016 (16.9%) and the steadily decreased to 10.2% in 2019 (P=0.01).

**Conclusions:** The population of patients receiving antiviral treatment with DAAs is becoming older, it is composed by a thin majority of female and overall has a low-grade of liver fibrosis. Rates of successful treatment are moving toward 100%.

**Figure 1.** Trend in sex distribution, presence of cirrhosis, coinfection with HIV and SVR rates in the Pavia HCV-cohort according to year of treatment.

**One-stage extraction and replacement of infected cardiac implantable electronic devices**

Vittorio Attanasio¹, Stefano De Vivo¹, Carolina Rescigno¹, Sergio Severino¹, Raffaella Pisapia¹, Chiara Sordelli², Nicolina Capoluongo¹, Mariano Bernardo³, Giulia Palmiero¹, Mariagrazia Di Luca¹, Carlo Pailotto⁴, Carlo Tascini⁵

¹Cotugno Hospital, AORN dei Colli, First Division of Infectious Diseases, Naples, Italy, ²Monaldi Hospital, AORN dei Colli, UO Elettrastimolazione, Naples, Italy, ³Monaldi Hospital, AORN dei Colli, Department of Cardiology, Naples, Italy, ⁴Cotugno Hospital, AORN dei Colli, Microbiology and Virology Unit, Naples, Italy, ⁵University of Pisa, Laboratory of Microbiology, Department of Biology, Pisa, Italy, ⁶University of Perugia, Section of Infectious Diseases, Department of Medicine, Perugia, Italy

**Background:** Infective complications of CIED such as endocarditis and/or infections of the pocket had a constantly growing incidence in last years. International guidelines state that devices’ removal is mandatory to eradicate the infection and recommend a transvenous extraction. However, there is no evidence about the timing of reimplantation. Usually a new CIED is reimplemented 7-10 days after the extraction and during this period in CIED-dependent patients a temporary CIED is used.

The aim of this study is to evaluate the possibility of a one-stage strategy of transvenous extraction and replacement of CIED in CIED-dependent patients with a CIED-related infection.

**Materials/methods:** All patients with a CIED-related infection from March to September, 2019 were enrolled. All patients underwent one-stage CIED removal and reimplantation. Blood and lead culture were performed. Biofilm production was established by culture on Congo Red agar.

**Results:** Eighteen patients were enrolled (12/18 with a CIED-related endocarditis, 6/18 with infection of the pocket). Blood cultures resulted positive in 33% of patients at admission. In 17 patients Gram positive cocci were isolated (7 S. epidermidis [5/7 methicillin-resistant], 3 S. aureus [2/3 methicillin-resistant], 3 S. lugdunensis, 1 S. haemolyticus, 1 S. caprae, 1 S. schleiferi, 1 S. warneri) while in the remaining patient infection was due to Pseudomonas aeruginosa. A combination therapy with activity against (daptomycin plus ceftobiprole or cefazolin) biofilm was administered to the first 17 patients. In the case with P. aeruginosa isolation, a combination of cefiderocol and imipenem was given. All patients were cured with no complications nor infection recurrences [median follow-up 80 days]. Two S. epidermidis strains were tested for biofilm production and both resulted positive (black colonies growth on Congo Red agar).

**Conclusions:** One-stage extraction and reimplantation could be a promising strategy to treat CIED-related infection if associated with anti-biofilm antibiotic treatment [es: daptomycin] even in case of highly biofilm-producing S. epidermidis.

Abstract 2900

**Can a combination of several biological markers help to diagnose influenza co-infections?**

Nicolas Delettre*1, Aurelien Schrapp1, Adeline Baron1, Luc-Marie Joly1, Valery Brunel1

1CHU Charles Nicolle, Rouen, France

**Background:** Diagnosis of bacterial coinfection during an episode of community influenza is difficult to achieve in practice. The diagnosis is based on compatible clinical examination with aggravation of symptoms following an improvement, usually around the fifth day, associated with an increase in leukocyte count and CRP. The aim of this study was to propose a composite score based on biological exam able to differentiate patients with influenza with and without bacterial coinfection.

**Materials/methods:** In this retrospective cohort study, 47 consecutive patients who were admitted to the emergency department with positive influenza PCR and who had a blood count and CRP assay from 2018-12-26 to 2019-02-02 were included.

Patients were classified as coinfected or not based on their progress and the conclusion of the hospitalization report. Patients who returned home without antibiotic from the emergency department were classified as not coinfected. We created a composite score including leukocyte count and CRP assay by multiple linear regression. The score results for each patient were included in an ROC curve.

**Results:** Of these 47 patients, 18 were classified as coinfected and 29 as not coinfected. Using the CRP with a threshold at 77.5 mg/L, we obtain a sensitivity of 61%, a specificity of 93% and a likelihood ratio of 8.86. Using leukocytes, we obtain a sensitivity of 61%, a specificity of 90% and a positive likelihood ratio of 5.91.

Composite score determined by the multiple linear regression is calculated as:

Score = 0.00436 × (CRP) + 0.0282 × (Leucocyte count) - 0.1349.

The score results were represented in an ROC curve (Graph 1). With a cut off score at 0.41, we obtain a sensitivity of 83%, a specificity of 90% and a positive likelihood ratio of 8.61.

**Efficacy of a leukocyte count and CRP combination to diagnose a superinfected flu**

**Conclusions:** We have shown that a score combining two biological markers having low diagnostic values can obtain a score with a higher diagnostic value.

The categorization of patients based on hospitalization reports without objective clinical criteria, generally based on CRP and leucocytes that have been evaluated, and the small size of our cohort limit the impact of our study. Our study is preliminary to work combining other biomarkers to create a more effective score.

Abstract 2907

The Global Point Prevalence Survey of Antimicrobial Consumption and Resistance (Global-PPS): roll-out of a successful antimicrobial stewardship programme in Nigeria using the global-PPS tool

Oyin Oduyebo 1, Alero Roberts 2, Olafoyekemi Ola-Bello 3, Ann Versporten 4, Ines Pauwels 4, Chioma Osuagwu 1, Iretiolu Fajolu 5, Phillip Oshun 1, Herman Goossens 4, Patricia Akintan 5, Edamisan Temiye 5

1Nigeria, Department of Medical Microbiology & Parasitology, College of Medicine, University of Lagos, Lagos, Nigeria, 2Department of Community Health & Primary Care, College of Medicine, University of Lagos, Lagos, Nigeria, 3Lagos University Teaching Hospital, Department of Medical Microbiology & Parasitology, Lagos University Teaching Hospital, Lagos, Nigeria, 4Vaccine and Infectious Diseases Institute, University of Antwerp, Antwerp, Belgium, 5Nigeria, Department of Paediatrics, College of Medicine, Lagos, Nigeria

Background: There are no formal stewardship programs in Nigeria. We aimed to assess the effect of antimicrobial stewardship actions in the “Lagos University Teaching Hospital” in Nigeria using the standardized Global-PPS (www.global-pps.com).

Materials/methods: The Global-PPS was conducted in April 2015, August 2017 and December 2018. Detailed data was collected for all in-patients receiving an antimicrobial on the day of PPS. Data collected details on antimicrobial agents, indications for antibiotics and a set of quality indicators. From 2016, survey data were periodically disseminated at hospital grand rounds and clinical meetings to educate prescribers and inform all paramedical staff. An antibiotic policy was also formulated, and disseminated to all clinical departments. Surgeons were counselled on surgical prophylaxis at a clinical meeting. In the paediatric department, antibiotic guidelines were developed in December 2017 and a prospective audit with intervention and feedback was initiated a month before the 2018 Global-PPS.

Results: Out of 183, 258 and 305 admitted patients, 82.5%, 65.5% and 51.1% were on antibiotics in 2015, 2017 and 2018 respectively (table). All quality indicators, except for missing guidelines in adult wards, improved in 2018 as compared to 2015 and 2017. Prospective audit over 6 months in 2019 revealed 59.3% compliance with guidelines. Out of 360 interventions, compliance was 51.1%. Inappropriate antibiotic prescribing was mainly related to unnecessary and wrong type of antibiotic while de-escalation was the intervention most commonly complied with.

Conclusions: The gradual initiation of several antimicrobial stewardship interventions since 2016 enhanced substantial improvements of appropriate antibiotic prescribing as measured by three Global-PPS. The follow up Global-PPS in 2018 revealed satisfying results. Repeated measurements are needed to enhance sustainable improvements.

Table. Quality indicators for antibiotic prescribing following three Global-PPS

Impact of early appropriate antimicrobial therapy on a new hierarchical endpoint for ventilator-associated bacterial pneumonia

Emmanuel Weiss¹², Stéphane Ruckly¹, Claire Dupuis⁴, Jean-Ralph Zahar⁵⁶, Jean-François Timsit*³⁴⁶

¹Inserm UMR S1149 and University of Paris, Paris, France, ²Hospital Beaujon AP-HP, Department of anesthesiology and critical care, Clichy, France, ³Outcomerea Research Network, Aulnay sous Bois, France, ⁴Bichat-Claude Bernard Hospital, Medical and infectious diseases ICU, Paris, France, ⁵Avicenne Hospital (AP-HP), Department of clinical microbiology and infection control unit, Bobigny, France, ⁶Inserm UMR S1137, IAME and University of Paris, Paris, France

Background: Recently, a multinational expert consensus was obtained on a definition of clinical cure and on a composite endpoint (including survival, mechanical ventilation (MV)–free days though day 28, and clinical cure at day 8-10 after treatment initiation) that could be used in ventilator-associated pneumonia (VAP) trials (1). The aims of this work were to evaluate the impact of early adequate antimicrobial treatment (EAT) on VAP outcome using these clinical cure definition and consensus composite endpoint.

Materials/methods: Retrospective analysis of French database OutcomeRea (1997 -2016) including patients with VAP. Adequate treatment was considered early if administered within the 24h after pneumonia. Clinical cure was defined as the resolution of signs present at enrolment i.e. hypoxemia, vasopressor, fever/hypothermia, purulent tracheal secretions and leucocytosis/leukopenia. A variable was computed to assess the three elements of the composite endpoint successively; its rank ranged from 1 (patient alive, never required mechanical ventilation and cured) to 709 (patient died).

Results: 1181 VAP episodes were included. Antimicrobial treatment was adequate early in 599 episodes (51%); The median [IQR] delay before adequate treatment was 3 [2 ; 4] days in the other patients (p<0.01). Mortality rates were 200/599 (33.4%) and 192/582 (33.0%) in the EAT and the no-EAT groups respectively (p=0.88). Among the survivors at day 28, MV duration was long (12 in EAT vs 11 days in no-EAT, p=0.94) and clinical cure rate was high (84.0 vs 87.7%, p=0.13). Resolution rates of signs of pneumonia were variable ranging from more than 80% (fever and tracheal secretions) to less than 50% (hypoxemia). The composite outcome did neither differ according to EAT (median rank 370 vs 359, p=0.69). This lack of difference persisted regardless of the pathogen involved.

Conclusions: A composite outcome validated by a Delphi process, involving international expert panel, is able to better classify VAP patients. We did not find any impact of EAT on mortality, clinical cure rate and duration of MV in survivors or this new hierarchical composite endpoint. This result suggests a minimal impact of early appropriate therapy of VAP on patients’ outcome.

**Abstract 2912**

**esp17 and its importance in dry stress resistance**

Nikoloz Kordzakhia*1

1David Tvoidiani Medical University, Tbilisi, Georgia

**Background:** *Staphylococcus aureus* has been documented to have resistance in various stressful conditions outside of the host. One prominent characteristics of *Staphylococcus aureus* is desiccation tolerance. My project focuses on one of the genes found in our group as ones expressing in subpopulation termed esp. (expression in subpopulation). The esp17 gene is predicted to be a transcription factor [arsR homologue] and a part of a three- gene operon [esp17-arsB-arsC]. Our group had previously documented high desiccation tolerance in an esp17-overexpressed strain compared to Wild type RN4200. Our group also found an esp17 operon deletion mutant has increased susceptibility to desiccation. I aimed to show further importance of esp17 in desiccation resistance by generating an esp17 single gene deletion mutant and testing its effect in desiccation related experiments.

**Materials/methods:** RN4220, overexpression and esp17 were cultures for 16 hours in 5mL TSB medium. Due to the overexpression strain esp17 being in Trans with pRIT plasmid it was exclusively supplemented with chloramphenicol. Optical density was measured, and cultures were adjusted to an OD600. Serial dilutions of the adjusted cultures were plated on TSA to enumerate CFU at T=0. 10 µL of the adjusted cultures were placed into 96 well plates in triplicate after which they were dried under airflow at room temperature. The 96 well plates were incubated in an ADVANTEC™ humidity-controlled incubator and bacteria were collected in 200uL TSB by vigorous scraping and mixing with a pipette at 2- and 5-days post inoculation. Survival under dry stress was calculated as the fraction of CFU at each time point relative to at T=0.

**Results:** The results show clear survivability advantage in both strains, RN4220 and overexpression whilst esp17 and esp17-operon survival is greatly diminished in dry stress conditions. These results are significant in day 2 comparing RN4220 with esp17. Notably there is high number of CFU in day 2 results compared to day 0 results.

**Conclusions:** The experiments carried out shows the importance of esp17 in desiccation resistance.

Prevalence of different resistance mechanisms in carbapenemase-producing organisms in Kenya: a phenotypic study

Anne Amulele*, Joseph Waichungo1, Alfred Mwanzu1, Edwin Machanja1, David Wareham2, James A Berkley1, Nicola Claire Gordon3

1KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, 2Queen Mary University of London, London, United Kingdom, 3Mott MacDonald, London, United Kingdom

Background: Antimicrobial resistance is currently one of the leading threats to human health globally. Carbapenem resistant organisms (CROs) are a top priority, however, knowledge on these organisms in Africa is limited. The aim of this study is to determine the resistance mechanisms in CROs from Kenya.

Materials/methods: We identified imipenem non-susceptible Enterobacterales, Acinetobacter spp and Pseudomonas aeruginosa isolated from clinical samples from patients admitted to Kilifi County Hospital (KCH) from 2005 to 2019. Additionally, rectal swabs were obtained from malnourished children admitted to KCH, Coast General Hospital, Mombasa and Mbagathi Hospital, Nairobi and screened for carbapenem resistance. Antibiotic susceptibility was determined using the disc diffusion method and carbapenem resistance confirmed using imipenem, meropenem and ertapenem discs. We detected carbapenemases using the modified carbapenem inactivation method (mCIM) and Triton Hodge test (THT), metallo-β-lactamases (MBLs) using EDTA-mCIM (eCIM) and AmpC cephalosporinase using MAST-AmpC detection set.

Results: We identified 104 imipenem non-susceptible bacteria from historic samples; 86 were confirmed to be carbapenem resistant on repeat testing. Of these, 32 were from blood, 30 from rectal swabs, urine (11), pus (9), aspirate (2), cerebrospinal fluid (1) and sputum (1). There were 36 Acinetobacter spp (18 A. baumannii), 9 P. aeruginosa and 41 Enterobacterales namely: 25 E. coli, 11 K. pneumoniae, 3 E. cloacae, 1 M. morganii and 1 C. freundii. Carbapenemases were detected in 28/34 (82%) and 25/34 (74%) of Enterobacterales by mCIM and THT respectively of which 22/28 (79%) were MBLs and 6/28 were serine-based carbapenemases. We did not detect carbapenemases in P. aeruginosa by either method while 33/35 Acinetobacter spp were positive by THT. AmpC activity was detected in only 3/17 non-producers and were E. cloacae, K. pneumoniae and M. morganii.

Conclusions: Metallo-β-lactamases were the main carbapenem resistance mechanism in Enterobacterales isolates tested, while resistance in P. aeruginosa was likely to be due to non-enzymatic methods. Given that carbapenems are rarely available in public hospitals in Kenya, the range of species and mechanisms identified in this study is concerning and demonstrates that the emergence and spread of CROs in this region is multifactorial rather than due to establishment of a successful clone.

Salvage treatment of invasive pulmonary aspergillosis with isavuconazole and caspofungin combination in a lung transplant recipient

Paolo Pavone*, Carolina Carillo1, Ylenia Pecoraro1, Federico Venuta1, Claudio M. Mastroianni1, Gianluca Russo1

1Sapienza University, Rome, Italy

**Background:** Isavuconazole (ISA) has recently been approved as a first line treatment for invasive pulmonary aspergillosis (IPA). Anyway clinical data in lung transplant recipients and/or patients failing voriconazole are lacking.

**Case Report:** A 50 years-old man underwent bilateral lung transplant in April 2019 and was started on tacrolimus and azathio- prine. During the hospital stay he received antifungal prophylaxis with inhaled liposomal amphotericin B (AMPHO) at the dose of 25 mg/day. In July 2019 he came back to emergency reporting shortness of breath and a CT scan of the chest showed diffuse peri-bronchial ground glass opacities, galactomannan was strongly positive in the BAL (7.3 index), fungal culture growed *Aspergillus flavus* so that a diagnosis of IPA with radiological airway invasive pattern was made. The patient was consequently started on iv AMPHO 3 mg/kg but after two weeks he was switched to voriconazole (VORI) (6 mg/kg loading dose and then 4 mg/kg q 12 hours) because of kidney toxicity. Given the wide fluctuations of VORI plasma levels (last value: 0.6 μg/ml despite TDM-guided dose adjustment), the lack of clinical response (persistently positive galactomannan in BAL and positive fungal culture, respiratory insufficiency, no significant change in the CT chest) and the development of liver toxicity the treatment was switched to iv ISA (200 mg q 8 hours loading dose for 2 days and then q24 hours) combined with caspofungin (70 mg loading dose and then 50 mg/day). After 14 days of treatment ISA plasma value was 2.66 μg/ml. *Aspergillus flavus* susceptibilities excluded azole-resistance: VORI MIC 0.125, ISA MIC 0.125, caspofungin MIC 0.016, AMPHO MIC 2. After 8 weeks lung function and CT chest had mild improvement while BAL galactomannan was reduced but still positive (2.92 index). Lung biopsy after treatment showed chronic lung inflammation but no hyphae and other signs of fungal invasive disease. Class I and II-HLA antibodies were negative in the blood.

Conclusions: ISA and caspofungin combination was well tolerated and associated with normal ISA plasma levels but treatment didn’t lead to microbiological cure in a lung transplant recipient with invasive pulmonary aspergillosis by *A. flavus* and possible chronic lung rejection.

Abstract 2921

**Bacteraemia with ESBL-producing Enterobacteriaceae is associated with increased levels of IgG antibodies specific to CTX-M-15 and/or CTX-M-27**

Thomas Sahlström, Oskar Ljungquist*, Yu-Ching Su, Fredrik Resman, Emma Mattsson, Johan Tham, Kristian Riesbeck

1Lund University, Clinical Infection Medicine and Clinical Microbiology, Dept. of Translational Medicine, Malmö, Sweden, 2Lund University, Clinical Microbiology, Dept. of Translational Medicine, Malmö, Sweden

**Background:** Infections with extended spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae (EPE) are increasing worldwide. Molecular methods such as whole genome sequencing have been used successfully to reveal antimicrobial resistance and virulence genes of pathogenic EPE, but considerably less is known about the adaptive immune response to such infections.

**Materials/methods:** Patients with previous bacteraemia with EPE (n=59) or non-ESBL-producing Enterobacteriaceae (n=42) were recruited in this prospective observational study in Skåne, the south of Sweden. Sera were collected from 9 up to 21 months after bacteraemia. Enzyme-linked immunosorbent assay (ELISA) was used for detection of specific IgG antibodies directed against His-tagged recombinant beta-lactamases CTX-M-15 and CTX-M-27 that were expressed in *Escherichia coli* BL21 (DE3). Recombinant BRO-1 and TEM-1 were included as controls. The beta-lactamase resistance genes of EPE blood isolates were amplified by colony PCR with CTX-specific primers and typed by DNA sequencing.

**Results:** Out of 59 patients with EPE bacteraemia, 18 (30.5%) had detectable IgG specific to CTX-M-15 and/or CTX-M-27. In the control group with non-ESBL-producing *E. coli* bacteraemia, only 4 (9.5%) out of 42 patients carried detectable IgG against CTX-M-15/CTX-M-27 (p<0.01). Our preliminary data revealed that the majority (94%) of the EPE blood isolates from patients with detectable anti-CTX antibodies indeed carry the *blaCTX-M-15* or *blaCTX-M-27* genes. The patients of the EPE group had a significantly higher median Charlson comorbidity index and greater portion of renal disease, compared to the control group.

**Conclusions:** This study implies that bacteraemia during EPE infection has triggered a substantial adaptive immune response resulting in production of antibodies targeting one of the EPE virulence factors, the CTX enzyme. It is interesting to further investigate the importance or protective role of the humoral immune responses against EPE infections. In addition, our finding sheds new light upon the potential of the host immune response as a prognosis/diagnostic tool for detection of EPE-related infections.

Abstract 2923

Analysis of adherence to treatment among rural patients with various behaviour and social characteristics
Lubov Parolina1, Natalia Pshenichnaya*

1National Medical Research Center of Phthisiopulmonology and Infectious Diseases, Moscow, Russian Federation

Background: Non-adherence to tuberculosis (TB) treatment remains one of the main obstacles that need to be overcome by multi-drug resistant (MDR) TB control programmes especially in the remote rural areas. The present study attempted to identify various factors accounting for non-adherence that could help to achieve better treatment outcomes among rural patients.

Aim: To analyse the correlation between both social and behaviour characteristics and adherence to MDR TB treatment among rural patients.

Materials/methods: A cohort of 210 rural patients of older than 18 years with newly diagnosed sputum smear-positive pulmonary MDR TB and admitted to the principal Saratov regional tuberculosis hospital were enrolled in the case-control study divided between 70 non-adherent (with 2 and more violations of the regimen - NA) and 140 adherent (A) patients. Each participant was interviewed using a structured questionnaire after first 6 months of direct observation treatment at the hospital.

Univariate logistic regression analysis was performed to identify significant factors associated with treatment default. Statistical significance was taken as P < 0.05.

Results: The main factors associated with MDR TB treatment non-adherence were social, family and personal factors. Missing treatment was significantly associated with the patient’s income (OR: 5.6, 95% CI: 4.4-6.8), unsolved medical and social problems in the family (OR: 2.7, 95% CI: 2.4-3.1), concern to lose a job (OR: 2.2, 95% CI: 2.0-2.4) and problems while interacting with others (OR: 2.2, 95% CI: 1.9-2.5). Unemployment, alcoholism, previous imprisonment and homelessness as a cause of MDR TB treatment default were associated with rural marginal population. Factors significant in the bivariate analyses—literacy and low status occupation—were not found to be significantly associated with non-adherence.

Conclusions: Low socio-economic status and marginal features are important risk factors for non-adherence to TB treatment of rural TB patients. Social support and adequate psychological supplies for treatment can help patients overcome structural and personal barriers.

Decrease in antibiotic days of therapy after notification of *Clostridioides difficile* carriage status: an interventional study

Maayan Gilboa*1, Eyal Meltzer2, Leonid Maizels3, Shir Raibman-Spector4, Amitai Segev5, Galia Rahav6, Gill Smollan7, Avshalom Leibowitz3, Gili Regev-Yochay6

1Sheba Medical Center -Infectious disease unit, Ramat Gan, Israel, 2Sheba Medical Center -Internal medicine C, Ramat Gan, Israel, 3Sheba Medical Center - Internal Medicine D, Ramat Gan, Israel, 4Sheba Medical Center - Internal Medicine E, Ramat Gan, Israel, 5Sheba Medical Center - Internal Medicine T, Ramat Gan, Israel, 6Sheba Medical Center - Infectious Disease Unit, Ramat Gan, Israel, 7Sheba Medical Center - Microbiology Laboratory, Ramat Gan, Israel

**Background:** *Clostridioides difficile* (CD) is a leading cause of healthcare-associated infections. Screening asymptomatic patients for CD carriage is controversial. We assessed changes in antibiotic prescription practices after notification of carriage status and its effect on the incidence of CDI among carriers.

**Materials/methods:** Since June 2017 patients admitted to internal medicine wards were screened for CD carriage by CD toxin-B PCR using rectal swabs. During phase I, June-August 2017, we screened all patients but clinicians were blinded to carriage status. During phase II (2018), only high-risk patients (elderly & those recently hospitalized) were screened and clinicians were notified about carriage status. Additionally, antibiotic stewardship meetings were held with an infectious disease specialist. CDI diagnosis protocol in both study phases included a stool sample for 2-step EIA/PCR in any patient with >3 unformed stools/24h.

**Results:** During phase I, 92 carriers were detected, of these 69 had high risk and fulfilled the screening criteria implemented in phase II. During phase II, 421 carriers were detected. Despite no change in CDI diagnosis protocol, the proportion of stool samples sent for CDI diagnosis among carriers increased, when CD carriage was notified (Phase II); from 16.0% of carriers having an unformed stool sent, to 28.4% in the first quartile of phase II (p=0.0038).

Despite this, a significant decrease in CDI among carriers was observed; from 16.0% of carriers developing CDI during hospitalization to 7.5% in phase II (p=0.006), a 51% reduction in the incidence rate of CDI among carriers (12.23/1000 HD to 6.24/1000 HD).

Concurrently, a significant reduction in antibiotic treatment (days of therapy (DOT)/hospital days; %DOT) of carriers was observed; from 57.1% in phase I, to 41.5% in phase II, p=0.009. An even greater reduction (of 32%) was observed when the same time periods in the subsequent years were compared (from 57.1% to 38.9%, p=0.009).

**Conclusions:** Screening for CD carriage on admission and notifying clinicians increased the index of suspicion of active CDI, yet resulted in reduced rates of CDI among carriers. This is probably due to a significant reduction in the percentage of antibiotic DOT during hospital stay.

**Presenter email address:** mayangilboa@yahoo.com
Abstract 2927

**Effect of augmented renal clearance on the extended-interval dosing of aminoglycosides in critically ill pediatric patients**

Nathaniel J. Rhodes*1,2; Sean Avedissian3,4; Alla Hadid1; John Bradley5,6; Jennifer Le7

1Midwestern University, Department of Pharmacy Practice, Downers Grove, United States; 2Midwestern University, Pharmacometrics Center of Excellence, Downers Grove, United States; 3University of Nebraska Medical Center, College of Pharmacy, Omaha, United States; 4University of Nebraska Medical Center, Antiviral Pharmacology Laboratory, Omaha, United States; 5UC San Diego School of Medicine, Division of Infectious Diseases, San Diego, United States; 6Rady Children’s Hospital - San Diego, San Diego, United States; 7University of California San Diego, Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, United States

**Background:** Augmented renal clearance (ARC) has been documented among critically-ill pediatric patients treated with aminoglycosides. However, the effect of ARC on aminoglycoside PK/PD attainment with extended-interval dosing is unknown. We evaluated the effect of ARC on the probability of achieving efficacious or potentially nephrotoxic aminoglycoside exposures in pediatric patients.

**Materials/methods:** We fit a population model of gentamicin and tobramycin PK from pediatric patients with normal to high renal function using Pmetrics. Total clearance was scaled to total body weight \((CL0 \times TBW/70)^{0.75}\), age \((age/TM+ageH)\), and serum creatinine \((CL1 \times Scr/0.5)\). An additive categorical variable \((CL2)\) was integrated for ARC severity (i.e., none, moderate, or severe). Monte Carlo simulations were conducted based on age (fixed at 1, 4 and 12yrs) and TBW (fixed at 8.5, 15, and 50kg). Scr was fixed at 0.5mg/dL. Extended-interval dosing regimens of 5-12 mg/kg/day were compared against MICs from 0.25-1mg/L. In the PTA, an AUC\(_{0-24hr}\)/MIC ratio of 70 was considered for efficacy. The probability of nephrotoxic exposures \(P_{toxicity}\) was defined as the projected incidence of \(C_{min0-24hr}\) of >2mg/L.

**Results:** A total of 85 pediatric patients (range 1.25-21yrs, 54% female) contributed 175 concentrations [median (IQR) 2 [1-2] concentrations/patient]. A two-compartment covariate-adjusted model was best and most parsimonious [population \(R^2=0.872\), individual \(R^2=0.981\), AIC=227]. The mean value of the model parameters \(CL0, CL1, CL2, Q, Vc, Vp, TM, and H\) were 9.2L/hr, 0.41L/hr, 0.4L/hr, 1.03L/hr, 18.1L, 67.6L, 10yrs, and 2 respectively. The simulation analyses are summarized in the Table below. Above an MIC of 1mg/L, all regimens had <90% PTA.

<table>
<thead>
<tr>
<th>Age (yrs)</th>
<th>MIC [mg/dL]</th>
<th>Dose (mg/kg/day) yielding PTA&gt;90% and (P_{toxicity}&lt;5%)</th>
</tr>
</thead>

<td>Severe</td>
<td>None</td>
</tr>
</tbody>
</table>

**Conclusions:** ARC and elevated MICs were associated with lower PTA using standard extended-interval dosing regimens. More intense regimens may be required for moderate to severe ARC, but a careful assessment of toxicity risk and post-antibiotic effect is needed. Empirical combination with non-aminoglycosides in critically-ill patients appears prudent.

Abstract 2929

Serum \((1 \rightarrow 3)\-\beta\-D\-glucan\) has suboptimal performance for the diagnosis of \textit{Pneumocystis jirovecii} pneumonia and correlates poorly with respiratory burden measured by quantitative PCR in patients with cancer

Ariel Szvalb\*1, Alexandre E. Malek\*1, Ying Jiang1, Dimitrios P. Kontoyiannis\*1

1The University of Texas MD Anderson Cancer Center, Houston, United States

\textbf{Background:} \textit{Pneumocystis jirovecii} pneumonia (PCP) is a common opportunistic infection. Serum \((1 \rightarrow 3)\-\beta\-D\-glucan\) (BDG) has shown both excellent correlation with high fungal burden and clinical performance as a surrogate diagnostic marker for PCP in HIV/AIDS patients. Non-HIV immunocompromised patients are characterized by lower fungal burden. We evaluated the test performance of BDG and its correlation with quantitative PJP PCR in non-HIV cancer patients.

\textbf{Materials/methods:} The study extended from 04/2014 to 02/2019. Definite PCP was defined as presence of clinical-radiological features suggestive of PCP plus both PCR(+)\_microscopy(+) in BAL samples, while probable PCP shared the same features but with PCR(+)\_microscopy(-). PCR(-) patients were used as non-PCP controls. Patients had concomitant serum BDG. After excluding those with another fungal pneumonia or recent IVIG (\(\leq 60\) days), we performed a correlation analysis between PCR and BDG, and assessed BDG clinical performance.

\textbf{Results:} Among 2972 patients, we identified 101 PCR(+) patients (73 definite/probable, 28 possible) and 76 non-PCP controls. Data analysis showed low positive BDG/PCR correlation among 101 PCR(+) cases (Spearman's coefficient= 0.48; \(p<0.001\)). The analysis was performed on definite/probable cases, and also showed low positive correlation (0.31; \(p=0.02\)). BDG performance on PCR(+) cases at different BDG cutoffs (\(\geq 80\); \(\geq 200\) and \(\geq 400\) pg/mL), demonstrated poor sensitivity, while at BDG cutoff \(\geq 400\), specificity increased (93%) and NPV decreased (47%). The analysis was repeated on definite/probable cases using different PCR levels as method of reference, at different BDG cutoffs (\(\geq 80\); \(\geq 200\) and \(\geq 400\)). At PCR \(\geq 84\) and BDG \(\geq 80\), the test showed sensitivity=67%; specificity=85%; PPV=85% and NPV=72%. Performance improved at increasing PCR levels, achieving sensitivity=65%; specificity=93%; PPV=81% and NPV=85%, when both PCR \(\geq 2000\) and BDG \(\geq 400\) were used.

\textbf{Conclusions:} BDG and PCR levels do not correlate well in non-HIV cancer patients, and their combined test performance to rule out PCP suffers from suboptimal sensitivity and NPV. Only at high values of both tests, the NPV was acceptable, but this was seen only in patients with definite/probable PCP. A negative BDG test should not be used to rule out PCP in non-HIV cancer patients. BDG appears to be a suboptimal surrogate marker for diagnosis of PCP in this population.

**Abstract 2930**

**Two-photon microscopy contribution for exploration of innate immunity pulmonary mechanism after influenza virus infection of mice model**

Frédéric Riviere¹, Clarisse Vigne¹, Julien Burger¹, Annabelle Garnier¹, Jean Nicolas Tournier¹, Emmanuelle Billon-Denis¹

¹IRBA, Bretigny sur orge, France

**Background:** flu is important public health threat, very contagious and causing morbimortality. anti-viral treatments are not totally effective in severe cases and recent studies showed that adding anti-inflammatory treatment could reduce mortality. the precise knowledge of pulmonary innate immune mechanism appears to be essential, the role of innate immunity has already been studied after influenza virus infection but exclusively by indirect techniques. the emergence of high-resolution imaging tools can now allow precise exploration of cellular interactions. intravital microscopy has previously, but rarely, been used in respiratory infectious diseases only with bacillus anthracis. it should be evaluated for more conventional and usual pathogens. the objective of this work is to investigate the immune mechanisms and cellular interactions linked to influenza virus infection with two-photon microscopy in murine model.

**Materials/methods:** infection by nasal inhalation of transgenic mice (c57bl6/J whose cd11c+ cell was coupled with yellow fluorescent protein) with influenza virus strains adapted to mice: pr8 (h1n1, a/pr/8/34) and wsn (h1n1, a/wsn/33) whose ns1 protein was coupled with red fluorescent protein. after euthanasia, lungs are explanted and studied with different techniques: flow cytometry, two-photon microscopy. different cell types have been analyzed: macrophage, neutrophil polynuclear, nk cell, dendritic cell. this exploration has been done at day 1, 2, 3, 4 post-infection.

**Results:** our data in flow cytometry confirmed important macrophage and neutrophil polynuclear recruitment. two-photon microscopy showed temporal evolution of bronchial epithelium infection, epithelial damages and massive local macrophages influx [figure below]. the two viral strains seemed to have same immune recruitment but different in importance and kinetics. we have also developed technique for in vivo analysis of dendritic cells and macrophages trafficking and interactions after influenza virus infection.

**Conclusions:** two-photon microscopy, allowed us to visualize infection, location and kinetics of immune recruitment, pulmonary damages and evaluation of cells trafficking. this microscopy seems to be an excellent tool for in vivo exploration of immune mechanisms after influenza virus infection. our results are importants for design of future in vivo pre-clinical studies of vaccines trial or development of new therapeutic strategies.

Methicillin-susceptible Staphylococcus aureus in community-acquired pneumonia: risk factors and outcomes

Catia Cilloniz Campos1, Estela Moreno1, Cristina Dominedò2,3, Carolina García Vidal1, Carmen Rosa Vargas1, Albert Gabarrus1, Jose Becerril4, Celia Cardozo1, Diego Tovar4, Antoni Torres4

1Hospital Clinic of Barcelona, Barcelona, Spain, 2Università Cattolica del Sacro Cuore, Rome, Spain, 3Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Department of Anesthesiology and Intensive Care Medicine, Rome, Italy, 4National Polytechnic Institute, Mexico, Mexico

Abstract third-party references: Dr Cillóniz is the recipient of a postdoctoral grant (Strategic plan for research and innovation in health; ERIS 2016–2020), the SEPAR fellowship 2018, and a grant from the Fondo de Investigación Sanitaria (PI19/00207).

Background: The epidemiology of Staphylococcus aureus is changing, with several studies reporting a decline in methicillin-resistant S. aureus (MRSA) infection and an increase in methicillin-susceptible S. aureus (MSSA) infection. We aimed to describe and compare the prevalence, clinical features, and risk factors of community-acquired pneumonia (CAP) caused by MSSA with that caused by Streptococcus pneumoniae.

Materials/methods: This was a prospective observational cohort study of consecutive adults with CAP and a definitive etiology that were enrolled between January 2004 and December 2018. Patients were divided into groups with MSSA CAP and pneumococcal CAP for analysis.

Results: A microbial etiology was established in 1,548 patients with CAP, of which 52 cases were caused by MSSA and 734 were caused by S. pneumoniae. MSSA affected 1% of all patients hospitalized with CAP, and 3% when a microbiological diagnosis was obtained. The presence of fever was independently associated with a lower risk of MSSA CAP. Patients with CAP due to MSSA had higher 30-day mortality than patients with pneumococcal CAP, both before and after adjustment for potential confounders. MSSA infection, older age, inhaled corticosteroid use, lymphopenia, acute renal failure, acute respiratory distress syndrome, and septic shock were associated with 30-day mortality (table 1).

Conclusions: MSSA CAP was associated with worse outcomes compared with pneumococcal CAP in our cohort. The absence of fever was associated with an increased risk of MSSA CAP. Methicillin-susceptibility in S. aureus strains causing CAP should not be regarded as a marker of lesser severity.

Table 1. Significant risk factors for 30-day mortality in all study population in Cox regression analyses (N = 786)

Abstract 2934

**Sepsis due to Gram-positive bloodstream infections in critically ill patients during a five-year period (2012-16): dissemination of linezolid-resistant *Staphylococcus epidermidis* ST22 and predictors of fatality**

Matthaios Papadimitriou Oliiveris*, Fevronia Kolonitsiou, Vasileios Karamouzos, Katerina Tsilipounidaki, Maria Plota, Alexandra Nikopoulou, Fotini Fligou, Markos Marangos, Efi Petinaki, Iris Spiliopoulos

1 University Of Patras, Panepistimioupoli Patron, Greece; 2 University of Thessaly, Larisa, Greece

**Background:** Even though Gram-negative bacteria predominate among Greek critically ill patients, Gram-positive cocci provoke a considerable proportion of bloodstream infections especially catheter-related (CR-BSIs). The aim of the present study was to identify the molecular characteristics of Gram-positive cocci isolated from blood cultures and clinical outcome among critically ill patients.

**Materials/methods:** This retrospective study was conducted in the general Intensive Care Unit of the University General Hospital of Patras, Greece, during a five-year period (2012-16). All adult patients with a Gram-positive BSI were included. PCR was applied to identify mecA gene (staphylococci); vanA, vanB and vanC genes (enterococci). Linezolid-resistant *S. epidermidis* were further typed by multilocus sequence typing. Mutations in region V of 23S rDNA and ribosomal protein L4 were investigated by PCR and sequencing analysis. The presence of cfr gene was tested by PCR.

**Results:** In total, 141 Gram-positive BSIs were included. Coagulase negative staphylococci predominated (n=69; 65 methicillin-resistant, 23 linezolid-resistant carrying both C2534T and T2504A mutations and belonging to ST22 clone), followed by enterococci (n=46; 11 vancomycin-resistant carrying vanA gene), *S. aureus* (n=22; 10 methicillin-resistant) and streptococci (n=4; two *S. agalactiae*, one *S. galolyticus*, one *S. mitis*). The most common type of infection was catheter-related (66; 46.8%), followed by primary BSI (28; 19.9%). Septic shock was observed among 57 patients (40.4%). Overall 14-day fatality was 24.8% (35 patients). Multivariate analysis revealed septic shock (P=0.039; OR 4.0, CI 1.1-10.9) as independent predictor of fatality, while appropriate empiric antimicrobial treatment (P=0.011; OR 0.20, CI 0.06-0.69) and catheter-related BSI (P=0.024; OR 0.28, CI 0.09-0.85) were identified as a predictor of good prognosis. In order to investigate risk factors for development BSI due to linezolid-resistant *S. epidermidis*, a multivariate analysis was performed and revealed administration of linezolid (P=0.015; OR 4.9, CI 1.4-18.1) as the only independent risk factor.

**Conclusions:** Even though most Gram-positive cocci were multidrug-resistant, fatality rate was low since most BSIs were catheter-related. Among CNS, linezolid-resistant isolates represented one third of BSIs due to the dissemination of ST22 *S. epidermidis* propagated by utilization of linezolid.

**Presenter email address:** papadimitrioumat@gmail.com
Combination empiric treatment is equivalent to monotherapy in 317 sepsis episodes due to carbapenemase-producing Klebsiella pneumoniae in critically ill patients

Matthaios Papadimitriou Olivieris*, Christina Bartzavali1, Anastasia Lambropoulou1, Vasileios Karamouzos1, Alexandra Georgakopoulou1, Fevronia Kolonitsiou1, Fotini Fligou1, Myrto Christofidou1, Markos Marangos1

1University Of Patras, Panepistimioupoli Patron, Greece

Background: Combination treatment was found to be superior to monotherapy in the treatment of carbapenemase-producing Klebsiella pneumoniae (CP-Kp). The objective was to study the epidemiology, and outcome of CP-Kp bacteremia among critically ill patients.

Materials/methods: During a 9-year period (2010-18), CP-Kp isolates, from bacteremic Intensive Care Unit (ICU) patients, at a University Hospital, were studied. Antibiotic susceptibility testing was performed by the agar disk diffusion method according to EUCAST guidelines. MICs of meropenem, tigecycline and ceftazidime/avibactam were determined by Etest (bioMerieux), whereas for colistin, the broth microdilution method was applied. All isolates were tested by PCR for the presence of $bla_{KPC}$, $bla_{VIM}$, $bla_{NDM}$ and $bla_{OXA-48}$ genes.

Results: Among 2780 ICU hospitalized patients, 317 (11.7%) CP-Kp bloodstream infections were observed (284 patients). Resistance to gentamicin was found in 207 isolates (65.3%); colistin in 146 (46.1%); tigecycline in 89 (28.1%). The majority of infections were caused by KPC-producing isolates (260 episodes; 82%), followed by VIM-producing (28 episodes; 8.8%), NDM-producing (16 episodes; 5.0%) and KPC and VIM co-producing isolates (13 episodes; 4.1%). 14-day mortality was 25.5% (81 patients). Multivariate analysis identified septic shock ($P<0.001$; OR 5.1, CI 2.4-10.8), SOFA score upon BSI onset ($P<0.001$; OR 1.3, CI 1.1-1.4), corticosteroid co-administration ($P<0.001$; OR 2.6, CI 1.3-5.0) and infection by $bla_{VIM}$-carrying isolate ($P=0.006$; OR 4.6, CI 1.6-13.6) as independent predictors of mortality, whereas treatment with at least one appropriate antibiotic was a predictor of survival ($P=0.027$; OR 0.463, CI 0.233-0.916). Among septic shock patients (151; 47.6%), multivariate analysis revealed SOFA score upon BSI onset ($P=0.001$; OR 1.3, CI 1.1-1.4) and corticosteroid co-administration ($P=0.016$; OR 2.5, CI 1.2-5.2) as independent predictors of mortality, whereas treatment with at least one appropriate antibiotic was a predictor of survival ($P=0.022$; OR 0.407, CI 0.188-0.877). No difference on mortality was observed among monotherapy or combination treatment, even in patients with septic shock (Figure 1).

Conclusions: KPC-producing isolates remain the most prominent among CP-Kp. Septic shock and corticosteroid administration were associated with increased mortality. Better outcome was observed in patients who received empirically at least one appropriate antibiotic, while combination treatment did not offer any additional effect.

Dihydropyridine-class antihypertensive drugs exhibit strong bactericidal activities against *Helicobacter pylori* and significantly reduce gastric colonisation in mice.

Andrés González Rodríguez*1,2; Javier Casado1, Eduardo Chueca1,4; Sandra Salillas2,5; Adrián Velázquez-Campoy3,4,6; Vladimir Espinosa Angarica1; Lucie Benejat8,9; Jérome Guignard9; Alban Giese9; Javier Sancho1,2,5; Philippe Lehours8,10; Angel Lanas4,5,11

**Background:** *Helicobacter pylori* is the most prevalent human pathogen worldwide and a major cause of gastritis, peptic ulcer disease and gastric cancer. In previous works, we validated a new effective anti-*H. pylori* therapeutic target, the essential response regulator HsrA. A high-throughput screening of a repurposing collection of 1120 FDA-approved, off-patent small drugs using a fluorescence-based thermal shift assay led to identifying several non-antibiotic drugs that specifically bound to HsrA and notably increased the protein conformational stability, causing a shift of the protein unfolding curve to higher temperatures due to the increased melting temperature. One of these HsrA ligands was the dihydropyridine (DHP)-class of calcium channel blocker Nicardipine. In the present study, we investigated the effect of Nicardipine and other highly prescribed commercially available DHP-class antihypertensive drugs on the biological activity of the *H. pylori* essential response regulator HsrA. The *in vitro* and *in vivo* antimicrobial activities of DHP-class inhibitors of HsrA against *H. pylori* were also evaluated.

**Materials/methods:** The ability of different DHP-class drugs to inhibit the HsrA function was determined by electrophoretic mobility shift assays. The antibacterial activity of HsrA inhibitors was tested against three different strains of *H. pylori* by determining their minimal inhibitory/bactericidal concentrations [MIC/MBC]. The efficacy of two representative DHP drugs in eradicating the *H. pylori* gastric mucosal colonization was assessed in a mouse model.

**Results:** Six different DHP-class drugs, including Nifedipine, Nicardipine, Nisoldipine, Nimodipine, Nitrendipine and Lercanidipine, noticeably inhibited the DNA binding activity of HsrA and showed potent bactericidal activities against *H. pylori*, with MIC values in the range of 4 to 32 mg/L. Oral treatments with 100 mg/kg/day of marketed formulations of Nimodipine or Nitrendipine in combination with omeprazole significantly reduced the *H. pylori* gastric colonization in mice.

**Conclusions:** The results support the use of DHP-class antihypertensive drugs in novel antimicrobial strategies against *H. pylori* infections. Currently prescribed DHP-class drugs could be also employed as “lead compounds” to synthesize more efficacious antimicrobials against *H. pylori*, even when the antihypertensive effects of these molecules result mitigated.

Abstract 2939

Emergence of mobile mcr-8 colistin resistance in Klebsiella pneumoniae from clinical infections of hospitalised patients in Bangladesh

Refath Farzana1,2, Lim Jones1, Andrew Barratt2, Anisur Rahman2, Kirsty Sands1, Edward Portal1, Qiue Yang1, Timothy R. Walsh1

1Cardiff University, Cardiff, United Kingdom, 2Public Health Wales, Cardiff, United Kingdom, 3Dhaka Medical College, Dhaka, Bangladesh

Background: Emergence of colistin resistance in Klebsiella pneumoniae has become a serious concern in clinical practice, compromising treatment options for life-threatening infections.

Materials/methods: Bacterial strains were characterized by phenotypic and genomic analysis in both Illumina MiSeq and Oxford Nanopore minION sequencing. Plasmid profile was further evaluated by PFGE followed by probing with gene of interest and conjugation assay. Stability of colistin resistance in plasmid was assessed by serial passaging up to 12 days without selection and DNA quantification by QPCR.

Results: Colistin resistant K. pneumoniae were recovered from 3 patients admitted in urology and NICU from 3.4.17 to 13.07.17, belonged to ST15. The first strain was isolated from urine of a patient with benign prostate enlargement with diabetes mellitus and the second from urine of a patient with renal carcinoma. Both patients were catheterized and were discharged at 20 and 35 days of hospital stay, respectively. The third case was a pre-term, low-birth weight neonate who died on the 18th day of hospitalization and colistin resistant K. pneumoniae was identified from blood. There was no overlapping of hospital stay among the cases. All 3 strains had common resistance profile: resistant to amoxicillin-clavulanate, piperacillin-tazobactam, cephalexins, ciprofloxacin, levofloxacin, gentamicin, trimethoprim-sulfamethoxazole and colistin and susceptible to carbapenems, amikacin and fosfomycin. Whole genome sequencing and S1 PFGE confirmed that colistin resistance of all 3 isolates was linked to mcr-8.1, found in an identical IncFIB(pQil) plasmid of 113,102 kb. Genetic environment analysis showed that two genes upstream of mcr-8.1 (Δgtf-ΔNAT-mcr-8.1) were flanked by IS5 and the downstream (mcr-8.1-ΔcapR-ΔbaeS-ΔgksA-Δgtf-ΔHTH-ΔHP-De-ΔgkA-MipA-sbmC-ΔHP-bla) by ISKpn21. Additional resistance profiles was found: sul2-1d-APH(6′)-APH(3′)-Ib; flanked by IS101 at the downstream and blaCTX-M-15 and blaTEM-1b within a composite transposon. Conjugation assay demonstrated that mcr-8.1 can be transferred to E. coli J53 with a frequency range of 3.1 x 10-2 to 8 x 10-2. MCR-8 in the plasmid was found to be highly stable without antibiotic selection in K. pneumoniae.

Conclusions: Report of mcr in clinical infections from Bangladeshi hospital highlights the urgent need for rational usage of antimicrobials in the country.

Abstract 2940

**What is the optimal timing and technique for the source control in the subgroup of septic shock patients with intra-abdominal infections?**

Uğur Önal¹, Deniz Akyol², Ayse Uyan³, Cansu Bulut¹, Günel Guliyeva⁴, Seichan Chousein Memetai², Dilshah Baskol², Gamze Şanildağ⁵, Melike Demir⁶, Merve Mert⁷, Meltem Isikgöz Tasbakan², Sercan Ulusoy², Oguz Reşat Sipahi²

¹Kastamonu State Hospital, Kastamonu, Turkey, ²Ege University Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Izmir, Turkey

**Background:** In this study it was aimed to evaluate the efficacy and optimal timing with technique of the source control for the subgroup of septic shock (SS) patients with intraabdominal infections (IAI) in a tertiary-care educational hospital.

**Materials/methods:** Patients who had SS (sepsis+hypotension+adrenergic agent; after the date of 28th Feb 2016, arterial lactate level of >2mg/dl criterion was also added) with IAI and consulted by Infectious Diseases consultants between December 2013 and October 2019 in our centre were recorded prospectively. Statistical analysis was performed via Chi square test and Student T test while a p value less than 0.05 was considered significant.

**Results:** There were a total of 143 patients (mean age 67.2±1.22 years and 42.7% female). Microbiological etiology was elucidated in 69 (48.2%) of 143 IAI cases (Table 1). The most common pathogen was *E.coli* (29/69, 42%) and multiple pathogens were recorded in 25 of 69 culture positive cases (Table 1). Overall mortality was 46.1% at the 72nd h visit while day 14 and 30 mortality rates were 69.2% and 73.4%, respectively. Source control by surgical or percutaneous operation was performed in 48 of 143 cases (33.5%) and mortality rate was significantly lower in cases that were performed source control at anytime during SS (24/48 vs 81/95, p=0.000007). In 18 of 48 cases (37.5%) source control was performed during the first 12 hours (as suggested by guidelines) and mortality was significantly lower in this group versus others (6/18-33.3% vs 99/125-79.2%, p=0.000038). In 31 of 48 cases invasive surgical operation was performed while percutaneous source control was performed in 17 cases and mortality rates among invasive operation group was statistically higher than the percutaneous group (20/31 vs 4/17, p=0.015) while the mean SOFA scores were recorded as 9.58±1.08 for invasive source controlled group and 12.75±1.31 for percutaneous source controlled group (p=0.195).

**Conclusions:** Source control has major and vital importance in terms of mortality rates for IAI related septic shock patients especially during the first 12 h of identification. The more favourable outcomes observed during the source control via percutaneous procedures in our cohort needs to be confirmed in larger studies.

Abstract 2942

**Carbapenemase-producing and colistin-resistant Enterobacteriaceae in intensive care unit patients from Mediterranean countries, 2019**

Sandra Borges Dos Santos, Seydina Diene, Benoua Amina, Khalid Zerouali, Doaa Ghaith, Rasha H. El-Mahdy, Sawsan El Tayeb, Adnene Hammami, Ilhem Boutiba, Ziad Daoud, Laurent Mereghetti, Patrice François, Nathalie Laure Van Der Mee-Marquet

1CHRU Hôpitaux De Tours, Tours, France, 2IHU-Méditerranée Infection, Marseille, France, 3Microbes Evolution Phylogeny and Infections [ME-PHI], IHU-Méditerranée Infection, Marseille, France, 4Hôpital Cheikh Zayd, Rabat, Morocco, 5CHU Ibn Rochd, Faculté de Médecine et Pharmacie, Casablanca, Morocco, 6Faculty of Medicine, Cairo University, Cairo, Egypt, 7Faculty of Medicine, Mansoura University, Mansoura, Egypt, 8Al Hussein University hospitals, Cairo, Egypt, 9CHU Habib Bourguiba, sfax, Tunisia, 10CHU Charles Nicolle, Tunis, Tunisia, 11Lebanese American University Medical Center, Rizk Hospital, beirut, Lebanon, 12Faculty of Medicine and Medical Sciences, Saint George Hospital-UMC, beirut, Lebanon, 13CHRU Hôpitaux De Tours, Tours, France, 14Geneva University Hospitals, Faculty of Medicine, Geneva, Switzerland

**Background:** Carbapenemase-producing (CPE) and colistin-resistant (colRE) Enterobacteriaceae are associated with an increased mortality in ICUs. Routine monitoring of antimicrobial resistance in acute care hospitals from Mediterranean countries remains uncommon. Data regarding CPE and colRE-carriage in ICU patients are scarce.

**Materials/methods:** We conducted a 1-day prevalence study in 9 ICUs from Morocco, Tunisia, Egypt and Lebanon (in January 2019). In each center, 30 consecutive patients were consented for medical records accession and sampled for fecal/rectal swab culture. Clinical data were collected (morbidities, duration of hospitalization before screening, previous hospitalization and antibiotic use). Swabs were streaked on CHROMagar-mSuperCARBA agar plates. Enterobacteriaceae isolates were sent to a central laboratory for antibiotic susceptibility testing, molecular characterization of the mechanisms involved with resistance against β-lactams, carbapenems and colistin, and 50 representative CPE were subjected to WGS.

**Results:**
- 256 patients (neonates and adults, mean age 57y) were enrolled and screened for CPE carriage; 44 and 48% with previous hospitalization or antibiotics, respectively.
- 110 Enterobacteriaceae on mSuperCarba plates were detected, including 102 CPE (61 K.pneumoniae, 30 E.coli, 11 others). CPE carriage rate of 28% (figure 1). 29 CPE only susceptible to tigecycline (100%) and colistin (81%). High diversity of carbapenemase determinants: 52% **bla**\_OXA48, 6% **bla**\_OXA244, 4% **bla**\_OXA181, 3% **bla**\_OXA232, 23% **bla**\_NDM1, 22% **bla**\_NDM5, 1% **bla**\_NDM-7 and 1% **bla**\_NDM-19; 14 CPE with 2 determinants.
- 14 ColRE detected (4 E.coli, 10 K.pneumoniae; MIC 4-16 mg/L), susceptible to tigecycline. ColRE carriage rate of 5%.
  - **mcr**\_1 in 1 ESBL-ST359-E.coli, 3 **bla**\_OXA48-ST1196-E.coli
  - **mcr**-like genes sharing 43% identity with **mcr**-7 or -10 in 10 K.pneumoniae.
  - mutations in **pmr**A and **pmr**B: 2 **bla**\_NDM-ST1162-K.pneumoniae (**pmr**A-A44T,**pmr**B-T246A/L213M/T157P); 1 **bla**\_NDM-ST383-K.pneumoniae carrying various carbapenemase genes (**pmr**A-G144D/D149E/N219H,**pmr**B-T246A/A228T/M175V/N105S/ASV);
- CPE carriage was associated with neonatal status and prolonged hospitalization (p<0.001).

**Conclusions:** We documented the worldwide spreading of conjugative plasmids and the establishment of CPE and colRE in Mediterranean ICUs. While colonization increases the risk of infection, and given the high mortality rate observed with CPE infection, our findings underline a crucial need to intervene forcefully and control the spread of CPE/ColRE into neonatal and adult ICUs.

Clinical effectiveness of 13-valent and 23-valent pneumococcal vaccination among middle-aged and older adults with immunocompromising conditions

Angel Vila-Córcoles1, Olga Ochoa-Gondar1, Eva Satue1, Cinta De Diego1, Angel Vila-Rovira2, Clara Rodriguez2

1Primary Health Care, Institut Catala de la Salut, Tarragona, Spain, 2Institut Universitari d’Investigació en Atenció Primària (IDI-AP Jordi Gol), Barcelona, Spain

Abstract third-party references: Funding by PERIS SL T002/16/00063

Background: Clinical benefits using the 13-valent pneumococcal conjugate vaccine (PCV13) and/or the 23-valent pneumococcal polysaccharide vaccine (PPsV23) are controversial. This study investigated clinical effectiveness for both PPsV23 and PCV13 in preventing pneumonia among immunocompromised adults.

Materials/methods: Population-based cohort study involving 203,447 Catalan adults (aged ≥50 years) with potential immunocompromising conditions (i.e., asplenia, immunodeficiency/HIV infection, severe renal disease, solid or haematological neoplasia and/or immunosuppressive treatment), who were prospectively followed between 01/01/2017 - 31/12/2017 (Funding: PERIS SL T002/16/00063). Primary outcomes were hospitalisation from pneumococcal or all-cause pneumonia and main explanatory variable was PCV13/PPsV23 vaccination status. Cox regression was used to estimate vaccination effectiveness adjusted for age, sex and presence of other baseline-risk conditions.

Results: Cohort members were followed for a total of 192,716 person-years (7248 PCV13 vaccinated and 115,574 PPsV23 vaccinated), observing 480 pneumococcal pneumonias (36 in PCV13 vaccinated, 364 in PPsV23 vaccinated) and 3622 all-cause pneumonias (264 in PCV13 vaccinated, 2817 in PPsV23 vaccinated). Global incidence rates (per 100,000 person-years) were 249.1 for pneumococcal pneumonia (496.7 in PCV13 vaccinated, 314.9 in PPsV23 vaccinated) and 1879.4 for all-cause pneumonia (3642.4 in PCV13 vaccinated, 1810.6 in PPsV23 vaccinated). Pneumococcal vaccination did not significantly alter the risk of pneumococcal pneumonia [multivariable hazard ratio [HR] for PCV13: 1.43, 95% confidence interval [CI]: 0.99-2.06, p=0.057; HR for PPsV23: 1.27, 95% CI: 0.99-1.64, p=0.065] but it appeared significantly associated with an increasing risk of all-cause pneumonia among vaccinated subjects [HR for PCV13: 1.34, 95% CI: 1.17-1.54, p=0.001; HR for PPsV23: 1.15, 95% CI: 1.05-1.27, p=0.004]. The PCV13 did not significantly alter the risk of death from pneumococcal pneumonia [HR: 2.02; 95% CI: 0.58-7.07, p=0.270] or death from all-cause pneumonia [HR: 0.88; 95% CI: 0.56-1.38, p=0.581], whereas the PPsV23 did not alter the risk of death from pneumococcal pneumonia [HR: 2.77; 95% CI: 0.94-8.13; p=0.064] and was associated with a marginally significant reduction in the risk of death from all-cause pneumonia [HR: 0.75; 95% CI: 0.56-1.00; p=0.046].

Conclusions: Data does not support clinical benefits from adults pneumococcal vaccination (nor PCV13 neither PPsV23) in preventing pneumonia among immunocompromised subjects.

A study of Bartonella bacilliformis bacteraemia in asymptomatic individuals during an inter-outbreak period in an endemic region

Helena Biasizzo*1,2, Palmira Ventosilla3, Cesar Augusto Ugarte Gil1,3,4, David Moore1,5

1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2General Hospital Novo mesto, Nova mesto, Slovenia, 3Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru, 4School of Medicine, Universidad Peruana Cayetano Heredia, Lima, Peru, 5Laboratorio de Investigacion de Enfermedades Infecciosas, Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru

Background: Carrion’s disease is a bacterial disease that affects remote Andean communities, principally in Peru, Colombia and Ecuador. It is caused by bacteria Bartonella bacilliformis, and it is believed to be transmitted from human to human by sand fly vector of the genus Lutzomyia. There are two distinct clinical forms of the disease: acute form, also known as Droya fever and chronic form or Verruga peruana. The disease tends to occur in outbreaks, usually during the rainy season. Many candidates for reservoir have been proposed until now such as Euphorbia plants and various domestic and wild animals. No animal reservoir has been found, but individuals with asymptomatic infection have been identified, raising the possibility that human asymptomatic B. bacilliformis carriers act as reservoirs for the infection between the outbreaks. The aim of this study was to investigate the prevalence of asymptomatic B. bacilliformis bacteraemia in individuals living in endemic Andean communities during a non-outbreak period.

Materials/methods: A cross-sectional field study was done in July 2019 in Ancash, Peru in two different communities which had previously experienced outbreaks of B. bacilliformis. Community members older than one year were invited to participate: eligible were those who were without any clinical signs or symptoms of acute or chronic B. bacilliformis infection. Demographic data and medical history were collected by questionnaire. B. bacilliformis bacteraemia was determined using blood culture.

Results: 177 people were included in the study from two different communities in endemic region. 64.4% were females and the median age of the participants was 34 years (interquartile range 25-49 years). More than half of them were farmers or house workers (83.6%). 11 participants out of 177 reported having experienced the acute form of the disease in the past, whereas 50 of them reported having experienced the chronic form of the disease. None of the blood cultures was positive after 56 days of incubation. Thus, the prevalence of B. bacilliformis bacteraemia in the communities was 0%.

Conclusions: Our data do not support the hypothesis that asymptomatic humans represent a significant reservoir of infection between outbreaks. Further investigation on alternative reservoir species is now warranted.

Optimal PK/PD target and high efficacy rates of ceftolozane-tazobactam in patients with infections caused by extensively drug-resistant Pseudomonas aeruginosa

Eugenia Navarrete-Rouco, Sonia Luque, Luisa Sorlí, Ana Belén Arancon, Nuria Campillo, M. Milagro Montero, Nuria Prim, Adela Benitez-Cano, Enric Samso, Juan P. Horcajada*, Santiago Grau

1Parc de Salut Mar, Barcelona, Spain, 2Hospital La Paz, Madrid, Spain

Background: Ceftolozane/tazobactam is a new drug active against extensively drug-resistant Pseudomonas aeruginosa (XDR-PA). The aim was to describe the PK/PD target of ceftolozane in patients with XDR-PA infections and its association with clinical outcomes.

Materials/methods: Retrospective observational study conducted from February 2018-October 2019. Demographic, clinical, microbiological and pharmacokinetic variables were collected. Ceftolozane plasma concentrations were obtained pre-dose at steady state (Cmin in intermittent/extended infusion) or Css in continuous infusion and analysed by HPLC. Free concentrations were calculated assuming a ceftolozane plasma protein binding of 21%. A 100% freeT>MIC was considered as optimal PK/PD target and 100% freeT>10MIC as supratherapeutic. Ceftolozane MIC was determined by broth microdilution.

Results: Thirty patients included (23.3% critically ill). Most common infections were urinary tract infections (23.3%), osteomyelitis (16.7%) and pneumonia (13.1%).

</table>

Clinical cure was achieved in 27 (90%) patients and microbiological eradication in 21 (70%). No differences were observed in the free ceftolozane concentrations between patients with and without clinical cure [34(26.5-46.4) vs 36.7(10.2-84.8) mg/L] (p=0.384). A supratherapeutic PK/PD ratio was not related to better clinical outcomes (p>0.53).

Conclusions: Ceftolozane/tazobactam showed a high rate of clinical and microbiological cure regardless of the strategy of administration. All patients achieved an optimal PK/PD target being this index supratherapeutic in 66.7 of the patients. Therapeutic drug monitoring may be useful to optimize the PK/PD of ceftolozane/tazobactam, especially in patients with overexposure in which a dosage reduction may reduce potential adverse events and treatment costs.

Presenter email address: jhorcajada@parcdesalutmar.cat
Abstract 2949

**Evaluation of effect of combination chemotherapy with tetracycline and fluoroquinolone for Japanese spotted fever**

Shigetoshi Sakabe*, Yuuki Nakanishi1, Hirokazu Toyoshima1, Kentaro Azuma1, Tomu Nakagawa2, Naohisa Yamazoe1, Hiroyuki Tanaka1

1Ise Red Cross Hospital, Ise, Japan, 2Minami-ise Municipal Hospital, Minami-ise, Japan

**Background:** Japanese spotted fever (JSF) is an emerging infectious disease caused by *Rickettsia japonica* and is endemic in Japan and Korea. JSF is a nationally notifiable disease in Japan, and recently 200 to 350 cases occur annually. The precise mortality is unclear, but at least 11 deaths in 278 cases were confirmed by October from January in 2019 and its mortality was estimated approximately 4% under standard medical care. For JSF, the chemotherapy with tetracycline is recommended like other rickettsial diseases, because of lack of evidence for JSF treatment. However, several cases reported that tetracycline is ineffective, but fluoroquinolone is effective. Hence, the combination chemotherapy with tetracycline and fluoroquinolone begun from initial treatment in some medical institutions. The aim of this study is to evaluate the combination therapy with tetracycline and fluoroquinolone for JSF.

**Materials/methods:** We retrospectively reviewed the medical records of JSF cases from 2012 to 2019 in Ise Red Cross Hospital and Minami-ise Municipal Hospital, that initiated the combination therapy immediately after diagnosis. Diagnostic criteria were positive results in molecular-based tests at the acute phase and/or increased serum antibody titers.

**Results:** A total of 196 cases (male; 45%, age; 70.5 ± 14 years) was investigated. Of those, 189 cases were hospitalized. The 194 cases were treated with the combination therapy: 192 cases of minocycline (200 mg/day) and levofloxacin (250-500 mg/ day); and 2 cases of minocycline (200 mg/day) and ciprofloxacin (300 mg/day). The time from onset to administration was 3.8 ± 2.4 days and the administration period was 3-14 days. Two cases died within a week. The first case was an 88-year-old woman who treated from the second day of onset but died on the third day with multiple organ failure. Another case was a 74-year-old woman who died suddenly due to gastrointestinal bleeding during the recovery. The average period of stay was 9.4 ± 7.3 days. Forty-seven percent of the patients were discharged within 7 days, while 4 cases were weakened and hospitalized for more than 30 days.

**Conclusions:** Although there are some fulminant cases, early combination therapy with tetracycline and fluoroquinolone improves JSF mortality to approximately 1%.

Clinical outcomes of 3-day course of adjunctive oral ivermectin for the patients with chikungunya viral infection: a preliminary study

Sarunyou Chusri*, Thanaporn Hortivakul1, Pornapat Surasombatpattana2, Kachornsak Silpapojakul3

1Faculty of Medicine, Prince of Songkla University, Kho Hong, Thailand

Background: Chikungunya (CHIK) fever is characterized by abrupt onset of high grade fever, rash and debilitating joint pain. Ivermectin has in vitro efficacy to inhibit replication of chikungunya virus (CHIKV), then clinical trial of this drug is needed.

Materials/methods: Forty patients with symptoms of CHIK fever with virological confirmation of CHIKV infection were enrolled and randomized (1:1) to receive 200 mcg/kg/day of oral ivermectin for 3 days as the adjunctive therapy to standard treatment. Physical examinations and blood tests including basic laboratories, polymerase chain reaction (PCR) for CHIKV, c-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were performed in first weeks and every week for 12 weeks.

Results: Clinical characteristics and basic laboratories of these 2 groups was indifferent. Time to disappearance of fever and joint pain among the patients receiving adjunctive ivermectin were significantly shorter than those receiving only supportive treatment [1.3 days VS. 2.2 days, P = 0.002 and 1.9 days VS. 2.8 days, P < 0.001, respectively]. Pain score in first 7 days and among those receiving adjunctive ivermectin was significantly lower than those receiving only supportive treatment [P < 0.001]. Persistent joint pain was observed in 2 patients receiving adjunctive ivermectin and 9 patients receiving only supportive treatment accounting to relative risk of 0.22 (0.05-0.90), P = 0.04. Time to disappearance of CHIKV among the patients receiving adjunctive ivermectin were significantly shorter than those receiving only supportive treatment [1.9 days VS. 5.1 days, P < 0.001]. The level of CRP and ESR in first 7 days among those receiving adjunctive ivermectin was significantly lower than those receiving only supportive treatment [P < 0.001]. Adverse drug reactions were not different between these 2 groups.

Conclusions: Favorable outcomes of 3-day course of adjunctive oral ivermectin for the patients with CHIKV infection was demonstrated

Abstract 2951

Incidence and risk of hospitalised pneumococcal pneumonia among Catalonian adults with distinct underlying medical conditions

Olga Ochoa-Gondar*, Angel Vila-Córcoles¹, Imma Hospital-Guardiola¹, Angel Vila-Rovira², Cinta De Diego¹; Eva Satue¹

¹Primary Health Care, Institut Catala de la Salut, Tarragona, Spain, ²Institut Universitari d’Investigació en Atenció Primària (IDI-AP Jordi Gol), Barcelona, Spain

Abstract third-party references: Supported by grant (FIS-P15/01230)

Background: This study investigated the incidence of pneumococcal pneumonia requiring hospitalisation among middle-aged and older adults with and without specific underlying medical conditions, evaluating the influence of these conditions in the risk of developing pneumonia.

Materials/methods: Population-based prospective cohort study that included 2,025,730 individuals ≥50 years around Catalonia, Spain. The information system for the development of research in primary care of Catalonia (SIDIAP Research Database) was used to establish baseline characteristics of the cohort (vaccination status [PCV13 and/or PPV23], comorbidities and underlying medical conditions). Hospitalisations from pneumococcal pneumonia occurred among cohort members between 01/01/2015-31/12/2016 were collected from hospital discharge codes of 68 reference Catalonian hospitals (FIS-P15/01230). Cox regression was used to estimate the association between baseline conditions and the risk of developing pneumonia.

Results: Cohort members were followed for a total of 3,897,151 person-years, observing 3259 first episodes of hospitalised pneumococcal pneumonia across study period. Incidence rate (per 100,000 person-years) was 83.6 globally (106.1 in men vs 64.7 in women; 34.4 in 50-64 years vs 90.9 in 65-79 years vs 239.8 in aged 80 years or older). Greatest incidence emerged among persons with haematological neoplasia (729.5) followed by immunodeficiency (539.1), severe renal disease (377.1), HIV infection (325.2), chronic pulmonary disease (300.4), immunosuppressive treatment (245.4), chronic heart disease (206.1), chronic liver disease (195.3), solid neoplasia (176.4), alcoholism (165.1) and diabetes mellitus (148.3). In multivariable analyses, apart from increasing age, haematological neoplasia (Hazard Ratio [HR]: 5.65), HIV infection (HR: 4.32), immunodeficiency (HR: 3.48) and chronic pulmonary disease (HR: 2.86) were the conditions most strongly associated with an increasing risk. Pneumococcal vaccination (nor PCV13 neither PPVs23) did not emerge associated with reduced risks.

Conclusions: Old age, immunocompromising conditions and chronic pulmonary diseases are major risk factors for pneumococcal pneumonia in adults. Our data underlines the need for better prevention strategies in these persons.

Abstract 2952

The genetic architecture of tuberculosis susceptibility: comprehensive research synopsis, meta-analysis, and epidemiological evidence

Lin Jiao*, Jiajia Song1, Binwu Ying1

1Sichuan University West China Hospital, Chengdu, China

Background: Hundreds of studies have been conducted to investigate associations between variants and tuberculosis risk so far. But results have been inconclusive. Here we systematically provide a summary of the understanding of the genetic architecture of tuberculosis susceptibility.

Materials/methods: We searched PubMed, Embase and Web of Science to identify genetic association studies of tuberculosis published through July 22, 2019. We conducted meta-analyses for the genetic association on tuberculosis risk. We graded levels of cumulative epidemiological evidence of significant genetic associations using the guidelines proposed by the Human Genome Epidemiology Network and false-positive report probability tests. We performed functional annotations for these variants using data from the Encyclopedia of DNA Elements (ENCODE) Project and other databases.

Results: We identified 634 eligible articles comprising 268737 cases and 841031 controls through screening a total of 22041 citations. Meta-analyses were conducted for 591 genetic variants in 309 genes. We found 37 variants were nominally significantly associated with tuberculosis risk. Cumulative epidemiological evidence for a significant association was graded strong for 10 variants in or near 10 genes which together explained approximately 9.59% of familial relative risk of tuberculosis. Data from the ENCODE and other databases suggested that 8 of these 10 genetic variants with strong evidence might fall within putative functional regions.

Conclusions: Our study summarizes current literature on the genetic architecture of tuberculosis susceptibility and provides useful data for designing future studies to investigate genetic association for tuberculosis risk.

Abstract 2953

Posaconazole dosing and association with therapeutic drug levels in allogeneic cell transplant recipients

Mateja Kraljevic*1, Nina Khanna1, Michael Medinger1, Jakob Passweg1, Yves Chalandon1, Stavroula Masourni Levrat2, Nicolas Mueller1, Urs Schanz1, Christian Van Delden2, Dionysios Neofytos2

1University Hospital of Basel, Basel, Switzerland, 2Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland, 3University Hospital of Zürich, Zürich, Switzerland

Abstract third-party references: Department of Hematology, Bone Marrow transplant Unit, University Hospital of Basel, Basel, Switzerland, Division of Hematology, Bone Marrow transplant Unit, University Hospital of Geneva, Geneva, Switzerland, Department of Medical Oncology and Hematology, Stem Cell Transplant Unit, University Hospital of Zurich, Zurich, Switzerland, Division of Infectious Diseases, University Hospital of Zurich, Zurich, Switzerland, Division of Infectious Diseases, University Hospital of Geneva, Geneva, Switzerland, Division of Infectious Diseases, University Hospital of Basel, Basel, Switzerland

Background: Real-life data on posaconazole (POS) therapeutic drug monitoring (TDM) in allogeneic hematopoietic cell transplant recipients (allo-HCTr) are limited.

Materials/methods: All allo-HCTr participating in the Swiss Transplant Cohort Study (STCS) who received POS as prophylaxis and/or treatment between 1.1.2016 and 31.12.2018 were identified through hospital-pharmacy and the STCS databases at the three allo-HCT-centers in Switzerland. Allo-HCT, POS-administration, POS-TDM, and other laboratory variables were recorded. Herein, we present preliminary data on POS-TDM distribution from 2 allo-HCT-centers.

Results: A total of 1554 POS-TDM-levels were recorded in 230 patients in 2 allo-HCT-centers: 1066 and 488 POS-TDM-levels were performed in 157 and 73 patients, who received POS-prophylaxis and POS-treatment, respectively (Figure 1a-b). POS was administered for 120 days [mean, range: 2-1218]; 117 and 137 days in the POS-prophylaxis and POS-treatment groups, respectively. The mean POS-TDM-level was 1.47mg/L [range: 0-8.28]: 1.4 and 1.65mg/L in the POS-prophylaxis and POS-treatment groups, respectively (P-value<0.001; Figure 1c). POS-TDM-levels on day(D)7±3, 14±3, 28±3, 42±3, and 84±3 were available for 170, 131, 111, 82, and 40 patients, respectively. The mean POS-TDM-levels by D7±3, 14±3, 28±3, 42±3, and 84±3 were 1.03, 1.3, 1.55, 1.64, and 1.76mg/L, respectively (Figure 1d). Amongst 157 patients who received POS-prophylaxis, 214/1066 (20.1%) of POS-TDM-levels were <0.7mg/L. The mean POS-TDM-levels on D7±3, 14±3, 28±3, 42±3, and 84±3 were 1.02, 1.18, 1.57, 1.62, and 1.76mg/L, respectively (Figure 1e). A total of 43/118 (36.4%) and 11/74 (14.5%) patients with POS-TDM-levels available by D7±3 and D28±3, respectively, had POS-TDM-level<0.7mg/L. In multivariable analyses, allo-HCT at center-A was protective of POS-TDM-level <0.7mg/L by D7±3 (odds ratio, OR:0.19, P-value:0.001). Amongst 73 patients who received POS-treatment, 149/488 (30.5%) of POS-TDM-levels were <1.0mg/L. The mean POS-TDM-levels on D7±3, 14±3, 28±3, 42±3, and 84±3 were 1.06, 1.45, 1.51, 1.69, and 1.74mg/L, respectively (Figure 1f). A total of 20/46 (43.5%) and 11/35 (31.4%) patients with POS-TDM-levels available by D7±3 and D28±3, respectively, had a POS-TDM-level<1.0mg/L. There were no variables associated with POS-TDM-level<1.0mg/L by D7±3.

Conclusions: Large variability in POS-TDM-levels is observed in allo-HCTr, with subtherapeutic POS-TDM-levels observed in up to 1/3 of patients and incremental changes attained with longer administration courses. Local practices are important determinants of POS-TDM-levels.

*Clostridium butyricum* S88 modifies lipid metabolism in gut microbiome and colon tissue to protect antibiotic-induced colon epithelial damages

Tadashi Ariyoshi※1,2, Mao Hagihara1, Yasutoshi Kuroki1,2, Seiya Higashi1, Kentaro Oka1,2, Motomichi Takahashi1,2, Yuka Yamagishi1, Hiroshige Mikamo1

1Aichi Medical University, Nagakute, Japan, 2Miyarisan Pharmaceutical Co., Ltd, Saitama, Japan

**Background:** *Clostridium butyricum* MIYAIRI S88 (CBM 588) is a life biotherapeutic product that has been used for anti-diarrheal medicine in Japan. In our previous study, we admitted that antibiotics caused gut dysbiosis and colon epithelial damage. Then, CBM 588 showed the contribution to modify the gut microbiome and reduce the colon epithelial damage. However, the mechanisms of CBM 588 on the protection from the gut epithelial damage has not been cleared.

**Materials/methods:** In vivo study, mice were divided into four groups and CBM 588, clindamycin (CLDM), and normal saline (control) was orally administered for 4 days (only CLDM, only CBM 588, CBM 588 + CLDM, water). After 4 days administration, colon tissues were removed for analysis lipid metabolites and metabolic enzyme expressions. Lipid metabolites were measured with LC-MS/MS.

**Results:** In lipid metabolome analysis, eicosanoids (EPA, stearic acid, linoleic acid) and some fatty acids (oleic acid, palmitoleic acid) were enhanced in only CLDM administration group, compared with other groups. On the other hand, in CBM 588 + CLDM administration group showed the up-regulation of flavonoids (genistein, daidzein) than that of CLDM group (Figure).

**Conclusions:** CLDM administration increased some eicosanoids and fatty acids productions related to inflammation. However, CBM 588 protected from the up-regulation of these lipid metabolites. Additionally, CBM 588 increased flavonoids (genistein, daidzein) have anti-oxidant stress effects. Therefore, our results suggest that CBM 588 has impacts to reduce oxidative stress and anti-inflammation in gut epithelial cells. These results support the facts that CBM 588 has protective effects from colon gut epithelial damage due to antibiotics.

Abstract 2958

Use and impact of aminoglycoside empirical combination therapy in intensive care unit patients with ESBL-producing Enterobacteriaceae bloodstream infections: a multi-centre retrospective observational cohort

Lucie Benetazzo1, Pierre-Yves Delannoy1, Marion Houard2, Fabien Lambiotte3, Anne Vachée4, Christian Batt5, Nicolas Van Grunderbeeck6, Saad Nseir2, Olivier Robineau1, Agnes Meybeck*1

1CH Dron, Tourcoing, France, 2CHRU Lille, Lille, France, 3CH Valenciennes, Valenciennes, France, 4CH Roubaix, Roubaix, France, 5CH Dunkerque, Dunkerque, France, 6CH Lens, Lens, France

Background: Empirical prescription of aminoglycoside (AG) combination therapy may be of particular interest in case of septic shock due to extended-spectrum beta-lactamase producing enterobacteriaceae (ESBL-E) bloodstream infections (BSI), because of synergistic bactericidal activity, and antimicrobial spectrum broadening. We conducted a retrospective study to evaluate use and impact of initial prescription of AG in ICU patients with ESBL-E BSI.

Materials/methods: Between January 2011 and September 2017, patients treated for ESBL-E BSI in the ICU of 6 French hospitals were included in a retrospective observational cohort study. The primary endpoint was mortality at day 30. Secondary endpoints were empirical antibiotic therapy adequacy and renal failure occurrence.

Results: Three hundred and seven patients were included. Among them, 169 (55%) received an AG as initial treatment. Patients who were treated with AG were more likely to receive immunosuppressive therapy (15% vs 5%, p=0.01) and to show septic shock (57% vs 43%, p=0.02) at BSI onset. ESBL-E isolates were sensitive to at least one AG in 55% of cases. Death rate at day 30 was 40% (43% with AG vs 39% without AG, p=0.55). By multivariate analysis, factors independently associated with death were age≥70 years (OR: 2.67; 95%CI: 1.09-6.54, p=0.03), history of transplantation (OR 5.2; 95% CI: 1.4-19.35, p=0.01), hospital acquired infection (OR 8.67; 95% CI: 1.74-43.08, p=0.008), need for vasoactive drugs >48h after BSI onset (OR 3.61; 95% CI: 1.62-8.02, p = 0.001), occurrence of acute respiratory distress syndrome (OR 2.42; 95% CI: 1.14-5.16, p=0.02) or acute renal failure (OR 2.49; 95%CI: 1.14-5.47, p = 0.02). Rate of renal impairment occurrence was similar in patients treated with or without AG (21% vs 24%, p=0.59). The adequacy rate of empirical antibiotic therapy was higher in the AG group (91.7% vs 77%, p = 0.001).

Conclusions: In our cohort of ICU patients with ESBL-PE BSI, prescriptions of AG as empirical combination therapy represented more than one half of antibiotic therapies. Our study showed no impact of AG prescription on 30 days mortality rate, even if appropriateness of initial antibiotherapy increased in case of AG prescription.

Triangulating the molecular epidemiology of carbapenem-resistant Enterobacteriales in humans, food-producing animals and the environment in a One Health context

Yogandree Ramsamy¹, Koleka Mlisana², Daniel Gyamfi Amoako³, Mushal Allam⁴, Arshad Ismail⁵, Abia Akebe Luther King⁶, Ravesh Singh⁷, Sabiha Y. Essack⁸

¹University of KwaZulu-Natal, National Health Laboratory Services, Antimicrobial Research Unit, Durban, South Africa, ²National Health Laboratory Services - Johannesburg, University of KwaZulu-Natal - Durban, Johannesburg, South Africa, ³University of KwaZulu-Natal, Infection Genomics and Applied Bioinformatics Division - Antimicrobial Research Unit, Durban, South Africa, ⁴Sequencing Core Facility, National Institute of Communicable Diseases, National Health Laboratory Services, Johannesburg, South Africa, ⁵Sequencing Core Facility, National Institute of Communicable Diseases, National Health Laboratory Services, Johannesburg, South Africa, ⁶Antimicrobial Research Unit, University of KwaZulu-Natal, Durban, South Africa, ⁷University of KwaZulu-Natal, National Health Laboratory Services, Durban, South Africa, ⁸Antimicrobial Research Unit, University of KwaZulu-Natal, Durban, South Africa

Background: Antimicrobial resistance (AMR) is a consequence of selection pressure from indiscriminate antibiotic use in humans, animals and the environmental, requiring a One Health approach towards its understanding and containment. This study aims: 1) to determine carriage and colonization of carbapenem resistance Enterobacteriaceae (CRE) in humans, livestock animals (pigs), and environmental sources within the same geographical area of UMgungundlovu district, KwaZulu-Natal, South Africa. 2) to comprehensively delineate the molecular epidemiology, nature and extent of AMR specifically in CRE in the “One Health” context to inform evidence-based strategies for its monitoring, prevention and containment.

Materials/methods: This study was approved by the Biomedical Research Ethics Committee[BE599/16], the Animal Research Ethics Committee[AREC/P9/018D] University of KwaZulu-Natal and Department of Agriculture, Forestry and Fisheries, Republic of South Africa[Ref12/11/15]. Screening rectal swabs were obtained from pigs and humans with water samples collected from a wastewater treatment plant. ChromID CARBA chromogenic agar [bioMerieux] was used to isolate CRE from all samples. Following microbial identification and antibiotic susceptibility tests, isolates were subjected to whole genome sequencing (WGS).

Results: Of 587 rectal swab samples screened for CRE, 230 (39.1%) were from humans, 345 (58.7%) were from pigs with 12 (2%) water samples. A total of 19/587 (3.2%) samples i.e. 15 from humans and 4 from the environment yielded CRE. No CRE were isolated from the pig samples. The commonest CRE identified was K. pneumoniae 9/19 (47%), followed by Enterobacter hormaechei 6/19 (32%), K. quasi-pneumoniae 2/19 (11%), a novel ST498 Citrobacter freundii 1/19 (5%) and Serratia marcescens 1/19 (5%). Eighteen of the 19 isolates were extensively drug resistant (XDR). K. pneumoniae (ST17) and Enterobacter hormaechei (ST90) were the predominant CRE strains isolated from both humans and the environment. The blaOXA 48, blaNDM-1 and blaGES-5 bearing plasmids mediating carbapenem resistance were found in multiple species/clones from both sectors. The isolates also harboured other mobile genetic elements [insertion sequences, integrons and transposons] propagating the spread of AMR across sectors.

Conclusions: This One Health Study highlights common CRE with associated resistome isolated from humans and the environment, highlighting the potential fluidity of resistome and mobilome propagation.

Abstract 2960

The comparison of the rapid blood identification results within/after 8 hours from positive signal of blood culture bottle

Hyun Jin Kim*, Kyu Tae Choi1, Mosae Koo1, Jong Wan Kim2, Sun Hoe Koo3

1Chungnam National University Hospital, Daejeon, South Korea, 2Dankook University Hospital, Cheonan, South Korea

Background: The BioFire Filmarray Blood Culture Identification Panel (BCID) is a test for the rapid identification of major pathogen/organism groups that are main causes of sepsis and for detection of three antibiotic resistance genes by using a multiplexed PCR assay. The accuracy for the BCID panel is assessed only for tests within 8 hours of positive blood cultures. However, in practical situations, it is often necessary to perform BCID tests after 8 hours of positive blood culture. Therefore, we conducted the evaluation of the BCID after 8 hours of positive blood culture, as compared to the tests within 8 hours of positive blood culture.

Materials/methods: We tested BCID panel on 141 samples (67 within 8 hours, 74 after 8 hours from positive signal of blood culture bottle) from patients hospitalized in a tertiary hospital in Korea. The bacterial identification and antimicrobial sensitivity of all samples were confirmed by VITEK2 as reference method.

Results: Fifty-eight (within 8 hours) and 63 (after 8 hours) samples were analyzed, except for samples with bacteria which were not in BCID panel. The agreement of results of BCID with VITEK2; within 8 hours was 94.8% (55/58), after 8 hours was 92.1% (58/63), respectively. The discrepancies within 8 hours were 2 misidentification and 1 false negative for mecA gene. On the other hands, the discrepancies after 8 hours were 3 false negative for bacteria, 1 misidentification, and 1 false positive for mecA gene.

Conclusions: In this study, the BioFire Filmarray BCID test results performed after 8 hours of positive blood culture showed good performance compared to those performed within 8 hours. If necessary, BCID test after 8 hours may be helpful in the diagnosis and treatment of bacteremia patient.

Abstract 2961

Serum IFI27 mRNA as a novel host response biomarker of monitoring the influenza A virus infection
Wei Dong*1, Demin Yu1, Dong-Hua Zhang1, Guo-Chao Shi2, Xinxin Zhang1,3

1Ruijin Hospital, Shanghai Jiaotong University, School of Medicine, Department of Infectious and Respiratory Diseases, Institute of Infectious and Respiratory Diseases, Research Laboratory of Clinical Virology, Shanghai, China, 2Ruijin Hospital, Shanghai Jiaotong University, School of Medicine, Department of Respiratory Diseases, Shanghai, China, 3Ruijin Hospital North, Shanghai Jiaotong University School of Medicine, Clinical Research Center, Shanghai, China

Background: Biomarkers for detection of influenza A virus (IAV) infection are limited and can hardly monitor the activity for IAV infection. Previous research had found that the IFI27 mRNA in the whole blood samples could be regarded as a single-gene biomarker discriminating IAV and bacterial infection. This study aims to further investigate serum IFI27 mRNA as a novel host response biomarker for monitoring the severity of IAV infection and the efficacy of therapy.

Materials/methods: 261 patients were included with well-defined phenotypes (influenza infection, bacterial infection and respiratory virus infection without IAV) and 100 healthy controls. Serum IFI27 mRNA was analyzed in all participants and in vitro and in vivo experiments were performed to validate this biomarker.

Results: Serum IFI27 mRNA expression in influenza infection patients was significantly higher than other infected patients and controls. It displayed 81.8% and 77% diagnostic accuracy (AUC) in discriminating influenza infections from bacterial infections and other respiratory virus infections without IAV. Among the IAV infected patients, the serum IFI27 mRNA peak levels of severe IAV infections were significantly higher than mild and moderate infections. Blood samples were collected at five time-points from 91 IAV infected patients after being hospitalized (D1, D3, D5, D7 and Discharged) to observe IFI27 mRNA expression trend during IAV infection treatment. Serum IFI27 mRNA expression was consistent with the temperature and CRP trend, and for most patients it had returned to a very low level when they recovered. The analysis for serum extracellular vesicles showed that most serum IFI27 mRNA might exist in serum exosomes. In vitro studies confirmed that both endocellular and extracellular IFI27 mRNA in A549 cells were up-regulated and consistent with the increase of influenza virus RNA. In mice infection model, IFI27 mRNA in serum and lung was up-regulated according with influenza virus in lung tissues and the serum IFI27 mRNA declined significantly when the influenza RNA replication was ceased.

Conclusions: Serum IFI27 mRNA may be a novel potential host response biomarker which could not only distinguish the influenza infection from bacterial or other respiratory virus but also facilitate the monitoring of IAV infection and the therapeutic efficacy.

Comparison of clinical manifestations, antimicrobial susceptibility patterns, and carbapenem resistance determinants between *Acinetobacter seifertii* and *Acinetobacter nosocomialis* isolated in Taiwan

Yi-Tzu Lee*, Ya-Sung Yang, Jun-Ren Sun, Li-Hua Li

1Department of Emergency Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, 2Division of Infectious Diseases and Tropical Medicine, Department of Internal Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan, 3Institute of Preventive Medicine, National Defense Medical Center, Taipei, Taiwan, 4Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

**Background:** *Acinetobacter seifertii*, a new member of the *Acinetobacter calcoaceticus-Acinetobacter baumannii* (Acb) complex, has emerged as a cause of severe infections in humans. Using reference molecular methods, *A. seifertii* is most closely related to *Acinetobacter nosocomialis*, which is the major pathogen of Acb complex. We aimed to explore the clinical and molecular differences between these two species.

**Materials/methods:** This retrospective study enrolled 83 adults with *A. seifertii* bloodstream infection (BSI) and 402 with *A. nosocomialis* BSI at 4 medical centers over a 9-year period. The species identification was confirmed by MALDI-TOF MS and rpoB sequencing. Clinical information, antimicrobial susceptibility, and carbapenem resistance determinants were analyzed.

**Results:** There were no significant differences in underlying diseases and mortality between patients with *A. seifertii* BSI and those with *A. nosocomialis* BSI. Compared to patients with *A. nosocomialis* BSI, those with *A. seifertii* BSI were more likely to have acquired the isolate in the intensive care unit (ICU), and have recent ICU stay, central venous catheter and ventilator use at the onset of bacteremia, and pneumonia as the source of BSI. Compared with *A. nosocomialis*, *A. seifertii* was significantly less susceptible to colistin, amikacin, gentamicin, ceftazidime, cefepime and piperacillin/tazobactam, and more susceptible to imipenem, meropenem, ciprofloxacin and tigecycline. Carbepenem non-susceptibility was observed in 16.3% *A. seifertii* isolates and 34.6% *A. nosocomialis* isolates. Plasmid-borne ISAba1-bla<sub>OXA-51</sub>-like and IS1006-ΔISAba3-bla<sub>OXA-58</sub>-like contributed to carbapenem resistance in most *A. seifertii* and *A. nosocomialis* isolates, respectively.

**Conclusions:** Patients with *A. seifertii* BSI and those with *A. nosocomialis* BSI had similar underlying diseases and mortality rates. *A. seifertii* was significantly less susceptible to colistin, amikacin, gentamicin, ceftazidime, cefepime and piperacillin/tazobactam, and more susceptible to imipenem, meropenem, ciprofloxacin and tigecycline than *A. nosocomialis*. The major carbapenem resistance determinants of *A. seifertii* and *A. nosocomialis* were plasmid-borne ISAba1-bla<sub>OXA-51</sub>-like and IS1006-ΔISAba3-bla<sub>OXA-58</sub>-like, respectively.

Abstract 2965

**Endemicity of carbapenemase-producing Enterobacteriaceae in Hong Kong**

Shuk-Ching Wong*, Vincent Cheng

1Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong

**Background:** To study the epidemiology of carbapenemase-producing Enterobacteriaceae (CPE) in a healthcare region in Hong Kong.

**Materials/methods:** We adopted multi-pronged screening strategy for early recognition of gastrointestinal colonization of CPE in our healthcare region with 3,200 beds. Patients were prospectively screened by collection of fecal specimens upon admission (targeted screening) and during hospitalization (opportunistic screening, safety net screening, and extensive contact tracing). Newly diagnosed CPE patients were put on contact precautions with cohort nursing. Specimens were collected and subjected to broth enrichment culture and multiplex polymerase chain reaction. Newly acquisition of nosocomial CPE was assessed per 1,000 CPE colonization-days.

**Results:** From July 1, 2011 through June 30, 2019, 193,703 fecal specimens collected from 77,195 patients, 3,287 specimens (1.70%) from 1,501 patients (1.36%) had CPE. The number and prevalence (per 100,000 patient-days) of CPE increased from 1 (0.13) in 2011 to 315 (75.22) in the first 6 months of 2019 (P<.001). In the acute care setting, nosocomial CPE cases were first observed in 2014. With an increasing trend of CPE colonization day from 878 days (2014) to 8215 (January to June 2019), total number of nosocomial acquisition of CPE per 100,000 CPE colonization day reduced from 1253 (2014) to 621 (January to June 2019) with enforcement of staff and patients' hand hygiene, and environment disinfection. Community acquired CPE in patients without prior hospitalization in the past 2 years increased from 0.67 (2014) to 22.73 (January to June 2019) per 100,000 admission (P<0.01), which constituted 3.3% (35/1051) of newly diagnosed CPE case. New Delhi metallobeta-lactamase (NDM) constituted 73.2% (769/1051) carbapenemase, followed by OXA (20.6%), KPC (5.2%), and others (1.1%).

**Conclusions:** Although proactive infection control measures mitigated the risk of nosocomial transmission of CPE in the hospitals, community acquisition of CPE is increasingly reported. Epidemiological analysis to understand risk factors for community acquisition of CPE is urgently warranted.

Abstract 2972

Performance evaluation of the STANDARD F Influenza A/B FIA for detection of influenza A/B virus infection

Kyu Tae Choi*, Hyun Jin Kim¹, Mosae Koo¹, Jong Wan Kim², Sun Hoe Koo¹

¹Chungnam National University Hospital, Daejeon, South Korea, ²Dankook University Hospital, Cheonan, South Korea

Background: Rapid diagnosis of influenza is important for early treatment and infection control. PCR test, currently used as a confirmatory test for influenza infection, has a disadvantage in that the method is complicated and it takes long time to report the results. In the case of conventional rapid antigen test, the result can be confirmed in a short time, but the sensitivity is low. We evaluated the performance of STANDARD F Influenza A/B FIA test, which uses fluorescence immunochromatography for improving sensitivity.

Materials/methods: The evaluation was performed using 269 patient samples that were referred for examination due to suspicion of influenza infection. Performance of the STANDARD F Influenza A/B FIA was compared to that of the SD BIOLINE Influenza Ag test. A real-time reverse transcriptase-polymerase chain reaction assay (Allplex Respiratory Panel 1) was used as reference standards.

Results: In detecting influenza A virus, STANDARD F Influenza A/B FIA showed sensitivity of 73.3% and specificity of 96%. SD BIOLINE Influenza Ag test showed 56.7% sensitivity and 100% specificity. In detection of influenza B virus, STANDARD F Influenza A/B FIA and SD BIOLINE Influenza Ag test showed 100% and 93.3% sensitivity, respectively. Specificity for influenza B virus was 100% in both tests.

Conclusions: The STANDARD F Influenza A/B FIA test was more sensitive than conventional rapid antigen test to detect influenza A and B viruses. It might be useful for rapid diagnosis of influenza.

Genetic characterisation of co-produced KPC-3, CTX-M-15 and SHV-1 β-lactamases in carbapenem-resistant Klebsiella pneumonia ST512 causing bloodstream infections in an endemic tertiary hospital

Alessandra Piccirilli, Mariagrazia Perilli, Laura Maccacaro, Alda Bazaj, Laura Naso, Valentina Piccirilli, Bernardetta Segatore, Gianfranco Amicosante, Giuseppe Cornaglia, Giuliana Lo Cascio

1University of L’Aquila, L’Aquila, Italy, 2Azienda Ospedaliera Universitaria Integrata Verona, Microbiology Unit, Verona, Italy, 3University of Verona, Verona, Italy

Background: Carbapenem-resistant (CR) Klebsiella pneumoniae (KPN) is designated by the CDC (Centers for Disease Control and Prevention) as one of the microorganisms that poses an urgent threat to public health worldwide. As an opportunistic pathogen, KPN is responsible of urinary, respiratory and bloodstream infections (BSI) in nosocomial settings and community. The most common carbapenemase found in KPN is KPC enzyme but KPN is also considered a reservoir of classes B and D carbapenemases and extended-spectrum β-lactamases (ESBLs) such as CTX-M-enzymes. Aim of the study was to investigate the genetic variants and genetic context of ESBLs and carbapenemases in KPN isolates causing BSI in an endemic tertiary hospital.

Materials/methods: Thirty-three KPN were isolated from blood culture samples of hospitalized patients in a tertiary hospital. Antimicrobial susceptibilities of these strains were evaluated towards clinically relevant β-lactams and other antibiotics using Vitek2 instrument (bioMérieux, Marcyl-Etoile, France) and confirmed with Etest (bioMérieux). The results were interpreted according to the EUCAST breakpoints as updated in 2016 and later version (http://www.eucast.org). Genotyping was performed by Multilocus Sequence Typing (MLST). Identification of β-lactamase genes and mobile genetic elements were performed by PCR and sequencing.

Results: All KPN strains were showed MIC values for meropenem, ertapenem and imipenem higher than 64 μg/mL. MLST analysis ascertained that the K. pneumoniae isolates could be included in sequence type ST512. The blaKPC-3 and blaCTX-M-15 were found in a large plasmid of more than 100 Kb. The analysis of genetic context of these bla genes demonstrated that the blaKPC-3 gene was found in Tn4401a transposon with the trpR, trpA, ISKpn6 and ISKpn7 mobile elements and blaCTX-M-15 was found downstream the insertion sequence ISEcp1. A class 1 integron carrying aadA2 gene cassette that encode for an aminoglycoside adenyltransferase was identified.

Conclusions: Bloodstream infection causes significant patient morbidity and mortality and KPN is the second Gram-negative bacteria, after E. coli, involved in BSI worldwide. Carbapenem resistant KPN are endemic in many tertiary hospitals. Genetic characterization of carbapenemases permit to monitor also other molecular antibiotic resistance gene responsible of the extensively drug resistance of this dangerous epidemic hospital plague.

Molecular epidemiology and spatiotemporal analysis of carbapenem-resistant Acinetobacter baumannii in networks hospital in southern Thailand

Sarunyou Chusri*, Thanapon Hortivakul1, Kamonnut Singkhamanan1, Arnon Chukamnerd1, Kachornsak Silpapojakul1

1Faculty of Medicine, Prince of Songkla University, Kho Hong, Thailand

Background: Carbapenem-resistant Acinetobacter baumannii (CRAB) is a major hospital-acquired pathogen in Thailand. The nature of its transmission is poorly understood. Here, we investigated the genotypic and spatiotemporal pattern of CRAB infection at network hospitals in southern Thailand.

Materials/methods: We prospectively collected clinical data and clinical specimens of patients infected with CRAB at 9 networks hospitals (one university hospital, 3 tertiary care hospitals and 5 provincial hospitals) in southern Thailand between October 2018 and September 2019. We also did active systematic surveillance of CRAB from throat swab, rectal swab, endotracheal tube aspiration and gastric content. In addition, we collected environmental cultures in each hospital. Each CRAB was identified at the genomospecies level including carbapenemase genes. A spatiotemporal analysis was performed by admission wards, hospitals, time of infection and pulsed-field gel electrophoresis (PFGE) groups of CRAB.

Results: Fifty PFGE groups were identified among the 1,205 CRAB infections. All CRAB isolates were assigned to International Clonal Lineage II. Gene blaOXA-23 was the most prevalent carbapenemase gene. Outbreaks were observed mainly in university and 3 tertiary hospitals. The association between PFGE group and hospitals was significant. Spatiotemporal analysis identified 38 clusters of single PFGE group infections. Twenty clusters involved multiple hospitals simultaneously. Fifteen clusters involved only isolates from patients with CRAB infection while up to twenty-five cluster involved isolates from surveillance (colonization). Ten clusters involved isolates collected from hospital environment. Previous use of carbapenems is strongly associated with CRAB infection and colonization.

Conclusions: CRAB transmitted both within hospitals and between network hospitals. Better understanding and control of the transmission of CRAB are needed.

Abstract 2981

Ultrasound-guided local administration of personalised cocktail of bacteriophages followed by suppressive antibiotherapy as salvage therapy in patients with relapsing total femur prosthetic joint infection (PJI)

Tristan Ferry*1;2, Camille Kolenda1;2, Fabien Craighero1, Sebastien Lustig1, Stanislas Gunst1, Cindy Fevre1, Charlotte Petitjean1, Elise Fiaux4, Manuel Etienne1, Christian Chidiac1, Leboucher Gilles1, Frédéric Laurent1;2

1Hospices Civils De Lyon - Hcl, Lyon, France, 2Claude Bernard University Lyon 1, Centre International de Référence en Infectiologie, Villeurbanne, France, 3Pherecydes Pharma, Romainville, France, 4Hospital Center University De Rouen, Rouen, France

Abstract third-party references: Lyon BJI study group

Background: Lytic bacteriophages are of interest to treat patients with PJI based on their synergistic activity with antibiotics on bacteria in biofilm. In patients with relapsing total femur PJI, disarticulation is often unfortunately the only final option. In such a population, suppressive antimicrobial therapy is sometimes used after performing an open “DAIR” procedure, but the skin closure may be not possible and the success rate of this conservative approach is so low in such patients.

Materials/methods: In our reference regional center “CRIOAc Lyon” ultrasound-guided (panel A) local administration of personalized cocktail of bacteriophages of anti-S. aureus or anti-P. aeruginosa bacteriophages followed by suppressive antibiotherapy is proposed for relapsing total femur PJI with no therapeutic option or therapeutic dead-end (panel B, C). Each case was discussed with the French health authority. Bacteriophages were produced following the Good Manufacturing Practice (GMP) guidelines and were selected by Pherecydes, according to their activity (panel D). Hospital pharmacist mixed each phage (1 ml of 1x10^10 PFU/ml) extemporaneously as “magistral” preparation (final dilution 1x10^8 PFU/mL).

Results: Two patients (55 and 84 yo) experiencing a relapsing S. aureus or P. aeruginosa total femur PJI following previous debridement and implant retention procedure, were treated with personalized cocktails. One patient had soft-tissue defect with suppurative discharge (panel C). At the time of injection, both patients had already received targeted antibiotics, cefoxitin (for S. aureus) and ceftazidime (for P. aeruginosa), respectively. After the phage injection, antibiotics were switched to daptomycin-levofloxacin followed by doxycycline for the first one, and ceftazidime was maintained for the second. After a follow-up of 8 months, clinical signs of infection were improved, as systemic biologic markers of infection, in the first patient (panel E). Superinfection with C. albicans was unfortunately discovered at the time of phage injection, with C. albicans persistence and unfavorable outcome in the second one.

Conclusions: Ultrasound-guided local administration of personalized cocktail of GMP bacteriophages followed by suppressive antibiotherapy in patients with relapsing total femur PJI has the potential to be used as salvage therapy to control the infection and avoid disarticulation. Dramatic superinfection could be diagnosed at the time of phage administration.

Severe candidaemia in a tertiary care hospital

María Paz Vaquer-Herrero*, Silvio Ragozzino, Maria Siller Ruiz, Miguel Marcos, Hugo Guillermo Ternavasio De La Vega

Salamanca, Salamanca, Spain

Background: We describe the main epidemiologic, clinical, microbiological characteristics and mortality of a cohort of severe candidaemia (SC) in University Hospital of Salamanca.

Materials/methods: All cases of candidemia in adults detected at our Hospital were prospectively registered from 2010 to 2016. We analyzed the differential characteristics according to the severity of presentation. SC was defined as cardiovascular, respiratory, renal, neurologic or hematological failure. Continuous variables were compared using the Student’s T test. Categorical variables were compared using X^2-test or Fisher’s test.

Results: Among the 233 episodes of candidemia included, 98 were SC. The group of patients with SC was significantly older (72 vs 68, P<0.01), had more alcohol abuse related disorder (8.2% vs 1.5%, P=0.02) and chronic kidney disease (10.2% vs 3.0%, P=0.02). Patients with SC had significantly less hematologic neoplasm (12.2% vs 26.7%, P<0.01), bone marrow transplantation (4.1% vs 14.1%, P=0.01), solid organ neoplasm (35.7% vs 52.6%, P=0.01) and chemotherapy (12.2% vs 29.6%, P=0.01). Patients with hematologic neoplasm had more frequently a vascular catheter focus (39.6% vs 31.6%, P=0.29) and C. parapsilosis infection (52.1% vs 39.0%, P=0.10). Patients with SC had more previous intensive care unit stay (31.6% vs 8.9%, P<0.01), blood products transfusion (53.6% vs 39.3%, P=0.03) and presence of urinary catheter (67.3% vs 34.1%, P=0.01). C. albicans was more frequent in the SC group (46.9% vs 32.6%, P=0.03) and C. parapsilosis was less frequent (31.6% vs 49.6%, P=0.01). Urinary tract focus was more frequent in SC patients (11.2% vs 3.7%, P=0.03) and vascular catheter focus was less frequent (28.6% vs 37.0, P=0.18). Patients with SC receipt more appropriate empirical antifungal treatment (30.6% vs 19.3%, P=0.04). Candidemia-related mortality at 30 days was more frequent in patients with SC (37.8% vs 9.6%, P<0.01). C. albicans and C. parapsilosis related mortality was 46.0% and 28%, respectively.

Conclusions: Remarkably, we found that patients with SC had less frequently hematologic neoplasm, chemotherapy and bone marrow transplantation. This could be explained because of a higher frequency of catheter associated candidemia and C. parapsilosis infection in patients with these conditions both factors widely known to be related with less severe disease and mortality.

Abstract 2985

**Short-term peripheral venous catheter-related bloodstream infections in French healthcare settings, 2019**

Marie Decalonne¹, Rémi Gimenes¹, Florent Goube¹, Agnès Petiteau¹, Anne Berger-Carbonne², Stéphane Le Vu², Nathalie Laure Van Der Mee-Marquet*¹

¹CHRU Hôpitaux De Tours, Hôpital Bretonneau, Tours, France, ²Agence santé Publique France, Saint-Maurice, France

Abstract third-party references: SPIADI network

**Background:** Widely used in healthcare settings, short-term peripheral venous catheters (PVCs) can be responsible for potentially severe bloodstream infections (pvcRBSI), especially when caused by *S.aureus*, in relation to the possible severe complications associated with *S.aureus*-BSIs. pvcRBSI- and *S.aureus*-pvcRBSI-incidence rates are scarce. Through a large French hospital network we aimed at quantifying pvcRBSI incidence and associated factors.

**Materials/methods:** A nation-wide 3-month survey of central and peripheral venous catheter RBSIs [January-April 2019] in ICU and non-ICU settings was conducted by the SPIADI [Surveillance and Prevention of Invasive Devices Associated Infections] network, using a unit-based protocol close to ECDC-HAI-Net-ICU protocol 1.02. For all nosocomial BSIs in SPIADI network, patient age and sex, place of acquisition, portal of entry, and for catheter RBSI, insertion site and time between insertion and first signs of BSI were collected. BSI-incidence rates are provided per 1000 patient-days (PD).

**Results:**

- 1001 participating hospitals (including 64% of the 529 French tertiary-hospitals, 54% of the 570 acute-care clinics, 89% of the 18 oncology specialized-hospitals), covering 179477 beds (including 60% of the 6313 French ICU-beds), 13390393 patient-days (PD) and 701277 dialysis-sessions.
- Of 9381 nosocomial BSIs, 31% were Catheter_RBSIs, and of these 13% were pvcRBSIs recorded in medical wards (73%), surgical wards (17%), ICUs (4%), and other wards (6%).
- pvcRBSI incidence ranged between 0 and 1.11/1000PD, according to hospital-type and patient-category.
- pvcRBSIs were mostly associated with *S.aureus* (52%) of which 11% were MRSA, *Enterobacteriaceae* (21%) and CoNS (15%);
- the time between PVC-insertion and the first signs of BSI was >7 days in 22% of the pvcRBSIs, and 20% of the *S.aureus*-pvcRBSIs.

**Conclusions:** The pvcRBSIs remain scarce events. However, as *S.aureus*-BSI is associated with possible severe complications, the preponderance of *S.aureus* responsible for pvcRBSI is worrying. The frequent >7 days-lapse of time between PVC insertion and first signs of pvcRBSIs suggests substantial long-term use of PVCs. In line with the current guidelines, the local infection control teams should promote an appropriate length of PVC use: PVC should be removed as soon as it is no longer required. Our findings provide multiple opportunities for improvement, and allows defining local observation of catheter insertion and use as a SPIADI-network priority for 2020.

**Presenter email address:** n.vandermee@chu-tours.fr
Detection and antibiogram of *Escherichia coli* O157 from *Oreochromis niloticus* (Tilapia) Sold in Ibadan, Nigeria

Seto Ogunleye*, Olufemi Adedeji†, Olabisi Ishola‡, Olajemis Ogunnla†

†University Of Ibadan Faculty of Veterinary Medicine, Ibadan, Nigeria

**Background:** *Escherichia coli* - (*E. coli*) are classified as part of non-indigenous bacteria of fish. Most *E. coli* strains are non-pathogenic, however few pathogenic *E. coli* varieties that produce toxins and other virulence factors that enable them to invade and damage host cells are known. They play roles in fish spoilage and causing humans' diseases - (food poisoning, gastroenteritis, septic shock, meningitis, and urinary tract infections). *E. coli-O157* is a pathogenic strain attributed to estimate of 3,600 human hospitalization the in US. Presence of *E. coli-O157* in food products especially, fish and fish products indicates unhygienic aquatic environment and/or post-harvest handling procedures. *E. coli-O157* isolation from food materials, antimicrobial resistance and Multi-Drug Resistance -(MDR) patterns are of global-public-health concerns. This study, therefore, investigated prevalence and antibiogram of *E. coli-O157* from *Oreochromis niloticus*-(O. niloticus) sold in Ibadan.

**Materials/methods:** A total number of 156 samples consisting of gills-(n=52), intestines-(n=52) and skins-(n=52) were collected from 52 *O. niloticus* from Egbeda, Ido, Ibadan North-East and Ibadan North-West for bacteriological analysis. *E. coli-O157* isolation and identification were performed according to the European Union Reference Laboratory standards (EU, 2017). Antibiogram was performed with agar disk diffusion method and interpreted with Clinical and Laboratory Standards Institute-(CLSI) 2017 standard.

**Results:** Overall *E. coli-O157* prevalence of 62.5% was obtained from *O. niloticus* in this study. The prevalence comprises of 62.5%, 37.5% and 87.5% for Gill, Intestine, and Skin, respectively. Isolates exhibited resistance patterns comprising:- 100.0%-(Ceftazidime-CPZ, Cefuroxime-CRX and Meropenem-MEM), 91.7%-(Cefotaxime-CTX), 83.3%-(Tetracycline-TET), 41.5%-(Cotrimoxazole-COT), 75%-(Ceftriaxone-CTR), 16.7%-(Gentamycin-GEN), 0%-(Amikacin-AMK), 8.3%-(Ciprofloxacin-CIP) and 0.0%-(Chloramphenicol-CHL). A multi-drug resistance pattern: CRX-CFZ-MEM-(100%), CRX-CTR-CFZ-MEM-(83.3%), CRX-CTR-CTX-CFZ-MEM-TET-(66.7%), CRX-CTR-CTX-CFZ-MEM-TET-COT-(58.3%) and CRX-CTR-CTX-CFZ-MEM-TET-COT-GEN-(8.3%) were observed.

**Conclusions:** Prevalence of *E. coli-O157* in *O. niloticus* sold in Ibadan is indicative of high aquatic contaminations and portends public health risks. High resistances and MDR patterns of isolates to antibiotics signifies misuse and/or indiscriminate disposal of antibiotics and risks of possible transmission of resistant/MDR genes to fish consumers.

**Presenter email address:** ogunleyeseto@yahoo.com

**Genetic relatedness of ceftriaxone-resistant multidrug-resistant Neisseria gonorrhoeae isolates in Singapore**

Nurdyana Abdul Rahman1, Martin Tze-Wei Chio2,3, Sui Sin Goh1, Ai Ling Tan1,3, Tse Hsien Koh1,3, Kwan Ki Karrie Ko3,4

1Singapore General Hospital, Department of Microbiology, Singapore, Singapore, 2National Skin Centre, Department of Sexually Transmitted Infections Control, Singapore, Singapore, 3Duke-NUS Graduate Medical School, Singapore, Singapore, 4Singapore General Hospital, Department of Molecular Pathology, Singapore, Singapore

**Background:** Multidrug-resistant Neisseria gonorrhoeae is a significant public health threat. We recently reported the first case of ceftriaxone-resistant multidrug-resistant N. gonorrhoeae in Singapore (2018). Since then, we have encountered two further cases of ceftriaxone-resistant N. gonorrhoeae. We report here the phenotypic characteristics and genetic relatedness of these local ceftriaxone-resistant N. gonorrhoeae strains.

**Materials/methods:** Urethral swabs were inoculated onto GC-LectTM Agar and colonies were identified using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry and API NH. Minimum inhibitory concentration values for ceftriaxone and 13 other antimicrobials were determined using Etests. Ceftriaxone-resistant isolates 19DG543 and 19DG787 were whole genome-sequenced with Illumina MiniSeq platform. Core genome single nucleotide variation (SNV) analysis was used to determine genetic relatedness of the ceftriaxone-resistant isolates.

**Results:** Both 19DG543 and 19DG787 were phenotypically similar to the 2018 ceftriaxone-resistant N. gonorrhoeae isolate (18DG342). All three isolates were non-susceptible to ceftriaxone; resistant to cefixime, penicillin and ciprofloxacin; and of intermediate resistance to tetracycline. They remained susceptible to azithromycin and spectinomycin. All three cases were treated with intramuscular Ceftriaxone 500g with clinical cure.

*In silico* molecular typing showed that 19DG787 was genetically similar to 18DG342. They both belong to the novel Neisseria Multi Locus Sequence Typing (MLST) ST 13871, which so far has only been reported by our group. 19DG787 and 18DG342 were of the same N. gonorrhoeae multiantigen sequence type (NG-MAST) ST1086 and had the same N. gonorrhoeae sequence typing for antimicrobial resistance (NG-STAR) profile 233. 19DG543 was distinct from 19DG787 and 18DG342. 19DG543 belonged to MLST ST1903, which is the global circulating ceftriaxone-resistant N. gonorrhoeae MLST type reported in Japan, Australia and Canada.

Core genome SNV analysis showed that 19DG787 is closely related to 18DG342; with a difference of 4 SNVs between the core genomes. 19DG543 clustered most closely with the ceftriaxone-resistant strain reported in Australia (47707).

**Conclusions:** This study confirms that both the importation of global circulating ceftriaxone-resistant strain(s) and the dissemination of a local ceftriaxone-resistant ST13871 strain are threatening the efficacy of the current mainstay ceftriaxone and azithromycin dual therapy. Continued surveillance will determine the extent of ceftriaxone-resistant N. gonorrhoeae dissemination to inform local therapeutic and surveillance practices.

In the absence of pressure, physical interaction within nasopharyngeal pneumococcal biofilms leads to acquisition of cephalosporin resistance but not to capsule switch events

Xueqing Wu*1, Latter Santiago2, Yih-Ling Tzeng3, David Stephens3, Jorge Vidal4

1Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Hangzhou, China, 2Rollins School of Public Health, Emory University, Atlanta, United States, 3School of Medicine, Emory University, Atlanta, United States, 4Department of Microbiology and Immunology, The University of Mississippi Medical Center, Jackson, MS, United States

Background: Streptococcus pneumoniae (Spn) acquires genes for antibiotic resistance, for example cephalosporin resistance via PBP mutations and undergoes capsular switch events while residing in the nasopharynx. We simulated nasopharyngeal pneumococcal colonization to study population dynamics, acquisition of resistance, and capsule switch events.

Materials/methods: Nasopharyngeal biofilm consortia made by two Spn strains belonging to non-vaccine serotype (S) 2, and vaccine types S4, S6B, S19A, or S19F was investigated. The relative density of each strain within the biofilm consortia was obtained and the ultrastructure of biofilms was analyzed by super-resolution, confocal laser scanning, and electron microscopy. Transference of cephalosporin resistance from strains isolated from pneumococcal disease was investigated. To investigate capsule switch events, we engineered a donor vaccine strain carrying resistance to erythromycin near the capsule locus. This strain transferred the resistance marker to a recipient Spn strain when incubated in the simulated nasopharyngeal environment. The recombination frequency (rF) was obtained and capsule switch events of the recombinants was investigated by Quellung reactions and Sanger sequencing of a ~30 kb region surrounding the capsule locus for 10 recombinants.

Results: Mixtures of any two Spn strains formed a nasopharyngeal biofilm consortium. Microscopy studies demonstrated spatial localization of Spn strains within these consortia characterized by a fused structure. Formation of this structure preceded a rapid acquisition of cephalosporin resistance from donor vaccine strains to a non-vaccine recipient. Acquisition of resistance located upstream the capsule locus did not lead to capsule switch events in the recombinants.

Conclusions: In the absence of antibiotic pressure, or antibodies against the capsule, physical interaction within pneumococcal nasopharyngeal biofilm consortia allows passive acquisition of cephalosporin resistance without affecting the capsule expression of recipients.

Genetic polymorphism of metabolic enzymes of Leishmania spp. parasites isolated from different clinical types of cutaneous leishmaniasis patients

Mahmoud Nateghi Rostami*, Mansoureh Hosseini, Fatemeh Darzi

1Pasteur Institute of Iran, Department of Parasitology, Tehran, Iran

Background: Cutaneous leishmaniasis (CL), mainly caused by Leishmania major and L. tropica species, is a geographically extensive disease with diverse clinical manifestations. The most common CL lesion is a self-healing typical ulcer, leaving a scar, however, lesions can be highly polymorphic, and frequently appear as atypical lesions described as ‘eczematoid’, ‘chancriform’, ‘erysipeloid’, ‘zosteriform’, ‘lupoid’, ‘sprotrichoid’, etc. Parasite genetic diversity is proposed to be one of the factors affecting the characteristics of clinical lesions in CL. This study aim to explore potential association of genetic diversity of enzymatic markers with clinical type of CL.

Materials/methods: Totally 38 CL patients including 18 atypical CL due to L. major/L. tropica, 10 typical CL due to L. major and 10 typical CL due to L. tropica were included in the study. Specific PCRs were used for amplification of 6 genes encoding metabolic enzymes, mainly used for MLEE, including isocitrate dehydrogenase (icd), mannose phosphate isomerase (mpi), glucose-6-phosphate dehydrogenase (g6pd), fumarate hydratase (fh), 6-phosphogluconate dehydrogenase (6pgd) and aspartate aminotransferase (asat). Alignment, phylogenetic analysis and genetic diversity analyses were performed using BioEdit, Mega7, DnaSP and MLSTest softwares.

Results: The comparison of partial sequences of enzyme genes with reference sequences allowed for the identification of a few polymorphisms in particular in 6pgd gene in L. major (Eta index=24) and icd gene in L. tropica (Eta index=30). Highest rate of haplotype diversity (Hd) in L. major was for 6pgd gene (0.377) and in L. tropica was for icd gene (0.659). Totally, 12 distinct Diploid Sequence Type (DST) in L. major and 8 distinct DST in L. tropica strains were recognized. Neucleotide diversity (π) and Hd indices of sequenced genes were not significantly different between atypical and typical CL patients.

Conclusions: The sequence analysis of six metabolic enzyme genes suggests genetic variability in L. major and L. tropica strains causing CL. A high number of new DSTs has been found among the isolates showing a significant variations in the sequences of these enzyme genes. However, no correlation between polymorphism of these genes and clinical type of CL has been detected.

Abstract 3004

A second surgical debridement for acute periprosthetic joint infections should not be discarded
Marjan Wouthuyzen-Bakker1*, Claudia Löwik1, Joris Ploegmakers1, Bas Knobben2, Baukje Dijkstra3, Astrid De Vries4, Glen Mithoe4, Greetje Kampinga5, Wierd Zijlstra3, Paul Jutte1

1University of Groningen, University Medical Center Groningen, Groningen, Netherlands, 2Martini Hospital, Groningen, Netherlands, 3Medical Center Leeuwarden, Leeuwarden, Netherlands, 4Martini Hospital, Certe, Groningen, Netherlands, 5University of Groningen, University Medical Center Groningen, Groningen, Groningen, Netherlands

Background: In acute periprosthetic joint infections (PJI), a second surgical debridement (DAIR) after a failed first one is disadvised in current international recommendations. We identified the failure rate of a second DAIR and aimed to identify patients in whom an additional debridement might still be beneficial.

Materials/methods: Patients with acute PJI of hip or knee and treated with DAIR between 2006 and 2016 were retrospectively evaluated. Failure of a second DAIR was described as: i) the need for additional surgical intervention to achieve infection control, ii) the need for antibiotic suppressive therapy due to persistent clinical and/or biochemical signs of infection or iii) PJI related death.

Results: From the 455 cases treated with DAIR, 144 cases underwent a second debridement (34.6%). Thirty-seven cases failed (37/144, 25.7%). The implant needed to be removed in 23 cases (23/144, 16%). Positive cultures during the second DAIR (OR 3.16 [95% CI 1.29–7.74]) and chronic renal insufficiency (OR 3.6 [95% CI 2.03–91.33]) were independent predictors for failure in the multivariate analysis. No difference in failure was observed between persistent infection with the same microorganism and reinfection with a new microorganism (failure rate 31.6% versus 34.6% resp., p 0.83). A BMI > 30 kg/m² was an independent predictor for treatment success (OR 0.26 [95% CI 0.09–0.72]).

Conclusions: A second DAIR had a low failure rate in our cohort of patients and the implant could be retained in the majority of them. A second DAIR should not be discarded in acute PJIs, especially not in obese patients and those without chronic renal insufficiency.

Antimicrobial susceptibility and clinical characteristics of severe pneumonia due to Haemophilus influenzae: an observational study

Pierre Danneels1, Maria Concetta Postorino1, Alessio Strazzulla*1, Aurelia Pitsch2, Sebastien Jochmans3, Mehran Monchi3, Vincent Dubee4, Sylvain Diamantis1

1Centre Hospitalier de Melun, Infectious Diseases Unit, Melun, France, 2Centre Hospitalier de Melun, Laboratory of Microbiology, Melun, France, 3Centre Hospitalier de Melun, Intensive Care Unit, Melun, France, 4University of Angers, Angers, France

Background: Treatment of Haemophilus influenzae (Hi) pneumonia is of concern because resistance to amoxicillin enhances prescription of third generation cephalosporins (C3G). However, this practice should be discouraged to minimize the impact on microbiota and selection of extended-spectrum β-lactamases (ESBL). Aim of this study was to describe the evolution of resistance patterns and clinical characteristics of patients hospitalized in intensive care unit with Hi associated pneumonia.

Materials/methods: We conducted a retrospective observational study including patients from 2008 to 2017 with diagnosis of pneumonia hospitalised in ICU. As comparator, we confronted characteristics of Hi pneumonia with Streptococcus pneumoniae (Sp) pneumonia. General characteristics, medical history, risk factors for pneumonia, co-morbidities and critical illness criteria were collected. Data about antimicrobial resistance were interpreted according to 2005-2013 EUCAST guidelines.

Results: Overall, 113 patients with Hi and 132 with Sp pneumonia were included in the study. Percentages of amoxicillin/clavulanic acid (AMC) resistance among Hi strains decreased over years (from 10% in 2008-2009 to 0% in 2016-2017, p=0.15). Also, percentages of Sp resistant strains for amoxicillin and moxifloxacin decreased over years (respectively from 25% to 0%, p<0.001, and from 21% to 0%, p<0.001) as shown in Figure 1. Patients with Hi experienced higher prevalence of bronchitis (18% vs. 8%, p=0.02), chronic obstructive pulmonary disease (43% vs. 30%, p=0.03), hospital-acquired pneumonia (HAP) (18% vs. 7%, p=0.01), ventilator associated pneumonia (13% vs. 5%, p=0.02) and longer duration of mechanical ventilation (8 days vs. 6 days, p=0.04) than patients with Sp pneumonia. On the contrary, patients with Sp pneumonia had more frequently local complications (17% vs. 7%, p=0.03). De-escalation of antibiotics was more frequent in patients with Sp than in patients with Hi (67% vs. 53%, p=0.03).

Conclusions: Patients with Hi pneumonia had higher risk of clinical complications than Sp pneumonia. Our data suggest that mono-therapy with AMC was effective on both Hi and Sp and could be considered as empirical treatment in patients with community-acquired pneumonia and HAP, permitting to spare C3G and, therefore, to reduce the impact on microbiota and the selection of ESBL bacteria.

Abstract 3009

Activities of eight antifungal agents against Candida auris biofilms
Athanasios Chatzimoschou1,2, Jacques F. Meis*3, Emmanuel Roilides3

1Ippokrateio - General Hospital of Thessaloniki, Thessaloniki, Greece, 2Canisius Wilhelmina Hospital, Nijmegen, Netherlands, 3Aristotle University, Infectious Diseases Laboratory, 3rd Department of Pediatrics, Hippokration Hospital, Thessaloniki, Greece

Background: Candida auris (CAU) has emerged rapidly as a prolific nosocomial pathogen, causing infections worldwide, surviving and persisting in the hospital environment and most of the times developing multi-drug resistance (MDR). CAU forms biofilms (BF) on biological and inert surfaces, such as intravascular catheters. Polyene, triazoles and echinocandins, three classes of antifungal agents with distinct mechanisms of action, are used as standard therapy for Candida infections.

Materials/methods: Five CAU isolates, each belonging to a different clade, were grown in RPMI-1640/2% glucose in 96-well plates under constant shaking for 48h/37°C in order to form BF. BFs were then incubated with no-drug (controls) or with two-fold dilutions of amphotericin B, posaconazole, voriconazole, fluconazole, itraconazole, caspofungin, anidulafungin and micafungin ranging from 2-2048 mg/L for further 24h. Percent BF damage was assessed colorimetrically by XTT assay. BF-MIC was defined as the minimal drug concentration causing ≥50% reduction in metabolic BF activity vs. controls. Susceptibility of PL cells was tested using EUCAST method (n=6).

Results:

All CAU isolates except one were FLU-R for PLK. South american, korean and indian isolates had high PLK-MIC to all antifungals compared to standard C. albicans and C. parapsilosis (CA-M61 and CP-A71). All isolates had much higher BF-MIC ranging from 16-2048mg/L compared to PLK except for Iran isolate. AMB exhibited BF-MICs that were low and close to PLK-MIC.

Conclusions: While CAU BFs have MICs of azoles and echinocandins much higher than PLKs, AMB exhibits much lower BF-MICs that are comparable to those of corresponding PLK.

In vitro activity of omadacycline against pathogens isolated from mainland China during 2017-2018

Yan Guo1,2, Dong Dong1,2, Qingqing Chen3, Yonggui Zheng1,2, Yang Yang1,2, Shi Wu1,2, Demei Zhu1,2, Jun Deng4, Patricia Bradford5, Harald H. Reinhart*, Fupin Hu1,2

1Huashan Hospital, Fudan University, Institute of Antibiotics, Shanghai, China, 2 Ministry of Health, Key Laboratory of Clinical Pharmacology of Antibiotics, Shanghai, China, 3First Hospital of Quanzhou City, Laboratory Medicine, Quanzhou, China, 4Zai lab, Shanghai, China, 5Antimicrobial Development Specialists, New York, United States

Background: Antibiotic resistance of bacterial pathogens isolated in China is a major concern, and new antibacterial agents are needed in this country. Omadacycline is a novel tetracycline derivative and was developed to address such resistance. The efficacy of Omadacycline has been demonstrated in clinical trials for acute bacterial skin and skin structure infections (ABSSSI) and community acquired bacterial pneumonia (CABP). However, susceptibility data has largely been limited to Western countries. This study was conducted to determine the in vitro activity of Omadacycline against a large collection of patient isolates from a geographically diverse group of medical centers in Mainland China.

Materials/methods: 1,041 recent clinical isolates obtained from patients hospitalized in 29 provinces and municipalities across China. The in vitro activity of Omadacycline and comparator agents was assessed using microbroth dilution according to CLSI methodology.

Results: Omadacycline was very active against methicillin-susceptible and -resistant Staphylococcus aureus with MIC90 values of 0.25 and 1 mg/L, respectively. All isolates of Enterococcus faecalis and E. faecium, including vancomycin-resistant isolates, were inhibited by ≤0.25 mg/L of Omadacycline. It was highly active against Streptococcus pneumoniae irrespective of susceptibility to penicillin or macrolides (MIC90 values 0.06-0.12 mg/L). It was also active against β-hemolytic and viridans group streptococci (MIC90 values 0.06-0.12 mg/L). The MIC distribution of Omadacycline was nearly identical against ESBL-positive and ESBL-negative E. coli. In addition, 95% of carbapenem-resistant E. coli (KPC or NDM producers) isolates were susceptible to Omadacycline (MIC90 = 4 mg/L). Omadacycline was as potent as tigecycline against Enterobacter cloacae and Citrobacter freundii. Omadacycline also showed good activity against Acinetobacter baumannii, inhibiting all isolates (including carbapenem-resistant) at ≤8 mg/L. Against Hemophilus influenzae and Moraxella catarrhalis, the MICs of omadacycline were low and not influenced by the presence of β-lactamase (100% susceptible).

Conclusions: Overall, the activity of Omadacycline was very good against isolates commonly associated with ABSSSI or CABP, and the susceptibility of Chinese isolates was similar to that reported for these pathogens from large surveillance studies outside China. This, coupled with the oral dosing option, makes omadacycline an attractive option for treatment of these infections in Chinese patients.

Abstract 3014

Quantitative PCR detection of circulating DNA for the diagnosis of mucormycosis: prospective evaluation in the ModiMucor study

Laurence Millon*, Denis Caillot2, Ana Berceanu3, Houssein Gbaguidi-Haore3, Valérie Letscher-Bru4, Frédéric Dalle3, Blandine Denis3, Stéphane Bretagne3, Alexandre Alanio2, David Boutoille5, Florent Morio6, Fanny Lanternier5, Marie Elisabeth Bougnoux5, Françoise Botterel5, Catherine Cordonnier6, Taieb Chouaki7, Stéphie Rocchi3, Emeline Scherer3, Raoul Herbrecht

1Parasitology-Mycology department, University Hospital of Besançon, Besançon, France, 2University Hospital of Dijon, Dijon, France, 3University Hospital of Besançon, Besançon, France, 4University Hospital of Strasbourg, Strasbourg, France, 5APHP Saint Louis Hospital, Paris, France, 6University Hospital of Nantes, Nantes, France, 7APHP Necker Hospital, Paris, France, 8University Hospital of Creteil, Creteil, France, 9University Hospital of Amiens, Amiens, France, 10University Hospital of Lyon, Lyon, France

Background: Modimucor is a French prospective multicentre study that aims to assess the performance of Mucorales PCR on blood samples for the diagnosis of mucormycosis.

Materials/methods: Patients with risk factors for invasive mold infection (hematological diseases, burns diabetes, solid organ transplantation, trauma, or diabetes) and patients diagnosed with mucormycosis were enrolled prospectively. Serum samples were collected twice-a-week, and Mucorales PCR were performed at the time of serum sampling, in each center, as previously described [Millon, Clin Microbiol Infect 2016]. Clinical data and biological data were collected up to 6 months after enrollment. Data analysis was performed using STATA 14 software.

Results: 249 patients from 9 University Hospital in France were enrolled from January 2015 to June 2017.

Forty-two patients were diagnosed with probable (n=11) or proven (n=31) mucormycosis according to EORTC/MSG criteria (including 12 mixed Aspergillus-Mucorales infections). Sensitivity and specificity of Mucorales PCR for diagnosis of probable or proven mucormycosis were 88.1% (37/42), and 89.7% (183/204), respectively. The first PCR-positive sample was observed in an average of 3.3 days before the first imaging criteria. Liposomal Amphotericin B was initiated in an average of 4.7 days after the first PCR-positive sample. Survival at 6 months was 53.9% (14/26) in patients with PCR becoming negative within 7 days after treatment initiation, and 0% (0/11) in patients with PCR remaining positive (Fisher’s exact test p = 0.002).

Eighteen patients with host factor and radiological signs for possible IMI had positive Mucorales PCR, including 11 patients with at least 2 consecutive positive samples. All of them were given liposomal Amphotericin B, in an average of 1.8 days after the first PCR-positive sample. In this subgroup, survival at 6 months was 80% (12/15) in patients with PCR becoming negative within 7 days after treatment initiation, and 0% (0/3) in patients with PCR remaining positive (Fisher’s exact test 0.025).

Conclusions: Mucorales PCR is a sensitive tool that helps to anticipate the diagnosis of mucormycosis. Decrease in DNA load after treatment was associated with a better outcome. This new tool is becoming essential in the clinical management of mucormycosis.

**β-lactam allergy and risk of multidrug-resistant bacteria acquisition in an intensive care unit: a cohort study**

Alessio Strazzulla*, Laura Iordache, Astrid De Pontfarcy, Aurelia Pitsch, Nabil Belfeki, Sebastien Jochmans, Guillaume Lezmi, Mehran Monchi, Sylvain Diamantis

1Centre Hospitalier de Melun, Infectious Diseases Unit, Melun, France, 2Centre Hospitalier de Fontainebleau, Internal Medicine Unit, Fontainebleau, France, 3Centre Hospitalier de Melun, Laboratory of Microbiology, Melun, France, 4Centre Hospitalier de Melun, Intensive Care Unit, Melun, France, 5Paris Descartes University/Hopital Necker, Department of Paediatric Pulmonology and Allergy, Paris, France

**Background:** Patients with β-lactam allergy are frequently exposed to treatments by broad spectrum antibiotics. However, the risk of extended spectrum β-lactamase (ESBL) carriage in this population has been poorly investigated. Aim of this study was to evaluate characteristics and clinical outcomes of patients admitted in intensive care unit (ICU) with and without declared β-lactam allergy at admission.

**Materials/methods:** The study included patients admitted in ICU from 2007 to 2012. The presence of multidrug resistant bacteria was documented in rectal and nasal swab at admission and discharge. Clinical characteristics and outcomes of patients labelled allergic to β-lactams and unlabelled patients were compared.

**Results:** Patients labelled allergic had significantly higher rates of ESBL at admission (13.3 % vs 4.3%, p=0.0220) and at discharge (20% vs 8.9%, p=0.0460) than unlabelled patients but no significant difference in rates of ESBL acquisition was detected. No differences in mortality, duration of hospitalisation and typical risk factors of ESBL acquisition (intubation, CVC and duration of hospitalization) were reported. No differences in carriage of methicillin resistant *Staphylococcus aureus* were detected (Table 1).

**Conclusions:** This study showed that patients with declared β-lactam allergy had a higher risk of ESBL carriage at admission and at discharge.

Effectiveness of trimetoprim-sulfametoxazole for treatment of ventilator-associated pneumonia: a cohort study

Alessio Strazzulla*1, Maria Concetta Postorino1, Anastasia Purcardea1, Catherine Chakvetadze1, Astrid De Pontfarcy1, Gianpiero Tebano1, Aurelia Pitsch1, Lyvan Yong2, Sebastien Jochmans2, Christophe Vinsonneau2, Mehran Monchi2, Sylvain Diamantis1

1Centre Hospitalier de Melun, Infectious Diseases Unit, Melun, France, 2Centre Hospitalier de Melun, Intensive Care Unit, Melun, France, 3Centre Hospitalier de Melun, Laboratory of Microbiology, Melun, France

Background: Trimetoprim-sulfametoxazole or co-trimoxazole (TMP-SMX) is naturally active against a broad spectrum of microorganisms, including the most frequent agents of ventilator associated pneumonia (VAP), except for Pseudomonas aeruginosa. It is currently approved for pneumonia (notably Pneumocystis jirovecii pneumonia and community acquired pneumonia) but it is neither recommended nor formally contraindicated for the empiric treatment of VAP. Aim of this study is to evaluate the effectiveness of trimetoprim-sulfametoxazole (TMP-SMX) for treatment of ventilator associated pneumonia (VAP).

Materials/methods: Retrospective cohort study including patients with VAP from 2011 to 2017. Two groups were analysed: TMP-SMX group, including patients who had received TMP-SMX (as first line and as de-escalation), and No-TMP-SMX group, including patients who had not received TMP-SMX treatment. Primary clinical outcome was mortality at 30 days from starting the antibiotic treatment (T30). Secondary outcomes were: mortality at end of treatment (EoT), day survival at T30, acquisition of multidrug resistant bacteria during hospitalization in intensive care unit.

Results: Eighty cases of VAP were included and distributed into two groups: No-TMP-SMX (31/80; 39%) and TMP-SMX (49/80; 61%). Univariate analysis reported no significant differences when the TMP-SMX group was compared to No-TMP-SMX group, except for frequency of male gender (p=0.025), as shown in Table 1. No significant statistical correlations between mortality at T30 and individual factors were detected by the multivariate model. No cases of either severe allergy or Clostridium difficile disease were reported in TMP-SMX and No-TMP-SMX group.

Conclusions: TMP-SMX treatment was not associated with higher mortality at EoT and T30 in comparison to the No-TMP-SMX group. TMP-SMX had a good safety profile, in terms of ecology (acquisition of MDR bacteria and Clostridium difficile disease) and clinical management (no allergy events).

Background: Critical illness has been shown to affect the pharmacokinetics of antibiotics, which can lead to ineffective antimicrobial exposure and the potential emergence of antimicrobial-resistant bacteria. The lack of studies describing antimicrobial pharmacokinetics in critically ill patients has led to significant off-label dosing. Conventional sampling to conduct clinical pharmacokinetic studies usually involve sampling of frequent and large volumes of blood (>2 mL) obtained using arterial or venous cannula. This can impact on the pathophysiology and/or the well-being of a patient, particularly a neonate or pediatric patient. Capillary microsampling (CMS) facilitates the collection of small volumes (<0.05 mL) by using minimally invasive procedures, such as finger prick. Implementation of CMS into clinical studies requires a two-stage assessment: a bioanalytical validation and clinical bridging study.

Materials/methods: Twenty-four paired plasma samples from critically-ill adults receiving intravenous meropenem were collected as both CMS from a finger-prick and as conventional sampling from an arteriovenous cannula. A 2.5 µL plasma sample was mixed with internal standard, [2H6]−meropenem and treated with acetonitrile and analyzed using HILIC LC-MSMS.

Results: Bioanalytical validation testing across the range of 0.2 to 100 µg/mL met acceptance criteria. Figure 1 illustrates a mean pharmacokinetic profile of six critically ill patients receiving meropenem. The maximum concentration and the minimum concentration measured were 32.1 mg/L and 6.33 mg/L for CMS and 36.2 mg/L and 6.40 mg/L for conventional sampling, respectively. The area under the concentration-time curve from 0 to 6 hours (AUC0–6h) ranged between 8.06 and 260 mg/L.h for CMS and from 8.08 and 270 mg/L.h for conventional sampling. Peripheral CMS results showed a mean bias of 1.5 (limits of agreement: -7.3 to 10.3) µg/mL compared to conventional sampling; the difference in concentration between the paired plasma samples was within 20% of the mean of the paired samples for 88% of the 24 samples tested.

Conclusions: Laboratory-based bioanalytical validation found the method was suitable for measuring meropenem in plasma. The clinical bridging study revealed no significant bias and a strong correlation between both sampling methods demonstrating that plasma samples collected as CMS from finger prick were a valid alternative to conventional plasma sampling.

Abstract 3029

A nation-wide parent survey of antibiotic use in Australian children

Rebecca Anderson1, Anthea Rhodes1,2, Noel Cranswick1,2,3, Marnie Downes2,3, Jonathan O’hara1, Mary-Anne Measey1,3, Amanda Gwee*1,2,3

1The Royal Children’s Hospital, Melbourne, Melbourne, Australia, 2University of Melbourne, Melbourne, Australia, 3Murdoch Children’s Research Institute, Melbourne, Australia

Background: Antimicrobial resistance is increasing globally, largely due to high rates of antibiotic use and misuse. Factors that influence frequent antibiotic use in children are poorly understood. This study describes rates of antibiotic use in Australian children and investigates parental factors including knowledge, attitudes and behaviours that influence antibiotic use.

Materials/methods: An online questionnaire relating to antibiotic use was administered as part of the Royal Children’s Hospital National Child Health Poll to a randomly-recruited nationwide sample of parents or guardians of children aged 0–17 years in Australia. Data on antibiotic use in children, and parental knowledge of appropriate indications for antibiotics and behaviours were collected. Standard binary logistic regression was used to assess associations between parent demographics and behaviour with antibiotic administration.

Results: The survey was completed by 2157 parents (64% completion rate), of which 1131 (52%) reported having given oral antibiotics to one or more of their children in the preceding 12 months. Of the 3971 children represented overall, 1719 (43%) had received at least one course of antibiotics. The average number of courses per child was 0.86 overall and 1.96 courses per child among those with reported antibiotic use. Notably, 194/1131 (17%) parents reported giving antibiotics to their child without a prescription, accessing the medication from leftover courses, family or friends, pharmacies or purchasing the medication online. Poor parental knowledge of antibiotic indications was associated with antibiotic use.

Conclusions: Reducing excessive use of antibiotics in children is necessary in the global strategy for preventing antimicrobial resistance. To the best of our knowledge, this is the first nationwide study of parent-reported antibiotic use in children that also accounts for non-prescription antibiotic use. We have demonstrated high community rates of antibiotic use in children and highlighted an urgent need to improve prescribing practices, increase governance over access to antibiotics and provide routine educational interventions at a primary care level.

Abstract 3030

Acceptability and usefulness of self-collected mid-turbinate swabs to diagnose and measure viral shedding in a pilot randomised controlled trial of hypertonic saline nasal irrigation and gargling in adults with a common cold

Sandeep Ramalingam*1, Cat Graham2, Jenny Dove1, Lynn Morrice1, Aziz Sheikh2

1Royal Infirmary of Edinburgh, Edinburgh, United Kingdom, 2University of Edinburgh, Edinburgh, United Kingdom

Abstract third-party references: NHS Lothian, University of Edinburgh, Cornish Sea Salt, Copan, Edinburgh And Lothians Health Foundation

Background: There are no effective interventions for a viral upper respiratory tract infection (URTl). We conducted a pilot randomised controlled trial of hypertonic nasal irrigation and gargling (HSNIG) vs standard care in adults with URTI to confirm laboratory evidence that epithelial cells utilise chloride ions to fight viral infections. As saline could not be a placebo, we used viral shedding as an independent marker of viral inhibition (www.clinicaltrials.gov:NCT02438579).

Materials/methods: Adults within 48 hours of URTI were minimised by sex/smoking status. The intervention arm were taught to prepare hypertonic saline with Cornish sea-salt and perform HSNIG. The control arm received usual care. All were taught to collect a mid-turbinate (MT) swab in eNAT transport medium (Copan) and baseline samples collected. Sequential MT swabs were self-collected first thing in the morning on 4 consecutive days and returned by post for testing. A validated symptom diary (WURSS-21) was maintained (until well for two days, ≤14 days). Day 0 samples were tested by the respiratory panel. If a virus was identified, all 5 samples were tested in parallel. The cycle threshold value was converted to log10 values to determine change in viral shedding.

Results: Of 68 participants recruited, follow up data was available from 61 (Intervention:30, Control:31). Both arms found collecting swabs easy (93% Vs 72%; p=0.08) and returning swabs easy (100% Vs 97%). Viral aetiology was identified in 74% of baseline swabs (49/66). In the intervention arm, 87% found HSNIG acceptable, 93% thought HSNIG made a difference to their symptoms, duration of illness was lower by 1.9 days (p=0.01), over-the-counter medication use was lower by 36% (p=0.004), transmission within household contacts was lower by 35% (p=0.006). A higher proportion in the intervention arm had a fall in viral shedding by ≥0.5log10/day compared to controls (p=0.04).

Conclusions: HSNIG is an acceptable intervention. The reduction in duration of symptoms, over-the-counter medication use, illness within households and viral shedding point to its effectiveness against the common cold. The ease of collection and return of swabs, and virus detection in a large proportion of samples will help design the definitive trial.

Rising incidence and mortality of bloodstream infections in Finland: a nation-wide population-based study during 2004–2018

Keiju Kontula*, Kirsi Skogberg1, Jukka Ollgren3, Outi Lyytikainen3, Asko Järvinen2

1Helsinki University Hospital, Division of Infectious Diseases, Inflammation Center, Helsinki, Finland, 2Helsinki University Hospital, Division of Infectious Diseases, Inflammation Center, Helsinki, Finland, 3National Institute for Health and Welfare, Department of Health Security, Helsinki, Finland

Background: Bloodstream infections (BSI) are related to significant morbidity and mortality. Our aim was to explore temporal changes in the incidence, outcome and causative agents of BSIs in Finland.

Materials/methods: We used data from the nationwide laboratory-based surveillance to analyze all BSIs in Finland during 2004–2018. Data on the date of death was retrieved from the Population Information System. Age- and gender-specific incidence and mortality rates were calculated by using population data from Statistics Finland.

Results: During 2004–2018, a total of 173,715 BSIs among 147,953 patients were identified (average annual incidence, 2.16 BSIs/100,000 population). The annual incidence increased from 150 to 309/100,000 population during 2004–2018; average annual increase was 5.2%. The increasing trend was sharpest among elderly, whereas among children there was a decreasing trend. Of all BSIs, 22,474 (1.3%) were fatal within 30 days; case fatality was highest (1.3.5%) in 2011 and lowest (1.2.1%) in 2017. The all-cause mortality within 30 days increased from 20 to 39/100,000 population during 2004–2018. The average annual increase was 4.8%; it was most notable among elderly. The proportion of gram-negative bacteria as causative agents increased from 42% to 48%, whereas BSIs caused by gram-positive bacteria decreased from 50% to 43%. No changes were observed in fungal or polymicrobial BSIs (from 1.7% to 1.1% and 6.5% to 7.1%, respectively). The incidence of Escherichia coli increased from 39 to 91/100,000 and Staphylococcus aureus from 19 to 39/100,000. Altogether, 3150 (1.8%) BSIs were caused by multi-drug-resistant microbes, and their proportion increased from 0.4% in 2004 to 2.8% in 2018, mostly due to extended-spectrum β-lactamase-producing E. coli and Klebsiella pneumoniae.

Conclusions: A twofold increase was noted in the incidence and mortality of BSIs in Finland during 2004–2018, and most of it occurred among elderly persons. However, case fatality remained unchanged, maybe related to improved diagnostics and treatment. The proportion of gram-negative bacteria as causative agents increased, and a rising trend in resistance was observed, which may cause problems in the future regarding of antimicrobial therapy. Our findings highlight the need for continuous surveillance of BSIs and active implementation of preventive measures.

Synthesis of nano-capsulated caprylic acid: evaluation of antifungal activity and its effect on EFG1 gene expression in Candida albicans

Maryam Roudbary1, Shahla Roudbarmohammadi2, Reyhaneh Zarimeidani3, Sara Mardani2

1Iran University of Medical Sciences, School of Medicine, Department of medical mycology and parasitology, Tehran, Iran, 2Tarbiat Modares University, Faculty of Medical sciences, Department of Medical Mycology, Tehran, Iran, 3Tarbiat Modares University, Faculty of Medical Sciences, Department of Medical Mycology, Tehran, Iran

Background: Increasing reports of resistant Candida species in clinical settings, discovering new antifungal agents with minimum side effects are highly deliberated worldwide. Nowadays, the nanotechnology approach can be used as an alternative option in drug delivery system. Recently, the antifungal properties of the medium chain fatty acid include Caprylic acid have been presented. This study aimed to investigate the antifungal activity of Caprylic acid and nano-encapsulated Caprylic acid on Candida albicans (C. albicans) and its effect on the expression of EFG1 gene was assessed.

Materials/methods: Minimum inhibitory concentration (MICs) of the Caprylic acid and nano-encapsulated Caprylic acid on C. albicans was evaluated according to CLSI method (M27-S3) compared to fluconazole. For this, serial dilution of Caprylic acid and nano-encapsulated Caprylic acid was prepared in concentration of 400, 450, 500, 550, 600, 625 µl/ml and 50, 25, 12.5, 6.25, 3.125, 1.5625 µl/ml respectively. RNA extracted from C. albicans before and after exposure to Caprylic acid and nano-encapsulated Caprylic acid, then cDNA synthesized and the mRNA expression of EFG1 gene of each group was evaluated using Real-time PCR assay. Cellular viability of epithelial cell line against Caprylic acid and nano-encapsulated Caprylic acid was examined using MTT assay.

Results: According the findings, MIC90 of Caprylic acid was 500µg/ml and MIC50 was 450µg/ml, whereas MIC90 for nano-encapsulated Caprylic acid indicated 6.2µg/ml and MIC50 showed 3.1µg/ml. The MFC of Caprylic acid and encapsulation Caprylic acid determined as 600µg/ml and 12.5µg/ml respectively. mRNA level of EFG1 gene significantly decreased in C. albicans treated with Caprylic acid and nano-encapsulated Caprylic acid compared to control group. Moreover, the EFG1 expression after exposure to Caprylic acid nanocapsulated was 4-fold lower than Caprylic acid treatment (p=0.002). The MTT results showed, Caprylic acid indicated higher cell viability than nano encapsulated caprylic acid.

Conclusions: Design of drug delivery systems based on nanotechnology could be overcome the defects of available common drugs. According the obtained results, nanoencapsulated Caprylic acid successfully inhibited the C. albicans growth with the low MIC compared to Caprylic acid. Taken together, it is suggested Caprylic acid nano-encapsulated may be used as a safe and suitable agent against Candida species, however more studies are required in the future.

Abstract 3035

Impact of an antimicrobial stewardship programme on antibiotic resistance profile of urinary Enterobacteriaceae isolated from nursing home residents: a retrospective cohort study

Alessio Strazzulla1, Samuel Bokobza2, Edgar Ombandza1, Khadjah Kherallah1, Stéphane Hommel1, Raouf Draidi1, Cédric Bonutto2, Dominique Bonnet Zamponi1, Rémy Gauzit1, Sylvain Diamantis1

1Centre Hospitalier de Melun, Infectious Diseases Unit, Melun, France, 2Centre Hospitalier de Provins, Provins, France, 3Sorbonne University, Paris, France, 4Centre Hospitalier Universitaire de Cochin, Paris, France

Background: Antibiotic resistance is common in isolates from nursing home residents, affecting in particular urinary isolates. This study investigates the impact of an antimicrobial stewardship program on fluoroquinolone (FLQ) resistance in urinary Enterobacteriaceae isolated from residents of three French nursing homes.

Materials/methods: A multicentric retrospective before-and-after study was conducted. All the first urinary Enterobacteriaceae isolates obtained from nursing home residents were included. Two time frames were analysed: 2013-2015 and 2016-2017. The antimicrobial stewardship program started in 2015 and was based on: i) a single training day for use of an "antimicrobial stewardship kit for nursing homes"; ii) daily support and training of the coordinating-physician by an antibiotic mobile team (AMT) in two out of three nursing homes.

Results: Overall, 338 urinary isolates were analysed. Escherichia coli was the most frequent species (212/338, 63%). A significant reduction of resistance to ofloxacin was observed between 2013-2015 and 2016-2017 in the whole set of isolates (p=0.004), among isolates obtained from patients hospitalised in the county nursing home with AMT support (p<0.01) and among Enterobacteriaceae isolates other than E. coli (p=0.006).

Conclusions: Our antimicrobial stewardship program allowed to reduce the rate of resistance to FLQ among urinary Enterobacteriaceae isolated from nursing home residents. A support of the AMT and a continuous training of the coordinating-physician seemed to be an important component to ensure the efficacy of the intervention.

Hospital Universitario Gregorio Marañón, Madrid, Spain, 4Servicio de Microbiología. Hospital Universitaritio Virgen Macarena, Sevilla, Spain, 5Servicio de Microbiología. Hospital Universitario San Espéres, Palma de Mallorca, Spain, 6Laboratorio de Microbiología. Hospital Clínico y Provincial, Barcelona, Spain, 7Servicio de Microbiología. Hospital Universitario Marqués de Valdecilla, Santander, Spain, 8Servicio de Microbiología. Consorcio Hospital General Universitario de Valencia, Valencia, Spain, 9Departamento Médico, MSD-España, Madrid, Spain

Background: Ceftolozane/tazobactam (C/T) is a novel β-lactam/β-lactamase inhibitor combination used for infections caused by multidrug-resistant (MDR) gram-negative bacteria. We studied the population structure and resistome of MDR Enterobacterales and Pseudomonas aeruginosaisolates, either C/T-susceptible or -resistant, recovered from intraabdominal and urinary tract infections in 8 Spanish Hospitals (SUPERIOR Study, 2016-2017).

Materials/methods: MICs were determined (ISO-broth microdilution, EUCAST criteria). Forty-fiveEscherichia coli, 43Klebsiella spp. and 13P. aeruginosaisolates were selected for whole genome sequencing (WGS) regarding C/T susceptibility. DNA extraction (Chemagic-DNA Bacterial External Lysis Kit, PerkinElmer, USA) and WGS (Illumina-NovaSeq 6000 platform, OGC, UK) were performed. SPAdes and Prokka were used for de novo assembling and annotation, respectively. In silico MLST assignment was performed. Resistance genes were identified using Abricate with ARG-ANNOT database (95% identity/90% coverage).E. coli phylogroups (ClermonTyping), serotypes (SerotypeFinder) and fimH-types (FimTyper) were determined. Kleborate software was used for capsule (K) and LPS (O) serotype prediction in Klebsiella spp. P. aeruginosao-specific antigen was identified (Blastn, OSA database).

Results: Overall C/T susceptibility was: 96.2%E. coli, 72.9%K. pneumoniaeand 91.3%P. aeruginosais. AmongE. coli, two carbapenemase producers [VIM-2+SHV-12-STnew-O:9:H12-H35 and OXA-48-ST38-O:0?H15-H65] but C/T-susceptible [MIC=0.5/4 mg/L] were detected. The most prevalent clone was the ST131-B2-O25:H4-H30 [n=16] associated with CTX-M-15 [11/16] and C/T-susceptibility [14/16] [MIC range=0.25/2-1/4 mg/L]. Among C/T-resistant isolates [n=8] [2/4->64/4 mg/L], a high diversity was found in ESBL [4/8] and non-ESBL [4/8] producers. AmongKlebsiella spp., 16 OXA-48+CTX-M-15 producers were detected [ST11-KL24-O2v1 (12/16), ST392-KL27-O4 (2/16), ST15-KL112-O1v1 (2/16)], all of them C/T-resistant [4/4->64/4 mg/L]. Moreover, ST101-NDM-1+CTX-M-15-KL17-O1v1 [->64/4 mg/L] and ST15-OXA-48+VIM-2+CTX-M-1-KL112-O1v1 [64/4 mg/L] were identified. A higher diversity of high-risk clones [ST11, ST15, ST30P] was also detected among ESBL/non-ESBL producers irrespective of C/T susceptibility. InP. aeruginosais, 6 carbapenemase producers C/T-resistant [16/4->64/4 mg/L] were detected: VIM-20-ST175-04 [3/6], VIM-1-ST309-011 [2/6] and VIM-2-ST175-04/011 [1/6]. Moreover, a C/T-susceptible VIM-36-ST175-04 isolate [2/4 mg/L] was identified.

Conclusions:K. pneumoniae-ST11-OXA-48+CTX-M-15 C/T-resistant andE. coli-ST131-CTX-M-15-OXA-48:H4-H30 C/T-susceptible are the most frequent clones in Spanish Hospitals. InP. aeruginosais, C/T-resistance is mainly related to VIM enzymes and the ST175 clone. Carbapenemase genes do not always correlate to C/T resistance, but other mechanisms might be involved.

The rapid method for detecting Neisseria gonorrhoeae and antimicrobial susceptibility

Jun Sakai*, Norihito Tarumoto¹, Kazuo Imai¹, Takuya Maeda¹, Shigefumi Maesaki¹

¹Saitama medical university hospital, Marayama-cho, Saitama, Japan

**Background:** Neisseria gonorrhoeae is known as a microorganism that transfers from infected genitalia and causes urinary tract infection. The diagnosis of N. gonorrhoeae infection has been used polymerase chain reaction (PCR). However, these diagnostic kits and methods could not analyze antimicrobial susceptibility. Therefore, we tend to use broad spectrum antimicrobial agents and make multiple resistance N. gonorrhoeae. We created a new rapid method that detects mutation of penA (penicillin resistance associated gene) and gyrA (quinolone resistance associated gene) at the same time as diagnosis of N. gonorrhoeae.

**Materials/methods:** The N. gonorrhoeae were extracted directly from urine sample. Secondary, we extracted and purified DNA of N. gonorrhoeae. Thirdly, we made the specified primers with locked nucleic acid (LNA) and probes for the purpose of detecting SNP mutations on penA and gyrA genes, and amplified via real time PCR. These primers were designed only to amplify against wild types. The real time PCR were finished 15 minutes.

**Results:** Total 38 N. gonorrhoeae samples were amplified by real time PCR using N. gonorrhoeae specific primers and probes. No other species causing urinary infections were not increased. All wild type of penA and gyrA were amplified by penA and wild type gyrA specific primers and probes. On the other hand, all mutant type of penA and gyrA were not detected. These reactions were detected 15 mins from PCR starting.

**Conclusions:** We presented that N. gonorrhoeae infections could not been only detected quickly but also detected antibiotics resistance in same time via this study. We have been trying to develop next generation methods that detecting N. gonorrhoeae infection and antimicrobial susceptibility easily and quickly.

Abstract 3040

An emerging methicillin resistance mechanism due to loss-of-function of the GdpP protein in mec gene-negative staphylococci undetected by reference methods

Geraldine Durand*1, Celine Dupieux-Chabert2, Michele Bes2, Claude-Alexandre Gustave2, Bérangère Fruiquières1, Corine Fulchiron1, Lorette Munoz1, Sarah Rivat1, Anne-Gaëlle Ranc2, François Vandenesch2, Frédéric Laurent2, Anne Tristan2, Patricia Martins Simoes2

1bioMérieux, R&D Microbiology, La Balme les Grottes, France, 2Hospices Civils de Lyon, French National Reference Center for Staphylococci, Lyon, France

Background: B-lactam resistance in Staphylococci is mediated by mec genes and usually diagnosed by Cefoxitin disk diffusion and PCR testing. Here, we report methicillin-resistant Staphylococcus lugdunensis and Staphylococcus aureus strains lacking mec gene misdiagnosed by reference methods. Since the strains are not B-lactamase hyperproducers we investigated the molecular basis of their methicillin resistance.

Materials/methods: We tested 2 Staphylococcus lugdunensis (SL1, SL2) and 4 Staphylococcus aureus isolates (SA1, SA2, SA3, SA4): (i) by Cefoxitin disk diffusion (DDFOX), (ii) for agar dilution Oxacillin MIC (AD), (iii) by VITEK®2 (bioMérieux) for antimicrobial susceptibility testing containing Oxacillin MIC (V2OXA) and Cefoxitin Screen Test (V2OXSF), (iv) for mec genes (meca, B, C) and (v) by whole genome sequencing (WGS).

Results: The 6 isolates were detected as methicillin susceptible by DDFOX and were mec negative. However all isolates displayed variable results for V2OXA MIC (0.5 to >=4mg/L) and V2OXSF [POSITIVE or NEGATIVE]. For S. lugdunensis isolates the V2OXSF growth curve atypical pattern has led to investigate the OXSF wells. The plates inoculated with the broth extracted from the OXSF well showed two colony morphotypes (small “P” and regular “G”) for both isolates. The small colonies (SL1P, SL2P) were Oxacillin resistant (V2OXA MIC≥4; AD MIC=4) and V2OXSF POSITIVE whereas the regular colonies (SL1G, SL2G) were Oxacillin susceptible (V2OXA MIC<2; AD MIC=0,5) and V2OXSF NEGATIVE. The 4 morphotypes were confirmed as Cefoxitin susceptible by DDFOX and mec negative. Interestingly, WGS revealed, in phenotypically Oxacillin resistant isolates, a GdpP truncation in the N-terminal domain containing a diguanylate cyclase (GGDEF) motif for the subpopulation of small colonies of S. lugdunensis (SL1P, SL2P) and also for S. aureus isolates SA1 and SA3. However, GdpP non synonymous mutations were detected in SA2 and SA4 isolates. GdpP is a cyclic diadenosine monophosphate phosphodiesterase enzyme which function is the hydrolysis of a signaling nucleotide (c-di-AMP).

Conclusions: We described mec negative S. lugdunensis and S. aureus strains detected by VITEK2 OXSF test expressing heterogeneous methicillin resistance due to a loss of function of GdpP previously described as associated with reduced growth which may arise as a result of the selective pressure of exposure to B-lactams.

Abstract 3047

**Prognostic factors in HIV-infected patients with lymphoma: a single-centre experience**
Francesca Volpato*, Alessandra Cascavilla, Michele Bartoletti, Pierluigi Viale

1Alma Mater Studiorum - Università di Bologna, Unit of Infectious Diseases, Bologna, Italy

**Background:** with the present study we aimed to evaluate prognostic factors in HIV patients with non-AIDS and AIDS-related lymphoma.

**Materials/methods:** This was a retrospective cohort study of patients with lymphoproliferative disorders and HIV infection, enrolled from January 2000 to July 2019 and followed up for at least 2 years.

**Results:** Overall, 94 patients were included. Of these, 73/94 (77.6%) were male and the median (IQR) age was 46 (13-79). At lymphoma diagnosis the median CD4+ cell count was 228 cell/mmc (11-1377) and 34/94 (36.6%) of patients had undetectable HIV-RNA, 21/94 (20%) patients had a prior AIDS-defining condition. Histologic subtypes were diffuse large B-cell lymphoma (DLBCL; n=44, 51%), plasmablastic lymphoma (PBL; n=4, 4.9%), Burkitt lymphoma (BL; n=27, 29%), T-cell lymphoma (n=3, 3.2%), Hodgkin lymphoma (n=21, 19%). Chemotherapy was administered to 79/94 (84%) pts. The most frequently used chemotherapy regimen was CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone), administered in 42% of the patients with DLBCL, followed by BFM (Berlin-Frankfurt-Munster). Rituximab was administered to 27% of the patients and autologous stem cell transplantation was performed in 7 (8.5%) cases. Forty (51.3%) patients achieved complete remission. At the end of 2-year follow-up 82 (87%) cases were evaluable, after excluding lost to follow-up, 2-year mortality rate was 42% (35 fatal cases). Variables associated with survival at univariate analysis were prior AIDS (p=0.046), CD4+ <15% at the diagnosis of lymphoma (p=0.041), histologic subtype (p<0.001), Ann Arbor III-IV stage (p=0.033), B symptoms (p=0.009), extranodal disease (p=0.022), IPI score >2 (p=0.003) and complete remission at first line chemotherapy (p=0.0001). At multivariable analysis performed with a Cox regression model, IPI score > 2 [HR 3.18 (95% CI 1.20-8.42)], Burkitt subtype [HR 2.60 (95% CI 1.32-5.14)] were associate with mortality whereas receiving cART was associated with survival [HR 0.38 (95% CI 0.17-8.56)].

**Conclusions:** cART introduction had entailed a significant improvement in complete response rate and overall survival. Tumor-related factors became the most consistent prognostic factors of survival. In our study IPI score > 2, extra-nodal disease predicte significantly worse final outcome. These findings suggest that aggressive chemotherapy for patients with HIV-related lymphoma, must be adopted, regardless of their HIV status.

Characterisation of carbapenemase-producing Serratia marcescens clinical isolates recovered in a hospital in Madrid (Spain) using whole genome sequencing

Marta Hernández García1, Blanca Pérez-Viso*1, Maria Isabel Morosini Reilly1, Patricia Ruiz-Garbajosa1, Rosa Del Campo1, Rafael Canton Moreno1

1Servicio de Microbiología. Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: The prevalence of carbapenemase-producing Serratia marcescens (CPSm) causing infection is increasing in hospital settings. We study the population structure and plasmid content of CPSm isolates recovered from infected patients admitted at the Ramón y Cajal University Hospital using whole genome sequencing.

Materials/methods: Between March-2016 and December-2018, 50 CPSm isolates (42 VIM-1-CPSm and 8 OXA-48-CPSm) from 34 infected patients were recovered in our Hospital. Carbapenemase genes identification (PCR and sanger sequencing) and Pulse-field gel electrophoresis (PFGE) were performed. DNA extraction (Chemagic DNA Bacterial External Lysis Kit, PerkinElmer, USA) and Whole Genome Sequencing (Illumina-NovaSeq 6000 platform, OGC, UK) were carried out on one representative CPSm isolate of each PFGE-clone (n=5). SPAdes and Prokka were used for de novo assembling and annotation, respectively. Bacterial identification was confirmed using Kraken. Resistance and virulence genes were identified by Abricate (ARG-ANNOT and vfdb databases) (95% identity-90% coverage). MASH and iTOL application were used to generate and trace a similarity tree. Plasmid characterization and reconstruction were performed using PlasmidFinder and PLACNETw tools, respectively.

Results: Carbapenemase production was confirmed in the 5 CPSm isolates [VIM-1 (n=3) and OXA-48 (n=2)]. Similarity tree construction revealed a MASH-distance ≤0.03 among VIM-1-CPSm isolates and 0.00007 between OXA-48-CPSm isolates. Genome analysis confirmed the presence of genes conferring co-resistance to other antimicrobial groups in both VIM-1-CPSm (aacA4, blaSR T-1, dfrB1, sul1, catB2, catA1, msrE, mphE and aadA1) and OXA-48-CPSm (aacA4, blaSR T-1) isolates. The virulence factor daaF was identified in one VIM-1-CPSm isolate. Plasmid reconstruction shown that OXA-48- and VIM-1-CPSm isolates harboured an IncL-pOXA-48 (62038 pb) and an IncL-pVIM-1 (65114 pb) plasmid, respectively, with a 91% of coverage (~57 Kb) and 99,98% of identity. blaOXA-48 was located as part of the Tn1999 composite transposon in a ~5 Kb specific region without any other antibiotic resistance gene. pVIM-1 plasmid harboured a class 1 integron (~8 Kb) containing 'blaVIM-1+aacA4+dfrB1+aadA1+catB2+qacEDelta1+sul1'.

Conclusions: S. marcescens plays an important role in the spread of VIM-1 and OXA-48 carbapenemases in our Hospital. An ~62kb IncL-pOXA-48 plasmid widely disseminated in other Enterobacterales spp. (Klebsiella pneumoniae and Escherichia coli) and a closely related ~65kb IncL-pVIM-1 were detected in CPSm isolates.

Abstract 3049

Does early de-escalation to anti-staphylococcal beta-lactams impact the duration of bacteraemia in patients with methicillin-susceptible Staphylococcus aureus endocarditis?

Minkey Wungwattanap1, Marlee Manginob, George Ben1, Patricia Stogsdill1, Anthony Casapao3

1Maine Medical Center, Portland, United States, 2Saratoga Hospital, Saratoga Springs, United States, 3University of Florida College of Pharmacy, Jacksonville, United States

Background: Anti-staphylococcal beta-lactam (ASBL) antibiotics are widely accepted as superior agents over vancomycin for the treatment of methicillin-susceptible Staphylococcus aureus (MSSA). Mortality risk increases by 16% for each day of Staphylococcus aureus bacteremia. Current standard for identification and susceptibility testing of blood cultures requires 36-48 hours from the time of positivity. Rapid diagnostic tests (RDT) have significantly reduced this time. We aimed to study the impact of Verigene® Nanosphere on the duration of bacteremia in patients with MSSA bacteremia due to infective endocarditis.

Materials/methods: Retrospective, quasi-experimental, single center, cohort study that included adult patients with a diagnosis of MSSA endocarditis from January 2013 to June 2018. Enrolled patients must have reviewable dates and times of the following: initial culture collection, initial culture positivity, RDT results, empiric antibiotic initiation, and first doses of ASBLs. Patients were divided into two cohorts based on the implementation of Verigene® RDT in September 2015. Patients post-implementation were compared to patients pre-RDT. Primary outcome was defined as time to clearance of blood cultures.

Results: Total of 105 patients were included. Nanosphere test was performed in 54/105 patients (51.4%). Median time to positivity in the pre-RDT and RDT was 14.1 and 14.5 hours, respectively [p = 0.166]. Median time to ASBL in the pre-RDT and RDT was 63.5 and 37 hours, respectively [p < 0.01]. Five patients (4.8%) did not clear their MSSA bacteremia. The median time to culture clearance in the pre-RDT patients was 96.8 hours (IQR 64.8-120.6) compared to RDT cohort was 94.6 hours (IQR 67.2-142.8); p = 0.807.

Conclusions: Time to definitive beta-lactam therapy was statistically shorter with Verigene® while time to positivity was similar in both cohorts. However, a difference in time to bacteremia clearance was not observed between MSSA endocarditis patients who had RDT performed on their blood cultures and those who were managed traditionally. Further evaluation of factors such as early vancomycin exposure and source control is necessary to assess the impact of RDT coupled with early de-escalation on the duration of MSSA bacteremia in infective endocarditis patients.

Monitoring and drug resistance analysis of isolated bacteria from tuberculosis patients in west China hospital of Sichuan University from 2010 to 2019

Zhihong Liu*1

1Department of experimental medicine/medical laboratory medicine, west China hospital, sichuan university, Sichuan Province, China

Background: Anti - tuberculosis treatment using multiple antibiotics, drug use and treatment for a long time. It is not known whether bacteria isolated from TB patients who have been treated with antibiotics for a long time have higher drug resistance. Therefore, we intend to investigate the distribution of bacteria isolated from TB patients and the characteristics of drug resistance.

Materials/methods: By retrospective method, bacteria isolated from tuberculosis patients in west China hospital of sichuan university from January 2010 to July 2019 were statistically analyzed. VITEK2 compact automatic microbiological analyzer was used for bacterial strain identification and drug susceptibility test, and WHONET5.6 software was used for statistical analysis of drug sensitivity results. SPSS19.0 statistical analysis software was used to compare the bacterial culture results of isolated bacteria in tuberculosis patients with 101,415 hospitalized patients in the same period.

Results: Among 1808 patients with positive mycobacterium tuberculosis culture, 444 strains of effective bacterial strains were isolated after eliminating the duplicate strains of the same patients. The top five bacteria were klebsiella pneumoniae (16.2%), acinetobacter baumanni (14.2%), pseudomonas aeruginosa (9.7%), escherichia coli (9.0%).

The antimicrobial resistance rate of bacteria isolated from tuberculosis patients was generally higher than that of hospitalized patients during the same period. Among them, the drug resistance rates of escherichia coli to ciprofloxacin, tetracycline, ceftriaxone, ampicillin/sulbactam, cefotaxime, compound xinnoxacin, levofloxacin, amtronan and gentamycin were statistically different between the two groups (P < 0.05). The resistance rate of klebsiella pneumoniae to antibiotics other than gentamicin, cefuroxime and cefutetan was statistically significant between the two groups (P < 0.05). The drug resistance rate of other antibiotics except piperacillin/tazobatam, tetracycline and donipenem showed statistical difference between the two groups (P < 0.05). Rifampin had a statistically significant difference in staphylococcal resistance between TB patients and hospitalized patients. The drug resistance rate of enterococci isolated from tuberculosis patients was generally higher than that of hospitalized patients, and there were significant differences between penicillin G, vancomycin, ampicillin and levofloxacin (P < 0.05).

Conclusions: Because anti-tb treatment requires long-term multi-drug combination therapy, bacteria isolated from tuberculosis patients treated with long-term antibiotics have higher resistance to most antimicrobial agents than common bacterial infections in hospitalized patients.

Hospital Infante Dom Pedro, Aveiro, Portugal, 8Serviço de Patologia Clínica, Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal, 9Serviço de Microbiologia, Hospital Garcia de Orta, Almada, Portugal, 10Serviço de Patologia Clínica – Microbiologia – CHUA – Unidade de Portimão, Algarve, Portugal, 11Serviço de Microbiologia, Centro Hospitalar Universitário do Porto, Porto, Portugal, 12Serviço de Microbiologia, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal, 13MSD Portugal, Paço de Arcos, Portugal

Background: Ceftolozane/tazobactam (C/T) is frequently used for infections caused by multidrug-resistant (MDR) gram-negative bacteria. We study the population structure and the resistome of MDR-Enterobacterales isolates, C/T-susceptible and -resistant, recovered from low respiratory, intraabdominal and urinary tract infections of ICU patients from 11 Portuguese Hospitals (STEP study, 2016-2017).

Materials/methods: MICs were determined (ISO-broth microdilution, EUCAST criteria). Thirty E. coli and 79 Klebsiella spp. isolates were selected. DNA extraction (Chemagic DNA Bacterial External Lysis Kit, PerkinElmer, USA) and whole genome sequencing (Illumina-NovaSeq 6000 platform; OGC, Oxford, UK) were performed. SPAdes and Prokka were used for de novo assembling and annotation, respectively. Bacterial identification was confirmed using Kraken. In silico MLST assignment was performed. Resistance genes were identified using Abricate with ARG-ANNOT database (95% identity/90% coverage). Among E. coli isolates, phylgroups [Clermontyping], serotypes [SerotypeFinder] and fimH types [FimTyper] were determined. Capsule (K) and LPS (O) serotype prediction was performed in Klebsiella spp. isolates by Kleborate software.

Results: Among E. coli, two VIM-2 producers susceptible to C/T (0.5/4-1/4 mg/L) were detected [ST131-B2-H30-025:H4-CTX-M-15 and ST188-C-H39-022:H4]. A C/T-resistant (16/4 mg/L) KPC-3-producing-ST5463-cladeV-H160-0164:H55 isolate was also identified. Among ESBL producers (n=39), the most frequent clone was ST131-B2-H30-025:H4 (n=14) associated with CTX-M-15 [10/14] or CTX-M-27 [4/14] production, all of them C/T-susceptible [MIC range: 0.25/4-1/4 mg/L] except one [2/4 mg/L]. In non-ESBL producers (n=8) [0.25/4-1/4 mg/L], a high clonal diversity was found. Among Klebsiella spp. isolates, K. pneumoniae was the most frequent species (n=68), followed by K. aerogenes (n=7), K. variicola (n=2) and K. oxytoca (n=2). All carbapenemase producers (n=21) were C/T-resistant [2/4-64/4 mg/L], except one (OXA-48-ST215-KL16-01v1) [1/4 mg/L]. The most frequent K. pneumoniae clones were: KPC-3-ST13-KL3-01v2 (n=5), KPC-3-ST5-KL112-01v1 (n=2), KPC3-ST231-KL51-01v2 (n=2), OXA181-ST17-KL25-05 (n=2) and OXA-48-ST215-KL16-01v1 (n=2). KPC-3+VIM-2 co-production was identified in a ST405-KL151-04 isolate. A high diversity [ST15, ST307, ST405], mainly C/T-resistant [2/4-64/4 mg/L], was also detected among ESBL (n=41) and non-ESBL (n=17) producers.

Conclusions: E. coli-ST131-CTX-M-15-B2-025:H4-H30 C/T-susceptible is the most frequent clone in ICU Portuguese Hospitals. A high diversity of K. pneumoniae clones was also found mainly associated with KPC-3 and C/T-resistance. Carbapenemase genes are not always correlated to C/T resistance, but other mechanisms might be involved.

Serviço de Patologia Clínica, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal, ⁴Laboratório de Microbiologia Clínica Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal, ⁵Serviço de Microbiologia, Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal, ⁶Serviço Patologia Clínica, Centro Hospitalar Universitário de São João, Porto, Portugal, ⁷Serviço Patologia Clinica. Hospital Infante Dom Pedro, Aveiro, Portugal, ⁸Serviço de Patologia Clínica, Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal, ⁹Serviço de Microbiologia, Hospital Garcia de Orta, Almada, Portugal, ¹⁰Serviço de Patologia Clínica – Microbiologia – CHUA – Unidade de Portimão, Algarve, Portugal, ¹¹Serviço de Microbiologia, Centro Hospitalar Universitário do Porto, Porto, Portugal, ¹²Serviço de Microbiologia, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal, ¹³MSD Portugal, Paço de Arcos, Portugal

**Background:** Ceftolozane/tazobactam (C/T) is frequently used for the treatment of infections by multidrug-resistant (MDR) *Pseudomonas aeruginosa* isolates. We characterized the population structure and the resistome of *P. aeruginosa* isolates with a phenotype compatible with carbapenemase production, susceptible or resistant to C/T, collected between 2016 and 2017 from low respiratory, intraabdominal and urinary tract infections of ICU patients from 11 Portuguese Hospitals (STEP study).

**Materials/methods:** MICs were determined (ISO-broth microdilution) and interpreted according to EUCAST criteria. A total of 21 C/T-resistant *P. aeruginosa* isolates recovered during the STEP surveillance study were analyzed and compared with 21 C/T-susceptible *P. aeruginosa* from the same study. DNA extraction from exponential growth cultures was carried out (Chemagic DNA Bacterial External Lysis Kit, PerkinElmer, USA). Whole genome sequencing was performed by the Illumina-NovaSeq 6000 platform (OGC, Oxford, UK). SPAdes was used for de novo assembling and assembly evaluation was performed by QUAST. Draft genomes were annotated by Prokka. In silico MLST assignment was performed. Antimicrobial resistance genes were identified using Abricate and ARG-ANNOT database (threshold, 95% identity; 90% coverage). O-specific antigen was identified using Blastn with OSA database.

**Results:** Among C/T-resistant *P. aeruginosa* (MIC range: 8/4->64/4 mg/L), carbapenemase production was detected in 16 isolates (61.5%). The most frequent carbapenemase was GES-13 (n=13) associated with the clone ST235-O11 [32/4->64/4 mg/L]. VIM-2 production was also detected in ST244-05 (n=2) and ST179-06 (n=1) clones (>64/4 mg/L). Among non-carbapenemase producers, the most frequent clone was the ST348-O12 (n=3) (8/4 mg/L), followed by ST554-02/05 (n=1) (>64/4 mg/L) and ST313-01 (n=1) (16/4 mg/L). In C/T susceptible isolates (0.5/4-4/4 mg/L), a higher clonal diversity was found (ST235-011, ST253-010/012, ST179-06, ST244-05/06/012, ST2959-011, ST308-011, ST309-011, ST3292-06, ST446-011, ST499-01 and ST971-01). Moreover, KPC-3 production was detected in two isolates (ST499-01 and ST253-012) (1/4 mg/L).

**Conclusions:** Production of GES-13 and VIM-2 is associated with C/T resistance in certain *P. aeruginosa* clones (ST235-011 and ST244-05) in ICU Portuguese Hospitals. Interestingly, *blaKPC-3* gene was also identified in two C/T-susceptible *P. aeruginosa* isolates. C/T resistance is not always due to the presence of carbapenemase genes and other mechanisms might be involved.

Abstract 3058

Validation of serum procalcitonin measurement for the diagnosis of rickettsial infections disease
Shigetoshi Sakabe¹, Hiroyuki Tanaka*, Yuuki Nakanishi¹, Hirokazu Toyoshima¹

¹Ise Red Cross Hospital, Ise, Japan

Background: Rickettsiosis presents systemic inflammation without organ specificity disorders and requires differential diagnosis of viral infections, vasculitis and autoimmune diseases, etc. Rickettsiosis is known to increase serum C-reactive protein (CRP) level. CRP is a useful biomarker for differentiation from viral infections but is not a sufficient marker due to its low specificity for bacterial infections. Procalcitonin (PCT), on the other hand, has been reported to be highly specific for bacterial infections, but there is no evidence for rickettsial disease diagnosis.

Materials/methods: The purpose of this study is to investigate whether serum PCT level is elevated during the acute phase of Japanese spotted fever (JSF), a rickettsial disease caused by Rickettsia japonica in eastern Asia. The subjects were JSF patients who were hospitalized at the Ise Red Cross Hospital between 2013 and 2018. Serum PCT and CRP concentrations were measured within one day after the patient visited. Measurements were evaluated at multiple cut-off points to determine sensitivity. Diagnostic criteria were positive results in molecular-based tests at the acute phase and/or increased serum antibody titers.

Results: A total of 104 cases (male: 45%, age: 69.7 ± 13.1 years), diagnosed with JSF and were cured with tetracycline and fluoroquinolone. The time from onset to arrival was 3.8 ± 3.1 days. The average serum PCT concentration was 1.8 ± 5.1 ng/mL. As determined by PCT levels, 57% were positive at the facility’s normal upper limit of 0.5 ng/mL and 11% were positive at the sepsis cut-off point of 4.0 ng/mL used in the literature. The average serum CRP level was 11.5 ± 6.8, 100% positive for the upper limit of normal 0.1 mg/dL of the facility and 85% positive for the acute inflammation cut-off point of 5 mg/dL. Serum PCT levels did not correlate with CRP levels (R=0.146, ns).

Conclusions: Among JSF cases with elevated CRP levels, the sensitivity of PCT is low, but some cases show high PCT concentrations. Serum PCT measurement is unlikely to be a reliable biomarker in the diagnosis of rickettsiosis.

Non-invasive ventilation in patients with acute respiratory failure secondary to viral respiratory infection: a nested case-control study

André Almeida*, Matteo Boattini1, Eirini Christaki4;5, Gabriele Bianco1, Torcato Marques2, Valentina Tosatto2, Lourenco Cruz2, Maria Inês Moreira2, Diogo Antao2, Cristina Costa1, Georgios Tsiolakkis5, Diamanto Kasapi4, Elina Khattab4, Rossana Cavallo1, Rita Corte Real2

1University Hospital Città della Salute e della Scienza di Torino, Turin, Italy, 2Central Lisbon University Hospital Centre, Lisbon, Portugal, 3NOVA Medical School, Lisbon, Portugal, 4Medical School, University of Cyprus, Nicosia Cyprus, 5Nicosia General Hospital, Cyprus, Department of Medicine, Nicosia, Cyprus

Background: While non-invasive ventilation (NIV) can often be an effective strategy to tackle acute respiratory failure (ARF) on exacerbations of chronic respiratory disease and decompensation of heart failure, its role on viral and bacterial pneumonia remains controversial. We aimed to study possible predictors of NIV failure in a cohort of patients admitted for acute viral respiratory infections.

Materials/methods: We recruited our study subjects from a multi-center southern European cohort of patients admitted with lower respiratory viral infections over the 2017-2018 and 2018-2019 winter seasons. Cases were defined as patients who either died in the course of admission and/or required invasive mechanical ventilation (IMV), after being submitted to NIV. Controls were patients who were submitted to NIV and survived admission without the need for IMV. Predictive variables with p values <0.25 on univariate analysis were included in the multivariate logistic regression model.

Results: There were a total of 150 patients included in this study. Mean age was 68.9 years. Concerning the most relevant comorbidities, 19% (n=28) had a history of smoking, 31% (n=46) diabetes, 43% (n=65) heart failure, 33% (n=65) either chronic obstructive lung disease or asthma and 17% (n=25) active malignancy (11% haematological, 6% solid). The majority of infections (55% n=83) were caused by Influenza A, of which 41 (27%) were sub-typed as H1N1; RSV was isolated in 40 patients (27%). There were 47 patients who were ultimately submitted to IMV, 43 deaths and a total of 64 (43%) meeting study criteria for failure (cases). On univariate analysis lower age, absence of heart failure, infection by H1N1 strains and the presence of a radiological infiltrate were associated with NIV failure (p<0.05), while on multivariate analysis the variables which were found to be significant predictors were the presence of a solid malignancy (adjusted odds ratio [aOR] 4.8 CI95%[1.0-24.5]) and H1N1 (aOR 4.2 CI95%[1.7-10.7]).

Conclusions: Almost half of all patients in our study had a failure of NIV. Particular Influenza strains might be predictive of NIV failure. Even though NIV has a role in managing patients with ARF, its use in cases related with respiratory viral infection should be considered judiciously.

Abstract 3061

Comparison of *Escherichia coli* multilocus sequence typing from the UK, Saudi Arabia and Kazakhstan indicates that UK sepsis rates are directly related to carriage of pathogenic *E. coli* strains in the community

Abdulrahman Almusallam¹, Jordan Mathias², Mark Alexander Toleman*¹², Dmitriy Babenko³

¹Cardiff University, Cardiff, United Kingdom, ²Cardiff University, Cardiff, United Kingdom, ³Karaganda Medical University, Karaganda, Kazakhstan

**Background:** *E. coli* consists of commensal and pathogenic strains. We sought to understand the increasing *E. coli* sepsis rates in the UK by identifying the prevalence of pathogenic phylogroup B2 *E. coli* strains in the community. We did this by randomly selecting *E. coli* isolates from sewage and comparing prevalence between countries with high and low sepsis rates.

**Materials/methods:** Sewage samples were collected April-June 2019 from Kazakhstan, Saudi Arabia and the UK. Each 30ml sample was collected on entry to a single sewage works that served populations of 200-500 thousand people. Circa 50-100 *E. coli* isolates were randomly picked from well-spaced colonies on UTI brilliance agar plates. A further c. 50 ciprofloxacin resistant and 50 cefotaxime resistant isolates were randomly selected from UTI brilliance plates containing 1mg/L ciprofloxacin and 10mg/L cefotaxime, respectively. Species ID was confirmed by MALDI-TOF-MS. Each isolate was tested for phylogroup by multiplex PCR (Doumith method). Isolates belonging to the pathogenic B2 phylogroup were further identified by a multiplex PCR designed to detect known pathogenic *E. coli* MLST groups.

**Results:** The prevalence of B2 phylogroup *E. coli* strains varied considerably between different countries. Sewage collected from the Qassim region of S. Arabia had the lowest prevalence of B2 strains (2%) as compared to Karaganda, Kazakhstan (13%) and Ponthir, South Wales (43%). This same trend was found with resistant isolates with 66% of ciprofloxacin resistant isolates and 52% of cefotaxime resistant isolates were randomly selected from UTI brilliance plates containing 1mg/L ciprofloxacin and 10mg/L cefotaxime, respectively. Species ID was confirmed by MALDI-TOF-MS. Each isolate was tested for phylogroup by multiplex PCR (Doumith method). Isolates belonging to the pathogenic B2 phylogroup were further identified by a multiplex PCR designed to detect known pathogenic *E. coli* MLST groups. Specific multiplex PCR for known sepsis causing *E. coli* sequence types (ST) identified ST73, ST95 and ST131 isolates from the UK and Kazakhstan but not from Saudi Arabia. These three pathogenic *E. coli* ST accounted for 35% and 9% of all *E. coli* strains carried in the community (80% and 66% of B2 strains) in S. Wales and Karaganda, respectively.

**Conclusions:** The UK *E. coli* sepsis rate is closely related to high carriage rates of pathogenic *E. coli* ST in the community. The rising rate over the last 20 years is most likely explained by increasing prevalence of these strains through time.

Syndromic tests for meningitis: patient screening before testing allows a high efficient medical value

Olivier Dauwalder*1,2, Casalegno Jean-Sebastien1,2, Lamia Chelghoum1, Benoît Visseaux1, Claude-Alexandre Gustave1, Damien Dupont1, Pascale Girardo1, Hélene Salord1,2, Maude Bouscambert-Duchamp1,2, Genevieve Billaud1,2, Marie-Paule Milon1, Gerard Lina1, Florence Morfin1,2, Frédéric Laurent2, Martine Wallon1, Diane Descamps1, Bruno Lina2, François Vandenesch1,2

"Hospices Civils De Lyon - HcI, Plateau de Microbiologie 24/24 - Centre de Biologie et Pathologie Nord, Lyon, France, 2Hospices Civils De Lyon - HcI, Plateau de Microbiologie Moléculaire - Centre de Biologie et Pathologie Nord, Lyon, France, "Bichat-Claude Bernard Hospital, Laboratoire de Virologie, Paris, France"

Background: Evaluation of the impact of the syndromic molecular test Biofire Meningitis / Meningoencephalitis (FAME, bioMérieux) on the diagnosis, the anti-infectious therapy, the para-clinical examinations, the isolation and the project of care of the patient.

Materials/methods: Prospective single-center study (2017-2019) on 149 patients (86♂, 63♀ - mean age 29 years) admitted to the emergency room or intensive care units (pediatric and adult) or in infectious clinical ward for a suspected community-acquired meningitis / meningoencephalitis (MME) and with CSF with more than 9 leukocytes/μL. The FAME was produced 24 hours on 7 and a standardized survey of 44 questions was filled during the telephone communication of the FAME results to the clinicians by the medical biology student (MS Form).

Results: Of 149 patients, 57 and 65 were suspected of bacterial and viral meningitis respectively, and 68 patients had a positive FAME (45%): enterovirus (36), VZV (10), HSV (8), N. meningitidis (3), Streptococcus pneumoniae (3), S. agalactiae (3), Listeria (2), H. influenzae (2). FAME was delivered in 57% and 32% of cases in less than 4 and 8 hours after CSF sampling respectively. 47 and 97 patients were on anti-infectious drugs respectively before and after CSF puncture. In 43%, the FAME help to establish the final diagnosis of meningitis/encephalitis and in 27% to exclude it. FAME modify isolation status for 19% of patients and the care project in 63% of cases with only 7% of "go back home". Antibiotic therapy was affected (addition, dis-continuation, modification) by the FAME in 34% of patients against 23% for antivirals. Finally, in 12 and 8% of cases, the FAME helped to cancel or add additional exams.

Conclusions: Screened according to clinic and biological restrictive criteria, carried out 24 hours a day according to an "emergency" pre-analytical workflow and systematically associated with stewardship, the FAME shows a high positivity rate associated with therapeutic, para-clinical and multiple organizational impacts demonstrating the high medical value of this syndromic molecular test in an emergency context.

Abstract 3070

Exploring the utility of optimised meropenem exposures against carbapenem-resistant Escherichia coli with and without KPC

Chelsea Jones¹, Ellen Kline¹, Alina Iovleva¹, Yohei Doi¹, Ryan Shields*¹

¹University of Pittsburgh, Pittsburgh, United States

Background: The complexity of treating carbapenem-resistant Enterobacteriaceae (CRE) is growing as carbapenemase- and non-carbapenemase-producing isolates are encountered across diverse species. Rates of carbapenem-resistance among Escherichia coli (CREc) are low, but increasing. CREc typically demonstrate meropenem minimum inhibitory concentrations (MICs) ≤8µg/mL suggesting treatment with meropenem may be viable.

Materials/methods: We investigated the killing effects of standard [1g q8h over 30 minutes] and optimized [2g q8h over 3 hours] meropenem regimens in 1-compartment and hollow-fiber (HFIM) infection models using a starting inoculum of 1x10⁶ and 1x10⁸ CFU/mL, respectively. Meropenem exposures were confirmed by LC-MS/MS. Subpopulations were selected by agar plates containing meropenem 4x baseline MIC. Isolates were characterized by whole-genome sequencing.

Results: 29 CREc were screened. Meropenem MICs ranged from 0.12–16µg/mL. 38% produced KPC. 8 isolates were selected for testing (Table). In 1-compartment model, standard dosing resulted in bactericidal killing (>3-log₁₀ CFU/mL) at 72 hours in one isolate [meropenem MIC=1µg/mL, KPC-negative]; regrowth occurred in the remaining 7 isolates. Optimized dosing resulted in bactericidal activity against 3 isolates [all KPC-negative]. Mean log-kills were significantly greater against non-KPC compared to KPC-producing isolates [-3.23 vs. 0.91; P=0.01]. Subpopulations were selected against isolates that produced KPC and demonstrated meropenem MICs ≥2µg/mL; mutant colonies demonstrated 8–64-fold increased MICs. For validation, we tested two isolates (one w/ one w/o KPC; meropenem MIC=4µg/mL for both) over 10 days. Against the non-KPC-producing isolate, regimen was bactericidal. Standard and optimized exposures selected for higher-level resistance at 72 and 96 hours, respectively, meropenem MICs increased 2–4-fold. Against the KPC-producing isolate, higher-level resistance was selected within 12 hours by both regimens; MICs increased 4–16-fold. Interestingly, meropenem-vaborbactam 4g q8h demonstrated rapid bactericidal killing and suppression of resistance against both isolates.

Conclusions: Against CREc, both meropenem MIC and presence of KPC predict in vitro responses to meropenem. For KPC-producing CREc, meropenem was not bactericidal and selected for further resistance despite optimized exposures. For non-KPC-producing CREc, bactericidal killing occurred over 72 hours against isolates with MICs ≤4µg/mL, but resistance emerged after 72 hours in HFIM. These data underscore the role of novel β-lactam/β-lactamase inhibitor combinations for treatment of CREc despite lower meropenem MICs.

Abstract 3077

**Benzofuroxans: discovering new compounds to fight tuberculosis**

Debora Leite Campos*,1, Guilherme Fernandes1, Jean Santos1, Fernando Pavan1

1São Paulo State University (UNESP), Faculty of Pharmaceutical Sciences, Araraquara, Brazil

**Abstract third-party references:** Supported by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP 2018/21778-3 and 2018/00163-0)

**Background:** Tuberculosis (TB), an infectious disease caused by *Mycobacterium tuberculosis*, remains as the world’s leading cause of death from a single infectious pathogen. In 2017, the number of deaths was estimated in 1.3 million. The recommended treatment is becoming increasingly ineffective against the resistant strains. Thus, there is an urgent need to new antimicrobials for TB, that could reduce the duration of treatment, lowering adverse effects and providing a more effective therapy for multidrug-resistant TB.

**Materials/methods:** New benzofuroxan (BZ) compounds were synthesized employing molecular hybridization techniques, using as the base the chemical structure of linezolid and the BZ 8 (C13H9O3N5). The primary analysis was the determination of minimal inhibitory concentration (MIC90), by Resazurin Microtiter Assay (REMA) method using the standard strain H37Rv and clinical isolates. This assay is based on micro dilution in 96-well microplates, ranging the concentration compounds from 0.1 to 25 mg/mL, using a bacterial inoculum concentration of 10⁵ CFU/mL. The microplates are incubated during 7 days and, after that, a solution of resazurin is applied and the fluorescence was read after 24-48 h. The MIC90 is considered the minimal concentration that inhibit 90% of the bacterial inoculum. The cytotoxicity was assessed using lung fibroblasts (MRC-5) and macrophages (J774A.1) seeded in a 96-well cell culture plate. After 24 h the substances were added in concentrations ranging from 0.4 to 100 µg/mL. After 24 h of incubation, resazurin solution was added and the fluorescence measured and determined the half inhibitory concentration (IC50).

**Results:** The results obtained against the standard strain demonstrated the large potential of these compounds, presenting MIC90 values from 0.1 to 3.8 µM. Against clinical strains, the compounds presented MIC90 values ranging from 0.2 to 9.3 µM, an inhibitory potential comparable to standard strain. Cytotoxic effects were observed in MRC-5 above 28.0 µM and in J774A.1 only above 40.8 µM, with selectivity index (SI) (SI=IC50/MIC90) higher than 50 in all cellular types.

**Conclusions:** These results evidenced that the BZ compounds can be considered as promising anti- *M. tuberculosis* agents that, comparing to BZ 8, presented better potential against resistant strains.

**Abstract 3079**

**Bacillus subtilis as a causative of true bacteremia in patients with peritonitis**

Chihiro Sassa*, Kazunari Sonobe¹, Naoya Ichimura¹, Yoshiro Hadano¹, Shuji Tohda²

¹Tokyo Medical and Dental University, Tokyo, Japan

**Background:** Bacillus subtilis is a spore-forming gram-positive rod and found ubiquitously in soil, in air, in human gastrointestinal tracts and others. Because of its high ubiquity and low pathogenicity, *B. subtilis* has been regarded as a culture contaminant and little is known about its bacteremia. Recently, we isolated *B. subtilis* from two of two blood-culture sets and ascites from patient with secondary bacterial peritonitis due to bowel obstruction and perforation. This suggests the possibility of true *B. subtilis* bacteremia.

Therefore, we supposed that true *B. subtilis* bacteremia may be related to intra-abdominal infections and that the number of bacteremia caused by the organism has been underestimated. The aim of this study is to clarify the clinical picture of *B. subtilis* bacteremia and define the significance of *B. subtilis* isolated from blood cultures.

**Materials/methods:** This study was performed at a 750-bed University Hospital in Tokyo, Japan. To compare isolates from blood and ascites of a single patient, we performed multilocus sequence typing (MLST). We analyzed data obtained in our hospital from January 2010 through October 2019 to compare the difference in risk for *B. subtilis* bacteremia between peritonitis and pneumonia patients. We also constructed antibiogram of *B. subtilis* isolated from stool samples. Antimicrobial susceptibility was determined using a fully automated identification/susceptibility test system RAISUS ANY.

**Results:** The strains isolated from different specimens from a patient showed the same MLST sequence type. *B. subtilis* was isolated from multiple sets from 7 out of 831 peritonitis and 6 out of 7612 pneumonia patients, which means the risk for *B. subtilis* bacteremia was about 11 times higher in peritonitis patients. In addition, the organism was isolated from single sets from 12 out of 831 peritonitis and 35 out of 7612 pneumonia patients, which indicates even single positive culture could represent true *B. subtilis* bacteremia in patients with peritonitis. The antibiogram indicates most of the strains were susceptible to major antibiotics.

**Conclusions:** We suggest to consider *B. subtilis* as a causative of true bacteremia when it is isolated from peritonitis patients. *B. subtilis* may therefore be a more important human pathogen than previously thought.

Abstract 3080

Validity of International Classification of Diseases (ICD) for the identification of herpes zoster virus infection requiring hospitalisation
Eve Capistran*, Vincent Morin², Dominique Marcoux³, Sandra Proulx³, Micheline Gagné³, Claire Nour Abou Chakra³, Nicolas Gagnon³, Alex Carignan¹,4

¹Faculté de médecine et des Sciences de la santé, Département de microbiologie et d’infectiologie, Sherbrooke, Canada, ²Faculté de médecine et des Sciences de la santé, Département de médecine interne tronc commun, Sherbrooke, Canada, ³CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada, ⁴CRCHUS, CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada

Background: In Quebec, the provincial administrative database MED-ECHO (Maintenance et exploitation des données pour l’étude de la clientèle hospitalière) is used to assess the burden of hospitalizations related to herpes zoster (HZ) disease. This study aims at determining the positive predictive value (PPV) of primary and secondary HZ diagnosis, as established by MED-ECHO.

Materials/methods: We performed a validity study as part of a retrospective cohort study of all adult (≥ 18 years old) HZ cases hospitalized at the Centre Hospitalier Universitaire de Sherbrooke between 2000 and 2015. The cases were identified using ICD codes from MED-ECHO. The ICD-9 (053.xx) and ICD-10 (B02.x) codes were used to search for hospitalizations due to HZ with or without complications. Potential cases were reviewed to confirm the management of a problem related to HZ during hospitalization.

Results: A total of 1238 hospitalizations (310 as primary diagnosis and 928 as secondary diagnosis) due to HZ with or without complications were identified in MED-ECHO during 2000-2015. Among these, 530 hospitalizations (43%) were due to active disease or a complication related to a recent or previous HZ episode. These hospitalizations were due to active disease at the time of admission (333/530, 63%), HZ that developed during hospitalization (126/530, 24%), or a complication related to a recent or previous HZ episode (e.g., post-herpetic neuralgia; 71/530, 13%). The PPV was significantly higher when HZ was the primary diagnosis (276/310, 89%, 95% CI: 85%-92%) than when HZ was a secondary diagnosis (254/928, 27%, 95% CI: 25%-30%) (p <0.0001). Primary diagnoses were represented mainly by active disease upon admission (231/276, 84%) and complications related to a recent or previous HZ episode (40/276, 15%), and secondary diagnoses by HZ that developed during hospitalization (122/254, 48%) and active disease upon admission (102/254, 40%).

Conclusions: The PPV of ICD codes for HZ disease is high when HZ is the primary diagnosis in the MED-ECHO administrative database. Although its predictive value is lower, it is essential to consider HZ-related ICD codes identified as secondary diagnoses, which accounts for one-third of all active infections, and to adequately assess the burden of hospitalization related to HZ.

Abstract 3083

Usefulness of anaerobic blood culture vials for the microbiological diagnosis of candidaemia
Eric Farfour*, Cécile Le Brun², Assaf Mizrahi³, Thomas Guillard⁴

¹Hôpital Foch, Microbiologie, SURESNES, France, ²CHU de Tours, Microbiologie, Tours, France, ³Hôpital Paris Saint-Joseph, Paris, France, ⁴CHU de Reims, Microbiologie, Reims, France

Abstract third-party references: On behalf of the GMC study group

Background: Despite Candida spp growth in aerobic atmosphere, some clinical strains have been isolated from anaerobic blood culture (BC) vials. We aimed to assess the usefulness of these vials for the diagnosis of Candidemia.

Materials/methods: This retrospective multicentric study was performed by 4 centers between September 1, 2016, and August 31, 2019. A single episode of monomicrobial candidemia per patient and Candida species was included. For each episode, microbiological data of all BC vials sampled within 2 hours before and after the first positive BC vials were recorded, including: i) type of vials; ii) the origin of the sample; iii) result and, for positive vials, iv) Candida species and time-to-positivity (TTP).

The Becton Dickinson and the bioMérieux systems were used by 2 centers each.

Results: 297 episodes of candidemia were included involving 173 (58.2%) C. albicans, 58 (19.5%) C. glabrata, 24 (8.1%), C. parapsilosis, 14 (4.7%) C. tropicalis, 11 (3.7%) C. krusei and 17 (5.8%) others Candida species.

Both aerobic and anaerobic vials were positives in 36 (14.7%) episodes, while only the aerobic or the anaerobic vials were positives in 244 (82.2%) and 17 (5.7%) episodes respectively. All episode with only anaerobic vials positives involved C. glabrata and represents 29.3% of all C. glabrata episodes. This rate was significantly higher for the BD than the bioMérieux systems (39.5% vs 10.0%; P<0.01).

The median TTP was significantly shorter for C. albicans than C. glabrata in aerobic vials (34.0 vs. 67.0; P<0.01). Considering C. glabrata, the median TTP was significantly shorter for anaerobic than aerobic vials (41.0 vs. 67.0; P<0.01). Despite, both devices display similar TTP for C. albicans, median TTP for C. glabrata was shorter using the bioMérieux system for both aerobic (31.2 vs 68.5; P<0.01) and anaerobic vials (17.8 vs 43.0; P<0.01).

Conclusions: The anaerobic vial is essential for the microbiological diagnostic of C. glabrata fungemia mainly when using the BD system. Furthermore, the BioMérieux system seems more accurate for C. glabrata.

Development of a biosensor for the detection of Campylobacter jejuni
Saeed Shams1*, Bita Bakhshi2, Tahereh Tohidi Moghadam3

1Qom University of Medical Sciences and Health Services, Cellular and Molecular Research Center, Qom, Iran, 2Tarbiat Modares University, Department of Bacteriology, Faculty of Medical Sciences, Tehran, Iran, 3Tarbiat Modares University, Department of Nanobiotechnology, Faculty of Biological Sciences, Tehran, Iran

Abstract third-party references: This project is supported by Tarbiat Modares University, Tehran, Iran.

Background: C. jejuni is an important human pathogen and causing campylobacteriosis which is known as diarrheal disease worldwide. Due to fastidious growth requirements, the isolation of the bacterium is not routinely done in many clinical laboratories. Most methods including culture, biochemical tests, serological and molecular assays are time-consuming, high costs and variable sensitivity in results. The aim of this study was to design a biosensor using the plasmonic properties of gold nanorods in the detection of campylobacteriosis.

Materials/methods: By evaluating different studies, cadF gene was selected as the target gene. Using bioinformatics tools such as CLC Sequence Viewer 7.6 software, GeneRunner, NCBI, etc, a C. jejuni-specific part of the cadF gene (44 bp) was specified and two probes were designed on this fragment. Gold nanoparticles were synthesis according to seed-mediated growth protocol and then characterized using UV-vis, zeta potential, FT-IR, and transmission electron microscopy. Then, probes were conjugated with nanoparticles to produce nanoprobes. To confirm nanoprobes, all the above-mentioned assays were performed again. The system was evaluated on 50 fecal specimens previously tested as positive for C. jejuni DNA by real-time PCR. Finally, limits of detection (LOD), sensitivity, specificity, and turnaround time of the assay were done using the standard strains of Campylobacter spp. and other intestinal bacteria.

Results: The theoretical assessments of the selected fragment showed that it was highly conserved among C. jejuni. In addition, probes were completely specific and no significant matches to other bacteria genome sequences were seen. The plasmonic evaluation of the nanoparticles and nanoprobes using UV-vis and other methods showed that they were synthesized as rod-shaped nanostructures (~32×~11 nm) and were correctly conjugated with probes. Comparison with real-time PCR results on clinical samples, the sensitivity of the biosensor was 88% (44/50 cases). The specificity of the assay was 100% and plasmonic changes were detected only for C. jejuni. The limit of detection biosensor (10^2 copies) was identified. The result was obtained about 5 min for each test.

Conclusions: Due to acceptable specificity and sensitivity, speed, and simplicity, the biosensor could be applied as a new diagnostic tool in the clinical diagnostics.

Presenter email address: sshamsmed@gmail.com
Background: Thailand is classified as a high tuberculosis-burden country with 156 cases per 100,000 population in 2018. Reported cases of tuberculosis among prisoners may account for 30% of tuberculosis with an incidence of 880-5,803 cases per 100,000 inmates in low- to middle-income countries. Beginning in 2017, an active case–finding strategy for tuberculosis was implemented in all prisons in Thailand. Mass chest radiograph screening is performed in all prisoners to identify and bring into treatment tuberculosis cases as soon as possible.

Materials/methods: A retrospective descriptive study was conducted at Songkhla provincial hospital between 2016 and 2019. Inmates of four prisons in Songkhla Province were assessed by tuberculosis screening using mass chest radiographs from 2017. If abnormal chest radiography revealed compatibility with tuberculosis, sputum microscopy and sputum GeneXpert were performed. Data were analyzed using descriptive statistics.

Results: After implementing the active case-finding strategy in 2017, the incidence of tuberculosis in prisons rose from 739 cases per 100,000 inmates in 2016 to 1,548 in 2017, 1,882 in 2018, and 3,694 per 100,000 inmates in 2019. The tuberculosis cases in the prisons accounted for 5% in 2016 and continued to rise to 20% in 2019 of all tuberculosis cases in Songkhla Province. Furthermore, sputum microscopy or GeneXpert detected tuberculosis positive between 10% and 16% of all tuberculosis cases in the four prisons. The rates of treatment success were 90%-94% and the case fatality rates were 11-58 cases per 100,000 inmates at the four prisons.

Conclusions: The active case-finding strategy using mass chest radiography increases the early detection of tuberculosis cases in prisons. Prisoners are at a high risk for tuberculosis infection due to multiple factors such as overcrowding, poor ventilation, poor nourishment, and repeated prison transfers that encourage the transmission of tuberculosis infection. A recent TB infection can cause active disease in two years. Thus, early recognition of active tuberculosis using mass chest radiography can reduce further transmission of infection.

Treatment of hepatitis C with direct-acting antiviral (DAA) agents: sustained virological response rate in a real care setting in the state of Ceará, north-eastern Brazil

Roberto Da Justa Pires Neto1,2,3, Elodie Bomfim Hyppolito2,3,4,5, José Milton De Castro Lima6, Érico Antonio Gomes De Arruda3,4,7, Francisco Sérgio Rangel De Paula Pessoa8

1Federal University of Ceará - Campus Porangabuçu, Department of Community Health, Faculty of Medicine, Fortaleza, Brazil, 2Federal University of Ceará - Campus Porangabuçu, Pós-Graduação em Saúde Pública, Fortaleza, Brazil, 3Hospital São José de Doenças Infecciosas (HSJ), Fortaleza, Brazil, 4UNIFOR - Universidade de Fortaleza, Fortaleza, Brazil, 5EBSERH - Hospital Universitário Walter Cantídio, Fortaleza, Brazil, 6Federal University of Ceará - Campus Porangabuçu, Department of Internal Medicine, Fortaleza, Brazil, 7Ceará State University - Itaperi Campus, Medicine School, Fortaleza, Brazil, 8Hospital Geral De Fortaleza, Fortaleza, Brazil

Background: Hepatitis C affects 0.8% of the Brazilian population and is the leading cause of liver transplantation and hepatocarcinoma. The Brazilian public health system has provided treatment with direct-acting antiviral (DAA) agents since October 2015. This study aims to analyze sustained virological response (SVR) in patients with chronic hepatitis C treated with DAA in the state of Ceará, northeast of Brazil.

Materials/methods: Medical records of hepatitis C patients treated with DAA from October 2015 to March 2019 were reviewed. Only patients with chronic hepatitis C over 18 years old, and without previous treatment with DAA were analyzed. The treatments were prescribed according to the recommendations of the Brazilian Ministry of Health. SVR was defined as undetectable hepatitis C virus viral load after three months of treatment completion.

Results: A total of 654 patients with a mean age of 57.4 years (SD ± 3.5) were included, 403 (61.6%) men, and 303 (46.3%) cirrhotics. Overall, 625 (95.5%) achieved SVR. When analyzing SVR for different treatments, SVR was achieved in 92.8% of patients treated with sofosbuvir + daclatasvir (n = 197), 95.5% with sofosbuvir + daclatasvir + ribavirin (n = 290), 99% with sofosbuvir + simeprevir (n = 107), 96.1% with sofosbuvir + simeprevir + ribavirin (n = 25), 100% with ombitasvir + paritaprevir + dasabuvir + ritonavir with or without ribavirin (n = 21). SVR was achieved in more than 95% of patients with genotypes 1A, 1B, and 3. SVR was achieved in over 95% of patients in special situations such as cirrhosis, HBV coinfection, HIV coinfection and liver transplantation.

Conclusions: SVR was obtained in more than 95% of patients with hepatitis C treated with DAA in a setting of real care practice in the state of Ceará, northeast Brazil. SVR rates were high even among patients with cirrhosis, HBV coinfection, HIV coinfection and liver transplantation.

Abstract 3088

**SUSANA project: real-world data coming from the use of new antimicrobial drugs**

Paolo Bonfanti1*, Elena Ricci2, Alessandro Pandolfo1, Filippo Baragli3, Marco Merli4, Davide Lo Porto5, Sara Benedetti6, Nicholas Geremia7, Lorenzo Sanna8, Goffredo Angioni9, Katia Falasca10, Ilaria Caramma11, Alessandra Bandera2, Nicola Squillace7, Paola Maggi1, Anna Spolti11, Francesca Vichi3, Massimo Puoti4, Antonio Cascio5, Giuseppe De Socio6, Paolo Viganò10, Giordano Madeddu13, Francesco Luzzaro14

1*A.Manzoni Hospital*, ASST Lecco, Lecco, Italy, 2Fondazione IRCCS Ca’Granda, Ospedale Maggiore Policlinico, Milan, Italy, 3Santa Maria Annunziata Hospital, Firenze, Italy, 4AO Ospedale Niguarda Cà Granda, Milan, Italy, 5Policlinico “F.Giaccio”, University of Palermo, Palermo, Italy, 6Santa Maria Hospital, Perugia, Italy, 7Department of Medical, Surgical and Experimental Sciences, University of Sassari, Sassari, Italy, 8SS Trinità Hospital, Cagliari, Italy, 9University of Chieti, Chieti, Italy, 10Legnano Hospital, ASST Ovest Milanese, Legnano, Italy, 11S. Gerardo de’ Tintori Hospital, ASST Monza, Monza, Italy, 12University of Campania “Luigi Vanvitelli”, Napoli, Italy, 13Department of Medical, Surgical and Experimental Sciences, University of Sassari, Sassari, Italy, 14A. Manzoni Hospital, ASST Lecco, Lecco, Italy

**Background:** Although randomized clinical trials are considered the standard criterion for generating clinical evidence, real-world evidence evaluating efficacy and safety of new drugs is essential to improve their use. We present the preliminary data from the SUSANA Project, a study designed to evaluate the safety of new antibiotics in the real life.

**Materials/methods:** This observational retrospective study started on April 2019 in a network of Italian Infectious Diseases Units. Patients treated with ceftazidime/avibactam, ceftolozane/tazobactam, dalbavancin, and fosfomycin e.v. were included. Primary objective was the surveillance of adverse events (AE), to evaluate their frequency, type and severity. Secondarily, we aimed at investigating factors associated with AE onset. Causality was evaluated according to Jones’ algorithm.

**Results:** The study started on April 2019. To date, 40 patients entered the study (33% women). Mean age was 64.1 (range 18-89). Infection site was skin (14), breathing apparatus (7), genitourinary tract (7), osteoarticular tissue (6), abdomen (5), cardiovascular system (5), CNS (1), other or unidentified (5). Infection was at multiple sites in 7 cases. Antibiotic treatment was empirical in 13 (32.5%) patients. Fifteen subjects received ceftazidime/avibactam (6 with fosfomycin), 7 ceftolozane/tazobactam (1+fosfomycin, 12 dalbavancin (1+fosfomycin, 1+ceftolozane/tazobactam) and 6 fosfomycin. Ten patients (25%) suffered from at least 1 AE: 3 patients on ceftazidime/avibactam + fosfomycin had multi-organ failure (remote causality); 1 subject on ceftazidime/avibactam presented a skin rash (probable causality) and 1 had vomiting and peripheral ischemia (both remote causality); among 10 on dalbavancin alone, 1 had diarrhea and 1 limbs edema (both possible causality); 1 patient on fosfomycin alone had hyponatremia (remote causality). One patient on ceftolozane/tazobactam + fosfomycin presented hypernatremia (highly probable causality), atrial fibrillation, myocardial infarction, and intestinal stoma obstruction (all remote causality). Outcome was known for 32 patients: infection relapsed in 5 of them, 23 recovered, 1 interrupted an empiric treatment, 3 died because of multiorgan failure.

**Conclusions:** Preliminary results of the SUSANA project show a high prevalence of AE in patients treated with the antimicrobials evaluated. However, most of them had low relationship of causality with the drugs and were probably related to the clinical evolution of the primary conditions.

How to screen OXA-244, a difficult to detect emerging OXA-48 variant?

**Background:** OXA-244, a single-point mutation variant of OXA-48, possesses a weaker hydrolytic activity towards carbapenems and temocillin compared with OXA-48. Of note, these molecules are present at high concentrations in several screening culture media used for the detection of carbapenemase-producing Enterobacteriaceae (CPEs). Thus, it has been reported that OXA-244-producers often do not grow on screening media. Unfortunately, the prevalence of OXA-244-producers is constantly increasing in France. Indeed, the number of OXA-244-producers received at the French National Reference Center (F-NRC) for CPEs rose from 7 (0.6% of all CPE) in 2015 to 44 (3.2%) in 2019, with a majority of *E. coli* (96%). Therefore, it is crucial to detect them accurately in order to avoid their massive dissemination.

**Materials/methods:** Here, we evaluate the performances of 3 commercially available CPE screening media for their ability to detect OXA-244-producers: chromiD CARBA SMART (bioMérieux), Brilliance CRE (Thermofisher), and mSuperCARBA (MAST Diagnostic). Since most OXA-244-producers expressed an ESBL, two additional ESBL screening media were also tested: Brilliance BLSE and ChromiD ESBL. MICs of temocillin and imipenem were performed by broth microdilution. The clonality of OXA-244-producing *E. coli* (*n* = 42) was assessed by MLST (S, 32 and 5 in 2017, 2018 and 2019, respectively).

**Results:** Overall, the sensitivity of the ChromiD CARBA SMART, Brilliance CRE and mSuperCARBA media were respectively 13% (IC95=7.4-21.2%), 53% (IC95=42.8-62.9%) and 99% (IC95=93.4-100%) for the detection of OXA-244-producers. Among the 100 OXA-244-producing strains, 76% grew on ESBL screening medium. MLST analysis identified two major STs in OXA-244-producing *E. coli* (*n* = 42) as ST-38 (n = 13) and ST-361 (n = 9).

**Conclusions:** Our results confirmed that ChromiD CARBA SMART medium is inefficient to detect OXA-244-producers. At the opposite, OXA-244-producers perfectly grow on the mSuperCARBA medium. The huge prevalence of ESBL in OXA-244-producer allow to detect 76% of them on ESBL screening media.

Accordingly, a positive signal for *bla*OXA-48 using molecular method directly from rectal swab sample but with no growth on ChromiD CARBA SMART or Brilliance CRE might be an OXA-244 producer. Therefore, inoculation of mSuperCARBA medium might be of interest to cultivate this CPE.

Darunavir/cobicistat monotherapy as simplification strategy for HIV patients: a retrospective Multi-centre Spanish Study (DRV-simply)

Alexy Inciarte Portillo, Jose Ignacio Bernardino, Alvaro Mena De Cea, Rafael Mican Rivera, Dueñas Carlos, Coral García-Vallecillos, Pilar Callau, María De Los Angeles Castro Iglesias, Juan Pasquau, Esteban Martinez, Jose Luis Blanco

1Hospital Clinic of Barcelona, Barcelona, Spain, 2Institute of Biomedical Research August Pi i Sunyer, Barcelona, Spain, 3Universidad de Barcelona, Barcelona, Spain, 4University Hospital La Paz, Madrid, Spain, 5Complexo Hospitalario Universitario A Coruña, Coruña, Spain, 6University Clinical Hospital of Valladolid, Valladolid, Spain, 7Virgen De Las Nieves, Granada, Spain

Abstract third-party references: Hospital Clinic de Barcelona, Barcelona Spain., Universidad de Barcelona. Barcelona Spain, Hospital Universitario Virgen de las Nieves. Hospital General, Granada, Spain., Hospital Universitario La Paz, Madrid Spain., Hospital del Norte. Tenerife Spain., IDIBAPS. Barcelona Spain.

Background: Darunavir 800mg plus ritonavir 100mg (DRV/r) monotherapy has been a has proved to be an interesting reverse transcriptase inhibitor (NRTI)-sparing simplification strategy recommended in selected patients in some European guidelines in the past and still used in some patients. Darunavir/cobicistat 800/150mg (DRV/c) is bioequivalent to and simpler than DRV/r as it is co-formulated. For these reasons, DRV/c has widely replaced DRV/r in Spain. Because DRV/c has a 25% lower trough levels than DRV/r, the efficacy and safety of switching to DRV/c monotherapy is unclear.

Materials/methods: A multicenter retrospective-longitudinal study was performed from September 2015 to December 2017 in all HIV-adult participants with at least prior 24 weeks of HIV-1 RNA<50 copies/ml who switched to DRV/c. Primary end-point was the percentage of patients with ≥ 50 copies/mL at 48 weeks. Secondary endpoints were virological success, side-effects and CD4, lipid, and creatinine changes.

Results: 530 patients were included in this study. Median (IQR) age, treatment duration and previous treatments were: 50 years (47–55), 12 months (9–15), and 6 (4-9), respectively. Median nadir and baseline CD4+ T-cell counts were 216 (126–343) and 695 (538–866) cells/mm3, respectively. Previous treatments were PI monotherapy 91% (71% of them DRV/r) and 9% dual or triple therapy. At 48 weeks, percentage of patients with ≥ 50 copies/mL was 78 (14.7%): 61 (11.5%) discontinued treatment for non-virological reasons, 7 (1.3%) developed VF (none of them selected any DRV-resistance associated mutations (RAM) and all were re-suppressed with a dual-triple DRV/c-containing regimen) and 10 (1.9) had blip. Median CD4/CD8 ratio was 1.01 at baseline and 1.00 at week 48 (p=0.450). Median triglycerides levels decreased from 167 mg/dL to 151 mg/dL (p =0.0001) and HDL increased 1.5 mg/dl from baseline to 48 weeks. Creatinine plasma levels increased from 0,79 mg/dL at baseline to 0,86 mg/dL at 48 weeks (p =0.001). No significant differences in LDL and total Cholesterol levels.

Conclusions: Switching to DRV/c monotherapy from DRV/r was safe and effective in virologically suppressed HIV-infected patients.

**Abstract 3096**

**Clinical characteristics and outcome of bloodstream infections in HIV-infected patients with febrile neutropenia: A case-control study.**

Pedro Puerta*1, Juan Ambrosioni1, Marta Hernández-Meneses1, Celia Cardozo1, Mariana Chumbita1, Estela Moreno1, Nicole García-Pouton1, Francesc Marco Reverte1, José Mensa1, Montserrat Rovira1, Jordi Esteve3, Alex Soriano1, Carolina García Vidal1, José M. Miró Meda1

1Hospital Clinic de Barcelona, Infectious Diseases Department, Barcelona, Spain, 2Hospital Clinic de Barcelona, Microbiology Department, Barcelona, Spain, 3Hospital Clinic de Barcelona, Hematology Department, Barcelona, Spain

**Background:** We aimed to compare the clinical characteristics and outcomes of bloodstream infections (BSI) in febrile neutropenic patients (FNP) with and without HIV infection, and to analyze the prognostic factors for mortality.

**Materials/methods:** All episodes of BSI in FNP were prospectively collected (1997-2018). A case (HIV-infected) – control (non-HIV-infected) sub-analysis was performed with a ratio of 1:2, matching the patients for age, gender, baseline disease and etiological microorganism. Factors associated with 30-day mortality in the overall and case-control cohorts were assessed using logistic regression models.

**Results:** Among 1,756 BSI episodes in FNP, 60 (3.4%) occurred in HIV-infected patients. In those, most prevalent risk behavior was that of men who had sex with men (51.7%); 58.3% had CD4 <200 cells/mm3; 51.7% had a positive HIV-1 RNA viral load before the episode; and 70% met AIDS-defining criteria. Most patients (93.3%) were taking antiretroviral therapy (ART) at the time of the BSI, with a protease inhibitor-based ART being the most common regimen (53%). Overall, HIV-infected patients were younger, more frequently male and more commonly presenting chronic liver disease (p<0.001 for all). Conversely, HIV-infected patients received significantly less hematopoietic stem cell transplantation (HSCT) (p<0.001). No differences in the source of infection or proportion of patients with severe neutropenia (<100 cells/mm3) were detected. BSI due to Enterococcus spp. was significantly more frequent among HIV-infected patients (p=0.017) with no differences in other pathogens. Finally, HIV-infected patients presented with shock more frequently (p=0.014) and experienced higher mortality (31.7% vs. 18.1%, p=0.008). However, in multivariate analysis, HIV infection was not an independent risk factor for mortality. When comparing the case-control cohort, cases (HIV-infected) had chronic liver disease (p=0.003) more frequently, while acute leukemia (p=0.13) and HSCT (p=0.23) were more frequent among controls (non-HIV). Cases had a non-significant trend towards receiving inappropriate empirical antibiotic treatment (p=0.206), presenting with shock (p=0.105) and having higher mortality (p=0.084). However, in multivariate analysis, HIV infection was not associated to mortality.

**Conclusions:** FNP with HIV infection presenting BSI have different epidemiological and clinical profile and had higher mortality. However, HIV infection by itself was not associated with mortality, neither overall nor within the case-control cohorts.

Abstract 3097

**Laboratory productivity index and efficiency gains at 3 benchmark BD Kiestra TLA sites**

Krešimir Renić, Katja Lehmann*

1BD, Mississauga, Canada

Abstract third-party references: On behalf of Krešimir Renić, P.Eng. Lean Healthcare Consultant, Supported by Becton Dickinson

Background: Microbiology labs face many challenges including increasing sample volumes, cost containment pressures and staff shortages. Institutions respond by consolidating and automating processes to improve efficiency, quality and cost-effectiveness. This abstract describes a summary of efficiency gains realized through the combination of BD Kiestra™ Total Lab Automation (TLA) technology and Lean process improvements at three benchmark sites.

Materials/methods: A metric known as Laboratory Productivity Index (LPI) was used to measure the capacity of laboratory staff to process microbiological specimens. LPI is the ratio of specimens processed per day divided by the combined fulltime equivalent (FTE) of in-scope staff. In-scope labor is the proportion of FTE involved in the processing of specimens prior to and after incubation. Average daily specimen volumes for each of the benchmark sites were respectively calculated using LIS data from two-week periods with high specimen volumes relative to other periods throughout the year. In-scope FTE was established based on in-lab workflow observation prior to and following lab training and TLA go-live.

The average weekday specimen volume (\(Vol_{avg}\)) and the in-scope FTE were used as the numerator and denominator respectively to calculate the pre-and-post automation LPI. Post-automation LPI was validated using anonymized instrument data.

Results: In a non-automated lab, an LPI under 20 is typical. Pre-automation LPI values were captured at each benchmark site through MPD™ Lean & Automation Impact Assessment (AIA) engagements. Post-automation LPI values were calculated through BD Kiestra System Performance data in June 2019.

The three benchmark BD Kiestra TLA labs improved LPI by 2.9 – 4.2× compared to pre-automation; LPI increased from:

- 16.7 to 48.8 – benchmark site 1
- 14.8 to 63.5 – benchmark site 2
- 19 to 65.6 – benchmark site 3

Conclusions: The combination of BD Kiestra technology and Lean process improvement consulting can significantly improve lab productivity while reducing turn-around time in a consolidated testing environment.

Abstract 3099

Discordant *Clostridioides difficile* diagnostic assay and treatment practice: a retrospective observational study

Lauriane Lenggenhager*1, Marie-Céline Zanella1, Antoine Poncelet2, Laurent Kaiser3, Jacques Schrenzel1

1Geneva University Hospitals, Laboratory of Bacteriology, Division of Laboratory Medicine and Division of Infectious Diseases, Genève, Switzerland, 2Geneva University Hospitals, Division of Clinical Epidemiology, Genève, Switzerland, 3Geneva University Hospitals, Laboratory of Virology, Division of Laboratory Medicine and Division of Infectious Diseases, Geneva, Switzerland

**Background:** *Clostridioides difficile* infection (CDI) diagnosis relies on multiple-step algorithms and the decision to treat patients with discordant results is determined by individual clinical evaluation. We aim to determine the proportion of patients with discordant test results who received a treatment for *Clostridioides difficile* infection (CDI) and to identify patient characteristics associated with the decision to treat CDI.

**Materials/methods:** Retrospective and observational study of all adult patients with *C. difficile* discordant test results (positive nucleic acid amplification test [NAAT+]/negative enzyme immunoassay [EIA-]) between March 2017 and March 2019. A multiple, stepwise, backward logistic regression model was used to determine the association of nine patient characteristics with treatment introduction, including risk factors for CDI.

**Results:** Among 4562 adult patients tested for *C. difficile* between March 2017 and March 2019, 239 patients with discordant test results (positive nucleic acid amplification test [NAAT+]/negative enzyme immunoassay [EIA-]) were included. CDI treatment was administered in 147/208 (71%) cases. In multivariate analysis, the presence an abdominal computed tomography (CT) scan with signs of colitis (OR 14.7; 95% CI 1.96 to 110.8) was independently associated with CDI treatment.

**Conclusions:** The proportion of NAAT+/EIA- patients who received treatment questions the contribution of the EIA for the detection of toxin A/B after NAAT to limit overtreatment. Additional studies are needed to investigate if other factors are associated with the decision to treat.

Abstract 3101

Identified beta-lactamase genes in *Aeromonas* species: an experience from Qatar

Ahmed Husain*1, Sini Skariah2, Mazen Sid Ahmed1, Mohamed Badawi1, Hasan Ahmedullah1, Muna Al-Maslamani1, Abdullatif Al-Khal1, Hussam Al Soub1, Ali A Sultan1, Emad Ibrahim1, Hisahm Ziglam1

1Hamad Medical Corporation, Doha, Qatar, 2Weill Cornell Medicine-Qatar, Doha, Qatar

**Background:** *Aeromonas spp.* are ubiquitous aquatic organisms, associated with multitude of diseases in several species of animals, including fishes and human. They were resistant to frequently used antibiotics for human infections. We aim to explore the genes responsible for β-lactamase enzymes in *Aeromonas*.

**Materials/methods:** Thirty-five preserved *Aeromonas* positive blood cultures between 2012 and 2016 were identified at Hamad General hospital laboratory department (State of Qatar). *Aeromonas* species and sensitivity were identified by BD Phoenix. Sixteen isolates were revived successfully, out of which 10 isolates underwent whole-genome sequencing. Two separate databases were used for antibiotic resistance gene finding: CARB and Resfinder.

**Results:** *Aeromonas hydrophila* was the most identified species (4/10). Followed by *Aeromonas veronii* and *Aeromonas sobria*, (3/10) and (2/10) respectively. *Aeromonas caviae* was found in one isolate.

All isolates were resistant to Ampicillin but susceptible to Ceftazidime, Cefepime, and Meropenem. 90% of isolates remain susceptible to Amoxicillin-clavulanate. Cefuroxime was sensitive in 50% of isolates while ceftriaxone was sensitive in 90% of the isolates.

The majority of isolates possess OXA-12 [9/10]. CphA7 gene was found in six isolates. Other identified genes are cphA3 (3/10), AOU-3 [2/10], DHA-17 [2/10], Escherichia coli ampH beta-lactamase [1/10], and ACT-2 [1/10] (Figure 1).

**Conclusions:** *Aeromonas* species possess different β-Lactamase genes. The most common genes are OXA-12 and CphA7. Cefazidime, fourth-generation cephalosporins and carbapenems (Meropenem) remain reasonable options for empiric therapy in bacteremic patients till final culture susceptibility result for other antibiotics is identified.

**Figure 1. Resistance genes distribution**

Abstract 3103

High-resolution mapping reveals emergence and autochthonous transmission of dengue fever outbreak in a previously low-epidemic region in south-east China, 2019

Yi Zhang*1, Jingwen Ai2, Wenhong Zhang2

1Huashan Hospital Affiliated to Fudan University, Shanghai, China

Background: Dengue fever is a mosquito-borne febrile illness affecting more than 100 countries in tropical and subtropical areas. South-east Asia is facing horrible dengue outbreak this year and over 1000 cases have been reported in Jiangxi, a low-epidemic region in China. We performed this study to investigate the origin and driving force of Jiangxi dengue outbreak.

Materials/methods: We recruited clinically or laboratory diagnosed dengue infections from Nanchang ninth Hospital, Zhangshu People’s Hospital, Fengcheng People’s Hospital and Nanchang Xian People’s Hospital in Jiangxi Province, China, from April 2019 to September 2019. Blood samples were collected from those who gave consents. We performed real-time PCR with specific probe and calculated relative quantification copies. 14 samples from Jiangxi with relatively higher viral copies and 2 samples retrieved from Huashan Hospital were prepared for high-throughput sequencing. A total of 61 complete dengue virus genomes including nucleotide and accordingly amino acid sequences were downloaded from NCBI database to analyze.

Results: A total of 154 patients were enrolled in the study and 113 blood samples from 91 patients received real-time PCR test. Among enrolled patients, 42 cases were identified as overseas inputs and the majority of which came from Cambodia. No severe cases were reported. In 113 samples, 106 were classified as DENV-1, 2 were identified DENV-2 and 5 were negative. 16 DENV-1 genomes sequenced in this study were in high similarity with Cambodia stains and other south-east Asia strains. 114 SNPs were detected among 16 strains, revealing genome changes of strains among Nanchang, Zhangshu and Fengcheng. A total of 20 non-synonymous mutations were detected in 16 strains, indicating fast variation throughout transmission. Geographic and temporal analysis based on sequenced data identified transmission events of DENV-1 resulting long-term establishment of epidemic situation in south-east Asia and southern China.

Conclusions: This epidemiologic study demonstrated this dengue fever outbreak in Jiangxi originated from input cases from Cambodia. New air line from Nanchang to Cambodia brought dengue emergence and autochthons transmission to different cities in Jiangxi. Not only epidemic places, any place with travelers from epidemic areas should emphasize the prevention and control of dengue fever in the future.

Abstract 3104

**Should Chlamydia trachomatis be part of migrant screening?**

Marion Bonneton*1, Laure Surgers1, Valerie Lalande1, Nadia Valin1, Karine Lacombe1

1Hôpital Saint Antoine, AP-HP, Paris, France

**Background:** With 22.3 billion migrants living in Europe in 2018, migrant’s health is becoming a major public health issue. Europe is presently reflecting upon the best strategy for sexually transmitted infections (STI) screening in migrants. Yet, there are few data about *Chlamydia trachomatis (CT)* prevalence among this population. The main objective of our study is to evaluate *CT* prevalence in asymptomatic migrants consulting in STIs clinics then to identify risks factors associated to *CT* infections.

**Materials/methods:** All asymptomatic individuals over 18 years of age attending a STIs free clinic in Paris from 01/2017-12/2018 were eligible. They were screened for *CT* in urinary, vaginal, oral, rectal samples according to gender and sexual behaviors. Non-migrants were individuals born in France, newly arrived migrants had migrated to France within the past year, and long-term migrants had migrated more than a year ago. Prevalence were estimated and adjusted OR (aOR) were calculated using logistic regression.

**Results:** During the study period 5959 individuals attended the STIs free clinic. A total of 4948 were retained in the analysis, including 771 (16%) migrants. *CT* prevalences were: 7.7% (n=41) in long term migrants, 5.9% (n=14) in newly arrived migrants and 5.1% (n=212) in non-migrants. Compared with non-migrants, the risk of *CT* infections in migrants was higher in newly arrived and long-term migrants, aOR=2.50 [95% CI 1.19-5.24] and aOR=2.04 [95% CI 1.43-2.93]. Other factors associated with *CT* infections were: number of sexual partners in the last year [aOR=1.51 [95% IC 1.06-2.17] for 6-10 and aOR=2.47 [95% IC 1.44-4.23] for >10 partners], sexual orientation [aOR=0.26 [95% IC 0.14-0.48] for men having sex with men], age [aOR=4.48 [95% IC 2.35-8.56] for <35 years of age] and gender [aOR=1.72 [95% IC 1.32-2.22] for women].

**Conclusions:** Our study suggests that *CT* screening should be recommended in all migrants. Yet, *CT* screening is currently not recommended in migrants neither in the French guidelines nor in the European Center for Disease Prevention and Control (ECDC) guidelines on newly arrived migrants.

Abstract 3106

 Artificial intelligence and automation of microbiology: the urinalysis 3.0

Agathe Michel1, Cécile Eymard1, Kevin Santos1, Laura Chanel1, Anatole Luzzati1, Pablo Roy-Azcorra2, Jean Francois Sauzon1, Marc Guillaumont1, Geoffrey Pipaud3, Pascale Girardo1, Fuhrmann Christine1, Gerard Lina1, Frédéric Laurent1, François Vandenesch1, Chantal Roure-Sobas1, Olivier Dauwalder*1

1Hospices Civils De Lyon - Hcl, Plateau de microbiologie 24/24 - Centre de Biologie et Pathologie Nord, Lyon, France, 2Hospices Civils De Lyon - Hcl, PAM Biologie - LBMMS - Centre de Biologie et Pathologie Nord, Lyon, France, 3Mips France, Vincennes, France

Background: Design, evaluation and implementation of an artificial intelligence (AI) system PhenoMATRIX ™ (PNMX) for the automated interpretation of urine analysis (UA).

Materials/methods: The interpretation of UA needs i) clinical signs (fever, clinical signs of urinary tract infection, pregnancy) collected since the connected prescription (Easily, HCL); ii) population and hospitalization data from the laboratory informatics system (LIS, GLIMS, MIPS); (iii) cytology derived from urinary cytology machines (UF1000i®, Sysmex) or manually entered in the LIS; and iv) prior anteriories (antibiotic susceptibility testing (AST) <7 days). Based on the chromogenic medium (CHROMID®CPSE, bioMérieux), the PNMX IA integrates algorithms applied to images produced by WASPLab® systems (Copan) and synthesizes with the data from the third party systems [see above]. During the design, 3 decision trees (mid-jet ECBU, catheter, stoma) were constructed by the laboratory team to describe the reading and interpretative workflow (MS Visio). The PNMX IA was then coded in the system and evaluated using a previously obtained collection of 4802, 957 and 97 images of UA mid-jet, by catheter and stoma respectively. The PNMX IA data was compared to the manual-acquired Data (MAD) by laboratory technicians. For the mid jet UA, a second version of the decisional tree was carried out then evaluated on an additional collection of 2131 images. In case of discrepancy between the two methods, the images were reviewed by 4 TLBMs and 1 medical microbiologist and reclassified on the basis of previously established standard operative procedures (SOP) and decision trees.

Results: The performance data are presented in Table 1. The categorization errors between identification (ID) versus ID + AST are defined as minor. Are defined as major, the categorization errors between contaminated UA/non-significant culture urine versus ID or ID/AST.

Conclusions: The PNMX IA applied to UA has a high performance level (=91%). In just a few clicks, a large number of urines are quickly, securely, reproducibly and faithful to the laboratory interpretation thanks to the large number of data collected, including clinic signs provided by the connected prescription.

Adherence to antibiotic guidelines at a Danish university hospital, a quantitative and qualitative prospective study
Peter Frimand Kiel Rasmussen*, Signe Sørensen¹, Lone Mygind²

¹Aalborg University Hospital, Aalborg, Denmark

Background: Both government and local committees publish antibiotic guidelines, but less is known about adherence. This study aims to examine guideline adherence in a low resistance area as Denmark and factors influencing doctors’ antibiotic prescriptions.

Materials/methods: The study was conducted at the inpatient emergency medical department of Aalborg University Hospital. All patients 18 years or older, who had systemic antibiotics prescribed within their 24 hours of admission, from 1 September through 31 December 2018 were included. Age, gender, allergy, nursing home, reduced kidney function, chronic obstructive pulmonary disease (COPD), blood culture, tentative diagnosis, prescription was done by doctor from department of infectious diseases (ID) or clinical microbiology (CM). Interviews using semi-open and rubricated questions were conducted with both junior and special doctors.

Results: 952 were included (median 70 years, 28.9% had COPD, 17.5% prescriptions by ID/CM doctor). 80.2% of the patients received tentative diagnoses: most often acute exacerbation of COPD 21.2%, pneumonia 20.6% and urinary tract infection 12.5%. The most prescribed antibiotic was piperacillin/tazobactam 16.9%, amoxicillin/clavulanic 16.4%, penicillin 14.8%, gentamicin 13.1% and ampicillin 9.6%. Blood culture was taken on 70.7% of patients.

Overall guideline adherence therapy was 59.8%. 763 patients were treated under a diagnosis and 70.3% of them received guideline adherent therapy. Significant higher guideline adherence was also found among patients with acute exacerbation of COPD (p-value 0.000), erysipelas (p-value 0.000), febrile neutropenia (p-value 0.016), reduced kidney function (p-value 0.003) and the prescriptions were made by ID/CM doctor (p-value 0.000).

24 interviews were conducted with: 1 medical student, 20 junior doctors, 3 special doctors. 75.0% stated they had problems finding the desired guideline. 62.5% stated education to increase adherence. 33.3% wanted to change electronic to printed guideline.

Conclusions: We report guideline adherence in 59.8% of the antimicrobial prescriptions at the inpatient emergency medical department of Aalborg University Hospital. A tentative diagnosis showed a higher adherence on 70.3%. 62.5% of the doctors stated education, on both junior and senior doctors, as most important focus area as the doctors answered, that if they experience discrepancy between a guideline and advice from a senior, they follow their senior doctor.

Delayed diagnosis of infectious endocarditis: retrospective analysis conducted at an university hospital in the south of Italy

Annamaria Spera*1, Rossella Benvenga2, Gennaro Galasso2

1University of Salerno - OO RR San Giovanni di Dio e Ruggi d’Aragona, Department of Infectious Disease, Fisciano, Italy, 2University of Salerno - OO RR San Giovanni di Dio e Ruggi d’Aragona, Department of Cardiology, Fisciano, Italy

Background: Infectious Endocarditis (IE) is a potential life threatening disease with variable clinical onset and course. Despite the improvement of diagnostic techniques, a high percentage of delay in diagnosis persists, with related morbidity and mortality. The aim of the study is to evaluate the presence of delayed diagnosis and its supportive factors at the University Hospital in Salerno.

Materials/methods: observational retrospective study conducted from January 1st 2013 to May 30th 2019. A total of 111 patients with IE (according to modified Duke criteria) enrolled. Statistical analysis done with SPSS software for Macintosh.

Results: 111 patients (68 males, 61.3% of total) were enrolled. The mean age was 64. 61 patients (55% of the total) received inappropriate antibiotic therapy before diagnosis. The most isolated microorganism was Coagulase Negative Staphylococcus (17.1% of total). 35 patients (31.5% of total) developed IE on prosthetic valve. The lag time symptoms onset - diagnosis of IE was 20 days (OR 10-40); the lag time hospitalization - diagnosis of IE was 4 days (OR 2-8). Linear regression analysis showed a statistically significant correlation between lag time symptoms onset/diagnosis (independent variable) and diagnosis of Staphilococcus Aureus IE (non standardized coefficient of linear correlation B 23.71, R2 0.037, P < 0.05). Moreover, this study shows that a delay of > 15 days in the diagnosis of IE, increases of 3.7 times the risk of death (OR 3.75; IC95% 1.29-10.93; P < 0.05). IE on prosthetic valve is a RF for worst outcomes because it increases the death risk of 3.4 times (OR 3.4; IC95% 1.21-9.59; P < 0.05). Multivariate analysis confirmed the significance between independent RF for statistical analysis such as diagnostic delay of more than 15 days, infection of prosthetic valve and unfavorable outcome (diagnostic delay >15 days OR 5.2, IC 95% 1.62-16.7, P 0.01; prosthetic valve OR 4.8, IC 95% 1.52-15.7, P <0.01)

Conclusions: Diagnostic delay of IE is significantly related to S. aureus etiology and it correlates with unfavorable outcomes. Delayed diagnosis of IE represents a big challenge in the management of this disease requiring an “Endocarditis Team” able to guarantee a multidisciplinary approach of IE.

Inflammatory changes on routinely-performed Papanicolaou smear are more frequently associated with bacterial vaginosis

Stavroula Baka*1, Anthia Chasiakou1, Stella Demeridou1, George Kaparos1, Evangelia Kouskouni1, Vasiliki Gennimata1, Athanassios Tsakris1

1Aretaieio Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: The results of cervical Papanicolaou (Pap) smears tests frequently include comments on the possible presence of infection based on cytological criteria. However, the clinical importance of these findings is unknown. This study assessed the possible association, if any, between inflammatory changes reported on Pap smears with the isolation of pathogens in the genital tract of asymptomatic women.

Materials/methods: Reproductive age nonpregnant women and menopausal women with inflammatory changes on routinely performed Pap smear in the last five years were included in the study. Genital tract samples were inoculated onto appropriate plates for standard cultures and incubated at 37°C. A wet mount and a gram-stained smear were examined to obtain valuable information about the microorganisms present and to apply Nugent criteria for the diagnosis of bacterial vaginosis. The identification of the isolated pathogens was performed with the automated system VITEK 2 (BioMerieux, Marcy l’Etoile, France). Statistical analysis was performed using chi square test and values ≤ 0.05 were considered statistical significant.

Results: A total of 2939 women (1708 of reproductive age and 1231 menopausal) with inflammation on the Pap smear, participated in the study. Negative cultures were detected in 40% and 64% of the reproductive age and menopausal women, respectively. Bacterial vaginosis was diagnosed more frequently, specifically 70.3% in reproductive age women and 79.7% in menopausal women. Candida species were isolated in 17.3% of reproductive age women and in 7.7% of menopausal women. In contrast, aerobic vaginitis was diagnosed in similar percentages in the two groups of women studied, 12.3% and 12.6% in reproductive age and menopausal women, respectively.

Conclusions: Our results suggest that a report of inflammatory changes on the cervical Pap smear cannot be used to reliably predict the presence of a genital tract infection since, in a significant proportion of our subjects, cultures were negative. However, the isolation of different genital tract pathogens in 60% and 36% of reproductive age and menopausal women with inflammation on Pap smears, respectively, cannot be overlooked and must be regarded with concern. Interestingly, in these women, bacterial vaginosis was diagnosed more often than other clinical entities.

Abstract 3111

Contaminating microflora during examination for tuberculosis: saprophytes or potential pathogens?

Artem Lyamin*1, Danir Ismatullin1, Alexandr Zhestkov1, Alexander Kovalyov2, Tatiana Persiyantseva2, Dinara Davydova2, Andrey Kozlov2

1Samara State Medical University, Samara, Russian Federation, 2Samara Regional Clinical Tuberculosis Dispensary named N.V. Postnikov, Samara, Russian Federation

Background: Various representatives of the order Actinomycetales may exhibit an acid resistance property. Acid-fast bacteria can be a true contaminating microflora, and can be associated with a clinical picture similar to tuberculosis.

Materials/methods: The study included 1024 clinical samples that were inoculate in the Mycobacteria Growth Indicator Tube (MGIT) for the diagnosis of tuberculosis and were identified by the BACTEC system as contaminated by extraneous microflora. Mycobacterium tuberculosis complex DNA was not detected in all samples. Then, of all the selected MGITs, reseeding was culture on blood agar in order to isolate and identify microorganisms that caused the contamination. The cultivation was carried out for 21 days at a temperature of 28 and 37 °C. Grown microorganisms were identified using a MALDI-ToF mass spectrometer (Bruker ™, Germany). Only acid-fast microorganisms were included in the analysis.

Results: The total number of microorganisms isolated from clinical samples was 933 strains. Of these, 80 strains (8.6%) belonging to 6 genera were acid-fast. The most numerous was the group of bacteria from the genus Streptomyces - 37 strains: S.violaceoruber - 12, S.phaeochromogenes - 11, S.badius - 2, S.chartreusis - 2, one strain each - S.albus, S.hirsutus, S.lavendulae, S.avidinii; 6 strains could only be identified before the genus. All bacteria belonging to the genus Nocardiа - 13 strains were identified to the species: N.farcinica - 6, N.cyriacigeorgica - 3, N.brevicatena - 2, N.nova - 1, N.carnea - 1. Out of 13 strains of Gordonia spp. 12 strains were identified to the species: G.sputi - 7, G.rubripertictata - 4, G.bronchialis - 1. In 8 cases, bacteria of the genus Brevibacterium were isolated: B.casei - 6, B.celere - 1, B.barstelensis - 1. Tsukamurella paurometabola 4 strains were isolated, one strain was identified before the genus Tsukamurella. Four strains of Cellulosimicrobium cellulans were also isolated.

Conclusions: The identification of microorganisms isolated from clinical specimens during screening for tuberculosis is an important criterion, which allows differentiating contaminating microflora from bacteria of clinical significance. Using MALDI-ToF mass spectrometry, it was possible to identify 91.3% of acid-fast bacteria isolated from clinical specimens during examination for tuberculosis.

Abstract 3112

Diagnostic value of the molecular detection of Sarcoptes scabiei from a skin scraping in patients with suspected scabies

Moonsuk Bae*, Jiyeun Kim1, Joung Ha Park1, Seongman Bae1, Jiwon Jung1, Hye Hee Cha1, Na Young Jeon1, Hyun Jung Lee1, Min-Jae Kim1, Sung Eun Chang1, Sung-Han Kim1

1Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Scabies is a highly contagious parasitic disease associated with long-term residence in nursing homes, and it is a public health burden worldwide. However, atypical skin manifestations are frequent and the widely used diagnostic test based on microscopic examinations have limited sensitivity. We evaluated the diagnostic value of polymerase chain reaction (PCR) from skin scraping in patients with suspected scabies

Materials/methods: Adult patients with suspected scabies, unrelated diseases or healthy volunteers were enrolled at a tertiary hospital, in Seoul, South Korea, from December 2017 through October 2018. We classified participants based on the consensus criteria established by the International Alliance for the Control of Scabies in 2018; confirmed (microscopic mite detection), clinical (scabies burrow or typical lesions with two history features including itch and close contact with scabies patients), suspected scabies (typical lesion with one history feature or atypical lesion with two history features), or no scabies. PCR was performed on the skin scrapings to target the cytochrome c oxidase subunit 1 (cox1) gene of Sarcoptes scabiei.

Results: A total of 57 participants, 43 with suspected scabies, 14 with unrelated diseases, and 4 healthy volunteers were enrolled. Of the 43 patients, 22 were classified as confirmed scabies, 2 as clinical scabies, 6 as suspected scabies, and 3 as no scabies (Table 1). The sensitivities of the microscopic examination were 100%, 92%, and 73% in confirmed scabies; confirmed and clinical scabies; and confirmed, clinical, and suspected scabies, respectively (p=0.006). The sensitivities of PCR were 86%, 83%, and 80% in confirmed scabies; confirmed and clinical scabies; and confirmed, clinical, and suspected scabies, respectively (p=0.59). The specificity of the scabies PCR in the no scabies control was 100% (95% CI=80–100).

Conclusions: PCR testing for scabies may be helpful in the improvement of sensitivity for the diagnosis of scabies by clinical criteria.

Abstract 3113

Application of peptides as a novel method to enrich and identify of Candida species

Mansoureh Vatanshenassan1*, Carlo Brouwer2,3, Teun Boekhout4, María Ríos Carrasco2, Ferry Hagen4,5,6

1Westerdijk Fungal Biodiversity Institute, Westerdijk institute, Utrecht, Netherlands; 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands; 3CBMR Scientific Nanoscience BV, Doornenburg, Netherlands; 4Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands; 5UMC Utrecht, Department of Medical Microbiology, Utrecht, Netherlands; 6Jining No.1 People’s Hospital West Branch Parking Lot, Laboratory of Medical Mycology, Jining Shi, China

Background: Among invasive fungal infections, Candida species are responsible for more than 50% of all cases worldwide. Invasive candidiasis causes a high range of morbidity and mortality, and therefore the pathogens need to be rapidly identified. In this study, we set up a novel method to detect Candida species using a synthetic antimicrobial peptide. The peptide was modified by labelling with a fluorescent probe. Adherence of this peptide to the fungal cell wall was tested by immunofluorescence microscopy, and its identification was performed by MALDI-TOF MS.

Materials/methods: Different strains of Candida species, including C. albicans, C. glabrata, C. tropicalis, and C. parapsilosis were tested. Escherichia coli (NCCB 100297) and Staphylococcus aureus (NCCB 100294) were used as control. Cells were suspended and further diluted in 1 ml RPMI1640 and incubated at room temperature for 15 min with fluorescently-labelled peptides. Thereafter, it was washed with PBS and coverslips were mounted. Fluorescent images were obtained with an immunofluorescence microscope (Zeiss, Axioplan) adjusted with a wavelength in the range of 488 nm (green). Identification by MALDI-TOF MS was done by lysing the cells and spotting in duplicate. Dried spots were firstly overlaid with the peptide and then with 1 µl of MALDI matrix. Spectra were acquired in the mass range between 2 and 20 kDa and analyzed by FlexAnalysis 3.3 software (Brüker Daltonics).

Results: The cell wall of the tested Candida species was clearly stained with the fluorescent-labeled peptide. E. coli cells did not stain while those of S. aureus were intracellularly labeled. By MALDI-TOF MS, each microorganism was correctly identified. The peptide peak was obviously distinguished in the mass range between 2 and 20 kDa. Peak-shifting of labeled peptide combined with each of the microorganisms supported the identification and confirmed peptide binding.

Conclusions: This study showed that there is a significant binding of fluorescently-labeled peptide to the cell wall of Candida species. This method may help us to detect and identify the yeasts from sepsis in seriously ill patients in the future.

**Abstract 3114**

**French general practitioner attitude regarding human papilloma virus vaccine in females and males: positive perceptions but missed opportunities**

Marine Degoue¹, Olivier Epaulard*¹

¹Université Grenoble Alpes, Grenoble, France

**Background:** In France, HPV vaccination is recommended for all females up to 19 years, and for two male categories: men who have sex with men (MSM) up to 27 years (since 2016), and immunocompromised males up to 19 years (since 2014). However, vaccine coverage in France is below 20% for females, and probably even lower for MSM. We aimed to evaluate the attitude of general practitioners (GP) regarding this vaccine in these two populations.

**Materials/methods:** We elaborated an anonymous, online questionnaire exploring GP perceptions and practices related to this vaccine through scores ranging from 0 to 100. The questionnaire was diffused between June 2018 and January 2019.

**Results:** A total of 337 GP participated (age 44.4±12, females 58.8%); 84.3% declared they generally knew their patient sexual orientation.

When asked whether they were in favor of HPV vaccine in girls and MSM, on a 0-100 scale, the medians/IQT answers were 99[80-100] and 10 [71-100], respectively. They were concerned by HPV vaccine potential adverse effects at a median of 10[0-30]. They declared, on a 0-100 scale, that they took the opportunity of a contraceptive prescription in females to check HPV vaccination status at a median of 60 [20-90]; answers regarding this behavior were higher in the participants above 44 years (median 80[30-100] vs 50[20-80], p=0,001). 59.1% proposed the HPV vaccine to females with the DTPP booster at the age of 11. They evaluated that 43.6±22% of their females patients under the age of 20 were vaccinated.

Among the participants, 62.8% were aware of the 2016 recommendations regarding MSM vaccination; they were younger than the others (42.9±11 vs 46.6±11 years, p=0.037). Only 15.7% had already offered this vaccine to males. On a 0-100 scale, they declared that they had in mind the HPV vaccine when seeing a male of 27 or younger at a median of 0[0-10]. They supported an equal vaccination of both genders at a median of 100[50-100].

**Conclusions:** Adherence to HPV vaccination among GP in this study is strong, but missed opportunities remain regarding females and males. This would probably be improved by undifferentiated vaccination of both genders.

**Presenter email address:** oepaulard@chu-grenoble.fr
Impact of a dedicated Clostridiodes difficile infection isolation ward on clinical outcomes

Maithili Varadarajan*, Gavin Barlow1,2,3

1Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom, 2Hull York Medical School, Heslington, United Kingdom, 3University of York, Heslington, United Kingdom

Background: Clostridium difficile infection (CDI) remains a globally important adverse event of antibiotics. In the UK, CDI accounts for an additional £4,000 per patient. In 2012, a dedicated CDI ward at Hull University Teaching Hospitals (HUTS) was opened; it closed in 2016 following a sustained reduction in incidence. This analysis aimed to assess the impact of the CDI ward on readmission, recurrence and 30-day, 90-day and 1-year mortality.

Materials/methods: From all CDI patients treated at HUTS during the periods before (N = 148, 04/10-12/11), during (N = 332, 04/12-05/16) and after (N = 89, 09/16-12/18) the CDI ward was open, a random sample of N = 75 patients was selected for each period (N = 223). Data including comorbidities, clinical data, treatment and outcomes was collected from discharge letters and hospital systems. Data was analysed using STATA. Predictor variables with p<=0.1 by univariate analyses were included in multivariate logistic regression analyses.

Results: The median age of patients was 76, 80 and 78 years in the before, during and after periods. The commonest ribotypes were 001 (13%) and 078 (13%). 28%, 16% and 23% of patients died within 30-days in the before, during and after periods. Admission to the CDI ward was not significantly associated with outcomes.

<table>
<thead>
<tr>

<tr>
<td>Co-morbidities</td>
<td>1.29 (1.12-1.48), 0.000</td>
<td>1.20 (1.05-1.38), 0.008</td>
</tr>
<tr>
<td>Neutrophils on onset</td>
<td>1.07 (1.02-1.13), 0.011</td>
<td>1.06 (1.01-1.11), 0.023</td>
</tr>
<tr>
<td>Albumin on onset</td>
<td>1.06 (1.01-1.12), 0.03</td>
<td>3.69 (1.02-13.3), 0.046</td>
</tr>
<tr>
<td>Radiological changes</td>
<td>1.06 (1.01-1.12), 0.03</td>
<td></td>
</tr>
</tbody>
</table>

Conclusions: The dedicated CDI ward had no identifiable impact on outcomes. However, variables associated with the nature of the patient and severity of infection at onset were independent predictors of negative outcomes; suggesting that these are more important in determining CDI outcomes.

Identification of clinical isolates of Tannerella forsythia by MALDI-TOF mass spectrometry

Tjaša Teržan*, Mateja Pirs1, Marja Furlan1, Petra Hrvat1, Vesna Cvitković-Spišk1, Tjasa Cerar Kšek1, Katja Seme1

1University of Ljubljana, Faculty of Medicine, Institute of Microbiology and Immunology, Ljubljana, Slovenia

**Background:** Tannerella forsythia (Tf) is an anaerobic, nutritionally fastidious gram-negative bacterium, regularly regarded as periodontal pathogen. Isolation of Tf from clinical samples and cultivation are used for research and diagnostic purposes. Identification of Tf grown in culture is time-consuming and is based either on colony morphology and biochemical characteristics (API, BANA) or DNA-based assays (DNA-DNA hybridization, 16S rRNA sequencing). Recently, matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF) has become a widespread routine rapid and reliable method for identification of bacterial and fungal pathogens. Bruker’s commercially available MBT MSP Library includes mass spectra of all clinically relevant periodontal pathogens (Prevotella nigrescens/intermedia, Fusobacterium nucleatum, Porphyromonas gingivalis, Aggregatibacter actinomycetemcomitans) except Tf. The aim of our study was thus to create a custom MALDI-TOF library for fast and simple identification of Tf.

**Materials/methods:** Pure cultures of Tf were cultivated on Tryptic soy agar with N-acetylmuramic acid in anaerobic conditions for 7 days. MALDI-TOF library was constructed using spectra generated from DSM 1028359 reference strain and 14 clinical isolates which were identified by sequencing the 16S rRNA gene. Mass spectra for library creation were acquired with Microflex LT (Bruker Daltonics, Germany). Spectra were analysed using FlexControl software; a minimum of 20 good quality spectra with minimum peak shift of individual masses (500 ppm) per isolate were used to create main spectrum profiles using Compass Explorer software. The custom library was then challenged with 13 routine isolates.

**Results:** A total of 28 periodontal Tf isolates were included. MALDI-TOF identification for all tested isolates matched the results of identification based on morphological characteristics and 16S rRNA sequencing with highly probable species identification (LogScore >2.0). Protein profiles did not match existing profiles in the database containing 7595 bacterial species (Vdb-8468), dendrogram showed Tf clustering in a branch separate from the genus Bacteroides.

**Conclusions:** Mass spectra of our isolates identified as Tf by 16S rRNA sequencing were found to significantly differ from other mass spectra included in the Bruker’s commercially available MBT MSP Library. We have created a custom MALDI-TOF library, which allows fast and simple identification of Tf grown in culture.

Abstract 3121

National survey of carbapenemase-producing Klebsiella pneumoniae and Escherichia coli in Belgium in 2019

Te-Din Daniel Huang1*, Pierre Bogaerts2, Catherine Berhin3, Martin Hoebeke1, Youri Glupczynski1, Olivier Denis1

1National Reference Center of Antibiotic-resistant Gram-negative bacilli, CHU UCL Namur - Site Godinne, Yvoir, Belgium

Background: Carbapenemase-producing Enterobacteriaceae (CPE) isolates are spreading and represent a serious threat for global public health. We conducted a nationwide survey to monitor the evolution of the epidemiology of carbapenemase-producing K. pneumoniae (CPKP) and E. coli (CPEC) in Belgium.

Materials/methods: The survey includes 75 (63 hospital-based and 12 community-serving) laboratories requested to refer non-duplicate consecutive K. pneumoniae and E. coli isolates collected from clinical specimens (fecal samples excluded) between May and October 2019 to the National Reference Center for decreased carbapenem susceptibility or suspicion of CPE. Isolates were tested for susceptibility phenotype by disk diffusion and for carbapenemase production by Beta-Carba test (BioRad) and by immunochromatographic lateral flow assay (LFA) RESIST-4 OKVN (Coris BioConcept). Other carbapenemases were sought by molecular methods in case of suggestive phenotype with negative result by LFA.

Results: Of the 235 referred isolates, 175 (74%) including 144 K. pneumoniae and 31 E. coli, collected from 48 laboratories were confirmed as CPE. Distribution of the different carbapenemase types by decreasing frequency was: OXA-48 (n=136; 78%), KPC (n=18; 10%), NDM (n=14; 8%), VIM (n=3; 2%) and IMP (n=1; 1%); 3 K. pneumoniae coproduced two different types (2 OXA-48+NDM and 1 KPC+NDM). Compared to a previous survey including the same laboratories in 2015, the number (proportion) of laboratories reporting CPKP/CPEC increased from 35 (47%) in 2015 to 46 (61%) in 2019 (p=0.07). The number of local CPKP/CPEC grouped cases (>1 case of the same CPE type) increased significantly from 24 in 2015 to 37 in 2019 (p=0.027) as did the number of laboratories reporting two or more different carbapenemase types (n=8 in 2015 and n=13 in 2019; p=0.21).

Conclusions: Our data confirm the worsening epidemiological status of CPKP/CPEC in Belgium in 2019. Overall, OXA-48 remained by far the predominant carbapenemase, but the increasing number and proportion of laboratories having more than one carbapenemase type detected from clinical specimens strongly suggests their spread and diversification both in hospital and community settings.

Heat wave-associated Vibrio infections in Germany 2018 and 2019

Thomas Theo Brehm*1,2, Laura Berneking3, Holger Rohde1,3, Martin Christner1, Stefan Schmiedel1,2

1University Medical Center Hamburg-Eppendorf, Division of Infectious Diseases, I. Department of Medicine, Hamburg, Germany, 2German Center for Infection Research (DZIF), Partner Site Hamburg-Lübeck-Barstel-Riems, Hamburg, Germany, 3University Medical Center Hamburg-Eppendorf, Institute of Medical Microbiology, Virology and Hygiene, Hamburg, Germany

Background: Climate change already has enormous implications for human health, especially for the burden of vector- and waterborne infectious diseases. Vibrio spp. are gram-negative bacteria with a worldwide distribution in marine ecosystems that are regarded as emerging human pathogens due to a rapidly warming ocean environment. Unprecedented heat waves in summers of 2018 and 2019 have led to high sea surface temperatures in Europe. Such heat waves have previously been linked to Vibrio outbreaks in other countries. In Germany, reporting of Vibrio infections is not mandatory, so high numbers of unreported infections must be assumed.

Materials/methods: We are conducting a retrospective multi-center analysis of patients that were diagnosed with autochthonous infections with Vibrio spp. in the summers of 2018 and 2019 in German hospitals and outpatient clinics.

Results: At the time of this preliminary analysis, a total of 32 patients diagnosed with autochthonous infections with V. vulnificus, V. parahaemolyticus, V. cholerae (non-O1/O139), V. alginolyticus and V. fluvialis respectively could be included in our study (Table 1). Seventeen patients acquired wound infections, 10 patients suffered from ear infections, 5 patients presented with gastroenteritis. All Vibrio infections have been acquired in the Baltic Sea during the months July and September.

Conclusions: The heat waves in 2018 and 2019 respectively caused unprecedented numbers of human infections with Vibrio spp. acquired in the German Baltic Sea. Ongoing global warming will likely lead to a worldwide increase of these emerging waterborne pathogens warranting awareness among physicians, microbiologists and health care authorities.

1Arsi University, College of Health Sciences, Asella, Ethiopia, 2University of Düsseldorf, Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital, Düsseldorf, Germany, 3University of Düsseldorf, Hirsch Institute of Tropical Medicine, Asella, Ethiopia, 4University of Düsseldorf, Institute of Medical Microbiology and Hospital Hygiene, University Hospital, Düsseldorf, Germany, 5University of Düsseldorf, Hirsch Institute of Tropical Medicine, Asella, Ethiopia, 6University of Düsseldorf, Institute of Tropical Medicine, Asella, Ethiopia, 7University of Düsseldorf, Hirsch Institute of Tropical Medicine, Asella, Ethiopia

Background: Local data from the Asella Referral and Teaching Hospital (ARTH) reveal a high prevalence of extended-spectrum β-lactamase- (ESBLs) producing Gram-negative bacteria in clinical isolates. To investigate possible routes of transmission, we determined the colonization of houseflies with ESBL-producing Gram-negative bacteria at the ARTH compound and in Asella town.

Materials/methods: In August 2019, we collected a total of 85 houseflies; 20 from the neonatal intensive care unit (NICU), 12 from the orthopedic ward, 26 from the hospital’s waste disposal area and 27 from a butchery 1.4 km from the hospital. The flies were trapped with retail flycatchers and stored in sterile normal saline. After maceration in sterile saline suspensions were inoculated on MacConkey-Agar and incubated at 37°C. Identification and antimicrobial susceptibility testing were performed using MALDI-TOF-MS and VITEK2.

Results: A total of 103 isolates were obtained from 85 flies (NICU: 11, orthopedic ward: 10, waste disposal area: 37, butchery: 45). The prevalence of ESBL was 2.2 % (1/45) in the butchery and 69 % (40/58) in the hospital compound (orthopedic ward: 90 %, NICU: 82 %, waste disposal area: 58 %), with the difference between hospital and surroundings was statically significant (p ≤0.001). The frequency of ESBL was 75 % (6/8) in Enterobacter spp., 75 % (6/8) in Raoultella spp., 67 % (6/9) in Citrobacter spp, 64 % (7/11) in Klebsiella pneumoniae and 56 % (5/9) in Escherichia coli isolates, respectively. Of the 41 confirmed ESBL genes detected, 83 % were CTX-M-like, 80 % TEM-like, 22 % SHV-like and 2 % CTX-M-2-like. CTX-M-9 and CTX-M-8/25-like genes were not detected. All ESBL positive Klebsiella pneumoniae possessed both CTX-M-1 and SHV genes.

Conclusions: A high proportion of houseflies trapped within the hospital compound were colonized with ESBL-producing bacteria, whereas houseflies collected in a butchery 1.4 km from hospital were colonized at a much lower rate. Houseflies may be a factor in the spread of multidrug-resistant (MDR) microbes in hospitals. Further studies are needed to determine the possible source of MDR in houseflies and the impact on the high rate of MDR nosocomial infections.

Piperacillin-tazobactam versus carbapenem for the treatment of bloodstream infection caused by CTX-M-type ESBL-producing Enterobacteriaceae

Lorenzo Roberto Suardi1*, Filippo Lagi1, Eleonora Riccobono1, Tommaso Giani1,2, Alberto Moggi Pignone1,3, Alessandro Morettini4, Carlo Nozzoli1, Filippo Pieralli6, Andrea Berni1, Gian M. Rossolini1,2, Alessandro Bartolini1,8, Filippo Bartalesi8

1Università di Firenze, Dipartimento di Medicina Sperimentale e Clinica, Firenze, Italy, 2Azienda Ospedaliero Universitaria Careggi, SOD Microbiologia e Virologia, Firenze, Italy, 3Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna 4, Firenze, Italy, 4Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna 2, Firenze, Italy, 5Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna 1, Firenze, Italy, 6Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna ad Alta Intensità, Firenze, Italy, 7Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna 3, Firenze, Italy, 8Azienda Ospedaliero Universitaria Careggi, SOD Malattie Infettive e Tropicali, Firenze, Italy

Background: In the MERINO trial, piperacillin/tazobactam [PTZ] failed the non-inferiority challenge with meropenem as target-ed therapy for bloodstream infection [BSI] due to E.coli or K.pneumoniae ceftriaxone-resistant. Microbiological methods were criticized due to AmpC enzymes inclusion, predicting no response to PTZ, and a non-reference method use rather than broth microdiluition, as susceptibility test for PTZ.

Materials/methods: Retrospective study of adult patients with E.coli or K.pneumoniae ceftriaxone-resistant positive BC admitted to five medicine wards, at Careggi Hospital (Firenze-Italy), between 2014 and 2018 with availability of bacterial strains [CARESBLI Study, Ethical Approval 07/05/2019, code 14445/OSS]. Molecular screening for blaCTX-M genes and others ESBLs as well antimicrobial susceptibility testing with broth microdiluition were performed. E. coli ATCC 25922 and ATCC 35218 were used as control strains. Patients were grouped according to whether they were treated entirely with carbapenem or with PTZ or empirically with PTZ and then escalated to carbapenem [figure 1]. Aim was to determine whether PTZ was efficacious as carbapenems, empirically or targeting therapy, focusing on clinical improvement within 48-72 hours of starting empirical therapy (decreasing SOFA score) and on 30-day mortality since BC withdrawal.

Results: Eighty patients were included with a median age of 79 years whom 36 (45%) women. E.coli isolates were prevalent [93.8%] and the most frequent ESBL was CTX-M [95%]. 58 strains [72.5%] had MICs <=8 µg/ml to PTZ. Urinary source was predominant [80%] with non-severe presentation for the majority of cases [62.5%]. Median Charlson Comorbidity Index was 6. Overall 30-day mortality was 13.8%. No significant differences, regarding demographic, microbiological, clinical presentation and outcomes characteristics, were found between the treatment groups. In logistic-regression, an inappropriate empirical therapy resulted associated [OR 0.13,CI 95%0.02-0.06,p=0.001] against clinical improvement. Neither empirical nor targeted treatment, with PTZ or carbapenem, included escalation regimen, were associated with 30-day mortality.

Conclusions: The study did not reveal any significant difference, regarding clinical improvement and mortality, between PTZ and carbapenem, treating BSI due to CTX-M-type ESBL-producing Enterobacteriaceae, mainly from urinary and abdominal sources, in a real-life elderly population with a high comorbidity burden. Therefore it confirms the relevance of appropriate empirical therapy on outcome in these difficult-to-treat infections.
Clonal characterisation of Acinetobacter baumannii strains in a public hospital in Brazil

Ana Andrade1, Lavinia Arend*1, Juliette Cieslinski1, Victoria Stadler Tasca Ribeiro1, Leticia Kraft1, João P. Telles1,2, Felipe Tuon1

1Pontifical Catholic University of Paraná, Curitiba Campus, Laboratory of Emerging Infectious Disease - Department of Medicine, Curitiba, Brazil, 2A.C. Camargo Cancer Center, Department of Infectious Disease, Sao Paulo, Brazil

Abstract 3133

Background: The survival and spread of CRAB (Carbapenem-resistant Acinetobacter baumannii) in the hospital environment is a constant concern. Identification of strains in molecular aspects can be used to identify outbreaks of infection and to monitor inter-institutional, regional and international CRAB transmission, and are extremely useful for rapidly identifying the emergence and spread of multiresistant clones. The aim of this study was to verify the genetic similarity of the isolates found from A. baumannii by MALDI-TOF and automated rep-PCR.

Materials/methods: The strains were subjected to a protein extraction process. One microliter of the extracted slide solution was added after drying at room temperature 1µL of the matrix (α-cyano-4-hydroxy-cinnamic acid solution) was added. Then, direct detection of the microorganism was performed by MALDI-TOF mass spectrometry on Vitek® MS equipment, where clones were considered when similarities were greater than 75%. The different clones identified were confirmed by Diversilab® automated rep-PCR system, and isolates with similarity greater than 95% were considered rep-PCR clones.

Results: Fifty bacterial CRAB isolates were analyzed. Through direct identification by MALDI-TOF, the isolates were verified for similarity using the taxonomy tool of the Saramis software, where three clusters were observed. The first cluster had a similarity in 94% of the samples (n = 47). Two more clusters were observed, where one was contemplated only by one bacterial isolate, and the other cluster was contemplated by two bacterial isolates. Ten bacterial isolates were selected from the total of samples, and evaluated for similarity by automated rep-PCR, which demonstrated the presence of the same three clusters among the CRAB isolates, corroborating the similarity data obtained by the Saramis software.

Conclusions: Clonal similarity of bacterial isolates of A. baumannii can be evaluated and studied using Saramis software. The presence of a large clonal group showed that there is only one widespread strain in the hospital setting, which may be caused by its easy spread due to its survival in inanimate environments and cross-resistance between objects, surfaces and health professionals.

Abstract 3134

**Anti-biofilm and antibacterial properties of cationic amphipatic AMP mimics**

Christiane Forestier*, Nicolas Charbonnel*, Radhe Shyam†, Claude Taillefumier†, Sophie Faure‡

†Université Clermont Auvergne, Clermont Ferrand, France, ‡Université Clermont Auvergne, Clermont Ferrand, France, §Université Clermont Auvergne, Clermont Ferrand, France

**Background:** The development of antibiotic resistances by microorganisms has led to a need to find novel antibacterial agents or combinations of agents as the first line of treatment for various infections. Peptoids, oligomers of N-substituted glycines, are attracting due to their advantageous properties as peptidomimetics, including designable well-defined three-dimensional structures and stability toward proteolysis. This study aimed to investigate the anti-biofilm and antimicrobial properties as well as their potential synergy with antibiotics of a set of peptoids mimicking helical antimicrobial peptides (AMPs) using Gram-positive and Gram-negative bacteria.

**Materials/methods:** Antibiofilm activity was determined by measuring the biofilm biomass (viable bacteria) after 3h of cocultivation and after treatment of formed biofilms with the peptoid molecules to be tested. Antibacterial activity was measured by determining the minimum inhibitory concentration (MIC) by a microtiter broth dilution in Müller-Hinton and mammalian cells culture media. Based on the MIC of each antimicrobial agent, a checkerboard assay was performed to investigate the synergy between them, which was expressed as the fractional inhibitory concentration (FIC).

**Results:** Several cationic amphipatic peptoids displayed antibiofilm and antibacterial activity, the latter being enhanced in mammalian culture cells medium compared to MH medium, with low hemolytic activity and cytotoxicity. The combination of a selected peptoid and the antibiotic erythromycin showed synergistic activity against Gram-negative bacteria, and this activity was retained and even enhanced when incubated in mammalian cells culture medium compared to standard bacteriologic media.

**Conclusions:** Peptoid-type AMP mimics alone and in combinations with antibiotic are promising strategies to fight biofilm formation and antibiotic resistant bacteria

Should serum D-dimer be added as a first-line screening test for prosthetic joint infection?

Marta Fernandez Sampedro*1, Iria Sanlés González2, Carmen García Ibarbia1, Natalia Fañanas Rodríguez1, Daniel Pablo-Marcos3, Guillermo Menendez Solana1, Carmen Fariñas1

1Hospital Marques de Valdecilla, Santander, Spain

**Background:** Although the updated definition of prosthetic joint infection (PJI) introduced serum D-Dimer in the preoperative score in evaluating, this new biomarker has not yet been validated between the different workgroups. We investigate the value of serum D-dimer prior to revision arthroplasty and compare with the measurements of serum C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) levels for the diagnostic of PJI.

**Materials/methods:** This prospective study enrolled patients undergoing revision arthroplasty from February 2012 to February 2014. PJI was defined according to Infectious Diseases Society of America (IDSA) criteria. The four types of PJI were classified according to the Tsukayama et al. criteria. In all patients, serum D-dimer, ESR and CRP level were measured preoperatively. The diagnosis accuracy of different tests was evaluated constructing receiver-operating-characteristic (ROC) curve areas.

**Results:** Of the 185 patients studied, 145 had aseptic failure (AF) and 40 PJI. There were 5 (12.5%) type I infections, 26 (65%) type II, 4 (10%) type III and 5 (12.5%) type IV according to the Tsukayama et al. classification. The median of D-Dimer levels was higher in PJI 1727 (185-6681) than in AF patients 640 (67-5958) (p=0.032). The areas under the ROC curve for D Dimer, PCR and ESR were 0.763 (95% confidence interval 0.683-0.844), 0.790 (0.712-0.868) and 0.733 (0.636-0.830), respectively. Based on the Youden’s index, 950 ng/ml was the optimal threshold value for serum D-dimer for diagnosing PJI. D-dimer showed a sensitivity and specificity of 77% and 66%, respectively, while serum CRP (>0.5mg/dl) and ESR (>12mm/h) demonstrated a sensitivity of 82% and 80% and specificity of 61.4% and 64%, respectively. Serum D-dimer diagnosed 73% of type II infections, 60% of type IV and all the cases of Types I and III.

**Conclusions:** Serum D-dimer levels are higher in patients with PJI than those with AF. However, the value of D-Dimer compared to traditional inflammatory parameters is limited. Due to factors that influences serum biomarkers, diagnostic strategies as the first-line approach should be individualized according to the patients’ age, comorbidity, clinical presentation or implant-related factors.

Contaminating microflora at a tuberculosis test: dependence on medium for primary inoculation

Artem Lyamin*1, Danir Ismatullin1, Alexandr Zhestkov1, Alexander Kovalyov1, Tatiana Persiyantseva2, Andrey Kozlov1, Olga Kondratenko1

1Samara state medical university, Samara, Russian Federation, 2Samara Regional Clinical Tuberculosis Dispensary named N.V. Postnikov, Samara, Russian Federation

Background: A microbiological study of tuberculosis involves the use of certain artificial nutrient media and a decontamination process aimed at suppressing the growth of concomitant bacterial flora.

Materials/methods: The study analyzed the culture of the following types of clinical material: bronchial washings, sputum, urine, separated from fistulas, gastric lavage, pleural fluid. We used dense Levenshtein-Jensen media and Finn II, as well as Middlebrook 7H9 liquid medium. The material was represented by 865 samples with contaminating flora, which were scattered on solid nutrient media: 5% blood agar (Bio-Rad), universal chromogenic medium (Bio-Rad), Saburo agar (HiMedia). After incubation and cultivation in the case of growth detection, the cultures were identified using a MALDI-ToF mass spectrometer (Microflex LT, Bruker). A total of 1093 microorganism strains were isolated and identified.

Results: As a result, in 457 samples (52.8%), growth was detected on Levenshtein-Jensen medium, in 322 samples (37.2%), growth was detected on Finn II medium, in 214 cases (24.7%), growth was detected on Middlebrook 7H9 medium. In 168 cases (19.4%), growth was detected immediately on two solid media. The increase in the probability of seeding from clinical material when using Middlebrook 7H9 medium of microorganisms of the genera Arthrobacter spp., Brevibacterium spp., Cellulosimicrobium spp., Gordonia spp., Lysinibacillus spp., Microbacterium spp., Sporothrix spp. Was statistically significant. (from 1 to 3.9% of the total number of crops in comparison with dense nutrient media). However, these bacteria and micromycetes were not detected when sowing on solid nutrient media. Also, Nocardia spp., Paenibacillus spp., Ralstonia spp., Streptomyces spp. Were more often detected on Middlebrook 7H9 liquid medium. (2.6-14.9% of the total number of crops compared with solid nutrient media). In turn, Aspergillus spp., Candida spp., Pseudomonas spp., Corynebacterium spp., Escherichia spp., Klebsiella spp., Staphylococcus spp., Were detected much more often on dense nutrient media of Levenshtein-Jensen and Finn II.

Conclusions: Thus, the use of Middlebrook 7H9 liquid medium increases the likelihood of identifying some acid-resistant actinomycetes (Gordonia spp., Nocardia spp.) That have a clinical and radiological picture similar to tuberculosis. This reduces the likelihood of seeding bacteria from the order Enterobacteriales, some micromycetes and non-fermenting gram-negative bacteria.

Abstract 3138

**Presence and persistence of hepatitis E virus PCR in patients with specific IgM positivity**

Claudia Mendoza Lopez*, Joaquina Gil*, Antonio Rivero-Juarez, Alba Leyva, Rafael Benito

1Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain, 2Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba, Spain, 3Vircell S L, Granada, Spain

**Background:** Diagnosis of Hepatitis E virus (HEV) infection is based on specific IgM and/or RNA, besides, PCR is not always available so IgM, IgG follow-up sample and avidity could be essential for diagnosis of the HEV acute infection.

Analyse the presence and persistance of HEV-RNA in patients with specific IgM, evaluated with four comercial assays, to know the IgM utility as viremia predictor.

**Materials/methods:** From 2011 to 2018, 131 patients were HEV positive with indirect EIA IgM (HEV IgM Dia.Pro, Italy), being also analyzed 106 with an in-house PCR (with the WHO Standard HEV strain as positive control) and with: Capture IgM EIA (Wantai Diagnostic, China), indirect IgM EIA (Mikrogen, Germany), CLIA IgM and IgG (Vircell, Spain). In 38 patients follow-up samples were obtained.

**Results:** RNA-HEV was positive in 39 patients. Samples were obtained between 2-26 days after symptoms onset (DAO) (mean 11.1±6.28) for positive PCR and between 1-120 DAO (mean 27.8±30.17) for negative PCR.

Following-up samples in 38 patients were collected after 33 DAO. Only one, with normal ALT, continued being repeatedly positive at 77 DAO.

**Conclusions:** All analyzed IgM kits detect practically 100% of the positive PCR cases in samples less than 30 DAO, but the persistence of IgM could be prolonged in negative PCR patients. Viremia may be negative in a few patients less than 30 DAO. The high IgM-index could help to predict the PCR positivity. Vircell IgM detects less positive cases in patients with negative HEV-RNA.

Abstract 3141

The predictive value of disc diffusion assay results for resistance in Gram-negative bacteraemia: a UK district general hospital experience

Thomas Swaine1*, Catherine Dominic2, Ruaridh Buchanan1

1Newham University Hospital, Barts Health NHS Trust, London, United Kingdom, 2Barts and The London School of Medicine and Dentistry, London, United Kingdom

Abstract third-party references: Barts Health NHS Trust

Background: Gram negative bacteremia poses both significant clinical and antimicrobial stewardship concerns for clinicians. Direct sensitivity testing through antimicrobial disc diffusion (DD) assays can provide a rapid guide to resistance patterns, potentially allowing the avoidance of unnecessary escalation and even safe de-escalation in blood stream infections. However, DD assays are only cautiously recommended by the British Society for Antimicrobial Chemotherapy due to concerns over disparity with automated methods, reflecting a dearth of experience and data with their use. The data presented here aims to further inform this evolving practice.

Materials/methods: 710 Gram negative blood culture isolates identified over 2 years at Newham University Hospital in East London were analyzed. 650 samples were then identified that had undergone resistance and susceptibility testing with DD and microbroth dilution assays, with 583 samples returning comparable paired results for commonly used antimicrobials. These samples were then analyzed to calculate predictive values for DD results, with further sub-analysis performed on a species level for common pathogens.

Results: In sample sizes ranging from 472 to 574 isolates, DD assays accurately predicted sensitivity to amikacin (negative predictive value = 95.59%), ampicillin (97.09%), co-amoxiclav (95.37%), cefuroxime (97.10%), ciprofloxacin (96.61%), ertapenem (98.81%), gentamicin (98.25%), and piperacillin/tazobactam (96.83%). However, a resistant DD result was less predictive of true resistance, which was particularly apparent for beta-lactam agents (co-amoxiclav positive predictive value = 60.37%; ertapenem = 61.90%; piperacillin/tazobactam = 42.86%).

Conclusions: DD assays consistently overcall resistance for certain beta-lactam antimicrobials in Gram negative blood stream infections, particularly beta-lactam/beta-lactamase inhibitor combinations; however, they can confidently predict sensitivity for a range of commonly used antimicrobial agents. This suggests that infection specialists can use these results to narrow antimicrobial therapy with a good degree of certainty, improving not only patient care but also antimicrobial stewardship.

Abstract 3145

**Antimicrobial resistance surveillance data of Helicobacter pylori in Belgium (2016-2019)**

Te-Din Daniel Huang*1, Olivier Denis1, Catherine Berhin1, Martin Hoebeke1, Wassifa Bouchahrouf1, Youri Glupczynski1, Pierre Bogaerts1

1National Reference Center for Helicobacter pylori, CHU UCL Namur - site Godinne, Yvoir, Belgium

**Background:** Resistance to antibiotics is the major cause of treatment failure of Helicobacter pylori (HP) infection and recommendations of HP eradication therapy schemes are based on the resistance levels among the treatment-naive population. This study aimed to monitor primary antimicrobial resistance rates of HP in Belgium.

**Materials/methods:** Between Jan. 2016 and Oct. 2019, more than 16000 gastric biopsy specimens of patients attending upper gastrointestinal endoscopy (around 85 % originated from five large endoscopy clinics located in three different cities) were referred to the national reference laboratory for HP detection either by culture and/or by PCR (Amplidiag® H. pylori +ClariR PCR assay, Mobidiag). In vitro susceptibility testing to clarithromycin (CLA), metronidazole (MTZ), levofloxacin (LVX), amoxicillin (AMX) and tetracycline (TET) was performed using gradient strip (Etest, bioMérieux) diffusion method and interpreted according to EUCAST clinical breakpoints. Isolates from patients known to have received previous eradication therapy were excluded from the analysis.

**Results:** In total, 3310 samples were positive for HP by culture and/or by PCR. The HP positive rate was significantly higher in period where first-line PCR was performed compared to first-line culture (19.3% vs 17.7%; p=0.01). The mean primary resistance proportions in 2019 were of 20.6% for CLA, 39.7% for MTZ and 24.5% for LVX, while resistance rates to AMX and TET remained constantly less than 1%. Double drug resistance (CLA/MTZ) rate significantly increased yearly from 2016 to 2019 (8.0% to 12.0%; p=0.04), while the triple resistance (CLA/MTZ/LVX) rate was also higher in 2019 compared to 2016 (5.4% vs 4.1%). The primary resistance to MTZ was significantly higher in females while higher resistance rates to CLA and to LVX were found in subjects aged > 40 years.

**Conclusions:** High resistance rates to CLA, MTZ and LVX together with the significant trend of increase in double drug resistance [CLA/MTZ] rate observed in Belgium support documented susceptibility guided therapy of H. pylori infection instead of empirical treatment. Resistance surveillance data of H. pylori are important to optimize the therapeutic strategies.

Extracorporeal membrane oxygenation does not impact the pharmacokinetics of liposomal amphotericin B

Camille Mane*1, Stephanie Ruiz1, Caroline Monchaud21, Didier Concordet1, Georges Bernard2, Peggy Gandia32

1INHERES, Université de Toulouse, INRA, ENVT, Toulouse, France, 2Toulouse University Hospital, Toulouse, France, 3Limoges University Hospital, Limoges, France, 4URM 1248, INSERM, Limoges, France

Background: Extracorporeal membrane oxygenation (ECMO) is a temporary life support technique which is increasingly used for cardiac and/or respiratory failure. Amphotericin B is a major antifungal drug with a broad-spectrum activity. To circumvent its renal toxicity, a liposomal formulation (L-AmB) was developed which is extensively used in the Intensive Care Unit (ICU). Even though the influence of ECMO on pharmacokinetics (PK) has been demonstrated for many drugs very little data relating to the effect of ECMO on L-AmB pharmacokinetics has been reported to date.

Materials/methods: Six-point PK profiles of L-AmB were analysed to monitor the efficacy of treatment in three patients undergoing ECMO. Monte Carlo simulations were performed, in parallel for each patient, based on the L-AmB population pharmacokinetic model published by Würthwein et al. for hematopoietic stem cell recipients. The Empirical Bayes Estimates of PK parameters were subsequently computed, and the most likely kinetic profile of the patient deduced. This profile was used to estimate the Area Under the Curve (AUC) and the through concentration (Cmin) for each individual patient.

Results: Estimated AUCs were 176.6, 113.0 and 92.7 mg.h/L and estimated Cmin were 4.0, 1.9 and 2.4 mg/L for the three patients, respectively. PK profiles of Patients 2 and 3 were determined before steady state was reached, leading to lower AUCs and through concentrations compared with Patient 1. However, estimated profiles were consistent with observed concentrations in all three patients.

Conclusions: Estimated Cmin at T24 after the start of infusion and estimated AUCs were similar to those reported in ICU patients with or without ECMO. Moreover, our study does not appear to highlight any difference in L-AmB pharmacokinetics between ICU patients undergoing ECMO and hematopoietic stem cell recipients, even before reaching steady state. Based on these preliminary results, no L-AmB dose adjustment seems necessary for patients undergoing ECMO. These results need to be confirmed in a larger cohort.

Clinical and epidemiological characteristics of infective endocarditis with negative blood cultures: a multi-centre case-series in the south of Spain

Lorenzo Roberto Suardi*, Luis E. Lopez-Cortes†, Luque Rafael‡, Josefa Ruiz Morales‡, Antonio Plata Ciezar‡, Javier De La Torre Lima‡, Carmen Hidalgo Tenorio§, David Vinuesa García‡, Francisco Javier Martinez-Marcos‡, Aristides De Alarcón‡, Guillermo Ojeda‡, Jose Mª Reguera Iglesias‡, Juan Gálvez-Acebal‡,10

1Università di Firenze, Dipartimento di Medicina Sperimentale e Clinica, Firenze, Italy, 2Hospital Universitario Virgen Macarena/CSIC/Instituto de Biomedicina de Sevilla (IBiS), Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Sevilla, Spain, 3Hospital Universitario Virgen del Rocío, Sevilla, Spain, 4Hospital Universitario Virgen de la Victoria, Málaga, Spain, 5Hospital Costa del Sol, Marbella, Spain, 6Hospital Universitario Virgen de las Nieves, Granada, Spain, 7Hospital Universitario San Cecilio, Granada, Spain, 8Hospital Juan Ramón Jiménez, Servicio de Enfermedades Infecciosas, Huelva, Spain, 9Hospital de Sevilla, Departamento de Medicina, Sevilla, Spain

Background: Negative blood-cultures infective endocarditis (NBC-IE) account for 3-31% of all infective endocarditis (IE) and, historically, these patients suffers of worse outcome due to delay in diagnosis, inappropriate antimicrobial therapy and frequent need for surgery.

Materials/methods: The study included all adult patients, prospectively recruited from eight hospitals in Andalusia region (Spain), with definite IE diagnosis, according to modified Duke criteria, with at least two sets of blood-cultures drawn and with hospital admission between 2008 and 2018. In the case of NBC-IE, systematic serological assessment for C.burnetii, Bartonella spp, M.pneumoniae and L.pneumophila was provided as well as polymerase chain reaction (PCR) analysis and culture on valvular surgical specimens. Exclusion criteria: concomitant infected intracardiac-device and life expectancy less than 48 hours since admission. Positive blood-cultures infective endocarditis (PBC-IE) refers to consistent with IE microorganism recovery from blood-cultures according to modified Duke criteria. Main aims were to investigate NBC-IE group features comparing to PBC-IE counterpart and to describe non-blood-cultures-made etiologies.

Results: One-thousand-and-nine patients were included whom 921 (91.2%) had PBC-IE while 88 (8.8%) with NBC-IE. Six-hundred-seventy-one (66.5%) were male and median age was 67 years (IQR 55-75). Previous antibiotic (OR 5.3, CI95% 3.3-8.3) and community-acquired onset (OR 2.3, CI95% 1.4-3.9) were more frequent in the NBC-IE. Previous vascular manipulation (OR 2.2, CI95% 1.3-3.2) was significantly associated with PBC-IE. A significant proportion of patients with NBC-IE required cardiac-surgery (57% vs 37%, p=0.001) while no statistical difference regarding in-hospital/30-days mortality and length of in-hospital were found. Non-bloodculture-made diagnosis was achieved for 34 patients, of whom 26 (76.5%) with PCR or culture on surgical specimen (figure 1).

Conclusions: This case-series revealed no difference, regarding clinical complications and mortality, between PBC-IE and NBC-IE despite a significant higher cardiac-surgery requirement in the latter. C. burnetii and T. whipplei were confirmed as fastidious pathogens with a remarkable amount of surgical diagnosis through valvular PCR analysis or culture. Therefore, several traditional bacterial etiologies could have been missed because of prompt antibiotic courses. To maximize the chances to reach a microbiological diagnosis, is strongly recommended to delay any antimicrobial treatment, according to patient’s clinical stability, after correct blood samples withdrawal.
Clinical experience of dalbavancin in infectious endocarditis: stratifying its impact on treatment

Maricela Valerio Minero*, Maria Cristina Veintimilla Yanez1, Simone Mornese Pinna2, Marina Machado1, Ana Alvarez-Uria1, Alicia Galar Recalde1, Maria Olmedo Samperio1, Cristina Rincón1, Emilio Bouza1, Patricia Muñoz1

1Clinical Microbiology and Infectious Diseases Department, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 2Infectious Diseases Unit, University of Turín, Turin, Italy

Background: Dalbavancin (DAL) is approved for SSTI treatment caused by Gram-positive cocci (GPC). Recently, it has been used, off-label, as part of Infectious Endocarditis (IE) treatment, although evidence is low.

There is little experience with prolonged IE treatment with DAL, as it is generally indicated as consolidation therapy. Assessing the impact of DAL in IE treatment is challenging.

Objective: To describe our experience on IE cases treated with DAL, its efficacy, safety profile and the impact on their treatment.

Materials/methods: Retrospective, observational study of IE adult-patients treated with DAL, during 2016-2018. The impact of DAL on the IE treatment was classified as:

- Medium: when DAL was given for ≥7 days, but it was <50% of total treatment.
- High: when DAL was given for ≥7 days and represent ≥50% of total treatment.

We analyzed clinical characteristics, outcome, adverse effects, economic impact of savings in hospitalization days.

Results: Overall, of the 150 IE cases treated during the study period, 119 were caused by GPC. 14 patients (9.3%) of the total and 11.8% of the GPC IE cases received DAL as part of their treatment; 85.7% were males, median age was 61y. The majority were patients with aortic IE (8 cases, 57.1%), prosthetic IE (8, 57.1%), 5 (35.7%) were due to S. aureus and 7 (50%) underwent surgery.

According to our classification, in 4 cases DAL had a HIGH impact on treatment and in 10 a MEDIUM impact.

Median treatment days was 14 (range:19-98) and 85.7% were treated with 1,500mg every two weeks.

Treatment tolerance was good, two patients had a mild adverse event. After six months follow-up, all cases were cured without recurrences. Moreover, 12 patients (85.7%) could be treated as outpatients. After considering DAL and hospitalization-days cost, we calculated an average saving of 7,119 euros per-patient.

Conclusions: Dalbavancin has been used mostly as a sequential IE treatment, only in four patients DAL had a high impact on treatment. Dalbavancin is safe and well-tolerated, even in larger treatments and allows the outpatient management, reducing hospital stay cost. Future IE series treated with dalbavancin must assess its impact on treatment.

Abstract 3160

Implementing antibiotic stewardship in humanitarian contexts: MSF’s experience
Amel Filali*, Rupa Kanapathipillai1, Lisa Noonan1, Bastien Mollo1, Justine Michel1, Northan Hurtado2, Malou Nada1, Clair Mills1
1 Doctors Without Borders, Paris, France, 2 Doctors Without Borders, New York, United States

Background: Antibiotic resistance (ABR) is a significant threat to human health worldwide. MSF has implemented 11 antibiotic stewardship (ABS) programmes, aiming to be effective, sustainable and context-adapted. Inpatient surgery, neonatal and burns units, and services managing immunocompromised patients (e.g. malnourished children) were prioritized for implementation.

Materials/methods: ABS programmes are led by non-specialised doctors, trained by infectious disease physicians. Tools developed to standardise implementation include context-adapted guidelines (given heterogeneity in ABR) and surveillance systems to facilitate local cumulative antibiograms.

Results: Median implementation time was six months. Resistance rates in clinically significant isolates were higher in the Middle East. In 2018, 59% of samples from Aden had at least one multi-resistant organism (MRO), with 70% extended spectrum beta-lactamase (ESBL)-producing enterobacteriaceae; in Amman, 51% of samples had at least one MRO. Carbapenem-resistant enterobacteriaceae were identified in five of six projects in the Middle East. By comparison, 24% of the enterobacteriaceae in Mali were ESBL-producers. Higher rates of resistance (such as those in the Middle East) tend to be associated with more restrictive ABS programmes. Lessons learned include the need to strengthen infection prevention and control alongside, or before, ABS programme implementation. Access to microbiology should be implemented after strengthening stewardship.

Conclusions: Implementing successful stewardship programs in humanitarian contexts is feasible. A restrictive model of stewardship appears to be easier to implement. Antibiotic costs and human resource constraints limit duplication of the ABS model in public hospitals in contexts where MSF works.

Abstract 3161

Infectious complications in kidney transplant recipients: a prospective cohort study

Anne Scemla,1 Marie-Cécile Perier,2 Olivier Aubert,3 Victoria Manda,1 Nassim Kamar,4 Sophie Girerd,5 Valérie Garrigue,5 Clarisse Kerleau,6 Fanny Buron,7 Fanny Lanternier,6 Christophe Legendre,9 Magali Giral,6 Alexandre Loupy

1Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris, Université Paris Descartes, INSERM U970, RTRS «Centaure,» Paris, France, 2Service de Néphrologie et transplantation rénale adulte, Paris, France, 3Université Paris Descartes, INSERM U970, INSERM U970, Paris Cardiovascular Research Centre (PARCC), Paris, France, 4Centre hospitalo universitaire Rangueil, Département de Néphrologie et Transplantation d’Organes, Toulouse, France, 5Centre hospitalo-universitaire de Nancy-Brabois, université de Lorraine, Vandoeuvre-lès-nancy, France, 6CHU de Montpellier, Hôpital Lapeyronie, Montpellier, France, 7Hôpital Hotel Dieu, ITUN, Université de Nantes, Inserm U1064, Service de néphrologie et transplantation rénale adulte, Nantes, France, 8Hospices civils de Lyon, Lyon, France, 9Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris, Université Paris Descartes, Paris, France, Service de maladies infectieuses et tropicales, Paris, France, 10Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris, Université Paris Descartes, RTRS «Centaure,» Paris, France, Service de Néphrologie et transplantation rénale adulte, Paris, France

Background: Although Infectious complications are a major cause of morbidity and mortality in kidney transplant (KT) recipients, little is known about their natural history and determinants at a population level in the recent era.

Materials/methods: Nationwide cohort including all consecutive patients from 6 french centers, receiving a kidney transplantation from 2000 to 2015 with prospective uniform and quality-checked extensive data collection including a systematic record of post-transplant infectious complications (site and pathogen involved).

Results: 9,563 KT recipients were included with a median follow-up time post-transplant of 7 years (IQR 4-10). During the follow-up, 11,173 infectious complications were diagnosed in 4,482 patients. The first infectious episode occurred after a median 192 days (IQR 23–852) after KT. Infections were bacterial (n=6,119, 54.7%), viral (n=1,912, 17.1%), fungal (n=462, 4.1%) or parasitic (92, 0.9%), and 2,583 (23.1%) where from unknown pathogen. Main sites were upper urinary tract (n=4,636, 41.5%), followed by lower respiratory tract (2,546, 22.8%), GI tract (n=1051, 9.4%), and skin (977, 8.7%). Main pathogens were bacterial: Enterobacteriaceae (3,522, 31.5%), staphylococci (627, 5.6%), enterococci (545, 4.9%), pseudomonas (446, 4%), Clostridium difficile (189, 1.7%), tuberculous and non tuberculous mycobacteria (105, 0.9%) and Streptococcus pneumoniae (103, 0.9%); viral: Cytomegalovirus (626, 5.6%), Varicello-zoster virus (582, 5.2%), BK virus (231, 2.1%), Norovirus (129, 1.6%), Hepatitis E virus (82, 0.7%); fungal: Pneumocystis jiroveci (138, 1.2%), candida (129, 1.2%) and aspergillus (108, 1%). Infectious episodes were associated with an increased risk of death (p<0.001). The main independent determinants for infection were: recipient age, female gender, history of diabetes, hypertension, major cardiovascular events, induction treatment, eGFR at 1-year post KT, acute rejection, donor age and graft rank (p<0.001 for all comparisons).

Conclusions: In this first population-based assessment of infections after KT, upper urinary tract and lower respiratory tract infections were the most frequent infections. Improvement of prevention measures would prevent many of them. These results suggest the potential for a data driven approach of infectious disease to improve patients risk stratification and help clinicians in the clinical management and immunosuppressive regimens adaptation.

An unusual case of a Spanish traveller patient with chyluria and molecular diagnosis of schistosomiasis

Marco Antonio Sempere Alcocer*1,2,3, Fernández Montero Jose M.4, Crego Vicente Beatriz1, Hidalgo Luis4, Jose Maria Saugar5, Pedro Fernández-Soto6

1HC Marbella International Hospital, Laboratorio de Microbiología [Semlab 2000], Marbella, Spain, 2Hospital Punta Europa, Laboratorio, Algeciras, Spain, 3Universidad Internacional de la Rioja [UNIR], Facultad de la Salud, Logroño, Spain, 4HC Marbella International Hospital, Marbella, Spain, 5Universidad de Salamanca, e-INTRO, IBSAL-CIETUS, Facultad de Farmacia, Salamanca, Spain, 6Instituto de Salud Carlos III, Centro Nacional de Microbiología, Madrid, Spain

Background: Schistosomiasis is a Neglected Tropical Diseases that affects about 250 million of people in tropical and subtropical areas and also in travelers. The infection occurs after a contact with cercariae contaminated water, often clinically silent and after a long-term of time presenting serious damage in organs. Schistosoma mansoni adult worms reside in mesenteric veins causing intestinal and hepatosplenic schistosomiasis. Sporadically, eggs and worms are found outside the portal system, causing ectopic schistosomiasis.

The recommended treatment with praziquantel (40 mg/Kg) achieve a cure rate of 77%, and repeated treatment is often needed for a complete cure. In infected travelers, the diagnosis and treatment of schistosomiasis is a challenge because the elimination of eggs is very scarce compared to infected people in endemic areas of schistosomiasis.

Materials/methods: We present a rare case of schistosomiasis in a Spanish teenager who, after 10 months of a travel to Puerto Rico, presented an intense chyluria and eosinophilia (>900/mm3), without other symptoms. Tests to rule out microfilariae, including Knott’s test, thick drop, serology with filarial recombinant antigens (Loa loa, Onchocerca, Wuchereria) and PCR for filaria were negative. Strongiloides stercoralis [PCR and serology] and Toxocara [serology] were discarded.

Schistosomiasis mansoni was diagnosed through serology tests and specific S. mansoni DNA detection by LAMP [Loop-mediated isothermal amplification] in feces, serum and urine. No Schistosoma eggs were observed in urine or feces by Kato-Katz slides and concentration. One month before treatment, the chyluria disappears and a normal isotopic lymphography rule out another cause of chyluria.

Results: Initial treatment was carried out in December 2018 with a single dose of praziquantel [40 mg/Kg]. Four months after treatment, the eosinophilia and LAMP assay remained positive. A second dose of praziquantel was administered in April 2019 but eosinophilia and LAMP remain positive after 12 months. Actually, a new treatment with praziquantel [40 mg/Kg, 3 doses/day] is being considered.

Conclusions: To our knowledge this is the first case of chyluric Schistosomiasis caused by S. mansoni.

New specific and sensitive molecular techniques as LAMP can help diagnosis and monitoring treatment of schistosomiasis, especially in patients with low parasitic load, as often occurs in travelers.

Abstract 3163

Short-term peripheral venous catheter-related bloodstream infections
Trung Vu¹, John Goritsas², Heidi Torres Diaz¹, Kelly Reveles², Charmayne Dickerson¹, Jose Cadena-Zuluaga³

¹University Of Texas Health Science Center At San Antonio, Infectious Disease Department, San Antonio, United States; ²University Of Texas Health Science Center At San Antonio, Pharmacy Department, San Antonio, United States; ³Audie Murphy South Texas Veterans Health Care System, Infection Control, San Antonio, United States

Background: In the United States, nosocomial bloodstream infections (BSIs) are the eighth-leading cause of mortality, with approximately 31,000 deaths per year. Most nosocomial BSIs are associated with intravascular catheter use. Almost 80% of hospital admissions involve an average of two peripheral intravenous catheters (PIVC) per patient, and PIVC-related BSI rates range from 0.1 to 0.18 per 1000-patient days. To improve nursing satisfaction, a new institutional policy change was implemented to extend duration between required PIVC change in our local hospital. We aimed to evaluate if this change was associated with higher rate of BSI.

Materials/methods: The Audie L Murphy South Texas Veterans Health Care system, a 268-bed tertiary care center, implemented a policy whereby PIVC was changed every 3 days to every 7 days or as needed (whichever was shorter). We performed a retrospective chart review of pre- and post-intervention BSI rates. Patients admitted to acute care units – surgical ICU, surgical ward, medical ward, medical ICU, cardiac ICU, and intermediate care unit – were included for analysis. May to October 2016 was defined as the pre-intervention period, and September 2017 to February 2018 as post-intervention. PIVC-related BSI was defined as BSI with a recognized non-commensal pathogen on or after the 4th day of those patients with PIVC present for 3 or more consecutive days. We excluded those with concomitant central venous catheter, or BSI secondary to another site. BSI rates were compared between the pre- and post-intervention period using the chi-square test.

Results: A total of 102 BSI cases in 14553 bed-days occurred during the pre-intervention period; 8 of the 102 cases had no identifiable source, and 2 of those met the definition of PIVC-related BSI. Similarly, 61 BSI cases in 14108 bed-days occurred during the post-intervention period; 14 cases had no identifiable source, and 3 of those were PIVC-related BSI. PIVC-related BSI rate pre-intervention was 0.14 per 1000 bed-days, compared to post-intervention rate of 0.21 per 1000 bed-days (p=0.6298).

Conclusions: Decreasing the frequency of scheduled PIVC changes from every 3 to every 7 days (or as needed) did not appear to increase the rate of PIVC-related BSI in our institution.

**Abstract 3164**

**Daptomycin plus fosfomycin or ceftaroline is active in vitro against high-level aminoglycoside-resistant and vancomycin-resistant or vancomycin-susceptible Enterococcus spp. strains**

Cristina Garcia-De-La-Maria*1, Javier García-González1, Diana Panessò1, Maria Alexandra Cañas Pacheco1, Anders Dahl1,2,3, David Fuster1, Bàrbara Vidal1, Andres Perissinotti1, Elena Sandova1, Jose M Tolosana1, Eduard Quintana1, Manel Almela1, Juan Ambrosioni1, Maria Moreno Camacho1, Cesar Arias2, José M. Miró Meda1

1Hospital Clinic-IDIBAPS. University of Barcelona, Barcelona, Spain, 2Center for Antimicrobial Resistance and Microbial Genomics (CARMiG), UTHealth Mc Govern Medical School, Houston, United States, 3Department of Cardiology, Gentofte University Hospital, Copenhagen, Denmark

**Background:** Together Enterococcus faecalis (EFS) and Enterococcus faecium (EFM) account for up to 15% of infectious endocarditis. Multidrug resistance to aminoglycosides (HLAR), beta-lactams and vancomycin often occur and therefore synergistic bactericidal combinations of two antibiotics are recommended. This *in vitro* synergy study evaluates the activity of DAP+FOM or CTL against eight HLAR Enterococcus strains.

**Materials/methods:** Four VRE EFM and four EFS [two VRE and two VSE] strains were tested. DAP, CFT, FOM MICs/MBCs were determined by the microdilution broth method. *In vitro* synergy was performed by time-kill studies (TKC). TKC antibiotic concentrations ranged from ¼xMIC to 1xMIC and two inocula were tested: a standard inoculum (SI) equal to 10^5-6 cfu/ml and a high inoculum (HI) equal to 10^8 cfu/ml mimicking the cfu density in mature infected vegetations. The results of the combination at 24h were compared with those of the most active single drug; synergy was defined as a ≥2-log increase in killing. Bactericidal activity (BA) was defined as a ≥3-log_10 decrease in cfu/ml of the initial inoculum at 24h.

**Results:** EFM strains were ampicillin and ceftaroline resistant (MIC/MBC ≥ 32 µg/mL). EFS strains were ampicillin (MIC/MBC ≤ 2/2 µg/mL) and ceftaroline (MIC/MBC ≤ 4/16 µg/mL) susceptible. All the strains were FOM resistant (MIC/MBC ≥ 64 µg/mL). VRE-1 was DAP resistant (MIC/MBC = 4/8 µg/mL) and VSE-188 showed daptomycin non-susceptibility when grown under sub inhibitory daptomycin conditions (MIC/MBC = 8/16 µg/mL). TKC results are displayed in the table below.

Both combinations were effective in preventing the development of DAP-resistance in the VRE-1 and VSE-188 strains.

**Conclusions:** *In vitro* DAP+FOM was as active as DAP+CTL, suggesting that these combinations could be effective in treating Enterococcus infections and thus worthy of further studies in the *in vivo* experimental model.

Tolerance of pyrazinamide for the treatment of tuberculosis in elderly patients over 75 years

Stella Rousset*1, Hélène Guet-Revillet1, Caroline Protin1, Jean Le Grusse2, Hélène Derumeaux1, Pierre Delobel1, Guillaume Martin-Blondel1

1Toulouse University Hospital, Toulouse, France, 2Hôpital Joseph Ducuing, Toulouse, France

Background: Pyrazinamide for the treatment of tuberculosis in patients over 75 years old has a controversial tolerance profile. Our aim was to assess frequency, severity and risk factors of adverse events (AEs) in elderly subjects treated for tuberculosis with or without pyrazinamide.

Materials/methods: Retrospective monocentric study at Toulouse University Hospital (France) including patients over 75 years treated for active tuberculosis between 2008 and 2018. The frequency, type, severity, accountability of AEs of anti-tuberculosis treatment were compared between patients receiving or not pyrazinamide. The risk factors for AEs were investigated by univariate and multivariate analyses by binary logistic regression.

Results: Among the 110 patients included, 54 (49.1%) received pyrazinamide (group 1) and 56 (50.9%) received pyrazinamide free-regimens (group 2). Groups were comparable regarding the severity and locations of tuberculosis. Compared to group 1, patients in group 2 were older (aged over 85: 46.4% versus 24%, p=0.025), less autonomous (median Katz ADL: 5.0 versus 6.0, p=0.049), had higher levels of transaminases (median SGOT: 29 versus 23 IU.L⁻¹, p=0.028) and received more often empirical tuberculosis treatments (66.1% versus 42.6%, p=0.013). AEs related to anti-tuberculosis treatment occurred in 31/54 (57.4%) in group 1 and 14/56 (25%) in group 2 (p=0.0017), with a trend for higher rates of allergy and digestive disorders, but not hepatotoxicity, in group 1. Pyrazinamide-related AEs occurred in 22/54 (40.7%) of exposed subjects, leading to stop pyrazinamide in 14/22 (63.6%). AEs definitely or potentially related to ethambutol occurred in 13/44 (31.7%) of exposed subjects in group 1, and 3/52 (5.4%) in group 2 (p=0.0025). Serious AEs occurred in 13/31 (41.9%) in group 1, and 5/14 (35.7%) in group 2 (p=0.69). Three deaths potentially related to AE occurred in group 1 and none in group 2. Independent risk factors for AEs of anti-tuberculosis treatment were the use of pyrazinamide [odds ratio 4.5, CI95 1.7-12, p=0.003] and diabetes [odds ratio 3.5, CI95 1.06-11.6, p=0.04]. No predictive factors of pyrazinamide-related AEs were identified.

Conclusions: In elderly French subjects, use of pyrazinamide was associated with more frequent AEs of anti-tuberculosis treatment and of ethambutol, and its toxicity was not predictable.

Abstract 3168

Impact of beta-lactam allergy label on preoperative antibiotic prophylaxis
Cynthia Nguyen*, Kerilyn Petrucci1, Ellen Daily1, Amanda Brown1, Jennifer Pisano1, Natasha Pettit1

1University of Chicago Medicine, Chicago, United States

Background: Surgical site infection (SSI) is a common post-procedure complication which may be prevented by adhering to established recommendations, including the administration of preoperative antibiotic prophylaxis. Patients with a beta-lactam allergy (BLA) have an increased risk of SSI, which has been attributed to the lack of optimal preoperative antibiotic administration.

Materials/methods: This was a single-center, retrospective, matched cohort study of adult patients who underwent a clean or clean-contaminated abdominal hysterectomy, coronary artery bypass graft (CABG), colon surgery, or knee replacement between July 1, 2018 and June 30, 2019. Patients with a BLA label were matched to patients without a BLA label based on procedure, age, and BMI. The primary outcome was the rate of appropriate preoperative antibiotic prophylaxis, defined as concordance with the institution’s guideline. The guideline includes recommendations for appropriate antibiotic selection based on the presence or absence of a severe BLA and MRSA risk factors as well as appropriate antibiotic dose timing prior to incision. Secondary endpoints included surgical site infection (SSI), length of stay (LOS), mortality, and colonization or infection with a multidrug resistant organism (MDRO).

Results: Among the 867 procedures identified, 160 patients had a BLA at the time of the procedure and 130 matches were identified. Consequently, a total of 260 patients were included. Knee replacement (38%) was the most common procedure type, followed by hysterectomy (25%), colorectal (18%), and CABG (18%). Among patients with a BLA label, severe IgE-mediated reaction (44%) was most the common reaction type, followed by mild-moderate (32%), unknown (13%), and intolerance (10%). Appropriate preoperative antibiotic prophylaxis was significantly higher among patients without a BLA (76% versus 37%, p<0.001). This difference remained when removing the requirement to assess for patient-specific MRSA risk factors (80% versus 39%, p<0.001). Among the 54 patients with a mild-moderate reaction or intolerance, 29 (54%) patients received antibiotics that would have been appropriate only if the patient had a severe BLA. No differences in SSI, LOS, mortality, and MDROs were observed.

Conclusions: Patients with a BLA were more likely to receive inappropriate preoperative antibiotic prophylaxis compared to patients without a BLA.

Efficacy of temocillin versus carbapenems for the treatment of extended spectrum beta-lactamase-producing Enterobacteriaceae urinary tract infections: a case control study

Simon Gravier*, Tristan Delory1, Diane Le Puart2, Géraldine Gaube1, Soline Siméon1, Benjamin Davido1, Stéphanie Lejeune2, Emilie Piet2, Raphael Lepeule2, Philippe Lesprit2, Matthieu Lafaurie1

1Saint-Louis Hospital, AP-HP, Paris, France, 2Foch Hospital, Suresnes, France, 3Mondor Hospital, AP-HP, Créteil, France, 4Raymond-Poincaré Hospital, AP-HP, Garches, France, 5Annecy-Genevois Hospital, Annecy, France

Background: Temocillin may represent an alternative to carbapenems for the management of ESBL-E UTI. However, clinical data regarding its efficacy are scarce.

Materials/methods: Multicenter retrospective case-control study (6 French tertiary-care hospitals), to assess the efficacy of definitive therapy with temocillin or carbapenems in patients with ESBL-E UTI. Cases and controls were adults with definite diagnosis of ESBL-E UTI between January-2015 and October-2019. Cases were treated with temocillin for ≥50% of the effective antibiotic therapy duration [TEMO-arm]. Control exclusively received carbapenem over the effective antibiotic therapy duration [CP-arm]. They were statistically matched (1:1 ratio) on sex and age. Primary endpoint was clinical response at the End-of-Treatment [EOT]. Secondary endpoint was mortality within 3-months after the start of effective antibiotic therapy. Analysis using descriptive statistics and logistic regression.

Results: A total of 178 patients were screened for eligibility and 142 (80%) retained in analysis after statistical matching [71 cases, 71 controls]. Median age was 69.7-years [IQR,58.3-68.3] and 94(66%) were male. There was no difference between TEMO-arm and CP-arm for Charlson’ score [4 [IQR,2-6] vs. 3 [IQR,2-5], p=0.362] and immunocompromised status [53/71(56%) vs. 48/71(53%), p=0.611]. A total of 49(34%) patients were renal-transplant recipients [SOT-status, p=0.717], 47(33%) had bacteremia [p=1.000] and 18(13%) had sepsis [p=0.382]. Microorganisms involved were similar between arms [p=0.994]: K.pneumoniae in 59/142(42%), E.coli in 55/142(39%), Enterobacter spp. in 24/142(17%), others in 4/142(2%). Overall, time to effective antibiotic therapy was 0-days [IQR,0-2], 29/71(41%) patients received carbapenems as empirical therapy in TEMO-arm and 32/71(45%) in CP-arm. Empirical antibiotic therapy was significantly more often effective in TEMO-arm [OR=2.71 [95%CI,1.33-5.50], p-value=0.006]. In TEMO-arm, 6/71(8%) patients received temocillin in first line, for others temocillin was initiated after 3-days of effective therapy [IQR,1-4]. Temocillin was given at 2g-b.i.d [IQR,1-2] for 11-days [IQR,8-14], sparing 832-days of carbapenems. Overall, effective antibiotic duration was significantly shorter in TEMO-arm [14-days [IQR,12-16] vs. 16-days [14-21], OR=0.93 [95%CI,0.88-0.99], p=0.017]. Clinical response rate at EOT was 68/71(96%) in TEMO-arm vs. 70/71(95%) in CP-arm, without difference after adjustment on SOT-status [aOR=0.33, [95%CI,0.03-3.22], p=0.337]. There was no difference in mortality [10/142(7%), p=0.981].

Conclusions: Temocillin efficacy seems comparable to carbapenems in the treatment of ESBL-E UTI.

Prevalence of antibiotic resistance among Enterobacterales isolates recovered from urinary samples in France

1Hôpital Foch, SURESNES, France, 1'BioPath Laboratoires, Dunkerque, France, 1'Bicêtre, Kremlin-Bicêtre, France, 4'Bio Ard'Aisne, Rethel, France, 5'CHU de Reims, Reims, France, 6'Hôpital Paris Saint-Joseph, Paris, France, 7'CHU de Besançon, Besançon, France, 8'CHU de Nice, Nice, France, 9'CHU, APHP Centre - Université de Paris, site Cochin, Paris, France, 10'HIA Sainte-Anne, Toulon, France, 11'CHU Henri Mondor, Créteil, France, 12'CHU de Nantes, Nantes, France, 13'CHU de Poitiers, Poitiers, France, 14'CHU de Tours, Tours, France, 15'Institut Gustave Roussy, Villejuif, France, 16'CHU de Brest, Brest, France, 17'CHU de Strasbourg, Strasbourg, France, 18'CHU Necker-Enfants Malade, Paris, France, 19'CHU de Montpellier, Montpellier, France, 20'Hôpital André Mignot, Le Chesnay, France, 21'CHU Avicenne, Bobigny, France, 22'CHU de Caen, Caen, France, 23'EA2656, GRAM2.0, CHU de Caen, Caen, France, 24'CHU de Rennes, Rennes, France, 25'CH de Valenciennes, Valenciennes, France, 26'CH de Dieppe, Dieppe, France, 27'HIA Bégin, Saint-Mandé, France, 28'CHU Lariboisière, Paris, France

Abstract third-party references: On behalf of the GMC study group

Background: Antibiotic resistance in Enterobacterales is a major public health issue and community-acquired urinary tract infections (cUTIs) are the most frequent infections due to Enterobacterales in the community. The worldwide spread of ESBL-producing isolates (ESBL-E), especially Escherichia coli, is of particular concern because of its spread in the community. In France, 3.6% of cUTI are due to ESBL-E. Their management was recently updated in France. The aim of the study was to assess the prevalence of resistance to antibiotics recommended for the treatment of UTI in France.

Materials/methods: Twenty-seven French clinical laboratories participated in the study. All Enterobacterales isolates collected from urinary samples between September 2017 and August 2018 were retrospectively included. Duplicates were excluded. Antimicrobial susceptibility testing and interpretation were performed according to EUCAST guidelines 2017.

Results: A total of 135,065 clinical isolates were included among which 72.1% E. coli, 9.4% Klebsiella pneumonia, and 5.8% Proteus mirabilis. ESBL-E accounted for 6.7%, while ESBL-E prevalence was significantly different among French regions, ranging from 3.9% in Centre to 11.7% in Ile-de-France (P<0.01). ESBL-E rate ranged from 3.4% [outpatients] to 15.9% [geriatric wards]. The rate of ESBL-E was significantly lower among E. coli than among K. pneumoniae isolates (5.6% vs 19.5% respectively, P<0.01).

Overall, the rates of resistance were lower for fosfomycin (4.6%), mecillinam (11.8%) and nitrofurantoin (15.2%), than for ciprofloxacin (16.7%), cotrimoxazole (30.4%) and amoxicillin-clavulanate (40.7%). In E. coli, the prevalence of fosfomycin and nitrofurantoin resistance and was both 1.1%.

The 3 main species displayed specific profiles of resistance, P mirabilis being significantly more susceptible to amoxicillin-clavulanate (11.8%) and cefotaxime (1.5%) but more resistant to cotrimoxazole (39.7%) and mecillinam (36.6%). K. pneumoniae was more resistant to fosfomycin (22.1%), cefotaxime (30.1%), nitrofurantoin (40.6%) and ciprofloxacin (32.0%). E. coli was significantly less resistant to nitrofurantoin (1.1%) and fosfomycin (1.1%).

Conclusions: Our results show heterogeneous rates of ESBL-E in France depending on the French region, the clinical context, and the bacterial species. Consequently, probabilistic treatment should be adapted to the clinical, microbiological and local context. Longitudinal studies are needed to assess the evolution of the prevalence of antibiotic resistance prevalence in urinary tract isolates.

Abstract 3174

Clinical and economic outcome evaluation of cefepime 4 grams/day extended infusion in pneumonia and sepsis

Emily Dionne1, Aalok Khole2, Maureen Campion*1

1UMass Memorial Medical Center University Campus, Worcester, United States, 2Cheshire Medical Center, Keene, United States

Background: Cefepime displays time-dependent bactericidal activity, and its efficacy is optimized when free drug concentrations exceed the minimum inhibitory concentration (MIC) for at least 60-70% of the dosing interval. Cefepime regimens utilizing 1 gram infused over 3 hours every 6 hours are able to achieve pharmacodynamic efficacy against bacteria with an MIC of ≤8 mcg/mL in Monte Carlo simulations. This regimen’s impact has not been evaluated in clinical practice. UMass Memorial Medical Center in Massachusetts, USA changed its cefepime intermittent infusion (II) protocol, 2 grams infused over 30 minutes every 8 hours to an extended infusion protocol (EI), 1 gram infused over 3 hours every 6 hours. Dosing was adjusted for renal function. The objective of this study was to compare clinical and economic outcomes between II and EI.

Materials/methods: A retrospective cohort study was conducted on inpatients who received EI or II between 2016 and 2018. Inclusion criteria were: age > 18 years, diagnosis of sepsis or pneumonia and prescribed cefepime. Exclusion criteria included: receipt of an additional beta-lactam with activity against Pseudomonas aeruginosa, receipt of both EI and II, comfort measures only, febrile neutropenia with unknown source or organism resistant to cefepime.

Results: The study included 111 patients who received II and 93 who received EI. Baseline characteristics were similar between the two groups. Hospital and intensive care unit (ICU) length of stay was not different between groups (hospital days: II: 7.67 vs EI: 8.07, p=0.67; ICU days: II: 2.6 vs EI: 2.2, p=0.15). Mortality was infrequent in both groups, though deaths were numerically fewer in EI (II: 5.4% vs EI: 3.2%, p=0.45). 90-day readmission rates were similar between groups (II 61.3% vs EI 67.7%, p=0.34). Cefepime cost per patient was lower in EI (average cost II:$86.06 vs EI $43.39).

Conclusions: EI is feasible to administer in the inpatient setting, optimizes pharmacodynamics and did not result in different clinical outcomes in this study. Costs may be reduced by utilizing a prolonged infusion dosing regimen with 4 grams/day vs 6 grams/day. Larger studies should be conducted to evaluate the impact of cefepime prolonged infusion on inpatient mortality.

Abstract 3175

**Infective endocarditis in older adults: distinguishing features**

Luiz Henrique Lemos¹, Leonardo Ribeiro-Da-Silva², Marcelo Correia², Juliana De Andrade¹, Daniela Menezes¹, Rafael Garrido², Bruno Zappa², Giovanna Ianini Barbosa², Clara Weksler², Wilma Golebiovski², Cristiane Lamas*¹,²,³

¹Unigranrio Barra da Tijuca, Rio de Janeiro, Brazil, ²Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil, ³INI - Instituto Nacional de Infectologia Evandro Chagas, Fiocruz, Rio de Janeiro, Brazil

**Abstract third-party references:** FAPERJ/Brazil

**Background:** Infective endocarditis (IE) is a severe disease, especially in older adults.

**Materials/methods:** This is a cohort of adults with definite IE enrolled January 2006 - September 2019. The International Collaboration on Endocarditis case report form was used to collect data. Patients older than 60 years were compared to the remaining cohort in order to identify distinguishing characteristics of IE in older adults. Jamovi 1.0.7 software was used for statistical analysis.

**Results:** Older adults corresponded to 93/359 (25.9%) episodes of IE; they were more often male (72% vs 60.2%, p=0.04) and had significantly more associated conditions: heart failure (53.3% vs 35.7%, p=0.003), COPD (10.9% vs 2.7%, p=0.002), coronary artery disease (31.5% vs 61.1%, p<0.001), cerebrovascular disease (10.8% vs 4.9%, p=0.047), pacemakers (20.4% vs 8.3%, p=0.002), chronic renal failure (27.5% vs 17.2%, p=0.044), and neoplasia (12.9% vs 3.9%, p=0.002). Regarding previous procedures, they significantly more often had previous heart surgery (52.7% vs 32.2%, p<0.001), percutaneous cardiac interventions (10.9% vs 3.4%, p=0.006) and CABG (16.2% vs 2.3%, p<0.001). Older patients less often had rheumatic valvulopathy (20.2% vs 37.7%, p=0.002), but more often presented late prosthetic valve IE (25.7% vs 11.8%, p=0.006) and hospital-acquired IE (39.8% vs 24.5%, p=0.005). Differences regarding clinical features were that older patients less often had fever (88.2% vs 94.7%, p=0.034), embolism (35.2% vs 56.9%, p<0.001), including central nervous system events (12.2% vs 29.1%, p=0.025) and splenomegaly (10.5% vs 26.5%, p=0.002). Regarding etiology, older patients more often had enterococci (20.4% vs 7.5%, p<0.001) and less often had *viridans* group streptococci (16% vs 26%, p=0.047). They more often needed to be mechanically ventilated before surgery (30.3% vs 18%, p=0.015) and to have inotropes (33.7% vs 21.8%, p=0.028). Although older patients had surgical indication in 81.7%, only 66.3% were operated on; in comparison, of the 88.7% of younger patients for whom surgery was indicated, 94% were operated on. Mortality was significantly higher for older patients (43.0 vs 18.1%, p<0.001).

**Conclusions:** Older patients more often had associated comorbidities, late prosthetic IE, hospital-acquired infection and high mortality.

Abstract 3176

**Retrospective study of nosocomial infections in patients with extracorporeal membrane oxygenation therapy in a coronary unit**

Simone Mornese Pinna*1,2, Maricela Valerio Minero1, Iago Sousa Casasnovas1, Alicia Galar Recalde1, Maria Olmedo Samperio2, Carolina Devesa1, Ana Alvarez-Uria1, Marina Machado1, Manuel Martinez-Selles1, Emilio Bouza1, Francisco Fernandez-Aviles1, Patricia Muñoz1

1Clinical Microbiology and Infectious Diseases Department, Hospital General Universitario Gregorio Marañón. Instituto de Investigación Sanitaria Gregorio Marañón., Madrid, Spain, 2Infectious Diseases Unit. University of Turin., Turin, Italy, 3Cardiology Department. Hospital General Universitario Gregorio Marañón., Madrid, Spain

**Background:** The use of extracorporeal membrane oxygenation therapy (ECMO) in the treatment of patients admitted to coronary units has increased. Data regarding infections in this population is scarce.

**Objective:** To describe the epidemiology of infections in patients with ECMO at a coronary unit, risk factors, outcome and factors associated with mortality.

**Materials/methods:** Retrospective study including all adult-patients admitted to the coronary unit between July 2013 and March 2019, with ECMO implanted for >48 hours.

Demographics, comorbidities, duration of ECMO, number and type of infections, other complications and outcome were collected. Risk factors related to infection and mortality were analyzed.

**Results:** Overall, 69 patients were admitted to the coronary unit and had an ECMO >48 hours. 82.5% were men, median age of 58 years, 75.4% had previous cardiac disease and cardiogenic shock was the main indication for ECMO (55.1%).

30.4% of patients were previously colonized and 14.5% had an infection prior to ECMO placement.

A total of 29 patients (42%) presented infection while on ECMO. Thirty-three episodes of infection were diagnosed, the most frequent were: VAP (19 cases, 57.6%), tracheobronchitis (3 cases, 9.1%), bacteremia (3 cases, 9.1%), SSTIs (3 cases, 9.1%) and CMV reactivation (3 cases, 9.1%). There were no ECMO-related infections. Most frequent non-infectious complications were: thrombopenia (50.7%), hypoxemia (47.8%), hemorrhage (29.9%) and acute renal failure (29.4%).

Mortality during ECMO was 39.1%, hospital mortality 46.4% and infection-related mortality 5.8%.

Patients who developed infection had lower survival, although the difference was not significant. The only variable related to infection development was: days on ECMO [OR 1.14, 95% CI 1.01-1.30, p=0.029] and the only variables related to mortality were lactic acidosis after ECMO [OR 2.08, 95% CI 1.19-3.62, p=0.009] and higher Cr after ECMO [OR 13.35, 95% CI 1.43-124.8, p=0.023].

**Conclusions:** Overall, 42% of patients in a coronary unit in ECMO >48h develop an infection, mostly VAP (57.6%) followed by tracheobronchitis (9.1%), bacteremias, CMV reactivation and SSTIs (9.1%) each.

Mortality in patients with ECMO was 46.4%, and infection-related mortality was 5.8%. The survival of patients who develop an infection is lower. The risk factor related to developing an infection is the ECMO duration.

Prevalence of high- and low-risk human papilloma virus in the anus and rectum, vagina and pharynx of asymptomatic men and women attending a sexually-transmitted diseases clinic

Orit Yossepowitch\(^1\), Orna Schwartz\(^2\), Yael Goor\(^3\), Keren Landsman\(^3\), Rivka Sheffer\(^4\), Yasmin Maor\(^*4\)

\(^1\)Wolfson Medical Center, Infectious Disease Unit, Wolfson Medical Center, Holon, Israel, \(^2\)Wolfson Medical Center, Microbiology laboratory, Holon, Israel, \(^3\)Ministry of Health, Tel Aviv District Health Office, Tel Aviv, Israel, \(^4\)Wolfson Medical Center/Tel Aviv University, Infectious Disease Unit, Wolfson Medical Center, Holon, Israel

**Background:** There are gaps in knowledge regarding the epidemiology of high and low risk human papilloma virus [HPV] in people with risk factors for sexually transmitted diseases [STDs].

**Materials/methods:** A random sample of people attending an STD clinic in Tel Aviv were tested for the presence of HPV genotypes by rectal vaginal and throat swabs using the Anyplex\(^{TM}\) II (Seegene) kit which detects 19 high risk and 9 low-risk HPV genotypes. Data regarding sexual habits and medical history was obtained.

**Results:** Of 99 people included 77 (77.8%) were males. Mean age was 30.5 years. 52 (52.5%) were heterosexuals, 51 (51.5%) were men who have sex with men, 5 were sex workers, and 3 were HIV positive. 85 (85.9%) had a recent new sexual partner and 73 (73.7%) had >20 sexual partners. 66 (66.7%) reported anal intercourse and 91 (91.9%) oral intercourse. Only 25 (25.3%) used condoms regularly. 39 (39.4%) had an STD in their past. Only 16 people (16.2%) received HPV vaccine. 18 (18.2%) reported known HPV lesions in the past. 52 (52.5%) people were positive for HPV in at least one site, of these 42 (80.7%) had ≥1 high risk HPV genotype. HPV was most common in the vagina (12/21, 57.1%) and 8 (66.7%) had high risk HPV genotypes. 47 (51.1%) had positive HPV from the anus, of these 33 (70.2%) had high risk HPV. 7 (11.5%) had a positive HPV from the throat, of these in 5 (71.4%) HPV were high risk. The median number of HPV genotypes/person in HPV positive people was one (1-8). The most common HPV genotypes were HPV6, HPV42, HPV53 and HPV68. Of infected people 41 (78.8%) were HPV positive in only one body site, 9 (17.3%) in two sites and 2 women were infected in 3 sites. In 10 (90.9%) there was concordance in ≥1 genotype between ≥2 body sites.

**Conclusions:** In high-risk patients, carriage of HPV was common regardless of the presence of warts. Most of the prevalent HPV genotypes were carcinogenic. Most people were infected only in one body site but concordance between genotypes was high when multiple body sites were involved.

Abstract third-party references: On the behalf of the RéJMiC [study group of French Microbiology Society]

Background: Residents and young clinical microbiologists (CM) sometimes experience difficulties in reaching their elders, connecting with their peers and accessing relevant information to build their career. Creating a network where specialty knowledge is shared, and professional issues discussed, can help and result in sustainable partnerships among the youngest. However, development of such networks is challenging and may face obstacles. The aim of the study was to share our one-year experience in France to promote the importance of young professional network creation.

Materials/methods: One-year post creation, founding members of RéJMiC [Réseau des Jeunes Microbiologistes Cliniques] [n=16] were consulted to assess the five biggest challenges faced in the network creation. To assess the extent of our network, data were extracted from RéJMiC Facebook group from 18 November 2018 to 18 November 2019.

Results: The following were found to be the most important steps toward the creation of the network:

1. Defining young microbiologists status and writing purposes of the network: promote knowledge sharing, bring together microbiologists from different backgrounds (bacteriology, virology, parasitology, mycology and infection control), ease access to information [up-to-date literature, available grants, ESCMID activities], collaborate with existing networks and societies (i.e. Réseau des Jeunes Infectiologues Français) through common projects

2. Reaching the national society for CM in France [Société Française de Microbiologie, SFM] by the written proposition of creating a network (cf. 1.)

3. Meeting on a regular basis (every 6 weeks) through conference calls with founding members

4. Building a local network with regional representatives in each university hospital in France

5. Communicating regularly through social media and SFM website

One year from creation, we reached 13/30 university hospitals in France, with presently a regional representative in each. A total of 269 members requested to join our closed Facebook groups from 53/101 counties in France [Fig.1]. Fifty percent of memberships were reached in one month, following a logarithm curve.

Conclusions: This one-year experience can be helpful for young CM willing to create their own national network. Future aims are to improve our communication skills through other social medias [Twitter, Instagram], further develop our network and strengthen ongoing collaborations.

Abstract 3183

Neuroparacoccidioidomycosis: analysis of 10 cases observed in an endemic area in Argentina
Pedro Villalba, Gustavo Mendez, Carla Niveyro*, Vanesa Sosa
1Hospital Madariaga, Posadas, Argentina

Background: To describe the epidemiological, clinical, imaging and evolutionary characteristics of patients diagnosed with paracoccidioidomycosis associated with the involvement of the central nervous system in the Hospital Escuela de Agudos Dr. Ramón Madariaga from 2012 to 2019.

Materials/methods: All cases with a diagnosis of paracoccidioidomycosis were reviewed. Those with neuroparacoccidioidomycosis were analyzed and studied prospectively from 2012 to 2019. Nuclear magnetic resonance imaging was reassessed by personnel specialized in diagnostic imaging.

Results: From 52 cases of paracoccidioidomycosis (PCM) who were assisted in our center in the period evaluated 10 (19.2%) of them were diagnosed as neuroparacoccidioidomycosis (NPCM). All were men, residents of the endemic zone, 100% smokers. Mean age of 52.5 (40-67 years). Concomitantly 1 patient had a diagnosis of stomach cancer and 1 patient with Hansen disease. 70% of the patients presented neurological symptoms at diagnosis. Of the 7 patients who neurological clinic, the most frequent symptoms were headache and weakness (57.1%), paresthesias and gait disorders (42.9%), vomiting, dizziness and paresis (28.6%), blurred vision (10%), involuntary movements (10%), seizures (10%) and dysarthria (10%). All patients presented respiratory compromise due to positive cultures (20%) or presence of concomitant infiltrate in patients with mucous involvement (30%) and nodal involvement (20%). Two patients had brain biopsy with pathology and positive culture. The presence of the fungus were by pathological anatomy in 70% and by culture in 60%. In the imaging assessment, the patients presented a unique brain lesion (60%), post contrast enhancement (90%), being peripheral in 66%, annular in 22% and nodular in 11%. Restricted diffusion was evident in 90% of the patients, and in 33% the restriction was slight. All patients began antifungal treatment. During hospitalization, 2 patients died due to complications secondary to hospitalization. Outpatient follow-up was abandoned by patients in most cases.

Conclusions: The presence of Paracoccidiodes spp by direct observation, culture or histopathology outside the CNS should make us extend the search towards cerebral compromise, which is why we consider it essential to request a nuclear magnetic resonance with gadolinium and an open communication with the image specialists about what we are looking for.

**Background:** Lyme's neuroborreliosis (LNB), a neuroinfection caused by *Borrelia burgdorferi sensu lato*, has recently been added to the list of notifiable diseases under European Union epidemiological surveillance aiming to achieve reliable information on the incidence of the disease and to assess the trend over time of LNB. We aimed to describe the seasonal effect on LNB incidence and to identify risk groups and high incidence regions as well as describe changes in yearly LNB incidence in Denmark.

**Materials/methods:** From all Danish Departments of Microbiology we identified all patients who performed a positive *B. burgdorferi* intrathecal antibody index between 1996 to 2015 (n= 2,791). From the Danish National Registries, we obtained data on gender, age, yearly income, highest educational attainment and county of residence for each year between 1996 to 2015 on all Danish residents. We calculated the number of LNB cases per month, and incidence and incidence ratios of LNB by comparing gender and categories of age, income, education, county of residency and calendar year.

**Results:** The average yearly incidence of LNB for the entire study period was 2.6 per 100.000 individuals. The number of LNB cases was highest in the months from July to November (p-value < 0.000001) with the number of new cases per month being lowest in March (2.8 cases of LNB/month) and highest in August (26.6 cases of LNB/month). The incidence per year was highest among men (3.0 LNB cases per 100.000 individuals), individuals aged 0-15 (4.2 LNB cases per 100.000 individuals), individuals with a yearly income of >449.000 DKK (3.6 LNB cases 100.000 individuals) and individuals with a master’s degree or higher (3.3 cases per 100.000 individuals). We observed the highest incidence per year in eastern Denmark. The incidence per year was 2.2 per 100.000 individuals in 1996-1999, rose to 2.7 in 2004-2007 and then declined again to 1.1 per 100.000 individuals in 2012-2015.

**Conclusions:** The monthly incidence of LNB was highest in late summer and early fall. The yearly incidence of LNB was increasing from 1996 to 2007 but thereafter declined to 2015, irrespective of gender, age, income, education or county of residency.

Background: We performed a population-based, nationwide cohort study to examine the association between LNB and mood affective disorders.

Materials/methods: We identified all Danish residents with a positive *Borrelia burgdorferi* intrathecal antibody index between 1995 and 2015 (n=2,898). From national registries, we identified a comparison cohort from the general population matched on gender and date of birth (n=28,980) and extracted data ICD-10 diagnoses and hospital contact due to psychiatric diseases as well as on type and dosage of prescribed medicine. We examined the short-term (<1 year) and long-term (>1 year) risk of all mood affective disorders (F30-F39), manic disorders (F30-F31), episodic depression (F32), periodic depression (F33) and persistent mood affective disorders (F34) by calculating hazard ratios (HR). We also compared the difference in the proportion of individuals with a hospital contact due to these diseases and a prescription for psychoanaleptics (N06) and antidepressants (N06A) between LNB patients and the comparison cohort. All analyses were performed with 95% confidence intervals (95% CI) and stratified according to gender and age (< versus >= 50 years of age).

Results: LNB patients were at increased long-term risk of mood affective disorders (HR 1.4, 95% CI: 1.1 to 1.8) and periodic depression (HR 1.7, 95% CI: 1.2 to 2.5) but not of any other diagnoses compared with the comparison cohort. LNB patients seemed to have more hospital contacts due to mood affective disorders, although the difference was not statistically significant. There was no difference in the proportion of individuals with a hospital contact due to any of the other psychiatric diseases examined. LNB patients were prescribed more psychoanaleptics [1 year after and 16-18 years after LNB diagnosis] and antidepressants [1-2 years and 8-18 years after LNB diagnosis]. In the stratified analyses, the increased risk of diagnosis, hospitalization and medicine prescription applied only for women aged >= 50 years.

Conclusions: Our data indicate that LNB patients are at increased risk of- and burden from mood affective disorders/depression and warrant an individualized follow-up after LNB with special emphasis on depression risk among women aged more than 50 years.

Abstract 3186

A computerised decision support system (CDSS) for antibiotic prescribing in primary care: Antibioclic: implementation, adoption and sustainable use in the era of extended antimicrobial resistance.

Tristan Delory*, Pauline Jeanmougin1,2, Sylvie Lariven2,3, Jean-Pierre Aubert2, Nathan Peiffer-Smadja4,5, Pierre-Yves Boëlle1,2, Elisabeth Bouvet2,3, Xavier Lescure2,4, Josselin Le Bel2,5,6

1 Sorbonne Université, UMRS1136 - Equipe 1, Paris, France, 2 Antibioclic steering committee, Paris, France, 3 Nantes University, Family medicine department, Nantes, France, 4 Bichat Hospital, AP-HP, Paris, France, 5 University of Paris, IAME, Paris, France, 6 HPRU Healthcare Associated Infections and Antimicrobial Resistance, Imperial College London, London, United Kingdom, 7 Saint-Antoine Hospital, AP-HP, Paris, France, 8 University of Paris, Family medicine department, Paris, France

Background: Computerized decision support systems (CDSS) for antimicrobial prescribing could be effective and induce prolonged impact on practices. CDSS development for primary care and data regarding their implementation, use and adoption are scare.

Materials/methods: To describe the development, implementation, adoption and sustainable use of a French CDSS for antibiotic prescribing in primary care (Antibioclic), which targets 37 infectious diseases, is freely available 24/24-7/7 on a website since 2011, and as a smartphone application since 2017. Analysis of the requests performed between 2012 and 2018, and the results of 2 web-based cross-sectional studies conducted over 2-months in 2014 and 2019.

Results: The number of requests increased from a median of 796/day [IQR,578–989] in 2012 to 11,125/day [5,592–12,505] in 2018. Unique users increased from 414/day [245–494] in 2012 to 5,365/day [2,891–5,769] in 2018. The smartphone application was downloaded 22,970 times on Android and 15,200 times on iOS. Time to perform a request was 2 minutes [1·9–2·1]. Among 3,542,347 requests in 2018, 78% were for adults and an antibiotic was recommended systematically in 2,254,866 (63·7%), not systematically in 1,223,013 (34·5%), and not recommended in 64,468 (1·8%). Six situations accounted for ≥50% of requests: cystitis 504,428 (1·4·2%); acute otitis media 410,219 (11·6%); acute sinusitis 340,128 (9·6%); community-acquired pneumoniae 327,669 (9·3%), sore throat 210,954 (6·0%), and pyelonephritis 210,847 (6·0%). Of 4,959 users surveyed, 4,016 (81%) were GPs, 2,314 (58%) women, median age 38-years [31–52]. Using cross-sectional responses and number of requests over time, we estimated that approximately 5,743 GPs are using Antibioclic daily, corresponding to a 9·9% coverage rate of the 58,140 GPs registered in primary care in France. Among users, 972 (24%) reported systematically using Antibioclic when initiating an antibiotic course and 3,743 (93%) strictly followed Antibioclic recommendation for the latest antibiotic prescription. Median level of satisfaction for CDSS use and CDSS ergonomics were 5/5 [4 – 5].

Conclusions: Antibioclic has been adopted and is widely used in primary care in France. Its interoperability could allow an adaptation and implementation in other countries as part of national antimicrobial resistance action plans.

Abstract 3187

**Efficiency of antibiotic prophylaxis in recurrence of UTI among kidney transplant recipients**

Florence Runyo*, Olivier Aubert1, Perrine Parize1, Hervé Lecuyer1, Lucile Amrouche1, Rebecca Sberro Soussan1, Christophe Legendre1, Caroline Charlier1, Anne Scemla1

1Department of Kidney Transplantation, Université de Paris, Necker-Enfants Malades University Hospital, AP-HP, Paris, France, Paris, France, 2Department of Kidney Transplantation, Université de Paris, Necker-Enfants Malades University Hospital, AP-HP, Paris, France, Paris, France, Paris Translational Research Center for Organ Transplantation, INSERM, UMR-S970, Paris, France, Paris, France, 3Department of Infectious Diseases and Tropical Medicine, Université de Paris, Necker-Enfants Malades University Hospital, AP-HP, Paris, France, Paris, France, 4Clinical Microbiology Laboratory, Necker-Enfants Malades University Hospital, AP-HP, Paris, France, INSERM U1151, CNRS UMR8253, Paris, France

**Background:** Upper urinary tract infections (UUTI) are the most frequent of severe infections in kidney transplant recipients (KTR). Recurrences of UUTI are also associated with hospitalization, graft dysfunction and loss. Antibiotic prophylaxis (ABP) might be useful to prevent recurrence, but its efficiency has never been demonstrated in KTR.

**Materials/methods:** We conducted a monocentric retrospective study in our kidney transplant unit from 2004 to 2018. We included all KTR with recurrent UUTI who received ABP for at least 3 months. Recurrent UUTI were defined as follows: 3 pyelonephritis in 12 months or 2 pyelonephritis in 6 months. We excluded patients with ureteral or bladder catheter.

**Results:** We included 18 KTR (11 female). Mean age was 55y (±16.8). Post-transplant diabetes was observed in 11, rejection in 8 cases. Causes of transplantation were chronic abnormalities of kidney urinary tract (n=5), chronic glomerulonephritis (n=4), polycystic kidney disease (n=3) and others (n=6). Before ABP initiation, patients experienced a mean of 4.4 (±2.1) recurrence UUTI during a mean time-interval of 33.6 (±42.5) months. Recurrent UUTI were explored by bladder/graft ultrasound (n=10/18), cystourethrography (n=12/18) and gynecological consultation (n=7/11 women).

Pathogens involved in UUTI (n=79) before ABP were mainly Escherichia coli (n=40, 50%), Klebsiella pneumoniae (n=10, 12%). Ten patients were reported ≥1 Extended spectrum beta-lactamase producing enterobacteria (ESBL-E) UUTI.

ABP consisted in 1 antibiotic (n=5), or a combination of 2 (n=6), 3 (n=6), or 4 (n=1) antibiotics. Main antibiotics were fosfomycin-trometamol (n=16), cefixime and pivmecillinam (n=7, each), amoxicillin-clavulanate (n=4). No severe adverse event was observed. Mean ABP exposure was 35.4 months (±17.2). Under ABP, 9/18 reported a complete resolution of symptoms without any recurrent of UUTI over 39 months, 8 reported an improvement with an average decrease of 70% of their recurrences over 32 months and 1 reported no benefit (no side effect).

11/23 recurrences of UUTI were caused by pathogens resistant to at least one molecule of the antibiotic prophylaxis combination, including 5-ESBL-E.

No graft loss or death was observed under ABP.

**Conclusions:** In KTR experiencing recurrent UUTI, continuous prophylaxis may be safe and efficient to reduce recurrences.

Abstract 3189

**Caspofungin weight-based dosing supported by a population pharmacokinetic model**

Anne-Grete Märtson1, Kim Van Der Elst2, Anette Zijlstra3, Jan G. Zijlstra3, Albertus Beishuizen4, Tjip S. Van Der Werf5, Jos Kosterink2, Michael Neely6,7, Jan W. C. Alffenaar8,9,10

1University Medical Center Groningen, University of Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, Netherlands, 2University Medical Center Utrecht, Department of Clinical Pharmacy, Utrecht, Netherlands, 3University Medical Center Groningen, University of Groningen, Department of Internal Medicine, Groningen, Netherlands, 4Medisch Spectrum Twente, Intensive Care Center, Enschede, Netherlands, 5University Medical Center Groningen, University of Groningen, Department of Pulmonary Diseases and Tuberculosis, Groningen, Netherlands, 6Children’s Hospital of Los Angeles, Los Angeles, United States, 7Laboratory of Applied Pharmacokinetics and Bioinformatics, Los Angeles, United States, 8The University of Sydney, Sydney Pharmacy School, Sydney, Australia, 9Westmead hospital, Sydney, Australia, 10Marie Bashir Institute of Infectious Diseases and Biosecurity, Sydney, Australia

**Abstract third-party references:** Anne-Grete Martson was supported for this project by the Foundation “De Drie Lichten” in The Netherlands. Anne-Grete Martson was funded by Marie Skłodowska-Curie Actions [grant agreement no. 713660—PRONK-JEWAIL—H2020-MSCA-COFUND-2015].

**Background:** Caspofungin exposure varies in critically ill patients with invasive *Candida* infections. The objective of this study was to determine a dosing regimen of caspofungin using population pharmacokinetic modelling.

**Materials/methods:** This study included data from a prospective study in 20 critically ill patients. The sampling was performed before the dose and after 1, 2, 3, 4, 6, 8, 12 and 24 h of the dose (on days 2-4). Non-parametric population pharmacokinetic modelling, probability of target attainment (PTA), and internal validation was performed using Pmetrics. For the PTA a target 24-hour steady-state AUC value of 98 mg*h/L was used as an efficacy threshold and 200 mg*h/L as an arbitrary maximum.

**Results:** The median age was 56 (range 25-83) years, and the median weight was 78 (range 48-139) kg. The final model was a 2-compartment model which included normalized weight as a covariate on volume of distribution (Vd). The mean Vd of the central compartment was 7.89 (SD 3.12) L/kg, the mean elimination rate constant Ke was 0.09 (SD 0.04) h⁻¹, the rate constant for the caspofungin distribution from the central to the peripheral compartment was 0.42 (SD 0.39) h⁻¹, and the rate constant for the caspofungin distribution from the peripheral to the central compartment was 0.60 (SD 1.04) h⁻¹. The visual predictive check showed good performance of the model.

A loading dose of 1.5 mg/kg on the first day, followed by a maintenance dose of 1.25 mg/kg resulted in target AUC (≥ 98*h/L) on day 1 and day 3 in 80% and 95% of the patients respectively. Moreover, this dosing schedule results in only 12% of patients with an AUC ≥ 200mg*h/L.

We also simulated the currently registered fixed dose of caspofungin [70 mg daily dose] in 80 and 120 kg patients and observed that only 48% and 8% would reach the target AUC on day 3 respectively.

**Conclusions:** This study suggests that the standard caspofungin dose might not be suitable for critically ill patients. A weight-based dose regimen might be appropriate to achieve adequate exposure and the PTA should be prospectively evaluated.

**Presenter email address:** annegretem@me.com
Variable number tandem repeat analysis on patient Pseudomonas aeruginosa (PsA) bacteraemia isolates and hospital shower water PsA strains to determine their links

Ozge Yetiş*, Peter Wilson2, Jane Turton3, Zoe Payne4, Shanom Ali2

1University College London, Division of Infection and Immunity, London, United Kingdom, 2University College Hospital, Clinical Microbiology & Virology, London, United Kingdom, 3Public Health England, HCAI & AMR Division, London, United Kingdom, 4Public Health England, London, United Kingdom

Background: PsA is a major cause of hospital acquired infections and genomic typing has being performed in recent years. VNTR sequencing allows rapid and straightforward comparative analysis in epidemiological investigations. PsA’s genome is relatively rich in tandem repeats, enabling Multiple loci VNTR analysis (MLVA) to find the relatedness of strains by comparing their VNTR profiles.

Materials/methods: VNTR profiles of strains from nine clinical (hospital-acquired bacteraemia from five wards A-E) and nineteen environmental (shower water from six wards B-G) isolates collected between November 2018 and January 2019 from a multi-disciplinary London teaching hospital were compared. MLVA targeted nine loci: ms172, ms211, ms213, ms214, ms217, ms222, ms2017, ms209 and ms61. Patient and environmental VNTR profiles were matched by time and location to determine potential transmission routes.

Results: One shower water isolate from a single-isolation-room in augmented-care-ward (B) was taken three days before the occupying patient (same room) developed bacteraemia; isolates showing indistinguishable VNTR profiles (1, 2, 3, 5, 5, 2, 3, 7, 2, 14). This profile was found in another shower water isolate (ward B). A similar VNTR profile (1, 2, 3, - , 4, 1, 9, 2, 11) caused bacteraemia on ward A during the same week.

On ward C, the same VNTR profile (1, 2, 4, 1, 9, 2, 11) was detected in a shower three days after isolation from a patient who probably had used the shower.

Two similar VNTR profiles (1, 2, 3, 6, 6, 3, 8, 2, 9 and 1, 2, 3, 6, 6, 3, 8, 2, 9) were isolated from two showers (ward B) on the same day with a third related profile (1, 2, 3, 6, 6, 3, 8, 2, 9) causing bacteraemia in a different room (same ward). Their single-locus-variant (1, 2, 3, 6, 6, 3, 8, 2) was seen in two different shower water isolates (wards D&F).

A further strain (VNTR: 1, 2, 3, 6, 3, 2, 13, 5, 7) was isolated in two different showers (wards E,F).

The most prevalent environmental strain (VNTR: 1, 2, 5, 3, 2, 6, 1, 6, 4, 13) was isolated on (3/19) occasions (16%). More than half of patient (5/9) and 21% of environmental (4/19) strains showed unique VNTR profiles within this cohort.

Conclusions: MLVA demonstrated that VNTR profiles among patient and shower water PsA isolates of this hospital are quite diverse. However, there were a few indistinguishable VNTR profiles observed in bacteraemia isolates and shower water strains from the same locations (rooms and wards) suggesting that the shower environment should be considered as a source of transmission of PsA.

Urinary tract infections in nursing homes in the era of multidrug resistance: a 4-year study

Eva Riquelme-Bravo*, Lorena Robles Fonseca1, Caridad Sáinz De Baranda Camino1, Javier Parra Martínez1, Verónica Solves Ferriz1

1University General Hospital of Albacete, Laboratory of Microbiology, Albacete, Spain

Background: Urinary tract infections [UTIs] are very common in residents of nursing homes, related to their own comorbidities and the risk of spreading microorganisms from direct contact between patients. Also, the spread of antimicrobial resistance is an important health concern.

Our aim was to study UTIs in nursing homes in the province of Albacete [Spain], and define their etiology and multidrug-resistance [MDR] profile compared to those found in the general population: primary care [PC] and specialised care [SC].

Materials/methods: A retrospective study of the urine samples from 11 nursing homes in our health area during the last 4 years [2015-2018]. Identification and bacterial susceptibility testing were performed using chromogenic medium [CPSE bioMérieux] and MaLDI-ToF [bioMérieux], and microdilution-based methods [VITEK® and MicroScan] respectively.

Results: We received 5212 urine samples from nursing homes: 4534 (86.9%) mid-stream urines, and 678 (13%) catheter specimen urines. Of these, 61.2% were positive samples, while in PC and SC the percentage decreased to 21.1% and 24% respectively \( (p<0.05) \). We found that 22.9% of the pathogens isolated in samples from nursing homes were MDR, compared to 6.1% in PC and 8.1% in SC \( (p<0.05) \). The frequency of MDR in nursing homes was higher in catheter specimen urines [32.1%] than in mid-stream urines [20.8%] \( (p<0.05) \).

The percentages of MDR found in samples of nursing homes, and the statistical significance of their difference with respect to those isolated in PC and SC, are shown in the table below

<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Conclusions: Overall, the percentage of positives and MDR isolates were significantly higher in urine samples from geriatric patients compared to PC and SC. In those patients, almost one-quarter of the microorganisms were MDR. ESBL-Enterobacteriaceae were the most frequent, with *K. pneumoniae* prevailing over *E. coli*. The percentages of MRSA and MDR-PA were also significantly higher. Instead, there weren't significant isolates of CPE.

Overdiagnosis of UTIs in nursing homes may cause inappropriate use of antibiotics, acting as a reservoir of MDR microorganisms, as seen in other studies. Our results suggest the need to extend the specific strategies and programs to nursing homes, and ensuring a sufficient number of specialized staff in infection control.

Abstract 3192

Hemagglutinin sequence-derived phylogenetic and genetic characterisation of A(H3N2) influenza viruses circulating during 2013-2019 winter seasons in Southern Greece

Athanasios Kossyvakis1, Aspasia Kontou1, Anastasia Flountzi2, Maria Euagelidou1, Vasiliki Pogka1, Antonios Kalliaropoulos1, Ioannis Karagiannis3, Emmanouil Antalis3, Theodore Lytras3, Dionysios N. Sgouras1, Sotirios Tsiodras4, Andreas Mentis1

1 National Influenza Reference Laboratory of Southern Greece, Hellenic Pasteur Institute, Athens, Greece, 2 European Programme for Public Health microbiology Training (EUPHEM), European Centre for Disease Prevention and Control (ECDC), Athens, Greece, 3 Laboratory of Medical Microbiology, Hellenic Pasteur Institute, Athens, Greece, 4 4th Academic Department of Internal Medicine and Infectious Diseases, Attikon University Hospital, University of Athens Medical School, Athens, Greece, 5 Hellenic National Public Health Organization, Athens, Greece

Background: Seasonal genetic characterization of influenza viral haemagglutinin (HA), monitors amino acid substitutions within the antigenic (A-E) receptor binding sites and substitutions associated with potential glycosylation gain/loss (potential effects in masking/uncovering antibody epitopes). We aim to compare genetic and phylogenetic characteristics of the circulating viruses to the seasonal vaccine viruses during peak influenza activity in Southern Greece for surveillance purposes.

Materials/methods: During 2013-2019 winter seasons, 1,315 respiratory samples were tested positive for H3N2 virus by RT-PCR (120-2013/14, 352-2014/15, 7-2015/16, 691-2016/17, 11-2017/18 and 134-2018/19). Sanger sequencing of the complete viral HA gene was attempted directly on the 10% percentage of representative original samples (N=131).

Results: Comparative mutation analysis to seasonal vaccine viruses, Greek viruses circulating in 2013-14 and 2015-2016 seasons exhibited substitutions only in A and B sites, whereas during 2016-2017, seasonal viruses revealed amino acid substitutions in all antigenic sites. F159Y amino acid substitution within the immunodominant antigenic site B in 2014-2015 and 2015-2016 viral HA was associated with vaccine mismatches. The aa alteration K160T (site B) associated with gain of a glycosylation site, was observed in all viruses circulating since 2014.

Conclusions: Our genetic characterization data are in line with evidence from 1968-2013 seasonal surveillance studies, that most H3N2 vaccine mismatches attributed to HA antigenic site B mutations. The 2014-2015 3C.2a-clade emergence was associated with an increased level of genetic diversification among circulating Greek viruses. In line, during 2014-2016 A[H3N2] epidemics included in our study, WHO recommended twice a vaccine virus change need. In addition, seasonal vaccine escape viruses circulated in 2015-2016 season exhibited diversity in phylogenetic grouping and mutations only in A and B antigenic sites. Phylogenetic clustering patterns not only update on the virus evolution but heavily influence vaccine decisions.

*Clostridioides difficile* NAAT-positive with toxin-negative test results: impact of antibiotic treatment on clinical outcomes

Javeria Haque*, Aprill Dawson1, Kristen Osinski1, Madhuli Thakkar1, Andres Yarur1, L. Silvia Munoz-Price1

1Medical College of Wisconsin, Wauwatosa, United States

**Abstract third-party references:** Medical College of Wisconsin

**Background:** In our study, we aimed to characterize the clinical outcomes among *C. difficile* (Cdiff) NAAT+ patients with either toxin+ or toxin- results and the effect of antibiotic treatment.

**Materials/methods:** This retrospective cohort of consecutive adult inpatients with diarrhea and Cdiff NAAT+ results was performed at a 604 bed academic medical center in Milwaukee, Wisconsin. Cdiff tests consist of a two-step process: NAAT (Xpert® *C. difficile*; Cepheid) and if positive a toxin assay (C. diff Quik Check Complete; Alere, Waltham, MA). Only the first positive Cdiff NAAT test per patient was included. Antibiotic treatment against Cdiff was captured if received within 3 days of NAAT+ result. Outcome variables included length of stay (LOS) from NAAT+ to discharge, 30-day mortality, colectomy, and CDI recurrence within 30-90 days. Analyses included generalized linear models and COX-proportional hazards models. Backward stepwise selection logistic regression model with a p-value threshold of 0.1 was used to analyze for Cdiff recurrence.

**Results:**

<td>9.9 ± 7.3</td>
</tr>
<tr>
<td>Creatinine</td>
<td>1.5 ± 1.7</td>
<td>1.7 ± 2.1</td>
</tr>
</tbody>
</table>

**Results:**

From January 2017 to June 2019, 755 NAAT+ patients were identified: 264 [35%] toxin+ and 491 [65%] toxin-. Out of NAAT+/toxin- patients 256 [52%] were treated. NAAT+/toxin+ patients had higher WBC counts [12.7 vs. 9.9, p=0.001] and higher antibiotic exposure in the preceding 3 months of NAAT+ result [97.4% vs. 88.4%, p=0.001]. Among NAAT+/toxin- patients, patients who received treatment had higher WBC counts [11.3 vs. 8.4, p=0.001] and more antibiotic exposure [95.3% vs. 80.9%, p=0.001]. There was no statistical difference in outcome variables between NAAT+/toxin+ and NAAT+/toxin- groups. Antibiotic treatment for NAAT+/toxin- patients increased the odds of CDI recurrence [OR:3.27, 95%CI 1.19-9.01, p=0.02]; however, this effect dissipated in the adjusted model. CDI recurrence was associated with immune-modulators exposure [OR:2.93, 95%CI 1.05-8.21, p=0.04] and a higher Elix-Hauser Comorbidity score [OR:1.21, 95%CI 1.03-1.43, p=0.02] in treated vs. untreated NAAT+/toxin- patients.

**Conclusions:** There was no difference in outcomes based on toxin results or treatment among NAAT+/EIA- patients. CDI recurrences were greater in patients with higher comorbidity scores or receiving immune-modulators.

Abstract 3196

**Bacteriophage control the prevalence of *Escherichia coli* ST131 in different countries**

Jordan Mathias*, Dmitriy Babenko, Abdulrahman Almusallam, Refath Farzana, Mark Alexander Toleman

1Cardiff University, Cardiff, United Kingdom, 2Karaganda Medical University, Karaganda, Kazakhstan, 3Cardiff University, Cardiff, United Kingdom

**Background:** *Escherichia coli* is the most important bacterial species in Europe, being the main cause of both urinary tract and blood infections. The *E. coli* species consists of at least 10,000 sequence types (ST) with ST131 being the dominant cause of quinolone and β-lactam resistant infections throughout Europe.

**Materials/methods:** We collected 193 ST131 isolates from human bacteraemia, faeces and sewage in the UK in 2014 and performed whole genome sequencing of these by Miseq technology. Core genome (CG) comparison of the ST131 isolates was achieved using blast 2.7.1 on 2513 CG targets and CG tree generated using Ridom seqsphere. Each ST131 isolate was tested for susceptibility to bacteriophage. Bacteriophages were isolated from human sewage collected from four countries in April-June 2019: The UK, Kazakhstan, Saudi Arabia and Bangladesh. Bacteriophage were tested for activity by plaque assays on each ST131 isolate and characterized by electron microscopy and sequencing. The *E. coli* ST131 prevalence was also assessed in each country by random selection of 100 *E. coli* from the sewage samples and confirmation of the number of ST131 isolates by specific PCR.

**Results:** The 193 *E. coli* ST131 isolates represented a broad range of cgMLST types and were spread throughout the ST131 cgMLST tree. We found that *E. coli* ST131 prevalence was dramatically different in the four countries: 11% in the UK, <1% in S. Arabia, 4% in Kazakhstan and undetectable in Bangladesh. However, ST131 specific bacteriophages were highly prevalent in Bangladesh and Saudi Arabia (able to kill 70% and 72% of UK ST131 isolates, respectively) yet much less common in the UK (32%) and rare in Kazakhstan (5.8%). Electron microscopy revealed that ST131 bacteriophage belonged to several different families including the siphoviridae, podoviridae and myoviridae.

**Conclusions:** We found that the UK had the highest and Bangladesh the lowest carriage rates of *E. coli* ST131. Thus ST131 prevalence varies greatly by geographical location. Conversely, sewage from Bangladesh contained bacteriophage that could kill 72% of UK ST131 whereas sewage from the UK could only kill 32% of strains. This strongly suggests that prevalence of ST131 in different countries is controlled by bacteriophage.

**Presenter email address:** mathiasj@cardiff.ac.uk
Non-beta-lactam antibiotic hypersensitivity reactions in children

Lisa Grinlington1, Sharon Choo1, Noel Cranswick2, Amanda Gwee*1

1The Royal Children's Hospital, Melbourne, Parkville, Australia

Background: Antibiotics are among the most common prescriptions in children and non-β-lactam antibiotics (NBLA) account for almost half of those prescribed in Australian paediatric hospitals.1) Despite this, there is a current paucity of data on the clinical presentation and frequency of true NBLA allergies in children. NBLA allergies were reported in 4.7% of children in a previous paediatric study, with macrolides and sulfonamides the most frequently implicated.1) This study describes reported hypersensitivity reactions to NBLAs in children and the results of allergy evaluation.

Materials/methods: A total of 141 children, aged between 0 and 18 years, with a suspected NBLA allergy who had skin testing and/or an intravenous or oral challenge test (OCT) between May 2011 and June 2018 were included. Patients were excluded if they were older than 18 years or did not complete the OCT for reasons other than allergic reaction. Patients records were retrospectively reviewed and data on the clinical history of the NBLA reaction was entered into a REDCAP® database. Patients were classified as having an immediate or non-immediate reaction based on timing of symptoms and further classified as severe or non-severe. Data was then critically analysed and evaluated.

Results: Over the 7-year study period, 141 children had 150 allergy evaluations to 15 different NBLAs. The median time from the initial reported reaction to allergy evaluation was 1.9 (range 0.1 to 14.9) years. Overall, 27/150 (18.0%) challenge tests to a NBLA were positive with the rate of positive OCTs highest for trimethoprim-sulfamethoxazole [15/46, 32.6%] and macrolides [8/77, 10.4%]. Although 4 children reported initial anaphylactic reactions, no patients had severe symptoms on rechallenge or required adrenaline. Of the challenges that were positive, the majority of children [23/27, 85.2%] had similar symptoms on repeat challenge to those that were initially reported.

Conclusions: Overall, almost one-fifth of reported NBLA allergies were confirmed by allergy evaluation. Timely access to allergy evaluation on to de-label these patients is needed to preserve first line antibiotics.

Are neurological co-infections common in AIDS-related cerebral toxoplasmosis?: a prospective cohort study on late cART era in São Paulo, Brazil

João P. Telles\textsuperscript{*1,2}, Ruan Fernandes\textsuperscript{1}, Alvino Maestri Neto\textsuperscript{1}, Thiago Vitoriano\textsuperscript{1}, Tiago Dahrug Barros\textsuperscript{1}, Rosa Marcusso\textsuperscript{1}, Luciana Borges\textsuperscript{1}, Ralcyon Teixeira\textsuperscript{1}, Michel Haziot\textsuperscript{1}, Augusto Penalva De Oliveira\textsuperscript{1}, José Ernesto Vidal Bermúdez\textsuperscript{1,2}

\textsuperscript{1}Instituto de Infectologia Emilio Ribas, São Paulo, Brazil, \textsuperscript{2}Hospital das Clínicas FMUSP, São Paulo, Brazil

Background: Cerebral toxoplasmosis continues to be the most frequently neurological cause of hospital admission in people living with HIV/AIDS (PLWHA) from resource-limited settings. Concomitant neurological diseases in PLWHA is a challenging subject that has not been sufficiently evaluated in prospective clinical studies. The aim of this study was to identify the frequency, main features, and outcome of cerebral toxoplasmosis with neurological co-infections in PLWHA.

Materials/methods: We conducted a prospective observational cohort study at a tertiary teaching center in São Paulo, Brazil, between January-July 2017. PLWHA with age ≥ 18 years old and cerebral toxoplasmosis were consecutively included. Standardized neurological exam was performed at admission and weekly up to discharge or death. Diagnosis and treatment followed institutional routine; neuroradiology, molecular diagnosis on cerebrospinal fluid (CSF), neurosurgery, and Intensive Care Unit (ICU) were available. Main outcomes were frequency and in-hospital mortality of related cerebral toxoplasmosis with neurological co-infections in PLWHA. \(P\leq0.05\) was considered significant in univariate analysis.

Results: Were included 44 (4.3\%) cases among 1,032 hospitalized patients in the study period. Cerebral toxoplasmosis was the more frequent diagnosis among all patients with neurological diseases [44/105, 42\%]. Median age was 44 years-old (interquartile range, IQR: 35-50) and 50\% were male. Median CD4 lymphocytes cell count was 50 cells/mm\(^3\) (IQR 15-94). Multiple lesions on computed tomography were present on 59\% of cases. Neurological co-infections were diagnosed in 20\% (\(n=9\)) of cases and \textit{Cytomegalovirus} (CMV) was the most common etiology (\(n=5\); encephalitis, \(n=3\); polyradiculopathy, \(n=2\)). PLWHA with neurological co-infections presented higher length of hospitalization [30 vs. 62 days (\(P=0.021\))] and more frequent ICU admission [14 vs. 44 (\(P=0.045\))]. Trimethoprim-sulfamethoxazole was used in all but 2 patients. Global mortality rate was 13.6\% (\(n=6\)) (co-infections, 33\% vs. no co-infection, 8.6\%, \(P=0.054\)).

Conclusions: Neurological co-infections were common in PLWHA with cerebral toxoplasmosis and CMV was the main concomitant infection. PLWHA with neurological co-infections showed higher length of hospitalization and more frequent ICU admission. Co-infection is probably associated with increased mortality but further investigation is necessary. These findings highlight the impact of neurological co-infections and its potential implications in the management and outcome of cerebral toxoplasmosis in PLWHA.

Abstract 3199

From OPAT to COpAT in a regional New Zealand hospital

Massimo Giola*, Jean-Pierre Meyer2, Michael Addiddle3, Vani Sathyendran3, James Chua4

1Rotorua Hospital, Lakes DHB, Infectious Diseases Service, Rotorua, New Zealand, 2Rotorua Hospital, Lakes DHB, Pharmacy, Rotorua, New Zealand, 3Clinical Microbiology, Pathlab, Tauranga, New Zealand, 4Rotorua Hospital, Rotorua, New Zealand

Background: Rotorua Hospital is a 180-bed general regional hospital serving Rotorua (a 59,500-inhabitants’ town in the upper North Island of New Zealand/Aotearoa). The Antimicrobial Stewardship Service is run by the Hospital Pharmacy with the support of the Infectious Disease (ID) Physician and the Clinical Microbiologists (CM) from the local laboratory. Historically, the Hospital had a busy Outpatient Parenteral Antibiotic Therapy (OPAT) service, using 24-hour infusers and PICC lines to deliver long (4 to 6 weeks) antibiotic treatments at the patients’ homes; in the peak month (July 2018) 208 infusers were utilised. Following the publication of large trials (eg OVIVA and POET) supporting the switch to oral antibiotics, the AMS service initiated in February 2019 a systematic review of all antibiotic treatment plans before discharge, implementing mandatory ID or CM approval and offering instead advice about optimising oral antibiotics as COpAT (Complex Outpatient Antibiotic Therapy). A large proportion of infusers were loaded with beta-lactams (penicillin, flucloxacillin, and cefazolin) that were replaced with the oral equivalents boosted with probenecid. A smaller proportion was loaded with piperacillin/tazobactam or vancomycin, which largely account for the remaining OPAT after the policy change. For orthopedic or other bioprosthetic infections, combinations of biofilm-active antibiotics (rifampicin plus either cotrimoxazole or ciprofloxacin) were also used.

Materials/methods: The Rotorua Hospital Pharmacy extracted from their electronic dispensing records the numbers and costs of the antibiotic infusers in 6 months before the new policy was implemented (Feb to Aug 2018) and in the same 6 months after the implementation (Feb to Aug 2019).

Results: From Feb to Aug 2018, 1,005 antibiotic infusers were dispensed; this fell to 472 (a 53.1% decline) from Feb to Aug 2019. The cost fell from NZD11,422 before implementation to NZD51,591 after implementation (a 54.9% decline).

Conclusions: Our policy change lead to a significant reduction of the use of antibiotic infusers, with savings that go beyond the pure pharmaceutical cost and also involve avoiding the necessity of a PICC-line and the need for a visiting Nurse at home to change the infusers daily. The PICC line-related complications (thrombosis and infections) were also avoided.

Ceftolozane-tazobactam for treatment of severe ESBL-producing Enterobacteriaceae infections: a multi-centre nationwide clinical experience (Ceftabuse II Study)

Matteo Bassetti1, Antonio Vena1, Daniele Roberto Giacobbe1, Marco Falcone2, Giusy Tiseo2, Maddalena Giannella2, Renato Pascale1, Marianna Meschian1, Margherita Digaetano2, Alessandra Oliva3, Cristina Rovelli4, Novella Carannante5, Angela Raffaella Losito4, Sergio Carbonara4, Michele Fabiano Marian4, Antonio Mastroianni5, Gioacchino Angarano5, Mario Tumbarello5, Carlo Tascini7, Paolo A. Grossi5, Claudio M. Mastroianni5, Cristina Mussini4, Pierluigi Viale1, Francesco Menichetti5, Claudio Viscoli5, Alessandro Russo*5

1Genoa, Italy, 2Pisa, Italy, 3Bologna, Italy, 4Modena, Italy, 5Rome, Italy, 6Varese, Italy, 7Naples, Italy, 8Bari, Italy, 9Cosenza, Italy

Background: few data are reported in literature about outcome of patients with severe ESBL-producing enterobacteriaceae infections treated with ceftolozane/tazobactam (C/T), in empiric or definitive therapy.

Materials/methods: a retrospective study was performed at 24 hospitals in Italy (June 2016-June 2019). All adult patients treated with ≥4 days of C/T were enrolled. Successful clinical outcome was defined as complete resolution of clinical signs/symptoms related to ESBL-producing enterobacteriaceae infection and lack of microbiological evidence of infection. Primary endpoint was to identify predictors of clinical failure of C/T therapy.

Results: C/T treatment was documented in 153 patients: pneumonia was the most common diagnosis (n= 46, 30%) followed by 34 cases of complicated urinary-tract infections (22.2%), 25 cases of acute bacterial skin and skin-structure infections (16.3%), and 25 cases of complicated intra-abdominal infections (16.3%). Septic shock was observed in 36 (23.5%) patients. C/T was used as empiric, then confirmed therapy, in 46 (30%) patients; as monotherapy in 127 (83%) patients. C/T doses were 1.5 g q8h in 115 patients (75%) and 3 g q8h in 38 patients (25%). When used as second-line or later, the most common reasons for discontinuation of previous antibiotics were in vitro resistance of strains and clinical failure of previous therapy. Favorable clinical outcome was observed in 128 (83.7%) patients; 25 patients considered to have failed C/T therapy. Overall, 30-day mortality was reported for 15 (9.8%) patients. At multivariate analysis, Charlson Comorbidity Index >4 (OR 3.3, CI95% 2.1-4.2, p=0.01), septic shock (OR 5.2, CI95% 3.2-7.4, p=0.001), continuous renal replacement therapy (OR 2.3, CI95% 1.87-4.3, p=0.02) were independently associated with clinical failure, while C/T in empiric therapy (OR 0.22, CI95% 0.11-0.67, p<0.001), and adequate source control of infection (OR 0.32, CI95% 0.24-0.77, p=0.001) with clinical success.

Conclusions: data showed that C/T could be a valid option in empiric and/or targeted therapy also in patients with severe infections caused by ESBL-producing enterobacteriaceae. Clinicians should be aware of the risk of clinical failure with C/T therapy in septic patients receiving CRRT.

Figure 1. Successful clinical outcome and clinical failure in patients receiving C/T as empiric therapy, targeted or rescue therapy

**Bacteriophage-controlling dominant sequence types of carbapenem-resistant Escherichia coli in Bangladesh**

Jordan Mathias¹,², Dmitriy Babenko²², Abdulrahman Almusallam¹, Refath Farzana¹, Mark Alexander Toleman¹

¹Cardiff University, Cardiff, United Kingdom, ²Karaganda Medical University, Karaganda, Kazakhstan

**Abstract 3202**

**Background:** E. coli is universally carried in the human gut and the main cause of urinary tract and blood infections. Previously, we have noted that carbapenem resistance (NDM) is restricted to a small number of prevalent E. coli sequence types (ST).

**Materials/methods:** Sewage was collected from 58 sites across Dhaka, Bangladesh in 2012, 2018 and 2019. E. coli were isolated by plating on meropenem (0.5mg/L) with species confirmation by MALDI-TOF-MS. At the same time bacteriophage were isolated by centrifugation and filtration and pooled for each time point. E. coli ST were identified using a combination of CH typing and whole genome sequencing using Miseq technology. Fifty-three carbapenem resistant isolates of E. coli collected in 2012 were individually tested for susceptibility to bacteriophage pools isolated in 2012, 2018 and 2019 by bacteriophage plaque assays. Bacteriophage titre and plaque size were recorded. Bacteriophage were also characterized by electron microscopy and sequenced using Miseq technology.

**Results:** From 2012 sewage we recovered 53 carbapenem resistant E. coli isolates that belonged to only three different ST: ST101, ST648 and ST405. E. coli ST101 isolates were commonly found at numerous locations but E. coli ST405 was found only at a single location. ST648 isolates were found at an intermediate prevalence. The prevalence of bacteriophage, able to kill each E. coli ST group was directly yet inversely related to the prevalence of each E. coli ST. Bacteriophages were found in 2012 (at high titre 10⁶-10⁸ pfu/ml) that were able to kill all ST405 isolates (5/5). However, the bacteriophage pool from 2012 sewage was only able to kill a single ST101 E. coli isolate (1/20). The 2018/2019 samples contained a similarly high abundance of bacteriophages against ST405 and ST648 (similar to that seen in 2012). However, the 2019 sewage sample contained bacteriophage capable of killing 5 different ST101 E.coli- a 5-fold increase compared to 2012.

**Conclusions:** These results give evidence that bacteriophages play a key role in modulating dominant resistant E. coli populations. They also suggest that these natural processes could be artificially manipulated to favour non-resistant E. coli types and control resistant E. coli populations.

**Presenter email address:** mathiasj@cardiff.ac.uk
Successful use of the novel antifungal olorofim in the treatment of disseminated coccidioidomycosis

Emma Harvey1, Lesley Fitton1, John H. Rex1, George Thompson

1F2G, F2G, Manchester, United Kingdom

Background: Infection due to Coccidioides spp. ranges from asymptomatic acquisition with resultant immunity, to severe, multifocal, life-threatening disease. There is a high failure rate with currently approved antifungals and new therapeutic options are needed. Olorofim, a novel antifungal, has potent anti-Coccidioides activity in a murine model of infection.

Materials/methods: An open-label Phase 2 study of olorofim in patients with Invasive Fungal Disease lacking alternative treatment options is ongoing.

Results: A 45 y/o African-American man with insulin-dependent diabetes mellitus developed disseminated coccidioidomycosis with severe lung disease and concurrent meningitis. He was treated with fluconazole 800 mg daily, however four weeks later exhibited continued progression of disease and changed to voriconazole 200 mg twice daily. His pulmonary disease continued to worsen and therapy changed to itraconazole 200 mg twice daily due to voriconazole intolerance.

The patient continued to deteriorate and therapy was changed to liposomal amphotericin B (L-AMB) (5 mg/kg/day) and posaconazole 300 mg daily (tablet). His serum Coccidioides complement fixation titer (CF) was 1:128. One month later he was significantly hypokalemic, L-AMB was stopped, and salvage posaconazole and micafungin 150 mg IV initiated. He continued to deteriorate, was unable to work, was dependent on supplementary oxygen, and required a walking frame.

Eight months after his initial infection therapy was changed to posaconazole 300 mg daily plus olorofim 120 mg twice daily. The patient noted rapid improvement of his cough and malaise within a week with resolution of all other symptoms in this time frame.

After three months of posaconazole plus olorofim he returned to his normal activity level without use of oxygen or a walking frame. CSF examination showed complete normalization of his CSF indices and negative coccidioidomycosis serology from spinal fluid. The serum Coccidioides CF titer declined to 1:64. Repeat pulmonary CT scan showed improvement in multifocal infiltrates.

After 5 months of therapy he returned to work and the Coccidioides CF titer had declined to 1:32. He has tolerated all medications.

Conclusions: Adding olorofim to a failing regimen for severe, disseminated coccidioidomycosis resulted in significant clinical, serologic, and radiologic improvement. Olorofim should be further evaluated in coccidioidomycosis.

Abstract 3205

Haemodialysis-associated infective endocarditis

Rafael Garrido1,2, Marcelo Valle1, Lucas Vasconcelos-Silva3, Marcelo Correia1, Bruno Zappa1, Luiz Henrique Lemos1, Leonardo Ribeiro-Da-Silva2, Juliana De Andrade2, Daniela Menezes2, Wilma Golebiovski1, Clara Weksler1, Giovanna Ianini Barbosa1, Cristiane Lamas*1,2,3

1 Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil; 2 INI - Instituto Nacional de Infectologia Evandro Chagas, Fiocruz, Rio de Janeiro, Brazil; 3 Unigranrio Barra da Tijuca, Rio de Janeiro, Brazil

Abstract third-party references: FAPERJ, Rio de Janeiro, Brazil

Background: Patients with chronic renal failure (CRF) undergoing haemodialysis (HD) are at increased risk of infective endocarditis (IE) due to vascular access-related bacteraemia, accelerated degeneration and calcification of heart valves, and immune dysfunction.

Materials/methods: We compared cases of HD-associated IE in adults with other IE cases from a prospective cohort in a cardiac surgery hospital from 2006 to 2019. All IE was definite by Duke’s modified criteria. Jamovi 1.0.7 software was used for statistical analysis.

Results: We identified 26 patients on HD out of 359 with IE (7.2% of the cohort). They were male 19/26 (73%), aged 47.3 ±16.2 years; 88.5% vs 51.2% were transferred from other sites (p <0.001). Half came from HD clinics and half from other hospitals, while in the rest of the cohort this represented 26.8% and 4.8%, respectively (p <0.001). Accesses were femoral in 9 (34%); 5 had arteriovenous fistula (AVF), the median time from HD to diagnosis of IE was 85 days. There were no differences regarding comorbidities, except for diabetes (30.8% vs 10.2%, p = 0.002). Only 8.5% of HD IE patients had rheumatic valvulopathy vs 35.1% (p = 0.006). There was no difference between valve types (native or prosthetic), blood culture positivity (73.1% vs 67.8%), presence of fever (96.2% vs 92.7%), splenomegaly (15.4% vs 23%) and embolic vascular events (57.7% vs 50.8%). Enterococci were the most common microorganisms (34.6% vs 9.0%), there were fewer viridans group streptococci (3.8% vs 25.2%, p < 0.014), more coagulase-negative staphylococci (19.2% vs 8.1%, p = 0.069) and no difference for Staphylococcus aureus and Gram negative bacilli. There was no difference regarding surgical indication (30.8% vs 24.1%) and actual surgical rates (73.1% vs 80.1%). Moreover, no difference in mortality (30.8% vs 24.1%) was seen.

Conclusions: HD-associated IE occurred shortly after the procedure (median 3 months). Enterococci were the most common pathogens, probably due to the insertion of femoral catheters. Fever, complications, and mortality were similar to patients with IE in general. The high frequency of HD-associated IE from other hospitals suggests that infection control practices should be improved in those institutions, as well as in dialysis clinics.

Abstract 3210

Clinical evaluation of the mosquito-borne virus panels of Genematrix based on multiplex real-time PCR

Janghyuk Ju1, Sung Eun Cho1, Seungmin Yang1, Kyumin Lee1*, Sun Pyo Hong1, Soo-Ok Kim1

1Genematrix, Inc., Gyeonggi-Do, South Korea

Background: Fast and accurate early diagnosis of mosquito-borne viral infection diseases is crucial for its prevention of transmission. NeoPlex™ ARV-6 and NeoPlex™ ZDC Detection Kits are single-tube multiplex real-time RT-PCR assays based on Genematrix proprietary C-Tag™ technology, simultaneously detecting Zika, Dengue, Chikungunya, YellowFever, WestNile and RossRiver (ARV-6), and Zika, Dengue and Chikungunya virus (ZDC), respectively. Here we report the clinical evaluation of NeoPlex™ ARV-6 and ZDC Detection Kits.

Materials/methods: To evaluate NeoPlex™ ARV-6, total 629 plasma and serum specimens (Beir resources, VA; Cerba Xpert, France; ABO Pharmaceuticals, CA) including 393 spiked serum specimens were prepared. To evaluate the clinical performance of NeoPlex™ ZDC, 372 human serum and 364 plasma specimens were retrospectively collected in Philippines. The samples were cross-examinationally tested with type-specific sequencing for NeoPlex™ ARV-6 and RealStar Zika, DENV and CHIKV RT-PCR Kits (Altona diagnostics, Germany) for NeoPlex™ ZDC, following manufacturer’s instructions. The sensitivity and specificity (with 95% CI) were calculated by the comparators and type-specific sequencing as a gold standard. The correlations between NeoPlex™ ZDC and comparators were measured by positive, negative and overall percent agreements.

Results: The clinical sensitivity for NeoPlex™ ARV-6 was as following respectively: Zika 98.1% (0.93-0.99), Dengue 100% (0.97-1.00), Chikungunya 96.6% (0.91-0.98), WestNile 100% (0.92-1.00), YellowFever 100% (0.93-0.99), RossRiver 95.0 (0.83-0.98). The clinical specificity for NeoPlex™ ARV-6 was as following respectively: Zika 98.5% (0.97-0.99), Dengue 100% (0.99-1.00), Chikungunya 99.3% (0.99-1.00), WestNile 99.7% (0.98-0.99), YellowFever 100% (0.99-1.00), RossRiver 99.8% (0.99-0.99). The clinical sensitivity for NeoPlex™ ZDC in human plasma and serum were as following respectively: Zika 100% and 98.48% (94.34-100, 91.90-99.73), Dengue 99.10% and 99.12% (95.07-99.84, 95.20-99.84), and Chikungunya both 100% (91.43-100, 91.80-100), while the clinical specificity for those were as following respectively: Zika both 100% (98.74-100, 98.76-100), Dengue 99.60% and 99.61% (97.80-99.93, 97.84-99.93), and Chikungunya both 100% (99.82-100, 98.85-100). Positive, negative and overall percent agreements were over 98.66%, showing Cohen’s kappa between 0.9866-1.

Conclusions: Compared with commercial diagnostics, Neoplex™ ARV-6 and ZDC, based on C-Tag™ multiplex real-time PCR technology, have proved their usefulness on clinical and diagnostic uses for detecting mosquito-borne viruses in a single-tube PCR reaction with high clinical sensitivity and specificity.

Abstract 3212

In vitro activity of eravacycline and comparators against 931 non-fastidious and 323 fastidious clinical isolates from China

Yang Yang*, Qingyu Shi1, Yue Sun1, Yonggui Zheng1, Dong Dong1, Yan Guo1, Demei Zhu1, Fupin Hu1

1Huashan Hospital, Fudan University, Institute of Antibiotics, Shanghai, China

Background: Eravacycline (ERV), a novel fluorocycline antimicrobial agent approved for the treatment of complicated intra-abdominal infections (cIAI) in the USA and EU in 2018, has demonstrated in vitro activity against multi-drug-resistant (MDR) strains. We evaluated the activity of ERV against clinical isolates of Enterobacteriaceae, A. baumannii, Staphylococcus spp, Enterococcus spp, S. pneumoniae, H. influenzae and M. catarrhalis including those that are MDR, from hospitals in China.

Materials/methods: A total of 1254 organisms collected from intra-abdominal and respiratory infections during the China Antimicrobial Surveillance Network (CHINET) 2017-2018 were included. Isolates were identified by standard biochemical algorithms and MALDI-TOF-MS. Antimicrobial susceptibility testing was performed by the broth microdilution reference methods, and MICs were interpreted per EUCAST criteria.

Results: ERV inhibited 98.3% E. coli isolates at 0.5 µg/ml. ERV had similar MIC90 values (2 µg/mL) against Klebsiella spp, Enterobacter spp and Citrobacter spp to tigecycline. ERV and tigecycline showed decreased activity against Proteus spp and Morganii spp with MIC50 values (1-2 µg/mL). The MIC50 and MIC90 values against A. baumannii were 0.5 and 1 µg/ml, respectively, two-fold lower than that of tigecycline. MIC90 values of ERV against S. aureus, CoNS, E. faecalis (including 8 linezolid-nonsusceptible strains) and E. faecium (including 21 vancomycin-resistant strains) were 0.125, 0.5, 0.125 and 0.06 µg/ml, two/four-fold lower than that of tigecycline. The modal MIC of ERV against S. pneumoniae, H. influenzae and M. catarrhalis were 0.008, 0.125 and 0.06 µg/ml respectively.

Conclusions: ERV possessed significant in vitro activity against contemporary clinical isolates of Enterobacteriaceae and A. baumannii from China, including carbapenem-resistant strains. ERV demonstrated lower MIC90 values than tigecycline against Staphylococcus spp, Enterococcus spp, S. pneumoniae, H. influenzae and M. catarrhalis.

Abstract 3215

Development of new bicyclic nitroimidazoles as antitubercular and antiparasitic agents
Chee Wei Ang1, Angie Jarrad1, Anjan Debnath2, Lendl Tan1, Melissa Sykes4, Yuehong Wang5, Mark Butler1, Paul Bernhardt3, Nick West3, Vicky Avery4, Amirali Popat6, Scott Franzblau5, Matthew Allister Cooper1, Mark Blaskovich*1

1The University of Queensland, Institute for Molecular Bioscience, Saint Lucia, Australia, 2University of California San Diego, Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, United States, 3The University of Queensland, School of Chemistry and Molecular Bioscience, Saint Lucia, Australia, 4Griffith University, Discovery Biology, Griffith Institute for Drug Discovery, Nathan, Australia, 5University Of Illinois At Chicago, Institute for Tuberculosis Research, College of Pharmacy, Chicago, United States, 6The University of Queensland, School of Pharmacy, Saint Lucia, Australia

Background: Infectious diseases are a major global health threat requiring new treatment options. The nitroimidazoles are an old class of antibiotics that have been widely used to treat parasites, mycobacteria, and both Gram-positive/Gram-negative bacteria [1]. Delamanid and pretomanid, nitroimidazoles with bicyclic cores, are new candidates for the treatment of tuberculosis [2,3]. They also show repurposing potential against Leishmania donovani, the causative agent of visceral leishmaniasis [4]. Another bicyclic nitroimidazole, fexinidazole, was recently approved as the first oral treatment for Human African Trypanosomiasis. Inspired by the dual antitubercular and antiparasitic activities of these compounds, we have developed a new bicyclic subclass, 2-nitroimidazo-pyrazinones, with activity against Mycobacterium tuberculosis, intestinal parasites (Giardia lamblia) and kinetoplastids (Trypanosoma brucei brucei and Trypanosoma cruzi) [5]. Similar to other bicyclic nitroimidazoles, our compounds have limited aqueous solubility and therefore require further optimization, as well as assessment in vivo.

Materials/methods: New analogs, designed to improve solubility, were synthesized using modifications of previous synthetic routes. They were assessed in biological assays for antimicrobial activity against a range of organisms, along with measurements of aqueous solubility. Promising compounds were tested for protein binding and plasma/microsomal stability, and advanced into mouse pharmacokinetic and efficacy testing. We also investigated the potential of nanoparticle formulations to improve solubility for oral delivery.

Results: We describe three new series of pyrazinones with improved solubility. The structure-activity relationship (SAR) study showed distinct trends across tested organisms, suggesting their selectivity for different pathogens. Selected potent analogues had low cytotoxicity against human cell lines, good oral availability in mice with favourable pharmacokinetic profiles, and were efficacious in in vivo models. Nanoparticle formulation with lactoferrin, an iron-binding glycoprotein, enhanced solubility by over 3-fold.

Conclusions: This work has highlighted the potential of different subclasses of nitroimidazoles to be developed as therapeutics to address the unmet medical needs caused by bacterial and parasitic infections. We have been able to improve both solubility and potency of our novel 2-nitroimidazo-pyrazinones, and demonstrate in vivo efficacy.

Abstract 3216

**Antibiotic utilisation and Clostridoides difficile rate: a 12-year time series and cross-correlation analysis**

David Lye*1,2,3,4, Shi Thong Heng1,4, LI Wei Ang1,4, Sock Hoon Tan1, Hui Lin Tay4, Min Yi Yap1, Boon Hou Chua1, Jason Quek1, Tat Ming Ng1, Tau Hong Lee1,2,3,4

1National Centre for Infectious Diseases, Singapore, Singapore, 2Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 3Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, 4Tan Tock Seng Hospital, Singapore, Singapore

**Background:** Clostridoides difficile infection was independently associated with extended-spectrum cephalosporins, fluoroquinolones, carbapenems and clindamycin. We observed declining rate of *C. difficile* after 10 years of antimicrobial stewardship programme in a university teaching hospital in Singapore. We aimed to investigate the temporal relationship between antibiotic usage and *C. difficile* rate.

**Materials/methods:** Monthly utilisation of antibiotics in defined daily doses (DDD) and incidence of *C. difficile* per 1,000 patient-days from January 2007 to December 2018 were obtained from the hospital’s database. Each time-series was pre-whitened to account for autocorrelation. An autoregressive integrated moving average (ARIMA) model was fitted to an antibiotic utilisation time-series filtered to obtain white noise residuals. The *C. difficile* incidence time series was filtered with the same model. The cross-correlation function (CCF) was computed between the filtered time-series for each antibiotic use and *C. difficile* incidence at lags up to 12 months. We investigated the lag in the CCF at which the peak correlation of statistical significance (p<0.05) occurred, to determine the lead time of antibiotic utilisation relative to *C. difficile* incidence.

**Results:** The incidence rate of *C. difficile* showed downward trend from monthly average of 0.60/1000 patient-days in 2007 to 0.46/1000 patient-days in 2018. *C. difficile* rate was correlated with overall broad-spectrum antibiotic utilisation (0.22, p=0.01). Utilisation of beta-lactams with beta-lactamase inhibitors (BLBLI) (0.20, p=0.01) and carbapenems (0.20, p=0.02) was correlated with *C. difficile* incidence. No significant correlation was found with fluoroquinolones (0.12, p=0.16) and 3rd generation cephalosporins (0.11, p=0.18). Utilisation of individual antibiotics; co-amoxiclav (0.20, p=0.02), imipenem (0.27, p=0.01), ertapenem (-0.19, p=0.02) and clindamycin (-0.17, p=0.047) was correlated with *C. difficile* rate. The lead time at which peak correlation occurred was 0 month for overall broad-spectrum antibiotics, BLBLIs and co-amoxiclav, 1 month for ertapenem, 2 months for imipenem, 3 months for the carbapenem group and 7 months for clindamycin.

**Conclusions:** Utilisation of overall broad-spectrum antibiotics, carbapenems and BLBLI significantly correlated with *C. difficile* incidence rate. Focusing on individual antibiotics may not be effective in controlling *C. difficile*.

In vitro activity of ibrexafungerp in pH 7.0 and pH 4.5 testing environments against 187 fluconazole-susceptible and -resistant Candida species from vulvovaginal candidiasis patients

Jack Sobel*, Stephen Barat2, Katyna Borroto-Esoda2, Nkechi Azie1, David Angulo Gonzalez2

1Wayne State School of Medicine, Detroit, United States; 2SCYNEXIS, Inc., Jersey City, United States

Abstract

Background: Recent studies report a rapidly growing incidence of resistance to the azole drug class in Candida species, notably C. glabrata, C. parapsilosis, and C. krusei. Among patients with vulvovaginal candidiasis (VVC), C. albicans is the most frequently observed Candida species. What is extremely worrisome is the increase in fluconazole (FLU) resistance observed in C. albicans vaginal isolates. Previous in vitro studies have shown that fluconazole in low pH testing environments, pH 4.5, has a negative effect on the activity of fluconazole. Ibrexafungerp is an oral anti-fungal agent belonging to a novel class of glucan synthase inhibitors, triterpenoids, and has shown activity against azole-resistant Candida species.

Materials/methods: Ibrexafungerp was evaluated in vitro against 187 vaginal Candida isolates: 52 FLU–resistant C. albicans (FLU MIC > 2 ug/mL), 30 FLU–sensitive C. albicans (FLU MIC < 2 ug/mL), 30 randomly selected C. glabrata isolates and 25 each randomly selected isolates of C. krusei, C. parapsilosis, and C. tropicalis. Susceptibility tests were performed according to CLSI M27-A4 guidelines with the media adjusted to pH 7.0 and pH 4.5; ibrexafungerp MIC readings were conducted at 24 and 48 hrs.

Results: Ibrexafungerp demonstrated in vitro activity against all the VVC clinical isolates tested. No differences were observed in ibrexafungerp's MIC90 values (24 hr endpoint at pH7) between the FLU-resistant and FLU-sensitive C. albicans isolates (MIC90 = 0.03 µg/mL). Against the C. glabrata, C. krusei, C. parapsilosis, and C. tropicalis isolates, ibrexafungerp MIC90 values were 0.125, 0.5, 0.25, and 0.125 µg/mL, respectively. Ibrexafungerp's MIC values were not adversely affected when tested at lower pH (4.5). These values are similar to those observed in earlier epidemiologic studies of ibrexafungerp.

Conclusions: Ibrexafungerp exhibited significant in vitro activity against FLU-resistant and FLU-sensitive, vaginal, Candida spp isolates. The potent in vitro activity of ibrexafungerp was retained at lower pH (4.5), relevant for the vaginal milieu. These results suggest that ibrexafungerp is a highly-promising, orally bioavailable antifungal agent for the treatment of VVC and prevention of recurrence.

**Abstract 3221**

**Using saliva for precision dosing of antifungal drugs: saliva population pharmacokinetic model**

Hannah Yejin Kim1, Anne-Grete Märtson2, Erwin Dreesen3, Isabel Spriet4, Sebastian Wicha5, Andrew Mclachlan6, Jan W. C. Alffenaar7

1The University of Sydney/Westmead Hospital, Sydney, Australia, 2University of Groningen/University Medical Center Groningen, Groningen, Netherlands, 3KU Leuven, Leuven, Belgium, 4KU Leuven/ University Hospitals Leuven, Leuven, Belgium, 5University of Hamburg, Dept. of Clinical Pharmacy, Institute of Pharmacy, Hamburg, Germany, 6The University of Sydney, Sydney, Australia, 7The University of Sydney/Westmead Hospital, Sydney, Australia

**Background:** Evidence supporting precision dosing has grown stronger for many antifungal drugs. Prompt action on sub- or supra-therapeutic drug exposure will likely optimize treatment outcomes for invasive fungal infections. Saliva sampling is being considered as a non-invasive, more feasible alternative to plasma sampling for therapeutic drug monitoring (TDM). However, very limited studies have explored the saliva-based TDM, with currently no clinically-validated saliva models.

**Materials/methods:** We conducted a systematic review using database search of up to July 2019 on PubMed® and Embase® to evaluate the evidence supporting saliva-based TDM for azoles, echinocandins, amphotericin B and fluocytosine. For eligible drugs, a saliva population pharmacokinetic analysis was performed using Nonlinear Mixed Effects Modelling in NONMEM 7.4.

**Results:** From the systematic review of 14 included studies, fluconazole and voriconazole demonstrated a good saliva penetration with an average saliva-plasma ratio of 1.21 (±0.31) for fluconazole and 0.56 (±0.18) for voriconazole, and strong correlation [r=0.89-0.98] between saliva and plasma total drug concentrations. Based on the evidence for TDM, and available data, a population pharmacokinetic analysis was performed for voriconazole. 137 voriconazole plasma and saliva concentrations from 11 patients (10 adults, 1 child) were available from the included studies. Voriconazole pharmacokinetics was best described by a 1-compartment model with first order absorption, parameterized by clearance of 4.56 L/h (36.9% CV), volume of distribution of 60.7 L, absorption rate constant of 0.858 (fixed), and bioavailability of 0.849. Distribution from plasma to saliva was kinetically identical to the plasma kinetics, but the extent of distribution was lower, which was modelled by a scale factor of 0.5 (4% CV) to describe distribution from the plasma compartment to saliva [Figure 1]. This value is also consistent with the free fraction of voriconazole (42%), which penetrates saliva. A proportional error model best accounted for the residual variability.

**Conclusions:** The developed saliva model provides a promising framework for facilitation of saliva-based precision dosing of voriconazole. Development of saliva assays, prospective pilot studies on saliva-based TDM, and salivary pharmacokinetic studies on newer antifungal drugs, will help to implement this innovative precision dosing framework in clinical practice.

**Figure 1.** Saliva population pharmacokinetic model of voriconazole.

Abstract 3224

Risk factors for treatment failure of prosthetic joint infections: a multi-centre prospective cohort study

Luis Gustavo Cardoso1, Juliana Matos2, Luciana Jorge3, Marcelo Carneiro4, Karen Morejon5, Bil Bassetti6, Maria Esther Graf7, Cristine Pilati8, Rodrigo Leme9, Mauro Jose Costa Salles*11

1UNICAMP Universidade Estadual de Campinas, Campinas, Brazil, 2Instituto Nacional De Traumatologia E Ortopedia, Rio de Janeiro, Brazil, 3Hospital de Base, São José do Rio Preto, Brazil, 4Universidade De Santa Cruz, Santa Cruz do Sul, Brazil, 5University of São Paulo, Ribeirão Preto, Brazil, 6Hospital Estadual Central, Vitória, Brazil, 7Hospital Universitário Cajuru, Curitiba, Brazil, 8Univerisidade Federal da Fronteira do Sul, Passo Fundo, Brazil, 9Hospital VITA, Curitiba, Brazil, 10Hospital Da Unimed Volta Redonda, Volta Redonda, Brazil, 11Federal University of São Paulo – UNIFESP, São Paulo, Brazil

Background: According to current guidelines, two-stage exchange revision remains the gold standard for the treatment late prosthetic joint infections (PJIs), whereas debridement, antibiotics, and implant retention (DAIR) has been widely accepted for acute infections. While the rates of success following prosthesis removal reaches up to 80-90%, unacceptable higher rates of failures after DAIR have been frequently described. We aimed at evaluating the epidemiology and the outcome of patients treated for PJIs and identify factors predictive of failure.

Materials/methods: From July 2013 to December 2015, patients with PJIs were prospectively enrolled in a national cohort study among 12 hospitals to describe pathogens, diagnosis, surgical strategies adopted, and factors associated with failure after 2-years follow-up. PJIs was defined using the IDSA criteria. Treatment failure was defined as recurrent PJIs, amputation, death, or chronic antibiotic suppression. Potential risk factors for treatment failure were assessed using a Cox regression model.

Results: A total of 199 patients undergoing hip, knee and shoulder (n=3) arthroplasty were available for analysis. Twenty-two (11%) patients died during the follow-up. In the two-year post-diagnosis analysis, overall treatment failure occurred in 17% (n=34/199). Knee and hip rate failure in the 2-year follow up were 16.2% (n=11/68), 18.2% (n=14/77), respectively. DAIR, one-stage exchange, two-stage exchange, and arthrodesis was performed in 44.7%, 25.4%, 22.3%, 7.6% respectively. Failure rates for DAIR, one-stage exchange, two-stage exchange, and arthrodesis after 2-year follow-up were 28.6% (n=16/56), 4.8% (n=2/42), 15.8% (n=6/38), 0% (n=0/15), respectively. Factors independently associated with PJIs failure were older age (adjusted hazard ratio [aHR], 1.03; 95% confidence interval [CI], 1.00–1.07; p =0.017), DAIR strategy (aHR, 3.21; 95% CI, 1.56–6.57; p <0.001), and infection due to Acinetobacter sp. (aHR, 3.38; 95% CI, 1.03–11.04; p =0.044). Microbial diagnosis yielded positive culture in 71.7%. Staphylococcus aureus (34%), coagulase-negative staphylococci (28%), Pseudomonas aeruginosa (17%) were more prevalent. Polymicrobial PJIs were diagnosed in 32.8%.

Conclusions: In this cohort of patients with PJIs an overall 2-years failure-free survival rate was 83%, in which patients undergoing DAIR for PJIs eradication and Acinetobacter sp. infection was independently associated with failure.

Abstract 3225

**Efflux pumps contribute to intrinsic clarithromycin resistance in clinical *Mycobacterium abscessus* isolates**

Qi Guo*, Bing Li, Haiqing Chu

1 Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, 2 Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

**Background:** The emergence of clarithromycin resistance is a challenge in treating *Mycobacterium abscessus* infections. Known mechanisms that contribute to intrinsic clarithromycin resistance focus on *rrl* gene-related mutations, but resistant clinical isolates often exhibit an inconsistent *rrl* genotype.

**Materials/methods:** In this study, 194 clinical *Mycobacterium abscessus* isolates were collected from patients with lung infections and the whole-genome of each isolate was sequenced. A comprehensive examination of the molecular mechanisms underlying intrinsic clarithromycin resistance was performed, combining MIC determination, comparative genome sequence analysis and qRT-PCR.

**Results:** Of the 194 isolates, 13 (6.7%) were clarithromycin resistant; only seven of these harbored a *rrl* 2270/2271 mutation. The remaining 6 resistant isolates did not exhibit a specific resistance-associated mutation in the clarithromycin target-site genes, *rrl, rplC, rplD and rplV*, or in the *rrl* modification gene *erm* [41]. qRT-PCR analysis showed that the increased expression of the efflux pump genes, MAB_2355c, MAB_1409c and MAB_1846, as well as their positive regulatory gene *whiB7*, consistently correlated with increased clarithromycin resistance. The presence of efflux pump inhibitors significantly decreased the MIC of clarithromycin for nonsusceptible isolates, especially the intrinsic resistant isolates that exhibited no *rrl* 2270/2271 mutation.

**Conclusions:** These findings indicate that efflux pumps play a prominent role in the intrinsic resistance of *M. abscessus* to clarithromycin, complementing other known resistance mechanisms.

Clinical impact of metagenomic next-generation sequencing of plasma cell-free DNA for the diagnosis of infectious diseases: a multi-centre retrospective cohort study

Catherine Hogan*,1,2,3, Shangxin (Shaun) Yang4, Omai Garner4, Daniel Green5, Carlos Gomez6, Jennifer Dien Bard5, Benjamin Pinsky1,2,3,8, Niaz Banaei1,2,3,8

1Department of Pathology, Stanford University School of Medicine, Stanford, United States, 2Clinical Microbiology Laboratory, Stanford Health Care, Stanford, United States, 3Clinical Virology Laboratory, Stanford Health Care, Stanford, United States, 4Department of Pathology and Laboratory Medicine, University of California Los Angeles, Los Angeles, United States, 5Department of Pathology, Columbia University Irving Medical Center, New York, United States, 6Division of Infectious Diseases, Department of Medicine, University of Utah, Salt Lake City, United States, 7Department of Pathology, Children’s Hospital of Los Angeles, Los Angeles, United States, 8Division of Infectious Diseases and Geographic Medicine, Department of Medicine, Stanford University School of Medicine, Stanford, United States

Background: Metagenomic next-generation sequencing (mNGS) of plasma cell-free DNA has emerged as an attractive diagnostic modality allowing broad-range pathogen detection, noninvasive sampling, and earlier diagnosis. However, little is known about its real-world clinical impact as used in routine practice.

Materials/methods: We performed a retrospective cohort study of all patients for whom plasma mNGS (Karius test) was performed for all indications at 5 U.S. institutions over 1.5 years. Comprehensive chart review was performed, and standardized assessment of clinical impact of the mNGS based on the treating team’s interpretation of Karius results and patient management was established.

Results: A total of 82 Karius tests were evaluated, from 39 (47.6%) adults and 43 (52.4%) children and a total of 53 (64.6%) immunocompromised patients. Karius positivity rate was 50/82 [61.0%], with 25 [50.0%] showing two or more organisms (range, 2-8). The Karius test results led to positive impact in 6 [7.3%], negative impact in 3 [3.7%], no impact in 71 [86.6%], and was indeterminate in 2 [2.4%]. Cases with positive Karius result and clinical impact involved bacteria and/or fungi but not DNA viruses or parasites. In 10 patients who underwent 16 additional repeated tests, only one was associated with clinical impact.

Conclusions: The real-world impact of the Karius test as currently used in routine clinical practice is limited. Further studies are needed to identify high-yield patient populations, define the complementary role of mNGS to conventional microbiological methods, and how best to integrate mNGS into current testing algorithms.

Abstract 3227

**Applicability of dried blood spot for molecular epidemiology of HCV in coagulopathy patients**

Livia Villar*, Ana Carolina Da Fonseca Mendonça¹, Bianca Leires Marques¹, Jakeline Ribeiro Barbosa², Jeová Keny Colares², Danielle Malta Lima²

¹Oswaldo Cruz Foundation, Oswaldo Cruz Institute, Rio de Janeiro, Brazil, ²UNIFOR - Universidade de Fortaleza, Fortaleza, Brazil

**Abstract third-party references:** Supported by FAPERJ, CNPQ, FIOCRUZ

**Background:** Hepatitis C virus (HCV) can be transmitted by contact with blood and biological fluids. HCV infection is highly prevalent in certain groups, including individuals with coagulopathy who are frequently exposed to blood. The objective of this study is to evaluate the genetic variability of HCV using serum and dried blood spot (DBS) samples in patients with coagulopathy.

**Materials/methods:** A total of 40 patients with chronic hepatitis C were recruited, 18 of whom had hereditary coagulopathy and 22 had no coagulopathy. Serum and DBS samples were collected from each patient and submitted to qualitative PCR for amplification of NS5B regions. Samples with detected RNA were then submitted to Sanger nucleotide sequencing for genotype determination, phylogenetic analysis and determination of resistance mutations.

**Results:** Mean age of the studied population was 44.6 ± 10.7 and the majority of the individuals were male (80%). HCV RNA was detected in 31 (77%) serum and 32 DBS (80%) where 28 individuals had HCV RNA in serum and DBS simultaneously. NS5B detection was associated to serum viral load and was more frequent in patients without coagulopathy. Regarding the HCV genotypes in serum, most of them belongs to genotype 1 (n = 14), where 5 of them had coagulopathy. Other genotypes were observed only in control group: genotype 2 (n = 1), genotype 3a (n = 7) and genotype 4 (n = 1). The same genotypes were observed in serum and DBS from the same individual and high homology between these isolates.

**Conclusions:** In this study, high prevalence of genotype 1, high concordance of genotypes obtained in serum and DBS and similarity between these isolates were observed, showing the applicability of DBS to molecular epidemiological studies of HCV.

A phase II open-label clinical trial of investigational microbiota-based drug RBX2660 for prevention of recurrent *Clostridioides difficile* infection: two-years evaluation of efficacy, durability, microbiome changes and participant demographics

Christina Reimer*, Robert Orenstein1, Lindy Bancke3, Carlos Gonzalez4, Ken Blount3

1Ferring Pharmaceuticals, Medical Director, Translational Medicine, Copenhagen, Denmark, 2Mayo Clinic in Arizona, Phoenix, United States, 3Rebiotix Inc., Roseville, United States, 4BioRankings, LLC, St. Louis, United States

Abstract third-party references: This analysis was funded by Rebiotix Inc., Roseville, MN

**Background:** Recurrent *Clostridioides difficile* infection (rCDI) is associated with mortality, compromised quality of life, and substantial medical cost worldwide. Disruption of the intestinal microbiome contributes to rCDI and microbiota therapy is gaining acceptance to prevent rCDI in multi-recurrent individuals. We present the 24-month analysis of safety, efficacy, and microbiome restoration from a Phase 2 open-label trial of the investigational microbiota-based drug RBX2660 for prevention of CDI recurrence. In addition, we report a subpopulation analysis to address potential demographic differences on treatment outcome and durability.

**Materials/methods:** This multicenter, open-label Phase 2 study included participants with multi-recurrent CDI who received ≤2 doses of RBX2660 delivered via enema 7 days apart. Efficacy was defined as absence of CDI recurrence through 8 weeks after the last dose. Durability was defined as continued CDI absence beyond 8 weeks. Safety and durability assessments occurred at 3, 6, 12, and 24 months. A general linear model was performed to assess the influence of age (≥65 years, <65 years), sex (female, male), and their interaction on clinical outcome. Participant stool samples were collected prior to and for up to 720 days after treatment, and microbiome changes were assessed by shallow shotgun sequencing.

**Results:** The RBX2660 efficacy to prevent rCDI at 8 weeks (79%;112/142) was higher than the CDI-free rate in the historical control group (31%, 23/75; p<.0001). The safety profile was consistent with previous reports for RBX2660. Among 97 participants who achieved treatment success at 8 weeks and were evaluable for long-term durability, 8 experienced a new CDI episode by the 24-month follow-up for an overall durability of 92%. Microbiome analysis of 503 stool samples from 110 treatment responders showed that the relative abundance of Bacteroidia and Clostridia shifted significantly higher within 7 days of treatment relative to baseline while Gammaproteobacteria and Bacilli declined sharply, and these changes persisted to at least 24 months. Age and sex did not have a statistically significant impact on efficacy or durability.

**Conclusions:** RBX2660 was efficacious for preventing rCDI, with clinical durability and maintained shifts in microbiome composition to 24-months after treatment. Importantly, neither efficacy nor durability was dependent on age or sex.

Abstract 3238

**Amikacin resistance due to the aphA6 gene in multiply antibiotic-resistant Acinetobacter baumannii isolates belonging to global clone 1 from Iran**

Masoumeh Douraghi*1, Parisa Aris1, Sedighe Ghourchian1, Mohammadali Boroumand2

1School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, 2Department of Pathology, Tehran Heart Center, Tehran University of Medical Sciences, Tehran, Iran

**Background:** TnaphA6-carrying repAci6 plasmids have been detected in Acinetobacter baumannii isolates belonging to global clones, GC1 and GC2, worldwide. Here, we examined whether RepAci6 plasmids family play a role in the dissemination of the aphA6 in GC1 A. baumannii isolates from Iran.

**Materials/methods:** A set of 55 multiply antibiotic-resistant A. baumannii isolates belonging to GC1 were included in this study. The susceptibility testing to amikacin (30 μg), kanamycin (30 μg), and neomycin (30 μg) was performed. PCR was used to examine the presence of the aphA6 gene and also to determine if it is located in TnaphA6. PCR was also used to examine whether TnaphA6 is present in a context similar to the backbone of plasmids encoding RepAci6. Unique sequences on either side of the repeated sequence 1, 2 and 3 (often found in repAci6 plasmids) were joined using previously designed PCRs, in cases that TnaphA6 was found in a context similar to the backbone of plasmids that carry the repAci6 gene.

**Results:** We found that 22 isolates carried the repAci6 gene, suggesting that they contain a RepAci6 plasmid family. Using primers linking the aphA6 gene to the backbone of repAci6 plasmid, it was revealed that 16 isolates from different hospitals harbored TnaphA6 on a repAci6 plasmid.

**Conclusions:** This study provides evidence for the dissemination of TnaphA6 on the plasmids encoding RepAci6 in Iranian A. baumannii isolates. Furthermore, it seems that TnaphA6 might be acquired by distinct plasmids separately as it was found to be located on the variants of repAci6 plasmids.

Abstract 3242

Effective utilisation of limited isolation rooms to provide safe patient care and staff safety in lower/middle-income country

Rozina Roshan\(^1\), Zohra Rafique\(^1\)

\(^1\)Aga Khan University Hospital, Pakistan, Aga Khan University, Karachi, Pakistan

**Background:** A tertiary care hospital is a 750 bedded hospital with only 17 airborne infection isolation room (AIIR)/negative pressure rooms to isolate patients who have been diagnosed or are suspected with prevalent diseases like tuberculosis, measles, and chickenpox. On the other hand, only 14 single room isolation are available to isolate multi drug resistant organisms (MDRO) like CRE (Carbapenem Resistant Enterobacter) or Colistin Resistant MDRO. Due to limited number of isolation rooms average number of hours to isolate infected patients took around 20 hours which ultimately places direct health care staff at risk of exposure to infected patients.

**Materials/methods:** Plan-Do-Study-Act (PDSA) quality improvement methodology was utilized to decrease the average number of hours to isolate infected patients and to reduce the exposure of health care workers to communicable diseases. Detailed analysis were done to identify root cause and its effect at multiple levels to ascertain reasons. Multiple strategies were done with multidisciplinary team which include but are not limited to coordination with IT team to place isolation alerts in system, screening flyers and questions at ED triage, close coordination with admission and bed management office (BMO), daily morning and evening rounds by IPs in ED, daily morning meeting with microbiology and BMO to intervene immediately to isolate patient timely, introduction of IPs 24/7 on-call system to facilitate units, ED, BMO and admission office immediately to provide recommendations for patient placement and cohorting same infection patients wherever possible.

**Results:** Results showed significant reduction in the number of hours to isolate infected patients from 20 hours to 4 hours in one year. As a result, rate of Health Care Worker’s exposures to communicable diseases also decreased from 6.7 to 1.5. TB exposure decreased from 6.0 to 1.9, Measles 4.75 to 1.5 and Chickenpox 7.3 to 1.0. Significant reduction on cost incurred by organization for the employees who were exposed to these diseases for post exposure prophylaxis also decreased i.e. from around Rs. 290000 ($3000) to Rs. 59520 ($600).

**Conclusions:** Multidisciplinary approach provides a proven strategy to bring improvement and enhance patient and staff safety in limited resource settings.

**Efficacy of cefiderocol against carbapenem-resistant Acinetobacter baumannii in ventilator-associated pneumonia mouse model**

Kenji Ota*1, Norihito Kaku1, Naoki Uno1, Kei Sakamoto1, Yoshitomo Morinaga1, Hiroo Hasegawa1, Taiga Miyazaki1, Koichi Izumikawa1, Hiroshi Mukae1, Katsunori Yanagihara1

1Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

**Background:** Cefiderocol (CFDC) is a novel siderophore cephalosporin with potent activity against carbapenem-resistant Gram-negative bacilli and stability against carbapenemase. We evaluated the efficacy of cefiderocol against carbapenem-resistant A. baumannii in ventilator-associated pneumonia (VAP) mouse model.

**Materials/methods:** Carbapenem-resistant A. baumannii (blaOXA-51-like) was used in this study. MICs of CFDC and meropenem (MEPM) were measured by micro dilution assay. In VAP model, 5mm length tube was inserted through a vocal code of cyclophosphamide-induced immunocompromised ddY mouse (6 weeks old, male), followed by bacterial inoculation (5x10^5 cell/mouse). Antibiotics were administered intraperitoneally three hours post infection. Drug administration doses and intervals were determined based on plasma drug concentrations of infected mouse. In treatment study, survival rates for 120 hours and number of bacterial loads of the lungs and blood were counted and histopathological examination of the lungs at 48 hours post infection were evaluated.

**Results:** MICs were 0.5 mg/L for CFDC and 128 mg/L for MEPM. According to PK analysis, 55 mg/kg of CFDC and 1,100 mg/kg of MEPM (combined with same dose of cilastatin) was administered every six hours, in order to achieve time above MIC >70% for CFDC and >30% for MEPM, respectively. These exposures could be achieved in human for CFDC, but could not be achieved for MEPM due to high MEPM MIC of the test strain. In treatment study, all the mice in both treatment groups survived and survival rate was statistically significantly improved, compared to 28.6% (2/7) survival rate in control group. The number of bacterial load of the lungs (n=6-7, log10 CFU/lung±SEM) was significantly reduced in CFDC group (4.64±0.29, \(P<0.0001\)) and MEPM group (3.19±0.11, \(P<0.0001\)), compared to 7.99±0.44 in control group. Bacteremia was observed in 33.3% (2/6) of mice in control group, while no mouse in treatment groups. In lung histopathological examination, infiltration of inflammatory cells and hemorrhage in alveoli were observed in control group, which were limited in treatment groups.

**Conclusions:** In this study, we showed the efficacy of CFDC against carbapenem-resistant A. baumannii in VAP mouse model. CFDC can be a potent treatment option against VAP caused by carbapenem-resistant A. baumannii.

**Presenter email address:** kenjiotamd@nagasaki-u.ac.jp
**Intracellular drug targets in Mycobacterium tuberculosis revealed by a chemogenetic approach**

Kin Ming Tsui; Flavia Sorrentino; Gagan Narula; Adama Bojang; Abraham Lopez; Xingji Zheng; Modesto Remuiñan; Yossef Av-Gay

1Sidra Medicine, Doha, Qatar; 2University of British Columbia, Vancouver, Canada; 3GlaxoSmithKline, Madrid, Spain

**Background:** Mycobacterium tuberculosis (Mtbg), the etiological agent of tuberculosis, causes chronic lung diseases to one third of the global population. Due to increasing prevalence of multi-drug-resistant tuberculosis with limited alternatives to first-line antituberculosis drugs, there is an urgent need to combat these resistant Mtb by novel drug discovery approach. We develop an advanced intracellular drug-screening assay to screen compounds in Mtb infected macrophages. The objective of this investigation is to identify hit compounds mode of action or drug targets from this drug discovery approach using WGS and bioinformatics analysis.

**Materials/methods:** 80 hit compounds were subject to in vitro MICs in different carbon sources. High-throughput phenotypic screening were performed and 1-6 resistant mutants were obtained from each hit compound. The genomes of parental strain and the mutants were sequenced using Illumina MiSeq. The reads were mapped to the standard reference genome H37Rv using BWA, and the variants were identified and annotated by GATK and snpEff.

**Results:** The genomes of 53 Mycobacterium tuberculosis mutants, screened from 15 different hit compounds, were sequenced. We found 90 mutations in at least 25 different genes that was associated with potential drug resistance acquisitions. Independent mutations were reported in ethA, which is a mycobacterial enzyme responsible for the drug ethionamide bio-activation to treating tuberculosis. A mutation was found in rpoB, which is a known drug target, encoding the beta subunit of RNA polymerase. Apart from known drug targets, multiple mutations were discovered in novel antimycobacterial drugs such as mmpL3, which is a membrane transporter in the resistance-nodulation-cell division family. Mutations were also reported in candidate drug targets such as prrB, which belongs to a two-component regulatory system composed of PrrB histidine kinase, and other genes.

**Conclusions:** Bioinformatics analysis of WGS of mutants screened against various compounds identified several promising genes that confer resistance to given chemical entity and as such may provide insight into their mode of action or drug targets. Some targets of these chemical libraries are consistent with those that are tied to the proposed mechanism of action or resistance. The investigation has extended our understanding of the biological basis for the antituberculous actions.

Tetanus prophylaxis in wound management of patients with rheumatoid arthritis

Albert Vollaard1, Aernout Bos2, Maria Gonçalves3, Monique Andersson4, Isabel Furtado3, Lurdes Santos5, Oriol Manuel6

1National Coordination Centre for Communicable Disease Control, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 2Leiden University Medical Center, Leiden, Netherlands, 3Centro Hospitalar do Porto, Porto, Portugal, 4Oxford University Hospitals, Oxford, United Kingdom, 5Centro Hospitalar Universitário São João, Porto, Portugal, 6Lausanne University Hospital, Lausanne, Switzerland

Background: Adults with wounds who have received primary tetanus toxoid (TT) vaccines are given a booster if the last TT-dose was ≥ 5-10 years. Immunocompromised patients frequently receive a booster regardless of a recent dose plus additional tetanus immunoglobulin (TIG). We aimed to evaluate this strategy for patients with rheumatoid arthritis (RA).

Materials/methods: Studies were searched in PubMed that examined immunogenicity of a TT 20 IU booster in adult RA patients. Protection was defined as anti-TT IgG > 0.1 IU/ml.

Results: In 5 studies antibody response was measured 4-5 weeks after TT vaccination in 347 patients, age 18-81 years. No healthy controls were examined for comparison. Treatment consisted of DMARDs and/or biologicals with or without corticosteroids.

At baseline 15/269 (5.6%) patients were not protected. It was unclear if this was due to old age, missing primary vaccinations or a very long period since the last dose. In one study (n=68) the lower bound of the 95% CI of the geometric mean titer was > 0.1 IU/ml. One study (n=10) did not provide baseline titers, but only post-vaccination titers: all > 1.0 IU/ml.

After vaccination 5/269 patients (1.9%) were not protected: they used MTX alone (n=3), or rituximab/MTX or tocilizumab/MTX (1 each). A ≥2-fold increase was demonstrated in 57-74% and ≥4-fold increase in 40-59% of patients. Responses in patients with rituximab/MTX (n=64), tocilizumab/MTX (n=50) or tabalumab/MTX (n=51) were similar to those with MTX alone. Use of baricitinib with or without MTX gave similar ≥2- or ≥4-fold changes as other immunosuppressants.

Conclusions: The booster response in case of a TT-dose < 5 years has not been evaluated in RA patients. Most patients (94%) are protected before vaccination if the last dose was ≥ 5 years ago. A single booster raises this to 98%. Unclear is if age, insufficient number of childhood vaccines, long interval since last dose, or immunosuppressive therapy limits antibody response. Recall response is not affected by treatment combinations compared to methotrexate alone. Consequently, additional TIG next to TT-vaccination should be considered in tetanus prophylaxis in case of a TT-dose > 5 year since last dose or incomplete childhood vaccinations.

Background: Invasive fungal infections (IFI) are a major cause of mortality in lung transplant recipients (LTRs). The earlier the diagnosis is made, the sooner appropriate treatment can be initiated and better would be the prognosis. Unfortunately, diagnostic tools’ performance varies according type of immunodepression. EORTC-MSG criteria are used in clinical trials to classify IFI in proven, probable or possible form. In critically ill patients, clinical algorithm was proposed to diagnose putative aspergillosis. We assessed if these criteria are relevant in LTRs population.

Materials/methods: A retrospective study of IFI occurring in LTRs followed in Bordeaux University Hospital, France, from 2011 to 2017 was conducted. All episodes considered by clinicians as IFI in LTRs were analyzed. Proven and probable IFI fulfilling EORTC-MSG criteria were compared to probable IFI treated but not fulfilling all EORTC-MSG criteria. We described IFI and compared 6-months survival.

Results: During the 7-years study period, 36 IFI were diagnosed, among them 28 pulmonary IFI were selected for comparative analysis. Twenty-five episodes were considered as invasive pulmonary aspergillosis (IPA). IFI occurred at a median time of 436 days post-transplantation (2-9031 days). Twenty-four (67%) occurred in patients who had fungal colonization before IFI. Seven (19%) occurred despite specific antifungal prophylaxis and 15 (42%) patients had bacterial co-pathogens with Pseudomonas spp in 9 cases (60%). Aspergillus fumigatus was found in 53% and galactomannan in bronchoalveolar lavage was positive in 75% but realized only for 16/25 (64%) IPA. Main radiologic abnormalities were nodules (n=23, 69%), with halo sign (n=11, 48%), cavity (n=8, 24%), consolidation (n=7, 21%) and air-crescent sign (n=4, 12%). Twelve patients (63%) had specific radiologic signs defined in EORTC-MSG criteria. There were no statistically differences between EORTC group and non-EORTC group in term of 6-months survival (55% vs 75%, p=0.32), as well as in clinical, radiological and mycological data. Twenty-two (88%) IPA fulfilled putative invasive aspergillosis criteria. Cumulative incidence over the study period reached 20,2%.

Conclusions: Survival was not statistically different between LTRs who developed IFI fulfilling EORTC-MSG criteria and those not. Radiological criteria should be improved and other lesions as tree-in-bud micronodules, ground-glass opacities and consolidation have to be considered.

**Rapid, direct antimicrobial susceptibility testing of positive blood cultures within 4 hours using ATP bioluminescence detection and machine learning method**

Shunsuke Kawabe*1, Yuichi Uchiho1, Hideyuki Noda1, Atsushi Matsui2, Hideki Niimi2, Isao Kitajima2

1Hitachi, Ltd., Tokyo, Japan, 2University of Toyama, Toyama, Japan

**Background:** To prevent the spread of drug-resistant bacteria, a rapid and accurate antimicrobial susceptibility test (AST) is required. Since the amount of adenosine triphosphate (ATP) increases prior to bacterial division, ATP bioluminescence-based detection can serve as an AST method that can rapidly detect bacterial growth. We performed rapid AST by the ATP bioluminescence method using clinical samples of positive blood cultures (PBCs). A minimum inhibitory concentration (MIC) that was determined by a machine learning-based algorithm within 4 h was compared to the conventional MIC results obtained by the turbidity method at 24 h.

**Materials/methods:** We prepared two kinds of AST panels, one each for a gram-negative rod (GNR) and a gram-positive coccus (GPC). The GNR panel contained 12 antimicrobials and the GPC panel contained 10 antimicrobials; a set of 7 or 8 two-fold serial dilutions were prepared for each antimicrobial. At first, we developed the dataset by measuring the ATP bioluminescence for 4 h and conventional turbidity at 24 h, using pure colonies of *Escherichia coli* (77 strains) and *Staphylococcus aureus* (94 strains). The MIC determination algorithms for GNR and GPC were created using a machine learning method based on the dataset, and were validated by evaluating the essential agreement (EA) rates. These algorithms were then applied to the ATP bioluminescence data obtained from 14 clinical samples of PBCs at the Toyama University Hospital. The determined MICs were compared with the conventional MICs obtained by the turbidity method to evaluate the EAs and the categorical agreements (CAs).

**Results:** The EAs of *E. coli* and *S. aureus* from pure colonies at 4 h were 97.3% and 96.3%, respectively. These data indicated that the algorithm can accurately determine the MIC for pure colonies. The EAs and CAs for the PBCs are shown in Table 1. The EAs and the CAs in average for 14 clinical samples were 89.2% and 89.9%, respectively.

**Conclusions:** The rapid AST method using ATP bioluminescence detection could successfully determine MICs directly from PBCs within 4 h. Thus, this method is promising as it can facilitate appropriate antimicrobial treatment, and reduction in medication and hospital admission charges.

**Table 1. EAs and CAs of positive blood culture samples determined after 4 h of culture using ATP bioluminescence detection and machine learning method.**

Abstract 3259

Serum levels of neutrophil elastinase-associated lipocalin in acute brucellosis and brucellar spondylodiscitis
Sua Sumer1, Nazlim Aktug Demir1, Lutfi Saltuk Demir2, Duygu Findik3, Servet Kolgelier4, Onur Ural*1

1Selcuk University, Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Konya, Turkey, 2Necmettin Erbakan University, Faculty of Medicine, Department of Public Health, Konya, Turkey, 3Selcuk University, Faculty of Medicine, Department of Medical Microbiology, Konya, Turkey, 4Dr.Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Infectious Diseases and Clinical Microbiology, Ankara, Turkey

Abstract third-party references: This study was supported by the Scientific Research Projects Coordination Unit of Selcuk University with project number 18401011.

Background: Brucellosis is a zoonotic infectious disease caused by Brucella spp., an intracellular bacterium. Its most common complication is musculoskeletal system involvement. The neutrophil gelatinase-associated lipocalin (NGAL) molecule is a major component of the natural antimicrobial immune system. It appears early in granulocyte differentiation and is, therefore, a marker of neutrophil formation. NGAL acts as a siderophore-binding protein to prevent bacterial iron uptake. The objective of this study is to measure the serum levels of NGAL in patients with acute brucellosis and brucellar spondylodiscitis, and to determine whether there is a correlation between serum NGAL levels and the progression and complications of the disease.

Materials/methods: This study was conducted with 240 patients and 120 healthy controls. Acute brucellosis was diagnosed with standard tube agglutination test (≥ 1/160), and/or there was Brucella spp. growth in the blood culture. NGAL levels were determined with ELISA assay.

Results: The median NGAL value was 456.67 ng/L in patients with acute brucellosis and 113.84 ng/L in the control group. The median NGAL value was statistically higher in the patient group (p=0.001). The median NGAL value was 1885.62 ng/L in patients found to have brucellar spondylodiscitis and 356.87 ng/L in those who had no brucellar spondylodiscitis. This difference was statistically significant (p=0.001) (Figure 1). The erythrocyte sedimentation rate (ESR) and C-reactive protein values were found higher in patients who had brucellar spondylodiscitis than in those who did not. The blood culture positivity rate was 36.02%. Patients whose blood cultures were positive had higher NGAL levels (p=0.001). The blood culture positivity rate was higher in patients who were diagnosed with brucellar spondylodiscitis than in those who had no brucellar spondylodiscitis (p=0.001). A regression analysis showed that female gender and high levels of NGAL, ESR, and alanine aminotransferase could be used as predictors of brucellar spondylodiscitis. The explanatoriness of the model was 82.3%.

Conclusions: NGAL seems to be a useful marker for the diagnosis of acute brucellosis and to predict the presence of brucellar spondylodiscitis.

Figure 1: NGAL levels of acute brucellosis patients with and without brucellar spondylodiscitis.

**Clinical evaluation of a multiplex real-time PCR-based Neoplex RV-Panel A kit for the simultaneous detection of respiratory viral pathogens**

Ae-Ri Cho, Jeongwoo Kim, Jahyun Gu, Seongsoo Hong, Woojae Cho, Kyumin Lee*, Sun Pyo Hong, Soo-Ok Kim

1Genematrix, Inc., Gyeonggi-Do, South Korea

**Background:** Nucleic acid amplification assay, in particular, multiplex real-time PCR has become one of the routine clinical diagnostic tools for the detection of respiratory infectious agents, because it is faster, more accurate and convenient than traditional methods. Neoplex™ RV-Panel A detection kit (Genematrix, Seongnam, Korea) applies single-tube multiplex real-time RT-PCR based on Genematrix’s proprietary C-Tag™ technology. High multiplexing based on C-Tag™ technology allows simultaneous detection of 10 respiratory viral pathogens in a single tube. This study aims to evaluate the clinical performance of Neoplex™ RV-Panel A detection kit compared with Allplex™ Respiratory Panel 1 and 2 (Seegene, Seoul, Korea) in nasopharyngeal swab.

**Materials/methods:** A total of 439 samples were retrospectively collected from residual nasopharyngeal swab samples. Nucleic acid eluted to a final volume of 50 ul was extracted using QIAamp® DSP Viral RNA Mini kit (Qiagen, Hilden, Germany). Using the comparators with Neoplex™ RV-Panel A, the cross-examination was performed on Influenza virus A(Flu A), Flu A/H1N1pdm09, Flu A/H3N2, Influenza B(Flu B), Respiratory syncytial virus(RSV) A, B, Parainfluenza virus(PIV) 1,2,3, and Adenovirus(AdV) by randomized single-blind method. The clinical sensitivity and specificity of Neoplex™ RV-Panel A were calculated by comparing the true positive and negative results confirmed by the comparators and reference method (sequencing assay). The correlation was measured by positive, negative percent agreement (PPA, NPA), overall percent agreement and Cohen's kappa. The estimates were given along with 95% CI.

**Results:** A total of 439 samples were identified without screening failure. The clinical sensitivity of Neoplex™ RV-Panel A was respectively calculated as followed: 100% for Flu A(96.87-100), A/H1N1pdm09(94.34-100), A/H3N2(93.47-100), RSV A(91.43-100), RSV B(94.08-100), PIV 1(92.73-100), PIV 2(91.43-100) and PIV 3(91.80-100), 98.25% for Flu B(90.71-99.69) and 97.50% for AdV(91.34-99.31). The clinical specificity was 100% (98.81-100) for all targets. The PPA, NPA and overall percent agreement were over 96.51% (94.11-97.95), and Cohen's kappa values were measured 0.9528-1.0.

**Conclusions:** Neoplex™ RV-Panel A detection kit is a sensitive and specific multiplex assay that is highly comparable to the commercial diagnostic kits. By detecting 10 respiratory viral pathogens simultaneously in a single test, Neoplex™ RV-Panel A detection kit could be a convenient tool for clinical and diagnostic facilities.

Abstract 3265

First-described human fatal encephalitis caused by avian paramyxovirus serotype 1: agent of Newcastle disease
Sarah Winter1, Emmanuèle Lechapt2, Guillaume Gricourt3, Melissa Ndebi1, Nathalie Boddart1, Manoelle Kossorotoff4, Thomas Blauwblomme4, Demontant Vanessa1, Paul-Louis Woerther1, Jean-Michel Pawlotsky1, Stéphane Blanche4, Benedicte Neven4, Christophe Rodriguez*3

Background: Emerging diseases pose a significant risk to human health and are largely zoonotic. Accurately and early estimating the burden of these diseases is critical to identify public health policy and assessing its impact on control of them. One aspect of surveillance involves diagnosing the first human cases of transmitted pathologies including new pathogens. In this case, the broad spectrum of clinical metagenomics (CMg) is an unprecedented tool to achieve this goal. We report here a case of fatal zoonotic encephalitis by an avian virus described for the first time in human.

Materials/methods: A Turkish patient, diagnosed with ARPC1B deficiency was treated with bone marrow transplantation at the age of 12. Four months later, after a 3-day trip to Dubai, she presented with partial and then generalized seizures leading to the diagnosis of meningo-encephalitis confirmed by MRI. The exploration of different CSFs, negative by conventional microbiological techniques and the deterioration of clinical and radiological signs, led to a cerebral biopsy that establish the diagnosis by CMg but without saving the patient who died 2 months after the beginning of the symptoms. An 15189 accredited CMg technics was routinely performed with specific pan-pathogen extraction, DNA/RNA library prep followed by sequencing with NextSeq500 (Illumina) and analyzed with MetaMIC software.

Results: CMg have identified an Avian Paramyxovirus type 1 [APMV-1] responsible of New Castle Disease Virus (NDV) with a viral load of 3.7 log copies of genome/mg of biopsy. This result was confirmed retrospectively by qPCR [2.7-3.3] log copies of genome/mg of biopsy. Genome reconstruction of the virus yielded a sequence covering 99.8% and its analysis show (i) a closeness with pigeons from the Middle Eastern Region, (ii) the presence of avian most neuro-virulent described mutations in fusion protein [F].

Conclusions: Clinical metagenomics is the only microbiology technique that has made it possible to establish the diagnosis, quantification and characterization of the virus without a priori. To date it has not been established whether the virus came from Dubai or Turkey. However, the neurovirulence of the virus associated with the patient’s immune deficiency probably explains the severity of the infection.

Abstract 3274

**Normocellular bacterial meningitis in adults: a prospective nationwide cohort study**

Hannah Holm Vestergaard*1, Jacob Bodilsen1, Henrik Nielsen1

1 Aalborg University Hospital, Aalborg, Denmark

**Background:** Normocellular community-acquired bacterial meningitis (CABM) is rare and likely underdiagnosed. The risk factors and outcome for this condition are poorly known. We aimed to examine the incidence, predisposing factors and outcome of patients with normocellular CABM.

**Materials/methods:** We accessed the nationwide and prospective database of the Danish Study Group of Infections of the Brain (DASGIB) to identify all adults with normocellular CABM treated at departments of infectious diseases in Denmark from year 2015 through 2018. Normocellular CABM was defined as a clinical presentation consistent with CABM combined with isolation of a pathogen in the cerebrospinal fluid (CSF) and a CSF leukocyte count ≤10 x 10^6/L. Outcome was categorised according to the Glasgow Outcome Scale (GOS) at discharge.

**Results:** Normocellular CSF was found in 12/696 (1.7%) CABM patients [Table 1]. The median age was 69.5 years [range 17-92] and 8/12 were male. Causative pathogens included *Streptococcus pneumoniae* in 10 patients [CSF cultures], *Staphylococcus aureus* in one [CSF culture], and *Neisseria meningitidis* in one [PCR of the CSF]. Eight patients had immuno-compromising conditions or were treated with potential immunomodulating drugs. In 4/11 patients, empirical treatment for CABM was interrupted due to low CSF cell count. Fatal outcome occurred in 3/12 patients and 8/12 had a Glasgow Outcome Scale (GOS) score of 1-4 at discharge.

**Conclusions:** Although infrequent, normocellular CABM should be considered in immuno-compromised patients and antimicrobial therapy for CABM continued until CSF microbiology examinations prove negative.

Abstract 3275

Comparison of pneumonia and bacteraemia Caused by Stenotrophomonas maltophilia: analysis of risk factors, clinical outcomes and impact on antibiotic resistance

Wen-Sen Lee*, Fu-Lun Chen

1Wanfang Hospital-Taipei Medical University, Division of Infectious Disease, Department of Internal Medicine, Taipei, Taiwan

Abstract third-party references: On behalf of Taipei Medical University

Background: Stenotrophomonas maltophilia (S. maltophilia) infections has increasingly emerged as a nosocomial pathogen in healthcare setting, especially in pneumonia and bacteraemia patients associated with high morbidity and mortality. The objective of this study was to compare clinical feature, risk factors, treatment outcome, and antibiotic resistance in patients with pneumonia and bacteraemia caused by S. maltophilia infections.

Materials/methods: We conducted a retrospective study in a tertiary teaching hospital in northern Taiwan. The medical records of the 319 patients of hospital-acquired S. maltophilia infections between July 1, 2016 and June 30, 2019 were reviewed, and sorted into groups of S. maltophilia bacteraemia (n = 56) and pneumonia (n = 263).

Results: The hospital-acquired S. maltophilia bacteraemia group was found to be significantly has higher 30-day mortality, more frequently central venous catheter use, respiratory failure with ventilator, Thrombocytopenia, solid organ malignancy, heart failure, and renal failure with hemodialysis than pneumonia group. The old aged patients were found to be more frequently in pneumonia group. The antibiotic susceptibility test of S. maltophilia revealed that the most susceptible agent of bacteraemic and pneumonic group was Tigecycline, followed by TMP/SMZ, levofloxacin and moxifloxacin respectively.

Conclusions: In this study, we found significantly higher mortality rate in the S. maltophilia bacteraemic group. The susceptibility test of tigecycline revealed better susceptible rate than TMP/SMZ (91.3% in pneumonic group and 85.7% in bacteraemic group respectively), and the levofloxacin had better susceptible rate in the pneumonic group than in the bacteraemic group. This result impact the empiric therapy of S. maltophilia infections in both pneumonic and bacteraemic patients, and the combination therapy of tigecycline + fluoroquinolones may be consider for severe sepsis or multidrug drug resistant of S. maltophilia infections.

Characterisation of prevalence and resistance of *Aeromonas* isolated from patients with acute diarrhoea in Zhejiang province from 2010 to 2017

Xiao Chen*1, Wang Ruonan*2, Zhu Qiaoyun*2

*1 the First Affiliated Hospital, College of Medicine, Zhejiang University, hangzhou, China; *2 the First Affiliated Hospital, College of Medicine, Zhejiang University, hangzhou, China

**Background:** To learn the distribution and antimicrobial susceptibility of *Aeromonas* isolated from Patients with Acute Diarrhea in Zhejiang Province, and to provide basis for prevention and treatment.

**Materials/methods:** The fecal specimens of patients with acute diarrhea in 5 hospitals of Zhejiang Province from January 2010 to December 2017 were collected. The routine microbiological test procedure combining with MALDI-TOF mass spectrometry was carried out to identify the common intestinal pathogenic bacteria. The *Aeromonas* isolated were subjected to antimicrobial susceptibility test by Kirby-Baur method.

**Results:** A total of 12509 patients with acute diarrhea were enrolled in the study. 636 (5.1%, 636/12509) specimens were positive for *Aeromonas* strains and this pathogen was the third most prevalent bacterial pathogen after *DEC* and *Vibrio parahaemolyticus*. The *Aeromonas* could be isolated among different age groups, and the highest among the elderly was over 60 years old. *Aeromonas* was isolated whole year round and the peak season was summer (June to August). There was no significant difference in the detection rate between male and female.

A total of 688 strains of *Aeromonas* were isolated from 636 patients, among which only one *Aeromonas* species was isolated from 587 specimens, two *Aeromonas* species were isolated from 46 specimens, and three *Aeromonas* species were isolated from 3 specimens. As the sole pathogen, 587 strains were mainly composed of *Aeromonas veronii* (194, 28.20%) and *Aeromonas caviae* (182, 26.45%), followed by *Aeromonas hydrophila* (97, 14.10%).

Nearly half of *Aeromonas* is relatively less sensitive to cefoxitin (63.37%), tetracycline (61.63%) and imipenem (60.47%), and >85% isolates were sensitivity to quinolones. The resistance of *Aeromonas* to most antibiotics was significantly different among the three strains of *A. hydrophila*, *A. caviae* and *A. veronii* (P<0.05). The resistance rate of cefoxitin is higher than that of *A. caviae* and *A. veronii*.

**Conclusions:** *Aeromonas* is one of common pathogenic bacteria causing diarrhea in summer and autumn in coastal areas. The resistance of *Aeromonas* to most antibiotics was significantly different among different species.

Abstract 3280

Malaria outbreak investigations reveal high seroprevalence of arbovirus infections among febrile cases in Baringo County, Kenya

Timothy Nzomo*1, Roba Abdi1

1National Public Health Laboratories Services, Nairobi City, Kenya

Background: Clinical symptoms of malaria remain virtually indistinguishable to those of arbovirus infections, including Dengue and Chikungunya viruses, leading to misdiagnoses in a significant number of individuals. Baringo County in Kenya recently experienced an upsurge of malaria cases. We aimed at providing differential diagnoses to support outbreak investigation, and hereby describe arbovirus co-infections among 63 febrile, clinically suspected cases in Baringo County, Kenya

Materials/methods: Sixty three matched samples of plasma, whole blood and Giemsa-stained blood smears were collected from febrile cases clinically suspected of malaria in the field and shipped to the national reference laboratory. Samples were tested using enzyme-linked immunosorbent assay (ELISA) for Dengue virus (DENV) and Chikungunya virus (CHIKV) IgM antibodies. Blood smear slides were examined by microscopy for malaria. Additionally, real-time PCR was performed for DENV, CHIKV and malaria.

Results: Out of the 63 matched blood smear that were received at the central lab for verification of field investigations, malaria was detected in 30 (47.6%) by microscopy. By PCR, malaria was detected in 17 (53.1%) of the 31 samples that passed the specimen quality assurance criteria for the test. All malaria parasites belonged to the *P. falciparum* species. Anti-DENV and anti-CHIKV IgM was detected in 28% and 53% respectively of the 63 samples tested, with 17% co-infected with both viruses. PCR results were negative for the two viruses. Malaria and arbovirus co-infection was found in 22.2% of the cases.

Conclusions: The results indicate co-circulation of malaria parasites with arboviruses and underscore the need for heightened surveillance for the viruses in the region. Further, there is need to increase clinician suspicion index for arbovirus infections in individuals presenting with acute febrile illness.

Abstract 3282

**Plasmid diversity among genetically related *Klebsiella pneumoniae* blaKPC-2 and blaKPC-3 isolates collected in the Dutch national surveillance**

Antoni P.A. Hendrickx1, Fabian Landman1, Angela De Haan1, Dyogo Borst1, Sandra Witteveen1, Marga Van Santen1, Han Van Der Heide1, Leo Schouls1

1National Institute for Public Health and the Environment, Center for Infectious Disease Control (CIb), Bilthoven, Netherlands

**Background:** Carbapenemase-producing *Klebsiella pneumoniae* emerged worldwide the past three decades as an important pathogen causing high morbidity and mortality in hospitalized patients. For genomic pathogen surveillance, it is important to track the spread of bacterial strains including the plasmids they contain. However, little is known concerning the plasmid repertoire among *K. pneumoniae* strains. Therefore, the aim was to recapitulate the size, contents and diversity of the plasmids of genetically related *K. pneumoniae* strains. Hence, the aim was to recapitulate the size, contents and diversity of the plasmids of genetically related *K. pneumoniae* strains harboring the beta-lactamase gene *blaKPC-2* or *blaKPC-3* to determine their dissemination in The Kingdom of the Netherlands.

**Materials/methods:** Illumina next-generation genome sequencing was combined with Nanopore long-read sequencing to reconstitute complete plasmids (plasmidome) of *K. pneumoniae* isolates. wgMLST, UPGMA clustering, PHASTER and automated resistome (ResFinder) and replicome (PlasmidFinder) analyses were performed to determine the genetic relatedness and diversity of the contents of plasmids among *K. pneumoniae* cluster isolates.

**Results:** wgMLST revealed five genetic clusters (termed KpnClusters) comprised of *K. pneumoniae* blaKPC-2 isolates and four clusters consisted of *blaKPC-3* isolates. Each cluster had a distinct resistome and plasmidome, while isolates within clusters were highly similar. Only KpnCluster-019 blaKPC-2 isolates were found both in the Netherlands and the Caribbean islands. *K. pneumoniae* blaKPC-3 isolates were found predominantly in the collection from the Netherlands. Eighteen plasmids were identified and UPGMA analysis revealed that the plasmids were unrelated. However, the large [150-250 kb] and medium [50-150 kb] sized plasmids contained one or two replicons from the incompatibility group IncFIB(K) and IncFII(K), IncHI2 and IncHI2a, or IncFIB[pQil] and IncFII(K). These plasmids carried multiple different antibiotic resistance genes, but shared a variety of transposons, insertion sequence elements, conjugal transfer systems, cation transport systems, toxin/antitoxin systems, and RCS47 P1-prophage-related sequence elements. The small plasmids (<50 kb) with ColRNAI or IncY/IncX3/IncP6 type of replicons carried genes implicated in virulence, including a Type IV secretion system, colicin, and a biofilm dispersion protein.

**Conclusions:** A *K. pneumoniae* blaKPC-2 strain from KpnCluster-019 with unique resistome and plasmidome was transmitted between The Netherlands and the Caribbean. Implementing long-read sequencing in the Dutch surveillance provides important new insights in the success of transmission of *K. pneumoniae* strains and plasmids.

**Abstract 3290**

**In vitro activity of cefiderocol against Gram-negative pathogens from different infection types**

Anne Santerre Henriksen¹, Christopher Longshaw¹, Yoshinori Yamano²

¹Shionogi BV, London, United Kingdom, ²Shionogi & Co Ltd, Osaka, Japan

**Background:** Cefiderocol (CFDC) is a novel siderophore cephalosporin that has demonstrated potent activity against Gram-negative pathogens including carbapenem non-susceptible (NS) strains. We conducted a series of surveillance studies (SIDERO-WT) to evaluate *in vitro* activity of CFDC against clinical isolates collected in 2014-2018 mainly from Europe and North America. In this study, we compared *in vitro* activity of CFDC and comparator agents against Gram-negative pathogens from different infection types.

**Materials/methods:** A total of 38288 Gram-negative pathogens were included in the study (including 17234 from North America and 20911 from Europe). Minimum inhibition concentrations (MICs) were determined for CFDC, cefepime (FEP), cef-tazidime-avibactam (CZA), ceftolozane-tazobactam (C/T), ciprofloxacin (CIP), colistin (CST) and meropenem (MEM) by broth microdilution according to Clinical and Laboratory Standards Institute (CLSI) guidelines. CFDC was tested in iron-depleted cation-adjusted Mueller–Hinton broth according to CLSI guidelines. The CFDC susceptibility rate was estimated based on CLSI provisional susceptible breakpoint (4 mg/L) while for the comparators EUCAST breakpoints were applied.

**Results:** Pathogens isolated from respiratory samples represented 34% of the strains while pathogens from cUTI samples represented 22% and from bloodstream infections 14.9%. The distribution of pathogens varied with the site of infection with *Pseudomonas aeruginosa* being mostly present in respiratory samples and *Escherichia coli* in the samples from urinary tract and from blood stream infections. Meropenem non-susceptible isolates [MIC>2 mg/L] were mostly present in respiratory samples [26.3%], followed by bloodstream infections [12.8%] and samples from urinary tract [7.7%]. Susceptibility to cefiderocol varied between 98.7% and 99.6% depending on the source of infection.

**Conclusions:** CFDC maintained potent antibacterial activity against Gram-negative pathogens regardless of the site of infection.

Abstract 3291

**Mother-to-child transmission of curable sexually-transmitted infections in HIV-infected women in South Africa**

Remco Peters*, Ute Feucht, Dawie Olivier, Lindsey De Vos, Phuti Ngwepe, Jeffrey Klausner, Andrew Medina-Marino

1Foundation for Professional Development, Pretoria, South Africa, 2University of Pretoria, Pretoria, South Africa, 3University of California, Los Angeles, Los Angeles, United States

**Background:** South Africa has a very large burden of sexually transmitted infections (STIs). STIs can be transmitted from mother to child during pregnancy or delivery. Newborn infections have been associated with morbidity and mortality. We report on the frequency and characteristics of mother-to-child transmission of three curable STIs: *Chlamydia trachomatis* (CT), *Neisseria gonorrhoeae* (NG) and *Trichomonas vaginalis* (TV).

**Materials/methods:** Nasopharyngeal swabs were obtained from newborns of HIV-infected mothers diagnosed with CT, NG or TV at their postnatal visit at three primary healthcare facilities in Tshwane District, South Africa. Swabs were tested using the Xpert® CT/NG and TV assays. Targeted treatment was provided to newborns with a positive Xpert® result and test-of-cure was done after three weeks.

**Results:** Eighty-five mother-newborn pairs were enrolled within 60 days of delivery (Median= 6 days; IQR= 4 days). The frequency of mother-to-child transmission was highest for CT followed by NG and TV (Table 1); these frequencies were 43%, 29% and 24% if analysis was limited to visits within two weeks from delivery. Positive Xpert results were recorded in asymptomatic newborns for CT at up to 45 days post-delivery and for TV up to 44 days.

**Table 1. Frequency of Mother-to-child STI transmission**

<table>
<thead>
<tr>
<th></th>
<th>Number of mothers with positive test</th>
<th>Proportion of neonates with positive test</th>
<th>Transmission rate</th>
</tr>
</thead>

<tr>
<td><em>Neisseria gonorrhoeae</em></td>
<td>7</td>
<td>2/7</td>
<td>29%</td>
</tr>
<tr>
<td><em>Trichomonas vaginalis</em></td>
<td>28</td>
<td>8/28</td>
<td>29%</td>
</tr>
</tbody>
</table>

Lower maternal CD4 count (p=0.020) and emergency caesarean section (p=0.095 vs. normal vaginal delivery and p=0.043 vs. elective caesarean) were associated with CT transmission to the newborn, but not with TV transmission. Maternal age, gestational age at delivery, (un)suppressed viral load and breastfeeding were not associated with a positive Xpert® result. Newborn test-of-cure showed that STIs had been cleared following treatment.

**Conclusions:** Mother-to-child transmission of curable STIs is common amongst STI-HIV co-infected women in South Africa. These STIs may be present in the airways of exposed newborns for considerable time after delivery, result in infection or colonization and may increase their risk for other infectious or chronic health conditions. Screening for STIs during pregnancy is warranted in high prevalence settings to prevent mother-to-child transmission.

Six versus four weeks of intravenous antibiotic treatment for Staphylococcus aureus endocarditis

Sabrine Douiyeb*1, Anda Samson2, Nienke Roescher3, Thomas Van Der Vaart4, Jan Van Der Meer4, Wazir Baig5, Jianhua Wu5, Anna Collell Prats1, David Harvey6, Richard Gillott1, Kim Sigaloff1, Jonathan Sandoe1

1Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands, 2Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom, 3St. Antonius Hospital, Nieuwegein, Netherlands, 4Academic Medical Centre, Amsterdam, Netherlands, 5Leeds General Infirmary, Leeds, United Kingdom, 6Wirral University Teaching Hospital NHS Foundation Trust (WUTH), Birkenhead, United Kingdom, 7University Hospitals Plymouth NHS Trust, Plymouth, United Kingdom

Background: There is limited evidence to guide the duration of treatment of left sided Staphylococcus aureus native valve (SA-NVE) which is reflected in different guideline recommendations; European Society guidelines (ESC) advise 4-6 weeks, while the British guidelines recommend 4 weeks. We compared outcome and characteristics of patients treated with 4 vs 6 weeks antibiotics.

Materials/methods: A multi-center retrospective study in 7 hospitals in England (Leeds, Wirral, Hull and Plymouth) and the Netherlands (Amsterdam, Nieuwegein). Eligible were patients admitted between 2011 and 2018 with definite methicillin-sensitive SA-NVE (modified Duke criteria). Exclusion criteria were: <18 years, prosthetic valve or device, right sided endocarditis, MRSA or complications requiring extension of antimicrobial treatment, such as vertebral osteomyelitis, abscess (spleenic, cerebral, intracardiac) or death during therapy. Demographics, treatment and outcome variables were collected. Clinical cure was defined as the absence of relapse or death within 6 months following completion of antibiotic therapy.

Results: Sixty-two patients met the inclusion criteria; 17 were treated for 4 weeks; 28 days (IQR 26 to 30) and 43 patients for 6 weeks; 43 days (IQR 42 to 48). Selected complications (septic arthritis, embolic event, lung empyema and endophthalmitis) were more prevalent in the 6 week group (24% vs 60%). Fifty-one percent of the 6 week group required surgery versus 27% in the 4 week group. Sixteen patients (94%) achieved clinical cure in the 4 week group versus 32 (71%) patients in the 6 week group.

Conclusions: 4 weeks treatment was effective for some patients with SA-NVE. Patients treated with 6 weeks had more complications, suggesting our patients groups were not equivalent. A prospective randomized controlled trial may be justified to evaluate the optimal treatment duration for SA-NVE. If the duration of treatment can be shortened safely, patients well-being, adverse drug events and healthcare costs could be positively impacted.

Abstract 3294

Safe and high-throughput screening of natural compounds using pseudo-virus expressing SFTSV glycoprotein

Hye Hee Cha*1, Ji Yeun Kim1, So Jung Park2, In Ki Kim2, Sung-Han Kim1

1Asan Medical Center, Ulsan University College of Medicine, Seoul, South Korea, 2Asan Medical Center, Asan Institute for Life Science, Seoul, South Korea

Background: Severe fever thrombocytopenia syndrome (SFTS) is an emerging tick borne infectious disease, which is prevalent in Korea, China, and Japan. The mortality rate of SFTS has been high as ever, that was 20.0% (173/866) in Korea through 2013 to 2018. However, any antiviral therapies for the SFTS were not developed yet.

Materials/methods: We generated pseudotype vesicular stomatitis viruses (VSV) expressing SFTS virus (SFTSV) glycoprotein (SFTS-PV) and developed a safe high-throughput inhibition assay using the SFTS-PV. We screened 502 natural compounds as entry inhibitors of SFTS-PV. The dose dependence of inhibition by hit compounds against SFTS-PV and VSV-PV was measured, and the dose-dependent cytotoxicity of hit compounds was also evaluated. The entry blocking effects of hit compounds were determined by comparing the infectivity between the compounds treatment before and after SFTS-PV attachment.

Results: Chelerythrine, Dihydrotanshinone, and β-Zearalanol treatment at low concentrations (1 μg/ml) resulted in >50% inhibition of SFTS-PV infectivity without significant cytotoxicity (Fig. 1). The compounds showed reduced inhibition activity after SFTS-PV had already been entered into cells, signifying their role as SFTS-PV entry inhibitors.

Conclusions: The results of this study suggest that a high-throughput assay using SFTS-PV is useful for massive screening antiviral compounds against SFTSV. Further studies using authentic SFTSV and animal challenge study are warranted to evaluate antiviral effects of these three hit compounds, Chelerythrine, Dihydrotanshinone, and β-Zearalanol.
Relative infectivities of the three hit compounds [A] Chelerythrine, [B] Dihydrotanshinone, [C] β-Zearalanol were dose-dependently evaluated against SFTS-PV (red bar) and VSV-PV (blue bar) from 0.25 to 4 μg/ml. At the same dose, cell viabilities (green bar) of hit compounds were also determined. The experiment was repeated three times and the data are presented as mean percentages and standard deviations.

A highly sensitive, non-amplification detection method of nucleic acids in bacilli and viruses

Etsuro Ito*, Naoki Kawada1, Yuta Kyose1, Masatoshi Okamatsu2, Yoshihiro Sakoda1, Teruki Yoshimura1, Rikiya Takeuchi4, Yoshiya Ohta4, Kazunari Nakaishi4, Satoshi Watabe4

1Waseda University, Tokyo, Japan, 2Hokkaido University, Sapporo, Japan, 3Health Sciences University of Hokkaido, Ishikari-Tobetsu, Japan, 4TAUNS Laboratories, Inc., Izunokuni, Japan

Background: Even though the definite diagnoses for infectious diseases have been long believed to be performed with PCR, there are many issues in PCR. For example, they are non-specific or false positive amplifications; volume limit for a target sample; deactivation of enzymes used; complicated techniques, and so forth. To overcome these, we propose a de novo detection method for nucleic acids without any amplification, and show the results for DNA of MPB 64, a specific protein in Mycobacterium tuberculosis [1B] and those for RNA of an avian influenza A virus HA gene.

Materials/methods: We combined nucleic acid hybridization and thio-NAD cycling. The nucleic acid probes, linked with ALP, were hybridized to the target sequences. A cycling reaction was conducted by a dehydrogenase [3α-hydroxysteroid dehydrogenase] with co-factors [NADH and thio-NAD] and substrates [androsterone phosphate]. We then measured accumulated thio-NADH at the absorbance of 405 nm. That is, our new method does not amplify the target nucleic acids.

Results: We obtained that the limit of detection (LOD) was $4.2 \times 10^3$ copies/μL, and that the limit of quantification (LOQ) was $1.4 \times 10^4$ copies/μL for the single strand of MPB64. Using the double strand, the LOD was $1.4 \times 10^4$ copies/μL, and the LOQ was $4.7 \times 10^4$ copies/μL. Furthermore, the LOD and LOQ of the synthesized RNA for an avian influenza A virus HA gene were $2.3 \times 10^4$ copies/μL and $7.7 \times 10^4$ copies/μL, respectively.

Conclusions: Because the protocol of washout is included in our method and the measurement volume is larger than PCR, the possibility of false positive or negative results is decreased. The deactivation of enzymes can be avoided because the thermal cycle is not performed. Our method does not need DNA amplification, and thus designing probe sequences is not restricted by amplification products. Therefore, we deal with high mutation rates of RNA viruses. In addition, we can detect samples by only using a small microplate reader, so that we do not need to use the expensive device for PCR. Therefore, our new method overcomes every difficulty of PCR.

Abstract 3306

Antibiotic treatment for paediatric outpatients with community-acquired pneumonia: findings from 10 years of prescribing habits in Italy

Paola Costenaro*, Anna Cantarutti1, Elisa Barbieri1, Antonio Scamarcia2, Andrea Oletto3, Paolo Sacerdoti4, Rebecca Lundin4, Luigi Cantarutti2, Carlo Giaquinto1,3,4, Daniele Donà1

1University of Padua, Department for Woman and Child Health, Padua, Italy, 2University of Milano-Bicocca, Department of Statistics and Quantitative Methods, Unit of Biostatistics Epidemiology and Public Health, Milan, Italy, 3Pedianet Project, Padua, Italy, 4Penta Foundation, Padua, Italy

Abstract third-party references: University of Padua

Background: Despite national and international efforts to promote appropriate antibiotic prescribing, Italian paediatric antimicrobial prescription rates are among the highest in Europe, with an overuse of broad-spectrum antibiotics. Community-acquired pneumonia (CAP) is one of the most common infections in pediatrics, and a main cause of antibiotic prescriptions. Aim of this study is to describe the first-line treatment approach for CAP at primary care level in Italian children.

Materials/methods: Retrospective observational study conducted among children with CAP enrolled in Pedianet, a network of community-based paediatricians from 12 Italian regions (http://www.pedianet.it). Children (3 months-14 years of age) with at least one reported CAP from 01/01/2009 to 31/12/2018 were included, if treated with antibiotics (ABT). CAP was defined according to ICD-9-CM (codes 485, 486, 482.9, 481), a new episode was recorded if occurring >=30 days after previous CAP. We defined “narrow-spectrum” (NS) ABT if treatment was amoxicillin and “broad-spectrum” (BS) if amoxicillin/clavulanic acid, cephalosporins or any combination ABT. Chi-squared and Fisher’s test were used for categorical or continuous variables. Crude and adjusted logistic regression for the ODDS of receiving a NS-ABT were conducted (all episodes of CAP and per patient). A p-value <0.05 was considered statistically significant.

Results: Among 9691 CAP, 7260 episodes from 6409 children followed by 147 pediatricians were included. The 16.7% of CAP (95% C.I.15.9%-17.6%) received a narrow-spectrum ABT while 53.3% (95% C.I.52%-54.4%) received a broad-spectrum ABT and 30% (95% C.I. 28.9%-31.1%) a macrolide. Within 10 years, an increasing trend of NS-ABT prescription was observed [p<0.001, Chi-square test for linear trend]. Factors independently associated with reduced ODDS of receiving a NS-ABT compared to BS-ABT including macrolides were being older than 5 years (OR 0.45, 95% C.I.0.39 - 0.52), living in Center/South of Italy (OR 0.13, 95% C.I.0.10 - 0.16) and being exposed to ABT 3 months before (OR 0.61, 95% C.I. 0.53 - 0.70). These findings were confirmed comparing NS-ABT versus BS-ABT excluding macrolides (n=5079) and when adjusted analysis was limited to index CAP.

Conclusions: Our findings provide an alarming overview of the Italian prescribing habits, reporting a very limited use of NS-ABT for children with CAP.

Abstract 3311

Utility of central venous catheter cultures in predicting blood culture susceptibilities in catheter-related bloodstream infections due to *Staphylococcus* spp.

Hidetoshi Nomoto*1,2, Masahiro Ishikane1,2, Kazuhisa Mezaki4, Norio Ohmagari1,2,3

1Tohoku University, Collaborative Chairs Emerging and Reemerging Infectious Diseases, Graduate School of Medicine, Sendai, Japan, 2National Centre for Global Health and Medicine (NCGM), Disease Control and Prevention Center, Tokyo, Japan, 3National Centre for Global Health and Medicine (NCGM), AMR Clinical Reference Center, Disease Control and Prevention Center, Tokyo, Japan, 4National Centre for Global Health and Medicine (NCGM), Tokyo, Microbiology Laboratory, Tokyo, Japan

**Background:** Central venous catheter (CVC) and blood cultures are frequently collected from patients undergoing evaluation for catheter-related bloodstream infection (CRBSI). However, whether CVC culture susceptibility results predict blood culture results in patients diagnosed with CRBSI remains unknown.

**Materials/methods:** We conducted this retrospective observational study of all CRBSI cases at the National Center for Global Health and Medicine, Japan between April 2012 and September 2019. CRBSI was defined as positive if microbiology culture results from both CVC and blood were the same. CVC culture susceptibility results (consistent completely and not consistent) were compared with corresponding blood culture results for antimicrobials against *Staphylococcus* spp., Enterobacteriaceae, and non-fermenting bacteria (NFB).

**Results:** Of 275 patients with CRBSI, 139 (50.5%), 77 (28.0%), 23 (8.4%), 16 (5.8%), and 20 (7.3%) patients were infected with *Staphylococcus* spp., *Candida* spp., *Enterobacteriaceae*, NFB, and other organisms, respectively. The proportions of completely consistent antimicrobial susceptibility between CVC and blood among *Staphylococcus* spp., *Enterobacteriaceae*, and NFB were 92.1%, 60.9%, and 56.3%, respectively. Antimicrobial susceptibilities of *Staphylococcus* spp. were more statistically consistent than those of *Enterobacteriaceae* (Odds Ratio [OR] = 7.5, 95% Confidence Interval [CI] 2.6-21.2, p<0.001) or NFB (OR=9.1, 95% CI 2.8-30.0, p=0.001) (Table 1).

**Conclusions:** Early targeted therapy using CVC culture results may lead antimicrobial stewardship among CRBSI due to *Staphylococcus* spp. However, the results of both CVC and blood cultures are needed for de-escalation in CRBSI due to *Enterobacteriaceae* and NFB.

Abstract 3312

**Exploration of the added value of rifampicin to antibiotic regimens for the management of *Cutibacterium* periprosthetic joint infection**

1University Hospital of Zürich, Zürich, Switzerland, 2Cantonal Hospital St. Gallen, St. Gallen, Switzerland, 3Hospital Universitaria Marques de Valdecilla, Cantabria, Spain, 4Fundacion Jimenez Diaz, Madrid, Spain, 5Orthopedic University Hospital Balgrist, Zürich, Switzerland, 6Universitat Autònoma de Barcelona, Barcelona, Spain, 7Infectious Diseases Unit, Hospital de la Santa Creu i Sant Pau, Institut d’Investigació Biomèdica Sant Pau, Barcelona, Spain, 8Centre Hospitalier Universitaire de Nantes, Nantes, France, 9Humanitas University of Medicine, Rozzano, Italy, 10Charité Universitätsmedizin Berlin, Berlin, Germany, 11Evangelisches Waldkrankenhaus Spandau, Berlin, Germany, 12University Medical Center Groningen, Groningen, Netherlands, 13Hospital Univ. 12 de Octubre, Madrid, Spain, 14Mayo Clinic, Rochester, United States, 15Valdoltra Orthopedic Hospital, Ankaran, Slovenia, 16Cochin Hospital Paris, Paris, France, 17Universisty Hospital Basel, Basel, Switzerland, 18Schulthess Clinic Zurich, Zurich, Switzerland, 19University Hospital Bern, Bern, Switzerland

**Background:** Despite considerable advances in prevention strategies, periprosthetic joint infection (PJI) remains a feared complication of joint replacement. *Cutibacterium* species are common pathogens in PJI. These infections are treated with β-lactams or clindamycin as monotherapy, or in combination with rifampicin. Clinical evidence supporting the value of adding rifampicin for treatment of *Cutibacterium* PJI is lacking.

**Materials/methods:** In this multicenter retrospective study, including centers in Europe and the USA, we evaluated patients with *Cutibacterium* PJI, defined by growth from at least two cultures from two different diagnostic samples. A minimum of 12 months of follow-up alongside availability of information about clinical presentation, antibiotic and surgical treatment, and infection outcome was required. The primary endpoint was infection relapse, defined as persisting signs or symptoms of infection or microbiologically proven infection with the same *Cutibacterium* species. We used Fisher exact tests to analyze whether rifampicin had an added value to an antibiotic regimen for cure of *Cutibacterium* PJI, for different surgical strategies.

**Results:** In this ongoing study, 137 patients (68.6% male, median age 67 years) were analyzed to date, including 68 (49.6%) hip, 56 (40.9%) shoulder, 12 (8.8%) knee, and 1 (0.7%) elbow prostheses. Most infections presented more than one month after the last surgical intervention (median 1.4 years, range 0.3-25.5 years). The most frequent surgical intervention was two-stage exchange (75, 54.7%), followed by one-stage exchange (29, 21.2%), and debridement and implant retention (DAIR, 29, 21.2%). Rifampicin was included in the antibiotic regimen in 49 (35.8%) cases. Infection relapse occurred in 23 (16.8%), and new infection with another microorganism in 11 (8.0%) cases. The use of rifampicin had no obvious association with relapse for all cases (p = 1), or when the different surgical strategies were separately analyzed (Figure).

**Conclusions:** In this observational, retrospective study, there was no apparent benefit of the use of rifampicin combination therapy in *Cutibacterium* PJI, independent of surgical strategy.

**Presenter email address:** yvonne.achermann@usz.ch
Leishmaniasis in Turkey: assessment of the efficacy of antimicrobial peptides against *Leishmania tropica* in vitro

Nihan Unubol¹, Ibrahim Cavus², Özdür Kurt*¹, Ahmet Özbilgin², Tanil Kocagoz¹

¹Acıbadem University School of Medicine, Department of Medical Microbiology, Istanbul, Turkey; ²Manisa Celal Bayar University, School of Medicine Department of Parasitology, Manisa, Turkey

**Background:** Emerging worldwide resistance of *Leishmania* isolates to antimonial compounds indicates the urgent need for novel therapeutic agents in leishmaniasis treatment. Various natural or synthetic compounds are assessed in laboratories for their efficacy against *Leishmania* isolates to develop a non-toxic, relatively inexpensive and highly effective new drugs. Antimicrobial peptides (AMPs) are involved in the development of natural immunity in humans and are promising candidates due to their large efficacy spectrum, fast-activity and low resistance risk. Among them, cathelicidins are positively charged peptides that interact with negatively charged membranes of bacteria, fungi and protozoa and kill directly or through formation of pores on the membranes. The aim of this study is to design cathelicidin-like helical peptides (CLHP) by mimicking phylogenetically protected general sequences and structures of cathelicidins and compare their in vitro anti-parasitic activities with an antimonial compound, meglumine antimoniate (MA) on *Leishmania tropica* isolate of a native cutaneous leishmaniasis (CL) patient.

**Materials/methods:** Five study (TN1 -5) and two control groups (MA and Drug-Free Control [DFC]) were developed initially. MA-susceptible *L. tropica* isolate kept at liquid nitrogen were thawed and inoculated first in NNN, and then in RPMI-1640 medium with 10% FBS (fetal bovine serum), 1% Penicillin-Streptomycin and 0.2% Gentamicin. Five CLHPs (TN1 -5), initially designed in our lab and received lyophilized from the producing company, were diluted in dimethyl sulphoxide before use. One hundred microliters of each CLHP and MA were added in the first wells of the test plate and serial dilutions were made to obtain doses within 512 and 4 ug/ml. One hundred microliters of culture having 1x10⁸*L. tropica* promastigotes was added in all wells, except DFCs. Counts and viability of parasites were tested with XTT method after 24 and 48 hours.

**Results:** Our findings indicated that TN-3 maintained its efficacy against *L. tropica* at lower dose (32 ug/ml) until the end of 48th hours. Only TN-5 showed no anti-*Leishmania* activity, even at its highest dose tested (Table 1).

**Conclusions:** This preliminary study showed that, owing to its long-lasting anti-parasitic activity at a lower dose, TN-3 deserves further assessments against different *Leishmania* species, along with in vivo toxicity tests.

Abstract 3318

Predicting antistaphylococcal effects of daptomycin and gentamicin combinations in an in vitro dynamic model using MICs determined at pharmacokinetically-derived concentration ratios

Maria Golikova1, Elena Strukova1, Yury Portnoy1, Stephen Zinner*2, Alexander A. Firsov1

1Gause Institute of New Antibiotics, Moscow, Russian Federation, 2Mount Auburn Hospital, Cambridge, United States

Background: The checkerboard technique is widely used to determine the activity of antibiotic combinations. However, ratios of antibiotic concentrations utilized in this method do not always relate to concentration ratios that mimic antibiotic pharmacokinetics in humans. To explore whether susceptibility testing with daptomycin (DAP) + gentamicin (GEN) at concentration ratios that correspond to the ratios of 24-hour area under the concentration – time curve (AUC24) is a better predictor of the antibiotic combinations, *Staphylococcus aureus* was exposed to daptomycin and gentamicin in an in vitro dynamic model that simulates single and combined treatments with the therapeutic AUC of GEN (AUCGEN) and sub-therapeutic AUCs of DAP (AUCDAP).

Materials/methods: Susceptibility of *S. aureus* ATCC 25923 to DAP (MICDAP) and GEN (MICGEN) was tested for single and combined agents at DAP-to-GEN concentration ratios that correspond to their AUC ratios in five-day treatment simulations: 1:2 [AUCDAP 30 μg×h/ml to AUCGEN 65 μg×h/ml], 1.5:1 [AUCDAP 100 μg×h/ml to AUCGEN 65 μg×h/ml]. Based on time-kill data, the area under time-kill curve (AUBC) was determined from the beginning of treatment to 120 h.

Results: The anti-staphylococcal activity of DAP and GEN in combination was greater than with single agents. The results of susceptibility testing were interpreted as additive according to FICs (0.64 (1:2 ratio) and 1.18 (1.5:1 ratio)). In combined DAP plus GEN multiple-dose simulations, *S. aureus* killing was more pronounced at each time point compared to single treatments, possibly as a result of lowering the MIC of both antimicrobial agents and thereby increasing the actual AUC/MIC ratios. AUBCs for both combined treatments were similar and 1.3-fold lower than in mono-treatment with GEN (as a more active single agent) indicating that the effect of DAP plus GEN combination can be considered as additive.

Conclusions: These findings suggest that the combination of DAP with GEN against *S. aureus* is additive given the results of both susceptibility testing and pharmacodynamic experiments; antibacterial effects of DAP plus GEN combinations can be predicted by AUC/MICs of antibiotics using their MICs determined at pharmacokinetically-derived DAP-to-GEN concentration ratios.

Abstract 3319

**Antimicrobial resistance in urinary tract infection cases submitted to a computerised decision support system for antibiotic prescribing in primary care in France**

Tristan Delory*1,2, Pauline Jeanmougin1,3, Sylvie Lariven1,4, Florence Tubach1,5, Pierre-Yves Boëlle1,2, Elisabeth Bouvet2,4, Xavier Lescure5,6, Josselin Le Bel2,8

1Sorbonne Université, UMRS11 36 - Equipe 1, Paris, France, 2Antibioclic steering committee, Paris, France, 3Nantes University, Family medicine department, Nantes, France, 4Bichat Hospital, AP-HP, Paris, France, 5Centre de Pharmaco-Epidémiologie, AP-HP, Paris, France, 6Sorbonne Université, UMRS1136 - Equipe 6, Paris, France, 7Saint-Antoine Hospital, AP-HP, Paris, France, 8University of Paris, Family medicine department, Paris, France

**Background:** Global surveillance of antimicrobial resistance (AMR), including the European Antimicrobial Resistance Surveillance Network (EARS-NET), report aggregated data, making impossible to characterize AMR by infection type and patient characteristics. Furthermore, the reports are available after ≥1-year due to the collection process, delaying measurement of benchmarks for Health Policy impact. General practitioners (GPs) using online CDSS for antimicrobial prescribing in UTI could provide more detailed and timely data on AMR in primary care.

**Materials/methods:** We used data collected daily between November-1, 2017 and August-19, 2019 in the web-based CDSS "Antibiotic+" to describe resistance rates in UTI seen in Paris area. We compared, using Chi-squared test, AMR frequencies to the data last transmitted to EARS-NET (year-2017) for France.

**Results:** Over study period, 1741 GPs registered to the CDSS. Median age was 50-years [IQR, 38-60] and 1131 [65%] were female. Overall, they used the CDSS for prescription in UTI in 27,813 cases, including 25,613 [92%] adults. Most cases concerned treatment of cystitis [13,619 [49%]], masculine-UTI [7,382 [27%]] and pyelonephritis [6,746 [24%]]. Few concerned asymptomatic bacteriuria in pregnant women [66 (<1%)]. In the previous 6 months, fluoroquinolones [FQ] had been used in 19% [n=5,318] of the cases, and 4% [n=1,143] had been hospitalized. In approximately 4 cases out of 10 [n=10,757], urine cultures were available at the time of consultation. Reported microorganisms included *E.coli* [7,078 [66%]], *K.pneumoniae* (1,039 [10%]), *P.mirabilis* (626 [6%]), and others [2,014 [19%]]. Resistance to C3G and FQ were respectively 6% and 16% in *E.coli*, 8% and 11% in *K.pneumoniae*, 3% and 13% in *P.mirabilis*. ESBL-production rates [ff2%] were similar in all species. FQ-resistance rate was higher in upper-UTI than in lower-UTI [958/5,482 (17%) vs. 680/5,215 (13%), p-value<0.001]. It was similar for C3G-resistance [479/5,482(9%) vs. 473/5,212(9%), and ESBL-production [86/5,275 (2%) vs. 93/5,482 (2%)]. Overall, FQ-resistance rate in *E.coli* was higher in patients seen by "Antibioclic" users than reported to EARS-NET for France [1,167/7,078 (16%) vs. 3,451/42,630 (8%), p-value<0.001]; but did not statistically differ from *E.coli* invasive strains issued from blood-cultures in EARS-NET [2,003/13,352,15%, p=0.087].

**Conclusions:** The use of CDSS data allows monitoring AMR in primary care by infection type in real-time. AMR rates may be more informative than in EARS-NET since only clinically relevant urine cultures were considered.

Abstract 3322

Implementation of EUCAST rapid antimicrobial susceptibility testing combined with routine infectious disease bedside consultation

Thomas Valentin*, Tobias Loizenbaur¹, Elisabeth König¹, Juergen Prattes¹, Stephanie Wunsch¹, Christoph Zurl¹, Robert Krause¹, Ines Zollner-Schwetz¹

¹Medical University of Graz, Section of Infectious Diseases and Tropical Medicine, Graz, Austria

Background: Recently, EUCAST methodology for rapid antimicrobial susceptibility testing (RAST) directly from positive blood cultures was released. The aim of our prospective single-center clinical study was to assess the proportion of readable and discrepant results compared to routine antimicrobial susceptibility testing, and the clinical consequences drawn by infectious disease (ID) physicians from RAST results during same-day bedside consultation.

Materials/methods: All positive blood cultures suitable for RAST from January to November 2019 were included and RAST results at 4 and 6 hours compared to standard disk diffusion. The real-life impact of RAST on clinical decisions was assessed during same-day infectious disease bedside consultation based on 6-hour-RAST-results.

Results: RAST was performed in 131 bacterial isolates. The proportion of readable results was higher after 6 hours of incubation than after 4 hours (751/815 versus 569/751, p<0.0001). Major discrepancies (“S to R” or “R to S”) were observed less often after 6 hours than after 4 hours (7/751 vs 15/569, p=0.029). ID consultation was performed in 113 patients after RAST results. Following RAST results, antimicrobial treatment was changed in 68/113 patients, empiric treatment left unchanged because of the RAST result in 13/113 patients, and RAST results had no effect on antimicrobial treatment in 23/113 patients. Change of antimicrobial treatment was most often observed in patients with bacteraemia due to S.aureus (38/42) and E.faecium (6/7), less commonly in E.coli (11/41), K.pneumoniae (3/9), P.aeruginosa (3/8) and E.faecalis (1/2) and never in S.pneumoniae (0/4).

Additional measures such as contact isolation, additional resistance testing or radiologic tests were ordered in 49/113 (43.4%) of cases (S.aureus (35/42), E.faecium (3/7), E.coli (8/41), and K.pneumoniae (1/9), but not in E.faecalis or S.pneumoniae). There was only one therapeutically misleading RAST result (cefoxitin “R” after 4 hours and “ATU” after 6 hours in S.aureus leading to daptomycin treatment for one day).

Conclusions: RAST results after 4 hours were significantly less often readable than at 6 hours and more often discrepant and should thus be interpreted with caution. Misleading results were rare. RAST results led to a clinical consequence in 71% of same-day infectious disease bedside consultations.

Alvaro Cunqueiro, Vigo (Pontevedra), Spain, 5H. Universitario Donostia, San Sebastián, Spain, 6H. Galdakao-Usansolo, Galdácano (Bizkaia), Spain, 7H. Clínica de Barcelona, Barcelona, Spain, 8Pfizer, Madrid, Spain

Background: Age is a clear risk factor for Community Acquired Pneumonia (CAP) and for pneumococcal disease. Hospitalisation due to pneumococcal-CAP is associated with cardiac complications, worsening of quality of life and decrease in life expectancy. Pneumococcal vaccination of adults aged 60/65 is recommended. PCV13 has demonstrated efficacy and effectiveness against vaccine type CAP in the elderly. The burden of disease due to PCV13 serotypes in the context of childhood immunization is a key factor for the evaluation of the value of PCV13 for the elderly. This study aimed to determine the evolution of PCV13 serotypes causing CAP and pneumococcal-CAP in elderly adults in Spain from 2011 to 2016.

Materials/methods: A prospective, observational, hospital-based study of chest X-ray confirmed CAP in immunocompetent adults (≥18years) performed in 4 Spanish hospitals from November 2011 to November 2016. Microbiological confirmation was obtained by the novel UAD (Pfizer’ PCV13 serotype specific urinary antigen detection) test, BinaxNow® and conventional cultures. Serotyping of pneumococcal isolates was accomplished in a central laboratory by multiplex-PCR and confirmed by the Quellung reaction.

Results: For this analysis we included 1,323 adults aged ≥65 hospitalised with confirmed CAP during the 5-year period. Mean age was 78. S. pneumoniae was confirmed by any microbiological test in 363 (27.4%) of the cases. At least 1 underlying condition was present in 94.9% and 93.4% of the adults with CAP and pneumococcal-CAP cases. 91.7% of CAP cases had a PSI ≥III. The most frequent conditions in pneumococcal-CAP cases were, COPD (94,25.9%), diabetes (92,25.3%) and previous pneumonia (73,20.1%). Nearly 66% (239) had received flu vaccine in the previous year, and 13.2% (48) had received a pneumococcal vaccine. Fatality rate at 30 days was 5.2% for pneumococcal cases. Table shows distribution of PCV13 serotypes causing CAP and both invasive1 and non-invasive2 pneumococcal-CAP by study period. By region, in 2015-2016, PCV13-type CAP was 19.2% in Catalonia, 11.3% in Vizcaya, 9.1% in Valencia, and 7.7% in Galicia.

Conclusions: In Spain a significant burden of PCV13-type serotypes continued to cause CAP in older adults in a context of PCV13 immunization of children and PPV23 immunization of older adults.

IDIBELL-UB, L’Hospitalet de Llobregat, Spain, 2Research Network for Respiratory Diseases (CIBERES), ISCIII, Madrid, Spain, 3Infectious Diseases Department, Hospital Universitari Bellvitge. IDIBELL-UB, L’Hospitalet de Llobregat, Spain, 4Pneumococcal Reference Laboratory, ISCIII, Madrid, Spain, 5Pathology and Experimental Therapeutics Dept. School of Medicine, University of Barcelona, Barcelona, Spain, 6Spanish Network for Research in Infectious Diseases (REIPI), ISCIII, Madrid, Spain

Background: The introduction of pneumococcal conjugate vaccines (PCVs) has led not only to a reduction in the incidence of invasive pneumococcal disease (IPD) but also to a change in its epidemiology. In Spain, PCV7 and PCV13 conjugate vaccines were introduced in 2001 and 2010, respectively. The objective of this study was to analyze the effect of the introduction of PCVs in children in adult IPD caused by antibiotic-resistant pneumococci.

Materials/methods: All confirmed IPD episodes (CDC criteria) of adults admitted to Hospital Universitari de Bellvitge (Barcelona, Spain) are prospectively collected. Isolates are routinely identified, serotyped, tested for antimicrobial susceptibility (CLSI) and genotyped (PFGE/MLST). Clinical data are prospectively recorded. This study includes a 25-year period which, for analysis purposes, was divided as follows: pre-PCV(1994-2001), early-PCV7(2002-2005), late-PCV7(2006-2010), early-PCV13(2011-2015) and late-PCV13(2016-2018). Isolates were classified according to their resistance phenotype: penicillin susceptible (PS; MIC<0.12mg/L), penicillin non-susceptible (PNS; penicillin MIC≥0.12mg/L) or multidrug-resistant (MDR; PNS plus resistant to other 2 groups). Differences in the incidence of IPD, rates of resistance and clinical characteristics were assessed using the Chi-square test.

Results: 2095 episodes of adult IPD were analyzed. The overall IPD incidence showed a non-significant decrease from 13.9 to 12.1 episodes/100000 population (-13.1%; 95%CI, -25.7% to 1.6%; pre-PCV vs late-PCV13). The incidence of PS remained stable (9.1 to 8.7; -4.0%, -20.4% to 15.7%), whereas that caused by MDR/PNS significantly decreased (4.9 to 3.4; -30.1%, -6.8% to -47.5%). Reductions in rates of resistance were observed for: penicillin (34.8% to 28.0%), cefotaxime (18.5% to 10.3%), chloramphenicol (15.5% to 5.1%) and co-trimoxazole (42.8% to 25.7%). Resistance to erythromycin increased (18.7% to 24.8%). IPD caused by MDR/PNS pneumococci was statistically associated to older patients, higher McCabe score, nosocomial acquisition, existence of comorbidities and prior antibiotic therapy. 30-day mortality was significantly higher for MDR/PNS episodes (24.1% vs 16.6%). Currently, two PMEN clones are responsible for 50% of the IPD caused by MDR/PNS pneumococci: Spain9V-3(ST156) and Denmark14-32(ST230).

Conclusions: The introduction of PCVs in children has had a limited impact on the adult IPD in our geographical area. Nevertheless, a beneficial effect on the rates of resistance was observed for most antimicrobials.

Clinical evaluation of the ID-fungi plates for direct identification of dermatophytes on nail, hair and skin samples by MALDI-TOF MS

Rosalie Sacheli*, Simon Winandy, Akole Adjetey, Rajae Darfouf, Quentin Legras, Cécile Meex, Ludwig Marechal, Jorge Arrese, Marie-Pierre Hayette

1University Hospital of Liege, Clinical Microbiology-National Reference Center for Mycoses, Liege, Belgium, 2University Hospital of Liege, Clinical Microbiology-National Reference Center for Mycoses, Liege, Belgium, 3University Hospital of Liege, Dermatology unit, Liege, Belgium

Background: The identification of filamentous fungi (FF) by Maldi-Tof MS is still not optimal. One of the main pitfalls is the colony harvesting for deposit on the Maldi plate which is often difficult due to fungal adherence to the medium. To improve this limiting factor, a new ID-fungi® plate medium (Conidia, France) has been recently developed. This medium allows the growth and easy sampling without the need for subculture. This study presents the preliminary results of the detection and identification of FF by Maldi-Tof from colonies directly harvested from ID-fungi® plates. The results have been compared with traditional diagnostic methods.

Materials/methods: A total of 86 Conidia® plates have been inoculated with nails, skin and hair from patients presenting to the dermatology unit of the University Hospital of Liège. In parallel, Sabouraud medium with antibiotics and cycloheximide (bioMérieux, France) have been inoculated. From Conidia® plates, each positive culture has been analysed by Maldi-Tof-MS using the extended direct deposit with formic acid or complete formic acid/acetonitrile extraction. From Sabouraud medium, the identification was done by microscopy. ITS sequencing was run on every colony as gold standard for identification.

Results: Among the 86 Conidia® plates, 19 (22%) were positive for dermatophytes. The Maldi-Tof identification rate by extended direct deposit was 16/19 (84,7%) considering that the three misidentified dermatophytes were T. interdigitale strains identified as T. tonsurans, a cross-reaction already seen in our previous study and well described in the literature. In comparison with the Sabouraud agars, Conidia® let grow 6 additional dermatophytes. However, 7 other dermatophytes growing on Sabouraud were not present on Conidia®. These discordances are possibly due to insufficient sample volume inoculated on each medium. On Conidia® plates, we also perfectly identified 6/9 (66,6%) other non-dermatophytes molds. The three missing species are not represented in the Bruker Filamentous fungi 2.0 database.

Conclusions: The Conidia plates are a promising tool to reduce the TAT for filamentous fungi identification. A fast and accurate identification can be obtained for the main fungal species by Maldi-Tof MS. However the Bruker database has to be improved because it is still incomplete.

**Abstract third-party references:** This is a Pfizer sponsored study

**Background:** Introduction of PCV7 and PCV13 for children in national immunization programs (NIP) has reduced incidence of Invasive Pneumococcal Disease (IPD) and pneumococcal Community Acquired Pneumonia (CAP) in adults with and without underlying conditions. Nevertheless, reductions in overall IPD and PCV13-type IPD incidence differ by age and comorbidities, suggesting that not every adult is equally protected by the indirect effect. In Spain, PCV13 was introduced in the childhood NIP in 2015-2016. PCV7 and PCV13 were available but afforded by parents (estimated uptake 61%) from 2000 and 2010 respectively. PPV23 was recommended for at risk subjects since 2001 and for adults aged 60/65 since 2004 with moderate uptake. PCV13 was recommended for at high risk adults since 2012 with low uptake. This study aimed to evaluate indirect effects on CAP and pneumococcal-CAP caused by PCV13 serotypes from 2011-2012 to 2015-2016 among adults with and without comorbidities.

**Materials/methods:** Prospective, observational study of immunocompetent adults (≥18y) admitted to 4 Spanish hospitals with chest X-ray confirmed CAP between November 2011 and November 2016. Microbiological confirmation was obtained using the Pfizer PCV13 serotype specific urinary antigen detection (UAD) test, BinaxNow® and conventional cultures. Serotyping of isolates was accomplished in a central laboratory by multiplex-PCR and confirmed by the Quellung reaction.

**Results:** Of the 2,086 adults hospitalized with CAP included in the study, 548 (26.3%) had pneumococcal-CAP. Mean age 67. Patients with ≥1 comorbidity accounted for 88.2% and 87% of CAP and pneumococcal-CAP cases respectively. Most frequent conditions in adults with CAP: diabetes (488; 23.4%), COPD (384; 18.3%), previous pneumonia (373; 17.9%) and smoking (354; 17%). Table shows evolution of PCV13 serotypes causing CAP and non-invasive1 and invasive2 pneumococcal-CAP, between 2011-2012 and 2015-2016 by presence of most frequent underlying conditions.

**Conclusions:** In Spain, PCV13-type CAP and pneumococcal-CAP decreased in adults possibly due to the indirect effect of childhood immunization. Nevertheless, no significant decrease was observed in adults with chronic respiratory disease, heart failure and in adults without underlying conditions. PCV13 serotypes accounted for up to 50% of pneumococcal-CAP cases in adults with comorbidities 6 years after PCV13 use in children and more than a decade of PPV23 recommended for people at risk.

Background: Accurate tuberculosis (TB)-diagnostic is imperative to initiate an effective treatment. In parallel to low sensitive smear microscopy and time-intense culture, nucleic acid amplification tests (NAATs) detecting Mycobacterium tuberculosis complex (MTBC) and important antibiotic resistances have become available in the past years. Besides fully automated and cartridge based test, NAATs such as FluoroType MTB (FT-MTB), GenoType MTBDRplus (GT-plus) and GenoType MTBDRsl (GT-sl) of Hain Lifescience need external DNA preparation of decontaminated sputum prior to testing. This requires a well-equipped and expensive laboratory infrastructure, which might not be affordable in high incidence countries. We have developed a low-cost DNA extraction cartridge that is run in a programmable centrifuge. In this study we evaluated whether cartridge-extracted DNA (Crt.-DNA) is suitable for MTBC, rifampicin (rif), isoniazid (inh) and second line antibiotic resistance testing using FT-MTB, GT-plus, GT-sl and pre-characterized sputum samples from TB-patients.

Materials/methods: GeneXpert MTB/RIF (Xpert, Cepheid) confirmed MTBC-positive sputum samples were obtained from the German-Nepal tuberculosis project (Genetup, Nepal) and the National Reference Laboratory Tashkent (Uzbekistan). After liquefaction, sputum was loaded in extraction cartridges that were processed in a programmable centrifuge harboring a special rotor. The extracted DNA was subject to FT-MTB. All MTBC-positives were further screened for rif and inh resistance by GT-plus. Rif and multidrug resistant (MDR) samples were additionally tested for resistance against second line antibiotics using GT-sl.

Results: 86% (36/41) of Xpert positive samples were identified as MTBC-positive by FT-MTB after cartridge-based DNA extraction (Crt.-DNA). While 100% of Xpert high and medium positives were positive, FT-MTB only detected around 75% of Xpert low/very low positives. 82% (31/38) of subsequently GT-plus tested samples yielded a valid result. Again, Xpert low/very low positives performed less well with only around 50% being analysable. 6 MDR samples were identified and further screened for resistance against second line antibiotics by GT-sl. 100% (6/6) of test results were valid and resistances against fluoroquinolones, kanamycin, amikacin and capreomycin were detected. 100% specificity was obtained.

Conclusions: We could show that cartridge-extracted DNA is suitable for molecular diagnostics including MTBC-screening as well as rif, inh and second line antibiotic resistance testing using Hain technology.

Abstract 3336

Outbreak of an uncommon rifampicin-resistant blaNDM-1 *Citrobacter amalonaticus* strain in a digestive rehabilitation centre: the putative role of rifaximin

Guilhem Royer*, 1 Frederic Fourreau1, Camille Gomart1, Audrey Maurand1, Bruno Hacquin1, David Ducellier1, Florence Cizeau1, Stéphane Lo1, Catherine Cordonnier Jourdin1, Mélanie Darty1, Jean-Winoc Decousser1

1Hôpital Henri-Mondor AP-Hp, Créteil, France

**Background:** We report a sudden emergence and spread of an uncommon carbapenemase-producing Enterobacteriaceae (CPE) strain in a digestive rehabilitation center that exhibited phenotypic and genotypic resistance to rifamycins.

**Materials/methods:** Due to a history of CPE exposure in another healthcare facility, a cirrhotic patient was screened one month after his admission to a 22-bed digestive rehabilitation center that is east of a Parisian suburb. A rectal swab yielded a *Citrobacter amalonaticus* harboring a NDM carbapenemase. Three successive weekly screening campaigns of the hospitalized patients identified four additional carriers. An outbreak investigation was performed by the local infection control team. Antimicrobial consumption was obtained from the Pharmacy Department. Antimicrobial susceptibility was tested [MIC - microdilution method]. All five epidemic strains were whole genome-sequenced, allowing their resistome identification, their comparison through the core genome MLST approach and a phylogenetic analysis through single nucleotide polymorphisms (SNP).

**Results:** This digestive rehabilitation unit mainly hosted patients suffering from cirrhosis, and some of them were at the stage of hepatic encephalopathy. Some patients suffering from alcoholic addiction were disoriented, and were not compliant with basic hygiene recommendations. Regarding antimicrobial selection pressure, three out of the five carriers were under long-term rifaximin treatment to prevent recurrent overt hepatic encephalopathy. All five strains were identical (0 to 1 different alleles among the 2706 genes of the cgMLST scheme). Only meropenem (MIC = 2 mg/L), amikacin (4 mg/L), tigecyclin (0.5 mg/L) and colistin (0.5 mg/L) presented in vitro activity. Regarding rifaximin, the epidemic strain MIC was 512 mg/L, far above the reported breakpoint of 32 mg/L. The in silico analysis identified bla NDM-1, mcr-9 and arr-3 that encodes a rifampin ADP-ribosyl transferase conferring a high level of rifampin resistance. The phylogenetic analysis confirmed the inclusion of the epidemic strain in the C. amalonaticus clade and its distance from the other published strain harboring a bla NDM-1 gene. In this ward in 2018 the rifaximin consumption was 162 DD per 1000 patient days.

**Conclusions:** We support the prudent use of long-term rifaximin therapy in wards where infection control measures are not strictly respected and recommend the thorough monitoring of emerging rifampicin-resistant MDR strains.

Predominant mechanisms of carbapenem resistance in *Pseudomonas aeruginosa* and *Klebsiella pneumoniae* and tools for their detection

Petukhova Irina*1, Nataliya S. Bagirova2, Victoria Aginova3, Inna Tereshchenko4, Zlata Grigoryevskaya1, Svetlana Dyakova2, Kulaga Elena2, Natalia Dmitrieva1

1NN Blokhin National Medical Research Center of Oncology of the Ministry of Health of Russia, Moscow, Russian Federation, 2NN Blokhin National Medical Research Center of Oncology of the Ministry of Health of Russia, Moscow, Russian Federation, 3Medical college №1, Moscow, Russian Federation, 4NN Blokhin National Medical Research Center of Oncology of the Ministry of Health of Russia, Moscow, Russian Federation

**Background:** The aim was to determine predominant mechanisms of carbapenem resistance in *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*.

**Materials/methods:** 85 isolates of *P. aeruginosa* and 113 isolates of *K. pneumoniae*, isolated in January-September 2019, were analyzed. Identification was performed using MS Maldi-ToF (Bruker, Germany), antibiotic susceptibility - Vitek-2 (BioMerrieux, France). The Advanced Expert System with a set of Global European-based plus Phenotypic parameters was used. Susceptibility to carbapenems was manually adjusted to EUCAST breakpoints, v. 9.0 (2019). Analysis of carbapenem resistance was performed automatically by VITEK-2. The obtained results were compared with the data of molecular genotyping, performed jointly with the Institute of antimicrobial chemotherapy (Smolensk, Russia).

**Results:** 34/85 (40.0%) isolates of *P. aeruginosa* and 35/113 (31.0%) isolates of *K. pneumoniae* were carbapenem-resistant (Car-R). MICs of imipenem or meropenem for Car-R *P. aeruginosa*, were 8 µg/ml (6/34, 17.6%) and ≥16 µg/ml (28/34, 82.4%). Carbapenemase production was observed in 24/34 (70.6%) cases (not otherwise specified [NOS], VITEK-2) and in all cases, it was accompanied with carbapenem impermeability. Only carbapenem impermeability was observed in additional 10 cases, totally accounting for 100% of Car-R *P. aeruginosa* isolates. Among 35 Car-R *K. pneumoniae*, MICs of imipenem or meropenem were 8 µg/ml in 13/35 (37.1%), ≥16 µg/ml in 22/35 (62.9%) cases. Carbapenemase production was observed in 35 (100%) isolates (NOS, VITEK-2). In 32/35 (91.4%) isolates carbapenemase production was accompanied by carbapenem impermeability. Appropriate genotyping results were obtained for 11 *P. aeruginosa* and 10 *K. pneumoniae* isolates. 5/11 (45.5%) *P. aeruginosa* isolates were producers of VIM metal-beta-lactamases, and all *K. pneumoniae* isolates produced serine carbapenemases, including 9 (90.0%) OXA-48 and 1 (10.0%) KPC.

**Conclusions:** A 9-month analysis (2019) showed that carbapenemase production by *P. aeruginosa* and *K. pneumoniae* isolates was noted in 70.6% and 100% of cases, respectively. Moreover, carbapenem impermeability in *P. aeruginosa* [100%] and *K. pneumoniae* [91.4%] in parallel with carbapenemase production was seen. The combination of these 2 mechanisms makes it impractical to use high doses and prolonged infusions of carbapenems, and requires treatment based on modern inhibitor-protected cephalosporins.

Abstract 3339

**A common protocol for the simultaneous processing of multiple bacterial species for whole genome sequencing**

Kathy Raven*, Sophia Girgis¹, Beth Blane¹, Asha Akram¹, Danielle Leek², Nicholas Brown², Sharon Peacock¹²

¹Department of Medicine, University of Cambridge, Cambridge, United Kingdom, ²Clinical Microbiology and Public Health Laboratory, Public Health England, Cambridge, United Kingdom

**Abstract third-party references:** This publication presents independent research supported by the Health Innovation Challenge Fund [WT098600, HICF-T5-342], a parallel funding partnership between the Department of Health and Wellcome Trust. The views expressed in this publication are those of the author[s] and not necessarily those of the Department of Health or Wellcome Trust.

**Background:** Bacterial whole genome sequencing (WGS) will become increasingly used by local microbiology laboratories where test volume is low compared with national capabilities. The need for rapid turnaround (frequent sequencing runs) of relatively low isolate numbers must be balanced with cost-effectiveness achieved by maximizing the number of multiplexed isolates in any given run. Here, we describe a single universal protocol for simultaneous DNA extraction and sequencing of numerous different common bacterial species, allowing the sequencing of mixed isolate runs to meet variable needs.

**Materials/methods:** We assembled test panels comprising 71 isolates representing 20 clinically important bacterial species. Panels 1 and 2 were selected from clinical isolates to represent leading causes of outbreaks and infection. Panels 3 and 4 were selected from previous studies used to demonstrate the utility of WGS in the clinical setting. The basis for the DNA extraction process was the QIAgen mini DNA kit, to which different combinations of reagents that are commonly used for specific pathogens were added to optimize DNA recovery from each test panel. DNA recovery was quantified using a Qubit fluorometer, with >3.3ng/ul required for library preparation. Thereafter, a common processing pathway was used to prepare the sequencing libraries using the Illumina Nextera Flex kit, which were sequenced overnight on an Illumina MiniSeq.

**Results:** The addition of lysostaphin, lysozyme or buffer ATL (a tissue lysis buffer) alone did not produce sufficient DNA for library preparation (<3.3ng/ul) across the species panels tested. By contrast, lysozyme plus lysostaphin produced sufficient DNA across all 20 species. 15/20 species could be extracted from a 24 hour culture plate, while the remainder ([Campylobacter jejuni, Haemophilus influenzae, Legionella pneumophila, Neisseria meningitidis, and Streptococcus pneumoniae]) required 48-72 hours incubation for sufficient growth. Tests performed by different people on different days demonstrated 100% reproducibility. Sequencing of the resulting DNA was used to recapitulate previous findings for species, relatedness and outbreak detection, antimicrobial resistance gene detection and capsular type.

**Conclusions:** This single protocol for simultaneous processing and sequencing of multiple bacterial species supports low volume rapid turnaround time sequencing of multiple species of clinical importance by local clinical microbiology laboratories.

Identification of anti-TPI H8 antibody-epitope analogues as putative active vaccine against *Staphylococcus aureus*

Liza Rummler1,2, Sonja Mertins1,2, Martin Kroenke1,2, Alexander Klimka1,2

1University Hospital of Cologne, Institute for Med. Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Centre for Infection Research, Partner site Bonn-Cologne, Germany

**Background:** *Staphylococcus aureus* (*S. aureus*) is a major human pathogen that can cause clinical infections like bactereemia and endocarditis. The morbidity and socioeconomic burden associated with infections with methicillin-resistant *S. aureus* (MRSA) combined with a lack of new antibiotics define a clear unmet medical need for novel approaches, including vaccination. Currently, there is no vaccine available. By proteomic approach, we identified vaccine candidates involved in essential metabolic pathways also displayed on the surface of *S. aureus*. Vaccination with triose-phosphate isomerase (TPI), a highly conserved glycolytic enzyme, showed significant protection in our murine sepsis model. Subsequently, anti-TPI monoclonal antibodies (moAbs) were generated for passive immunization of mice. One anti-TPI moAb (H8) provided significant higher survival rates compared to others after *S. aureus* challenge. Obviously, protection is epitope specific. By using this reverse immunology approach we identified the H8-TPI-epitope which could serve as protective active vaccine. However, moAb H8 recognizes a discontinuous epitope contained in a stretch of 100 amino acids. For cost-effective production of an epitope vaccine, the moAb H8 epitope sequence needs to be shortened without losing its ability to generate anti-TPI H8-like antibodies. In this study, we used different approaches to identify H8 epitope analogues.

**Materials/methods:** Using the NEB 12-mer peptide-phage display library H8-mimotopes, structurally mimicking the H8-TPI-epitope, were selected. After three rounds of biopanning against immobilized H8 antibody, three mimotopes were enriched and analyzed for specific binding to moAb H8. Additionally, based on antigen fragment cloning and binding assay results we generated a peptide assumed to contain the discontinuous H8 epitope, called H8-Disco. After immunization of mice with KLH-conjugated mimotopes and H8-Disco, serum was analyzed for the presence of TPI-specific antibodies by ELISA.

**Results:** Three mimotopes bind specifically to moAb H8 in phage ELISA binding assays, while they do not bind an isotype matched IgG1 control antibody or BSA. However, the mimotopes did not induce TPI-specific antibodies in mice. In contrast, H8-Disco does induce a humoral TPI-specific immune response after active vaccination.

**Conclusions:** H8-Disco could serve as epitope vaccine against *S. aureus*. The protection potential needs to be evaluated in our *S. aureus* mouse infection model.

Abstract 3341

**Miconazole/domiphen bromide: a fungicidal combination treatment against biofilms of various azole-sensitive and azole-resistant Candida spp.**

Jana Tits1, Freya Cools2, Paul Cos1, Kristof Verbruggen3, Judith Berman4, Bruno Cammue1, Karin Thevissen1

1KU Leuven, Centre of Microbial and Plant Genetics, Heverlee, Belgium, 2University of Antwerp, Laboratory of Microbiology, Parasitology and Hygiene, Antwerp, Belgium, 3Purna pharmaceuticals, Puurs, Belgium, 4Tel Aviv University, Dept. of Molecular Microbiology & Biotechnology, School of Molecular Cell Biology and Biotechnology, George Wise Faculty of Life Sciences, Tel Aviv, Israel

**Background:** Mucosal biofilm-related Candida infections are very common and can occur for example on genital organs. Such infections are difficult to treat, since miconazole (MCZ), the preferred topical treatment, is only moderately active against biofilms. We discovered a fungicidal combination consisting of MCZ and a quaternary ammonium compound, domiphen bromide (DB), that is active against biofilms of *Candida albicans* and *Candida glabrata*. Here we investigated the activity spectrum of MCZ-DB, the combination’s effect *in vivo* and its mode of action.

**Materials/methods:** Activity against *Candida albicans*, *Candida auris* and *Candida glabrata* biofilm and planktonic stationary cultures was assessed by treating cultures with MCZ, DB or a combination and performing CFU determination after 24h (biofilms) or 2,5h (planktonic cultures) treatment. The *in vivo* activity of the MCZ-DB combination was examined in a *Candida* vaginitis rat model during 14 days. The combination treatment’s mode of action was studied in planktonic *C. glabrata* cultures, using a fluorescently labeled ketoconazole derivative (FKD) (1) to investigate the effect of DB on azole uptake and its subcellular localization, via FACS analysis and confocal microscopy, respectively. BCECF-AM staining was used to study DB’s effects on *C. glabrata* vacuolar pH.

**Results:** MCZ-DB leads to a significant CFU reduction as compared to single compound treatments in biofilms of azole-resistant *C. albicans* isolates, *C. auris* biofilms and planktonic cultures of *C. albicans* and *C. glabrata* in stationary phase. Moreover, the combination treatment significantly reduces the infection burden as compared to single compound treatment in an in vivo vaginitis rat model. Apparently DB (i) enables increased FKD uptake in *C. glabrata* cells at low doses, (ii) alters cytoplasmic distribution of high FKD doses and (iii) negatively affects vacuolar integrity.

**Conclusions:** Our data reveal that MCZ-DB combination treatment has fungicidal antibiofilm activity against various azole-resistant and azole-sensitive Candida spp., probably because DB increases intracellular MCZ availability.

Abstract 3342

Amikacin initial dosing in emergency surgery: pharmacokinetics and determinants of optimal dose

Sylvain Goutelle*, Guérin Fritsch1, Marie Leroy1, Catherine Piron1, Camille Salvez1, Arnaud Friggeri1

1University Hospitals of Lyon, Lyon, France

Background: Amikacin usual dose (15-30 mg/kg) may not be optimal in emergency surgery. The objectives of this study were to describe the pharmacokinetics (PK) of amikacin in emergency surgery patients and to evaluate optimal initial dosage.

Materials/methods: This was a retrospective analysis of data from patients who underwent emergency surgery, over 3.5 years in Centre Hospitalier Lyon Sud, Lyon, France. We performed Bayesian estimation (BestDose software) of patients’ individual PK parameters based on peak (Cmax) and trough concentration (C24h) after the first dose. We calculated the optimal dose that would have been necessary to achieve the target Cmax of 64 mg/L in each patient. We also simulated the target attainment (TA) for various alternative doses. Determinants of optimal dose were investigated by using regression tree analysis.

Results: Data from 84 patients (36 women and 48 men) were available. The population characteristics (mean ± SD) were as follows: creatinine clearance, 85 ± 45 mL/min; age, 63 ± 16 years; body weight, 71 ± 18 kg. The mean first amikacin dose was 1753 ± 548 mg. The mean Cmax and C24h were 78 ± 28 mg/L and 7 ± 9 mg/L, respectively, with 32% of patients having Cmax < 64 mg/L. Median (min-max) values of amikacin volume of distribution, plasma clearance and half-life, were as follows: 0.24 (0.13-0.66) L/kg, 46 (5-367) ml/min and 2.5 (1.7 – 10.3) h, respectively. Optimal doses estimated by the model ranged from 773 mg to 4803 mg (median = 1449 mg). The simulated TA for doses of 20, 25 and 30 mg of TBW were 36%, 79%, and 94%, respectively. A fixed dose of 2500 mg was associated with TA of 95%. Ideal body weight (IBW) was the primary predictor of optimal dose, with a dose of 2180 mg in patients with IBW > 71.2 kg versus 1414 mg in patients with IBW ≤ 71.2 kg.

Conclusions:Considerable variability in amikacin PK and dosage requirements was observed in emergency surgery patients. A dose of 30 mg/kg of TBW or a fixed dose of 2500 mg appear to be the best dosing strategies.

Abstract 3344

Clinical characteristics, disease management and treatment outcome of paediatric tuberculosis in Denmark

Anne Christine Nordholm*1, Inge Kristine Larsen Holden1,2,3,4, Ulla Birgitte Hartling1, Peter Henrik Andersen6, Troels Lillebaek1,2, Isik Somuncu Johansen2,3,4

1Statens Serum Institut, Department of Tuberculosis and Mycobacteriology, København, Denmark, 2Odense University Hospital, Department of Infectious Diseases, Odense, Denmark, 3University of Southern Denmark, Department of Clinical Research, Odense, Denmark, 4University of Southern Denmark, Mycobacterial Centre for Research Southern Denmark – MyCRESO, Odense, Denmark, 5Odense University Hospital, Hans Christian Andersen Children’s Hospital, Odense, Denmark, 6Statens Serum Institut, Department of Infectious Disease Epidemiology and Prevention, Copenhagen, Denmark, 7University of Copenhagen, Global Health Section, Department of Public Health, Copenhagen, Denmark

Background: In Western Europe, pediatric tuberculosis (TB) is rare and clinical characteristics often unspecific potentially causing diagnostic delay and poor treatment outcome.

Materials/methods: Nationwide study of children ≤ 18 years with TB from 2009 through 2014 in Denmark. Demographic-, clinical- and microbiological data and treatment outcome results were obtained from registers and medical records.

Results: In total, 168 pediatric TB cases were identified; the majority were immigrants (71%), primarily from Africa (40%) and Asia (38%). Co-morbidities were rare (4.8%) of which asthma was the most common (63%). Danish children were more likely to be diagnosed as part of contact tracing (69%) whereas the majority of immigrants (66%) were diagnosed due to symptoms (p<0.0001). Mean health system delay was longest for immigrants with extra pulmonary TB (39 days). The most common symptoms were fever, night sweat, cough, enlarged lymph nodes and pain. C-reactive protein and erythrocyte sedimentation rate were often elevated, however, 1/3 of the children had normal blood tests at the time of diagnosis. The treatment success rate was 93%, slightly higher in Danish children (98%) compared to immigrants (92%) and cases of treatment failure were restricted to adolescents of which 88% (7/8) were among immigrants.

Conclusions: The majority of pediatric TB in Denmark occurs among otherwise healthy immigrant children with symptomatic TB and a health system delay of just over one month. The treatment success rate was 93%, and possible improvements should be targeted enhanced case detection and treatment adherence of immigrant adolescents.

Abstract 3345

Antimicrobial-resistant Bacteroides fragilis detected from blood culture in 2 tertiary hospitals
Kana Ohgane*1, Masahiro Kodana1, Azusa Onodera2, Kazuo Imai3;4, Jun Sakai3;4, Toru Kawamura1, Shinichi Takeuti1, Norihito Tarumoto3;4, Kenji Ikebuchi1, Shigefumi Maesaki3;5, Takuya Maeda1;3

1Saitama Medical University Hospital, Laboratory Medicine, Moroyama, Japan, 2Saitama Medical University Moroyama Campus, Moroyama, Japan, 3Saitama Medical University, Infectious Disease and Infection Control, Moroyama, Japan, 4Saitama Medical University, Center for Clinical Infectious Diseases and Research, Moroyama, Japan, 5Saitama Medical University International Medical Center, Infectious Diseases and Infection Control, Hidaka, Japan

Background: The presence of drug-resistant Bacteroides fragilis is a major problem in the selection of empirical treatments for intraabdominal infections. In particular, chromosome-located β-lactamase cfiA is associated with resistance to carbapenems, and as the frequency of clinical use of carbapenem increases, there is a concern about the increase in the frequency of colonization and infection of the isolates. In this study, we examined the drug susceptibility of B. fragilis strains isolated from blood culture in clinical settings and the possession of each drug resistance gene.

Materials/methods: 43 strain of B. fragilis were isolated from blood culture at the 2 tertiary referral hospitals from January 2014 to December 2018 and identified in MALDI Biotyper (Bruker). DNA was extracted from each strain, and the presence or absence of the nine genes (cepA, cfxA, cfiA, IS, ermA, ermB, mefA, tetQ, nimB) elated to the antimicrobial agent was confirmed using PCR.

Results: As a result of drug susceptibility test, resistance rate to carbapen (doripenem and meropenem) showed 9.3% [4/43]. The resistance rates to sulbactam/ampicillin and cefmetazole recommended for the treatment of anaerobic bacteria were as low as 14.0% and 7.0%. The resistance rate of clindamicin is over 30%. Also, no resistant strain of metronidazole was found. In the result of PCR, cepA gene of β-lactamase was detected at a high rate of 86% [37/43], followed by 72.1% [31/43] of tetQ gene involved in tetracycline resistance. All two carbapen-resistant strains carried the cfiA gene, but only one had an Insertion Sequence (IS).

Conclusions: The expression of cfiA gene involves IS element as a promoter, but some strains of IS element was not detected. Involvement of penicillin binding protein, increase of efflux pump, and mutation of outer membrane porin protein was also considered as the cause of carbapenem resistance. In addition, in this study, sensitivity to metronidazole was maintained in all strains and was considered to be one of the excellent treatment options for cases suspected of having B. fragilis involvement.

Insight into Chlamydia trachomatis persistence

Claudio Foschi\textsuperscript{1}, Massimo Bortolotti\textsuperscript{2}, Chiara Zalambani\textsuperscript{1}, Romana Fato\textsuperscript{3}, Letizia Polito\textsuperscript{2}, Andrea Bolognesi\textsuperscript{2}, Antonella Marangoni*\textsuperscript{1}

\textsuperscript{1}University of Bologna, DIMES, Microbiology, Bologna, Italy, \textsuperscript{2}University of Bologna, DIMES, General Pathology Unit, Bologna, Italy, \textsuperscript{3}University of Bologna, FaBiT, Bologna, Italy

Background: Chlamydia trachomatis is the agent of the most common bacterial sexually transmitted infection. Under stressful conditions, Chlamydia fails to successfully replicate inside the epithelial cells and switches to a persistence state. In vitro, this condition can be induced by beta-lactam antibiotics, as penicillin, and reversion to productive infectious elementary bodies can be obtained upon removal of the drug.

The aim of this study was to get new insights into the interactions between C. trachomatis and the epithelial host cells during persistence condition.

Materials/methods: The normal chlamydial development cycle was compared with penicillin-induced persistence and the following aspects were investigated: (i) cell survival/death, (ii) externalization of phosphatidylserine, (iii) caspase 1 and caspase 3/7 activation, and (iv) reactive oxygen species (ROS) production. Experiments were conducted using HeLa cells and two different serovars (D and L2) at three different levels of multiplicity of infection (MOI 0.3, 1, 3). In particular, the exposure of phosphatidylserine in Chlamydia-infected cells was evaluated at three different time points (8, 24, 48 h post-infection) by flow cytometry analysis, whereas the determination of caspases activation was carried out by a biochemical approach. Finally, ROS production was assessed on HeLa cells at 48 hours post infection by means of a fluorescent probe.

Results: At 72 hours post-infection, the cytotoxic effect displayed by Chlamydia was completely abolished for both serovars and for all levels of multiplicity of infection only in the cells with aberrant inclusions. At the same time, C. trachomatis was able to switch off the exposure of the lipid phosphatidylserine on the surface of epithelial cells and to strongly inhibit the activation of caspase 1 and caspase 3/7 only in penicillin-treated cells. Forty-eight hours post-infection, C. trachomatis elicited a significant ROS expression both in case of a normal cycle and in case of persistence. However, serovar L and penicillin-free infection activated a higher ROS production compared to serovar D and to penicillin-induced persistence, respectively.

Conclusions: In conclusion, we added knowledge to the cellular dynamics taking place during chlamydial persistence, demonstrating that C. trachomatis creates a suitable niche to survive, switching off signals able to activate phagocytes/leukocytes recruitment.

Optimal antimicrobial therapy duration for patients with acute cholangitis after successful drainage by Endoscopic retrograde cholangiopancreatography (ERCP)

Sylke Haal1,2, Britt Ten Böhmer1, Sebastiaan Balkema1, Annekatrien Depla4, Paul Fockens1, Jeroen Jansen5, Sjoerd Kuiken5, Boris Liberov6, Ellert Van Soest2, Jeanin Van Hooft1, Elske Sieswerda*, Rogier Voermans1

1Amsterdam UMC, location AMC / University of Amsterdam, Amsterdam, Netherlands, 2Spaarne Gasthuis, Hoofddorp, Netherlands, 3Dijklander Ziekenhuis, Hoorn, Netherlands, 4MC Slotervaart, Amsterdam, Netherlands, 5OLVG, Amsterdam, Netherlands, 6Zaans Medisch Centrum, Zaandam, Netherlands, 7Amsterdam UMC, location VUMC / Vrije Universiteit Amsterdam, Amsterdam, Netherlands

**Background:** Recommendations regarding the duration of antimicrobial therapy in cholangitis after successful endoscopic biliary drainage vary. Aim of this study was to compare the occurrence of local infectious complications in patients with acute cholangitis treated with antibiotics for three days or less compared to four days or more.

**Materials/methods:** We performed a retrospective multicenter study in seven hospitals in the Netherlands. Patients who received a successful biliary drainage by endoscopic retrograde cholangio-pancreatography (ERCP) because of cholangitis due to common bile duct stones between 2012-2017 were included. The primary outcome was the occurrence of a local infectious complication within three months after ERCP. Secondary outcomes included *Clostridioides difficile* infection, total length of stay and all-cause mortality.

**Results:** A total of 426 patients with cholangitis were identified and 296 patients met all inclusion criteria. Therapy duration was ≤ 3 days in 137 patients (46.3%). During follow-up 41 patients (13.9%) developed a local infectious complication. Occurrence of infectious complications did not differ between the two groups \(P=0.32\). No patient developed *Clostridioides difficile* infection. Median hospital stay was six days [IQR 4-8 days] in the short antibiotic group compared to seven days [IQR 5-9 days] in the long group \(P=0.03\). Four (1.4%) patients died during follow-up, all were treated for ≥ 4 days \(P=0.13\).

**Conclusions:** Antimicrobial therapy of three days or less seems to be sufficient after successful biliary drainage in patients with acute cholangitis. Randomized trials should confirm our findings.

Abstract 3356

**Differential resistance of Candida auris biofilms against surface disinfectants commonly used in the hospital**

Beata Zatorska¹, Magda Diab-Elschahawi*, Doris Moser¹, Elisabeth Presterl¹

¹Medical University of Vienna, Vienna, Austria

**Background:** Candida auris is an emerging fungal pathogen causing hospital outbreaks. The aim of our study was to test Candida auris for susceptibility to surface disinfectants commonly used in hospitals.

**Materials/methods:** The efficacy of seven disinfectants was tested in a static biofilm microtiter plate model using tetrazolium salt reduction (XTT) assay and a modified crystal violet staining. The log10 reduction assay was used to quantify the viable cells after exposure to the disinfectants. Four biofilm forming reference strains of C. auris (the non-aggregating NCPF 8971, aggregating NCPF8977, NCPF8984, DSM 21092) and a C. albicans ATCC10231 strain were tested against: A: an ethanol based disinfectant, B: a quaternary ammonium based disinfectant, C: a disinfectant based on a mix of glutaraldehyde, quaternary ammonium and surfactant, D: and E: 3.4% and 4.25% hydrogen peroxide alone respectively, F: a potassium peroxymonosulfate based disinfectant and, G: a micelic formulation containing 12% v/v hydrogen peroxide. All tests were done in quadruplicate.

**Results:** In the XTT assay disinfectants A, B, and C achieved more than 80% reduction of biofilms metabolic activity and more than 5 log10 reductions of viable cells in all strains tested. The non-aggregating C. auris 8971 was resistant to H2O2 alone (D, E) and to the H2O2 micelic biocide (G), but susceptible to the potassium peroxymonosulfate based disinfectant [F] showing more than 5log10 viability reduction. The aggregating NCPF8977 and DSM21092 showed equally a resistance to D and G but not to E and F. C. auris NCPF8984 was resistant to F but sensitive to H2O2 (D and E). C. albicans ATCC10231 biofilms were resistant to disinfectants D, E, F and G.

**Conclusions:** The susceptibility of Candida auris to surface disinfectants is highly differential. Levurocidal activity of tested surface disinfectant is highly depending on the Candida species and its phenotypical growth pattern.

MPC-based prediction of anti-mutant effects of linezolid/daptomycin combinations against Staphylococcus aureus: a study in an in vitro dynamic model

Kamilla Alieva*1, Maria Golikova1, Elena Strukova1, Yury Portnoy1, Stephen Zinner2, Alexander A. Firsov1

1Gause Institute of New Antibiotics, Moscow, Russian Federation, 2Mount Auburn Hospital, Cambridge, United States

Background: In our studies with linezolid (L) + rifampicin- and L + gentamicin-exposed Staphylococcus aureus, the enhancement of anti-mutant effects of the antibiotic combinations was attributed to lengthening times above the mutant prevention concentration (MPC; T>MPC) caused by lowering the MPCs. To explore if this is applicable to combinations of L with daptomycin (D), the enrichment of L- and D-resistant mutants of S. aureus was studied by simulating single (L or D) and combined (L+D) treatments.

Materials/methods: The MPCs of L and D alone and in combination at a pharmacokinetically derived L-to-D concentration ratio (1:2) that corresponds to the simulated ratio of the areas under the concentration-time curve (AUCs) were determined for S. aureus ATCC 700699 and S. aureus 2061. Five-day treatments with twice-daily L and once-daily D were simulated at two therapeutic (240 and 480 μg×h/ml – regimens L240 and D480, respectively) and two sub-therapeutic AUC (120 and 240 μg×h/ml – regimens L120 and D240, respectively). Simulated combined treatments were L240+D480 and L120+D240. Areas under the bacterial mutant concentration–time curve were calculated for mutants resistant to L (AUBC_M(L)) or D (AUBC_M(D)).

Results: Under the influence of D the MPCs of decreased from 10 to 3 (S aureus ATCC 700699) and to 4 μg/ml (S. aureus 2061). Under the influence of L the MPCs of D decreased from 14 to 6 and from 10 to 8 μg/ml, respectively. Lowering the MPC led to an increase in T>MPC that resulted in lower AUBC_M(L) and AUBC_M(D) in combined treatments compared to single drug treatments. A strain-independent relationship was established between AUBC_M(L) and T>MPC (sigmoid, r² 0.97) and between AUBC_M(D) and T>MPC (monoexponential decay, r² 0.90).

Conclusions: These findings suggests that [1] suppression of L- and D-resistant S. aureus exposed to L+D combinations is consistent with an increase in T>MPC caused by lowering the MPCs of antibiotics in combination, and [2] T>MPC could be used as a predictor of staphylococcal resistance to the L+D combination.

Abstract 3358

EUCAST improved screening algorithm for beta-lactam resistance in Haemophilus influenzae

Erika Matuschek*, Jenny Ahman1, John Thegerström1, Fredrik Resman2, Stina Bengtsson1, Gunnar Kahlmeter1

1EUCAST Development Laboratory, Växjö, Sweden, 2Lund University, Clinical Microbiology, Department of Translational Medicine, Malmö, Sweden

Background: EUCAST recommends screening for beta-lactam resistance in Haemophilus influenzae with the benzylpenicillin (PCG) 1 unit disk. The PCG screening test is a sensitive test to detect all known beta-lactam resistance mechanisms, but it cannot differentiate between beta-lactamase production and PBP3 mutations. The aim of this study was to evaluate if the amoxicillin-clavulanic acid (AMC) 2.1 µg disk can be used as an additional test to identify beta-lactam resistant H influenzae with beta-lactamase only.

Materials/methods: Disk diffusion was performed according to EUCAST on MH-F agar from BD (BBL) and Thermo Fisher Scientific (Oxoid) on an international collection of H.influenzae (n=144). All isolates were beta-lactamase positive. PBP3 mutations were identified by PCR (mutations at AA 517, 526 or 528) in 57 isolates (40%). Broth microdilution (BMD) for beta-lactam agents was performed according to ISO 20776-1 on custom Sensititre panels (Thermo Scientific) using MH-F broth as recommended by EUCAST. EUCAST Breakpoints v. 9.0 were used to interpret the results.

Results: All isolates were correctly detected as beta-lactam resistant with the PCG disk (<12 mm). Isolates with beta-lactamase only were susceptible with BMD for amoxicillin-clavulanic acid and all cephalosporins and carbapenems tested. Seventy-eight isolates were susceptible with the EUCAST standard breakpoint for AMC 2.1 µg (≥15 mm), and 75 of these had beta-lactamase only [Figure 1]. Three isolates with PBP3 mutations were also categorised as susceptible with the AMC disk. Two of these were susceptible for all beta-lactamase stable agents tested. The third isolate had an elevated MIC for cefuroxime only (4 mg/L). Isolates with AMC <15 mm and PBP3 mutations had various susceptibility patterns for the beta-lactam agents tested.

Conclusions: The amoxicillin-clavulanic acid 2.1 µg disk can be used with the EUCAST disk diffusion test to identify beta-lactam resistant H.influenzae with beta-lactamase only. Beta-lactamase positive isolates with AMC 2.1 µg ≥15 mm can be reported susceptible for penicillins with beta-lactamase inhibitors, cephalosporins and carbapenems for which EUCAST breakpoints are available. We propose to include AMC 2.1 µg to be used together with the PCG 1 unit disk and a beta-lactamase test in the EUCAST screening algorithm for beta-lactam resistance in H.influenzae.

![Figure 1. Inhibition zones for H. influenzae (144 beta-lactamase positive isolates) and amoxicillin-clavulanic acid 2.1 µg.](image-url)

Black bars correspond to isolates with beta-lactamase only (n=87) and red bars to isolates with beta-lactamase and PBP3 mutations (n=57). The EUCAST zone diameter breakpoint for amoxicillin-clavulanic acid is shown as a dotted line.

**Invasive *Haemophilus influenzae* type b (Hib) disease in children in Italy, after 20 years of routine use of conjugate Hib vaccines**

Maria Giufre*, Erika Lindh1,2, Rita Cardines1, Marina Cerquetti1

1Istituto Superiore di Sanità, Rome, Italy, 2European Program for Public Health Microbiology Training (EUPHEM), European Centre for Disease Prevention and Control, Stockholm, Sweden

**Background:** *Haemophilus influenzae* serotype b (Hib) was the leading cause of bacterial meningitis in children before the implementation of infant immunization with conjugate Hib vaccines. In Italy, children are scheduled for Hib vaccination at 3, 5 and 11 months. Despite the effectiveness of the vaccine, invasive Hib disease cases are reported in children either because of incomplete vaccination status (failure to vaccinate) or through true vaccine failure (TVF).

**Materials/methods:** Data on invasive *H. influenzae* cases were detected through the National Surveillance of Invasive Bacterial Disease. All invasive Hib disease cases in children <18 years reported during 2012-2018 were included in the study. Hib isolates were subjected to MLST and PFGE analysis. The number of copies of the *capb*-locus was determined by Southern blot analysis.

**Results:** Overall, 31 cases of invasive Hib disease in children were reported. The median age of children was 12 months (range 3 months-15 years). A decrease in coverage (by 36 months of age) was observed in 2014-2016, corresponding to a clear rise in incidence starting from 2016 until 2018, especially in children <5 years. Fourteen children were fully vaccinated (TVFs), 14 were unvaccinated and 2 partially vaccinated. Most cases in children ≤2 years occurred in unvaccinated subjects. Meningitis was more frequent among unvaccinated children (71.4%) than among TVFs (42.8%), although this data was not statistically significant, p=0.12. No significant association was found between characteristics of children and TVF. Out of 31 cases of invasive Hib disease, 24 isolates were available. The predominant ST was ST6 (17/24, 71%) followed by ST95 (n=2). Cluster analysis of ST6 isolates by PFGE identified five variants. Six isolates (25%) contained multiple copies of the *capb*-locus distributed among TVFs (30%) and unvaccinated children (16.7%).

**Conclusions:** Our data show that both failure to vaccinate and TVFs are associated with the occurrence of invasive Hib disease in children in Italy, during the present vaccination era. Most cases in children ≤2 years were vaccine-preventable. No host predisposing factors for TVF were recognized. TVF were not significantly associated with either specific genotypes or amplification status of the *capb* locus.

Abstract 3364

Incidence of venous thromboembolism among patients receiving outpatient parenteral antimicrobial therapy at Sheffield Teaching Hospitals NHS Foundation Trust, UK: an observational study

Alexander Keeley*1,2, Christopher Keil1, Heather Hiles1, Natalie Hopka1, Chris Durojaiye1, Katharine Cartwright1

1Sheffield Teaching Hospitals NHS Foundation Trust, Department of Infectious Diseases and Tropical Medicine, Sheffield, United Kingdom, 2The University of Sheffield, Department of Infection, Immunity and Cardiovascular medicine, Sheffield, United Kingdom

Background: Outpatient parenteral antimicrobial therapy (OPAT) is increasingly used to facilitate early discharge from hospital and prevent hospital admission, for patients with infections requiring intravenous antibiotics. It is routine, evidence-based practice to prescribe venous thromboembolism (VTE) prophylaxis for medical and surgical inpatients. However, optimal practice for patients receiving OPAT is not known. The aim of our study was to describe current clinical practice in relation to VTE risk assessment and prophylaxis, and determine the 90-day incidence of VTE events in our cohort of OPAT patients.

Materials/methods: Electronic records were used to retrospectively review OPAT episodes at Sheffield Teaching Hospitals between September 2018 and March 2019. Region-wide electronic results systems were used to determine if any VTE episodes occurred within 90 days of an OPAT episode.

Results: 261 OPAT patient episodes were included. The median age was 59 years (range 16-94). 163 (62%) were inpatients prior to OPAT, with 138 (85%) receiving either prophylaxis or full anticoagulation at the time of transfer to OPAT. The most common conditions treated were skin and soft tissue infection n=128 (49%), bone and joint infection n=48 (18%), abdominal/urogenital infection n=21 (8%), endocarditis/endovascular infection n=20 (7%). 46 patients (16%) were assessed for VTE at the onset of the illness requiring OPAT, with 9 (3%) new VTE diagnoses.

201 (77%) episodes had a VTE risk assessment upon commencing OPAT, using the standard hospital-wide VTE risk assessment tool. Median number of VTE risk factors was 2 (range 0-5). 10 patients (4%) were prescribed VTE prophylaxis while receiving OPAT and 37 (14%) were fully anticoagulated for other reasons. The reason for not prescribing VTE prophylaxis was documented in 188 (75%) of 251 episodes: ambulatory n=144 (77%), already anticoagulated n=34 (18%), resolving infection n=5 (3%).

No new episodes of VTE occurred in the 90 days following OPAT therapy.

Conclusions: In this cohort, the incidence of VTE following OPAT was zero. The main limitations of the study were its small size and retrospective nature. Larger prospective studies are required to evaluate the risk of VTE in OPAT patients, in order to develop risk assessment tools appropriate to OPAT.

Presenter email address: alex.keeley@gmail.com
Importance: The incidence of acute viral and bacterial infections in children are often presented separately for different pathogens in epidemiological studies making direct comparisons of morbidity burden between pathogens difficult. Despite the modern immunisation program, pediatric emergency departments [ED] still have numerous annual visits. We aimed to demonstrate the current morbidity burden of microbes leading to ED visits in acutely ill children, using enhanced microbiological diagnostics.

Materials/methods: This population-based registry study used a cohort of all infants and children that visited Oulu University Paediatric ED, Finland, during one epidemiological year. We actively used multiplex respiratory viral and bacterial PCR (Allplex respiratory panel 4, Seegene Inc, detecting Chlamydia pneumoniae, Mycoplasma pneumoniae, Legionella pneumophila, Bordetella pertussis, Bordetella parapertussis, and an Anyplex II RV16 kit for 16 respiratory viruses) in all children with respiratory symptoms or fever of unknown origin. We reviewed all medical records and systematically collected data on bacterial samples, including urine, CSF, and blood culture samples, specific viral or bacterial PCR samples, such as HSV, VZV, enterovirus, Chlamydia pneumoniae and Bordetella pertussis. Serological data were collected for several pathogens including EBV, Mycoplasma pneumoniae and pathogens typical for Finland, Puumala hantavirus infection and tularemia. Specific clinical diagnoses for infectious diseases were recorded.

Results: In 4639 acutely ill children, infection diagnoses covered 55% of all ED diagnoses. The most common viral pathogens leading to ED visits were rhinovirus, accounting for 26% of visits due to respiratory symptoms, followed by adenovirus [10%), and RSV [7%]. Mycoplasma comparisons and Chlamydia pneumoniae caused 4% of respiratory infections. The most common bacterial pathogen was Escherichia coli, accounting for 4% for all ED visit due to any infection. Vaccine-preventable diseases, including rotavirus and pneumococcal sepsis, were rare findings during the study period. Full list of pathogens and their morbidity burden at pediatric ED will be presented.

Conclusions: Currently, rhinovirus and Escherichia coli account for the largest morbidity burden of infections leading to ED visits at a pediatric hospital. To reduce pediatric ED visits, future research should aim for preventing the most prevalent infections leading to ED visits in acutely ill children.

Global increase in antibiotic-resistant *Escherichia coli* in food-animals: a genomic public data approach

João Pires¹, Jana Huisman¹, Sebastian Bonhoeffer², Thomas Van Boeckel¹

¹ETH Zürich, Institute for Environmental Decisions, Zürich, Switzerland, ²ETH Zürich, Institute of Integrative Biology, Zürich, Switzerland

**Background:** The use of genomic technologies in antibiotic-resistance epidemiology is increasing the number of deposited genomes in public repositories. Globally, this data is largely unexplored due to its heterogeneous nature. This is especially problematic in food-animal data, where isolation sources and hosts are very diverse. We aim to query *Escherichia coli* genomes of food-animal origin in public repositories to perceive global resistance trends.

**Materials/methods:** A systematic search for *E. coli* genomes was performed in NCBI, PATRIC and EnteroBase. Metadata was standardized by assigning a food-animal host, an isolation location and date. Assemblies were downloaded and duplicates removed. Assemblies were screened for acquired resistance genes (ARG) with ResFinder and population structure was analyzed using cgMLST and ClermonTyping. The number of affected classes were calculated based on ARG's predicted phenotypes and modeled with a Poisson regression to understand resistance evolution overtime.

**Results:** A total of 7635 *E. coli* genomes had an identifiable food-animal host. Most genomes were recovered from cattle (51.8%), followed by poultry (26.4%) and swine (16.4%). The majority originated from USA (59.7%), and to lesser extent China (13.9%) and UK (11.6%). *E. coli* belonged mostly to B1 (43.4%) and A (22.9%) phylogenetic groups which have been widely associated with animals. Identified clonal complexes (CCs) were also consistent with previous reports: CC11 (14.7%), CC10 (10.5%) and CC155 (8.4%). 4496 genomes (59%) contained ARG, being the most frequent those conferring resistance to aminoglycosides (*aph(6)-Id*, 56.5%), sulphonamides (*sul2*, 53.8%), tetracyclines (*tet(A)*, 52.7%) and narrow-spectrum β-lactams (*bla*<sub>TEM-1</sub>, 34.4%). Extended-spectrum β-lactamases were identified in 18% genomes containing ARGs. Poisson regression indicated that the number of affected antibiotic categories increased between 1970 and 2018. This increase was more pronounced in poultry isolates (from 1 antibiotic to 5), than in swine (from 2 to 4) or cattle (from 1 to 2) isolates.

**Conclusions:** Our analysis yielded information consistent with reports on antibiotic-resistant *E. coli* from food-animals, highlighting the reliability of using public genomes in global surveillance. Moreover, our data suggests that resistance is increasing at different rates in the different animal hosts, indicating that measures to contain resistance spread need to be adapted to each food-animal species.

Abstract 3372

Effectiveness of the 23-valent pneumococcal polysaccharide vaccine against vaccine serotype pneumococcal pneumonia in adults

Hannah Lawrence*, Tricia Mckeever1, Caroline Trotter1, Chamira Rodrigo1, Priya Daniel4, Harry Pick1, Deborah Ashton1, Vadsala Baskaran1, Carmen Sheppard5, Seji Eletu5, David Litt5, Norman Fry6, Samuel Rose5, Wei Shen Lim1

1Nottingham University Hospitals NHS Trust - City Hospital Campus, Department of Respiratory Medicine, Nottingham, United Kingdom, 2University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom, 3University of Cambridge, Disease Dynamic Unit, Department of Veterinary Medicine, Cambridge, United Kingdom, 4University Hospitals of Derby and Burton NHS Foundation Trust, Department of Respiratory Medicine, Derby, United Kingdom, 5Public Health England, Respiratory and Vaccine Preventable Bacteria Reference Unit, London, United Kingdom, 6Public Health England, Immunisation and Countermeasures Division, London, United Kingdom

Abstract third-party references: Nottingham National Institute for Health Research Biomedical Research Centre [NIHR BRC]

Background: Vaccination with the 23-valent pneumococcal polysaccharide vaccine (PPV23) is available in the UK to adults aged 65 or over and those in a clinical risk group. We evaluated the vaccine effectiveness (VE) of PPV23 against vaccine-type pneumococcal pneumonia in a cohort of adults hospitalised with community-acquired pneumonia (CAP).

Materials/methods: This was a secondary analysis of data collected from a prospective cohort study of adults hospitalised with CAP from September 2013 to August 2018. A modified case-control test negative design was used. Pneumococcal serotypes were identified from urine samples using a multiplex immunoassay (Bio-plex24) or from blood cultures positive for Streptococcus pneumoniae. The exposure of interest was PPV23 vaccination at any time point prior to the index admission. The primary outcome was PPV23 serotype-specific pneumococcal pneumonia. A case was defined as pneumococcal pneumonia where a PPV23 vaccine serotype was detected; a control as non-PPV23 serotype pneumococcal pneumonia or non-pneumococcal pneumonia. Logistic regression was used to derive adjusted odds of vaccination in cases compared to controls; VE estimates were calculated as (1-odds ratio) x100%.

Results: Of 2357 patients, vaccine status was obtained from primary care records in 77.2% and self-reported in 32.8%. There were 717 PPV23 cases (48% vaccinated) and 1640 controls (54.5% vaccinated). Compared to controls, cases were a similar age (65.4 vs 66.5 years) with a better baseline performance status (p-trend=0.01), had higher severity disease on admission (26.2% vs 21.5% high severity by CURB65; p-trend=0.01), were less likely to have malignancy (7.3% vs 10.3%; OR 0.68 95%CI 0.49-0.95, p=0.02) or cardiac disease (12% vs 16.9%; OR 0.67 95%CI 0.52-0.87, p=0.003) but more likely to be alcohol dependent (3.6% vs 2.1%; OR 1.78 95%CI 1.06-2.99, p=0.03). The adjusted VE estimate against PPV23 serotype disease was 24% (95%CI 7 to 38%, p=0.01). When cases were restricted to serotypes in PPV23 but not in the 13-valent pneumococcal conjugate vaccine (PPV23/non-PCV13), the adjusted VE estimate was 29% (95%CI 4 to 45%, p=0.01).

Conclusions: PPV23 vaccination in line with current UK vaccine policy appears modestly effective against PPV23 serotype pneumococcal pneumonia. The estimated VE against PPV23/non-PCV13 serotypes was similar.

Abstract 3373

High-dimensional single cell analysis identifies unexpected distribution of T cell populations in liver transplanted HIV-positive patients

Erica Franceschini1, Sara De Biasi2, Margherita Digaetano1, Marianna Menozzi2, Giuseppe Tarantino1, Domenico Lo Tartaro2, Elena Bianchini2, Milena Nasi2, Mauro Codeluppi3, Giovanni Guaraldi2, Fabrizio Di Benedetto2, Andrea Cossarizza2, Cristina Mussini2

1azienda ospedaliero-universitaria di modena, Modena, Italy, 2university of modena and reggio emilia, modena, Italy, 3azienda ospedaliero-universitaria di modena, modena, Italy, *Azienda Unità Sanitaria Locale Piacenza, Piacenza, Italy

Background: In patients undergoing orthotopic liver transplant (OLT), immunosuppressive (IS) treatment is mandatory and infections are the leading cause of morbidity/mortality. Thus, it is essential to understand the functionality of cell-mediated immunity after OLT and which alterations can increase the infection risk. For this reason, we studied T cell subsets and functionality in these patients, comparing HIV positive and HIV negative patients.

Materials/methods: In each of these groups we enrolled 27 patients (total 108): HIV+ transplanted patients; HIV- transplanted patients; HIV+ non-transplanted patients; healthy subjects (CTR). Activation and differentiation of T cells were analyzed by 18-parameter polychromatic flow cytometry; cytokine production was assessed by intracellular staining after PBMC in vitro stimulation.

Results: Median age was 55 years (52-59), median CD4 count in HIV+ patients was 567/mcl (342-744), all had undetectable viral load. The majority of transplanted patients had tacrolimus as immunosuppressor (72%) with no differences between HIV+ and HIV- patients. No differences in tacrolimus plasma levels were observed between HIV+ and HIV- patients. Different distributions of CD4+ and CD8+ T cell subtypes were found among liver transplanted patients with or without HIV (figure 1). In particular, a cluster representing effector memory (EM) cells expressing PD1 was mostly abundant in non-HIV transplanted patients if compared to HIV positive transplanted patients. Regarding polyfunctionality, HIV negative transplanted patients were characterized by higher levels of CD4+ T cells able to produce at the same time IFN-g and TNF-a, showing a marked Th1-skewed phenotype.

Conclusions: HIV negative transplanted patients have more exhausted/immunosenescent T cells compared to HIV positive transplanted patients. This seems to indicate that patients who already experienced a form of immunosuppression due to HIV infection respond differently to anti-rejection therapy.

Abstract 3377

Distribution of capsular types among multi-resistant Klebsiella pneumoniae in the south of Spain by using a whole genome sequence-based solution

Lorena Lopez-Cerero1, Mikel Urrutikoetxea-Gutierrez2, Jesús Machuca Bárcena1, Mercedes Delgado-Valverde2, Inmaculada López-Hernández1, Felipe Fernández-Cuenca1, Álvaro Pascual Hernandez3

1University Hospital Virgen Macarena, Sevilla, Spain, 2University Hospital Basurto, Bilbao, Spain, 3University Hospital Virgen Macarena, Sevilla, Spain

Background: Polysaccharide capsule or K-antigen, a major virulence factor of K. pneumoniae, has long been used as the main method for typing and is the most promising antigen for a vaccine candidate for humans. Traditional serotyping could be inconsistent due to cross-reactivity. PCR-based genotyping using the wzy and wzc capsular genes yielded limited results due to modifications of the cps region in specific strains. A new whole genome sequencing (WGS) based tool, Kaptive web, has been recently developed for serotype prediction. The aim was to study the prevalence of K and O loci among multi-resistant isolates in our region with this typing method.

Materials/methods: After routine PFGE analysis of the strains remitted to the Regional Reference Laboratory of Andalucía [PIRASOA] (South of Spain) from 24 hospitals, 134 isolates as representative of every pulsotype were selected. Genomic DNA was extracted and sequenced via Illumina MiSeq and reads were de novo assembled using CLC genomics. Genome assemblies were uploaded to CARD and ResFinder for resistance determinants, and to MLSTFinder and Kaptive web for typing.

Results: At least one carbapenemase was identified in 81 (61%) isolates. The main carbapenemases were OXA-48 (28 isolates, 35%) and KPC-3 (27 isolates, 33%), followed by VIM-1 (10 isolates, 12%). Thirty-eight clones were identified in total and 5 STs were predominant (74%) among carbapenemase producers [ST512/KPC-3, ST307/OXA-48, ST307/KPC-2, ST15/OXA-48, ST15/VIM-1, ST11/NDM-7]. Good confidence level or better with K locus were obtained with 114 (86%) assemblies yielding 30 K and 9 O loci among carbapenemases producers. The predominant clones showed 10 K types and 5 O types: all ST512 and ST258 genomes were KL107/O2v2; ST307 genomes were KL102/O2v2 and KL10/O3/O3a; ST11 genomes were KL25/O5, KL24/O2v1 and KL27/O2v2; ST15 were KL64/O1v1, KL48/O1v1, KL28/O1v1 and KL112/O1v1.

Conclusions: 1) Kaptive web is an easy-to-use tool which simplifies the study of K-locus-related genes; 2) a reduced number of K-antigens were identified among the predominant carbapenemases producers in our region; 3) ST15 and ST11 harbored a higher diversity of K-loci than other carbapenemases-producing clones, reflecting the existence of multiple sub lineages dissemination.

Local signs at insertion site and prediction of catheter-related infections in short-term central venous and arterial catheters in the intensive care unit: individual findings from four multi-centre randomised controlled trials

Niccolò Buetti*, Stéphane Ruckly, Jean-Christophe Lucet, Lila Bouadma, Maité Garrouste-Orgeas, Carole Schwebel, Olivier Mimoz, Bertrand Souweine, Jean-François Timsit

Abstract 3378

1) University of Paris, INSERM IAME, DeSCID Team, Paris, France; 2) AP-HP, Infection Control Unit, Bichat-Claude Bernard University Hospital, 46 rue Henri Huchard, 75877, Paris Cedex, France; 3) Medical and Infectious Diseases Intensive Care Unit, AP-HP, Bichat-Claude Bernard University Hospital, 46 rue Henri Huchard, 75877, Paris Cedex, France; 4) Medical unit, French British Hospital, Levallois-Perret, France; 5) Medical Intensive Care Unit, Grenoble University Hospital, Grenoble 1 University, La Tronche, France, Grenoble, France; 6) Services des Urgences Adultes et SAMU 86, Centre Hospitalier Universitaire de Poitiers, 86021, France; 7) Medical ICU, Gabriel-Montped University Hospital, Clermont-Ferrand, France

Background: Little is known on the role of exit-site signs in predicting intravascular catheter infections. This study aimed to describe the association between local signs at the exit-site and catheter-related bloodstream infections (CRBSI) and which clinical conditions may predict CRBSIs if inflammation at insertion site is present.

Materials/methods: We used individual data from four multicenter randomized-controlled trials in intensive care units (ICUs) that evaluated various prevention strategies regarding colonization and CRBSI in arterial and central venous catheters. We used univariate and multivariate logistic models stratifying by center in order to identify variables associated with redness, pain, non-purulent discharge, purulent discharge and ≥1 local sign and subsequently evaluate the association between CRBSI and local signs. Moreover, we evaluated the role of the different local signs for developing CRBSI in subgroups of clinically relevant conditions.

Results: A total of 6,976 patients and 14,590 catheters (101,182 catheter-days) and 114 CRBSI (0.8%) from 25 ICUs with described local signs were included. Redness, pain, non-purulent discharge, purulent discharge and ≥1 local signs at removal were observed in 1,633 (11.2%), 59 (0.4%), 251 (1.7%), 102 (0.7%) and 1,938 (13.3%) episodes, respectively. The sensitivity of ≥1 local sign for CRBSI was by 40.4%. Positive predictive value (PPV) was low for redness (2%), pain (3%), non-purulent discharge (3%) and ≥1 local sign (2%), but increased for purulent discharge (12.7%). After adjusting on confounders, CRBSI was associated with redness, non-purulent discharge, purulent discharge and ≥1 local sign (Figure). The presence of ≥1 local sign was more predictive for CRBSI in the first 7 days of catheter maintenance (OR 6.30 vs. OR 2.61 for >7 catheter-days, p = 0.02).

Conclusions: This post-hoc analysis showed that local signs were significantly related to CRBSI in the ICU. In the first 7 days of catheter maintenance local signs were highly predictive for CRBSI.
Figure: Unadjusted and adjusted CRBSI-risk for the different local signs.

Legend. *For redness we adjusted for the following confounding factors: Age, SOFA score, duration of catheter maintenance, immunosuppression, insertion site. **For pain we adjusted for the following confounding factors: mechanical ventilation at insertion and vasopressor at insertion. ***For non-purulent discharge we adjusted for the following confounding factors: Age, duration of catheter maintenance, insertion site and mechanical ventilation at insertion. ****For purulent discharge we adjusted for the following confounding factors: duration of catheter maintenance and catheter type. *****For ≥1 local sign we adjusted for the following confounding factors: Age; SOFA score, immunosuppression, duration of catheter maintenance and insertion site. CRBSI: Catheter-related bloodstream infection.

1University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom, 2Oxford University Hospitals NHS Trust, John Radcliffe Hospital, Oxford, United Kingdom, 3PHE National Mycobacteria Reference Service, Birmingham Public Health Laboratory, Birmingham, United Kingdom

**Background:** Mycobacteria tuberculosis (MTB) is the leading cause of death from infection. Improved access to rapid diagnosis and antimicrobial resistance determination, such as by whole genome sequencing, is required in regions with the highest incidence. Our aim was to develop a simple, low-cost method of preparing DNA for MinION (Oxford Nanopore Technologies) sequencing direct from MTB positive clinical samples without culture. Commercial kits which increase cost, shipping, storage requirements, and protocol complexity were avoided.

**Materials/methods:** Simultaneous sputum liquefaction, heat-inactivation and sample enrichment for target DNA was performed in a novel thermo-protection buffer. The buffer was designed to protect DNA from thermo-degradation, by emulating intracellular conditions of hyperthermophiles. An equal volume of buffer (4M KCl, 0.05M HEPES buffer pH7.5, and 0.1% DTT) was added to sputum. Following liquefaction, samples were heated at 99°C for 30 minutes. Two wash/centrifugation steps were followed by DNA extraction, sequencing (one MinION R9.4.1 flow cell/sample) and assembly against a reference. GeneXpert (Cepheid) and Microscopy (ZN/auramine stain) data were collected.

**Results:** Initial experiments confirmed that KCl buffer protected Mycobacteria DNA (extracted and intracellular) during heating at 99°C for 30 minutes. Human DNA degraded faster than Mycobacteria DNA, therefore target DNA content was improved. Standardised, mock clinical samples comprising infection-negative sputum spiked with BCG at 0-10⁷/ml, underwent direct-from-sample sequencing in four replicate experiments. The limit of detection (LOD) was 10⁵ BCG cells/ml, with 31, 49, 51, and 59 MTB complex reads (Figure). The GeneXpert LOD for the same samples was 10² and Microscopy 10³. Maximal genome coverage (>97% at 5x depth) was achieved at 10⁴ BCG cells/ml; >91% coverage (1x depth) at 10³ BCG cells/ml.

Ten MTB positive clinical samples were sequenced. Initial sample volumes ≥1ml yielded higher average depth of coverage (range 5.89-45.01); ≤0.5ml less (0.55-4.75). All six samples ≥1ml yielded >99% 1-fold genome coverage and 5/6 yielded >98.7% 5-fold genome coverage. Four of these were high titre by GeneXpert/microscopy, two low. The depth across 22 antimicrobial susceptibility genes mirrored the average, confirming potential for resistance prediction.

**Conclusions:** Direct-from-sample MinION sequencing of MTB genomes can be achieved from 1ml positive sputum, using a low cost thermo-protection buffer.

**Invasive aspergillosis by cryptic Aspergillus species in a 700-bed third level hospital**

Mariana Fernandez*1, Izaskun Alejo1, Elisa Rubio García1, Celia Cardozo1, Pedro Puerta1, Miriam Garrido1, Miriam López1, Ana Alastruey-Izquierdo2, Cristina Pitart1, Carolina Garcia Vidal1,3,4, Francesc Marco Reverte1,3,5

1Hospital Clínic de Barcelona, Barcelona, Spain, 2Instituto Carlos III, Prado del Rey, Spain, 3University of Barcelona, Barcelona, Spain, 4Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 5ISGlobal, Barcelona, Spain

**Background:** Aspergillus species are the moulds most commonly involved in invasive fungal infection. These infections are usually severe and have emerged as a significant cause of morbidity and mortality. Cryptic species retrieved from clinical samples ranged from 12 to 14% according to two multicenter studies of filamentous fungi and antifungal resistance in Spain (FILPOP), and were generally more resistant to commonly used antifungal agents. The objective of this study was to describe the frequency, clinical and microbiological characteristics and outcomes of invasive aspergillosis caused by cryptic species in our center.

**Materials/methods:** We retrospectively identified all microbiologically documented cases of aspergillosis in our center from January 2013 to December 2018. Information about the patient's demographics, clinical data and received treatment was obtained from their medical records. The definitive species identification of the clinically significant isolates was achieved by sequencing methods (ITS region and β-tubulin).

**Results:** A total of 629 Aspergillus spp were recovered, from 489 patients. One hundred-nine of these episodes were clinically relevant, whereas 321 were considered as colonizations/contaminations. We identified 10 cryptic species, representing 9.17% of all the clinically relevant isolates, namely: Aspergillus arcoverdensis [2], Aspergillus lentulus [2], Aspergillus ellipticus [2], Aspergillus alliaceus [1], Aspergillus nomius [1], Aspergillus tubingensis [1] and Aspergillus amstelodami [1]. All patients were males, three patients presented HIV infection, two malignant tumors, one solid organ transplantation, one previous pulmonary cavity, one hematologic disease and one local corticoid injection. 40% of patients died from the fungal infection.

**Conclusions:** The frequency of cryptic species in our center was 9.17%. Most patients had some type of immunosuppression and the mortality rate was 40%. The identification of cryptic species is important, not only to improve the appropriateness of antifungal treatment but also to increase the knowledge about these new species.

Abstract 3384

Jack Kowalik*1, Angela Blake1, Rachel Russell1, Dragos Mircea2, David Leonard2, Nicholas Meadows2

1Pfizer Ltd, Pfizer Ltd, Tadworth, United Kingdom, 2PricewaterhouseCoopers LLP, London, United Kingdom

Background: With publication of the ‘value assessment frameworks for antibiotics’ by the Office for Health Economics (OHE) and others, it has become widely accepted that antibiotics are undervalued when assessed through existing health technology appraisal processes. Therefore, the inclusion of a more complete set of value elements is required when valuing an antibiotic to ensure the wider societal value of an antibiotic is captured.

Materials/methods: The value elements considered within this analysis are enablement-, insurance-, and productivity-value;

1) Insurance value - withholding wider use of an antibiotic, and reserving it for tackling resistant infections, thus providing insurance against possible future outbreaks of infections with resistant pathogens.

2) Enablement value - benefits associated with enabling other treatments or procedures to take place, e.g., surgical and medical procedures that may not be possible if antimicrobials were not available to prevent or treat surgical site or post-procedure infections.

3) Productivity benefits associated with having a larger, more active workforce, due to the changes in the mortality and in-hospital morbidity associated with infections.

Novel methodical approaches have been explored for each value element with methods proposed created through collaboration and expert elicitation from several stakeholder groups, including; microbiologists, actuaries, economists, life science experts and medical doctors across various specialty areas including; oncologists, neurologists, generalist-, cardiac- and orthopaedic-surgeons.

Results: The outlined methods build on the work from OHE and others, demonstrating a quantifiable output can be determined and associated to the antibiotic included within the modelling. Through these methods we begin to capture the additional benefits that a new antibiotic can bring to the healthcare system and patients. Work is to be continued on both insurance value, whereby a stochastic modelling approach will be taken, and enablement value, as we build this into a dynamic transmission model.

Conclusions: Value alone will not tackle the wide-reaching concerns of antimicrobial resistance, continued efforts on stewardship and building of R&D initiatives need to be increased. However, these methods proposed aim to accelerate the development of quantifying these value elements, building a more comprehensive picture of the value antibiotics bring to society.

MBT STAR-Carba assay: going beyond the routine protocol
Michał Złoch*, Markus Peer², Katrin Sparbier², Markus Kostrzewa³, Bogusław Buszewski³

¹Nicolaus Copernicus University in Toruń, Centre for Modern Interdisciplinary Technologies, Toruń, Poland, ²Bruker Daltonik GmbH, Bremen, Germany, ³Nicolaus Copernicus University in Toruń, Chair of Environmental Chemistry and Bioanalytics, Faculty of Chemistry, Toruń, Poland

Abstract third-party references: Supported by SONATINA 2 project No. 2018/28/C/ST4/00434 from National Science Centre, Poland.

Background: The increasing frequency of resistance against carbapenems represents a serious threat to public health. Therefore, the development of new techniques for rapid detection of carbapenemase-producing bacteria is globally of great importance. A promising tool could be the monitoring of carbapenemase hydrolytic activity by MALDI-TOF/MS. The main goal of our study was to evaluate the effect of bacterial suspension density and incubation time on the sensitivity of the MBT STAR®-Carba kit (Bruker Daltonics) for the detection of hydrolytic activity of bacteria possessing different classes of carbapenemases.

Materials/methods: Hydrolytic activity was investigated in 12 Enterobacteriaceae and 3 Pseudomonadaceae strains expressing various carbapenemases (e.g. KPC, NDM-1, OXA-type) using in parallel the MBT STAR®-Carba kit according to the manufacturer’s protocol with 1 µl loop of material as well as applying an in-house method with different bacterial suspension concentrations (1–7 McFarland) and incubation times (1–30 minutes). Samples were analyzed via microflex LT/SH instrument (Bruker Daltonics) and MBT Compass platform with MBT STAR-BL Module (Bruker Daltonics). Results were analyzed based on the level of antibiotic hydrolysis (normalized logRQ value) dependent on the density of the bacterial suspension, kinetic curves as well as on grouping of the strains in principal component analysis (PCA).

Results: Analysis revealed a class dependent effect of bacterial density on the normalized logRQ values. In general, Pseudomonadaceae strains demonstrated relatively lower hydrolytic activity and distinct normalized logRQ/suspension density correlations compared to the Enterobacteriaceae members. Moreover, a significant variation in incubation time needed to detect hydrolytic activity was noted. PCA analysis also revealed a carbapenemase class dependent effect, grouping strains mostly into class D and class A harboring strains. Nevertheless, in almost all cases a present hydrolytic activity was obtained after less than 30 minutes of incubation.

Conclusions: The MBT STAR®-Carba assay represents a very rapid and highly sensitive but also robust tool for detection of a broad spectrum of carbapenemase-producing bacteria. Moreover, besides the standard workflow, the application of a defined suspension density can increase knowledge about differences in the antibiotic hydrolysis level of an investigated strain. Further, it might enable to shorten individual incubation times and thus the whole analysis.

Abstract 3386

The antimicrobial susceptibility profile and prevalence of known anaerobic resistance genes in less common anaerobic Gram-negative bacteria, isolated in the Netherlands

Kathleen Boiten1*, Willy Baas1, Pauline Buijs1, John W. A. Rossen1, Alida Veloo1

1University of Groningen, University Medical Center Groningen, Department of Medical Microbiology and Infection prevention, Groningen, Netherlands

Background: In the past years antimicrobial resistance among anaerobes, as in aerobes, is increasing. Well studied is the increase of resistance in the Bacteroides group, Clostridium spp. and Prevotella spp. Studies focusing on the antimicrobial resistance in less common gram-negative anaerobes, e.g. Fusobacterium and Bilophila, are scarce. In this study we assessed the antimicrobial susceptibility profile and the prevalence of antimicrobial resistance genes among less common gram-negative anaerobes.

Materials/methods: In this study, a total of 163 anaerobic gram-negative anaerobes were included, covering the genera Alistipes spp. (n=7), Bilophila spp. (n=41), Dialister spp. (n=10), Fusobacterium spp. (n=101) and Sutterella spp. (n=4). All isolates were consecutively isolated in the years 2015-2018 from a variety of human clinical samples. Isolates were identified using MALDI-TOF MS. MIC values for different antibiotics were determined using E-test and interpreted according EUCAST guidelines. Nitrocefinase discs were used to detect the production of beta-lactamases. A targeted PCR, using specific primers, was used to detect the presence of resistance genes (cfxA, ermF, nim and tetQ).

Results: Resistance to amoxicillin was detected in 58 of the 163 (36%) tested isolates, ranging from >90% in Bilophila isolates to 0% in Dialister isolates, while 10 of the 163 (6%) isolates were shown to produce beta-lactamase. All Sutterella isolates (n=4) were resistant to clindamycin and 3 were resistant to metronidazole. The tetQ gene was detected in 2 of the 7 (29%) Alistipes isolates. However, resistance to tetracycline was not detected. No cfxA, ermF or nim genes were detected in all tested isolates.

Conclusions: No correlation was observed between phenotypic resistance and the presence of a known antimicrobial resistance gene nor between amoxicillin resistance and the production of beta-lactamase. This might suggest that novel antimicrobial resistance mechanisms or other unknown resistance mechanisms are present in the tested isolates. Whether the observed resistance is intrinsic needs to be assessed. Whole genome sequencing might help understanding the origin of the detected antimicrobial resistance.

Minimum Inhibitory Concentration distributions and putative new resistance mechanisms for mecillinam and trimethoprim in *Staphylococcus saprophyticus*

Filip Jansåker*1,2, Jonathan Monk3, Opeyemi U. Lawal4,5, Sarah Mollerup1, Jesper Iversen1, Maria Luisa Goncalves6, Paula Paixão7, Elsa Filipa Pasmal De Almeida Goncalves8, Cristina Toscano8, Joanna Empel9, Małgorzata Brzozowska9, Mª Ángeles Domínguez Luzon10, Maria Joao Fraqueza11, Herminia De Lencastre5,12, Maria Miragaia4,1, Henrik Westh1, Jenny Knudsen2

1Hvidovre Hospital, Department of Clinical Microbiology, Hvidovre, Denmark, 2Rigshospitalet, Department of Clinical Microbiology, København, Denmark, 3University of California San Diego, Department of Bioengineering, La Jolla, United States, 4ITQB NOVA, Laboratory of Bacterial Evolution and Molecular Epidemiology, Oeiras, Portugal, 5ITQB NOVA, Laboratory of Molecular Genetics, Oeiras, Portugal, 6SAMS Hospital, Lisboa, Portugal, 7Hospital da Luz Lisboa, Lisboa, Portugal, 8Hospital Egas Moniz, Lisboa, Portugal, 9Narodowy Instytut Leków, Warszawa, Poland, 10Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain, 11Faculdade de Medicina Veterinária, CIISA - Centro de Investigação Interdisciplinar em Sanidade Animal, Lisboa, Portugal, 12The Rockefeller University, The Laboratory of Microbiology and Infectious Diseases, New York, United States

**Background:** *Staphylococcus saprophyticus* is the second most common bacteria causing uncomplicated urinary tract infections (UTI). As a Gram-positive coccus it is considered non-susceptible to the beta-lactam mecillinam, with no defined breakpoint and minimum inhibitory concentration (MIC) distribution from 8-256 mg/L. However, this consideration does not correlate with clinical outcome, as cure rates with pivmecillinam are high. With this study we wanted to provide a more comprehensive MIC distribution analysis of mecillinam for *S. saprophyticus* and investigate any potential resistance mechanisms. The MIC distribution for trimethoprim was also investigated, as no data were available at the time.

**Materials/methods:** 117 isolates representative of *S. saprophyticus* population structure described in a previous study were included: 113 isolates were from human UTI (Denmark, 90; Poland, 1; Spain, 9; Portugal, 13) and four from veterinary sources (Portugal). E-tests were used to determine MICs. All isolates had been whole-genome sequenced and a machine-learning approach was used to identify 198 genetic features that distinguish mecillinam resistant isolates with MIC≥256 from isolates with MIC<256.

**Results:** For mecillinam, MICs ranged from 4 to ≥ 256, with a binary clustering around 32 and ≥256, respectively (figure 1). Only one isolate was below the currently considered breakpoint (8 mg/L) of mecillinam for Enterobacterales. Some top genetic features for isolates with MIC≥256 include mutations in coding regions for proteins involved in cysteine metabolism, mecA presence (n=3), regulatory regions for glutamine transporters, and the multidrug resistance protein Ykkc. For trimethoprim, the MICs clustered around 0.5 and only six isolates had a MIC above the currently considered breakpoint (2 mg/L) for Enterobacterales. Of these, three had the previously described trimethoprim resistance gene *dfrG*.

**Conclusions:** All but six investigated isolates could be considered susceptible to trimethoprim. The clinical success often seen after pivmecillinam treatment of uncomplicated UTI caused by *S. saprophyticus* infections could be explained by the binary clustering of MICs found here, as the mecillinam urine concentration (about 200 mg/L) surpasses the former clustering group but not the latter, during conventional pivmecillinam therapy.

Figure 1. MIC distribution of mecillinam and trimethoprim in 117 *S. saprophyticus* isolates
Abstract 3389

**Optimising the treatment of upper respiratory tract infections and tackling antibiotic resistance: effect of online education on physician knowledge and confidence**

Julia Duffey*1, Valerie Lund2, Daryl Hoban3, Bruce Rubin4, Shanti Voorn5

1Manifold Medical Communications, Matlock, United Kingdom, 2University College London, London, United Kingdom, 3University of Manitoba, Winnipeg, Canada, 4Virginia Commonwealth University, Richmond, United States, 5Medscape, New York, New York, United States

Abstract third-party references: Medscape Education

**Background:** Macrolides are established and widely used for treating a range of upper respiratory tract infections (URTIs). We assessed if online medical education for pulmonologists, paediatricians and primary care physicians could improve knowledge regarding optimal use and effectiveness of macrolides in the treatment of URTIs [including otitis media and bacterial rhinosinusitis] and best practice in antibiotic stewardship. We also assessed physician confidence in their ability to optimally select the appropriate macrolide for URTIs.

**Materials/methods:** Online independent CPD program featuring 4 short sequential expert video commentaries. Repeated pairs of pre- and post-assessment questions with data assessed by Pearson's Chi-Square ($P<0.05$ statistically significant) and Cramer's V [modest impact 0.1; extensive impact $>0.26$]. Data collected 6th June to 29th October 2019.

**Results:** 5,567 physicians participated from Asia, Latin America, Middle East/North Africa and Australia/New Zealand. Overall, there was a 100% relative increase ($P<0.001$) with extensive impact in physician knowledge gains. The activity significantly improved knowledge in all aspects of macrolide use and resistance in URTIs (Table). Significant differences were also reported in the average confidence shift ($P<0.001$) and the shift to mostly or very confident ($P<0.01$) in the physician's ability to select the optimal and appropriate antibiotic for URTIs.

Abstract 3397

**Qualitative detection of OXA-23-like, OXA-24-like and OXA-58-like carbapenemases from Acinetobacter species by real-time PCR**

Massimo Mentasti1, Kerry Prime1, Kirsty Sands2, Swati Khan1, Mandy Wootton*1

1Public Health Wales N H S Trust, Cardiff, United Kingdom, 2Cardiff University, School of Medicine, Cardiff, United Kingdom

**Background:** Carbapenemase producing Acinetobacter species, especially Acinetobacter baumannii, are often associated with treatment failures and hospital outbreaks, consequently rapid and reliable detection of specific resistance markers is paramount. The most common carbapenemase found in A. baumannii, namely OXA-23-like, OXA-24-like and OXA-58-like, belong to the Oxacillinase group (Class D β-lactamases) which is notoriously difficult to identify phenotypically due to the lack of specific inhibitors, therefore a multiplex real-time PCR assay was designed and validated.

**Materials/methods:** All available variants of the above three carbapenemases were downloaded [as of November 2019] from the Beta-Lactamase DataBase (http://bldb.eu/) aligned with Clustal Omega and oligonucleotides designed using Primer-BLAST. Monoplex assays were optimized on the Rotor-Gene Q (Qiagen) using the Rotor-Gene Multiplex PCR Kit (Qiagen) and then combined into a 4-plex assay that included an internal control to discount inhibition. A panel of 120 previously characterised strains (18 different species in total) carrying a total of 20 OXA-23-like, 17 OXA-24-like and 20 OXA-58-like markers plus a wide range of different β-lactamases, often in combination, was tested to determine assay sensitivity and specificity. DNA was extracted by heat treatment (10min at 100°C) and extracts diluted 1:20 in nuclease-free water to avoid PCR inhibition.

**Results:** The in silico approach allowed to design oligonucleotides in conserved regions of the OXA-24-like and OXA-58-like alignments. Among the 42 OXA-23-like variants, a SNP was identified in OXA-27, OXA-166, OXA-811, OXA-812 and OXA-816 (five different SNPs in total); none among these variants was available for in vitro analysis, however given the SNPs location (i.e. non-3’ end of binding sites) they should still be detected. Expected results were obtained for all 120 strains (100% sensitivity and specificity) and for all possible target combinations using A. baumannii NCTC 13301 (OXA-23), A. baumannii NCTC 13302 (OXA-24) and A. baumannii NCTC 13305 (OXA-58). Cross-reaction with other resistance markers, including Oxacillinases, was not observed. Inhibition was also not observed.

**Conclusions:** The assay is easy to perform with results available in ca. 70 minutes (plus the heat-inactivation time). It enables unequivocal detection and differentiation of OXA-23-like, OXA-24-like and OXA-58-like carbapenemases even when more than one resistance marker is simultaneously present.

**Presenter email address:** mandy.wootton@wales.nhs.uk
**Abstract 3398**

**Comparison of environmental Legionella pneumophila and Legionella spp. detection from water and swab samples by culture and qPCR**

Santina Castriciano*1, Michela Savoldi Boles2, Cristina Pilotti2, Marianna Martinelli3, Rosario Musumeci3, Clementina Cocuzza3

1Copan Italia Spa, Brescia, Italy, 2Bioside s.r.l., Lodi, Italy, 3Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy

**Background:** Water is the recommended sample for environmental Legionella spp. detection by culture and molecular tests. Copan SRK™ environmental collection kit, a FLOQSwabs® and a medium tube, has been previously validated for Legionella pneumophila viability at room temperature (RT) for 48hrs and at 2-8°C for 72hrs by culture and different molecular assays. The objective of this study was to compare water to swabs collected at the water source using SRK™ environmental collection kit, for the detection of Legionella spp. (LS) and Legionella pneumophila (LP) by culture and qPCR.

**Materials/methods:** Paired water and SRK™ swabs samples (N= 361) were collected in duplicate from wells (n=85), house water (n=268), and cooling towers (n=8). Two liters of water were collected and SRK™ sampling was performed by swabbing the water source and storing the FLOQSwab® in the SRK™ medium tube (Copan). One liter of water was processed for culture following SOP. The other liter was filtered, nucleic acids extracted using the DNA Extraction Kit I (Bioside) and analyzed with the qualyfast® Legionella qPCR (Bioside) for simultaneous detection of LS and LP. Swab samples were vortexed and 200μl of SRK™ medium were plated on BCYE agar and incubated at 32°C for 10 days. Nucleic acids were extracted from 200μl of SRK™ medium and 5μl of extract analyzed using qualyfast® Legionella qPCR (Bioside).

**Results:** Concordant results were obtained from 98.9% (357/361) of paired swab and water samples using culture. 81 resulted positive (41 LS and 40 LP) and 276 were negative. Contrarily, 4 swabs resulted positive (3 LS, 1 LP) with paired negative water. qPCR detected 136 positives in both sample types (93 LS, 43 LP) and 219 negatives. Six SRK™ swabs resulted positive (4 LS, 2 LP) with corresponding negative water.

**Conclusions:** Data obtained in this study demonstrates that swabs samples collected with the SRK™ environmental kit detected the same number of positive Legionella spp and Legionella pneumophila as in paired water samples by both culture and qPCR using qualyfast® Legionella assay. SRK™ environmental kit collected samples are easier to process compared to water and can be stored for up to 72 hrs. before testing.

**Presenter email address:** santina.castriciano@copangroup.com
Abstract 3402

Evaluation of CARBA PAcE, a novel rapid test for detection of carbapenemase-producing Enterobacterales
Janko Sattler*1,2, Anne Brunke1,2, Axel Hamprecht1,2,3
1University of Cologne, University Hospital, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research, Partner Site Bonn-Cologne, Cologne, Germany, 3University of Oldenburg, University Hospital, Institute for Medical Microbiology and Virology, Oldenburg, Germany

Background: Rapid detection of carbapenemase producing Enterobacterales (CPE) is indispensable for patient management and infection control. Today, there is an increasing number of commercially available tests kits, which differ strongly in accuracy and turnaround time. Recently, MAST CARBA PAcE was released, a new colorimetric test for rapid detection of CPE with a turnaround time of only 10 minutes. This study evaluates the performance of this test against the well-established zinc supplemented carbapenemase inactivation method (zCIM).

Materials/methods: CARBA PAcE (Mast Diagnostica, Reinfeld, Germany) and zCIM (in-house) were challenged with 108 molecularly characterized CPE and 46 non-CPE controls. CARBA PAcE was performed according to manufacturer’s recommendations. zCIM was performed as previously described using tryptic soy broth, but with a higher zinc concentration (1.5 mM ZnSO4).

Results: CARBA PAcE correctly detected 76 (70%) CPE when isolates were grown on Mueller-Hinton agar (MHA). Forty-two (91%) non-CPE were tested correctly negative. False negative samples were additionally tested after cultivation on Columbia blood agar, which improved the overall sensitivity to 87% and the sensitivity for class B carbapenemases from 66% to 92%. Using zCIM 104 (96%) CPE and 46 (100%) non-CPE were correctly classified (Table 1).

Table 1: Test sensitivity of CARBA PAcE with isolates from Mueller-Hinton agar and zCIM according to carbapenemase type

Conclusions: To the best of our knowledge, this is the first systematic evaluation of the CARBA PAcE assay. A big advantage is the low turnaround time of 10 minutes, making it the most rapid colorimetric test available. We strongly recommend to perform this test on isolates cultured on blood agar, as the sensitivity is insufficient when MHA was used, especially for metallo-beta-lactamase producing isolates. GES and IMI were only insufficiently detected by CARBA PAcE. The zCIM showed an excellent sensitivity and specificity, but at the cost of a rather long turnaround time of about 20 hours.

Detection of transferable CTX-M-producing multidrug-resistant Enterobacteriaceae from public transportation in China

Xin Wen*1,2, Mohamed El-Sayed Ahmed1,2,3, Guanping Chen*, Cong Shen1,2, Zihan Zhao1,2, Wanfei Liang1,2, Yanxian Yang1,2, Guo-Bao Tian1,2

1Sun Yat-sen University, Department of Microbiology, Zhongshan School of Medicine, Guangzhou, China; 2Sun Yat-sen University, Key Laboratory of Tropical Diseases Control, Ministry of Education, Guangzhou, China; 3Miss University for Science and Technology (MUST), Department of Microbiology and Immunology, Faculty of Pharmaceutical Sciences and Drug Manufacturing, Cairo, Egypt; 4Sun Yat-sen University, School of Medicine, Guangzhou, China

Abstract third-party references: Department of Microbiology, Zhongshan School of Medicine, Sun Yat-sen University

Background: Multidrug resistance (MDR) in bacteria is a serious public health problem. In China, ∼248 million people are in daily direct contact with public transportation. However, no focus has been given to transportation as a source of acquisition of bacteria encoding Extended-Spectrum β-Lactamases (ESBLs). Herein, for the assessment of the blaCTX-M transmission, we investigated CTX-M-producing MDR Enterobacteriaceae from public transportation and explored their genomic characteristics.

Materials/methods: A total of 800 non-duplicated surface samples were collected from public transportation in Guangzhou, China, from October 2016 to April 2017. Polymerase chain reaction (PCR) assays were performed to detect blaCTX-M genes. Minimum inhibitory concentrations were determined by broth microdilution method. Liquid mating was performed to check the transferability of blaCTX-M genes. S1-nuclease digestion and pulsed-field gel electrophoresis (S1-PFGE) and Southern blotting were performed with blaCTX-M carrying plasmids. Whole-genome sequencing (WGS) was performed.

Results: Out of 800 surface samples, 737 (92.13%) were successfully cultured and screened for the different blaCTX-M variants using PCR and Sanger sequencing. Out of 737 samples, 30 (4.07%) were confirmed as CTX-M positive isolates. MALDI-TOF identification and 16S rDNA sequencing revealed that 22/30 (73.33%) isolates were Escherichia coli, 6/30 (20%) were Klebsiella pneumoniae, and 2/30 (6.67%) were Leclercia adecarboxylata. WGS analysis identified four subtypes of CTX-M including; CTX-M-55 (7/22 E. coli isolates), CTX-M-65 (7/22 E. coli isolates), CTX-M-190 (4/22 E. coli isolates), and CTX-M-14 (4/22 E. coli and 2 Leclercia adecarboxylata isolates), and CTX-M-3 (6 K. pneumoniae isolates). In silico MLST analysis identified nine sequence types (STs), out of them, one is a novel ST related to the K. pneumoniae isolates. Antibiotic resistance genes were identified using ResFinder3.2, where 27 resistant genes were detected. S1-PFGE, Southern blotting, and WGS revealed a ~220kb IncHI2 plasmid carrying CTX-M-65 (7/22 E. coli isolates) and a ~65kb IncI2 plasmid carrying CTX-M-190 (4/22 E. coli isolates), where both were transferable.

Conclusions: These results suggest that CTX-M-producing bacteria are circulating within the public transportation system during the time of our analysis, indicating that these bacteria are likely to transfer to humans through public transportsations that may act as a potential reservoir for the transferable ESBLs genes.

Evaluation of neuro-filament light chain as a biomarker for neuronal damage in experimental pneumococcal meningitis

Ngoc Dung Le*, Denis Grandgirard1, Jens Kuhle2, David Leppert2, Stephen L. Leib1

1University of Bern, Institute for Infectious Diseases, Bern, Switzerland, 2University Hospital and University of Basel, Neurologic Clinic and Policlinic, Departments of Medicine, Biomedicine and Clinical Research, Basel, Switzerland

Background: Pneumococcal meningitis (PM) is associated with an excessive neuroinflammation causing injury to the brain and the inner ear, leading to neurological sequelae. Neurofilaments are intermediate filaments, which provide structural support for the neurons. Upon neuronal injury, neurofilament light chain proteins (NFL) are released into blood and cerebrospinal fluid (CSF). Quantification of NFL allows the detection of pathologies in various neurological diseases including multiple sclerosis and traumatic brain injury. Since PM is associated with neuronal injury, this study characterizes NFL levels in CSF and serum in the course of experimental PM.

Materials/methods: Eleven-day old Wistar rats were infected intracisternally with 6.25 ± 5.3 x 10^3 CFU S. pneumoniae (n=20) or saline (n=8). All animals received ceftriaxone (100 mg/kg, i.p.) at 18 hours post infection (hpi). CSF and blood were sampled at 18 and 42hpi, centrifuged, supernatants were collected and stored at -80°C. NFL levels in CSF and serum were measured on a Simoa HD-1 instrument (Quanterix) using the capture monoclonal antibody (mAB) 47:3 and the biotinylated detector mAB 2:1 from UmanDiagnostics.

Results: First, we assessed whether intracisternal puncture caused an artificial increase of NFL. Results ruled out this possibility, both in CSF or serum. At 42hpi, CSF and serum levels of NFL correlated significantly in infected and mock-infected animals (p<0.0001). NFL concentrations in CSF were approximately 35 times higher than in serum. Infected animals revealed higher NFL levels in serum at 42hpi compared to mock-infected animals (p=0.0456). In addition, infected animals displayed a significant increase (p<0.0001) of NFL level in serum between 18hpi to 42hpi while no increase was observed in mock-infected animals.

Conclusions: NFL has recently been established as a biomarker in several neurological diseases. Given the strong correlation of NFL levels in CSF and serum, NFL determination in serum would be more clinically applicable and less invasive. This study showed that NFL level in serum significantly increases during the course of PM and therefore supports its use as a biomarker for neuronal damage in this disease.

Whole genome sequence analysis of *Klebsiella pneumoniae* isolates belonging to sequence type 231 harbouring rapidly disseminating *bla*OXA-232 located on ColKP3 plasmid in Kuwait

Amani Al Fadhli*1, Wafaa Jamal1, Vincent O. Rotimi1

1Kuwait University, Faculty of Medicine, Jabriya, Kuwait

**Background:** The commonly encountered carbapenem-resistant Enterobacteriaceae (CRE) isolates responsible for most infections/colonization in Kuwait have been known to harbor *bla*NDM, *bla*KPC, *bla*VIM, and *bla*OXA-48 genes. Recently, a shift to OXA-48-like-producing strains such as OXA-181, has become prominent. OXA-232, another variant of OXA-48 carbapenemases have not been reported previously in Kuwait. The aim was to determine the genetic backbone of *K. pneumoniae* harboring *bla*OXA-232 genes, isolated from the rectal swabs of ICU patients in Mubarak Al Kabeer hospital.

**Materials/methods:** A total of 41 carbapenem-resistant *K. pneumoniae* (CRKP) were isolated from the rectal swabs of ICU patients during a period of 1 year. They were identified by VITEK-2 and their susceptibility to various antibiotics determined by E-test. DNA was extracted from 24-h-old culture using qiaamp DNA mini kit. The isolates were subjected to whole genome sequencing using an Illumina MiSeq platform. The genome was annotated using Rapid Annotation Subsystems Technology (RAST). Genome sequences were screened for presence of insertion sequences, mobile genetic elements, plasmid replicons, resistance genes and Multi-Locus Sequence typing (MLST) using different software tools.

**Results:** Two isolates (4.9%) were OXA-232 producers and harbored several β-lactamase genes, including *bla*CTX-M-15, *bla*TEM-1b, *bla*SHV-100, *bla*OXA-232 in conjunction with many other resistance genes such as *acc*(6′)-lb-cr, *qnr*S1, *ARR*-3, *sul*1, *aadA*2, *erm*[B], *mph*[A], *dfr*A12, *cat*A1, *aadA*2, *aqpA* and *aqpB* that confer resistance to aminoglycosides, chloramphenicol, erythromycin, fluoroquinolones, rifampicin and sulfonamides. Seven replicon plasmid types were detected in both isolates (MK-4 and MK-5), namely Col (BS51 2), Col4401, ColKP3 that carried carbapenemase gene *bla*OXA-232, IncFIA, IncFIB (pQil), IncFII(K) and IncFII (pAMA1167-NDM-5), with one extra (IncX4) in MK-5. Sequence type ST231 was confirmed in the two isolates. Insertion sequences, ISEcp1, ISKpn2, ISKpn6, ISKpn7, ISKpn13, ISKpn14, ISKpn21, ISKpn25, ISKpn26, ISKpn28, ISKpn31, ISKpn34, ISKpn38, ISKpn37, ISKpn40, ISKpn41, ISKpn49 ISKpn50, and transposons Tn903 and Tn3, were present. The *bla*OXA-232 –plasmid was 100% identical to the plasmid Pkp3-A bearing the *bla*OXA-181.

**Conclusions:** This represents the first report of CRKP harboring *bla*OXA-232 in Kuwait. This gene, being carried on ColKP3 plasmid, with insertion sequence ISEcp1 upstream, may silently spread amongst the Enterobacteriaceae populations with potentially serious clinical management challenge.

Abstract 3412

**MRSA transmission and hospital-acquired bacteraemia in a neonatal intensive care unit in Greece**

Georgios Kalogerias1, Maria Militsopoulou2, Elisavet Bouzavoutoglou1, Anastassios Doudoulakakis1, Nikolaos Giormezis2*, Angeliki Nika3, Anastassia Papaioannou4, Maria Tsolia3, Iris Spiliopoulou2, Evangelia Lebessi1

1Department of Microbiology Children’s Hospital “P & A. Kyriakou”, Athens, Greece, 2Department of Microbiology, School of Medicine, University of Patras, Patras, Greece, 3Neonatal Intensive Care Unit, 2nd Department of Paediatrics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 4Infection Control Committee P & A. Kyriakou Children’s Hospital, Athens, Greece

**Background:** Staphylococcus aureus is a common pathogen causing hospital acquired infections (HAIs) in neonates. In this study, the epidemiology of methicillin-resistant S. aureus (MRSA) transmission and infections in a 30-bed, level III university-affiliated neonatal intensive care unit (NICU) located in a children’s hospital was investigated.

**Materials/methods:** Surveillance cultures (throat and rectal samples) were routinely collected on admission and weekly thereafter to identify multi-resistant colonized neonates in order to apply contact precautions. Surveillance and clinical care cultures of neonates that grew MRSA were retrospectively reviewed for the period 2014-2018, after a case outbreak of MRSA infections from August 2017 to January 2018. Genes encoding Panton-Valentine Leukocidin (lukS/lukF-PV, PVL), toxic shock syndrome toxin (tst), exfoliative toxins (eta, etb), and the resistance genes mecA and mecC, were defined in 46 representative strains by PCRs. Relatedness of strains was assessed by MLST.

**Results:** Of 1538 neonates accounting for 26673 patient days (mean length of stay 17 days), 77 (5%) had a positive culture for MRSA [23/77 were NICU-acquired and 54/77 imported cases]. Most isolates were multi-resistant, with higher resistance observed against kanamycin (71%), macrolides (49%), lincosamides (47%) and ciprofloxacin (39%). All 46 analyzed strains were mecA-positive. One major clone was identified, ST225, among 40 tested neonatal strains (23/40, 58%). Of these, 14/23 were imported from the same maternity hospital (MH). Another clone, ST217, was predominant (4/6) among isolates from health care workers (HCWs) found colonized during screening performed on Jan18. NICU-acquired bacteremia occurred in four neonates on Nov16, Aug17, Oct17 and Jan18 due to ST217 and ST225, three and one cases, respectively [figure 1]. Four isolates classified as ST80 were PVL-positive. Additional four strains carried tst (10%), belonging to ST30 and ST225 [two strains each], and two etb (5%, ST225). The implicated MH was notified for the problem, decolonization treatment was successfully performed in HCWs and neonates. Strengthening of infection control measures with emphasis on hand hygiene was applied.

**Conclusions:** Uncovering reservoirs for on-going MRSA transmission in NICUs has proved challenging. Well known nosocomial MRSA clones are being constantly introduced and transmitted via MHS and HCWs. Effective infection prevention and control requires constant vigilance.

Understanding the molecular history of an ancient Pseudomonas species isolated from a pharaonic Egyptian mummy: a genomic tale from the 11th dynasty of the middle kingdom

Mohamed El-Sayed Ahmed1,2,3, Yongqiang Yang1,2, Cong Shen1,2, Xin Wen1,2, Yanxian Yang1,2, Guo-Bao Tian1,2

1Sun Yat-sen University, Department of Microbiology, Zhongshan School of Medicine, Guangzhou, China, 2Sun Yat-sen University, Key Laboratory of Tropical Diseases Control, Ministry of Education, Guangzhou, China, 3Misr University for Science and Technology (MUST), Department of Microbiology and Immunology, Faculty of Pharmaceutical Sciences and Drug Manufacturing, Giza, Egypt

Background: Pseudomonas spp. are highly adaptable, as evidenced by their successful colonisation in different ecological niches. Origin and evolution of the genus Pseudomonas are still not entirely clear. Herein, understanding the evolution of Pseudomonas spp. depends on the investigation of a Pharaonic Egyptian mummy dating back to ca. 2130 BC–ca. 1991 BC, preserved in the Grand Egyptian Museum, Cairo, Egypt.

Materials/methods: Samples were taken from the mummy of the Lady Amanit, Priestess of Hathor, from oral, throat, abdominal cavity, and finger toes. The samples were inoculated on Blood agar, MacConkey agar, Brain Heart Infusion agar with vitamin K and hemin for the enrichment of anaerobes, and Sabouraud agar with chloramphenicol. Identification was performed using 16S ribosomal DNA and MALDI-TOF mass spectrometry. MICs were detected by the broth microdilution method for 16 antimicrobial agents. Whole-genome sequencing was performed. The surface topography of our isolate was detected using the scanning electron microscope (SEM). Bacterial growth rates were determined using Microplate Spectrophotometer. A Galleria mellonella infection model was used to evaluate virulence.

Results: Biochemical identification showed bacterial growth; no fungi were detected. 16S ribosomal DNA and MALDI-TOF identified Pseudomonas species in the throat sample. SEM revealed that Pseudomonas spp. was rod-shaped and ∼3.00 μm in length with monotrichous flagella and pili-like structures. MICs showed resistance to ampicillin, cefotaxime, and nitrofurantoin while sensitivity to all other tested antimicrobials. Average Nucleotide Identity (ANI) analysis indicated that the ANI of our isolate was 97.63% for Pseudomonas lutea LMG 21974 and 97.62% for Pseudomonas luteola NBRC 103146. In silico MLST showed a novel sequence type. Antibiotic resistance genes were identified; only one gene was found, namely, blaLUT-1. Several virulence factors were detected. Our strain exhibited a slow-killing mode in the G. mellonella within ten days, indicating its low virulence. The growth rate of our strain was also low.

Conclusions: The absence of other microbes with our isolate confirming the probability that our strain is an ancient bacterium that colonised the mummified body thousands of years ago. Further studies are required to get more information about the role of our strain in the evolution of the genus Pseudomonas.

Abstract 3414

Pandrug-resistant Bacteroides fragilis clinical isolates in the Netherlands: true or fiction

Kathleen Boiten*1, Ed J. Kuijper2,3, Floor Smit3, Lonneke Schoffelen3, Leonard Schüle3, Annelot Notermans2, Sjoukje Woudt2, Heinrich. L. J. Winter1, Joffrey Van Prehn3, Alida Veloo1

1University of Groningen, University Medical Center Groningen, Department of Medical Microbiology and Infection prevention, Groningen, Netherlands, 2Centre for Infectious Disease Control (Cib), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 3Department of Medical Microbiology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Antimicrobial resistance among anaerobic bacteria is increasing and multi drug resistant (MDR) strains have been published by different groups. Bacteroides fragilis is a well-studied species. It can harbour several antimicrobial resistance genes (ARGs), but resistance to both carbapenems and metronidazole is very rare, and less than five strains are reported worldwide. Within this study we report three B. fragilis isolates, derived from three different university hospitals in the Netherlands, which were resistant to carbapenems and metronidazole, besides other antibiotics.

Materials/methods: After finding a pan-resistant B. fragilis (isolate A, 2019) at the LUMC from a wound of a liver transplantation patient, a search was performed in the national antimicrobial resistance surveillance database (ISIS-AR) for similar isolates. This resulted in one more isolate from the Erasmus MC (isolate B, 2018), from a blood culture of a patient with malignancies in the urogenital region. One more isolate was identified at the UMCG (isolate C, 2014) from a young patient suffering from complicated appendicitis. Antimicrobial resistance was determined using Etest. Presence of ARGs and other mobile genetic elements (MGEs) that play a role in antimicrobial resistance was, to date, determined for isolates A and C using whole genome sequencing.

Results: The patient from which isolate C was cultured, recovered without specific antimicrobial treatment. The other two patients died due to underlying conditions. All three isolates were resistant to carbapenems, metronidazole and tetracycline. Short read sequencing of isolate A & C showed that both isolates harboured the cfiA gene with an IS-element (carbapenems), a nim gene (respectively nimE and nimA; metronidazole) and the tetQ gene (tetracycline). Isolate A harboured ermF (clindamycin) and a mefE gene (macrolide efflux protein). Isolate C also harboured the cfiA gene (beta-lactams) and a bexA gene (fluoroquinolones). Presence of ARGs in isolate B will also be assessed.

Conclusions: The finding of three pan-resistant B. fragilis isolates harbouring resistance to both carbapenems and metronidazole is worrying. To better understand these isolates we intend to perform a hybrid assembly with short and long reads, enabling us to obtain the whole genome and determine whether ARGs are located on plasmids or other MGEs.

Whole genome sequencing: epidemiologic surveillance of carbapenemases present in Enterobacteriaceae isolated at Sant Pau Hospital (Barcelona) in 2018

Elisenda Miro*, Daniella Miniac1, Raúl Altaba2, Marc Rubio3, Alba Rivera4, Ferran Navarro1

1Hospital de la Santa Creu i Sant Pau, Microbiology Dept, Barcelona, Spain

Background: Whole-genome sequencing (WGS)-based typing has emerged as a promising and highly discriminative epidemiological tool. In this study, we used a gene-by-gene allele calling approach to investigate carbapenemase-producing enterobacterial isolates and discount any outbreaks.

Materials/methods: As a routine laboratory task, WGS was applied to the carbapenemase-producing Enterobacteriaceae detected by Real Cycler OXVIKP during 2018 at Sant Pau Hospital (Barcelona). DNA was extracted using the DNeasy UltraClean Microbial Kit. The libraries were prepared using Nextera XT v.01 and sequenced on an Illumina MiSeq sequencer (Novogen Corporation). After sequencing, the reads were quality trimmed and de novo assembled using BioNumerics 7.6 software. ResFinder website was used to obtain the resistome.

Results: The incidence of carbapenemases in the hospital was 3.44% (23/669) for Klebsiella pneumoniae, 0.17% (5/2843) for Escherichia coli, 1.45% (2/138) for Enterobacter cloacae (group) and 1.17% (1/85) for Citrobacter amalonaticus. In K. pneumoniae, 3 clusters and 5 singletons were found. The predominant cluster (10 isolates) belonged to ST392, followed by ST307 (6 isolates). Both clusters included OXA-48- plus CTX-M-15-producing isolates. The third cluster, belonging to ST258, only included 2 KPC-3- plus OXA-9-producing isolates. The 3 clusters generated by core genome analysis differed by 380 to 400 loci, whereas the difference between isolates belonging to the same cluster was between 1 and 15 loci. Similar results were obtained by wgMLST. In E. coli, 4 of the 5 isolates produced OXA-181: 2 of them belonged to ST471 and 2 to ST692; the remaining NDM-5-producing isolate was nontypeable. In E. cloacae, one isolate (ST32) produced a VIM-1 and the other (ST50) an OXA-48. Finally, an OXA-48-producing C. amalonaticus was isolated. In carbapenamase-producing strains, 14 different resistomes were found in K. pneumoniae and 4 in E. coli.

Conclusions: Through WGS we were able to clearly and objectively characterize carbapenemases detected in our hospital. In addition, it allowed us to start a database including both epidemiological and multi-drug resistance data associated with Enterobacteriaceae strains, which is used to modify empiric treatment.

**Abstract 3418**

**Enhancing fosfomycin activity via glycerol-3-phosphate transporter activation**

Miriam Ortiz Padilla*, Inés Mª Portillo Calderón*, Belén De Gregorio Laria*, Jesús Rodríguez-Baño*, Alvaro Pascual Hernández*, Jose Manuel Rodriguez Martinez*, Fernando Docobo Perez*

1Instituto de Biomedicina de Sevilla, Sevilla, Spain, 2University of Seville, Sevilla, Spain, 3Hospital Universitario Virgen Macarena, Unidad de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Sevilla, Spain, 4Red Española de Investigación en Patología Infecciosa (REIPI), Carlos III Health Institute, Madrid, Spain

**Background:** Fosfomycin disrupts the first step in peptidoglycan biosynthesis inhibiting the enzyme UDP-N-acetylgluosamine-3-enolpyruvitransferase (MurA) leading to cell death. To carry out its activity, fosfomycin enters the bacteria through a hexose phosphate (UhpT) and glycerol-3-phosphate (GlpT) transporters, which are induced by their substrates. Additionally, glycerol is transformed, intracellularly, into glycerol-3-phosphate by the glycerol kinase (GlpK). In the susceptibility assays, glucose-6-phosphate is used to induce UhpT however, the role of GlpT remains unknown. The objective of this study was evaluating fosfomycin activity under GlpT activation.

**Materials/methods:** Escherichia coli wild-type (WT) strains and five isogenic mutants (∆glpT, ∆uhpT, ∆glpT-uhpT, ∆glpK) was used. The induction of the transporters with addition of glucose-6-phosphate (25mg/L), glycerol-3-phosphate (0.1%) and glycerol (0.1%) was monitored in the wild-type strain using the reporter-plasmid pMS201 (PglpT::gfp mut2 and PuhpT::gfp mut2) and measuring the emitted fluorescence during 48 hours. Fosfomycin susceptibilities were tested using disk-diffusion method ±glycerol-3-phosphate and ±glycerol in Mueller-Hinton agar. Halo of inhibition were measured and compared using ANOVA and post-hoc test. Fosfomycin activity was quantified spectrophotometrically using M9 (succinate) supplemented ±glucose-6-phosphate, ±glycerol or both and fosfomycin ranging from 0.25 to 256mg/L. The area under the curve from de dose-viability plot was calculated and compared among the different conditions.

**Results:** Glucose-6-phosphate rapidly activated uhpT (>6 times, peak at 4h), while glpT showed a slow expression [peak at 34h and 41h] increasing 2.29 and 3 times in the presence of glycerol-3-phosphate and glycerol, respectively. With respect to the susceptibility, glycerol increased fosfomycin susceptibility significantly in WT and ∆uhpT. However, glycerol-3-phosphate increased fosfomycin resistance in WT, ∆glpT, ∆glpK and derepressed glpT strain (ΔglpR) (Figure 1). Fosfomycin activity increased against the WT and ΔglpT strains by the addition of glucose-6-phosphate, and against WT and ΔuhpT strains with glycerol. The addition of both inducers increased the activity in all strains except ΔglpT-uhpT.

**Conclusions:** Enhancing fosfomycin penetration via glpT may be a good strategy to increase its activity. The addition of glycerol-3-phosphate reduce fosfomycin susceptibility, by the competition of glycerol-3-phosphate against fosfomycin to be transported by GlpT. The use of a non-competitive inductor, as glycerol, increased fosfomycin susceptibility.

Figure 1. Fosfomycin susceptibility by disk-diffusion assay.

Abstract 3419

Multilevel analysis of the regional variation in healthcare-associated infections and antimicrobial use prevalence in acute-care hospitals in Greece

Evangelos Kritsotakis¹, Eirini Astrinaki², Theodora Machaira³, Stamatis Karakonstantis*⁴, Achilleas Gikas⁵

¹University of Crete, Laboratory of Biostatistics, Medical School, Heraklion, Greece, ²University Hospital of Heraklion, Infection Control Committee, Heraklion, Greece, ³National and Kapodistrian University of Athens, Medical School and Department of Mathematics, Athens, Greece, ⁴University of Crete, Infectious Diseases Unit, Medical School, Gofirakia, Greece, ⁵University Hospital of Heraklion, Department of Internal Medicine, Iraklio, Greece

Background: To identify targets for quality improvement in hospital infection control (IC) and antibiotic stewardship strategies in Greece, we investigated the regional variability in the prevalence of healthcare-associated infections (HAIs) and antimicrobial use. Because regional health authorities may implement programs to foster prudent antibiotic use and strengthen IC practices in addition to those implemented by individual hospitals, we utilized multilevel statistical modelling to assess both the individual effect of hospitals and the regional effect.

Materials/methods: Data for 87 public hospitals were obtained from the second national point-prevalence survey of HAIs and antimicrobial use in November 2016. Data included patient characteristics aggregated at the hospital level (mean values for age and Charlson comorbidity score, and proportions of patients with emergency admission, recent surgery, neutropenia, intensive care unit [ICU] admission and rapidly fatal prognosis) and hospital characteristics (hospital size and type, and numbers of single rooms, IC nurses and IC physicians). Regional variation was examined in relation to the seven Regional Health Districts comprising the health authorities that supervise hospitals and public health in Greece. The regional effect was estimated using hierarchical linear regression with a random intercept on the region.

Results: Overall, the prevalence of antimicrobial use was 58.8% and the prevalence of HAIs was 9.0%. Mapping by region showed wide variation for both antimicrobials (regional range, 54.0% to 64.6%) and HAIs (regional range, 6.8% to 11.6%). In unadjusted analysis, the regional effect explained 18.6% of the variability in antimicrobial use and 14.1% of the variability in HAI prevalence. In the multivariable analysis, adjustment for patient and hospital characteristics explained 48.5% and 71.2% of the variability in the prevalence of antimicrobials and HAIs, respectively. The regional variance component was largely reduced for HAIs (explained by 56.6%), but largely persisted for antimicrobial use (explained by only 26.4%).

Conclusions: Multilevel analysis of national prevalence data proved useful in identifying targets for improvement. Differences in patient case mix and hospital characteristics explained largely the regional variation in HAI prevalence, but not use of antimicrobials. Thus, regional health authorities in Greece must sought to harmonize local antibiotic stewardship policies, dissemination of guidelines and audits.

Abstract 3423

Setting up antimicrobial stewardship programme in tertiary area hospitals in India
Kamini Walia*, V. Ramasubramanian1, Vinod Ohri3

1Indian Council of Medical Research, Delhi, India, 2Apollo Hospitals, Chennai, India, 3ICMR, New Delhi, India

Background: One of the best methods to prolong the shelf-life of existing and newer future antimicrobials is antimicrobial stewardship programme (AMSP). The Indian Council of Medical Research (ICMR), New Delhi, India, has launched the Anti Microbial Resistance Stewardship Initiative with an avowed purpose of rationalizing antimicrobial prescriptions. The initiative is currently limited to tertiary care hospitals in the country.

Materials/methods: Following the gaps highlighted by ICMR baselines survey of AMSP practices in hospitals in India1, capacity building efforts were initiated by ICMR. Twenty tertiary care hospitals were subsequently funded to undertake AMSP interventions like creating institution specific antimicrobial use guideline, introducing AMSP interventions like prescription audit and feedback and formulary restriction. A new software was developed to capture antimicrobial consumption. The sites also undertook education and awareness activities. One clinical pharmacist was provided to all hospitals.

Results: All hospitals formulated a multidisciplinary AMSP Committee and were able to create a treatment guideline specific to antibiogram of the hospital. All hospitals were able to initiate all the activities although the number of ICUs and wards included varied between the hospitals. Most hospitals documented decline in usage of broad spectrum antibiotics in the intensive care units(ICUs) after introduction of treatment guideline. The culture rate varied between 20 and 100 percent. Some hospitals introduced formulary restriction on prescription of antimicrobials like fosfomycin, polymyxin, colistin, linezolid and tigecycline. All hospitals organized the education and awareness workshops.

Conclusions: Through this effort we have established structure and process of AMSP in twenty tertiary care hospitals in the country. The hospitals can now use this structure for testing other AMSP interventions like adherence to treatment guidelines, de-escalation following culture report. Sustaining the efforts would require additional manpower and commitment on part of leadership to provide logistics and human resources to continue this activity.

**Abstract 3424**

**Genomic characterisation of meropenem/vaborbactam resistant KPC-producing Klebsiella pneumoniae strains isolated from bacteraemic patients**

Paolo Gaibani*, Maria Carla Re¹, Simone Ambretti¹

¹Policlinico Sant’Orsola-Malpighi, U.O. Microbiology, Bologna, Italy

**Background:** In the last years, novel antimicrobial drugs have been developed to treat infections due to KPC producers. Among them, meropenem-vaborbactam (MER-VAB) represents a promising antimicrobial option for treatment of infections caused by class A serine carbapenemase producing Enterobacteriaceae. MER-VAB is an antimicrobial combination of a carbapenem antibiotic associated with novel boronic acid-based ß-lactamase inhibitor. Recently, few cases of MER-VAB-resistant clinical isolates have been reported worldwide. Here, we described four MER-VAB-resistant KPC-producing Klebsiella pneumoniae (KPC-Kp) isolated from patients with bloodstream infection.

**Materials/methods:** Between 1st March and 31st August 2018, we collected all KPC-producing Klebsiella pneumoniae strains isolated from patients with bloodstream infection and recovered at the St. Orsola Malpighi University Hospital in Bologna, Italy. MIC values for meropenem/vaborbactam were assessed by MIC test strip and results were interpreted following EUCAST breakpoints. Carbapenemase production was investigated by MALDI-TOF MS peak-specific analysis and NG-Test CARBA S assay. Whole-genome sequencing of MER-VAB KPC-Kp strains was performed by using MiSeq platform (Illumina, USA).

**Results:** During the study period, we collected four KPC-Kp strains resistant to MER-VAB. All strains were resistant to ciprofloxacin, penicillins, cephalosporins, carbapenem and amikacin, while remained susceptible to colistin. In detail, all KPC-Kp strains exhibited high MIC values (≥256 mg/L) for MER-VAB and one out of three KPC-Kp was also resistant to Ceftazidime-Avibactam (16 mg/L). Genetic analysis demonstrated that all KPC-Kp strains belonged to the ST258 and shared similar genetic determinants for antimicrobial resistance to fluoroquinolone and ß-lactams. Analysis of porin genes showed that all MER-VAB-resistant KPC-Kp strains had truncated ompK35 and GD1 34-1 35 insertion within ompK36. Plasmid content analysis showed that all MER-VAB-resistant KPC-Kp strains shared IncFIB(pKPHS1), IncFII(K), ColRNAI and IncX3 plasmids, while two strains harbored an additional plasmid [IncFil(K)].

**Conclusions:** Here we described four MER-VAB-resistant KPC-Kp strains isolated from bacteraemic patients. Resistance to MER-VAB in KPC-Kp strains are associated to non-functional ompK35 and mutated ompK36 porins. In one KPC-Kp strain, porins mutations has been associated to ceftazidime-avibactam resistance.

Abstract 3425

**Stool versus rectal swab for microbiome composition analysis in critical care patients**

Elisa Rubio Garcia*, Andrea Vergara¹, Mariana José Fernández¹, Berta Fidalgo¹, Genoveva Cuesta Chasco¹, Fatima Aziz², Maria Hernandez-Tejero², Javier Fernandez³, Alex Soriano³, Jordi Vila Estape⁴, Climent Casals-Pascual²,⁴

¹Hospital Clinic de Barcelona, Department of Clinical Microbiology, Barcelona, Spain, ²Hospital Clinic de Barcelona, Department of Hepatology, Barcelona, Spain, ³Hospital Clinic de Barcelona, Department of Infectious Diseases, Barcelona, Spain, ⁴Hospital Clinic de Barcelona, Department of Clinical Microbiology and ISGlobal, Barcelona, Spain

**Background:** Stool samples are frequently used for clinical microbiome studies. These samples are not always readily available in critical care patients, as patients may be unable to produce a faecal sample. Rectal swabs (RS) are easier to collect, transport and store. However, it is unclear if RS are representative of the stool microbiome. In this study we compared the microbiome composition of RS and faecal samples from critically-ill patients.

**Materials/methods:** Fifteen patients admitted to a 14-bed hepatic intensive care unit were randomly selected. For each patient, a RS and a stool sample were simultaneously collected. Stool samples were homogenized with PBS and all samples were stored at -80°C until processing. DNA was extracted using PureLink™ Microbiome DNA Purification kit (Invitrogen) and the V3-V4 region of 16S rRNA gene was amplified and sequenced on a MiSeq platform (Illumina). Sequences were filtered and demultiplexed using DADA2, taxonomy was assigned using SILVA-132 and statistical analyses were conducted using QIIME2 and R environments. Three patients were excluded due to low sequence counts in one of their samples (2 stools, 1 RS).

**Results:** Median Charlson comorbidity index was 5 (IQR:3.6-6.25), median age was 66 (IQR:57.75-64.25), 83.3% (10/12) were male and 91.7% (11/12) had liver cirrhosis. Microbial (alpha) diversity was not significantly different between RS and stool samples (Faith index, p-value:0.22). Figure 1A shows relative abundance of bacterial communities of analysed samples demonstrating taxonomical similarity between stool and rectal swabs from the same patient. Figure 1B shows principal coordinate analysis plot using unweighted unifrac distances. Unweighted unifrac distances between samples belonging to the same subject (median:0.46, IQR:0.27-0.57) were significantly lower than between samples belonging to different subjects (median:0.68, IQR:0.62-0.77) (p<0.0001) (Figure 1C).

**Conclusions:** RS and stool samples are comparable in terms of microbial diversity. Bacterial communities from RS and stool samples belonging to the same patient were similar and compositional differences between samples from the same patient were lower than between samples from different patients. Our results suggest that RS are adequate representative samples of gut microbiota composition in critically-ill patients. However, we recommend selecting one type of sample when designing gut microbiota studies to reduce possible sample-related variabilities.

Abstract 3430

Emergence of multiple ESBL-producing \textit{Salmonella enterica} serovars in hospitalised horses due to an epidemic spread of a CTX-M-3 plasmid pSEIL-3

Ziv Dor\textsuperscript{1}, Anat Shnaiderman-Torban\textsuperscript{2}, Kira Kondratyeva\textsuperscript{3}, Maya Davodovich\textsuperscript{1}, Assaf Rokney\textsuperscript{3}, Amir Steinman\textsuperscript{2}, Shiri Navon-Venezia\textsuperscript{*1,4}

\textsuperscript{1}Ariel University, Department of Molecular Biology, Ariel, Israel, \textsuperscript{2}The Hebrew University of Jerusalem, Koret School of Veterinary Medicine, The Robert H. Smith Faculty of Agriculture, Food and Environment, Rehovot, Israel, \textsuperscript{3}Ministry of Health, Government Central Laboratories, Jerusalem, Israel, \textsuperscript{*}Ariel University, Sheldon School of Medicine, Ariel, Israel

\textbf{Background:} \textit{Salmonella enterica} is a highly important zoonotic pathogen causing human Salmonellosis. This bacterium is mainly recognized as a food-borne pathogen often associated with food animal colonization. ESBL-producing \textit{S. enterica} has emerged worldwide and currently poses therapeutic challenges and a risk for resistance spread. Considering 'one health' significance and taking into account close animal-human contact, we aimed to investigate ESBL-producing \textit{Salmonella} (ESBL-PS), and to decipher the mode of ESBL dissemination among hospitalized horses.

\textbf{Materials/methods:} ESBL-PS isolates were collected in the Koret-School of Veterinary-Medicine during a prospective ESBL-P Enterobacteriaceae survey (Dec2015-Dec2017). The isolates were recovered from fecal and clinical samples using Chromagar-ESBL plates following with identification, susceptibility testing (VITEK2), and serovar determination (Kaufmann-White-Le-Minor). ESBL genes were detected by multiplex-PCR and sequencing. ESBL-encoding plasmids were purified, transformed and sequenced (Nanopore) and WGS was performed for each serovar (Illumina-HiSeq). Conjugation experiments were performed to prove plasmid transferability.

\textbf{Results:} Twelve ESBL-PS isolates were recovered from foals (n=8) and adult horses (n=4). All Isolates produced the same ESBL gene-\texttt{bla}\textsubscript{CTX-M-3}, and showed an identical MDR profile, with co-resistance to trimethoprim/sulfamethoxazole and aminoglycosides. Three ESBL-PS serovars were identified- Cerro (n=7), Havana (n=3), and Liverpool (n=2), all reported for the first time in horses. Molecular epidemiology analysis revealed clustered-in-time clonal spread of serovar Cerro among seven horses, together with an epidemic spread of a single CTX-M-3-encoding plasmid (designated pSEIL-3), which horizontally and serovar-independently disseminated among horses. pSEIL-3, a 86.4Kb IncM2 plasmid, encoded nine antibiotic resistance genes and was highly similar (>95%) to other \texttt{bla}_{CTX-M-3} or \texttt{bla}_{NDM-1} IncM2 broad-host-range plasmids from various Enterobacteriaceae of human origin. Using a multiplex-PCR designed specifically for pSEIL-3 screening, we proved the presence of this plasmid in other ESBL-P Enterobacteriaceae co-colonizing three horses, demonstrating transfer of pSEIL-3 in horses' gut in situ. Five out of the eight foals deceased following ESBL-PS infections.

\textbf{Conclusions:} This is an alarming report on the emergence of ESBL-P MDR \textit{S. enterica} in hospitalized horses, associated with gut colonization and severe foal morbidity. We demonstrate the potential of horses to host and shed ESBL-P \textit{Salmonella} and serve as a reservoir for highly transferrable broad-host-range MDR plasmids posing a frightening 'one-health' risk.

Abstract 3433

Nikolai Lvov*1

1Military Medical Academy named after S.M. Kirov, Saint-Petersburg, Russian Federation

**Background:** The World Health Organization recommends the use of neuraminidase inhibitors for treatment of influenza. The increasing resistance of influenza viruses against current anti-influenza drugs demonstrates the challenging need to identify new antiviral agents. At the end of the 20th century ribavirin was seen as a possible treatment. Currently novel anti-influenza drugs from nucleoside analogues like favipiravir are being researched. In the Russian Federation in 2014 riamilovir (Triazavirin®) was registered.

**Materials/methods:** In this retrospective study we evaluated the clinical effectiveness of riamilovir (53 cases) with that of oseltamivir (57 cases) for treating influenza. All included in-patients were young men (18-26 years) with moderate severe PCR confirmed influenza A (H1N1, H3N2) and B during epidemic seasons 2016-2017 and 2017-2018. The treatment was initiated within 48 hours of clinical symptoms. We compared infectious intoxication syndrome duration, total febrile period, duration of acute rhinitis, acute pharyngitis, acute laryngitis, acute tracheitis, acute bronchitis, cough duration as well as pneumonia occurrence.

**Results:** There was no statistically significant difference in the duration of developed syndromes. In riamilovir-treated group and oseltamivir-treated group mean duration of intoxication was 3.6±2.24 days vs. 3.2±2.21 days, total febrile period – 2.0±1.05 days vs. 1.8±1.19 days, acute rhinitis – 4.9±2.28 days vs. 4.6±3.09 days, acute pharyngitis – 4.2±2.77 days vs. 3.9±2.41 days, acute laryngitis – 2.5±0.71 days vs. 2.2±1.10 days, acute tracheitis – 2.4±1.28 days vs. 2.3±1.24 days, acute bronchitis – 2.7±1.53 days vs. 3.3±2.65 days, cough – 6.1±2.91 days vs. 4.6±3.15 days accordingly. No incidence of pneumonia was observed in both groups.

**Conclusions:** Riamilovir and oseltamivir were equally effective in treating adult patients with influenza. The duration of infectious intoxication syndrome, total febrile period, duration of respiratory syndromes were comparable for both medications. Thus, nucleoside analogue riamilovir (Triazavirin®) as well as neuraminidase inhibitor oseltamivir can be recommended for treatment of influenza.

Seroprevalence of Coxsackievirus B1-6: retrospective study in an Italian population
Ilaria Sciandra1,2, Francesca Falasca3, Paola Maida1, Giulia Tranquilli1, Daniele Di Carlo1, Laura Mazzuti1, Taulant Melengu1, Gianluigi Giannelli4, Guido Antonelli1, Ombretta Turriziani1

1Sapienza University of Rome, Department of Molecular Medicine, Roma, Italy, 2Institute of Gastroenterology Saverio De Bellis, Castellana Grotte, Italy, 3Sapienza University of Rome, Department of Public Health and Infectious Diseases, Roma, Italy, 4National Institute of Gastroenterology Saverio De Bellis, Castellana Grotte, Italy

Background: Group B Coxsackieviruses (CVB) include 6 serotypes (CVB1-6) responsible for a wide range of clinical diseases comprising meningitis, pancreatitis, and myocarditis. Moreover, CVB infection could be a trigger for the onset of insulin-dependent diabetes. Seroepidemiologic data on CVB are limited and no recent studies are available in our geographical area. Therefore, the aim of this study was to investigate CVB1-6 seroprevalence in a wide Italian population.

Materials/methods: The study retrospectively included 2,459 subjects referring to Umberto I University Hospital (Rome) in the period 2004-2016. Information about age was available for 2,114 individuals, that were divided into 11 age-groups. Serum samples were screened with a micro-neutralization assay to detect neutralizing antibodies (nAb) against all six CVB. Statistical analysis was performed evaluating seroprevalence rates and nAb titers in relation to years of observation and subjects’ gender and age.

Results: Positivity for at least one serotype was detected in 69.1% of individuals. Overall, the prevalent serotype was B4 (45.2%), followed by B3 (33.3%), B5 (26.2%), B1 (12.7%), B2 (11.0%), and B6 (1.7%). Positivity rates of B1, B3, B4, and B5 varied over years with cyclical trends. B2 seroprevalence was the highest among CVB in 2004 (64.8%) but significantly decreased in 2005 and 2006 (50.5% and 31.2%), settling at levels lower than 8.5% starting from 2007 (p<0.0001). The percentage of seropositivity was higher in females than in males, and this difference was significant for B2 and B3 (p<0.05). Positivity to at least one virus was lowest in toddlers aged 0-2 years (25.2%), but significantly increased in pre-school (3-5 yr) (50.3%) and school (6-10 yr) children (70.4%) (p<0.0001). The number of individuals with multiple positivity also increased with age. The age-related positivity increase is significant also analyzing B1-B5 specific seroprevalence. Higher nAb responses for B3 and B4 were observed in children of 3-5 years of age (p<0.05).

Conclusions: A high overall CVB prevalence was found. Type-specific variations in prevalence over time probably reflect the fluctuations in circulation typical of Enteroviruses. Children are at greater risk for CVB infection given the high number of seronegative subjects aged less than 10 years.

Abstract 3435

**Preliminary analysis of a pilot study using a new oral encapsulated formulation of faecal microbiota**

Veronica Rico Caballero*, Andrea Aira, Elisa Rubio Garcia, Climent Casals-Pascual, Andrea Vergara, José Antonio Martínez Martínez, Alex Soriano

1Barcelona, Hospital Clinic de Barcelona, Barcelona, Spain

**Background:** *Clostridioides difficile* infection (CDI) is the main cause of health care–associated diarrhoea, and there is an increasing in the incidence of CDI in the community. Numerous publications have demonstrated that the most effective treatment is the faecal microbiota transplantation (FMT) from a healthy donor. Oral capsules obtained from processed stool samples by adding excipients (vivapur-101 and magnesium stearate) to microbial pellet have shown high viable bacterial concentration. Here we present the preliminary results of a pilot study that evaluated the efficacy of this formulation to prevent recurrence in patients with CDI.

**Materials/methods:** All CDI cases in our institution from March to October 2019 were prospectively detected. Written informed consent was obtained from all participants. Eligible patients were female and male adults (> 18 years) presenting an acute episode of diarrhoea (> 3 unformed bowel movements every 24 hours). Exclusion criteria were oral intolerance, severe immunosuppression, pregnancy, concomitant antibiotic treatment, severe CDI and life expectancy inferior to 1 month.

**Results:** Ninety-one patients presented with an acute episode of CDI. Among them, only 17 patients met the inclusion criteria. The main reasons for exclusion were: severe immunosuppression (12 patients), concomitant antibiotherapy (27 patients), severe disease (4 patients) and short-life expectancy (13 patients). Of the 17 eligible patients, only 8 were included. The mean age was 64.75 years, 50% were female, 87% had community-acquired CDI, 62.5% had cancer, 50% had received antibiotics in the prior month and for the majority of them it was their first episode (62.5%). FMT consisted in a single dose of 20 capsule after at least 5 days of vancomycin or fidaxomicin treatment. All patients reported a good oral and gastrointestinal tolerance. The mean follow-up was 84 days. Only one patient had a CDI recurrence and two of them died more than 90 days post-FMT from underlying malignancy condition.

**Conclusions:** Our experience shows that oral FMT is well tolerated and suggests that our FMT formulation is effective in terms of reducing the recurrence rate of CDI.

Global metabolism indicates novel mechanism of GreA-induced dormancy in Mycobacterium tuberculosis

Zihan Zhao1,2*, Wanfei Liang1,2, Daixi Lin1,2, Siyuan Feng1,2, Xin Wen1,2, Cong Shen1,2, Lujie Liang1,2, Jiachen Li1,2, Guo-Bao Tian1,2

1Sun Yat-sen University, Department of Microbiology, Zhongshan School of Medicine, Guangzhou, China, 2Sun Yat-sen University, Key Laboratory of Tropical Diseases Control, Guangzhou, China

Background: Dormancy is a nonreplicating, reversible cellular state that enables mycobacteria to circumvent and survive adverse stresses. Our recently study has been shown that GreA, a transcription elongation factor, is involved in drug tolerance, reactive oxygen, starvation in M. smegmatis and M. tuberculosis H73Ra. Our hypothesis is that the important role of GreA in stress induced dormancy in mycobacteria.

Materials/methods: To explore the role of GreA in stress induced dormancy, we constructed strains by recombineering the native greA gene fused with gfp fluorescent protein. The intracellular distribution of GFP was measured by time-lapse microscopy. Flow cytometric analysis of fluorescence after different hours exposure to nutrient limited medium. qRT-PCR was implemented to detect the expression of greA between active and dormant mycobacteria. In addition, CFU was used to evaluate the vitality of dormant bacteria between wild-type and ΔgreA. Furthermore, GC/MS was performed to find the differential metabolites between ΔgreA strain and wild type strain in a dormant state. Finally, the phenotype of GreA was confirmed in M. tuberculosis.

Results: Both results of FCM and time-lapse microscopy revealed greA expression was increased with early starvation treatment. The analysis of RT-PCR also confirmed that the mRNA of greA was increased in M. smegmatis, suggesting a critical role of GreA in the regulation of dormancy in M. smegmatis. Loss of greA resulted in M. smegmatis becoming more sensitive to nutrient scarcity based on the CFU counts. Further the GC/MS data demonstrated that more than 40 differential metabolites were identified between M. smegmatis WT strain and ΔgreA strain under starvation and most of them were decreased in greA mutant. Notably, lipid-related metabolic pathways, were generally down regulation in ΔgreA strain compared with WT. Furthermore, the intracellular energy resource significantly declined due to deficient of greA in mycobacteria. Consistent with these results, M. tuberculosis lack of greA also exhibit a reduced survivability under starvation.

Conclusions: Our data indicate that the deletion of greA mainly down regulation of lipid metabolic pathways, caused a shift ATP concentration and a suppression of dormancy. This study would likely provide vital clues to design novel drugs for the control of dormant TB.

Ultrasonic guidance and risk for intravascular catheter-related infections among peripheral arterial catheters. A post hoc analysis of two large randomised controlled trials

Niccolò Buetti*1, Stéphane Ruckly1, Jean-Christophe Lucet1–2, Lila Bouadma1–3, Carole Schwebel4, Olivier Mimoz5, Jean-François Timsit1–3

1 University of Paris, INSERM IAME, U1137, Team DesCID, Paris, France., Paris, France, 2 AP-HP, Infection Control Unit, Bichat-Claude Bernard University Hospital, 46 rue Henri Huchard, 75877, Paris Cedex, France, Paris, France, 3 Medical and Infectious Diseases Intensive Care Unit, AP-HP, Bichat-Claude Bernard, Paris, France, 4 Medical Intensive Care Unit, Grenoble University Hospital, Grenoble 1 University, La Tronche, France, Grenoble, France, 5 Services des Urgences Adultes and SAMU 86, Centre Hospitalier Universitaire de Poitiers, Poitiers 86021, France; Université de Poitiers, Poitiers, France; Inserm U1070, Poitiers, France

Background: The ultrasound guidance effect on infectious risk remains controversial in short-term arterial catheters (ACs). The present study aimed to investigate the association between ultrasound guidance (US) in AC insertion and intravascular catheter-related infections or colonizations.

Materials/methods: We used individual data from two multicenter randomized-controlled trials (RCTs) in intensive care units (ICUs) that evaluated various prevention strategies regarding major catheter-related infections (MCRI), catheter-related bloodstream infections (CR-BSI) and colonization. The skin colonization at catheter removal was evaluated using semi-quantitative insertion-site cultures. Univariate and multivariate marginal Cox model for clustered data were used for the evaluation of the daily hazard rate for MCRI, CR-BSI and catheter-tip colonization.

Results: A total of 3,029 patients were included by 10 ICUs and 3,950 ACs were analyzed. The US was used for 386 catheter placements. In the univariate Cox model analysis, the risk for MCRI (HR 0.86, CI 95% 0.27–2.72, p = 0.79), CR-BSI (HR 0.87, CI 95% 0.20–3.72, p = 0.85) and catheter colonization (HR 1.31, CI 95% 0.92–1.86, p = 0.13) were similar for catheters inserted with US and without US. After adjustment on confounders, US showed similar risk to non-US for MCRI (HR 0.71, CI 95% 0.23–2.24, p = 0.56), CR-BSI (HR 0.71, CI 95% 0.17–3.00, p = 0.63) and catheter colonization (HR 0.92, CI 95% 0.63–1.34, p = 0.67, Figure). No differences between US and non-US for MCRI, CR-BSI and colonization were observed for the radial and the femoral site, respectively. The skin colonization at catheter removal was similar between US and non-US groups (p = 0.69).

Conclusions: Using the largest dataset ever collected from large multi-centric RCTs conducted with consistent catheter care, we showed that the infection risk was similar for US and non-US utilization. With regard to the infectious risk, our results support the utilization of US for ACs.
Figure: Adjusted analyses for risk of MCRI, CR-BSI and colonization for ultrasound guidance versus without ultrasound guidance.

Role of AcrAB-TolC multidrug efflux pump in mcr-1-mediated colistin resistance

Wanfei Liang*1,2, Zihan Zhao1,2, Daixi Lin1,2, Siyuan Feng1,2, Luju Liang1,2, Jiachen Li1,2, Xin Wen1,2, Cong Shen1,2, Guo-Bao Tian1,2

1Sun Yat-sen University, Department of Microbiology, Zhongshan School of Medicine, Guangzhou, China, 2Sun Yat-sen University, Key Laboratory of Tropical Diseases Control, Guangzhou, China

Background: A growing number of mobile colistin resistance (MCR) proteins is threatening the renewed interest of colistin as a “last-resort” defense against carbapenem-resistant pathogens. A recent study reported that efflux pump inhibitor CCCP can reverse colistin resistance mcr-1 colistin-resistant strains, suggested the role of efflux pump in colistin resistance in the mcr-1 positive bacteria. However, the precise relationship is unclear.

Materials/methods: We focused on AcrAB-TolC, a major Escherichia coli multidrug efflux pump. The expression of AcrAB-TolC in isolates and engineering bacteria was detected by RT-qPCR. Minimum inhibitory concentration (MIC) of colistin of E. coli was conducted using the agar dilution method. The alternative of the lipopolysaccharide (LPS) was verified through MALDI-TOF.

Results: The expression of AcrAB-TolC was significantly decreased in the E. coli BW25113 strains carrying mcr-1 when compared to wild-type BW25113. ΔacrA or ΔtolC containing mcr-1 showed a reduced colistin resistance and the slower growth. As expected, overexpression of acrA or tolC enhanced the colistin resistance. Moreover, mutants for acrA or tolC does not abolish the modification of the lipid A in BW25113 strains.

Conclusions: Colistin susceptibility will be rescued when the strains carrying mcr-1 lack acrA or tolC. Given the role of AcrAB-TolC in drug efflux, we concluded that AcrAB-TolC is dispensable for mcr-1-mediated colistin-resistance.

Abstract

Background: Fosfomycin and aminoglycosides are antibiotics with activity against multidrug-resistant Enterobacteriaceae. Fosfomycin heteroresistant isolates could lead to treatment failure with fosfomycin monotherapy. Combination therapy with aminoglycosides could solve fosfomycin suboptimal efficacy. The aim of this study was to evaluate the effect of fosfomycin and amikacin alone and combined against fosfomycin-heteroresistant E. coli isolates.

Materials/methods: Fosfomycin-heteroresistant clinical E. coli isolates, hypermutable (M9, M11, M34, P86) and normo-mutable (3203, S0406), were studied. E. coli ATCC25922 was used as control. Fosfomycin and amikacin MICs were determined using gradient strip (GSA) and broth microdilution (BMD) assays. Fosfomycin (50mg/L and 200mg/L) and amikacin (32mg/L) mutant frequencies were determined. Fosfomycin (64mg/L, susceptibility breakpoint and 307mg/L, human Cmax) and amikacin (16mg/L, susceptibility breakpoint and 45mg/L, human Cmax) activity were assayed alone and combined (fosfomycin/amikacin: 64/16 mg/L) in 48h time-kill curves. Drug interactions were assessed in checkerboard assays (analyzed with SynergyFinder). Fosfomycin (8g/8h) and amikacin (15 mg/kg/24h) human regimens were assessed in 72h hollow-fiber infection model (HFIM) [M11, M34, 3203, 50406]. Total and resistant bacterial populations were quantified and susceptibility from recovered colonies were reassessed (time-kill and HFIM). Glucose-6-phosphate (25mg/L) was added in fosfomycin experiments.

Results: GSA/BMD (mg/L) fosfomycin and amikacin MICs were, respectively: M9 (0.5/16; 2/16), M11 (0.5/256; 2/16), M34 (0.25/256; 2/16), P86 (0.5/64; 1/4), 3203 (0.25/512; 2/8), 50406 (4/≥1024; 1/4), ATCC25922 (0.5/2; 1/4). Mutant frequencies >10⁻⁷ were observed in all isolates, except ATCC25922, at fosfomycin 50mg/L and in M34, 3203 and 50406 at 200mg/L. Amikacin mutant frequencies were <10⁻⁹. In checkerboard assays, synergy was found against M9, M11, M34 and 3203 isolates. In time-kill assays, all clinical strains were able to growth at 64mg/L and only M34, 3203 and 50406 at 307mg/L fosfomycin. ATCC25922, M9, M11 and 3203 survived at 16mg/L, but none at 45mg/L amikacin. Combination assays cleared all bacterial cultures. In HFIM, fosfomycin and amikacin monotherapies failed to eradicate the bacterial burden. Recovered strains showed MIC above susceptibility breakpoints.

Conclusions: Fosfomycin might be inefficacious as monotherapy to treat hypermutator and normo-mutator fosfomycin-heteroresistant E. coli infections. Combined therapy with amikacin could be a successful alternative. PK/PD studies of these combination should be performed.

### Abstract 3444

**Comparison of the performance of two galactomannan detection tests: Platelia Galactomannan (Bio-Rad) and Galactomannan Virclia (Vircell)**

Emilio Bouza Santiago¹, Roberto Alonso*¹, María Dolores Montero Vega², Marina Alguacil¹, Marina Machado⁴, Ignacio Gadea Gironés³, Ricardo Fernández Robla³, Patricia Muñoz⁴, Julio García Rodríguez², Alba Leyva⁶

¹Gregorio Marañón, Madrid, Spain, ²La Paz, Madrid, Spain, ³La Paz, Madrid, Spain, *Gregorio Marañón, Madrid, Spain, ⁴Fundación Jiménez Díaz, Madrid, Spain, ⁵Fundación Jiménez Díaz, Madrid, Spain, ⁶Granada, Vircell SL, Granada, Spain

**Background:** The reference technique for the detection of Galactomannan (GLM) is the Platelia-Aspergillus (Bio-Rad) (Plate- lia) test. In its current format, it is a technique that requires batching and makes it very difficult to be used with individual samples as a “same day test”. A new monotest for GLM [Aspergillus Galactomannan Ag VIRCLIA® Monotest] using detection by chemiluminescence, developed by Vircell SL (Granada, Spain), could improve some of the limitations of Platelia. Our study consists of comparing Platelia and Virclia performed simultaneously in blood or Broncho Alveolar Lavage.

**Materials/methods:** Adult patients with only a single sample per patient. One of the hospitals (HGM) included selected retrospective samples mainly from patients with known proven or probable IA, in order to have a greater number of positive controls. In the remaining two hospitals, samples were included prospectively along 2019. Platelia and Virclia were run in parallel, according to the manufactures recommendations. Significant indexes were 0.5 for Platelia and 0.2 for Virclia.

The results of both techniques compared were classified as Concordant (Both techniques have a positive or negative result) or Discordant. In discordant results the presence of clinical criteria of proven or probable IA of the EORTC criteria was used as reference.

**Results:** Of the 323 patients, 120 were collected retrospectively (25 from controls and 95 from patients with IA criteria) and the remaining 203 were prospectively obtained from daily requests. Globally, 102 determinations were positive for one technique or another, 78 with Platelia and 98 with Virclia. Overall, the results were concordant in 294 of the 323 samples (91%) of the patients and 29/323 (9%) were discordant. Of the 29 discordant cases 19 had IA and the remaining 10 did not. Platelia was positive in only 4 of 19 IA cases while Virclia detected 15. Of the 10 cases without IA, Platelia was negative in 9 and Virclia in 1.

**Conclusions:** Both tests showed concordant results in 91% of the cases. Virclia was more convenient for rapid detection of GLM and proved more sensitive for the detection of cases of IA when results were discordant.

**In vitro activity of fosfomycin against Escherichia coli and Klebsiella pneumoniae isolates recovered from bloodstream infections (2017-2018)**

Iskin Pinar Zarakolu Kosker¹, Özgen Eser¹, Baris Otlu², Öznur Gürpinar¹, Cüneyt Özakin³, Emin Halis Akalin¹, İftihar Köksal¹, Serhat Unal*¹

¹Hacettepe Üniversitesi Tıp Fakültesi, ankara, Turkey, ²Inonu Üniversitesi, malatya, Turkey, ³Uludag University Medical Faculty Hospital, Bursa, Turkey, ⁴KTU Faculty of Medicine, Trabzon, Turkey

**Background:** Among the members of the family Enterobacteriaceae, the carbapenemase-producing *Klebsiella pneumoniae* and *Escherichia coli* are within the scope of Fosfomycin.

**Materials/methods:** A total of 336 *E.coli* (*n=116*) and *K.pneumoniae* (*n=220*) isolates from nosocomial bloodstream infections were included in the study. They had been isolated between January 2017 and December 2018 in Hacettepe (800-bed), Uludag (996-bed) and Black Sea Technical (1050-bed) University Hospitals located in Ankara, Bursa and Trabzon cities, respectively. Blood cultures are processed with the Bactec FX system (BD Diagnostics, Sparks, MD, USA) according to the manufacturer’s recommendations and identification of the isolates were performed by MALDI-TOF MS (BD Diagnostics, Sparks, MD, USA) at each center. **Agar dilution method** was performed for susceptibility testing. The EUCAST MIC breakpoints were used to interpret the susceptibility results. IMP, VIM, OXA-48, NDM, KPC type carbapenemases and TEM, SHV, CTX-M type extended spectrum beta-lactamases (ESBLs) were determined. FosA3 activity of the fosfomycin-resistant ones were also screened.

**Results:** Of the total isolates, 25.8% of *E.coli* and 59.5% of *K.pneumoniae* were producing at least one of the carbapenemases. OXA-48 was the most common carbapenemase type and the frequency of NDM and KPC types were increasing. Majority of the isolates were producing at least one of the ESBLs particularly CTX-M and TEM types. None of the fosfomycin-resistant isolates were positive for FosA3 gene. In vitro fosfomycin susceptibility of *E.coli* and *K.pneumoniae* isolates were presented in Table 1:

**Conclusions:** Fosfomycin susceptibility of carbapenemase-producing *E.coli* and *K.pneumoniae* isolates was 96.6% and 76.8%, respectively showing that fosfomycin has substantial in vitro activity against these isolates, even though the majority are producing carbapenemases and ESBLs. The activity of fosfomycin did not appear to be influenced by the expression of the specific resistance genotypes. The potential clinical utility of the drug merits further evaluation.

Abstract 3450

**It’s a trap! The development of a versatile drain biofilm model**

Katarzyna Ledwoch*1,2; Jean-Yves Maillard1; Phillip Norville2

1Cardiff University, University, Cardiff, United Kingdom, 2GAMA Healthcare Ltd., Company, Watford, United Kingdom

Abstract third-party references: GAMA Healthcare Ltd.

**Background:** There is little information on the effectiveness of drain disinfection, despite the association of contaminated drains with infection outbreaks. We report the development of a complex drain biofilm model that was used for measuring the efficacy of drain disinfection.

**Materials/methods:** A complex bacterial culture from a communal sink drain was used. Identical drain biofilms were initially grown in six silicone tubes for 2 days then developed as a mature complex biofilm for 6 days, fitting the tubes into glass bottle with screw cap twin hose connector to imitate a sink trap. During the maturation phase, biofilms were exposed to periodical media flushes to mimic sink usage. Samples were taken from the front, middle and back sections of the tube corresponding to biofilm formed under the strainer, inside trap reservoir and on the pipe outlet to wastewater. Drain biofilm composition, appearance and susceptibility to disinfection was investigated with next generation sequencing (NGS), scanning electron microscopy (SEM), viability test and regrowth tests.

**Results:** Following biofilm formation, our model consisted of 84 different species with *S. marcescens*, *K. oxytoca*, *K. pneumoniae*, *S. bangori* and *E. coli* dominating. SEM revealed a dense biofilm matrix, uniformly covering the tubing surface. Diversity and composition were reproducible between the 6 concurrent biofilms and between experiments, with 8.2 ± 0.8 log10 biofilm recovered from 27 samples of 9 independent batches.

Sodium hypochlorite (NaOCl) 1,000ppm, non-ionic surfactant and sodium dichloroisocyanurate 1,000 ppm treatments were most effective in eliminating the biofilm in the front part of drain biofilm model but failed to control the biofilm in the other sections. Biofilms also fully recovered within 1 day following NaOCl treatment. NaOCl treatments eliminated or decreased *S. marcescens* and *K. oxytoca* content, further increasing *K. pneumoniae* percentage content. In contrast, peracetic acid 4,000ppm effectively eliminated biofilm in all parts of the drain and prevented regrowth for at least 4 days.

**Conclusions:** Our model mimicking sink usage showed that conventional treatments fail to eradicate drain biofilm or prevent regrowth. Our reproducible complex drain biofilm model also enabled to understand the impact of disinfectants on biofilm spatial composition, diversity, viability and recovery post-treatment.

Abstract 3451

Resistance patterns and serotype distribution of *Streptococcus pneumoniae* isolates responsible for respiratory tract infections in Poland, 2006-2018

Agnieszka Golebiewska1*, Izabela Wałość1, Patrycja Ronkiewicz1, Marlena Kiedrowska1, Izabela Wróbel1, Agnieszka Bojarska1, Bartłomiej Zieniuk1, Alicja Kuch1, Ewa Sadowy1, Waleria Hryniewicz1, Anna Skoczyńska1

1National Medicines Institute, Warsaw, Poland

**Background:** The aim of the study was to characterise *S. pneumoniae* isolates responsible for lower respiratory tract infections [LRTIs] in Poland between 2006 and 2018, by determining their antimicrobial resistance patterns and serotype distribution.

**Materials/methods:** Pneumococcal isolates (n=2849, including 1611 from blood) were serotyped by the Pneumotest-Latex kit, PCR or the Quellung reaction. MICs were determined either by the broth microdilution or Etest method, and interpreted according to the EUCAST criteria.

**Results:** Among studied isolates, 8.5% were from children under 5 years of age and 41.0% from patients older than 65 years. The most common were isolates of serotype 3 (20.1%), 14 (9.2%), 19F (8.0%), 4 (5.0%), 23F (4.8%), 19A (4.8%), 9V (4.3%) and 6B (4.2%). The overall coverage rates of PCV10, PCV13 and PPV23 were 42.5%, 69.3% and 83.0%, respectively but they differed significantly within age groups. Penicillin MICs higher than 0.06 mg/L were found in 25.8% of all isolates and in 66.1% of isolates from children under 5 years of age, whereas MICs higher than 2.0 mg/L in 72.8% and 22.0%, respectively. The susceptibility of *S. pneumoniae* was as follow: penicillin (74.2%), oral amoxicillin (81.4%), oral cefuroxime (76.9%), intravenous cefuroxime (79.0%), ceftriaxone (83.3%), macrolides (68.7%), clindamycin (74.7%), tetracyclines (72.9%), rifampin (93.6%) and trimethoprim/sulfamethoxazole (65.7%). Among pneumococci resistant to erythromycin, 83.3% represented phenotype cMLSβ, 15.7% M-phenotype and 1.0% iMLSβ. Multidrug resistance [MDR] characterized 30.1% of all pneumococci, but it was more common in non-invasive in comparison to invasive isolates (40.1% vs 22.9%, p<0.0001) and in children under 5 years old when compared to older population (59.9% vs 27.3%, p<0.0001). MDR phenotype was the most prevalent among pneumococci of serotypes 19A (83.0%), 19F (81.5%), 6B (73.3%) and 14 (68.8%). Since 2010 to 2018 susceptibility to penicillin have increased from 65.6% to 84.2% (p<0.0001) and MDR isolates decreased from 38.8% to 20.0% (p<0.0001).

**Conclusions:** Although pneumococcal susceptibility rates differed by age groups, types of infection and serotypes, MDR isolates numbers decreased significantly during the study period. This may be explained by wider use of antypneumococcal vaccination and its introduction into vaccination calendar in 2017.

Staphylococcus aureus pathogenicity in cystic fibrosis patients: virulence genes, phylogeny and horizontal gene transfer

Jonas Lange*, Kathrin Heidenreich†, Katharina Higelín†, Kristina Dyck†, Vanessa Marx†, Christian Reichel†, Dennis Görlich‡, Barbara C. Kahl†

†University Hospital Münster, Medical Microbiology, Münster, Germany, ‡University Hospital Münster, Institute of Biometry and Clinical Research, Münster, Germany

Background: Cystic fibrosis (CF) patients suffer from chronic respiratory infections. Staphylococcus aureus has the highest prevalence in the airways of CF patients and has shown to contribute to airway inflammation. However, the impact of S. aureus on lung function and disease progression especially in older patients has not yet been elucidated. This analysis aims to identify bacterial factors associated to clinical deterioration in these patients.

Materials/methods: During an observational prospective multicenter study, respiratory specimens from 195 CF-patients (16 centers in Germany, 1 center in Austria) were processed at a central laboratory. All S. aureus isolates (n=3180) were analyzed for the presence of virulence genes by single and multiplex PCR (adhesin genes: cap, clfA/B, cna, eap, emp, fnbA/B, sasG/H, sdrC/D/E; toxin genes: eta/etb, hlg, pvl, seA/B/C/D/E/G/H/I/J, tst; immune escape: chip. Molecular typing was performed by spa-typing. Clinical data related to lung disease exacerbation (4 out of 12 clinical parameters) were reported in case report forms including change of sputum, fever, decrease in pulmonary function, radiographic changes and others.

Results: The average follow-up time was 80 weeks with a mean of 7 visits. Neither the quantity of virulence genes, nor the presence of specific virulence genes characteristic for S. aureus were associated to a clinical deterioration. However, for the agr-types 1 and 4 a link to the subject’s clinical status became evident. Moreover, the agr-types showed a clear association to the clonal background of S. aureus. Further, the analyses revealed a significant longitudinal decrease regarding the number of virulence genes present in the patients’ clones. Analyses concerning the plasticity of the virulence genes revealed significantly increased plasticity rates in the presence of environmental stress.

Conclusions: These results provide evidence for the concept that rather the phylogenetic background than the presence of specific virulence genes accounts for differences in S. aureus pathogenicity. The significantly increased gene plasticity rates in the presence of environmental stress suggest a host and iatrogenic influence on S. aureus genome plasticity. The loss of virulence genes during persistence most likely reflects the adaptation process directed towards a persistent and colonizing rather than an infecting lifestyle.

Interleukin-1α and vascular endothelial growth factor support the growth and persistence of biofilm-growing Cutibacterium acnes in individuals with acne

Ilaria Cavallo*, Francesca Sivori, Giovanna D’agosto, Grazia Prignano, Fulvia Pimpinelli, Bruno Capitanio, Fabrizio Ensoli, Enea Gino Di Domenico

1San Gallicano Dermatological Institute IRCCS, Microbiology and Virology, Roma, Italy, 2San Gallicano Dermatological Institute IRCCS, Division of Dermatology, Roma, Italy

Background: Acne vulgaris is a common inflammatory disorder, affecting more than 80% of young adolescents. Cutibacterium acnes plays a role in the pathogenesis of acne lesions, although the mechanism(s) are, as yet, poorly understood. The aim of the study was to measure the prevalence of C. acnes in comedogenesis and in the progression towards inflamed acne lesions; to analyze the role of C. acnes as well as the impact of biofilm production; to assess the level of different inflammatory molecules on the skin of acne patients and their role in promoting bacterial growth and persistence.

Materials/methods: Samples for microbiological analysis were collected from the skin of 10 healthy subjects, and the unaffected skin, the comedones and the papulo-pustular lesions of 30 acne patients. Samples were characterized using 16S rRNA gene sequencing. Biofilm production was measured by the clinical BioFilm Ring Test in all C. acnes isolates. Tape adsorption tests were performed on the skin of acne patients and in 10 healthy controls, to measure the levels of skin inflammatory molecules. In vitro studies were performed to evaluate the response of C. acnes isolates to different concentrations of inflammatory molecules.

Results: Microbiome analysis showed a significantly higher relative abundance of C. acnes [P < 0.05] in inflammatory (papule and pustule) compared with noninflammatory (comedones) acne lesions, unaffected skin and the skin of healthy subjects. All the strains analyzed were able to produce comparable levels of biofilm, independently from the site of isolation. The level of cutaneous interleukin (IL)-α, and vascular endothelial growth factor (VEGF) was significantly higher [P < 0.05] in the skin of acne patients as compared to control subjects. Additionally, both IL-1α and VEGF selectively promoted a concentration-dependent increase of C. acnes growth.

Conclusions: C. acnes proliferates in the inflammatory lesions of acne patients. The increased level of IL-1α and VEGF in the skin of acne patients, may play a role in promoting the growth of C. acnes. Biofilm production by C. acnes may contribute to sustaining bacterial adhesion and chronic persistence in acne.

Abstract 3457

Impact of positive blood culture occurring in early post-operative cardiac surgery: a retrospective study

Michael Thy1;2, Helene Chaussade1;3, Richard Raffoul4, Nathalie Grall5, Jean-Christophe Lucet6;7, Soleiman Alkhoder4, Nathalie Grall5, Jean-Christophe Lucet6;7, Soleiman Alkhoder4, Constance Verdonk8, Walid Ghodhbane1, Claire Cimadevilla8, Laurence Armand-Lefevre5;7, Patrick Nataf9, Yazdan Yazdanpanah1;7, Xavier Lescure1;7

1CHU Bichat - APHP, Department of Infectious and Tropical Diseases, Paris, France, 2CHU Bichat - APHP, Department of Anesthesiology and Intensive Care, Paris, France, 3CHU Bordeaux, Department of Internal Medicine, Bordeaux, France, 4CHU Bichat - APHP, Department of Cardiac Surgery, Paris, France, 5CHU Bichat - APHP, Department of Microbiology, Paris, France, 6CHU Bichat - APHP, Infection Control Unit, Paris, France, 7Université Paris Diderot, Sorbonne Paris Cité, INSERM, Paris, France, IAME, UMR 1137, Paris, France, 8CHU Bichat - APHP, Department of Cardiology - Cardiac Surgery, Paris, France

Background: The occurrence of bacteremia after cardiac surgery is common, secondary to surgical site infection or not. The objectives of this study were to assess the complications of early postoperative bacteremia after sternotomy, their diagnosis process and therapeutic management.

Materials/methods: This monocentric retrospective study included patients over 18-year of age with bacteremia within 30 days after coronary bypass (CBP) and/or valvular surgery hospitalized at Bichat hospital in Northern Paris from January 2013 to December 2016.

Results: After excluding positive blood culture considered as contamination (n=83), 104 patients were enrolled in this study (Figure 1). Among these, 69.2% were men and the median age was 68.3 years [IQR=58.2-75.1]. The median EuroSCORE II was 4.4 [1.7-11.2]. The most common identified pathogens were Methicillin-susceptible Staphylococcus aureus (n=24, 23%) and Enterobacteriaceae (n=34, 33%). Thirty-five patients [34%] were in septic shock during bacteremia with a median IGS 2 score at 47 [38-75]. The median delay between surgery and positive blood culture was 9 days [4-18]. Infections were due to surgical site infection in 20 patients, including mediastinitis (n=13) and superficial wound infection (n=7) or secondary to other site infection with principally respiratory tract infections (n=19) or urinary infections (n=14). 19 patients had endocarditis: 15 after valvular surgery, and 4 after CBP. Endocarditis diagnosis was made by echocardiography (n=14) or WBC scintigraphy or PET/CT (n=5). Valvular surgery group was treated with higher antibiotic doses (55.8% (n=43) versus 33.3% (n=9) in the CBP group) (p=0.024) and longer median duration (21 days [14-42] against 14 days [7-21] in the CBP group) (p=0.033). Surgical treatment was done in 25 patients. Mortality at 30 days concerned 16 patients, 10 in valvular surgery group against 6 in the CBP group (p=0.404) and mortality at 1 year 32 patients, 22 in valvular surgery group against 10 in the CBP group (p=0.617).

Conclusions: Positive blood culture occurring after cardiac surgery is a complication with a high rate of mortality. Surgical site infection and endocarditis, particularly after valvular surgery, should be tracked and antibiotic therapy started immediately with high doses. As long as guidelines are lacking, prospective studies will be needed.

Adaptation to triclosan in carbapenemase-producing Klebsiella pneumoniae clinical isolates

Ana Gual-De-Torrella*, Patricia Pérez-Palacios, Mercedes Delgado-Valverde, Jesus Oteo, Alvaro Pascual Hernandez, Felipe Fernández-Cuenca.

1UGC Enfermedades Infecciosas, Microbiología Clínica y Medicina Preventiva. Instituto de Biomedicina de Sevilla (IBIS), Hospital Universitario Virgen Macarena/CSIC/Universidad de Sevilla, Sevilla, Spain, 2Spanish Network for the Research in Infectious Diseases (REIPI RD16/0016), Instituto de Salud Carlos III, Madrid, Spain, 3Laboratorio de Referencia e Investigación en Resistencia a Antibioticos e Infecciones relacionadas con la Asistencia Sanitaria, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain, 4Departamento de Microbiología, Universidad de Sevilla, Sevilla, Spain

Background: Carbapenemase-producing Klebsiella pneumoniae (CP-Kp) is a serious public health problem. Environmental reservoirs contaminated with biocides are acquiring increasing relevance in the dissemination of CP-Kp. Triclosan is a biocide widely used for multiple purposes (ie. antiseptic, preservative, etc.) which can accumulate in environmental reservoirs, enhancing the competitiveness and spreading ability of triclosan-adapted CP-Kp. The aim of this study was to i) determine if CP-Kp can be adapted to grow in increasing triclosan concentrations and ii) detect mutations in the gene encoding the target of triclosan (fabI; enoyl-acyl carrier reductase) in triclosan-adapted isolates.

Materials/methods: Six CP-Kp isolates representing different clones and carbapenemase types (ST15/bla VIM-1, ST11/bla OXA-48, ST258/bla KPC-3, ST15/bla OXA-48, ST147/bla VIM-1, ST405/bla OXA-48) were selected from the Andalusian reference laboratory PIRASOA and Reference and Research for Resistance to Antibiotics Laboratory of Carlos III. MICs of triclosan were determined by microdilution in MHB. Isolates were sequentially adapted by subculture in MHB containing rising subinhibitory triclosan concentrations, until MIC stabilisation. The nucleotide sequences of fabI of parental and triclosan-adapted isolates were determined by Sanger DNA sequencing (Macrogen). Aminoacid sequences of parental and corresponding adapted isolates were aligned by Clustal Omega for comparison.

Results: for parental CP-Kp isolates the MICs of triclosan were 0.1 mg/L [ST405/bla OXA-48] and ST15/bla VIM-1, 0.5 mg/L [ST15/bla OXA-48 and ST11/bla OXA-48] and 1.9 mg/L [ST258/bla KPC-3 and ST147/bla VIM-1]. In contrast, the MIC of triclosan determined against all the parental isolates after 1 week of adaptation to triclosan were ≥15 mg/L. No mutations were detected in two triclosan-adapted CP-Kp (ST15/bla VIM-1 and ST11/bla OXA-48). Mutations G93V and F203L, previously described in triclosan-resistant Escherichia coli, were detected in ST258/bla KPC-3 and ST15/bla OXA-48 (G93V), and ST147/bla VIM-1 (F203L). Mutation Y146H was detected in ST405/bla OXA-48.

Conclusions: (1) CP-Kp is able to adapt rapidly to grow in presence of triclosan, which might suppose a competitive advantageous under triclosan exposure. (2) Four out of the six triclosan-adapted CP-Kp isolates tested harbor one mutation in fabI, which could be involved in triclosan tolerance as has been previously described in E. coli. (3) The absence of mutations in fabI of two triclosan-adapted CP-Kp isolates suggest that mechanisms other than fabI mutations could be implicated in triclosan adaptation.

Presenter email address: gualdetorrella.ana@gmail.com
Impact of restricting procalcitonin measurements on antibiotic use, clinical outcomes and costs in a Swiss tertiary care hospital: an interrupted time-series analysis

Mohamed Abbas*,1, Nathalie Vernaz1, Elodie Von Dach1, Nicolas Vuilleumier1, Stephan J. Harbarth1, Benedikt Huttner1

1Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland

Background: Although biomarkers such as procalcitonin (PCT) can help avoiding unnecessary antimicrobial treatments, data suggest that overuse and misuse of PCT is frequent in routine practice. The primary objective of this study was to analyse the effect of the restriction of PCT measurement on antibiotic use in the wards concerned by the prescription limitation before and after its implementation. Secondary objectives were to assess the impact of the restriction on clinical outcomes and costs.

Materials/methods: This quasi-experimental study was conducted in Geneva University Hospitals. Due to the substantial financial burden of PCT-reagent costs it was decided to restrict PCT measurements as of February 3, 2016, except for the paediatric emergency department, the intensive care and transplantation units. We conducted an interrupted time-series analysis, using a Prais-Winsten regression, of rates of monthly antibiotic use in defined daily doses [DDD] per 1000 patient-days (PD), LOS, and in-hospital mortality, before and after the start of the restriction policy. We modelled the predicted number of PCT measurements per month based on the trend before the intervention. The difference between the observed and predicted number of PCT measurements was then used to calculate cost savings from the perspective of the hospital.

Results: After the intervention, there was an immediate statistically significant decrease in level of PCT measurements per month (-637.4; 95% CI 539.7-735.0) without a statistically significant change in slope (-0.05; 95% CI -8.2 to 8.1) (Figure). Before the intervention, there was an increasing trend of monthly antibiotic use of 4.3 DDD/1000 PD (95% CI 1.4-7.1). After the intervention, there was a non-significant decrease in level of 47 DDD/1000 PD (95% CI -1.0-95.6), followed by an upward change in slope of 1.6 DDD/1000 PD (95% CI -0.2-3.5) which was not statistically significant (Figure). There was no evidence of deleterious effect on mortality or LOS, and costs decreased considerably.

Conclusions: This study shows that the restriction of PCT measurements in our hospital did not have an impact on overall antibiotic use and was not associated with increases in LOS or mortality. At the same the restriction led to significant cost savings.

Figures – Changes in (A) monthly number of PCT measurements; (B) monthly rates of antibiotic consumption (measured in DDD per 1000 patient-days) before and after restriction of procalcitonin measurements.

Ten-year trends in Estonian ambulatory antibiotics use and comparison of ESAC quality indicators with Nordic countries

Jana Lass1, Ott Laius2, Elviira Linask3, Epp Sepp4, Irja Lutsar*4

1Tartu University Hospital, Tartu, Estonia, 2Estonian State Agency of Medicines, Tartu, Estonia, 3Estonian State Agency of Medicines, Tartu, Estonia, 4Department of Microbiology, University of Tartu, Tartu, Estonia

Abstract third-party references: Project RITA1/02-75-02

Background: The ambulatory antimicrobial use in Estonia has been among the lowest in the EU. However, there has not been lately any thorough country-wide assessment of the pattern of antimicrobial prescribing. Therefore we aimed to analyse the prescribing trends of systemic antimicrobials for better guided local antimicrobial stewardship.

Materials/methods: Consumption of systemic antibiotic was based on the wholesalers annual reports from 2008 to 2018. Antibiotics were grouped according to the active substances [ATC groups, 4th level], consumption is presented as defined daily doses per 1000 inhabitants per day [DDD/1000 inhabitants/day]. ESAC [European Surveillance of Antimicrobial Consumption] quality indicators were used to describe time-trends and compare outpatient antibiotic use in Estonia and selected Nordic countries.

Results: Over the past 11 years total antibiotic consumption has been very stable in Estonia ranging from 1.28 in 2008 to 1.22 in 2018 DDD/1000 inhabitants/day. There have been, however, changes in the consumption of specific antibiotics. Most commonly prescribed antibiotics (36% in 2018) were penicillins (J01C, DDDs/1000 inhabitants/day increased from 3.8 in 2008 to 4.4 in 2018). The prescribing of wide-spectrum penicillins (J01CA) has decreased and changed to the combinations of penicillins with betalactamase inhibitors (BLI, J01CR) (Figure 1)

Figure 1. Ten years changes in the consumption of penicillins

Important changes at the ESAC quality indicators:

Ratio of the consumption of broad-spectrum [J01 [CR+DC+DD+[F-FA01]]] antibiotics to the consumption of narrow-spectrum penicillins, cephalosporins and macrolides [J01 [CE+DB+FA01]] has changed markedly. In 2008 the ratio of broad spectrum antibiotics used in Estonia was 5.42 compared to the 15.95 in 2018 [annual percent change [APC] +16.2%, p<0.05]. The respective ratios in Nordic countries were <0.6 in 2018.

Consumption of BLI/BLI [J01CR] expressed as percentage of the total consumption of antibacterials for systemic use [J01] has increased from 8.4% in 2008 to 19.4% in 2018 [APC +8.9%, p<0.05]. The respective percentages in Nordic countries in 2018 were <6.

Conclusions: The shift in consumption from narrow to broad spectrum antibiotics despite stable low rate of AMR is of concern and suggests the need for more extensive monitoring of antibiotic prescriptions and improving antibiotic stewardship.

Abstract 3469

**Pathogenic, antimicrobial-resistant Escherichia coli in low-income settings household soils: origins and genomic diversity**

Maria Camila Montealegre*1, Alba María Talavera Rodríguez1, Subarna Roy3, Muhammed Iqbal Hossain1, Val Fernandez Lanza2, Mohammad Aminul Islam4, Timothy R. Julian1

1Eawag, Swiss Federal Research Institute of Science and Technology, Dübendorf, Switzerland, 2Hospital Ramón y Cajal, Madrid, Spain, 3International Centre for Diarrhoeal Disease Research, Bangladesh, Dakha, Bangladesh, 4Washington State University, Pullman, United States

**Background:** Soils in households in low-income settings are reservoirs for Escherichia coli and have been suggested to be important for disease transmission, particularly in areas with inadequate sanitation. The aims of this study were to investigate the risk factors for and genomic diversity of E. coli in soils collected from household plots to gain insights into their origins.

**Materials/methods:** E. coli was enumerated and isolated from soil and human, chicken, and cattle fecal samples collected in 52 rural Bangladeshi households. Associations between E. coli concentrations in soil, household-level risk factors, and soil physicochemical characteristics were evaluated. Susceptibility to 16 antibiotics was investigated among 175 collected isolates and whole-genome comparative analyses were performed for a subset of 60.

**Results:** E. coli was detected in 44.2% of the soil samples with an average of 1.95 log10 CFU/g dry soil. Soil moisture and clay content were associated with the E. coli concentration in soil, whereas no household-level risk factor was significantly correlated. Antibiotic resistance was detected in 42.3% of the 175 isolates and amongst the 60 isolates sequenced, 23 encode at least one resistance gene. Detected virulence factor-related genes are linked not only to intestinal pathotypes but also to environmental adaptation. The number of plasmid replicons detected ranged from 1 to 7 amongst 49 isolates (81.7%). E. coli from soils were genetically diverse and located across multiple branches of the reconstructed phylogeny, intermixed with isolates from fecal sources. Analyses of the accessory genome identified 1764 protein-coding genes, including a large number with unknown functions, statistically significantly enriched in the Bangladeshi isolates relative to genomes of the nearest neighbors available in databases.

**Conclusions:** Together, these findings indicate that E. coli detection in soils, including pathogenic and antimicrobial-resistant, appears to be driven by soil physicochemical characteristics and inputs from multiple and diverse E. coli sources (human and animal) that share a common accessory gene pool. Thus, public health interventions in low-income setting settings must consider soil as an important source for the transmission of E. coli variants with the potential to cause disease in people and that could pose treatment difficulties.

Nasal carriage of livestock-associated *Staphylococcus aureus* in Poland

Aneta Mroczyńska*, Natalia Marszałek, Monika Orczykowska-Kotyna, Magdalena Tomczak, Małgorzata Brzozowska, Jacek Żmudzki, Anna Skoczyńska, Joanna Empel

*1Department of Epidemiology and Clinical Microbiology, National Medicines Institute, Warsaw, Poland, 2Department of Swine Diseases, National Veterinary Research Institute, Puławy, Poland

**Background:** Livestock-associated *Staphylococcus aureus* (LA-SA) draws increasing attention due to its particular ability to colonize farm animals and be transmitted to people, which in turn leads to its spread in the environment.

The aim of the study was to investigate the nasal carriage of *S. aureus*, in particular LA-SA, among people having professional contacts with pigs in Poland in 2009 vs. 2017.

**Materials/methods:** 204 and 210 nasal swabs were taken from volunteers participating in annual conferences concerning pig health and farming (risk group) in 2009 and 2017, respectively. In parallel, nasal swabs from volunteers without contact with pigs (control group), were collected. For all identified *S. aureus* isolates, PCR-detection of *mecA*, *mecC*, *lukS-PV/lukF-PV* genes and *spa*-typing was performed. In all *mec*-positive isolates SCCmec types were defined. MLST was performed on selected isolates. Resistance to antimicrobials was determined.

**Results:** Table. Comparison of *S. aureus* nasal carriage in risk and control group (2009 vs. 2017).

All CC398 isolates identified in 2009 and 2017 were negative for *pvl* genes. The most prevalent *spa*-type among CC398 was t034 (65%), followed by t011 (17%). 61% CC398 isolates were *mec*-positive and carried element SCCmecV (91%) or SCCmecIVA (9%). The most prevalent resistance profile in 2009 was penicillin, erythromycin, clindamycin, tetracycline (62.2%) while in 2017 penicillin, erythromycin, clindamycin, tetracycline, chloramphenicol (64.7%). Increase in resistance rate for chloramphenicol (5% in 2009 vs. 98% in 2017) was observed.

**Conclusions:** Within a few years, percentage of CC398-MRSA carriers increased significantly fourfold in risk group (p<0.0001). CC398-MSSA were replaced by CC398-MRSA strains. Nasal carriage of CC398-MRSA in the control group remained at the same low level. The observed increase in incidence of CC398-MRSA among people having professional contact with pigs indicates the need to monitor *S. aureus* carriage in this risk group.

Abstract 3473

Prevalence and genetic characterisation of Shiga toxin-producing Escherichia coli isolates from cattle in Portugal

Hugo Oliveira*1, Andressa Balem2, Soraia Gonçalves3, Isidro García Meniño3, Saskia C Flament Simon1, Jesus Eulogio Blanco Alvarez1, Carlos Pinto1, Jorge Blanco1, Gonçalo Almeida2, Carina Almeida2

1University of Minho, CEB - Centre of Biological Engineering, Braga, Portugal, 2INIAV, IP - National Institute for Agrarian and Veterinary Research, Vila do Conde, Portugal, 3Universidad de Santiago de Compostela, Laboratorio de Referencia de E. coli, Facultad de Veterinaria, Lugo, Spain

Abstract third-party references: Project PhageSTEC (POCI-01-0145-FEDER-029628)

Background: Shiga toxin-producing E. coli [STEC] cause significant foodborne diseases in humans. They are natural residents of ruminants and are transmitted to humans through contaminated food. From 500 STEC serotypes known to infect humans, only few groups are responsible for the majority of cases [e.g. O157, the leading serotype worldwide]. However, the epidemiological link between STEC serotypes transmitted by animals to humans remains unclear. Their prevalence varies based on the type of animal, age, region and country, being unknown in Portugal.

Materials/methods: From November 2018 to June 2019, we collected 409 faecal specimens from the rectum of healthy dairy cattle [adults lactating cows, n=254 and heifers, n=155], at 21 milk farms located across the Northern region of Portugal. After enrichment with modified TSB with novobiocin, samples were analyzed by qPCR to detect virulence genes (stx1, stx2 and eae) in accordance with ISO/TS 13136:2012(E). Conventional PCR was used to confirm the strains profile and to detect stx1 (stx1a, stx1c and stx1d) and stx2 (stx2a, stx2b, stx2c, stx2d, stx2e, stx2f and stx2g) subtypes according to VTEC European Union Reference Laboratory guidelines. Additionally, serotyping was performed to establish O (O1 -O181) and H (H1-H56) antigens.

Results: A total of 141 isolates were recovered from 114 positive animals [dairy cows and heifers]. The STEC prevalence was higher in heifers (60/155; 38.7%) than in adult cows (54/254; 21.3%) [p<0.05]. PCR showed that 69 (49.9%) isolates carried stx1 genes, 114 (80.9%) stx2 genes and 41 (29.1%) both stx1 and stx2, with several stx subtypes identified. STEC isolates have shown a great diversity in terms of O and H antigens. Although the notorious O157:H7 and O26:H11 were found, others serotypes [e.g. O29:H12, O113:H21, O15:H16] were the most prevalent.

Conclusions: The high level of STEC prevalence in Portuguese dairy cattle, demand new strategies to prevent food contamination and subsequent human infection.

Abstract 3474

A case of recurrent Campylobacter cured by faecal microbiota transplant in an immunosuppressed patient with common variable immune-deficiency

Aravind Gokul Tamilarasan¹, Raphael Luber¹, Patrick Yong², Kuldeep Cheent², Peter Irving¹, Manjula Meda², Simon Goldenberg*¹

¹Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, ²Frimley Park Hospital, Frimley, United Kingdom

Background: We report a case of a 69 year old immunosuppressed patient with a 7 year history of recurrent Campylobacter infection, who was successfully treated with Faecal Microbiota Transplant (FMT) administered via nasojejunal tube.

Materials/methods: The patient was diagnosed with Common Variable Immune-deficiency (CVID) in 2000 and is treated with fortnightly intravenous immunoglobulin (IVIG). She has suffered from numerous infectious complications including EBV-driven diffuse large B-cell lymphoma, toxoplasma chorioretinitis, chronic bacterial sinusitis and recurrent Campylobacter jejuni gastroenteritis. This was first identified in 2012 following a trip to Brazil, but was isolated again (with the same sensitivity pattern so assumed to be a relapse) in 2014 which corresponds with a break in IVIG treatment. Between May 2018 and 2019 she suffered at least 6 further episodes, despite prolonged treatment with numerous courses of clarithromycin to which the isolates were sensitive. Further antimicrobial susceptibility testing revealed resistance to ciprofloxacin and doxycycline. She consented to FMT which was performed via push enteroscopy from an anonymous donor according to our standard methods. This was undertaken in May 2019 following a course of fosfomycin to treat the Campylobacter.

Results: After initial improvement in diarrhea, she suffered a further microbiologically confirmed relapse. She was treated with an extended (6 week) course of fosfomycin and her dose of IVIG was increased. She underwent a second FMT (using a different donor) at the end of July 2019, again with good response. She remains asymptomatic at the time of writing [four months after the 2nd FMT] and has gained 5kg in weight.

Conclusions: Recurrent Campylobacter infections [including gastroenteritis and bacteraemia] have previously been reported in patients with CVID and are particularly problematic to manage. To our knowledge, this is the first time FMT has been used to successfully treat such a patient.

**Abstract 3477**

**Differentiation of the members of the Staphylococcus aureus complex by MALDI-TOF using the VITEK MS platform**

Béatrice Celliere*, Valerie Monnin, Michele Bes, Frédéric Laurent, Anne-Gaelle Ranc, Sandrine Arend, Priscillia Courault, François Vandenesch, Geraldine Durand, Anne Tristan, Victoria Girard

1bioMérieux, La Balme les Grottes, France, 2Hospices Civils de Lyon, Lyon, France

**Background:** Staphylococcus argenteus and Staphylococcus schweitzeri have been recently described as new species within the Staphylococcus aureus complex. The need to distinguish species within the complex for routine purposes is currently questionable as no difference in morbidity, mortality or transmission between *S. aureus* and *S. argenteus* have been described and no human infections with *S. schweitzeri* have been reported so far. However, the distinction is valuable to further clarify the epidemiology and clinical impact of these two novel species. In this study, we tried to establish if their differentiation is possible using the MALDI TOF technology.

**Materials/methods:** A total of 234 spectra were acquired on 49 strains (29 *S. aureus*, 18 *S. argenteus* and 2 *S. schweitzeri* strains) obtained from different sources, including the French National Reference Center for Staphylococci. Spectra were acquired following direct deposit on a VITEK MS slide, in the 3000 to 17000 Da mass range and integrated into the next release of the VITEK MS knowledge base. Data were analyzed using Multidimensional Scaling (MDS). Performance was evaluated using a cross-validation approach.

**Results:** The cross-validation study performed on the updated database, containing 41922 spectra covering 1257 bacterial species, showed that the correct identification rates at species level reached 97.3% for *S. aureus* and 100% for *S. argenteus*. Conversely, only 8.3% of the spectra from *S. schweitzeri* were identified at species level, 66.7% were identified in low discrimination with the two other members of the complex, 8.3% were not identified while 16.7% were misidentified either to *S. aureus* or *S. argenteus*. The MDS confirmed that a clear differentiation is possible between *S. aureus* and *S. argenteus* but not between *S. schweitzeri* and the two other members of the complex.

**Conclusions:** This study demonstrates that MALDI TOF using VITEK MS platform is able to differentiate *S. argenteus* from *S. aureus* but not *S. schweitzeri* from *S. argenteus* and *S. aureus*. The identification of *S. argenteus* at species level could help to clarify its involvement in clinical infection and, if warranted, to implement future surveillance or infection control measures.

Abstract 3478

Coxiella burnetii DNA in cheeses and bulk milk samples of sheep and goats in Puglia and Basilicata, Italy

Maria Grazia Basanisi¹, Donato Antonio Raele¹, Maria Assunta Cafiero¹, Gianfranco La Bella¹, Gaia Nobili¹, Roldano Sottili², Sebastiana Tola², Giovanna La Salandra*¹

¹Istituto Zooprofilattico Sperimentale della Puglia e della Basilicata, Foggia, Italy, ²Istituto Zooprofilattico Sperimentale della Sardegna, Sassari, Italy

Background: Coxiella burnetii is a Gram-negative obligate intracellular bacterium that is responsible for Q fever, a worldwide zoonosis. C. burnetii infects a wide range of wild and domestic mammals, including humans. Domestic ruminants are the main reservoir. Infected animals can shed C. burnetii at high concentrations in their urine, feces, milk and birth products. Consumption of contaminated raw milk and dairy products might be source of human infection, although the transmission by the oral route is still controversial.

Materials/methods: This study included a total of 200 samples of dairy products of ovine-caprine origin [71 short-seasoned cheese and 129 raw milk samples], collected from October 2018 to October 2019 by the local health services and transferred to the Istituto Zooprofilattico della Puglia e della Basilicata in Foggia. A loop-mediated isothermal amplification assay (LAMP) was performed for rapid and simple detection of the IS1111 transposon of C. burnetii. The C. burnetii Nine Mile strain strain (Ampli-run® Coxiella burnetii DNA control, Vircell Microbiologists) was used as a positive control.

Results: C. burnetii DNA was found in 14 out of 200 (7%) samples analysed. In particular, 12 of the 129 samples of raw milk (9.3%) and 2 of the 71 cheese samples (2.8%) came out to be positive for IS1111.

Conclusions: LAMP assay can rapidly detect C. burnetii DNA and does not require any specific or expensive equipment. Some studies suggest that the consumption of raw milk could be the cause of some cases of Q fever in humans. Indeed, there is epidemiological evidence that the consumption of milk and/or milk-based products contaminated by C. burnetii is associated with seroconversion in humans. Therefore, the results of this study emphasize the importance of a One Health approach to Q fever, that includes active monitoring, vaccinations and correct hygiene measures to prevent the dispersion of the bacterium in the environment, between animals and a possible transmission to humans.

Differentiation at species level of the members of the PSC complex (Pseudallescheria boydii / Scedosporium apiospermum) involved in cystic fibrosis by MALDI-TOF MS

Valerie Monnin1, Laetitia Picoulet2, Delphine Giraud1, Sandrine Arend1, Béatrice Celliere1, Priscillia Courault1, David Pincus2, Geraldine Durand1, Victoria Girard1

1bioMérieux, La Balme Les Grottes, France, 2bioMérieux, Inc., Hazelwood (MO), United States

**Background:** The species of the Pseudallescheria boydii/Scedosporium apiospermum complex (PSC) are ubiquitous molds reported as emerging pathogens causing invasive fungal diseases and colonization especially in cystic fibrosis (CF) patients with a prevalence of about 10%. The distinction of the species within the complex is of great importance as they show different antifungal susceptibility profiles to azoles or echinocandins.

The current molecular methods can be fastidious and time-consuming. In this study, we propose a rapid identification of these organisms at species level via an inactivation/extraction protocol followed by a MALDI-TOF MS identification.

**Materials/methods:** A total of 343 spectra from 64 well-characterized PSC strains (Pseudallescheria boydii [n=5], Pseudallescheria ellipsoidea [n=4], Pseudallescheria minutispora [n=4], Scedosporium apiospermum [n=17], Scedosporium aurantiacum [n=4], Scedosporium dehoogii [n=4], and Scedosporium prolificans [n=6]) were acquired with the VITEK MS after an inactivation/extraction protocol and within the mass range of 3,000-17,000 Da.

The spectra were integrated into the next VITEK MS knowledge base update and data were analyzed using dendrograms and multidimensional scaling (MDS). Performance was evaluated using a cross-validation approach.

**Results:** The MDS shows that a clear differentiation is possible between all species of the complex despite a very high spectrum similarity (>50%) as shown by the dendrogram analysis.

The cross validation study performed on the updated database, containing 15,557 spectra covering 327 fungal species, shows that 97.7 to 100% correct identification rates are obtained at the species level for all seven species.

**Conclusions:** This study demonstrates that MALDI-TOF MS is a rapid and reliable tool to differentiate close species within the PSC complex. It could help in the management of CF patients by improving the identification of molds responsible for colonization and by reducing the time to start appropriate antifungal therapy.

Case report: microbiological effects of phage therapy on *Pseudomonas aeruginosa* in a pneumonia patient

Annabel Niessen*, Ana Rita Costa, Franklin Nóbrega, Pieter-Jan Haas

1UMC Utrecht, Utrecht, Netherlands, 2Delft University of Technology [TU Delft], Delft, Netherlands

**Background:** Due to growing concerns about multi drug resistant bacteria, interest in phage therapy has increased. Especially the ESKAPE organisms are seen as a potential target for phage therapy. In this case report we present a case of adjunctive phage nebulization for a pulmonary infection with *Pseudomonas aeruginosa*. By analyzing the isolates obtained during the course of treatment, we evaluated the effect of phage nebulization on the bacterial populations in the lung.

**Materials/methods:** A 7 year old girl with recurrent pulmonary infections, was treated for a new episode of pneumonia with sputum cultures showing *Pseudomonas aeruginosa* and *Klebsiella variicola*. The isolated pathogens were susceptible for the administered antibiotics. During hospitalization, on request of the patient’s family, adjunctive phage therapy was started through nebulization of two phage cocktails from Tbilisi containing multiple phages against the *Pseudomonas* strain. Different *pseudomonas* phages were isolated based on plaque morphology and were whole genome sequenced. Daily sputum samples were taken to monitor microbiological response. *Pseudomonas* isolates were tested for phage susceptibility using plaque assays. Several isolates were whole genome sequenced for phylogenetic analysis and analysis of phage resistance mechanisms.

**Results:** 14 phages with lytic activity against the *pseudomonas* strain were isolated from the two phage cocktails. Genetic assembly revealed two phage variants: Myoviridae with genetic similarities between the isolates of >99% and Podoviridae sharing a homology of >90%. *Pseudomonas* isolates were collected till 47 days after start of phage nebulization. A varying phagogram was seen between the isolates over time. All isolates had the same antibiogram and all 7 sequenced isolates had identical MLST-types. None of the bacterial isolates carried a CRISPR system. We are still in the process of analyzing the underlying resistance mechanisms and the phylogenetic relationship between the *pseudomonas* isolates.

**Conclusions:** Current analysis indicates that there have been no major shifts in bacterial strains. We hypothesized that due to heterogeneous spread of phages through the lung, variations in phage susceptibility are seen between exposed an unexposed *pseudomonas* populations. This case report provides important insights about the microbiological response on phage nebulization which will be valuable in planning future trials.

Abstract 3486

Widespread distribution of the acquired colistin resistance gene, mcr-9, amongst Enterobacterales in England and Wales

Matthew Ellington*1, Tim Dallman1, Daniele Meunier1, Katie Hopkins1, Neil Woodford1

1Public Health England, London, United Kingdom

Background: Colistin is a last-line treatment option for infections due to multi-resistant Gram-negative bacteria. The emergence of mobile colistin resistance (mcr) genes threatens to cause widespread colistin resistance. We determined the distribution of the most recently described variant, mcr-9, amongst large collections of Enterobacterales isolates including carbapenemase-producing Enterobacterales (CPE).

Materials/methods: PHE's National Infection Service reviewed WGS data (Illumina HiSeq 2500) for isolates of: Salmonella (N=39,697), gastrointestinal E. coli (N=13,082) isolated in 2014-17; ExPEC (N=529) referred in 2017-18 and 3089 CPE (N=3089) referred between 2010-16.

AMR genes, bacterial species and MLST were determined via PHE-genefinder, kmer-ID and MOST, respectively. Antimicrobial MICs for CPE were determined by agar dilution according to BSAC methodology and interpreted using EUCAST breakpoints.

Results: We detected mcr-9 in 210 isolates of Enterobacterales. These were comprised of 38/39,697 Salmonella, of which 24 were ST19 S. Typhimurium, and 0/13,082 gastrointestinal E. coli. Twenty-eight of the Salmonella encoded CTX-M-9 or -15 ESBLs.

HCAI/AMR mcr-9 isolates from 41 English centers comprised: 5/529 HCAI-E. coli isolates from 5 centers and 167/3089 CPE from 41 centers (three centers referred 68 isolates). CPE were dominated by Enterobacter spp. (125) belonging to 55 STs, followed by K. pneumoniae (16), K. oxytoca (7), E. coli (10) representing 24 different STs, C. freundii (4) and five isolates from four other Enterobacterales species.

Amongst mcr-9 CPE, OXA-48 isolates dominated (61 isolates) followed by KPC-2 (49 isolates), NDM-1 (24 isolates) and VIM-4 (15 isolates). Six IMP isolates encoded IMP-1, IMP-4 or IMP-10. The remaining 12 isolates were variants from these main families. All mcr-9+ CPE harboured IncHI2 replicons, except five isolates from three species, with different carbapenemases. Of the 125 mcr-9+ CPE with colistin MIC data: 99 were <=0.5mg/L, 23 were 1-2 mg/L, only three were resistant (>2 mg/L).

Conclusions: The mcr-9 gene is disseminated amongst diverse Enterobacterales and was found in more isolates than other mcr variants. Whilst its clinical significance remains unclear, we will further investigate MICs amongst populations with and without the gene.

The association of mcr-9, IncHI2 replicons and ESBLs or carbapenemases raises concern for the co-selection of mcr-9 with other resistances.

Abstract 3488

**Carbapenem-resistant *Escherichia coli* causing neonatal sepsis: NDM-5 gains prominence**

Amrita Bhattacharya¹, Shravani Mitra¹, Sharmi Naha¹, Bijan Saha², Shanta Dutta¹, Sulagna Basu*¹

¹ICMR-National Institute of Cholera and Enteric Diseases, Kolkata, India, ²IPGMER, Kolkata, India

**Background:** *Escherichia coli* causes sepsis in neonates. Carbapenem-resistant *E. coli* (CREc) are rapidly spreading. An important family of carbapenemases are the Zn(II)-dependent –β-lactamases, known as metallo-β-lactamases (MBLs). Among them, the New Delhi metallo-β-lactamase (NDM) is a potent enzyme. This study maps the *E. coli* causing neonatal sepsis in a tertiary care hospital in India during a decade focusing on carbapenem resistance, the phylogroups, sequence types and virulence determinants of *E.coli* with a view to understand changing patterns of the prevalent variants and the corresponding sequence types.

**Materials/methods:** *E.coli* were collected from the Neonatal Intensive Care Unit (2008-2017). Isolates were confirmed, MIC for meropenem was determined by broth dilution. Presence of **bla**<sub>NDM</sub> and other resistance genes were determined by PCR followed by sequencing. Phylogroup and sequence types were determined by standard procedures.

**Results:** Thirty-four percent of the isolates were carbapenem-resistant, harbouring **bla**<sub>NDM</sub> (MIC 2-64mg/L). The different allelic variants were distributed as follows: NDM-1, 50%; NDM-5, 36%; 9% NDM-7 and one isolate possessed NDM-15. The amino acid differences of the variants in comparison to NDM-1 were V88L and M154L for NDM-5, D130N and M154L for NDM-7 and M154L and A233V for NDM-15. Most isolates co-harboured **bla**<sub>CTX-M-15</sub> along with different combinations of other resistant-genes such as **aac-(6’)-Ib-cr**, **bla**<sub>SHV</sub>, **rmtB**, AmpC. CREc also revealed diverse plasmid types (HI1, I1, FIA+FIB, FIA, FII, FIIK, FIIS, and Y). Virulence genes such as **traT**, **papC**, **fimH**, **iucC**, **usp**, **hlyA** which encoded diverse virulence traits were also present. The distribution of the phylogroups among the strains were A, B2, C, and B1, of which phylogroup A predominated. CREc were of diverse sequence types ST2, ST43, ST471, ST922 (Pasteur scheme). There was no association between any particular phylogroup or ST types and the NDM variants, their presence in a particular ST or phylogroup was random.

**Conclusions:** Carbapenem-resistance in *E. coli* in this unit has been primarily due to NDM-1. Lately NDM-1 is slowly being replaced with NDM-5.

Assessment of ceragenin CSA-131-poloxamer for treatment of Stenotrophomonas maltophilia infections as a potential antimicrobial agent

Özlem Oyardı,* 1, Cagla Bozkurt Guzel1, Paul B. Savage1, Elif Sena Demir1, Zayre Erturan1

1Istanbul University, istanbul, Turkey, 2Brigham Young University, Provo, United States

Background: Stenotrophomonas maltophilia is an important Gram negative opportunistic pathogen causing variety of infectious. As well as extensive intrinsic resistance, multi drug resistance was reported worldwide. Therefore, new drugs need to develop to combat S. maltophilia infections. Ceragenins were developed as alternative antimicrobial agents to antimicrobial peptides (AMPs) to improve AMPs antimicrobial and chemical properties. The aim of this study was to evaluate antimicrobial activities of ceragenin CSA-131 (Cationic Steroid Antibiotic) by formulating in poloxamer micelles as well as CSA-13 and CSA-131 against S. maltophilia isolates.

Materials/methods: S. maltophilia clinical isolates (n=40) were collected from Istanbul University, Faculty of Medicine between 2006-2016. CSA-13 and CSA-131 were synthesized from cholic acid Scaffold technique. CSA-131 was combined with Pluronic F-127 to decrease the cytotoxicity of CSA-131. Minimum inhibitory concentrations (MICs) and Minimum bactericidal concentrations (MBCs) of CSA-13 (prototype ceragenin) and CSA-131 with or without 5% pluronic F-127 were determined as well as conventional antibiotics ceftazidime, cefaperazon, sulfamethoxazole-trimethoprim (SMX-TMP) and levofloxacin. Five different isolates that have lowest MIC results were selected and time kill curve experiments were performed with 1x, 2x and 4x MICs of ceragenins. Also, Minimum biofilm eradication concentrations (MBECs) of ceragenins were investigated against four isolates that have biofilm forming ability.

Results: MIC and MBC ranges, MIC50/MIC90 and MBC50/MBC90 results were shown at Table 1. CSA-131-poloxamer displayed the lowest MICs and MBCs. While seven isolates were determined as susceptible to ceftazidime and SMX-TMP, all of the isolates tested were resistant to cefaperazon. Only one isolate was resistant to levofloxacin. According to time kill curve results, all 4xMICs of ceragenins showed bactericidal activity (3 log reduction) after four hours. CSA-131-poloxamer (320->640 µg/ml) displayed better antibiofilm activity than CSA-131 (2560->5120 µg/ml).

Conclusions: CSA-131-poloxamer with 5% pluronic F-127 had better antimicrobial properties than CSA-131 and CSA-13 against S. maltophilia. For treatment of S. maltophilia infections, CSA-131-poloxamer can be potential antimicrobial agent.

Abstract 3490

Heterogeneity of Clostridiodes difficile infection testing and the impact on missed diagnoses: results from COMBACTE-CDI

Virginie Viprey\textsuperscript{1}, Duncan Ewin\textsuperscript{1}, William Spittal\textsuperscript{1}, Jonathan Vernon\textsuperscript{1}, Anthony Benson\textsuperscript{1}, Georgina Davis\textsuperscript{1}, Mark H. Wilcox\textsuperscript{1}, Kerrie Davies*\textsuperscript{1}

\textsuperscript{1}Healthcare Associated Infections Research group, University of Leeds, Leeds, United Kingdom

Abstract third-party references: on behalf of the COMBACTE-CDI consortium

\textbf{Background:} ESCMID guidelines for CDI diagnosis largely focus on the diagnostic method, not the testing rate. Here we investigate the impact of both testing rates and methodology on detection of cases in hospitalised patients.

\textbf{Materials/methods:} Sites were recruited from 12 European countries (1 site/3 million population). On two days, all diarrhoeal faecal samples (regardless of tests requested) were sent to the European coordinating laboratory (ECL) for toxin testing and culture. The CDI results/test-not-requested at each original submitting site were compared with the ECL results to determine the number of missed cases. Additional information on testing rates and methodology was collected from the sites via an online questionnaire. Estimates of missed cases/10,000 pbds for each site, country and European region were calculated.

\textbf{Results:} There was wide heterogeneity in testing methods, and 100/105 (95\%) used more than one test to diagnose CDI; 16/105 (15\%) did not detect toxin, including 9/16 sites in France. There was wide variation in testing rates in hospital based facilities across European countries; country range 20.4-218.6 tests/10,000 pbds/site. There was also wide variation in case rates; country range 2.5-27.9 cases/10,000 pbds/site. The average number of missed cases ranged from 0.0-8.8/10,000 pbds/site, with the highest in Romania (8.8 missed cases/10,000 pbds/site) and Sweden (6.52 missed cases/10,000 pbds/site). These countries also had the highest proportion of sites using one only CDI test - Sweden (single molecular test) and Romania (standalone toxin EIA).

The site CDI rate in Northern Europe was 3-fold higher in sites using methods that did not directly detect faecal toxin, compared with those using at least one toxin detection test (18.1 vs 6.4 case/10,000 pbds/site) (Figure 1). In addition, the missed CDI case rate was twice as high in the former sites (4.9 vs 2.1 missed cases/10,000 pbds/site respectively).

\textbf{Conclusions:} Heterogeneity of testing impacts not only on reported CDI rates, but also on the number of cases that are missed. Missed CDI rates were higher in countries using single tests, or tests that did not detect toxin, suggesting important potential consequences of not following current ESCMID recommendations.
Abstracts 2020

Figure 1. Testing and CDI rate by European region in countries that use any tests (A), at least one test detecting toxin (B), and test(s) that did not detect toxin (C).

Abstract 3492

Combined inhibition of CD14 and C5 in *Escherichia coli* and Group B streptococci induced inflammation in human cord blood

Aline Bjerkhaug,1 Hildegunn Norbakken Granslo,1 Pauline Cavanagh,1 Judith Ludviksen,2 Åshild Bjørnerem,3 Tom Eirik Mollnes,2 Claus Klingenberg1

1 UiT-The Arctic University of Norway/University Hospital of North Norway, Tromsø, Norway; 2 Somatic Research Center/Nordland Hospital, Bodø, Norway; 3 Department of Obstetrics and Gynecology/University Hospital of North Norway, Tromsø, Norway

Abstract third-party references: Nordlandssykehuset, UiT - The Arctic University of Norway, HelseNord

Background: *Escherichia coli* (*E. coli*) and Group B streptococci (*GBS*) are the main causes of early-onset neonatal sepsis (EONS). Treatment with antibiotics is not always sufficient to inhibit a massive systemic inflammatory response, associated with increased morbidity and mortality. Activation of CD14 and the complement system have important roles in this inflammatory response, and are therefore potential targets for novel therapy in order to prevent harmful effects. Studies indicate that combined inhibition of CD14 and complement (C5) may attenuate Gram-negative bacteria-induced inflammation, but less is known about their roles in Gram-positive infections. The objectives with this study are to first compare inflammatory response between *E. coli* versus *GBS*, with a focus on complement activation and cytokines, in an EONS-human cord blood model. Second, to assess the efficacy of the combined inhibition of CD14 and C5 in the same model.

Materials/methods: Human cord blood from term infants (*n* = 30) is anti-coagulated with lepirudin. A combination of anti-CD14 and eculizumab (C5 inhibitor) is added 8 min prior to or 15 min or 30 min after adding *E. coli* (ATCC 33572) or *GBS* (SO-SAG18-1). Total incubation time for the experiments is 120 min. Cytokines and the terminal complement complex (TCC) are measured using multiplex technology and ELISA.

Results: The combined regimen of anti-CD14 and Eculizumab totally blocked complement activation (TCC) when supplemented 8 min prior to adding the bacteria. For the post-challenge time-points 15 min and 30 min we found a 70-80% and 60-70% reduction in complement activation (TCC), respectively.

Conclusions: Preliminary results show that the combined CD14/C5 inhibition in this EONS-human cord blood model dramatically reduces the complement activation induced by both *E. coli* and *GBS*. The study is ongoing, and complete data on cytokine response and the results from the combined inhibition in the post-challenge experiments will be presented. Future studies in animal models are the next steps to evaluate a potential future clinical role for this therapy in severe cases of EONS.

Abstract 3493

A quality improvement project to increase influenza vaccination uptake amongst inpatients in a tertiary care centre supported by Electronic Healthcare Records (EHR)

Anna Orourke*1, Mary Kelly2,3, Conal Cunningham4, Grainne Courtney4, Una Geary4, Simon Moores4, Gail Melanophy3, Aimee McGreal-Bellone1, Kieran Murray6, Cathal O’broin8, Colm Bergin1;2;9

1St. James’s Hospital, Department of Genitourinary Medicine and Infectious Diseases, Dublin, Ireland, 2St James’s Hospital, Antimicrobial Steering Committee, Dublin, Ireland, 3St James’s Hospital, Department of Pharmacy, Dublin, Ireland, 4St James’s Hospital, Department of Medicine for the Elderly, Dublin, Ireland, 5St. James’s Hospital, Chief Clinical Informations Officer, Dublin, Ireland, 6St James’s Hospital, Patient Quality and Safety, Dublin, Ireland, 7St James’s Hospital, Chief Operating Officer, Dublin, Ireland, 8St Vincent’s University Hospital, St Vincent’s University Hospital, Dublin, Ireland, 9Trinity College Dublin, Trinity College Dublin, Dublin, Ireland

Background: Influenza infection is an important cause of morbidity and mortality; vaccination remains the single best preventative public health initiative[1]. Much of the focus to date has been on community-delivered vaccination. In 2015 there was a large outbreak of nosocomial acquired influenza infection in St James’s Hospital. A subsequent audit performed in 2017 focused on the vulnerable Medicine for the Elderly inpatient cohort. This audit concluded that less than one quarter of eligible patients received vaccination and many patients had cognitive impairment. Best practice in administering vaccination to patients with cognitive impairment is to inform both patients and their next-of-kin (NOK).

The primary aim was to increase inpatient vaccination uptake amongst eligible inpatients with prolonged length of stay (LOS).

Materials/methods: An action learning quality improvement approach was used, based on iterative Plan-Do-Study-Act (PDSA) cycles. Data was collected using the EHR system for inpatients under the care of a single Medicine for the Elderly consultant. Patients included were those over 65 years old and with length of stay (LOS) greater than 21 days. Baseline characteristics collected included gender, age, LOS and documented Mini Mental State Examination (MMSE) score.

Results: 71% of patients were male, mean age was 82 (68-90). Mean LOS was 84 days (34-111). Of those with a documented MMSE score, 100% scored < 24 indicating mild cognitive impairment.

For the primary group studied, 98% of patients’ NOKs raised no objections to proceeding with influenza vaccination. 12% declined fearing an adverse reaction. Of 88% of these patients, 75% were themselves agreeable and received influenza vaccination. Opportunistic education on the benefits of influenza vaccination was provided to all patients, their NOK and staff.

Conclusions: While influenza vaccination strategies are predominantly and appropriately focused on primary care, prolonged inpatient admission necessitates consideration of this important public health intervention. EHR aided in timely and efficient identification of patients who required vaccination. The learning from this primary PDSA cycle will be extended to other patient cohorts at risk of influenza and other in-patient and out-patient vaccination programmes to include pneumococcal vaccination.

Abstract 3496

Public health implications of prevalent antibiotic resistance genes and integrons in commensal Escherichia coli inhabiting a major Indian river

Somendro Singh Nambram*1,2, Jugsharan Singh Virdi1, Manish Kumar2

1University of Delhi, Department of Microbiology, New Delhi, India, 2University of Delhi, Department of Biophysics, New Delhi, India

Background: Rapid emergence of antibiotic resistance (AR) is a major global public health concern. Due to lesser clinical implications, commensal strains of Escherichia coli are less studied than pathogenic strains. The current study aimed to investigate the prevalence of AR and integrons in commensal E. coli isolated from river Yamuna, Delhi India.

Materials/methods: Eighty-three well-characterized E. coli strains of phylogroups A and B1 were studied. Antibiotic susceptibilities to major classes of antibiotics viz. β-lactams, aminoglycosides, tetracycline, quinolone/fluoroquinolone, and chloramphenicol were assessed according to CLSI guidelines. The strains were also tested for extended spectrum β-lactamases (ESBL) and AmpC production. Resistance determinants to β-lactamases (blaTEM, blaSHV, blaCTX-M, blaOXA, blaCMY-42) aminoglycosides (rmtA, rmtB, rmtC, armA, str, aacC2) tetracycline (tetA, tetR, tetM, tetW), plasmid mediated quinolone resistance (PMQR) (qnrA, qnrB, qnrC, qnrD, qnrS, qep, aac), integrons and variable gene cassette arrays were PCR-characterized.

Results: Resistance profiling revealed high prevalence of ampicillin resistance 95% (n=79) followed by cefazolin 45% (n=39). About 15% (n=12) strains were resistant to tetracycline. Approximately 19% strains were multidrug resistant and 15% (n=12) were ESBL producers. AmpC production was not detected. Co-resistance to fluoroquinolone and ESBL antibiotics was observed in 6% (n=4) of the strains. blaTEM was the most widespread (95%) gene followed by blaOXA (15%). Genes conferring resistance to aminoglycoside viz. str and armA were detected in 5 and 7 E. coli strains, respectively. Genes tetA and tetR genes which confer resistance to tetracycline were detected in 3 and 5 E. coli strains, respectively. The PMQR gene qnrS was detected in 15% of the strains investigated. The upstream of blaCTX-M had insertion sequence ISEcp1 and orf477 in the downstream region. intI gene of class 1 integron was detected in 64% (n=53) isolates. Of the 53 intI harboring strains, 7 strains had variable gene cassettes. Sequencing revealed the presence of aacA4, catb3, dfrA1, aadA1, dhfr1, and aadA2 gene arrays. None of the strains had class 2 and 3 integrons.

Conclusions: The presence of antibiotic resistance genes (ARGs) and integrons along with co-existence of ESBL and PMQR genes in aquatic E. coli suggests that these strains might serve as reservoirs for transmission of ARGs to other bacteria.

The female reproductive tract microbiome and its relationship with infertility and hydrosalpinx

Yael Yagel*, Adi Weintraub², Ella Pardo¹, Stefan J. Green³, Yair Motro¹, Jacob Moran-Gilad¹

¹Ben Gurion University, Be’er Sheva, Israel, ²Soroka Medical Center, Be’er Sheva, Israel, ³University of Illinois at Chicago, Chicago, United States

Background: The vaginal microbiome has been thoroughly investigated but little is known on the upper female reproductive tract microbiome. Hydrosalpinx, a blocked edematous fallopian tube, is a known cause of infertility and may result from previous pelvic infections, endometriosis or post-surgical adhesions. However, the role of the microbiome in this process is yet unknown. This study aimed to describe vaginal and fallopian tube microbiota (VM, FTM) in 32 women undergoing surgery for hydrosalpinx or other indications.

Materials/methods: We studied 9 cases that underwent salpingectomy for hydrosalpinx (due to recent pelvic infection and/or infertility) and 23 controls that underwent surgery that included salpingectomy for other indications. Samples for VM and FTM were obtained and subjected to DNA extraction and high-throughput 16S rRNA gene amplicon sequencing. Bioinformatics analysis was carried out using the QIIME software package (v1.9.1). Microbial alpha-diversity was calculated using Shannon index, with Kruskal-Wallis used for group significance tests. Differences in mean taxonomical abundance were calculated using t-test.

Results: The mean age of studied women was 41 (range: 29-54). Alpha diversity as measured by Shannon index was significantly different between FTM and VM in controls (3.365 vs. 1.7 1 7, p<0.005), but not cases (2.7 vs. 2.45, p=0.77). A significant difference was found between the VM composition of cases and controls (2.45 vs. 1.77, p=0.027) as well as in the FTM composition between the groups (p=0.0002). Figure 1 shows abundance at phylum level; Firmicutes (including Lactobacillus) dominated in VM of controls. Notably, the average relative abundance of the genus Lactobacillus in all VM samples was 63% vs. 8% in FTM (p<0.0001). Lactobacillus relative abundance in cases and controls was 52% vs. 68% (p=0.3) in VM samples, and 2% vs.10% (p=0.1) in FTM samples, respectively.

Conclusions: Vaginal and fallopian tube microbiota are altered in women undergoing salpingectomy for hydrosalpinx as compared to other indications. This may reflect dysbiosis associated with recent pelvic infections or altered upper genital micro-environment of blocked fallopian tubes. This observed dysbiosis warrants further study, with particular focus on the possible contribution of microbial composition to the pathogenesis of hydrosalpinx and associated infertility.

Abstract third-party references: VINCat Program [Infection Control and Antimicrobial stewardship Catalonian Program].

**Background:** to analyze the changes in the adequacy of empirical antimicrobial therapy to local guidelines, in bacteraemia caused by *E. coli* of urinary source in Catalan hospitals along a three-year period. The impact of a voluntary survey asking for analyzing local results and implementing correction measures was also analyzed.

**Materials/methods:** Multicentric prospective observational study including all episodes of *E. coli* bacteraemia of urinary source, between May 2017 and September 2019, in adult hospitalized patients in 45 Catalan hospitals. Adequacy of the empirical therapy (AET) to local guidelines was prospectively recorded. A survey evaluating local results of 2017-2018 and asking for correcting measures was sent to the hospitals at the end of 2018. Percentages of AET in 2017, 2018 and 2019 were compared by means of chi squared test.

**Results:** 3,804 episodes of bacteraemia were recorded. 845 in 2017, 1,861 in 2018 and 1,098 until 30/09/19. Globally, AET to guidelines increased from 73.7% in 2017 to 78.2% in 2019 (p=0.06). Interestingly, in the 24 hospitals responding to the survey, the AET increased significantly from 72.9% in 2017 to 79.9% in 2019 (p=0.009), while in those who did not respond, adequacy did not change (76.7% in 2017, 75.1% in 2019, p=0.90). In the 24 responding hospitals, improvement of adequacy was especially important in ambulatory healthcare-associated infections (65.7% in 2017 vs. 72.2% in 2018, p=0.050) and in hospital-acquired infections (56.7% in 2017 vs. 79.9% in 2019, p = 0.0001). Correction measures applied were: meetings with the antimicrobial stewardship team to evaluate the results (100%), review of local resistance rates (62%), review of local guidelines (58.3%), improving guidelines diffusion (75%), education sessions for improving guidelines adherence (58%), and analysis of adherence after education (65%).

**Conclusions:** Adequacy of empirical antimicrobial therapy to local guidelines for the treatment of patients with bacteraemia caused by *E. coli* of urinary source improved from 2017 to 2019 in Catalonia, but only in hospitals answering a voluntary survey for improving adequacy. Improvement of the adequacy was more important in ambulatory healthcare associated infections and hospital-acquired infections.

Abstract 3501

Pulmonary sparganosis: a case report with 20 months follow-up
Ziying Lei1, Jing Liu*1, Shu Zhu1, Yihua Pang1, Han MA2, Jianyun Zhu1, Lejia Xu1, Bingliang Lin1, Zhiliang Gao1

1The third affiliated hospital of Sun Yat-sen university, Guangzhou, China, 2The fifth affiliated hospital of Sun Yat-sen university, Zhuhai, China

Background: Sparganosis is a zoonotic parasitic disease caused by the sparganum of Spirometra species. Pulmonary sparganosis had seldom been reported. Currently, the efficacy of antiparasitic therapy is uncertain, only surgical resection is recommended in Sanford Guide. However, surgical resection is unsuitable for multiple visceral lesions. Here we present a case of pulmonary sparganosis with multiple lesions, the patient was treated with praziquantel and had been followed up for 20 months.

Materials/methods: A 43-year-old woman from Guangdong China present at April 2018, complained of cough and low-grade fever for one month, and a subcutaneous nodule about 1cm x 1cm in size was palpated in the right thigh. Chest spiral computer tomography (CT) showed multiple lung lesions. Bronchoalveolar lavage and thoracoscopic pulmonary nodule biopsy were performed for suspected of pulmonary aspergillus or tuberculosis. The histologic examination of the pulmonary nodule revealed tapeworms. Antisparganum antibody was detected in serum by enzyme-linked immunosorbent assay. Next-generation sequencing (NGS) reported detecting 236 Spirometra erinaceieuropaei nucleotide sequences in bronchoalveolar lavage fluid. Meanwhile, the subcutaneous nodule resection and pathological biopsy also revealed parasite structure, which was identified as sparganum.

Results: The patient was diagnosed as pulmonary sparganosis and cutaneous sparganosis, she was administrated praziquantel 60mg/kg/day and low-dose prednisone (10mg/day) for 10 days. Fever and cough improved rapidly after the treatment, but there was little improvement in lung lesions. Eight courses of praziquantel were given at an interval of 1 or 2 months afterwards, and the last course was at April 2019. The patient is still under follow-up, pulmonary lesions improved gradually even if the treatment had been stopped (Fig 1).

Conclusions: NGS is a promising tool for the rapid and accurate diagnosis of pulmonary sparganosis. Surgical removal is recommended for the treatment of sparganosis, but is impossible for pulmonary sparganosis with multiple lesions. Multiple pulmonary lesions improved gradually after nine courses of praziquantel treatment in this case, suggests multiple courses of praziquantel may be an alternative treatment for surgically unresectable cases.

Fig 1 Sequential imaging of chest spiral CT. Sequential imaging from April 2018 to August 2019 reflects the changes of lung lesions after multiple courses of praziquantel.

Abstract 3502

**Antibiotic utilisation and carbapenem-resistant *Acinetobacter baumannii*: a 12-year time series and cross-correlation analysis**

Tau Hong Lee1,2,3,4, Shi Thong Heng1, Li Wei Ang1,2, Sock Hoon Tan1, Hui Lin Tay1, Min Yi Yap1, Boon Hou Chua1, Jason Quek1, Tat Ming Ng1, David Lye*1,2,3,4

1Tan Tock Seng Hospital, Singapore, Singapore, 2National Centre for Infectious Diseases, Singapore, Singapore, 3Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 4Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

**Background:** Carbapenem-resistant *Acinetobacter baumannii* (CRAB) is endemic in many hospitals causing nosocomial infections. Reducing carbapenem usage is one control strategy. We observed declining incidence density of CRAB after ten years of antimicrobial stewardship programme in a university teaching hospital in Singapore. We investigated the temporal relationship between antibiotic usage and CRAB incidence density.

**Materials/methods:** Monthly utilisation of antibiotics in defined daily doses (DDD) and CRAB incidence per 1,000 patient-days from January 2007 to December 2018 were obtained from the hospital’s database. Each time-series was pre-whitened to account for autocorrelation. An autoregressive integrated moving average (ARIMA) model was fitted to an antibiotic utilisation time-series filtered to obtain white noise residuals. The CRAB incidence time series was also filtered with the same model. We then computed the cross-correlation function (CCF) between the filtered time-series for each antibiotic use and CRAB incidence at lags up to 12 months. We investigated the lag in the CCF at which the peak correlation of statistical significance (p<0.05) occurred, so as to determine the lead time of antibiotic utilisation relative to CRAB incidence.

**Results:** The monthly incidence density of CRAB reduced significantly from 0.45/1,000 patient-days in 2007 to 0.14/1,000 patient-days in 2018, at a rate of -0.003/1,000 patient-days per month (p<0.001). CRAB incidence was correlated with beta-lactams with beta-lactamase inhibitors (BLBLI) utilisation (0.19, p=0.02) among major antibiotic groups. No significant correlation was found with fluoroquinolones (-0.14, p=0.09) and carbapenems (-0.13, p=0.13). Utilisation of individual antibiotics like co-amoxiclav (0.21, p=0.01), ceftazidime (0.20, p=0.02), ceftriaxone (0.17, p=0.04?) and clindamycin (0.18, p=0.03) were also correlated with CRAB incidence. The lead time at which peak correlation occurred was 2 months for BLBLI, co-amoxiclav and clindamycin, 10 months for ceftazidime and 11 months for ceftriaxone.

**Conclusions:** BLBLI, co-amoxiclav, clindamycin, ceftriaxone and ceftazidime correlated significantly with CRAB incidence density, but not fluoroquinolones and carbapenems. Reducing a single antibiotic class may not be effective in controlling the incidence of CRAB.

Abstract 3504

High-level AmpC beta-lactamase-producing Escherichia coli and Klebsiella pneumoniae in Dutch hospitals and livestock farms: results from the i-4-1-Health project

Evert Den Drijver*1,2, Marjolein Kluytmans - Van Den Bergh4, Bram Diederens5, Suzan D. Pas1, Joep Stohr1,2, Francisca Velkers6, Carlo Verhulst1, Jaco Verweij7, Arjan Stegeman6, Jan A. J. W. Kluytmans - Van Den Bergh3,4

1Amphia Hospital, Breda, Netherlands, 2Elisabeth-TweeSteden Hospital, Tilburg, Netherlands, 3Amphia Hospital, Academy Infectious Disease Foundation, Breda, Netherlands, 4Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 5ZorgSaam Hospital, Terneuzen, Netherlands, 6Universiteit Utrecht Faculty of Veterinary Medicine, Utrecht, Netherlands

Abstract third-party references: i-4-1-Health Study Group

Background: High-level AmpC beta-lactamase-production in Escherichia coli and Klebsiella pneumoniae (HL-AmpC-Ec/Kp) is emerging as antimicrobial resistance mechanism and is based on mutations in the promoter/attenuator of the chromosomal AmpC gene (cAmpC) or plasmid-located AmpC genes (pAmpC). This study aimed to determine the prevalence of HL-AmpC-Ec/Kp among patients in Dutch hospitals and in livestock farms.

Materials/methods: In 2017/2018, HL-AmpC-Ec/Kp prevalence surveys were performed in 2 hospitals, 16 pig farms and 14 broiler farms in the South of the Netherlands. Perianal swabs (human) or fecal swabs (livestock) (FecalSwab, CopanItaly) were pre-enriched in a non-selective tryptic soy broth (CopanItaly) and subsequently cultured on an AmpC screening agar plate (McC, cefoxitin 8mg/L, cefotaxime or ceftazidime 1mg/L, Mediaproducts). MastDiscs (D68C, MastGroup) were used to confirm AmpC-production. Whole-genome sequencing of phenotypic AmpC-producing Ec/Kp was performed on a MiSeq (Illumina), followed by de novo assembly with SPAdes v3.9.1 and whole-genome multilocus sequence typing (wgMLST) with SeqSphere (Ridom). ResFinder v3.1 (CGE) was used to detect acquired-resistance genes and chromosomal mutations.

Results: A total of 370 patients were cultured. Of those, 12 (3%) were carrier of HL-AmpC-Ec/Kp. Mutations in the cAmpC promoter were identified in 7 Ec isolates and pAmpC (blaCMY-4, blaDHA-1) in 3 Ec and 2 Kp isolates. HL-AmpC-Ec/Kp isolates from patients were clonally unrelated. From 16 pig farms and 15 broiler farms, 128 and 119 cultures were obtained, respectively. HL-AmpC-Ec was detected on 2 pig farms (prevalence 60% and 70%) and 6 broiler farms (prevalence 10% to 90%). Mutations in the cAmpC promoter were present in all 10 HL-AmpC-Ec isolates from pig farms and in 2 (10%) of 21 HL-AmpC-Ec isolates from broiler farms. The other 19 (90%) broiler Ec isolates carried pAmpC (blaCMY-2). Five within-farm wgMLST clusters of 2 to 8 HL-AmpC-Ec isolates were identified in two pig farms and one broiler farm (Figure).

Conclusions: Rectal carriage of HL-AmpC-Ec/Kp was low among patients in Dutch hospitals. The prevalence of HL-AmpC-Ec/Kp in varied between livestock farms and livestock species. The genetic diversity of HL-AmpC-Ec/Kp isolates was high, with clusters of clonally-related isolates within farms, but not between farms, patients or between the human and veterinary domain.

Abstract 3506

Clinical and economic impact of three different strategies for the management of schistosomiasis in Sub-Saharan immigrants to Italy

Annarita Botta*, Marta Tilli¹, Alessandro Bartoloni¹², Lorenzo Zammarchi¹², Sara Boccalini³

¹University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy, ²Careggi University Hospital, Infectious Disease Unit, Firenze, Italy, ³University of Florence, Department of Health Science, Florence, Italy

Background: Recently an increased migration flow from Sub-Saharan Africa (SSA) to Europe and Italy has been recorded. Schistosomiasis, highly prevalent in migrants from SSA, can lead to irreversible complications if left untreated. Italian guidelines and the European Centre for Disease Control and Prevention recommend a serological screening for schistosomiasis in migrants from SSA. However, studies on clinical and economic impact of this strategy in the Italian and European setting are lacking. This study aims to compare benefits and costs of different strategies to manage schistosomiasis infection in Italy in migrants from SSA.

Materials/methods: A decision tree and a Markov model was developed to assess the health and economic impacts of three interventions for schistosomiasis: a) passive diagnosis of symptomatic patients (current practice in Italy); b) serological screening of all immigrants and treating those positive; c) presumptive treatment for all immigrants with praziquantel in a single dose. The time horizon of analysis was one year, to investigate the punctual expenses, and 28 years, to consider possible sequelae, in the Italian health-care perspective. We assumed that each diagnosed patient will be managed according to the standard of good practice. Inputs data were derived by available literature; costs were taken from the pricelist of Careggi University Hospital, Florence, and from National Hospitals Records.

Results: Assuming a population of 100,000 migrants with a schistosomiasis prevalence of 21.2%, at one year passive diagnosis option is the least expensive, costing €709,042. Screening option (€4,512,018) is more expensive than presumptive treatment (€2,848,212). At 28 years the cheapest option is presumptive treatment (€6,958,223) while the passive diagnosis and screening strategy accounts for €7,775,631 and €9,331,608, respectively. Considering the cost/QALY presumptive treatment appears the more favorable intervention compared with the passive diagnosis.

Conclusions: The results of model suggests that presumptive treatment strategy compared with the current strategy are more favorable from an economic point of view.

Abstract 3508

Which anatomic sites should be screened for carbapenem-resistant Acinetobacter baumannii?

Amir Nutman*, Jonathan Lellouche, David Schwartz, Anat Lerner, Polet Elmaliah, Reut Rov, Azza Vaturi, Debby Ben-David, Yehuda Carmeli

1Tel-Aviv Sourasky Medical Center, National Center for Infection Control and Antibiotic Resistance, Tel Aviv-Yafo, Israel

Background: Acinetobacter baumannii is a global, multidrug-resistant nosocomial pathogen causing severe infections in hospitals and long-term care facilities. Active surveillance for carbapenem-resistant Acinetobacter baumannii (CRAB) has been recommended to control the spread of CRAB. Early and accurate identification of carriers is important to effectively direct infection prevention measures. We aimed to identify the best anatomic sites and method of screening for CRAB.

Materials/methods: This evaluation was conducted in two centers in Israel: adult wards at Tel-Aviv Sourasky Medical Center (TASMC); and the chronic ventilation ward at Beit-Rivka (BR), a subacute care facility. CRAB screening was performed for routine active surveillance. Our sample included only patients who screened positive in at least one anatomic site. Four anatomic sites were cultured: buccal mucosa and rectum using swabs, skin using pre-moistened sponges, and sputum using tracheal aspirate (from ventilated patients only). Study specimens were transferred to the National Center for Infection Control laboratory. Samples were inoculated after overnight enrichment in brain-heart infusion broth onto CHROMagar MDR Acinetobacter plates, and incubated overnight. Suspected colonies were further identified to the species level, and susceptibility testing performed. We compared yield by anatomic site using a test of proportions.

Results: We analyzed data from 201 patients who screened positive for CRAB; 100 from TASMC and 101 from BR. Yield by body site is presented in Table 1. The site with the highest yield was skin (92%), and yield was similar in both facilities (91% at TASMC, 92.8% at BR, p=0.64). In carriers whose skin screened negative for CRAB, the buccal mucosa was positive in 9/10 (90%), rectum in 2/4 (50%), and sputum in 2/7 (28.6%). The buccal mucosa, sputum, and rectum had much lower yields, even when combined (Table 1).

Conclusions: Our data support culturing the skin using pre-moistened sponges as a single site for active surveillance of CRAB. A negative screening culture from the other sites had unacceptably high false negativity, and may not be taken as evidence for CRAB non-carriage when directing an infection control program for CRAB.

Table 1: CRAB screening yield among 201 patients positive for CRAB, by body site.

Management and cost-analysis of a *Klebsiella pneumoniae* carbapenemase-producing cluster in the cardiac intensive care unit in Vicenza hospital, Italy  

Sara Mondino*1, Vinicio Manfrin2, Mario Rassu3, Romina Cazzaro4, Davide Brodesco5, Anna Diiquigiovanni6, Laura Zaghis7, Irene Zecchinato5, Maria Paola Zanon8, Elena Bovolenta5, Sofia Zanovello8, Salvatore Barra9

1AULSS 8 Berica - Vicenza Hospital, Risk Management, Vicenza, Italy, 2AULSS 8 Berica - Vicenza Hospital, Infectious Diseases Department, Vicenza, Italy, 3AULSS 8 Berica - Vicenza Hospital, Microbiology Department, Vicenza, Italy, 4AULSS 8 Berica - Vicenza Hospital, Hospital Medical Direction, Vicenza, Italy, 5AULSS 8 Berica - Vicenza Hospital, Cardiac Surgery Department, Vicenza, Italy, 6AULSS 8 Berica, Prevention Department, Vicenza, Italy, 7University of Verona, Specialization School in Hygiene and Preventive Medicine, Verona, Italy, 8University of Padova, Specialization School in Hygiene and Preventive Medicine, Padova, Italy, 9AULSS 8 Berica - Vicenza Hospital, Health Management Office, Vicenza, Italy

**Background:** *Klebsiella pneumoniae* carbapenemase-producing (KPC) is a Gram-negative bacterium resistant to a wide spectrum of beta-lactam antibiotics. It can cause infections, sepsis and deaths in immunocompromised or fragile patients. Patients can acquire this microorganism mainly through the healthcare workers' hands or through environment or devices. In December 2017, KPC was detected in several patients admitted to a Heart Rehabilitation Centre, who were previously discharged from the cardiac surgery department of Vicenza Hospital.

**Materials/methods:** The hospital infection and prevention control team immediately carried out an epidemiological investigation. The index case was identified as a patient admitted to the cardiac intensive care unit and previously hospitalized in a clinical ward where KPC cases had been detected. The screening method for KPC was implemented, adding a rectal swab at discharge to identify patients who acquired KPC colonization during the hospitalization. An on-site inspection was carried out and environmental samples were performed. Contact isolation measures were applied for all patients. Staff education and training were provided to underline the importance of hand hygiene and contact precautions. An increased number of medical equipment and devices was acquired and most of them were dedicated to single patient use. An extraordinary sanitation of the department was carried out and additional cleaning measures were adopted.

**Results:** From 1 January to 31 October 2018, 1527 rectal surveillance swabs were performed on 682 patients admitted to cardiology surgery department and 104 patients were identified as colonized (15%). Most positive patients were detected in the first four months of the year, cases gradually decreasing during the following months. The hospital had to bear huge economic costs due to environmental sanitization and cleaning measures enhancement, the purchase of medical devices and enormous quantities of equipment for contact isolation and disinfection. The total amount due to the KPC cluster was approximately € 139.282.

**Conclusions:** Some critical issues had emerged in the cardiac intensive care unit during the cluster. Staff education raised awareness on multidrug-resistant microorganisms among healthcare workers and, together with the enhancement of preventing and hygiene measures and the use of patient-dedicated equipment, it led to the successful resolution of the cluster.

Abstract 3511

**Vertical and horizontal dissemination of an IncA/C plasmid harbouring rmtB 16S-rRNA methylase conferring resistance to amikacin and plazomicin among KPC-producing Klebsiella pneumoniae in a Brazilian tertiary centre**

Melanie Roch1, Priscila Dantas2, Roberto Sierra1, William Brasileiro Martins1, Kirsty Sands4, Timothy R. Walsh4, Eduardo Alexandrino Medeiros2, Ana Gales1, Diego Andrey1*

1Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland, 2São Paulo Hospital, Sao Paulo, Brazil, 3Escola Paulista de Medicina – Unifesp, Sao Paulo, Brazil, 4Cardiff University, Cardiff, United Kingdom

**Background:** Carbapenemase resistant KPC-producing K. pneumoniae (KPC-KP) infections are among the most important clinical challenges, and not least in middle-income countries, where novel beta-lactams/beta-lactamase inhibitors are often not available. Remaining antimicrobial options are often restricted to “old antibiotics” such as aminoglycosides and polymyxins.

**Materials/methods:** We studied a collection of 125 KPC-KP strains isolated from bloodstream infections between 2014 and 2016 at the Hospital São Paulo, a Brazilian teaching hospital, where KPC-2 KP is endemic. All isolates were typed by MLST and a subset of representative strains were fully sequenced (Illumina MiSeq, MinIon long-reads). Susceptibility to the commonly used aminoglycosides amikacin and gentamicin were determined by agar dilution according to EUCAST recommendations. Susceptibility to plazomicin (E-test), a new aminoglycoside, and to apramycin, a veterinary approved aminoglycoside were investigated to evaluate alternative treatment options.

**Results:** Forty-nine (39%) of the 125 KPC-2-KP isolates showed high resistance to both amikacin and gentamicin. Genomic analysis revealed that 95% of aminoglycoside resistant were carrying the 16S-methylase rmtB. Among the rmtB positive, 43 strains (91%) belonged to the ST258 clone, representing 95% of all KPC-ST258 isolates. Presence of rmtB was also confirmed in one ST16 isolate. Plasmid sequence assembly of the two different ST type isolates revealed that rmtB was harboured by a highly similar 175-177 kb IncA/C2 plasmid (>95% identity) suggesting clonal dissemination of a rmtB-positive, KPC-2-positive ST258 clone and horizontal transfer to the ST16 clone. All the strains carrying rmtB were fully resistant to the new aminoglycoside plazomicin [MIC >256mg/L], but remained susceptible to veterinary approved apramycin [MIC range 4-8mg/L].

**Conclusions:** Herein, we report the clonal spread of a KPC-2 producing rmtB-positive ST258 in a tertiary hospital, and we documented a case of horizontal acquisition of the IncA/C2 plasmid by an ST16 KPC-KP isolate. Dissemination of the rmtB 16S-rRNA methylase plasmid in the endemic setting for KPC-producing K. pneumoniae CC258 clones is worrisome, since it provides resistance to most aminoglycosides approved for human usage including new therapeutic options as plazomicin. Human drug development of apramycin like molecule could be of great interest for the treatment of these multi-drug resistant clones.

Imipenem/sulbactam, a repurposed drug combination for the treatment of MDR Acinetobacter baumannii infections

Meiqi Tan¹,², Lynette Phee¹, Joe Standing³, David Wareham*²

¹Singapore General Hospital, Singapore, Singapore, ²Queen Mary University of London, London, United Kingdom, ³UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Background: Multi-drug resistant (MDR) Acinetobacter baumannii are an increasing cause of nosocomial infection in the severely ill. Limited treatment options has renewed interest in repurposing older antibiotics in unorthodox combinations. The potential of IMP / SUL as a novel β-lactam / β-lactamase inhibitor combination was assessed both in-vitro and in-vivo.

Materials/methods: Antimicrobial susceptibility testing was performed on 119 MDR A. baumannii with imipenem (IMP), sulbactam (SUL), and fixed ratios of IMP / SUL (2:1, 1:1, 1:2) by disc diffusion. Minimum inhibitory concentrations (MIC) were determined for 57 strains by agar dilution using IMP / SUL (1:1 and 1:2). Monte Carlo simulation of human pharmacokinetic (PK) / pharmacodynamic (PD) data was used to predict therapeutic success (PTA > 60% / TA≥MIC) of bolus, extended or continuous infusion dosing regimens of 3-8g / day, modelled across putative IMP / SUL breakpoints of ≤16 / ≤0.25 mg/L. In-vivo efficacy of IMP / SUL was assessed using a Galleria mellonella therapy model with humanised dosing regimens of IMP / SUL (25 mg/kg).

Results: IMP / SUL (1:1 or 1:2) displayed enhanced activity against A. baumannii with 4 - 64 fold reduction in MIC (MIC₉₀ / MIC₉₀ 8/8 – 64/128 mg/L) compared to either drug alone (MIC₉₀ / MIC₉₀ >256 mg/L). PK / PD modelling predicted up to 65% of A. baumannii with IMP / SUL MIC ≤16 / 16 mg/L may be treatable with a high-dose (8g / day) fixed-ratio (1:1 or 1:2) combination. IMP / SUL (25 / 25 mg/kg) was effective in the treatment of 2 MDR A. baumannii-strains in the G. mellonella model but only at low inocula (≤10⁴ cfu / larvae).

Conclusions: IMP / SUL has potential as a repurposed β-lactam / β-lactamase inhibitor combination therapy. If targeted at A. baumannii, MIC and PK / PD simulation data suggest a 1:1 or 1:2 fixed dose regimen of 3-8 g of IMP / SUL would be required to treat 90% of IMP resistant strains with an IMP / SUL MIC of up to 8 / 8 mg/L. Extended or continuous infusion of both compounds would be needed to optimise a precise dosing regimen.

Non-carbapenem beta-lactams for the treatment of Acinetobacter baumannii bacteraemia: a multi-centre retrospective analysis

Giulia La Martire*, Vincent Fihman2, Adrien Galy3, Diane Le Pluart4, Latifa Noussair5, Anne Lise Lecapitaine6, Etienne Canoui7, Anne Lise Munier8, Clemence Richaud9, Charlotte Wemmert1, Raphael Lepeule1

1Hôpital Henri-Mondor Ap-Hp, Antimicrobial stewardship team, Créteil, France, 2Hôpital Henri-Mondor Ap-Hp, Microbiology department, Créteil, France, 3Hospital Beaujon AP-HP, Internal medicine department, Clichy, France, 4Bichat-Claude Bernard Hospital, Infectious and tropical diseases department, Paris, France, 5Ambroise Paré Hospital (AP-HP), Microbiology department, Boulogne-Billancourt, France, 6Compiegne-Noyon Hospital, Microbiology department, Boulogne-Billancourt, France, 7Hospital Cochin, Antimicrobial stewardship team, Paris, France, 8Hospital Lariboisiere, Infectious diseases department, Paris, France, 9Institute Mutualiste Montsouris, Internal medicine department, Paris, France

Background: Unlike the French and American committees (CA-SFM and CLSI), the European Committee for Antibiogram (EUCAST) does not establish clinical breakpoint (CB) for beta-lactam antibiotics other than carbapenems (BL TnC) for Acinetobacter baumannii (Ab). EUCAST considers these CB technically unreliable. On top of it, pharmacokinetic and pharmacodynamic studies highlighted theoretical potential risk for failure of BL TnC in Ab infection treatment. However, BL TnC are often prescribed for treating Ab bacteraemia (Abb) in several French centres. Our objective was to evaluate local habits for Abb treatment and to highlight eventual adverse events linked to these practices.

Materials/methods: This was a multicentre retrospective study in which all patients treated with a BL TnC or carbapenem (CP) for monomicrobial Abb between January 2015 and December 2018 were included. Clinical and microbiological failures and mortality at day 7 and 30 were analysed.

Results: Eight centres participated to this preliminary analysis. A total of 93 patients were screened for eligibility and 22 retained for analysis [details of exclusions are presented in the figure]; 18 patients were treated with BL TnC (82%). Preferred empirical treatments in BL TnC group were piperacilline/tazobactam 7/18(40%) and cefotaxime 6/18(33%) and preferred definitive treatments were cefepime 7/18(40%) and piperacilline/tazobactam 7/18(40%). Patients were relatively young (median age of 56); 10/22(45%) were immunosuppressed, mean Charlson comorbidity index was 3,4; 7/22(31%) of Abb occurred in ICU. Origin of bacteraemia was a central venous catheter in 14/22(64%) of cases. Outcome was favourable in 15/18 patients (83%) in BL TnC group. One patient on palliative care died on day 17, with a secondary NDM Klebsiella pneumoniae bacteraemia, 1 patient had persistent bacteremia cleared after infected catheter removal (he kept on BL TnC), 1 patient presented secondary ESBL E. cloacae bacteraemia. Outcome was favourable in 4/4 in CP group.

Conclusions: Abb is an uncommon event in our setting, and MDR Ab are still rare. Treating these infections with BL TnC appears to be a standard practice in several centers even if EUCAST doesn’t provide clinical breakpoints. We couldn’t highlight adverse events related to this practice in this preliminary analysis. More centers are expected to participate to this study for larger analysis.

Trends of emerging multidrug-resistant nosocomial strains and development of antimicrobial resistance in the years 2007 - 2018

Jan Koren1, Andrea Longauerová2, Adriana Krajčíková3, Livia Slobodnikova3, Mária Blažeková3, Adriana Liptáková3, Tibor Maliar3, Vladimir Krcmery1

1Faculty of Medicine, Comenius University and University Hospital Bratislava, Institute of Microbiology, Bratislava, Slovakia, 2University Hospital Bratislava, Institute of Microbiology, Bratislava, Slovakia, 3Faculty of Natural Sciences University of SS. Cyril and Methodius in Trnava, Department of Biotechnologies, Trnava, Slovakia

Abstract third-party references: Study was supported by the project APVV-16-0173.

Background: Global spreading of multidrug-resistant strains should be related to highest national priority for preventive measures in healthcare facilities. Otherwise, developing antimicrobial resistance may be associated with treatment failure and higher mortality. We aimed to assess occurrence of MDR pathogens such as ESBL and carbapenemase-producing Enterobacteriales/Enterobacteriaceae - CPE, MRSA, VRE and Clostridioides difficile toxin A/B as well antimicrobial resistance over the last 12 years.

Materials/methods: Specimens were obtained from patients hospitalized at the University Hospital Bratislava [UHB] Old Town between 2007 and 2018. Resistance mechanisms were detected according to EUCAST guidelines and interpretive breakpoints. C. difficile toxin A/B was proved by immunochromatographic assay. Antimicrobial resistance assessment was relied upon colorimetric micro- and E-test methods including disc diffusion susceptibility testing.

Results: Emergence of ESBL producers in our hospital for investigated years was following: 131, 169, 383, 314, 269, 293, 511, 402, 400, 449, 473 and 504. Confirmed CPE numbers in last years were: 1, 6, 17 and 19. MRSA outcomes accounted for monitored years: 10, 13, 27, 29, 44, 52, 90, 62, 77, 121, 156 and 173. VRE occurrence represented data as follows: 2, 3, 5, 18 and 28 strains. Determined C. difficile toxin A/B findings were: 7, 43, 34, 16, 24, 29, 24, 44, 35, 73 and 129. Klebsiella pneumoniae meropenem resistance in the beginning of period was 1% and in last year 4%. Escherichia coli ceftazidime resistance increased from 11% (2007) to 21% (2018), in Proteus mirabilis from 12% to 15% but in Pseudomonas aeruginosa decreased from 23% to 12%. Staphylococcus aureus oxacillin resistance elevated from 5% to 19% and in Enterococcus spp. vancomycin resistance raised from 0% to 8%.

Conclusions: Analyzed period noticed increasing E. coli and P. mirabilis ESBL-producing strains with established resistance development. Higher prevalence of CPE mostly involved K. pneumoniae NDM strains resulted in resistance to carbapenems. P. aeruginosa resistance decreased to aminoglycosides and no ascertained resistance to colistin at the end of reporting period. C. difficile toxin A/B production, including MRSA and VRE demonstrated increasing trend implying that Staphylococcus aureus with Enterococcus spp. expressed higher resistance.

Evaluation of two Aspergillus PCR assays testing of bronchoalveolar lavage fluid and serum for diagnosis of chronic pulmonary aspergillosis

Zhengtu Li*, Peiyin Zeng1, Shaoqiang Li1, Zhixian Wang2, Feng Ye1

1State Key Laboratory of Respiratory Disease, National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Disease, First Affiliated Hospital of Guangzhou Medical University, (Guangzhou Medical University), Guangzhou, China,
2Beijing Key Laboratory for Mechanisms Research and Precision Diagnosis of Invasive Fungal Disease, Beijing, China

Background: Chronic pulmonary aspergillosis has been increasingly reported in patients with underlying respiratory disorders, such as COPD, cavitary pulmonary tuberculosis, bronchiectasis and in patients given glucocorticoids or immunosuppressants. Because of the relatively intact immune system, these patients often display atypical symptoms coupled with non-standard imaging results, making the early diagnosis difficult. Molecular biological diagnostic methods such as PCR for the diagnosis of aspergillosis have the advantages of rapidity, sensitivity and high specificity, and is a research hotspot in recent years. At present, most of the PCR research focuses on invasive aspergillosis patients with immunodeficiency in patients with hematologic malignancies, hematopoietic stem cell transplant recipients and solid organ transplant recipients. There is less research on PCR in Chronic pulmonary aspergillosis. Recently, two multiplex PCR AsperGenius® (Pathonosdics, Netherlands) and MycoMDx™ (Dynamiker, China) have been released to the market. Our purpose was to compare the performance of the two PCR assay in Chronic pulmonary aspergillosis.

Materials/methods: This diagnosis was based on [ESCMID and ERS] guidelines and IDSA guidelines for the management of CPA. All the samples from the First Affiliated Hospital of Guangzhou Medical University. The sample include 20 serum and 15 BALF samples from the CPA patient group, and 30 serum samples from the non-CPA patient group. The samples were tested in parallel using MycoMDx Aspergillus PCR assay and AsperGenius® Aspergillus PCR assay as recommended by the manufacturer.

Results: The sensitivity and specificity of Dynamiker MycoMDx Aspergillus PCR for serum sample were 60% and 77%, respectively. The sensitivity of Dynamiker multiplex PCR for BALF sample were 80%. For the AsperGenius® multiplex PCR assay the sensitivity and specificity of the serum sample in the diagnosis of CPA were 50% and 80%, and the sensitivity of the BALF sample in the diagnosis of CPA were 80%. [Table 1]

Table 1 Diagnostic performance of Dynamiker and AsperGenius multiplex PCR assay

**Abstract 3520**

**Effects of ceragenins to intracellular *Pseudomonas aeruginosa* infections formed in human airway epithelial cells**

Özlem Oyardı*, Cagla Bozkurt Guzel¹, Paul B. Savage²

¹Istanbul University, istanbul, Turkey, ²Brigham Young University, Provo, United States

**Background:** Ceragenins are the newly investigated antibiotic candidates. They were synthesized to mimic antimicrobial peptides and it was proven that they had potential antimicrobial properties. However, there is limited information about their cytotoxicity on the human cells. As well as cytotoxicity, their effects of intracellular bacteria in human airway cell is not well known. The aim of this study is to investigate cytotoxicity of ceragenins on A549 cell and effects against intracellular *P. aeruginosa* in A549 cell.

**Materials/methods:** A549 cell which is a human airway carcinoma cell line was growth in DMEM, 10% FBS and 1% penicillin-streptomycin and 1% glutamine. IC₅₀ results of ceragenins were determined by using XTT (the second generation tetrazolium dye) assay. To investigate antibacterial activity of ceragenins against intracellular bacteria, *P. aeruginosa* PA0-1 strain, which has green fluorescent protein, was added to the A549 cell for co-infection. After co-infection, gentamycin was added to the co-culture to kill extracellular bacteria. Then, ceragenins were added and CFU counting was performed while lysising the cells by Triton-X solution. CSA-13, CSA-44, CSA-90, CSA-131, CSA-138, CSA-142, CSA-144, CSA-192 and CSA-131-poloxamer were used as antimicrobial agents.

**Results:** Whereas the most cytotoxic ceragenin was determined as CSA-90 (IC₅₀:18.76 µg/ml), the least cytotoxic agent was CSA-142 (IC₅₀: 94.54 µg/ml). According to IC₅₀ results, 20, 10 and 5 µg/ml concentrations of ceragenins were included to the study to investigate anti-intracellular bacteria activities. Among all ceragenins studied, CSA-13 showed the best activity and decreased 3 log CFU even if 10 µg/ml concentration was used.

**Conclusions:** Ceragenins especially CSA-13 displayed good activity against intracellular *P. aeruginosa* formed in human airway epithelial cells. These results make ceragenins good candidates for treatment of *P. aeruginosa* infections associated with lungs.

Abstract 3524

Costs and impact of whole genome sequencing on tuberculosis diagnostics in a high prevalence and high MDR-TB burden country

Monica Vogel*1, Altyn Iskakova2, Christian Utpatel13, Caroline Corbett5, Harald Hoffmann5, Stefan Niemann6

1IMLred GmbH, IMLred GmbH, Gauting, Germany, 2National Tuberculosis Hospital, Bishkek, Kyrgyzstan, 3Research Center Borstel, Sülfeld, Germany, 4Molecular and Experimental Mycobacteriology, Research Center Borstel, Borstel, Germany, 5IMLred GmbH, Gauting, Germany, 6Molecular and Experimental Mycobacteriology, Research Center Borstel, Borstel, Germany

Background: Genetic resistance testing of tuberculosis (TB) isolates recovered from clinical samples of TB patients will soon become an indispensable tool in TB diagnostics as it is faster and more thorough than phenotypic susceptibility testing. This type of testing can be done by use of either whole genome sequencing (WGS) or targeted sequencing on next generation sequencing (NGS) platforms.

Materials/methods: We report our experiences with the implementation of NGS in the Kyrgyz Republic National Reference Laboratory (NRL), a lower-middle income Central Asian Republic with a TB incidence of 144/100,000 and 30% MDR-TB resistance. The Illumina MiSeq NGS platform was chosen after careful estimation of long-term needs based on epidemiological data. Technology and skill transfer required 68 weeks. Resistance markers were identified using WGS for the first 133 samples, and compared to phenotypic Drug Susceptibility Testing (DST) results when available.

Results: Total procurement costs were 307,157 USD (230,528 USD and 76,629 USD for equipment and consumables, respectively). Costs per sequenced genome were 277 USD during the training phase, and 167 USD and 141 USD after training using the MiSeq® Reagent kits v2 and v3, respectively. NGS was fully implemented in the Kyrgyz Republic in approximately 68 weeks. Two laboratory employees were trained by NGS experts from Forschungszentrum Borstel, they have since trained two additional sequencing technicians. Quality was externally assessed by lab-to-lab comparison of 30 WGSs with outstanding results. A total of 101 of the first 133 samples that were sequenced also had DST, of which 5 samples were identified with at least one additional antibiotic resistance marker using WGS.

Conclusions: The five major lessons we have learned were that: [1] the identification of the optimal platform is a complex process which needs to involve a team of experienced experts in the field; [2] knowledge and skill transfer to the NRL was relatively straightforward; [3] procurement was much more complicated and took longer than expected; [4] material costs per sequence were higher than expected, and [5] the transitioning process should be initiated in an early project phase and demands both financial support and strong guidance.

Abstract 3525

Serotype, antimicrobial resistance and virulence profile of invasive Streptococcus pneumoniae isolates in a nationwide surveillance study in Lebanon

Lina Reslan*1, Sarah Khafaja2, Mohamad Bahij Moumneh1, Marc Finianos1, Malak Darwish1, Celina Boutros2, George Araj3, Ghassan Mata1;4, Ghassan Dbaibo1;5

1American University of Beirut/Faculty of Medicine/Center for Infectious Diseases Research, Beirut, Lebanon, 2AUB Medical Center/Department of Pediatrics and Adolescent Medicine, Center for Infectious Diseases Research (CIDR), Beirut, Lebanon, 3AUB Medical Center/Department of Pathology & Laboratory Medicine, Beirut, Lebanon, 4American University of Beirut/Faculty of Medicine/Department of Experimental Pathology, Immunology and Microbiology, Beirut, Lebanon, 5AUB Medical Center/Department of Pediatrics and Adolescent Medicine, Beirut, Lebanon

Background: Streptococcus pneumoniae infections cause millions of deaths worldwide. Despite the introduction of pneumococcal conjugate vaccines (PCV), pneumococcal disease burden remains high. Pathogenesis of Streptococcus pneumoniae is promoted by various virulence factors providing it with pathogenic advantages. We evaluated the serotype prevalence and antimicrobial susceptibility patterns of invasive isolates in Lebanon over a 14 year period. We also assessed the carriage of seventeen virulence genes and their association with specific serotypes and sites of infection.

Materials/methods: A total of 528 isolates were collected from patients with invasive pneumococcal disease. Identification and antimicrobial susceptibility testing of the isolates were performed. Serotypes were determined using capsular multiplex PCR. Genes coding for Streptococcus pneumoniae virulence proteins were assessed by singleplex PCR including the pneumococcal surface adhesin (psaA), pneumococcal surface protein (pspC), enolase (ena), choline binding protein (cbpE) which occurs by recruitment of host proteases to the bacterial cell surface. We present evidence supporting the role of choline-binding protein E (CBPE, polyhistidine triad (phtA, B, E, D), pneumococcal adherence and virulence factor (pavA), pneumococcal choline binding protein (pcpA), plus islet (Pi-1, Pi-2), neuraminidases (nanA, B, C), immunoglobulin A1 (IgA1) protease, and high temperature requirement (htrA).

Results: Non-susceptibility rates by disc diffusion were the highest for Trimethoprim-sulfamethoxazole (56.6%), oxacillin (52.1%), and erythromycin (30.8%). For oxacillin-resistant isolates, 11.4% were resistant to penicillin (MICs ≥2.0 μg/ml). The PCV-7 and PCV-13 serotypes represented 35.1% and 65.3%, respectively. Three virulence genes (ena, psaA, and nanA) were carried by more than 85% of isolates while 9 genes (phtA, phtB, nanB, nanC, IgA1, pspC, Pi-1, cbpE and pcpA) differed significantly among the predominant serotypes (1, 14, 18, 19A, 19F, 23F, 3, 5, 6A, 9V/9A and 22F/22A). A significant difference in nanC and phtA prevalence was observed between the PCV13 and non-PCV13 serotypes. We did not find a statistical association between the presence of virulence genes and the three sites of infection (bacteremia, meningitis and pneumonia).

Conclusions: PCV13 serotypes were the most prevalent and accounted for the majority of isolates with increased antimicrobial resistance. The virulence genes carriage varied significantly among predominant serotypes without being associated with a preferential site of infection. The common virulence genes (ena, psaA, and nanA) may be evaluated as possible vaccine candidates.

Abstract 3526

**Unravelling the anti-biofilm mechanism of action of an antimicrobial peptide: an atomic force microscopy study**
Ana Silva Herdade*1, Susana A Dias1, Sandra Pinto2, Ana Coutinho2, Miguel Castanho1, Ana Salomé Veiga1

1Universidade de Lisboa, Instituto de Medicina Molecular, Faculdade de Medicina de Lisboa, Lisboa, Portugal, 2Universidade de Lisboa, Centro de Química-Física Molecular e IN, Instituto Superior Técnico, Lisboa, Portugal

**Background:** Biofilms are three-dimensional communities of bacteria encased in a highly hydrated extracellular matrix that have high impact on public health given their decreased susceptibility to conventional antibiotics. Antimicrobial peptides (AMPs) have been proposed as an alternative to fight biofilm infections. For the development of new antibiofilm peptides, it is essential to understand their mechanism of action. Here, we study the mechanism of action of vCPP2319, a peptide with proven antibacterial activity against bacterial cells in the planktonic and biofilm form, by atomic force microscopy (AFM).

**Materials/methods:** In this work, we started by the optimization of the AFM imaging conditions for the visualization of the biofilm structure. For that, 24h pre-formed Staphylococcus aureus (S. aureus) biofilms were imaged in the presence and absence of glutaraldehyde, used as a fixation agent. Then, the effect of increasing concentrations of vCPP2319 on the morphology of the biofilm was visualized by AFM.

**Results:** Glutaraldehyde fixation preserves the biofilm structure and enables a better visualization of its three-dimensional assembly, thus allowing high-resolution images of the biofilm morphology. The AFM images obtained in presence of the peptide show that vCPP2319 reduce the thickness of the S. aureus biofilm and increase the roughness of their surface.

**Conclusions:** AFM images allow the visualization of vCPP2319 effect on the S. aureus biofilm structure. The peptide act on the bacterial cells, causing a perturbation of the cells membranes and a reduction in the biofilm volume.

Abstract 3527

**Inhibition of *Candida albicans* biofilms by Gram-negative bacteria and their cell-free supernatants**

Özlem Oyardı*, Mayram Hacioglu¹

¹Istanbul University Faculty of Pharmacy, Istanbul, Turkey

**Background:** Multispecies biofilms, which were mostly formed by polymicrobial species, represent an unexplained and clinically relevant health problem, as a potential infectious reservoir. The biofilm forming ability of *Candida albicans* is a major virulence factor and correlated with increasing mortality and morbidity compared to infections caused by planktonic cells and can be in relation with other microorganisms in infection site and can form biofilm together. Several studies have shown the increasing lethality in the case of polymicrobial biofilms especially *C. albicans* formed between and Gram negative microorganisms. The aim of this study was to evaluate the growth of *C. albicans* in biofilms with four clinically important Gram negative bacteria or their cell free supernatants (SNs).

**Materials/methods:** *C. albicans* (SC 5314), *Acinetobacter baumannii* ATCC 19606, *Pseudomonas aeruginosa* PA01, *Escherichia coli* ATCC 25922, and *Klebsiella pneumoniae* ATCC 700603 strains were used in this study. Polymicrobial biofilms containing *C. albicans* + Gram negative bacteria were formed in 96-well tissue culture-treated polystyrene plate. The anti-biofilm activities of SNs derived from sessile growths of these bacteria, were also tested for inhibitory properties against *C. albicans*. Viability was monitored by CFU assay and a colorimetric method utilizing MTT. Biofilms were visualized using the Olympus CKX41 fluorescence microscope and imaging with Olympus DP72 camera.

**Results:** It was shown that Gram negative bacteria negatively affected and decreased the numbers of *C. albicans* cells (more than 3 log). The anti-biofilm activity was also present in cell free SNs, especially with *P. aeruginosa* SN (near 3 log decrease). MTT test also proved that the metabolic activity of *C. albicans* during biofilm formation reduced. Inhibition of biofilm development of *Candida* cells with Gram negative bacteria and their SNs was confirmed through fluorescence microscopy images.

**Conclusions:** Overall, our study highlighted that Gram negative bacteria can negatively affect *C. albicans* biofilms even with or without cells. Additionally, reducing in *C. albicans* biofilms with cell-free SNs was less than with Gram negative cells, which is suggesting that the physical coexistence of the cells affected *C. albicans* biofilms more.

Interpretation of WGS data for surveillance of vancomycin-resistant Enterococcus faecium in an endemic setting: challenges and limitations

Vanessa Eichel1; Sabrina Klein1, Uwe Frank1, Klaus Heeg1, Sebastien Boutin1, Dennis Nurjadi1

1 Heidelberg, Germany

Background: The rapid spread of Vancomycin-resistant Enterococcus faecium (VRE) in Europe over the last years led to endemic regions with high colonization and infection prevalences in hospitals. High resolution VRE sequencing methods provide new information, though the interpretation still bears some difficulties. In this study we explored the potential added benefit of incorporating the patient epidemiology within the hospital and colonization status at admission to distinguish between accumulations and outbreaks.

Materials/methods: All VRE isolated from blood cultures in the year 2016, as well as admission screening results of these patients underwent whole-genome-sequencing (WGS) (n=73). Genetic relatedness was determined by SNP distance (≤10) between isolates. The patient movement data along with admission screening was analyzed to identify potential transmissions.

Results: ST177, ST80 and ST203 were the most predominant in our study population. Most patients were rectally screened positive for VRE (30/43, 70%), 60% (18/30) were colonized and infected with the identical clone. SNP analysis of infection and colonization isolates revealed 9 potential transmission clusters. 19 out of 43 (44%) belonged to 5 transmission clusters. Incorporation of prior colonization status revealed that transmission is very likely in only 63% (12/19) of patients in these transmission clusters.

Conclusions: Care should be taken, when interpreting WGS data to investigate transmission, especially in an endemic setting. Although interpretation of WGS data is challenging, incorporation of patient movement data and colonization status by admission screening of high-risk patients may have and added benefit provide additional resolution when interpreting the magnitude of an outbreak in an endemic setting. Furthermore, we urgently need further studies in a multi-center approach to investigate regional spread and local diversity of VRE with the aim to better understand emerge and transmission dynamics of Enterococci.

Healthcare resource utilisation for treatment of Clostridioides difficile infection across 12 European countries: health economic results of COMBACTE-CDI

Sebastian Wingen-Heimann1, Lise Lurienne2, Kerrie Davies3, Anthony Benson1, Georgina Davis3, Virginie Viprey3, Mark H. Wilcox3, Marc J.M. Bonten1, Oliver A. Cornely1, Jörg Janne Vehreschild1

1University Hospital of Cologne, Cologne, Germany, 2Da Volterra, Paris, France, 3University of Leeds, School of Medicine, Leeds, United Kingdom, 4University Utrecht, University Medical Center Utrecht, Utrecht, Netherlands

Background: Clostridioides difficile infection (CDI) is one of the leading healthcare associated infections resulting in prolonged hospital length of stay and increased costs. CDI related data of healthcare resource utilization across Europe are scarce.

Materials/methods: A questionnaire to assess current CDI practices and CDI-related costs was sent out in 10/2018 to both hospital and community settings in 12 European countries. Countries were divided into four regions: West (Belgium, France, The Netherlands), North (Ireland, Sweden, United Kingdom), East (Poland, Romania, Slovakia), and South (Greece, Italy, Spain). Bootstrapped CDI related direct costs were expressed in Euro (€), year 2019 values. For international comparison of health expenditures, price level indices published by the Organisation for Economic Co-operation and Development (OECD) were used to ensure comparability of cross-country variations.

Results: Overall, 158 sites participated in the survey, predominantly hospitals (n= 109, 69%) and community physicians (n= 49, 25%). Median overall costs for one C. difficile stool sample test was €21.8 [interquartile range (IQR): €13.8 - €37.2], with lowest and highest values in Northern Europe [€15.0; IQR: €11.6 - €22.9] and Western Europe [€31.9; IQR: €16.2 - €37.6; p= 0.046], respectively. Across Europe, community physicians reported higher median drug costs for a one-day treatment with metronidazole iv [€14.4; IQR: €9.9 - €52.9 vs. €1.9; IQR: €1.4 - €9.5; p= 0.005] and vancomycin [€15.6; IQR: €7.9 - €22.0 vs. €6.5; IQR: €3.7 - €12.8; p= 0.017] compared to the hospital setting. In the pan-European hospital setting, median costs for severe CDI cases treated in intensive care units ranged from €1,437.5/day (IQR: €1,292.7 - €1,839.9) in Eastern Europe to €2,094.7/day (IQR: €1,063.8 - €3,191.5; p= 0.175) in Western Europe. Median costs for one general ward bed-day with isolation measures due to CDI was 2-fold higher in Southern Europe [€769.2; IQR: €567.9 - €1,623.9] compared to Eastern Europe [€324.0; IQR: €166.8 - €690.0; p= 0.010].

Conclusions: Healthcare costs of CDI diagnostic and treatment measures vary markedly in both hospital and community settings across Europe. The impact of the prevalence of hypervirulent strains, severity of illness, and guideline adherence are subject of future health economic evaluations of COMBACTE-CDI.

Abstract 3530

Non-vancomycin antibiotic resistance genes in vancomycin-resistant *E. faecium*: variation linked to MLST and mismatch between aminoglycoside resistance geno- and phenotypes

Zsuzsanna Adamecz*1, Karen Leth Nielsen1, Nikolai Kirkby1, Niels Frimodt-Moller1

1Rigshospitalet, Copenhagen, Denmark

Background: Vancomycin resistant and -variable Enterococcus faecium have been endemic in the capital region hospitals during the last 4-5 years. Many of the isolates are whole-genome sequenced (WGS), enabling investigation of other antibiotic resistance genes than the van genes. We noted disappearance of chloramphenicol resistance (*cat*) and some of the aminoglycoside-resistance (*amgr*) genes, while others of the latter increased in frequency. We therefore scrutinized 232 genomes from 2014-2019 for MLST and resistance genes and studied resistance phenotypes.

Materials/methods: A total of 232 *E. faecium* strains screening isolates from hospitalized patients were collected and whole-genome sequenced in Copenhagen from 2014 to 2019. To predict resistance genes and genotypes ResFinder was used based on WGS data. We screened for phenotype performed on 22 selected VRE strains by testing for susceptibility towards nine antibiotics (streptomycin, gentamicin, tobramycin, amikacin, erythromycin, tetracycline, chloramphenicol, vancomycin) with MIC determination or agar disc diffusion method. ResFinder results were compared with antimicrobial susceptibility testing results.

Results: Amgr genes were linked to MLST, which fluctuated during the period: ST203 (*vanA, erm(B), ant(6)-Ia, tet(M), lsa(A), cat, msr(C), dfrG*) dominated in 2014-18, but was overtaken by ST17 (*vanA, erm(B), ant(6)-Ia, oac[6′]-aph(2′), aph(3′)-III, lsa(A), msr(C), or vanB, erm(B), ant(6)-la, aph(3′)-III, lsa(A), msr(C), dfrG*) and the none-MLST-typeable vancomycin-variable clone (*vanA, erm(A), erm(B), oac[6′]-aph(2′), aph(3′)-III, tet(M), lsa(A), spc, msr(C), dfrG*) as well as a mix of diverse ST80 with fluctuating resistance profile during the later years. *cat* virtually disappeared in isolates from 2015 (96% positive) to 2019 (6% positive). There was complete concordance with pheno- and genotypes for macrolides, tetracycline and chloramphenicol. Discordance with presence of amgr gene combinations and amgr resistance was seen for 14/22 isolates (*oac[6′]-aph(2′), ant(6)-la* and *aph(3′)-III*). This discrepancy was due to presence of pseudogenes, i.e. non-functional genes.

Conclusions: The fluctuation in different non-vancomycin antibiotic resistance genes is in most cases related to shifts in ST-types. The reason for this variation cannot be deduced from antibiotic use in humans alone: Chloramphenicol has not been used in humans for decades except for topical administration in ophthalmology, and aminoglycoside consumption (gentamicin and tobramycin) is decreasing.

Abstract 3531

**New evidence-based recommendations for cefazolin prophylaxis in patients undergoing cardiac surgery with cardiopulmonary bypass**

Sheryl Zelenitsky1,2, Divna Calic1, Robert Ariano1,2, Rakesh Arora3, Hilary Grocott4

1The University of Manitoba, College of Pharmacy, Winnipeg, Canada, 2Saint Boniface Hospital, Department of Pharmacy, Winnipeg, Canada, 3The University of Manitoba, Departments of Surgery, Anaesthesia & Physiology, University of Manitoba, Winnipeg, Canada, 4The University of Manitoba, Departments of Anesthesia & Perioperative Medicine, Winnipeg, Canada

**Background:** Antimicrobial prophylaxis (AP) with cefazolin is central to the prevention of serious wound infections following cardiac surgery. Despite the unique conditions and complex procedures, there is limited data on whether standard AP dosing maintains adequate concentrations during cardiac surgery. Furthermore, there is no guidance on how AP dosing should be adjusted appropriately for reduced renal function. Our goal was to develop and implement a comprehensive cefazolin AP protocol for patients undergoing cardiac surgery with cardiopulmonary bypass (CPB).

**Materials/methods:** Our previous study of cefazolin AP in patients with normal renal function (CrCl > 50 mL/min) concluded that 2 g pre-operatively and every 3 hours (Q3H) during surgery was more appropriate than the Q4H recommended in clinical practice guidelines. In the current study, the pharmacokinetics of cefazolin during cardiac surgery with CPB were described using population-pharmacokinetic modelling (Pmetrics®). Next, Monte Carlo simulations were conducted with relevant patient demographic, pharmacokinetic and surgery data to investigate cefazolin AP regimens for various degrees of renal dysfunction. A new cefazolin AP protocol was constructed and further refined for feasible and practical implementation in the surgical setting.

**Results:** Simulations for the new cefazolin AP protocol are depicted below. Data for prolonged surgery was selected to show the potential for drug accumulation over time. For CrCl’s of 50 mL/min [grey line] to 100 mL/min [black line], the AP protocol incorporated our previously established standard regimen of 2 g pre-operatively and Q3H during surgery. For CrCl’s <50 mL/min, however, that regimen led to significant accumulation with twice the exposure to cefazolin over 24 hours [i.e., area-under-the-concentration curve, AUC24]. Simulation results supported a renal-adjusted regimen of 2 g pre-operatively and at 3 hours; and again at 11 hours for ongoing surgery and CrCl of 20-49 mL/min. The exposure to cefazolin was similar for the standard and renal-adjusted regimens with predicted AUC24 ranges of 1960-3560 mgxh/L and 2570-3880 mgxh/L, respectively.

**Conclusions:** The current study provides evidenced-based dosing recommendations for cefazolin AP in patients with various degrees of renal function undergoing cardiac surgery. The new cefazolin AP protocol was implemented successfully into practice by our provincial cardiac surgery program.

**Antibacterial and anti-biofilm activities of mucolytics, alone and in combination with antibiotics against Gram-negative pathogens**

Fatima Nur Yılmaz*1, Sibel Dosler2

1Istanbul university, Istanbul, Turkey, 2Istanbul University, Istanbul, Turkey

**Background:** *Pseudomonas aeruginosa*, *Klebsiella pneumonia* and *Acinetobacter baumanii* are the most important Gram negative, opportunistic human pathogens. They cause infections that are difficult to treat because of forming biofilms in the airways and lungs. Because of the biofilm-associated bacteria are not affected by therapeutically achievable concentrations of antimicrobial agents, new biofilm control strategies should be carried out by the researchers. Due to their mucus lysis effects mucolytics are one of the promising agents which are medicines that used to help treatment of airway and lung infections. The aim of this study was to evaluate the antimicrobial and anti-biofilm activities of mucolytics alone and in combination with antibiotics against planktonic cells and mature biofilms of *P. aeruginosa*, *K. pneumonia* and *A. baumanii* strains.

**Materials/methods:** Among mucolytic agents; N-acetyl cysteine (NAC), Erdosteine and Ambroxol, and antibiotics colistin, meropenem, levofloxacin and ceftazime were selected and used in our study. Minimum inhibitory concentration (MIC), Minimum Biofilm Eradication Concentration (MBEC) and fractional inhibitory concentration (FIC) indexes were determined by the microbroth dilution and chequerboard techniques, respectively.

**Results:** The MIC values of mucolytics were within the 3.1-12.5, 3.1-12.5, 1.5-6 mg/L for planktonic *P. aeruginosa* ATCC 27853, *K. pneumonia* ATCC 4352 and *A. baumanii* ATCC 19616 strains, respectively. Also, the MBEC values were determined as 6.25-25, 3.1-50, 1.6->50 mg/L for *P. aeruginosa*, *K. pneumonia* and *A. baumanii* biofilms, respectively. According to these results, however the MBEC/MIC ratios of antibiotics were very high, mucolytics MBEC/MIC ratios were 1-8 fold. When we perform the checkerboard assay, we found the NAC-Colistin combination was synergistic against *K. pneumonia*, and Erdosteine-Colistin against *P. aeruginosa* strains.

**Conclusions:** In this study, we showed that the mucolytics displayed similar MIC and MBEC results due to their possible biofilm lysis effect. Among mucolytics, erdosteine was the most effective agent against not only planktonic cells but also biofilms of the isolates, and it was synergistic with colistin.

Abstract 3538

Oral versus intravenous antibiotics in the treatment of osteomyelitis in adults: a systematic review and meta-analysis

Ramon Jr Larrazabal1, Harold Henrison Chiu1, Marlon Arcegono*2, Cybele L. R. Abad2

1University of the Philippines Manila - Philippine General Hospital, Department of Medicine, Manila, Philippines; 2University of the Philippines Manila-Philippine General Hospital, Department of Medicine - Section of Infectious Diseases, Manila, Philippines

Background: The worldwide incidence of osteomyelitis is approximately 21.8 cases per 100,000 person-years. The cornerstone of treatment is prolonged (4-6 weeks) intravenous antibiotic administration. This entails additional cost, inconvenience, and added manpower from the healthcare system. Thus, studies have explored the possible use of oral antibiotics as alternatives to improve patient compliance and reduce costs. Our meta-analysis aimed to compare the efficacy of oral versus intravenous antibiotics in treating adult patients with osteomyelitis.

Materials/methods: Electronic databases (PubMed, Medline, EMBASE, Cochrane Central Register of Controlled Trials, Google Scholar, and Research Gate) from 1966 to November 2019 were searched using the terms "oral antibiotics", "osteomyelitis", "randomized controlled trial". Only studies that directly compared oral versus intravenous antibiotics and confirmed osteomyelitis through biopsy and/or imaging were included. Primary outcome is remission (resolution of symptoms with no relapse and bacteriologic eradication); secondary outcomes, (a) relapse (persistence of the pathogen after treatment) and (b) adverse events. The validity of included studies was assessed using the Cochrane Handbook for Systematic Reviews of Interventions. We performed a random-effects model in Review Manager Version 5.3 with 95% confidence interval. The I2 test was used to assess heterogeneity.

Results: Seven of 89 trials comprised of 1,282 patients were included in the final analysis. All studies included patients with osteomyelitis of the lower extremities. Oral antibiotics used were Ciprofloxacin, Ofloxacin, and Co-trimoxazole; intravenous antibiotics used were deemed appropriate by the infectious disease specialist. Patients were only given either oral or intravenous antibiotics. Results showed an 8% increase in remission rates [RR 1.08 (0.81 to 1.44, 95% CI, Z = 0.52, p=0.60)] with no heterogeneity (I2 = 0%) in the intravenous antibiotics group. However, this was not statistically significant. Furthermore, there was a 62% decrease in relapse rates in the intravenous antibiotics group [RR 1.62 (0.85 to 3.07, 95% CI, Z = 1.47, p = 0.14)] with no heterogeneity (I2 = 0%), but was not statistically significant.

Conclusions: Oral are comparable to intravenous antibiotics in treating osteomyelitis in terms of remission and relapse rates. However, larger and double-blinded trials should be done to generate more robust data to validate these claims.

Abstract third-party references: Centre d’Infectiologie Charles Mérieux

Background: Antimicrobial resistance is recognized as a global public health problem. The main objective of this study is to determine the prevalence of extended-spectrum beta-lactamases producing Escherichia coli (ESBL-E.coli) as an indicator of resistance in human, food chain, and environmental sectors in Madagascar, by following the protocol developed by WHO-AGISAR group.

Materials/methods: This pilot study lasted 13 months (April 2018 - April 2019). The human survey was carried out in seven laboratories from the RESAMAD network, in collaboration with local Maternity Hospitals. The rates of ESBL strains among E.coli isolated from patients with bloodstream infections documented by positive blood cultures were assessed in hospitalized patients. In the community, the rate of fecal ESBL-E.coli colonization was determined in healthy pregnant women close to delivery. The search of ESBL-E.coli in food chain was done from the ceca of chickens collected from Antananarivo markets over the year. The environmental component of the ESBL-E.coli surveillance, was realized by collecting upstream and downstream water samples of Ikopa river which crosses Antananarivo, the communal wastewater and the water of slaughterhouse. E.coli strains isolation was done on chromogenic and selective media, followed by indole test for E.coli identification, and by antimicrobial susceptibility testing for ESBL detection.

Results: In the community settings, 176 out of 535 (32.9%) samples from pregnant women, were tested positive for ESBL-E.coli. In hospitals, 310 out of 1,150 blood cultures were positive, of which 16 (5.16%) were ESBL-E.coli. The results of the food chain showed that 155 out of 274 (56.6%) tested chickens were carrying ESBL-E.coli. Seven rounds of environmental water samples were taken along one-year study. On average, ESBL-E.coli was present at a concentration of 1 CFU/100 mL in upstream water, 2.4 log CFU/100 mL in downstream, 4.2 CFU/100mL in wastewater and 4.1 CFU/100mL log in slaughterhouse water.

Conclusions: This study on antimicrobial resistance was effective in measuring a single indicator in three interdependent sectors using a “One health” approach. A follow up over time of this indicator is necessary to better understand risk factors linked to resistance propagation and to monitor the effectiveness of the fight against antimicrobial resistance.

Background: Impaired cytomegalovirus (CMV)-specific cellular immunity (CMV-CMI) is a major cause of uncontrolled CMV reactivation and associated complications in solid-organ and hematopoietic stem cell transplantation (SOT, HSCT). Reliably assessing CMV-CMI is desirable to individually adjust antiviral and immunosuppressive therapy. We demonstrate here the suitability of an IFN-γ ELISpot assay (T-Track® CMV), based on the stimulation of peripheral blood mononuclear cells with pp65 and IE-1 CMV proteins, to monitor CMV-CMI in immunocompromised SOT and HSCT patients.

Methods: Two independent prospective, longitudinal, observational, multicenter studies were conducted, the first one in 86 intermediate-risk (D-/R+, D+/R+) renal transplant recipients [ClinicalTrials.gov ID: NCT02083042], the second one in 154 intermediate- and high-risk (D+/R+, D+/R-, D-/R+) HSCT recipients [ClinicalTrials.gov ID: NCT02156479]. In both studies, patients underwent pre-emptive antiviral therapy, and CMV-CMI, CMV viral load and clinical complications were monitored over approximately six months post-transplantation.

Results: In the kidney transplantation setting, CMV-specific response was reduced following immunosuppressive treatment and increased in patients with graft rejection, indicating the ability of the ELISpot assay to monitor the patients’ immunosuppressive state. Interestingly, median pp65-specific response was 9-fold higher in patients with self-clearing viral load compared to antivirally-treated patients prior to first detection of viral load (p<0.001), suggesting that reactivity to pp65 represents a potential immunocompetence marker. In HSCT recipients, 40/101 (39.6%) patients with a first CMV reactivation experienced at least one recurrent reactivation, mainly in the D-/R+ high-risk group. The positive predictive value (PPV) of T-Track® CMV (patients with a negative test after the first reactivation experienced at least one recurrent reactivation) was 84.2% (16/19) in high-risk patients. Kaplan-Meier analysis revealed a higher probability of recurrent CMV reactivation in high-risk patients with a negative test after the first reactivation [hazard ratio 2.73; p=0.007, Figure 1]. A post-hoc analysis considering T-Track® CMV measurements at day 100 post-transplantation, a time point highly relevant for outpatient care, showed a PPV of 90.0% (9/10) in high-risk patients.

Conclusions: Altogether, the standardized IFN-γ ELISpot assay (T-Track® CMV) is a highly sensitive immune-monitoring tool, suitable for the follow-up of SOT and HSCT recipients, and with a potential use for the risk assessment of CMV-related clinical complications.

Abstract 3544

**Dual-function antimicrobial laundry supplement and textile coating for the decontamination of healthcare laundry**

Lucy Owen*1, Katie Laird1

1De Montfort University, Infectious Disease Research Group, Leicester, United Kingdom

**Background:** In the UK nurses’ uniforms are domestically laundered, posing a threat of cross contamination of healthcare-associated infections. The UK Department of Health recommends washing uniforms at 60°C, however nurses most commonly wash them at 40°C. Bacteria survive on textiles washed at low temperatures; 4.28-4.62 log10 *Escherichia coli* and *Staphylococcus aureus* survived washing at 40°C and cross contaminated other textiles in the wash. Antimicrobial laundry supplements could sanitise textiles and limit cross-contamination. A supplement that deposits an antibacterial coating onto textiles could also reduce contamination between washes. This study aimed to investigate a silver-based antimicrobial textile coating product (Micro-Fresh 1911) as a dual-use antimicrobial laundry supplement and textile coating.

**Materials/methods:** Polycotton inoculated with 10⁸ colony forming units (CFU)/mL *E. coli* or *S. aureus* (type and clinical isolates) were washed with 2% Micro-Fresh 1911 in a domestic washing machine (40°C) and surviving microorganisms enumerated. Washes were conducted with and without soiling and biological detergent. Control washes were water alone.

The antimicrobial activity of polycotton washed with Micro-Fresh 1911 at 40°C was assessed against *S. aureus* and *E. coli* using International Standards Office (ISO) 20645 and ISO 20743 methods. Controls were polycotton washed in water and textile padded with Micro-Fresh 2611.

**Results:** Washing with Micro-Fresh 1911 reduced *E. coli* and *S. aureus* by 7.14-8.08 log₉₀⁰. No cells were recovered from sterile textile, whereas washing with water alone reduced *E. coli* and *S. aureus* by 2.21-4.25 log₉₀⁰ and resulted in 3.13-4.01 log₉₀⁰ CFU cross-contamination. Combining Micro-Fresh 1911 with biological detergent reduced *E. coli* and *S. aureus* by 5.56-6.65 log₉₀⁰.

Fabric washed with Micro-Fresh 1911 was antimicrobial against *E. coli* and *S. aureus* type and clinical isolates according to ISO 20645 and ISO 20743. The antimicrobial coating remained after washing the fabric in water once at 40°C and 73°C.

**Conclusions:** Micro-Fresh 1911 exhibits antimicrobial activity in a 40°C domestic wash and deposits an antimicrobial layer onto polycotton. Micro-Fresh could be employed as an antimicrobial laundering product to reduce microbial contamination of healthcare laundry washed at low temperatures.

Can machine learning predict a positive blood culture?
Ben Mcfadden*, Mark Reynolds¹, Timothy John Jay Inglis¹²

¹The University of Western Australia, Crawley, Australia, ²PathWest Laboratory Medicine WA, Nedlands, Australia

Background: The early detection of bacteria in peripheral blood is relied on to improve patient outcomes and reduce mortality rates associated with bloodstream infections. More effective screening methods for identification of patients with a suspected bloodstream infection are needed to improve on current diagnostic and treatment pipelines. The aim of this study was to evaluate the effectiveness of machine learning for the classification of blood samples, identifying those that contain clinically relevant bacteria in the blood.

Materials/methods: We conducted a preliminary, retrospective study of data from all blood samples collected from hospital patients in 2018, which were analysed by a Sysmex XN-9000 haemocytometer system. Bacteriological data from all blood cultures generated from the same patient group during corresponding hospital admissions was linked to the haemocytometer data. The combined dataset was extremely imbalanced, with blood culture-positive samples representing less than 1% haemocytometer-analysed total. The Python programming language was used, accompanied by open source libraries for machine learning and data analysis.

Results: During this preliminary study, the complete 2018 dataset was split into training, validation and unseen test sets. Classes in each of the sets represent either the absence or presence of the verifiable laboratory outcome i.e. a positive blood culture. Samples belonging to the negative class (absence of positive blood culture) were not stratified further. Only data available from complete blood counts produced by the Sysmex XN-9000 was utilized. The results from the training, validation and test sets respectively had a sensitivity of 0.9359, 0.9275, 0.8974 and a specificity of 0.6721, 0.6737 and 0.6686.

Conclusions: This study demonstrates the potential use of a machine learning-based approach as a screening method to predict the subsequent growth of bacteria in blood cultures, using routinely generated full blood count data up to 24 hours before auto analysers indicate a positive result. These results provide the foundation for future work in this field, and highlight the importance of taking advantage of readily available datasets.

Automated surveillance of urinary tract infections in a tertiary care hospital in Stockholm

Suzanne Desirée Van Der Werff*, Emil J. Thiman, Hideyuki Tanushi, John Karlsson Valik, Aron Henriksson, Mahbub Ul Alam, Hercules Dalianis, Anders Ternhag, Pontus Naucler

1Karolinska Institutet, Division of Infectious Disease, Department of Medicine Solna, Stockholm, Sweden, 2Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden, 3Stockholm University, Department of Computer and Systems Sciences, Stockholm, Sweden

Background: Healthcare-associated infections (HAI) pose a major burden on the healthcare system and are associated with prolonged hospital stay, increased morbidity, mortality and costs. Healthcare-associated urinary tract infections (HA-UTI) account for about one fifth of all HAI. Traditional surveillance methods are time consuming and resource intensive. We aimed to develop a fully automated surveillance algorithm for HA-UTI.

Materials/methods: The study was performed using electronic health record data from Karolinska University Hospital. Both structured and unstructured free-text data was used. Natural language processing was used for processing free text medical notes. Four algorithms were developed using data from 3700 healthcare episodes with a positive urine culture from July 2010 till March 2011: Algorithm 1) positive urine culture; Algorithm 2) positive urine culture combined with UTI ICD-10 codes; Algorithm 3) positive urine culture combined with presence of fever and/or UTI symptoms; Algorithm 4) algorithm 3 with negation for fever without UTI symptoms by non-correspondent positive blood cultures or relevant ICD-10 codes. Subsequently, these algorithms were validated in 409 episodes with a positive urine culture from January till March 2012. UTI were manually annotated according to the ECDC definitions by trained healthcare personnel.

Results: In the validation set 158/409 (39%) of episodes fulfilled the ECDC HA-UTI definition. In preliminary analyses the four algorithms classified 403, 143, 201 and 169 episodes, respectively as being an HA-UTI. In the table below the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for all four algorithms are shown.

<table>

<td>0.82 (0.77-0.86)</td>
</tr>
</tbody>
</table>

Conclusions: Simple algorithms based on positive urine culture or ICD-10 codes only are insufficient to adequately classify HA-UTI. More advanced algorithms based on text mining of unstructured data to detect symptoms performed better. This study shows that it is feasible to develop fully automated surveillance algorithms based on text mining, with adequate performance, for surveillance of HAI.

Management of a vancomycin-resistant Enterococcus faecium outbreak in the haematology unit of an Italian hospital

Sara Mondino*1, Vinicio Manfrin2, Mario Rassu3, Romina Cazzaro4, Marco Ruggeri5, Giulia Cavaliere5, Anna Diquigiovanni6, Davide Brodesco4, Sofia Zanovello6, Maria Paola Zanon7, Salvatore Barra8

1AULSS 8 Berica - Vicenza Hospital, Risk Management, Vicenza, Italy, 2AULSS 8 Berica - Vicenza Hospital, Infectious Diseases Department, Vicenza, Italy, 3AULSS 8 Berica - Vicenza Hospital, Microbiology Department, Vicenza, Italy, 4AULSS 8 Berica - Vicenza Hospital, Hospital Medical Direction, Vicenza, Italy, 5AULSS 8 Berica - Vicenza Hospital, Hematology Department, Vicenza, Italy, 6University of Padova, Specialization School in Hygiene and Preventive Medicine, Padova, Italy, 7University of Verona, Specialization School in Hygiene and Preventive Medicine, Verona, Italy, 8AULSS 8 Berica, Health Management Office, Vicenza, Italy

Background: Enterococci are normally present in the intestinal flora and in the environment. Many of these bacteria develop resistance to antibiotics, such as vancomycin, thus being defined Vancomycin-Resistant Enterococci (VRE). The percentage of vancomycin resistance in E. faecium in the EU has significantly increased in the last years. In Italy, the percentage has reached 18.9% in 2018. Long-term hospitalization, immunodepression and antibiotic therapy represent some of the risk factors for developing a VRE infection. Aim of the study is to report an outbreak investigation and point out strategies to prevent or solve a new potential outbreak.

Materials/methods: VRE screening was performed with rectal swabs. A cluster of VRE colonization was detected in hematology in April 2019. The index case was found to be a patient who had sepsis from VRE in February 2019 with prolonged persistence of colonization. She was subsequently readmitted to the ward several times. Many preventive measures were adopted to avoid the spreading of VRE colonization: cohorting of patients (one filter room, swab + rooms, swab – rooms), sphygmomanometer and phonendoscope per person, oximeter per room, personal protection equipment, food consumption with single-use dishware, disinfectants trolleys outside every room, no common areas, information for patients on hand hygiene. Environmental samples were collected. Moreover, one health and social care worker was employed.

Results: 29 people were colonized in total, 3 patients had VRE sepsis (including the index case). Up to 12 colonized people were hospitalized simultaneously (on a total of 27 beds). The outbreak was contained in about 5 months [April-September], this timing being lower than the estimated average in literature [11 months]. The ward has never been shut down. All environmental samples tested were negative for VRE.

Conclusions: Early detection of colonized patients, strict preventive measures, a good communication among healthcare professionals and between staff and patients/relatives played a crucial role in solving the outbreak. Rectal swabs must be performed at admission to early detect colonized patients in order to adopt supplementary preventive measures. Hand hygiene is one of the most important infection-control measures to be adopted by patients and staff to avoid the spreading of VRE.

Monitoring enterovirus human infections in Italy: molecular analysis of two recent outbreaks due to Echovirus 30
Stefano Fontana¹, Daniela Cimini¹, Katia Marinelli², Giada Gori², Vania Moroni³, Lucia Collini⁴, Elisabetta Pagani⁵, Elisa Masi⁵, Gabriele Buttinelli⁵, Stefano Fiore¹, Concetta Amato¹, Valter Carraro⁴, Paola Stefanelli¹

¹Istituto Superiore di Sanità, Roma, Italy, ²Azienda Sanitaria Unica Regionale - Area Vasta 2 Fabriano, Fabriano, Italy, ³Azienda Ospedaliera Ospedali Riuniti Ancona, Ancona, Italy, ⁴Azienda Provinciale Per i Servizi Sanitari, Trento, Italy, ⁵Comprensorio Sanitario di Bolzano, Bolzano, Italy

Abstract third-party references: This work was partially supported by the grant from the Italian Ministry of Health, CCM, "Monitoraggio della circolazione di enterovirus a supporto delle attività di sorveglianza per il mantenimento dello status polio-free".

Background: The Regional Reference Laboratory (RRL)/WHO Collaborating Centre for polio at the Istituto Superiore di Sanità (ISS) in Italy is involved in all activities to monitor a possible reintroduction of poliomyelitis and to maintain the polio free status. To support polio eradication activities and due to the fact that there is not routine data collection on non-polio enteroviruses in Italy, the RRL started, in April 2019, with the support of the Italian Ministry of Health, the surveillance on enteroviruses that cause human diseases. Lab-capacity for the diagnosis of enterovirus through the country and two recent outbreaks due to Echovirus 30 (E-30) are, here, described.

Materials/methods: A questionnaire to explore the enterovirus diagnosis lab-capacity has been administered through the laboratories identified in each Italian Regions. For surveillance purpose, a dedicated form with the patient’s clinical information is required. Twenty-six enterovirus infections, of which 17 were aseptic meningitis, were reported by the Marche Region and the autonomous provinces of Trento and Bolzano. These enterovirus infections have been studied by sequencing the genomic region of Viral Protein (VP)1 for characterization and possible genomic correlation.

Results: Hospital laboratories in Italy carry out the diagnosis of enterovirus mostly on cerebrospinal fluids and nasopharyngeal swabs using molecular techniques. More than 50 lab-confirmed enterovirus infections have been reported to the ISS from April to September 2019. Over the period, epidemiological investigations and VP1 nucleotide sequences have identified two E-30 outbreaks: the first including 21 cases of E-30 infections in the Marche Region and the second with 5 cases occurring in the autonomous provinces of Trento and Bolzano. The two outbreaks are not correlated to each other.

Conclusions: A great heterogeneity in the lab-capacity to identify enterovirus infections has been highlighted among the Italian Regions. In the first months of surveillance, two different outbreaks of E-30 were identified and confirmed by molecular analysis. Thus underlines the need to monitor the circulation of non-polio enterovirus in the country in order to know the burden of the disease in Italy.

Abstract 3551

**Validation of Colorex (CHROMagar) Serratia agar on WASP/WASPLab in screening for Serratia marcescens in neonatal intensive care units using the ESwab**

Mark Gaskin*1, John Korver1, Debbie Yamamura1

1Hamilton General Hospital, Hamilton, Canada

**Background:** Serratia marcescens is commonly associated with outbreaks in neonatal intensive care units. Investigations of outbreaks require efficient recovery of clinical and environmental isolates to prevent potentially fatal sepsis, meningitis or pneumonia. The objective of this study was to validate a new Colorex™ (CHROMagar™) Serratia agar for neonatal Serratia screening using the WASP™ and WASPLab™.

**Materials/methods:** This study used 579 Serratia surveillance specimens collected with ESwab™ kits processed on the WASP™. Known reference strains (N=105) of Serratia marcescens were also tested. The Colorex™ Serratia agar plates were incubated in the WASPLab™ for 20 hours then imaging analysis was performed. Results were compared to current testing method which uses MacConkey agar. Positive results were confirmed with Vitek MS.

**Results:** Of the 579 samples tested, 6 were positive for Serratia marcescens by the current method using MacConkey plates, versus 24 positives for Serratia species with Colorex™ Serratia agar and the WASP™ and WASPLab™ imaging analysis. 22 identified as Serratia marcescens, 1 as S. liquefaciens and 1 as S. odifera. All 24 isolates were blue in colour and grew heavy on the Colorex™ Serratia agar. 18 specimens showed very light growth of target colour blue colonies that identified as Klebsiella oxytoca, Citrobacter freundii and Enterobacter cloacae. 11 specimens showed a light growth of non-target clear colonies that identified as Proteus, Morganella and Pseudomonas species. 102 known Serratia isolates grew well on Colorex™ Serratia agar with varying blue to blue-green colour. Interestingly, a few red pigmented strains resulted in pink to purple colonies. Colorex™ Serratia agar sensitivity: 100% (95CI 0.61-1) and specificity: 97% (95CI 0.95-0.98).

**Conclusions:** Results showed Colorex™ Serratia agar (CHROMagar™) had a significantly greater sensitivity than MacConkey agar in isolating Serratia marcescens from neonatal surveillance specimens. The use of the WASP for set up provides efficient and consistent processing and WASPLab™ imaging allows for high resolution digital imaging analysis. The WASPLab™ also has the capability to use segregation software to analyze images and put no growth images into a separate screen for rapid resulting.

Abstract 3552

The role of the eye microbiome in health and disease states of the lacrimal system

Yael Yagel*, Yair Motro1, Tom Kornhauser2, Sofia Kordeluk3, Stefan J. Green4, Jacob Moran-Gilad1, Erez Tsumi1

1Ben Gurion University, Be’er Sheva, Israel, 2Hadassah-Hebrew University Medical Center, Jerusalem, Israel, 3Soroka Medical Center, Be’er Sheva, Israel, 4University of Illinois at Chicago, Chicago, United States

Background: The ophthalmic microbiome remains poorly studied. Nasolacrimal duct obstruction (NLDO), either primary or secondary, leads to stagnant fluid in the lacrimal sac, occasionally leading to dacryocystitis. Dacryocystorhinostomy (DCR) is a surgical procedure creating an alternative path for tear drainage between the lacrimal sac and nasal cavity for alleviating NLDO. We studied the microbiome of these anatomical structures in patients undergoing DCR.

Materials/methods: Samples were taken intraoperatively from 22 patients undergoing DCR, including the conjunctival fornix (F), plica semilunaris (P) and the inferior nasal turbinate (N) from both sides. Samples from the lacrimal sac (L) were taken only from the diseased side. The samples were subjected to DNA extraction and high-throughput 16S ribosomal RNA gene amplicon sequencing. Bioinformatics analysis was carried out using the QIIME software package (v1.9.1). Microbial alpha diversity was calculated using Shannon index, with Kruskal-Wallis used for group significance tests. Beta diversity was calculated using Bray-Curtis dissimilarity and principal coordinate analysis (PCoA).

Results: Of studied patients, 61% were women and the mean age was 49 (range: 19-86). A total of 156 samples were taken from both diseased and healthy sides. The dominant phylum in the ocular surface (F&P) of all studied eyes was Proteobacteria (41%), whereas nasal samples were mainly comprised of Firmicutes (40%). Figure 1 is a PCoA plot including all studied samples, showing the clustering by anatomic site. Shannon diversity did not differ between F and P microbiota, but significant differences were found between the ocular surface and the lacrimal (P=0.03) and nasal (P=0.002) sites. No difference was found between lacrimal and nasal diversities (p=0.55). Comparison between healthy and diseased sides revealed no significant difference between ocular and nasal microbiota on the healthy side (p=0.07), and a significant difference on the pathological side (p=0.01).

Conclusions: The normal nasolacrimal system demonstrates a gradient between ocular and nasal microbiota, representing an ocular surface-nasal cavity microbial continuum. This gradient appears disrupted in patients with NLDO, resulting in demarcation between microbiota of ocular and nasal structures. Whether disrupted microbiota represents an underlying cause or a result of NLDO deserves further study.

Abstract 3553

Intestinal microbiome in critical care patients: association with patient status and outcome

Elisa Rubio García1, Andrea Vergara1, Mariana José Fernández1, Berta Fidalgo1, Genoveva Cuesta Chasco1, Fatima Aziz2, Maria Hernandez-Tejero2, Javier Fernandez2, Alex Soriano2, Jordi Vila Estape4, Climent Casals-Pascual4

1Hospital Clinic de Barcelona, Department of Clinical Microbiology, Barcelona, Spain, 2Hospital Clinic de Barcelona, Department of Hepatology, Barcelona, Spain, 3Hospital Clinic de Barcelona, Department of Infectious Diseases, Barcelona, Spain, 4Hospital Clinic de Barcelona, Department of Clinical Microbiology and ISGlobal, Barcelona, Spain

Background: Acquisition and infection by multi-drug resistant bacteria (MDRB) remains a major challenge in critical care patients. The role of intestinal microbiome in MDRB colonization resistance has been previously reported but not completely understood. Our aim was to investigate the association of diversity and composition of intestinal microbiota with MDRB colonization, infection and subsequent mortality in critical patients.

Materials/methods: We conducted a prospective study in 277 patients admitted to a 14-bed hepatic intensive care unit (hICU) between July-December 2018. Rectal swabs were obtained at admission to hICU and weekly during hICU-stay. Finally, 170 rectal swabs from 64 patients (minimum 2 rectal swabs per patient) were included for microbiome analysis. Rectal swabs were used to determine the presence of MDRB by plating them on selective media. Bacterial communities were studied by amplifying and sequencing the 16S rRNA gene V3-V4 region on an Illumina Miseq platform. Sequences were filtered and demultiplexed using DADA2, taxonomy was assigned using SILVA-132 and statistical analyses were conducted using QIIME2 and R environments.

Results: Median Charlson comorbidity index among patients was 5 (IQR:4-7), median age was 67 (IQR:55-74) and 52.7% were male. Regarding MDRB intestinal colonization, 20 patients were colonized at admission, 16 patients were colonized during hICU-stay and for 28 patients MDRB colonization was not detected. Microbial diversity and composition were not associated with MDRB colonization or time to colonization. However, lower microbial diversity indexes were significantly associated with suspected clinical infection (p<0.01), confirmed infection by a positive microbiological culture (p=0.04) and fatal outcome post-discharge (p=0.01). Microbial diversity was lower in patients with liver cirrhosis (p<0.01). Higher Enterococcaceae family relative abundance was observed in cirrhotic, infection and fatal outcome groups (Figure).

Conclusions: Despite the limited sample size and patient complexity our results show that lower intestinal microbial diversity is associated with infection and clinical outcome in critical patients. These findings are important and in line with our research hypothesis. Larger prospective studies are required to establish the role of the intestinal microbiome in MDRB colonization and infection.

Figure 1. Shannon alpha-diversity index and bacterial community composition according to clinical factors. Enterococcaceae family relative abundances are shown.

Abstract 3556

Identification of a multidrug-resistance cluster in clinical isolates of Streptococcus pyogenes that confers resistance to macrolides, lincosamides, tetracyclines, chloramphenicol and co-trimoxazole

Dàmaris Berbel Palau1, Guillem López De Egea2, Jordi Càmara*1, Aida González Díaz2, Meritxell Cubero1, Fe Tubau1, Mª Ángeles Domínguez Luzón1, Carmen Ardanuy Tisaire1

1Microbiology Department, Hospital Universitari de Bellvitge, University of Barcelona, IDIBELL, CIBER de Enfermedades Respiratorias., L’Hospitalet de Llobregat, Spain, 2Microbiology Department, Hospital Universitari de Bellvitge, University of Barcelona, IDIBELL, L’Hospitalet de Llobregat, Spain, 3Microbiology Department, Hospital Universitari de Bellvitge, University of Barcelona, IDIBELL, REIPI, L’Hospitalet de Llobregat, Spain

Background: Acquired resistance in Streptococcus pyogenes (group A streptococci; GAS) is mainly mediated by transposons of the Tn916-family. The present study describes the characteristics of GAS with an uncommon multidrug-resistant phenotype to macrolides, lincosamides, tetracycline, chloramphenicol and co-trimoxazole (MLTChSxT).

Materials/methods: Among all GAS clinical isolates collected from 1998-2018 from adults, multidrug-resistant (MLTChSxT) isolates were selected for the present study. Antibiotic susceptibility testing was performed by microdilution. All isolates were subjected to WGS (Illumina MiSeq 2x150pb). The emm-type and MLST were deduced in silico. Acquired resistance genes were initially searched using ResFinder. The genetic environment of the resistance genes was analysed in detail.

Results: Eight out 1027 GAS shared a resistant phenotype MLTChSxT. These isolates belonged to three emm-ST types: emm25-ST350 (n=6), emm81-ST117 (n=1), emm82-ST320 (n=1). All the isolates harboured a multidrug-resistance cluster containing erm[B] (resistance to macrolides, lincosamides, and streptogramins B), aph[3’]III-ant[6]-Ia (kanamycin and streptothricin resistance), cat (chloramphenicol resistance), tet[M] (tetracycline resistance) and dfrF (co-trimoxazole resistance) genes. The erm[B] gene was found into a MAS element together with the aminoglycoside modifying enzymes cluster aph[3’]III-ant[6]-Ia. The tet[M] gene was embedded in a partial Tn916-like structure. The mobilization and replication module was highly conserved among the strains. The multidrug-resistance element was inserted downstream the hsdM or rpmH genes. All the strains harboured different genes necessary for the genetic element mobilization of the T4SS (type IV secretion system).

Conclusions: A new genetic element conferring a multidrug-resistant phenotype has been identified in GAS. The identification of this element with a conserved mobilization structure among clonally unrelated GAS suggests its ability to spread. The presence of resistance mechanisms to different antimicrobials that could be used in the treatment of GAS infections is a matter of concern.

Delafloxacin in vitro activity in skin and soft tissue infections by methicillin-resistant and levofloxacin-resistant Staphylococcus aureus

María Gracia Liras Hernández*, Julio García Rodríguez1, Rosa Gomez1

1University Hospital La Paz, Madrid, Spain

Background: Delafloxacin (formerly W0-3034, ABT492, RX-3341) is a novel fluoroquinolone approval for the treatment of acute bacterial skin and skin structure infections (ABSSSIs) by US Food and Drug Administration (FDA).

The objective was to determine the in vitro sensitivity of delafloxacin against methicillin-resistant Staphylococcus aureus (MRSA) strains resistant also to levofloxacin isolated from clinical samples of patients with skin and soft tissue infections at the Hospital Universitario La Paz. Madrid. Spain.

Materials/methods: Sixty-six levofloxacin-resistant MRSA isolates from clinical samples of patients with skin and soft tissue infections were studied. Microdilution panels Beckman® and delafloxacin Etest Biomerieux® were used for sensitivity study. As a quality control S. aureus ATCC 29213 was used. EUCAST 2018 cut points were used except for delafloxacin. The FDA cut-off points were used for delafloxacin considering MRSA with MIC ≤ 0.25 mg/l sensitive and MIC > 0.5 mg/l resistant. Only one isolate per patient was considered.

Results: The patients presented thirty-five abscesses (53%), twenty-seven surgical wound infection (41%) and four osteoarticular infection (6%). 63.6% of the patients were male and 36.3% female.

The resistance to levofloxacin in the MRSA studied had a MIC 90 > 4 mg/l. Forty-four (66.7%) of MRSA resistant to levofloxacin had a MIC sensitive to delafloxacin (≤ 0.25 mg/l) and fifteen (22.7%) an intermediate MIC (0.5 mg/l). Seven of the MRSA (10.6%) were resistant to delafloxacin.

Conclusions: Only 10.6 % of MRSA resistant to levofloxacin were resistant to delafloxacin.

Delafloxacin could be an alternative for the treatment of Staphylococcus aureus resistant to other fluoroquinolones.

Surface plasmon resonance as a new tool to measure vaccine response to 13-pneumococcal conjugated vaccine

Marta Garrido Jareño *, Letizia Orti Pérez 1, María Del Carmen Meyer García 2, Joan Mollar Maseres 1, M. José Giménez Martí 1, Carmen Lloret Sos 1, Ana Gil Brusola 3, Jose Luis López-Hontangas 1, Juan Manuel Beltrán Garrido 2, Javier Peman Garcia 3, Antonio Pineda Lucena 1

1 Drug Discovery Unit, Health Research Institute Hospital La Fe, Valencia, Spain, 2 Preventive Medicine department, La Fe University Hospital, Valencia, Spain, 3 Microbiology department, La Fe University Hospital, Valencia, Spain

Background: the multiserotype ELISA (enzyme-linked immunosorbent assay) pneumococcal test is usually used in clinical laboratories to measure pneumococcal vaccine response in vaccinated patients. However, this approach has some disadvantages: enzyme activity may be affected by plasma constituents, experimental time of approximately 2 hours and substantial intra and inter-laboratory variation observed in quantitative results. In this context, Surface Plasmon Resonance (SPR) could provide a relevant tool for measuring anti pneumococcal capsular polysaccharides (PnP) IgGs generated in vaccinated patients. In our study SPR and ELISA were evaluated for measuring the concentration of anti-PnP IgGs generated in patients vaccinated with the 13-pneumococcal conjugated vaccine (PCV13).

Materials/methods: fast protein liquid chromatography (FPLC) was performed for antibody purification (IgGs). PCV13 was immobilized using amine coupling chemistry. Free amines of diphtheria toxoid (contained in PCV13) were covalently immobilized to a carboxy-methylated CM5 sensor chip. Binding/stability SPR experiments were performed in serum samples.

Results: a strong correlation between anti-PnP IgGs (ELISA) and the SPR signal was obtained (Spearman’s Rho = 0.89). The approach was successfully used to measure the interaction between anti-PnP IgGs and PCV13 and offered further significant advantages over classic ELISA. Thus, it provided additional information regarding the binding and stability of the interaction between anti-PnP IgGs and PCV13, and it was possible to detect and measure sera anti-PnP IgGs in a very short experimental time (2.5 min). Figure 1 shows injection of the patient’s serum an binding between the PCV13 and the anti-PnP IgGs and the sensorgram obtained by SPR. Sensorgram 1 represents RU level obtained in a patient with poor vaccine response and Sensorgram 2 represents RU level obtained in a patient with high vaccine response.

Conclusions: SPR offered an important advantage from a clinical perspective as it was possible to regenerate the sensor and perform approximately 250 of analytical sessions on the same chip, thus resulting in cost-effectiveness over commercial ELISA kit.

Figure 1: serum injection and SPR sensorgram obtained in two patients

Abstract 3564

Benzylpenicillin gradient tests underestimate MICs for penicillin non-susceptible Streptococcus pneumoniae

Frida Nilsson¹, Erika Matuschek²*, Gunnar Kahlmeter²,³

¹Clinical microbiology, Karlskrona, Sweden, ²EUCAST Development Laboratory, Växjö, Sweden, ³Clinical microbiology, Växjö, Sweden

Background: The EUCAST oxacillin 1 μg disk screening test detects all beta-lactam resistance mechanisms in Streptococcus pneumoniae, but it cannot quantify the level of benzylpenicillin (PCG) resistance and a PCG MIC must be performed for screen-positive isolates (oxacillin <20 mm). For MIC testing, gradient tests are often the first choice for clinical laboratories. The objective of this study was to evaluate the performance of commercially available benzylpenicillin gradient tests for S. pneumoniae using broth microdilution (BMD) as reference.

Materials/methods: Benzylpenicillin MICs were determined in 57 S. pneumoniae using gradient test from two manufacturers (Etest®, bioMerieux®; and MIC Test Strip (MTS)® Liofilchem®). Antimicrobial susceptibility testing was performed using MH-F agar from BD® (BBL®) and Thermo Fisher Scientific (Oxoid) in parallel. BMD was performed according to ISO standard 20776-1 on custom Sensititre plates (Thermo Fisher) using MH-F broth. In addition, PCG BMD MICs were performed on 68 S. pneumoniae from 11 external laboratories and compared with the PCG Etest® MICs submitted by the original laboratory. Results were interpreted according to EUCAST Breakpoints v 9.0. Categorical (CA) and essential agreement (EA, MICs within ± 1 dilution of reference) were calculated for each combination of gradient test brand and media.

Results: PCG BMD MICs ranged from 0.016-4 mg/L and 45 of 57 isolates had MICs above the susceptible breakpoint (0.06 mg/L). For both Etest and MTS, MICs were systematically lower than with BMD: 60.5% were 1-3 dilutions below and only 3.5% above (Table 1). There were differences related to brands of gradient test and agar, but categorical errors were observed for all combinations. The tests on isolates from external laboratories (n=68) showed similar results with 66% of the Etest MICs being 1-4 dilutions below the BMD MICs.

Conclusions: Both Etest and MTS systematically underestimate benzylpenicillin MICs in S. pneumoniae. This results in several categorical discrepancies where resistant isolates risk being categorised as false susceptible - even when a large part of the results are within EA. EUCAST has published a warning against the use of benzylpenicillin gradient tests in S. pneumoniae with beta-lactam resistance mechanisms (http://www.eucast.org/ast_of_bacteria/warnings/).

Abstract 3567

Is there any risk factor in terms of mortality in patients with nosocomial colistin-resistant Klebsiella pneumoniae infection?

Çiğdem Ataman Hatipoğlu1, Fatma Şebnem Erdinç2, Gulay Cetin2, Salih Cesur1, Esra Kaya Kılıç1, Şerife Altun Demircan1, Kader Arslan1, Ayse Buyukdemirci1, Necla Tulek2*, S. Kinikli1

1Health Sciences University/ Ankara Training and Research Hospital, Ankara, Turkey, 2Atılım University, Faculty of Medicine, Ankara, Turkey

Background: Colistin resistance is increasing in Klebsiella pneumonia isolates. In this study, risk factors for mortality were investigated in patients with nosocomial colistin-resistant Klebsiella pneumonia (CoRKP) infections.

Materials/methods: Between January 2014 and October 2019, 105 CoRKP infections were detected in 87 patients. Only the first CoRKP infection was included in the study for each patient. Identification and antibiotic susceptibility tests were performed using VITEK-2 automated system. Colistin resistance verified by Etest. Concomitant diseases, risk factors including invasive devices and procedures were recorded. Risk factors for mortality were compared between death and survival groups.

Results: Study group included 87 patients with CoRKP infection. Of patients, 49 was female (56%), mean age was 67.3±17.457 years. Most of patients were hospitalized in intensive care units (ICU), mean length hospital stay was 84.48±77.555 days. Among CoRKP isolates, 87% had also carbapenem resistance, 95% extended spectrum beta-lactamases. The most common concomitant diseases were hypertension, diabetes mellitus, cerebrovascular disease (44%, 35%, 31%, respectively). Most commonly detected risk factors were central venous catheter, urinary catheter, H2 receptor antagonist use, nasogastric tube, mechanical ventilation (99%, 95%, 93%, 81%, 79%, respectively). Overall mortality rate was 68%. There was no statistically difference between dead and survivor patients according to the gender (p=1.000). Mean age was significantly higher in patients who died compared with survivors (70.8±14.618 versus 60.0±20.728 years, p=0.017). Staying in ward or in ICU was not detected as a risk factor for mortality (63.6% versus 68.4%, p=0.741). We didn’t find any difference in terms of mean length of hospital stay (89.75±62.580 versus 81.98±84.117 days, p=0.665). The presence of carbapenem resistance and ESBL in CoRKP isolates was not found as risk factors for mortality (p=0.741 and p=0.591). We found no difference between the groups in terms of concomitant diseases and risk factors as invasive devices and procedures (p>0.05 for each).

Conclusions: In this study, gender, staying in ward/ICU, length of hospital stay, presence of carbapenem resistance and ESBL, concomitant diseases, invasive devices and procedures were not found as risk factors for mortality in patients with nosocomial CoRKP infections. Mean age was found significantly higher in patients who died.

Abstract 3568

Genetic diversity of *bla*KPC gene containing IncF plasmids from epidemiologically related and unrelated Enterobacteriaceae

Joep Stohr1,2, Marjolein Kluytmans - Van Den Bergh1,3,4, Veronica Weterings1, John W. A. Rossen5, Jan A. J. W. Kluytmans1,2,3,4

1Amphia Hospital, Breda, Netherlands, 2Elisabeth-TweeSteden Hospital, Tilburg, Netherlands, 3Amphia Academy Infectious Disease Foundation, Breda, Netherlands, 4Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 5University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: Knowledge of the within-replicon-group genetic diversity of resistance-encoding plasmids is limited. This study aimed to compare *bla*KPC-containing IncF plasmids of epidemiologically related and unrelated Enterobacteriaceae isolates.

Materials/methods: Short-read sequence data (MiSeq, Illumina, San Diego, US) of two *Klebsiella pneumoniae*, one *Escherichia coli* and one *Enterobacter cloacae* with *bla*KPC-containing IncF plasmids (IncFII(k2) and IncFIB(pQiL)) were available from a previously described KPC-E outbreak in a Dutch nursing home (2013-2014). For the present analysis isolates were additionally sequenced on a MinION (Oxford Nanopore Technologies, Oxford, United Kingdom). Hybrid assembly was performed with Unicycler v.0.8.4, followed by extraction of circular IncF replicon and *bla*KPC-containing contigs from the assembly graph with BANDAGE v.0.8.1. Eight epidemiologically unrelated *bla*KPC-containing plasmids of similar size, GC-content, and replicon group (IncFII(k2) and IncFIB(pQiL)), but isolated in a different country (Greece, Italy, Israel and the US) and year of isolation (between 2006 and 2011), were selected from GenBank. Pairwise single nucleotide polymorphisms (SNPs) were identified using Snippy v.4.4.5. The GenBank plasmid that was first isolated was used as reference genome for the pairwise SNP analysis. All plasmids were annotated using Prokka v.1.13.3. ComParison of gene presence or absence was performed with Roary v.3.12.

Results: The number of SNPs ranged from 0 to 13 between the outbreak plasmids and from 0 to 32 between the outbreak and the unrelated plasmids (Figure 1). A total number of 132 genes were detected, of which 121 (92%) were present in all plasmids. The number of genes being either variably present or absent ranged from 0 to 2 between the outbreak plasmids and from 1 to 8 between the outbreak and unrelated plasmids (Figure 1).

Conclusions: *bla*KPC-containing IncFII(k2)-IncFIB(pQiL) plasmids isolated from epidemiologically related and unrelated Enterobacteriaceae show a high degree of sequence similarity in terms of SNP differences and the number of shared genes. Therefore, judgements on the horizontal transfer of these plasmids based on genetic identity should be made with caution.

Abstract 3573

Serum lateral flow tests for invasive aspergillosis: a prospective cohort study

Toine Mercier*1,2, Ellen Guldentops2, Katrien Lagrou1,3, Johan Maertens1,2

1KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium, 2University Hospitals Leuven, Department of Hematology, Leuven, Belgium, 3University Hospitals Leuven, Department of Laboratory Medicine and National Reference Centre for Mycosis, Leuven, Belgium

Background: Recently, two lateral flow tests for the diagnosis of invasive aspergillosis (IA) were commercialized and have been evaluated in bronchoalveolar lavage fluid. However, there are no studies on their performance in serum.

Materials/methods: We prospectively collected screening serum samples twice a week from a cohort of hematology patients at high risk for IA, and bronchoalveolar lavage fluid whenever bronchoscopy was performed. We tested the performance of the OLM AspLFD (LFD) and the IMMY Aspergillus galactomannan (LFA) tests on serum and compared it to the serum galactomannan (Platelia Aspergillus Ag, Bio-Rad, Hercules, California, United States) with a cutoff ≥ 0.5. Results from the LFD and LFA were recorded digitally using a dedicated reader (Cube reader, Chembio Diagnostics GmbH, Berlin, Germany).

Results: Between January 2017 and June 2019, we included 266 patients: 5 were eventually classified as proven, and 36 as probable IA according to the 2008 revised EORTC/MSG definitions. Six patients were excluded as they were not classifiable and were started on mould-active therapy for suspected IA. The performance of the LFD and LFA is shown in Table 1. The LFA outperformed the LFD on all parameters (p < 0.05). Serum galactomannan had a similar sensitivity as the LFA (0.45 vs 0.52, p=0.317) and a slightly higher specificity (0.99 vs 0.96, p=0.014). In the subgroup of patients undergoing bronchoscopy due to suspected IA (n=67), we found a prevalence of IA of 61%. The negative predictive value of the LFA was slightly higher in this subgroup (0.54 vs 0.46, p=0.03), whereas the positive predictive value was equally high (0.95 vs 1.00, p = 0.48).

Conclusions: Performance of the LFA in serum was better than that of the LFD. However, in patients undergoing bronchoscopy for suspected IA, the predictive values are clinically similar.

**Abstract 3578**

**Importance of selection of nucleic acid extraction kits for viral nucleic acid extraction**

Hyun Soo Kim*, Eun Jin Lee

1Hallym University, Hwaseong, South Korea, 2Hallym University, Hwaseong, South Korea

**Background:** The extraction and purification of nucleic acids is critical for the molecular detection of viral infection. Although several RNA/DNA extraction kits are available, little information is available on the importance of the selection of viral nucleic acid extraction kits. Here, we compared the viral nucleic acid extraction efficiencies of five commercial kits using culture supernatants from rotavirus (RoV), respiratory syncytial virus (RSV), herpes simplex virus (HSV) and cytomegalovirus (CMV). We also compared the results of viral nucleic acid concentrations measured with NanoDop and Qubit.

**Materials/methods:** The nucleic acid extraction kits used were as follows: QIAamp Viral RNA Mini kit (A kit), QIAsymphony DSP Virus/Pathogen Kits (B kit), QIAamp DSP Virus kit (C kit), QIAamp DNA mini kit (D kit), and QIAamp DNA stool mini kit (E kit) (all QIAGEN, Germany). Supernatants from the cultures of RoV, RSV, HSV, and CMV were extracted in triplicates using these kits. The average yield of each sample was compared using the threshold cycle (Ct) value measured with commercialized real-time PCR assays for each virus, NanoDrop (Thermo Scientific), and Qubit (Thermo Scientific).

**Results:** Based on the results of real-time PCR, QIAamp Viral RNA Mini kit (A kit) and QIAsymphony DSP Virus/Pathogen Kit (B kit) showed higher nucleic acid extraction yield, especially for RNA viruses (average Ct values of A, B, C, D, and E kits: 30.45, 29.93, 33.35, and 34.43 for RoV; 18.48, 18.87, 21.82, 22.55, and 26.02 for RSV; 18.94, 19.60, 21.29, 20.00, and 22.41 for HSV; 28.86, 29.65, 32.61, 29.59, and 32.45 for CMV, respectively). Nucleic acid concentrations measured with NanoDrop were much higher than those measured with Qubit.

**Conclusions:** The extraction performance significantly varied depending on the extraction kit and species of viruses. Nanodrop results for DNA/RNA concentrations extracted from virus-cultured fluids were much higher than those of Qubit. These results may help laboratories to select the best extraction method for viruses and to understand the difference between NanoDrop and Qubit results for measuring viral DNA/RNA concentrations.

Abstract 3581

Epidemiology and outcomes of microbiologically documented bacterial foodborne infections in solid organ transplant recipients: a 10-year nationwide cohort

Lorena Van Den Bogaart*1,2, Adrian Egli3, Laura Walti4, Dionysios Neofytos5, Christian Garzoni6, Katia Boggian7, Christoph Berger8, Nicolas Mueller9, Oriol Manuel2, Matteo Mombelli2

1Department of Biomedical and Clinical Sciences, FBF-Sacco Hospital, University of Milan, Milan, Italy, 2Service of Infectious Diseases and Transplantation Center, Lausanne University Hospital, Lausanne, Switzerland, 3Clinical Microbiology, Basel University Hospital, Basel, Switzerland, 4Department of Infectious Diseases, Bern University Hospital, Bern, Switzerland, 5Transplant Infectious Diseases Unit, Geneva University Hospital, Geneva, Switzerland, 6Clinic of Internal Medicine and Infectious Diseases, Clinica Luganese, Lugano, Switzerland, 7Division of Infectious Diseases and Hospital Hygiene, Cantonal Hospital St Gallen, St Gallen, Switzerland, 8Division of Infectious Diseases and Hospital Epidemiology, Zurich University Children’s Hospital, Zurich, Switzerland, 9Division of Infectious Diseases and Hospital Epidemiology, Zurich University Hospital, Zurich, Switzerland

Background: Food-safety measures are generally recommended in solid organ transplant (SOT) recipients. However, little is known about the incidence and outcomes of bacterial foodborne infections after transplantation. We assessed the epidemiology, clinical characteristics and outcomes of bacterial foodborne infections in a nationwide cohort of SOT recipients.

Materials/methods: Patients transplanted between 2008 and 2018 and enrolled in the Swiss Transplant Cohort Study (STCS) were included. In the STCS, infection episodes are prospectively collected after transplantation. Testing for infection is performed at each center as part of routine clinical practice. Data not available in the STCS database were collected retrospectively by chart review.

Results: Among 4405 SOT recipients with a median follow-up of 4.5 years [IQR 2.2-7.3], 157 episodes of bacterial foodborne infection occurred in 143 (3.3%) patients [3.9% [98/2467] kidney, 2.1% [20/944] liver, 4.18% [14/335] heart, 1.5% [6/403] lung, 2.8% [3/106] kidney-pancreas, and 1.4% [2/38] kidney-liver]. The pathogens more frequently identified were *Campylobacter* spp. in 136 (86.6%), followed by *Salmonella* spp. in 16 (10.2%), *Yersinia enterocolitica* and *Listeria monocytogenes* in two (1.3%), and *Shigella* in one (0.6%) episode. Co-infection with enteropathogenic *E. coli* occurred in 3 (1.9%) cases. Resulting incidence rate was 6.37 (95% CI 5.43-7.60) and 0.76 (95% CI 0.46-1.23) per 1000 patient-years for *Campylobacter* and *Salmonella*, respectively. Median time from transplantation to infection was 1.6 years [IQR 0.6-3.3]. Diarrhea (92.7%, 127/137) and fever (37%, 51/137) were the most common symptoms and antibiotics were given in 74.5% (157/211) of cases. Invasive infections were diagnosed in 12 (7.6%) episodes: 9 bloodstream infections [3 *Campylobacter, 4 Salmonella, and 2 Listeria], 2 arthritis [one *Campylobacter* and one *Salmonella* arthritis with bacteremia] and one *Salmonella* aortitis. Hospital and intensive-care-unit admission were required in 42% [66/157] and 4.5% [7/157] of cases, respectively. Two patients [1.4%] died by day-30 after infection [one *Salmonella* aortitis and one *Salmonella* bacteremia] and 180-day graft loss rate was 2.1% [3/143].

Conclusions: Bacterial foodborne infections are common, occur late after transplant, and are associated with significant morbidity in SOT recipients. We observed a high rate of hospitalization and invasive infections, highlighting the essential role of education for food-safety measures in SOT recipients.

Sputum iron metabolism in patients with cystic fibrosis as a marker of infectious complications

Andrey Kozlov*1, Artem Lyamin1, Oksana Gusyakova1, Olga Kondratenko1, Danir Ismatullin1, Almaz Khaliulin1

1Samara state medical university, Samara, Russian Federation

Background: Today, cystic fibrosis is one of the most common hereditary diseases. The etiology of cystic fibrosis is a mutation of the gene Cystic Fibrosis Transmembrane Regulator (CFTR), which leads to a violation of the synthesis and operation of the protein of the same name. In the respiratory tract, there is a favorable environment for infection with bacteria and the development of inflammation, which can lead to complications (“cepation-syndrome”) and death of the patient. First of all, representatives of non-fermenting gram-negative bacteria such as Burkholderia cepacia complex and Pseudomonas aeruginosa have clinical significance. The aim of the study was to identify in sputum possible markers of infectious and inflammatory complications caused by non-fermenting gram-negative bacteria in the respiratory tract in patients with cystic fibrosis.

Materials/methods: The study analyzed sputum from 97 patients with cystic fibrosis. Sputum culture was carried out on dense nutrient media: 5% blood agar (Bio-Rad), universal chromogenic medium (Bio-Rad), selective medium for cultivation of B. cepacia complex (HiMedia). A MALDI-ToF mass spectrometer (Microflex LT, Bruker) was used to identify the cultures. Biochemical sputum examination was carried out on an automatic biochemical analyzer Cobas integra 400 plus (Roche, Germany).

Results: As a result, 77 (group 1) patients were identified non-fermenting gram-negative bacteria Burkholderia cepacia complex and Pseudomonas aeruginosa, 20 (group 2) other microorganisms. According to the results of biochemical sputum examination, there was a correlation between the detected microorganisms and the indicators of iron metabolism. In group 1 patients in sputum were significantly increased indicators of iron and iron-binding proteins-ferritin and transferrin, compared with patients of group 2. These differences were statistically significant. In group 1, the median iron level was 16.1 mmol/l, in group 2, 3.05 mmol/l. The median ferritin level in group 1 was 831.6 µg/l, in group 2, 45.35 µg/l. The median transferrin level in group 1 was 0.01 g/l, in group 2, 0 g/l.

Conclusions: Thus, indicators of iron metabolism in sputum can be used as additional markers of infectious and inflammatory complications caused by non-fermenting gram-negative bacteria in the respiratory tract in patients with cystic fibrosis.

Galleria mellonella as a novel in vivo drug discovery platform using bioluminescent KAPE pathogens

Vanessa Francis*, Ashley Smith1, Christian Kemmer2, Vincent Trebosc2, Birgit Schellhorn2, Richard Titball1, Olivia Champion1

1BioSystems Technology, University of Exeter, Exeter, United Kingdom, 2Bioversys AG, Basel, Switzerland

Background: Drug discovery is costly and time consuming. A major rate-limiting factor in drug development is the screening of candidate drugs in a cost effective manner through an appropriate model prior to mammalian testing. The objective of this project is to investigate the feasibility of using research grade Galleria mellonella (TruLarv) as an in vivo model for screening antimicrobials. We aim to establish a protocol for imaging intracellular Acinetobacter baumannii within TruLarv by engineering the bacterium to be bioluminescent. We would then be able to monitor A. baumannii infection within the larvae by the luminescent signal, and assess modulation of the infection when the larvae are dosed with antimicrobials.

Materials/methods: An extensively drug resistant A. baumannii strain was engineered to express the Lux operon (BV642) and a subsequent bioluminescent target mutant was produced (BV647). These strains were tested for growth, luminescence intensity and colistin resistance. BV642 and BV647Δcsm were tested in TruLarv with and without colistin (4 mg/kg). TruLarv were monitored for luminescence signal from bacteria, survival, motility and melanisation.

Results: We were able to visualise bioluminescent A. baumannii within TruLarv and monitor infection over 72 hrs. When the larvae were dosed with colistin and then challenged with either colistin-resistant or colistin-sensitive A. baumannii, we were able to visualise the infection dynamics, with the sensitive strain unable to establish an infection.

Conclusions: We have shown that we can visualise modulation of infection by antimicrobials, in real time, in an in vivo model. Within the Impact2 Eurostars project, we aim to configure the system as an in vivo high throughput drug screen for KAPE strains, allowing faster and more efficient drug discovery, which reduces the number of mammals required for screening by selecting the best drug candidates to be taken forward for further testing.

A novel pathogenic bacteria Scardovia wiggsiae involved in early childhood caries: ultrastructural characterisation of biofilm by an original scanning electron microscopy protocol

Gianluca Vrenna1, Rosanna Papa2, Marco Artini2, Giuseppe Familiari3, Patrizia Spigaglia4, Fabrizio Barbanti4, Alessandro Salucci5, Gianni Di Giorgio2, Maurizio Bossu5, Michela Relucenti1, Antonella Polimeni5, Laura Selan*6

1Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy, 2Sapienza University, Department of Public Health and Infectious Diseases, Rome, Italy, 3Sapienza University, Department of Anatomy, Histology, Forensic Medicine and Orthopaedics, Rome, Italy, 4Istituto Superiore di Sanità, Department of Infectious Diseases, Rome, Italy, 5Sapienza University, Department of Oral and Maxillo-Facial Sciences, Rome, Italy, 6Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy

Background: Recently a newly identified anaerobic Bifidobacterium named Scardovia wiggsiae has been related to the Early Childhood Caries (ECC), a particularly severe manifestation of carious pathology with rapid and disruptive progression, whose microbiota includes a wide variety of bacterial species. This study aims at providing the first ultrastructural morphological characterization of S. wiggsiae and its biofilm, adopting an innovative protocol for scanning electron microscopy (SEM).

Materials/methods: S. wiggsiae DSM 22547 strain was cultivated at 35°C for 48h in anaerobic chamber, transferred in tubes containing discs of bioglass [a material that mimics dentin surface] and incubated for 120 h to allow biofilm growth. S. wiggsiae was investigated for its ability to produce biofilm on polystyrene plate, and biofilm was quantified by crystal violet staining. S. wiggsiae biofilm on bioglass discs was observed at SEM (VPSEM Hitachi SU 3500) after fixation with glutaraldehyde and treatment with a mixture of osmium tetroxide and Ruthenium Red. Samples were mounted on aluminum stubs and dried in a desiccator at 40°C

Results: Based on quantification of the total biomass at 590 nm, S. wiggsiae can be considered a strong biofilm producer. At low magnifications (1000X) in SEM we saw a well preserved biofilm aspect including areas with different surface texture. Very high magnifications (ranging from 10000X to 35000X) allowed to identify bacterial cells embedded in the matrix bulk. Focusing on matrix trabeculae, in both spongy and granular areas, it was possible to distinguish an heterogeneous density. Biofilm matrix surface was irregularly dotted with small globular aggregates. At extremely high magnifications also the surface appeared irregular due to the presence of very fine globular aggregates of matrix components. Where matrix was less dense, numerous and intimately packed bacteria were visible. In these areas the ultrastructural morphology of the individual bacterial cells could be appreciated. Cell length and diameter were measured.

Conclusions: We report the first ultrastructural description of S. wiggsiae biofilm and the morphology of the bacterial cells embedded in biofilm. To this aim an innovative and unusual protocol for SEM analysis was adopted.

Abstract 3586

**Which is the best progressive multifocal leukoencephalopathy risk stratification strategy in natalizumab-treated patients affected by multiple sclerosis?**

Carla Prezioso*1, Maria Antonella Zingaropoli1, Marco Iannetta2, Donatella Maria Rodio1, Marta Altieri1, Antonella Conte1, Vincenzo Vullo1, Maria Ciardi1, Anna T. Palamara3, Valeria Pietropaolo1

1Sapienza University, Department of Public Health and Infectious Diseases, Rome, Italy, 2Tor Vergata University, Department of System Medicine Infectious Disease Clinic, Rome, Italy, 3Sapienza University, Department of Public Health and Infectious Diseases, Institute Pasteur, Cenci-Bolognetti Foundation, Rome, Italy

**Background:** The risk of progressive multifocal leukoencephalopathy (PML), a brain infection caused by John Cunningham virus (JCPyV), is the main limitation to the use of natalizumab, highly effective in the treatment of relapsing remitting multiple sclerosis (RRMS). Establishing the PML risk against expected benefits represents an obligatory requirement of MS treatment algorithms. In order to achieve this goal, the aims of this study were to establish if JCPyV DNA detection and NCCR arrangements could play a role of biomarkers, supporting anti-JCPyV antibodies measurement, actually the only parameter for PML risk stratification.

**Materials/methods:** Thirty RRMS patients, in treatment with natalizumab, were enrolled. Urine and blood samples were collected according to natalizumab treatment calendar (baseline or 0 infusions) and every 4, 8, 12, 16, 20 infusions. In detail, 30 urine, 30 plasma and 30 peripheral blood mononuclear cells (PBMC) samples were obtained, for a total of 540 specimens. After JCPyV-DNA extraction, a specific quantitative-PCR (Q-PCR) and arrangements’ analysis of NCCR and VP1 was carried out.

**Results:** Q-PCR detected JCPyV-DNA in urine and blood from baseline to 20 months of natalizumab treatment, although JC viral load in urine was significantly higher compared to viremia, at all selected time points. A contextual analysis of the anti-JCPyV-antibodies versus JCPyV-DNA detection displayed that viral DNA preceded the antibodies’ presence in the serum. At T0, only 1 patient exhibited anti-JCPyV-antibodies and viral DNA in plasma and in PBMC, simultaneously. At T3, although the number of anti-JCPyV-antibodies-positive patients increased, all RRMS patients presented JCPyV-DNA. Sequences isolated from blood showed an archetype JCPyV NCCR structure with the occurrence of point mutations. At T3, a NCCR reorganization was observed in plasma and PBMC with duplication of box C and deletion of box D. VP1 analysis showed a prevalence of genotypes 1A and 1B. Phylogenetic analysis suggested a stability and a similarity across different isolates of the JCPyV VP1.

**Conclusions:** Given our real-life laboratory experience we highly recommend considering JCPyV-DNA detection and NCCR reorganizations as viral biomarkers in order to accurately identify JCPyV-infected patients with a specific humoral response not yet detectable and to identify NCCR arrangements correlated with neurovirulent variants.

**Presenter email address:** carla.prezioso@uniroma1.it
Characterisation of the human cytomegalovirus genome diversity in longitudinally collected breast milk samples

Jasper Götting1, Katrin Lazar2, Nicolás Suárez1, Lars Steinbrueck1, Tabea Rabe2, Thomas F. Schulz1, Andrew Davison3, Klaus Hamprecht2, Tina Ganzenmueller1,2

1Hannover Medical School, Institute of Virology, Hannover, Germany, 2University Hospital Tuebingen, Institute of Medical Virology, Tuebingen, Germany, 3MRC-University of Glasgow, Centre for Virus Research, Glasgow, United Kingdom

Background: Shedding of human cytomegalovirus (HCMV) into breast milk (BM) is very common in HCMV-seropositive mothers and a key transmission route for postnatal HCMV infection leading to potentially severe disease in preterm neonates. Little is known about the HCMV population composition or dynamics in BM from immunocompetent donors.

Materials/methods: We performed high-throughput sequencing (HTS) directly from 23 BM samples (obtained between day 10 and 60 after giving birth) from 13 mothers with HCMV-DNA lactia recruited for the BlooMil study (Tuebingen). Target-enriched sequencing libraries were prepared using HCMV-specific RNA baits covering the known HCMV genome diversity and HTS carried out on an Illumina MiSeq sequencer. Consensus sequences were assembled de novo. The HCMV genotype distribution and number of strains present in each sample were determined by quantifying genotype-specific sequence motifs of 12 hypervariable viral genes (RL5A, RL6, RL12, RL13, UL1, UL9, UL11, UL73, UL74, UL120, UL146, and UL139) using the Virus Analysis Tool Kit (https://github.com/centre-for-virus-research/VATK).

Results: We observed a wide range of different genotypes for the 12 hypervariable viral genes in the cohort (75 out of 109 possible genotypes). Multiple infections involving up to 3 HCMV strains were detected in 3 out of 13 mothers. In contrast to most participants, these three mothers had stated their country of origin as being outside Germany. Analysis of longitudinal time-points for individual mothers (data available for 8 women) revealed stable genotype compositions over time, i.e. shifts in the abundance ratio of the identified genotypes were observed but no superinfections.

Conclusions: HTS revealed a remarkable genotypic complexity of HCMV with longitudinally stable intra-individual population compositions in BM in this cohort of immunocompetent women of predominantly European origin. BM as a main source of transmission may serve as repository for viral diversity. In contrast to studies in transplant recipients or HIV-infected patients with a different risk pattern for acquisition of multiple HCMV infections, analyzing BM from healthy mothers with HCMV reactivation opens an opportunity to study the “natural” epidemiology of HCMV in immunocompetent adults.

Pharmacodynamics of amikacin and fosfomycin combination therapy in neonatal sepsis modelled in a hollow fibre infection model

Christopher Darlow*, Fernando Docobo Perez†, Nikki Farrington‡, Adam Johnson§, Laura Mcentee¶, Ana Jimenez-Valverde‖, Jennifer Unsworth‖, Renata Da Costa†, Sally Ellis‡, François Franceschi‡, Mike Sharland§, Laura Piddock†, Shampa Das§, William Hope†

1University of Liverpool, Liverpool, United Kingdom, 2University of Seville, Sevilla, Spain, 3GARDP – Global Antibiotic Research & Development Partnership, Genève, Switzerland, 4St George’s, University of London, London, United Kingdom

Background: Antimicrobial resistant pathogens in neonatal sepsis cause an estimated 214,000 deaths annually, rendering the empiric antimicrobial regimen recommended by the World Health Organisation, amoxicillin and gentamicin, increasingly ineffective in a global context. One potential replacement combination for an empiric treatment regimen is fosfomycin and amikacin. We characterised the pharmacodynamics of this combination using a hollow fibre infection model (HFIM) of neonatal sepsis.

Materials/methods: Both amikacin and fosfomycin were assessed in a HFIM using a CTX-M14-producing E. coli and neonatal pharmacokinetic parameters. A 4x4 matrix combination HFIM experiment using dosages of amikacin and fosfomycin that achieve 20%, 50%, and 80% of maximal bacterial killing as monotherapy was performed over 96 hours. Further 7-day 2x2 matrix HFIM experiments using candidate neonatal clinical regimens were performed on six MDR Gram-negative strains (all with MICs above the EUCAST breakpoint to fosfomycin and/or amikacin) to assess the potential real-world performance of the regimen.

Results: The 4x4 matrix experiment demonstrated: (i) a dose-response relationship in terms of bacterial killing and prevention of emergence of resistance in the monotherapy arms; (ii) attainment of complete bacterial killing and prevention of emergence of resistance in the combination arms at lower doses of amikacin and fosfomycin than in the monotherapy arms.

The 2x2 matrix experiments demonstrated: (i) failure of monotherapy to kill where the minimum inhibitory concentration (MIC) was above the EUCAST breakpoint; (ii) initial killing with subsequent regrowth and emergence of resistance in 6/7 arms treated with monotherapy where the MIC was below the EUCAST breakpoint; (iii) sustained kill with no emergence of resistance with combination therapy in 3 strains with a fosfomycin MIC of <32mg/l or an amikacin MIC of <8mg/l; (iv) Failure to kill in all arms in 2/3 strains with a fosfomycin MIC of ≥32mg/l and an amikacin MIC of ≥8mg/l.

Conclusions: These experiments demonstrate the potential value of an amikacin-fosfomycin regimen for treatment of neonatal sepsis. There is a protective effect of the second antimicrobial agent in terms of prevention of emergence of resistance, enhanced antibacterial activity, even with organisms with an MIC to one agent that is above current EUCAST breakpoints.

Abstract 3591

**Antibiotic utilisation and incidence rate of extended-spectrum beta-lactamases: a 12-year time series and cross-correlation analysis**

Tau Hong Lee*1,2,3,4, Shi Thong Heng1, LI Wei Ang1,2, Sock Hoon Tan1, Hui Lin Tay1, Min Yi Yap1, Boon Hou Chua1, Jason Quek1, Tat Ming Ng2, David Lye1,2,3,4

1Tan Tock Seng Hospital, Singapore, Singapore, 2National Centre for Infectious Diseases, Singapore, Singapore, 3Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 4Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

**Background:** Extended-spectrum beta-lactamases (ESBL) can be selected by various antibiotics, with extended-spectrum cephalosporins (ESC) and fluoroquinolones frequently associated. We observed significant reduction in ESC and fluoroquinolone usage over ten years of antimicrobial stewardship programme (ASP) in a public university teaching hospital in Singapore. We aimed to investigate the temporal relationship between antibiotic usage and ESBL *Escherichia coli* and *Klebsiella pneumoniae*.

**Materials/methods:** Monthly utilisation of antibiotics in defined daily doses (DDD) and incidence of third-generation cephalosporin-resistant (3GCR) *E. coli* and *K. pneumoniae* per 1,000 patient-days from January 2007 to December 2018 were obtained from the hospital's database. Each time-series was pre-whitened to account for autocorrelation. An autoregressive integrated moving average (ARIMA) model was fitted to an antibiotic utilisation time-series, which was filtered to obtain white noise residuals. The incidence time series of 3GCR organisms was filtered with the same model. The cross-correlation function (CCF) was computed between the filtered time-series for each antibiotic use and 3GCR organism incidence at lags up to 12 months. We investigated the lag in the CCF at which the peak correlation of statistical significance (p<0.05) occurred, to determine the lead time of antibiotic utilisation relative to incidence of 3GCR organisms.

**Results:** The monthly incidence of 3GCR organisms fluctuated with no apparent underlying trend between year 2007 and 2018. Monthly range was 2.64/1,000 patient-days to 5.71/1,000 patient-days (mean of 3.99, standard error=0.17). Among major antibiotic groups, utilisation of ESC comprising third- and fourth-generation cephalosporins (0.22, p=0.01) was most significantly correlated with incidence of 3GCR organisms. Utilisation of antibiotics like ertapenem (0.22, p=0.01), imipenem (-0.17, p=0.04), levofloxacin (0.18, p=0.03) and ceftriaxone (0.22, p<0.01) was each correlated with incidence of 3GCR organisms. The lead time at which peak correlation occurred was 0 month for imipenem, 1 month for ESC and ceftriaxone, 5 months for ertapenem and 8 months for levofloxacin.

**Conclusions:** ESC, ceftriaxone, imipenem, ertapenem and levofloxacin usage significantly correlated with 3GCR *E. coli* and *K. pneumoniae* incidence density. Community transmission of ESBL may explain minimal impact of the ASP on ESBL incidence in the hospital.

Abstract 3593

Detection of carbapenemases in *Pseudomonas* and *Acinetobacter* by the Mast Carba PAcE kit

Damien Fournier¹, Katy Jeannot*¹, Loreen Gabriel¹, Pauline Triponney¹, Julie Rousselot¹, Anais Potron¹, Patrick Plésiat²

¹Centre National de Référence de la Résistance aux Antibiotiques, Centre Hospitalier Universitaire de Besançon, Besançon, France

**Background:** The objective of the study was to evaluate the performance of the Carba PAcE kit, a new rapid colorimetric test proposed for the detection of carbapenemases in *Enterobacteriaceae*, *Pseudomonas* spp. and *Acinetobacter* spp. (OXA-23 positive only). This test includes a chromogenic cephalosporin, HMRZ, combined with beta-lactamase inhibitors of classes A and C, respectively.

**Materials/methods:** 164 carbapenemase-producers (104 *Pseudomonas* and 60 *Acinetobacter*), representative of the French epidemiology, were studied as well as 78 control strains, not susceptible to imipenem (58 *Pseudomonas* and 20 *Acinetobacter*). The tests were carried out according to the supplier’s recommendations and read by 2 operators after 10 and 30 minutes of incubation at 35°C. An orange or red colour was interpreted as the production of a carbapenemase, and a yellow colour as a negative result.

**Results:** After 10 and 30 minutes of incubation, the test was positive for 90 (86.5%) and 98 (94.2%) of the 104 carbapenemase-producing *Pseudomonas* strains, respectively. At 30 minutes, only 1 strain (GES-27) remained negative while 5 strains (GES-5) gave rise to an equivocal yellow-orange colour, not interpretable according to the supplier’s criteria, which turned into orange after 60 minutes. At 30 minutes, 4 control strains expressing an extended-spectrum oxacillinase (1 OXA-14, 2 OXA-35 and 1 OXA-19) were misjudged as carbapenemase producers, while 4 others could not be classified (1 GES-1, 1 OXA-17, 1 PSE and 1 VEB-1/OXA-10). In *Acinetobacter*, the sensitivity and the specificity of the test were 75% and 95%, respectively. Almost all strains positive for carbapenemase OXA-23 (n=26/27) or OXA-24/72 (n=7/8) were correctly detected, unlike those producing OXA-58 (n=3/7) and NDM-1 (n=1/9).

**Conclusions:** Carba PAcE is a reliable and rapid test for the detection of carbapenemases in *Pseudomonas*. After a prolonged incubation (60 minutes), the test was able to detect GES-5 producers, that are usually screened negative by most colorimetric assays. Furthermore, Carba PAcE could identify >95% of *Acinetobacter* harbouring class D carbapenemases found in France and Europe, but should be supplemented with a test for class B beta-lactamases in the event of negative result.

Abstract 3601

**Systemic inflammation and activation of immunity in HIV-positive patients receiving antiretroviral therapy**

Anna Matuzkova¹, Natalia Pshenichnaia*, Alexander Suladze¹, Ludmila Dosyagaeva¹, Tatyana Tverdokhlebova¹

¹Rostov Scientific Research Institute of Microbiology and Parasitology, Rostov-on-Don, Russian Federation, ²National Medical Research Center of Phthisiopulmonology and Infectious Diseases, Moscow, Russian Federation

**Background:** Antiretroviral therapy (ART) does not always lead to improvement the quality of life of HIV-positive patients due to development of systemic inflammation. Aim: to study the markers of systemic inflammation (MSI) and immune activation in HIV-positive patients receiving ART.

**Materials/methods:** The study included 276 HIV-positive patients receiving ART in the age of 39.4±8.2 years, the observation period was 5.4±2.1 years. Patients were divided into 2 groups depending on the CD4+T-lymphocyte counts after 6 months of ART: Group 1 has CD4 level less than 350, group 2 - more than 350 cells/mcL. The concentration of lipopolysaccharide-binding protein (LBP), procalcitonin and cytokines (TNF-α, IL-1β, IL-6, IL-8, IL-10, INF-γ, INF-α) was determined in serum. Parameters of the cellular immunity were detected by flow cytometry. The specific features of changes in the phenotype of CD4 + and CD8 + lymphocytes were determined by the expression of immunological markers CD38, RO, RA, HLA-DR.

**Results:** More high level of MSI and increased immune activation were detected in the 1st group compared to the 2nd. The concentration of LBP in the 1st group was 87.1±6, in the 2nd - 73.6 ± 2.8 μg/ml (p <0.05). In the 1st group, the level of IL-6, INF-γ and INF-α was significantly higher than in the 2nd group (4.9±0.7 versus 3.8±0.3 pg/ml; 32.6±2. against 23.4±3 pg/ml; 12.2±1 against 9.2±0.6 pg/ml, respectively, p <0.05). The proportion of activated lymphocytes with the phenotype CD3+/CD8+/CD38+/HLA-DR in the 1st group was also more higher than in the 2nd group (27.2±2.2% versus 21.5±1.3%, p <0.05). No significant difference was found for other studied parameters (PCT, TNF-α, IL-1β, IL-8, IL-10).

**Conclusions:** Even after several years of effective ART, immunological disorders, elevated MSI were found in a significant proportion of HIV-positive patients, which indicates the presence of additional, uncontrolled by ART, mechanisms that accelerate the progression of the disease. To predict the progression of HIV infection, it is advisable to determine the concentration of the anti-endotoxin protection marker (LBP) in the blood, the level of pro-inflammatory cytokines (INF-γ, INF-α and IL-6), as well as the percentage of activated CD3+/CD8+/CD38+/HLA-DR cells.

Antibiotic use at the end-of-life in patients with advanced cancer: a systematic literature review

Alexandre Marra¹, Mireia Puig-Asensio*², Eli Perencevich³

¹University of Iowa Carver College of Medicine, Iowa City, IA, United States; ²University of Iowa Carver College of Medicine, Iowa City, IA, United States; ³Center for Access & Delivery Research and Evaluation (CADRE), Iowa City VA Health Care System, Iowa City, IA, United States

Background: Improving the use of antibiotics across the care continuum will be necessary as we strive to protect our patients from antimicrobial resistance. One potential target for antimicrobial stewardship is during end-of-life (EOL) care of patients with advanced cancer. We aimed to perform a systematic literature review measuring the burden of antibiotic use during EOL care in patients with cancer.

Materials/methods: We searched PubMed, CINAHL, and Embase through July 2019 for studies with the following inclusion criteria in the initial analysis: (1) end-of-life patients [cancer, dementia, organ failure, frailty or multi-morbidity]; (2) antibiotic use in the EOL care; with the final analysis restricted to (3) patients with advanced cancer. Risk of bias was evaluated using the Downs and Black score.

Results: Of the 93 full-text articles, 21 studies (22.5%) met the selection criteria for further analysis. All the included studies were retrospective (n=17) or prospective (n=4) cohort studies. These studies in combination included 34,971 patients with advanced cancer. Fifteen studies (4,439 patients, [12.7%]) included patients with any type of cancer (solid or hematologic malignancy). In sixteen studies where data was available, less than one sixth of patients (12.3%, 4,317) with advanced cancer were referred to palliative care. In fourteen studies more than 50% of patients received antibiotics during end-of-life period. Fourteen studies did not report the duration of antimicrobial therapy. None of these studies reported the antimicrobial consumption in days of therapy per 1,000 patient-days. Only eleven studies examined whether the use of antibiotics was associated with beneficial outcomes [survival or comfort], and one of them evaluated potential adverse effects associated with antibiotic use. Studies had high risk of bias, with scores (up to 28 points) ranging from 4 to 20 with a median of 12.

Conclusions: There are significant gaps in the literature surrounding antimicrobial use at the EOL in patients with advanced cancer. Future studies are needed to evaluate the benefits and harms of using antibiotics for patients during EOL care in this patient population.

Abstract 3606

**Antimicrobial activity of XF-73 against clinically relevant Gram-positive bacteria**

Isabella Romeo-Melody*, Daniel Hynes2, William Rhys-Williams2, Bill Love2, Peter Lambert1, Tony Worthington1

1Aston University, Birmingham, United Kingdom, 2Destiny Pharma plc, Brighton, United Kingdom

**Background:** Antimicrobial resistance is a global health issue and the need for new, effective antimicrobials is crucial. The synthetic dicatonic porphyrin, Exeporfinium chloride (XF-73), is a proprietary, clinical stage drug with a novel bacterial membrane-acting mechanism of action. In addition, XF-73 is an antimicrobial agent with photosensitising potential, able to generate singlet oxygen and free radicals which may further enhance its antimicrobial activity following exposure to blue light. The aim of the current study was to determine the antimicrobial efficacy of XF-73 against a range of clinically relevant Gram-positive bacteria in the presence and absence of blue light.

**Materials/methods:** Minimum inhibition concentrations (MIC) and minimum bactericidal concentrations (MBC) were determined by micro-broth dilution in Mueller-Hinton Broth in accordance with the Clinical and Laboratory Standards Institute (CLSI) guidelines. The panel of Gram-positive bacteria consisted of: *Staphylococcus aureus* ATCC 6538, *Staphylococcus aureus* ATCC 29213, *Corynebacterium striatum* ATCC 1293, *Staphylococcus epidermidis* ATCC 12228 and *Enterococcus faecalis* ATCC 29212. Enhancement of XF-73 activity following exposure to blue light was investigated by placing the inoculated microtiter plate on the surface of a Waldmann Therapy System light box incorporating 36W Blue bulbs (emission peak 420 nm) for 15 minutes prior to incubation (light dose 13.7 J/cm²).

**Results:** XF-73 demonstrated significant intrinsic antimicrobial activity against the panel of test bacteria with MICs ranging from 0.25 – 0.125 μg/mL. MBCs recorded for all bacteria equated to the MIC values thus demonstrating bactericidal activity. Following exposure of XF-73 to blue light, the MICs and MBCs were significantly reduced with an approximate 8-fold reduction (0.25 – 0.03 μg/mL) for *E. faecalis*.

**Conclusions:** XF-73 has potent bactericidal activity against Gram-positive bacteria, which is further enhanced by 15 minute exposure to blue light. Further work is currently in progress to determine MIC/MBC values for Gram-negative bacteria, and the potential effect of XF-73 against single cell and polymicrobial bacterial biofilms with and without photoactivation.

Escherichia coli bloodstream infections in a university hospital of northern Italy: resistance pattern and prognostic factors

Gianmarco Volpato*1, Daria Pocaterra2, Guendalina De Nadai3, Federica Tordato1,2, Benedetta Varisco1, Lorenzo Canzianii, Francesco De Fazio2, Maddalena Casana2, Paola Morellii,2

1Humanitas University, Pieve Emanuele, Italy, 2Humanitas Research Hospital, Rozzano, Italy

Background: Escherichia coli (Ec) is responsible for the majority of gram-negative bloodstream infections (BSIs), being isolated in one third of the episodes in our hospital. In the absence of risk factors for extended-spectrum β-lactamase (ESBL) strains, empiric therapy generally consists in a carbapenem-sparing regimen with piperacillin/tazobactam (PTZ). If a preliminary ESBL screening test on positive blood cultures is negative, the ongoing therapy is confirmed, otherwise is switched to carbapenems. Our study aimed to evaluate the 30-day mortality of Ec BSIs and identify factors related to outcome, with a specific focus on strains that are resistant to PTZ solely.

Materials/methods: We conducted a monocentric retrospective study. All consecutive cases of monomicrobial Ec BSIs between July 2018 and June 2019 were included. For every patient, demographics, source of infection, central catheter presence, Charlson comorbidity index and Pitt bacteraemia score were reported. Therapy adequacy (48h) was evaluated in ESBL and non-ESBL groups. Univariate and multivariate analysis were performed according to Poisson regression test.

Results: We collected 156 cases of Ec bacteraemia in 143 patients (mean age 71, range 25-94; males were 56.6%); resistance pattern is showed in Table 1. The most common source of infection was urinary tract (47.4%). Overall 30-day mortality was 14.7%. Multivariate analysis showed that Charlson (IRR=1.32; 95%CI 1.11-1.57; p=0.002) and Pitt score (IRR=1.51; 95%CI 1.16-1.97; p=0.003) were independently associated with mortality. When mortality was studied in separate groups, results were: 15.6% in ESBL, 13.3% in PTZ-sensitive non-ESBL and 23.1% in PTZ-resistant non-ESBL. Although mortality in the latter group was almost double the one in PTZ-sensitive cases, statistical significance was not reached (IRR=9.64; 95%CI 0.91-102.54; p=0.06).

Conclusions: We found an overall mortality of 14.7%, significantly associated with Charlson and Pitt scores. PTZ-resistant non-ESBL strains represented approximately 10% of the episodes and were associated to an increased mortality despite lack of significance. This phenomenon should be taken into account upon initiation of empiric therapy in our centre. Studies among emerging isolated PTZ-resistance are strongly awaited.

Abstract 3608

**Detection of OXA-244 producing Escherichia coli of ST131 from surface water of Pavia urban area, northern Italy**

Federica Marchesini*, Melissa Spalla, Alessandra Mercato, Marika Mancinelli, Vittoria Mattioni Marchetti, Giorgio Pilla, Renato Sconfietti, Roberta Migliavacca, Elisabetta Nucleo

**Background:** The spread of multidrug-resistant microorganisms in surface water represents a risk for human health. Water samples from 12 different sampling sites in Pavia urban area (Northern Italy) have been screened for the presence of non-wild type and/or ESBL- or carbapenemase-producing Enterobacteriales.

**Materials/methods:** On May 13th-14th 2019, a total of 18 water samples were collected from four streams, two ponds, four spring waters, one sewer and one wastewater treatment plant (WWTP) in Pavia. One ml of water from each sample was filtered using 0.45 µm-pore size membranes. The filters were placed on Plate Count Agar, MacConkey (MC) and selective MacConkey containing cefotaxime (1µg/ml; 2µg/ml) of meropenem (0.25µg/ml; 4µg/ml). Species identification and antimicrobial susceptibility tests were performed by MicroScan autoSCAN-4 (Beckman Coulter). Susceptibility results were interpreted according to EUCAST 2019. Double disk (DD) test, CT103XL microarray (Check-Points), acc(6')Ibcr and blaOXA PCR, blaOXA sequencing, PFGE and MultiLocus Sequence Typing were accomplished.

**Results:** Thirty isolates belonging to Enterobacteriales grew on the MacConkey media. The 70% (n=21/30) were *E. coli*, 16.6% (n=5/30) Klebsiella spp. (n=3 *K. pneumoniae*; n=1 *K. oxytoca*; n=1 *K. aerogenes*), 6.66% (n=2/30) Citrobacter freundii and 6.66% (n=2/30) Kluyvera intermedia. A high proportion of the isolates (80%; n=24/30) resulted ESBL-positive by DD (n=21 *E. coli*; n=3 *K. pneumoniae*). The 66.6%, 66.6%, 38.0% and 19.04%, of the ESBL-producing *E. coli* were ciprofloxacin, levofloxacin, trimethoprim-sulfamethoxazole (TSX) and gentamicin resistant, respectively. Microarray detected blaCTX-M (groups 1; 2; or 9) determinants in 80% of the isolates. The 30% of the isolates resulted acc(6')Ibcr positive by PCR. A blaTEM/SHV- and blaKPC-type genes positive *K. pneumoniae* ST258, collected from a stream sample, resulted only colistin and TSX susceptible. An *E. coli* collected from a stream next to a WWTP, harboured both blaVEB- and blaMDX-2 determinants. Moreover, two blaOXA-244 positive *E. coli* strains of ST131 were detected from stream and sewer samples. PFGE typing on 21 *E. coli* ESBL-positive strains showed clonal heterogeneity.

**Conclusions:** This is the first report on the occurrence of both blaKPC-type *K. pneumoniae* and ST131 *blaOXA-244 E. coli* in the surface water of the urban area in Pavia, Northern Italy.

Hospital lanyards: a potential reservoir for Candida auris and other Candida species identified in a hospital outbreak

Charlotte Patterson1, Hannah Mitchell2, William Newsholme3, Duncan Wyncoll1, Heather Winteridge1, Yusupha Ceesay1, Meera Chand1,2, Amita Patel3, Jonathan Edgeworth1,3

1Guys and St Thomas’s NHS Foundation Trust, London, United Kingdom, 2Public Health England, Department of Infection, London, United Kingdom, 3Kings College London, Centre for Clinical Infection and Diagnostics Research, London, United Kingdom

Abstract third-party references: Public Health England, Centre for Clinical Infection and Diagnostics Research, Guys and St Thomas’s NHS Foundation Trust

Background: Candida auris (CA) has been implicated in hospital outbreaks worldwide and is notable for colonising patients and causing invasive disease, being difficult to identify and treat, and its resilience in the environment.

Materials/methods: A 5 month CA outbreak was identified in two 15-bed and one 11-bed general adult intensive care units (ICU) at a UK teaching hospital. Stepwise implementation of enhanced infection prevention and control precautions were introduced including twice-weekly screening, isolation, barrier precautions, equipment and environmental cleaning. A detailed environmental screen was performed to identify potential reservoirs. This included the patient bed space, ECG leads, pulse oximeters and temperature probes as well as the key used to access controlled drugs (CDs) (eg, opiates) attached to a lanyard. Personal possessions such as mobile phones, lanyards and ID badges were also screened.

Results: The index case and 6 linked acquisitions were identified of which 1 patient had a bloodstream infection. 4/6 (67%) patients were identified with CA after discharge of all known previous cases from ICU highlighting potential for an environmental reservoir. Environmental screening was undertaken around patient beds. The areas screened and results are shown in figure 1. CA was cultured from the environment following deep cleaning with Sodium Hypochlorite and Vaporized Hydrogen Peroxide (VHP), prompting enhanced deep cleaning, although no patient knowingly acquired CA after arriving in a bed-space of a previous positive case. The CD lanyard was positive for CA, which prompted culturing of staff lanyards and discontinued use on ICU. CA was identified on 1/100 (1%) staff lanyards with Candida parapsilosis being the dominant lanyard-isolate (12/100, 12%). No mobile phones or identification badges were positive for CA.

Conclusions: This outbreak further implicates environmental reservoirs as sustaining Candida auris ICU outbreaks. Identification on the CD-key lanyard highlights need to identify commonly-handled moveable objects during an outbreak, even those that are non-patient contacting. Culture of C. parapsilosis from staff lanyards despite it being an infrequently identified isolate on patients and healthy adults, suggests preferential contamination of material by certain candida species, which could have implications for ICU outbreaks.

Figure 1: Environmental screening for Candida Auris on the ICU

Evaluation of EUCAST rapid antimicrobial susceptibility testing (RAST) on blood cultures in a clinical laboratory
Per Rydström1*, Emma Jonasson1
1Centrallasarettet i Växjö, Klinisk mikrobiologi, Växjö, Sweden

Background: EUCAST has developed a rapid antimicrobial susceptibility testing method (RAST) based on disk diffusion to be used directly from blood culture bottles for species commonly involved in bloodstream infections. This method was introduced in our routine clinical laboratory in May 2018 and replaced a non-standardised method for antimicrobial susceptibility testing (AST) directly from blood cultures.

Materials/methods: All isolates from clinical blood cultures with RAST breakpoints were included from 25 May 2018 to 22 October 2019. One blood culture bottle per patient and sampling time was included in the analysis. Polymicrobial cultures and follow-up cultures to previously positive blood cultures were excluded (79 and 16 bottles respectively). Laboratory open hours were weekdays 07:30-17:00 and weekends 08:00-13:00. All work was performed by routine laboratory staff. Time started when the first positive bottle was removed from the blood culture instrument (BACTEC FX, BD) and ended when the first AST result was delivered (regardless of AST method used). The control group consisted of the last 100 positive consecutive blood culture isolates with RAST breakpoints immediately prior to the introduction of RAST. To further shorten reporting times reading RAST after 4 hours of incubation was prioritised from 28 May 2019 to 22 October 2019.

Results: On average more than 78% of all isolates with RAST breakpoints were reported the same day and 52% before 15:00 (fictitious time for afternoon rounds) (Table). After May 2019 this was further improved to 82% and 71%, respectively, by insisting on the 4 hour read. Median time to first AST result regardless of AST method decreased from 19 hours and 3 minutes (before RAST) to 7 hours and 13 minutes (all RAST) and even further to 5 hours and 56 minutes after May 2019. Species distributions before and after RAST were almost identical. The most frequent reason why RAST was not performed was a positive signal from the instrument late in the workday making even the 4 hour read impossible (60% of the no-shows).

Conclusions: RAST delivers a reliable and rapid way of dramatically shortening the average and median time to AST results compared to before its introduction.

Abstract 3617

Presentation, treatment and natural course of severe symptoms of urinary tract infections measured by a smartphone app
Akke Vellinga1,2, Karen Farrell*1,2

1National University of Ireland Galway, Galway, Ireland, 2Irish Primary Care Clinical Trial Network, Galway, Ireland

Background: Mobile phones offer new opportunities to efficiently and interactively collect real-time data from patients. Our study aim was to assess the feasibility of a smartphone app to collect symptoms of urinary tract infection (UTI) to estimates UTI symptom duration according to treatment strategy.

Materials/methods: A smartphone app was developed to collect data from adult, non-pregnant and otherwise healthy women diagnosed with suspected uncomplicated UTI. Patients were requested to record demographic information and treatment details [antibiotic and painkiller type and duration]. Push notifications remind women twice a day for seven days to submit a severity score [dysuria, frequency, urgency and low abdominal pain].

Results: The currently recruited 128 participants ranged in age from 18-72 (mean 28), 81% had at least one child and 51% were students. Complete diary entries are available for 75% of patients. Antibiotics [mainly nitrofurantoin] were prescribed to 53% of patients and a painkiller to 27%. The duration of moderately bad or worse symptoms was 2.8 days and mean symptom duration was 4.3 days. No differences were observed for those who did or did not receive an antibiotics, while painkillers did seem to be symptom free faster. 75% of patients indicated to feel cured after 4 days and 83% was symptom free on day 7. A large drop in symptom score was observed immediately after visiting the GP, suggesting a placebo effect of the consultation for all patients.

Conclusions: Our analysis showed lower mean symptom duration than indicated in previous research using paper diaries. The detail obtained through the use of a twice daily smartphone request of pain scores is providing new insights.

Abstract 3619

**The results of laboratory monitoring of post-vaccination measles immunity**

Alyona Ereshchenko¹, Oksana Gusjakova², Gilmiyarova Frida³, Andrey Kozlov*¹

¹Samara state medical university, Samara, Russian Federation

**Background:** The incidence of measles in most European countries (including Russia) has increased significantly over the past year. Vaccination is the only way to achieve measles elimination. There is evidence that up to 10% of individuals do not form or maintain specific postvaccinal humoral immunity. Measles cases are also reported among vaccinated persons. The purpose of this study is to dynamically monitor postvaccinal IgG to measles virus (MV).

**Materials/methods:** A total of 1166 persons at the ages of 18 and 55 were examined, all of them had documents about vaccination and re-vaccination against measles. Determination of IgG to MV in serum was carried out by ELISA («Vector-Best», Russia). Further a group of seronegative persons (n=30) was twice vaccinated by live clumsy cultural vaccine («Mikrogen», Russia) and monitoring of content of IgG to MV was carried out by him in 1 month after vaccination and a revaccination and also in 12 months.

**Results:** The average concentration of IgG to MV was 0,741±0,025 IU/ml. Despite earlier vaccination, 27,44% of persons had no specific humoral immunity. The results of the dynamic laboratory monitoring of vaccination against MV were as follows. In one month after vaccination (V1), 28 of 30 people formed anti-measles immunity. The average IgG to MV was 1,20±0,2 IU/ml. In one month after a revaccination (V2) 29 of 30 people formed anti-measles immunity. The average IgG to MV was 1,14±0,11 IU/ml. Thus, 1 of 30 people did not have post-vaccinal anti-measles immunity. In twelve months, the average IgG to MV in the test group was 1,0±0,12 IU/ml. An individual with initially non-formed after vaccination and revaccination, immunity did not occur IgG the increase in the concentration of lead to VC. In addition, 2 individuals showed a decrease in anti-measles IgG below the values required for anti-measles immunity. However, 18 out of 30 people showed an increase in the concentration of IgG to VC compared to V2.

**Conclusions:** Interindividual variability of humoral immune responses to measles vaccination was revealed. Laboratory monitoring of vaccination efficacy should be an integral part of planned and emergency vaccine prevention.

Abstract 3620

Commercial real-time PCR implementation for rapid diagnosis of onychomycosis: a new workflow in a clinical laboratory

Ana Blanco Suárez*, Eva María Cuchi Burgos, Rosa Rubio Casino, Mónica Ballestero Tellez, Pepita Perez

*CatLab (Parc Logístic de Salut), Viladecavalls, Spain

Background: Classical microbiological onychomycosis diagnosis based on culture and microscopic observation is slow and has low sensitivity. Objective: evaluate the utility of incorporating in the clinical laboratory workflow a commercial real-time PCR (qPCR) for dermatophytes detection in nails after potassium hydroxide (KOH)-based screening.

Materials/methods: Nail samples received during 4 months were observed microscopically after KOH treatment. For every 3 positive KOH samples, one negative was included. All samples were cultured in Sabouraud Gentamicine Chloramphenicol-2 (bioMérieux) and Dermatophyte solid agar (bioMérieux) [30°C, 21 days]. Identification was made by MALDI-TOF MS (VITEK MS version 3.2, bioMérieux) using VITEK® MS MOULD extraction kit. DermaGenius® 2.0 qPCR (Pathognostics) was performed using CFX96 (BioRad) using both supplied mixes. MIX-1 detects C. albicans, T. tonsurans, T. mentagrophytes, T. rubrum/soudanensi, T. interdigitale and T. violaceum and MIX-2 detects T. benhamiae, T. verrucosum, Microsporum audouinii, M. canis and Epidermophyton floccosum.

Results: 152 nail samples were included. In the negative KOH group (n=34), only one dermatophyte grew in culture and three were detected by qPCR. In the group of positive KOH (n=118), 57 dermatophytes grew in culture and 81 were detected by qPCR. In this group, 25% of diagnosed dermatophytes were detected only by qPCR (Table 1). The sensitivity of qPCR compared to culture is 92.8% and time of response decreases from days to hours.

Conclusions: Based in our results, we propose a workflow algorithm for a clinical laboratory that performs qPCR in all positive KOH samples. In this group, culture is eliminated but remains for negative KOH samples.

Seawater: a risk for transmission of antimicrobial resistance?

Kelly Fitzhenry1,2, Brigid Hooban1,2, Aoife Joyce1,2, Niamh Cahill1,2, Benjamin Wong Ngie Xiong1, Blathnadh Mahon1,2, Louise O’Connor1,2, Martin Cormican1,2,3, Paul Hickey4, Shane Keane4, Dearbhaile Morris*1,2

1Antimicrobial Resistance and Microbial Ecology Group, School of Medicine, National University of Ireland Galway, Galway, Ireland, 2Ryan Institute, Centre for One Health, National University of Ireland, Galway, Galway, Ireland, 3Health Service Executive, Galway, Ireland, 4Environmental Health Service, HSE West, Galway, Ireland

Background: Under EU bathing water regulations, bathing waters are monitored for indicators of fecal contamination between June and September each year. Seawaters are frequently used for recreational purposes and may represent a previously unrecognized risk for transmission of AMR to humans. The aim of this study was to examine seawaters for the presence of extended spectrum beta-lactamase producing Enterobacterales (ESBL-PE) and carbapenemase-producing Enterobacterales (CPE).

Materials/methods: Twenty-five samples (30L) of seawater were collected between May and September in 2018 and 2019 at two beaches (Beach A and B) in Ireland. All samples were filtered using the CapE method, and filters were enriched overnight in buffered peptone water. Enrichments were cultured on agars selective for CPE and ESBL-PE. Species were identified by MALDI-TOF, and examined for susceptibility to 16 antimicrobial agents in accordance with EUCAST criteria. Relevant isolates were screened for blaVIM, blaIMP, blaOXA-48, blaNDM, blaKPC, blaCTX-M-group1, blaCTX-M-group2 and blaCTX-M-group9 as appropriate by real-time PCR.

Results: Four CPE were isolated from individual samples. Two NDM-producing E.coli were isolated in 2019 (1 at Beach A, 1 at Beach B). KPC-producing Klebsiella pneumoniae was isolated from 1 sample collected at Beach B in 2019. One OXA-48-producing Klebsiella pneumoniae was isolated at Beach B in 2018. A total of 50 ESBL-PE were isolated from 13/14 (93%) samples collected in 2018 and from 3/11 samples collected in 2019. The majority of ESBL-PE collected in 2018 harboured blaCTX-M-group1 (n = 41 [91%]), 3 isolates [7%] harboured blaCTX-M-group9. Six ESBL-PE were isolated from 3/11 samples collected in 2019. Isolates harbouring blaCTX-M-group9 were detected at Beach A (n= 1) and in Beach B (n= 2) and 3 isolates harbouring blaCTX-M-group9 were isolated at Beach B.

Conclusions: Antimicrobial resistant bacteria were isolated from 18/25 (72%) seawater samples collected in 2018 and 2019. The isolation of CPE from 4 samples is of particular concern. These findings highlight major limitations of current EU bathing water regulations as the seawaters at the locations at which CPE and ESBL-PE were isolated were consistently designated as Good/Excellent quality. These findings also demonstrate the potential importance of seawater as a transmission route for AMR to humans.

Genomic analysis of Panton-Valentine leukocidin-positive methicillin-resistant Staphylococcus aureus in hospitalised patients in Germany by whole genome sequencing: 2015-2018

Sabrina Klein*1, Julius Hannesen1, Philipp Zanger2, Klaus Heeg1, Sebastien Boutin1, Dennis Nurjadi1

1University Hospital Heidelberg, Department of Infectious Diseases, Heidelberg, Germany, 2University Hospital Heidelberg, Institute for Public Health, Heidelberg, Germany

Background: Although the rate of MRSA infections in Germany has been declining on the past years, infections caused by MRSA remain challenging. Panton-Valentine Leukocidin (PVL) - positive isolates are often associated with recurrent skin and soft tissue or severe courses of infection. The presence of PVL is often regarded as a hallmark of community-acquired (CA) MRSA infections. Previous studies on the composition of community-onset MRSA in our hospital could show a high proportion of PVL-positive MRSA. Several reports have demonstrated the occurrence and transmission of PVL-positive strains in hospitals. However, there are very few data on the prevalence and clonal composition of PVL-positive MRSA in hospitalized patients in Germany.

Materials/methods: Patients admitted to Heidelberg University Hospital for more than 48 hours between 2015 and 2018 with detection of MRSA were included in the study. MRSA was identified according to microbiological routine diagnostic procedures and confirmed by nuc and mecA–PCR. All MRSA isolates were spa-typed and tested for the presence of PVL by PCR. PVL-positive isolates were then characterized by WGS.

Results: Between 2015 and 2018, 757 MRSA were isolated from hospitalized patients at Heidelberg University Hospital, Germany. Of these, 6.1% (n=46/757) were PVL-positive. 58.7% (n=27/46) of the patients with PVL-positive MRSA had an infection, 69.6% (n=32/46) were colonized. 15 patients (32.6%) met the criteria for nosocomial MRSA acquisition. Among the PVL-positive strains, the most frequent spa-types were t044 (n=10/46; 21.7%) and t008 (n=9/46; 19.5%). 8 of the t008 belonged to the USA300 cluster and one was the Latin American variant (USA-300-LV). SNP analysis suggested 3 possible transmission clusters involving seven patients.

Conclusions: To our knowledge, this is the first systematic study on the prevalence and characteristics of PVL-positive MRSA in hospitalized patients in Germany. As PVL is an important virulence marker for S. aureus and is associated with recurrent and severe courses of infection, the presence and composition, also in an in-hospital setting, needs to be monitored. Surveillance may help to identify and control the potential clonal spread of highly transmissible and virulent strains like ST08-USA300 in hospitalized patients.

Imported leishmaniases in a Parisian hospital, France: a 6-year experience

Nesrine Aissaoui1,*, Samia Hamane1, Maud Gits-Muselli1,2, Nicolas Guigue1, Antoine David Petit1, Sarah Deliere1,2, Alexandre Alanio1,2, Stéphane Bretagne1,2

Background: Leishmaniases are regularly seen in non-endemic areas because of multiplicity of international travels. Their clinical presentations are divided in cutaneous leishmaniases (CL), muco-cutaneous leishmaniases (MCL), and visceral leishmaniasis (VL), hence the necessity of a sensitive diagnosis to exclude the differential diagnoses and the need of species identification for appropriated treatment.

Materials/methods: We reviewed our diagnostic strategy based on a quantitative PCR assay targeting a consensus 18S kinetoplasmic RNA and sequencing of the cytochrome for species identification. Skin scrapings or biopsies for suspicion of CL and MCL were performed by skilled microbiologists. For VL the search was performed on all the specimens sent (bone marrow, blood, and/or tissue biopsies). Microscopy was performed after May-Grunwald staining of thin smears. DNA was processed as already described (Foulet F et al, J. Clin. Microbiol. 2007, 45(7):2 110).

Results: Seventy-six patients had a definite diagnosis of leishmaniasis between January 1st 2013 and June 30th 2019. The sensitivity of microscopic examination was 81% in CL and CML, and 86% in VL compared to qPCR. Seven patients had VL [all with L. infantum] with known immunodepression but one [HIV n=2; lymphoma: n=3; vascularitis n=1]. Eleven patients had MCL after a trip in Latin America with four different species [6 L. guyanensis, 2 L. braziliensis; 2 L. mexicana; 1 L. panamensis]. Fifty-eight had CL from the Mediterranean basin. CL lesions were unique (41.4%) or multiple (34.5%) and occurred around 120 days after returning from endemic areas. Identification failed in 7 cases because of very low parasite burden. Leishmania major was the most frequently identified species [76%], followed by L. tropica/killicki [12%], and L. infantum [12%]. In 88% of the CL cases, the patients were of African origin resident in France. Among them, 31% of CL cases concern patients who travelled to south Tunisia, confirming the dramatic increase of CL in this region.

Conclusions: The risk of contracting leishmaniasis should be more widely known and more specifically from patients of African origin visiting relatives. Our diagnostic strategy was shown to be very satisfying for both positive diagnosis and species identification.

Abstract 3630

Analysis of analytical performances of the new MDR/MTB ELItE MGB kit for the detection of *Mycobacterium tuberculosis* complex and rifampicin- and isoniazid-associated mutations in comparison with the MTB ELItE MGB kit

Sanela Svraka-Latifovic*1, Leendert Bakker1, Cornelis P. Timmerman1, J. Wendelien Dorigo-Zetsma1

1Tergooi - locatie Hilversum, Hilversum, Netherlands

Background: ElitechGroup has a new kit that can be used for the detection of the DNA of *Mycobacterium tuberculosis* complex and in addition identify rifampicin and/or isoniazid associated mutations. This new kit is compared to the already existing MTB ELItE MGB® kit, which is used for routine diagnostics of MTB complex in our laboratory.

Materials/methods: 48 samples have been tested, of which 38 samples were positive for MTB complex. 11 samples had a confirmed rifampicin of isoniazid resistance. All samples were tested by an Elite InGenius® system which is able to perform extraction, amplification and result interpretation.

Results: The results of the analytical performances were within predetermined parameters, no cross reaction was seen for other Mycobacterium species. An analysis of the diagnostic sensitivity and specificity resulted in a 100% agreement between the MDR/MTB ELItE MGB and the MTB ELItE MGB kit. In addition all rifampicin and/or isoniazid resistant strains were correctly identified. Interpretation of the results involves Ct values and Tm and is done by InGenius.

Conclusions: The analytical performances of the new MDR/MTB ELItE MGB kit were satisfactory. The diagnostic comparison between the new MDR/MTB ELItE MGB kit and the old MTB ELItE MGB kit resulted in no diagnostic inconsistencies. Furthermore, this kit detects mutations associated with resistance for rifampicin and/or isoniazid and can be used directly on clinical specimens. This allows faster resistance detection. This kit will be introduced into our routine diagnostics.

Molecular biomarker to monitor NDM-producing *Klebsiella pneumoniae* outbreak in two Belgian hospitals: a whole genome sequencing-based infection control application

Amélie Heinrichs*1, Maria Angeles Argudín1, Louise Nienhaus2, Claire Nonhoff1, Lorenzo Filippin1, Pierre Bogaerts4, Te-Din Huang4, Youri Glupczynski4, Olivier Denis1

1Université Libre de Bruxelles, Brussels, Belgium, 2Hôpital Erasme, Brussels, Belgium, 3Epicura, Baudour, Belgium, 4UCL Namur Godinne Dinant, Yvoir, Belgium

**Background:** A large ST716 NDM carbapenemase-producing *Klebsiella pneumoniae* outbreak occurring in two Belgian hospitals (A and B) was previously described using whole genome sequencing (WGS) combined to epidemiological data [Heinrichs et al. CID 2018]. We developed a molecular biomarker in order: 1) to identify the putative origin of the outbreak strain circulating in hospital A; 2) to detect new NDM-producing *K. pneumoniae* isolates belonging to the outbreak strain.

**Materials/methods:** A clone-specific multiplex PCR was designed based on capsular genes alleles wzc941 and wzi89 identified in outbreak isolates. Their specificity as distinctive DNA signatures was tested by using BLASTn. Primers for PCR targeting these alleles were designed using Clone Manager Professional 9 (Sci-Ed Software). The efficiency of this PCR was evaluated on 74 fully sequenced NDM-positive *K. pneumoniae* strains recovered in Belgium in 2015, including 30 ST716 strains. A total of 393 *K. pneumoniae* resistant to 3rd generation cephalosporins (3GC-R) collected between 2010 and 2015 in hospital A were screened for the putative origin of the outbreak clone. In addition, all NDM-positive *K. pneumoniae* detected in hospital A and B in 2016 and 2017 were subjected to the clone-specific PCR.

**Results:** Out of the 74 fully sequenced NDM-positive *K. pneumoniae*, the 30 ST716 strains were positive for both targets (sensitivity 100%; specificity 100%). Among the 393 screened 3GC-R *K. pneumoniae* from hospital A, only one isolate showed a false-positive result for wzc941 and wzi89, as it belonged to ST1119 unrelated to ST716. In 2016 and 2017, 25 and 61 additional NDM-positive *K. pneumoniae* were identified in hospital A and B respectively. In hospital A, only one isolate (4%) was positive for the clone-specific PCR, while in hospital B, 22/29 (76%) and 13/32 (41%) isolates were tested positive in 2016 and 2017, respectively.

**Conclusions:** Our clone-specific PCR showed that the NDM-producing outbreak clone ST716 still circulated in hospital B in 2016 and 2017, whereas in hospital A, this epidemic clone was substituted by new genotypes. Such in-house designed PCR based on whole genome sequencing could be an useful infection control tool to follow up the local circulation of this successful clone.

**Presenter email address:** amelie.heinrichs@ulb.ac.be
PD-L1 expressing CD4+ and CD8+ T cells as a biomarker of tuberculosis disease and treatment response

Irina Kontsevaya1,2,3*, Maja Reimann1,2,3, Jessica Hofmeister1,2,3, Franziska Daduna1,2,3, Susanne Dox1,2,3, Dagmar Schaub1,2,3, Barbara Kalsdorf1,2,3, Eva Tolosa4, Laura Glau4, Jan Heyckendorf1,2,3, Christoph Lange1,2,3, Patricia Sanchez-Carballo1,2,3

1Research Center Borstel, Division of Clinical Infectious Diseases, Borstel, Germany, 2German Center for Infection Research, Braunschweig, Germany, 3University of Luebeck, International Health/Infectious Diseases, Luebeck, Germany, 4University Medical Center Hamburg-Eppendorf, Department of Immunology, Hamburg, Germany, 5Karolinska Institute, Department of Medicine, Solna, Sweden

Background: Programmed death ligand 1 (PD-L1) is involved in the response to Mycobacterium tuberculosis. It has been shown to be up-regulated in certain blood cells of patients with active tuberculosis.

Materials/methods: A set of immune cell markers was analysed by flow cytometry in peripheral blood of 29 drug susceptible, 33 multi-drug resistant tuberculosis (MDR-TB) patients, and 23 healthy donors. Mean values for percentage of cell populations among three cohorts were compared using Kruskal-Wallis and pairwise Wilcoxon rank sum tests.

Results: At baseline (TB diagnosis, therapy naïve), the percentage of T cell populations expressing PD-L1 were higher among CD4+ T cells in drug susceptible (6.07% vs 0.37%, P<0.001) and MDR-TB patients (12.79% vs 0.37%, P<0.001) compared to healthy controls. The same was observed in the population of CD8+ PD-L1-expressing cells among both drug susceptible (2.67% vs 0.33%, P<0.001) and MDR-TB (7.25% vs 0.33%, P<0.001) patients. Thus, the relative proportion of CD4+ and CD8+ PD-L1-expressing T cells was able to discriminate between TB patients and healthy controls as well as between drug susceptible and MDR-TB patients (P=0.041 for CD4+ and P=0.044 for CD8+). Over the course of anti-TB treatment, the percentage of PD-L1-expressing cells was decreasing in both CD4+ and CD8+ populations in susceptible and MDR-TB patients (P<0.001). At the end of treatment, these populations in drug susceptible patients reached levels similar to those in healthy controls (0.47% vs 0.37%, P=0.061 in CD4+ and 0.09% vs 0.33%, P=0.242 in CD8+). In MDR-TB patients the values even with a two-fold decrease compared to baseline were still higher than in the control group (6.54% vs 0.37%, P<0.001 in CD4+ and 3.37% vs 0.33%, P<0.001 in CD8+).

Conclusions: The frequency of PD-L1-expressing CD4+ and CD8+ T cells was elevated in drug susceptible and MDR-TB patients at diagnosis and decreased over the course of effective anti-TB treatment. However, this decrease was not significant in MDR-TB patients. These cell populations have a potential to be used as a clinical biomarker of TB disease, for monitoring treatment response and predicting successful therapy end. The role of PD-L1 as a potential target for host directed therapy requires further evaluation.

Toward an improvement of the measles vaccine platform by rationalizing the muscle immune response

Emmanuelle Billon-Denis*1, Annabelle Garnier1, Laurence Cheutin1, Clarisse Vigne1, Thepenier Cédric1, Julien Burger1, Frederic Tangy2, Jean Nicolas Tournier1

1IRBA, Brétigny sur Orge, France, 2Institut Pasteur, Paris, France

Background: little is known about the immunological mechanisms involved in the muscle, although most vaccines are administered intra-muscularly. Measles vaccine (mv) is a live attenuated virus derived from the schwarz strain. This vaccine is very safe and effective; it also confers a strong and prolonged protection against measles virus. Using reverse genetic it is very easy to introduce new sequences coding for different proteins in this vector. Therefore, mv platform is currently used for the development of new vaccines against chikungunya or zika viruses with very promising results. Vaccination still remains an empiric process and there is a lack of knowledge between vaccine development and vaccine response.

Materials/methods: we used mv platform to explore cellular and molecular processes involved during vaccination. Combining two-photon microscopy and flux cytometry, we analysed the cellular immune response following vaccine injection. In parallel, we also developed a new animal model for vaccinology allowing infection by human viruses (ifnar ko), and expressing fluorescent proteins in immune cell subsets (cx3cr1gfp+/−), and albino.

Results: in our mouse model, adapted to intravital imaging, we made dynamic imaging with two-photon microscopy. We were able to visualise the muscular macrophages (cd11b+/F4/80+) as the cells infected first with the mv virus vaccine, while patrolling monocytes (cd11b+/cx3cr1+) were recruited in the muscle [at the injection site]. In the draining lymph nodes, we observed the kinetic of mv+ cells, while b and t cells were actively recruited.

Conclusions: we have shown for the first time, by using innovating tools the different cellular partners involved in the vaccine immune response. These results demonstrate that immune resident muscular cells interact with blood recruited cells to process the virus and address it at the draining lymph node. Our results provide a better understanding of the immune mechanisms involved in vaccination that can help improving the design of new vaccines.

Antimicrobial stewardship intervention in FLU/respiratory syncytial virus adult hospitalisations: major impact on antimicrobial management of a systematic epidemiological surveillance process including training and feed-back

Marc Bourgeois¹, Nathalie Ausselet¹, Emilie Dupont¹, Louis De Cannière², Nathan Scius², Isabelle Michaux¹, Te-Din Huang⁴, Pierre Bogaerts¹, Olivier Denis⁴*, Benoit Bihin⁵, Bénédicte Delaere¹

¹CHU UCL Namur - Site Godinne, Infectious Diseases Dept, Yvoir, Belgium, ²CHU UCL Namur - Site Godinne, Emergency Dept, Yvoir, Belgium, ³CHU UCL Namur - Site Godinne, Intensive Care Dept, Yvoir, Belgium, ⁴CHU UCL Namur - Site Godinne, Laboratory of Microbiology, Yvoir, Belgium, ⁵CHU UCL Namur - Site Godinne, Scientific Support Unit, Yvoir, Belgium

Background: Influenza (FLU) and Respiratory Syncytial Virus (RSV) are known causative pathogens in adult hospitalizations for severe acute respiratory infections (SARI). While rapid molecular techniques confirm the diagnosis, the impact of patient screening at admission and viral detection on antimicrobial management remains controversial. We aimed to evaluate the setup of a systematic epidemiological surveillance process and its effectiveness as antimicrobial stewardship intervention during four consecutive epidemic seasons.

Materials/methods: Annual surveillance timelines were defined according to epidemiological criteria related to the seasonal circulation of RSV and FLU viruses in the general population during a four-year period (2015-2019). Patients were screened according to a SARI case definition at the Emergency Department (ED) of a University hospital, and enrolled for molecular assay targeting FLU/RSV viruses. Initial ED staff training, weekly national and local epidemiological updates, and hospital-wide level targeted communications were organized by the Infectious Diseases Department. Epidemiological and clinical data, microbiological investigations results and antimicrobial prescription data were reviewed.

Results: A FLU or RSV virus was documented in 316 (33%) out of 963 SARI patients. Globally, a positive viral diagnosis allowed an optimization of antimicrobial therapy in 162 (61%) out of 265 patients with no bacterial infection documented at admission (antibiotic treatment not initiated: n=111; discontinued: n=51). By contrast, 128 (28%) out of 462 patients with negative microbiological investigations had an antibiotic treatment not initiated (n=116) or discontinued (n=12). An early targeted antiviral treatment was prescribed in 197 (92%) out of 213 patients with a confirmed FLU diagnosis. The proportion of full course empirical antibiotic treatments initiated at admission was significantly lower in the FLU/RSV (+) than in the FLU/RSV (-) patients (38.9 % vs 72.3 %, respectively, P<0.0001). A yearly trend towards decrease of empirical treatments was noticeable in patients with and without a documented viral infection, while epidemiological, clinical and outcome data remain similar in both patient groups during the four-year surveillance period.

Conclusions: An epidemiological surveillance process including regular targeted communications associated with a FLU/RSV molecular diagnosis allowed an exhaustive screening and viral disease detection in SARI patients, and dramatically impacts the antimicrobial (antibiotics, antivirals) management.

Abstract 3642

**Optimisation of duplex next-generation digital PCR assays for molecular diagnosis of infection**

Irene Merino Velasco1,2,3, Alicia Ortega2,3, Marta Domínguez-Gil1, Jose María Eiros4, Jesus F. Bermejo-Martin2,3, Ana P. Tedim2,3

1 Servicio de Microbiología, Hospital Clínico de Salamanca, Salamanca, Spain, 2 Grupo de Investigación Biomédica en Sepsis (BioSepsis)-IBSAL, Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, 3 Unidad de Investigación, Hospital Universitario Río Hortega, Valladolid, Spain, 4 Servicio de Microbiología, Hospital Universitario Río Hortega, Valladolid, Spain

**Background:** Early diagnosis and initiation of treatment are crucial factors in handling patients with bloodstream infections (BSIs). However, the appropriate treatment for these patients is impaired due to the delay and low rentability of the gold standard microbiological diagnosis technique (blood culture). Droplet digital PCR (ddPCR) is a next-generation PCR with high sensitivity, low impact of PCR inhibitors and no need for a standard curve. Our objective was to develop a ddPCR assay for the detection of the most common pathogens in Spanish ICUs.

**Materials/methods:** Based on the ENVINE-ICU 2017 report the most common BSIs pathogens were selected for our ddPCR assay: *Escherichia coli* (Eco), *Klebsiella pneumoniae* (Kpn), *Enterococcus spp.* (Ent), and *Staphylococcus aureus* (Sau). Based on a review of the literature several genes were selected for possible identification of each of the species/genus mentioned (Eco-gad, Kpn-khe, Sau-SA442, Ent-23S). The selected genes have previously been used for bacterial identification (qPCR or ddPCR). DNA was extracted from reference strains of each pathogen obtained from the CECT using alkaline lysis. ddPCR assays were initially performed separately for each bacterial species/genus and then duplexed (Eco+Sau and Kpn+Ent). Different initial DNA concentrations (2ng/µL -0.25ng/µL) were tested to evaluate the dynamic range of ddPCR duplex assays. All assays for all DNA concentrations were performed in triplicate using the QX200 ddPCR platform (BioRad) according to manufacturer instructions.

**Results:** All ddPCR assays (simplex/duplex) were performed successfully and were highly specific for each bacterial species/genus. A quantity of 1ng of bacterial DNA was established as the lower limit of the method. Results showed high replicability for all the pathogens tested, with low SD (Figure 1). The time involved in processing all samples and assays was less than 5 hours.

**Conclusions:** Our results show that the ddPCR assays are highly sensitive and robust for the detection of pathogens, specifically Eco, Sau, Kpn and Ent. The focus of ongoing work from our group is to apply these ddPCR assays to blood from patients with BSIs.

Figure 1. ddPCR assays results for the different species analyzed: a) *Escherichia coli*; b) *Klebsiella pneumoniae*; c) *Staphylococcus aureus*; d) *Enterococcus faecalis*; e) *Enterococcus faecium*.

**In vitro study of TEM inhibition by the nanobody cAbTEM-1 in view to a potential way out of the bacterial resistance**

Frédéric Cawez*1, Frédéric Kerff2, Raphaël Herman2, Marylène Vandevenne3, Paola Mercuri4, Moreno Galleni4

1University of Liege, Center for Protein Engineering, Biological Macromolecules Lab, Liege, Belgium, 2University of Liège, Center for Protein Engineering, Structural Biology, Liège, Belgium, 3University of Liège, Center for Protein Engineering, Liège, Belgium, 4University of Liege, Center for Protein Engineering, Biological Macromolecules Lab, Liège, Belgium

**Abstract third-party references**: SPF santé public, University of Liege

**Background**: The intensive use of β-lactam antibiotics lead to an increasing bacterial resistance, mainly by the production of enzymes, called β-lactamases (BLAs), which are able to hydrolyze those antibiotics. Therefore, in order to fight bacterial resistance, it is needed to develop new antibiotics and/or therapeutic approaches. In our lab, we developed a camelid antibody (nanobody) called cAbTEM-1 directed against TEM β-lactamases. A nanobody has a small size (15 KDa) and a very long CDR3 that are features very interesting in view to develop inhibitors against bacterial resistance.

**Materials/methods**: The first part of this project consists on the study of the inhibition mechanism of TEM β-lactamases by cAbTEM-1 by following the residual activity in presence of increasing concentration of the nanobody. Our second goal is to verify the specificity of cAbTEM-1 by bio-layer interferometry. Finally, structural studies of the VHH-TEM complexes by X-ray crystallography and molecular modelling were achieved in order to determine the essential factors that mediate the interaction of TEM enzymes and their inhibitor.

**Results**: Our kinetic results showed that cAbTEM-1 was able to interact specifically with members of TEM family: TEM-1 and TEM-121. Furthermore, the profile of inhibition is function of the TEM enzyme and the nature of the β-lactam considered. For example, using nitrocefin, the nanobody acts like a competitive and a non-competitive inhibitor for TEM-1 and TEM-121, respectively. We showed also that the inhibition is related to the size of the antibiotic. Finally, structural studies of the VHH-TEM complexes showed that cAbTEM-1 does not bind in the active site of the TEM enzymes. Nevertheless, its binding to the enzymes induces a steric hindrance and decreases the flexibility of the active site. The studies help us also to define the sequences of the epitope and the paratope respectively.

**Conclusions**: The complete characterization of the interaction between cAbTEM-1 and TEM give us new insights on β-lactamases inhibition. For example, the identification of the paratope sequence of VHH may lead to the synthesis of new inactivators by peptidomimetics.

Seroprevalences of ten ToRCH infectious pathogens in women residing in Europe, Latin America and China

Marc Pollmann*1, Viola Borchardt-Lohölter1, Andrés Moreira-Soto2, Selcuk Kaya1, Asli Gamze Sener1, Eduardo Gómez-Gusmán4, Liliana Figueroa-Hernández5, Wenhan Li6, Fangyi Li6, Katarzyna Buska7, Katarzyna Zakaszewska8, Katarzyna Ziólkowska9, Julia Janz1, Antonina Ott1, Thomas Scheper1, Wolfgang Meyer1

1EUROIMMUN Medizinische Labordiagnostika AG, Institute for Experimental Immunology, Lübeck, Germany, 2Charité-Universitätsmedizin Berlin, Berlin, Germany, 3Ataturk Training and Research Hospital, İzmir Katip Çelebi University, Department of Medical Microbiology, İzmir, Turkey, 4INOCHEM SA de CV. Department of Science and Biotechnology, Mexico City, Mexico, 5National Institute of Respiratory Diseases. Immunology and Autoimmunity Laboratory, Mexico City, Mexico, 6EUROIMMUN Medical Laboratory Diagnostics (China) Co., Ltd., Hangzhou, China, 7EUROIMMUN Poland, Wroclaw, Poland, 8Diagnostic Laboratory CM Luxmed, Wroclaw, Poland, 9Department of Laboratory Diagnostics of K. Marcinkowski Poznan University of Medical Sciences, Poznan, Poland

Background: The determination of antibodies against ToRCH antigens before or at the beginning of pregnancy allows assessment of both the maternal immune status and the risks to an adverse pregnancy outcome. Here, we compared the seroprevalences of antibodies against ten ToRCH antigens in women of childbearing age between six countries.

Materials/methods: Seroprevalences were determined in serum samples from healthy women (N=991, 15-47 years) residing in Germany (n=202), Turkey (n=97), Mexico (n=100), Brazil (n=160), Poland (n=193) or China (n=239) using the EUROLINE Anti-TO.R.C.H. 10-Profile (IgG) (EUROIMMUN). This lineblot contains native and recombinant antigen substrates against ten pregnancy-related pathogens (Toxoplasma gondii, rubella virus, cytomegalovirus (CMV), herpes simplex viruses (HSV-1, HSV-2), parvovirus B19, varicella zoster virus (VZV), Bordetella pertussis, Treponema pallidum and Chlamydia trachomatis). The lineblot’s band intensities were evaluated with the EUROLineScan software (EUROIMMUN).

Results: Seroprevalences of IgG antibodies against VZV [seroprevalence range across six countries: 90-99%], rubella virus [range: 91-99%], and Treponema pallidum [range: 1-3%] were on comparable levels between countries. Anti-HSV-1 antibodies had seroprevalences between 74-95% across countries. Brazil showed elevated seroprevalences of IgG antibodies against HSV-2 [39%, range across the other five countries: 21-25%], Chlamydia trachomatis [48%, range across the other five countries: 5-18%] and Bordetella pertussis [59%, range across the other five countries: 0-15%] antibodies. Seroprevalences of anti-Toxoplasma gondii antibodies were in the range of 24-28% in Germany, Poland, Turkey and Mexico, but 59% in Brazil and 1% in China. Seroprevalence of anti-parvovirus B19 antibodies were low in China [12%, range across the other five countries: 36-55%]. German women had a low seroprevalence of anti-CMV antibodies [38%, range across the other five countries: 61-99%].

Conclusions: The observed seroprevalences speak in favour of global differences in immune status of women in childbearing age. This evidence advocates country-specific infection prophylaxis strategies and close monitoring as part of prenatal care. The EUROLINE Anti-TO.R.C.H. 10-Profile (IgG) is a suitable tool to assess both maternal immunity and consequent risks for an adverse pregnancy outcome.

Ibrexafungerp demonstrates potent and consistent in vitro activity against >400 global Candida auris isolates, including isolates with elevated MIC’s to echinocandins

Stephen Barat1, Katyna Borroto-Esoda1, David Angulo Gonzalez*1
1SCYNEXIS, Inc., Jersey City, United States

Background: Candida auris is a urgent global threat; a pathogen associated with high mortality (up to 60%), multi-drug resistance, the ability to spread from person-to-person and surface-to-person, presenting high risk for outbreaks in healthcare facilities. Echinocandins are the first-line treatment for patients with Candida auris infections given the high degree of resistance to azoles and polyenes. Ibrexafungerp is a novel IV/oral glucan synthase inhibitor (triterpenoid) antifungal with activity against Candida, Aspergillus and Pneumocystis spp, in Phase 3 development. Given the potent activity of ibrexafungerp against Candida spp., Scynexis has embarked on a development program to understand the activity and effectiveness of ibrexafungerp against Candida auris. We will present a compilation of >400 Candida auris isolates from four studies, including 32 Candida auris isolates with elevated MIC’s to the echinocandins.

Materials/methods: In vitro MIC data for ibrexafungerp against Candida auris isolates were compiled from across 4 independent studies with the majority of isolates originating in the US and India. In vitro susceptibility was determined by broth micro-dilution using CLSI (M27-S3) and/or EUCAST methods. Overall, 445 isolates were evaluated including 32 isolates with elevated MIC values to one or more echinocandins.

Results: The ibrexafungerp MIC90 value against the 445 clinical isolates was 1 µg/mL; the modal and MIC50 values were 0.5 µg/mL each. These results were consistent across the four studies and no differences were observed between MIC results generated using CLSI or EUCAST methods. Similar results were obtained for the 32 isolates with elevated MIC values to one or more of the echinocandins. Among this echinocandin-resistant population, the mode, MIC50, and MIC90 for ibrexafungerp were 0.5, 0.5, and 1 µg/mL, respectively, with only 1 isolate showing reduced sensitivity.

Conclusions: This data demonstrates that ibrexafungerp possesses potent and consistent in vitro activity against Candida auris and remains highly active against C. auris isolates with high MIC’s to the echinocandins.

Abstract 3650

**Clinical characteristics and outcomes in patients with severe West Nile neuroinvasive disease in Croatia**

Marija Santini*1,2, Sara Haberle1, Vladimir Savic1, Irena Tabain1, Klaudija Viskovic1, Marko Kutlesa1,2, Vladimir Krajinovic1, Ljubo Barbic3, Tatjana Vilibic-Cavlek2,4

1University Hospital for Infectious Diseases “Dr Fran Mihaljevic”, Zagreb, Croatia, 2School of Medicine, University of Zagreb, Zagreb, Croatia, 3Croatian Veterinary Institute, Zagreb, Croatia, 4Croatian Institute of Public Health, Zagreb, Croatia, 5Faculty of Veterinary Medicine, University of Zagreb, Zagreb, Croatia

Abstract third-party references: Croatian Science Foundation, project No. IP 2016-06-7456, CRONEUROARBO.

**Background:** West Nile virus (WNV) neuroinvasive disease is a rare (<1%), but often severe manifestation of WNV infection. The clinical presentation varies and includes meningitis, encephalitis, and poliomyelitis-like syndrome. Risk factors include older age, comorbidities (arterial hypertension, diabetes) and immunosuppression. So far, 92 clinical cases of neuroinvasive WNV infection were reported in Croatia. The aim of this study was to analyze the clinical characteristics of patients with severe WNV neuroinvasive infection, hospitalized at the Department for Intensive Care Medicine and Neuroinfectology, University Hospital for Infectious Diseases “Dr Fran Mihaljevic”, Zagreb, from 2013 to 2019.

**Materials/methods:** Among 23 patients with severe WNV infection, 18 (78.2%) were male. Twenty-one patients were from Croatia, while two cases were imported from Hungary and the USA, respectively. Diagnosis was confirmed by detection of WNV RNA in cerebrospinal fluid (CSF) and/or urine samples using RT-PCR and/or detection of WNV IgM and IgG antibodies of low avidity in serum and CSF samples.

**Results:** The median patient’s age was 72 (range 33-84) years. Majority of patients reported underlying diseases, most commonly arterial hypertension (19/82.6%) and diabetes (9/39.1%). Three patients had kidney transplantation. The most common clinical presentations were encephalitis (13/56.5%) and encephalitis with acute flaccid paralysis (9/39.1%). Twelve patients (52.2%) were mechanically ventilated with the median duration of 12 (range 5-73) days. The median ICU stay was 19 days (range 5-73) while the median hospital stay was 34 days (range 7-97). Two patients (8.7%) died during the ICU treatment and 15 patients had moderate to severe disability at discharge, evaluated by modified Rankin Scale (mRS), score 3-5. The follow-up was performed in July 2019. Nineteen of 21 patients were available. Additional five patients (21.7%) died while five patients (21.7%) had moderate to severe disability. An improvement, according to mRS, was reported in 11 patients (47.8%).

**Conclusions:** WNV neuroinvasive disease affected mainly the elderly with comorbidities. These patients often need a prolonged intensive treatment and have moderate to severe neurological disability. Improvement is noted after several months in one half of the patients.

Abstract 3656

The Mycosands initiative: exploring fungal contamination in the sand and water around the Mediterranean Sea and other water bodies of Europe: relevance to human health and well-being

Joao Brandao¹, Jean-Pierre Gangneux², Esther Segal*³

¹National institute of Health Dr. Ricardo Jorge, Lisboa, Portugal, ²Centre Hospitalier Universitaire de Rennes, Inserm, Irset [Institut de recherche en santé, environnement et travail], UMR S, Rennes, France, ³Tel Aviv University, Sackler School of Medicine, Tel Aviv-Yafo, Israel

Abstract third-party references: ECMM, ISHAM

Background: Beaches are considered therapeutic for many clinical situation and are widely used for recreation purposes. In 2003, the World Health Organization (WHO) published the "Guidelines for safe recreational water environments", dedicated a chapter to sand as exposure to pathogens and opportunists, especially at latitudes where the population tends to spend less time bathing due to colder waters.

Most publications on beach sand address methodology, including microbiome characterization and its influence on human health. To date, however, there has been no clear guidance from regulation and the fungi are an under-investigated biological group, which is also not considered for regulation of the recreational water either.

Materials/methods: In order to characterize the typical mycobiota of European beach sands, a consortium of Medical Mycologists and Recreational Water Quality researchers joined in 2018 to collect samples from 28 sites representing European coasts and inland water bodies. This consortium/initiative is active during two years. The sampling sites are grouped in four different regions: Northwest, Southwest, Mediterranean and Black Sea and the number of samples of water and sand gathered until now is represented in the following table:

<table>

Results: This initiative showed that there is no common mycobiota in European beaches and that the Aspergillus Fumigati complex is distributed everywhere. The same applies to Penicillium spp and other Aspergilli, with the exception of Aspergillus section Nigri which was found more frequently in warmer sands (p=0.019), Rhodotorula spp (p=0.044) follows the same pattern of latter. A. section Nigri is also associated with urban beaches (p<0.001), along with Fusarium spp (p=0.003) and Cryptococcus spp (p=0.019).

Conclusions: From these results, the initiative’s team believes that fungi in sand should be analyzed routinely because of providing relevant information to: Susceptible beach visitors, beach professionals [exposed to sand contaminants during the whole duration of their working periods], and beach managers [fungal contaminants may be used as proxy for information on causes of pollution events].

A novel chaperone-usher pili system associated to the worldwide-disseminated high-risk clone *Klebsiella pneumoniae* ST-15

Eva Gato¹,²; Bruno Kotska Rodiño-Janeiro²; María Pérez-Vázquez³; Antonio Romero⁴; Germán Bou Arevalo⁵; Astrid Pérez²

¹Hospital Universitario A Coruña, Instituto de Investigación Biomédica A Coruña (INIBIC), A Coruña, Spain; ²Hospital Universitario A Coruña, Instituto de Investigación Biomédica A Coruña (INIBIC), A Coruña, Spain; ³Centro Nacional de Microbiología Instituto de Salud Carlos III, Laboratorio de Referencia en Resistencia a Antibióticos, Madrid, Spain; ⁴CSIC, Centro de Investigaciones Biológicas, Madrid, Spain; ⁵Hospital Universitario A Coruña, Laboratorio Microbiología, A Coruña, Spain

**Background:** Emergence and global spread of carbapenem-resistant *Klebsiella pneumoniae* is considered as a dire threat to public health. The convergence of resistance and virulence determinants could promote the emergence of untreatable *K. pneumoniae* infections. Therefore, understanding the mechanisms involved in the pathogenesis and epidemiology of *K. pneumoniae* is required for managing outbreaks and developing therapeutics. We previously identify a chaperone-usher pili (CUP) operon, *kpiABCDEFG*, codifying for a novel CUP system (*Kpi*) and demonstrated the key role in adherence-related virulence functions in a *K. pneumoniae* isolate (Kp3380). The aim of this work was to perform the genetic and structural characterization of the *Kpi* system and evaluate its distribution in *K. pneumoniae*.

**Materials/methods:** Rapid Annotation using Subsystem Technology (RAST) was used for *in silico* analysis of the *kpiABCDEFG* operon. Protein structure modeling of the *Kpi* system was predicted using RaptorX. A phylogenetic analysis based on the usher amino acid sequence was performed to classify the *kpiABCDEFG* fimbrial operon. BLASTn was used to evaluate the presence/absence of the *kpiABCDEFG* operon in *K. pneumoniae*. Its sequence was used as query against 1649 *K. pneumoniae* strains isolated in 32 European countries. A core-genome MLST was performed to describe the distribution of the *Kpi* system.

**Results:** The operon *kpiABCDEFG*, consists of one usher gene (*kpiG*), 3 molecular chaperone genes (*kpiB, kpiE and kpiF*) and 3 fimbrial genes (*kpiA, kpiC and kpiD*). Protein structure modeling revealed that *Kpi* system is structurally related to CUP system type 1. The phylogenetic analysis showed that *Kpi* is included into the largest uncharacterized phylogenetic clade γ, and most of the *Kpi*-positive isolates (77%) belonged to ST-14 (9.5%), ST-15 (46%), ST-25 (4.7%) and ST-405 (16.8%). The 91.1% of ST-15 isolates shared exactly the same operon with Kp3380. The distribution of ST-15 isolates was analyzed and it was involved in outbreaks in Hungary, Croatia, Romania and Spain.

**Conclusions:** The novel *Kpi* system is associated to ST-15, which could explain the superior capacity of these clones to spread and cause outbreaks, being a specific target to control the emergence of that successful high-risk clone.

**Presenter email address:** eva.gato@hotmail.com
Area of technical uncertainty for ciprofloxacin in Enterobacterales: evaluation of MIC values using the E-test method

Valentina Viaggi1, Elisa Meroni1, Orazio Spezia1, Silvia Tonolo1, Beatrice Pini1, Francesco Luzzaro*

1A. Manzoni Hospital, ASST Lecco, Microbiology and Virology Unit, Lecco, Italy

Background: Area of Technical Uncertainty (ATU) is a term coined by EUCAST on 2019 to warn laboratories with respect to uncertain interpretation of some antimicrobial susceptibility testing results, due to technical problems. To this regard, a MIC value of 0.5 mg/L (interpreted as Susceptible, increased exposure according to current EUCAST criteria) is classified ATU for ciprofloxacin in Enterobacterales. Different options are suggested by EUCAST to manage this result. The aim of this study was to evaluate isolates showing a MIC value of 0.5 mg/L (as routinely obtained) using the Etest method (bioMérieux).

Materials/methods: From June to October 2019, 120 non duplicated clinical isolates of Escherichia coli showing a MIC value of 0.5 mg/L for ciprofloxacin were collected at the Manzoni Hospital (Lecco, Italy). Bacterial identification was performed using matrix-assisted laser desorption ionization time-of-flight mass spectrometry (Vitek MS, bioMérieux). Antimicrobial susceptibility for ciprofloxacin was at first evaluated by Vitek2 (bioMérieux), and then re-evaluated using the Etest method. Results were interpreted according to EUCAST criteria.

Results: One hundred and fifteen isolates (95.8%) showed MIC values for ciprofloxacin ranging from 0.012 mg/L to 0.25 mg/L, thus interpreted as Susceptible, standard dosing regimen. Of them, three strains had a MIC value lower than the epidemiological cut-off (ECOFF) and were then classified as wild-type. Nine isolates showed a MIC value ranging from 0.38 mg/L (n=6) to 0.5 mg/L (n=3). Two strains had MIC values greater than 0.5 mg/L (0.75 mg/L, and 2 mg/L) thus being classified as resistant to ciprofloxacin. MIC50 and MIC90 were 0.19 mg/L and 0.25 mg/L, respectively.

Conclusions: According to EUCAST warning, our data confirm the difficulty of reproducible interpretation in case of ATU for ciprofloxacin. It is noting that most isolates appeared to be susceptible using the Etest method. However, the study shows that in most cases the strains had MIC values higher than ECOFF. Therefore, these isolates cannot be classified as wild-type and the presence of mechanism[s] of resistance to ciprofloxacin should be suspected. Additional information concerning the performances of automated systems appear essential to help microbiologists to choose the best option in case of ATU for ciprofloxacin in Enterobacterales.

Abstract 3659

**Antifungal susceptibility description in Candida parapsilosis bloodstream infection: is there a change in the last years?**

Adrian Ferre Beltran*, Alexandre Olmos Torres1, Helem Vilchez Rueda1, Francisco Fanjul Losa1, Eva Alcoceba1, Antonio Oliver1, Javier Murillas Angoitia1, Melchor Riera1

1Hospital Universitari Son Espases, Palma de Mallorca, Spain

**Background:** To develop a profile of antifungal sensitivity of Candida parapsilosis bloodstream infection (BSI) over a period of 6 years (2013 to 2018) and compare C. parapsilosis BSI with non-parapsilosis candidemia.

**Materials/methods:** Retrospective observational study from January 2013 to December 2018 of all candidaemias diagnosed in Hospital Son Espases (Palma de Mallorca, Spain) in patients older than 18 years.

**Results:** Among 224 episodes of Candida BSI identified, 84 (37.5%) were due to C. parapsilosis. In this group, 66.7% were male, with a mean age of 63.5 years old (SD 13.8). The main baseline characteristics were: solid organ cancer (38.1%), diabetes mellitus (22.6%), renal failure (16.7%) and hematological malignancy (4.8%). The Charlson score mean was 5.3 (SD 3.1).

The main predisposing factor were: central venous catheter (CVC) (90.5%), surgery in the previous 3 months (77.4%), parenteral nutrition (46.4%), prior antibiotic therapy (90.5%), prior echinocandin therapy (34.5%), prior glucocorticoid therapy (22.6%) and previous or concurrent colonization by Candida spp. (54.8%).

The candidaemia causes were: catheter-related (56.0%), primary (35.7%), abdominal (7.1%) and urologic (1.2%). 59.5% met sepsis criteria and 27.4% septic shock. The Pitt bacteremia median was 2 [IQR: 0-4] and on the SOFA score was 3 (0-5). Echinocandins were the initial antifungal in 65.5% (67.9% caspofungin). Early CVC removal (first 48 hours) was performed in 71.1%. Appropriate management (appropriate antifungal and early CVC removal) was performed in 55.7%. The 30-day all-cause mortality was 21.4%.

The antifungal susceptibility patterns were: Amphotericin B (0%), echinocandins (29.7%), fluconazole (54.8%), voriconazole (44.0%). 21.4% [18] of the C. parapsilosis species were resistant to both fluconazole and echinocandins. The univariate analysis showed: admission to the Post-Anesthesia Care Unit (p<0.001), surgery in the previous 3 months (p: 0.001), mechanical ventilation (p: 0.014), prior echinocandin therapy (p<0.001), prior carbapenem therapy (p: 0.010) and prior linezolid therapy (p: 0.005) were associated with a higher incidence of candidaemia due to C. parapsilosis.

**Conclusions:** Currently, C. parapsilosis is the main responsible for candidaemias in our hospital. More than 50% isolated were resistant to fluconazole and almost 30% to echinocandins. Amphotericin B was the appropriate antifungal treatment in 20% of cases.

Estrogen enhances host-pathogen interactions in ex vivo and in vitro models of the inflammatory phase of age-related impaired healing

Mohamed El Mohtadi*, Kathryn Whitehead1, Nina Dempsey-Hibbert1, Jason Ashworth1

1Manchester Metropolitan University, Manchester Metropolitan University, Manchester, United Kingdom

Background: Chronic wounds in the elderly often become infected, leading to substantial morbidity and mortality. Age-related impaired healing is mediated by age-related changes in steroid hormones, particularly declining levels of estrogen with increasing age. Although the anti-inflammatory activity of estrogen has been defined, little is known about the effects of estrogen deprivation on bacterial clearance. The aim of this study was to determine the effect of ageing (estrogen deprivation) on the ability of human monocyte-derived macrophages to eliminate bacteria via phagocytosis.

Materials/methods: Host-pathogen assays were used to measure macrophage-mediated phagocytosis of two major wound pathogens, methicillin-resistant *Staphylococcus aureus* (MRSA) and *Pseudomonas aeruginosa*, under in vitro and ex vivo conditions that model estrogen levels in the elderly, young adults and following estrogen supplementation. Fluorescence and scanning electron microscopy (SEM) were used to visualise host-pathogen interactions and protein mediators of phagocytosis were measured by immunoblotting.

Results: Estrogen at concentrations typical of youth or supraphysiological levels significantly \(P<0.05\) increased the phagocytosis of MRSA and *P. aeruginosa* in a dose-dependent manner compared to estrogen deprivation with significantly enhanced clearance of bacteria by M1 macrophages compared to M2 macrophages. Epifluorescence, confocal and SEM confirmed estrogen increases co-localisation of fluorescent GFP-*S. aureus* or mCherry-*P. aeruginosa* within macrophages and promotes bacterial internalisation. Activation of estrogen receptor-alpha (ER-\(\alpha\)) mirrored the stimulatory effect of estrogen on phagocytosis whilst ER-\(\alpha\) antagonism significantly \(P<0.01\) blocked the phagocytic effect of estrogen. In contrast, activation of ER-beta (ER-\(\beta\)) had no significant effect on phagocytosis, confirming estrogen mediates bacterial clearance via ER-\(\alpha\). Immunoblotting analysis demonstrated that estrogen-enhanced phagocytosis is associated with altered levels of mediators involved in the actin cytoskeleton of phagocytes including increased levels of FAK, Rac1, Cdc42 and RhoG, but reduced levels of RhoA.

Conclusions: Findings suggest estrogen may promote the resolution of wound infections during youth but this protection is lost as estrogen levels decline with increasing age, resulting in increased propensity and progression of age-related wound infections. Thus, novel wound dressings providing estrogen supplementation or selective activation of ER-\(\alpha\) and/or specific targeting of downstream mediators of the actin cytoskeleton may provide effective treatment options for infected wounds in the elderly.

Abstract 3661

**Review of the hospital empiric antibiotic guideline in treating community-onset bloodstream infection in a Singapore tertiary hospital**

Geraldine Foo*, Jyoti Somani1, Christine B Teng2, Tricia Tan2, Kean Lee Chew1

1National University Hospital, Singapore, Singapore, 2National University of Singapore, Singapore, Singapore

**Background:** Empiric antibiotic guidelines based on the local antibiogram and suspected site of infection reduce unnecessary broad-spectrum antibiotic use. With the increasing prevalence of community antibiotic resistance, we wanted to ensure the appropriateness and safety of our hospital’s empiric antibiotic guideline. Our objectives were to determine the adequacy of our empiric antibiotic guideline and the impact of guideline adherence on patient outcomes in treating community-onset bloodstream infections (CO-BSIs).

**Materials/methods:** A retrospective study was conducted on adult patients admitted to the hospital with CO-BSI in 2018. CO-BSI was defined as positive blood cultures upon admission. Patients who were discharged from hospital in the last 48 hours, transferred to intensive care unit or another hospital within 24 hours or died within 24 hours were excluded.

**Results:** 377 patients were included in the study, 301 had Gram negative bacteraemia, 70 had Gram positive bacteraemia and 6 had both. The most common pathogens were Escherichia coli, Klebsiella pneumoniae and Staphylococcus aureus. The ESBL rates for E.coli and Klebsiella were 21.5% and 7.9% respectively while MRSA rates were 18.8%. Guideline recommended empiric antibiotics adequately covered bacteria isolated in 87.3% of the cohort. Guideline adherence was 75.9%. A significantly higher proportion of patients in the non-adherent group had Gram positive bacteraemia (31.9% vs 14.3%, p<0.001) and had escalation of empiric antibiotic (56.0% vs 18.2%, p<0.001) for broader coverage of causative bacteria. However, there was no statistical difference in 30-day mortality (8.0% vs 7.8%, p=1.00) and median length of stay (8 days vs 10 days, p=0.116) between adherent and non-adherent groups.

**Conclusions:** Our hospital empiric antibiotic guideline adequately covers for causative bacteria in CO-BSI. Adherence to guideline antibiotics was not associated with higher 30-day mortality and longer hospital stay. Results from this study can assure physicians to adhere to the empiric guideline and not to escalate antibiotics in stable patients with CO-BSI pending culture and susceptibility results. This is an evidence-based step to encourage guideline compliance and reduce unnecessary use of broad-spectrum antibiotics.

Abstract 3666

**Estimating the burden of influenza on hospitals using severe acute respiratory infections in metropolitan France, 2012-2018**

Anne Bernadou1, Noémie Fortin2, Bruno Hubert3

1Santé publique France, Nouvelle Aquitaine Regional office, Bordeaux, France, 2Santé publique France, Pays de Loire Regional office, Nantes, France, 3Santé publique France, Regional direction, Saint-Maurice, France

**Background:** In France, estimating the burden of seasonal influenza on hospital workload is restricted to influenza diagnoses in patients who present to emergency departments (ED) and are subsequently admitted, representing an hospitalization rate ranging from 2 to 15 per 100,000 over six influenza seasons (2012-2018). However, many hospitalizations for respiratory complications (e.g. pneumonia, bronchitis) occur without virological influenza confirmation, especially among the elderly. We aimed to estimate the burden of influenza on hospitals, from the proportion of severe acute respiratory infections (SARI) attributable to influenza, in order to improve health authority response.

**Materials/methods:** Using national hospital discharge data from 1/7/2012 until 30/6/2018, we extracted SARI hospitalizations based on ICD-10 codes: J09-J11 (influenza codes) in primary or associated diagnoses, and J12-J20 (pneumonia and acute bronchitis codes) in primary diagnoses. We estimated influenza-associated SARI hospitalisations, stratified by age group, as the number of influenza-coded hospitalisations plus the excess number of pneumonia- or bronchitis-coded hospitalisations using Serfling regression during influenza seasons.

**Results:** Over six influenza seasons, we identified 533,456 SARI hospitalisations and estimated 227,154 influenza-associated SARI hospitalisations (42%). Fifty-six percent had influenza as a diagnosis, 33% pneumonia and 11% bronchitis. Diagnoses varied among age groups; 14% of those 15 years and under had pneumonia or acute bronchitis, versus 59% of those 85 and older. We estimated the influenza-associated SARI hospitalization rate at 59 per 100,000 population, on average over the 6 seasons. This rate varied significantly by age group: 23 per 100,000 population in 15-64 year olds to 475 per 100,000 population among 85 year olds or older.

**Conclusions:** Compared to current influenza surveillance, analysis of SARI hospitalizations provided a much larger estimate of the true burden of influenza on hospitals, and allowed accurate assessment by age. This analysis should be implemented annually to better assess the socio-economic impact of influenza. These findings will inform the use of real-time SARI analysis from ED data, to measure the magnitude of hospital pressure during the influenza season, and support better health services planning and prompt intervention.

A new rapid test on whole blood and on serum for the toxoplasmosis screening in pregnancy

Valeria M.V. Meroni1, Guglielmo Ferrari2, Francesca Genco3, Elena Dore1, Bianca Mariani2, Milena Furione2, Maurizio Zavattoni2, Luigia Scudeller3,4, Francois Peyron5

1IRCCS policlinico San Matteo, Pavia, Italy, 2Microbiology and Virology Unit, Fondazione IRCCS Policlinico, San Matteo, Pavia, Italy, 3Clinical Epidemiological unit, Fondazione IRCCS Policlinico, San Matteo, Pavia, Italy, 4IRCCS Ca’ Granda Ospedale Maggiore Policlinico di Milano Foundation, Milano, Italy, 5Civil hospices of Lyon. Department of Parasitology and Mycology, Croix Rousse Hospital Lyon France, Lyon, France

Background: In Italy the screening for toxoplasmosis in pregnancy is free of charge and recommended by Italian guidelines. The screening includes anti-Toxoplasma IgG and IgM antibodies at the beginning of pregnancy and monthly follow-up for seronegative women. Many studies have demonstrated the effectiveness of such a screening, but the decrease in seroprevalence of toxoplasmosis, has brought forward the cost-benefit ratio of screening itself. We wanted to evaluate the diagnostic efficacy of a new rapid test (ICT wb-TOXOPLASMA LDBIO Diagnostic Lyon France) on whole blood taken by finger puncture in comparison with clinical data and the same test on serum

Materials/methods: All the pregnant women, screened for toxoplasmosis at the Centro Unico Prelievi and at the Outpatient of Infectious Diseases department of the Fondazione IRCCS Policlinico San Matteo Pavia, were asked to take part to the study. At the same time they underwent the sampling for routine test: LIAISON® XL Toxoplasma IgG and IgM, IgG Avidity (Diasorin, Saluggia, Italy) VIDAS Toxo IgG II, IgG Avidity and ISAGA IgM (Biomerieux - Mercy l'Etoile - France) and when possible for ICT on the serum

Results: Two hundred and seventy pregnant women underwent ICT whole blood test, ICT on sera was performed on 218 sample from the same patients and the results compared with the clinical diagnosis. Concordance (Cohen’s kappa Test) was very good with K = 0.9084 for whole Blood ICT and K = 0.9599 for serum ICT. Sensitivity was 89.5% [CI 95% 87.5-98.6], specificity 99% [CI 95% 96.8-100] for whole blood. On sera sensitivity was 94.9% [CI 95% 97.4-98.6], specificity 100% [CI 95% 97.4-100]. The K value between the 2 test was 0.859. Only 30 (10%) patients refused to take part to the study

Conclusions: The use of the rapid test can be an alternative to traditional tests for ease of execution, rapid response and reduced cost. Both the tests on different matrices showed a good specificity avoiding most of IgG/IgM false positive results, but all positive cases must always be tested with routine tests to discriminate between different antibody classes and to date the infection.

Abstract 3668

Detection of ST131, ST410 and ST69 Escherichia coli KPC-2/3, OXA-181, and VIM-1-producers from a long-term care facility in Milan, Italy

Federica Marchesini1, Aseel Abu-Alsha’ar1, Alessandra Mercato2, Marika Mancinelli*1, Vittoria Mattioni Marchetti1, Elena Fogato2, Fabio Lattanzi1, Elisabetta Nucleo1, Roberta Migliavacca1

1University of Pavia, Dept. Clinical-Surgical, Diagnostic and Pediatric Sciences, Microbiology and Clinical Microbiology Unit, Pavia, Italy, 2Azienda di Servizi alla Persona “Golgi-Redaelli”, Laboratory of Clinical Microbiology, ASP “Golgi-Redaelli”, Milan, Italy, Milano, Italy

Background: The prevalence of MDR Escherichia coli is increasing in Italian long-term care facilities (LTCFs). Objective of the study was to characterize all the carbapenemase-producing E. coli clinical isolates collected in the period 2017-18 from a LTCF of Milan, Italy.

Materials/methods: In a two years’ period, a total of 14 ertapenem and/or imipenem non-susceptible E. coli strains, were collected at the LTCF “Golgi-Redaelli” Clinical Microbiology Laboratory. Identification and susceptibility tests were performed by both Vitek-2 and Microscan Autoscan-4. Colistin and fosfomycin MICs were obtained by broth-microdilution [UMIC CO] and agar dilution methods, respectively (EUCAST 2019 guidelines). The presence of ESBLs, carbapenemases and aac-(6')Ib-cr -resistance determinants was evaluated by PCR, microarray and sequencing. Strains and plasmids characterization was accomplished by multiplex-PCR, PFGE, MLST and FBRT-kit (Diatheva), respectively.

Results: The 14 E. coli studied accounted for the 5.5% of all the MDR Gram-negative microorganisms identified in the period 2018-19 at “Golgi-Redaelli” LTCF. All the E. coli isolates, obtained from urine (n = 10/14) and rectal swabs (n = 4/14) resulted MDR. The resistance phenotypes included third generation cephalosporins, fluoroquinolones, aminoglycosides and co-trimoxazole in 100%; 86%; 78.6%; 57.1% of the E. coli, respectively. Susceptibility to colistin, phosphomycin and tigecylin was always retained, while ceftazidime-avibactam showed activity in 86% of cases. The strains harbored mainly blaKPC-2 (n=6) or blaKPC-3 (n=1) genes, followed by blaOXA-181 (n=5) and blaVIM-1 (n=2); the coexistence with aac-(6')Ib-cr, blaCTX-M-type and blaSHV-5 genes was detected in eight, six and one isolate, respectively. Eight pulsotypes, five STs and three phylogenetic groups were identified: PFGE clone A (ST69), B, C, E (ST131), D, F (ST410), G (ST1288) and H (ST648). Six/14 E. coli belonged to group A, 7/14 to D and 1/14 to B2. The plasmid characterization showed FIA, FIB and FI replicons in the KPC-2/3, X3 in OXA-181, and B/O, A/C in the blaVIM-1-positive isolates.

Conclusions: The identification of ST131 blaKPC-2/3, ST410 blaOXA-181 and ST69 blaVIM-1 positive E. coli from LTCF residents underlines an alarming scenario in the Italian LTCF. Moreover, we detected blaKPC-2-positive E. coli of ST648 and ST1288, currently of rare reporting.

Background: Host genetics play an important role in susceptibility to severe infections such as bacteraemia, of which Escherichia coli and Staphylococcus aureus are the leading causes. Variations in genes encoding two proteins within the NLRP3 inflammasome, C10X within the regulatory CARD8 gene and Q705K within the NLRP3 gene, have been associated with increased risk of chronic inflammation. The present study aimed to investigate whether these specific gene polymorphisms influence the risk of contracting bacteraemia caused by E. coli or S. aureus.

Materials/methods: Samples from blood cultures displaying growth of S. aureus or E. coli, and from negative blood cultures were consecutively included between November 2013 and December 2015 at four study centers in Sweden. Human DNA was extracted, followed by genotyping of the polymorphisms Q705K in the NALP3 gene and C10X in the CARD8 gene using TaqMan® SNP genotyping assays (Applied Biosystems, Foster City, CA).

Results: Table 1 shows the prevalence of genotype distribution of C10X, with a significant association between the homozygote variant and patients with bacteraemia caused by S. aureus or E. coli compared to patients with negative blood culture (p=0.007 and p=0.002, respectively). There were no difference in genotype distribution of Q705K, neither heterozygote nor homozygote variant, between patients with bacteraemia and those with negative blood culture.

Conclusions: The prevalence of the C10X homozygote variant in the CARD8 gene was significantly higher in patients with bacteraemia caused by E. coli or S. aureus compared to patients with negative blood cultures. Individuals carrying this gene variant may have an increased risk of contracting bacteraemia.

*S. aureus and E. coli bacteraemia compared with negative blood cultures.

*Calculated by logistic regression

Presenter email address: gunlog.rasmussen@regionorebrolan.se
Background: Staphylococcus aureus is a commensal of the upper respiratory tract. When mechanical ventilation overcomes natural defenses, S. aureus is frequently isolated from the airways, but distinguishing between colonisation and infection is difficult. The aim of this work was to describe genotypical and phenotypical features of S. aureus isolated from mechanically ventilated patients.

Materials/methods: A set of 48 clinical isolates were selected. Patients were classified as pneumonia [10], tracheobronchitis [11] and bronchial colonization [13]. Isolates were characterized with a DNA microarray (Alere Technologies) and underwent whole genome sequencing using Illumina HiSeq4000. Minimal inhibitory concentrations for daptomycin, vancomycin and teicoplanin were determined by UMIC test (Biocentric). THP-1 cytotoxicity assay was assessed after incubating cells with bacterial supernatants and later adding a specific viability reagent. Adhesion to solid-phase fibronectin (Fn) was determined by a standardized microtitre plate assay. Detection of alpha-toxin (AT) in bacterial supernatants was performed by Western-Blot.

Results: Isolates belonged to 14 different clonal complexes (CCs). The most frequent CC for methicillin resistant S. aureus (33.3% of all isolates) was CC5 (56.25%), as well as for methicillin susceptible (15.62%). All strains were vancomycin, teicoplanin and daptomycin susceptible, with the exception of one strain daptomycin resistant. All strains were positive for hla and fibronectin binding protein A (fnbA), 80% were positive for fibronectin binding protein B (fnbB) and only one isolate was positive for pvl. Cytotoxicity was variable among isolates with 14 strains showing no cytotoxicity, with these latter presenting an unaltered Fn binding capacity. No changes on cytotoxicity were reported when comparing study groups. FN binding capacity was reported for almost all strains, with the exception of 2 strains that presented the lowest values. Strains isolated from patients with pneumonia presented a lower capacity of adhesion in comparison to those isolated during tracheobronchitis (p=0.0029). AT was detected in 35 strains (73%), and no correlation with cytotoxicity, adhesion or study group were found.

Conclusions: There is an important diversity of clonal complexes in the set of S. aureus isolates.

Cytotoxicity is variable among strains, but no association with study groups was found, whereas isolates from patients with pneumonia had lower adhesion capability.

The use of whole genome sequencing will enable a more accurate identification of genetic variations.
Abstract 3672

Impact of BD urine culture application on clinical microbiology laboratory activity
Francesco D’alò1, Angelica Cesarini1, Riccardo Paggi*, Donatella Pietrella2, Antonella Repetto1, Elio Cenci2, Antonella Mencacci2

1Hospital Santa Maria della Misericordia in Perugia, Microbiology, Perugia, Italy, 2University of Perugia, Department of Medicine - Medical Microbiology Section, Perugia, Italy

Background: Laboratory automation and intelligent use of informatics are showing a dramatic impact on microbiology diagnostics. The development of intelligent images analysis based on algorithms tailored on type of specimens and patient characteristics represents a major innovation that has the potential to increase laboratory efficiency while reducing turn-around-time. This study evaluates the impact on the routine laboratory activity of the BD urine culture application (UCA), implemented on the BD Kiestra automated system (Becton Dickinson, Sparks, MD, USA).

Materials/methods: Ten microliters of 753 midstream and 251 permanent catheter urines were inoculated onto CHROMagar Orientation, Blood agar supplemented with colistin and nalidixic acid, and MacConkey agar (Becton Dickinson) with the BD Kiestra InoqulA using the #4 zig-zag streaking pattern. For the algorithmic analysis, plate images were acquired using the OPTISTM software, at times 0 (reference of no growth), 12 h (early positive culture workup), and 18 h (imaging endpoint). In the absence of leukocytes, growth <10,000 CFU/ml and <100 CFU/ml were considered to be negative for midstream and catheter urine samples, respectively. Other types of urine specimens were excluded from UCA analysis.

Results: During a 20-days period, 519/1004 (51.6%) urines analyzed by UCA were automatically released as negative. Sensitivity was 99.3% and specificity 74.5%. Negative Predictive Value (NPV) was 99.6%. Theoretical time to report (mean ± SD) for negative samples (i.e., negative samples released by UCA for clinical validation) was 18.65 ± 1.03 h, and actual time to report was 20.86 ± 1.73 h, due to laboratory opening hours. UCA negative samples were all reported to clinicians between 7:30 and 9:52 a.m., with 75% being reported between 7:30 and 7:58 a.m. Time-to report of negative samples excluded from the UCA was 24.87 ± 4.33 h. UCA analysis of about 50 urines per day allowed saving about 20 min per day.

Conclusions: The implementation of the BD UCA to automatically release negative urine samples decreases the time to report of negative samples, and allows to save time in the laboratory practice, with optimal NPV.

Abstract 3673

Prevalence and impact of meropenem-resistant among nonresistant OXA-48-producing *Klebsiella pneumoniae*

Natalia Bustos De Godoy¹, Lorena Lopez-Cerero*², María Del Mar Sánchez³, Esther Recacha³, M. Carmen Conejo¹, Alvaro Pascual Hernandez²

¹Medical School, University of Seville, Sevilla, Spain, ²University Hospital Virgen Macarena, Sevilla, Spain

Background: OXA-48-producing *Klebsiella pneumoniae* isolates frequently show growing subpopulations within inhibition zones in meropenem diffusion assays, leading to a low agreement between diffusion and broth dilution susceptibility methods (affecting to 20-60% of isolates recovered in our region). This feature has only been studied in carbapenemase-producing isolates from a hospital outbreak-based study and was associated to mutations in the *ompK36* porin gene. The aim of this study was to assess the frequency of these subpopulations among multiple OXA-48-producing *K. pneumoniae* strains, as well as to compare the porin expression and growth rate of the clinical isolates and their resulting subpopulations.

Materials/methods: Thirty OXA-48-producing *K. pneumoniae* clinical isolates, corresponding to 12 sequence types were selected: 27 with a meropenem MIC of ≤2 mg/L and 3 with MIC of 8 mg/L, S and I categories according to EUCAST, respectively, and showing resistant subpopulations by diffusion agar methods. They were detected between 2014-2017 from 12 hospitals from Andalusia. Population Analysis Profile (PAP) was performed to calculate the frequency of these subpopulations. Stability was determined by 5 passages without antibiotic. Porin profile was studied by SDS-PAGE. The Infinite 200Pro appliance was used to compare differences in growing among native strains and subpopulations at different concentrations of meropenem for 24 hours, with optic density lecture every hour.

Results: All strains showed subpopulations with an average of 5 times higher meropenem MIC values (range: 2-7 times) than their native populations, 21 (70%) with an MIC >8 mg/L (range 1-64 mg/L), with an average frequency of 1.47x10⁻⁷ (range: 15.5x10⁻⁶-8.93x10⁻¹⁰), and all were stable. All the native populations expressed OmpK35/36 porins comparing to half of the more resistant subpopulations. Regardless of porin profiles, subpopulations showed initial growth at meropenem MIC of >8 mg/L similar to that of native populations without antibiotic.

Conclusions: 1) All OXA-48-producing *K. pneumoniae* strains show a low frequency of subpopulations, most of them into the clinical meropenem resistance category; 2) these subpopulations were observed in all the studied clones and are stable mutants; 3) loss of porin expression could explain this phenomenon in only half of them; 4) all strains showed initial heterogenic populations.

Presenter email address: ilopez@us.es
Does our microbiome travel well? Microbiome resilience and acquisition of multidrug-resistant bacteria in travellers

Matthew Davies*1,2, Maris Arcilla3, Janne Van Hattem4, Constance Schultsz5, Menno De Jong5, Damian Melles3, Alan McNally1, Willem Van Schaik1, Petra Wolffs6, John Penders6,7

1University of Birmingham, Institute of Microbiology and Infection, Birmingham, United Kingdom, 2Maastricht University, School of Public Health and Primary Care, Maastricht, Netherlands, 3Erasmus University Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands, 4Tergooi - Blaricum, Blaricum, Netherlands, 5Academic Medical Centre, Department of Medical Microbiology, Amsterdam, Netherlands, 6Academic Hospital Maastricht, School of Public Health and Primary Care, Maastricht, Netherlands, 7Academic Hospital Maastricht, School for Nutrition and Translational Research in Metabolism, Maastricht, Netherlands

Background: The international spread of antimicrobial resistance poses a serious health risk, compounded by approximately 1.4 billion travellers in 2018, many of which to countries that are hotspots of resistance. A previous study focusing on the carriage of multidrug resistant bacteria after travel showed that there is extensive acquisition and persistence of extended spectrum beta lactamase producing Enterobacteriaceae (ESBL-E) in the gut of travellers visiting Asia and Africa.

Materials/methods: Using shotgun sequencing data from 190 of these travellers, the metagenomics profile of the gut microbiome has been analysed to understand its role in this context. A metagenomics species concept approach was used to determine the taxonomic composition, population diversity and metabolism of the microbiome at baseline (before travel) and how these are altered longitudinally. Predicted genes are clustered by their abundance profile across multiple samples, providing a more powerful signal for analysing metagenome data.

Results: Here we show that these aspects at baseline do not significantly differ between travellers that were or were not subsequently colonised by ESBL-E, so are not predictive of the risk of acquiring ESBLs. Alternatively, there were longitudinal changes detected in the taxonomy and functional profile which were specific to the travel destination.

Conclusions: The lack in predictive power of the baseline microbiome suggests that a traveller’s risk of ESBL acquisition is difficult to determine before travel. Alternatively, the longitudinal results highlight the taxa and metabolic processes that may have a role in the protection against, or clearance of, ESBL producing Enterobacteriaceae. These are therefore potential targets as a prophylactic treatment or as adjuvants in the decolonisation of ESBL-E. However, the destination of travel is be a key factor to focus on, as this is a significant contributor to how the gut microbiome is altered.

Presenter email address: mxd455@student.bham.ac.uk
Effectiveness and safety of utilising oral vancomycin as prophylaxis for Clostridioides difficile infections in high-risk patients

Anthony Casapao\textsuperscript{a,1}, Lacey Nilles\textsuperscript{b}, Conner Sothoron\textsuperscript{b}, Calvin Tucker\textsuperscript{b}, Ameen Pirasteh\textsuperscript{b}

\textsuperscript{a}University of Florida College of Pharmacy, Jacksonville, Florida, United States; \textsuperscript{b}Baptist Medical Center, Jacksonville, Florida, United States

\textbf{Background:} Reducing the incidence of \textit{Clostridioides difficile} infections (CDI) is a desirable goal for many hospitals. Recent data have shown favorable results to administer oral vancomycin as CDI prophylaxis especially in patients at high-risk of developing CDI. Purpose of this study was to determine the effectiveness of oral vancomycin prophylaxis on the incidence of CDI.

\textbf{Methods:} Retrospective, quasi-experimental, propensity-matched cohort study that examined adult patients admitted with empiric broad-spectrum antibiotics for an infection. Patients admitted from June 2017 to November 2018 were given oral vancomycin as CDI prophylaxis (VANPPX) and compared to patients admitted from June 2016 to May 2017 as the no prophylaxis (NOPPX). Primary outcome was incidence of CDI, diagnosed anytime from the initiation of antibiotics until discharge.

\textbf{Results:} Of 532 patients, 266 patients were in each group. Mean age was 71 years (±13) and 47.0% (252/532) were given more than one broad-spectrum antibiotic. Fifty-seven percent (304/532) received a proton pump inhibitor with a higher proportion in the NOPPX (66.5% vs. 47.7%; \( p < 0.001 \)). There were more admissions to intensive care unit in NOPPX (34.6% vs. 22.2%; \( p = 0.002 \)). Overall, the incidence of CDI was 2.4% (4/532); 1.5% (4/266) patients had CDI in VANPPX as compared to 3.4% (9/266) patients in NOPPX (\( p = 0.261 \)) with an unadjusted odds ratio (OR) of 0.436; 95% confidence interval (CI) (0.133, 1.433). Eighty-eight percent (468/532) patients had no history of CDI with an unadjusted OR of 0.542; 95% CI (0.165, 1.786). Propensity-matched cohort included 468 patients for analysis, 234 patients in each group. Similar results were found after propensity matching with the incidence of CDI in VANPPX and NOPPX, 1.7% (4/234) compared to 3.8% (9/234), respectively; \( p = 0.130 \).

\textbf{Conclusions:} There were no statistical differences in the incidence of CDI between groups. This study may suggest no additional benefit in the use of oral vancomycin as primary CDI prophylaxis in patients that are high risk of developing CDI. There was a larger proportion of patients without history of CDI; however, there was no effect measure modification identified with the development of CDI. Further evaluation of CDI prophylaxis is needed according to a stratification of CDI risk factors.

\textbf{Presenter email address:} casapao@cop.ufl.edu
Abstract 3677

**Antimicrobial susceptibility and resistance determinants in Enterobacteriaceae and Staphylococcus aureus among febrile patients hospitalised in the African region.**

1Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, 2Centre de Recherches Médicales de Lambaréné [CER-MEL], Lambaréné, Gabon, 3Institut für Tropenmedizin, Universitätsklinikum Tübingen, Tübingen, Germany, 4German Centre for Infection Research [DZIF], Braunschweig, Germany, 5Nouna Health Research Center, Nouna, Burkina Faso, 6Department of Infectious Diseases & Tropical Medicine, Ludwig Maximilian University of Munich, Munich, Germany, 7Universitätsklinikum Hamburg-Eppendorf, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, 8Mbeya Medical Research Center, Mbeya, Tanzania, 9Kumasi Centre for Collaborative Research in Tropical Medicine [KCCR], Kumasi, Ghana, 10Institute of Medical Microbiology, University Hospital Münster, Münster, Germany, 11Department of Infectious Diseases & Tropical Medicine, Ludwig Maximilian University of Munich, Munich, Germany, 12Max-van Pettenkofer Institute, Medical Microbiology and Hospital Epidemiology [LMU], Munich, Germany, 13Heidelberg Institute of Global Health (HIGH), Heidelberg University Hospital, Heidelberg, Germany

**Background:** The severe under-documentation of bacterial resistance in Africa hampers formulation of adequate treatment guidelines, antimicrobial control policies and appropriate action plans. The study presents data on bacteria the WHO has highlighted as being key antimicrobial resistance (AMR) concerns in Africa, outlining their susceptibility to standard antibiotics and the corresponding resistance determinants, with the purpose of guiding empirical treatment of common infections.

**Materials/methods:** Blood, stool and urine specimens of 3,607 febrile patients, aged between ≥30 days and ≤81 years, hospitalized in Burkina Faso, Gabon, Ghana and Tanzania, from November 2013 to March 2017 were cultured. Antibiotic susceptibility testing was performed for all Enterobacteriaceae and *Staphylococcus aureus* isolates using disk diffusion method. Extended-spectrum β-Lactamase (ESBL) production was confirmed by combined disc test and further characterized by amplifying the *bla*CTX-M, *bla*TEM and *bla*SHV genes. Ciprofloxacin resistance among *Salmonella* spp. was confirmed by E-test and non-susceptible isolates were screened for plasmid-mediated resistance genes and *gyrA*, *gyrB*, *parC*, *parE* mutations. *S. aureus* isolates were further differentiated by *spa*-typing and multi-locus-sequence-typing.

**Results:** Of 4,464 specimens, positive cultures comprised: 3.3% (N=3423) blood, 15.4% (N=629) urine and 2.2% (N=412) stool. Enterobacteriaceae were the most common isolates (88.2%, N=220), including 90 (46.4%) *Salmonella* spp., 73 (37.6%) *Escherichia coli* and 22 (11.3%) *Klebsiella pneumoniae*. The rate of ESBL-producers (all CTX-M15 genotype) was highest in Burkina Faso (n=15; 38%), followed by Gabon (n=8; 23%), Ghana (n=18; 14%) and Tanzania (n=0; 0%). ESBL positive *Salmonella* (N=3) were detected in Burkina Faso only. Similarly, ciprofloxacin resistance in Enterobacteriaceae was notably higher in Burkina Faso (53%) relative to ≥13% in the other countries.

Screening among ciprofloxacin resistant *Salmonella* revealed 2 (1.7%) isolates in Ghana with *gyrA* mutations D87G and, 7 (22%) isolates in Burkina Faso, 6 with *qnrB* genes and one with a *gyrA* mutation E133G. Methicillin resistant *S. aureus* were detected in one blood and one urine culture, only in Ghana.

**Conclusions:** Our findings reveal a distinguishable susceptibility pattern across the various African countries; thus, highlighting the need for local AMR assessments to inform empirical treatment. We additionally exhort for continued investigations of AMR in Africa, to augment the existing scarce data.

**Presenter email address:** rehema.moirongo@bnitm.de
**Enterococcus faecalis inhibits Klebsiella pneumoniae growth in polymicrobial biofilms**

Victoria Del Pilar Ballén Torres*1, Sara Maria Soto1

1iSGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

**Background:** Catheter-related urinary tract infections are one of the most common biofilm-associated diseases. Inside the biofilms, bacteria cooperate, compete or have neutral interactions according to the species involved. The aim of this investigation was to study the interspecies interactions in polymicrobial biofilms formed by *Klebsiella pneumoniae* and *Enterococcus faecalis*, two of the most common uropathogens.

**Materials/methods:** One *K. pneumoniae* and three *E. faecalis* strains were included in the study. Biofilms were evaluated by crystal violet (CV) assay, percentage of inhibition in biofilm formation, enumeration of colony-forming units (CFUs) and competitive index (CI). The competition was also studied in planktonic cultures. Antimicrobial and antibiofilm activities of lyophilized cell-free supernatants (L-CFS) from *E-faecalis* were evaluated against the *K. Pneumoniae* strain. In addition, pH and lactic acid production in *E. faecalis* L-CFS were measured at 30 minutes, 1, 2, 3, 4, 8, 24, 48 and 72 hours.

**Results:** *K. pneumoniae* was the most adherent strain, but it was not capable to maintain dominance when it grows in polymicrobial biofilms with *E. faecalis*. Furthermore, a statistically significant decrease in total biomass volume and CFUs of *K. pneumoniae* in polymicrobial biofilm was found compared with the monomicrobial biofilms. Negative CI values also indicate a competitive advantage of *E. faecalis* over *K. pneumoniae*. However, the reduction in CFUs was not statistically significant in planktonic cultures. Antimicrobial, antibiofilm, and eradication biofilm capacities against the *K. Pneumoniae* strain were observed using L-CFS collected from different *E. faecalis* biofilms. Otherwise, this effect was not present when the pH of L-CFS collected from biofilm was adjusted in 6.5. In addition, lactic acid production around 2.4 g/L was measured in biofilm supernatants, demonstrating that *E. faecalis* decreases pH in polymicrobial biofilm by lactic acid production, resulting in *K. pneumoniae* growth inhibition.

**Conclusions:** *K. pneumoniae* and *E. faecalis* interact in a competitive mode. L-CFS collected from *E. faecalis* biofilms, had an antimicrobial, antibiotic and eradication of biofilm effects over *K. pneumoniae*. For this reason, in polymicrobial biofilms, *E. faecalis* is able to modify the pH by lactic acid production, compromising the appropriate growth of *K. pneumoniae*.

Ceftaroline fosamil for the treatment of methicillin-resistant Staphylococcus aureus bacteraemia: a real-world comparative clinical outcomes study

Jennifer Hammond¹, Michael Benigno², Richard Chambers¹, Nataly Patino², Wajeeha Ansari*², Jennifer Nguyen²

¹ Pfizer, Collegeville, United States, ² Pfizer, New York, United States

Background: MRSAB is associated with significant clinical and economic healthcare system burden. This large real-world study explored whether MRSAB treatment outcomes differ with ceftaroline fosamil versus vancomycin and daptomycin.

Materials/methods: This study utilised US data from the Premier Healthcare Database (July 2011–March 2019). Adults hospitalized with MRSAB and treated with intravenous ceftaroline, vancomycin, or daptomycin were classified into three treatment groups: ceftaroline [no concurrent vancomycin or daptomycin] (Group 1); vancomycin or daptomycin [no concurrent ceftaroline] (Group 2), or combination therapy with ≥two of these three agents (Group 3). Clinical outcomes were compared using propensity score-adjusted odds ratios (ORs) from logistic regression models. Outcomes included clinical response [hospital discharge with no further need for antibiotic treatment, or with treatments indicating clinical improvement]; switch to another intravenous anti-MRSA treatment after 2 days; discharge status [expired/discharge to hospice/skilled nursing facility, discharge to health home organization/home and other/unknown]; and 30-day readmission (all-cause and MRSAB).

Results: In total, 24,479 patients were included (Group 1, n=532; Group 2, n=21,555; Group 3, n=2,392). Group 3 was, on average, younger with fewer comorbidities versus Groups 1 and 2 (mean age [SD]: 57.4 [17.4] vs. 59.6 [17.0] and 60.8 [17.5], Charlson Comorbidity Index score [SD]: 2.0 [2.8] versus 3.0 [3.2] and 2.3 [3.0], respectively; all p<0.01). Versus Group 2, Groups 1 and 3 were more likely to have clinical response (OR: 1.18 [95% CI 0.98-1.44]; p=0.08, and OR: 1.20 [95% CI 0.97 - 1.47]; p=0.09, respectively) and less likely to switch treatment (both p<0.001). However, Group 1 was more likely to have 30-day all-cause readmission (OR: 1.38 [95% CI 1.06-1.80]; p=0.02), while Group 3 was less likely (OR: 0.77 [95% CI 0.58-1.00]; p=0.05) versus Group 2. Compared with Group 1, Group 3 more often had clinical response (OR: 1.38 [95% CI 1.27-1.51]; p<0.001), was less likely to switch treatment (p<0.001), and more often discharged to home (p=0.01).

Conclusions: Ceftaroline monotherapy resulted in greater probability of clinical response versus vancomycin or daptomycin monotherapy. Combination therapy was associated with improved outcomes versus monotherapy. These results provide valuable real-world insights into ceftaroline fosamil as a potential MRSAB treatment option.

Study sponsored by Pfizer.

Impact of positive microbiological testing on antimicrobial de-escalation and clinical outcomes in community-acquired pneumonia

Gabriela Abelenda Alonso*1,2; Alexander Rombauts1,2; Carlota Gudiol1,2,3; Carmen Ardanuy Tisaire2,4; Yolanda Meije Castillo5; Lucía Ortega5; Mercedes Clemente5; Jordi Niubò4; Jordi Carratalà1,2,3

1Bellvitge University Hospital, Infectious Diseases Department, l’Hospitalet de Llobregat, Spain; 2University of Barcelona, Barcelona, Spain; 3REIPI (Spanish Network for Research in Infectious Disease), Instituto de Salud Carlos III, Madrid, Spain; 4Bellvitge University Hospital, Clinical Microbiology Department, l’Hospitalet de Llobregat, Spain; 5SCIAS- Barcelona Hospital, Infectious Diseases Department, Barcelona, Spain

Background: We aim to determine the impact of positive microbiological (PM) testing on antimicrobial de-escalation and outcomes of patients with community-acquired pneumonia (CAP).

Materials/methods: Analysis of a prospective cohort of non-immunosuppressed adults hospitalized for CAP. Antimicrobial de-escalation was considered when the initial empirical antimicrobial therapy was narrowed to a penicillin, amoxicillin or amoxicillin/clavulanate, when microbiologically feasible; to a quinolone or macrolide in Legionella pneumonia; and to oseltamivir in cases of influenza disease. Exclusion criteria were early mortality (<72h), empirical antimicrobial therapy with an already narrow coverage, and/or lack of data regarding de-escalation. Study outcomes were time to switch to oral antimicrobial therapy, overall duration of antimicrobial therapy, ICU-admission, length of hospital stay, and 30-day case-fatality rate.

Results: Of 4393 hospitalized patients with CAP, 2257 (51.4%) had a PM testing. The three main causative agents were: Streptococcus pneumoniae (n=1479), Legionella pneumophila (n=234), and Haemophilus influenzae (n=187). Pre-hospital antimicrobial use for the acute CAP episode was associated with negative microbiological results (NM) (18.9% vs. 26.7%; p<0.001). Antimicrobial de-escalation was performed in 841 (19.2%) patients and was independently associated with PM testing (PM: 25.4% vs. NM: 12.6%; OR=3.00; p<0.001). ICU-admission was associated with PM testing (OR=1.776; p<0.001) and inversely related with antimicrobial de-escalation (OR=0.491; p<0.001). A propensity score (PS) was generated using eight variables that could have influenced the decision to de-escalate treatment [age, comorbidities, aspiration CAP, empyema, bilateral involvement, SAPS severity score>15, ICU-admission and PM testing]. Multivariate analysis adjusted by PS showed that antimicrobial de-escalation was less often associated with PM testing (OR=1.3; p=0.0051). Days to antimicrobial oral switching (OR=0.931; p=0.56) and overall length of antimicrobial treatment (OR=0.760; p=0.002) were shorter in patients who underwent de-escalation. Thirty-day mortality was not found to be independently associated with antimicrobial de-escalation (OR=0.786; p=0.414).

Conclusions: PM testing was associated with antimicrobial de-escalation in CAP, leading to shorter time to switching to oral antibiotics and overall duration of antimicrobial therapy. De-escalation was not independently associated with higher 30-day mortality. Further research is necessary to determine the potential impact of new point-of-care tests in antimicrobial stewardship strategies and outcomes in CAP.

Abstract 3692

**Predicting the effect of single nucleotide polymorphisms on fluoroquinolone resistance in Mycobacterium tuberculosis by computational methods**

Alice Brankin*,1, Philip Fowler1, A. Sarah Walker1

1University of Oxford, Nuffield Department of Medicine, John Radcliffe Hospital, Oxford, United Kingdom

**Background:** Multi-drug resistant (MDR) tuberculosis (TB) presents an increasing challenge for TB treatment globally. The WHO recommends fluoroquinolone antibiotics to treat MDR TB. However, fluoroquinolone resistance can be conferred by a small number of point mutations in the gyrA and gyrB genes of the antibiotic target, DNA gyrase. It is important to know whether novel mutations confer fluoroquinolone resistance in order to effectively treat patients and prevent transmission of resistant strains. Current TB drug susceptibility testing takes 6-8 weeks, yet most gyrA and gyrB mutations will result in susceptibility to fluoroquinolones. Therefore, computational approaches able to rapidly predict fluoroquinolone-susceptibility from genetic sequences would be invaluable for TB diagnostics.

**Materials/methods:** A physics-based tool, alchemical free energy methods, was applied to make susceptibility predictions based on relative binding free energy estimates. This method was tested using three control mutations, gyrA A90V (fluoroquinolone-resistant), gyrA S95T (fluoroquinolone-susceptible) and gyrA A90S (fluoroquinolone-hypersusceptible). A logistic regression model was then trained to classify previously observed gyrA and gyrB mutations as susceptible or resistant to moxifloxacin and levofloxacin. Training data included structural and chemical features of the wild type and mutant amino acids associated with the CRyPTIC catalogue of gyrA and gyrB mutations obtained from ~10,000 published genomes.

**Results:** Alchemical free energy methods made binding free energy estimates with error of +/- 1 kcal/mol, enabling confident prediction of the correct phenotype for all three test mutations, but took ~160,000 CPU hours per mutation. Logistic regression accurately classified mutants conferring fluoroquinolone-susceptibility and false positives were predicted at a low rate based on cross-validated error estimates for known mutations. Distance of the mutated amino acid from the fluoroquinolone binding site proved an important predictor. However, the phenotype of several mutants was predicted by the machine learning algorithm to be susceptible with low confidence, and additional novel mutations were predicted to be resistant. The impact of these mutations could then be predicted using more time-consuming alchemical free energy methods.

**Conclusions:** A combination of machine learning and physics-based approaches could help reduce the time needed to diagnose fluoroquinolone susceptibility in Mycobacterium tuberculosis isolates with novel or rare DNA gyrase mutations.

Abstract 3694

**Differences in risk and outcomes for patients with Clostridium difficile toxin positive versus only cytotoxigenic culture positive faecal samples: results from COMBACTE-CDI case-control study**

Kerrie Davies*, Virginie Viprey, Duncan Ewin, Alice Banz, William Spittal, Jonathan Vernon, Anthony Benson, Georgina Davis, Philippe Cleuziat, Mark H. Wilcox

1Healthcare Associated Infections Research group, University of Leeds, Leeds, United Kingdom, 2bioMerieux, Marcy l’Etoile, France, 3bioMérieux, Chemin de l’Orme, Marcy l’Etoile, France

**Abstract third-party references:** on behalf of the COMBACTE-CDI consortium

**Background:** Currently reported risk factors for and outcomes of *C. difficile* infection (CDI) may be clouded by the use of different diagnostic methods in studies.

**Materials/methods:** Sites were recruited from 12 countries across Europe (1 site/3 million population). On two days, all diarrhoeal samples (regardless of tests requested, n=3613) were sent to the European coordinating laboratory for *C. difficile* toxin detection; cell-cytotoxin neutralisation testing (CCNA) ultrasensitive immunoassay (SIMOA) and cytotoxigenic culture (CTC). Cases were defined as C1 (CCNA positive n=94), C2 (CCNA-negative/SIMOA-positive n=43), C3 (toxin-negative/CTC-positive n=34), C4 controls (negative by all assays n=444). Data were collected on patient outcomes and risk factors and comparisons made according to diagnostic categories C1-4.

**Results:** C1 cases were significantly older vs C3 (median age 71 vs 47 years, p=0.013), and vs controls (C4) (71 vs 55 years p<0.0001). C2 cases were significantly older than controls (p=0.006), but not C3 (p=0.132); C3 were not significantly older than controls (p=0.859).

Mean white cell count of cases in C1 and C1+C2 (toxin positive) was significantly higher than controls (14.8x10^9/L vs 10.3x10^9/L, p=0.008 and 14.4 vs 10.3x10^9/L, p=0.002). Median length of stay (LOS) was significantly longer for C1 (12 versus 10 days, p=0.011) and C1+C2 (14 vs 10 days p=0.011) than controls. There was no significant difference in LOS between C3 and controls. 30-day mortality rate was significantly higher for C1 cases (15.9% vs 6.0%, p=0.002) and C1+C2 (13.3% vs 6.0%, p=0.007) versus controls.

The significant risk factors according to diagnostic categories are shown in Figure 1. There were no significant risk factors identified for C3 patients.

**Conclusions:** There are significant differences in outcome between patients diagnosed as toxin positive versus only CTC positive cases, when compared with controls, such as higher mortality rates and length of stay in toxin positive individuals. Risk factors for the development of toxin positive CDI were observed, but there were no risk factors identified for the presence of the organism alone, e.g. increasing age, use of antibiotics and increased co-morbidities appear to be a risk factors for toxin positive CDI, but not acquisition of the organism itself.
Figure 1. Risk factors for different CDI diagnostic categories

**In vitro activity of imipenem/relebactam against non-Morganellaceae Enterobacterales, Pseudomonas aeruginosa and Acinetobacter baumannii isolates from patients with respiratory tract infections in the United States: SMART 2016-2018**

Krystyna Kazmierczak*1, Daryl Depestel2, Katherine Young2, Mary Motyl2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Merck & Co., Inc., Kenilworth, United States

**Background:** Relebactam (REL) is a diazabicyclooctane inhibitor of class A and C β-lactamases approved in the United States (US) in combination with imipenem and cilastatin for treatment of complicated intra-abdominal and urinary tract infections. A phase 3 clinical trial comparing imipenem/cilastatin/REL to piperacillin/tazobactam (TZP) for the treatment of hospital-acquired or ventilator-associated bacterial pneumonia (RESTORE-IMI 2) was recently completed. This study evaluated the in vitro activity of imipenem and REL (imipenem/REL), TZP and other comparators against organisms collected from US patients with respiratory tract infections (RTI) as part of the SMART surveillance program, including the most common pathogens identified during RESTORE-IMI 2.

**Materials/methods:** Twenty-eight medical laboratories each collected up to 100 consecutive clinically-significant gram-negative pathogens from patients with RTI. MICs were determined by broth microdilution and interpreted using CLSI breakpoints with the exception of imipenem/REL, for which US Food and Drug Administration (FDA) breakpoints were used.

**Results:** *K. pneumoniae, P. aeruginosa, A. baumannii, E. coli, and E. cloacae* were the five most prevalent gram-negative pathogens, in rank order, isolated from patients during the RESTORE-IMI 2 trial. These organisms composed 11.7%, 32.4%, 2.7%, 10.5%, and 5.8%, respectively, of isolates collected from US patients with RTI (n=5832) as part of SMART in 2016-2018. Imipenem/REL demonstrated potent *in vitro* activity against the collection of all non-Morganellaceae Enterobacterales (NME) (MIC90, 0.5 mg/L; 97.6% susceptible), *K. pneumoniae, E. coli* and *E. cloacae* isolates (MIC90, 0.25-0.5 mg/L; ≥99.7% susceptible), and *P. aeruginosa* (MIC90, 2 mg/L; 93.0% susceptible) collected in the US (Table). In contrast, imipenem/REL showed limited activity against *A. baumannii* isolates, which often harbor class D β-lactamases (MIC90, >32 mg/L; 53.9% susceptible). Similar activity was observed across US census regions, with susceptibility to imipenem/REL consistently exceeding that of TZP against individual species, the combined collected of most prevalent organisms, and all NME by 5-30 percentage points.

**West:** California, Colorado, Utah, Washington; **Midwest:** Illinois, Indiana, Iowa, Michigan, Minnesota, Nebraska, Ohio, Wisconsin; **Northeast:** New York, Pennsylvania; **South:** Florida, Georgia, Kentucky, North Carolina, Texas. REL, relebactam; TZP, piperacillin/tazobactam; S, susceptible. NME, non-Morganellaceae Enterobacterales.

* US FDA breakpoints for imipenem/REL: ≤1/4 mg/L, susceptible; 2/4 mg/L, intermediate; ≥4/4 mg/L, resistant (Enterobacterales); ≤2/4 mg/L, susceptible; 4/4 mg/L, intermediate; ≥8/4 mg/L, resistant (*P. aeruginosa*). No FDA breakpoints were assigned for *A. baumannii*; CLSI breakpoints were applied for comparison only.

**Conclusions:** IMI/REL demonstrated potent *in vitro* activity against non-Morganellaceae Enterobacterales, including the three most prevalent species identified during RESTORE-IMI 2, and *P. aeruginosa* collected in the US. Imipenem/REL could provide an important option for treatment of RTI caused by organisms with similar resistance mechanisms.

Accuracy of emergency department diagnosis of community-acquired pneumonia

Aaron Bloch*1, Vijaya Sundarajan2, Olivia Wawryk2, Ahmed Siddiqui1, Anmol Attreya3, Kumar Visvanathan1,3

1St. Vincent’s Hospital Melbourne, Fitzroy, Australia, 2La Trobe University, Melbourne Campus, Bundoora, Australia, 3University of Melbourne, Parkville, Australia

Abstract third-party references: St Vincent’s Hospital Melbourne

Background: Community acquired pneumonia (CAP) is usually diagnosed in the emergency department (ED), with patients commenced on broad spectrum antibiotics. A review of the literature indicates that around one third of these patients may not truly have CAP. Misdiagnosis leads to delays in obtaining an accurate diagnosis and commencing appropriate treatment. Additionally, unnecessary use of broad spectrum antibiotics contributes to bacterial resistance. Little research has been undertaken into the accuracy of pneumonia diagnosis in Australia.

Materials/methods: The sample was identified from coded ED data in 2017 at a tertiary hospital in Melbourne, Australia. Charts for ED visits with a code for CAP, excluding those hospitalized within 14 days, underwent a standardized chart review. A strict definition of CAP was applied using international guidelines, based on presence of radiographic chest infiltrates, accompanied by a characteristic clinical presentation. Analyses were performed using STATA 15.0.

Results: Of 133 patients with an ED diagnosis of CAP, 34% (n=45, CI: 26-42%) were found to have an alternate diagnosis when a strict definition of CAP was applied. Although symptoms consistent with a lower respiratory tract infection were present in all patients who were misdiagnosed, only 18% (n=8, CI: 9-32%) had chest X-ray (CXR) changes suggestive of CAP. When the treating physician’s interpretation of the CXR was compared with the official radiology report in the misdiagnosed group, there was a disagreement in 42% of cases (n=19, CI: 28-57%). All patients misdiagnosed received antibiotic treatment on admission. Over fifty-one percent of these patients were deemed to have received unnecessary antibiotics courses (n=23, CI: 36-66%) for a median of 4 days (IQR=3). Patients misdiagnosed with CAP were older, with a median age of 76 (IQR: 64-82) compared to a median age of 68 (IQR 48-84) in the correctly diagnosed CAP group.

Conclusions: There is a high rate of misdiagnosis of CAP in the emergency department with 34% of cases having an alternate diagnosis. Many patients misdiagnosed as having pneumonia had symptoms of an acute respiratory infection but often did not have radiological changes consistent with pneumonia. Further work is underway to determine factors that influence the rate of misdiagnosis.

Abstract 3697

**An agent-based model to simulate the transmission of glycopeptide-resistant enterococci in hospital according to several control strategies**

Stéphanie Deboscker¹, Thierry Lavigne⁎¹, François Severac¹, Céline Ménard¹, Nicolas Meyer¹, Jean Gaudart²

¹Hopitaux Universitaires Strasbourg, Strasbourg, France, ²Ap-Hm, Marseille, France

**Background:** We studied the epidemic spread of glycopeptide-resistant enterococci (GRE) between 3 specialized care units (2 conventional units and 1 intensive care unit) according to several control strategies.

**Materials/methods:** The literature review revealed that the most relevant model was the agent-based model (ABM). The parameters of ABM were derived from data observed in our hospital and from data of the literature. We simulated GRE transmission during one year under different scenarios: different rates of hand hygiene compliance for healthcare workers (HCW) in the care of all patients and particularly GRE carrier patients (scenario with contact precautions), geographical cohorting of carrier patients in one of the two conventional care units, and creation of an isolation unit with dedicated HCW.

**Results:** With less than 50% hand hygiene compliance, the spread was not under control. With 80% hand hygiene compliance in the care of all patients, there were no secondary cases in 50% of the simulations. It was the better scenario. The establishment of an isolation unit with dedicated HCW was efficient when the level of hand hygiene compliance was low. The simple geographical cohorting of GRE carrier patients was less effective.

**Conclusions:** The simulations confirmed the importance of hand hygiene in patient care regardless of their infectious status. The part of the environment remains to be studied.

Abstract 3698

**Diagnosis of bone and joint infections using nanopore metagenomic sequencing of synovial fluids and tissue samples**

Camille Kolenda*, Teresa Street, Nicholas Sanderson, Carol Taunt, Martin Llewelyn, Bridget Atkins, Derrick Crook, David Eyre

1University of Oxford, Modernising Medical Microbiology, Oxford, United Kingdom, 2Oxford University Hospital, Oxford, United Kingdom, 3Royal Sussex County Hospital, Brighton, United Kingdom

**Background:** Metagenomic sequencing has the potential to replace culture for the microbiological diagnosis of bone and joint infection (BJI). However, the large proportion of human DNA in clinical samples reduces the extent of bacterial sequence data obtained. We assessed whether a human DNA depletion protocol improved bacterial DNA recovery sufficiently to identify bacterial species and predict antimicrobial resistance.

**Materials/methods:** Tissues and synovial fluids were processed using standard culture procedures. In parallel, DNA was extracted from 27 culture positive tissue samples, with and without saponin treatment followed by DNase exposure for host DNA depletion. Additional optimisations that aimed to improve human DNA depletion were performed on 35 tissue and synovial fluid samples, including: preexposure to dithiothreitol or mechanical lysis before saponin treatment and extension of the DNase step. Human DNA depletion was assessed by qPCR. Samples were sequenced on the Oxford Nanopore GridION platform. Bacterial species were determined to be present if ≥10% of bases classified as bacterial originated from the species.

**Results:** Human DNA depletion improved pathogen detection in tissues: 84% (26/31) versus 65% (20/31) of bacteria identified by culture were detected using sequencing when tissue samples were treated with or without saponin respectively. In these samples, mean bacterial genome coverage breadth and mean depth significantly increased using saponin (44% versus 28%, p<0.003, and 1.17-fold versus 63-fold, p<0.001, respectively, Figure 1). Extension of the DNase treatment step increased human DNA depletion in synovial fluids, but not in tissues, and correlated with improvement of the bacteria detection rate using sequencing (80% (12/15) versus 67% (10/15)). Antimicrobial resistance prediction was improved by human DNA depletion and optimisation of the protocol for synovial fluids and could be performed in total for 21/37 bacteria identified by sequencing (all with coverage breadth >70%). We detected acquired resistance genes accounting for all beta-lactams, macrolides, fusidic acid and tetracycline resistance phenotypes found by conventional sensitivity testing.

**Conclusions:** Nanopore metagenomic sequencing can provide diagnostic information for BJI from tissue and synovial fluid samples. Human DNA depletion is necessary to obtain sufficient genome coverage for AMR prediction and the protocol should be adapted depending on the sample type tested.

Abstract 3700

Clinical development of a meningococcal group A, C, W, and Y tetanus toxoid conjugate vaccine
Lidia Serra1, Paul Balmer1, John L. Perez1, Paula Peyrani1, Jamie Findlow2, Susan Mather1, Matthew Marsden1, Chris Webber4

1Pfizer Inc, Pfizer Inc, Collegeville, United States, 2Pfizer Ltd, Tadworth, United Kingdom, 3Pfizer Ltd, Sandwich, United Kingdom, 4Pfizer Ltd, Hurley, United Kingdom

Abstract third-party references: Supported by Pfizer

Background: Meningococcal serogroup W (MenW) and Y (MenY) disease has proliferated in Europe in recent years, affecting all ages. MenW cases are often associated with a hypervirulent ST-11 strain and a more recently emergent ST-9316 strain, which primarily affects children <4 years of age. In response, many countries updated their immunization programs to include quadrivalent meningococcal (MenACWY) vaccines [Figure], often replacing monovalent MenC vaccines.

MenACWY-TT (Nimenrix®) is a MenACWY tetanus toxoid conjugate vaccine licensed in the European Union and 49 other countries. It is administered to infants as a 2-dose [6 weeks–<6 months] or 1-dose [6–<12 months] primary series plus 1-dose booster in the second year of life, and as a single dose from age 12 months. Booster dosing can be administered from age 12 months if previously vaccinated with a conjugated or plain polysaccharide meningococcal vaccine.

Materials/methods: Immunogenicity and safety data from MenACWY-TT clinical studies supporting licensure are summarized.

Results: Across studies and age groups, MenACWY-TT elicited comparable antibody responses against serogroup C compared with MenC vaccines in infants/toddlers and against serogroups A/C/W/Y compared with MenACWY vaccines in other age groups, with robust antibody responses after booster dosing. Recent data demonstrate antibody persistence through 10 years after primary MenACWY-TT vaccination and 6 years after booster dosing, which were comparable to those following MenC vaccination for serogroup C. MenACWY-TT can be concomitantly administered with many typically recommended vaccines.

MenACWY-TT had an acceptable safety/reactogenicity profile in a pooled analysis of toddlers, children, adolescents, and adults [n=9621] and separate studies in older adults (>55 years; n=274), infants [n=1052], and toddlers receiving a booster dose [n=1008]. Reactogenicity profiles were generally similar across age groups and doses.

Conclusions: The MenACWY-TT clinical study program demonstrated consistency of vaccine-induced immunogenicity and safety across age groups. Immune responses persisted through 10 years after primary vaccination and 6 years after booster dosing. These data support MenACWY-TT licensure and current recommendations to prevent meningococcal group A/C/W/Y disease from age ≥6 weeks, which may help reduce the increasing burden of MenW and MenY disease in Europe.

Funded by Pfizer.

Abstract 3704

Modulation of antibiotic-associated virulence of Pseudomonas aeruginosa in cystic fibrosis bacterial biofilms
Marwa Hassan¹, Niamh Harrington*¹, Freya Harrison²

¹University of Warwick, School of Life Sciences, Coventry, United Kingdom

Abstract third-party references: School of Life Sciences, University of Warwick, Coventry, UK

Background: Bacterial biofilms are known to have high antibiotic tolerance which directly affects clearance of bacterial infections in people with cystic fibrosis (CF). Current antibiotic susceptibility testing methods are either based on planktonic cells or do not reflect the complexity of biofilms in vivo. Consequently, inaccurate diagnostics affect the treatment choice, preventing bacterial clearance and developing antibiotic resistance. This leads to prolonged ineffective treatment.

Materials/methods: In this study, we are using an ex-vivo biofilm lung model to study antibiotic tolerance of Pseudomonas aeruginosa in a single and co-infection with Stenotrophomonas maltophilia. Sections of pig bronchiol e were dissected, prepared and infected with clinical isolates of P. aeruginosa and/or S. maltophilia and incubated in artificial sputum media to form biofilms, as previously described. Then, lung-associated biofilms were challenged with antibiotics, at therapeutically relevant concentrations, before their bacterial load and virulence were quantified and detected, respectively.

Results: The results demonstrated minimal effect on the bacterial load with ciprofloxacin and meropenem, with the later causing an increased production of protease and pyocyanin of P. aeruginosa. Comparison with combination of meropenem and tobramycin did not show any additional decrease in bacterial load but demonstrated a slight decrease in total protease and pyocyanin production. In co-infection, S. maltophilia modulated the persistence and virulence of P. aeruginosa, which was strain dependent.

Conclusions: P. aeruginosa showed high levels of persistence and increased virulence production which negatively would affect lung functions. In co-infection, it was further protected even against levofloxacin, which might derive increased antibiotic resistance in mixed CF infections. Therefore, we demonstrate a realistic model for understanding antibiotic resistance and tolerance in biofilms clinically and in anti-biofilm drug development.

Abstract 3706

Microbiological surveillance of duodenoscope reprocessing following an outbreak with OXA-48 producing *Klebsiella pneumoniae*

Axel Kola*1, Kathrin Kelterborn2, Frank Schwab2, Petra Gastmeier1

1Charité University Medicine, Institute for Environmental Medicine and Infection Control, Berlin, Germany, 2Charité CFM Facility Management GmbH, Unit for Medical Device Processing, Berlin, Germany

**Background:** Between December 2012 and February 2013, Charité University Medicine, Berlin, a tertiary hospital with 150,000 hospital admissions a year, experienced an outbreak with OXA-48 producing *K. pneumoniae* due to ERCP which involved 12 patients. In consequence, several improvements were made to the reprocessing process of the duodenoscopes: i) strict adherence to the procedures recommended by the different manufacturers of the duodenoscopes ii) use of connectors for the duodenoscope washing machines as recommended by the manufacturers iii) implementation of Standard Operation Procedures. To increase the sensitivity of the quarterly microbiological surveillance testing, brushing of the working channel was added to the procedure recommended by German guidelines.

**Materials/methods:** Duodenoscopes were sampled by flushing the working channel with 20 ml of sterile saline solution, brushing and then flushing it again. A 10 ml sample of the each flushing solution (before / after brushing) was neutralized, filtered and incubated on Columbia agar plates at 36±1°C. After 48 hours, colony forming units (cfu) were counted. In addition, the cantilevered elevator mechanism of the duodenoscopes was swabbed. Swabs were enriched in trypticase soy broth (TSB) for 48 hours at 36±1°C. Subsequently, the enriched TSB samples were cultured on Columbia and MacConkey plates.

**Results:** Channel flushing:

![Image](image_url)

Figure 1: Number of duodenoscopes undergoing microbiological surveillance 2013 - 2018 and the cfu’s of filtered flushing solutions. A limit of < 10 cfu / 10 ml is in concordance with the German guidelines for successful reprocessing.

Elevator mechanism swabbing: No pathogens were detected.

**Conclusions:** The reprocessing procedure of duodenoscopes improved substantially. In 2018, none of the microbiological surveillance samples exceeded the limit of < 10 cfu [versus 43% in 2013].

Microbiological surveillance testing by brushing and flushing the channels had higher sensitivity than just flushing the channels [10 of 16 limit violations would have been missed without brushing].

The complex design of duodenoscopes requires accurate and stringent reprocessing and adherence to the manufacturer's recommendations.

An opportunity for antimicrobial stewardship in urinary tract infections using rapid tests directly on urine samples

Ana Alvarez-Uria*1,2, Almudena Burillo1,2, Laura Jiménez-Navarro2, Nadire Perez2, Cristina Sánchez-Sánchez2, María Palomo1,2, María Olmedo Samperio1,2, Patricia Muñoz1,2,3,4, Emilio Bouza2,3,4

1Hospital Gregorio Marañón, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3Complutense University of Madrid, Madrid, Spain, 4CIBERES, Madrid, Spain

Abstract 3707

**Background:** Time to identification and antimicrobial susceptibility testing (AST) of microorganisms causing urinary tract infections (UTIs), impacts antimicrobial treatment. We propose a “Fast Track” algorithm for early etiological diagnosis of complicated UTIs, based on rapid tests directly on urine samples, combined with antimicrobial stewardship.

**Materials/methods:** Prospective study in a 1200-bed tertiary hospital from October 2018 to June 2019. Adult hospitalized patients with blood cultures taken and a urine sample received in the Microbiology laboratory were evaluated. Patients with microorganisms seen in gram stain of uncentrifuged urine were finally included. Direct identification using MALDI-TOF and direct AST were performed. Detection of carbapenemase production was evaluated by PCR (Xpert Carba®) when *Klebsiella pneumoniae* was identified by MALDI-TOF. Rapid results were informed to physicians in charge of each patient and antimicrobial adjustment was advised by a clinical microbiologist within the working shift. Results and turnaround time (TAT) were compared for both rapid and conventional methods. Antimicrobial adjustment within 24 hours after rapid results was recorded.

**Results:** During the study period, 1535 urine samples were evaluated. Of them, 269 (17.5%) ended to have a positive urine culture (>10^5 cfu/ml). Of these 269 urines, microorganisms were seen in gram stain in 212 samples (79%) from 211 patients. Compared to standard urine culture, MALDI-TOF identified, directly on urine, 69% of gram negative bacilli (GNB), 55.5% of gram positive cocci and 0% of yeasts. Out of the 22 GNB identified as *K. pneumoniae*, 5 were OXA-48 producers and all were early detected in urine by Xpert Carba®. Mean TAT were as follows: identification by MALDI-TOF directly on urine, 4 hours; preliminary AST, 22h; identification of microorganism in standard culture, 28h; standard AST report, 94h. Empirical treatment was considered adequate in 89 patients (42%). Of the remaining 123, rapid results lead to a change in treatment within 24h in 87 episodes (70.7 %), either de-escalation or adjustment due to resistance.

**Conclusions:** The proposed diagnostic algorithm provides advanced information, within 4 hours, in 79% of all episodes of UTIs requiring admission in our Hospital, with an important impact on antimicrobial stewardship during the first 24 hours.

**Presenter email address:** ana.miyares@yahoo.es
Posaconazole versus voriconazole as antifungal prophylaxis for invasive fungal diseases in patients with haematological malignancies

Reem Almutairy*1, Mansoor Khan1, Majed Shamrani1, Hassan Almarhabi1, Mohamad Aseeri1, Doaa Naeem1

1King Abdulaziz Medical City, Jeddah, Saudi Arabia

Background: The incidence of Invasive Fungal Diseases (IFDs) has been dramatically increased in patients with hematologic malignancies due to prolonged neutropenia. IFDs are associated with significant morbidity and mortality. Due to these risks, international guidelines have recommended antifungal prophylaxis for Acute Myeloid Leukemia (AML) and Myelodysplastic syndromes (MDS) patients. Posaconazole has been recommended as the prophylactic agent of choice in these patients. Also, voriconazole has been recommended by guidelines with different levels of recommendations. Data on a direct comparison between Posaconazole delayed-release tablets (DR) and Voriconazole for IFD prophylaxis are lacking. Therefore, we aim to compare the efficacy and safety of the fungal prophylaxis; voriconazole versus posaconazole in AML/MDS patients at Princess Nourah Oncology Center (PNOC), Jeddah.

Materials/methods: Retrospective chart review study for eligible patients from January 2017 to February 2019 to identify the breakthrough IFD rates and assess the frequency of adverse events within AML/MDS patients at PNOC, Saudi Arabia.

Results: A total of 48 patients (130 chemo cycles) were included in the study: 50 using posaconazole (DR) and 80 using oral voriconazole as antifungal prophylaxis. The incidence rates of IFD in the posaconazole group was 8.0% (4/50) of those 2 were probable, and 2 were possible infections while 6.26% (5/80) of patients in the voriconazole group have developed IFD of them 4 had a possible infection, and one had a probable infection (p=0.7325). A higher percentage of patients in the voriconazole group discontinued prophylaxis due to adverse events (5 patients vs. 2 patients). Use of voriconazole as antifungal prophylaxis for 15 days in 130 cycles in 48 AML/MDS patients would cost 1,755,500 SR in comparison to the cost of the posaconazole for the same duration of 1,350,130 SR. So, use of voriconazole would save 1.13 million SR and is more cost effective when used as antifungal prophylaxis in AML/MDS patients in comparison to posaconazole although it is category 1 recommended antifungal prophylaxis in international guidelines.

Conclusions: Our study has shown that both posaconazole and voriconazole have comparable efficacy and safety in the prevention of IFD in AML and MDS receiving chemotherapy but voriconazole is more cost effective.

**French Urinary Tract Infections in Healthcare Facilities (FURTIHF): an historic cohort**

Leslie Grammatico-Guillon*1;2;3, Sixtine De Lafforest3, Alexandre Magnier4;5, Fabien Saint6;7, Franck Bruyere2;3;8

1CHRU de Tours, Unit of Epidemiology and Public Health, Tours, France, 2François Rabelais University, Comité d’infectiologie de l’Association française d’urologie (CIAFU), Tours, France, 3François Rabelais University, School of Medicine, Tours, France, 4CHU de Tours, Tours, France, 5Centre hospitalier universitaire d’Angers, Angers, France, 6Centre Hospitalier Universitaire Amiens, Department. Urology and Transplantation, Amiens, France, 7Association française d’urologie, Comité d’infectiologie de l’Association française d’urologie (CIAFU), Tours, France, 8University Hospital of Tours, CHRU de Tours, Tours, France

**Background:** Urinary tract infections (UTI) are so common, including very various infections: cystitis, acute pyelonephritis (APN), prostatitis or kidney abscesses but their incidence remains unknown. UTIs could lead to hospitalization in acute care settings and a substantial UTI amount is also hospital-onset UTIs. The incidence of UTIs in France is unknown. The objective was to assess performance parameters of an UTI case definition based on the French hospital medico-administrative databases (F-DRG: PMSI) and estimate the national incidence of UTIs in acute-care settings.

**Materials/methods:** An historic cohort of adult patients with UTIs hospitalized in France was performed using the PMSI databases 2014-2018. Hospital stays with at least one ICD-10 code of UTI were selected via the F-DRG algorithm built by a multidisciplinary team (ID specialists, urologists, epidemiologists). The performance parameters were calculated by reviewing 500 medical reports as gold standard (250 cases/250 non cases according to the F-DRG definition), blindly by physicians in charge of the patients. The national incidence rate was estimated after adjusting on the predictive positive value (PPV) of the case definition.

**Results:** The internal validation of the algorithm showed: PPV 82.7% [74.1%-91.2%], predictive negative value and sensitivity 100%, specificity 85.2% [77.2%-93.3%]. From 2014 to 2018, over 2 million acute UTIs (n=2,083,973) were hospitalized in France, occurring mainly in female, and of whom 36% were device-associated UTIs. Acute cystitis represented almost 2/3 of the cases (66%), followed by APN (22%) and prostatitis (12%). The most frequent comorbid conditions were diabetes mellitus (15%), obesity (9.5%), chronic respiratory disease (9%) and chronic kidney failure (7%). The adjusted incidence rate of UTIs hospitalized in France was 67 4 cases/100,000 inhabitants, stable over the period and increasing with age.

**Conclusions:** With a validated and performant algorithm, this national cohort study is the first to date to estimate the incidence of hospitalized UTIs in France. UTIs, even if not severe, are very common, representing a substantial burden of care. Further analyzes of the French medico-administrative databases using the algorithm will provide data for more informed goals-of-care discussions and may help target hospital UTIs surveillance and prevention, especially in device-associated UTIs.

Screening of bovine and human bacterial strains by diagnostic assays for detection of β-lactamases

Frédéric Cawez1, Paola Mercuri1, Marylène Vandevenne1, Virginie Guérin2, Damien Thiry2, Jacques Mainil2, Marc Saulmont3, Pierre Bogaerts4, Moreno Galleni*1

1University of Liège, Center for Protein Engineering, Biological Macromolecules Lab, Liège, Belgium, 2University of Liège, Laboratory of Bacteriology, Department of Infectious and Parasitic Diseases, FARAH, Liège, Belgium, 3ARSIA, Association Régionale de Santé et d'Identification Animale, Ciney, Belgium, 4CHU UCL Namur Site de Godinne, Laboratoire de biologie clinique, Yvoir, Belgium

Abstract third-party references: SPF santé public, University of Liège

Background: The intensive use of β-lactam antibiotics selected resistant environmental and nosocomial bacterial strains. Among all bacterial resistance mechanisms, expression of enzymes called β-lactamases (BLA) stays the major cause of resistance in bacteria. Today, we count around three thousand bla genes. A goal of this work is to develop specific diagnostic assays in order to assess the type of β-lactamases expressed by bacteria.

Materials/methods: To develop our technologies, we focused our work on BLA TEM family. In our lab, we selected a camelid antibody (nanobody), called cAbTEM−1, and a rabbit polyclonal antibody, with high affinity and specificity, directed against TEM enzymes. We decided to screen a large panel of bovine strains from a collection of pathogenic E. coli collected from diarrheic faces, enteritis cases and blood samples. Our tests will be also developing on human bacterial strains collected by the CHU UCL Namur hospital (BE). We assessed the presence of a β-lactamase by three different methods. Firstly, we make PCR to check presence of TEM genes. Moreover, we set up a classical sandwich ELISA assay with the cAbTEM−1 for capture and the polyclonal antibody for revelation. Finally, we develop a technology based on bio-layer interferometry phenomenon (ForteBio).

Results: A panel of 46 pathogenic E. coli strains from bovines, previously characterized by PCR, micro-array and sequencing, were used in order to assess our sandwich ELISA assay. All genetically positive and negative strains for bla TEM had a positive and negative signal, respectively. That means our assay is very specific, recognizing TEM WT but also TEM IRT and TEM ESBL, and very sensitive with a limit of detection around 1 ng/mL of antigens.

Conclusions: At this stage of our work, we confirmed that our ELISA assay works for detection of TEM BLA. Finally, the presented data give us the possibility to develop our technologies for detection of other β-lactamases families such as other ESBLs and/or carbapenemases. For these reasons, we continue to select nanobodies against interesting BLAs and to develop those technologies in order to favor a rapid sensitive and robust diagnostic assays.

Abstract 3714

**Current practices and evaluation of barriers and facilitators to surgical site infection prevention measures in Jimma, Ethiopia**

Andrew Lang*, Leigh Berman¹, Beshea Gelana², Daniel Yilma³, Dawd Siraj², Daniel Shirley²

¹UW Health, Madison, United States, ²University of Wisconsin School of Medicine and Public Health, Madison, United States, ³Jimma University, Jimma, Ethiopia

**Abstract third-party references:** This project was funded/ partially funded through a Faculty and Staff Travel Award from the University of Wisconsin-Madison Global Health Institute

**Background:** The burden of surgical site infection (SSI) is high in low- and middle-income countries (LMIC) such as Ethiopia. In Ethiopia, SSI complicates 10-20% of surgeries. The WHO has provided guidelines for implementation of SSI prevention tools, but many barriers exist. We sought to understand the barriers and facilitators to SSI prevention in Jimma, Ethiopia.

**Materials/methods:** Interview participants and surgical procedures were selected by convenience sampling, but efforts were made to include a variety of healthcare providers and types of surgery. Theoretical saturation determined participant number. An interview guide was designed to probe knowledge, barriers, and facilitators within the SEIPS model’s five components of the work system: tools and technology, person, organization, task, and environment. Interviews were recorded, transcribed, and coded thematically using the qualitative data analysis software QSR Nvivo (Version 12.4.0). An observation checklist was created based on WHO and UW Health SSI prevention bundles.

**Results:** Twenty healthcare providers were interviewed resulting in 543 interview excerpts which were coded into themes. Of these, 64% were deemed barriers and included shortage of supplies [antiseptics, water, and gloves], lack of protocols or guidelines, low involvement of an Infection Prevention team, and lack of training on SSI prevention. Facilitators included sterile instrument indicators, culture of communication around maintenance of sterility, and knowledge about SSI prevention. In 19 total surgeries observed, 100% compliance was noted for surgical scrub, glove use, sterile instrument sterility, incision site cleaning, maintenance of sterility, fraction of inspired oxygen kept >=50%, and wound care completed post-operatively. Surgical Safety Checklist use, antibiotics given within 120 minutes of incision, and OR door kept closed during surgery were observed in 95% of cases. Peri-operative antibiotics were discontinued within 24 hours in 79%, and all patients who received antibiotics received ceftriaxone. Pre-operative bathing and glucose monitoring were rare.

**Conclusions:** While many barriers to SSI prevention exist, our findings help identify several areas towards which resources can be directed to improve patient safety. Highest priorities include improved communication with and education by the Infection Prevention team, formation of guidelines and improved access to them, and standardization of supply chain for antiseptics and gloves.

Comparative study of two susceptibility testing methods for carbapenem-resistant Klebsiella pneumoniae clinical isolates

Areti Tychala1,2, Aikaterini Stamou1, Paraskevi Mantzana1, Georgios Meletis1, Fotini Netsika1, Ioanna Gkeka2, Dimitra Papadopoulou1, Harikleia Katsanou2, Georgia Kagkalou2, Olga Vasilaki2, Melina Kachrimanidou3, Lemonia Skoura2, Ethymia Protonotariou*2

1Thessaloniki Psychiatric Hospital, Stavroupoli, Greece, 2AHEPA University Hospital, Department of Microbiology, Thessaloniki, Greece, 3Aristotle University of Thessaloniki, School of Medicine, Department of Microbiology, Thessaloniki, Greece

Background: Carbapenem resistant Klebsiella pneumoniae (CRKP) is a leading cause of life-threatening infections. Therefore, accurate antimicrobial susceptibility testing is crucial for the adequate treatment selection. In the present study, the performance of the Vitek2 automated system [bioMérieux, France] was assessed against the broth microdilution Micronaut-S system [MN] [Merlin, Germany].

Materials/methods: 135 CRKP non-duplicate isolates collected from patients hospitalized in AHEPA University Hospital from 2017 to 2019 were included in the study. The performance of the Vitek2 AST-318 card was compared with the Micronaut-S MDR MRGN-Screening-2 panel. The latter served as reference. MICs were interpreted according to EUCAST breakpoints. Escherichia coli ATCC 25922 was used for quality control. Essential agreement (EA), categorical agreement (CA), minor errors (mE), major errors (ME) and very major errors (VME) were assessed.

Results: Overall 10 antimicrobials were evaluated with both methods. The results are presented in the Table. The overall CA ranged from 33.60% (for amikacin) to 98.45% (for trimethoprim/sulfamethoxazole) while EA varied from 12.78% (for tigecycline) to 90.69% (for ceftazidime). The rate for VME was below 5% for all antimicrobials tested with the exception of colistin (6.01%). ME were observed at >5% for amikacin, fosfomycin, imipenem, and tigecycline.

Conclusions: The MN method reported significantly higher susceptibility rates for amikacin, fosfomycin, imipenem and tigecycline suggesting that these antimicrobials should be furtherly tested with an alternatively method besides the automated one. Our study reinforce the need for further studies regarding the performance of automated systems, especially when multi-drug resistant bacteria are to be tested.

Abstract 3719

Systematic comparison of three commercially available combination disc tests for carbapenemase detection in Enterobacterales isolates

Janko Sattler*1,2, Anne Brunke1,2, Axel Hamprecht1,2,3

1University of Cologne, University Hospital, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research, Partner Site Bonn-Cologne, Cologne, Germany, 3University of Oldenburg, University Hospital, Institute for Medical Microbiology and Virology, Oldenburg, Germany

Background: Early detection of carbapenemases in Enterobacterales is crucial for patient treatment and infection control. EUCAST guidelines propose combination disk tests (CDT) with different inhibitors (e.g. EDTA, boronic acid) for identification of carbapenemases. However, little data on the performance of these assays is available except for areas of high endemicity where only few carbapenemases prevail. In this study, we compare the performance of three commercially available CDT using a collection of molecularly characterized carbapenemase producing Enterobacterales (CPE) isolates.

Materials/methods: Mastdiscs Combi Carba plus (Mast Diagnostica, Reinfeld, Germany), KPC/MBL and OXA-48 Confirm Kit (Rosco, Taastrup, Denmark) and KPC&MBL&OXA-48 disc kit (Liofilchem, Roseto degli Abruzzi, Italy) were challenged with 103 molecularly characterized CPE and 46 non-CPE. Tests were performed according to manufacturers’ recommendations.

Results: Carbapenemases were detected in 85% (Mast), 84% (Rosco) and 88% (Liofilchem) of the CPE. Specificity was 96% (Mast and Rosco) and 85% (Liofilchem). Correct classification of the Ambler class was recorded in 80% (Mast), 81% (Rosco) and 77% (Liofilchem), see Table 1. Mast CDT performed poorly for detection of class A carbapenemases.

<td>100%</td>
</tr>
<tr>
<td>OXA-58 (n=2)</td>
<td>0%</td>
<td>50%</td>
<td>0%</td>
</tr>
</tbody>
</table>

Table 1: Sensitivity of combination disk tests according to Ambler class and carbapenemase subtype.

Conclusions: Performance varied greatly between Ambler classes and test kits. The choice for a CDT should therefore be based on the local prevalence of carbapenemases. Mast CDT worked best for class B carbapenemases, ROSCO for class A and Liofilchem for class D. However, the overall performance of the tests included in this study was comparatively weak (sensitivity 84%-88%). These data suggest that CDT should only be used complimentary (if at all) to other assays like zCIM, colorimetric tests, immunochromatographic tests or PCR.

Abstracts 2020

Abstract 3721

**HBV RNA and HBcrAg: two new biomarkers for monitoring chronic hepatitis B virus infection**

Greta Roncarati*1, Silvia Galli1, Alessandra Moroni1, Giuliano Furlini1

1Operative Unit of Clinical Microbiology, St. Orsola-Malpighi University Hospital, Bologna, Italy

**Background:** Chronic hepatitis B virus (HBV) infection is a highly dynamic process, defined by several serovirological profiles. Presently, HBV eradication is not possible for the constant presence of intrahepatic persistent form of the virus (cccDNA). The detection of cccDNA needs an invasive investigation and, at present, there are no standardized methods. Recent studies suggest new biomarkers to control the transcriptional activity of intrahepatic cccDNA, including HBV RNA and HBcrAg (*Hepatitis B core-related antigen*).

We evaluated those two biomarkers and their correlation to HBV DNA and quantitative HBsAg level in blood samples.

**Materials/methods:** Blood samples from 55 HBeAg-negative infected patients were analyzed. The level of HBV DNA was detected by COBAS AmpliPrep/COBAS TaqMan (Roche), a fully automated viral load quantitative hepatitis B test (ranging from 20 to 1.7 x 10^9 IU/mL). HBsAg was evaluated by Architect (Abbott), the limit of detection declared was 0.05 IU/mL. HBcrAg was measured by chemiluminescent enzyme immunoassay (Fujirebio, Lumipulse GHBcrAg), the range declared was from 2 to 7 Log U/mL. Finally, HBV RNA was detected by a home-made qRT-PCR.

The results were also matched to the HBV genotype and the ALT levels.

**Results:** A total of 55 patients were included in the study. All patients were negative for hepatitis delta virus co-infection.

Overall, a median HBcrAg value of 3.5 Log U/mL was detected. For quantitative HBsAg levels, a range from 2.26 to 4.45 Log IU/mL was identified, while HBV-DNA ranged from 2.42 to 8.30 Logs IU/mL. HBV RNA ranged from 1.76 to 6.82 Log copies/µL.

The HBV RNA levels significantly correlated to HBcrAg (r=0.426; P<0.01) and to ALT levels (r=0.405; P<0.01). On the contrary, we didn't find a significant correlation to HBsAg levels (P=0.658).

Nonetheless, the HBcrAg level significantly correlated with the HBV DNA level (r=0.342; P<0.05).

**Conclusions:** Chronic hepatitis B virus infection is associated with a broad spectrum of clinical profiles. These preliminary observations have been validated in a restrict cohort, the quantization of different biomarkers was also proposed as a novel tool for the monitoring of chronic infected patients.

Further studies are needed to understand and to determine the utility of these assays.

Abstract 3723

The efficiency of antimicrobial coatings in whole blood: development of a realistic in vitro model

Juliane Valtin*1, Carsten Werner1,2
1Leibniz Institute for Polymer Research Dresden, Max Bergmann Center of Biomaterials, Dresden, Germany, 2Technical University of Dresden, Center for Regenerative Therapies, Dresden, Germany

Background: The serious medical consequences and cost-intensive management of catheter-associated blood stream infections have led to an enhanced interest in antimicrobial coatings. Many materials show promising performance in standard microbiological assays, but fail in animal studies. This shows the need for more realistic in vitro models to test antimicrobial coatings in a physiological environment.

Materials/methods: Experimental Design: The setup consists of a microfluidic device which allows the adjustment of shear forces equivalent to those occurring on a catheter surface. A bacterial culture was incubated on the surface for 1 hour to allow bacterial adherence, prior to the incubation with hirudin-anticoagulated whole blood.

Hemocompatibility: In a pilot study, informative parameters of coagulation and inflammation after up to 24 h incubation of bacteria \( [c = 10^4 \text{ CFU/ml}] \) with whole blood were determined.

Bacterial performance: First experiments were run with GFP labelled E. coli (MG1655 eGFP) in blood plasma. The bacterial attachment on the model surface was evaluated after 2, 4, 20 and 24 hours via fluorescence microscopy. Additional results of whole blood incubation and analysis of the biofilm with fluorescence in situ hybridization will be shown.

Results: The preliminary hemocompatibility tests revealed IL-1 \( \alpha \) and MIP-1 \( \beta \) (analyzed by ProcartaPlex) to be the most promising parameters to analyze inflammation after long-term incubation. They reflect the influence of gram-positive and negative bacteria still after 12 and 24 hours while other examined factors (e.g. cell count, CD11b-expression, IFN-\( \gamma \), TNF-\( \alpha \)) lose their significance after 4 or 8 hours.

Figure 1: cytokine expression in whole blood inoculated with S. epidermidis and E.coli in dependency of incubation time

Analysis of bacterial fluorescence signal revealed a significant decrease during the first 2 hours, presumably due to the flushing of non-adherent bacteria. Thereafter the number of bacterial cells remained constant on the used model surfaces (Thermoplastic Polyurethane).

Conclusions: The reported results suggest that our developed in vitro model will be able to evaluate antimicrobial coatings under consideration of the mutual influence of bacteria and human whole blood – an attempt existing in vitro models failed so far.

Clinical diagnostic evaluation of a real-time PCR assay for the quantitative detection of cytomegalovirus from EDTA-plasma and urine samples

Ulrich Eigner, Nadine Hefner, Melissa Kolb, Ulrike Betz

1Labor Limbach, Study Dept. for Infectious Diseases, Heidelberg, Germany

Background: The cytomegalovirus (CMV) is a wide-spread virus and like other members of the herpes virus family, it can cause latent infection. In newborns and individuals with congenital or acquired immune deficiencies or in persons undergoing immunosuppressive therapy, the infection can cause complications and damage numerous organ systems. The aim of the study was to evaluate the clinical performance of the newly commercialized RIDA®GENE CMV assay with EDTA-plasma and urine samples.

Materials/methods: The performance of the RIDA®GENE CMV assay was compared to a reference test - FluoroType® CMV (Hain Lifescience GmbH). The diagnostic sensitivity and specificity were determined by using 100 EDTA-plasma and 104 urine samples from patients with request for CMV diagnostics. In addition, the analysis of quantitation differences in log [IU/mL] between the two assays was evaluated. All samples were pre-determined with FluoroType® CMV and retrospectively analyzed with RIDA®GENE CMV. Analysis of discrepant results was performed with the CMV R-gene® assay (bioMérieux).

Results: The overall diagnostic sensitivity and specificity of RIDA®GENE CMV with EDTA-plasma samples were 100% and 90%, respectively. By comparing to the reference assay, FluoroType® CMV, 66% of the EDTA-plasma samples quantified with RIDA®GENE CMV were within the limits of ±0.5 log difference. In case of urine samples, six were discrepant positive and after discrepant resolution, a diagnostic specificity of 91% was achieved. The overall diagnostic sensitivity of the RIDA®GENE CMV assay was of 100% and in comparison to the reference method, 63.8% of the urine samples were correctly quantified within the limits of ±0.5 log.

Conclusions: The RIDA®GENE CMV assay can be recommended as an efficient and reliable method for the direct qualitative and quantitative detection of cytomegalovirus in EDTA-plasma and urine clinical samples.

Abstract 3729

**Congenital toxoplasmosis: outcomes of newborns from mothers with documented seroconversion out of a multi-centre cohort in two tertiary referral hospitals**

Valeria M.V. Meroni¹, Alice Bonetti¹, Agnese Comelli², Lina Rachele Tomasoni², Francesca Genco¹, Annacarla Chiesa², Federico Prefumo², Vania Spinoni², Silvio Caligaris², Carlo Bonfanti²

¹IRCCS Policlinico San Matteo, Pavia, Italy, ²Spedali Civili di Brescia, Brescia, Italy

**Background:** Primary Toxoplasma gondii infection during pregnancy can cause congenital toxoplasmosis (CT) and documented seroconversion (SC) is the only serological evidence of such event. The aim of our study was to describe the newborns outcomes from a multicenter cohort of seroconverted mothers.

**Materials/methods:** We retrospectively reviewed all T. gondii SCs among pregnant women referred to Brescia (Spedali Civili) and Pavia (IRCCS Policlinico San Matteo) from 2007 to 2017. Serologic data, amniocentesis results, neonatal outcome, antibiotic treatments and characteristics of CTs were recorded.

**Results:** 247 pregnant women were included: 12 with periconceptional infection and 235 with documented SC with a total of 238 newborns expected (3 twin pregnancies). We didn’t record the pregnancy outcome in 23.5% cases. The observed transmission rate was 25.3%; 46.7% among the 3rd trimester SCs, 8.8% among 2nd trimester SCs and 0/38 among the 1st trimester ones. Among the infected fetuses, 12/46 had clinically apparent CT (26.7%) 11 live births (5 with ocular and 7 with CNS localization – 1 newborn with CNS and retina disease localization) and 1 terminated fetus. The clinically apparent CT rate was 20% among the 3rd trimester SCs and 45.5% among the 2nd trimester ones. Two miscarriages and 1 more termination of pregnancy were recorded without any information about fetuses. All the infected newborns were treated with pyrimethamine-sulfadiazine for one year.

Spiramycin was the mother’s first choice treatment (89.8%) and in only 3 cases it was interrupted because of side effects. Six women did not receive treatment and for 4 subjects we didn’t have any records. Amniocentesis was performed in 83/235 cases (35.3%), no complication was recorded and no false positive or false negative results were registered. No CT was recorded among periconceptional infections.

**Conclusions:** The results are in line with the fetal risks reported in literature for T. gondii infection during pregnancy. In our cohort the treatment was promptly initiated after SC evidence. The incidence of CT is lower than expected. The high number of missing data on SC outcomes show how is still difficult to guarantee an efficient multidisciplinary management of such complicated pregnancies.

Abstract 3735

Measles issue in Georgia

Eliza Vashakidze*1, Tamar Megrelishvili1, Ia Mikadze1, Elene Pachkoria1, Nino Kipiani1, Nino Tavelashvili2, Mariam Kvitashvili1

1Tbilisi State Medical University Department of Infectious Diseases, Tbilisi, Georgia, 2Infectious Diseases and AIDS Center, Tbilisi, Georgia

Background: Measles - a vaccine-managed acute viral infection. For Georgia, as well as for many countries around the world, it remains a major health problem. Since the end of 2018 the outbreak Measles has become intense and we are currently experiencing a widespread outbreak that could turn into a full-scale epidemic.

Materials/methods: The purpose of the work was to identify the features of measles [2018-19] according to clinical material of the infectious Diseases and AIDS Center. Measles was diagnosed in 787 patients with measles-specific M antibodies.

Results: 75.2% of patients were adults and 24.8% - the children. The disease progressed in all cases with typical clinical symptoms, with cycle duration, with the development of abundant maculo-papular rash. The hemorrhagic component was reported in 6 adult patients. The most common complication of the disease was acute bacterial bronchitis and pneumonia [87 and 48 cases, respectively]. Lethality occurs in 1 case - patient died from severe distress syndrome which developed as a result of pneumonia. 3/4 of patients had no vaccination at all, and / or their vaccine status was not known.1/4 had the measles vaccine only once, and even more than 10 years ago, in childhood. In adults, hyperpyretic fever was common: intoxication - severe asthenia, appearing dazed, and sometimes somnolence. In 4/5 of patients hyperfermentemia was seemed [2.5-10 times increase], enzymes normalized when clinical signs improved. The dramatic increase in the incidence of measles was preceded by the circulation of the H1N1 virus in population because of this there was the increased incidence of bronchitis and pneumonia.

Conclusions: Our clinical cases analysis fully confirms the importance of the measures that the National Center Diseases Control provides to prevent further spread of the disease [to create a vaccinated layer of population due to fully vaccinating adults and children].

Abstract 3739

A diagnostic accuracy study of a novel blood-based assay for identification of tuberculosis in people living with HIV

Erik Södersten1, Anna Mantsoki2, Romain Wyss2, Dave Persing3, Sara Banderby1, Linda Stromqvist Meuzelaar1, Jacqueline Prieto1, Devasena Gnanashanmugam1, Purvesh Khatri4, Stefano Ongarello2, Samuel Schumacher2, Claudia Denkinger*2,5

1Cepheid, Solna, Sweden, 2FIND, Geneva, Switzerland, 3Cepheid, Sunnyvale, United States, 4Stanford University School of Medicine, Stanford, United States, 5University Hospital Heidelberg, Heidelberg, Germany

Background: Non-sputum triage or diagnostic tests for tuberculosis disease have been identified as a high-priority need for diagnostic development to reach the End-TB targets of WHO. Such a test would aid the identification of the 3 millions of patients currently not diagnosed and reported. A combinatory score based on a novel 3-gene host-signature has shown promise in discriminating TB disease from other respiratory illnesses.

Materials/methods: We evaluated the accuracy of an early-prototype cartridge assay (Xpert Prototype, developed by Cepheid, USA) of this 3-gene signature on biobanked blood samples from people living with HIV (PLHIV) against a comprehensive microbiological reference standard (CMRS, culture and Xpert® MTB/RIF). Whole blood from symptomatic PLHIV in South Africa were collected from February 2016 to August 2017 in PAXgene tubes. We depict results based on performance targets set by WHO and compare the performance of the Xpert Prototype with that of a laboratory-based CRP assay.

Results: Of the 201 patients included, 67 were culture-positive for Mycobacterium tuberculosis. The AUC for the Xpert-Prototype was 0.89 (CI 0.83-0.94) against the CMRS. Considering the Xpert-Prototype as triage test (at nearest upper value of sensitivity to 90%), the corresponding specificity was 55.8% (CI 47.2-64.1). At fixed value of sensitivity near 95% (95.5% nearest upper value; CI 87.6-98.5), the specificity was 25.6% (CI 18.8-33.7). In comparison, the laboratory-based CRP test had AUC = 0.86 (CI 0.8-0.91), and at fixed value of sensitivity near 90% (90.9% nearest upper value; CI 81.6-95.8), would achieve a specificity of 69.0% (CI 60.6-76.3; CRP-value of 12.3 mg/L). Similarly, at a fixed value of sensitivity near 95% (95.5% nearest upper value; CI 87.5-98.4), the specificity was 45.7% (CI 37.4-54.3) (CRP-value of 6.2 mg/L). Considering the Xpert-Prototype as stand-alone diagnostic test, at a specificity of 95%, the test achieved a sensitivity of 65.7% (CI 53.7-75.9). In comparison, CRP-test performance at a specificity of 95.4% (nearest value; CI 90.2-97.9), the sensitivity is only 13.6% (CI 7.3-23.4) (CRP-value of 253.6 mg/L).

Conclusions: In this first accuracy study of a prototype blood-based host-marker assay, we show the possible value of the assay for particularly for diagnosis but also for triage in PLHIV.

Abstract 3742

Variables associated with higher readmission frequency in an OPAT program

Luis E. Lopez-Cortes*,1, Elena Fraile-Ramos2, Juan Manuel Carmona-Caballero2, Maria Gutierrez2, Lola Navarro2, Belén Gutiérrez-Gutiérrez1, Pilar Retamar Gentil1, Julia Fraena2, Jose Angel Pazod2, Maria Victoria Gil-Navarro2, Luque Rafael2, Jose Miguel Cisneros Herreros2

1Hospital Universitario Virgen Macarena, Sevilla, Spain, 2Virgen del Rocio Hospital, Sevilla, Spain

Background: Adequate selection of candidate patients intravenous for outpatient parenteral antimicrobial therapy (OPAT) is a key aspect for clinical success. The aim of this analysis was to describe the reasons of readmission during OPAT to improve the selection of candidate patients.

Materials/methods: Prospective observational study of patients admitted in OPAT in 2 Spanish university hospitals between July 2012 and August 2019. All patients were evaluated by an infectologist previous to the admission in the program. Bivariate statistical analysis using Chi-square test and Mann-Whitney U test, as well as multivariate logistic regression analysis.

Results: Of the 1,225 patients treated in our OPAT program, 128 (10.4%) had an unexpected readmission, and 12 (0.9%) died during this admission. Readmission occurred after a median of 8.5 days (IQR 4-16) in OPAT. Fifty-nine (50.9%) of the patients who had to be readmitted, continue their therapy again in OPAT once the reason for readmission was solved. The most frequent causes of readmission were: unfavorable clinical evolution (44.5%), insufficient control of the source (18%) and decompensation of comorbidity (14.8%). The mean age (p=0.012) and the mean Charlson score (p=0.001) were associated with a higher frequency of readmission. Of the variables included in Charlson score, heart failure (OR 1.78, 95%CI 1.22-2.60), neoplastic disease (OR 1.45, 95%CI 0.99-2.12), and chronic liver disease (OR 1.92, 95%CI 1.12-3.32) were associated with the outcome variable. After stratification by syndromes, abdominal source of the infection was also associated (OR 1.66, 95%CI 1.07-2.57). The clinical experience on OPAT based on the year of inclusion, the centre, and the experience of the infectologist (codified as age under or over 45 years) were not associated with higher readmission. In the multivariate analysis presence of heart failure (aOR 1.92, 95%CI 1.31-2.84), neoplastic disease (aOR 1.53, 95%CI 1.08-2.27) as well as the abdominal source interacting with chronic liver disease (aOR 3.14, 95%CI 0.95-10.35) were the variables associated with higher readmission.

Conclusions: Comorbidity and abdominal source of the infection were the circumstances associated with unexpected readmission in our OPAT cohort. It is crucial to add these variables to the selection criteria of candidate patients for OPAT.

Considerations in the design and analysis of antibiotic duration trials in the presence of non-adherence

Yin Mo*1,2,3,4, Cherry Lim2,3, Mavuto Mukaka2,3, Ben Cooper2,3

1National University Hospital, Singapore, Singapore, 2University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 3Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, 4National University of Singapore, Singapore, Singapore

Background: Non-inferiority trials have been widely adopted to evaluate whether antibiotic treatment duration can be safely reduced. They are also used in other areas of infectious disease research and account for 27% of late phase randomized trials published in leading medical journals in the past two years. However, non-adherence in non-inferiority trials often increases the chance of claiming non-inferiority under the standard intention-to-treat analysis.

Materials/methods: We performed a computer-based simulation study to: i) explore the impact of various patterns of non-adherence and analysis methods on effect estimates; ii) quantify the probability of claiming non-inferiority when long treatment duration is actually inferior; and iii) evaluate alternative analytical methods such as inverse probability weighting and instrumental variable estimation to reduce the chance of incorrectly concluding non-inferiority.

Results: We found that the probability of concluding non-inferiority when long treatment duration is actually inferior depends on whether non-adherence is due to confounding factors that influence both adherence and outcome, and on the actual treatment durations received by the non-adherent participants. Under most patterns of non-adherence, intention-to-treat analysis leads to an inflated tendency to conclude non-inferiority when long duration is actually inferior. Even when adherence is relatively high at 90%, the probability of incorrectly concluding non-inferiority can be as high as 0.1 from the nominal value of 0.025. The direction of bias for the per-protocol analysis depends on the directions of influence the confounders have on adherence and outcome. The inverse probability weighting approach can reduce bias but will only eliminate it if all confounders can be measured accurately and appropriately adjusted for. Instrumental variable estimation overcomes this and gives unbiased estimates even in the presence of unmeasured confounders, but typically requires large sample sizes to achieve acceptable power. We developed an online power calculator allowing for various patterns of non-adherence.

Conclusions: Patterns of non-adherence and potential confounders are important considerations in trial designs. These data from both adherent and non-adherent participants should be collected and analysed. Adjusted analysis of the per-protocol population with sensitivity analyses on confounders and other approaches, such as the instrumental variable estimation, should be considered when non-adherence is anticipated.

Abstract 3748

High levels of carbapenem resistance in paediatric bloodstream infection across WHO regions influenced by variation in relative pathogen prevalence

Aislinn Cook1, Yasmine Yau1, Julia A. Bielicki1, Mike Sharland1

1St George’s, University of London, Paediatric Infectious Diseases Research Group, London, United Kingdom

Background: WHO empiric antibiotic regimens for childhood sepsis do not account for regional variation in pathogen prevalence or resistance rates. Recent data suggests high use of meropenem in child sepsis treatment. This study aimed to assess pathogen variation and its influence on meropenem coverage across WHO regions.

Materials/methods: A questionnaire on aggregate paediatric (0-<18 years) blood culture data from 1 January 2018-31 December 2018 was sent to a global network of paediatric sites. Data requested included total blood cultures taken, number positive, a predefined pathogen list and resistance phenotypes for selected pathogens (e.g. CRE, ESBL, MRSA, VRE). Meropenem monotherapy coverage was estimated at site-level for centres reporting >100 isolates. Coverage was estimated using a Bayesian decision tree model for bloodstream infection antibiograms incorporating intrinsic resistance and EUCAST interpretive guidelines.

Results: A total of 252,022 blood cultures were reported from 51 sites (median: 3179/site, IQR:1395-5069, range:539-23650) across 5 WHO regions of which 6.6% (95%CI:5.7-8.5%; 19788 total) were positive. Excluding coagulase-negative staphylococci (CoNS), Klebsiella spp. was one of the most common pathogens for all regions (AFRO: median:12.1%, IQR:5.0-38.1%; EURO: median:4.0%, IQR:1.9-9.5%; PAHO: median:12.3%, IQR:9.9-12.7%; SEARO: median:11.2%, IQR:5.3-22.5%; WPRO: median:6.7%, IQR:3.7-10.3%); In three regions, S. aureus (AFRO: median:7.8%, IQR:3.4-10.8%, EURO: median:6.3%, IQR:4.1-12.0%, WPRO: median:6.9%, IQR:6.0-8.9%) and E. coli (AFRO: median:4.1%, IQR:2.8-6.1%, EURO: median:5.9%, IQR:5.2-9.8%; WPRO: median:8.1%, IQR:6.6-13.6%) were two of the most common pathogens. Acinetobacter spp. (median:8.9%, IQR:8.1-10.7%) and Salmonella typhi (median: 11.2%, IQR: 0.2-15.0%) were in the top three pathogens in SEARO and Enterococcus spp. (median:6.7%, IQR:0-7.5%) and Candida spp. (median:8.3%, IQR:8-9.5%) were in the top three pathogens in PAHO.

For the 21 sites reporting >100 isolates, meropenem coverage by site ranged between 56% (95%CI:49-62%) and 91% (95%CI:89-93%) (Figure 1). Across all 21 hospitals, Acinetobacter spp. and Pseudomonas spp. were the Gram-negative pathogens with the highest carbapenem resistance however their impact on the coverage estimate is small given their low frequency compared to other pathogens.

Conclusions: Current global high use of empiric meropenem is not supported by the coverage levels identified. Future empiric guidance should consider variation in both pathogen prevalence and resistance.

Figure 1. Carbapenem coverage estimates for 21 centres reporting >100 isolates.

Abstract 3753

**Escherichia coli** bloodstream infections: a multinational population-based perspective

Melissa Mackinnon*1, Scott McEwen2, Outi Lytyikainen1, Gunnar Jacobsson3,4, Peter Collignon5, Daniel Gregson6,7, Kevin Laupland8,9,10

1University of Guelph, Department of Population Medicine, Ontario Veterinary College, Guelph, Canada, 2Department of Health Security, National Institute for Health and Welfare, Helsinki, Finland, 3Skaraborg Hospital, Department of Infectious Diseases, Skövde, Sweden, 4Gothenburg University, CARE - Centre for Antibiotic Resistance Research, Institute of Biomedicine, Gothenburg, Sweden, 5The Australian National University, Department of Infectious Disease and Microbiology, The Canberra Hospital and School of Clinical Medicine, Canberra, Australia, 6University of Calgary, Departments of Medicine, and Pathology and Laboratory Medicine, Calgary, Canada, 7Alberta Health Services, Calgary Zone, Calgary, Canada, 8Royal Inland Hospital, Department of Medicine, Kamloops, Canada, 9Royal Brisbane and Women’s Hospital, Department of Intensive Care Medicine, Brisbane, Australia, 10Queensland University of Technology, Faculty of Health, Brisbane, Australia

Abstract third-party references: On behalf of the International Bacteremia Surveillance Collaborative

**Background:** *Escherichia coli* is the most common cause of blood stream infections (BSI). However, population-based multi-national comparative data is lacking. Our objective was to define the epidemiology and outcome of *E. coli* BSI in a large multi-national population-based cohort.

**Materials/methods:** All incident *E. coli* BSI occurring among residents of the western interior region of British Columbia (Canada), Calgary (Canada), Skaraborg county (Sweden), Canberra region (Australia), and Finland nationally between 2013 and 2018 were identified. Incidence rates were directly age and sex standardized to the 2018 EU-28 population. Univariable Poisson models were used to analyze temporal and regional variation in standardized incidence rates. The *E. coli* BSI were categorized as community-onset or hospital-onset, whether 30-day mortality occurred and whether they were third-generation cephalosporin (3GC) resistant. Data from all centres was available for calculation of the overall crude incidence rate but some additional analyses were based on a subset of centres.

**Results:** Overall 31,112 incident *E. coli* BSI were identified during 39 million person-years of surveillance for an annual crude incidence of 79.7 per 100,000 population. The standardized incidence rates were 64.2, 68.8, 93.6, and 115.3 per 100,000 person-years for western interior, Calgary, Skaraborg and Finland, respectively. Compared to western interior, the incidence rates from Skaraborg and Finland were significantly higher (IRR:1.46 95%CI:1.26-1.68; IRR:1.79, 95%CI:1.56-2.05, respectively). There was no significant difference in rates between western interior and Calgary (p=0.37) and no significant temporal variation in rates (p=0.35). The *E. coli* BSI were predominantly community-onset (81.6%), and this varied significantly by region (p<0.001). Resistance to 3GC was present in 7.8% and was higher in Calgary, western interior and Canberra as compared to Skaraborg and Finland. The 30-day all-cause case-fatality proportion was 9.7% and ranged from 9.3% (Finland) to 12.8% (western interior). The annual standardized mortality rate was 7.8 per 100,000 population and ranged from 8.4 to 11.2 per 100,000 population [western interior and Finland, respectively].

**Conclusions:** *E. coli* BSI are associated with a major burden of illness. The significant differences in the rates and characteristics of *E. coli* BSI between regions merits future research.

Abstract 3754

Challenges in setting-up and conducting a global multi-centre prospective observational cohort of sepsis in hospitalised neonates: the NeoOBS study

Amy Riddell*1

1St George’s, University of London, Institute for Infection and Immunity, Paediatric Infectious Diseases Research Group, London, United Kingdom

Abstract third-party references: on behalf of the NeoOBS study team

Background: There have been no large international pragmatic trials of the optimal antibiotic management of neonatal sepsis in the hospitalised setting. NeoOBS was designed to inform the design and conduct of trials of treatment of neonatal sepsis caused by MDR pathogens in low-middle income neonatal units.

Materials/methods: NeoOBS is a cohort study of inpatient management of neonatal sepsis in 5 WHO regions. Setting-up and conducting a multicentre, prospective observational study required a multidisciplinary team to ensure good communication and on-going management throughout the study. Web-based programs like REDCap™ (a secure web-based data collection platform hosted at SGUL) and telecommunications applications were used.

Results: Currently 1853 patients have been enrolled from 19 secondary and tertiary neonatal units in 11 countries. Setup took 12 months (Aug2018–2019) with ethics committee (EC) approvals and agreement of contracts taking on average 3½ months (range 1-8 months) and 4.4 months (range 2-7 months) respectively. REDCap™ has been used successfully at a low cost and has proven to be an excellent database due to its user-friendly application to suit the needs of the study. Piloting the database before study launch is essential. Monitoring has been conducted on-site (verification of 10% of consent forms and data at time of visit) and off-site (data verification of case report forms and REDCap from 10% of patients) to ensure data quality remains high throughout the study.

The main challenges have been navigating different EC and contractual processes (including material transfer agreements), translation requirements (>15 different languages), and use of local templates. Delays in EC approvals were due to errors in submissions, irregular/cancelled EC meetings, and additional approvals due to foreign sponsorship. Issues with consent were due to the widespread geographic and social factors of parents who are unable to be present at the hospital, and cultural mistrust of research. Regulations and requirements for exporting bacterial isolates vary widely by country and must be considered before site selection.

Conclusions: Global multicentre studies in neonatal sepsis are complex but NeoOBS has indicated that they can be achieved. Understanding the barriers that have been identified will aid setup and conduct of future sepsis trials.

Abstract 3758

CRISPR-based rapid and ultra-sensitive diagnostic test for smear-negative or sputum-scarce tuberculosis using bronchoalveolar lavage fluid: a prospective, multi-centre study in China

Xian Zhou*1, Jingwen Ai2, Wenhong Zhang1

1Huashan Hospital Affiliated to Fudan University, shanghai, China, 2Huashan Hospital Affiliated to Fudan University, shanghai, China

Background: Rapid and simple-to-use diagnostic methods for tuberculosis are urgently needed. Recent development has unveiled the diagnostic power of CRISPR system in the detection of Mycobacterium tuberculosis complex (MTB) infections. However, its accuracy and impact when performed on bronchoalveolar lavage fluid (BALF) obtained from patients with sputum-scarce or smear-negative TB is unclear.

Materials/methods: We conducted a prospective multicenter study (NCT04074369) in China of 272 HIV-negative patients suspected with pulmonary TB, who were sputum-scarce or smear-negative underwent bronchoscopy. The rapid CRISPR-based assay for TB detection (CRISPR-MTB) was performed on uncentrifuged BALF (300μl), in parallel with culture and the GeneXpert MTB/RIF assay (Xpert). Final clinical diagnosis of the enrolled cases was made by the attending physicians according to clinical guidelines, combining the patient’s clinical manifestations, imaging findings and patient’s responsiveness to anti-TB treatment after one month of follow-up. Patients with MTB culture-positive or Xpert-positive results for MTB would be classified as microbiologically confirmed TB cases.

Results: Of the 272 included, 101 were diagnosed with micro-confirmed TB and 42 were clinical TB cases. Among the confirmed cases, 89 were detected by CRISPR-MTB, which was similar as Xpert (n = 88), but significantly higher than culture (n = 62, p < 0.001). Among clinically diagnosed cases with negative Xpert and culture, CRISPR-MTB detected 15 cases. When evaluated in the overall cohort, the CRISPR-MTB test exhibited an overall improved sensitivity over both culture (73% vs 44%, p <0.001) and Xpert (73% vs 62%, p = 0.017), without compromise in specificity (126/129, 98%). All three CRISPR-MTB false positive patients had a history of tuberculosis. With processing time around 1.5 hours, the full turnaround time of CRISPR-MTB test in clinical practice, from the sample collection to reporting results to clinicians, was within 24h, which was same as Xpert but significantly shorter than culture.

Conclusions: The CRISPR-MTB test exhibits an improved overall diagnostic performance over culture and Xpert in patients with sputum-scarce or smear-negative TB and offers great potential as a new diagnostic technique for pulmonary tuberculosis.

**Abstract 3764**

**In vitro activity of carbapenemase-producing Enterobacterales to mecillinam**

Frieder Fuchs*, Axel Hamprecht1,2,3

1Universität zu Köln, Medical Faculty, Institute for Medical Microbiology Immunology and Hygiene, Köln, Germany, 2Oldenburg, Institute for Medical Microbiology and Virology, Oldenburg, Germany, 3Cologne, German Centre for Infection Research, Partner Site Bonn-Cologne, Cologne, Germany

**Background:** The increase in antibiotic resistance of Enterobacterales has complicated the treatment of urinary tract infections (UTI). Mecillinam (MCM) is an orally available beta-lactam antibiotic, which is also active against many Enterobacterales producing extended-spectrum beta-lactamases. *In vitro* activity in carbapenemase-producing Enterobacterales (CPE) has been discussed but data is still scarce. In this study we compare the *in vitro* activity of MCM to meropenem, imipenem and ertapenem in a collection of molecularly characterized CPE.

**Materials/methods:** The challenge collection consists of 105 isolates (Klebsiella spp. [N=49], Escherichia coli [N=30], Enterobacter cloacae [n=13], Citrobacter freundii [N=9], Proteus mirabilis [N=3], and Raoultella ornithinolytica [N=1]) producing different carbapenemases (OXA-48-like [N=36], VIM [N=21], NDM [N=22], KPC [N=11], IMI [N=9], IMP [N=6], GES [N=2] and OXA-58 [N=2]). MICs of carbapenems are determined by agar gradient diffusion using MIC test strips, MICs of MCM by agar dilution and disk diffusion methodology.

**Results:** Until 11/2019 susceptibility testing has been completed for 44/105 CPE isolates (table 1). In 6/44 isolates MCM MICs were ≤ 8 mg/L ([*E. coli* [N=4], *K. pneumoniae* [N=2] producing OXA-48-like). In 38/44 isolates (VIM, NDM, KPC, OXA-48-like and IMP producers) MCM MICs were >8 mg/L. Overall MICs for carbapenems ranged from ≤ 0.125 to >32 mg/L with a median MIC of 16 mg/L.

**Conclusions:** Our preliminary data indicate that *in vitro* activity of MCM in CPE is limited to isolates with OXA-48-like carbapenemases. MICs in different OXA-48 variants will be further assessed in this study. Most isolates with low MICs for MCM had also low carbapenem MICs. MCM could be a valuable oral alternative for the treatment of uncomplicated UTI caused by OXA-48-like producing *E. coli*, Klebsiella spp. and *P. mirabilis*.

Abstract 3767

Diagnostic accuracy of toxoplasma Western blot test in suspected seroconversion in pregnancy: a multi-centre study

1IRCCS Policlinico San Matteo, Pavia, Italy, 2Microbiology and Virology unit Fondazione IRCCS Policlinico San Matteo Pavia, Italy, 3Clinical Epidemiological unit Fondazione IRCCS Policlinico San Matteo Pavia, Italy, 4Parasitology-Mycology, University Hospital and Grenoble-Alpes University, Grenoble, France, 5Aix Marseille University, CNRS, IRD, INSERM, AP-HM, URMITE, IHU, Méditerranée-Infection Marseille, France, 6APHP, Hôpitaux universitaires Pitié-Salpêtrière/Charles Foix, Parasitology-Mycology, Paris, France

Background: The high sensitivity of the automated screening tests, widely employed for Toxoplasma gondii serology can yield false positive results due to cross and/or non-specific reaction. On the other hand therapy with spiramycin when IgM are found to be positive could delay IgG production and mask seroconversion. There is the need of second level test to early detect real toxoplasmic seroconversions. We planned an European multicentre study with 4 reference center for the diagnosis of toxoplasmosis: [Pitié-Salpêtrière Paris, CHU Grenoble-Alpes Grenoble, La Timone Marseille, IRCCS Policlinico San Matteo Pavia] to evaluate the diagnostic accuracy of the new LDBIO-TOXO II IgG/IgM Immunoblot (IgG-IgM WB) by LDBio Lyon - France. We also looked at the immunodominant antigen in the IgM WB

Materials/methods: We retrospectively analysed the leftover of laboratory samples after clinical diagnosis of 403 sera: 234 corresponding to 96 toxoplasmic seroconversions [2 to 3 sera/patient] and 169 sera corresponding to 69 patients with cross reactions and/or non-specific IgM [1 to 3 sera/patient]. All the patients had a documented seroconversion with first IgG/IgM negative results and then either IgG/IgM positive or a false positive result. All anonymised samples were processed in blind by LDBio. To validate WB we performed two different analyses: concordance [Cohen’s kappa] with final diagnosis [seroconversion or false positive] and diagnostic accuracy [sensitivity, specificity etc]

Results: The concordance between IgM and IgG type II WB with the diagnosis was good K = 0.89 and K = 0.89, respectively. In 4 cases the appearance of IgM and 46 cases the appearance of IgG was recorded by WB before the traditional tests. Sensitivity was 100% for IgM WB and 93.8% for IgG WB. Specificity was respectively 87% and 95.7%. Looking at the most antigenic bands, P30 was recorded in all but one positive sample and P40 in all but five.

Conclusions: The IgM WB not only detected all seroconversions, and even earlier than traditional tests in four cases, but also well discriminated the false positive results. The definition of immunodominant band will be extremely helpful in the interpretation of the results.

Abstract 3768

Neonatal screening for congenital cytomegalovirus infection: identification of a viral DNA diagnostic cut-off value in saliva samples

Massimo De Paschale¹, Gabriele Turello², Angela Chiareghin², Dino Gibertoni³, Silvia Santandrea², Federico Baiesi², Michele Borghi², Claudia Pavia¹, Maria Teresa Manco¹, Maria Grazia Capretti², Concetta Marsico², Antonia Ruscitto¹, Marta Bellini², Alessandro Porta², Laura Pogliani², Luciana Parola², Pierangelo Clerici¹, Tiziana Lazzarotto*²

¹Microbiology Unit, ASST Ovest Milanese, Presidio Ospedaliero di Legnano-MI, Legnano, Italy, ²Lab of Virology, Microbiology Unit, Polyclinic of St. Orsola, University of Bologna, Bologna, Italy, ³Department of Biomedical and Neuromotor Sciences, Unit of Hygiene and Biostatistics, University of Bologna, Bologna, Italy, *Neonatology Unit, Polyclinic of St. Orsola, University of Bologna, Bologna, Italy, ⁴Pediatrics Unit, ASST Ovest Milanese, Presidio Ospedaliero di Legnano-MI, Legnano, Italy, ⁵Pediatrics Unit, ASST Ovest Milanese, Presidio Ospedaliero di Magenta-MI, Magenta, Italy

Background: Congenital cytomegalovirus (cCMV) infection is the most prevalent infection-related cause of congenital neurological disability and sensorineural hearing loss. CMV-PCR in saliva has excellent sensitivity for cCMV screening. However, literature data has reported evidence that false positive cCMV diagnosis in saliva could be an issue. Viral contamination of newborn saliva samples could happen throughout the peri- and post-partum period. Our prospective multicenter study aims to determine in positive CMV-DNA saliva samples, i) if a viral DNA cut-off value can discriminate a congenitally infected newborn from a non-congenitally infected one, for which the positivity saliva samples are a result of contamination and, ii) if a repeat saliva sample is indicated as confirmatory testing for the diagnosis of cCMV infection or instead, it is mandatory to test a urine sample.

Materials/methods: We will analyze saliva swabs (COPAN UTM, IT) from a minimum of 3150 newborns up to 21 days of age in order to obtain at least 20 congenitally CMV-infected newborns (Z-test at α=0.05; power=0.80), at study sites in two Italian hospitals (Bologna and Legnano-MI). All infants will be classified as having symptomatic or asymptomatic infection. The serological CMV-maternal serostatus before or during pregnancy will be evaluated, when available. The search of CMV-DNA in saliva and urine samples will be performed with a real time-PCR (ELITe InGenius – CMV-MGB Kit, ELITechGroup, IT).

Results: To date, we have enrolled 1847 neonates and identify 13 infected infants, the rate was 0.7%. Twenty-seven (1.5%) of the saliva swabs were false positives and all with a number <250 CMV-DNA copies/ml. Out of 1847 mothers, 1728 (93.6%) knew their CMV serostatus. At birth, 11 out of 13 (84.6%) newborns were asymptomatic, 2 symptomatic newborns had severe bilateral deafness. Both mothers were primarily infected in the first trimester. Fifty-four percent of infected newborns came from maternal primary infection, 31% from non-primary infections and 15% unknown maternal CMV-serostatus.

Conclusions: The strengths of this study include the large number of prospectively collected newborn body fluids samples, the viral load data, the results of confirmatory neonatal urine and saliva tests, the identification of maternal CMV-test in pregnancy and the infant clinical information.

Real-time sampling of travellers to Laos: epidemiology of mobile genetic elements
Steven Dunn1*, Ann Snaith1, Anu Kantele2, Esther Kuenzli3, Jukka Corander4, Alan McNally1

1University of Birmingham, Birmingham, United Kingdom, 2University of Helsinki, Helsinki, Finland, 3University of Basel, Basel, Switzerland, 4University of Oslo, Oslo, Norway

Background: Antimicrobial resistance (AMR) is highly prevalent in low- and middle-income countries. International travel contributes to this substantially: of the 100 million annual visitors to tropical countries, 30–70% become colonized by MDR-GN bacteria. The phenomenon has been well documented, but since sampling has only been conducted after travellers’ return home, data on the actual colonization process are scarce. Further, genomic epidemiology of mobile genetic elements in this context is lacking.

Materials/methods: A group of 20 European volunteers visiting Lao People’s Democratic Republic for three weeks provided daily stool samples. Acquisition of extended-spectrum beta-lactamase-producing gram-negative bacteria (ESBL-GN) was examined by selective stool cultures followed by whole-genome sequencing (WGS) of isolates. Long read data was used to reconstruct plasmid sequences and identify shared mobile genetic elements.

Results: Daily sampling revealed that all participants had acquired ESBL-GN at some time point during their overseas stay, with individual colonisation status varying day to day. WGS analysis revealed a transient pattern of colonization, with sequential acquisition of new strains. All but one participant acquired multiple strains. Participants also shared conserved mobile genetic elements that were distributed across distinct bacterial strains, which conferred resistance to antimicrobials.

Conclusions: This is the first study to characterize in real time the dynamics of acquiring MDR-GN during travel. Our data show multiple transient colonization events indicative of constant microbial competition. It also highlights the importance of considering mobile genetic elements as a separate and crucial aspect of genomic epidemiology.

Genomic and transcriptomic approach to unravel the resistance mechanisms to ceftazidime-avibactam in *Pseudomonas aeruginosa* and *Enterobacter cloacae*

Anja Bösch*, Steven Schmitt, Martin Held, Jacqueline Findlay, Adrian Egli, Helena Seth-Smith, Vladimir Hnic, Valentin Gisler, Hans Fankhauser, Michael Oberle, Philipp Patrick Kohler, Salome Seiffert, Nolte Oliver, Baharak Babouee Flury

1Medical Research Centre, Cantonal Hospital St. Gall, St. Gall, Switzerland, 2Department of Biosystems Science and Engineering, ETH Zürich, Basel, Switzerland, 3University of Bristol, University Walk, School of Cellular & Molecular Medicine, Bristol, United Kingdom, 4Clinical Bacteriology and Mycology, University Hospital Basel, Basel, Switzerland, 5Department of Biomedicine, University of Basel, Basel, Switzerland, 6Institute for Laboratory Medicine, Cantonal Hospital Aarau, Aarau, Switzerland, 7Clinic of Infectious Diseases and Hospital Hygiene, Cantonal Hospital Aarau, Aarau, Switzerland, 8Division of Infectious Diseases and Hospital Epidemiology, Cantonal Hospital St. Gall, St. Gall, Switzerland, 9Division of Human Microbiology, Centre for Laboratory Medicine, St. Gall, Switzerland

**Background:** Ceftazidime-Avibactam (CAZ-AVI) is a novel antibiotic combination effective against multidrug-resistant pathogens carrying β-lactamases from different classes. Knowledge on molecular CAZ-AVI resistance mechanisms is scarce. We use adaptive laboratory evolution combined with deep sequencing to unravel resistance mechanisms of *Pseudomonas aeruginosa* and *Enterobacter cloacae* treated with CAZ-AVI at the genome and transcriptome level. In addition we provide insights into cross-resistance to meropenem (MEM) and allow pre-estimation of the potential resistance development under therapy.

**Materials/methods:** For single-step selections, strains were grown on agar plates containing CAZ-AVI (2x to 16x MIC, fixed AVI concentration of 4mg/L). For multi-step adaptions, cultures were grown in serial passages under sub-inhibitory concentrations (0.25x MIC) of CAZ-AVI or MEM. For CAZ-AVI multistep resistance selection we used the clinical powder (Zavicefta, Pfizer®), in order to display the changes in Avibactam concentration. Changes in MICs were monitored by E-test and the antibiotic concentrations for the next passages were adapted. Three different clones of each isolate were passaged in parallel to detect different resistance trajectories (n= 24 in total). Whole genome as well as -RNA sequencing of the resistant strains was done using the Illumina platform.

**Results:** Single-step selection revealed a CAZ-AVI resistance frequency of 10⁻⁷-10⁻¹⁰ when plated on 2x and 4xCAZ-AVI MIC while no resistant *P. aeruginosa* or *E. cloacae* were isolated on 8x and 16x MIC. When *P. aeruginosa* was cultured in the presence of sub-inhibitory concentrations CAZ-AVI, resistance to CAZ-AVI (up to 42x MIC) and MEM (>1000x MIC) developed (Figure 1ab). Sub-inhibitory concentrations of MEM led to CAZ-AVI resistance at a rate that was dependent on the initial MEM MIC of the parental strain (Figure 1cd). For *E. cloacae*, CAZ-AVI and MEM in sub-inhibitory concentrations only led to intermediate resistance (42x MIC) in 1 of 12 *E. cloacae* cultures and after 60 passages. We are currently analyzing changes in the genome and the transcriptome (RNA-seq) of the resistant strains and their susceptible progenitors to present genes putatively required for elevated resistance.

**Conclusions:** This ongoing study will provide a molecular insight in CAZ-AVI resistance mechanisms and selecting agents for CAZ-AVI resistance in *P. aeruginosa* and *E. cloacae*.

Abstract 3774

**Automation in full genotyping of human papilloma viruses: evaluation of the analytical performance of Anyplex HPV28 assay**

Ben Vanmassenhove*, Anne-Sophie Hervent, Lies Persijn, Liesbeth Vynckier, Gudrun Alliet

1AZ Damiaan, Oostende, Belgium

**Background:** It becomes increasingly important to know which high-risk human papillomaviruses (HR-HPV) types are present because persistent infection is related with cervical cancer and not every type is equally carcinogenic.

Pipetting and washing steps of our current reference method – DNA extraction with MagNA Pure LC32 (Roche) and genotyping with PapilloCheck® assay (Greiner Bio-One) - require a lot of hands on time.

"Seegene All-in-One Platform" is a streamlined automation solution that in combination with the Anyplex™ HPV28 Assay can genotype 19 high-risk and 9 low-risk HPVs (four more than PapilloCheck®).

**Materials/methods:** The test was performed following the manufacturer's instructions. Barcode labelled PreservCyt® (Hologic) samples were directly placed on board of the MICROLAB STARlet platform followed by extraction (STARMag96 Universal Cartridge Kit) and PCR setup. The PCR took place in the CFX96 Cycler (BioRad). Interpretation of melting curves was done by the Seegene Viewer Software. Results were directly sent to the laboratory information system.

The assay was checked for analytical sensitivity, accuracy and precision following Belgian guidelines (Raymaekers et al., 2011).

**Results:**

**Sensitivity:**
A negative PreservCyt® sample was spiked with the WHO HPV16 and HPV18 standards to determine the limit of detection (LOD with a 95% hit rate). The lowest concentration was 10000 international units/ml, correlating with 100 copies/PCR and was lower compared to PapilloCheck® (120 copies/PCR).

**Accuracy:**
65 specimens were tested. 17 external quality controls and 13 plasmids were typed correctly. 33 out of 35 clinical samples gave a concordant result (identical HPV types were detected in single/double infections or two or three identical HPV types were detected in multiple infections with three or four types respectively). In 12 out of 35 clinical samples Anyplex™ HPV28 detected one or more extra types. Two samples with a very low viral load were missed (HPV39 and HPV73).

**Precision:**
One negative and two positive samples with a multiple infection were extracted on 3 different days. PCR was performed on two cyclers. All results were concordant.

**Conclusions:** Anyplex™ HPV28 Assay met all our validation criteria, saved hands on time, avoided pipetting errors and was therefore successfully implemented in our routine diagnostic laboratory.

Abstract 3775

**Treatment of bacteraemia caused by *Enterobacter* spp.: should the potential for AmpC induction dictate therapy?**

Genady Drozdinsky*1, Ami Neuberger2, Mical Paul2, Dafna Yahav3

1Rabin Medical Center, Beilinson Hospital, Department of Medicine E, Petah-Tikva, Israel, 2Rambam Health Care Campus, Infectious Diseases Institute, Haifa, Israel, 3Rabin Medical Center, Beilinson Hospital, Infectious Diseases Unit, Petah-Tikva, Israel

**Background:** Carbapenems are considered treatment of choice for bacteraemia caused by potential AmpC producing bacteria, including *Enterobacter* spp. Data on the effectiveness of therapy with other antibiotics are limited.

**Materials/methods:** A retrospective study, conducted in two centers in Israel, including hospitalized patients with *Enterobacter* bacteraemia treated with either third generation cephalosporins (3GC), piperacillin/tazobactam, quinolones or carbapenem monotherapy, between 2010-2017. The primary outcome was 30-day all-cause mortality. Univariate and multivariate analyses were conducted, introducing type of antibiotics as an independent variable.

**Results:** Included were 277 consecutive patients. Of these, 73 were treated with 3GC as their main antibiotics, 39 with piperacillin/tazobactam, 104 with quinolones and 61 with carbapenems. All-cause 30-day mortality was 16% (45 patients). In either univariable or multivariable analyses, type of antibiotics was not significantly associated with mortality. With carbapenems as reference for multivariable analysis - odds ratio [OR] was 0.708, 95% confidence interval [CI] 0.231-2.176, p=0.547 for 3GC; OR 1.172, 95% CI 0.388-3.537, p=0.778 for piperacillin/tazobactam; and 0.586, 0.229-1.452, p=0.242 for quinolones. Type of antibiotics was not associated with repeated growth of *enterobacter* spp., including bacteremia (p=0.520). Resistance to the treating antibiotics developed in third of isolates (3/9) in each 3GC and piperacillin/tazobactam groups.

**Conclusions:** Type of antibiotic therapy was not associated with increased mortality or repeated growth of enterobacter spp. in cases of *enterobacter* bacteraemia in our cohort. Considering our results and previous studies, using antibiotics other than carbapenems for this infection seems reasonable, though randomized controlled trials are needed to confirm these findings.

Impact of suppression of envelope stress responses on bacterial sensitisation to antimicrobial agents

Esther Recacha*1;2;3;4, Sara Díaz Díaz2;3;4, Jesús Machuca Bárcena1;2;3;4, Ana García-Duque4, Fernando Docobo Perez2;3;4, Alvaro Pascual Hernandez1;2;3;4, Jose Manuel Rodriguez Martinez2;3;4

1hospital universitario virgen macarena, Sevilla, Spain, 2 Red Española de Investigación en Patología Infecciosa (Reipi), Seville, Spain, 3Instituto de Biomedicina de Sevilla, Sevilla, Spain, 4University of Seville, Sevilla, Spain

Background: New targets are necessary to fight against multidrug resistant bacteria. Stress response pathways suppression could be an interesting strategy to get it. The aim of this study was to evaluate the impact of disbalancing envelope stress responses as ςE, Cpx, Rcs, Bae and Psp responses on bacterial sensitization.

Materials/methods: Seventeen isogenic strains belonging to KEIO collection with deletions in genes corresponding to ςE response (rseA and rseB genes), Cpx response (cpxA, cpxR, cpxP and nlpE genes), Rcs response (rcsF, rcsA, rcsC, rcsD and rcsB genes), Bae response (baeR and baeS genes) and Psp response (pspA, pspB, pspC and pspF genes) were selected. Disk-diffusion for 19 antimicrobials, including agents disturbing cell wall (penicillins, cephalosporins, carbapenems, aztreonam, colistin and fosfomycin), protein synthesis inhibitors (aminoglycosides, tetracyclines and chloramphenicol), RNA synthesis inhibitors (rifampin), DNA synthesis inhibitors (fluoroquinolones) and folic acid synthesis inhibitors (sulphonamides and trimethoprim) were used as an initial screening to select the strains whose deleted genes caused an increase in susceptibility relative to wild-type strain E. coli BW25113. Then, gradient strip tests were performed for selected antimicrobials where >3 mm increase was observed by disk-diffusion.

Results: Three hundred and twenty-three antimicrobial/strain combinations were evaluated using disk-diffusion. Fifteen knockouts showed an increase in susceptibility in any of these antimicrobials: ampicillin, ceftazidime, cefepime, aztreonam, ertapenem, imipenem, fosfomycin, amikacin, chloramphenicol and trimethoprim/sulfamethoxazole. The reduction in the MIC of fosfomycin, trimethoprim/sulfamethoxazole, aztreonam, ertapenem, cefepime, ceftazidime and ampicillin ranged from 1,3 to 2,8-fold for rcsD, pspA, pspB and pspC knockouts. The major reduction in MIC was observed for ceftazidime (up to 2,8-fold) and trimethoprim/sulfamethoxazole (up to 2-fold). rcsD, pspA, pspB and pspC knockouts showed MIC reduction for 3 or 4 antimicrobials (Table 1).

Conclusions: Suppression of envelope stress response pathways could be a strategy to sensitize bacteria. According to these results, strains mutated in Psp response showed a greater increase of susceptibility compared to other envelope stress responses. Its role for repairing extensive disruptions of the inner membrane do it essential to bacterial survival, so that it would be the best target to address sensitization.

Abstract 3778

High clinical impact on antimicrobial stewardship using multiplex PCR syndromic panels for severe community-acquired infections: a real-life experience

Ana Alvarez-Uria*1,2, Maricela Valerio Minero1,2, Martha Kestler Hernandez1,2, Cristina Sánchez-Sánchez2, Sofia De La Villa Martinez1,2, Maria Cristina Veintimilla Yanez1,2, Marina Machado1,2, Patricia Muñoz1,2,3,4, Emilio Bouza2,3,4

1Hospital Gregorio Marañón, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3Complutense University of Madrid, Madrid, Spain, 4CIBERES, Madrid, Spain

Background: The different PCR panels of Biofire FilmArray have been individually studied with a focus on etiological diagnosis accuracy. Our study evaluates the clinical impact of using several FilmArray panels for severe community acquired infections (CAI) as a part of an antimicrobial stewardship program run by a Clinical Microbiology Department.

Materials/methods: Prospective study in a 1200-bed tertiary hospital from October 2018 to September 2019. Patients with CAI requiring admission in which sepsis was suspected (blood cultures obtained) with additional samples available in the Laboratory, were included. Meningitis/Encephalitis, Respiratory and Gastrointestinal FilmArray panels were performed in Cerebrospinal fluid (CSF), nasopharyngeal swabs (NPS) and feces respectively. Rapid results were informed to physicians in charge of each patient and antimicrobial adjustment was advised by a clinical microbiologist within the working shift. Conventional methods and FilmArray panels were compared regarding diagnostic yield and turnaround time (TAT). Antimicrobial adjustment within 24 hours after rapid results was recorded.

Results: During the study period, 146 samples from 142 patients were included. Filmarray panels were applied to the following samples: 46 fecal samples, 51 NPS and 49 CSF. Overall, 119/142 patients (83.5%) were clinically diagnosed with an infection. Of them, 102 were diagnosed with an infection covered by the three panels: respiratory infection in 50, gastrointestinal infection in 25 and central nervous system infection in 27. Seventeen cases had infection of other location and the remaining 23 were finally diagnosed with a non-infectious process. Of the 102 patients with an infection covered by the panels, an etiological diagnosis was obtained in 64 (62.7%): 54 (52.9%) by FilmArray panels and 25 (24.5%) by conventional methods (both yielded positive results in 13, 12.7%). Mean TAT was 2.4 hours for FA vs 94 hours for conventional methods. Antimicrobial adjustment within 24 h of rapid results was made in 64/142 patients (45%): de-escalation in 50 (35.2%), escalation in 14 (19.8%).

Conclusions: Filmarray panels provide higher diagnostic performance than conventional methods in a TAT as short as 2 hours. A high impact on antimicrobial stewardship was observed, leading to an early adjustment of empirical treatment in almost half of the patients.

Abstract 3779

An evaluation of an automated broth microdilution platform versus the EUCAST disk diffusion methodology
Philippa D’Arcy-Grover*, Isobel Taylor1

1University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Abstract third-party references: Supported by Thermo Fisher Scientific

Background: The objective of this study was to evaluate the results, performance and workflow of the Thermo Scientific™ Sensititre™ ARIS HiQ™ system (ARIS HiQ) when compared to the EUCAST disk diffusion methodology, using clinical isolates at University Hospital Southampton, UK.

The ARIS HiQ is an automated broth microdilution platform, which has the capacity to incubate, read and interpret up to 100 Thermo Scientific™ Sensititre™ Susceptibility MIC plates (Sensititre plates) simultaneously.

Materials/methods: Antimicrobial susceptibility testing was performed on a total of 358 clinical isolates, consisting of Staphylococcus spp. (n=165), Enterococcus spp. (n=33), Enterobacteriaceae (n=86), Pseudomonas spp. (n=66), and Acinetobacter spp. (n=8) from University Hospital Southampton. Disc diffusion was performed on all isolates using antimicrobial discs and Mueller-Hinton Agar following the EUCAST methodology. All isolates were tested using the relevant Sensititre plates on the ARIS HiQ, according to the manufacturer’s instructions.

Results: ARIS HiQ and disc diffusion results were compared and analysed following the guidelines stipulated in ISO 20776-2:2002. Results have been summarised into groups of Gram positive and Gram negative and are shown in Table 1.

Table 1. Result summary for disc diffusion vs. ARIS HiQ.

Conclusions: This evaluation found the ARIS HiQ to be an accurate alternative to disc diffusion. A review of results demonstrated the benefit of using an automated platform in reducing human error. In addition, automated interpretation and application of expert rules offers a more time efficient approach.

Clinical features and outcomes of patients with *Staphylococcus aureus* bacteraemia of unknown origin

Emi Minejima1, Erika Chan*2, Karen Tan1, Corey Kelsom2, Paul Nieberg3, Annie Wong-Beringer2,3

1University of Southern California School of Pharmacy, LAC-USC Medical Center, Los Angeles, United States, 2University of Southern California School of Pharmacy, Los Angeles, United States, 3Huntington Hospital, Pasadena, United States

**Background:** *S. aureus* bacteremia (SAB) of unknown origin (UO) occurs in a subset of patients and is challenging to manage as source control procedures may not be possible. We compare patients with SAB between those with known origin (KO) and UO to identify distinguishing clinical features and outcomes that could guide clinicians on optimal management.

**Materials/methods:** A multi-center, prospective, observational study of hospitalized SAB patients was conducted. Medical charts were reviewed to obtain relevant demographics, laboratory, and clinical data. Serum cytokine concentrations for TNF, IL-6, IL-8, IL-10, IL-1beta, IL-17, IFN-gamma at SAB onset and 72h after therapy initiation were measured by ELISA. Patient groups were compared on clinical features including cytokine response and outcomes.

**Results:** 1163 patients were included, 19% had UO. Overall mean age was 57y and 34% had MRSA SAB. UO group had more males (79% vs 69%, p=0.0048) and cirrhosis (17% vs 11%, p=0.027), however KO had more patients on dialysis (21% vs 12%), dyslipidemia (19% vs 13%), diabetes (43% vs 32%), anemia (11% vs 6%), and presence of hardware (32% vs 21%) (all p<0.05). UO patients had worse clinical presentation: more had Pitt bacteremia score ≥4 (17% vs 12%, p=0.03) and altered mental status (22% vs 14%, p=0.0043). All measured cytokine concentrations at SAB onset and after 72h were similar between the groups (p=ns). Initiation of effective antibiotic therapy was delayed by ≥1d in UO (38% vs 27%, p=0.0008) and duration of therapy was shorter (median 9d vs 10d, p=0.043). While duration of bacteremia >2d (UO 40% vs KO 39%, p=0.64) and length of stay (UO 13d vs KO 11d, p=0.26) were similar, 30d mortality was significantly higher in the UO group (14% vs 8%, p=0.0054).

**Conclusions:** The high proportion of UO patients presenting with altered mental status likely precluded the ability of clinicians to obtain a thorough history from the patients to ascertain the source of SAB. Prompt initiation of effective therapy and for sufficient duration is needed regardless of whether the source of SAB is known.

Abstract 3781

**Escherichia coli ST457: an emerging pathogen with wildlife and food-producing animals’ reservoirs**

Kristina Nesporova*1,2, Ethan Wyrsch1, Ivana Jamborova1, Adam Valček1,2, Ivan Literak1,2, Steven Djordjevic3, Monika Dolejska1,2

1University of Veterinary and Pharmaceutical Sciences Brno, CEITEC VFU, Brno, Czech Republic, 2University of Veterinary and Pharmaceutical Sciences Brno, Department of Biology and Wildlife Diseases, Brno, Czech Republic, 3University of Technology Sydney, The ithree institute, Sydney, Australia

**Background:** *Escherichia coli* ST457 is a globally dispersed lineage often reported to carry resistance to clinically important antibiotics including beta-lactams and colistin. Carbapenemase-producing strains of ST457 have also been detected in USA, Mexico, China and Italy. ST457 has been recovered from diverse sources including humans, animals and the environment.

**Materials/methods:** A high prevalence of *E. coli* ST457 was detected in two ongoing projects evaluating antibiotic resistance within Australian gulls (42 ST457 strains) and Paraguayan poultry (14 ST457 strains). All of these strains were subjected to whole genome sequencing (WGS) using MiSeq and NovaSeq Illumina platforms. Long-read sequencing using the PacBio Sequel platform was performed for three representative strains. Publicly available WGS sequences of ST457 were downloaded from EnteroBase and included in SNP-based phylogenetic analysis and to assess serotype and carriage of antibiotic resistance genes, virulence factors and plasmid incompatibility groups.

**Results:** SNP analysis of 136 ST457 strains identified five main clades. The Australian gulls partitioned in two clades reflecting their serotypes (O11:H25 or O11:H45) and most of them carried *bla*CMY-2 on IncI1/ST23 plasmids. Human strains of ST457 from Australia, New Zealand, UK, Germany and Japan clustered with the gull strains with serotype O11:H25. Notably, the O11:H45 clade contained human clinical strains from Australia which were closely related to one of the gull strains. The Paraguayan poultry strains represented a successful clonal lineage carrying *mcr-5* gene along with *bla*CTX-M-8 on IncI1/ST113 plasmids. Their clade contained several strains from poultry of US origin and human isolates from Peru and Japan. One clade comprises strains from human and food animal origin with representatives from most continents but mainly from USA and China. This clade, mostly human and food-producing animals, carried more resistance gene cargo compared with strains in the other 4 clades including *mcr-1.1*, *mcr-2.1*, *bla*CTX-M-27, *bla*CTX-M-55, *bla*CMY-2.

**Conclusions:** This is the first large-scale WGS comparison of ST457 from diverse sources. Our data indicate that *E. coli* ST457 is an emerging pathogen with potential reservoirs in wild (gulls) and food-producing animals (mainly poultry). Association of this ST with resistance to extended-spectrum beta-lactams and colistin and various virulence genes is a major concern.

Early-onset of bloodstream infections in a burn unit

Silvia Scabini*1, Anna Pensa2, Simone Mornese Pinna1, Claudia Filippini3, Antonio Curtoni4, Maurizio Stella5, Francesco G. De Rosa1, Silvia Corcione1

1University of Turin, Department of Medical Sciences, Infectious Diseases, Torino, Italy, 2University of Turin, Department of Medical Sciences, Torino, Italy, 3City of Health and Sciences, Molinette Hospital, Department of Anesthesia and Intensive Care Medicine, Turin, Italy, 4City of Health and Sciences, Molinette Hospital, Department of Public Health and Pediatrics, Microbiology and Virology Unit, Turin, Italy, 5CTO Hospital, Burn unit, Torino, Italy

Background: Severely burn patients are at high risk for bloodstream infections (BSI) due to loss of the skin barrier function and state of immunosuppression induced by significant thermal injuries.

Materials/methods: This retrospective study was designed to evaluate the epidemiology and risk factors for BSI in a burn intensive care unit. Additionally, we also investigated the risk factors for multi-resistant bacteria [multidrug-resistant Pseudomonas aeruginosa (MDRPA), carbapenem-resistant Acinetobacter baumannii (CRAB), carbapenem-resistant Klebsiella pneumoniae (CPKP)]. All patients with burn injury admitted to the 8-bed burn unit at CTO Hospital of Turin between January 2015 and July 2019 were enrolled in the study. All episodes of BSI were included.

Results: There were 183 episodes of BSI among 324 cases with 241 microbiological isolates. Eighty-eight patients had at least one positive BSI (27.2%). Among them, 26 patients (29.5%) had more than three episodes of BSI during their stay. The median time to first positive blood culture was 10 days. Most of the first positive blood cultures were documented during the first week of hospitalization [37/88; 42]. The leading isolate was A baumannii (24.1%), followed by P aeruginosa (20.7%). Klebsiella spp accounted for only 7% of total isolates. A large number of isolates showed antimicrobial resistance, particularly in gram-negative bacteria. Among A baumannii isolates, 93.1% of them were CRAB, while the rate of MDR strains in P aeruginosa isolates was 48%. The prevalence of BSI due CPKP was around 5% (5.5%). At multivariate analysis, the placement of central venous catheter within the first 24 hours (OR:3.576 95% CI:1.596-8.017) undergoing a surgical intervention (OR:3.608 95% CI:1.238-10.517) and a higher revised Baux score (OR:1.019 95% CI:1.008-1.031) increased the risk of acquiring BSI. Prior rectal colonization (OR: 13.543 95% CI: 3.553-51.621) was a predictor of MDR gram-negative BSI. Polymicrobial (p=0.0004) and MDR gram-negative BSI (p=0.0019) increased the risk of death.

Conclusions: In our local setting, BSI are predominantly caused by non-fermenting Gram-negative bacteria, with high rate of carbapenem resistance, since the earliest days of hospitalization. These data underscore the need for effective infection control measures.

Presenter email address: silviascabini88@gmail.com
Unveiling the role of nisin on resistance development by diabetic foot staphylococci: mutant selection window and horizontal gene transfer

Margarida Costa1, Eva Cunha1, Luís Tavares1, Manuela Oliveira*1

1CIISA - Centro de Investigação Interdisciplinar em Sanidade Animal, Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisbon, Portugal

Background: The most prevalent microorganism in diabetic foot infections (DFI) is Staphylococcus aureus, an important pathogen due to its multi-resistant profile. As such, it is mandatory to develop alternative compounds for DFI treatment. Nisin is a promising alternative, being effective against DFI S. aureus and used in food industry for 90 years. However, correct drug therapeutic doses must be established before including this peptide in new therapeutic protocols, to avoid the selection and amplification of resistant mutants.

Materials/methods: A collection of 23 S. aureus DFI isolates and the reference strain ATCC29213 were used. For mutant selection window (MSW) and mutant prevention concentration (MPC) determination, 10^10CFU/mL bacterial suspensions were inoculated in Mueller-Hinton agar supplemented with nisin at 5.63, 11.25, 22.5, 45, 90, 180, 360 and 720 μg/mL, and incubated for 72h at 37ºC. To understand if nisin could potentiate resistance transfer from Enterococcus, after inducting rifampicin resistance in the 24 S. aureus isolates, mating experiments were performed using the Vanr Rifr Enterococcus faecium CCUG 36804 strain as a donor for the vanA gene and the 24 Vans Rifr staphylococci as recipients.

Results: MSW ranged from 11.25-360 μg/mL (two isolates), 11.25-540 μg/mL (three isolates) and 11.25-720 μg/mL (one isolate). It was not possible to determine the MSW for the remaining 18 isolates since they were able to grow at the highest nisin concentration tested (720 μg/mL). Regarding the horizontal protocol, it was possible to observe that in the presence of the nisin concentrations tested no transconjugants were obtained.

Conclusions: Determining nisin MSW will contribute to avoid resistant mutants’ development. The high concentrations obtained can be applied in vivo, being lower than the acceptable daily intake dose established by EFSA. Also, similar doses were already applied in vivo on infected wounds, showing no toxic effects on patients. As vancomycin is applied in DFI treatment, it is important to understand if nisin could potentiate the transfer of vancomycin resistance genes. The horizontal gene transfer protocol performed in the presence of nisin revealed no transconjugants, indicating that, at the concentrations tested, nisin doesn’t promote vanA transfer, which supports its future application to DFI treatment.

Abstract 3793

CXCL13: a new marker in the diagnosis of Lyme neuroborreliosis?
Alexia Barbry1*, Camille André2, Anne Carricajo3, Anne Doelans Jordheim1, Fuhrmann Christine2, Pascale Girardo2, André Boibieux2, Frédéric Laurent1, Gerard Lina1, François Vandenesch2, Chantal Roure-Sobas1

1Hospital La Croix-Rousse - HCL, Lyon, France, 2University Hospital of Saint-Etienne, Saint-Priest-en-Jarez, France, 3Hospital Édouard Herriot, Lyon, France

Background: Lyme neuroborreliosis (LNB), early or late disseminated form of Lyme disease are caused by spirochaetes of the Borrelia burgdorferi sensu lato complex (Bb). LNB diagnosis is based on 3 criteria: neurological symptoms, intrathecal synthesis of anti-Bb IgG (IA) and CSF pleocytosis [1,2]. The CXCL13 chemokine produced by CSF monocytes has been proposed as a promising marker for early diagnosis and therapeutic efficacy in LNBs. CXCL13 is detectable at high levels in CSF before intrathecal anti-Bb Ig synthesis and is negative after effective treatment. Our study evaluated the performance of a rapid test detecting CXCL13 (ReascanCXCL13® kit) in the CSF as part of the LNB's diagnostic

Materials/methods: In this retrospective study conducted at the Institute of Infectious Agents (CHU Lyon) between July 2018 and August 2019, the CXCL13 assay was performed in the CSF of 59 patients using the ReascanCXCL13® kit according to the manufacturer’s recommendations [threshold of positivity 250 pg/mL]. For 2 patients with confirmed LNB, the CXCL13 assay was performed before and after antibiotic treatment [post-ATB]

<table>
<thead>
<tr>
<th>Diagnosis retained</th>
<th>Nb of patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confirmed LNB (3 criteria)</td>
<td>15</td>

<td>59</td>
</tr>
</tbody>
</table>

Results: Calculated diagnostic performances were sensitivity 100%, specificity 88.6%, positive predictive value 75% and negative predictive value 100%. Five CSF of infectious meningitis contained a level of CXCL13 ≥ 250 pg/mL [2 neurosyphilis, 1 H. influenzae, 1 S. pneumoniae and 1 P. aeruginosa]. No case of viral meningitis gave rise to a positive result. For the 2 patients who had a post-ATB control, CXCL13 was negative after 1 and 2.5 months of antibiotic therapy respectively, whereas the IA remained positive

Conclusions: This is the first clinical evaluation in France of ReascanCXCL13® kit in a near-real situation. In agreement with literature, sensitivity was excellent and specificity medium. Nevertheless, the lack of specificity concerns bacterial meningitis whose clinical picture is usually different of LNBs. Thus, the CXCL13 dosage arises as a fast and complementary marker in the LNBs diagnosis. Its usefulness as a marker of therapeutic efficacy is promising but remains to be assessed on a larger cohort

Presenter email address: alexia.barbry@chu-lyon.fr
If breaking a hip feels like a concern for the elderly, then getting pneumonia should be twice as concerning!

Leslie Grammatico-Guillon*1,2, Hermetet Coralie1,2, Christophe Gaborit1, Joseph Mizgerd3, Antoine Guillon1,2

1François Rabelais University, Medical School, Tours, France, 2CHRU de Tours, Tours, France, 3Boston University School of Medicine, Boston, United States

Background: Pneumonia is a common lung infection that can be life-threatening, especially in elderly. Despite these concerns, elderly mostly fail to accurately gauge their own pneumonia risk, leading to inadequate prevention efforts especially low uptake of existing vaccines. The mismatch between the high morbi-mortality and the low awareness of pneumonia potential severity represent a driver of unhealthy aging. On the contrary, breaking a hip is widely recognized as a major concern for the elderly. To change this trivialization of pneumonia in Elderly and help the vaccination uptake, we compared 2-year outcomes for elderly (≥80 y.o.) patients after hospitalization for acute respiratory infection (ARI) or hip fracture (HF).

Materials/methods: A 2009-15 population-based cohort study was performed in one French region (2.5 million inhabitants), using medico-administrative data collected from the French-DRG. We defined cases of patients ≥80 hospitalized for ARI or HF using ICD-10 and Current Procedural Terminology algorithms. The main outcome was the 2-year mortality of the two patient groups. Kaplan Meier curves described the overall survival and hazard ratios and 95% confidence intervals HR (95% CI) were calculated using Cox models.

Results: 16,917 patients hospitalized for ARI (n=12,159) or HF (n=4,758) were included. Patients hospitalized for ARI had more comorbidities and 3.3-fold greater in-hospital mortality (17.9% mortality for respiratory infection and 5.4% for hip fracture). The Kaplan Meier curves for elderly patients showed a significant difference in mortality for these two groups (log rank test p<0.0001). After adjusting for comorbid conditions and frailty score (as well as age and sex), the global risk of death at two years for elderly patients hospitalized for ARI compared to the HF was significantly higher (HR 1.8 [95% CI: 1.7 - 2.0]).

Conclusions: We hope that placing the consequences of pneumonia in relation to the consequences of a hip fracture may provide useful perspective for discussions of pneumonia and its prevention with aging populations. The population, but also their caregivers and clinical practitioners, should be more aware of this disease's risk and importance. Better recognition will improve the prevention of pneumonia by increasing uptake of vaccines, such as influenza and pneumococcus.

Abstract 3795

Prevalence of *Clostridioides difficile* strains found in Texas soil
Amina Zeidan*1;2, Eric Young1;2, Rupesh Panchal1;2, Alexander Yap1;2, Kelly Reveles1;2

1University of Texas at Austin, College of Pharmacy, Austin, United States, 2University of Texas Health Science Center at San Antonio - UT Health San Antonio, Pharmacotherapy Education & Research Center, San Antonio, United States

**Background:** *Clostridioides difficile* infection (CDI) is an urgent public health threat worldwide, with known isolates existing in both humans and animals. While commonly a hospital-acquired infection, recent reports have shown that community-acquired CDI can account for up to 41% of infections. Identifying environmental sources of *C. difficile* can give the scientific community a better idea of how non-hospital reservoirs can potentially contribute to *C. difficile* exposure and subsequent gastrointestinal colonization. The objective of the study was to identify *C. difficile* and toxin genes across various soil sources.

**Materials/methods:** This was a cross-sectional study utilizing soil samples obtained throughout Texas, USA, including dry dirt, sand, and wet soil near water sources. All samples were collected between September and November 2019. Samples were taken from areas where human and animal contact are frequent, such as recreational parks, and ranged from surface collection to 3 inches deep. Samples were stored at -80°C until processing. DNA extractions were performed using the DNeasy Powersoil Pro Kit (Qiagen) per manufacturer’s instructions. Real-time PCR was also performed on extracted DNA using the Microbial DNA qPCR Multi-Assay Kit for Clostridium difficile Pathogenicity (Qiagen) for the identification of *C. difficile*, toxin A (TcdA), and toxin B (TcdB) genes.

**Results:** A total of 89 soil samples were collected and processed for the presence of *C. difficile*. These included samples from parks and trails (59.6%), water sources (26.9%), and other public spaces (13.5%). *C. difficile* was identified in 40 (44.9%) soil samples, with 3 (3.4%) showing Toxin A and 1 (1.1%) showing toxin B production. *C. difficile* was most prevalent among samples taken from water sources (70.8%), followed by parks and trails (35.8%), and other public spaces (25%). The median (IQR) Cq value for the *C. difficile* gene was 39.83 among samples that tested positive.

**Conclusions:** We identified a high prevalence of *Clostridioides difficile* in soil samples, though toxin gene detection prevalence was low. Future studies will analyze other sources, including water and varying surface samples to obtain a comprehensive view of *C. difficile* in the environment.

Genomic analysis reveals persistence and microevolution of methicillin-resistant Staphylococcus aureus in recurrent carriers

Katinka Barasevich1, Christian Giske2, Inga Fröding2, Ulla-Britt Tollström1, Måns Ullberg2, Hong Fang*2

1Karolinska University Hospital, Stockholm, Sweden, 2Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

Background: Methicillin-resistant Staphylococcus aureus (MRSA) remains a public health problem worldwide. The duration of asymptomatic MRSA carriage is not well known. This study is aimed to investigate whether the recurrence of MRSA was caused by the same strain.

Materials/methods: Sixty-eight isolates, one each from the first and the second episode of 34 cases, were subjected to whole-genome sequencing and antimicrobial susceptibility testing. The patients had at least three negative samples between the first and the second episode of detected MRSA. The genomes of all isolates were analysed by multi-locus sequence typing (MLST), core-genome MLST (cgMLST), resistance traits and virulence factors. Broth microdilution method was applied for antimicrobial susceptibility testing.

Results: Among the 34 pairs of isolates, 27 pairs remained the same sequence type (ST) and seven pairs had different STs in two episodes. Of the 27 same-ST pairs, 26 cases presented 0 to 25 allelic difference by cgMLST, indicative of persistence of same strains, despite three negative samples between the two positive samples. Microevolution was suspected for one case, in which the paired isolates had 74 differed alleles, same ST and SCCmec type, same genomic traits for resistance and toxins. The paired isolates with different STs (n=7) had >1,000 allelic differences, indicating colonization with a new strain.

Despite persistence of the same strains, susceptibilities to clindamycin, erythromycin, tetracycline or tobramycin changed from resistant to susceptible in the second isolates in six cases. Re-sensitization to clindamycin, erythromycin or tetracycline could be explained by the loss of resistance genes ermC or tetK. All other paired isolates associated with persistence/microevolution had the same antimicrobial susceptibility patterns and genomic resistance traits.

The median span between two episodes was 25 months (1-63 months) in the persistence/microevolution cases, and 39 months (29-154 months) in the re-colonization cases.

Conclusions: The duration of asymptomatic persistent carriage could last up to 63 months among cases in the present study. Although same strains persisted over time, resistance genes could be lost which led to re-sensitization. Genomic analysis provides us a useful tool in assessing whether recurrence of MRSA carriage is due to low-level persistence or colonization with a new strain.

Development of fungal mock community standards for mycobiome studies

Nirmal Perera*, Sung-Oui Suh², Monique Hunter², Juan Lopera², Steve King², Anna Mccluskey², Briana Benton²

¹American Type Culture Collection - LGC, London, United Kingdom, ²American Type Culture Collection, Manassas, VA, United States

Background: To date, a significant amount of work has been performed on the human microbiome to evaluate its composition and influence on physiology; this research has led to additional studies on microbiomes localized at specific sites of the human body (e.g., skin, oral, vaginal). Given that fungi are ubiquitous and live in symbiosis with the human body, researchers are now actively looking into the role of the mycobiome in human health and disease. Recent advancements in sequencing technologies have enabled the community profiling of fungi; however, the complexities associated with metagenomics sequencing analyses have posed significant challenges toward standardization. To address this need, ATCC has developed genomic DNA and whole cell mock microbial communities comprising ten medically relevant fungal species mixed in even proportions. In this proof-of-concept study, we demonstrate the use these standards in evaluating DNA extraction and sequencing methods for mycobiome analysis.

Results:

DNA Extraction Efficiency

Conclusions: This proof-of-concept study demonstrates the utility of mycobiome standards as controls for evaluating run-to-run variability and optimizing assay performance at each stage of the mycobiome analysis workflow.

- Whole cell standards can help identify biases introduced during DNA extraction and can be used as full-process controls.
- Genomic DNA standards can be used for comparing various library preparation methods and sequencing platforms.
- The data analysis for mycobiome profiling is challenging due to the lack of complete fungal reference genomes and the limited availability of analyses pipelines.

Presenter email address: nirmal.perera@lgcgroup.com
Background: Chronic disseminated candidiasis (CDC) occurs after profound (neutrophils < 100/mm3) and prolonged (≥10 days) neutropenia, and consists in persistent fever and multiple small (<10 mm) abscesses in liver and/or spleen. The aim of this study was to assess 18F-fluorodeoxyglucose PET/CT in the diagnosis and follow-up of CDC.

Materials/methods: A pilot prospective study was conducted in 38 French onco-hematological centers from 2013-2017 (NCT01916057). Patients ≥18 y.o. suspect for CDC on conventional imaging (40 CT and 4 MRI) were included. PET/CT and conventional imaging were performed initially and at M3. Clinical follow-up was assessed until M12. Clinical success was defined by resolution of fever attributable to CDC, complete biological response by normal liver enzymes and CRP ≤20 mg/L, and complete radiological response by disappearance of lesions compared to initial imaging. The primary endpoint was the global response to antifungal treatment at M3 defined by clinical success and extinction of hepatosplenic metabolic uptake on PET/CT.

Results: Among 44 analyzed cases (7 proven, 13 probable, 24 possible CDC), 75% had acute leukemia, 55% were male (median age 47 [21-79]). At diagnosis, 82% had fever and 82% liver enzyme abnormalities, C-reactive protein was elevated in 85%. Conventional imaging showed abscesses on liver and spleen in 66%, liver in 25%, spleen in 9%. PET/CT showed metabolic uptake at CDC diagnosis in 84% but did not match with lesion localizations on conventional imaging in 34%. Patients received in median 153 days [18-399] of antifungal drugs, combined with corticosteroids in 50%. At M3, 25% (8/32) of evaluable patients met the primary endpoint criteria. However, among 37 patients who had clinical success at M3, 32% had biological success, and 78% failed to respond on conventional imaging. Among these patients, extinction of hepatosplenic metabolic uptake on PET/CT was observed in 17% (5/29). At M6, 10% (4/40) of patients had persistent fever attributable to CDC and 6% (2/33) at M12. The 11 deaths were not attributable to CDC.

Conclusions: Clinical improvement of CDC occurs before biological and radiological normalization. In patients with clinical success at M3, kinetic of PET/CT metabolic uptake decrease is more helpful than conventional imaging and could guide antifungal duration.

Development of electronic nano-sensors for the specific in situ detection of Escherichia coli
Yousra Benserhir*1, Anne-Claire Salaun1, Stéphanie Dutertre2, Olivier Loreal3, Laurent Pichon1, Anne Jolivet-Gougeon3

Background: Detection of bacterial pathogens directly on surfaces, without resorting to nucleic acid extraction, still remains difficult. We explored a new method using nanowire technology able to fix bacteria and detect their presence by electrical variations; a chemical functionalization of the process allows a specific bacterial detection. This work describes the development of a highly sensitive bacteria biosensor using silicon nanowire-based resistors for direct detection by electrical measurements.

Materials/methods: The resistors used for bacterial detection applications are manufactured using conventional silicon technology. Comb-shaped inter-digitated electrodes are devices, fabricated using a highly doped polycrystalline silicon (polySi). Silicon nanowires are synthesized on the teeth of polySi inter-digitated electrodes by the vapour-liquid-solid (VLS) growth mechanism at 460°C using gold as a catalyst and silane as gas precursor.

Results: Nanowire functionalization was used to facilitate the attachment of bacteria to silicon nanowires through specific anti-LPS antibodies. APTES [3-Aminopropyl-triethoxysilane] and then glutaraldehyde (C5H8O2) was vapor deposited on the nanowires, allowing the antibodies grafting (Ac anti-LPS) and the E. coli-gfp binding (Fig.1).

Figure 1: Bacterial grafting protocol.

To check it, fluorescent bacteria [Escherichia coli ATCC-25922-GFP] were attached to these functionalized nanowires and the fluorescence intensity was evaluated by confocal microscope. The electrical characterization (I-V) was used to determine the variation of the resistance as a function of the concentrations of bacteria. During the first tests, this system allowed E. coli to be easily detected at a concentration of 10^5 and 10^7 CFU/ml.

By the fluorescence microscope the area was measured without bacteria [6.18] and after addition of 10^5UFC/ml E.coli [59757,65] [magnification X20; image thresholds by an “intermode” threshold], indicating a specific detection of bacteria in situ without amplification steps.

Conclusions: The next step in the project is to test the specificity and to evaluate the sensitivity of our sensors, using several species and concentrations of bacteria. A new sensor will be designed, integrating resin-based wells (by inkjet printing), in order to guarantee complete reproducibility of measurements.

Abstract 3808

**Title:** TB screening and treatment in an Italian cohort of haematopoietic stem cell transplant recipients

**Authors:** Andrea Della Vecchia*, Carmen Di Grazia*, Alida Dominietto*, Anna Maria Raiola*, Emanuele Angelucci*, Matteo Bassetti*, Viscoli Claudio*, Malgorzata Karolina Mikulska*

1Università degli Studi di Genova - Dipartimento di Scienze della Salute, Division of Infectious Diseases, Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy and IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genova, Italy
2Division of Hematology and Bone Marrow Transplantation, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genova, Italy

**Background:** Hematopoietic stem cell transplant (HSCT) recipients are considered at increased risk of tuberculosis (TB), but in non-endemic countries available data report a low number of latent and active infections. Current guidelines recommend latent TB screening in a low endemicity setting but supporting data are limited. The aim of this study was to report the rate of active and latent TB, the factors associated with Quantiferon (QFT) results and the use and outcome of treatment of latent TB.

**Materials/methods:** Data from 933 consecutive allogeneic HSCT recipients from Ospedale Policlinico San Martino, Genova, Italy from years 2008-2019 were collected retrospectively. Patients were screened for latent TB with Quantiferon-TB In-Tube until May 2018, QuantiFERON-TB Gold Plus thereafter. Data on patients with TB, with latent TB and those re-tested with QFT were collected. Variables associated with QFT results (positive vs. negative vs. indeterminate) were analyzed in a multinomial regression model.

**Results:** Overall, 2/933 (0.002%) patients developed active TB during 5015 person-years of follow up, with an incidence of active TB of 39.88 cases per 100,000 person-years. Among screened patients, 15/254 (5.9%) resulted QFT positive and 32 (12.6%) indeterminate. Older age was associated with QFT positivity, while a transplant from a mismatched donor was associated with an indeterminate QFT result.

Of 51 patients who were re-tested with QFT after HSCT, 17 had discordant results: 11 from indeterminate to negative, 4 from positive to negative and 2 from negative to positive (one with active TB and one with latent TB after recent exposure). No cases of LTBI reactivation were observed in a 36 person-years follow-up.

Overall, 8/15 (53%) QFT positive patients and 1 with post-HSCT latent TB were treated with isoniazid (INH) for an average of 5.7 months and 3/9 (30%) developed hepatic toxicity that required drug discontinuation.

**Conclusions:** The incidence of active TB in allogeneic HSCT was higher than in the general Italian population (39.88 cases per 100,000 person-years), but none of the cases occurred in those with latent TB at HSCT, despite INH provided to only half of them. The benefits of latent TB screening should be re-evaluated in a low endemicity setting.

**Presenter email address:** andreadvmed@gmail.com
Abstract 3809

**Using metagenomics to study the impact of hospital stay on the human gut resistome**

Maho Yokoyama*1, Leon Peto2, A. Sarah Walker2, Martin Llewelyn2

1Brighton and Sussex Medical School, Brighton, United Kingdom, 2University of Oxford, Nuffield Department of Clinical Medicine, Oxford, United Kingdom

**Background:** Antimicrobials are vital for modern medicine. Antimicrobial use selects for antimicrobial resistant bacteria, particularly among the gut microflora. Minimising antimicrobial resistance (AMR) selection by avoiding unnecessary antibiotic use helps combat AMR. Metagenomic analyses have the potential to provide accurate detection and quantification of AMR genes (ARGs) within an individual’s gut microbiome (their gut ‘resistome’), allowing the impact of different types of antibiotic exposures to be evaluated and guide interventions to reduce AMR.

**Materials/methods:** We have developed a short-read sequencing approach to characterise the gut resistome and piloted this in two clinical sample sets. Briefly, DNA is extracted directly from faecal samples and sequenced by Illumina NovaSeq to a depth of $10^6$ million reads. The resulting reads are filtered, then mapped to known ARGs in the CARD database using the bioinformatics tool ARIBA.

**Results:** The first sample set was 25 paired stool samples from older hospitalised adults taken a median of 25 days apart (1 to 50 days). Both median ARG reads/kb/million total reads (RPKM) and median ARG count increased between first and second samples (1544 (IQR 1122 to 3062) to 2704 (IQR 1220 to 6308) and 48 (IQR 19 to 61) to 64 (IQR 23 to 72) respectively), but this did not reach statistical significance (paired Wilcoxon test, p=0.22 and p=0.19, respectively).

The second sample set comprised 168 faecal discards from *Clostridium difficile* testing at a hospital, taken over 14 months. In the first set of samples, from months 1-3 [group 1, n=11] and 12-14 [group 2, n=10], the median ARG RPKM increased from 883 (IQR 561 to 3107) to 1040 (IQR 570 to 3891), and the median ARG number increased from 18 (IQR 15.5 to 53) to 49.5 (IQR 22.5 to 54), but this did not reach statistical significance (two sample Wilcoxon test, p=0.7 and p=0.48, respectively).

**Conclusions:** Direct, deep sequencing can be used to quantify carriage of ARGs in faecal samples. Our data indicate this approach can be used to study the impact of healthcare exposure and antibiotic treatment on ARG carriage in individual patients. Large scale evaluation of this is underway within the ARK Hospital Project.

**Presenter email address:** m.yokoyama@bsms.ac.uk
A silent mcr-9 and a novel class A beta-lactamase in *Citrobacter telavivum* sp. nov. colonising hospital patients

Teresa Goncalves Ribeiro*1, Radosław Izdebski2, Paweł Urbanowicz2, Yehuda Carmeli3, Marek Gniadkowski2, Luisa Maria Vieira Peixe1

1UCIBIO-REQUIMTE. Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, 2Department of Molecular Microbiology, National Medicines Institute, Warsaw, Poland, 3Division of Epidemiology, Tel-Aviv Sourasky Medical Centre, Tel-Aviv, Israel

**Background:** Evolutive biomarkers and whole-genome sequencing (WGS) analysis are contributing to clarify taxonomic bacterial positions. In this study, two *Citrobacter* spp. strains (6105T and 6106) previously identified as *Citrobacter farmeri* by Vitek 2 and as *Citrobacter amalonaticus* by MALDI-TOF MS, and recovered during an epidemiological study of ESBL screening in rectal swabs of hospitalized patients at Tel-Aviv (Israel; 2010) were characterized by a polyphasic approach.

**Materials/methods:** The strains were characterized by WGS, phylogenetic analysis based on 16S rRNA or recN genes, multi-locus sequence analysis (MLSA; fusA, leuS, pyrG, rpoB), genomic comparisons [Average nucleotide identity (ANI) and digital DNA-DNA hybridization (GGDC)], and biochemical tests. Location and genetic surrounding of antibiotic resistance genes were investigated, and antibiotic susceptibility profiles were determined by disc diffusion, and broth microdilution methods.

**Results:** Phylogenetic analysis based on 16S rRNA gene sequences indicated that strains 6105T and 6106 belonged to the genus *Citrobacter*, while recN phylogeny and MLSA revealed one strongly supported clade encompassing both strains, and distinct from currently recognized species of the genus *Citrobacter*. ANI and GGDC showed 90.7% and 54.3% identity to the closest relative *C. farmeri*, respectively. The ability to metabolize different compounds also discriminated strains 6105T and 6106 from other species. Genomic analysis of strains 6105T and 6106 revealed that a novel class A beta-lactamase (TEL-1; sharing 90.5% identity with chromosomal β-lactamase CdiA of *Citrobacter koseri*), and mcr-9, flanked by two IS*Ehe*3-like elements, were chromosomally located. Sequence query of the region surrounding mcr-9 showed similarity to sequenced plasmids from other *Enterobacteriaceae*. The isolates were multidrug resistant, although colistin susceptible.

**Conclusions:** *Citrobacter telavivum* sp. nov. producing a novel class A beta-lactamase (TEL-1) is hereby described colonizing hospital patients in Tel-Aviv. Moreover, an acquired silent mcr-9 that seems to circulate among plasmids and chromosome of different *Enterobacteriaceae* was identified enlarging the species that could act as a host of this gene.

Abstract 3811

**Anti-biofilm activity of ozenoxacin against methicillin-resistant *Staphylococcus aureus* strains**

Yuly López Cubillos*1, Ilonka Zsolt2, Jordi Vila Estape1,3

1ISGlobal, Barcelona, Spain, 2Grupo Ferrer, Barcelona, Spain, 3Hospital Clínico de Barcelona, Barcelona, Spain

**Background:** Biofilm formation is an important virulence factor for methicillin-resistant *Staphylococcus aureus* (MRSA). Ozenoxacin (OZN) is an excellent option against Gram-positive cocci. We investigated the antibiofilm activity of OZN against quinolone-susceptible (QS) and -resistant (QR) MRSA compared with topical antibiotics.

**Materials/methods:** The minimal inhibitory concentration (MIC) of ozenoxacin (OZN), fusidic acid (FA) and mupirocin (MUP) was determined by microdilution in 4 MRSA-QS and 4 MRSA-QR producing biofilm. The same antibiotics were tested to determine the minimum biofilm inhibitory concentration (MBIC) and the minimum biofilm eradication concentration (MBEC) by microdilution assay. In addition, from MBEC plate was determined the frequency of resistant mutant.

**Results:** The geometric mean (GM) of the MIC of OZN was 0.031 µg/mL for MRSA-QS and 0.2 µg/mL for MRSA-QR. Values slightly higher were found for FA and MUP, showed a GM-MICs of 0.2 1 and 0.354 µg/mL for MRSA-QS and 0.07 and 0.044 µg/mL for MRSA-QR, respectively.

The GM of MBICs for OZN was 0.297 µg/mL for MRSA-QS and 1.4 µg/mL for MRSA-QR strains. The GM-MBICs of FA was 0.4 and 0.125 µg/ml for MRSA-QS and –QR, respectively. MUP showed than GM-MBICs for MRSA-QS and –QR were 0.5 and 0.2 µg/ml. GM-MBECs for OZN was 16 µg/mL and 128 µg/mL for MRSA-QS and -QR strains, respectively. FA, showed a GM-MBECs for MRSA-QS of 362 µg/ml and 512 µg/ml for MRSA-QR. Finally, MUP showed a GM-MBECs of 256 and 1024 µg/ml for MRSA-QS and –QR, respectively.

Worthy of note, OZN did not select mutant strains in this study. The selection rate of FA was 10^-10 in SA3 strain (MRSA-QS) and 10^-7 for SA-823 strain (MRSA-QR). Moreover, MUP has selected spontaneous mutant in three of four MRSA-QR strains. For SA-50 strain the mutant selection rate was 2.6x10^-10, 1x10^-10 for SA126 and 10^-10 SA-823 strain.

**Conclusions:** OZN shows an excellent *in vitro* activity against MRSA-QS and -QR strains. MBEC values to OZN in MRSA-QS were 5 and 16 times lower in comparison with other topical antibiotics and in the range of concentration achieved on the skin after topical application. In addition, OZN did not select spontaneous mutants in strains of this study.

**Discrepancy results with meningitis/encephalitis panel FILMARRAY in cerebrospinal fluid**

Cristina Matovelle Ochoa¹, Juan Sahagún¹, Sonia Algarate¹, Joaquina Gil¹, Tatiana Khaliulina Ushakova¹, Soledad Salvo¹, Rafael Benito¹

¹Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain

**Background:** CNS infections require a fast and reliable diagnosis. Filmarray® (FA) Meningitis/Encephalitis (ME) Panel (bioMérieux) is a rapid multiplex PCR platform which detects 14 pathogens in cerebrospinal fluid (CSF) in patients with ME. The aims of this study were to assess the performances of this test in comparison with routine methods (RM). In case of discrepancy an analysis based on patient records and laboratory results was performed.

**Materials/methods:** From January to November 2019 at Hospital Lozano Blesa, Zaragoza-Spain, CSF samples of patients with ME suspicion were tested with the RM: gram stain, India ink stain (IIS), bacterial culture, Herpesviridae and Enterovirus PCR (Entherpex Genomica®) and Cryptococcus sp. (Csp) antigen immunochromatography (IC) (RDT CryptoPS, BIO-RAD). Results were compared with FA.

**Results:** Fifty-three CSF from 49 patients were tested. RM global positivity rate was 14/49 (28.6%) versus 16/49 (32.7%) for FA. There was a good concordance between both methods in 10 samples (3 Enterovirus, 1 VZV, 2 HSV-1, 2 Streptococcus pneumoniae (SP) and 2 Listeria monocytogenes). Discrepancy was found in 5 samples. SP was detected by FA and not by culture in a CSF with bacterial pattern. In two samples VZV was detected by FA and not by PCR (Genomica®), in both cases, CFS had a viral pattern, and one of the patients had vesicular lesions. In one non pathological CFS, false positive HSV-2 was detected for Genomica® but not by FA. In one sample with lymphocytes, Csp was detected by IC and not with FA or IIS, this sample was FA negative at the arrival to the laboratory; however, sample showed a FA C. neoformans/gattii and IIS positive result after incubation for 48h at 37°C.

**Conclusions:** Discrepancy between FA and RM were detected for SP, VZV, HSV-2 and Csp. FA showed more sensitivity for VZV and SP FA sensitivity was deficient for Csp, requiring other methods to confirm. FA is a useful method in emergency cases; however, its results should be confirmed and always interpreted according to the CSF biochemistry results.

Abstract 3814

**Determining the value of sequential screening to detect carbapenemase-producing Enterobacteriales**

Jennifer Henderson*1,2, Holly Ciesielczuk1, Mark Wilks1,2, Shona Nelson2

1Barts Health NHS Trust, London, United Kingdom, 2University of the West of England - UWE Bristol, Stoke Gifford, United Kingdom, 3Queen Mary University of London, London, United Kingdom

**Background:** When CPE carriage is confirmed in hospital inpatients, the Public Health England acute trust toolkit for the early detection, management and control of carbapenemase-producing Enterobacteriaceae, stipulates the patient must remain in isolation for the duration of their hospital stay and all subsequent visits.

There are few publications that have determined the value of sequential screening to establish the optimal number of samples required to demonstrate transient versus established carriage and whether there is a requirement for the patient to remain in isolation. Therefore, we aimed to demonstrate whether multiple screens could determine whether the patient reverts and remains negative for a CPE.

**Materials/methods:** Screening data was extracted from the laboratory information management system (LIMS) during a suspected outbreak of Enterobacteriales producing OXA-48 type carbapenemases over an 18 month period, from May 2016 to March 2018. During this time screening was performed on admission, followed by weekly screening.

**Results:** Of the 815 patients screened, 137 had at least one positive result, with the majority considered as carriage and 4 isolated from clinical samples and, therefore, deemed to be a cause of infection.

Of the 137 patients with at least one positive CPE screen, 60% received only one screen, 24.1% had 2 screens, 8% had 3 screens, 3% had 4 screens, 2% had 5 screens, 1.5% had 6 screens and 0.7% had 9 screens.

Based on the patients receiving at least 3 CPE screens, we can report that 85% of patients had established CPE carriage, compared to 15% demonstrating transient carriage i.e. reverting back to negative carrier status.

**Conclusions:** This research demonstrates the necessity of serial screening of CPE carriers to determine transient versus established carriage. Patients with transient carriage could remain in open wards, which would have large cost savings for the hospital.

The results of this study, therefore, do not fully support the guidelines in the PHE toolkit which state that all CPE carriers should have a positive carrier status for their lifetime and always be in an isolated facilities.

Abstract 3818

Complex polyclonal outbreak of blaVIM-1-harbouring and mcr-9-cohabouring Enterobacter cloacae complex linked to drains in a German hospital

Monika Malecki1, Paul G. Higgins2,3, Kyriaki Xanthopoulou3,4, Harald Seifert3, Frauke Mattner1, Andreas Friedrich Wendel*1

1Cologne Merheim Medical Centre, University Hospital of Witten/Herdecke, Institute of Hygiene, Cologne, Germany, 2German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 3University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 4German Center for Infection Research (DZIF), Partner site Bonn-Cologne, Germany

Background: The dissemination of carbapenem or colistin resistance genes is a major public health threat. Over a period of 20 months a hospital-acquired extensively drug-resistant Enterobacter cloacae complex was detected in four patients in two adjacent single rooms of an intermediate care ward at a tertiary care centre in Germany.

Materials/methods: Identification, antimicrobial testing (VITEK2, colistin microdilution) and carbapenemase tests (mCIM, PCR) were performed. Genotyping was carried out by whole genome sequencing (Illumina MiSeq, analysis by Ridom Seqsphere+ with an ad hoc cgMLST scheme, JSpeciesWS, PlasmidFinder and ResFinder). Infection prevention and control measures introduced were as follows: contact precautions, screening, environmental sampling of all sinks and shower drains, change/cleaning and disinfection of the drainage, observations, and trainings.

Results: In January 2019, patient 2 was colonized in room 1 with a VIM-1-producing E. hormaechei that was related to an isolate of a prior occupant of the room (patient 1) treated 16 months earlier. Water samples were taken from all drains of the ward and the strain was found in the drains of room 1. A third patient became colonized with a VIM-1-producing E. cloacae in room 2 in March 2019. Finally, a blaVIM-1- and mcr-9-cohabouring E. hormaechei was detected in Patient 4 in room 1 in May 2019. A highly related strain was found in room 2 (shared drainage system with room 1) two weeks before the patient was admitted. Both isolates were colistin susceptible (MIC 0.1 25 mg/L, 0.25 mg/L) but the mcr-9 regulatory genes (qseC/qseB) were not detected. Observations carried out revealed possible environment-to-patient transmission events as medical equipment was stored nearby the washbasin. One hospital-acquired infections (UTI) was observed.

Conclusions: Transmissions of carbapenemase-producing Enterobacterales arising from the hospital waste-water system are complex, involving several species, genotypes and resistance genes. As the biofilm is difficult to eradicate it is important to emphasize standard precautions. To the best of our knowledge, this is the first report of a (silent) mcr-9 gene transmission in Germany. As the gene was not expressed, circulation was difficult to detect. However, further research about the transmissibility of the blaVIM-1 and mcr-9 genes is needed.

Abstract 3822

A low-cost nanoliter droplet handling system for pathogen identification and antimicrobial susceptibility testing on microtitre plates

Qiaolian Yi*, Wenbin Du, Yingchun Xu

1Peking Union Medical College Hospital, Beijing, China, 2The Institute of Microbiology, Chinese Academy of Sciences, Beijing, China, 3Beijing Key Laboratory for Mechanisms Research and Precision Diagnosis of Invasive Fungal Diseases, Beijing, China

Background: Antimicrobial resistance (AMR) has already threatened the effective treatment of an ever-increasing range of infections caused by bacterial pathogens due to extensive overuse and misuse of antibiotics. To correct analysis and implementation of prescription instructions, guiding patients safe, effective and rational drug use, antimicrobial susceptibility testing (AST) should be performed to evaluate the antibiotic resistance. A routine procedure usually takes 48-72 h from sampling to final report. Those laborious and time-consuming complicated steps hinder the clinicians choosing the most proper treatment timely, resulting in inappropriate prescription of antibiotics and the emergence of AMR. Shortening turn-around-time of diagnosis is notably a critical determinant of optimal treatment.

Materials/methods: We developed an automated nanoliter droplet handling system for low-cost minimum inhibitory concentration (MIC) testing and pathogenic bacteria identification suitable for early diagnosis with limited sample volumes. Nanoliter liquid handling was realized by a simple interfacial nanoliter injection (INI) method. The workflow included preparation of preloaded plates with nanoliter reagents, automated sample distribution, and results readout by a standard plate reader. For pathogen identification, the preloaded reagents were species-specific primers; while for AST, they were antibiotics. The addition of redox indicator provided the results could be read both by visual and fluorescence changing.

Results: A quality control strain (E. coli ATCC 25922) was chosen to verify this method for AST. Eight antibiotics including amikacin, ampicillin, chloramphenicol, meropenem, tetracycline, cefalotin, ceftriaxone, gentamicin were tested. The AST results obtained within 5 hours were consistent with the quality control range. The reaction volumes can be down to 20 nL. Nine strains isolated from clinical samples with four drugs were tested, and the results were comparable with those obtained from VITEK2 Compact (Table 1). Species distinctive PCR primers were designed and 17 species which are the most common cause of bloodstream infection pathogens were identified with 98.86% correspondence.

Conclusions: This system enables rapid MIC determination and species identification on the same platform, using common microtiter plates with preloaded antibiotics or PCR primers, greatly reduces the cost of reagents and saves time.

Bacterial and fungal contamination and simultaneous analysis of chemical indoor air pollution in medical-social establishment and liberal healthcare offices

Jean-Pierre Gangneux1*, Hélène Guegan1, Alexandre Baudet1, Olivier Blanchard1, Monique Guillaso2, Pierre Le Cann3, Estelle Baures3, Arnaud Florentin2

1Rennes, Univ Rennes, Inserm, Irsset (Institut de recherche en santé, environnement et travail) – UMR S 1085, Rennes, France, 2Nancy, Université de Lorraine, Faculté de Médecine, Département d’Hygiène, des Risques Environnementaux et Associés aux Soins, APEMAC, équipe MICS, Nancy, France, 3Rennes, EHESP, Univ Rennes, Inserm, Irsset (Institut de recherche en santé, environnement et travail) – UMR S 1085, Rennes, France

Background: Indoor air quality of medical-social establishment and liberal healthcare offices is poorly studied. This work aimed for the first time to describe simultaneously the microbial, chemical and particulate contamination of these indoor environments.

Materials/methods: Two campaigns were conducted in Rennes (Brittany, Western France) and Nancy (Lorraine, Eastern France) in summer 2018 and winter 2019 in six liberal facilities and four nursing homes. Samples were collected for microbial detection with a cyclonic liquid air sampler and surfaces using swabs. During both campaigns, bacteria and fungi were enumerated by cultural techniques. They were also detected as well as viruses by real time PCR on air samples. Besides, a huge panel of 40 volatile organic compounds (VOCs) and 13 semi-volatile organic compounds (SVOCs) were measured. Ambient parameters (temperature, relative humidity, pressure and carbon dioxide) and the number of fine particles (PM2.5) were also measured.

Results: Low median concentrations of bacteria (45 CFU/m3 in air and 307 CFU/100 cm2 on surfaces) and of fungi (11 CFU/m3 and 9 CFU/100 cm2) were detected. Among all bacteria, Stenotrophomanos maltophilia and Citrobacter freundii at high concentrations were the most potentially pathogens found, notably on surfaces of patient rooms from a medical-social establishment. Bacillus and Chryseobacterium were detected at lower levels in air. Low concentrations both in summer and winter of Cladosporium, Penicillium and Aspergillus were detected in air, but high levels of Rhodotorula were reported on surfaces. Regarding chemical compounds, median concentrations (µg/m3) were determined for alcohols (ethanol: 372.1 and isopropanol: 28.3 respectively for and), aldehydes (formaldehyde: 11.4), ketone (acetone: 27.2) and terpenes (limonene: 5.9). For phthalates, the highest median concentrations were measured for diisobutyl phthalate (0.27).

Conclusions: Indoor air contained a complex mixture of many microorganisms and pollutants found in rather low concentrations, below the indoor air quality guidelines. Our study showed a lower pollution compared to dwelling indoor environments. However, this pollution originated mainly from healthcare activities and uses, and was higher than that measured in hospitals (same campaigns in Rennes and Nancy hospitals) that are equipped with central air conditioning systems, decreasing indoor aerosols more efficiently than in healthcare offices often not equipped.

National outbreak of norovirus genogroup II in a sushi restaurant chain associated with an internationally distributed seaweed product

Tania Misra1, Dillon Jindal2, Clare Sawyer1, James Armitage1, Alison Patmore4, Anjana Pahwa1, Roxanne Pateman1, Andre Charlett1, Rachel Mearkle1, Sarah Lock7, Deborah Fenelon1, Wavney Jemmott1, Amor Waters1, Caroline Willis1, Caroline Handford5, Sriram Balasingam5, Martin D’agostino6, Rohini Manuel*1, James Sedgwick7, Hikaru Bolt1

Abstract 3826

Background: In July/August 2019, environmental health were informed of 176 reports of gastrointestinal illness linked to a sushi restaurant chain with 11 outlets nationally. A multi-agency outbreak control team was convened to investigate and implement control measures.

Materials/methods: Individuals reporting gastrointestinal illness were sent online questionnaires requesting information on demographics, symptoms, and food consumed at the restaurants. Cases were defined as having diarrhoea, vomiting, nausea, or fever within five days of dining at the restaurants. Stool samples were requested from cases and staff. Food samples were tested for pathogens. The Rapid Alert System for Food and Feed was reviewed for contaminated food sources, and links to the restaurants. A case-control study was conducted recruiting controls from the chain's online delivery service.

Results: 49/176 individuals completed the questionnaire and met the case definition. Median age was 28 years (range 12-71); 75% were female. 91% of cases reported nausea, 79% vomiting, 71% diarrhoea, and 10% bloody stools. Median incubation period was 38 hours (range 1-71). Most commonly consumed foods among cases were wakame seaweed salad (80%), soy sauce (63%), and salmon sashimi (57%). Norovirus genogroup II was detected in stool samples of two cases and two staff members. Genogroup II was also isolated from a sample of wakame seaweed salad, but no other foods samples. On 13th August, Spanish authorities reported isolating norovirus genogroups I and II in a seaweed salad product from China distributed via Germany. This product was supplied to the affected UK restaurants. The case-control study generated further evidence that the consumption of wakame seaweed salad (aOR: 50 CI: 1.2-203.0) was associated with becoming a case.

Conclusions: The epidemiological, microbiological, and food tracing investigations suggest the most likely cause of this outbreak was norovirus [genogroup II] through a contaminated seaweed product. The product was voluntarily withdrawn on 19th August 2019.

Abstract 3832

Comparison of vaccine opinion of parents in 5 key European countries: learnings from Vaccinoscopie Europe

1Hospital, Grenoble, France, 2Hospital, Créteil, France, 3Hospital, Bondy, France, 4Hospital, Angers, France, 5Hospital, Lille, France, 6GSK company, GSK France, Rueil-Malmaison, France, 7IDM Families, Issy-Les-Moulineaux, France

Abstract third-party references: The survey was conducted by IDM families and funded by GSK.

Background: Suboptimal vaccination coverage rates have led to vaccine-preventable disease resurgence and epidemics, such as measles in Europe these last years. Growing vaccine hesitancy is one of the key explanations of this situation. We aimed to compare vaccine opinion of parents, key target for vaccination, in 5 big European countries.

Materials/methods: Vaccinoscopie Europe is a web-based survey conducted in 2019 on a representative sample of 1,500 parents of 0-2 years old infants based in France, Germany, Italy, Spain and United-Kingdom (300 per country).

Results: Vaccination positive opinion of parents varied according to countries (from 73% for France to 94% for Spain). UK and Germany had 3% of opponents to all vaccinations versus <1% in the other countries. In all countries, more than 90% of parents were favorable to mandatory vaccination for at least certain vaccines. German and British parents were the most refractory.

In terms of vaccination knowledge, French parents felt significantly less well informed (77% of well informed) than parents from the other countries (90-94%) with less web consultations about vaccination (respectively 58% versus 70-81%). Trust level in Health authorities was highest in Spain and lowest in France (on a 10-point scale, respectively 88% and 68% with a score of 7 to 10).

Although the first source of information to decide to vaccinate their child was a health care vaccinator, the latter differed in each country based on health care system. The second source of information was Internet, with Health authorities’ websites the most consulted by all countries, followed by friends and families. Influence of these last two sources varied according to countries (respectively from 14 to 40% and from 9% to 30%).

Conclusions: Parents’ vaccination favorable opinion seemed to be linked with a better perceived vaccination knowledge. If the health care vaccinator was the first source of information, Internet was a valuable resource and friends and families might be influential. Local characteristics should be taken into account to increase confidence into vaccination. Evaluation should be harmonized at an European level, allowing to share public health best practices strategies.

Comparative outcomes of cefazolin versus anti-staphylococcal penicillins for treatment of methicillin-susceptible Staphylococcus aureus endocarditis: a prospective multi-centre cohort study

Raphaël Lecomte*1,2, Alexis Bourreau1,2, Deschanvres Colin1,2, Nahema Issa3, Paul Le Turnier1,2, Benjamin Gabori1,2, Marie Chauveau1,2, Thierry Le Tourneau4, Nathalie Asseray Madani1,2, Francois Raffi1,2, Fabrice Camou1, David Boutouille1,2

1Department of Infectious Disease, University Hospital, Nantes, France, 2CIC UIC 141 INSERM, University Hospital, Nantes, France, 3Intensive Care and Infectious Disease Unit, Groupe Saint-André, University Hospital, Bordeaux, France, 4Department of Cardiology, University Hospital, Nantes, France

Background: Cefazolin has been shown to be as effective as anti-staphylococcal penicillins (ASP) in methicillin-susceptible Staphylococcus aureus (MSSA) bacteremia. Both American and European guidelines recommend cefazolin as an alternative to ASP in MSSA endocarditis despite the lack of comparative study in this context.

The objective of this study was to compare the efficacy of cefazolin versus ASP in MSSA endocarditis.

Materials/methods: In this prospective multicenter cohort study from two reference centers, all consecutive patients with MSSA endocarditis confirmed by endocarditis team and treated either by cefazolin or ASP between July 2013 and December 2018 were included. Patients were excluded if they received more than 7 days of both treatments. The primary outcome was 90-day mortality and secondary outcome were relapse, emboli under treatment, duration of bacteremia and premature antimicrobial discontinuation due to adverse events (PAD).

Results: Of 225 patients included in the study, 162 (72.0%) were in the ASP group and 63 (28.0%) in the cefazolin group. Sixty-five of 225 patients (28.9%) had a prosthetic valve endocarditis. The median duration of treatment was similar in the two groups (32 days). The 90-day mortality rate was 28.4% (64/225 patients).

In multivariate analysis, the 90-day mortality was similar between cefazolin and oxacillin group (27.0% versus 29.0%; p=0.91), while age (p<0.01), Charlson index (p=0.01), brain emboli (p<0.01) and intensive care unit admission (p=0.01) were factors significantly associated with higher mortality and surgery (p=0.04) with lower mortality.

No patients relapsed in the cefazolin group while 5/162 patients (3.1%) relapsed in the ASP group (p=0.32) and 5 patients (7.9%) had emboli under treatment in the cefazolin group versus 19 (11.7%) in the ASP group (p=0.41). We did not find a difference in bacteremia duration between the two groups (median of 3 days for both groups, p= 0.76). Rates of PAD for 1000 patients-days of treatment were 3.3 in the cefazolin group versus 2.8 in the ASP group.

Conclusions: There was no significant difference of efficacy or tolerance between cefazolin and ASP for the treatment of MSSA endocarditis. Physicians might consider cefazolin as an adequate and well-tolerated treatment for MSSA endocarditis.

**Borrelia burgdorferi sensu lato in Ixodes ricinus in Slovenia**

Tjasa Čerar Kišek*1, Jana Sušnjari, Vesna Cvitkovič-Špik1, Meta Kodre1, Andrej Steyer1, Vladimir Ivović2, Eva Ruzic-Sabljic1

1University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia, 2University of Primorska, Faculty of Mathematics, Natural Sciences and Information Technologies, Koper, Slovenia

**Background:** Cultivation and isolation of Borrelia burgdorferi sensu lato, the causative agent of Lyme borreliosis, from any biological material are very challenging and labor-intensive but it remains the only approach for detailed genotypic characterization of strains, which is of great importance for epidemiological, clinical, and evolutionary studies.

The present study aimed to isolate and genotype B. burgdorferi sensu lato from ticks collected in different geographic areas of Slovenia in years 2017-2019.

**Materials/methods:** A total of 1007 (247, 172 and 588 in years 2017, 2018 and 2019, respectively) Ixodes ricinus ticks were collected by flag dragging. After morphological identification, ticks were washed with ethanol and sterile water, homogenized and placed in 1.5 ml MKP-F medium. Samples were incubated at 33 °C for up to 12 weeks. MluI-LRFP was used for Borrelia species determination from culture positive samples.

**Results:** B. burgdorferi s.l. was isolated from 70/1007 (7.1%) ticks (35, 5 and 30 in years 2017, 2018 and 2019, respectively). MluI-LRFP revealed the presence of 26 B. afzelii (subtypes Mla1 and Mla2), 24 B. garinii (subtypes Mlg2, Mlg4, Mlg6, Mlg8 and one new LRFP profile), 8 B. valaisiana (subtypes Mlv1 and Mlv2), and 3 B. burgdorferi sensu stricto (subtypes Mlb2 and Mlb8).

**Conclusions:** Cultivation and borrelia isolation from ticks is a technically demanding and low-yield method. Genetic diversity of B. burgdorferi s.l. strains from I. ricinus is high. All collected isolates will be available for further analysis and comparison with human isolates.

**Increase of daptomycin-resistant *Staphylococcus aureus* with a possible link to antiseptic wound treatment in three medical centres in Cologne, Germany**

Andreas Friedrich Wendel*, Robin Otchwemah¹, Frauke Mattner¹, Henrik Oberländer¹, Carlos J. Tellez-Castillo³, Robert L. Skov³, Guido Werner⁴, Franziska Layer⁴, Birgit Strommenger⁴

¹Cologne Merheim Medical Centre, University Hospital of Witten/Herdecke, Institute of Hygiene, Cologne, Germany, ²Cologne Merheim Medical Centre, University Hospital of Witten/Herdecke, Department of Plastic Surgery, Hand Surgery, Burn Center, Cologne, Germany, ³MVZ synlab Leverkusen GmbH, Köln-Merheim, Department of Clinical Microbiology, Cologne, Germany, ⁴Robert Koch Institute, National Reference Centre for Staphylococci and Enterococci, Wernigerode, Germany

**Background:** Emergence of daptomycin resistance in *Staphylococcus aureus* (SA) during treatment is a growing concern. After an increase of daptomycin resistance especially in methicillin-susceptible SA a molecular surveillance was established at three medical centres in Cologne.

**Materials/methods:** Identification and antimicrobial testing was performed with VITEK2. Daptomycin resistance was confirmed by broth microdilution (BMD). All available SA (daptomycin-resistant or daptomycin-susceptible SA [DR-SA, DS-SA]) of the affected patients were included. Polyhexanide MICs were determined by BMD. Whole genome sequencing (WGS, Illumina MiSeq), cgMLST analysis by SeqSphere+ (Ridom) and detection of resistance mechanisms were carried out. Epidemiological and clinical data were analysed.

**Results:** From May 2016 to July 2018 DR-SA were detected in 42 patients (31 MSSA, 11 MRSA). First DR-SA isolates had daptomycin MICs of 2 to 4 mg/L. Acquisition of resistance was almost exclusively healthcare-associated (n=41). Half of the 42 patients were identified with prior and 13 patients with subsequent DS-SA colonization (same location and similar antimicrobial susceptibility profile). Only few patients were treated with daptomycin (n=2) or vancomycin (n=4) before detection. First detection, mostly from wounds (n=37), was associated with a stay in a surgical department (n=39). Wound treatment was evaluated. At least 20 patients were treated with polyhexanide which is part of the local wound management standards. 71 SA isolates were available (42 first, 10 previous and 19 consecutive isolates; 54 DR-SA, 17 DS-SA). WGS displayed a diverse genetic background of DR-SA (only three possible transmission events) and showed that daptomycin resistance evolved in a patient and was reversible. Daptomycin resistance was associated with various polymorphisms in the mprF gene except in five isolates. Elevated polyhexanide MICs in DR-SA compared to DS-SA were demonstrated.

**Conclusions:** In this study, daptomycin resistance in SA was not linked to prior antibiotic therapy. Our hypothesis is that daptomycin resistance was induced by wound treatment with polyhexanide and genetically linked to adaptive changes of a membrane protein (MprF) of the cell wall, previously described in-vitro by Renzoni et al. (2017). Further research like in-vitro selection of polyhexanide and daptomycin resistance in clinical strains is under way.

Autochthonous human and canine Strongyloides stercoralis infection in Europe: a systematic review

Letizia Ottino*, Dora Buonfrate, Paola Paradies, Zeno Bisoffi, Alberto Antonelli, Gian M. Rossolini, Simona Gabrielli, Alessandro Bartoloni, Lorenzo Zammarchi

1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 2IRCCS Sacro Cuore Don Calabria, Centre for Tropical Diseases, Negrar, Italy, 3University of Bari, Department of Emergency and Organs Transplantation, Veterinary Section, Bari, Italy, 4Careggi University Hospital, Microbiology and Virology Unit, Florence, Italy, 5“Sapienza” University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy, 6Careggi University Hospital, Infectious and Tropical Diseases Unit, Florence, Italy, 7Careggi University Hospital, Referral Centre for Tropical Diseases of Tuscany, Florence, Italy

Background: Autochthonous human and canine strongyloidiasis is reported in Europe but is unclear whether the transmission of infection still occurs.

Materials/methods: We performed a systematic review of literature on autochthonous human and canine strongyloidiasis in Europe to investigate the dynamic of autochthonous transmission.

Results: Overall 109 papers published after 1987 were included and one previously unpublished Italian case was added. Eighty case reports were retrieved from 16 European countries and 42 of them (52.5%) had severe strongyloidiasis. Most of case reports described patients infected in Spain (n=21), Italy (n=17) and France (n=11). Median age was 58 and the most represented age group was 61-70 years (n=21, 26.5%). Eleven cases were diagnosed in the decade 2009-2018, including 2 cases in subjects aged <30 years. Concerning human epidemiological studies, 6 were carried out in Italy, 2 in Turkey and 1 each in Austria, France, Poland, Spain and Romania, showing prevalence ranging from 28% to 0.56%. Higher prevalence was found among elderly, farm workers and kids with characteristic symptoms of parasite infection. Data from epidemiological studies and case reports indicate that most of human autochthonous European infections have been acquired in the Valencia province, Northern Italy and several regions of France. Agriculture and mine work were the most commonly reported risk factors for infection but walking barefoot, solid organ transplantation, and homosexual male behavior were also reported. In no case there was mention of possible zoonotic transmission, but one study investigated and revealed the presence of the parasite in humans, dogs and soil in a segregated settlement in Eastern Slovakia. Canine strongyloidiasis was reported mainly in Italy (68 cases), few cases occurred also in Iceland, Finland, England, Germany, France, Switzerland, Russia, Slovakia, Romania and Greece.

Conclusions: Autochthonous strongyloidiasis is still sporadically reported in Europe. Cases in humans are mainly diagnosed in elderly subjects probably infected in the past, while recent infections are extremely rare. Health care professionals should be aware of this issue to timely identify infected subjects and avoid adverse outcome, especially in immunosuppressed patients. Further investigations are needed to clarify the zoonotic transmission of this nematode in Europe.

Abstract 3840

**Reporting antimicrobial susceptibilities and resistance phenotypes in *Staphylococcus* spp.: a nation-wide proficiency study**

Felipe Fernández-Cuenca*, Inmaculada López-Hernández¹, M. Carmen Conejo², Nuria Tormo¹, Concepción Gimeno Cardona¹, Emilia Cercenado¹, Alvaro Pascual Hernandez¹

¹Hospital Universitario Virgen Macarena, seville, Spain, ²University of Seville, seville, Spain, ³Hospital General de Valencia, Valencia, Spain, ⁴Hospital General Universitario Gregorio Marañon, Madrid, Spain

**Abstract third-party references**: on behalf of the Spanish Group of Nosocomial Infections (GEIH) and the Study Group of Mechanisms of Action and Resistance to antimicrobials (GEMARA) from the Spanish Society of Clinical Microbiology and Infectious Diseases (SEIMC), and the Spanish Network for Research in Infectious Diseases (REIPI)

**Background**: to evaluate the proficiency of Spanish Microbiology laboratories with respect to the antimicrobial susceptibility testing (AST) of *Staphylococcus* spp.

**Materials/methods**: Eight *Staphylococcus* spp. with different resistance mechanisms were selected: CC-01 (*S. aureus/meca*), CC-02 (*S. aureus/mecC*), CC-03 (*S. aureus/BORSA*), CC-04 (*S. aureus/MLSBI*), CC-05 (*S. epidermidis/23S rRNA mutation*), CC-06 (*S. aureus/blaZ*), CC-07 (*S. aureus/cfr*), and CC-08 (*S. capitis/daptomycin-resistant*). These isolates were sent to 48 Spanish centers which were asked to report: (i) the AST system used; (ii) MICs; (iii) breakpoints used (CLSI versus EUCAST); (iv) clinical category. Minor, major and very major errors (mE, ME and VME, respectively) were determined.

**Results**: the greatest discrepancies were: (i) by automated AST method: 50.0% (Wider) and 88.2% (Vitek); (ii) by breakpoints: 3.4% (EUCAST) and 2.1% (CLSI); (iii) by antimicrobial agent: amikacin (28.4% EUCAST), fosfomycin (25.0% EUCAST) and tobramycin (10.4% EUCAST). The highest categorical error rates were: (i) by AST method: broth microdilution (EUCAST: 11.1% ME), gradient strips (EUCAST: 10.7% VME; CLSI: 12.7% VME) (ii) by breakpoints: mE (80.1% CLSI, 58.4% EUCAST), ME (3.5% CLSI, 12.4% EUCAST) and VME (16.4% CLSI, 29.2% EUCAST); (iii) by antimicrobial agent: mE (EUCAST: 25.4% amikacin; CLSI: 7.3% erythromycin, ME (EUCAST: 28.6% fosfomycin, 16.2% tobramycin, 9.5% gentamicin and 5.6% amikacin, CLSI: 14.3% quinupristin-dalfopristin) and VME (EUCAST: 21.4% linezolid, 15.4% tetracycline, 12.0% daptomycin, 11.1% fusidic acid and 8.1%. CLSI: 16.7% quinupristin-dalfopristin, 7.3% erythromycin, 4.4% linezolid, 4.1% levofloxacin and gentamicin, and 3.4% oxacillin).

**Conclusions**: (1) Clinical Microbiology laboratories must improve their ability to determine antimicrobial susceptibilities of *Staphylococcus* spp. isolates. (2) The highest discrepancies were associated to the automated AST system (Wider I and Vitek), the EUCAST breakpoints, and the antimicrobial (mE for aminoglycosides, ME for fosfomycin, aminoglycosides and oxacillin, and VME for linezolid, tetracycline, daptomycin and oxacillin).

Abstract 3844

Understanding antibiotic prescribing behaviours among hospital physicians and exploring strategies currently used by infectious diseases physicians to influence change: a qualitative interview study

Veronica Zanichelli1*, Caroline Nott1,2,3, Jeremy Grimshaw1,4, Janet Squires1,5, Justin Presseau1,4, Kathryn Suh1,2,3

1Ottawa Hospital Research Institute, Ottawa, Canada, 2The Ottawa Hospital Academic Medical Organization, Ottawa, Canada, 3The Ottawa Hospital Department of Medicine, Ottawa, Canada, 4School of Epidemiology and Public Health, University of Ottawa, Ottawa, Canada, 5University of Ottawa - School of Nursing, Ottawa, Canada

Abstract third-party references: Ottawa Hospital Research Institute

Background: Inappropriate use of antibiotics contributes to antibiotic resistance and adverse patient outcomes. Infectious diseases (ID) physicians can act as change agents who can improve appropriate prescribing behaviours among their non-ID colleagues.

Materials/methods: A convenience sample of hospital ID and non-ID physicians participated in semi-structured interviews (Ottawa, Canada). We assessed 1) non-ID physicians’ experiences to identify determinants of antibiotic prescribing, and 2) strategies ID physicians currently use to influence others’ prescribing behaviours. Responses were coded using the Theoretical Domains Framework (TDF), a framework including modifiable factors that explain behaviour change and a catalogue of behaviour change techniques (BCTs), respectively. Both sets of responses were mapped to identify areas where BCTs could be used to more strongly effect prescribing changes.

Results: Among 16 non-ID physicians interviewed, antibiotic prescribing was influenced by 5 themes 1) knowledge and availability of resources (“what to do” problem), 2) motivation and beliefs about consequences (“worried about this patient”), 3) automatic actions and skills (“this is how I do things”), 4) social influence (“someone else prescribed it”) and 5) deferring antibiotic-related decisions to ID (“this is not my role”).

On the other hand, current strategies to improve prescribing among peers that are used by 12 ID physicians interviewed include giving clear and precise instructions [e.g. providing recommendations for treatment, discuss in person controversial cases], explaining the rationale for the recommendation, providing evidence from a credible source [e.g. guidelines], promoting autonomy of their peers [e.g. giving license for experimenting with non-ID way first, then try with ID approach] and focusing on previous positive experiences.

We identified that prescribing behaviours among non-ID physicians may be more strongly influenced by better targeting fear of undertreatment, use of non-evidence based practices, and practices influenced by the dynamics and culture of the work environment.

Conclusions: ID physicians do use strategies to improve their peers’ prescribing; however, these may not be based on awareness of barriers and facilitators perceived by their non-ID colleagues. Training ID physicians to recognize barriers non-ID physicians face, and identify strategies to surmount these barriers, could help overcome this gap and ultimately improve antibiotic prescribing among non-ID physicians.

A five-species biofilm model for confirming the potential of a nisin-biogel aiming at canine periodontal disease control

Eva Cunha*, Sandra Rebelo1, Luís Tavares1, Miguel Carreira1, Manuela Oliveira1

1CIISA - Centro de Investigação Interdisciplinar em Sanidade Animal, Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisboa, Portugal

**Background:** Periodontal disease (PD), one of the most common diseases in dogs, is caused by the development of a polymicrobial biofilm at the tooth surface. Previous studies have shown that, when incorporated within a guar-gum biogel (nisin-biogel), the antimicrobial peptide nisin can inhibit and eradicate mono-species biofilms formed by canine oral enterococci, rendering nisin a potential agent for PD control. As the clear majority of the dental plaque biofilms in vivo are polymicrobial, we aimed to confirm the nisin-biogel antimicrobial ability against polymicrobial biofilms formed by five bacterial species frequently present in the canine dental plaque.

**Materials/methods:** Five reference strains commonly present in canine dental biofilms were used: *Neisseria zoodegmatis*, *Enterococcus faecalis*, *Corynebacterium canis*, *Porphyromonas gingivalis* and *Peptoniphilus canis*. First, strains coaggregation ability was evaluated as described by Datta et al. (2017). Then, a five-species biofilm model was established in 96-well microplates by simultaneously inoculating the strains in Brucella broth, followed by incubation in microaerophilia for 48 hours at 37ºC. After incubation, the presence of all strains in the multi-species biofilm was confirmed by Fluorescent In Situ Hybridization (FISH) using specific probes. Afterwards, the five-species biofilm model developed was used to determine the Minimum Biofilm Inhibitory (MBIC) and Eradication Concentrations (MBEC) of the nisin-biogel, as previously described by Cunha et al. (2018).

**Results:** All bacterial pairs exhibited a coaggregation percentage higher than 30% at 24 hours, showing their potential to form multi-species biofilms. The microplate assay developed allowed establishing five-species biofilms, as the presence of all PD bacterial strains on the biofilm model was confirmed by FISH. The nisin-biogel tested presented inhibitory activity against the polymicrobial biofilm, with a MBIC value of 25 µg/mL and a MBEC value > 100 µg/mL.

**Conclusions:** It was possible to develop an *in vitro* model of a periodontal polymicrobial biofilm, composed by five strains frequently present in dog’s dental plaque. This model, which better mimics the *in vivo* conditions present in the oral cavity of dogs, allowed to observe that the nisin-biogel developed by our research team can inhibit the formation of multi-species biofilms, reinforcing its potential for controlling a major disease of these animals.

Abstract 3846

**Dissecting the single-cell heterogeneity and subpopulation dynamics of quiescence in *Mycobacterium tuberculosis***

Lalit Singh*,1, Claudia Chica2, Natalia Pietrosemoli2, Giulia Manina1

1*Institut Pasteur, Microbial Individuality and Infection Group, Cell Biology and Infection Dept., Paris, France, 2Institut Pasteur, Centre for Bioinformatics, Biostatistics and Integrative Biology, Paris, France

**Abstract third-party references:** Microbial individuality and Infection Group, Cell Biology and Infection Dept., Institut Pasteur, Paris, Next Generation Sequencing, Institut Curie, 26 rue d’Ulm 75248 Paris, cedex 05 – France, Centre for Bioinformatics, Biostatistics and Integrative Biology, Institut Pasteur, Paris

**Background:** Quiescence is a complex process, in which cells experience metabolic reprogramming to achieve the minimal metabolic function required for survival. *Mycobacterium tuberculosis* is known to persist in the permissive host-niche for long periods of time, under a state of quiescence. Although, several factors have been implicated in persistence, but understanding the dynamics of this phenomenon is still insufficient, and limits considerably the control of tuberculosis. Here, we target to interpret the physiology of quiescent *M. tuberculosis*.

**Materials/methods:** We identified candidate genes that are upregulated under different stress conditions, including hypoxia. We developed the dual fluorescent reporter in the background of an existing ribosomal reporter strain, which we previously used to monitor the metabolic activity in *M. tuberculosis*. Further, to determine the behavior of the dual reporter strain in the host niche, we infected different cells lines that are associated to tuberculosis. The infection experiment was monitored from early to late stage of infection. To investigate the different molecular signatures between two subpopulations, i.e., quiescent versus active bacilli, we sorted bacteria and performed the comparative transcriptomic profiling of the two subpopulations.

**Results:** By single-cell snapshot microscopy, we found that the quiescence marker was upregulated in stationary phase, starvation, fatty-acids enriched medium and combined host-mimetic conditions. We infected cell lines that constitute the typical niche of *M. tuberculosis* and found substantial intracellular variation, and upregulation of the quiescence marker in macrophages and alveolar epithelial cells during late stage of infection, as opposed to dendritic cells, lung fibroblasts and osteoblasts. To understand the quiescent cell’s physiology, we carried out comparative transcriptomic profiling of subpopulations, sorted according to the expression of the quiescence marker. We optimized sorting and RNA extraction, and carried out low-input RNA-seq of metabolically active versus quiescent subpopulations. Preliminary differential analysis suggested that the two subpopulations differ in their transcriptomic profiles.

**Conclusions:** Preliminary functional analysis of the RNA-seq transcriptional profiling reveals up-regulation of pathways important for adaptation in the quiescent subpopulation. We envisage to identify molecular signatures of quiescence, which may prove useful as biomarkers for subclinical tuberculosis.

Abstract 3850

Leishmanial Localised Lymphadenopathy (LLL) by Leishmania infantum: a benign disease different from visceral leishmaniasis

Juan San Martin*, Jose Manuel Ruiz-Giardin, Luis Horrillo, Alicia Castro, Isabel Garcia Arata, Jesús Garcia-Martínez, Jeronimo Jaqueti, Laura Molina, Belen Matia

1Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain, 2Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain

Background: Leishmanial localized lymphadenopathy (LLL) is an atypical form of clinical presentation of leishmaniasis as an isolated adenopathy, and only a few cases by L. infantum have been confirmed. We update our experience in the management and outcome, and propose a modified definition of LLL case

Materials/methods: We retrospectively collected clinical variables of all consecutive LLL and VL with adenopathies in Hospital Universitario de Fuenlabrada since 1st January 2004 to 1st November 2019. LLL cases and VL cases with adenopathies were compared.

Results: 30 cases of LLL were collected. 27% had cutaneous lesion associated. 57% were male, mean age 45.6, 20% not born in Spain. All of them were immunocompetent. None had systemic symptoms. Only one patient with isolated adenopathy had splenomegaly and altered hematological results and acute phase reactants elevated. Diagnosis in LLL cases was made by fine needle aspiration showing granulomatous lymphadenitis with Leishmania parasites in 87%. 3 patients were cured without treatment and they had not relapsed [mean follow up 468 weeks]. The rest received liposomal amphotericin B (L-amphB) at different doses: 10 were treated with 10mg/kg [mean follow up after treatment 322 weeks], 7 with 15 mg/kg [472 weeks], 2 with 18 mg/kg [363 weeks] and 8 with 21 mg/kg [385 weeks]. The patient with splenomegaly showed progression [new adenopathies] at the end of treatment and needed retreatment. No patient has relapsed nor presented visceral disease during follow up. By the other hand, 121 patients with VL were revised, only 3 patients with typical VL had adenopathies. 2 were HIV co-infected. All of them had fever, splenomegaly, pancytopenia and elevated ferritin and C-reactive protein.

Conclusions: Due to its clearly differentiated clinical characteristics and evolution, LLL is a different entity from VL. We propose a definition of LLL case by L. infantum if adenopathy/s is the only form of presentation, without systemic or analytical repercussion, with normal acute phase reactants, in an immunocompetent patient. In our experience, LLL by L. infantum that fit this definition is a benign disease that could be safely treated with 10mg/kg L-amphB, and even in selected cases can resolve spontaneously.

Inter- and intra-clonal diversity in *Staphylococcus epidermidis* prosthetic joint infection

Anna Both*1, Jiabin Huang1, Minjue Qi2, Samira Weisselberg1, Henning Buettner1, Christian Lausmann1, Malik Alawi2, Paul Haffke1,2, Holger Rohde1

1University Medical Center Hamburg-Eppendorf, Institute of Medical Microbiology, Virology and Hygiene, Hamburg, Germany, 2University Medical Center Hamburg-Eppendorf, Bioinformatics Facility, Hamburg, Germany, 3HELIOS ENDO-Klinik Hamburg, Hamburg, Germany

Abstract third-party references: Damp Stiftung

**Background:** *S. epidermidis* colonizes the skin and nares of virtually all human beings. However, it is also the most important pathogen in foreign material associated infections. In the present study we collected clinical samples and data of 135 patients suffering from prosthetic joint infection, in order to investigate pathogenicity factors facilitating the establishment of infection, adaptation processes during infection and bacterial diversification in the infection.

**Materials/methods:** 135 patients suffering from a prosthetic joint infection (PJI) were prospectively included into the study. Twenty-eight were caused by *S. epidermidis* and thus selected for in-depth analysis. Multiple isolates from the patients’ nares as well as from the infected joint were analysed by PFGE and NGS. Phylogenetic trees were constructed and k-mer-based genome wide association study (GWAS) were conducted. Phenotypic tests were performed: Hemolysis as a phenotypic marker of agr-expression, biofilm formation, cell-cell aggregation, proteolysis, as well as growth phenotypes and antibiotic susceptibility were investigated. To analyze the basis for the observed differences, expression analysis of important genes like agr was conducted.

**Results:** We found evidence of marked inter- and intra-clonal phenotypic diversity. In 6/28 cases a nasal clone identical to the infectious isolate was identified. Interestingly, we observed marked intra-clonal phenotypic heterogeneity within the infection and in significant phenotypic divergence from the nasal clone. Strikingly, the scc-mec-element, conferring resistance to beta-lactams, was lost in a sub-population in 3/28 infections. This result provide important implications for resistance testing in PJI.

The GWAS provided a panel of sequences associated with infectious and commensal lifestyle.

**Conclusions:** There is pronounced inter- and intra-clonal diversity in PJI caused by *S. epidermidis*. Phenotypic and genotypic differences between commensal and infecting clones will provide new insights into the establishment and maintenance of *S. epidermidis* PJI. In a clinical context, diversity in antimicrobial resistance pattern within infections is of paramount importance for the microbiological diagnosis of PJI.

Extreme short course therapy for chronic hepatitis C infection

Giacomo Stroffolini*1, Lucio Boglione1, Tommaso Lupia1, Giuseppe Cariti1, Giovanni DI Perri1

1Hospital Amedeo di Savoia, University of Torino, department of medical science, Infectious Diseases Unit, Torino, Italy

**Background:** Hepatitis C chronic infection (HCV) therapy reached in recent years surprising sustained virological response (SVR) rate with almost no side effects. Glecaprevir/Pibrentasvir (G/P) is recommended in the EASL guidelines for the treatment of Hepatitis C Chronic Infection (CHC) and has a good pharmacokinetic and pharmacodynamics (PK/PD) profile. It is approved for CHC treatment in patients on hemodialysis with a 12 weeks course. We describe here the first case in our knowledge of extreme short term course therapy to treat a well known and challenging chronic condition in difficult-to-treat patients.

**Materials/methods:** Case report.

**Case report description:** A 79-year-old man on polypharmacy with a 25 years history of CHC, diabetes, IgA nephropathy and chronic kidney disease advanced stage requiring three time/week hemodialysis consulted our ambulatory to treat CHC. He had no history of crioglobulinemia, fibrosis stage was assessed using Fibroscan as 8.2 kpa[F2], abdominal ultrasonography normal, he had no history of atopia or intolerance [alimentar nor pharmacological]. HBsAg and HIV status tested were negative. Creatinine before treatment was 1.2 mg/dl. HCV RNA 567800 UI/mL. He started treatment with (G/P) with the recommendation of taking the medication after dialysis. No apparent adverse events were observed. After seven days of treatment he started suffering uncontrollable itching; was prescribed cetirizine with previous chronic steroid therapy. Due to the lack of clinical improvement, the patient interrupted the treatment at day twelve. Itching lasted for 15 days longer. No other adverse events nor complications occurred. He underwent two blood sample testing at the end of twelve days course treatment and at week 12 (SVR12). HCV RNA tested both negative.

**Conclusions:** in this case, twelve days course therapy with G/P resulted in SVR12 in the treatment of CHC Genotype 4 in an elderly patient on three/time week dialysis for chronic kidney disease. Despite prolonged itching no other side effect were recorded. Side-effects disappeared 15 days after stopping antiviral therapy. Clinical and PK/PD studies are needed to further assess the safety and effectiveness of G/P in the management of CHC in patient with renal diseases with the chance of shorter treatment in selected cases.

Abstract 3854

**Rapid detection of colistin resistance using a newly developed protocol for MALDI-TOF MS**

Nadine Perrot*1, Dominique Dechaume1, Fabien Javerliat1, Karen Pinkston2, Victoria Girard1, Gilles Zambardi1, Jean-Philippe Charrier3

1bioMérieux, La Balme-les-Grottes, France, 2bioMérieux Inc., Hazelwood, United States, 3bioMérieux, Marcy-l’Étoile, France

Abstract third-party references: bioMérieux

**Background:** In the last several years, colistin resistance has increased and its emergence has caused global concern. MALDI-TOF MS can be used as a rapid complementary method to conventional antimicrobial susceptibility testing methods. It allows the detection of the drug target, i.e. the lipid A (LpA) moiety of the lipopolysaccharide, which generates resistance when modified by addition of 4-amino-4-deoxy-L-arabinose and/or phosphoethanolamine.

**Materials/methods:** A rapid MALDI-TOF sample preparation was developed using weak hydrolysis in acetic acid solution. Modified and unmodified LpA were detected using VITEK®MS Plus mass spectrometer in negative ionization mode, norharmane matrix and a m/z 1000-4000 mass window. A panel of 200 collection isolates from 20 different bacterial species (Pseudomonas aeruginosa, Acinetobacter baumannii, and Enterobacteriaceae) were tested. This panel of isolates included susceptible and resistant bacteria harbouring either chromosomal- or plasmid-mediated resistance genes. The MALDI-TOF assay was compared to the colistin susceptibility status given by broth microdilution (BMD), growth on CHROMID® Colistin R agar, PCR testing of mcr genes and whole genome sequencing (WGS).

**Results:** Detection of mcr genes by PCR was a good predictor of colistin resistance, but the significance of mutations observed by WGS in pmrA, pmrB, phoP, and phoQ genes was frequently uncertain. Some mutations appeared to be associated to the resistance whereas others were clearly not.

Prediction of colistin resistance using the MALDI-TOF LpA assay was in agreement with the BMD method and CHROMID® Colistin R agar for a large majority of isolates and species, e.g. LpA versus BMD agreement was 100% (36/36), 98% (41/42), and 100% (6/6) in Escherichia coli, Klebsiella pneumoniae, and Klebsiella aerogenes, respectively. However, for a few species, inconsistent results were observed for some strains, e.g. LpA versus BMD agreement was 83% (33/40) and 87% (27/31) in A. baumannii, and P. aeruginosa, respectively. This observation may be due to colistin hetero-resistance, a still poorly understood phenomenon, making it challenging to diagnose in clinical settings.

**Conclusions:** The usefulness of a short sample preparation for LpA extraction, associated with a VITEK®MS Plus reading, was demonstrated as a rapid alternative to conventional methods for colistin resistance detection on a large panel of bacterial species and strains.

Abstract 3855

**Beta-lactam exposures to methicillin-resistant Staphylococcus aureus involve cell membrane and surface adaptation for daptomycin synergy**

Cassandra Lew*1, Nagendra Mishra2;3, Sabrina Farah2, Brianne Zapata2, Arnold Bayer2;3, Warren Rose1

1Madison, University of Wisconsin- Madison, Madison, United States, 2Torrance, The Lundquist Institute-Harbor UCLA Medical Center, Torrance, United States, 3Los Angeles, David Geffen School of Medicine UCLA, Los Angeles, United States

**Background:** The synergy of β-lactams with daptomycin (DAP) against DAP resistant (DAP-R) MRSA has been well documented in the literature, however the precise mechanism behind this phenotype has yet to be elucidated. DAP’s activity is dependent on cell wall and membrane homeostasis. Further, development of DAP-R is often caused by single nucleotide polymorphisms (SNP) in genes encoding phospholipid biosynthesis proteins. This study focused on potential cell membrane (CM) mechanisms by which β-lactam antibiotics promote DAP synergy against isogenic DAP-susceptible (DAP-S) / DAP-R MRSA strain pairs.

**Materials/methods:** Nine well characterized clinically derived DAP-S/DAP-R strain pairs were utilized in this study. CM characteristics were analyzed following growth to exponential phase in the presence of sub lethal concentrations of selected β-lactams cloxacillin (LOX), cefoxitin (FOX), meropenem (MEM), or nafcillin (NAF). Cell surface charge and CM fluidity were measured with Cytochrome C binding assay and fluorescence polarization respectively. Cardiolipin (CL) specific dye N-Acryl-amide Orange (NAO) was used to quantify CL content by spectrofluorimetry and CL localization by confocal microscopy.

**Results:** Exposure of DAP-R MRSA strains to sub lethal concentrations of LOX, FOX, MEM, and NAF lead to significant alterations in CM and surface characteristics including decreased CM fluidity and decreased net positive surface charge. NAO fluorescence indicated increased amount of CL and delocalization of CL in the membrane as shown in Figure 1. Similar trends were observed in DAP-S strains exposed to the same β-lactams, although the changes were less pronounced compared to respective isogenic DAP-R strains.

![Figure 1](image_url)

**Conclusions:** These results suggest that perturbations of the CM and cell surface may be critical for induction of β-lactam synergy with DAP in MRSA strains. In particular, the increase in CL content and distribution, reduction in positive surface charge, and alteration of membrane fluidity following β-lactam exposure could improve DAP activity, especially in DAP-R strains. Further studies correlating these data to strain specific synergy and associating genetic alterations responsible for CM and surface changes are underway.

**Presenter email address:** clew@wisc.edu
Analysis of the microbiological data from the delafloxacin (DLX) phase III community-acquired bacterial pneumonia (CABP) trial using European analysis sets

Sandra McCurdy¹, Laura Lawrence¹, Sue Cammarata¹, Alessandra Nuti², Daniela Zinzi*²

¹Melinta Therapeutics, Morristown, United States, ²A. Menarini Industrie Farmaceutiche Riunite Srl, Firenze, Italy

Background: DLX is a novel fluoroquinolone (FQ) antibiotic with gram-positive/MRSA, gram-negative and atypical activity. It offers IV and oral treatment and no QT restrictions. In a Phase 3 study in CABP patients, DLX was non-inferior to moxifloxacin (MOX) in the primary EMA endpoint, clinical outcome at T0C (91.0 vs 89.2; 95% CI: -2.6, 6.2) in the modified Intent-to-Treat (mod-ITT = modified to exclude PORT II patients) population. A detailed microbiological analysis was conducted.

Materials/methods: CABP pathogens were identified by culture/non-culture methods. Pathogens identified by non-culture methods included Streptococcus pneumoniae (culture, urinary antigen [UA], nasopharyngeal [NP] swab lytA PCR), Legionella pneumophila (culture, UA, serology), Mycoplasma pneumoniae (culture, serology), and Chlamydia pneumoniae (serology). All other pathogens were identified using culture only. For S. pneumoniae cultured from NP, a concomitant lytA PCR value of ≥ 1000 gene copies/mL was required. All isolates underwent susceptibility testing, and a subset of isolates underwent molecular or phenotypic characterization including whole genome sequencing for FQ resistance mechanisms, PCR for PVL/mecA genes (S. aureus), β-lactamases (Haemophilus/Moraxella spp), and serotyping (S. pneumoniae).

Serum C-reactive protein: a useful tool in the diagnosis of tuberculosis?
Tadhg Sullivan*, Aisling Brown

1St Thomas’ Hospital, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

Background: Tuberculosis (TB) remains a significant public health concern with an estimated 10 million cases and 1.5 million associated deaths in 2018.[1] Diagnosis is often delayed due to repeated presentations to non-specialist medical services with non-specific symptoms.[2] [3] Evidence for the use of C-reactive protein (CRP) in the diagnosis of tuberculosis is conflicting. A recent meta-analysis of patients undergoing screening for TB found a pooled sensitivity for CRP of 93% and a pooled specificity of 60%.[4] 72% of the patients in the analysis were HIV positive. In populations with lower HIV prevalence, the utility of CRP is less clear. This study examined the utility of CRP in the diagnosis of microbiologically confirmed TB in a low HIV-prevalence setting.

Materials/methods:

All patients with microbiologically confirmed TB between October 2019 and October 2017 were identified using the laboratory database. Clinical and demographic data were gathered from patient records, anonymized and transcribed into EpiData, and analysed using Stata.

Results: 150 cases of TB were identified over the study period; 117 patients (78%) had a CRP recorded at diagnosis. 65% were male, 6% were HIV positive. The median age was 36 years (range 0-79). The median CRP was 42mg/L (IQR 10-97) and was highest amongst patients with disseminated TB (87mg/L, IQR 28-123) followed by those with pulmonary TB (pTB) (50mg/L, IQR 9-118). Patients with extra-pulmonary TB (EPTB) had lower median CRP (27mg/L, IQR 3-71). Patients with smear-positive pTB had a significantly higher median CRP value than those with smear-negative pTB (57mg/L vs 23mg/L p=0.001).

36% of cases of smear-negative and 9.5% of smear-positive pTB cases had normal-range CRP (≤5mg/L). The sensitivity of an abnormal CRP for pTB was 80% (90.5% for smear-positive pTB, 64% for smear-negative pTB). For EPTB, the sensitivity of an abnormal CRP was 80.5% with 19.5% of cases having a CRP within the normal limits.

Conclusions: While elevated CRP levels was a sensitive marker of smear positive pulmonary tuberculosis, many patients with smear negative pulmonary and extra-pulmonary tuberculosis had normal CRP levels. This limits its utility as a test to exclude a diagnosis of tuberculosis.

Assessment of the performances of the second generation of the ID NOW influenza A&B and comparison with the GeneXpert

Eric Farfour*, Antoine Roux1, Marie Ballester1, Marc Vasse1

1Hôpital Foch, Suresnes, France

Background: Rapid and accurate diagnostic of flu is challenging for the management of patients, but conventional PCR methods are time-consuming and require specific competencies. Molecular methods based on isothermal amplification were developed first for point of care use. However, preliminary evaluations of the ID NOW® influenza A&B performances were heterogeneous, leading the company to improve their reagent. Therefore, we aim to:

i) assess the performances of the second generation of the ID NOW®,

ii) compare the ID NOW® influenza A&B 2 to the GeneXpert® Xpress Flu/RSV use when performed within a central laboratory.

Materials/methods: i) analytical performances of ID NOW® were assessed in comparison to a reference multiplex PCR (Allplex, Seegene®, Korea): 112 clinical samples collected in 2017, 2018 and 2019 were included of which 63 and 26 positives to influenza A and B respectively and 23 negatives for influenza viruses. All discrepant results were repeated by both methods.

ii) Invalid rate per operator and time-to-result were calculated for the GeneXpert® and the ID NOW® during 2017-2018 and 2018-2019 flu outbreaks, respectively.

Results: i) After discrepant resolution, ID NOW influenza reaches an overall sensitivity and specificity of 96.6% and 96.1% respectively. All but one false-negative results display a Ct > 37 using the reference method. A single false-positive was noticed for influenza B.

ii) Overall, the rate of invalid results was 2.02% and 1.93% for ID NOW® and GeneXpert® respectively (p = 0.86). For both instruments, a single operator was involved in about half of all invalid results. Excluding this operator, the invalid rate falls to 1.09% and 1.11% respectively (p=0.95). Time-to-result from arrival to the laboratory was significantly shorter in the ID NOW® versus the GeneXpert® group [33 vs 97 min, p < 0.01].

Conclusions: The second generation of the ID NOW® influenza A&B 2® displays high performances, comparable to conventional PCR method. In order to prevent invalid results, we highlight the need for adequate training of operators. Also, when implemented in a central laboratory, the location of the instrument could have a strong impact on time-to-results.

Abstract 3860

**Characteristics of bloodstream infections in patients with liver cirrhosis in a general hospital**

Sophie Nguyen*1, Pauline Wallard1, Olivier Oddoux1, Magali Anastay1, Dominique Descamps1

1Béthune Hospital, Béthune, France

**Background:** Data on bloodstream infections (BSIs) in patients with liver cirrhosis are scarce. The aim of our study was to analyse clinical characteristics, and prognosis of BSIs in liver cirrhosis (LC) patients followed in our General Hospital.

**Materials/methods:** In our centre, patients with BSIs are evaluated by an ID specialist who collects prospectively clinical and microbiological characteristics, and data on empirical antibiotic treatment. These records are inserted in an anonymous database (Epidata software). An extraction was performed on the period from May 1, 2017 to August 31, 2019, and patients with LC were analysed.

**Results:** During the study period, 126 BSI (including 81 male patients, 67%) occurred in LC patients, which represented 10.4% of all consecutive BSIs episodes (n=1210). Mean age was 65 ± 11 years, LC patients were younger than patients without LC (mean age 72 ± 17 years, p<0.001). Community-acquired infections were predominant (92/126, 73%), and the most frequent portal of entry was digestive tract (n=42, 33%), followed by urinary tract (n=21, 17%). A total of 138 strains were isolated, the most frequent were *E. coli* (n=44, 32%, among which 2 [4%] were ESBL), *S. aureus* (n=22, 16%, among which 2 [9%] were methicillin-resistant), and streptococci/enterococci (n=28, 20%), which was similar to patients without LC. Overall, an empirical antibiotic therapy was prescribed in 90 patients (71%), with at least one active drug in 74 patients (59%). Severe sepsis rate was 38% (n=48), and shock septic rate was 11% (n=14), with a 7-day mortality rate of 16% (tending to be higher than patients without LC [10%], p=0.06) and a 30-day mortality rate of 25% (higher than patients without LC [16%], p=0.004).

**Conclusions:** In our centre, more than 10% of BSIs occurred in LC patients. LC patients with BSIs were younger than patients without LC, with a majority of community-acquired infections, and a predominance of digestive tract infections. Epidemiological data were similar to patients without LC, the main pathogens were *E. coli* and *S. aureus*, with low-resistance rates, thus antibiotic protocols should not be modified in patients with LC. Mortality rate was higher in LC patients.

Abstract 3862

**Chagas disease diagnosis: performance of a new automated native antigen technique**

Jun Hao Wang Wang*, Belen Rivaya Sanchez1, Gema Fernández Rivas1, Noelia López González1, Lluís Valerio2, Lurdes Matas Andreu1

1Microbiology Department, Clinical Laboratory North Metropolitan Area, Germans Trias i Pujol University Hospital, Department of Genetics and Microbiology, Autonomous University of Barcelona, Badalona, Spain, 2North Metropolitan International Health Unit, Germans Trias i Pujol University Hospital, Badalona, Spain

**Background:** Chagas disease (CD) burden is growing in non-endemic countries due to population mobility and globalization. Spain is one of the countries with highest prevalence (up to 10-15%). Blood screening is a cost-effective strategy to prevent its transmission. CDC recommend performing two different CD diagnosis tests, ideally with both native and recombinant antigens for IgG detection. Except for chemiluminescence recombinant assays, most of commercialized native tests in Spain are not automated and manual processing is required. The rising number on CD demanded tests has made high throughput laboratories to start diagnosis algorithm with a recombinant antigen method, employing the manual native technique as confirmation test. Our aim was to compare a new automate native antigen test with our recombinant method as screening tool for CD.

**Materials/methods:** A total of 556 serums (202 retrospective and 354 prospective samples), mainly from Latin American patients, were tested by two CD tests: 1) Our reference assay, a chemiluminescence immunoassay employing a recombinant multi-antigen protein (Liaison® XL murex Chagas, DiaSorin, Italy); 2) A new chemiluminescence immunoassay based on native antigen (Vitros® Anti-T. cruzi assay, Ortho-Clinical Diagnostics, USA). Sensibility, specificity, positive and negative predictive values for the native technique over the recombinant assay were determined. Prevalence was calculated from the prospective cohort. Discrepant results between both assays were analyzed.

**Results:** Among the 556 samples, 160 (28.8%) were positive and 383 (68.9%) were negative by both assays. In the prospective cohort, 25/354 samples were positive. Therefore, our CD prevalence was 7%. Only in 1/556 samples (2.3%) discrepancies were observed. Compared to Liaison®, Vitros® sensitivity, specificity and positive and negative predictive values were respectively, 93.6%, 99.5%, 98.8% and 97.2%.

**Conclusions:** Due to lack of a unique gold-standard serological assay, combination of two tests remains to be the best approach, especially in those inconsistent results. Our data suggest that Vitros® could be a good option as CD screening assay, with a 97.7% of concordant results with our reference technique. Specifically, given its high specificity, Vitros® can be an option as confirmation assay for CD diagnose.

Development and validation of a specific real-time PCR assay for the rapid detection of Candida auris
Ahmad Ibrahim1, Sophie Baron1, Hanane Youssi1, Rym Lalaoui1, Linda Hadjadj1, Serge Morand2, Jean-Marc Rolain*1, Fadi Bittar1

1Aix Marseille Univ, IRD, APHM, MEPHI, IHU Méditerranée Infection, Marseille, France, 2CNRS ISEM-CIRAD ASTRE, Montpellier, France

Background: Since its description in 2009, Candida auris has been considered as an emerging and multidrug-resistant fungus with a high capacity to cause nosocomial infections especially in immunocompromised patients, it causes fungemia, internal organ infections, skin infections and otitis. A strong association between C. auris infection and mortality has been documented in the world. Given the recent global emergence of C. auris, a rapid detection and identification of this pathogen is necessary to control its spread. The aim of this study was to develop a specific molecular diagnostic tool able to detect the 4 emerging clades of C. auris.

Materials/methods: A RT-PCR (Real-time polymerase chain reaction) system was designed based on a GPI (Glycosyl-phosphatidylinositol) protein encoding-gene specific for C. auris. A collection of 50 bacteria and 70 fungi were tested to confirm its specificity and sensitivity. Then 2073 clinical and environmental samples from different geographical countries were tested also to detect C. auris.

Results: The in Silico analysis shows that this system was able to amplify only C. auris, it was highly specific (100%), reproducible and sensitive, with a limit of detection of 13 CFU/qPCR reaction. All clinical and environmental samples were negative.

Conclusions: To the best of our knowledge, we have developed a specific, sensitive and reproducible real time PCR system able to detect specifically C. auris.

Abstract 3866

**Visceral leishmaniasis by Leishmania infantum in immunocompetent adults: update of the leishmaniasis outbreak in Madrid (Spain)**

Juan San Martín*, Jose Manuel Ruiz-Giardin¹, Alicia Castro¹, Luis Horrillo¹, Laura Molina¹, Jeronimo Jaqueti¹, Jesús García-Martínez¹, Isabel Garcia Arata¹, Belen Matia¹

¹Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain

**Background:** Visceral leishmaniasis due to *L. infantum* mainly affects children and immunosuppressed, and there is scarce information on management in immunocompetent adults. Since June 2009, an outbreak of leishmaniasis on Fuenlabrada [Madrid, Spain] was declared. We update our experience in the management of ICVL in this outbreak.

**Materials/methods:** From the beginning of the outbreak in June 2009 until November 1, 2019 we have prospectively collected clinical variables, diagnosis, treatment and follow-up of all adult patients with VL treated at Hospital Universitario de Fuenlabrada.

**Results:** Since the beginning of the outbreak we have identified 85 immunocompetent patients with visceral leishmaniasis (ICVL). 72% were male, mean age 44.1 years (18-95). 53% were of sub-Saharan origin, but residing in the area for at least one year before diagnosis. 98% presented with fever, 29% splenomegaly (95% radiological), 87% anemia, 91% leukopenia and 92% thrombocytopenia. 76% had ferritin greater than 1000 mcg/dl. 38% met criteria for hemophagocytic syndrome. PCR was positive in 91% in bone marrow and 82% in blood of ICVL and was the most reliable technique. Regarding serology, rK39 rapid test was positive in 43% of patients with ICVL, but showed a positive predictive value of 99%. 93% of patients were treated with liposomal amphotericin B (L-amphB). There were 8 relapses of which 5 were patients of sub-Saharan origin (12% vs. 8% others, p NS). Total dose of L-amphB under 21mg/kg was the only variable related to failure, OR 30.0 (4.1-200), p = 0.001. 3 of the relapses occurred beyond 6 months.

**Conclusions:** There was a high proportion of patients of sub-Saharan origin among ICVL. One third met criteria for hemophagocytic syndrome, all resolved exclusively with VL treatment. The rapid rK39 test had a low sensitivity, but a high specificity that allows confirming the diagnosis in a few minutes. In our environment, we do not recommend using less than 21mg/Kg of liposomal amphotericin B in ICVL, and even higher doses could be assessed in sub-Saharan. The follow-up in ICVL should be at least one year after treatment.

Abstract 3867

**Health economics of nosocomial pneumonia in UK intensive care units: an exploratory study**

Adam Wagner1,2, David Turner1, Virve Irene Enne3, Rossella Baldan4, Charlotte Russell1, David Livermore1

1University of East Anglia, Norwich Medical School, Norwich, United Kingdom, 2Applied Research Collaboration East of England, Cambridge, United Kingdom, 3University College London, London, United Kingdom, 4Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

**Abstract third-party references:** On behalf of the INHALE WP2 Study group

**Background:** Both Hospital-Acquired and Ventilator-Associated Pneumonia (HAP and VAP) cause considerable health care costs, as well as significantly impacting patient outcomes. The United Kingdom’s (UK’s) National Institute for Health Research-funded INHALE (https://www.ucl.ac.uk/inhale-project/) programme is exploring the use of rapid molecular diagnostics to improve the treatment of HAP/VAP patients by more swiftly identifying causative pathogens and their antibiotic resistances. Resulting changes to patient management and antibiotic use potentially have substantial resource implications, and it is important to be able to quantify these. Accordingly, to establish a baseline, a cross-sectional health economic survey of recent HAP/VAP was undertaken.

**Materials/methods:** Patients, or their representatives, from four UK hospital Intensive Care Units (ICUs) were approached for involvement if they were either i) starting a course of antibiotics or ii) having a change of antibiotics for the treatment of HAP or VAP. We collected information to allow estimates of: cost of ICU stay [length of stay (LOS) and related health resource group (HRG)], acquisition cost (from the British National Formulary) of antibiotics used in the 21-days after recruitment; and quality of life [EuroQoL EQ-5D-5L] in those alive at 21-days.

**Results:** N=143 patients were recruited. They had considerable ICU-associated LOS and hospital costs: their mean stay was 22 days and mean costs were GBP £43,100). Both LOS and costs were heavily right-skewed (most values are low but the remainder take large values resulting in a long right ‘tail’ such that the mean is greater than the median). Compared with HAP, VAP caused greater LOS and ICU costs. Antibiotics themselves formed only a tiny fraction of total costs (mean 21-day cost was £321). A total of 43 people completed the EQ-5D-5L: a wide ranges of utilities resulted, ranging from 0.8 to -0.4 (with negatives indicating states valued worse than death).

**Conclusions:** HAP, and particularly VAP, are associated with significant hospital costs. Interventions that could improve the care of individuals with HAP/VAP and reduce their LOS would significantly free up scarce ICU resources, allowing other patients to be treated.

**Presenter email address:** v.enne@ucl.ac.uk
Intestinal colonisation by carbapenemase-producing Enterobacteriaceae detected by polymerase chain reaction in patients with negative cultures: do they really have an increased risk of infection?

Andres Nicolas Rearte1*, Fabian Herrera1, Jimena Nievas1, Diego Sanchez Thomas2, Rocio Rojas1, Federico Nicola1, Maria Silvia Relloso2, Jorgelina Smayevsky1, Elena Temporiti1, Fatima Gauna1, Wanda Alcalá1, Andrea Oviedo1, Florencia Bues1, Sofia Zerboni1, Pablo Bonvehi1

1CEMIC, Buenos Aires, Argentina; 2Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Background: Intestinal colonization detected by culture of carbapenemase-producing Enterobacteriaceae (CPE) is an important risk factor for infection. However, little is known about whether colonization detected only by polymerase chain reaction (PCR) has the same risk.

Materials/methods: Observational retrospective cohort study performed between 2017 and 2019. Adult patients admitted for any cause and screened for CPE gut colonization with cultures and multiplex PCR for blaKPC/blaOXA genes, in a University Hospital of Buenos Aires, Argentina were included. They were divided into 3 groups: Group 1 (G1) positive PCR results with negative cultures, Group 2 (G2) both positive tests, and Group 3 (G3) both negative tests. The main outcome was CPE infection episodes in the first 270 days. Categorical variables were analyzed by $\chi^2$ test and continuous variables by Kruskal-Wallis test. To analyse the PCR positive results in patients with CPE negative cultures, we performed a multivariate analysis for the main outcome using binary logistic regression analysis between G1 and G2.

Results: 477 patients were included. G1: 89 (18.7%), G2: 113 (23.7%) and G3: 275 (57.7%). Baseline characteristics were similar in all groups: Median age (IQR 25-75) 66 (54-78), 66 (56-79) and 69 (61-80), respectively; Charlson Comorbidity Index (IQR 25-75): 5 (3-7), 5 (3-6), and 5 (3-6), respectively. Risk factors for CPE acquisition were more frequent in G1 and G2 than in G3: previous antibiotic therapy: 53.9% vs 60.2% vs 21.8%, P=0.0001; previous carbapenem therapy: 29.2% vs 30.4% vs 8.3%, P=0.024; previous ICU admission: 34.8% vs 44.2% vs 25.8%, P=0.002; previous surgery: 25.8% vs 26.5% vs 9.5%, P=0.0001; length of hospitalization (IQR 25-75): 21 (7-30) vs 31 (8-32) vs 15 (5-14), P=0.0001. Finally, CPE infection episodes were more frequent in G1 and G2 than G3: 16.9% vs 27.4% vs 2.5%, P=0.0001. In multivariate analysis a positive PCR result was associated with higher risk of CPE infection: OR 4.24, P=0.008 (CI95% 1.46 - 12.3).

Conclusions: Patients that are colonized by CPE detected by PCR and have CPE negative culture results in rectal swabs have an increased risk of infection by CPE. This result is important for decision-making in clinical practice.

Abstract third-party references: Centers for Disease Control and Prevention (CDC)

Background: Multidrug-resistant tuberculosis (MDR-TB) is a major obstacle to TB elimination. Migration contributes to TB importation to low-burden countries. The aim of this investigation was to describe epidemiologic characteristics of travellers and migrants with MDR-TB reported to GeoSentinel, a global travel and tropical medicine network.

Materials/methods: Patients with a confirmed or probable diagnosis of MDR-, pre-extensively drug-resistant (pre-XDR), or extensively drug-resistant (XDR-TB) reported to GeoSentinel between 2008 and 2017 were analysed regarding demographics, travel or migration details, and disease attributes. The analysis was stratified according to two resistance levels (MDR-TB and pre-XDR/XDR) as well as three regions of birth (Georgia, the Former Soviet Union [FSU] excluding Georgia, and non-FSU/other countries).

Results: There were 164 patients from 16 GeoSentinel sites, 98.8% of whom were first-generation immigrants. Median age was 31 years [range: 11–63]; 61% were male. HIV co-infection was uncommon [3.7%]. Twenty-five percent were born in Georgia and 24% in other FSU states. Subclassification of MDR-TB was known for 147 patients [12.2% pre-XDR and 12.9% XDR-TB]. Time from immigration to presentation was shorter in patients from the FSU [median = 86 days [interquartile range [IQR]: 9–643]] and Georgia [4 [IQR: 1–13]] than other countries [300 [IQR: 97–1018]] and correlated with degree of resistance. Symptom onset before immigration was reported more frequently by patients with pre-XDR/XDR-TB as well as three regions of birth (Georgia, the Former Soviet Union [FSU] excluding Georgia, and non-FSU/other countries).

Conclusions: The temporal relation between immigration and presentation to a GeoSentinel site may be due to the need for specialized care not available in the home country of travellers and migrants with MDR-TB. Resources should be devoted to better understanding the factors contributing to the cross-border spread of MDR-TB.

Occurrence of sporadic human ascariasis in non-endemic regions: the importance of zoonotic transmission from swine

Thomas R. Fritsche*1,2, Jennifer Meece3, Susan Meyer1, Kelly Ortega1, Nicolette Wolff1, Matthew Hall4
1Marshfield Clinic Health System, Division of Laboratory Medicine, Marshfield, United States, 2University of Wisconsin-La Crosse, La Crosse, United States, 3Marshfield Clinic Health System, Marshfield Clinic Research Institute, Marshfield, United States, 4Ascension Medical Group, Weston, United States

Background: Ascariasis in developed countries occurs only sporadically, and usually in travelers or in children in rural settings with direct or indirect exposure to *Ascaris suum* from swine. Reciprocal transmission between humans and swine is possible given *A. suum* and *A. lumbricoides* are considered conspecific based on published mtDNA and nuclear ribosomal ITS-1 studies with recognized phenotypic/genotypic differences reflecting host-specific adaptive changes. Here we evaluated 15 cases of human ascariasis detected over 6 a year period from specimens submitted to a regional parasitology laboratory in a non-endemic region of the Upper Midwest USA.

Materials/methods: Fifteen helminth specimens spontaneously passed per rectum were submitted for laboratory identification during 2013-19 and identified morphologically as *A. lumbricoides/suum* (undifferentiated). All patients attended local clinics and brought specimens in for identification. Clinical records were available for 13 patients.

Results: Ages ranged from 14 months to 41 years with 13 cases (87%) occurring in children <=12 years and 2 (13%) >30 years; 9 patients (60%) were female. Thirteen (87%) of the *A. lumbricoides/suum* specimens were adults and 2 (13%) were juveniles. Individuals with records available either lived on or had visited a farm (5) or hobby farm (2) where pigs were currently or likely historically present; lived at a rural address (4); used animal manure for gardening (1); or lacked discernable farm connections though was active outdoors (1). International travel history was lacking in all cases. One 2-year old child from a rural address had passed 2 worms 6 months apart. All 13 patients were treated with albendazole per guideline without complication.

Conclusions: Ascariasis attributable to poor sanitation has been largely eradicated from the USA since the early 1980s. Sporadic infections in non-travelers have, however, continued to be recognized and likely represent zoonotic transmission from domesticated swine. While human and pig *Ascaris* have long been considered distinct species, recently published molecular and cross-transmission experiments point to conspecificity. This case series is a reminder of the zoonotic disease risks posed by swine-origin *Ascaris*, especially in young children, and reinforces the need for proper herd management and attention to personal hygiene for at-risk individuals.

Biomarkers help to stop secondary prophylaxis on Leishmania-HIV co-infected patients

Juan San Martin*, Jose Manuel Ruiz-Giardin, Eugenia Carrillo, Alicia Castro, Laura Botana, Laura Molina, Ana Victoria Ibarra-Meneses, Jeronimo Jaqueti, Isabel Garcia Arata, Jesus Garcia-Martinez, Francisco Javier Moreno Nuncio

1Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain, 2Centro Nacional de Microbiología, Instituto de Salud Carlos III, Majadahonda, Spain

Background: Secondary prophylaxis with liposomal amphotericin B (L-amphB) for HIV patients with visceral leishmaniasis (VL) is recommended, but it is not clear when to stop it. CPA-SLA (cellular proliferative assay to soluble Leishmania antigen) and interferon gamma (IFN-γ) have been tested as markers of specific cellular immunity. We update the usefulness of these tests for withdrawal of secondary prophylaxis in Leishmania-HIV coinfected patients.

Materials/methods: From January 2013 to 1st November 2019, Leishmania-HIV coinfected patients with previous or active VL were recruited after the end of treatment for VL. PCR, CPA-SLA and IFN-γ were included besides habitual test for HIV.

Results: 15 Leishmania-HIV coinfected patients were identified. 1 was lost and 3 died of events not related to leishmaniasis. 11 were recruited after standard treatment for VL with L-amph B. All of them were on HAART according guidelines, were asymptomatic when recruited and completed follow up (364 weeks).

7 patients showed negative PCR and positive CPA-SLA and IFN-γ. Prophylaxis had been stopped in 3 of them before they were recruited. These 3 patients have not relapsed during follow up. The other 4 patients were still on prophylaxis when were recruited. Prophylaxis was stopped after these results. CD4 levels were 152, 189, 243 and 359/mm3. None relapsed during follow up (mean 251 weeks, range 59-363, from the end of prophylaxis).

4 patients showed negative CPA-SLA. 1 showed negative PCR and positive IFN-γ, and prophylaxis was stopped when CD4 were 154, without relapses after 163 weeks. The other 3 showed positive PCR and negative IFN-γ. Prophylaxis were maintained but all of them relapsed and needed retreatment. After retreatment, 1 patient changed to negative PCR and positive CPA-SLA and IFN-γ. Prophylaxis was stopped (CD4 301) and this patient has not relapsed after 162 weeks of follow up. The other 2 showed still positive PCR and negative CPA-SLA and IFN-γ at the end of follow up, and are still on prophylaxis.

Conclusions: In this small sample of Leishmania-HIV coinfected patients, CPA-SLA and IFN-γ are valid markers of specific cellular immunity, and allowed withdrawal of secondary prophylaxis of leishmaniasis, not matter CD4 level.

Abstract 3874

The effect of live attenuated influenza vaccine on pneumococcal colonisation densities among children aged 24-59 months in Gambia

Chikondi Peno*, Edwin Armitage¹, Melanie Clerc¹, Carlos Lopez Balcasar¹, Ya Jankey Jagne², Sainabou Drammeh², Sheikh Jarju², Hadijatou Sallah², Elina Senghore², David Dockrell¹, Ed Clarke², Beate Kampmann¹, Debby Bogaert¹, Thushan I. De Silva²,³,⁵,⁶

¹University of Edinburgh, Queen Medical Research Institute, Edinburgh, United Kingdom, ²Medical Research Council Unit The Gambia at the London School of Hygiene and Tropical Medicine, Banjul, Gambia, ³Medical Research Council Unit The Gambia at London School of Hygiene & Tropical Medicine, Medical Research Council Unit The Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia, ⁴The London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom, ⁵Imperial College London, Centre for International Child Health, Section of Paediatrics, Department of Medicine, London, United Kingdom, ⁶University of Sheffield, The Florey Institute, Department of Infection, Immunity and Cardiovascular Disease, Sheffield, United Kingdom

Background: Live attenuated influenza vaccine (LAIV) has been shown to increase Streptococcus pneumoniae carriage duration and colonization densities in murine and human challenge models, similar to influenza virus infection. We investigated the effect of LAIV on S. pneumoniae colonization dynamics in the upper respiratory tract (URT) of Gambian children, a population with high pneumococcal colonisation rates, as a model to study the interaction between S. pneumoniae and influenza.

Materials/methods: In a clinical trial in The Gambia (NCT02972957), children aged 24-59 months were randomised 2:1 to receive LAIV at day 0 (n=213) or remain unvaccinated until day 21 (n=108). Children were recruited during January-April in either 2017 or 2018. Nasopharyngeal swabs (NPS) were collected at day 0, day 7 and day 21. Pneumococcal colonisation prevalence and densities were determined using quantitative polymerase chain reaction targeting the autolysin gene (lytA qPCR). Presence of other respiratory viruses was determined by a multiplex RT-PCR. Generalized mixed effects models were used to assess the effect of LAIV and other variables on pneumococcal colonisation densities.

Results: Pneumococcal colonisation prevalence was high (>75%) and similar in LAIV recipients and unvaccinated controls at each timepoint (day 0: p=0.1; day 7: p=0.45; day 21: p=0.24). We observed a positive association between LAIV and pneumococcal colonisation density (p=0.009). Lower age (p=0.003), recruitment in 2018 (p=0.008) and presence of another respiratory virus at baseline (p=0.008) were other contributory factors. Within the LAIV group, children with an asymptomatic respiratory viral infection at the time of LAIV had an earlier peak of pneumococcal density at day 7, compared to those with no other virus detected. An unexpected rise in pneumococcal density was observed in the control group between day 7 and 21, which was potentially explained by acquisition of a new respiratory virus between day 0 and 7, seen in 22% of children.

Conclusions: LAIV was associated with increased pneumococcal colonisation densities in the first 21 days following vaccination. LAIV-associated increase in S. pneumoniae densities was enhanced by asymptomatic viral co-infection prior to LAIV administration, suggesting that S. pneumoniae proliferation in the nasopharynx may be driven by sequential natural and induced viral infections.

Effect of biocides on the mobilization of plasmid-encoded OXA-48 carbapenemases from Klebsiella pneumoniae growing in biofilms

Patricia Pérez-Palacios1,2, Ana Gual-De-Torrella*,1,2, Mercedes Delgado-Valverde1,2, Jesus Oteo3,4, Alvaro Pascual Hernandez1,2,4, Felipe Fernández-Cuenca1,2

1UGC Enfermedades Infecciosas, Microbiología Clínica y Medicina Preventiva. Instituto de Biomedicina de Sevilla (IBIS), Hospital Universitario Virgen Macarena/CSIC/Universidad de Sevilla, Seville, Spain, 2Spanish Network for the Research in Infectious Diseases (REIPI RD16/0016), Instituto de Salud Carlos III, Madrid, Spain, 3Laboratorio de Referencia e Investigación en Resistencia a Antibióticos e Infecciones relacionadas con la Asistencia Sanitaria, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain, 4Departamento de Microbiología, Universidad de Sevilla, Seville, Spain

Background: The dissemination of plasmid-encoded carbapenemases represents a serious health problem worldwide. This is particularly worrying for blaOXA-48-producing K. pneumoniae (OXA-48/Kp) that it is spreading efficiently through diverse environmental reservoirs. Biofilm formation can contribute in the survival of OXA-48/Kp under adverse conditions, preventing or reducing the activity of biocides. Recent studies suggest that plasmids can be mobilized under stress conditions [ie. biocides]. The objective of this study was to evaluate the effect of sublethal concentrations of some commonly used biocides on the mobilization of plasmid-encoded OXA-48 carbapenemases from K. pneumoniae growing in biofilms.

Materials/methods: Seven representative isolates of different ST types of OXA-48/Kp (Table) were selected. For conjugation assay, Escherichia coli J53 (azide resistant) was used as a receptor. For biofilm formation, donor and receptor mixtures [1:1] were prepared in polystyrene plates in absence [control] and presence of concentrations of chlorhexidine (CHX), ethanol (EtOH), sodium hypochlorite (NaClO), povidone iodine (POV) or triclosan (TRI) equivalents to 0.25x their respective MICs and were incubated 24 hours at 37ºC. Biofilms adhered to wells were sonicated and subcultured in chromogenic agar containing azide (100,000 mg/L) and ertapenem (0.1 25 mg/L). Conjugation frequency (CF) in biofilms was calculated as Nº of UFC of transconjugants in solid medium with azide and ertapenem / Nº of E. coli J53 in azide medium. Differences associated with a p <= 0.05 (Student test) were considered statistically significant.

Results: The table shows the fold-change in the CF in biofilms determined in presence of biocide respect to the CF determined in absence of biocide.

Conclusions: The tested biocides showed a variable effect on the CF in biofilms of OXA-48/Kp. This effect was also clone-dependent.

Abstract 3881

High occurrence of Serratia spp. in abiotic surfaces at hospital intensive care unit areas during non-outbreak situations

Sonia Aracil-Gisbert*, Natalia Guerra-Pinto†, Almudena Ortiz-Fernández‡, Val Fernandez Lanza‡, Cruz Soriano‡, Miguel D. Fernandez-De-Bobadilla§, Sergio Gallego-Zarzosa‡, Marina López-Olivencia‡, Verónica Quinteros-Fiel‡, Patricia Ruiz-Garbajosa‡, Rafael Canton Moreno‡, Raúl De Pablo‡, Fernando Baquero‡, Teresa M. Coque‡

1Ramón and Cajal Hospital, Microbiology Service, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 2Ramón and Cajal Hospital, Bioinformatics Unit, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 3Ramón and Cajal Hospital, University of Alcalá, Department of Intensive Care, Madrid, Spain

Background: Serratia spp. (Se) is frequently involved in clonal or multiclonal nosocomial outbreaks at ICUs, often carrying genes encoding Extended Spectrum Beta-lactamases (ESBL) or carbapenem resistance (CR). Sinks (SK) are identified as reservoirs of ESBL/CRSe but the ecology of this species in built hospital environments (BE) remains largely unexplored.

Materials/methods: We weekly collected 5 samples/patient room (sinks-SK; ventilator’s-touchscreen-VT; washbasin-WB; bedrails-BR) and 2 samples from staff-areas (keyboards) using EZ-Reach-Sponges (April-October 2019). We plated the 1,728 samples [(5x14rooms+2)x24weeks] on ChromagarOrientation and characterized bacterial colonies (1/morphotype; 10,180 colonies). Identification (MALDI-TOF-MS), antimicrobial susceptibility (disk-diffusion, DDST, Hodge test), clonal diversity (XbaI, S1-PFGE, FTIR) were analyzed by standard procedures. Metadata (clinical, microbiology, surveillance) analysis using REDCap (Research Electronic Data Capture) application was used to integrate and further exploit comprehensive metadata [clinical records, IC, microlab, BE surveillance]. ICU-metrics for the period studied includes 95% occupancy, 244 patient admissions, 28% MDR colonization-rate (23% ESCAPEm, 6.8% CPSm).

Results: MALDI-TOF-MS identified 1,026 isolates as Se with a high-score (88% S. marcescens, Sem; 12% S. ureilytica). Sem was recovered in 14/14 ICU-rooms (45 isolates/week), from SK (97.6%) and also from WB and VT (2.4%). Sem isolates clustered according the antimicrobial susceptibility to beta-lactams (aminopenicillins-AMP; amoxicillin-clavulanic-AMC; cefoxitin-FOX; 3GCephalosporins-3GC; carbapenems) in 5 groups: i) susceptible to all beta-lactam classes (S;39.5%) ii) AMPc hyperproducers (AMPc;25.1%), iii) AMP+AMC resistant (AA;17%), iv) ESBLproducers (1.9%), v) CR (1.8%), vi) other phenotypes (12.8%). ESBLSm appeared in SK of 5/14 rooms, persistently in 2/14 rooms. Isolates with S, AMPc and AA phenotypes appeared in 12/14, 6/14 and 5/14, respectively. Different Sem populations were simultaneously recovered in rooms #8 (AMPc, AA), #10 (S, AMPc, A), #12 (S, AMPc, AA) and #13 (S, AMPc) along the time. Sem were detected in patients of rooms #3, #8 and #10, eventually related to Sem from BE.

Conclusions: Sinks are common reservoirs of “resident” Sem populations in hospitals. The low occurrence and persistence of ESBL/CRSm suggest differences in the adaptation of Sm populations to humans and abiotic surfaces. Fully characterization of unusual and consistently recovered isolates susceptible to beta-lactams [in progress] will facilitate the understanding of BE ecology.

A randomised prospective clinical trial to assess the role of procalcitonin-guided antimicrobial therapy to reduce long-term infections' sequelae [PROGRESS]

Evdokia Kyriazopoulou*, Lydia Liaskou-Antoniou1, Georgios Adamis2, Antonia Panagaki1, Georgios Chrysos1, Lianna Sybardi1, Zoi Alexiou2, Garyfallia Poulakou2, Malvina Lada1, Evangelos Giamarellos-Bourboulis1

1National and Kapodistrian University of Athens, Medical School, 4th Department of Internal Medicine, Athens, Greece, 2Gennimatas General Hospital of Athens, 1st Department of Internal Medicine, Athens, Greece, 3Tzaneio General Hospital of Piraeus, 2nd Department of Internal Medicine, Athens, Greece, 4Thriasio General Hospital of Eleusis, 1st Department of Internal Medicine, Athens, Greece, 5Thriasio General Hospital of Eleusis, 2nd Department of Internal Medicine, Athens, Greece, 6National and Kapodistrian University of Athens, Medical School, 3rd Department of Internal Medicine, Athens, Greece, 7Sismanogleio General Hospital of Athens, 2nd Department of Internal Medicine, Athens, Greece

Background: Procalcitonin (PCT) has already been introduced to guide duration of antimicrobial treatment for lower respiratory tract infections. Although data support a similar benefit in sepsis, the possible long-term benefit of this strategy has never been investigated. PROGRESS (ClinicalTrials.gov number, NCT03333304) was a multicenter randomized clinical trial in Greece, aiming to investigate long-term benefit of the PCT-guided stop of antimicrobials in sepsis.

Materials/methods: From November 2017 until January 2019, 266 sepsis (according to Sepsis-3 definition) patients with lower respiratory tract infections, acute pyelonephritis or primary bacteremia, were randomized to PCT-guided antimicrobial treatment (PCT group) or treatment according to local standard practice (SOC group). In the PCT group, PCT was daily measured starting from day 5 and physicians were advised to discontinue antimicrobials when values were lower than 0.5ng/ml or when any more than 80% baseline decrease was found. The composite primary endpoint was the change in the rate of infection-associated adverse events, i.e. infections by multidrug resistant organisms (MDRO), infection by Clostridium difficile and infection-associated death on day 180. Secondary endpoints were 28-day mortality, duration of antibiotic treatment and cost of hospitalization.

Results: The primary outcome was met in 15.3% of patients in the SOC group compared to 7.2% in the PCT group (hazard ratio, 0.45; 95% confidence intervals [CIs] 0.20 to 0.98; P=0.04) (Figure). 28-day mortality was 28.2% (95% CIs, 21.2%-36.5%) and 15.2% (95%CIs, 10.0%-22.2%) respectively (P=0.02). Median (interquartile range) treatment duration was 10 [8] and 5 [2] days respectively (P<0.001). The effect of PCT guidance on treatment duration was similar for all types of infection. Antimicrobial-associated adverse events were reported in 63.4% (95%CIs, 54.8%-71.1%) and 51.2% (95%CIs, 42.5%-59.8%) respectively (P=0.05). The mean (standard error) cost of hospitalization was 1,274.65€ (110.79) in the PCT group; this was 1,758.17€ (163.50) in the SOC group (P=0.02).

Conclusions: Use of an early PCT-guided stopping rule of antimicrobials in sepsis was proven of significant benefit by reducing secondary infections by MDRO and C.difficile, 28-day mortality and cost of hospitalization. Shorter duration of antibiotic treatment associated with lower adverse events may be a plausible explanation.

Abstract 3883

**Detection of Enterovirus in cerebrospinal fluid 24 hours a day by a fully-automated PCR assay is associated with improved management of aseptic meningitis in adult patients**

Marie-Pierre Otto1, Chrystelle Darles1, Julie Plantamura1, Stephane Foucher1, Patrick Benner2, Frédéric Janvier*1,3

1Hospital Instruction Of Armées Sainte-Anne, Microbiologie, Toulon, France, 2Hospital Instruction Of Armées Sainte-Anne, Urgences, Toulon, France, 3Val-de-Grâce School, Paris, France

**Background:** Molecular techniques are recognized as the reference standard for the diagnosis of enterovirus (EV) infections and enable to simplify aseptic meningitis (AM) patient management.

The aim of our study is to evaluate impact of performing 7 days a week and 24 hours a day (24/7) the RT-PCR Xpert EV on Geneexpert (Cepheid) in cerebrospinal fluid samples (CSF) from the emergency department.

**Materials/methods:** Our observational study consists in including all patients from emergency department with AM whose CSF has been analysed by EV RT-PCR from 01/01/2015 to 30/06/2019. Medical files were analyzed to collect therapeutic attitude especially antimicrobial treatments and length of hospitalization.

**Results:** Among the 1535 CSF collected at the emergency department during the study, 165 EV RT-PCR have been performed (10.75%). 133 remained negative (1st group) and 32 were positive (2nd group). None antibiotic or antiviral treatment have been given to 47 patients of 1st group (35.3 %) and to 12 patients of 2nd group (37.5%). Others patients, in two groups, were treated by one or several anti-infectives among cefotaxim, amoxicillin, gentamicin and acyclovir.

In the 2nd group, 97% of the patients with anti-infective therapy only receive the first dose: treatment was stopped when EV RT-PCR positive result was known. A significant difference was highlighted between the 2 groups concerning the hospitalization ($p<1.10^{-3}$). In the 1st group 119 (89.5 %) patients have been hospitalized with a mean length of stay of 10.5 days whereas in the 2nd group only 17 (53.2 %) patients were hospitalized (mean length of stay: 1.8 days), the 15 others (46.8 %) were sent back to home.

**Conclusions:** From 2014, the French Health Authority recommends to perform EV detection by molecular technique in less than 48 hours. Thanks to the implementation of automatized EV RT-PCR and reorganization of our microbiology laboratory, we can provide EV result 24/7 in less than 6 hours which improves management of AM by significantly reducing anti-infective therapy, decreased hospitalizations and length of stay.

Abstract 3887

**A surgical take on broncho-pulmonary Aspergillus: 20 years of experience**

Laurence Bertrand*1

*1University Hospitals of Leuven, Katholieke Universiteit Leuven, Leuven, Belgium

**Background:** *Aspergillus fumigatus* is an omnipresent opportunistic fungus causing a spectrum of pulmonary pathology from simple to complex aspergillomas, to pneumonia-like aspergillosis. Surgical resection continues to join drug- and embolization-therapy in the treatment options. This retrospective study aims to review one centre’s 20-year experience in surgical treatments of these patients, to evaluate their feasibility and safety, as well as differences in morbidity and mortality between the diagnostic groups of Pulmonary Aspergillosis (PA), Simple Aspergillomas (SA), and Complex Aspergillomas (CA).

**Materials/methods:** An existing surgical patient database of 23,244 operations was queried and reviewed to identify 47 patients that had a confirmed diagnosis of Aspergillus and were treated surgically for the purpose of fungal resection at the University Hospital of Leuven, Belgium. Patients were categorized into the main diagnostic groups: Pulmonary Aspergillosis (PA), Simple Aspergillomas (SA), and Complex Aspergillomas (CA), and subject to internal and external case analysis focusing on patient epidemiology, underlying disease, operative indication, and postoperative morbidity and mortality. A Kaplan-Meier Graph was generated to display and compare postoperative mortality.

**Results:** There was a total of 47 patients, 27 men and 20 women, with a mean age of 47.8y (range 2-82y). The most common underlying conditions for CAs and SAs were tubeculous caverns (38% and 10%), and for PAs were radio-chemotherapy (31%) and immunosuppressants (25%). The most common surgical indications were recurrent infections [56% of PAs], massive hemoptysis [52% of CAs], and preventive resection [60% of SAs]. Postoperative mortality rate (within 60 days) was 17%, with sepsis and pneumonia as the main causes of postoperative death – some, but not all, of which Aspergillus induced. The postoperative morbidity due to infection was also high, 36% fevers, 26% pneumonias, and 17% empyemas. At five-years the cumulative survival (Kaplan-Meier) dropped to 62% overall, 55% for PAs, 64% for CAs, and 77% for SAs.

**Conclusions:** In general, these results reconfirm surgery as a feasible treatment mode for SAs and CAs, with a lower threshold for surgical resection of SAs warranted. High mortality and morbidity should be taken into account for all groups, surgery of PAs in particular, continues to be controversial for this reason.

Influence of the Built Environment (BE) microbiota on the epidemiology of antimicrobial resistance at intensive care unit of a tertiary hospital

Sonia Aracil-Gisbert1, Natalia Guerra-Pinto1, Almudena Ortiz-Fernández2, Val Fernandez Lanza2, Cruz Soriano3, Miguel D. Fernandez-De-Bobadilla1, Marina López-Olivencia1, Verónica Quinteros-Fiel1, Sergio Gallego-Zarzosa1, Patricia Ruiz-Garbajosa1, Rafael Canton Moreno1, Raúl De Pablo1, Fernando Baquero1, Teresa M. Coque1

1Ramón and Cajal Hospital, Microbiology Service, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 2Ramón and Cajal Hospital, Bioinformatics Unit, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 3Ramón and Cajal Hospital, University of Alcalá, Department of Intensive Care, Madrid, Spain

Background: Emergence and transmission of antimicrobial resistant (AMR) pathogens remain to be fully understood. We comprehensively analyzed the ecology and dynamics of bacteria in built environment (BE) of a large ICU fully enrolled in AMR control programs.

Materials/methods: In ICU-Intensive Medicine, 5 samples/patient room (sinks-SK; ventilator’s-touchscreen-VT; washbasin-WB; bedrails-BR) and 2 samples from staff-areas (keyboards) were weekly collected using EZ-Reach-Sponges (April-October 2019). 1,728 samples were plated [(5x14rooms+2)x24weeks] on ChromagarOrientation and bacterial colonies. Bacterial identification (MALDI-TOF-MS), antimicrobial susceptibility (disk-diffusion agar, Hodge test, PCR of bla gene), clonal diversity (XbaI, P-FGE) were studied. Population structure of BE-isolates of ESKAPE species was fully addressed (FTIR, WGS). Ward epidemiological metrics in this 6m-period were 95% occupancy (14/14 rooms), 244 patients, 65%/35%-male/female, APACHEII-score 21, SAPS-index 47, 13.47% mortality-rate and 27.9% MDR colonization-rate at admission (23.7%/15.3% ESBL-Escherichia coli (EC)/K. pneumoniae (KP), 13.6% Pseudomonas aeruginosa (PA), 6.8%/6.8% carbapenem-resistant (CR)-Serratia marcescens (SM)/KP). REDCap (Research Electronic Data Capture) application was used to integrate and further exploit comprehensive metadata (clinical records, IC, microlab, BE surveillance).

Results: 10,180 isolates were recovered from abiotic samples (56 genera, 191 species). Predominant species in SK were SM (29.2%), Staphylococcus spp. (SC, 15.7%), PA (9.7%), Achromobacter spp. (5.2%), Burkholderia cenocepacia (5.1%), Stenotrophomonas maltophilia (4.2%), Klebsiella (2.0%), Sphingomonas spp. (2.0%), Bacillus spp. (BC, 2.0%), and other Enterobacteriaceae (3.8%). Predominant species in dry surfaces (VT, WB, BR) were SC (37%), Enterococcus spp. (5.0%), BC (3.3%), Corynebacterium spp. (2.2%), and Streptococcus spp. (2.2%). Consistent BE-microbial diversity patterns were identified in ICU-rooms. Abiotic AMR isolates of Enterobacteriaceae, BGNF (ESBL+, CR), SC (MRSA) and enterococci (AMPR) were related to AMR clinical isolates but time-limited. Abiotic persistent clones in SK were reservoirs of ESBLs. Diversity and co-occurrence patterns of ESKAPE species and transmission networks were established.

Conclusions: Abiotic surfaces in ICU rooms show specific microbial diversity profiles, maintained a long time, with resident clones often influencing the spread and/or maintenance of AMR genes. Combined surveillance data greatly improved risk assessment analysis.

Dalbavancin: to OPAT or not to OPAT

Alexander Richards*1, Laura Maclachlan1, Monica Ivan1, Gavin Barlow1,2, Kate Adams1, Patrick Lillie1, Lorraine Cullen1, Karen O’keeffe1

1Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom, 2Hull York Medical School (HYMS), Hull, United Kingdom

Background: As the demand on inpatient beds increases, there is a growing emphasis on outpatient infection management and admission avoidance. The use of novel antibiotics such as dalbavancin could play a key role. Dalbavancin is a second generation lipoglycopeptide and is licensed for use in acute bacterial skin and skin structure infections, and there is increasing evidence for its use as a 2-dose antibiotic in deep seated infections such as osteomyelitis or spinal infections. Dalbavancin’s unique pharmacokinetics yields a duration of action up to 8 weeks, however, the cost of using novel antibiotics which can be up to 10 times the cost of a common antibiotic is a major barrier to their use.

Materials/methods: The clinical outcomes of dalbavancin recipients (January to October 2019) were assessed using the available microbiology, clinical diagnoses, and social circumstances of the patients, and calculated the ‘bed-day’ savings from date of discharge to the theoretical ‘end-date’ of antibiotics as if a conventional intravenous antibiotic were used.

Results: Of the 15 patients reviewed, bone and joint, aortic graft and diabetic foot infections were identified. In 10 cases, the alternative treatment option would have been hospitalisation as traditional daily or three times a week OPAT antibiotic options weren’t appropriate due to either drug user status or social/geographical circumstances. The remaining 5 cases would have also required hospitalisation as a long course of antibiotics were needed where oral options were not appropriate due to drug interactions, intolerance or complex monitoring.

A dosing regimen of 1500mg (1000mg in renal impairment) on day 1 and 8 was used in all patients. The regimen was either initiated on the wards with prompt discharge or initiated in OPAT as admission avoidance. In total 14 patients clinically improved or remained stable and 1 patient was lost to follow up.

Compared to hospitalisation the use of dalbavancin resulted in a ‘bed-day’ saving of 738 days which yields a net saving of £153,000.

Conclusions: With acceptable clinical outcomes, the use of dalbavancin in this study saved on average £10,000 per patient, making it a significant contribution to overall outpatient infection management and admission cost reduction.

Use of a hospital-cumulative antibiogram to guide empirical antibiotics in gram-negative bloodstream infections
Charlotte Richardson*, Damien Mack1
1Royal Free Hospital, London, United Kingdom

Background: A hospital cumulative antibiogram provides an annual summary of culture isolates and antimicrobial susceptibility rates. This has utility in surveillance of local resistance trends, empirical antibiotic choice and in formulating local antimicrobial guidelines.

Materials/methods: We extracted the first blood culture isolate of an organism per patient in the 2018 calendar year from the laboratory information system at the Royal Free Hospital, a teaching hospital in London, UK, in accordance with the CLSI cumulative antibiogram guidelines. Organism identification was performed using the Brucker Biotyper (Brucker Daltonics, Bremen, Germany). Antibiotic susceptibility testing was performed using the BD Phoenix™ instrument (BD Diagnostic Systems, Sparks, MD) in accordance with EUCAST guidelines. Isolates reported as ‘resistant’ or ‘intermediate’ were deemed non-susceptible and samples without antimicrobial susceptibility data were excluded. Only species with susceptibility testing data for at least 30 isolates were included. We report susceptibility rates of gram-negative bloodstream infections to individual antibiotics and the combination of co-amoxiclav and gentamicin.

Results: There were 1252 isolates including 225 Escherichia coli, and 51 Klebsiella pneumoniae. Significantly more K. pneumoniae than E. coli were susceptible to co-amoxiclav (66% vs. 49%, p=0.021). The addition of gentamicin to co-amoxiclav significantly increased susceptibility for E. coli compared to co-amoxiclav alone (88% vs. 49%, p<0.001) but not for K. pneumoniae (80% vs. 66%, p=0.066). Significantly more E. coli were susceptible to the combination of co-amoxiclav plus gentamicin compared to K. pneumoniae (88% vs. 80%, p=0.037). Resistance rates to gentamicin were similar (E. coli 86%, K. pneumoniae 80%, p=0.103) (Table 1).

Conclusions: In our hospital, combination prescribing of co-amoxiclav and gentamicin can increase the proportion of E. coli isolates covered. Susceptibility differed between E. coli and K. pneumoniae which may have implications for the review of antimicrobial treatment at the time of organism identification. A cumulative antibiogram can help inform antimicrobial stewardship decisions at patient and hospital level.

Abstract 3891

Chagas disease diagnosis: comparison between two different native antigen assays

Jun Hao Wang Wang¹, Belen Rivaya Sanchez¹, Gema Fernández Rivas¹, Marina Navarro Albareda¹, Silvia Roure², Lurdes Matas Andreu¹

¹Microbiology Department, Clinical Laboratory North Metropolitan Area, Germans Trias i Pujol University Hospital, Department of Genetics and Microbiology, Autonomous University of Barcelona, Badalona, Spain, ²Germans Trias i Pujol University Hospital, International Health, Infectious Disease Unit, Badalona, Spain

**Background:** Chagas disease (CD) is an antropozoonosis caused by the parasite *Trypanosoma cruzi* and it is mainly transmitted by reduviid bugs. Due to population mobility and globalization, the burden is growing in non-endemic countries, especially through infected pregnant women and donations. Blood screening for CD antibodies in Latin American adults living in Europe is a cost-effective strategy. Spain is one of the European countries that receives most of Latin American immigrants. WHO recommends performing two different serological tests for CD diagnosis. Our diagnosis algorithm includes a recombinant antigen method screening and a manual native assay as confirmatory test. We aimed to compare two different native CD diagnostic tests, an immunofluorescence assay and an automated chemiluminescence test for the second-step CD diagnosis.

**Materials/methods:** We compare the performance of two CD diagnostic native antigen test: 1) An indirect immunofluorescent assay (Chagas IFA IgG+IgM, Vircell microbiologists, Spain) and 2) an automated chemiluminescence immunoassay (Vitros® Anti-*T. cruzi* assay, Ortho-Clinical Diagnostics, USA). For IFA, samples that show the same fluorescence brightness as positive control were considered positive and lower or no brightness cases were considered negative. For Vitros® Anti-*T. cruzi* assay, samples with index ≥ 1 were considered positive and <1 were considered negative, following the manufacturer's recommendations.

**Results:** A total of 180 samples (148 retrospective and 32 prospective serums) were tested by both methods. Among them, 157 (87.2%) were concordant positive and 11 (6.1%) were concordant negative. Thus, overall agreement was 93%. Discrepant results between assays were found in 12 samples (6.7%); 8 were IFA negative/chemiluminescence positive result and 4 were IFA positive/chemiluminescence negative result. Discordant samples corresponded to CD treated patients in 7 cases (58.3%) and to an 8-months baby from a CD infected mother, with 2 negative microhematocrit tests at birth.

**Conclusions:** An automated and rapid native antigen test is ideal for better efficiency in high-throughput laboratories. Manual techniques are time-consuming, subjective and rely on skilled technicians. Vitros® Anti-*T. cruzi* chemiluminescence immunoassay could be a good choice as a native assay test, combined with a recombinant technique and epidemiological data, for CD diagnosis.

Abstract 3894

Challenges in infective endocarditis: valvular infective endocarditis in patients with cardiac implantable electronic devices: clinical characteristics and outcome: analysis on a national cohort

Lucía Boix-Palop*1,2, Manuel Martínez-Selles1, Patricia Muñoz1, Mercedes Marín2, Gregorio Cuerpo1, M. Carmen Farías4, Marta Hernández-Meneses1, Karlos Reviejo1, Aristides De Alarcón2, Luis E. Lopez-Cortes1, Isabel Antorrena2, Juan Carlos Porres10, Esther Calbo Sebastian1,2

1Mútua Terrassa University Hospital, Terrassa, Spain, 2UIC Barcelona - Universitat Internacional de Catalunya, Barcelona, Spain, 3Gregorio Marañón Hospital, Madrid, Spain, 4Marqués de Valdecilla University Hospital, Santander, Spain, 5Hospital Clinico de Barcelona, Barcelona, Spain, 6Policlinica - Grupo Quirós, San Sebastián, Spain, 7Hospital Universitaria Virgen del Rocío, Sevilla, Spain, 8Hospital universitario virgen macarena, Sevilla, Spain, 9University Hospital La Paz, Madrid, Spain, 10Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: Among patients with valvular infectious endocarditis (valvular-IE) and a cardiac implantable electronic devices (CIED), some but not all have underlying cardiac device-related infection (CDRI). Last guidelines have no specific recommendations for the management of valvular-IE with non-infected CIEDs.

The aim of this study was to assess the clinical characteristics, evolution and prognosis of valvular-IE in patients with CIED (valvular-IE+CIED) without evidence of CDRI.

Results: 3966 cases of IE were identified, 284 (7.2%) were valvular-IE+CIED without CDRI.

Patients with valvular-IE+CIED as compared to valvular-IE without CIED (N=3258) were older (age (median): 75y vs 68y, \( p<0.001 \)) and had more comorbidities (Charlson index (median): 5 vs 4, \( p<0.001 \)). Enterococcus spp. (54 [19%] vs 457 [14%], \( p=0.02 \)), CNS (59 [20.8%] vs 506 [15.5%], \( p=0.02 \)) were more frequently identified among valvular-IE+CIED. Acute heart failure (134 [48%] vs 1340 [41.1%], \( p=0.04 \)) or acute renal insufficiency (128 [45.1%] vs 1140 [35.9%], \( p<0.001 \)) were also more frequent among valvular-IE+CIED. Surgery performance (83 [29.3%] vs 1383 [42.5%], \( p<0.001 \)) was less common and inhospital mortality (131 [46.1%] vs 1087 [33%], \( p<0.001 \)) was higher in CIED-carriers.

We compared patients with (34[12%]) or without device-removal (250 [88%]). In patients without device-removal surgery indication (153 [61.2%] vs 32 [94.1%], \( p<0.001 \)) and surgery performance (51 [20.4%] vs 32 [94.1%], \( p<0.001 \)) were less common. Inhospital mortality was higher (102 [40.8%] vs 7 [20.6%], \( p=0.02 \)).

Risk factors associated with in-hospital mortality in patients with valvular-IE+CIED were Charlson index (OR 1.16 [CI 95% 1.02-1.31]), acute heart failure (5.09 [2.85-9.08]) or acute renal insufficiency (1.99 [1.11-3.56]). Device-removal surgery was associated with lower mortality (0.17 [0.07-0.54]).

Conclusions: Almost half of the patients with valvular-IE+CIED without evidence CDRI died during admission. They were older, had more comorbidities and more complications than patients with valvular-IE without CIED. Device-removal surgery was associated with lower mortality, but it may indicate the success of the surgery itself in severe patients with surgery indication.

Microbial biosurfactants: a new approach for the control of polymicrobial biofilm development on biomedical materials

Chiara Ceresa*, Emanuele Fedeli1, Francesco Tessarolo2, Devid Maniglio3, Erica Tambone1, Maurizio Rinaldi1, Ibraim Banat*, Mayri Alessandra Diaz De Rienzo1, Letizia Fracchia1

1Università del Piemonte Orientale “A. Avogadro”, Department of Pharmaceutical Sciences, Novara, Italy, 2Bruno Kessler Foundation & University of Trento; Healthcare Research and Innovation Program (Ircs-Fbk-Pat), trento, Italy, 3University of Trento, Department of Industrial Engineering and Biotech Center, trento, Italy, 4University of Ulster, School of Biomedical Sciences, Coleraine, United Kingdom, 5Liverpool John Moores University, School of Pharmacy and Biomolecular Sciences, liverpool, United Kingdom

Background: Implantable medical devices are associated with a significant risk of microbial infections caused by biofilm formation at the interface between the device and tissues. In particular, polymicrobial biofilms are associated with more aggressive forms of infection due to the synergistic interactions between the species involved, which increase their virulence, biomass and resistance to antimicrobials. Surface-treated biomaterials commonly used in clinical practice have shown limited efficacy over time and potential toxicity toward cells. In this context, biosurfactants (BSs) have recently emerged as a new generation of anti-adhesive and antimicrobial agents with higher biocompatibility.

Materials/methods: Initially, the ability of microbial strains to form polymicrobial biofilms on silicone under appropriate experimental conditions was determined. Subsequently, silicone surfaces were treated with three different BSs (rhamnolipids, lipopeptides and sophorolipids) by physical adsorption. Anti-biofilm activity was evaluated at 24, 48 and 72 hours. Complementary aspects of biofilm were considered, such as biomass, metabolic activity, viable cell count and micro-structural characterization by SEM, for a complete understanding of the observed phenomenon. Two-way ANOVA was used to compare biofilms formed on BSs treated surfaces and untreated controls. The results were considered statistically significant when \( p < 0.05 \).

Results: Total biomass and metabolic activity of polymicrobial biofilms were significantly higher than the sum of the values detected for the single species. The percentage composition of mixed biofilms, evaluated by viable count, showed a predominance of the bacterial strain (98-99%) compared to the fungal strain (1-2%). All the tested BSs demonstrated an excellent inhibitory activity (>90%) against the formation of polymicrobial biofilms on silicone, both in terms of total biomass, metabolic activity and viable count up to 72 hours of incubation. The SEM observations of the biofilms were consistent with culture data.

Conclusions: The obtained results support the idea that silicone functionalization with biosurfactants represents a promising strategy for the prevention of polymicrobial colonization on medical devices.

Polyclonal New Delhi metallo-β-lactamase producers Acinetobacter sp. in Algerian hospital

Bachtarzi Mohamed Azzedine1, Tal Maamar Hassiba2, Djennane-Hadibi Fazia1, Fatiha Digdjig3, Ourida Lafer2, Farida Assaous3, Nora Zordani2, Mohamed Tazir3, Wahiba Amhis1

1Mustapha University Hospital Center, Algiers, Algeria, 2Pasteur Institute of Algeria, Deli Ibrahim, Algeria, 3Mustapha University Hospital Center, Sidi M’Hamed, Algeria

Background: Métallo-bêta-lactamases (MβLs) begin to play an important role in carbapenem resistance in Acinetobacter baumannii. A recent study, conducted in our hospital, estimates their prevalence at 13% of isolated CRABs (unpublished data). This work will aim to characterize at the molecular level, a collection of CRAB MβL(+) and to determine circulating clones in our hospital.

Materials/methods: One hundred CRAB phenotypically characterized as MβLs (+) was collected over a period of 13 years (2006-2018) at the CHU Mustapha in Algiers. All of them benefited from a PCR search of NDM, VIM, IMP, GIM, SIM, SPM, DIM, FIM, AIM, KHM, and oxacillinases OXA-23, OXA-24, OXA-58 and OXA-51. Each strain, according to its molecular profile, was candidate for one or more of the following techniques: PFGE with ApaI (N = 40), OXA-51 base typing (N = 60), MLST according to the Pasteur scheme (N = 20).

Results: NDM-1 was the only MβL detected. Intrinsic OXA-51 was found in 98% of strains that are distinguished into four profiles:

Profile (P1) NDM alone found in 73% of CRAB MβLs (+). All showed an OXA-94 variant and an ST85 clone. Six pulsotypes were distinguished by PFGE with a predominant profile (A) in 85% of the strains.

Profile (P2) NDM + OXA-23 found in 13 strains: All showed an OXA-64 variant and an ST25.

Profile (P3) NDM + OXA-24 found in one strain that had an OXA-64 variant and an ST25.

Profile (P4) NDM + OXA-58 found in one strain that had an OXA-66 variant and an ST63.

Finally, a last profile (P5) was found in two strains NDM (+), but OXA-51 negative. This result indicates that these species are other than A. baumannii. The MLST analysis distinguishes them in two clones: ST1309 and ST1315. We report with this work, the first world description of ST1315 clone.

Conclusions: This study demonstrates the existence of five different clones of NDM producers Acinetobacter sp in our hospital. These clones being phylogenetically distant testify to probable genetic exchanges between these species.

Abstract 3900

Would HIV infections and AIDS cases decrease in Japan? Time series analysis using Bayesian inference
Kentaro Iwata*1, Chisato Miyakoshi2
1Kobe University, Kobe, Japan, 2Kobe City Medical Center General Hospital, Kobe, Japan

Background: The number of newly diagnosed HIV infections and AIDS patients in Japan appears to be decreasing according to surveillance data, and some might feel optimistic to consider that Japan is catching up with other developed nations, which successfully declined number of new infections. However, whether they continue to decline or not is unclear. Therefore, we conducted a time series analysis using Bayesian inference to predict whether the number continues to decline.

Materials/methods: We used quarterly data on HIV/AIDS from the first quarter, 2001 (2001Q1) to the second quarter, 2019 (2019Q2), provided by Japan Foundation for AIDS prevention. Bayesian analyses were conducted using Markov chain Monte Carlo (MCMC) method, and local linear trend models were constructed for number of newly diagnosed HIV infection without AIDS diagnosis, AIDS cases, and their aggregate. Predictions for the following 5 years (up until the second quarter, 2024) were also made for both models.

Results: Total number of HIV/AIDS patients in the second quarter, 2024 (2024Q2) was predicted to be 214 (95% credible interval 130-443) in the local linear trend model, with declining trend from the latest reported number (295 in 2019Q2), yet with relatively wide credible interval (Figure). For HIV infections alone, cases in 2024Q2 was predicted to be 174 (95%CI 0-370). For AIDS, cases in 2024Q2 was predicted to be 53 (95%CI 0-158). Both again showed decreasing trend with wide credible interval, which could lead to either zero new infection to increased new infections.

Conclusions: Our local linear trend model suggested that number of HIV/AIDS cases in Japan could continue to decline, granted there is no significant change in the trend in future, although credible interval was quite wide. One might not be able to optimistic yet regarding future incidence of HIV/AIDS in Japan, and additional measures to further decrease it may be necessary.

Figure legend: Local linear trend model for quarterly reported data on number of HIV/AIDS patients in Japan from 2001 quarter 1 to 2019 quarter 2, with prediction for the following 5 years. Dot: actual number, solid line: forecasted number, band:95% credible interval, and gray rectangle: predicted numbers.

Abstract 3902

**Enterovirus D68: biennial circulation and molecular epidemiology in New York, USA, 2014-2018**

Guiqing Wang*1,2, Victoria Gilrane1, Jian Zhu1, Weihsia Huang1, Changhong Yin1, Christina Saleib3, Sheila Nolan1,2, Abhay Dhand1,2, John Fallon1,2

1New York Medical College, Valhalla, United States, 2Westchester Medical Center, Valhalla, United States

**Background:** Enterovirus D68 (EV-D68) infection has been associated with severe respiratory illness and acute flaccid myelitis (AFM). Following a nationwide outbreak in the US in 2014, only limited EV-D68 detection was reported in 2016 and no data are available thereafter. The objectives of this study were to determine whether EV-D68 continued circulating in the Lower Hudson Valley, New York, and to compare the viral strains recognized since 2014 at regional, national and global levels.

**Materials/methods:** Nasopharyngeal (NP) specimens collected from 2013 through August 2018 from patients in the Lower Hudson Valley, New York were examined for Rhinovirus/Enterovirus (RhV/EV) by the FilmArray Respiratory Panel. Selected RhV/EV-positive and negative NP specimens were analyzed using two EV-D68-specific rRT-PCR assays, Sanger sequencing and a RNA-Seq-based metagenomic next-generation sequencing. Genomic sequences of all EV-D68 strains since 1962 were also retrieved from the GenBank and analyzed for strain genotypes (clades) using genome-based algorithms.

**Results:** A total of 2,264 NP specimens from 2013 through 2018 were examined for EV-D68. EV-D68 was detected in NP samples collected in 2014 (29.4%, 94/320), 2016 (26.6%, 160/602), 2017 (0.9%, 5/562) and 2018 (14.4%, 80/556), respectively, but not in those collected in 2013 (n=25) or 2015 (n=199). Comparative genomic analysis confirmed that distinct EV-D68 strains were circulating and caused outbreaks in New York in 2014 (subclades B1 and B2) and 2016 (subclade B3) with a relatively high viral load in patient specimens. Only low levels of clade D strains were detected in 2017. The majority of EV-D68 strains (92.3%, 24/26) circulating in 2018 belonged to subclade B3. Bioinformatics analysis of 2,746 sequences worldwide (1962-2018) revealed temporal and spatial diversity in EV-D68 population but a shared global evolutionary trend.

**Conclusions:** We reported a biennial regional outbreak and circulation of EV-D68 in the lower Hudson Valley, New York, USA from 2014 to 2018. The establishment of distinct viral strains and variable levels of circulation provides essential information for surveillance, diagnosis and control of EV-D68 infection in the US and worldwide.

**Presenter email address:** guiqing_wang@nymc.edu
Abstract 3903

Long-read compared to short-read next-generation sequencing of the 16S-23S rRNA region for the identification of bacterial species in clinical samples: a pilot study

Evert Van Zanten¹, Guido Wisselink¹, Robin Benus¹, Mirjam Kooistra-Smid*¹,²

¹Certe, Groningen, Netherlands, ²University of Groningen, University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: The use of next generation sequencing (NGS) in diagnostic medical microbiology is increasing as these methods overcome limitations of culture and 16S rDNA Sanger sequencing. NGS of the 16S-23S rRNA region [16S-23S NGS] enables identification with a high taxonomic resolution of bacteria in polymicrobial infections. Here we present a pilot study comparing long read sequencing (ONT MinION) with short read sequencing (Illumina MiSeq) of the 16S-23S rRNA region for the identification of bacterial microorganisms in clinical samples.

Materials/methods: Twenty clinical samples were subjected to 16S-23S NGS using short read sequencing (NexteraXT 600-V2 kit, sequencetime 56 hours) as described previously (Sabat et al., 2017) and long read sequencing (ONTSK-LSK109, sequencetime 2 hours). The correct assignment of bacterial species was performed using de novo assembly or mapping to the RRN database (Benítez et. al, 2017) for short and long reads, respectively; this was followed by BLASTN using the NCBI database. Short read sequencing and long read sequencing were compared for length of contigs and consensus sequences. Contigs and consensus sequences with an abundancy of ≥5% were used for the assessment of bacterial identification concordance.

Results: Using Illumina, in total 53 contigs were assembled, with a medium length of 2657 bp (817–5060); in 15/53 (28%) contigs the length of the contig was >3900 bp. MinION yielded in total 46 consensus sequences with a medium length of 3949 bp (2276–4795); in 37/46 (80%) sequences the length was >3900 bp. Illumina detected bacterial species in 19/20 samples; a single bacterial species and polymicrobial communities (2-9 species) were identified in 9 and 10 samples, respectively. Using MinION in 17/20 samples bacterial species were detected; a single bacterial species and polymicrobial communities (2-8) were identified in 7 and 10 samples, respectively. Bacterial identifications using MinION was concordant with Illumina for 31/36 (86%) species. Five disconcordant identifications were only detected using Illumina.

Conclusions: This pilot study demonstrates that long read sequencing of the 16S-23S rRNA region, compared to short read sequencing, enables accurate identification of bacterial species in complex samples. Moreover, using long read sequencing the turnaround time of the application may be shortened by 54 hours.

Presenter email address: m.kooistra@certe.nl
Abstract 3904

**Trichomonas vaginalis trends for women and men in a national reference laboratory database**

Elizabeth Marlowe*1, Ron Kagan1

1Quest Diagnostics Infectious Diseases, San Juan Capistrano, United States

**Background:** Trichomoniasis is a common curable sexually transmitted infection (STI), which is not reportable to public health departments in the United States. In women, Trichomonas vaginalis (TV) preferentially infects the vaginal epithelial cells. While most women with trichomoniasis are asymptomatic, others may experience vaginal discharge and/or vulvar irritation. In men, trichomoniasis may be asymptomatic or may cause non-gonococcal urethritis. The objective of this study was to evaluate molecular testing data from a large US commercial laboratory to understand national TV rates.

**Materials/methods:** A retrospective analysis of TV status from January 2014 to August 2019 was conducted using the Quest Diagnostics national database. TV positivity rates were compared to *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoea* (NG) rates overall; rates were also assessed as a function of age, sex, geographic location and co-infection.

**Results:** Greater than 60 million STI test results over 5.5 years were analyzed and TV comprised 9.6% of the total results (women: 90.6% of TV results). Using the national database, TV positivity rates were compared to *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoea* (NG) rates overall; rates were also assessed as a function of age, sex, geographic location and co-infection. Higher rates were noted in certain regions of the US: 7.3% (TV) in women and 3.3% (TV) in men in the Midwest, 5.6% (TV) in women and 2.8% (TV) in men in the Southern United States. The median age for TV-positivity was significantly higher in men than in women (39.3 [IQR: 29.6 – 51.1] years vs 31.8 [IQR: 25.0 – 41.4] years, P<0.0001). TV rates peaked in women aged 41-55 but continued to increase with age in older men (Fig. 1). Among this cohort, CT and GC co-infection rates for TV-positive patients were low (<1%).

**Conclusions:** Compared to the overall rates of TV, the noted higher rates of TV in the Southern and Midwestern United States correlate with historical reported rates of CT and NG. TV rates among older women are consistent with previous reports. While the analysis was limited due to the lack of clinical information, the increase in TV rates in older men (>41 yrs), suggests that additional screening may be warranted in targeted populations.

**Abstract 3905**

**Intra-abdominal candidiasis after pancreatic transplantation: epidemiology, use of antifungal prophylaxis, risk factors and impact on pancreatic graft**

Laura Linares¹, Laura Nuzzolo¹, Laura Pacho¹, Pedro Ventura², Federic Cofan², Joana Ferrer³, Francesc Marco Reverte⁴, Fritz Diekmann², Maria Moreno Camacho¹, Marta Bodro Marimont*¹

¹Hospital Clinic de Barcelona, Infectious Diseases, Barcelona, Spain, ²Hospital Clinic de Barcelona, Kidney Transplant Unit, Barcelona, Spain, ³Hospital Clinic de Barcelona, Hepatobiliopancreatic Surgery Department and Transplant unit, Barcelona, Spain, ⁴Hospital Clinic de Barcelona, Microbiology, Barcelona, Spain

**Background:** Information regarding epidemiology and risk factors of intra-abdominal candidiasis (IAC) after pancreas transplantation and its impact on pancreatic graft is scarce. In the present study we aimed to determine the epidemiology, the role of antifungal prophylaxis, risk factors and impact of IAC on pancreatic function in pancreas recipients.

**Materials/methods:** We retrospectively reviewed patients receiving pancreas transplantation from 2008 to 2018. All patients were followed up for one year or until death or pancreas graft loss. IAC was defined as a symptomatic infection in the abdominal cavity presenting with Candida isolation in intra-abdominal fluid cultures. Hospital protocol indicated fluconazole prophylaxis (200mg per day) in all recipients during the first month post transplantation. Graft loss was defined as the need for permanent insulin therapy of ≥ 0.5 units/kg/day and c-peptide levels ≤ 1. Patients presenting graft loss in the first 7 days post transplantation were excluded.

**Results:** Over the ten-year study period, 208 pancreas transplants were performed: 157 simultaneous pancreas-kidney procedures, 26 pancreas-after-kidney and 25 pancreas alone procedures. One-hundred and eight patients (86%) received prophylaxis (mean 16 days, SD ± 12). IAC was developed in 12 recipients (6%), with median days from transplantation of 38 (IQR 5-159). Seventy-five percent of the episodes were developed during the first month post transplantation. Four patients that received antifungal prophylaxis developed an IAC caused by a fluconazole non susceptible Candida species. The one-year graft loss rate for recipients with IAC was 25% compared with 9% for those without IAC (p = 0.09). In the multivariate analysis, surgical reintervention [OR 9.8 (CI 95% 1.9-48.6)] and antifungal prophylaxis [OR 0.1 (CI 95% 0.04-0.6)] were independently associated with IAC. Six patients died during the study period, none related with IAC.

**Conclusions:** Six percent of pancreas recipients developed IAC, especially in the first month post transplantation. Surgical reintervention was a risk factor to developed IAC whereas antifungal prophylaxis was a protective factor. IAC was not associated with one-year graft loss neither related with mortality.

Performance of the sōna Aspergillus galactomannan lateral flow assay from serum samples for the diagnosis of invasive aspergillosis in patients after haematopoietic stem cell transplantation

Timothy Erb1, Renate Meyer1, Elmar Kotter2, Hartmut Bertz3, Jürgen Held*1

1Uniklinik Erlangen, Mikrobiologisches Institut, Erlangen, Germany, 2University Medical Centre Freiburg, Department of Diagnostic Radiology, Freiburg, Germany, 3University Medical Centre Freiburg, Department of Haematology/Oncology, Erlangen, Germany

Background: One cornerstone for diagnosis of Invasive Aspergillosis (IA) is the detection of galactomannan (GM). So far, enzyme-immunoassays (EIA) are used for this purpose but they are usually not performed daily resulting in an undesired delay of test results. Immunochromatographic assays, like the sōna Aspergillus-Galactomannan-Lateral-Flow-Assay (Asp-LFA), may overcome this disadvantage. The Asp-LFA detects GM in serum and bronchoalveolar-lavage fluid in approximately one hour without the need for batch testing. To compare the performance of the Asp-LFA with the Platelia™ Aspergillus-Ag-EIA (Asp-EIA) we have conducted a study on sera from patients after allogeneic hematopoietic stem cell transplantation (alloHSCT).

Materials/methods: All patients that underwent alloHSCT during a one-year period were enrolled. Patients with IA were classified according to the EORTC/MSG 2008 guidelines. The Asp-LFAs were analyzed with a digital reader provided by the manufacturer.

Results: A total of 547 sera from 101 patients after alloHSCT were tested. By the end of hospitalization one proven, 10 probable and 19 possible IA cases were diagnosed. The sensitivity and specificity of a single positive Asp-LFA for proven and probable IA were 80 % and 57 %, respectively. Repeat testing of the Asp-LFA-positive serum samples revealed that the positive result was reproducible in only 58 % of samples. The sensitivity and specificity of a reproducibly positive Asp-LFA for proven and probable IA were 80 % and 77 %, respectively. The Asp-EIA and the Asp-LFA are both detecting GM. To directly compare the assays the EORTC/MSG-classification was performed with only culture and [1→3]-β-D-glucan as mycological criteria. In this case 1 proven, 8 probable and 21 possible IA cases were diagnosed. The sensitivity and specificity of a reproducibly positive GM-test for proven and probable IA were 22 % and 97 % for the Asp-EIA and 78 % and 70 % for the Asp-LFA, respectively. The GM levels determined by both tests correlated significantly (r=0.32, p<0.001).

Conclusions: The Asp-LFA shows a superior sensitivity compared to the Asp-EIA. Handling of the Asp-LFA is easy and time-to-result is below 60 min. However, it is highly recommended to use a digital reading device and to repeat testing in case of positive results.

Abstract 3907

**The trend of changes in paranasal computed tomography of patients with haematologic malignancies and febrile neutropaenia**

Shervin Shokouhi*, Ilad Alavidarazam2,3, Shiva Shabani1, Dina Jalalvand4, Rayhaneh Jamily4

1Shahid Beheshti University of Medical Sciences, Tehran, Iran, 2Shahid Beheshti University of Medical Sciences, Tehran, Iran, 3Clinical Research Development Center, Loghman Hakim Hospital; Shahid Beheshti University of Medical Sciences, Tehran, Iran, 4Ayatollah Taleghani Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran

**Background:** The aim of this study was to evaluate the clinical significance of early screening of computerized tomography scan of paranasal sinuses (PNS CT) in hematologic malignancies before chemotherapy and evaluation of changes after chemotherapy and during neutropenia.

**Materials/methods:** All forty new case of hematologic malignancies with febrile neutropenia in a teaching referral hospital between 2017 and 2018 were enrolled in this study. All of these patients underwent PNS CT before chemotherapy, along with other preliminary investigations. Symptoms and signs indicating infectious process meticulously were followed and monitored before and during chemotherapy as well as occurrence of febrile neutropenia. All patients were clinically and radiologically evaluated regarding presumptive diagnosis of invasive fungal sinusitis during prolonged febrile neutropenia (more than 4 days). PNS CTs before and after chemotherapy of all patients were compared by two radiologists and were evaluated based on histopathologic findings of nasal and or paranasal biopsies.

**Results:** Around 50% of patients with paranasal abnormality suggesting inflammatory process including microbial and fungal sinusitis during prolonged febrile neutropenia (more than 4 days) were confirmed that have had similar involvement with no significant changes before starting chemotherapy. The histopathologic examination of sinuses also showed no evidence of invasive fungal infection by endoscopic biopsy. Therefore, the abnormal findings including mucosal thickening in PNS CT during prolonged febrile neutropenia were not consistent with the confirmed invasive fungal infection. The rate of mortality was 2.5% without association to invasive fungal sinusitis.

**Conclusions:** The considerable number of patients with underlying hematologic malignancies has paranasal sinus involvement such as mucosal thickening that may be misleading as probable invasive fungal sinusitis during hazardous phase of prolonged febrile neutropenia. Thus, performing PNS CT scan before initiation of chemotherapy even though in asymptomatic patients could be helpful to decrease the number of suspected and probable cases of fungal sinusitis based on abnormal findings in PNS CT scan followed by the number of cases undergoing sinus endoscopic surgery.

Abstract 3908

**BIOFIRE FILMARRAY pneumonia panel in the evaluation of severe lower respiratory tract infections**

Evdoxia Kyriazopoulou*1, Athanasios Karageorgos1, Lydia Liaskou-Antoniou1, Panagiotis Koufargyris1, Asimina Safarika1, Georgios Adamis2, Anastasia Antoniadou1, Evangelos Giamarellos-Bourboulis1

1National and Kapodistrian University of Athens, Medical School, 4th Department of Internal Medicine, Athens, Greece, 2G.Gennimatas General Hospital of Athens, 1st Department of Internal Medicine, Athens, Greece

**Background:** Although viruses are considered the most common detected cause of admitted cases of lower respiratory tract infections [LRITs] [Etiology of Pneumonia in the Community [EPIC] prospective, multicentre, active surveillance study], data for patients with severe LRIT are missing. This study aimed to define the epidemiology of severe LRIT using the BIOFIRE® FILMARRAY® Pneumonia plus Panel (PNplus Panel) and the association of the results with the host inflammatory state.

**Materials/methods:** This was a sub-study of the interventional PROGRESS trial where procalcitonin (PCT)-guidance for early stop of antibiotics was used to prevent infection-associated adverse events in patients with sepsis (ClinicalTrials.gov NCT03333304). PNplus Panel was performed retrospectively using frozen lower respiratory samples of 90 patients with LRIT and sepsis defined according to Sepsis-3. Primary endpoint of the present sub-study was the comparison of the detection rate of pathogens between conventional microbiology [blood, sputum, pleural fluid cultures and urine antigen detection] and PNplus Panel. Secondary endpoints were the association of the PNplus Panel with the inflammatory host response and detection of antibiotic resistance.

**Results:** 56 patients with community-acquired pneumonia (CAP) and 34 with healthcare-associated pneumonia (HCAP) were studied; median pneumonia severity index was 113 (interquartile range 88-135). PNplus detected at least one pathogen in 65 patients (72.2%) compared to 10% detected by conventional microbiology (p<0.0001); bacteria were the most common pathogens [Figure]. Median PCT was 0.49 ng/ml among patients with ≥105 copies/ml of a bacterial pathogen compared to 0.18 ng/ml in detection at lower loads (p=0.004). SOFA score, serum CRP and white blood cells did not differ between patients with undetected, bacterial, viral or bacterial-viral cause of infection. Median PCT was 0.52 ng/ml among patients with bacterial pathogens compared to 0.19 ng/ml among patients with viral pathogens (p: 0.045). At least one resistance gene was detected in 14.4% of samples, being more common in HCAP versus CAP (32.2% vs 5.1%; p: 0.001).

**Conclusions:** PNplus detects severe pneumonia pathogens at significantly greater rate than conventional microbiology. The greater circulating PCT levels reflect the true virulence of the detected pathogens.

Failure of artemether-lumefantrine treatment for Plasmodium falciparum malaria imported from sub-Saharan Africa to the UK

Hugh Adler*1,2,3, James Cruise1, Jayne Jones2, Iain Slack2, Anne Neary1, Jon J Van Aartsen2, Emma Carter1,2, Paul Hine1,4, Emmanuel Okenyi1,2,3, Rachel Taggart2, Debbie Nolder2, Lindsay Stewart1, Colin Sutherland3, Stephen J Aston1,6, Tom Blanchard1,2,6,7, Tim O’dempsey1,2, Mike Bj Beadsworth1,2, Nick Beeching1,2

1Liverpool University Hospitals NHS Foundation Trust, Tropical and Infectious Diseases Unit, Liverpool, United Kingdom, 2Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom, 3St Helen’s and Knowsley NHS Trust, Liverpool, United Kingdom, 4Liverpool School of Tropical Medicine, Cochrane Infectious Diseases Group, Liverpool, United Kingdom, 5London School of Hygiene and Tropical Medicine, Public Health England Malaria Reference Laboratory, London, United Kingdom, 6University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom, 7University of Manchester, Manchester, United Kingdom

Background: Oral artemisinin combination therapy (ACT) is recommended for all uncomplicated cases of Plasmodium falciparum malaria. ACT resistance is increasingly prevalent in South-East Asia, but uncommon in Africa.

Materials/methods: We report two cases of recrudescent falciparum malaria that occurred despite full adherence to ACT in the Tropical and Infectious Diseases Unit in Liverpool. We reviewed our pharmacy dispensing records to estimate the failure rate of ACT in our institution over the preceding year.

Results: Patient 1 is a 53-year old man who had been working in wildlife conservation in Zambia. He was admitted four days after his return with a P. falciparum parasitaemia of 1.3%. He initially received intravenous artesunate, followed by a course of artemether-lumefantrine (six doses over 60 hours) as an inpatient. Repeat blood films at 48 hours showed a 0.001% parasitaemia. His symptoms recurred 19 days after discharge, with a 1% parasitaemia. He was re-treated with artemether-lumefantrine, followed by a full course of quinine and clindamycin. His parasitaemia cleared within 48 hours and remained negative 13 days later.

Patient 2 is a 51-year old man with virologically-suppressed HIV infection, who returned from visiting relatives in Mozambique. He presented five days later with a 0.9% P. falciparum parasitaemia. He completed six doses of artemether-lumefantrine as an inpatient; repeat films at 48 hours showed a parasite count of 0.1%. One month later he complained of ongoing malaise and a repeat film showed a parasitaemia of 0.01%. He was treated with atovaquone-proguanil; repeat films on treatment and two weeks later were negative.

All blood films for both cases showed P. falciparum trophozoites only. Neither patient had travelled abroad between presentation and recrudescence.

Between July 2018—July 2019, 18 patients were prescribed artemether-lumefantrine as inpatients on the unit, of whom 16 had falciparum malaria acquired on the African continent. This translates to an ACT failure rate of 12.5% [95% CI 2.2—39.6%] for the treatment of P. falciparum.

Conclusions: Monitoring of malaria treatment outcomes in real-world settings is key to detecting emerging resistance. Ongoing genotypic analysis may elucidate the mechanism of treatment failure in the two cases reported here.

Abstract 3911

**Genetic score involving polymorphisms of innate immune receptors for predicting cytomegalovirus infection in solid organ transplant recipients: a prospective multi-centre cohort study**

Marta Bodro Marimont*1, Carlos Cervera2, Francisco Lozano1, Laura Linares1, Jaume Llopis1, Gemma Sanclemente1, Mario Fernandez Ruiz2, María Carmen Farinas3, Sara Cantisan1, Miguel Montejo Baranda1, Elisa Cordero Matias1, Isabel Griel Bermúdez2, María Angeles Marcos1, María Moreno Camacho1

1Hospital Clinic de Barcelona, Barcelona, Spain, 2University of Alberta Hospital, Infectious Diseases, Edmonton, Canada, 3Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain, 4Marqués de Valdecilla University Hospital, Santander, Spain, 5Hospital Reina Sofia, Córdoba, Spain, 6Hospital Universitaria Cruces, Barakaldo, Spain, 7Hospital Universitaria Virgen del Rocío, Sevilla, Spain, 8Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain

**Background:** Genetic polymorphism at the immune system may increase the risk of post-transplant infections. The aim of this study was to assess the influence of genetic variability of certain innate immune receptors on the risk of developing Cytomegalovirus (CMV) infection after solid organ transplantation (SOT) in patients at highest risk for CMV infection.

**Materials/methods:** CMV-seronegative recipients of grafts from CMV-seropositive donors undergoing heart, liver, kidney or pancreas transplantation from 7 centers in Spain during a 3-year period were included. All recipients received 100 days-prophylaxis with valganciclovir. Clinically and/or functionally relevant single nucleotide polymorphisms (SNPs) from TLR2, TLR3, TLR4, TLR7, TLR9, AIM2, MBL2, IL28, MYD88, IFI16, IRAK2 and IRAK4 were assessed by quantitative Polymerase Chain Reaction (qPCR) or sequence-based typing (PCR-SBT). The incidence of asymptomatic CMV infection and disease according to SNPs was estimated. A predictive CMV-score based on SNPs combinations was created by logistic regression analysis.

**Results:** A total of 116 patients in 7 centres were recruited. Sixty-one patients (53%) presented at least one episode of CMV infection, 33 asymptomatic and 28 had CMV disease, at a median time of 163 days. Recurrent CMV infection occurred in 11 (9%) patients. There were no differences regarding major characteristics among groups depending on receptor gene SNPs. In univariate analysis, none of the SNPs analyzed was associated with either asymptomatic CMV infection or CMV disease. According to the CMV-score, the probability of CMV disease with combined SNPs in TLR4, TLR3, TLR7, AIM2 and MBL2 was 83%, while decreased to 6% with combined SNPs in TLR9, IL28 and IFI16 (p =0.002). The AUC of the model for predicting CMV disease was 0.66, with sensitivity and specificity of 64 and 72%, respectively. In addition, the probability to develop a asymptomatic CMV infection, conferred by genetic variants of TLR4, TLR7 and AIM2 was of 68 % (p=0.07).

**Conclusions:** This genetic CMV-score was useful to calculate the risk of developing a CMV disease in CMV-seronegative recipients of grafts from CMV-seropositive donors undergoing SOT.

Abstract 3912

Rectal colonisation by drug-resistant bacteria in nursing home residents in Crete, Greece

Katerina Moschou1, Petros Ioannou*, Eleni Moraitaki1, Dimitra Stafylaki1, Georgios Vougiouklakis1, Sofia Maraki1, Georgios Samonis1, Diamantis Kofteridis1

1University Hospital of Heraklion, Heraklion, Greece

Background: Multidrug-resistant organisms (MDROs) pose important public health problem worldwide. Residents of long term care facilities (LTCFs) are at high risk of being colonized and infected by MDROs.

Materials/methods: This is a point-prevalence study detecting colonization of MDROs conducted in 6 LTCFs in Crete, Greece. Rectal swabs were cultured in order to detect MDROs, while risk factors for colonization were evaluated. Data collected included age, gender, duration of stay in LTCFs, comorbidities, antibiotic exposure, and recent hospitalization.

Results: A total of 137 LTCF residents aged 65 years or more were enrolled in this study. Mean age was 82.1 years and 19.7% were male (27 residents). In total, 255 isolates were cultured; E. coli, K. pneumoniae and P. aeruginosa were the commonest isolates cultured in 64.3%, 11.8% and 5.5% samples, respectively (164, 30 and 14, isolates respectively). Among the microbes cultured, 17.6% (45 isolates) had the extended-spectrum beta-lactamase (ESBL) phenotype, while 18% (46 isolates) were MDROs. Statistical analysis did not reveal any correlation between age, duration of stay in the LTCF and Charlson Comorbidity Index and the presence of the ESBL phenotype. However, contingency analysis identified male sex to be associated with higher possibility of ESBL production.

Conclusions: Colonization by MDROs is common in LTCFs in Crete, being in similar levels to other European countries.

Correlation between rubella IgM positivity and detection of cytomegalovirus/parvovirus B19 primary infection in pregnant women accessing the Tuscany Reference Centre for Infectious Diseases in Pregnancy

Susanna Giachè*1, Lorenzo Zammarchi1, Beatrice Borchi1, Giovanni Millotti1, Alessandro Bartoloni1, Michele Trotta2

1Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, 2Infectious and Tropical Diseases Unit, Careggi University Hospital, Florence, Italy

Background: In the majority of European countries, pregnant women are routinely tested for Rubella but not for Cytomegalovirus (CMV) and Parvovirus B19 (B19V), two potentially harmful pathogens for the fetus. Positive Rubella IgM results at screening may be due to recent Rubella infection or false positive, sometime do to cross-reactions between Rubella IgM and other intercurrent viral infections such as CMV and B19V. The aim of the study is to investigate the correlation between Rubella IgM positivity and CMV or B19V primary infection in pregnancy.

Materials/methods: Pregnant women consecutively evaluated between 2016 and 2019 at the Tuscany Reference Center for Infectious Diseases in Pregnancy for positive anti-Rubella IgM were enrolled in this retrospective observational study. All women were assessed for possible recent Rubella, CMV and B19V infections.

Results: A total of 380 pregnant women were included. The mean age was 34-years-old (16-49, SD 5.5), the mean gestational age was 14 gestational weeks (5-39, SD 6.1). 142/380 (37.4%) had a serological evidence of rubella immunity before pregnancy, 28/380 (7.4%) had been previously vaccinated. All women underwent a second serological test for Rubella, and IgM were confirmed in 119 (31.3%). No cases of Rubella acquired during pregnancy were diagnosed. Serology for CMV was performed in 327 (86.1%) women and B19V in 258 (67.9%) showing reactive IgM result in 18 (5.5%) and 6 (2.3%) cases respectively (details in Table). Only one primary CMV infection and one recent B19V infection have been detected. The patient with primary CMV infection had negative CMV IgM (despite Rubella IgM positivity at qualitative test), low CMV IgG avidity index and positive DNA in urine sample. The patient with recent B19V infection had borderline IgM and IgG (IgM antibody titer for Rubella less than 2 times the cut-off of positivity) and positive DNA in blood sample.

Conclusions: Recent CMV or B19V infections were found in 1 of 327 (0.3%) and 1 of 258 (0.4%) pregnant women with positive IgM Rubella suggesting that these infections are a rare cause of false positive Rubella IgM. However, considering the potential fetal adverse outcome of these infections, testing may be justified.

Epidemiological characteristics of *Stenotrophomonas maltophilia*-associated lower respiratory tract infection in Qatar: a one-year retrospective study

Arun Prabhakaran Nair¹, Sreethish Sasi²*, Mohammad Abukhattab¹, Kadavil Chacko¹, Anandh Rajan³, Anand Deshmukh⁴, Mariamma Abraham⁴, Muna Al-Maslamani¹

¹Communicable Disease Center, Hamad Medical Corporation, Doha, Qatar, ²Department of Internal Medicine, Hamad Medical Corporation, Doha, Qatar, ³Medical Research Center, Hamad Medical Corporation, Doha, Qatar, ⁴Department of Microbiology, Hamad Medical Corporation, Doha, Qatar

**Background:** Stenotrophomonas maltophilia is rapidly emerging as a multi-drug resistant nosocomial pathogen causing life-threatening opportunistic pneumonia. Incidence of infections by *S. maltophilia* has been reported as 0.07-0.4% of hospital discharges. This is the first study from Qatar indexing the epidemiological characteristics and antibiotic susceptibility of *S.maltophilia*.

**Materials/methods:** This retrospective descriptive epidemiological study was done by analyzing inpatient respiratory isolates of *S.maltophilia* during 2016-17. Out-patients, children below 14 years and non-respiratory samples were excluded. Clinical records were reviewed to identify possible risk factors. Infection and colonisation was identified using CDC algorithm for clinically defined pneumonia and statistically analyzed using chi-square test and Pearson’s correlation.

**Results:** *S.maltophilia* was isolated from 2.07% (317/15312) of all respiratory samples received in microbiology lab during our study period. 317 patients studied had a mean age of 60.5±20 years and 68% were men. Most of the isolates were from sputum (179), followed by endotracheal tube (43), tracheal aspirate (39), Bronchial wash (25), bronchoalveolar lavage (17) and blood (14). 67% of them were hospitalised for more than 2 weeks, 39.1% were on mechanical ventilation and 88% had received a broad-spectrum antibiotic prior to the event. 29.1% were deemed to have infection and 70.9% colonisation. Incidence of infection in those with Charlson’s Co-morbidity Index (CCI) ≥3 was 36.5% compared to 24.2% in those with CCI<3 (Relative Risk (RR)=1.52;95%CI:1.04,2.18; p=0.01). Patients with recent chemotherapy, immunosuppressant or steroid use had a significantly higher risk of infection compared to those without [69.2% versus23.3% (RR=2.96;95%CI:2.2,3.9; p<0.05)]. Most common symptoms in patients with infection were fever (96%) and expectoration (61.9%). Most common radiological finding was lobar consolidation (71.6%). Mean CRP and procalcitonin were 106.5±15.5mg/l and 12.3±14ng/ml. Overall mortality was 16.3%. Patients with IBMP-10 score ≥2 had 22.8% mortality compared to 5.7% in those with score<2 (RR=3.9;95%CI:0.9,16.6; p=0.015). As per CLSI break-point values, Trimethoprim-Sulphamethoxazole (TMP-SMX) showed highest sensitivity (97.8%) followed by colistin (83.3%), levofloxacin (71.6%), ceftazidime (37.8%), tigecycline (36.6%), ciprofloxacin (8.8%) and aztreonam (5.6%). 0.3% of samples were pan-drug resistant.

**Conclusions:** *S.maltophilia* causes nosocomial pneumonia in immunocompromised and patients with CCI≥3 with high risk of mortality in those with IBMP-10≥2. Strains from Qatar show good susceptibility to TMP-SMX, colistin and levofloxacin. Tigecycline, aztreonam, ceftazidime and ciprofloxacin have high rates of resistance and should never be used alone.
Prevalence of Mycoplasma genitalium and macrolide resistance in Israel

Orit Treigerman*1, George Prajgrod1, David Shasha12
1Meuhedet Health Services, Tel Aviv, Israel, 2Tel Aviv Sourasky Medical Center, Tel Aviv-Yafo, Israel

Background: Mycoplasma genitalium (MG) is one of the leading pathogens causing urethritis, cervicitis and PID. Macrolide and quinolone resistance are increasingly reported in various parts of the world and have significant impact on treatment efficacy. We examined the prevalence of this pathogen in a large cohort of patients in Israel and looked for macrolide resistance mutations.

Materials/methods: Retrospective observational study over 7 years (2013-2019), in a Health Maintenance Organization insuring 1.2 million individuals. Urine and genital samples were examined by PCR for 5 clinically relevant pathogens (N. gonorrhoea, C. trachomatis, M. genitalium, U. urealyticum and T. vaginalis) using Allplex™ STI Essential Assay (Seegene, Seoul, South Korea). A subgroup of 191 MG positive samples were tested for mutations at positions 2058 and 2059 in the 23S rRNA gene, responsible for macrolide resistance using Segene Allplex MG & AzIIR Assay.

Results: In this study 74,000 samples were included, collected from both patients with a clinical syndrome or asymptomatic individuals going through screening. From 2013 to 2019, 8% of the samples were positive for one of the 5 clinically relevant pathogens. This rate was stable over the years. MG accounted for 22.6% of the positive samples (second only to CT, which accounted for 52%). The rate of MG increased gradually from 16% in 2013 to 27.9% in 2019. Of 191 MG positive samples (collected during the last study year) macrolide resistance mutation was found in 47 (24.6%).

Conclusions: MG is the second most prevalent pathogen identified in urine and genital samples in Israel. It is responsible for 23% of all positive tests and its prevalence has been increasing. Macrolide resistance in MG is substantial reaching 25%. These results highlight the need to reconsider current treatment guidelines of urethritis and cervicitis in Israel, considering implementation of resistance guided therapy.

EUCAST temocillin breakpoints and antimicrobial susceptibility testing guidelines
Christian Giske¹, Erika Matuschek², Rafael Canton Moreno³, John D. Turnidge⁴, Gunnar Kahlmeter²
¹Karolinska Institute, Stockholm, Sweden, ²EUCAST Development Laboratory, Växjö, Sweden, ³Hospital Universitario Ramón y Cajal-IRYCIS, Madrid, Spain, ⁴Adelaide Medical School, Adelaide, Australia

Background: Temocillin, a beta-lactam agent active against many ESBL-producing Enterobacterales, has primarily been used in infections originating from the urinary tract, including urosepsis caused by Escherichia coli and Klebsiella pneumoniae. Temocillin is approved in some EU countries, but was never subjected to the centralized European Medicines Agency procedure. In the absence of EUCAST breakpoints, several national breakpoints were used.

Materials/methods: The standard EUCAST processes for setting breakpoints were used. Clinical outcome and PK-PD data were assessed together with MIC distribution data. Both broth microdilution MIC testing (ISO 20776-1) using freeze-dried Sensititre™ plates and disk diffusion according to EUCAST were performed on E. coli (n=65), K. pneumoniae (n=19) and Proteus mirabilis (n=8). Disk diffusion was performed on Mueller-Hinton agar with temocillin 30-µg disks from four manufacturers (Figure 1), and for a subset of isolates, also on temocillin 5- and 15-µg disks (Mast Diagnostics). Inhibition zones were read both when i) ignoring isolated colonies within zones and ii) taking colonies into account.

Results: After assessing data on two alternative dosing schedules, clinical outcome, the PK-PD, and MIC distributions for organisms without and with resistance mechanisms, EUCAST concluded that wild-type organisms have MIC values below or equal to 16 mg/L which is the proposed susceptible breakpoint. Organisms with wild-type MIC values should be treated with the highest dose when causing complicated urinary tract infection (cUTI) [including non-severe urosepsis] whereas non-cUTI with complicated organisms can be treated with the standard dose schedule because of the high urinary concentration. The “Susceptible, increased exposure” (S≤0.001, R>16 mg/L) category is therefore appropriate. The best correlation between disk diffusion and broth microdilution MIC determination was achieved using a 30-µg disk (rather than a 5- or 15-µg disks) and when ignoring isolated colonies within zones [Figure 1]. Corresponding zone diameter breakpoints were set at S≥50 mm, R<17 mm.

Conclusions: The EUCAST breakpoints (S≤0.001, R>16 mg/L) and new disk diffusion methodology will enable to test and report temocillin for E. coli, K. pneumoniae and P. mirabilis with EUCAST methodology. The breakpoints and the category “Susceptible, increased exposure” signal the need for high exposure when treating cUTI, including non-severe urosepsis with temocillin.

Figure 1. Inhibition zone diameter distributions for temocillin 30 µg (disks from Bio-Rad, BD, Mast Diagnostics and Oxoid/Thermo Fisher Scientific) for isolates tested on Mueller-Hinton agar from BBL/BD and Oxoid/Thermo Fisher Scientific in parallel, resulting in 8 disk diffusion results per isolate for a) Escherichia coli (n=65), Klebsiella pneumoniae (n=19) and Proteus mirabilis (n=8) and b) Escherichia coli (n=65). Isolated colonies within the inhibition zones were ignored when reading zone diameters. EUCAST resistant zone diameter breakpoint (17 mm) is shown as a dotted line.

Type I interferons mediate antiviral resistance to Zika virus in human macrophages

Aidan Hanrath*1,2, Catherine Hatton1, Cathy Browne3, Jane Vowles1, Sally Cowley1, William James3, Sophie Hambleton1,4, Christopher Duncan1,2

1Newcastle University, Immunity and Inflammation Theme, Translational and Clinical Research Institute, Newcastle-upon-Tyne, United Kingdom, 2Royal Victoria Infirmary, Department of Infection and Tropical Medicine, Newcastle-upon-Tyne, United Kingdom, 3University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom, 4Great North Children’s Hospital, Department of Paediatric Immunology and Infectious Diseases, Newcastle-upon-Tyne, United Kingdom

Background: Since the recent emergence of Zika virus (ZIKV), major aspects of its pathogenesis remain poorly defined. ZIKV efficiently evades type I interferon (IFN-α/β) responses, which are central to innate antiviral defence: a key question is whether IFN-α/β is therefore redundant in human ZIKV immunity. Existing murine models are unhelpful as modelling ZIKV disease in mice has necessitated deletion of the IFN-α/β receptor (IFNAR). We therefore addressed this question in human macrophages, key effector cells of innate antiviral immunity, which are implicated in ZIKV persistence, transmission and neuropathology.

Materials/methods: We employed a validated model of human tissue macrophages derived from induced pluripotent stem cells (iPSC), incorporating unique patient-derived cells lacking the human IFN-α/β receptor (IFNAR2). Wild-type and IFNAR-deficient macrophages were challenged with African and Asian lineage ZIKV strains. Innate signalling, infection and cytopathic effects were quantified by qPCR, immunofluorescence, immunoblot, plaque assay and live cell viability imaging.

Results: Wild-type macrophages mounted a robust innate interferon response to ZIKV infection, resulting in the expression of key antiviral interferon stimulated genes (ISGs). This IFN-α/β-mediated antiviral state effectively restricted viral replication and limited cytopathic effects. In contrast, cells lacking IFNAR showed markedly enhanced viral infection (12.06% wild-type vs 63.75% IFNAR2/- macrophages expressing ZIKV antigen by immunofluorescence, p<0.0001) and virus-induced cell death (Figure 1). This was accompanied by an absence of antiviral ISG induction, despite normal induction of innate interferons, reflecting a failure of IFNAR signalling. This phenotype was recapitulated in wild-type control cells by (a) blockade of downstream IFNAR signalling with ruxolitinib and (b) deletion of IFNAR2 by CRISPR/Cas9 gene editing, and was partially rescued in IFNAR-deficient cells by IFNγ.

Conclusions: These data reveal that IFN-α/β is central to ZIKV resistance in human macrophages, and that despite ZIKV countermeasures, IFN-α/β plays an important role in human ZIKV immunity. Future work is needed to understand the generalisability of this mechanism in other disease-relevant cells and tissues. Nevertheless, our data raise the possibility that defects in IFN-α/β immunity may underlie some extreme clinical phenotypes of ZIKV disease.

Figure 1. Live-cell immunofluorescence. MOI = multiplicity of infection, ns = non-significant, Rux = ruxolitinib, *** = p<0.0001.

Abstract 3921

Ceftobiprole susceptibility of European Gram-positive and Enterobacteriaceae clinical isolates from different infection sources collected in 2018

Stephen Hawser*1, Ian Morrissey1, Nimmi Kothari1, Noëlle Jemmely2
1IHMA, Monthey, Switzerland, 2Correvio International Sàrl, Genève, Switzerland

Background: Ceftobiprole is an advanced-generation, broad-spectrum parenteral cephalosporin approved in 17 European and eight non-European countries for the treatment of adults with community-acquired pneumonia (CAP) and hospital-acquired pneumonia (HAP) (excluding ventilator-associated pneumonia) caused by susceptible Gram-positive pathogens, including methicillin-resistant Staphylococcus aureus (MRSA), and Gram-negative pathogens. The present investigation reports susceptibility of European Gram-positive and Gram-negative isolates from 2018 as part of an ongoing susceptibility surveillance program.

Materials/methods: A total of 4284 clinical isolates were collected from European hospitals in 2018, including Enterobacterales, Pseudomonas aeruginosa, MRSA, MSSA, Streptococcus pneumoniae and Haemophilus influenzae. These were collected from various infection sources including respiratory, skin, genitourinary tract, body fluid and gastrointestinal infection sources. MIC determination was performed by broth microdilution and susceptibility interpreted using EUCAST clinical breakpoints.

Results: A summary of ceftobiprole susceptibilities are shown in the Table.

*seven species including Enterobacter cloacae, Escherichia coli, Klebsiella aerogenes, K. oxytoca, K. pneumoniae, Proteus mirabilis, and Serratia marcescens; **Non-species related PK/PD breakpoint

Conclusions: The susceptibility data for ceftobiprole show that the majority of Gram-positive bacterial isolates were susceptible. All MSSA isolates were susceptible to ceftobiprole, followed by 98.9% of MRSA and 98.7% of pneumococci. All MSSA and MRSA were susceptible to daptomycin and vancomycin and 100% of pneumococci were linezolid-susceptible. Susceptibility of the enteric bacteria to ceftobiprole was 75.6%. Of those resistant to ceftobiprole, resistance to ampicillin and other cephalosporins was also high, as expected, indicating the vast majority of these were probably extended-spectrum beta-lactamase producers. Almost two-thirds of pseudomonads and all H. influenzae were susceptible to ceftobiprole. Overall, the data further support the clinical utility of ceftobiprole.

Abstract 3923

In silico and in vitro investigation of a novel putative toxin-antitoxin system in Acinetobacter baumannii

Shahira A. El-Banna*1, Reham Samir1, Ramy K. Aziz1, Nayera A. Moneib2

1Faculty of Pharmacy, Cairo University, Cairo, Egypt

Background: Toxin-antitoxin (TA) systems are widespread among bacteria, archaea and fungi. They play different roles, such as postsegregational killing, abortive infection, and persister formation, and have recently been identified as novel drug targets. TA systems have been classified into six types (I-VI), depending on the nature of antitoxin and its mode of action. CptAB Type IV-TA is one of the least characterized systems that remain limited to a few bacterial species, such as Escherichia coli. This study aimed to screen different Gram-negative bacteria for this Type IV-TA, especially in Acinetobacter baumannii, known for its antimicrobial resistance.

Materials/methods: BlastP similarity searches and maximum likelihood phylogenetic analysis for both CptA and CptB were used for in silico detection of the distribution and conservation of these proteins and their encoding genes among different bacteria. In vitro, real-time reverse transcription-PCR was used to determine the differential expression of the cptAB homologous system of A. baumannii ATCC 17978 upon exposure to different stresses, including high temperature (42°C), oxidative stress, and some antibiotics.

Results: BlastP analysis of CptAB showed its wide distribution among Gram-negative bacteria (amino-acid identity: 24%–100%, over 70% coverage). Maximum likelihood phylogenetic analysis for both CptA and CptB delineated two major groups, in each of which Acinetobacter spp. clustered together. Moreover, multiple sequence analysis indicated the conservation of cptA and cptB in 128 strains of A. baumannii in the same syntenic order. A slight increase in the transcription of both cptA and cptB was observed upon exposure of A. baumannii to either 42°C (by 1.3 folds) or the protein synthesis-inhibiting antibiotic, streptomycin (by 1.2 and 1.6 folds, respectively). However, exposure to oxidative stress and other classes of antibiotics, e.g., ciprofloxacin and meropenem, caused transcriptional downregulation of both genes.

Conclusions: In silico analysis suggested a potential TA system in A. baumannii, based on sequence similarity to CptAB features in E. coli. Under the influence of some antibiotics and other stresses, transcriptional changes were observed in the A. baumannii system. Taken together, these data suggest that CptAB contributes to the bacteriostatic or cidal mechanisms of antibiotics and other stress agents against A. baumannii.

Severe cryptococcal meningoencephalitis with large vessel vasculopathy and multi-territory cerebral infarcts
Caitlyn Sun1,2, Max Kernich1,2, Nicholas Chia1,2, Renjy Nelson1,2

1Royal Adelaide Hospital, Adelaide, Australia, 2The University of Adelaide, Adelaide, Australia

Aim: To describe a unique clinical case of suspected cryptococcus induced vasculitis.

Materials/methods: Clinical case report and literature review.

Results: A 29-year-old Indigenous Australian man presented with fever and seizures on a background of alcohol misuse and HTLV-1 infection. His conscious state deteriorated despite empirical antibiotics and he was admitted to intensive care for intubation and ventilation. No toxic or metabolic aetiology was identified.

Serum cryptococcal antigen was detected at a titre of 1:1024. Lumbar puncture revealed an elevated opening manometric pressure of >35 cmH2O, polymorphonuclear cell count of 70x106/L and elevated protein at 5.59g/L. CSF microscopy identified cryptococci on India ink stain with identification of Cryptococcus neoformans var. grubii via MALDI ToF.

CT brain demonstrated moderate hydrocephalus and MRI brain unexpectedly revealed cortical diffusion restriction in bilateral insulae, right anterior and left middle cerebral artery territories [Figure 1A]. Gadolinium-enhancement was demonstrated over the cerebral convexity [Figure 1B]. CT angiography revealed widespread long segment patchy calibre reduction of all intracranial arteries without atherosclerosis or extracranial arterial disease [Figure 1C]. The patient was commenced on flucytosine and liposomal amphotericin B, and a continuous lumbar drain was inserted. Opening CSF pressure was 55 cmH2O.

Investigations for other causes of small and medium vessel vasculitis were unremarkable. There was no improvement in the patient’s severe obtundation and he died after supportive measures were withdrawn.

Cryptococcal vasculitis is rarely reported and the exact mechanism is unknown. It has been postulated that an inflammatory process leads to vessel thrombosis, compression or spasm and subsequent infarction. Stroke in patients with Cryptococcus infection usually causes small vessel infarction of the basal ganglia, internal capsule and thalamus. Large vessel ischaemic stroke appears to be rare in patients with Cryptococcal meningitis. Three such cases have described, predominantly in older patients with cardiovascular and cerebrovascular comorbidities that may have provided a separate stroke mechanism.

Conclusions: Our case is unique given the severity and extent of the multi-territory cortical infarction in a patient with cryptococcal central nervous system infection.
Abstract 3926

Oral immunotherapy with secretory IgA improves survival in the hamster model of *Clostridioides difficile* infection

William Weiss*1, Michael Simon2,3,4, Stephan Kiessing1, Estelle Chiari2, Mark Pulse1, Stephen Brown2, Christoph Von Eichel-Streiber6, Hanne Gerding5, Maurice Mandago5

1UNT System College of Pharmacy, Fort Worth, United States, 2Secretory IgA Inc, Ann Arbor, United States, 3Wayne State University School of Medicine, Detroit, United States, 4Oakland University William Beaumont School of Medicine, Rochester, United States, 5PreviPharma Consulting, Mannheim, Germany, 6tgcBIOMICS GmbH, Bingen, Germany

**Background:** We propose that IgA antibodies recovered from healthy donor plasma have the potential to be a new orally administered antibody therapy for the treatment of *C. difficile* disease. This will create a new oral immunoglobulin application based on the oral use of IgA. The current study was performed to evaluate the efficacy of IgA preparations w/wo vancomycin in the hamster *C. difficile* infection model.

**Materials/methods:** The IgA was shown by ELISA and neutralization assays to possess specific antibodies to *C. difficile* toxins A and B. Hamsters were infected with $10^4$ *C. difficile* spores followed by 10 mg/kg SC clindamycin and then administration of 5 or 10 mg/kg vancomycin QD (q24hr) for 5 days. Animals were also orally administered either secretory IgA (recombinant secretory component+IgA dimer-polymer)/monomeric IgA mixture at 7 mg/kg TID (q8hr) for 21 days or hyperimmune secretory IgA/monomeric IgA mixture at 1 mg/kg BID (q12hr) for 11 days.

**Results:** Infection resulted in 100% mortality of untreated controls by day 4. Administration of vancomycin alone, at 5 mg/kg or 10 mg/kg, resulted in 70% or 90% survival, by day 13 and 40% or 60% survival at day 21, respectively. The combination of 5 mg/kg vancomycin + secretory IgA/monomeric IgA (TID x 21 days) or 10 mg/kg vancomycin + secretory IgA/monomeric IgA + hyperimmune secretory IgA (BID x 13 days) resulted in 90% and 100% overall survival, respectively. Survival of infected hamsters was prolonged for up to 8-14 days as compared to any individual agent alone. The survival curves for the pooled secretory IgA/monomeric IgA + 5mg/kg vancomycin dose group and the hyperimmune secretory IgA/monomeric IgA + 10mg/kg vancomycin group were significantly more efficacious as compared to vancomycin alone by Log-rank (Mantel-Cox) ($p=0.018$ and 0.029) and Gehan-Breslow-Wilcoxon ($p=0.017$ and 0.030) tests, respectively.

**Conclusions:** Administration of secretory IgA/monomeric IgA from healthy human plasma in conjunction with vancomycin resulted in enhanced survival of *C. difficile* infected hamsters and demonstrated its’ potential as a possible therapeutic treatment option.

**Presenter email address:** william.weiss@unthsc.edu
Metagenomic antimicrobial resistance prediction from nanopore sequencing of orthopaedic implant-related infections: can we do more than detect species from sonication fluids?

Teresa Street*1, Camille Kolenda2, Nicholas Sanderson1, Carol Taunt1, Sarah Oakley1, Bridget Atkins1, Martin McNally4, Justin O’grady5, Derrick Crook1, David Eyre6

1University of Oxford, Oxford, United Kingdom, 2Hôpital de la Croix-Rousse, Lyon, France, 3John Radcliffe Hospital, Oxford, United Kingdom, 4Nuffield Orthopaedic Centre, Oxford, United Kingdom, 5Quadram Institute Bioscience, Norwich, United Kingdom, 6Big Data Institute, Oxford, United Kingdom

Background: Metagenomic nanopore sequencing is demonstrating potential as a tool for diagnosis of infections directly from clinical samples. We have previously shown nanopore sequencing can be used to determine the causative bacterial species in prosthetic joint infections (PJI). However, to make predictions regarding antimicrobial resistance, human DNA contamination must be reduced so a greater proportion of sequence data corresponds to the microbial portion of the DNA extract. Here, we optimize selective DNA extraction from sonication fluid samples to make predictions regarding antimicrobial resistance in PJI.

Materials/methods: We investigated host cell DNA depletion with 5% saponin selective human cell lysis followed by nuclease digestion. Additionally, treatment with 1% or 0.1% saponin was tested in a subset of samples. Subsequently, bacterial cells were mechanically lysed before DNA extraction. Sequencing libraries from samples treated with and without saponin were prepared with the Oxford Nanopore Technologies Rapid PCR Barcoding Kit and sequenced in multiplexes of 4-7 samples/flowcell on a GridION. Sequencing reads were analysed using the Crumpit pipeline and a threshold of ≥10% of bases classified as bacterial was used to indicate presence of a specific bacterial genus/species. Antimicrobial resistance determinants were detected using the CARD database.

Results: 193 DNA extracts from 85 individual patient sonication fluids were subjected to metagenomic sequencing, comprising 42 monomicrobial, 2 polymicrobial and 41 culture-negative samples. 5% saponin depleted human DNA contamination most consistently, reducing the number of human sequenced bases in 64/68 samples which were tested in comparison to 5µm filtration without saponin (mean depletion 2.8 log10-fold, maximum depletion 5.0 log10-fold). Bacteria observed in sonication fluid culture were identified to species-level in 37/47 cases, and to genus-level in 40/47. 36/47 species obtained a reference genome coverage breadth of >70%. Here, we identified acquired antimicrobial resistance genes accounting for all resistance phenotypes observed by laboratory sensitivity testing for beta-lactams, macrolides, fusidic acid and tetracycline resistance.

Conclusions: Nanopore metagenomic sequencing can provide species identification and antimicrobial resistance prediction in PJI. Depletion of human DNA improves depth of coverage and allows detection of acquired antimicrobial resistance genes, enabling nanopore sequencing to potentially provide a complete diagnostic tool in PJI.

Abstract 3928

**Aetiology and antimicrobial susceptibility of anaerobic bacteria causing serious infections in a tertiary hospital of Madrid**

José María López-Pintor*, Ana Sánchez-Díaz, Patricia Ruiz-Garbajosa, Rafael Canton Moreno, Maria-Isabel Morosini Reilly, Sergio García-Fernández

1Ramón y Cajal, Madrid, Spain

**Background:** Anaerobic culture techniques and antimicrobial susceptibility testing (AST) are both cumbersome, so recovery and susceptibility assays imply difficulties for routinely laboratory activity. Thus, the anaerobic infection management is frequently based on empirical treatment. The aim of this study was to collect identification and AST data from anaerobic isolates obtained in routine work in the Microbiology Department of a tertiary hospital of Madrid.

**Materials/methods:** The study period comprises 15 months (June 2018 to September 2019). Samples were processed in appropriate anaerobic media and incubated using the Anoxomat system (MART Microbiology BV, Holland); final identification was performed by MALDI-TOF (Bruker, Germany). AST for 3-6 antibiotics was performed with MIC gradient diffusion strips (Liofilchem, Italy) using EUCAST-2019 [penicillin (P), co-amoxiclav (AUG), imipenem (IMI), clindamycin (CD), and metronidazole (LZ)] or CLSI-2019 [cefoxitin (FOX)] breakpoints.

**Results:** 440 anaerobic microorganisms were isolated from 363 samples with positive anaerobic culture, being 29% monomicrobial and 5.2% polymicrobial; coinfection with aerobic bacteria represented 65.8%. The most common source of infection was intraabdominal (28.7%). Anaerobic gram-negative bacilli (AGNB) were predominant, (41.3%), being *Bacteroides fragilis fragilis* [13.4%] the most prevalent; anaerobic gram-positive bacilli (AGPB) represented 35.9%, anaerobic gram-positive cocci (AGPC), 17.7%; and anaerobic gram-negative cocci (AGNC), 5.1%. Percentage of susceptible isolates and MIC\text{90} values are shown in the table.

**Conclusions:** Metronidazole and imipenem were the most active agents, while anaerobes showed a reduced susceptibility to clindamycin. Selection of antimicrobial agents may be complex in anaerobic infections due to the difficulties in obtaining appropriately isolated specimens. Thus, *in vitro* surveillance studies are necessary for the election of an adequate empirical therapy.

Peripheral venous catheter-related bloodstream infection in hospitalised children: the role of Gram-negative bacteria

Itay Berger*1,2, Tal Cohen1, Eyal Rahmani4, Itzhak Levy1,5, Alexander Lowenthal6, Lotem Goldberg3, Yoel Levinsky1,3, Haim Ben Zvi7, Oded Scheuerman1,3

1Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel, 2Schneider Children’s Medical Center in Israel, Department of Pediatrics A, Petah Tikva, Israel, 3Schneider Children’s Medical Center in Israel, Department of Pediatrics B, Petah Tikva, Israel, 4Schneider Children’s Medical Center in Israel, Department of Pediatrics C, Petah Tikva, Israel, 5Schneider Children’s Medical Center in Israel, Infectious diseases unit, Petah Tikva, Israel, 6Schneider Children’s Medical Center in Israel, Pediatric heart Institute, Petah Tikva, Israel, 7Beilinson, Microbiology Laboratory, Petah Tikva, Israel

Abstract third-party references: abstract is submitted on behalf of Itay Berger

Background: Peripheral venous catheter (PVC) is the most commonly used vascular access in medicine, allowing administration of intravenous fluids and medications. Known complications associated with PVC include extravasation, phlebitis and bloodstream infection (BSI). Data regarding PVC-related BSI in children are scarce. We evaluated the epidemiology, clinical and microbiologic characteristics of pediatric patients with PVC-related BSI.

Materials/methods: This is a retrospective study conducted in a pediatric tertiary care center. Children with BSI, admitted to the general pediatric departments, between January 2010 and November 2019, were identified and their medical records examined. Patients with BSI and phlebitis at the PVC site were further characterized and included in the analysis. We excluded patients with central venous catheters, those with other identified source of infection and those with BSI upon admission. Data collected included: patients’ demographics and clinical and microbiological characteristics.

Results: Twenty-six children with PVC-related BSI were identified and included in the analysis. They constituted 0.2% of the total cases of bacteremia during the study period. Median age was 24 months (range, 1.5–396 months); male and female were equally affected. Five patients were categorized as previously healthy while the others, had prior medical conditions. The mean time from catheter insertion to bacteremia was 4.4 (±1.5) days. Eighteen (69%) patients were infected with Gram-negative bacteria and six (23%) with Gram-positive. Mixed Gram-negative and Gram-positive and Candida albicans occurred in one patient (4%) each. Polymicrobial infection occurred in four patients (15%). The most common bacteria isolated were klebsiella spp and Staphylococcus aureus.

Conclusions: Gram-negative bacteria are more commonly associated with PVC-related BSI than Gram-positive bacteria. Clinicians should consider a broad-spectrum antibiotic coverage for the empirical treatment of PVC-related BSI in hospitalized pediatric patients.

Fail to perform a repeat ascitic tap at 48 hours is associated with poor outcome in patients with spontaneous bacterial peritonitis

Jaclyn Yizhen Tan*, Jade King1, Jennifer Ryan1, Marsha Morgan1, Rachel Westbrook1, Emmanuel Wey2,3

1University College London, UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, London, United Kingdom, 2University College London, Division of infection and immunity, London, United Kingdom, 3Royal Free London NHS Foundation Trust, Centre for clinical microbiology, Department of microbiology, London, United Kingdom

**Background:** In patients with spontaneous bacterial peritonitis (SBP), acute kidney injury (AKI) and high serum bilirubin are predictors of in-hospital mortality. Impact of patient management on mortality is unknown. This study aims to identify predictors of in-hospital mortality, accounting for management of patients with SBP, according to EASL Clinical Practice Guidelines published in 2010.

**Materials/methods:** Clinico-demographic, biochemical and microbiological data from patients presenting between 2014 and 2019, with a first episode of SBP (ascitic fluid neutrophil count >250 cells/cm³) were reviewed. The primary endpoint was in-hospital mortality. Logistic regression identified predictors of outcome.

**Results:** Overall, 130 patients (median [IQR] age 58 [51–66] yr; 65% male; aetiology: alcohol 36%, MELD score 18 [13–25]) were included. Infection was nosocomial in 49%; 35 had concomitant bacteraemia (n=14), respiratory (n=16) or urinary infections (n=9). Pathogens were identified in 57 (44%) patients within 42 [36–50] hr post initial ascitic tap; antibiotic sensitivities were available by 53 [49–62] hr. Multidrug resistant pathogens (MDRP) were identified in 12 (21%) of the 57; 10 of the 12 showed <25% reduction in ascitic neutrophil count at 48 hours.

There were 29 (22.3%) in-hospital deaths; median time to death was 6 [1–8] days. A total of 31 (24%) patients were admitted to ITU – one-third (n=13) of this cohort died. On univariate analysis, admission MELD, peripheral white cell count, INR, serum creatinine, failure to culture a pathogen, failure to perform a 48-hour ascitic tap and development of AKI were predictors of in-hospital mortality. Age, nosocomial infection or the presence of a MDRP were not. Failure to perform a 48-hour ascitic tap [OR [95% CI] = 11.2 [2.9–43.7], p<0.01], acute kidney injury [9.1 [2.0–41.5], p<0.01] and MELD score [1.2 [1.1–1.3], p<0.01] retained significance on multivariate analysis.

**Conclusions:** In-hospital mortality associated with SBP is unacceptably high at 22%. Failure to repeat the ascitic tap at 48 hours, a recommendation based solely on expert opinion in the EASL guideline, was a highly significant prognostic factor allowing early identification of patients who fail to respond to empirical antibiotic therapy. This requirement should now become recommended practice.

**Presenter email address:** j.tan@ucl.ac.uk
Tuberculosis in the elderly: a current challenge

Paloma Gijón1, Beatriz Alvarez Romasanta*1, Ana Valera1, Maria Cristina Veintimilla Yanez1, Sandra Rodriguez1, Maria Jesus Ruiz Serrano1, Dario Garcia De Viedma2

1Gregorio Marañón Hospital, Servicio de Microbiología Clínica y Enfermedades Infecciosas, Madrid, Spain

Background: Tuberculosis in the elderly (>65 y.o.) is a difficult-to treat disease. To decrease its high mortality, we need to improve our knowledge of the cases and their epidemiological scenario. We aim to describe current epidemiological characteristics, clinical presentation and outcome of TB in the elderly in our institution.

Materials/methods: All elderly patients with TB diagnosed by culture or PCR from 2012 to 2019 in a 1400-bed university hospital in Madrid were included. Socio-demographic characteristics, clinical findings, and outcome were recorded. One isolate from each case was genotyped and their MIRU-VNTR patterns were compared with those from a convenience sample from the same population to label which cases are likely due to recent transmission (clustered, identical patterns or SLVs, involving cases within 3 years) or to reactivation of latent TB (orphan, unique genotypes).

Results: From January 2012 to September 2019, 56/526 TB cases (10.64%) corresponded to patients aged 65-94y. Overall 29 (51.76%) were men; 8 (14.28%) migrants, 17 (30.35%) immunocompromised (mainly due to steroids). IGRA (Quantiferon TB gold) was positive in 30/39 patients (76.92%). Radiology was helpful in only 50%. Extrapulmonary disease was found in 20 patients (36%; mainly lymph node confused with tumors), and 7 presented with dissemination (12.5%). Mean diagnostic delay was 5 months (r: <1-24). For those with information about outcome (53), treatment toxicity grade 3 and 4 occurred in 25 %, 9-month mortality was 20.75% and 24-month survival was 56%.

The percentage of drug-resistant M. tuberculosis strains isolated was 10.71%, higher than in general population (7%). Isolates from 40 elderly patients were genotyped and only 2 clusters likely due to recent transmission (involving one elderly an another non-elderly case each) were identified. Six additional clusters were identified involving an elderly case with 1-3 non-elderly cases diagnosed 5-16 years before.

Conclusions: TB in the elderly is a severe disease, usually associated to diagnostic delay. Despite its prevalence decrease in our country, we must consider TB in old people, more likely associated to reactivation of latent infection than from recent transmission, though the latter should also be taken into consideration.

Abstract 3936

Diagnosis of amoebic liver abscess by detection of Entamoeba histolytica DNA in serum using quantitative PCR

Gheffenstein Ferreira Theo*1, Maud Gits-Muselli1,2, Nicolas Guigue1, Marie-Quitterie Picat3, Samia Hamane1, Stéphane Bretagne1,2

Background: Amebic liver abscess (ALA) is regularly seen, mainly in travelers or immigrants from tropical countries. The diagnosis relies on imaging and serology, which must be performed in emergency. However, positive serology cannot distinguish acute from previous infection. We wondered whether amebic DNA detection in serum using quantitative PCR (qPCR) assay could improve the diagnosis of ALA.

Materials/methods: We retrospectively tested all serum samples available from patients with a positive serology and a final diagnosis of ALA between 01/01/2010 and 26/11/2019. The control group included patients with a diagnosis of liver space-occupying lesions with a final diagnosis other than ALA seen during the same period in our hospital and with serum sample stored available. DNA was extracted using QIAsymphony DSP Virus/Pathogen Kits spin columns. The qPCR assay was performed as already reported [1]. The oligonucleotide primers specifically amplify a 99-bp fragment inside the 16S-like small-subunit rRNA gene of E. histolytica.

Results: 80 samples were tested (ALA n=26 and control group n=54). Among them, 72 serum samples had been collected at the time of diagnosis [median: 1 day, Q1-Q3: 0-4 days] for 20 ALA and 52 controls (ALA n=20, tumor process n=21, pyogenic liver abscess n=24, cyst n=3, others n=4).

The qPCR detected E. histolytica DNA in 80% serum samples (16/20) of ALA patients and all the serum samples of control subjects were negative. Among the four negative qPCR samples in ALA, three could be explained by an ancient seropositivity due to previous amebic infection in one regular traveler and by a prior anti-amebic treatment (≥ 5 days) in two patients. Indeed, 8 serum samples available after treatment in initially positive patients demonstrated a negativation in 4 to 6 days. Thus, in the absence of treatment within 5 days, predictive negative value and positive predictive value were 100% and 96%, respectively.

Conclusions: This study demonstrates that free-circulating amebic DNA can be detected and could help both for positive diagnosis and for following treatment efficacy. This circulating-DNA could come from the blood passage of intestinal ameba or more probably from DNA released by dying hepatic ameba.

Abstract 3939

**Staphylococcus lugdunensis**: coloniser or pathogen: outlining the clinical importance: a study of 295 clinical samples from hospital patients received for culture at the department of Medical Microbiology, SI Lillehammer, Norway, from November 2016 to November 2019

Susanne Hartvig Hartzen¹, Christoffer Dahlseide¹, Anders Hartzen²

¹Lillehammer Hospital, Lillehammer, Norway, ²University of Copenhagen, København, Denmark

**Background:** In 2018, a new initiative was set in motion by the Norwegian Working Group on Antibiotics providing recommendations for antibiotic panels and how to report cultures and susceptibility results based on information about clinical setting and signs of infection. The initiative was part of the overall strategy to limit the use of antibiotics and curb resistance. Placing the clinical presentation of the individual patient center stage, the microbiologist responsible for checking, interpreting and reporting culture results became a key player in the effort to avoid antibiotic treatment of patients with colonization states.

As growth of *S*. *lugdunensis* might represent normal skin flora or infection, we decided to study the clinical importance and impact of culture results of 295 samples with *S*. *lugdunensis* reported to hospitals in Oppland and Hedmark Fylker. Based on information on file we investigate the background for reporting the culture result, and the impact the culture result had on antibiotic treatment.

**Materials/methods:** The study used the following information sources: the requisition records, reporting cards, and hospital records concerning the 295 patient samples, where growth of *S*. *lugdunensis* was reported. Information extracted: age, sex, type of material, dominating growth of *S*. *lugdunensis*, antibiogram, symptoms of infection, and impact of culture report.

**Results:** Table 1: Information on 295 clinical samples from 280 patients where *S*. *lugdunensis* was reported.

All strains were susceptible to cefoxitin, 60% to penicillin, and 94% to clindamycin.

<table>

**Conclusions:** Uncertainty concerning the clinical significance of growth of *S*. *lugdunensis* was widely present, particularly with culture of non-sterile materials. Selective reporting of susceptibility results might be well suited in both cases of uncertainty and cases with no clear infection. Empirical antibiotic therapy was generally maintained - perhaps reflecting the equivocal nature of culture results.

Abstract 3940

Susceptibility of Gram-positive and Enterobacterales clinical isolates isolated during 2018 from France, Germany, Italy, Spain and the United Kingdom

Stephen Hawser*1, Ian Morrissey1, Nimmi Kothari1, Nowel Redder2

1IHMA, Monthey, Switzerland, 2Correvio International Sàrl, Genève, Switzerland

Background: Ceftobiprole is an advanced-generation, broad-spectrum parenteral cephalosporin approved in 17 European and eight non-European countries for the treatment of adults with community-acquired pneumonia (CAP) and hospital-acquired pneumonia (HAP) (excluding ventilator-associated pneumonia. The present investigation reports susceptibility of European Gram-positive and Gram-negative isolates from 2018 as part of an ongoing susceptibility surveillance program.

Materials/methods: A total of 2784 clinical isolates were collected from European hospitals in 2018, including Enterobacterales, Pseudomonas aeruginosa, MRSA, MSSA and Streptococcus pneumoniae. These were collected from various infection sources including respiratory, skin, genitourinary tract, body fluid and gastrointestinal. Isolates were from France, Germany, Italy, Spain, and the United Kingdom. MIC determination was performed by broth microdilution.

Results: Ceftobiprole susceptibilities are shown in the Table.

*Non-species related PK/PD breakpoint
**seven species including Enterobacter cloacae, Escherichia coli, Klebsiella aerogenes, K. oxytoca, K. pneumoniae, Proteus mirabilis, and Serratia marcescens;

Conclusions: Only minor variations in percent susceptibility to ceftobiprole were observed between countries for MRSA (95%-100%) and pneumococci (97%-100%). All MSSA isolates were susceptible to ceftobiprole. All MSSA and MRSA were daptomycin- and vancomycin-susceptible and all pneumococci were susceptible to linezolid. Susceptibility of Enterobacterales ranged from 59% (Italy) to 83% (France), and of Pseudomonas from 59% (Spain) to 76% (France). Although not specifically evaluated, it is probable that ceftobiprole-resistant Enterobacterales were extended-spectrum beta-lactamase producers. Overall, the data further support the clinical utility of ceftobiprole against important clinical Gram-positive and Gram-negative isolates from the five countries analysed.

**Abstract 3942**

**Clostridiodes difficile ribotypes 001 and 176 with reduced susceptibility to moxifloxacin are the main cause of healthcare-associated Clostridioides difficile infections in Slovakia**

Adriana Plankaova¹, Anna Šoltésová¹, Jana Skálová², Pavel Drevinek¹, Václav Čapek¹, Marcela Krutova*³

¹Alpha Medical Inc, Department of Clinical Microbiology, Rožňava, Slovakia, ²Svet Zdravia Inc, Department of Epidemiology, Bratislava, Slovakia, ³Charles University, 2nd Faculty of Medicine and Motol University Hospital, Department of Medical Microbiology, Prague, Czech Republic

**Background:** In 2016, the emergence of ribotype 176 was recognized in six hospitals in Slovakia (Novakova et al., IJID, 2019). In order to obtain current data on *Clostridium (Clostridioides) difficile* infection (CDI) epidemiology in Slovakia, we aimed to perform a CDI surveillance study and to characterize *C. difficile* isolates for all CDI cases.

**Materials/methods:** Between May 2018 and May 2019, fourteen Slovakian hospitals (Figure 1) collected stool samples and epidemiological data of patients with CDI. *C. difficile* isolates were characterised by capillary-electrophoresis ribotyping, multiplex PCR toxin genes detection and antibiotic susceptibility testing to metronidazole, vancomycin and moxifloxacin using the agar dilution method. The European Centre for Disease Prevention and Control (ECDC) CDI surveillance protocol v 2.3 was followed for the CDI case, CDI origin and recurrent infection definitions.

**Results:** Of the 381 CDI cases, 75.6% (n=288) were healthcare-associated, 11.5% (n=44) were community-associated or of unknown origin and 12.9 (n=49) of CDIs were recurrent. A complicated course of CDI was reported in 12.3% (n=47). Of the 27.6% patients (n=105) that died, 25.7% (n=98) did so within 30 days after a CDI diagnosis.

A total of 370 *C. difficile* isolates were further characterized. The most prevalent PCR ribotypes (RTs) were 176 (n=185, 50.0%) and 001 (n=129, 34.9%). A total of 322 (97.0%) of the isolates showed a reduced susceptibility to moxifloxacin (>4 mg/L), and the majority belonged to the epidemic RTs 001 and 176, (n=312). A reduced susceptibility to metronidazole (>2 mg/L) was observed in 16 isolates (RTs 001 and 176).

HA CDI was associated with CDI caused by strains showing a reduced susceptibility to moxifloxacin and HA CDIs were more likely to have a complicated course of CDI (p=0.0030, 0.0455). Mortality was associated with patients of an advanced age and a complicated course of CDI (p=0.0092 and 0.0000).

**Conclusions:** We revealed a dramatic proportion of *C. difficile* isolates that showed a reduced susceptibility to moxifloxacin in Slovak healthcare settings. The spread of ribotypes 001 and 176 drives current CDI epidemiology in Slovakia. Our findings call for an urgent reduction in prescriptions of fluoroquinolones in healthcare settings in Slovakia.

**Figure 1:** Distribution of Slovak hospitals participating in surveillance of CDI. Pie charts show the representation of *C. difficile* ribotypes 001 and 176 identified per hospital. The numbers in the centre represent the number of *C. difficile* isolates cultured for molecular characterisation

Chronic schistosomiasis and strongyloidiasis amongst Ethiopian immigrants in Netanya

Talya Finn*, Frida Babushkin1, Keren Geller1, Tamar Grossman3, Regev Cohen1,2

1Laniado Hospital, Netanya, Israel, 2The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel, 3Public Health Central Laboratories, Jerusalem, Israel

Background: Upon immigration from Ethiopia to Israel in the 1990s, very high rates of intestinal parasites were documented among immigrants. Despite this, diagnosis and treatment of these parasitic infections are still grossly inadequate. Here we describe cases of Ethiopian-born patients diagnosed with longstanding Schistosomiasis (SC) and Strongyloidiasis (SS) at Sanz Medical Center.

Materials/methods: We reviewed the medical records of adult Ethiopian-born patients hospitalized between 2012-2019 who were tested for SC/SS. Serology (ELISA and/or Western blot) and stool molecular tests were performed at the parasitology reference laboratory. Fisher’s exact and Chi square tests were used to determine significance.

Results: 82 patients were tested for antibodies against SC/SS or both. 55 (67%) were positive: 21 for SC, 20 for SS and 14 for both. The average time from immigration until diagnosis was 20 years (range 8-37). In 40 (49%) additional microbiological tests were performed: 33 stool ova and parasite microscopy tests were all negative, while 5/7 stool PCR tests were positive, 2 for SC and 3 for SS, showing 66-75% concordance with the serology tests. 73% of the study cohort had eosinophilia, which was significantly more common among patients with positive serology for SS vs SC (91% vs 68%, p=0.03). The mean maximal eosinophil count was significantly higher in SS (1481 vs 936 cells/mcl, p=0.01). Of the positive patients: 19 had respiratory complaints, 7 anemia or gastrointestinal symptoms, 4 neurological symptoms and 23 “other” symptoms. Asthma as a presenting or past symptom was observed in 53% (18/34) of SS and 37% (13/35) of SC cases (p=0.23). Treatment availability and culture barriers resulted in only 24/55 (43%) being accessed and treated.

Conclusions: Significant eosinophilia was a common finding and a trigger for testing. Nearly 70% of patients tested had serological evidence of SS/SC, neither of which is endemic in Israel. Diagnosis many years after immigration reflects chronic medical neglect of this community. Chronic significant eosinophilia, asthma-like, gastrointestinal, neurological and dermatologic symptoms, may serve as clues for diagnosis. Our results indicate the necessity of stipulating a strategy involving systematic laboratory screening for the diagnosis of helminthic infections among the Ethiopian-born community in Israel.

Utilisation of next-generation sequencing testing for diagnostic dilemmas: experience at a tertiary care centre

Maressa Santarossa*1, Rehman Ukani1, Kyle Walding1, Amanda Harrington1, Nina Clark1, Gail Reid1

1Loyola University Medical Center, Maywood, United States

Background: Next-generation sequencing (NGS) of microbial cell-free DNA is an evolving diagnostic tool. Current diagnostic methods for infectious diseases often require organism growth, and can delay timely initiation of appropriate antimicrobial therapy. Currently available NGS assays offer an advantage of early pathogen identification and increased sensitivity compared to other methods. However, more research is necessary to determine the optimal patient population to utilize NGS, and how to correctly interpret NGS results.

Materials/methods: This was a retrospective observational study performed at a tertiary care center. A list of all NGS tests performed from February 15, 2019 to June 30, 2019 at Loyola University Medical center was obtained. Next-generation sequencing testing (Karius, Redwood City, CA) was performed as part of the routine diagnostic work up at the discretion of the infectious diseases consult team and outcomes were examined.

Results: There were 31 patients included in our analysis. The mean age of our cohort was 54 years old, and 15 patients (48%) were immunocompromised. NGS detected at least one organism in 19 patients (61.3%), with a total of 25 bacteria, 7 viruses, 4 fungi, and 1 parasite. The mean time to NGS result from send out was 2.29 days. Antimicrobial therapy was changed based on the NGS result for 19 patients (61.3%); three patients (9.7%) were started on antibiotics, seven patients (22.6%) had antibiotics discontinued, four patients (12.9%) had antibiotics escalated, and 10 patients (32.2%) had antibiotics de-escalated. The median bacterial value for immunocompromised patients was significantly lower than that of immunocompetent patients (159 vs. 905, p = 0.006), and the median bacterial value was significantly higher in those where the NGS result correlated clinically (274 vs. 26, p < 0.001).

Conclusions: NGS is a diagnostic tool that can be beneficial to patient care if used in the appropriate clinical scenarios. At our institution, NGS testing was typically faster than traditional culture methods, and resulted in antimicrobial therapy changes in the majority of the cohort. However, optimal circumstances for testing and interpreting clinical relevance of results are still to be determined.

# Abstract 3949

**Cholera outbreak in Algeria, August-September 2018**

1Institut Pasteur of Algeria, Enterobacteria Laboratory, Algiers, Algeria, 2Boufarik Public Hospital, Infectious Diseases Department, Blida, Algeria, 3Specialized Hospital El Hadi Flici, Infectious Diseases Department, Algiers, Algeria, 4Specialized Hospital El Hadi Flici, Central Laboratory, Algiers, Algeria, 5Departmental Hygiene Laboratory, Tipaza, Algeria, 6University Hospital Center, Microbiology Laboratory, Oran, Algeria, 7Institut Pasteur of Algeria, annex of Oran, Bacteriology Laboratory, Oran, Algeria

**Background:** during summer 2018, cholera outbreak occurred in the northern and western regions of Algeria. This is the first epidemic recorded in Algeria for more than twenty years (the last cases have been reported in 1995). The purpose of this work is to report the epidemiological and microbiological characteristics of this epidemic.

**Materials/methods:** during the period August-October 2018, stool specimens were received for diagnosis (n=503) or screening (n=282) as well as strains for confirmation (n=23) from different departments: Bouira, Blida, Algiers, Tipaza, Ain Dèfla, Médéa and Oran. Environmental strains (n=6) were also sent. Bacteriological analysis was performed using conventional methods and/or rapid diagnostic test (Crystal VC®). The antimicrobial susceptibility testing was performed according to CLSI recommendations. Detection of cholera toxin gene and MLST were carried out on 7 selected strains [5 clinical strains of the epidemic, 1 clinical strain, isolated in 1992 and 1 environmental strain, isolated from the wastewater from Beni Azza river, Blida].

**Results:** among the clinical samples received (n=808), 118 (14.60%) were positive. 89/515 (17.28%) patients, including 44 (49.44%) cases from Blida and 29/293 (9.09%) healthy carriers were confirmed. The age of patients ranged from 2 months to 84 years (mean age: 33 years). The sex ratio was 0.85. Four deaths have been reported. All clinical strains belonged to the species *Vibrio cholerae*, el tor biovar, Ogawa serovar and showed the same antibiotic profile with resistance to aminopenicillins, nalidixic acid and cotrimoxazole. Of the environmental strains (n=06), 3 were *V. cholerae*, el tor biovar, Ogawa serovar with antibiotic profile identical to the clinical strains and were isolated mainly from wastewater. The clinical strains tested possessed the cholera toxin gene and the MLST revealed the presence of the same genotype.

**Conclusions:** although this epidemic remains limited, this alarming return highlights a decline in the actions taken in the fight against water-borne diseases. Although the epidemic strain was well identified, it was not possible to confirm the source of contamination. Further molecular investigations are needed. To maintain control of this disease, surveillance and the strengthening of vigilance must be pursued relentlessly.

Abstract 3951

Serodiagnostic testing for Lyme borreliosis: should we believe what we see?

András Zóka¹, Márton Gönczi¹, Veronika Barbaí², Radka Nikolova¹, Eszter Ujhelyi¹, Zsuzsa Kienle², Gabriella Bekő¹

¹Central Hospital of Southern Pest, National Institute of Hematology and Infectology, Budapest, Hungary, ²National Public Health Institute, Budapest, Hungary

Background: Two-tier serology (screening with a sensitive enzyme-immunoassay, confirmation with a specific Western blot or line immunoassay) remained the gold standard for the diagnosis of Lyme borreliosis. Remnant antibodies might be prevalent in the general population, thus recognizing relevant seropositivity might be challenging. The antibody response against Borrelia antigens is known to be sequential, which might be diagnostically utilized. We aimed to specify details which might potentially be useful in orientating the diagnostic schedule.

Materials/methods: We processed the sera of 1304 patients using a recombinant antigen-based enzyme-linked-immunosorbent assay (ELISA) between Aprils of 2017 and 2019. Reactive ELISA results (when coherent with ongoing infection according to the anamnestic data) were confirmed with a line immunoassay (LIA). Positivity was determined by the sum of the scores linked to certain antibodies according to the manufacturers recommendations. Antibody patterns and their relation with the symptoms were documented and analyzed.

Results: ELISA testing (IgG and/or IgM) was reactive in 539 cases. 107 patients with persistent postprimary symptoms tested positive or borderline with IgG ELISA. A significant difference was observed (Mann-Whitney U-test p=0.003) between the LIA scores of patients with characteristic (arthritis, acrodermatitis, neuropathy, other neurologic disorder following known exposure; n=83; median LIA score: 16) and non-specific symptoms (entirely subjective complaints, other known disease, or lone subfebrility; n=24; median LIA score: 6). 101 of the 107 patients tested positive for IgG against any specific Borrelia protein by LIA. When dividing them into two subgroups those with a LIA score reaching the group median of 15 (n=51) displayed strong anti-VlsE IgG positivity or a typical late antibody (IgG against p100, p18 or p39) response significantly more often than those with a LIA score under the group median (88,2% vs. 30% and 100% vs. 38% respectively, Chi square test p<0.0001 for both comparisons).

Conclusions: Weak LIA positivity, especially regarding the anti-VlsE IgG response, in combination with the lack of late antibodies in patients with persistent symptoms might suggest the presence of remnant antibodies and prompt scrupulous differential diagnosis, particularly in the presence of symptoms that are not characteristic for Lyme borreliosis.

Abstract 3952

Developing a pragmatic framework for genomics-informed surveillance of endemic Salmonella Typhimurium in Australia

Patiyan Andersson¹, William Pitchers¹, Daneeta Hennessy², Mary Valcanis¹, Joy Gregory², Zoe Cutcher², Marion Easton², Benjamin Peter Howden*¹, Deborah Williamson¹

¹University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ²Department of Health and Human Services, Melbourne, Australia

Background: Salmonella enterica serovar Typhimurium is the most common serovar notified to public health authorities in Australia. In the state of Victoria, investigation of S. Typhimurium clusters is initiated based on epidemiological data and multi-locus variable-number tandem repeat analysis (MLVA). Persistent and common MLVA types representing much of the disease burden remain largely unresolved due to insufficient resolution of the methodology. Whole genome sequencing (WGS) provides a comprehensive and highly discriminatory tool for characterising pathogens. Here we present the data underpinning the development of a pragmatic framework for WGS-informed surveillance.

Materials/methods: All S. Typhimurium (n=1477) from humans in Victoria between 1st July 2018 and 30th June 2019 were sequenced on an Illumina Nextseq platform, with bioinformatic analysis using in-house pipelines. Single-linkage clustering was performed at 2, 5 and 10 single nucleotide polymorphism (SNP) thresholds. Ten outbreaks encompassing 58 epidemiologically linked cases were used to validate clustering.

Results: The maximum pairwise distance in an epidemiologically confirmed outbreak was 2 SNPs. The 2-SNP level had 139 clusters (2-104 isolates), correctly clustered the known outbreak cases and clusters provided discrimination within common MLVA types (Figure). The 5-SNP level saw a loss of resolution with the formation of large clusters of up to 370 isolates, increasing at the 10-SNP level to 440 isolates. There were observations of the same MLVA type simultaneously occurring in multiple clusters, explaining challenges with MLVA-based investigations. MLVA type could not be reliably predicted from clusters, with several instances of multiple MLVA types occurring in a cluster.

The prospective routine surveillance will involve a tiered analysis approach with clustering at 2, 5 and 10-SNP levels; the 2-SNP identifies a core of cases with high probability of epidemiological links, subsequently serving to direct investigations of additional isolates related at 5 and 10-SNP levels. Weekly analysis of a 12-month sliding window, focusing on the most recent month for immediate public health action, and the previous 11 months for context and monitoring of persistent clusters.

Conclusions: We have developed a framework for WGS-informed surveillance of S. Typhimurium, capable of both detecting point source outbreaks and resolving slow-burning outbreaks constituting a large disease burden.

**Abstract 3953**

**In vitro modeling of patient-specific susceptibility to neurotropic flavivirus infection by using induced pluripotent stem cells**

Silvia Riccetti*, Alessandro Sinigaglia, Giovanna Desole, Monia Pacenti, Teemu Smura, Ravi Kant, Olli Vapalahti, Marta Trevisan, Luisa Barzon;

1University of Padova, Department of Molecular Medicine, Padova, Italy, 2Padua Hospital, Microbiology and Virology Unit, Padova, Italy, 3University of Helsinki, Helsinki, Finland, 4University of Helsinki, Department of Virology, Helsinki, Finland

**Background:** A characteristic feature of many infections is that only a proportion of exposed individuals develop clinical disease, such as in the case of West Nile virus (WNV) infection, which is associated with severe neuroinvasive disease in less than 1% of infected patients. The genetic basis of the inter-individual variability in the response to infections is poorly understood. Aim of this study was the development of an in vitro model based on patient-specific induced pluripotent stem cells (iPSCs) to investigate individual susceptibility to WNV and other neurotropic flaviviruses.

**Materials/methods:** iPSCs were generated from PBMCs of two patients with previous WNV encephalitis without comorbidity (cases) and two blood donors with asymptomatic WNV infection (controls). Patient-specific iPSCs were differentiated into neural stem cells (NSCs) and infected with WNV lineage 1, ZIKV Asian lineage, and USUV lineage Europe 1 at different MOI. Viral replication kinetics, cytopathic effect, and expression of host genes involved in innate antiviral response were investigated.

**Results:** USUV and WNV replicated more efficiently, yielding 10 and 100 fold higher viral load and inducing 70% and 40% higher cell mortality, respectively, in NSCs derived from cases than in NSCS derived from controls. Several genes involved in the antiviral IFN pathway were significantly upregulated after USUV, ZIKV and WNV infection, but the general trend indicated an attenuated response in NSCs derived from WNV encephalitis cases as compared to the response in NSCs derived from asymptomatic controls. Inactivating mutations of key genes involved in innate antiviral immunity were identified by genome sequencing of iPSCs from cases but not from the controls.

**Conclusions:** NSCs derived from patients with WNV encephalitis were more susceptible to WNV and USUV replication and cytopathic effect than NSCs derived from subjects with asymptomatic infection. This increased susceptibility to neurotropic flaviviruses was associated with a significantly attenuated innate antiviral response.

**Efficacy of temocillin against multidrug-resistant Enterobacterales: a retrospective cohort study**

François Leysour De Rohello1, Manuel Etienne2;3, Sandrine Dahyot1;2, Isabelle Tiret4, Martine Pestel-Caron1;2, François Caron2;3, Kévin Alexandre*2;3

1Microbiology Department, Rouen University hospital, Rouen, France, 2EA 2656 (GRAM 2.0), IRIB, Normandie Univ, Unirouen, Rouen, France, 3Infectious Diseases Department, Rouen University hospital, Rouen, France, 4Pharmacy Department, Rouen University hospital, Rouen, France

**Background:** Temocillin is in use in some European countries as a carbapenem-sparing agent for serious MDR Enterobacterales infections based on in vitro activity and limited clinical data. We aimed to evaluate a three-year routine use regarding infection site, dosage regimen and bacterial species.

**Materials/methods:** We reviewed all ≥3 days prescriptions in a teaching hospital from 2016-19. Temocillin susceptibility was determined by disk diffusion (S≥20 mm) and when feasible by Etest (MIC ≤8 mg/L). Overall failure was defined as clinical or microbiological failure within 30 days after the end of treatment. Regimens were compared according to corresponding daily dose in a normorenal subject.

**Results:** 171 episodes were analyzed, affecting overall old (median age: 69 years; 59-76) patients with comorbidities (median Charlson index of 3). There were 137 (80%) episodes of urinary tract infection (UTI) among which 32 (23%) catheter-related, 15 bacteremia (8 catheter-related), 6 intra-abdominal infections, 6 bone and joint infections and 7 miscellaneous. Bacterial documentation was available for 164 cases (96%) for a total of 181 Enterobacterales among which 94 Escherichia coli (52%) and 46 Klebsiella spp. (25%), with 120 (67%) ESBL and 7 (4%) AmpC-producers. All strains but 4 were susceptible, with MIC50 and MIC90 values of 4 and 8 mg/L according to the 97 E-tests. Temocillin was administered for a median duration of 1.4 days (8-18), at 2 g q12h for 77%, 2g q8h for 16% and 1g q12h for 6%. Overall failure occurred in 24% of episodes, more frequently in other infections (OI) than UTI (44% vs. 19%, P<0.01) and for E. coli rather than in other Enterobacterales infections (31% vs 16%, P<0.05). By multivariate analysis, overall failure was associated to OI (ORa=3.58, CI95%=1.37-9.48), immunosuppression (ORa=2.90, CI95%=1.22-7.00) and E. coli infection (ORa=3.27, CI95%=1.36-8.66). Clinical failure at the end of treatment was also more common for OI than UTI (38% vs. 9%, P<0.01).

**Conclusions:** Our data confirm that 2g q12h temocillin regimen can treat UTIs due to MDR Enterobacterales with MICs ≤ 8 mg/L. They suggest caution and further studies for infections of other sites.

Abstract 3955

A systematic review and meta-analysis of the risk of latent tuberculosis acquired during travel

Tanya Diefenbach-Elstob1, Balqis Alabdulkarim*, Paromita Deb-Rinker2, Steven Schofield1, Claire Nour Abou Chakra1, Guido Schwarzer4, Ian Shrier1, Jeffrey Pernica5, Christina Greenaway16

1McGill University, Jewish General Hospital, Lady Davis Institute for Medical Research, Centre for Clinical Epidemiology, Montreal, Canada, 2Public Health Agency of Canada, Ottawa, Canada, 3Department National Defence, Ottawa, Canada, 4University of Freiburg, Faculty of Medicine and Medical Center, Institute of Medical Biometry and Statistics, Freiburg, Germany, 5McMaster University, Department of Pediatrics, Division of Infectious Diseases, Hamilton, Canada, 6McGill University, Jewish General Hospital, Division of Infectious Diseases, Montreal, Canada

Background: To achieve tuberculosis (TB) elimination in low TB incidence countries, individuals at risk for latent TB infection (LTBI) will need to be identified and treated. Persons travelling to high TB burden countries, especially for prolonged periods, are at risk for TB exposure. We aimed to estimate the travel-acquired incidence of LTBI among persons travelling from low to higher TB burden countries, and the impact of travel duration and purpose.

Materials/methods: We conducted a systematic review and meta-analysis of incident LTBI [defined as either tuberculin skin test or interferon-gamma release assay conversions (negative pre-travel test and positive post-travel test)], among individuals travelling from low (<10 TB cases/100,000 population) to intermediate (50-100/100,000) or high (≥100/100,000) TB incidence countries. We searched five electronic databases from inception to September 6, 2019. Incident LTBI acquired per 1000 person-months (PM) of travel were estimated. Meta-analysis using a random effects model of log transformed rates was conducted. Sub-group analyses by travel duration, travel purpose, and TB incidence in the destination region were undertaken.

Results: Among 546 studies identified, 118 underwent full-text review, and 10 were included. These studies included 1,155,102 travellers with 13,199,330 PM of travel recruited between 1994 and 2013. There were 443 health care workers with 972 PM of travel, 1,068,636 military (11,654,495 PM) and 86,023 travellers/other volunteers (1,543,863 PM). Among individuals who travelled a median of six months or less, health care workers had the highest rate of incident LTBI (20.7/1000 PM, 95% CI 11.3-37.9), followed by military personnel [4.96 (3.9-6.3)] and leisure travellers/other volunteers [2.8 (1.8-4.5)]. There was no difference in incident LTBI for travel to high (3.4/1000 PM, 95% CI 2.1-5.4) or intermediate [4.9 (3.9-6.2)] TB incidence regions in military or leisure travellers/other volunteers. Analyses of incident LTBI in longer-term travellers (12-24 months) is ongoing and will be presented.

Conclusions: Among travellers with a median of 6 or less months of travel, health care workers had approximately a 5-fold higher risk of developing LTBI compared to other travellers and may benefit from post-travel LTBI assessment.

Figure 1: Forest plot of incident LTBI for six months of travel, stratified by travel purpose.

In vitro evolution reveals mutations in Candida auris ERG6 to confer high level amphotericin B resistance

Jeffrey M. Rybak*1, Katherine S. Barker1, Josie E. Parker2, Yu Li1, José F. Muñoz3, Glen E. Palmer1, Christina A. Cuomo1, Steven L. Kelly2, P. David Rogers1

1University of Tennessee Health Science Center, Department of Clinical Pharmacy and Translational Science, College of Pharmacy, Memphis, United States, 2Swansea University Medical School, Institute of Life Science, Swansea, United Kingdom, 3Broad Institute of MIT and Harvard, Cambridge, United States

**Background:** Candida auris is an emerging virulent pathogen of great clinical concern, associated with outbreaks of invasive candidiasis on multiple continents. When isolated, C. auris is commonly found to be multidrug-resistant, and numerous isolates have been recovered which are resistant to all available antifungals. The polyene antifungal amphotericin B (AMB) has been relied upon as an agent of last defense since its clinical introduction, possessing both a broad spectrum of activity and fungicidal activity. Unfortunately, 30% of C. auris clinical isolates are resistant to AMB, and at present the molecular mechanisms underpinning this resistance in C. auris remain completely unknown.

**Materials/methods:** AMB evolved strains were generated by passaging the AMB susceptible C. auris clinical isolate AR0387 in YPD supplemented with AMB (2 to 4mg/L) for 48 hours. AMB MIC were measured by Etest. Comprehensive sterol profiling was performed on the AMB evolved strains and the parental AR0387 to identify alterations in cellular sterols. Sanger sequencing was employed to identify mutations in AMB evolved strains relative to the parental AR0387. A Cas9 mediated transformation system was utilized to correct mutations of interest in the AMB evolved strains.

**Results:** Three AMB evolved strains were obtained following a single passage. AMB minimum inhibitory concentrations ranged from 8 to 16mg/L compared to 0.1–25mg/L in the parental AR0387. Sterol profiling revealed ergosterol to be the predominant sterol (77%) in the parental AR0387, while all three AMB evolved strains were found to have sterol profiles consisting predominantly of cholesta-5,7,24-tetraenol (55%) and zymosterol (28%) and completely lacking detectable ergosterol. Consistent with sterol profiles, sanger sequencing revealed all three AMB evolved strains to possess nonsense mutation in ERG6, the putative C. auris sterol methyl-transferase. Cas9-mediated correction of the ERG6 mutation in an AMB-evolved strain restored AMB susceptibility to the level of the parental AR0387 (MIC 0.125mg/L).

**Conclusions:** Taken together these studies demonstrate both that C. auris can rapidly acquire resistance to AMB in vitro, and that mutations in ERG6 can contribute to AMB resistance. Further research is needed to determine the extent to which mutations in ERG6 may contribute to AMB resistance among clinical isolates of C. auris.

Abstract 3959

Activity of the β-Lactamase inhibitor LN-1-255 against ceftazidime-resistant AmpC-hyperproducing Pseudomonas aeruginosa

Cristina Lasarte*1, Juan Vazquez-Ucha1, Jorge Arca Suárez1, Gabriel Torrens2, Carlos Juan Nicolau2, Antonio Oliver2, Germán Bou Arevalo1, Concepción González-Bello1, Alejandro Beceiro1

1INIBIC, Department of Microbiology, A Coruña, Spain, 2Hospital Son Espases-IDISPA, Palma de Mallorca, Spain, 3CIQUS - USC, Santiago de Compostela, Spain

Background: New therapeutic options for Pseudomonas aeruginosa, whose resistance to β-lactams is mainly due to the cephalosporinase AmpC overproduction, are urgently needed. Treatments are limited and the new combinations ceftolozane/tazobactam and ceftazidime/avibactam are frequently necessary. We propose a new antimicrobial strategy, combining ceftazidime (CAZ) and LN-1-255 [an experimental β-lactamase inhibitor] against AmpC-hyperproducing P. aeruginosa strains and comparing it to that of the CAZ/AVI established treatment.

Materials/methods: Susceptibility assays were performed using P. aeruginosa PAO1 isogenic mutants, expressing multiple combinations of the most relevant β-lactam resistance mechanisms, such as AmpC hyperproduction, OprD inactivation or plasmid-carrying PDC-1 and PDC-315 [a ceftolozane-resistance conferring AmpC], and a collection of over-expressing ampC clinical isolates. MICs to CAZ were determined by microdilution, in the presence/absence of avibactam and LN-1-255 (4 mg/L). Additionally, for PDC-1, the IC50 of both inhibitors was calculated.

Results: The isogenic mutants overexpressing ampC displayed MICs of 8-32 mg/L to CAZ, increasing the MICs of the parental strain. As expected, the combination CAZ/AVI boosted the efficacy of CAZ, lowering the MICs 4-16-fold. LN-1-255 displayed a very similar behavior and MICs to CAZ decreased 4-16-fold in its presence. Among the clinical isolates, MICs to CAZ decreased likewise in presence of both inhibitors [Table]. Finally, PDC-1 had an IC50 of 6 nM for LN-1-255 and of 51 nM for avibactam.

Conclusions: We describe the inhibitory activity of the compound LN-1-255 against the chromosomal ampC of P. aeruginosa. CAZ in combination with LN-1-255 was effective against these CAZ-resistant AmpC-hyperproducing P. aeruginosa strains. Therefore, LN-1-255 stands as a potential new therapeutic option to recover CAZ as an antibiotic treatment against AmpC-hyperproducing strains.

Abstract 3961

**Standard-dose vs higher-dose of rifampicin in patients with tuberculosis: a meta-analysis**

Valeria Gentile*1, Lorenzo Onorato1, Antonio Russo1, Giovanni Di Caprio2, Loredana Alessio2, Nicola Coppola1

1Università della Campania Luigi Vanvitelli, Napoli, Italy, 2 Azienda Ospedaliera Sant’Anna e San Sebastiano, Caserta, Italy

**Background:** evidence suggests that Rifampicin doses could be increased to achieve more effective tuberculosis treatment. We compared clinical and microbiological outcomes of patients treated with either standard dose (10mg/kg) or higher dose (>10mg/kg) of Rifampicin.

**Materials/methods:** A systematic review and meta-analysis was conducted using MEDLINE, Google Scholar and the Cochrane Library. All studies included had to fulfill the following inclusion criteria: [a] reported clinical (treatment failure, mortality and ADR) and/or microbiological outcomes [culture conversion at 8 weeks] comparing standard dose and higher dose of Rifampicin;[b] were available as a full text manuscript;[c] written in English;[d] included either pulmonary or extra-pulmonary infection;[e] enrolled either children or adult HIV-positive or HIV-negative patients. The exclusion criteria were:[a] letters, case reports, meeting abstracts, or editorial comments;[b] enrolled patients with Rifampin resistant or MDR infection;[c] studies enrolling less than 5 subjects.

**Results:** Nine studies, from a total of 11686, met the inclusion criteria, allowing a meta-analysis on 1163 patients. Three studies examined treatment failure showing no significant difference in the two observed groups (RR 0.95, 95% CI 0.81-1.12). In terms of mortality, both in CNS (RR 0.92, CI 0.76-1.12) and pulmonary TB (RR 1.53, CI 0.31-7.58), there was no statistically significant difference between the intensified treated patients and the control groups. Eight studies investigated ADR grade 3 and 4, showing a higher rate in terms of events between in the intensive treated group than the control group (RR 1.51, CI 1.20-1.91, p 0.003). Similarly, investigating into ADR leading to discontinuation of therapy more patients had their treatment suspended among the intensive therapy group compared to the control group (RR 1.52, CI 1.15-2.00; p 0.003). Treatment with higher doses of Rifampin was as efficacious as treatment with a standard dose, as it showed no difference in negativization of culture at eight weeks (RR 1.06, CI 1.00-1.13).

**Conclusions:** the meta-analysis showed a higher rate of ADR leading to discontinuation in the intensified treated patients. There were no statistical difference in terms of negativization of culture at eight weeks and mortality. Further studies are needed to clarify the role of higher dose of rifampicin in patients with tuberculosis.

**Table:** Summary of meta-analysis results in the achievement of the outcomes in experimental and control groups

Abstract 3962

High prevalence of *Plasmodium falciparum* and non-falciparum infections in asymptomatic adults in forest Ghana

Melina Heinemann*1,2; Richard Phillips3; Christof D. Vinnemeier1,2; Christina Rolling1; Egbert Tannich2,4; Thierry Rolling1,2,4

1University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 2Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, 3Kumasi Center for Collaborative Research in Tropical Medicine, Kumasi, Ghana, 4German Center for Infection Research (DZIF), partner site Hamburg-Lübeck-Borstel-Riems, Hamburg, Germany

Abstract third-party references: The study was supported by a Bayer AG grant to the University Medical Center Hamburg-Eppendorf.

Background: Mass screening and treatment is one option towards eradicating malaria. Due to the limited sensitivity of rapid diagnostic tests (RDT) normally used as diagnostic tool, a substantial number of parasite carriers may not be detected. The present study analyses prevalence of asymptomatic carriage of *Plasmodium* spp. in adults in a Ghanaian forest region during the high transmission season using RDT and polymerase chain reaction (PCR).

Materials/methods: Blood from asymptomatic adults was collected in September 2018 in five villages in the Asante Akim North district in the Ashanti region, Ghana, and tested for *Plasmodium* spp. with RDT and PCR. Exclusion criteria were clinical signs of infection, clinical conditions associated with a bleeding disorder, pregnancy and puerperium. The study was approved by the Committee on human research, publication and ethics at the Kwame Nkrumah University of Science and Technology, Kumasi, Ghana (CHRPE/AP/455/18).

Results: Two-hundred-six women and 185 men with a median age of 32 years were included in the study. A total of 284 study participants (72.6%) was tested positive for *Plasmodium* spp. by PCR. While 266 (68.0%) participants were positive for *P. falciparum*, 33 (8.4%) and 34 (8.7%) were positive for *P. malariae* and *P. ovale*, respectively. Both *P. ovale curtisi* (3.1%) and *P. ovale wallikeri* (3.8%) were identified. In a few cases of low-level *P. ovale* infection, sub-species differentiation was unsuccessful. All participants were negative for *P. vivax* and *P. knowlesi*. Non-falciparum infections were mostly combined with *P. falciparum*. *Plasmodium* spp. were detected by RDT in 126 study participants (32.2%). Sensitivity and specificity of the RDT for detection of *P. falciparum* infection were 43% (122/282) and 96% (102/106), compared to PCR. A lower cycle threshold value of the screening PCR was significantly associated with a positive RDT, adjusted for age, gender and village.

Conclusions: Asymptomatic adults represent a large reservoir for malaria transmission in forest Ghana, including for non-falciparum species. To reduce the malaria burden in Ghana, screening and treatment should not only be focused on children or individuals with a positive RDT.

**Vertebral osteomyelitis in patients with Staphylococcus aureus bloodstream infection: evaluation of risk factors for failure**

Norma Jung1, Angela Ernst1, Insa Joost2, Ayla Yagdiran3, Gabriele Peyerl-Hoffmann3, Martin Hellmich4, Harald Seifert4, Winfried Kern5, Achim Kaasch7, Siegbert Rieg5

1University of Cologne, Department of Internal Medicine, Division of Infectious Diseases, Cologne, Germany, 2University of Cologne, Institute of Medical Statistics and Computational Biology (IMSB), Faculty of Medicine, Cologne, Germany, 3Heinrich-Heine-University Düsseldorf, Institute of Medical Microbiology and Hospital Hygiene, Düsseldorf, Germany, 4University Hospital of Cologne, Department of Orthopedics and Trauma Surgery, Cologne, Germany, 5Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Division of Infectious Diseases, Department of Medicine II, Freiburg, Germany, 6University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 7Otto-von-Guericke-University Magdeburg, Institute of Medical Microbiology and Hospital Hygiene, Magdeburg, Germany

**Background:** Staphylococcus aureus is the most common cause of hematogenous pyogenic vertebral osteomyelitis (VO) in adults. Studies indicate that S. aureus VO results in a particularly poor outcome. We aimed to investigate risk factors for treatment failure in patients with *Staphylococcus aureus* bloodstream infection (SAB) associated with VO.

**Materials/methods:** We conducted a post hoc-analysis of data from a German bi-center prospective SAB cohort study (period 2006-2014). Patients were followed-up for one year. Primary outcome was treatment failure defined as relapse and/or death within one year. We performed a multivariable analysis and compared outcome of patients with VO with and without endocarditis and those with non-vertebral osteomyelitis.

**Results:** A total of 1069 patients with SAB were analyzed, with 92 patients presenting with VO. MRSA rate was 13%. Median antimicrobial treatment duration in hospital was 34 days (IQR 21-53) with all patients receiving combination therapy (cell wall-active agent plus predominantly rifampicin or fosfomycin). In addition to antibiotic treatment, surgery was performed in 60/92 (65%) patients. 44/92 patients (48%) failed (death, n=42; relapse, n=2). Multivariable analysis revealed higher age (HR 1.05 [per year], 95% CI 1.01 – 1.08), Charlson comorbidity index (HR 1.3, 95% CI 1.1 – 1.5), septic shock (HR 2.6, 95% CI 1.2 – 5.8), the presence of a neurologic deficit (HR 2.0, 95% CI 1.04 – 4.0) and secondary hematogenous foci (HR 2.0, 95% CI 1.01 – 3.9) as independent risk factors for treatment failure within one year. Patients with VO and endocarditis showed the highest rate of treatment failure (see figure).

**Conclusions:** SAB patients with VO exhibit a high treatment failure rate. Red flags are older age, comorbidities, secondary foci or neurologic deficits. Whether these patients benefit from intensified treatment (e.g. earlier radical surgery, prolongation of antibiotic treatment) should be investigated in further studies.

**Figure:** Kaplan-Meyer event-free survival plot (event defined as relapse and/or death); SAB= *Staphylococcus aureus* bloodstream infection, VO= vertebral osteomyelitis

Evaluation of multiplex PCR for rapid detection of bacteria and antibiotic resistance in spontaneous bacterial peritonitis: a pilot study

Jaclyn Yizhen Tan*1, Niall Thomas Burke1, Noam Pinchas Gessler Roth1, Dewi Rhys Dwen1, Jennifer Ryan1, Marsha Morgan2, Rachel Westbrook1, Emmanuel Wey2,3

1University College London, UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, London, United Kingdom, 2Royal Free London NHS Foundation Trust, Centre for Clinical Microbiology, Department of Microbiology, London, United Kingdom, 3University College London, Division of Infection and Immunity, London, United Kingdom

Background: Pathogen detection rates and antibiotic sensitivities in spontaneous bacterial peritonitis (SBP) are successful in only about 50% of cases. This pilot study aims to compare the diagnostic performance of the Curetis Unyvero IAI Intra-abdominal Infection Application, a multiplex PCR-based testing system, and conventional diagnostic procedures in the diagnosis of SBP.

Materials/methods: Ascitic fluid was collected from patients with cirrhosis admitted under the hepatology service between January and May 2019. Two samples were collected from each patient, one was sent for diagnosis via conventional protocols, the other was analysed via the Unyvero. SBP was diagnosed when ascitic fluid neutrophil count was > 250 cells/mm³. Independent-samples Mann-Whitney U test was performed to compare mean differences in time to results.

Results: Sixteen patients were included within the pilot study, 11 without SBP and 5 with SBP on conventional diagnostic methods. Overall, time to pathogen identification was reduced by a mean (± SD) of 42.0 (± 16.3) hr (p < 0.01). In patients without SBP, the Unyvero correctly concluded the ascitic fluid was negative for pathogens in 11 of 11 cases, and thus provided no false positive results. Conventional culture identified a Staphylococcus epidermidis on one bottle; which was subsequently negative on retesting and thus labelled a contaminant. In patients with SBP, there was concordance between Unyvero and conventional results in 3 of 5 cases. Two patients had discordant results. In the first patient, Staphylococcus aureus was identified by Unyvero but not by conventional ascitic culture. The patient responded well to targeted antimicrobial therapy. The next patient had Serratia marcescens, identified via conventional methods but not via the Unyvero. The pathogen was not within the Unyvero’s detection range. Key first-line antibiotic resistance profiles in the detected pathogens were concordant for both diagnostic tests.

Conclusions: The implementation of multiplex PCR-based testing for pathogens in SBP significantly reduces time to pathogen identification and antibiotic sensitivities. However, it is limited by its narrow diagnostic panel. Incorporation of such methods as an adjunct in the clinical setting has potential to improve timely and appropriate antibiotic prescribing in SBP.

The colonisation of Czech travellers and expatriates living in the Czech Republic by colistin-resistant Enterobacteriaceae including Escherichia coli harbouring mcr-1 genes on a plasmid or chromosome

Marcela Krutová¹, Alžběta Baráková¹, Elka Nycova¹, Gelbičová Tereza², Renata Karpiskova¹, Otakar Nyc¹, Pavel Drevinek¹, Jan Tkaldec¹

¹Charles University, 2nd Faculty of Medicine and Motol University Hospital, Department of Medical Microbiology, Prague, Czech Republic, ²Veterinary Research Institute, Department of Bacteriology, Brno, Czech Republic, ³Bulovka Hospital, Department of Clinical Microbiology, Prague, Czech Republic

Background: Travelers were recognized as risk cohort that can import mcr-1-mediated colistin resistant Enterobacteriaceae. We aimed to investigate the carriage of mcr-1-mediated colistin resistance in Enterobacteriaceae in Czech travelers or expatriates residing temporarily in the Czech Republic as a source of mcr-gene dissemination.

Materials/methods: Between August 2018 and September 2019, the stool samples were cultured in Enterobacteriaceae enrichment broth at 37 °C overnight. The enriched cultures were tested for the presence of mcr-1-8 genes by PCR and inoculated onto selective agar with colistin (3.5 mg/L). A minimal inhibitory concentration (MIC) of colistin was determined by using the broth microdilution method. Colistin resistant Enterobacteriaceae isolates were tested by PCR for the presence of mcr-1-8 genes and mcr-positive isolates were characterised by whole genome sequencing. The MICs of commonly used antimicrobials in Enterobacteriaceae infections were determined by the microdilution method.

Results: A total of 177 stool samples derived from Czech travelers (n=131; 74.0%) or expatriates residing temporarily in the Czech Republic (n=46; 26.0%) were investigated. Fifteen Enterobacteriaceae isolates (from 14 individuals) cultured, after enrichment, were resistant to colistin [Table]; the carriage prevalence rate of colistin resistant Enterobacteriaceae was 7.9%. Two enriched cultures proved positive for the presence of the mcr-1 gene and two colistin resistant E. coli (MIC 4 mg/L) isolates carrying mcr-1 were obtained; the carriage prevalence rate of mcr-1-positive samples was 1.1%. In the E. coli sequence type (ST) 156, the mcr-1 was located in an ISApl1-mcr-1-orf-ISApl1 (Tn6330) and incorporated into the chromosome; in the E. coli ST23 isolate, the mcr-1 was harboured by plasmid replicon type IncX4. Both, mcr-1 positive E. coli were multidrug resistant and, in addition, one isolate was an extended-spectrum β-lactamase (ESBL) producer (blaCTX-M-37).

Conclusions: Expatriates living in the Czech Republic, can be colonized by multidrug resistant Enterobacteriaceae including those harbouring mcr-1 genes on a plasmid or chromosome.

Acknowledgement: This study was supported by the Ministry of Health of the Czech Republic grant no: NV 18-09-00254. All rights reserved.

Measles seropositivity in renal transplant recipients in the presence of ongoing outbreaks: a single centre analysis

Fabian Wagner¹, Daniel Sidler², Maria Teresa Barbani³, Franziska Suter-Riniker², Philipp Jen⁴, Cédric Hirzel⁴, Laura Walti*⁴

¹University of Bern, Bern, Switzerland, ²Bern University Hospital, University of Bern, Department of Nephrology, Bern, Switzerland, ³University of Bern, Institute for Infectious Diseases, Bern, Switzerland, ⁴Bern University Hospital, University of Bern, Department of Infectious Diseases, Bern, Switzerland

Background: Measles outbreaks are ongoing worldwide. Measles infection has a high morbidity and mortality in the immunocompromised host. Healthcare-authorities recommend measles-antibody measurements pre- and post-transplantation [in Switzerland since 2014]. Seronegative transplant candidates should be offered pre-transplant immunization. Data on uptake of these guidelines and necessity of post-transplant reevaluation of measles immunity is lacking.

Materials/methods: We performed a retrospective analysis of measles serology among all renal transplant recipients (RTRs) transplanted between 07/1981-12/2018 at our center. Until 2005 anti-measles IgG was determined using Immunofluorescence (IF) [cut-off >40], from 2006 to 2012 using Vidas Measles Index IgG [cut-off >1.1], from 2013 onwards using SERION ELISA classic Measles Virus IgG [cut-off >200 mIU/ml]. Data on immunization was not uniformly available.

Results: Since 1981, 518 patients received kidney transplantation, 388 before and 130 after 2014. Median age at transplantation was 49 years (IQR 37-59). Measles serology was available for 38% of patients pre-transplantation and for 51% of patients post-transplantation [median time from transplantation to serology 7 years (IQR 2-13.5)]. Pre- and post-transplantation serology were significantly more often performed after the implementation of the guidelines in 2014 [pre-transplantation-serology: 18.3% before- vs. 95.4% after 2014; P < 0.0001; post-transplantation-serology: 45.0% before- vs. 68.5% after 2014; P < 0.0001]. In 130 patients measles serology was available before and after transplantation. Loss of protective antibody levels post-transplantation was rare (1.6%), and occurred in two immunized pediatric patients. Nevertheless, median antibody levels dropped significantly after transplantation in the 85 patients with paired SERION IgG serum samples [pre-transplantation 2023 mIU/ml (IQR 1332-2936) vs. 1427 mIU/ml (IQR 872-1961) post-transplantation; P < 0.0001]. Overall 4.8% of patients [13/269] had non-protective antibody levels post-transplantation, therefore considered at risk of measles infection. These patients were significantly younger [median age at transplantation 23y, IQR 16-36; P < 0.001]. Correlation of measles-IgG-levels with attainment of immunity [vaccination versus infection] was not possible, due to the lack of standardized vaccination documentation.

Conclusions: Almost five percent of RTRs are potentially at risk for measles infection post-transplantation. This highlights the importance of increasing vaccine uptake pre-transplant, and cocooning strategies. Pre-and post-transplant measles serology was performed rarely before the implementation of guidelines in 2014, but thereafter serology uptake pre-and-post-transplant increased.

*Investigation of intestinal parasites in immunocompromised and immunocompetent patients with diarrhoea: what About Blastocystis and Dientamoeba fragilis?*

Esra Kain*1, Nesteren Mansur1, Fatih Öguz Önder1, Ant Uzay1, Sinem Öktem Ökullu1, Özgür Kurt1, A. Nurdan Tözün1

1Acibadem University, Istanbul, Turkey

**Background:** *Dientamoeba fragilis* and *Blastocystis* have long been regarded as non-pathogenic gut protozoa; however, many clinical reports after 70’s indicated them, mostly *D. fragilis*, as causative agents of gastrointestinal and dermatological complaints and reported recovery in patients following antimicrobial treatment. Trials using PCR for their detection in stool indicated dramatically higher rates than microscopy, which then aroused the discussion whether *D. fragilis* and *Blastocystis* were actually pathogens or just residents of healthy gut. The aim of this study is to compare the prevalence of intestinal parasites between different patient groups with diarrhea and healthy controls, as the initial phase of a microbiota project that will investigate the gut microbiota in diarrheic patients and controls, involving the lifestyle and eating habits of participants.

**Materials/methods:** Study Group (SG) consisted of 57 diarrheic stools of immunocompromised patients that had recently received allogenic bone marrow transplantation (n=24) and immunocompetent irritable bowel syndrome patients diagnosed according to Rome IV criteria (n=33). Control Group (n=33) consisted of age and sex-matched healthy individuals. All stools were initially examined with saline-Lugol and concentration, followed by trichrome and Kinyoun acid-fast staining, and conventional PCR for *D. fragilis*.

**Results:** *Blastocystis* was found to be the leading protozoon (n=26; 31.7%), followed by *D. fragilis* (n=16; 19.5%) and *Entamoeba histolytica/dispar* (n=15; 18.3%) among all participants. *D. fragilis* DNA was identified in 12 of 82 eligible samples in PCR (14.6%), all of which were also positive in trichrome-stained smears. Half of both *D. fragilis* and *Blastocystis*-positive participants were in CG. *Taenia saginata* was the only helminth found in a patient with IBS. *Cryptosporidium spp.* (n=3) and *Cyclospora cayetanensis* (n=2) were found in 5 of 24 (20.8%) immunocompromised patients in the study.

**Conclusions:** *D. fragilis* and Blastocystis were both found to be more common in healthy controls compared to patients with diarrhea, while diarrhea was due to the coccidians in one of five immunocompromised patients in our study. Interpretation of these initial results with further microbiota analyses of the participants involving also their lifestyle and eating habits may help us better understand the roles of *D. fragilis* and *Blastocystis* in human health.

Abstract 3973

**A phase I study in healthy volunteers to assess the absolute bioavailability of the bilayer tablet of sulopenem etzadroxil with probenecid**

Michael Dunne*1, Mei Dai2, Rong Zhou2, Steven Aronin1, Jeff Wald3

1Iterum Therapeutics, Old Saybrook, United States, 2Medpace, Cincinnati, United States, 3qPharmetra, Cary, United States

Abstract third-party references: Iterum Therapeutics, Jeff Wald, Michael Dunne, Mei Dai, Rong Zhou

**Background:** Sulopenem etzadroxil is the oral prodrug of sulopenem. It is being studied for treatment of urinary tract and intra-abdominal infections. This study evaluated the absolute bioavailability of sulopenem by comparing the exposure achieved following oral administration in fed/fasted states of a single dose of the fixed-dose bilayer tablet to the exposure achieved following the equivalent amount of sulopenem administered as a one-hour infusion.

**Materials/methods:** 14 subjects were enrolled to examine the bioavailability of sulopenem as part of a bilayer tablet which contained 500 mg each of sulopenem etzadroxil and probenecid. Dosing in Period 1 and 3 was conducted in fasted state; Period 2 in fed state with 7-day washout between dosing.

Standard non-compartmental methods used for calculation of pharmacokinetic parameters.

**Results:** Exposures (Cmax and AUCs) of the bilayer tablet increased in fed compared to fasted state. Absolute bioavailability of bilayer tablet is 40% in fasted state; 64% in fed state. High-fat meal increased sulopenem bioavailability by 50%.

AUC0-inf = area under the plasma concentration-time curve from time 0 extrapolated to infinity; CV = coefficient of variance; SD = standard deviation; t1/2 = terminal elimination half-life. *n=12 in Period 2 for AUC and t1/2

**Conclusions:** The absolute bioavailability of sulopenem when delivered as sulopenem etzadroxil-probenecid bilayer tablet and compared to 1-hour IV infusion of 366 mg sulopenem is 40% in fasted state and increases to 64% when dosed with food. Given its low protein binding (11%), the bilayer tablet, dosed fed or fasted, should provide exposure above the MIC of target pathogens for a significant period of the dosing interval.

**Presenter email address:** michael.w.dunne@comcast.net
Abstract 3978

Effects of fluoroquinolone-sparing empiric therapy guideline implementation in a collaborative hospital network

Elizabeth Dodds Ashley*, Travis Jones1, Melissa Johnson1, Angelina Davis1, April Dyer1, Alicia Nelson1, Deverick Anderson1, Rebekah Moehring1

1Duke Center for Antimicrobial Stewardship and Infection Prevention, Durham, NC, United States

Abstract third-party references: Iterum Therapeutics, Jeff Wald, Michael Dunne, Mei Dai, Rong Zhou

Background: Clostridiodes difficile infection (CDI) remains a significant threat in US hospitals despite ongoing infection prevention and antimicrobial stewardship program (ASP) efforts. Guidelines recommend CDI-focused interventions to reduce broad-spectrum antibiotic use, particularly avoidance of fluoroquinolones. We aimed to describe effects of implementing a centrally developed fluoroquinolone-sparing empiric guideline customized and scaled across a collaborative hospital network.

Materials/methods: Ten acute care community hospitals enrolled in the Duke Antimicrobial Stewardship Outreach Network (DASON) as part of a larger study to evaluate implementation of the CDC's Core Elements for Hospital ASPs and 7 of 10 elected to implement fluoroquinolone-sparing empiric therapy guidelines as an “Action” element. Disease-specific empiric guidelines were developed and customized for each hospital to provide non-fluoroquinolone recommendations and highlight short durations. Guidelines were reviewed and approved by committees at each hospital between 2/2017 and 1/2018. Dissemination occurred through educational presentations to clinical staff, distribution on the back of the annual antibiogram, and posting at convenient locations for prescribers. Relevant order sets were updated. Pooled rates of inpatient antibiotic use in days of therapy/1,000 patient days (PD) and hospital onset (HO) CDI cases/10,000 patient days were tracked quarterly to describe trends among the 7 hospitals. The baseline period was defined as quarter 3 and Q4 of 2016 and the post-implementation period as Q3 and Q4 of 2018. Percent change was calculated comparing baseline to post-implementation periods.

Results: Network-wide fluoroquinolone use down-trended after Q2 2018, representing a 33% decline from baseline to post-implementation (125 vs. 84 DOT/1000PD, Figure). HO CDI declined 46% (8.9 vs 4.8 HO CDI/10,000PD). During the same time period, overall inpatient antibacterial use decreased by 10.1% (905 vs 813 DOT/1000PD).

Conclusions: Hospitals who implemented fluoroquinolone-sparing guidelines in a collaborative network decreased fluoroquinolone use and experienced corresponding declines in HO-CDI. This scalable intervention was easily implemented across a network of hospitals.

Quarterly Antibiotic Use and CDI

Employing tongue swabs and urine as clinical alternatives to sputum for *Mycobacterium tuberculosis* testing on a solid state nanopore sensor platform

Trevor Morin¹, David Alexander*¹

¹Ontera, Ontera, Santa Cruz, United States

**Background:** MTB continues to be a major health problem affecting 1 in 4 people worldwide. Imperfect phenotypic screening and costs of comprehensive molecular testing methods hinder effective public health measures to control the epidemic. Sputum, the most widely used biological material for most TB tests, is not ideal given the difficulty to process it for downstream testing, it is hard to produce on demand (especially for children), and 1 in 5 TB cases are ex-pulmonary. Thus, it is highly desirable to find an alternative bio fluid that is easily attainable and processed to facilitate high sensitivity and specificity molecular tests.

**Materials/methods:** We've developed two different tests for highly specific and sensitive detection of MTB on our solid-state nanopore sensor platform. The first is a multiplexed molecular test using tongue swabs as a MTB DNA source, the second detects the complex glycan lipoarabinomannan (LAM) in urine. These tests were first developed using benchtop methods and contrived samples, and later proofed using clinical samples and portable instrumentation employing a nanopore sensor for cost effective and field deployable testing.

**Results:** Our contrived swab testing indicates assay sensitivities down to 1 CFU per reaction, while clinical sample testing had high concordance with both laboratory based molecular (qPCR) testing and culture. Contrived urine testing for the LAM analyte indicates a sensitivity (fM) that matches a highly optimized, centralized lab ELISA test. Testing on neat clinical samples indicates assay performance is maintained using patient samples and a field applicable workflow, having sensitivities that exceed the existing lateral flow test being used in the field.

**Conclusions:** Preliminary results indicate that tongue swabs and urine samples, two easily obtainable biofluids, may prove to be sufficient, and even superior, to sputum when testing for MTB. These samples paired with the fast (<20 mins) time to result delivered from the solid state nanopore based platform offers low cost, impactful molecular testing in challenging environments needed to implement effective public health monitoring needed to control the TB epidemic.

Abstract 3980

Direct detection of PBP2a using the high-resolution Orbitrap mass spectrometer and rapid discrimination of antibiotic resistance in Staphylococcus aureus using the Acrion system

Jason Neil¹ *, Arvind Verma³, Marjaana Viirtola³, William Mcgee¹, Scott Kronewitter¹, Jim Stephenson¹

¹Thermo Fisher Scientific, Cambridge, United States; ³Thermo Fisher Scientific, Vantaa, Finland

Background: Methicillin-resistant Staphylococcus aureus (MRSA) is a common infectious agent in community and hospital environments. Molecular and phenotypic MRSA detection strategies are labor intensive and often indirectly detect the target responsible for antibiotic resistance, penicillin-binding protein 2a (PBP2a). While current clinical MALDI mass spectrometry methods in microbial diagnostics are low resolution, have limited mass range, and have had poor success in antibiotic resistance detection, we present a novel approach that enables direct detection of the PBP2a protein using a high resolution mass spectrometer system. While these systems usually employ peptide detection strategies, this workflow relies on detection and discrimination of intact proteins ions.

Materials/methods: S. aureus protein lysates were prepared from single colonies following 18 hours of growth on agar media and lysed with a formic acid/water/acetonitrile solvent mixture. Direct detection of PBP2a was performed using a Q Exactive™ HF mass spectrometer or Acrion™ system following a short chromatographic separation of protein lysates.

Results: Two detection approaches were designed for detection of this resistance marker, isolation of the intact protein or isolation of an in source dissociated fragment of the PBP2a protein. The latter method proved to be more robust and sensitive. Both approaches were successful across all SCCmec cassettes and the most common PFGE types. This method can be modified to facilitate detection of other PBP2a isoforms (i.e. mecB, mecC, and mecD) and other rare variants (e.g. BORSA) if the resistance mechanism(s) is known. While this approach relies on the initial identification of the microbe as S. aureus, it removes any extra culturing from the workflow to identify it as MRSA and significantly reducing the time to reporting. Initial success of this method has shown to be greater than 95% for true positives and no false-positive errors.

Conclusions: Rapid detection of antibiotic resistance using this mass spectrometry approach represents a promising leap forward in diagnostics and this work represents one of many workflows that can be adapted to the clinical laboratory.

Abstract 3981

**Legionnaires’ disease and sleep apnea devices: retrospective analysis of a 9-year-investigation and contribution of whole genome sequencing.**

Camille Allam*1,2, Christophe Ginevra1,2, Christine Campese1, Aline Prugne1, Delphine Morel1, Laetitia Beraud2, Ghislaine Descours1,2, Sophie Jarraud1,2

1Claude Bernard University Lyon 1, Team «Pathogénese des Légionelles» U1111 CIRI - INSERM - ENS de Lyon, Villeurbanne, France, 2Hospices Civils De Lyon - Hcl, Institut des Agents Infectieux (IAI) - CNR des Légionelles, Lyon, France, 3Santé publique France, Saint-Maurice, France, 4Hospital Center De Lunéville, Unité de soins continus, Lunéville, France, 5ARS Grand Est, Troyes, France

**Background:** Legionnaires’ Disease (LD) is due to inhalation of *Legionella* contaminated aerosols. Apnea therapy devices are increasingly employed for patients with obstructive sleep apnea and can represent a high risk of contamination by inhalation of aerosolized bacteria if not properly maintained or filled with tap water. However, the incidence of Lp transmission through such medical devices is not well described.

**Materials/methods:** We report a 9-year retrospective study on sleeping apnea devices (SAD) exposure in LD patients notified in France. The exposition to such devices reported on the mandatory notification and the number of microbiological and epidemiological investigations were collected. *Legionella* PCR and culture of SAD water, typing using Sequence-based typing (SBT), nested-SBT (nSBT) or whole genome sequencing (WGS) were performed on samples / strains sent to the French National Reference Centre for *Legionella*.

**Results:** A total of 12985 LD were reported in France between 2011 and 2019. SAD exposition was indicated for 106 (0.8 %) cases (0 to 1.4% per year). During this period, a comparison between SAD water and clinical samples was requested for 19/106 cases (18%). Regarding environmental samples, 1/16 *Legionella* culture and 7/12 *Legionella* qPCR were positive. Three comparisons gave results. One of them showed a difference between clinical ST [ST1] and water nSBT [ST36], another showed compatible results between water complete nSBT [ST1] and clinical nSBT [6/7 amplified genes]. For the last case, we isolated endemic ST23 strains from patient and water samples, and WGS analysis showed they were phylogenetically closely related.

**Conclusions:** SAD and any aerosolization systems are potential sources of *Legionella* infection if misused but are rarely investigated. We confirmed for the first time by WGS comparison this contamination source. Environmental investigations are often difficult to achieve, SAD water being in insufficient quantity or frequently thrown after device cleaning. However, it is important to mention that tank or rinse water could be better investigated and probably help to resolve the investigation with current qPCR and/or WGS sensitive techniques.

**Presenter email address:** camille.allam@chu-lyon.fr
Cognitive impairment following severe malaria in travellers

Alexandre Duvignaud1,2, Bertrand Glize3,4, Hannah Lemistre3,4, Pauline Perreau1, Duc Nguyen1, Lisa Martin1, Thierry Pistone1, Arnaud Desclaux1, Denis Malvy1,2

1CHU de Bordeaux, Department of Infectious Diseases and Tropical Medicine, Bordeaux, France, 2Université de Bordeaux, Inserm 1219 - IDLIC team, Bordeaux, France, 3CHU de Bordeaux, Department of physical medicine and rehabilitation, Bordeaux, France, 4Université de Bordeaux, Inserm 1219 - HACS team, Bordeaux, France

Abstract:

Background: Severe malaria is a complex disease in which people infected by Plasmodium sp can express various clinical and biological signs of organ dysfunction. Among those phenotypes is the involvement of central nervous system. Providing various brain injuries directly or indirectly due to malaria and its management, long-term consequences may include neuro-cognitive impairment or behavioural problems. Widely explored in children, these sequels are poorly described in adults. In this pilot study, we report in detail cognitive impairments in returning travellers to France following severe malaria.

Materials/methods: Nine adults with initial cognitive symptoms following an episode of imported severe malaria were assessed in our neuro-rehabilitation department 2 to 4 months post-acute. Exclusion criteria were: previous neurological or psychiatric history. A detailed cognitive assessment was performed based on patient's complaints, using standardised tools.

Results: Only two patients had no complaint. Among the others, five reported fatigue, four reported disturbances in attention, three reported disturbances in working memory, two reported word finding difficulties. For the patients that had a complaint, we assessed impairment in long term memory (information retrieval) for 4 patients, impairment in working memory for 5 patients, impairment in executive functions as well as in attention for 3 patients. Four patients had anxio-depressive symptoms. One patient had visuo-constructive problems and one had pathologic processing speed. Neuropsychological rehabilitation was proposed to patients who needed.

Conclusions: In this pilot study, we report detailed results of cognitive assessment following severe malaria in returning travellers with initial cognitive symptoms. Cognitive impairments were noted for almost all patients, particularly for cognitive functions that are not very localised in the brain such as working memory, attention and executive functions. This testifies the need for a better understanding of pathological mechanisms that provide these long-term consequences to prevent them. Moreover, these results suggest there is a need for improving the healthcare network, referring more systematically travellers following severe malaria for a complete neuro-cognitive assessment in order to identify needs in neuropsychological rehabilitation.

Assessing impact of Multiplex PCR Point-of-Care testing in patients with respiratory tract infection: a French national study

Olivier Dauwalder*1, Casalegno Jean-Sebastien1, Pierre L’Aour Dufour1, Julien Berthiller2, Estelle Bravant1, Astrid Vabret2, Nicolas Lévéque3, Christopher Payan1, Jean Christophe Plantier1, Marie-Edith Lafon1, Pozzetto Bruno4, Stephane Bonacorsis2, Leo Caudrelier10, Jacques Izopet11, Frédéric Laurent1, Gerard Lina1,2, François Vandenesch1, Bruno Lina1

1Hospices Civils De Lyon - Hcl, Plateau de Microbiologie 24/24 - Centre de Biologie et Pathologie Nord, Lyon, France, 2Hospices Civils De Lyon - Hcl, DRCI, Lyon, France, 3Hospital Center University Of Caen Normandie, Caen, France, 4Poitiers University Hospital, Poitiers, France, 5Hospital Center Regional University Morvan De Brest, Brest, France, 6Chu De Rouen, Rouen, France, 7Chu De Bordeaux - Haut-Lévêque, Pessac, France, 8University Hospital of Saint-Étienne, Saint-Priest-en-Jarez, France, 9Hôpital Necker, Paris, France, 10Hospital Center, Cahors, France, 11University Hospital De Toulouse, Toulouse, France, 12Societé Française de Microbiologie, Paris, France

Materials/methods: In this prospective multicentric observational study, data were collected on patients who underwent POCT on RTI admission in 10 participating centers. POCT were realized on FilmArray® BioFire® Respiratory Panel 2+ (bioMérieux) or ePlex® Respiratory Pathogen Panel (GenMark). For each patient, demographic data, admission diagnosis, potential antimicrobial treatments and the POCT results were collected. Dates and hours of admission, hospitalization, respiratory sampling, POCT results availability and, if used, antimicrobial treatment were also collected. To assess POCT impacts, comparison between test results and antimicrobial use was conducted between patients with POCT result available before and after antimicrobial prescription.

Results: Between November 2017 and December 2018 we enrolled 649 patients with a mean age of 56 yo [0;99]. Of these, 88% (n=558) were hospitalized: 58% in conventional wards and 42% in ICU. The most frequent admission causes were Influenza-like illness syndrome [26%; n=131] and pneumonia [19%; n=98]. After exclusion of patients previously treated before their admission, 52% (n=265) and 7% (n=41) of patients received antibiotics and antivirals respectively. Among them, only 30% (n=82) of antibiotic treatments were prescribed upon test result availability, with a median time to antibiotics of 7.4 hours (IQR: 2.1;22.1) and a median time from consultation to result availability of 18.9 hours [0;10.9]. The positivity rates of POCT were 49% (IC95: 37%-60%) versus 53% (IC95: 46%-60%, p=0.49) in patients with prescribed antibiotics before and after POCT results respectively. Moreover, mean durations of antibiotics were 9.9 (CI95: 8.6-11.1) days versus 10.4 (CI95: 9.0-11.7; p=0.58) when the POCT was positive versus negative respectively.

Conclusions: No association between antibiotic introduction nor antibiotic duration and POCT results were observed. Most [70%] antimicrobial treatments were introduced before POCT results. The potential lack of impact of POCT on antimicrobial therapies use could be explained by: (i) a long mean time to result incompatible with the necessities of emergency care, and (ii) limited physician reliance on POCT results.

Abstract 3984

**Culture-negative "tuberculosis": which patients are at risk of misdiagnosis?**

Oliver Collas*, Ivo Suchett-Kaye†, Jessica Barrett‡, Tumena Corrah§

*Northwick Park Hospital, London, United Kingdom, †Ealing Hospital, London, United Kingdom

**Background:** Patients are often started on anti-tuberculosis therapy (ATT) in the absence of positive culture results. While clinical suspicion is often proved correct, the patients that remain TB culture-negative are at risk of missed or delayed alternative diagnoses and are exposed to potentially unnecessary medication side effects. There is a paucity of information regarding the alternative diagnoses these patients receive during and after ATT.

**Materials/methods:** We retrospectively analysed prospectively collected tuberculosis (TB) patient data to identify all TB culture- and PCR-negative patients commencing treatment at Northwick Park between 01.01.2015 and 01.01.2018. Clinical records, imaging and laboratory results were reviewed to identify a) alternative (non-TB) diagnoses and b) risk factors for alternative diagnosis.

**Results:** Of 897 patients notified to the London TB register, 125 (13.9%) were TB culture- and PCR-negative. 14 patients were excluded (11 lost to follow up, 3 declined treatment).

Of the remaining 111 patients, 24 (22%) received a definite alternative diagnosis. Of these alternative diagnoses, malignancy was commonest (10), then non-TB infections (6) and sarcoidosis (3).

Median days to confirmation of alternative diagnosis was 37 (range 0-1081 days). Those with an alternative diagnosis were significantly older (median age 59 vs 38, *p*<0.01) and less likely to have diagnostic histology (4% vs 23%, *p*=0.04) or a positive Mantoux or IGRA (50% vs 81%, *p*<0.01). Additionally, they were more likely to have received steroids and less likely to have resolution of symptoms at 2 months or on finishing ATT, however these values did not reach statistical significance.

**Conclusions:** Clinical caution and vigilance is advisable when managing culture-negative suspected tuberculosis patients. The 2-month clinical review, when mycobacterial culture and sensitivity results are available, is a good time to revisit a presumptive diagnosis of TB and if risk factors for misdiagnosis are present, to prompt further imaging, histology or microbiology. In our culture-negative group, an alternative diagnosis to TB was more common in those with non-resolution of symptoms, older age, lack of positive Mantoux or IGRA and lack of strongly supportive histology and radiology at diagnosis.

**Presenter email address:** o.collas@nhs.net
Assessing Pharyngeal Respiratory virus Carriage in healthcare workers Over Time (APRICOT): a feasibility study
Anne Melhuish1, Jane Minton2

1St James’s University Hospitals, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, 2St James’s University Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Nosocomial transmission of respiratory viruses is a source of excess morbidity and mortality in hospitalised patients. Evidence suggests healthcare workers are at higher risk of acquiring respiratory viruses, but their role in onward transmission is unclear. This study aimed to assess the feasibility of surveillance pharyngeal swabs to determine the prevalence of respiratory virus carriage in healthcare workers.

Materials/methods: A single centre feasibility study was conducted on the Infectious Diseases inpatient unit at St James’s University Hospital, Leeds, UK during winter 2018-2019. Eligible participants were patient-facing staff who worked on the unit for >50% of their contracted hours, including nursing, medical, housekeeping and applied healthcare professionals. Each participant submitted a weekly pharyngeal swab for 10 weeks. Swabs were collected by researchers or the participant themselves, placed in Copan UTM™ viral transport medium and later processed using a multiplex polymerase chain reaction (PCR) containing 10 respiratory viral targets and a human RNAase P target to demonstrate sample adequacy. At the time of each swab, participants completed a questionnaire recording presence and duration of respiratory symptoms.

Results: 25 participants were recruited, of whom 85% were female and 52% were ≤35 years old. Nurses or nursing support workers comprised 52% of the cohort. 23 participants (92%) completed all 10 swabs and questionnaires, with 16 participants submitting self-taken swabs throughout. 10 participants (40%) had at least one positive swab. In total, 248 swabs were collected, of which 15 (6%) were positive for a respiratory virus, including influenza A and respiratory syncytial virus. All the subjects with positive swabs reported symptoms within 72 hours of sampling. The median number of reported sickness episodes was 2 (IQR 1-3), with the median number of reported sickness days 21 (IQR 8 – 36.5 days). Most symptomatic participants had negative swabs. 98.8% of samples were taken adequately, confirmed by RNase P detection.

Conclusions: This work has demonstrated that surveillance pharyngeal swabs can establish the prevalence of respiratory virus carriage in healthcare workers, and that self-taken swabs are adequately performed and acceptable to participants. Further work is needed to determine the risks of viral transmission between healthcare workers and patients.

Comparative virulence of respiratory viruses on the winter seasons from 2017 to 2019: a southern European multi-centre cohort study

André Almeida1,2; Matteo Boattini3; Eirini Christaki4,5; Torcato Marques1; Ines Moreira1; Lourenco Cruz1; Valentina Tosatto1; Diogo Antão1; Gabriele Bianco1; Marco Iannaccone1; Cristina Costa1; Georgios Tsiolakkis1; Elina Khattab1; Diamanto Kasapi4; Rossana Cavallo3; Rita Corte Real1

1Central Lisbon University Hospital Centre, Lisbon, Portugal, 2NOVA Medical School, Lisbon, Portugal, 3University Hospital Città della Salute e della Scienza di Torino, Turin, Italy, 4Medical School, University of Cyprus, Nicosia, Cyprus, 5Nicosia General Hospital, Nicosia, Cyprus

Background: Influenza and respiratory syncytial virus (RSV) are responsible for a great burden of disease, peaking over the winter months in Europe. This study aimed to determine which of the most frequent agents causing severe acute respiratory infections may be responsible for the worst outcomes.

Methods: Study subjects were recruited based on positive PCR results for Influenza or RSV on respiratory samples, obtained over the previous two winter seasons in three tertiary hospitals in Cyprus, Italy and Portugal. We included patients ≥ 18 years-old who were admitted to a hospital ward and/or intensive care unit for acute illness. Data on demographics, co-morbidities, viral agents, disease course and outcome were collected. Cases deemed to have possible nosocomial infection were excluded. Univariate analysis was conducted using Mann-Whitney and chi-square tests. Multivariate analysis used logistic regression and included variables which were deemed clinically relevant and/or had p values <0.25 on univariate analysis.

Results: A total of 1012 patients met the study inclusion criteria. Their median age was 75 years, 25.3% had history of diabetes, 29.8% heart failure, 29.2% chronic obstructive lung disease (COPD) or asthma, 17.8% active malignancy and 15.8% chronic kidney disease (CKD) stage 3 or worse. Influenza A was the most frequently isolated virus (n=575; 56.8%), of which 158 were further subtyped as H1N1 (15.6% of the total) and 304 as H3N2 (30.0%). Influenza B and RSV were positive respectively in 22.9% (232) and 22.3% (226) of patients. H1N1 was associated with younger age (p<0.001), while heart failure, CKD and COPD or asthma were associated with infection by RSV.

There were 106 deaths (10.5%) and 84 (8.3%) patients submitted to invasive mechanical ventilation (IMV). Median length of stay was 9 days IQR[6-15].

Patient characteristics independently associated with death were older age [adjusted odds ratio (aOR) 1.02 CI95%[1.0-0.1.04]) and solid malignancy [aOR 2.93 [1.53-5.63]. On adjusted analysis of virulence, H1N1 was associated with higher odds of death [aOR 2.01 [1.20-3.38]) and IMV [aOR 5.3 [3.2-8.8]].

Conclusions: RSV infection was associated with the presence of chronic comorbidities. Influenza A H1N1 afflicted younger patients and was associated with higher death and IMV rates.

Flexible implementation of microbiology laboratory automation using BD's solution of standalone instruments

Sindhushree Raghunandan1, Sarah Reinholt1, Brandon Pfrommer1, Ana Maria Cardenas*1

1BD, Sparks, United States

Background: The implementation of total lab automation requires significant investment, ample laboratory space, as well as considerable changes to the lab's workflows. BD is introducing a Connected Solution of standalone instruments that are logically connected and controlled, using BD Synapsys™, to mitigate some of these challenges. This modular platform allows labs to adopt automated workflows at a pace that is complementary to their growth, and reduces the physical space requirements for laboratory automation by providing a smaller, more flexible footprint of individual standalone instruments. At the heart of the Connected Solution is the BD Kiestra™ ReadA Standalone containing a 25MP camera with a telecentric lens for improved visualization of cultures.

Materials/methods: Connected Solutions consisting of combinations of BD instruments, including ReadA Standalone, Standalone InoquA+™, Standalone IdentifA, BACTEC™ FX, and Work Cell Automation (WCA), were tested in BD's microbiology laboratory. A wide variety of clinical laboratory workflows was evaluated using different clinically relevant organisms.

Results: Testing began with a configuration consisting of a ReadA Standalone and a Synapsys™ workstation. Manual inoculation was performed at the workstation, the inoculated plates were either incubated in the ReadA or externally (e.g. anaerobic plates), and all plates were imaged in the ReadA at predefined time points. The 25MP camera and telecentric lens improved visualization of complex cultures by eliminating shadows and allowing high-quality magnification of plate images. To demonstrate a step-wise approach, a BD BACTEC™ FX and BD Kiestra InoquA+™ were logically connected to the solution for automated processing of blood cultures and automated inoculation of media and slides. Plates processed by the InoquA+™ were incubated and imaged in the ReadA Standalone. In addition, a Standalone IdentifA was logically connected to a WCA where plates destined for workup on the IdentifA were automatically sent to a stacker, and manually transported to the IdentifA.

Conclusions: BD's new Connected Solution offers customizable configurations consisting of different standalone instruments. This enables laboratories to automate specific aspects of their workflows, or implement a gradual step-wise approach to lab automation. These configurations also provide increased flexibility to laboratories with space limitations, while providing all the benefits of lab automation.

Abstract 3992

The Caserta Model: an hepatitis C virus way out in persons who use drugs in Italy

Giovanni Di Caprio*1, Vincenzo Messina1, Antonio Russo2, Enrico Parente1, Giovanni Russo3, Tiziana Raimondo1, Angela Salzillo1, Filomena Simeone2, Mariantonietta Pisaturo3, Nicola Coppola2

1A.O. Sant’Anna e San Sebastiano, Caserta, Italy, 2University of Campania Luigi Vanvitelli, Caserta, Italy, 3UO Ser.T Teano, Caserta, Italy, 4Azienda Ospedaliera dei Colli - Ospedale Domenico Cotugno, Napoli, Italy

Background: The aim of the present study was to evaluate the efficacy of an innovative and simplified model to eliminate HCV infection in a high-risk population of PWUD.

Materials/methods: between January 2018 and April 2019 a prospective, interventional, before and after study, based on the active and close cooperation between all the 6 Caserta Services for the Dependence (SerD) starting from the Teano one and the corresponding 3rd level units of Infectious Diseases in Caserta, Campania, Italy, was performed. The intervention included periodic prospective audits conducted by the infectious disease consultants in the SerD to improve the knowledge on HCV infection and on the need to treat. The infectious disease consultants were responsible for writing and sharing diagnostic protocols for HCV infection to do at SerD; a simplified pathway to access the Infectious Disease Unit and to start DAA was planned and a protocol for the follow-up during and after DAA treatment with a close collaboration between SerD and ID Unit personnel was identified. The outcomes were to test the efficacy of the model. The pre-intervention period was defined as January-December 2017; the post-intervention period as January-September 2018.

Results: in this setting, in the 6 SerD, the linkage to care model, resulted in an increase of 506% of rates in DAA treatment. PWUD followed up by the Teano one in 2017 and in 2018 were 318 and 275, respectively. The Figure shows the HCV cascade in the two periods. Compared with the pre-intervention period the number of subjects tested for HCV increased, but no significantly, in the post-intervention period (78% vs. 72%, p 0.1). Compared with the pre-intervention period the number of subjects HCV Ab positive tested for HCV RNA increased (91% vs 27% p<0.05). Of the 75 HCV-RNA-positive subjects identified in post-intervention period 65 (86%) were linked to care to Infectious Disease Unit and started DAA regimen, a prevalence clearly higher than that observed in the pre-intervention period (17%, p<0.05).

Conclusions: This innovative procedures for micro-elimination of HCV infection is very effective in PWID with rates of diagnosis and linkage to care.

**Predictors of vancomycin-resistant enterococci gut microbiome colonization among patients with Clostridioides difficile infection 6.4.1**

Evan Zasowski*, Maryam Ali, Ada Anugo, Kierra Dotson, Bradley Endres*, Kevin Garey

Touro University California, College of Pharmacy, Vallejo, United States, University of Houston, College of Pharmacy, Houston, United States

**Background:** Vancomycin-resistant enterococci (VRE) commonly colonize patients’ gut microbiome and can cause subsequent infection. This risk is high among patients with *Clostridioides difficile* infection (CDI). Knowledge of VRE colonization can guide empiric antibiotic therapy to ensure timely appropriate therapy for patients with VRE while limiting unnecessary antibiotics in those without. The objective is to derive and compare predictive indices for VRE gut microbiome colonization in CDI patients.

**Materials/methods:** Single center, retrospective cohort study from 3/2017 to 4/2018. Inclusion criteria: age ≥ 18 years; positive CDI test. Exclusion criteria: CDI-positive stool sample unavailable for testing. VRE colonization was identified in stool samples through growth and speciation on selective antibiotic media and confirmed using resistance gene PCR. Multivariable logistic regression was used to identify factors associated with VRE colonization. A predictive index based on regression coefficients was computed for each patient. Predictive performance via area under the receiver operating characteristic curve (aROC) of this index was compared via Hanley and McNeil method with two other simplified risk stratification approaches: 1. prior healthcare exposure and/or high-CDI risk antibiotics; 2. number of prior high-CDI risk antibiotics.

**Results:** Two hundred-forty patients were included; 35 (14.6%) had a VRE-positive stool sample. The median (IQR) age and Charlson comorbidity index were 64.5 (52-74.8) years and 2 (1-3), respectively. Prior healthcare exposure (62.1%) and prior high-CDI risk antibiotics (60%) were common. In logistic regression, prior fluoroquinolone (OR 2.668, 95%CI 1.131-6.294) was independently associated with VRE colonization; prior vancomycin (OR 2.102, 95%CI 0.966-4.573), clindamycin (OR 3.291, 95%CI 0.807-13.432), and healthcare exposure (OR 2.379, 95%CI 0.900-6.289) were retained as explanatory variables. A risk index based on number of regression-derived risk factors significantly predicted VRE colonization (aROC 0.704, 95%CI 0.613 – 0.794), but was not significantly more predictive than prior healthcare exposure + prior antibiotics (aROC 0.650, 95%CI 0.564 – 0.736) or number of prior antibiotic exposures (aROC 0.641, 95%CI 0.539 – 0.742); P > 0.05 for both comparisons.

**Conclusions:** A simplified approach using prior healthcare exposure and receipt of prior antibiotics known to increase CDI risk identified patients at risk for VRE gut microbiome colonization as well as individual patient/antibiotic risk modeling.

Moxifloxacin for the treatment of latent tuberculosis infection in liver transplant candidates and recipients: a single-centre experience

Jose Tiago Sequeira¹, Mario Fernandez Ruiz*², Maria Pilar Hernandez Jimenez¹, Rafael San Juan Garrido², Alejandro Manrique-Municio², Óscar Caso-Maestro¹, Carmelo Loinaz³, Jose M. Aguado Garcia¹

¹Unit of Infectious Diseases. University Hospital 12 de Octubre, Instituto de Investigación Sanitaria Hospital 12 de Octubre [i+12], Madrid, Spain, ²Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” [imas12], Unit of Infectious Diseases, Madrid, Spain, ³Unit of HBP Surgery and Abdominal Organs Transplantation, Department of General Surgery. University Hospital 12 de Octubre, Instituto de Investigación Sanitaria Hospital 12 de Octubre [i+12], Madrid, Spain

Background: Solid organ transplant (SOT) recipients have an increased risk of developing active tuberculosis (TB). Screening for latent tuberculosis infection (LTBI) prior to transplantation and treatment with isoniazid or rifampicin is recommended. In the case of liver transplant (LT) recipients, however, this strategy is not usually feasible due to risk of anti-TB drug-induced hepatotoxicity. Fluoroquinolones are a promising alternative, although the occurrence of treatment-emergent severe tenosynovitis limited the use of a 9-month course of levofloxacin for the treatment of LTBI in LT recipients in a clinical trial previously conducted by our group.

Materials/methods: Descriptive study of the safety and efficacy of moxifloxacin (400 mg daily) for 6 to 9 months for LT candidates and recipients diagnosed with LTBI at our center between December 2015 and June 2019.

Results: A total of 31 patients received moxifloxacin for LTBI (23 males, mean age: 57 ± 8.7 years). Moxifloxacin was started prior to LT in 23 patients, and in 13 cases the transplantation was performed during the course of therapy. Main underlying conditions were chronic hepatitis C virus infection and/or alcoholic liver disease (71%). At the time of transplantation, 52.4% and 47.6% of patients showed a Child-Turcotte-Pugh class A and B, respectively. At the time of the current report, 24 (85.7%) and 20 (71.4%) patients had received moxifloxacin for more than 6 and 9 months, respectively. Overall, 15 patients (48.4%) experienced at least one treatment-emergent adverse effect, but only in 5 cases (16.1%) moxifloxacin had to be stopped permanently. In detail, such events included one case of hematological toxicity, one case of severe generalized arthralgia, and 3 cases of Clostridioides difficile infection [diagnosed at days 7, 116 and 198 from the initiation of therapy]. Six patients (19.4%) reported mild-to-moderate joint pain or tendinopathy, but only one case required for moxifloxacin to be stopped permanently. No cases of moxifloxacin-induced QT interval prolongation were detected. No cases of active TB were diagnosed during follow-up [median of 631 days].

Conclusions: Moxifloxacin appears to be a reasonably safe option in LT candidates and recipients to whom isoniazid or rifampicin cannot be administered for the treatment of LTBI.

Abstract 3995

**Legionella pneumophila sqPCR in serum and respiratory samples as a marker of Legionnaires’ disease severity**

Camille Allam*1,2, Noémie Fessy1, Christophe Ginevra1,2, Laetitia Beraud1,2, Joelle Chastang1, Florence Ader2,3, Ghislaine Descours1,2, Sophie Jarraud1

1Hospital La Croix-Rousse - HCL, Institut des agents infectieux - CNR des Légionelles, Lyon, France, 2Claude Bernard University Lyon 1, Team «pathogenèse des Légionelles» U1111 CIRI INSERM ENS de Lyon, Villeurbanne, France, 3Hospital La Croix-Rousse - HCL, Service des Maladies Infectieuses et Transmissibles, Lyon, France

**Background:** Legionnaires’ disease (LD) is a severe pneumonia, with a rate of intensive care unit (ICU) admission up to 50% and a global mortality of 8%. The aim of this study was to evaluate the prognostic value of quantitative Legionella pneumophila PCR (Lp qPCR) in serum and respiratory samples in comparison to LD clinical and biological severity markers, and to monitor the qPCR evolution during Lp infection.

**Materials/methods:** We included 82 patients from a national prospective cohort, "ProgLegio", hospitalized in ICU (n=55) or in conventional medical departments (n=27). SOFA severity score was evaluated (n=46). A Lp qPCR was performed from 24 to 48h after diagnosis (D0) on serum and respiratory samples, followed at D3, D5 and every 3 days until negativation (cohort sizes below) for respiratory samples. In parallel, 19 plasmatic inflammatory cytokines were measured by a multiplex technique on D0 (n=47).

**Results:** 14/46 patients (30%) had a positive qPCR in serum. They had a significantly higher SOFA (8 vs 2 p < 0.0001) and pro-inflammatory cytokine levels (IFNγ: 31.7 vs 7.5 pg/mL, p=0.004; IL6: 168.2 vs 36.3 pg/mL, p= 0.006; IL8: 81.6 vs 28.7 pg/mL, p= 0.002) than patients with negative qPCR and were mostly ICU patients. Serum and respiratory qPCR results were correlated on D0 (r=0.66; p<0.0001). Respiratory qPCRs were positive for 64/76 (84%) samples on D0, 34/40 (85%) on D3, 19/24 (79%) on D5, 13/20 (65%) on D8, 5/8 (62%) on D11, and 3/6 (50%) after D14. Patients with positive qPCR from D8 were all ICU patients and had a median SOFA compared to D0 median SOFA (10 vs 4, p=0.0048). One patient had positive qPCR results until D59.

**Conclusions:** qPCR on serum, is not appropriate for diagnosis but its positivity appears to be a marker of LD severity. Indeed, serum and respiratory DNA load are correlated and associated to an increased inflammatory cytokines release and high SOFA. Furthermore, respiratory qPCR is positive until D8 for most patients that were initially severe and had a prolonged ICU stay.

Abstract 3997

**Association between the Blastocystis spp. load and patient’s socio-demographic and clinical profile in the northeastern area of Spain**

Cristina Matovelle Ochoa1, Encarnación Rubio2, Patricia Chueca2, Pilar Goñi2, Antonio Betrán Rosel1

1Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain, 2University of Zaragoza Faculty of Medicine, Zaragoza, Spain

**Background:** Blastocystis spp. is the most prevalent eukaryote parasite found in human feces; however, pathogenicity remains uncertain and it has been associated with the parasitic load. The aim of this study was to assess the relationship between the parasitic load and presence of symptoms.

**Materials/methods:** A cross-sectional study was designed, including fecal specimens collected from January 1st 2018 to December 31st 2018, at the Microbiology and Parasitology Service of the Hospital Lozano Blesa Zaragoza – Spain. From 6,478 samples, 475 (7.33%) were positive to Blastocystis spp., 2 of them from patients who had an incomplete clinical history were excluded; therefore, a total of 473 samples were included in the study. The parasite was identified by optical microscopy (400x magnification), and 10 fields per sample was considered as "load of Blastocystis" variable. To investigate the relationship between the variable load of Blastocystis spp. with the socio-demographic and clinical variables and given the non-normality of the distributions, the U Mann-Whitney statistic was used and the level of significance was set at p<0.05.

**Results:** The analysis of the socio-demographic variables showed that 55.8 % of the patients were men and 44.2% were women, also the median age was 27 years (IR=41). The load of Blastocystis spp. by field was significantly higher in patients with abdominal pain (Median = 5.3; IR=10.8 vs 3.6, IR=5.2), chronic diarrhea (Median = 6.6; IR=12.1 vs 4.0, IR=7.9), vomit (Median = 8.6; IR=11.2 vs 4.2, IR=9.3) and aerophagy (Median = 7.0; IR=15.2 vs 4.4, IR=9.0) (table 1). There was not significant relationship between the load of Blastocystis is spp. by field and the rest of the symptoms.

**Conclusions:** It was identified that the load of Blastocystis spp. by field has a significant association between some symptoms described by the patients as abdominal pain, vomit, chronic diarrhea and aerophagy. The results suggested that Blastocystis spp. could behave as a pathogen and its pathogenicity is related with the parasitic load, but further studies are needed to determine the number of Blastocystis needed to be considered pathogenic.

**Table 1. Relationship between the load of Blastocystis spp. and symptoms**

Abstract 3999

Subtyping *Escherichia coli* in spontaneous bacterial peritonitis with use of IR biotyper and whole genome sequencing

Jaclyn Yizhen Tan*1,2, Clara Leboreiro1,2, Priya Solanki3, Rachel Westbrook3, Emmanuel Wey1,2

1Royal Free London NHS Foundation Trust, Centre for Clinical Microbiology, Department of Microbiology, London, United Kingdom, 2University College London, Division of Infection and Immunity, London, United Kingdom, 3University College London, UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, London, United Kingdom

**Background:** In cases of recurrent Spontaneous Bacterial Peritonitis (SBP), conventional diagnostics show similarities in pathogen antibiograms but are unable to swiftly determine if these pathogens originated from the same isolate. This study evaluates the use of Bruker Infrared (IR) Spectroscopy Biotyper and Whole Genome Sequencing (WGS) in recurrent SBP to address this limitation and evaluate their role in directing antibiotic selection and patient management.

**Materials/methods:** Ten clinical (*n* = 2) and reference (*n* = 8) *Escherichia coli* isolates were analysed retrospectively with an IR Biotyper and the IR Biotyper Software Revision C (Bruker UK). The two clinical isolates originated from a patient with bacteraemia and recurrent SBP. Isolates were prepared by aerobic incubation at 37°C for a total for 48 hrs, with the resulting homogenous suspension strain typed. Results were compared against a control Bruker Infrared Test Standard and an empty reference spot included in the 96-spot microtiter plate. A second set of the *Escherichia coli* isolates were also sent for WGS using the Illumina and Oxford nanopore platforms.

**Results:** Hierarchical cluster analysis by the IR Biotyper showed close clustering of the clinical isolates from the patient, when compared with the 8 other reference strains. WGS data from both Illumina and Oxford nanopore platforms was compared and contrasted with the IR Biotyper results.

**Conclusions:** The use of IR biotyper and WGS may be potential diagnostic adjuncts to guide swift and efficacious management in patients with recurrent SBP as it may shed light on the source of spread and pathogen sensitives quicker than conventional diagnostics. However, cost and availability of such tools should be considered if implemented in the clinical setting.

Figure 1: Dendogram produced by the Bruker IR biotyper platform demonstrated that clinical isolates (in red box) were indistinguishable from one another.

Abstract 4000

Template RNA loops determine aberrant RNA synthesis and innate immune activation during influenza virus infection

Hollie French*, Alannah King¹, Aartjan Te Velthuis¹

¹University of Cambridge, Division of Virology, Department of Pathology, Cambridge, United Kingdom

Background: Influenza A virus (IAV) infections usually cause a mild to moderate respiratory disease in humans. However, infections with highly pathogenic influenza viruses can cause severe or deadly pneumonia. Severe IAV infections have been linked to a dysregulated immune response that is triggered in part by detection of viral RNA by the pathogen receptor Retinoic Acid-Inducible gene-I (RIG-I). The segmented IAV viral RNA (vRNA) genome is replicated in the nucleus by the viral RNA dependent RNA polymerase (RdRp), in the context of viral ribonucleoprotein (vRNP) complexes. In addition to making full-length copies of the vRNA segments, the RdRp generates aberrant RNA products that contain internal deletions, such as defective interfering RNAs (>200nt) and mini viral RNAs (mvRNA) (56-125nt). mvRNAs are highly immunostimulatory compared to other replication products and induce interferon (IFN)-β expression by activating RIG-I. mvRNAs are therefore likely important factors in disease, but the mechanism by which they are generated and implicated in the severity of the immune response during IAV infection remains unclear.

Materials/methods: To investigate how mvRNA are generated, we analysed RdRp replication efficiency on model vRNA templates containing various secondary structures in vitro and in mammalian cells. We also investigated the ability of different templates and endogenous mvRNAs to induce an interferon response during infection.

Results: We find that the formation of an RNA duplex around the RdRp, which we call a template RNA-loop (tR-loop), can induce replication stalling and regulate the level of aberrant RNA production. Poor replication of the templates is correlated to the sub-cellular localisation of the template and aberrant products, and the induction of IFN expression. We further find that mvRNA levels vary per IAV genome segment and are influenced by adaptive mutations in the RdRp. Finally, we find that the introduction or removal of tR-loops in genome segments affects immune activation during infection.

Conclusions: We have identified a novel mechanism involving specific RNA structures that determines the generation of aberrant RNA products and regulates innate immune induction during influenza virus infection. This work advances our understanding of the replication of the virus and helps explain immune dysregulation during severe influenza disease.

Innate immune induction by aberrant mini viral RNA

Abstract 4002

Aspergillosis complicating severe respiratory syncytial virus in intensive care unit patients: a retrospective cohort study

Hannah Nam*, Michael G. Ison

1Northwestern University Feinberg School of Medicine, Northwestern University Feinberg School of Medicine, Chicago, United States, 2Northwestern University Feinberg School of Medicine, Northwestern University Feinberg School of Medicine, Chicago, United States

Background: There are recent reports that identify severe influenza pneumonia as an independent risk factor for the development of invasive pulmonary aspergillosis (IPA), even in patients without immunocompromise. We aimed to understand the incidence of IPA as well as other coinfections over multiple seasons in patients with RSV pneumonia in the intensive care unit (ICU).

Materials/methods: A retrospective cohort study was conducted in a single center in Chicago. Data was collected over 6 seasons [January 2012-March 2018] from adult patients admitted to the ICU at a large urban tertiary care center with severe RSV pneumonia. Patients were included if they had a positive RSV PCR test, older than 18 years, admitted to the ICU with acute respiratory failure, and had pulmonary infiltrates on imaging. IPA was defined per both the EORTC/MSG criteria as well as the revised AspICU criteria [Schauwvlieghe et al]. Descriptive statistics were calculated. In univariable analysis, we compared categorical variables by Fisher's exact test and Chi-square test, continuous variables by Student's t-test where appropriate.

Results: Patients diagnosed with invasive pulmonary aspergillosis (IPA) had an increased LoS in the hospital when [23.6 days vs. 13.9 days, p=0.03] and higher mortality [62.5% vs 18.4%, p=0.01]. History of hematological malignancy and neutropenia showed trends towards development of IPA. All patients with IPA were treated with voriconazole. Other coinfections among RSV-infected ICU patients included bacterial [39, 27.1%], viral [10, 6.9%], and non-IPA fungal [2, 1.3%] pathogens.

Conclusions: Although IPA is relatively uncommon in patients admitted to the ICU with severe RSV pneumonia, patients with IPA had significant increased LOS as well as mortality. Other coinfections with bacterial, viral, and non-IPA fungal pathogens are common in those with severe RSV pneumonia.

Prevalence and risk factors for Histoplasma Capsulatum infection amongst HIV patients attending the Buea Regional Hospital using the Histoplasma urine antigen detection enzyme immunoassay

Kuate Ngouanom Marius Paulin1, David W. Denning234, Christine Mandengue5, Nyasa Raymond1

1University of Buea, Buea, Cameroon, 2The University of Manchester, Manchester, United Kingdom, 3The Global Action Fund for Fungal Infections, Genève, Switzerland, 4National Aspergillosis Centre, Wythenshawe, United Kingdom, 5Université des Montagnes, Bangangte, Cameroon

Abstract third-party references: Optimum Imaging Diagnostics (OIDx)

Background: Human histoplasmosis is caused by two varieties called Histoplasma capsulatum var. capsulatum (Hcc) and Histoplasma capsulatum var. duboisii (Hcd), the latter only found in Africa. Histoplasmosis is an AIDS-related illness but can occur in both immunocompromised and immunocompetent individuals. Histoplasmosis has been reported in Cameroon, but few data on the prevalence are available. The objective of this study was to determine the prevalence of histoplasmosis in HIV patients and to investigate the risk factors associated with H. capsulatum infection.

Materials/methods: A descriptive cross-sectional study was conducted in the Buea Regional Hospital where 138 HIV positive patients, mostly outpatients were recruited. Urine samples were collected from HIV positive participants and analyzed using the Optimum Imaging Diagnostics (OIDx) antigen EIA kits, Risk factors associated with the infection were assessed using a questionnaire.

Results: Of the 138 participants, the mean age was 43.67 years (SD 12.18) and H. capsulatum antigen tested positive in 36 (26.1% [95%CI 18.77-33.43]). 5.6% [2] of the participants tested positive for H. capsulatum antigen had skin lesions. There was a significant association between the prevalence of H. capsulatum infection and a history of past chest infection [P=0.001, OR:3.632, 95%CI:1.635-8.07]. There was a marginal association between the prevalence of H. capsulatum infection and the viral load [P=0.07] and no significant correlation between viral load and the quantity of H. capsulatum antigen [P=0.371, r=-0.138].

Conclusions: H. capsulatum infection is present in HIV patients attending the Buea Regional Hospital. Awareness and management of HIV patients need to be improved with respect to H. capsulatum infection to limit the dissemination of the disease.

Abstract 4008

Comparison of a cartridge-based host gene expression test to a manual method for use in the diagnosis of sepsis

Will Sinclair1,2, Julie McCleave1, Peter Sillekens2, Inge Keuleers2, Thierry Vanhoey2, Silvia Cermelli3, Bert Lopansri1,4

1Intermountain Healthcare / Laboratory Services, 5252 South Intermountain Drive, Murray, United States; 2Biocartis NV, Mechelen, Belgium; 3Immunexpress Inc., Immunexpress Inc., Seattle, United States; 4Intermountain Healthcare / Division of Infectious Diseases, Murray, United States

Background: A novel approach to sepsis diagnosis is to characterize the host immune response to infection by measuring differential expression of immune response genes. Based on this approach, SeptiCyte™ LAB was the first-in-class sepsis diagnostic to gain FDA-clearance with results reported on a scale of 1-10 based on increasing probability of sepsis. However, due to the high complexity and lengthy turnaround time (TAT) the assay was not commercialized. A second-generation assay, SeptiCyte™ RAPID (on Biocartis Idylla™), currently under development, is a fully integrated sample-to-result test that includes in-cartridge sample preparation and quantitative polymerase chain reaction (qPCR) with a TAT of 1 hour. The purpose of this study was to compare performance and output of a prototype SeptiCyte™ RAPID test to its predicate.

Materials/methods: We conducted retrospective testing of prospectively collected clinical samples to compare performance and output of SeptiCyte™ RAPID with SeptiCyte™ LAB (N=28), and to compare interoperator performance using SeptiCyte™ RAPID cartridges (N=20). Whole blood was collected into PAXgene™ blood RNA tubes prior (“VENUS”, NCT02127502, Miller et al., 2018). Retrospective samples originated from patients suspected of sepsis and admitted to an intensive care unit at Intermountain Medical Center. Residual, cryopreserved samples were selected to represent the full score range of SeptiCyte™ LAB (0-10). Testing was conducted at a clinical lab (Intermountain Healthcare Central Lab) and Biocartis. SeptiCyte™ scores were calculated using a formula and qPCR Cq values. Hands-on-time (HoT) and assay TAT were recorded.

Results: Figure 1 demonstrates the correlation ($r^2=0.97$) for 28 clinical samples run using the manual SeptiCyte™ LAB test and SeptiCyte™ RAPID. Average HoT was 2 mins, and average TAT was 65 mins. Interoperator correlation on different Idylla™ machines located at different laboratories was 0.994 for SeptiCyte™ RAPID, with a coefficient of variation of 1.25%.

Conclusions: SeptiCyte™ RAPID prototype assay results, run on the Biocartis Idylla™ instrument, correlate strongly with SeptiCyte™ LAB, and are reproducible. This is the first demonstration of a fully-integrated, rapid, reproducible sepsis test that has the potential for near patient testing.

Figure 1: Scatter Plot of scores for SeptiCyte™ LAB versus SeptiCyte™ RAPID

$r^2 = 0.97$

Abstract 4009

Is the modified quick SOFA scale superior to quick SOFA in patients with diagnosed septic shock?

Deniz Akyol*1, Cansu Bulut1, Ugur Onal1, Ayşe Uygan1, Damla Akdağ3, Merve Mert1, Gamze Şanlıdağ2, Dilşah Başköl1, Seichan Chousein Memetali1, Günel Guliğeva1, Serhat Uyşal1, Melike Demir1, Sinan Mermer1, Hilal Sipahi1, Sercan Ulusoy1, Oğuz Reşat Sipahi2

1Ege University Medical Faculty Hospital, İzmir, Turkey, 2Bornova Public Health Center, İzmir, Turkey

Background: Herein, we aimed to compare the effects of qSOFA (Quick Sequential Organ Failure Assessment) score with modified qSOFA score (PLoS One. 2018 Sep 26;13(9):e0204608) for predicting one month survival (OMS) in patients with diagnosed septic shock (SS) in a tertiary-care educational university hospital in a developing country.

Materials/methods: Modified qSOFA was created by adding age factor (>50 years=1 point) to patients with qSOFA scale 1 or 2 or 3 who had SS (sepsis+hypotension+adrenergic agent) and consulted by Infectious Diseases consultants between December 2013-October 2019. Statistical analysis was performed via Chi square test and a p value <0.05 was considered significant.

Results: The number of patients with qSOFA score of 1 or 2 or 3 from 739 patients are in Table [some of the cases were diagnosed as septic shock according to elder definition (without lactate) and there was a subgroup with qSOFA score 1]. Among the >50-year aged group, OMS rate was lower in patients with qSOFA2 vs qSOFA 1 vs qSOFA 3 (Table 1, p=0.224). Among the <50 years group, OMS rate was lower in patients with qSOFA 3 vs qSOFA 2 vs qSOFA 1 (Table, p=0.047). According to modified qSOFA, there was a significant difference for OMS among SS cases with scores of 1, 2, 3 and 4 (16/28=57.14% vs 65/152=42.76% vs 143/357 -40.05 vs 101/202-50%, p<0.00001). On the other hand, there was no significant difference in terms of OMS when we performed subgroup analysis in qSOFA score 1 or 2 subgroups, as ≤50-year vs >50-year but interestingly OMS was significantly lower in <50-year old cases vs elders. (Table, 16/28 vs 46/109 p=0.202, 19/43 vs 134/323 p=0.869, 9/34 vs 101/202 p=0.014).

Table. Findings

<table>

Conclusions: In terms of OMS, there was significant difference between qSOFA score 1, 2, 3 and 4 subgroups. However, in patients with qSOFA 1 or 2 ≤50-year-old did not have a significant effect on OMS. Modified qSOFA may be beneficial to foresee the probable mortality but these findings need to be validated in larger cohorts. The question if mortality is higher in qsofa 3 and <50-year-old cases versus older in other cohorts needs further analysis.

Abstract 4013

**Prevalence of high-risk human papilloma virus genotypes responsible for cervical cancer in Blida, Algeria**

Samira Oukid*1, Mohammedi Kherroubi Dhakya2, Mohamed Lotfi Boudjella1, Nabila Sadouki2, Rachid Belouni3

1Faculty of Medicine, University Blida 1, Blida, Algeria, 2Laboratory of Papillomavirus and Herpesviridae and others- Institute Pasteur of Algeria, Algiers, Algeria

**Background:** Cervical cancer is the fourth most common cancer among women in Algeria. Few Algerian data are known about high-risk HPV (HR-HPV) and cervical cancer. The purpose of our study is to determine the prevalence of high-risk Humain Pa-pillomavirus genotypes responsible for cervical cancer in Blida and to know the distribution of high-risk Human Papillomavirus by age and by cytological abnormalities.

**Materials/methods:** Cervical samples testing for HR-HPV are taken with a cytobrush and stored in transport media at +4°C. The molecular analysis for HR-HPV genotypes is carried out by real-time PCR and end-point PCR, followed by reverse hybridization at the laboratory of Papillomavirus and Herpesviridae and others- Institute Pasteur of Algeria.

**Results:** Between January 2018 and April 2019, 444 cervical samples were selected for HR-HPV testing. The average age of women was 44 years [24-84, 95% CI=43.43-45.30]. The prevalence of HR-HPV among Blidean women was 3% (13/444). The peak prevalence rate was observed in women aged between 40-49 years. Eight different HR-HPV genotypes were found: HPV 16, HPV 18, HPV 31, HPV 45, HPV 52, HPV 56, HPV66 and HPV 68. The predominant genotypes were HPV 16 followed by HPV 45, HPV 18, HPV 66 and HPV56. Two out of 13 women had an infection with several HR-HPV genotypes. HR-HPV genotypes were found in 38% of smears without abnormality. Women with high-grade lesions were 15 times more likely to have HR-HPV [OR=15.49, p<0.005]. In our study, the acquisition risk factors for HR-HPV are multiple sexual partners [OR= 6.16, p<0.007, 95% CI=5.7% - 11.0%] and nulliparity [OR= 8.53, p<0.033, 95% CI=7.9% - 17.6%]. The use of the intrauterine device [OR= 0.1, p<0.001, 95% CI=12.5% - 19.2%], the swimming pool [OR= 0.07, p<0.002, 95% CI=41.4-59.8%] and a single sexual partner [OR= 0.16, p<6.5.10-3, 95% CI=3.4% - 26.9%] do not represent a risk factor for acquisition of HPV infection.

**Conclusions:** The prevalence of HR-HPV in Blida was 3%. The highest rate is observed in women aged between 40-49 years. The predominant genotype was HPV 16. The presence of HR-HPV is strongly related to the presence of High-grade lesions.

**Abstract 4015**

**Rapid detection of piperacillin/tazobactam resistance and extended spectrum resistance to β-lactams/β-lactamase inhibitors in clinical isolates of Escherichia coli**

Ángel Rodríguez Villodres*1,2, Alicia Gutiérrez-Linares1, Jeronimo Pachon-Diaz1, Jose Antonio Lepe1,2, Younes Smani1,2

1Clinical Unit of Infectious Diseases, Microbiology and Preventive Medicine, University Hospital Virgen del Rocío, Seville, Spain, 2Institute of Biomedicine of Seville (IBiS), University Hospital Virgen del Rocío/CSIC/University of Seville, Seville, Spain, 3Department of Medicine, University of Seville, Seville, Spain

**Background:** Piperacillin/tazobactam is a β-lactam/β-lactamase inhibitor (BL/BLI) recommended for the empirical treatment of severe infections. The excessive and indiscriminate use of piperacillin/tazobactam has promoted the emergence of piperacillin/tazobactam resistant *Escherichia coli* isolates. Recently, we demonstrated that piperacillin/tazobactam may contribute to the development of extended spectrum resistance to BL/BLI (ESRI) in piperacillin/tazobactam susceptible *E. coli* isolates but with low-level resistance to BL/BLI (resistance to amoxicillin/clavulanic acid and/or ampicillin/sulbactam) [Rodríguez-Villodres et al. Epub ahead of print]. This raises the need for development of rapid detection systems. Therefore, the objective of this study was to design and validate a method able to detect quickly resistance to piperacillin/tazobactam and ESRI in *E. coli*.

**Materials/methods:** A colorimetric assay based on the β-lactam ring hidrolysis by β-lactamases was designed (ESRI test). The ESRI test was evaluated by using piperacillin/tazobactam-susceptible isolates without ability to develop ESRI (n=22), piperacillin/tazobactam-susceptible isolates but ESRI developer’s (n=45) and piperacillin/tazobactam-intermediate or resistant isolates (n=47). All the isolates were obtained from bloodstream infections and intra-abdominal sources, and characterized according to their susceptibility profiles to BL/BLI. Detection of the three more frequent β-lactamases involved in BL/BLI resistance (*bla TEM, bla OXA-1* and *bla SHV*) was performed by PCR.

**Results:** The ESRI test was able to detect all the piperacillin/tazobactam-intermediate or resistant isolates, and all the piperacillin/tazobactam-susceptible isolates but with ability for ESRI development. Their mediane time-to-result were 5 and 30 minutes, respectively. All the isolates without BL/BLI resistance were negative for the ESRI test and did not harbour β-lactamase genes. For ESRI developer’s and piperacillin/tazobactam-intermediate or resistant isolates, *bla TEM* was the most frequent β-lactamase gene detected, followed by *bla SHV* and *bla OXA-1*. Sensitivity, specificity and positive and negative predictive values were 100%.

**Conclusions:** These results demonstrate the efficacy of the ESRI test, showing a great clinical potential which would lead to a reduction of health costs, ineffective treatments, and inappropriate use of BL/BLI.

Abstract 4018

Patient level predictors of vancomycin never events
Jiajun Liu*, Nicholas Mercuro1, Susan L. Davis3, Paul R. Yarnold4, Twisha S. Patel5, Lindsay Petty5, Gwendolyn Pais6, Keith S. Kaye5, Marc Scheetz1

1Midwestern University/Northwestern Memorial Hospital, Downers Grove, United States, 2Beth Israel Deaconess Medical Center, Boston, United States, 3Way State University/Henry Ford Hospital, Detroit, United States, 4Optimal Data Analysis, Chicago, United States, 5Michigan Medicine University of Michigan, Ann Arbor, United States, 6Midwestern University, Downers Grove, United States

Background: Vancomycin, the most commonly used antibiotic in the hospital, is often inappropriately used and can commonly lead to adverse drug events. We identified vancomycin ‘Never Events’ (NE), defined as clearly inappropriate use of vancomycin, and aimed to identify patient-level factors associated with NEs.

Materials/methods: Vancomycin NE were defined as either: 1) any vancomycin use for a non-susceptible organism after susceptibility results or 2) vancomycin use exceeding 48h after susceptibility report when safe de-escalation was possible. NE and controls were identified with an algorithm using an electronic data capture strategy from unique patient encounters between 1/2014 and 10/2017 at a large academic medical center. Cases and true positive NE were adjudicated via manual chart review. A logistic regression model was built to predict NE using Stata (College Station, TX: StataCorp LLC). Model building iteratively included variables according to p<0.2 using a forward selection process. Each variable inclusion required a difference greater than 3.84 for 2 times the log likelihood between the n and the n+1 model. Relative importance of identified factors to the final model was calculated as change in log likelihood (with one variable removed) expressed as percent of total log likelihood change from final model to model with the least important variable retained.

Results: A total of 100 cases and 100 controls were available, and final analysis included 96 NE and 26 controls due to partially missing data. Predictors associated with NE (OR, 95% CI) were length of stay (LOS) (1.1, 1.01-1.15), positive culture at therapy initiation (10.5, 2.78-39.43), hospital discharge from any level ICU (20, 1.39-288.4), and hospital admission to any level ICU (0.08, 0.1-0.6). Respectively, each of these predictors contributed 28.9%, 28.5%, 24.0% and 7.7% relative importance to the model. As depicted (Figure), increasing LOS greatly increased the likelihood that a vancomycin NE would occur.

Conclusions: LOS, positive culture at therapy initiation, hospital discharge from ICU, and ICU admission were significantly associated with NE. Further assessment of additional patient level data is needed to examine internal validity of model performance and cross-generalizability for NE predictions.

Predictive Margins for LOS (95% CIs)

Clinical metagenomic sequencing of positive blood cultures as a tool for rapid microbiological diagnosis

Kumeren Govender*1, Teresa Street1, Derrick Crook1, David Eyre1,2

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2University of Oxford, Big Data Institute, Oxford, United Kingdom

Background: Bloodstream infection has a high mortality worldwide with every hour delay in correct antibiotic prescription accounting for up to 7% increased mortality. Clinical metagenomics has the potential to provide quick and accurate real-time diagnostic results potentially reducing morbidity and mortality.

Materials/methods: Positive blood culture specimens were retrieved from the Oxford University Hospital’s microbiology laboratory. We evaluated four different human DNA depletion methods (Molysis Basic5, differential centrifugation, Saponin-based cell lysis, no pre-treatment) and three DNA extraction methods (MolYsis Complete5, QIAamp UCP, BiOstic Bacteraemia kit). Ten positive blood cultures, one unused blood culture bottle, and one water control were processed using each method in combination (n=144). Bacterial and human DNA yields were compared using 16S and beta-actin qPCR. Additionally, we processed 14 positive blood cultures and one water control using the BiOstic Bacteraemia kit with and without Saponin-based pre-treatment. Sequencing libraries were prepared using the Nanopore Rapid Barcoding Kit, and sequenced on R9.4 flowcells using the GridION platform, with 2-4 libraries multiplexed per flowcell. Sequenced reads were classified using Kraken2.

Results: By qPCR, the BiOstic Bacteraemia kit extracted the most bacterial DNA, yielding a median 1.55E+08 16S copies/µL (IQR 4.11E+07 - 3.34E+08), compared to the MolYsis Complete5 3.83E+07 (5.06E+06 - 8.26E+07) and the QIAamp UCP 7.17E+06 (1.54E+05 - 4.11E+07) (p<0.01). Saponin resulted in greater depletion of human DNA, with fewer beta-actin copies than differential centrifugation (p<0.01) and no pre-treatment (p<0.01). From sequencing, the median (IQR) number of human bases sequenced without saponin was 2.9E+08 (1.2E+08 - 1.4E+09) and with saponin was 2.7E+05 (2E+05 - 1.9E+06) (p<0.01). However, the median number of bacterial bases sequenced without saponin was similar to that with saponin, 2.2E+09 (1.1E+09 - 4.2E+09) and 2.3E+09 (1E+09 - 4.1E+09) respectively (p=0.50). A threshold of >1000 bacterial reads could be used to indicate a positive blood culture. All 14 samples [processed with or without saponin] contained the cultured species as the most common bacteria sequenced, at varying proportions of the total reads [Figure]. Species identification could be made within the first hour of sequencing.

Conclusions: We demonstrate that metagenomic sequencing can provide accurate and rapid diagnostic information in bloodstream infections.

Abstract 4024

Pharmacokinetic/pharmacodynamic simulation of cost-effective dosage regimens of ceftazidime/avibactam in patients with renal impairment

Lucile Dheyriat1, Laurent Bourguignon2, Marie Leroy1, Tristan Ferry1, Sylvain Goutelle*1

1University Hospitals of Lyon, Lyon, France

Background: The recommended dosage of ceftazidime/avibactam (CEF/AVI) is 2000/500 mg as a 2h-infusion every 8h (q8h) when creatinine clearance (CLcr) is from 51 to 80 ml/min. It should be adjusted to renal function, using 1000/250 mg q8h, 750/187.5 mg q24h in patients with CLcr of 31 to 50 ml/min, 16 to 30 ml/min, and 6 to 15 ml/min, respectively. The objective of this study was to identify alternative, cost-effective dosage regimens of CEF/AVI in patients with renal impairment.

Materials/methods: We performed a PK/PD Monte Carlo simulation study, based on a published population PK model of CEF/AVI (Li et al. Clinical Transl Sci 2019). We simulated the recommended dosage regimens as well as alternative dosage regimens using 2000/500 mg of CEF/AVI with variations of infusion time [2h, 4h, 6h] and dose interval [q12h or q24h] for different stages of renal impairment. Steady-state concentration profiles of 1000 virtual patients were obtained using the Pmetrics software. The probability of target attainment (PTA) was estimated for each regimen. For CEF, the PK/PD target was defined as a percentage of time during which the free plasma concentration remains above the MIC (fT>MIC) ≥ 50%. For AVI, the MIC was replaced by the minimum effective concentration (MEC), resulting in target fT>MEC ≥ 50% [Nichols et al. Antimicrob Agents Chemother 2018]. A PTA ≥ 90% was considered as acceptable.

Results: The results of simulations for the reference and some alternative dosage regimens are shown in Table 1. In patients with impaired renal function, the administration of the full 2000/500 mg dose of CEF/AVI every 12 or 24h with an infusion time of 2h up to 6h was associated with PTA as high as those for recommended dosage regimens. The alternative dosage regimens were not associated with overexposure except for 2000/500 mg q24h in patients with CLcr of 6 to 15 ml/min.

Conclusions: Dosing regimens of CEF/AVI based on the full dose with larger dosing interval and/or longer infusion duration appear to meet the PK/PD requirements of efficacy and could be associated with substantial cost savings.

The antimicrobial stewardship in surgery (ASCHI) project: long-term follow-up

Annacarla Chiesa*1, Alessia Zoncada2, Nigritella Brianese1, Evelyn Van Hauwermeiren4, Alice Ferraresi2, Silvia Lorenzotti2, Chiara Fornabaio2, Paola Lanza4, Andrea Patroni5, Carmine Tinelli6, Nicola Pasquali7, Massimo Rovatti8, Mario Martinotti7, Angelo Pan2

1Università degli Studi di Brescia/ASST Spedali Civili, brescia, Italy, 2Department of Infectious Diseases, ASST of Cremona, Cremona, Italy, 3Department of Infectious Diseases, San Gerardo Hospital, Monza, Italy, 4Department of Infectious and Tropical Diseases, ASST Spedali Civili, Brescia, Italy, 5Department of Internal medicine, Esine Hospital, Esine, Italy, 6Scientific Direction, IRCCS S. Matteo, Pavia, Italy, 7Department of General Surgery, ASST of Cremona, Cremona, Italy, 8Department of General Surgery, ASST of Cremona, Cremona, Italy

Background: Long term compliance with antimicrobial prescription indications is often reduced after an antimicrobial stewardship (AS) intervention. We report the long term follow-up of an AS intervention in a community hospital in northern Italy.

Materials/methods: Single center prospective study conducted in the General Surgery ward of Cremona’s hospital (1250 admissions/year) based on an abilitative strategy with peer education between surgeons and infectious disease (ID) doctor by weekly discussion of ID diagnosis, prophylaxis and treatment at patient’s bed-side. Surgical antimicrobial prophylaxis (SAP) and therapy (AT) appropriateness were evaluated through repeated prevalence analysis: appropriate AT prescription (AATP); wrong AT use (WATU); potential patient damage (PPD): ineffective antibiotic; and potential ecological damage (PED) on hospital microbiota: useless antibiotic.

The project had five phases: 1) pre-intervention (P1; May-October 2014); 2) intervention (P2 - November 2014-May 2015); 3) post-intervention (P3; June 2015-January 2017); 4) follow-up (P4 - July 2018-October 2018); 5) late follow-up (P5; August 2019). Data were presented and discussed with surgeons every 6 months. We conducted statistical analysis using EpiInfo™.

Results: We collected data on 2301 patients (P1 533, P2 672, P3 836, P4 227, P5 33). Correct use of AT was of 56% at baseline, while in P4 and P5 it was 84% and 85%, respectively (<0.001). Significant inappropriate use reductions were highlighted between P1 and P4/P5: WATU (23% in P1, 11% in P4, <0.001), PPD (22% vs 6%, <0.001), PED (26% vs 11%). A significant improvement in AATP was found between P1 and P2 (70% vs 84%, <0.001, X² 18.40). An improvement of SAP use with a reduction of PPD and PED was found comparing P2 and the follow-up phase (<0.001).

Conclusions: This abilitative AS intervention was associated with a significant improvement of antibiotic prescription appropriateness. The positive results of the intervention were still present 4 years after the AS intervention. This proves the durability of the abilitative intervention and the utility of a continuous teamwork between different specialist.

Horcajada1, Patricia Ruiz-Garbajosa1

1Hospital Universitario Ramón y Cajal, Madrid, Spain, 2Hospital Universitario Río Hortega, Valladolid, Spain, 3Hospital del Mar, Barcelona, Spain, 4Hospital de Bellvitge, Barcelona, Spain, 5Hospital Gregorio Marañón, Madrid, Spain, 6Hospital Santa Creu i Sant Pau, Barcelona, Spain, 7Hospital Marqués de Valdecilla, Santander, Spain, 8Hospital Universitaria Mutua Terrassa, Barcelona, Spain, 9Hospital Son Espases, Mallorca, Spain, 10Complexo Hospitalario de Pontevedra, Pontevedra, Spain, 11Hospital Clinic, Barcelona, Spain, 12Hospital Clínico Lozano Blesa, Zaragoza, Spain, 13Clínica Universidad de Navarra, Pamplona, Spain, 14Departamento Médico MSD España, Madrid, Spain

**Abstract third-party references:** Merck Sharp & Dohme [MSD]

**Background:** *Escherichia coli* (Ec) ST131 is a multidrug-resistant high-risk clone (HRC) associated with quinolone resistance, CTX-M-15 production and urinary tract infections. The emergence of a ST131-clade [C1-M27] associated with CTX-M-27 production has been recently described. The purpose of this study was to assess the microbiological characteristics and the presence of HRC-ST131 among ESBL-Ec causing healthcare-associated bacteraemia of urinary origin [HCA-BOU] (ITUBRAS-2 project) and compare these results with those previously obtained in 2011 (ITUBRAS project).

**Materials/methods:** Patients with HCA-BOU [Sep-2017 to Apr-2019] from 12 tertiary hospitals in Spain were prospectively included and blood isolates were stored. Bacterial identification (MALDI-TOF MS) and antimicrobial susceptibility (microdilution, EUCAST-2019) were performed. ESBL and carbapenemase production were confirmed by double-disk synergy and a colorimetric test (CarbaNP, BioMerieux), respectively. Genes encoding ESBLs (*bla*SHV, *bla*TEM, *bla*CTX-M) and carbapenemases (*bla*OXA-48, *bla*VIM, *bla*KPC) were characterized (PCR, sequencing). ST131 screening was performed (PCR).

**Results:** Overall, 424 BOU episodes with 449 microorganisms were included. 222 [49.4%) corresponded to Ec isolates. Prevalence of HCA-ESBL-Ec producers increased from 13.9% [30/215] in 2011 to 30.6% [68/222] in 2019 (p<0.01). One non-ESBL-Ec isolate was an OXA-48-producer. ESBL producers showed higher resistance rates than non-producers to ciprofloxacin (92.6% vs. 38.3%), tobramycin (54.1% vs. 13%), gentamicin (42.6% vs. 11.7%), piperacillin-tazobactam (36.7% vs. 14.8%) and amikacin (14.7% vs. 3.2%) [p<0.01 for all comparisons]. All ESBL-Ec isolates were susceptible to ceftolozane-tazobactam, carbapenems, tigecycline and colistin. ESBL-producing HRC-ST131 was identified in higher proportion than in the previous study [56% [17/30] in 2011 vs. 66% [45/68] in 2019; p>0.5], representing 20.3% of the total Ec population. ST131 showed higher resistance rates than non-ST131 isolates to piperacillin-tazobactam (46% vs. 17.4%, p<0.01) and ciprofloxacin (97.7% vs. 82.6%, p<0.05). CTX-M-15 was the most frequent enzyme [41/68, 60%] and was mainly associated with ST131 isolates [36/41, 87%]. CTX-M-27 (absent in the previous study) was identified in 8 ST131 isolates. Non-ST131 isolates showed a high ESBL diversity including different CTX-M and SHV types.

**Conclusions:** ESBL-Ec causing HCA-BOU has increased significantly in Spain, mainly associated with the expansion of CTX-M-15-ST131 and the emergence of CTX-M-27-ST131. Ceftolozane-tazobactam showed full coverage for ESBL-Ec isolates, including those belonging to the HRC-ST131.

Abstract 4028

Evaluation of rapid AST in blood cultures using CHROMagar Mueller-Hinton orientation agar

Basma Mnif1, Fatma Zouari1, Souhir Gouiaa1, Nesrine Sallem1, Adnene Hammami1

1Laboratory of Microbiology, Habib Bourguiba University Hospital, Sfax University, Sfax, Tunisia

Background: Rapid antimicrobial susceptibility testing (RAST) from blood cultures (BCs) guide early appropriate antibiotic therapy of sepsis that improve patient prognosis. We aimed to evaluate the EUCAST RAST directly from BC bottles on Gram-negative rods using a chromogenic Mueller Hinton (MH) agar.

Materials/methods: A total of 40 non-duplicated positive BCs bottles (BioMerieux) from patients with Gram-negative bacteremia were tested: 15 K. pneumoniae, 8 E. coli, 12 A. baumannii and 5 P. aeruginosa having different antibiotic resistance mechanisms. RAST was performed on 2 MH agars: standard (BioMerieux MH) and chromogenic (CHROMagar™ MH Orientation) following the EUCAST recommendations for short incubation (4, 6 and 8 hours) AST directly from positive BC. A conventional AST (CAST) and identification (Vitek2 automated system) was also performed from BC subcultures after overnight incubation at 37 °C. Comparisons between the RAST and CAST methods were expressed as categorical agreement (CA), very major error (VME, false susceptibility), major error (ME, false resistance), or minor error (mE), intermediate versus susceptible or resistant) taking into account the Area of Technical Uncertainty (ATU).

Results: The RAST, performed on standard MH (BioMerieux), showed an overall categorical agreement of 95.6%, a mE rate of 0.9%, a ME rate of 0.5%, and a VME rate of 2.5% compared to the CAST method. However, the RAST, performed on CHROMagar™ MH Orientation, showed a better categorical agreement to the CAST, of 96.6%, a mE rate of 1.4%, a ME rate of 0.3%, and a VME rate of 1.2% (table 1). Moreover, the chromogenic agar helped to identify all the E. coli and Klebsiella after 6-hours incubation and facilitated the inhibition zone reading.

Of note, more than half of the reported errors (> 16 errors), especially VME, were recorded for aminoglycosids with strains harboring methylases (15 strains), which appear fully resistant only after overnight incubation.

Conclusions: Our study showed that the CHROMagar™ MH Orientation could be used effectively for both rapid orientation of identification and RAST in Gram-negative positive BC. CHROMagar™ RAST could be successfully introduced into any clinical microbiology laboratory lacking MALDI-TOF MS.

Abstract 4029

Social and physical opportunities to improve surgical antimicrobial prophylaxis prescribing: utilisation of the behaviour change wheel

Courtney Ierano1,2, Arjun Rajkhowa1,2, Karin Thursky*1,2,3, Caroline Marshall1,2,4,5, Trisha Peel2,6,7, Darshini Ayton8

1University of Melbourne, Department of Medicine- Royal Melbourne, Parkville, Australia, 2National Centre for Antimicrobial Stewardship, Peter Doherty Research Institute for Infection and Immunity, Melbourne, Australia, 3Peter MacCallum Cancer Centre, Department of Infectious Diseases, Melbourne, Australia, 4The Royal Melbourne Hospital, Infection Prevention and Surveillance Service, Parkville, Australia, 5The Royal Melbourne Hospital, Victorian Infectious Diseases Service (VIDS), Parkville, Australia, 6The Alfred, Department of Infectious Diseases, Melbourne, Australia, 7Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia

Background: Surgical antimicrobial prophylaxis (SAP) is a leading indication for antibiotic use in hospitals, with demonstrated high rates of inappropriateness. A greater understanding of this behaviour is needed to inform the design of targeted antimicrobial stewardship (AMS) interventions to support the optimization of SAP. We previously published our findings on barriers and enablers to SAP decision-making. An extension of this research is to map these barriers and enablers to behaviour change interventions.

Materials/methods: A qualitative case study exploring the phenomenon of SAP decision-making. Focus groups were conducted with surgeons, anaesthetists, theatre nurses and pharmacists across three hospitals in Australia. Thematic analysis was guided by the Theoretical Domains Framework (TDF) and the Capabilities, Opportunities, Motivators-Behaviour (COM-B) model. Application of the Behaviour Change Wheel (BCW), allowed for mapping of behaviour to behaviour change interventions.

Results: Fourteen focus groups and one paired interview were completed. Two key themes were mapped to the TDF, COM-B and BCW intervention functions and 12 interventions have been proposed to address these barriers and support the enablers of appropriate SAP decision-making, summarized in Table 1.

<table>
<thead>
<tr>
<th>Themes</th>
<th>TDF (COM-B)</th>
<th>BCW Interventions</th>
<th>Proposed Interventions</th>
</tr>
</thead>
</table>
| Social codes of prescribing reinforce established practices | Social (Social opportunity) | Enablement | - Target seniors surgeons for AMS interventions  
- Engage senior surgeons in intervention development and implementation. |
| Need for improved communication, documentation and collection of data for action | Environment (Physical opportunity) | Restriction | - Computerised Physician Order Entry SAP order sets  
- Modified ‘Time-Out’ pathway for SAP cessation  
- Electronic SAP redosing prompts  
- Modified Enhanced Recovery After Surgery protocol/post-operative checklist  
- Intervention education/training  
- Guideline implementation resources  
- User evaluation of resources and training  
- Identify relevant quality indicators.  
- Continue SAP prescribing audits.  
- Increase capacity for auditing of outcomes in relation to quality of SAP prescribing. |

Conclusions: SAP prescribing is a complex process across the surgical setting. Utilisation of behaviour change frameworks identified barriers and enablers of optimal SAP prescribing and supports development of theory-informed AMS interventions. Interventions should aim to increase surgeon engagement, address underlying social factors, such as professional hierarchy and support physical infrastructure for standardisation of SAP documentation.

Abstract 4030

How we achieved improvement in diagnosis and management of sepsis at County Durham and Darlington Foundation Trust, UK

Joanne Malkin*, Alyson Robinson1, Lisa Ward1, Claire Stocks1, Paul Latimer1

1County Durham and Darlington NHS Foundation Trust, Durham, United Kingdom

Background: In 2015, a national sepsis target (CQUIN) was released in the UK. NHS trusts were asked to achieve 90% compliance in screening of sepsis and antibiotics within one hour, for emergency admissions and inpatients.

Materials/methods: 50 random patients’ notes from both the emergency department (ED) and inpatients were analysed per quarter from April 2015 to March 2019. Changes in practice are summarised below.

2015

Sepsis Nurse appointed in response to the CQUIN, to support sepsis and deteriorating patient work through the cardiac arrest prevention team.

Introduction of Nervecentre, an electronic observations tool for inpatients.

2016

An acute intervention team was formed (a hybrid model of a traditional critical care and outreach service) which supported the delivery of 24-hour acute care through education and responsive review.

Quarterly Sepsis Study Days for registered nurses and doctors were introduced.

2017

A sepsis steering group was formed within the Trust. This comprised sepsis, oncology and special project lead nurses, an antimicrobial pharmacist and consultants from microbiology, intensive care, emergency medicine, anaesthetics, acute medicine, paediatrics and obstetrics. This group met every 1-2 months. The aim was to improve the care of patients with sepsis within the trust, with an accompanying improvement in compliance with the national target.

A regional sepsis screening tool was created and introduced into the North-East England region. The aim was to improve consistency of approach between NHS Trusts and compliance with national guidelines. Sepsis screen and assessment within Nervecentre was introduced.

Symphony, an electronic sepsis screening tool, was introduced into the ED.

Results: The Acute Intervention Team provided sepsis education to 142 members of staff during 2018/19.

226 healthcare workers attended Sepsis Study Days. Sepsis screening is at 100% in both emergency admissions and inpatients with suspected sepsis. (Previously 70% in ED).

From April 2018 – March 2019, receipt of antibiotics within an hour for in-patients increased from 29% to 93% and from 55% to 100% in ED.

Conclusions: Through our interventions, we have improved in all areas assessed by the CQUIN. In 2018-19 we demonstrated improvement with sepsis screening and antibiotics within 1 hour for >90% of patients.

Abstract 4034

**Alternative, cost-effective dosage regimens of ceftolozane/tazobactam in patients with renal impairment: a simulation analysis**

Lucile Dheyriat1, Laurent Bourguignon1, Marie Leroy1, Tristan Ferry1, Sylvain Goutelle*1

1University Hospitals of Lyon, Lyon, France

**Background:** Ceftolozane/tazobactam (TOL/TAZ) dosage should be adjusted in patients with renal impairment. The recommended dosage regimens are as follows (1h infusion): 1000/500 mg every 8h (q8h), 500/250 mg q8h, and 250/125 mg q8h in patients with creatinine clearance (CCr) from 51 to 100 ml/min, 30 to 50 ml/min and 15 to 29 ml/min, respectively. The objective of this study was to identify alternative, cost-effective dosage regimens, in this patient group.

**Materials/methods:** We performed a pharmacokinetic/pharmacodynamic (PK/PD) simulation study based on a published population PK model of TOL/TAZ [Chandorkar et al. J Clin Pharmacol 2015]. Within the R package Pmetrics, we simulated the recommended dosage regimens, and alternative dosage regimens using 1000/500 mg of TOL/TAZ with various infusion times and dosing intervals (q8h, q12h or q24h), in patients with normal, moderately impaired (CCr = 30 to 50 ml/min), and severely impaired (CCr = 15 to 29 ml/min) renal function. Steady state concentrations profiles were obtained in 1000 virtual patients. Probability of target attainment (PTA) was estimated. For TOL the target was defined as a percentage of time during which the free plasma concentration remains above the MIC [fT>MIC] ≥ 32.2% [Craig et al. Antimicrob Agents Chemother 2013]. For TAZ, the MIC was replaced by the minimum effective concentration (MEC), resulting in target fT>MEC ≥ 35% [VanScocly et al. Antimicrobial Agents Chemother 2013]. A PTA ≥ 90% was considered as acceptable.

**Results:** PTA for the recommended and some alternative dosage regimens are shown in Table 1. In patients with renal impairment, a full dose of 1000/500 mg q12h or q24h can be associated with acceptable PTA for both TOL and TAZ when the infusion time is moderately increased up to 2h or 4h. In addition, such strategy is not associated with overexposure, as Cmax remains in a usual range.

</tbody>
</table>

The * symbol represent dosages recommended by the manufacturer. Cmax values are given as median (95% CI).

**Conclusions:** In patients with moderate to severe renal impairment, infrequent administration (q12h or q24h) combined with prolonged infusion of TOL/TAZ appears to be as effective as recommended dosages in terms of PK/PD. This strategy also has the potential for substantial cost savings by reducing the number of vials used and the nurse labor.

Abstract 4037

**Diagnostic utility of a novel Point-of-Care test of calprotectin for periprosthetic joint infection in total knee arthroplasty patients**

Alison Klika*1, Jared Warren1, Hiba Anis1, Kathy Bowers1, Susan Zhang2, Jessica Colon-Franco1, Nicolas Piuzzi1, Carlos Higuera3

1Cleveland Clinic - Main Campus, Cleveland, United States, 2University Hospital Main Campus, Cleveland, United States, 3Cleveland Clinic Weston, Weston, United States

**Background:** Recently several synovial fluid biomarkers for diagnosis of periprosthetic joint infection (PJI) are being investigated. Point-of-care (POC) tests using these biomarkers are not widely available. The purpose of this study was to test the sensitivity, specificity, positive and negative predicted values (PPV and NPV) of a calprotectin POC test for PJI in total knee arthroplasty (TKA) patients, using Musculoskeletal Infection Society (MSIS) 2013 PJI diagnosis criteria as the gold standard.

**Materials/methods:** Synovial fluid samples were prospectively collected from 107 patients who underwent revision TKA (rTKA) at two academic institutions from October 2018 to November 2019. The study was conducted under IRB approval. Patients followed hospital standards for diagnostic work-up. Data collection included demographic, clinical, and laboratory data in compliance with the MSIS 2013 PJI diagnosis criteria. Synovial fluid samples were analyzed by calprotectin POC tests for synovial fluid in accordance with manufacturer’s instructions. Quantitative calprotectin read-outs were categorized into high risk (>50 mg/L), medium risk (14-50 mg/L) and low risk (<14 mg/L) for infection by the test reader system.

Patients were categorized as septic or aseptic using MSIS 2013 PJI diagnosis criteria by two independent reviewers blinded to calprotectin results. Test performance characteristics including sensitivities, specificities, PPV, NPV, and areas under the curve (AUC) were calculated for 2 scenarios: 1) a threshold of >50 mg/mL for infection, 2) a threshold of >14 mg/L for infection.

**Results:** 51 rTKAs were MSIS positive, while 56 rTKA were MSIS negative. The corresponding calprotectin classifications were 52 high, 8 medium, and 47 low risk. Of MSIS criteria positive cases, 49 were high risk, 1 was medium risk, and 1 was low risk. In the 1) >50 mg/mL threshold scenario, POC performance showed a sensitivity, specificity, PPV, NPV and AUC, respectively, of 96.1%, 94.6%, 94.2%, 96.4%, and 0.954. In the 2) >14 mg/mL threshold scenario, there was a sensitivity, specificity, PPV, NPV and AUC, respectively, of 98.0%, 82.1%, 83.3%, 97.9%, and 0.901.

**Conclusions:** The calprotectin POC test has excellent diagnostic properties including high sensitivity and specificity for diagnosing PJI in rTKA. However, further investigations with larger cohorts are necessary to further validate these results.

Abstract 4038

Minimizing pseudo-cluster suggestions in infection control surveillance using pathogen DNA sequencing and artificial intelligence

Donald S. Chen¹, Rita M. Sussner¹, Moira Quinn², Guiqing Wang², Melissa Chanza³, Weihua Huang⁴, Corey Scurlock⁴, Christian D. Becker⁵, John T. Fallon⁴,⁶,⁷, Kyle R. Hansen⁸, Devon J. Holler⁹, Judy L. Ashworth⁹, Mary M. Fortunato-Habib⁹, Juan Carmona⁹, Brian D. Gross*⁹

¹Infection Prevention and Control, Westchester Medical Center, Valhalla, United States, ²Pathology and Laboratory Medicine, Westchester Medical Center, Valhalla, United States, ³Infection Prevention and Control, Westchester Medical Center, Valhalla, United States, ⁴Pathology, New York Medical College, Valhalla, United States, ⁵eHealth Center, Westchester Medical Center Health Network, Valhalla, United States, ⁶Pathology and Laboratory Medicine, Brody School of Medicine, East Carolina University, Greenville, United States, ⁷Vidant Health, Greenville, United States, ⁸Philips Research North America (PRNA), Cambridge, United States, ⁹Genomics for Infectious Disease (G4ID), Patient Care Analytics (PCA), Philips Healthcare, Cambridge, United States

Background: Infection prevention surveillance for probable cross-transmissions (PCTs) is performed by manual review of microbiologic culture results and geotemporal data to identify potentially related isolates. However, the likelihood of pseudo-clusters within this approach is uncertain. Incorporating artificial intelligence (AI)-enabled algorithms with pathogen whole-genome sequencing (WGS) can rapidly identify PCTs, improving manual efforts.

Materials/methods: We deployed a commercial precision infection prevention system that utilizes WGS (Philips IntelliSpace Epidemiology, Philips Healthcare) to compare effectiveness of two surveillance methods for identifying PCTs: (i.) a unit match (UM) algorithm utilizing antimicrobial susceptibility testing (AST) with the sample collection time and unit; vs. (ii.) a clinical matching (CM) algorithm with nuanced weighting of AST data, timing of sample collection, and shared hospital location stays. WGS was performed on unique inpatient and emergency department isolates of Enterococcus faecium, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, and Staphylococcus aureus. Single-nucleotide variants (SNVs) were compared using core genome regions on a per-species basis to determine PCTs.

Results: From August 2018 to July 2019, UM and CM data from 709 patients were paired with WGS data from 479 E. faecium, 284 E. coli, 98 K. pneumoniae, 61 P. aeruginosa and 724 S. aureus isolates. Previously published SNV-relatedness thresholds were applied to define genomically related clusters as follows: 161 patients in 48 E. faecium clusters, 54 patients in 18 E. coli clusters, 8 patients in 4 K. pneumoniae clusters, 2 patients in 1 P. aeruginosa cluster, and 85 patients in 36 S. aureus clusters. 482 isolates did not meet relatedness thresholds. The UM method categorized 349 patients in PCTs, of which 219 did not belong to genomic clusters—a rate of 45% of suggested patients in pseudo-clusters. The CM method suggested 178 patients, of which 84 were not in genomic clusters—only 17% in pseudo-clusters.

Conclusions: The UM method suggested 171 more PCTs, of which many lacked genomic relatedness. The CM method decreased pseudo-cluster suggestions by 62%, with greater specificity. Further refinement and integration of AI-enabled approaches involving clinical and WGS data will permit more specific detection of PCTs and minimize pseudo-cluster suggestions, thereby improving allocation of infection prevention resources.

Evaluation of the implementation of diagnostic automation into the bacteriology laboratory as part of pathology modernisation

Ghassan Mohammad*1,2, Jonathan Turner1

1North Bristol NHS Trust, Bristol, United Kingdom, 2Public Health England, London, United Kingdom

Background: Pathology services are undergoing transformation in response to a reducing budget, changing demographics and increased infection management demands, and the growing challenges of identifying multidrug-resistant micro-organisms. Advances in diagnostic laboratory technologies form part of the future direction for the re-configuration of pathology services. The shift from manual to automated operation poses many challenges and opportunities for service design and delivery, workforce skill mix and the measurement of productivity, not least the extent to which new technologies are being implemented successfully.

Methods: The research adopted an insider research case study approach combining quantitative and qualitative mix methods to investigate service improvements in the diagnostic automation of bacteriology services, including the extent of quality and productivity gains. The case focused the impact on the workforce development of laboratory staff in the four sites, managing the shift from manual to automated procedures. A range of secondary data sets analysed using descriptive statistical methods to examine indicators of laboratory workload, laboratory productivity and workforce roles. A series of 19 individual semi-structured interviews were conducted with selected managers and frontline staff and data analysed thematically using NVivo. The research proposed a systematic model to examine the various stages specific to technology innovation.

Results:

Fig1. Automation Performance

Conclusions: The research found that the automation implementation had varied successes and challenges, cost-effectiveness was dependent on a range of technological, clinical factors. Recommendations surrounding staff development and working practices are proposed

• To implement the automation does not improve the service alone, you have to change the process so that you can take full advantages of the robotics, it won’t be efficient.

• We are continuing to deal with complex human relationships when introducing automated technology. The lessons learnt from such a complex automation implementation will cover the human factors as a vital component in terms of skills required to run the new hi-tech environment.

• We find that initial performance gradually dips in the first stage of the transition period and requires more investment in staff, and no saving. Gradually the performance will improve toward the post automation stage as showing in Fig.1

Presenter email address: ghassan.mohammad@phe.gov.uk
Effectiveness of chlorhexidine dressings to prevent catheter-related infections: Does one size fit all? A systematic literature review and meta-analysis

Mireia Puig-Asensio*, Alexandre Marra1, Christopher A Childs2, Eli Perencevich3, Marin Schweizer3

1University of Iowa Carver College of Medicine, Iowa City, IA, United States, 2Hardin Library for the Health Sciences, University of Iowa Libraries, Iowa City, IA, United States, 3Center for Access & Delivery Research and Evaluation (CADRE), Iowa City, IA, United States

Background: Catheter-related bloodstream infections (CRBSIs) are associated with significant morbidity. We aimed to evaluate the effectiveness of chlorhexidine (CHG) dressings in preventing incident CRBSIs and exit-site/tunneled infections.

Materials/methods: We searched PubMed, Cochrane Library, CINAHL, Embase, and ClinicalTrials.gov through March 2019 for studies with the following inclusion criteria: (1) acute-care patients with short/long-term catheters; (2) CHG dressing was used in the intervention group and a non-antimicrobial impregnated dressing was used in the control group; (3) CRBSI was an outcome. Randomized controlled trials (RCTs) and quasi-experimental studies were included. We used random-effects models to obtain pooled RR estimates. Heterogeneity was evaluated with I2 test and the Cochran Q statistic.

Results: Twenty-one studies (15,690 catheters; 17 RCTs), without evidence of publication bias, were included. CHG dressings reduced incident CRBSIs (pooled RR, 0.67: 95%CI, 0.55–0.81), independent of the CHG dressing type used: transparent CHG dressings (8 studies, pRR, 0.64: 95%CI, 0.44–0.94) vs CHG-impregnated discs (10 studies, pRR, 0.74: 95%CI, 0.57–0.95). Significant results were limited to: adults with onco-hematological disease (3 RCTs, pRR, 0.54: 95%CI, 0.36–0.81) and ICUs (9 studies, pRR, 0.58: 95%CI, 0.41–0.81); and short-term catheters (11 studies, pRR, 0.67: 95%CI, 0.50–0.90). CHG effectiveness seemed to remain in ICUs with baseline CRBSI rates <1.5/1,000 catheter-days: (2 studies, pRR, 0.37: 95% CI, 0.15–0.90). CHG dressings did not significantly reduce CRBSIs in neonates/pediatric populations (6 studies, pRR, 0.90: 95%CI, 0.57–1.40) and long-term catheters. Conversely, CHG dressings only decreased exit-site/tunnel infections in long-term catheters (3 studies, pRR, 0.36: 95% CI, 0.21–0.61). Contact dermatitis was independently associated with CHG dressings (7 studies, pRR, 5.16: 95%CI, 2.09–12.70); particularly in neonates/pediatric populations (3 studies, pRR: 9.20, 95%CI, 2.10–40.26) in whom severe reactions were described. Two studies evaluated and did not find CHG resistant isolates on the skin.

Conclusions: CHG dressings reduce the incidence of CRBSI, but evidence is limited to adults with short-term catheters—particularly in ICU settings and in patients with an onco-hematological disease. CHG dressings reduce incident exit-site/tunneled infections in long-term catheters. Future studies should focus on non-ICU settings and monitor the risk of CHG resistance.

Community antimicrobial stewardship programme in pregnant women with urinary tract infections in primary care service

Jorge Asimbaya¹, Patricia Zambrano Sánchez*²

¹Universidad Central del Ecuador, Quito, Ecuador, ²Universidad UTE - Campus Occidental, Quito, Ecuador

Abstract 4043

Background: During the last 4 decades antibiotic resistance has been on the rise, so Antimicrobial Stewardship Programs (ASP) have emerged as tools to help us regulate and optimize their use. Since urinary tract infections (UTIs) in pregnancy are one of the most prevalent infectious pathologies with high resistance rates, it of the utmost importance to optimize its management considering that it is a factor that contributes to decrease perinatal morbidity and mortality, as well as it decreases bacterial resistance.

To demonstrate that the implementation of ASP is necessary to regulate and optimize antibiotic treatment in pregnant women with UTIs at the emergency area at the Guamani health center during the first quarter of 2019.

Materials/methods: We carried out a quasi-experimental analytical study pre-post trial type, through an educational intervention at the Obstetric Emergency service of the Guamani Health Center. Our study group consisted of 11 healthcare professionals at the obstetric emergency unit and the total number of patients treated in 3 months after the intervention was of 382. Our study had three phases. The first one sought to obtain data on the characteristics of healthcare attention prior to our intervention; the second consisted of masterclass lecture and persuasive interventions directed towards the obstetricians, and finally the third phase recorded the outcomes after our intervention.

Results: Pre-intervention: it was found that 46.62% of pregnant patients with UTIs were given Cefalexin as a first-choice treatment, followed by Nitrofurantoin with 33.33%. After the educational interventions, 72.51% of patients were treated with Nitrofurantoin as the first-choice treatment, compared to Cephalexin with 21.73%. The change in post intervention prescription was statistically significant with a p: 0.00, which was obtained using the Chi2 test.

Conclusions: Community Antimicrobial Stewardship Programs (C-ASP) based on masterclass and persuasive educational interventions are necessary to regulate and optimize the management of antibiotics in primary care.

**Th2 response may be deleterious to protect against Staphylococcus aureus bacteraemia**

Audrey Le Bot*1,2, Valérie Bordeau1, Sophie Reissier1, Sarah Dion1, Cintia D. Gonzalez1, Murielle Gregoire1, Mathieu Lesouhaitier2,4, Svetlana Chabelskaia1, Felden Brice1, Matthieu Revest1,2

1Université de Rennes 1, INSERM, Bacterial Regulatory RNAs and Medicine UMR1230, Rennes, France, 2CHU de Rennes, Maladies infectieuses et réanimation médicale, Rennes, France, 3Université de Rennes 1, IRSET, UMR 1085, Rennes, France, 4Université de Rennes 1, INSERM, UMR1236, Rennes, France

**Background:** Staphylococcus aureus vaccine development has been so far unsuccessful. SprD is a regulatory micro-RNA present in most of S. aureus strains. Its deletion leads to a dramatic decreased virulence of the mutant strain in an animal model. We aimed to evaluate the capacity of a SprD-deleted S. aureus strain to provide a protective immune response, as a live attenuated vaccine.

**Materials/methods:** Mice were divided into three groups, all intradermally inoculated at day (D) 0, D15 and D21: i) 0.9% NaCl solution (non-immunized control), ii) WT (immunized control, injections of wild-type (WT) S. aureus), iii) ∆SprD (inoculated with isogenic S. aureus ∆SprD). At D30, all mice were challenged with an S. aureus WT bacteremia. In all groups, we analyzed survival, weight loss, bacterial load in spleens and kidneys. Cytoxines production and anti-staphylococcal immunoglobulin G (IgG) in mice serum at different times of immunization and infection were evaluated.

**Results:** Blood cultures were all negative at D38 in the NaCl group, whereas 57.1% and 23.0% of the mice were still bacteremic in the WT and the ∆SprD groups respectively. No difference in survival was observed between the groups, as for weight losses and bacterial loads in spleens and kidneys. Serum interleukin (IL)-5, a Th2 cytokine, was significantly lower in the NaCl group (median 7.7 pg/mL, IQR 8.7) than in the WT (median 214, IQR 917, p=0.004) or in the ∆SprD groups (median 412, IQR 1496, p=0.001) during bacteremia; there was no difference for other pro-inflammatory cytokines and in cytokines of the Th1 and Th17 pathways. In all the groups the concentration of total IgG in serum increased at D38 compared to D0: 9.1 fold in the WT group, and 5.5 and 3.3 folds in the ∆SprD and the NaCl groups respectively. Neutrophils bactericidal activity decreased similarly within the three groups at D38 compared to D30.

**Conclusions:** Intradermal pre-exposure to a live-attenuated S. aureus was not protective in this mice model and lead to a longer S. aureus bacteremia duration, and increased serum level of IL-5 and total antistaphylococcal IgGs.

Burden of viral pneumonia among patients with lung infiltrates undergoing bronchoalveolar lavage: a retrospective one-year study

Cristina Maurel*, Enrico Gibbin1, Ludovica Segat2, Roberto Luzzati1

1ASUITS, Infectious Diseases Unit, Trieste, Italy, 2ASUITS, Virology laboratory, Trieste, Italy

Background: The etiology of lower respiratory tract infections remains often undetermined. Although viruses account for the majority of respiratory infections, frequently viral pathogens are not even investigated in patients with pneumonia. We performed a one-year observational retrospective study to define the burden of viral pneumonia in our tertiary care hospital in North-eastern Italy.

Materials/methods: We reviewed retrospectively all consecutive cases of adult patients with lung infiltrates undergoing bronchoscopy with bronchoalveolar lavage from January to December 2018, whose specimens had been analyzed with Real-time PCR for viral pathogens in addition to culture. Chi-square test has been used to establish correlation between variables.

Results: Of the 282 BAL performed, 259 patients were included. 40.5% (n=105) tested positive for viral pathogens. 64% (n=67) of these were defined as tracheobronchial viral shedding but 36% (n=38) were proven viral pneumonia; namely 14.7% of all patients enrolled. 14 patients had influenza-related pneumonia, 8 CMV, 8 HSV-1, 2 parainfluenza virus, 2 morbillivirus, 2 RSV, 1 metapneumovirus, 1 EBV pneumonia. Seasonal distribution confirmed a higher incidence of influenza, RSV, metapneumovirus and parainfluenza virus during the winter season, while CMV and HSV were evenly distributed within the year. Among patients with tracheobronchial shedding EBV was identified in 47 cases, CMV in 19, HSV-1 in 20. Viral pneumonia was associated to CAP (p-value 0.0045) and required hospitalization (p-value 0.0031) more frequently than viral shedding and or pneumonia due to other pathogens (p-value <0.0001 for both variables). Chemotherapy (p-value 0.0052), previous mechanical ventilation (p-value 0.0003) and diabetes mellitus (p-value 0.0271) were significant risk factors in our patient population. Lymphopenia (<1,000/μL) at presentation was also linked to viral pneumonia rather than tracheobronchial shedding (p-value 0.0009). No significant correlation was found with macroscopic pathological aspect of bronchial mucosa nor with radiological patterns.

Conclusions: In our study viral pneumonia seems to be not uncommon among hospitalized patients with CAP requiring diagnostic BAL and should be investigated especially in patients previously ventilated, lymphopenic or on chemotherapy. However the single-center retrospective design and the relatively small sample size do not permit to validate our conclusions. Further studies with larger populations are needed.
Use of chemiluminescence and electrochemiluminescence in the diagnosis and monitoring of hepatitis B viral infection

Desislava Velcheva¹, Anelia Gotseva*², Yana Slaveykova¹
¹MDL Cibalab, Department of Virology, Sofia, Bulgaria, ²Uni Hospital, Laboratory of Virology, Panagyurishte, Bulgaria

Background: Several serological markers are used in the diagnosis and monitoring of hepatitis B infection (HBV). The presence of the surface antigen of HBV (HBsAg) is the main indicator that a patient is infected and it is therefore the most suitable screening marker. Modern and innovative technologies allow for a quantitative assessment of HBsAg levels in serum (HBsAg quant). This marker has an important predictive value for the anti-HBV treatment response and an accurate differential diagnosis of the stage of infection. The aim of this study is to determine the diagnostic and prediction value of the tests for quantitative determination of HBsAg, based on chemiluminescence (CLIA) and electrochemiluminescence (ECLIA), in different clinical forms of HBV infection.

Materials/methods: For the period from 01.2016 – 10.2019, a total of 2976 serum samples were tested for HBsAg quant. A trace into dynamics was done parallel with the testing of HBeAg and anti HBe. The serum samples were analysed with two tests - LIAISON® XL MUREX HBsAg Quant. (DiaSorin) and HBsAg II Quant (Roche Diagnostics Ltd). Ten serum samples were tested parallel in MDL Cibalab and the laboratory of DiaSorin (Italy). Twenty serum samples were analysed parallel by CLIA and ECLIA methods.

Results: The results from the simultaneous analysis of the ten serum samples tested with the CLIA method in two independent laboratories showed full correlation. In the correlation analysis of twenty samples tested on LIAISON® XL and Cobas 6000 there was a correlation in nineteen and a discrepancy in only one of the serum samples for patients with CHB. The analysis of the obtained results showed high sensitivity of the tests in the low linear range.

Conclusions: HBsAg quant. with using CLIA and ECLIA is economically effective and have optimal sensitivity for early diagnosis and excellent specificity. With LIAISON® XL and Cobas 6000 was performed an exact quantitative determination of HBsAg in the clinical samples in the beginning and during the antiviral therapy. They are interchangeable and can be used for quantitative determination of HBsAg which is important when making therapeutic decisions in CHB and predict treatment response.

**Abstract 4048**

**First report of CC5-methicillin-resistant *Staphylococcus aureus*-IV-SCCfus “Maltese clone” in bat guano**

Mairi Assia1, Abdelaziz Touati2, Alix Pantel1,3, Albert Sotto1,4, Catherine Dunyach-Remy1,3, Jean Philippe Lavigne*1,3

1INSERM, U1047, Nîmes, France, 2Université de Béjaia, Laboratoire d’écologie microbienne, Béjaia, Algeria, 3CHU Nîmes, Service de Microbiologie, Nîmes, France, 4CHU Caremeau, Service des maladies infectieuses et tropicales, Nîmes, France

**Background:** *Staphylococcus aureus* is a well-known colonizer and cause of infection among animals. This bacterium has been described from numerous domestic and wild animal species. Methicillin-resistant *S. aureus* (MRSA) remains widespread around the world. It seems that these strains established new reservoirs, being currently disseminated in the community and notably among wild animals. The aim of the present study was to evaluate the resistance and virulence of *Staphylococcus aureus* strains isolated from bat guano in Aokas’s cave, Algeria.

**Materials/methods:** From March to May 2017, a total of 98 bat guano was collected using sterile swabs in Aokas’s cave (Bejaia, Algeria). Swabs were cultured in 1mL of Trypticase Soy Broth supplemented with colistin (10 mg/L), aztreonam (10 mg/L) and amphotericin B (2 mg/L) and incubated for 24h at 37°C. A 200 μL aliquot was plated onto mannitol salt agar plates and incubated for 24-48 h at 37°C. After isolation, the strains were identified by Vitek® MS system. Antibiotic susceptibility was determined by disk diffusion method according to EUCAST-CASFM 2018. DNA microarray analysis (Clondiag®) was used to characterize the molecular and antibiotic resistance profiles of Methicillin-resistant *S. aureus* (MRSA).

**Results:** A total of eleven *S. aureus* isolates were detected from 11 bat guanos (prevalence: 11.2%). All *S. aureus* isolates were sensitive for all the antibiotic tested excepted four isolates (36.3%) that were resistant to penicillin G, cefoxitin and fusidic acid. The four MRSA isolates belonged to a same clonal complex [CC]5/ST149. They harboured an SCCmec IV element and the fusidic acid resistance element Q6GD50 (fusC). The MRSA strains carried different virulence genes including enterotoxin A (sea), egc enterotoxin locus, enterotoxins C and L (sec, sel), toxic shock syndrome toxin (tst1) and hemolysins.

**Conclusions:** Wild animals could act as a reservoir of multidrug resistant bacteria. This study shows a global dissemination of CCS-MRSA-IV-SCCfus “Maltese clone” in Bat Guano in Algeria, demonstrating that this clone was not restricted to Malta.

Abstract 4050

**Pseudomonas aeruginosa prosthetic joint infection: results from a prospective cohort**

Héloïse Prié*1, Vanina Meysssonnier1, Y. Kerroumi1, Beate Heym1, Olivier Lidove1, Simon Marmor1, Valérie Zeller1

1Hospital Group Deaconesses Croix Saint-Simon, Paris, France

**Background:** *P. aeruginosa* prosthetic joint infections (PJIs) are rare (<5%). Data on their characteristics, management and outcome are very limited. The objective of the study was to describe the epidemiological, clinical and microbiological features of *P. aeruginosa* PJIs, their medical and surgical treatment and their 2 year outcome.

**Materials/methods:** Monocentric cohort study conducted from August 2004 to October 2018 including all mono and plurimicrobial *P. aeruginosa* PJIs. Data were extracted from the prospective data base. The following events were reported: relapse, new PJI, death related to infection or treatment. Results are expressed as median [min, max].

**Results:** Forty-four patients [29F/15M], the median age was 72 [35-90] years, with 27 hip, 16 knee and 1 shoulder arthroplasty infection, were included. Ten (23%) were immunosuppressed, 13 (29%) had been treated previously for another PJI. Twelve (27%) were plurimicrobial, 19 (43%) strains were wild type, 7 resistant to ciprofloxacin, none was resistant to ceftazidime.

Duration of symptoms before surgery was 190 [5-1473] days. Most PJIs were classified as late chronic [n=33, 75%], ten were early postoperative and one was a haematogenous infection.

Forty-one patients were operated: 27 underwent one-stage exchange (65%), 5 two-stage, 3 debridement and implant retention, 6 other strategies.

All patients except one received at least two antibiotics. Thirty (73%) patients were treated with continuous IV beta-lactam and oral ciprofloxacin for 6 weeks, followed by an exclusive oral ciprofloxacin regimen for 6 weeks. Eleven received 12 weeks of IV beta-lactam therapy combined with fosfomycin or colistin during 36 [24, 62] days. An aminoglycoside was used in 19 cases for 4 [2, 21] days.

After 2 years, one relapse, 3 new PJI, 2 related deaths were observed. No event was noted in 35 patients (85%).

Three patients were treated with prolonged suppressive antibiotic therapy.

**Conclusions:** The 2 year outcome of our cohort, including a majority of chronic PJI treated with one-stage exchange arthroplasty and prolonged IV antibiotic therapy, showed a favourable outcome in 85%, a higher rate than reported previously (~70%).

**Chemical genomics to reverse the colistin resistance of MDR *Klebsiella pneumoniae***

Bimal Jana*1, Kristin Baker1, Amy Cain2, William Doerrler3, Luca Guardabassi3

1University of Copenhagen, Copenhagen, Denmark, 2Macquarie University, Sydney, Australia, 3Louisiana State University, Baton Rouge, United States

**Background:** The emergence of multidrug-resistant (MDR) *Klebsiella pneumoniae* strains resistant to last resort antibiotics such as carbapenems and colistin are a global health concern. In a previous study, we used TraDIS (Transposon Directed Insertion site Sequencing) to identify the colistin secondary resistome, colistin-specific intrinsic-resistance genes, in MDR *K. pneumoniae* ST258 (ST258). The objectives of this study were to validate one of the identified colistin secondary resistance genes (*galE*) and to discover potential colistin adjuvant compounds that target this gene product.

**Materials/methods:** To validate the contribution of *galE*, which encodes UDP-Galactose-4-epimerase and is involved in LPS biosynthesis, to colistin resistance, a ∆galE mutant of ST258 was constructed through lambda-red mediated homologous-recombination. The phenotype of the ∆galE strain was confirmed by complementation of *galE* via arabinose-induced expression from a pBAD plasmid. Minimal inhibitory concentration (MIC) of colistin for wild-type, *galE* deletion and complementation strains were determined by broth microdilution. Compounds that target GaIE were identified through literature and PubChem search. Interaction between GaIE-targeting compounds and colistin was tested by checkerboard assay. To understand the effect of *galE* deletion on the envelope integrity of *K. pneumoniae*, fluorescence assay was performed using a membrane lipid-targeted probe NPN (1-N-phenylnaphthylamine).

**Results:** The colistin MIC of ST258 ∆galE mutant was 0.5 µg/mL, which was 8-16 fold lower than the MIC (8 µg/mL) of the wild-type strain. Complementation of *galE* in the mutant strain restored the colistin MIC to wild type level. A potential compound that interferes with the function of GaIE, ciclopirox olamine, exhibited synergistic growth inhibition with colistin with fractional inhibitory concentration index 0.28-0.5. Colistin MIC reduced to 0.5 µg/mL for wild-type ST258 in the presence of 4 µg/mL of ciclopirox. Envelope permeability assay showed increased NPN fluorescence in the ∆galE mutant compared to the wild-type, indicating compromised cellular envelope integrity in the absence of GaIE.

**Conclusions:** We identified a synergistic combination of colistin and ciclopirox that reverses the colistin resistance of MDR *K. pneumoniae* ST258. The approach demonstrated here, that employs chemical genomics to identify the antimicrobial adjuvant target, can be further explored to reverse the resistance of other antimicrobials and in different species.

Abstract 4054

Carbapenemase-producing *Klebsiella pneumoniae* in a Tunisian university hospital: emergence of hypervirulent strains

Basma Mnif*1,2*, Nesrine Sallem1, Fatma Zouari1, Adnene Hammami1

1Laboratory of Microbiology, Habib Bourguiba University Hospital, Sfax University, Sfax, Tunisia

**Background:** Carbapenemase-producing *Klebsiella pneumoniae* (CPKP) are increasingly reported worldwide. The aim of the study was to determine the molecular epidemiology of CPK in a Tunisian university hospital.

**Materials/methods:** All CPKP isolated in the Habib Bourguiba hospital between 2009 and 2016 were studied. Antibiotic susceptibility testing was performed by the agar disc diffusion method and E-test. String test was used to determine hypermucoviscosity activity of *K. pneumoniae*. The isolates were tested for the presence of carbapenemases and virulence genes by PCR. Plasmids carrying carbapenemase genes were analyzed by conjugation experiments and replicon typing method.

**Results:** 457 non-duplicate *K. pneumoniae* isolates harbored carbapenemase genes including 316 *bla*OXA-48, 127 *bla*NDM and 1 *bla*VIM and 1 coproduced *bla*OXA-48 and *bla*NDM. A gradual increase was noted in the number of CPKP isolates, ranging from 4.5% in 2009 to 26.4% in 2016. The CPKP isolates were collected mainly from urine (36%), bloodculture (20%) and sputum (16%). Their resistance rates to gentamicin, amikacin and colistin were 80%, 37% and 15%, respectively.

385 (82%) carbapenemase replicons were transferable by conjugation: 283 OXA-48 were carried on IncL/M plasmids, 30 OXA-204 on IncA/C, 1 OXA163 on IncR, 63 NDM on IncFIIk, 5 NDM-1 on IncA/C and 1 NDM on IncN plasmids.

*kpn*, *fimH1*, *ycfM*, *mrkD*, and *entB* virulence genes were detected in more than 90% of CPK isolates, *ybtS* in 80% and *kfu* in 56% of isolates. 5% of CPKP isolates were hypermucoviscous and 1% were hypervirulent and harbored *iroN*, *rmpA* and *iutA*, of which 2 hypervirulent *K. pneumoniae* strains belonged to K1 and K2 capsular types.

**Conclusions:** Our study demonstrates the increasing trend in OXA-48 and NDM carbapenemase-producing *K. pneumoniae* in our hospital and highlights the emergence of hypervirulent carbapenemase-producing strains in Tunisia.

Clinical features of late prosthetic valve endocarditis in a cardiac referral centre (2006-2019)

Leonardo Ribeiro-Da-Silva¹, Luiz Henrique Lemos¹, Marcelo Correia², Daniela Menezes¹, Juliana De Andrade¹, Rafael Garrido², Bruno Zappa², Giovanna Ianini Barbosa², Clara Weksler², Wilma Golebiovski², Cristiane Lamas*¹,²,³

¹Unigranrio Barra da Tijuca, Rio de Janeiro, Brazil; ²Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil; ³INI - Instituto Nacional de Infectologia Evandro Chagas, Fiocruz, Rio de Janeiro, Brazil

Abstract third-party references: Faperj, Rio de Janeiro, Brazil

Background: Prosthetic valve endocarditis is a severe subset of infective endocarditis (IE); it accounts for 10 to 30% of cases in IE series, and is usually associated with greater mortality than native valve IE.

Materials/methods: This is an analysis of a prospectively implemented cohort of adult patients with definite IE. ComParison between IE affecting valve prosthesis inserted for >1 year (late PVE, L-PVE) and the remaining cohort was done using Jamovi 1.0.7 software. The International Collaboration on Endocarditis case report form was used to collect data.

Results: Late PVE accounted for 53/359 episodes of IE (14.9%). Mean age of prosthesis was 8.2 ±5.9 years. Male sex was less frequent among patients with L-PVE (52.8% vs 64.9%, p NS), less patients were referred from other hospitals (26.4% vs 58.8%, p<0.001), acute presentation was more common (64.2% vs 48.6%, pNS). L-PVE was more frequently associated with prior CABG (11.8% vs 5%, p=0.06), atrial fibrillation (31.4% vs 13.9%, p<0.002), heart failure (62.3% vs 36.5%, p<0.001), cerebrovascular disease (20.8% vs 4%, p<0.001), previous IE (20.8% vs 8.6%, p=0.008), rheumatic valvopathy (65.4% vs 27.5%, p<0.001) and age above 60 years (23.7% vs 11.8%, p=0.006). No differences were found for essential hypertension, chronic renal failure or diabetes mellitus; site of acquisition (community, hospital, or healthcare-related, non-hospital) was not different. Blood cultures were more often positive for L-PVE (79.2% vs 66.1%, p=0.059) and enterococci more frequent (18.9% vs 9.3%, p=0.037). Aortic and mitral involvement were not different between groups. Conduction disturbances (mainly AV block) were more frequent in L-PVE (25.5% vs 7.4%, p<0.001), as were myocardial/paravalvular abscess (28.3% vs 18.9%, pNS). Preoperatively patients with L-PVE presented more often cardiac arrest (19.1% vs 9.8%, p=0.058), need for inotropes (43.5% vs 22.3%, p<0.002) and mechanical ventilation (37% vs 19%, p=0.006). Surgery was indicated at similar rates ( 81.1% vs 87.7%) but was done less often in L-PVE ( 63% vs 81.9%, p=0.003). Mortality was significantly higher in L-PVE (43.4% vs 21.6%, p<0.001).

Conclusions: Patients with L-PVE presented many years after valve insertion; they had more comorbidities, preoperative critical state and higher mortality.

Abstract 4058

Outcomes of respiratory viral infections in cancer patients receiving checkpoint inhibitors
Fareed Khawaja*, Mark Duna1, Patrick Chaftari1, Jean Tayar1, Ella Ariza Heredia1, Roy Chemaly1

1MD Anderson Cancer Center, Houston, United States

Background: Check point inhibitors (CPI) are commonly used for the treatment of many solid tumors (ST) and hematological malignancies (HM). By blocking PD-1 in fatigued T cells, an increase in viral clearance may be noted as evidenced in cases of JC virus. We undertook a descriptive analysis of all patients treated with CPI and diagnosed with a respiratory viral infection.

Materials/methods: All patients who were infected with either influenza, respiratory syncytial virus (RSV), parainfluenza virus (PIV), or human metapneumovirus (HMPV) from 7/2016 to 5/2019 with prior or concurrent CPI therapy were included in this study. Demographics and clinical data were collected retrospectively.

Results: A total of 192 patients were included in our study. Majority of the patients were undergoing treatment for ST, with nivolumab being the most common agent. The most common HM being treated with CPI was chronic leukemia [such as CLL and CML], whereas the most common ST being treated with CPI was lung cancer. Side effects from CPI were identified in 28% of patients. The most common side effects were related to dermatitis [10%], gastrointestinal issues [8%] and pneumonitis [8%]. Steroids were used in 44% of the cases. Lower respiratory tract infection due to respiratory viral infection was noted in 38% of cases. The 30-day mortality due to respiratory viral infection was 4%. Other outcomes are displayed in table 1. Sub analysis of patients on active therapy versus those off therapy for 6 months or greater showed no difference in outcome related to respiratory viral infections.

Conclusions: The rate of lower respiratory tract infections due to respiratory viral infections in substantial. Yet, mortality associated with respiratory viral infections in patients on CPI remains low.

Abstract 4059

**Antimicrobial use correlates with *Clostridioides difficile* incidence across the departments of an academic centre**

Nasstasja Wassilew*, Alexandra Zehnder2, Andrew Atkinson3, Andreas Kronenberg4, Jonas Marschall1

1 Bern University Hospital, Department of Infectious Diseases and Hospital Epidemiology, Bern, Switzerland, 2 University of Bern, Institute for Infectious Diseases, Bern, Switzerland, 3 Bern University Hospital, Department of Infectious Diseases and Hospital Epidemiology, Bern, Switzerland, 4 University of Bern, Institute for Infectious Diseases, Bern, Switzerland

**Background:** *Clostridioides difficile* is a common pathogen causing nosocomial *Clostridioides difficile* infection (CDI) in vulnerable patients. The association between broad-spectrum antibiotic consumption and the risk for CDI is well known, but the individual risk of specific antibiotic groups is less well characterized. The aim of the study was to correlate the CDI incidence in eight clinical departments of a tertiary care hospital with the total antibiotic consumption per department, and for specific antibiotic groups.

**Materials/methods:** A retrospective observational correlation study was performed over 11 years (2008 - 2018). Data on CDI and antibiotic prescriptions were collected from the Swiss Antibiotic Resistance Surveillance System (ANRESIS). First and new infections were defined as CDI episodes and duplicates and recurrent infections were excluded, according to the Centres for Disease Control and Prevention definition. CDI incidence was calculated as number of CDI episodes per 10'000 bed-days and year. The most frequently prescribed antibiotic groups were analysed individually. Antibiotic consumption data were transformed into defined daily doses (DDD) according to WHO definition. A mixed effects logistic regression model was fitted with department as random effect to determine CDI incidence as a function of year, and adjusted for antibiotic consumption.

**Results:** From a total of 1807 *Clostridioides difficile* positive samples from January 1st 2008 to December 31th 2018, 1314 episodes were considered for analysis, after exclusion of duplicates and recurrent infections. Incidence increased slightly over the years (IRR 1.03 95% CI [1.00, 1.05], p=0.01), following adjustment for antibiotic consumption. The amount of total antibiotic consumption (including all 10 antibiotic groups) correlated with a higher incidence for CDI for most departments (figure 1a). Scrutinizing each antibiotic group individually, the most notable correlation was between quinolone use and CDI incidence (figure 1b).

**Conclusions:** We found that global antimicrobial consumption correlated with C. difficile incidence for some of the clinical departments of a tertiary care hospital. There was substantial variability between the departments, both in terms of antimicrobial consumption and C. difficile incidence. Fluoroquinolones exhibited the strongest correlation and may be a first target for interventions.

**Presenter email address:** nasstasja.wassilew@insel.ch
ComParison of susceptibility of rifabutin and rifampicin on Staphylococcus spp. isolated in bone and joint infections

Pauline Thill¹, Olivier Robineau¹, Eric Senneville*¹, Blondiaux Nicolas¹

¹Centre hospitalier de Tourcoing, Tourcoing, France

Background: Rifampicin (RMP) combination therapy is the treatment of choice for acute staphylococcal prosthetic joint infections (SP JIs). However, RMP-related adverse effects and drug-drug interactions are frequently observed. Rifabutin (RFB) shares many of its properties with less adverse events. The present study aims to compare the antibacterial activity of RFB and RMP on staphylococcal clinical strains isolated from SP JIs.

Materials/methods: We studied 132 clinical strains of staphylococci (51 S. aureus (SA), 48 S.epidermidis (SE), and 33 coagulase negative staphylococci (CoNS)), isolated from SP JIs. The MICs, minimal bactericidal concentrations (MBC) and minimal eradication biofilm concentrations (MBEC) of RMP and RFB were determined using broth microdilution method (MIC) or the MBEC® Assay (MBC and MBEC) and then compared.

Results: RMP MIC₅₀ (0.016µg/ml [0.004-0.064]) was lower than RFB MIC₅₀ (0.032µg/ml [0.008-0.125]) for SA (p<0.001) but there was no statistically significant difference for SE [0.016 [0.002-0.064] vs. 0.016µg/ml [0.004-0.125] ; p=0.25] and CoNS [0.032 [0.002-0.064] vs. 0.032µg/ml [0.008-0.125] ; p=0.29]. RMP MBC₅₀ (0.032µg/ml [0.016-0.056]) was lower than RFB MBC₅₀ (0.064µg/ml [0.032-0.064]) for SA (p=0.003) but higher for SE [0.016 [0.008-0.032] vs. 0.004 [0.004-0.016]; p<0.001) and CoNS [0.00.24[0.008-0.016] vs. 0.008 [0.004-0.016]; p<0.01]. RMP MBEC₅₀ was significantly higher than RFB MBEC₅₀ for all strains, SA [2 [1-7] vs. 0.5µg/ml [0.25-0.5] ; p<0.001], SE [0.5 [0.015] vs. 0.064µg/ml [0.008-0.25]; p<0.001] and CoNS [0.25 [0.064-2] vs. 0.064 [0.0140.125]; p=0.004).

Conclusions: RFB has a better antimicrobial activity than RMPin biofilms encountered in SP JIs. It seems to be an excellent alternative to RMP in this indication.

Abstract 4061

**Urinary tract infections in children: antibiotic resistance of major pathogens in Western Attika, Greece (October 2014 to October 2019)**

Polyxeni Karakosta¹, Eleni Kalogeropoulou¹, Alexandra Vasilakopoulou¹, Evaggelia Oikonomou¹, Paraskevas Tsilikis¹, Sophia Bamianidou¹, Aikaterini Tarpazi¹, Athanasia Spiliopoulou¹, Kostas Tsekouras¹, Spyros Pournaras*¹

¹Athens Medical School/Attikon University Hospital, Clinical Microbiology Laboratory, Athens, Greece

**Background:** Urinary tract infections (UTI) in children are major drivers of antibiotic prescriptions with empirical initial therapy, which in turn drive antibiotic resistance. Knowledge of local antimicrobial resistance patterns is essential for evidence-based empirical antibiotic administration. We studied the causative uropathogens and their regional pattern of antimicrobial resistance among pediatric patients attending Attikon University Hospital, Athens, Greece during the past 5 years.

**Materials/methods:** A 5-year retrospective analysis of bacteria isolated from urine samples of children (age < 14 years) with suspected UTI was performed from October 2014 to October 2019 in Attikon University Hospital, Athens, Greece. Chi-square test was used to compare subgroups.

**Results:** 2062 non-duplicate urine cultures were screened, of which 402 were positive, and 435 isolates were found. 49.2% were males and 50.8% females. Their median (IQR) age was 1.6 (4.8) years. *Escherichia coli* was the leading uropathogen (51.3%), followed by *Proteus spp.* (15.4%) and *Klebsiella spp.* (9.3%). Among isolates of *Escherichia coli*, high susceptibility rates were recorded for gentamicin (91.4%) and ceftazidime (87.4%); the lowest frequencies were noted for ampicillin (43.4%), amoxicillin-clavulanate (71.0%), trimethoprim-sulfamethoxazole (76.7%) and cefuroxime (83.0%). Over the 5 years, we observed a significant decrease in susceptibility of *Enterobacteriaceae* to ciprofloxacin [from 95.0% (October 2014-March 2017) to 88.3% (April 2017-September 2019), p=0.03] and gentamicin [from 94.1% (October 2014-March 2017) to 84.7% (April 2017-September 2019), p=0.01]. No significant differences were observed between outpatients and inpatients.

**Conclusions:** Several first-line agents for empirical treatment of childhood UTI seem to have suboptimal efficacy in the area of this study. Regular monitoring of local antimicrobial resistance patterns is recommended to update national evidence-based guidelines on antimicrobial usage.

Abstract 4062

Household transmission of carbapenemase-producing Enterobacteriales: a prospective case-ascertained cohort study

Background: Household transmission may be an avenue for community spread of carbapenemase-producing Enterobacteriales (CPE). We studied the transmission rate of CPE in households with known CPE carriers

Materials/methods: We conducted a case-ascertained cohort study in two tertiary hospitals in Singapore. Newly identified CPE carriers and their household members were followed for one year. We collected household environmental samples and stool samples from study participants and their companion animals, weekly for 4 weeks, monthly for 5 months, and bimonthly for 6 months. We defined a transmission event (primary outcome) as when an identical carbapenemase gene was found in household contacts as the index, either by culture-PCR method or metagenomic analysis. Clinical transmission was studied further with whole-genome sequencing(WGS) to identify genomic transmission. We calculated hazard rates for CPE acquisition using a multi-state Markov model.

Results: Between October 2016 to August 2017, we recruited 10 index patients and 14 household contacts [7 households-one contact, 2 households-two contacts, and 1 household-three contacts]. Median ages of index patients and household contacts were 60 and 50 years, respectively. Index patients had a higher Charlson comorbidity index, and more antibiotics and healthcare exposures compared to household contacts. The index patients and family members provided an average of 11.4 (range, 8-13) and 10.7 (range, 6-13) stool samples respectively within a cumulative follow-up time of 9 years.

Index patients were colonized with $bla_{OXA-48-ISE}$ (n=4), $bla_{VPC2}$ (n=3), $bla_{IMP}$ (n=2), and $bla_{NDM1}$ (n=1), distributed among divergent species of Enterobacteriales. Three family members [21.4%,3/14] acquired four different types of CPE in the community. Of these four acquisitions, two [14.3%,2/14] ($bla_{OXA-48-ISE}$ and $bla_{VPC2}$) met the definition of transmission events [hazard rate, 0.22/year; 95%CI, 0.06-0.89] and classified as possible transmissions by WGS. The probability of CPE transmission from an index patient to a household contact in one year was 10% [95% CI 4.26]. All household environmental samples (n=472) and stool samples from pets (n=13) were negative for CPE.

Conclusions: We found evidence consistent with limited within-household transmission of CPE and estimated that up to about one in five index patients would be expected to transmit CPE to household contacts in one year.

Abstract 4063

**Evaluating emerging technologies in microbiology: what if your gold-standard isn’t gold?**

Lisa Brenton*, Mary Jo Waters1, Tyman Stanford2

1St. Vincent’s Hospital Melbourne, Fitzroy, Australia, 2University of South Australia, Adelaide, Australia

**Background:** As the Microbiology laboratory increasingly looks to emerging technologies, such as artificial intelligence, to image and interpret microbial growth, the ability to accurately evaluate this technology becomes important. This study presents an evaluation of microbiologist variability in the enumeration of urine cultures, and examines the effect that using microbiologists as the gold standard may have on instrument sensitivity and specificity parameters and on understanding its true performance.

**Materials/methods:** A randomly selected set of 480 urine culture images taken by the APAS® Independence was used to assess the variability in culture interpretation between microbiologists. The primary analysis variable was bacterial growth enumeration of a urine bi-plate (HBA/Brilliance UTI), classified as 0, 10³, 10⁴ and 10⁵+ CFU/mL. The cultures comprised 107 No Growth plates, 151 plates showing 10³ CFU/mL, 148 showing 10⁴ CFU/mL, and 74 with ≥10⁵ CFU/mL of growth, as determined by the APAS® Independence. Three microbiologists assessed the enumeration of the APAS® Independence images independently of each other in a blinded manner. The microbiologists’ enumeration values were then compared across all the microbiologists.

**Results:** Variability in growth enumerations was demonstrated across the three microbiologists. The lowest agreement between all microbiologists occurred for values of 10³ CFU/mL for both agars, whilst the highest concordance between all microbiologists for both agars occurred in the ≥10⁵ CFU/mL category. Differences could be seen between the two agars with total enumeration agreement achieved between all microbiologists in 69.6% of samples on HBA [334/480] and 72.9% on Brilliance UTI agar [350/480]. Microbiologist amalgamated enumerations in agreement with consensus was 88.6% [1,276 /1,440]

**Conclusions:** Although human assessment of bacterial cultures remains the gold standard, this evaluation has shown its subjective and variable nature. This creates a dilemma for laboratories when evaluating evolving technologies that automate culture interpretation. Whilst artificial intelligent technologies promise to standardize culture interpretation, how do laboratories perform comparative evaluations? Using the microbiologist as a gold standard will likely provide inaccurate estimates of the technology’s performance and microbiologists need to be cognisant of this when designing and interpreting results.

Abstract 4066

Platelet trends early during Staphylococcus aureus bacteraemia are predictive of persistence and mortality
Brian Lee*1, Corey Kelsom2, Karen Tan1, Annie Wong-Beringer2

1University of Southern California, Los Angeles, United States, 2Huntington Hospital, University of Southern California, Pasadena, United States

Background: Recent evidence suggests that platelets play key roles in the host defense against Staphylococcus aureus (SA). We have shown that persistent SA bacteremia (SAB) occurs in > 1/3 of the patients with each continued day of SAB increases the risk of death by 16%. We evaluated the relationship between platelet trends early during the course of infection and outcomes in patients with SAB.

Materials/methods: Medical charts of all hospitalized patients with SAB from 2012 to 2018 were reviewed for relevant demographics, laboratory, and clinical data. Baseline and daily platelet counts during were evaluated to assess the time course and magnitude of change. Thrombocytopenia was defined as platelet count <150 x 10^3/μL, with 100-150, 50-99, and <50 x 10^3/μL as mild, moderate, severe respectively. Patients were grouped based on platelet count and compared for clinical characteristics, and outcomes (duration of bacteremia, 30-day mortality).

Results: 378 patients were included; mean age was 66y ± 16. MRSA accounted for 34% of SAB. Comorbid conditions were primarily cardiovascular followed by diabetes and renal disease. Thrombocytopenia occurred in 29% of patients at baseline; 13% (n=5) were moderate to severe (MS). Compared to patients with normal platelet count (n=246), more in the MS group had liver disease (7%,16/246 vs 24%,12/51 p<0.05) and required ICU admission (41% vs 24%, p=<0.05). MS patients had longer duration of bacteremia (2.5 vs 3.2d, p=0.057) and higher 30-day mortality (16% vs 7%, p=0.044). Patients who had normal baseline platelet count but became thrombocytopenic by day 4 of receiving effective antibiotic therapy had worse outcomes than those who maintained normal platelet count (42% vs 22% persistence, 19.4% vs 6.5% 30-day mortality). Those with reversal of baseline thrombocytopenia on days 3 to 4 (n=75) compared to those with continued decline (n=59) had superior outcomes; shorter bacteremia duration (2.57 vs 3.02d), less day 4 persistence (23% vs 32%), and 30-day mortality (5.3% vs 20.3%).

Conclusions: Our results suggest that thrombocytopenia at baseline and platelet declines during the early course of SAB is significantly correlated with bacterial persistence and mortality. Further studies to examine S. aureus virulence on platelet dynamics during SAB is warranted.

Rapid generation of a standard inoculum direct from positive blood cultures using electrical biosensor technology

Eszter Deak*1, Suzanne Putney2, Yvonne Ngo1, Wendy Yip1, Kenny Vo2, Taylor Abbey2, Meike Herget2

1Avails Medical, Inc., Menlo Park, United States, 2Avails Medical, Inc., Menlo Park, United States

**Background:** Bloodstream infections are life threatening and every hour a patient is not treated with an effective antibiotic the survival chance decreases by 10%. This is aggravated by the emergence of multidrug resistant bacteria where antibiotics fail to be effective. Accelerating antibiotic susceptibility testing (AST) from a positive blood culture (PBC) to provide targeted antibiotic therapy early on is key to improving patient survival. Avails Medical uses electrical biosensor technology to generate a standardized direct from PBC inoculum (eMcFarland) in as fast as 1 hour, the eQuant method. Here we compare colony plate counts and antimicrobial susceptibility results generated with the eMcFarland to results generated using a 0.5 McFarland made from traditional PBC subcultures.

**Materials/methods:** Blood culture bottles were spiked with 40 organisms. Avails’ eQuant method was performed on each PBC. The generated eMcFarland was used to perform Vitek and disk diffusion antimicrobial susceptibility testing (AST). The PBCs were also subcultured, and following overnight incubation, used to generate a traditional 0.5 McFarland inoculum which was also tested in Vitek and disk diffusion as a reference. The eMcFarland generated from a PBC was plated for viable cell counts and compared to plate counts from direct suspension of the organism from a 18-24 hour culture plate.

**Results:** Of the 40 spiked PBCs for which an eMcFarland inoculum was generated, there were 7 *Escherichia coli*, 5 *Klebsiella pneumoniae*, 5 *Klebsiella oxytoca*, 5 Enterobacter cloacae, 5 Enterobacter aerogenes, 5 *Serratia marcescens*, 2 *Citrobacter freundii*, 3 *Staphylococcus aureus*, and 3 Enterococcus faecalis. The Avails’ eMcFarland yielded an overall AST categorical agreement of 96.1% for Vitek and 97.2% for disk diffusion. Essential agreement was 96.5% for Vitek. All eMcFarland colony plate counts were within 0.5 log difference of the colony plate counts measured using a 0.5 McFarland created direct from plate.

**Conclusions:** Avails eQuant technology provides a standardized inoculum directly from positive blood cultures in as fast as 1 hour, for use in commercial AST systems. It eliminates time-consuming subcultures and has the potential to provide physicians with AST results at least 18 hours earlier compared to current traditional methods.

**In vitro activity of four lytic bacteriophages specific for OXA-72-producing Acinetobacter baumannii**

Willames Brasilheiro Martins*,1,2, Juliana Cino1, Eduardo Alexandrino Medeiros3, Mark Alexander Toleman2, Ana Gales1

1Universidade Federal de São Paulo, UNIFESP, São Paulo, Brazil, 2Cardiff University, Medicine School, Cardiff, United Kingdom, 3Universidade Federal de São Paulo – Unifesp, Hospital São Paulo, São Paulo, Brazil

Abstract third-party references: The São Paulo Research Foundation (FAPESP)

**Background:** Bacteriophages are viruses with the ability to infect and kill bacteria and are the most abundant organisms on Earth. They are found in different environments and in the last years have been considered an alternative to treatment of several infections caused by MDR pathogens. Here, we performed an investigation and in-vitro characterization of bacteriophages recovered from hospital sewage against OXA-producing Acb isolates.

**Materials/methods:** Sewage samples were collected from four points of São Paulo Hospital and initially tested against 32 isolates of OXA-72-producing Acb as host. After selection by double-agar methodology, phages were purified, titrated, and stored at room temperature. Host range experiments were performed at 25°C and 37°C in a collection of MDR isolates: OXA-23 Acb (n=40), OXA-143 Acb (n=10), only OXA-51 Acb (n=20), without carbapenem-hydrolysing class D-β-lactamase (n=20), and OXA-72 Acb (n=106). Posteriorly, kinetics studies of phage infection were performed using different concentrations of phage (10^2 PFU, 10^3 PFU, and 10^4 PFU) by spectrophotometry during six hours at 37°C. Synergism effect of combination of 10^2 PFU of phages and 2 µg/mL of meropenem was also verified.

**Results:** Four phages were identified (PW55550, PW50186, PW53824, and P55640). PW55550 and PW50186 demonstrated activity at 25°C and 37°C, having 37°C as the optimal lytic temperature, while PW53824 and PW55640 just at 37°C and 25°C, respectively. Host range experiments showed which the phages were able to kill just OXA-72 Acb isolates. PW55550 and PW50186 were able to kill n=46 (43.4%) and n=43 (40.6%) OXA-72 Acb isolates with similar lytic profile. The remain phages showed lytic activity just against two isolates each (1.8%). Most OXA-72 Acb isolates were typed and belonged to CC79. Kinetics experiments of PW55550 and PW50186 showed that the inhibition of bacterial growth was just noted after the third hour of incubation at 37°C, with no difference in the concentration of phages used. No synergic in-vitro activity was observed when 10^2 PFU of PW55550 and PW50186 were combined to meropenem.

**Conclusions:** Hospital sewage is a rich font of bacteriophages against MDR pathogens. Two phages showed great activity against MDR OXA-72 Acb isolates and will be further characterized.

**Fluoroquinolone resistance in Escherichia coli isolates after exposure to non-fluoroquinolone antibiotics: a retrospective case-control study**

Linda Ernestina Chaname Pinedo\(^1\), Robin Bruyndonckx\(^2\), Boudewijn Catry\(^3\), Katrien Latour\(^1\), Steven Abrams\(^1\), Herman Goossens\(^4\), Samuel Coenen\(^1\)

\(^1\)University of Antwerp, Antwerpen, Belgium, \(^2\)Hasselt University, Hasselt, Belgium, \(^3\)Sciensano, Ixelles, Belgium, \(^4\)University Hospital Antwerp, Edegem, Belgium

**Background:** Fluoroquinolones, a major class of antibiotics, belong to the WHO list of highest priority antimicrobials for resistance surveillance in human medicine. Although the fluoroquinolone resistance percentage in Belgium has decreased from 26.7% in 2014 to 23.8% in 2017, it was still high compared to other northern European countries, such as the Netherlands (14.2%) and Denmark (12.8%) in 2017. Identification of a causal relationship between non-fluoroquinolone antibiotic use and fluoroquinolone resistance could guide treatment options to reduce fluoroquinolone resistance and enhance our understanding of co-selection. Here, we investigated whether, in routinely collected urinary Escherichia coli (E. coli) samples from primary and secondary healthcare settings in Belgium, the risk of fluoroquinolone resistance is increased by non-fluoroquinolone antibiotic use in the year prior to the sampling date.

**Materials/methods:** This was a secondary analysis of data collected retrospectively in a case-control study linking microbiological test results (isolated bacteria and their susceptibility) of urine samples routinely collected in primary and secondary care patients in Belgium with information on prior antibiotic use at the individual patient level up to one year prior.

**Results:** In urine samples from 6125 patients, 8313 E. coli isolates were retrieved; 2489 fluoroquinolone resistant isolates (cases) and 5824 fluoroquinolone susceptible isolates (controls). After adjusting for potential confounders (including fluoroquinolone use) and correcting for multiple testing, there was a 1.8 times higher odds of fluoroquinolone resistance in E. coli after exposure to trimethoprim/sulfamethoxazole [OR = 1.81, 95%CI, 1.40 - 2.34, \(p < 0.001\)] compared to no exposure to this non-fluoroquinolone antibiotic. Similarly, there was a 1.5 higher odds of fluoroquinolone resistance in E. coli isolates after exposure to nitrofurantoin [OR: 1.49, 95%CI: 1.20 - 1.84, \(p < 0.001\)]. These results were also observed for exposure at 6 and 3 months prior to the sampling date.

**Conclusions:** Under the assumption that confounding is addressed adequately and completely, exposure to non-fluoroquinolone antibiotics, i.e. trimethoprim/sulfamethoxazole and nitrofurantoin, might be causally related to fluoroquinolone resistance in E. coli isolates from urinary samples in Belgium. Future prospective research is needed to confirm non-fluoroquinolone antibiotics as potential drivers of fluoroquinolone resistance.

Abstract 4076

**Strategy for cytomegalovirus reactivation prevention with ganciclovir and high dose of valacyclovir in allogeneic stem cell transplantation**

Maria Jose Lopez*1, Enrique Pedraza1, Javier Figueroa1, Elena Mora1, Mauricio Gómez1, Sergio Ardila1, Angie Guarín1, Oscar Peña1, Cesar La Madrid1, Gustavo López1, Licet Villamizar1, Diego Díaz1

1Marly Clinic, Clinica de Marly, Bogotá, Colombia

**Background:** Cytomegalovirus (CMV) infection is an important cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). There are limited prevention strategies, and significant toxicity associated to them in developing countries.

**Materials/methods:** A retrospective analysis was performed on patients with allogeneic HSCT in Bogotá, Colombia. Patients were exposed to three CMV prevention strategies: from 2015 until 2018: universal prophylaxis with valganciclovir or preemptive strategy (once/week CMV viral load, with valganciclovir, ganciclovir or foscarnet initiation when it was positive), and since 2018: universal prophylaxis with ganciclovir from -6 until -3 and high dose of valacyclovir (1 gr q8h) since day -2 until + 100 (GVALA), with CMV viral load follow-up twice/week and treatment initiation when positive. The rate of CMV reactivation was compared.

**Results:** 262 transplants from 258 patients (4 were second transplantations because of graft failure) were analyzed. Mean age was 35 y (15-67 y), 60.7 % were men; most frequent transplantation causes were ALL (42.37 %), AML (27.1 %) and CML (10.69 %). 45.8 % were identical intrafamilial donors, 26 % haploidentical donors and 28.2 % unrelated donors. CMV D/R risk status was low in 2.68 % (n=7), intermediate in 76.72 % (n=201) and high in 20.23 % (n=53) of the cases studied.

There were 168 [64.12 %] patients with preemptive strategy, 63 [24.05 %] with GVALA prophylaxis and 31 [11.83 %] with valganciclovir prophylaxis. Overall reactivation was 45.24 % [n=76] with preemptive strategy, 42.86 % [n=27] with GVALA prophylaxis and 38.71 % [n=12] with valganciclovir prophylaxis (p=0.783). Reactivation within 100 days post-HSCT was 38.69 % [n=65] with preemptive strategy, 34.92 % [n=22] with GVALA prophylaxis and 25.8 % [n=8] with valganciclovir prophylaxis (p=0.378).

CMV mean reactivation time was 39 days (9-432 days); for patients under valganciclovir prophylaxis reactivation was delayed [64 versus 39 and 35 days, p=0.18]. There were no differences in CMV disease rate, hospitalization due to CMV or graft dysfunction.

**Conclusions:** No significant differences were observed in CMV overall reactivation, early reactivation or CMV disease in HSCT with a strategy based on ganciclovir pre-transplant administration and high dose of valacyclovir for post-transplant prophylaxis.

Abstract 4081

Opportunities to enhance empiric prescribing in community-acquired central nervous system infections among 187 US hospitals

Ahmed Babiker1,2, Sarah Warner2, Marissa Oshiro2, Sameer Kadri2

1Emory University, Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, United States, 2Clinical Epidemiology Section, Critical Care Medicine Department, National Institutes of Health Clinical Center, Bethesda, United States

Background: Central nervous system (CNS) infections carry a high burden of morbidity and mortality, which can be mitigated by implementing early effective empiric therapy. However, shifts in microbial etiologies and associated antibiotic-resistance patterns may impair appropriateness of empiric therapy and lead to deleterious outcomes. The current US landscape of CNS bacterial infections and their real-world management are unknown. Prior studies are based on billing codes and devoid of granular microbiological data. Herein we aimed to evaluate microbiological etiology, proportion of antibiotic-resistant phenotypes, use of rapid diagnostics and empiric therapy prescription patterns among community-acquired CNS infections from a large convenience US database.

Materials/methods: Clinical characteristics, in vitro susceptibility, antibiotic and adjuvant dexamethasone therapy were examined for adult inpatients with monomicrobial CNS bacterial and yeast cultures (within 48 hours of hospital admission) who received antibiotic therapy in the Premier Healthcare Database from 2016-2019. Antibiotic-resistant phenotypes were defined as resistance to methicillin in S. aureus (MRSA), vancomycin in enterococci (VRE), penicillin or vancomycin in pneumococci (VRP, PRP), extended-spectrum cephalosporins in Enterobacteriales (ESBL phenotype) and carbapenems in Enterobacteriales, Pseudomonas aeruginosa and Acinetobacter baumannii complex (CRO). Proportion of antibiotic-resistant phenotypes were compared to community-acquired CNS infection in 2009-2011.

Results: Between 2016-2019,1926 unique patient encounters in 187 centers had a positive CNS culture. Only 7 (4%) centers utilized multiplex rapid PCR testing. Mean age was 56 and 46% were males, Enterobacteriales (30%), of which E. coli (61%) predominated, followed by S. aureus (14%) and S. pneumoniae (10%) (Figure1A). Compared to 2009-11(n=878, 109 centers) there was a decrease in proportion of MRSA (p=0.001), while PRP, VRE, ESBL and CRO (p>0.50) remained stable (Figure1B) and no VRP was detected. Empiric therapy most commonly included vancomycin (80%), followed by ceftriaxone (64%), acyclovir (29%) and adjuvant dexamethasone (31%). 12.6% of patients received all three antibiotics in combination (Figure1C). Amongst patients >65 years, 23% received ampicillin.

Conclusions: Current patterns of pathogens, resistance and real-world empiric therapy suggest that opportunities exist to enhance guideline-compliant empiric prescribing practices for suspected community-acquired CNS infections. Wider implementation of reliable, rapid CNS diagnostics may increase the proportion receiving appropriate initial empiric coverage.

Increase of parenteral antibiotic use in Japan could be explained by the society aging

Ryuji Koizumi*1, Yoshiki Kusama1, Yoshiaki Gu1, Masahiro Ishikane2, Yuichi Muraki1, Daisuke Yamasaki4, Masaki Tanabe4, Norio Ohmagari2

1National Centre for Global Health and Medicine, AMR Clinical Reference Center, Tokyo, Japan, 2National Centre for Global Health and Medicine, Disease Control and Prevention Center, Tokyo, Japan, 3Kyoto Pharmaceutical University, Department of Clinical Pharmacoepidemiology, Kyoto, Japan, 4Mie University Hospital, Department of Infection Control and Prevention, Mie, Japan

Background: We reported that national antibiotic use, estimated by sales data, decreased between 2013 and 2017, while parenteral antibiotic use increased during this period. However, the reason for this increase is unknown.

Materials/methods: We obtained data from the National Database of Health Insurance Claims and Specific Health Checkups of Japan and calculated the defined daily doses [DDDs] and days of therapies [DOTs] for each parenteral antibiotic from 2013 to 2017. Antibiotics were defined as drugs classified as J01 according to the ATC/DDD classification. Antibiotics were sorted by the AWaRe classification and categorized into three age groups (<15 years, 15–64 years, and ≥65 years). All population data were obtained by the Statistics Bureau of Japan.

Results: Parenteral antibiotic use increased from 0.78 DDDs/1,000 inhabitants/day (DID) to 0.81 DID, which accounted for a 4% increase from 2013 to 2017. Throughout the study period, the highest DID was for the ≥65 years group [1.98–2.06], followed by the 15–64 years group [0.35–0.36]. DID increases were not observed in any age groups. In the ≥65 years group, DID and DOTs/1,000 inhabitants/day (DOTID) decreased by 2.03% and 10.4%, respectively. In the AWaRe classification, Access antibiotic use increased by 3.4%, while non-Access antibiotic use decreased by 3.2%. Moreover, population data showed that the population in the ≥65 years group increased by 10.2% during the study period.

Conclusions: The DID and DOTID for the ≥65 years group decreased. Given this decrease, the increase in parenteral antibiotic use was likely due to the growth in the population aged ≥65 years.

Table: Changes in parenteral antibiotic use according to age groups

Background: Therapeutic drug monitoring (TDM) of fluoroquinolones has been recommended to optimize efficacy and to reduce acquired drug resistance in the treatment of multidrug-resistant tuberculosis (MDR-TB). However, traditional TDM using liquid chromatography has not resulted in broad implementation in programmatic settings. Therefore, the aim of this study was to develop a simple, low cost, robust assay using mobile spectrophotometry to quantify levofloxacin in human saliva on site.

Materials/methods: Experiments were performed on a mobile NP80 NanoPhotometer (Implen, München, Germany) and saliva samples were collected using a salivette® (Sarstedt, Nümbrecht, Germany). Samples were filtered with a 0.22 µM syringe-driven filter from Millex (Tullagreen, Carrigtwohill, Ireland). A small drop (≥3µl) of saliva was placed on the sample surface of the nanophotometer with the use of a disposable Pasteur pipette. Derivative spectroscopy was used to increase selectivity and specificity.

Results: The levofloxacin calibration curve was linear over a range of 2.5 (lower limit of quantification [LLOQ]) to 50.0 mg/L for levofloxacin with a correlation coefficient of 0.9991. Inter-patient variance was assessed by spiking six separate blank saliva samples and ranged from 2.9% to 10.4%. The calculated accuracy ranged from -5.2% to 2.4%. Within-day precision ranged from 0.7-11.4% and between-day precision from 1.9-11.4%. Drugs frequently co-administered (analgesics, general antibiotics and anti-TB/HIV drugs) were tested for interference by spiking blank saliva at the expected maximum concentration of these drugs in saliva. Application of the Savitsky-Golay method reduced the effect of interferents on the quantitation of levofloxacin resulting in no clinically significant impact. Only a pyrazinamide peak concentration of 500mg/L caused interference of 27 ± 2.3 % with levofloxacin at LLOQ level. As for TDM of levofloxacin samples are collect at 2 and 6 hours after drug intake the level of pyrazinamide interference was found negligible (9.3 ± 0.8%).

Conclusions: A simple UV method to quantify levofloxacin in saliva has been validated. This method can be used as point of care test to detect low levofloxacin drug exposure in programmatic settings.

Abstract 4088

**Effect of short-term carbapenem restriction on the antimicrobial susceptibility of multidrug-resistant Gram-negative bacilli in an intensive care unit in Brazil**

Raquel Bandeira*, Mariana De Carvalho Melo, Braulio Couto, Giselle Dias, Luidy Cardoso, Anselmo Dornas

1Hospital Metropolitano Dr. Célio de Castro, Belo Horizonte, Brazil

**Background:** Carbapenem-resistant gram-negative bacilli (GNB) infections are a serious public health problem due to its high mortality and low number of therapeutic options. Objective: Evaluate the impact of a carbapenem restriction program on reducing bacterial resistance in an intensive care unit (ICU).

**Materials/methods:** A unicentric retrospective study conducted in two phases in the 80-bed ICU of an acute care hospital in Brazil. The pre-intervention (PE) phase lasting 16 months (Jan / 18 to April / 19) and the second phase, post-intervention (PI), lasting 4 months (May to August 2019). The intervention was defined as “carbapenem-sparing” and the use of meropenem was authorized in three situations: (1) treatment of serious infections by extended spectrum β-lactamase-producing Enterobacteriaceae (ESBL); (2) therapeutic failure with another antimicrobial; (3) infectious disease recommendation. Data collection was obtained through consultation of electronic medical records and microbiological results of patients with more than 48h in ICU and who met the criteria for healthcare-associated infection (HAI) according to the CDC definition.

**Results:** In PE, 50 cultures were obtained with positive results for multidrug resistant GNB (standard deviation – sd = 12.2) and in PI, 31 cultures (sd = 12.8; p-value = 0.010). Average carbapenem consumption decreased significantly with corresponding increase in cefepime consumption in the same period: ATB (DDD / 1000patient-day) in PE: Carbapenems = 110.6 (sd = 97.1) and Cefepime = 8.2 (sd = 5.9) and in PI: Carbapenems = 44.7 (sd = 38.5; p-value = 0.015) and Cefepime = 32.0 (sd = 20.3; p-value <0.001). In terms of multidrug resistance rate, PE x PI: Acinetobacter = 95/149 = 64% x 13/30 = 43% (p-value = 0.043); other GNB reduced the resistance rate, but without statistical significance. There was a reduction in the HAI rate per MDR-GNB, PE 22.7 (sd 5.5) X PI 16.5 (sd 7.7) p = 0.07, although not statistically significant. Nevertheless, the ICU Klebsiella infection rate showed a significant reduction: in PE = 5.5 (sd = 1.9) and PI = 2.4 (sd = 1.8), p = 0.009.

**Conclusions:** Short-term carbapenem restriction may be an effective strategy to reduce the incidence of carbapenem-resistant GNB infections in ICU.

Discriminating bacterial and viral infection using a rapid host gene expression test

Ephraim Tsalik*1,2, Ricardo Henao1,3, Jesse Montgomery4, Mert Aydin2, Emily Lydon2, Emily Ko2, Elizabeth Petzold2, Charles Cairns5,6, Seth Glickman5,7, Eugenia Quackenbush5, Stephen Kingsmore8,9, Anja Jaehne10, Emanuel Rivers10, Raymond Langley11, Vance G. Fowler2, Micah Mcclain1;2, Robert Crisp4, Geoffrey Ginsburg2, Thomas Burke2, Andrew Hemmert4, Christopher W. Woods12

1Durham VA Health Care System, Durham, United States, 2Duke University School of Medicine, Durham, United States, 3Duke University Pratt School of Engineering, Durham, United States, 4BioFire Diagnostics, LLC, Salt Lake City, United States, 5University of North Carolina Medical Center, Chapel Hill, United States, 6Drexel University College of Medicine, Philadelphia, United States, 7Intermountain Healthcare, Pravo, United States, 8Rady Children’s Institute for Genomic Medicine, San Diego, United States, 9Lovelace Respiratory Research Institute, Albuquerque, United States, 10Henry Ford Hospital, Detroit, United States, 11University of South Alabama, Mobile, United States

Background: Host gene expression-based signatures can discriminate bacterial and viral etiologies of acute respiratory illness but have not been translated to a clinical test nor validated in clinically indeterminate and complex cases. We therefore developed and evaluated the performance of a host gene expression-based test in subjects with confirmed infection, coinfection, and indeterminate infection compared to procalcitonin.

Materials/methods: Subjects were prospectively recruited from 2006–2016 in 4 US emergency departments. Enrollment blood samples were obtained for measurement of a 45-host gene expression test using a research-use-only (RUO) BioFire® test. The reference standard was an expert panel clinical adjudication, which was blind to gene expression and procalcitonin results.

Results: 623 participants (mean age 46 years; 45% male) were tested: 217 bacterial, 266 viral, 104 non-infectious illness, and 36 with bacterial/viral coinfection. The test provided independent probabilities of bacterial and viral infection in 45 minutes. In the training cohort, the HR-B/V test had an average weighted accuracy of 88.3% [CI: 81.7%-92.6%] for bacterial infection and 86.1% [CI 80.1%-90.1%] for viral infection corresponding to AUC values of 93.1% [CI 88.6%-96.1%] and 91.1% [CI 85.7%-94.4%], respectively. An independent validation cohort had similar performance with an average weighted accuracy of 85.6% [CI 70.7%-91.2%] for bacterial infection and 86.1% [CI 78.3%-91.5%] for viral infection with corresponding AUC values of 91.7% [CI 83.6%-96.4%] and 91.3% [CI 85.2%-95.4%], respectively. Among all subjects with respiratory bacterial infections, the test had 92.0% positive percent agreement (PPA) [CI 80.8%-97.8%], 82.4% negative percent agreement (NPA) [CI 77.3%-86.9%], 5.24 LR+ [CI 3.98-6.90], and 0.10 LR- [CI 0.04-0.25]. For viral infections, the test had 86.9% PPA [CI 81.1%-91.4%], 92.4% NPA [CI 86.1%-96.5%], 11.5 LR+ [CI 6.11-21.6], and 0.14 LR- [CI 0.10-0.21]. By comparison, procalcitonin distinguished bacterial from non-bacterial etiologies with 77% overall accuracy [CI 72.7%-81.0%] and 82.0% AUC [CI 73.9%-88.1%] but was inherently unable to discriminate viral from non-infectious etiologies.

Conclusions: Host gene expression, as measured on the BioFire System, rapidly and accurately diagnosed bacterial infection, viral infection, co-infection, or no infection. This test offers a new strategy to mitigate inappropriate antibiotic use through rapid and accurate discrimination of bacterial and viral infection.

**Abstract 4091**

**Shared hospital epidemiology of respiratory viruses: a 3-year analysis using multiplex PCR in a university hospital**

Audrey Valdes1,2, Benoit Visseaux*3,4, Donia Bouzid4,5, Nadhira Fidouh3, Diane Descamps3,4, Damien Van-Gysel6, Floriane Lenne2, Valérie Goldstein2,4, Jean-Christophe Lucet2,4

**Background:** Apart from a few high-risk wards, patients with other respiratory virus (RV) than influenza and RSV, are not systematically placed into droplet precautions. Our purpose was to retrospectively describe nosocomial infections associated to several RV.

**Materials/methods:** All respiratory samples from adult patients admitted for more than 24h and tested by multiplex PCR (mPCR) in a 900-bed university hospital for 3 winter periods from 2015 to 2018 were included. Detected viruses were adenovirus, coronavirus, metapneumovirus, influenza, parainfluenza, picornavirus (enterovirus and rhinovirus) and RSV. In the absence of well-defined incubation time for several viruses, infections were arbitrarily considered community-acquired, undetermined, or hospital-acquired if at least one virus was identified before 72 h, between 72 h and 96 h or over 96 h after hospital admission, respectively.

**Results:** Of 6335 samples, 1937 (30.6%) were positive, corresponding to 1604 single stays (only the first positive sample was included), with influenza accounting for 44% of cases: 1281 community-acquired (79.9%), 70 indeterminate (4.3%) and 253 hospital-acquired (15.8%) infections (Table). The viral distribution did not significantly vary across years (p=0.26), nor between community and hospital-acquired infection groups (p=0.09). Mortality among patients with hospital-acquired infection was higher than in community-acquired infection (9.5% vs 5.5%, p=0.02). The positivity rate among hospital-acquired cases varied by specialty (p=0.01) and was correlated with the proportion of double-occupancy rooms in each clinical ward (OR, 1.22; 95%CI, 1.03-5.56; p=0.03).

**Conclusions:** With the limit of a retrospective global analysis not based on systematic sampling in case of suggestive symptoms, all RV were responsible for hospital-acquired infection, with significant variations across wards and a correlation with the proportion of double-occupancy rooms. The unadjusted proportion of death was higher among hospital-acquired cases and higher for non-influenzae viruses. In view of frequency and associated death rates, droplet precautions should be discussed more widely, regardless of the virus responsible for respiratory tract infection and across all clinical wards.

Influenza vaccine in chronic obstructive pulmonary disease

Yinong Young-Xu1, Jeremy Smith*,1, Nabin Neupane1, Salaheddin Mahmud2, Ellyn Russo1, Rob Van Aalst1, Edward Thommes1, Jason Lee1, Ayman Chit1

1VA Medical Center, White River Junction, United States, 2University of Manitoba, Winnipeg, Canada, 3Sanofi Pasteur, Swiftwater, United States

Abstract third-party references: Sanofi Pasteur

**Background:** Prior studies have established that elderly patients with chronic obstructive pulmonary disease (COPD) are at elevated risk for developing influenza-associated complications such as hospitalization, intensive-care admission, and death. This study sought to determine whether influenza vaccination could reduce mortality among elderly patients with COPD.

**Materials/methods:** This study included Veterans (age ≥ 65 years) who received care at the United States Veterans Health Administration (VHA) during the 2014-2015 influenza season. The predominant A(H3N2) viruses, which are associated with higher rates of influenza-associated hospitalizations among the elderly, seem to have contributed to the highest recorded rate of laboratory-confirmed, influenza-associated hospitalizations. We linked VHA electronic medical records and Medicare administrative files to Centers for Disease Control and Prevention National Death Index cause of death records. A multivariable Cox proportional hazards model was performed on propensity score matched recipients of influenza vaccination to those who did not receive influenza vaccination. We estimated hazard ratios (HRs) adjusted for vaccination time and location, age, gender, race, socioeconomic status, as well as clinical characteristics such as comorbidity, medication use (bronchodilator, steroids), smoking, oxygen therapy, and pulmonary function.

**Results:** We identified 91,509 (70.3%) COPD patients without a record of influenza vaccination and 38,539 (29.7%) COPD patients with a record of influenza vaccination. Influenza vaccination was associated with reduced risk of death: 25% all-cause (HR=0.75; 95% CI: 0.64-0.86), 51% respiratory causes (HR=0.49; 95% CI: 0.47-0.51), and 57% COPD cause (HR=0.43; 95% CI: 0.40-0.45). We identified patients with severe to very severe COPD using the Global Initiative for Chronic Obstructive Lung Disease (GOLD) criteria for COPD severity, and found that influenza vaccination was associated with a greater reduction in risk of cause-specific COPD deaths compared to the overall COPD study population: 70% (HR=0.30; 95% CI: 0.11-0.79).

**Conclusions:** Among patients with COPD, influenza vaccination was associated with reduced risk for all-cause and cause-specific mortality.

This abstract is about identifying Rhodotorula mucilaginosa, an opportunistic yeast, in China from August 2010 to July 2015. The study aimed to determine the ability of MALDI-TOF MS to identify R. mucilaginosa and to understand antifungal agents susceptibility, ability of biofilm formation and phylogenetic situation of these isolates.

**Background:** Rhodotorula mucilaginosa is a rare opportunistic yeast. It often infects immunocompromised persons and most infections have been associated with intravenous catheters. In China, relatively little is known of identification of R. mucilaginosa and of its antifungal susceptibility patterns and ability of biofilm formation. In the present study, we sought to examine ability of MALDI-TOF MS to identify R. mucilaginosa and to understand antifungal agents susceptibility, ability of biofilm formation and phylogenetic situation of these isolates.

**Materials/methods:** Here we studied 50 non-duplicate R. mucilaginosa isolates from 50 patients at 18 hospitals participating in the National China Hospital Invasive Fungal Surveillance Net program (CHIF-NET; 2011-2017). Molecular rDNA ITS sequencing and matrix-assisted laser desorption ionization-time of flight (MALDI-TOF) MS identification methods were compared for their performance in species identification. Antifungal susceptibility testing was performed using Sensititre YeastOne™ YO10 methodology. The biofilm formation assay was carried out by crystal violet staining.

**Results:** All isolates were identified correctly by the Vitek MALDI-TOF MS system (bioMérieux) and the Clin-TOF MS system (Bioyong Technology Company Inc). The Bruker MS system (Bruker Daltoniks) also correctly identified all R. mucilaginosa isolates but using a lowered (≥1.700) cut-off score for species assignment. MICs of ≥256µg/mL for fluconazole were seen for all 50 isolates, whilst MICs of ≥4 µg/mL for voriconazole, ≥4 µg/mL for itraconazole and ≥2 µg/mL for posaconazole were seen for 74.0, 12.0, and 88.0% of isolates, respectively. All sequences can be divided into 4 ITS types compared to the reference sequence NR_073296.1 from R. mucilaginosa CBS316. Differences of biofilm quantification between 50 isolates were significant (0.75±0.24, 0.41±0.07, 0.19±0.07, P<0.001) with three classification.

**Conclusions:** The study has provided a global picture of the identification, antifungal susceptibility profile, phylogenetic situation and ability of biofilm formation of R. mucilaginosa in China during the period of the study.

Abstract 4095

Multidisciplinary engagement improves monitoring of Outpatient Parenteral Antimicrobial Therapy (OPAT) in solid tumour patients at a comprehensive cancer centre

Alison Robins*,1, Natalie Dailey Garnes1, Patrick McDaneld2, Meagan Rowan1, Jalen Bartek2

1Baylor College of Medicine, Houston, United States, 2The University of Texas MD Anderson Cancer Center, Houston, United States

Background: OPAT, in place since the 1970’s, improves patient quality of life, allowing for shorter hospital stays and earlier return to normal routine. Unfortunately, up to one in five patients discharged on OPAT are readmitted, but laboratory monitoring and hospital follow up within 2 weeks of discharge have been shown to reduce hospital readmissions. Whether the benefits of OPAT apply to patients undergoing antineoplastic therapy remains unclear. We aimed to improve laboratory monitoring and follow up in Infectious Disease (ID) clinic in solid tumor patients who were discharged on OPAT, per ID consultant recommendations, from a comprehensive cancer center.

Materials/methods: We previously used fishbone analysis and process mapping to analyze barriers to patients’ completing laboratory monitoring and following up in ID clinic. We used the Plan-Do-Study-Act methodology to initiate and analyze our interventions. Our initial intervention targeted clarification of ID physician recommendations through a standardized note. We invited case management to join our interdisciplinary OPAT team. During our next intervention, we asked teams to copy our standardized note into case management consult orders.

Results: After our initial intervention, we noted more complete recommendations for follow up and labs. Our ID clinic follow up rate improved from 44% to 72%. Recommendations for laboratory monitoring by ID providers increased from 43% to 90%, but the rate of completion of all recommended laboratory monitoring only increased from 33% to 45%. The percentage of patients without any lab monitoring declined from 25% to 17%. Although 50% of patients did not complete all recommended labs, OPAT-infection related readmission rates declined from 18.5 to 12.5 readmissions per 1000 OPAT-days. Infection-related emergency center visits remained stable during the study period.

Conclusions: Although our initial rates of follow up and laboratory monitoring rates according to OPAT guidelines were low, we were able to achieve improvement by using a simple intervention. Although a high percentage of our patients are still not completing recommended laboratory monitoring recommendations, we were able to achieve further improvements by engaging additional stakeholders. This improved laboratory monitoring helped achieve reductions in OPAT-infection related readmissions, similar to what has been reported in the general patient population.

Abstract 4096

**Factors associated with in-hospital mortality in hospitalised patients with HIV/AIDS**

Julián Andres Hoyos Pulgarin*, Alexander Alzate1, Omar Fernando Bolaños1, Jose William Martinez1

1Universidad Tecnológica de Pereira, Pereira, Colombia

**Background:** HIV infection continues to be a public health problem and the coffee triangle in Colombia has a higher incidence and prevalence vs. other areas of the country. The objective of the study was to evaluate the factors associated with mortality in hospitalized patients diagnosed with HIV in two, third-level hospital centers of the coffee triangle in Colombia.

**Materials/methods:** Descriptive study of non-concurrent cohort. Patients older than 18 years, with old or new diagnosis of HIV who entered between 2016 and 2018 were included. 180 variables grouped in sociodemographic, clinical, laboratory and death causes were defined. A univariate, bivariate and multivariate analysis was performed. The primary outcome was death as a function of time.

**Results:** 349 patients were included, male gender 71.8%, median age of 35 years, 72.6% in antiretroviral therapy, of these, 41% had adherence to treatment. 71.6% presented some defining condition of AIDS at hospital admission, tuberculosis [35.07%], pneumonia [16.3%], bacterial infections [13.7%], disseminated histoplasmosis [11.8%], wasting syndrome [10.49%], esophageal candidiasis [9.5%] and cerebral toxoplasmosis [9.18%]. Median CD4 103 cells/mL. The variables with the highest association to mortality were: enter due to respiratory symptoms (HR 2.62 IC95: 1.48-4.62), neurological symptoms (HR 4.7 1 IC95: 2.52-8.80), presence of seizures (HR 4.0 IC95: 1.67-9.6), have dementia from any cause or associated with HIV (HR 11.9 IC95: 3.92-36.3), elevation of AST upon admission (HR 1 IC95: 0.99- 1), Charlson comorbidity index of 6 or more points (HR 1.19 IC95: 1.06- 1.33) and orotracheal intubation (HR 3.46 IC95: 2.02-5.9). The variables that presented the greatest statistical weight when adjusted for the other variables were dementia of any cause and associated with HIV with a HR of 14.27 [p = 0.001].

**Conclusions:** The patients that were included in the present study present a high percentage of advanced disease due to their low CD4 count and high percentage in defining AIDS conditions. Factors that increase the risk of in-hospital mortality were identified, which can guide models of care and clinical strategies to identify early hospital admission, patients at high risk of death and be able to perform interventions aimed at reducing such risk.

Abstract 4099

The type of agar may affect the string test result and virulence gene detection of hyper-mucoviscous Klebsiella pneumoniae

Kenta Furusawa*, Kazue Fujita, Misato Gorai-Nishimura, Wataru Aoki, Yoko Mano, Takahiro Suzuki, Yoshibumi Akatsu, Yoshinobu Saito, Masahiro Seike, Akihiko Gemma, Nobuhiko Furuya

1Bunkyo Gakuin University Graduate School, Bunkyo City, Japan, 2Nippon Medical School, Bunkyo City, Japan, 3Hitachi, Ltd. Hitachi General Hospital, Hitachi, Japan, 4Keio University, Minato City, Japan, 5Bunkyo Gakuin University, Bunkyo City, Japan

Background: Hypermucoviscosity (HM) phenotype is a known virulent factor of Klebsiella pneumoniae. The string test to detect HM phenotype originally measured on 5% sheep blood agar after incubation at 37 °C overnight. However, the string test often performs different method previously described in the clinical settings. Therefore, we investigated the factors affecting the string test for the detection of HM Klebsiella pneumoniae (HMKP).

Materials/methods: A total of 48 K. pneumoniae isolates were used in this study. The string test was performed using 4 types of agar, including 5% sheep blood, Bromo Thymol Blue (BTB), MacConkey and Luria-Bertani (LB). A positive string test was defined as the formation of viscous strings of >5 mm in length. In addition, we assessed virulence factors associated with hypermucoviscosity by PCR, including capsular serotype (K1 and K2) and molecular genes (rmpA, magA, mrkD, wabG, uge, kfu, alls, fimH and cfa2a).

Results: Among the 48 KP isolates, 15 (31%) had the HM phenotype on blood agar. Ten (67%) on BTB, 11 (73%) on MacConkey and 1 (7%) on LB agar were negative string test among 15 HMKP on blood agar. The positive rates of K1 and K2 of HMKP were higher than those of non-HMKP on blood agar [13 and 13%, 8 and 3%, respectively]. Within HMKP on blood agar, the positive rate of K1 on BTB and K2 on MacConkey agar were same as those of blood agar. In contrast, there were no isolates with K1 on MacConkey and K2 on BTB agar. Although the positive rates of all tested genes except for magA and alls among all HMKP on all tested agar were almost same, magA and alls on MacConkey agar were not detected among all HMKP.

Conclusions: This study demonstrates that the type of agar affects the result of the string test of HMKP. Furthermore, the type of agar also affects virulence gene detection of HMKP. The string test using BTB and MacConkey agar may be overlooked the existence of HMKP. This study suggests that type of agar should be considered prior to the string test for reliable detection of HMKP.

**Abstract 4100**

**Metagenomic insights into the dynamics and transmission of resistance genes in poultry and human beings**

Qixia Luo*, Hao Fu¹, Yonghong Xiao²

¹The first affiliated hospital of Zhejiang University, Hangzhou, China

**Background:** The overuse of antibiotics in poultry farming contributes to the enrichment and spread of antibiotic resistance genes (ARGs). Numerous ARGs were identified in both poultry and human beings, but few studies described the transmission of ARGs from poultry to human beings in the metagenomic aspect.

**Materials/methods:** We collected and sequenced the metagenomes of 131 fecal samples in the same area, including 65 chicken fecal (CF) samples, 33 fecal samples of people who work in poultry farms or chicken slaughterhouses (CHF) and 33 fecal samples of nearby residents who haven’t contact with poultry farming (NCHF) as control. Bioinformatic tools were used to assemble the metagenomes, analyze the ARG contents and predict the possibility of transfer of ARGs.

**Results:** We found a similar gene diversity between CF and CHF samples, while a significant difference between CHF and NCHF samples. No distinguishable differences were found in the ARG types in three groups, but the abundance of ARGs in the gut of people who raise or slaughter chickens was significant higher than ARGs of chicken gut, followed by the control group. Fifteen ARG types were found present in all 131 samples. Quinolones and tetracycline resistance genes were the two most prevalence ARG types in both chicken and human guts. Moreover, we predict the transmission possibility of ARGs by identify if the ARG contigs were in plasmids and the integrated conjugative elements (ICEs) in ARG contigs. The results showed that the ratio of ARG contigs in plasmids and ICEs from chicken gut was significantly higher than those from human gut.

**Conclusions:** We described a higher risk of transmission of ARGs in chicken gut microbiome than human gut microbiome, and demonstrated that the gut microbiome of people who contact with poultry farming is a repository of ARGs and shares gene diversity of poultry gut microbiome.

Diversity of the gut microbiome before haematopoietic cell transplantation is an independent predictor of respiratory failure and sepsis requiring intensive care in the post-transplant period

Fatima Adhi1, Eric Littmann2, Eric Pamer1, Jonathan Feled3

1Respiratory Institute, Cleveland Clinic, Cleveland, United States; 2Duchossois Family Institute, University of Chicago, Chicago, United States; 3Adult Bone Marrow Transplant Service, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Diversity and composition of the gut microbiome of allogeneic hematopoietic cell transplant (allo-HCT) recipients is associated with poor overall survival, infections, disease relapse and graft-versus-host-disease (GVHD) post-HCT. Critical illness (CI) post-HCT has high short-term mortality rates. We hypothesized that pre-HCT fecal microbiome characteristics predict development of CI post-HCT.

Methods: We analyzed fecal samples from 828 adults who received their first allo-HCT from 2009 to 2017 at a single institution, collected within 10 days prior to cell infusion. The V4-V5 regions of 16S rRNA genes of DNA extracted from fecal samples were amplified and annotated taxonomically. Patients were heterogeneous with respect to transplant indication, conditioning intensity, graft source and manipulation. We analyzed time to intensive care unit (ICU) admission using survival-analysis methods.

Results: 75 patients (9%) were admitted to the ICU between the day of cell infusion (day 0) and day +50. The most common indications for ICU admission (ICUa) were respiratory failure (RF; n=52, 66%) and sepsis/septic shock (Sp/Ss; n=24, 27%). Patients were stratified based on pre-HCT fecal microbial diversity into high (inverse Simpson index ≥4) and low (<4) groups, following a previously published cutoff. Patients with low diversity pre-HCT had a strikingly higher risk of CI from RF and/or Sp/Ss than those with high diversity (HR 2.49 [95% CI 1.45-4.28], p=0.001; figure). This association remained significant in a multivariate Cox proportional hazard model (HR 2.17 [95% CI 1.24-3.76], p=0.007) that accounted for conditioning intensity, graft source, graft manipulation, and hematopoietic cell transplantation-specific comorbidity index (HCT-CI). Higher HCT-CI was also an independent predictor of ICUa for RF and/or Sp/Ss. All other ICUa indications including hemorrhage, anaphylaxis and isolated non-inflammatory dysfunctions of the cardiac, renal or neurological systems were deemed unlikely to be affected by, and did not correlate with, pre-transplant gut microbial diversity.

Conclusions: Pre-transplant fecal microbial diversity is an independent predictor of CI from RF and/or Sp/Ss requiring intensive care in the post-HCT period. These observations highlight the pre-HCT period as a window of opportunity to assess gut microbial injury; to inform antibiotic and GVHD prophylaxis, gut-decontamination, conditioning regimens; and to intervene with remedia- tion or prevention strategies.

Pre-transplant fecal microbial diversity predicts critical illness from respiratory failure and/or sepsis/septic shock after allo-HCT

Highly sensitive and specific detection and serotyping of five prevalent *Salmonella* serovars by multiple cross displacement amplification

Xiaomei Zhang*, Michael Payne, Qinning Wang, Vitali Sintchenko, Ruiting Lan

1UNSW Sydney, School of Biotechnology and Biomolecular Sciences, Sydney, Australia; 2UNSW Sydney, School of Biotechnology and Biomolecular Sciences, Sydney, Australia; 3NSW Health Pathology, Institute of Clinical Pathology and Medical Research, Sydney, Australia; 4The University of Sydney, New South Wales, Sydney, Australia

**Background:** *Salmonella* is a common cause of foodborne illness worldwide and in Australia. Over 70% of notifications of human salmonellosis in Australia are caused by five *Salmonella* serovars: Typhimurium, Enteritidis, Virchow, Saintpaul, and Infantis. Rapid, accurate and sensitive detection and identification of *Salmonella* serovars is vital for diagnosis and surveillance. Recently, an isothermal amplification technique termed Multiple Cross Displacement Amplification (MCDA) has been employed to detect *Salmonella* at the species level but not to the serovar level. We utilised seven serovar/lineage-specific gene markers for the five common Australian serovars identified through genomic comparisons from our previous study (two serovars had two lineages). An MCDA assay for each of these markers was developed and evaluated.

**Materials/methods:** Seven gene markers STM4494, SEN1384/R561 RS18155, SESV_RS06060, SeSPB_A1 7 49/SeSPA_A1 352 and L287_11 788, which were specific to the five most common *Salmonella* serovars in Australia: Typhimurium, Enteritidis, Virchow, Saintpaul, and Infantis respectively, were selected as targets. Seven MCDA primers sets were designed using Primer3 online software. The limit of detection (LoD) of the seven MCDA assays was performed on serially diluted genomic DNA template from target strains. The sensitivity and specificity of the seven MCDA assays were evaluated using 79 target strains and 32 non-target strains. Real-time fluorescence measurement was used to detect the seven MCDA products.

**Results:** The seven MCDA assays successfully amplified target gene markers from the five most common *Salmonella* serovars in Australia. The LoD of seven MCDA assays was 50 fg per reaction (10 copies of target DNA) from pure culture. Sensitivity ranged from 92.3% to 100% and specificity ranged from 93.3% to 100%. The MCDA assays can also provide test results from a minimum of 8 minutes at 5 ng concentration to a maximum of 20 minutes at 50 fg concentration.

**Conclusions:** We developed and evaluated seven rapid, accurate and sensitive MCDA assays for detection and differentiation of the five most common *Salmonella* serovars in Australia: Typhimurium, Enteritidis, Virchow, Saintpaul, and Infantis. With further validation in clinically relevant conditions these assays could be used for culture-independent serotyping of common *Salmonella* serovars directly from clinical samples.

Abstract 4109

Outcomes of a pharmacist-led antimicrobial stewardship programme within a family medicine resident clinic
Lisa Dumkow*, Lindsey Westerhof, Tarajo Hanrahan, Samantha Mcpharlin, Nnaemeka Egwuatu

1Mercy Health Saint Mary’s, Grand Rapids, United States

Background: Antimicrobial stewardship programs (ASP) are crucial to guiding antimicrobial prescribing. While infectious diseases-trained physicians and pharmacists typically lead inpatient ASP initiatives, the majority of antibiotics are prescribed in outpatient settings where ASP resources may be limited. Ambulatory care pharmacists (ACP) within primary care offices may serve as important ASP extenders to lead outpatient initiatives. The purpose of this study was to determine if an ACP-led ASP intervention combining baseline education with audit-with-feedback improved antibiotic prescribing in a family medicine residency clinic (FMRC) for common infections, including upper respiratory tract (URI), urinary tract (UTI), and skin and soft tissue (SSTI) infections.

Materials/methods: This quasi-experimental study compared antibiotic prescribing 6-months before (Pre-ASP group) and after (ASP group) implementation of an ACP-led audit-and-feedback process in a single FMRC. In September 2018, the health-system ASP physician and pharmacist provided live education, including review of baseline prescribing data, local resistance trends, and where to locate online institutional guideline recommendations. FMRC staff were additionally provided with pocket cards as a quick reference containing guideline recommendations. Audit-with-feedback was delivered electronically, bi-weekly for all URI, UTI, and SSTI prescriptions by the clinic’s ACP from October 2018 through March 2019. The primary endpoint of the study was total guideline-concordant antibiotic prescribing (drug, dose, and duration of therapy). Guideline-concordance was determined based on the health system’s local outpatient ASP guidelines.

Results: 514 antibiotic prescriptions were audited (pre-ASP n=79, ASP n=435). Total guideline-concordant antibiotic prescribing at baseline was 39.2% (URI 46.7%, SSTI 26.7%, UTI 47.4%). During the 6-month intervention period, 435 antibiotic prescriptions were audited (URI 183, SSTI 125, UTI 127) with all prescriptions receiving feedback from the ACP. Total guideline-concordant prescribing improved across all three infection types to 57.9% (URI 59.6%, SSTI 49.6%, UTI 63.8%, p=0.002). Significant improvements were seen in guideline-concordant antibiotic selection (68.4% vs. 80.2%, p=0.018), dose (73.4% vs. 86.2%, p=0.004), and duration of therapy (75.9% vs. 86.2%, p=0.02).

Conclusions: A pharmacist-led audit-and-feedback process within a FMRC significantly improved guideline-concordant antibiotic prescribing for the most common infectious disease states.

Rifampicin reduces tedizolid concentrations in healthy volunteers
Soon U Lawrence Lee*, Daryl Hee

1National University of Singapore, Singapore, Singapore, 2Tan Tock Seng Hospital, Singapore, Singapore

Abstract 4112

Background: Tedizolid is an oxazolidinone which is currently approved to treat skin and soft tissue infections. Rifampicin is a rifamycin antibiotic which can also treat skin and soft tissue infections such as those caused by Staphylococcus aureus. In addition, rifampicin is used to treat tuberculosis and we are investigating tedizolid for the same indication. Tedizolid and rifampicin could therefore be used concurrently to treat infections. There is currently no clinical data on whether rifampicin affects tedizolid concentrations. Rifampicin is known to be an inducer of cytochrome P450s. Tedizolid is not known to be cleared by cytochrome P450s, but other clearance mechanisms may be affected. Therefore we conducted a pharmacokinetic drug-drug interaction study to investigate whether 2 weeks of rifampicin can affect tedizolid concentrations.

Materials/methods: We conducted a healthy volunteer study in 8 subjects. Subjects were first given linezolid 600 mg on day 1, tedizolid 200 mg on day 4, rifampicin 600 mg daily from days 5 to 19 (2 weeks of rifampicin), and an additional dose of tedizolid 200 mg on day 19. Blood was obtained at pre-dose, 1, 2, 3, 4, 5, 6, 8 and 24 hours post dose on days 4 and 19. Concentrations of tedizolid were measured using a validated liquid chromatography / mass spectrometry method. Pharmacokinetic parameters were calculated by Non-Compartmental Analyses using Phoenix WinNonLin version 8.0. The bioequivalence module was used to obtain ratios of PK parameters pre- and post-rifampicin.

Results: Eight patients were included in the study. 6 were Chinese, 1 Indian and 1 Burmese. Median age [range] and weight were 34.5 (29-44) years and 64 (58.4-90.8) kg respectively. Tedizolid was well tolerated in the study. Tedizolid AUC (0-24 hours) was reduced after 2 weeks of rifampicin (GMR 0.80, 90% confidence interval 0.73-0.88), as was Cmin (0.54, 0.44-0.66) and Cmax (0.85, 0.79-0.91). Clearance / F of tedizolid was significantly increased after rifampicin (1.35, 1.21-1.50).

Conclusions: Rifampicin given for 2 weeks has the potential to reduce tedizolid concentrations, especially trough levels, which was reduced by 46%. Caution is recommended when using tedizolid together with rifampicin, especially when tedizolid MIC is high or treating difficult infections.

Abstract 4115

**Treatment patterns and healthcare resource use among hospitalised adults with carbapenem non-susceptible Gram-negative infections in a large US electronic health record database**

Ryan Dillon¹, Tanya Burton², Amy Anderson³, Jerry Seare⁴, Eilish Mccann*¹

¹Merck & Co., Inc., Kenilworth, United States, ²Optum, Boston, United States, ³Optum, Eden Prairie, United States, ⁴Optum, St. George, United States

**Background:** Carbapenem non-susceptible (C-NS) Gram-negative (GN) infections are difficult to treat and can be life-threatening. Limited data exist on healthcare resource use (HCRU) associated with these infections.

**Materials/methods:** Retrospective cohort study of hospitalized adults with complicated intra-abdominal infection (cIAI), complicated urinary tract infection (cUTI), bacterial pneumonia (BP), or bacteremia (BAC) attributable to GN C-NS (resistant/intermediate susceptibility to carbapenems) bacteria from January 2013-March 2018. Treatment patterns and HCRU were examined 6 months prior to the first qualifying hospitalization (pre-admission) through 12 months post-discharge, or fewer if due to death.

**Results:** 2,862 patients were included (mean age: 63.2 years, male: 55.6%). Patients had cUTI ±BAC (38.4%), BP ±BAC (21.5%), cUTI +BP ±BAC (18.7%), any cIAI (14.7%), or BAC only (6.7%). Pseudomonas was the most common pathogen (65.4%). Renal insufficiency was observed in 47.8% of patients. During index hospitalization, 83.6% received an antibiotic (74.3% combination therapy, median antibiotic classes: 2, maximum: 7). Of those given antibiotics, 38.9% received a carbapenem despite C-NS status (86.5% empiric, 13.5% post-susceptibility result confirming C-NS); 9.0% received polymyxins. Median length of stay was 12.0 days; 49.6% of patients were admitted to intensive care (median duration: 2.0 days) and 36.1% underwent mechanical ventilation (median duration: 8.0 days). Prior to admission, between one-third and two-thirds of patients had a bacterial infection in the same site as their qualifying index infection, 60.2% had inpatient visits, 46.4% received antibiotics, and 35.8% had renal insufficiency. Of those treated with a carbapenem during their index hospitalization, 27.5% also received a carbapenem pre-admission. During post-discharge, 63.9% of patients were re-hospitalized (44.3% within 30 days post-discharge, median time to first readmission: 37.0 days) and 27.7% died within 12 months post-discharge (median time to death: 82.5 days post-discharge).

**Conclusions:** Patients with C-NS infections had high levels of comorbidity and pre-admission antibiotic exposure, often received carbapenem treatment despite having non-susceptible infections, and exhibited poor outcomes in terms of high resource use and post-discharge mortality/readmission. Such patients may benefit from novel efficacious agents to which C-NS bacteria are susceptible. High levels of renal insufficiency were observed in this population, indicating a need for newer therapies with improved toxicity profiles.

Abstract 4116

Progressive disseminated histoplasmosis in a population with HIV/AIDS in the Colombian coffee triangle

Julián Andres Hoyos Pulgarín*, Alexander Alzate1, Germán Moreno1, Juan Felipe Sierra1, Andres Felipe Jaramillo Torres1

1Universidad Tecnológica de Pereira, Pereira, Colombia

Background: Histoplasmosis is an endemic mycosis considered worldwide as an orphan disease, which has a very variable clinical presentation and usually is disseminated in the population with HIV/AIDS. The objective of the study is determining the signs and symptoms associated with the definitive diagnosis of disseminated histoplasmosis and mortality associated variables.

Materials/methods: Retrospective cohort study that included patients diagnosed with HIV/AIDS and suspicion of disseminated histoplasmosis in a population attended in a reference hospital in a city in Colombia's coffee triangle, between January 2015 to April 2019. Clinical and laboratory variables were taken and univariate, bivariate and multivariate analyzes were performed to determine the characteristics associated with the diagnosis of disseminated histoplasmosis. A survival analysis was performed.

Results: Of 173 patients with HIV and clinical suspicion of histoplasmosis who underwent urinary antigen for histoplasma, 50 had positive and 123 negative urinary antigens. 76.3% were male, 79.2% came from urban areas, 50.9% had recently diagnosed HIV. CD4 count with a median of 54 cells/mL and viral load of 280000 copies/mL. The commonest clinical manifestations were constitutional symptoms 86.7%, weight loss 81.5% and fever 75.1%. Anemia was present in 90.8%, and lymphopenia 82.7%. Others infections were present in 65.9%, tuberculosis in 46.2%.

The conditions associated with the diagnosis of disseminated histoplasmosis in the bivariate analysis (p <0.05) were: leukopenia, thrombocytopenia, ferritin elevation, low CD4 count, AST and ALT elevation and pancytopenia; and in the multivariate analysis were: elevation of alkaline phosphatase, lactic dehydrogenase and CD4 count less than 50 cells/mL (OR 4.7 IC95% 1.4-15). 24.9% died in the hospital. The variables associated with mortality in all patients were: elderly (OR 3.9 IC95% 1.3-11.4), dyspnea (OR 4.4 IC95% 1.4-13.2), and ferritin greater than one thousand (OR 4.5 IC95% 1.3-15.7).

Conclusions: The behavior of histoplasmosis in our population establishes some differences with the reported in studies from other regions, such as less skin involvement and lymphadenopathy, but with greater hematological manifestations. The adequate analysis of these clinical and laboratory findings can facilitate decision-making to suspect the presence of disseminated histoplasmosis in patients with HIV/AIDS in our region.

Abstract 4118

Global dissemination of multidrug-resistant *Escherichia coli* co-expressing ESBL/pAmpC and mcr-1 genes in chicken farms in Lebanon

Myriam Mikhael*1,2; Sébastien Leclercq2, Benoit Doublet2, Dolla Karam Sarkis1

1Université Saint Joseph de Beyrouth, Laboratoire de microbiologie, Faculté de Pharmacie, Beirut, Lebanon, 2Université de Tours, UMR 1282, Infectiologie et santé publique, INRA, Nouzilly, France

Abstract third-party references: Université Saint Joseph de Beyrouth, Institut National de la Recherche Agronomique (INRA), Centre Val de Loire, France

**Background:** Poultry production is a main contributor of the global trend of antimicrobial resistance arising from food-producing animals worldwide. In Lebanon, abusive and inappropriate use of antibiotics is frequent in chickens for prophylactic reasons and to increase productivity. In absence of a surveillance system, the present objective is to decipher the spread of expanded-spectrum cephalosporin (ESC)-resistant *Escherichia coli* in poultry in Lebanon.

**Materials/methods:** Rectal swabs *(n=280 healthy chickens)* from 56 farms across the country were screened for the presence of ESC-resistant *E. coli* isolates. Antimicrobial susceptibility and expanded-spectrum β-lactamase (ESBL)/AmpC production were determined by the disk-diffusion method. Whole genome sequencing of a set of representative isolates *(n=221)* was performed to determine the phylogenetic diversity, acquired resistance genes and plasmids using the CGE tools suite.

**Results:** From 56 poultry farms, 51 harboured ESC-resistant *E. coli*. Nearly all ESC-resistant *E. coli* isolates were multidrug-resistant with frequent additional resistance to fluoroquinolones and aminoglycosides. Among the 221 sequenced *E. coli* isolates, the proportion of ESBL, pAmpC-producers and ESBL/pAmpC co-producers were 56%, 24%, and 20%, respectively. The most prevalent ESBL genes were *bla*$_{CTX-M-3}$, *bla*$_{CTX-M-15}$, *bla*$_{CTX-M-55}$, *bla*$_{CTX-M-27}$ (n=79; 40; 24; 21, respectively). Surprisingly, only one isolate harboured the *bla*$_{CTX-M-1}$ gene usually associated with livestock production. The pAmpC cephalosporinase gene *bla*$_{CMY-2}$ was dominant (n=91/91). The dramatic proportion of fluoroquinolone-resistant *E. coli* isolates co-expressing ESBL and/or AmpC genes and the mobile colistin resistance gene mcr-1 (n=54) is especially worrisome. These ESC-resistant isolates belonged to a great diversity of sequence-types, most being well-known avian-associated (ST-117, ST-10, ST-48 and ST-93), and sometimes pathogenic. Numerous different plasmids were identified suggesting their roles in the spread of these resistance genes in the *E. coli* population.

**Conclusions:** For the first time, this study illustrates the alarming prevalence of multidrug-resistant *E. coli*, especially to medically-important antibiotics, in broiler production in Lebanon. Further molecular studies are needed to understand the country-specific epidemiology of ESBL/AmpC and mcr-1 genes in the Lebanese poultry production. Our results also advocate the urge for surveillance programs and action plans in Lebanon to reduce the abusive use of antibiotics and to limit the spread of multidrug-resistance in food-producing animals.

Long-term exposure to ceftriaxone sodium induces alteration of gut microbiota accompanied by anxiety-like and depression-like behaviours in mice

Zhongyi Zhao*1, Linlin Zhou2, Chuanmin Tao1

1West China Hospital, Sichuan University, Chengdu, China, 2West China School of Basic Medical Sciences & Forensic Medicine, Sichuan University, Chengdu, China

Background: According to the theory of microbiota-gut-brain (MGB) axis, disturbance of the gut microbiota may affect gut-brain communication, influencing the development of brain and altering host behaviors. However, the extent to which alterations in microbiota composition and function mediate the dysregulation of the axis is unknown. Thereby we assess the effects of gut bacteria depletion on emotional behaviors and attempt to explore relevant mechanisms.

Materials/methods: Mouse in experimental group was given ceftriaxone sodium solution [250mg/ml, 0.2ml/d] and control group was given pyrogen-free saline (0.2ml/d) by gavage. Emotional behaviors were assessed by the open field test and the suspension tail test. Fecal samples were collected for 16s rRNA sequencing. Serum cytokines and corticosterone were measured by ELISA. Brain derived neurotrophic factor (BDNF) and c-Fos proteins were determined by immunohistochemistry.

Results: Eleven weeks later, we found that ceftriaxone administration led to decreased richness and diversity of gut microbiota and observed characteristic microbiota. This was accompanied by behavioral abnormalities in mice, including anxiety-like, depression-like and aggressive behaviors simultaneously. Thus, we presumed there may be an association between the above results. Next we found that pathways related to the MGB axis altered, including the activation of immune system [such as increased IL-6 and IL-10], the hyperactivity of hypothalamic-pituitary-adrenal (HPA) axis [such as elevated corticosterone] and neurochemical changes [such as down-regulated trend of BDNF and up-regulated trend c-Fos].

Conclusions: The findings highlight the important role of microbiota in the gut-brain communication and suggest the absence of conventional gut microbiota influence the development of behavior and function of the brain.

Fig.1 Heat maps of gut microbiota (a) at the phylum level and (b) at the genus level; Results of mice (c) in the suspension tail test and (d) in the open field test. *P<0.05, **P<0.01, ***P<0.001. AB: antibiotic group (n = 14), CT: control group (n = 19)

Abstract 4124

**Characterising a novel mechanism of inducible carbapenem resistance in toxigenic Corynebacterium diphtheriae**

Brian Forde*, Andrew Henderson2, Geoffrey Playford3, David L. Paterson2, Scott Beatson1

1The University of Queensland, School of Chemistry and Molecular Biosciences, Saint Lucia, Australia, 2The University of Queensland, Centre for Clinical Research, Herston, Australia, 3The University of Queensland, School of Medicine, Saint Lucia, Australia

**Background:** Diphtheria is a potentially fatal respiratory disease caused by toxigenic *Corynebacterium diphtheriae*. Although resistance to erythromycin has been recognised, β-lactam resistance in toxigenic diphtheria has not been described. Here we report a case of fatal respiratory diphtheria caused by toxigenic *C. diphtheriae* resistant [MIC ≥ 256 μg/ml] to penicillin and all other β-lactam antibiotics.

**Materials/methods:** Long-read whole genome sequencing was performed using Pacific Biosciences SMRT sequencing to determine the genome sequence of *C. diphtheriae* BQ11 and mechanism of β-lactam resistance. Meropenem sensitive isolates were grown, in parallel, with and without exposure to meropenem and sequenced on an Illumina Hi-Seq2000 sequencer. Sequence read coverage across the resistance locus was calculated and used to compare differences in tandem repeat copy number between resistant and susceptible isolates.

**Results:** On testing, BQ11 demonstrated high-level resistance to penicillin (benzylpenicillin MIC ≥ 256 μg/ml), β-lactam/β-lactamase inhibitors and cephalosporins (amoxicillin/clavulanic acid MIC ≥ 256 mg/L; ceftriaxone MIC ≥ 8 μg/mL) and carbapenems (meropenem MIC ≥ 32 mg/L). Genomic analysis of BQ11 identified acquisition of a novel transposon carrying the penicillin binding protein Pbp2c, responsible for resistance to penicillin and cephalosporins in *Corynebacterium jeikeium* K411. Remarkably we found that when strain BQ11 was exposed to meropenem, selective pressure drove expansion of the array resulting in multiple copies of the transposon and a corresponding change from a meropenem susceptible (MIC < 0.002 mg/L) to a meropenem resistant (MIC < 32 mg/L) phenotype.

**Conclusions:** Our research has identified a novel mechanism of inducible carbapenem resistance whereby isolates that appear to be carbapenem susceptible on initial testing can develop in vivo resistance to carbapenems with repeated exposure, which could have significant implications for treatment and may lead to clinical failure.

**Presenter email address:** b.forde@uq.edu.au
Abstract 4125

Assessment of antimicrobial molecules and bacteriocins isolated from Pseudomonas species for activity against multidrug-resistant bacteria

Sandra Adufa-Appeagyei1, Peter Wilson1, Shanom Ali1, Samuel Yui1

1University College Hospital, London, United Kingdom

Background: Antimicrobial treatment failures against infections caused by multi-drug resistant (MDR) organisms are increasing globally and alternative ways to treat these infections have seen a rise in research interest. Bacteriocins, antimicrobial proteins or peptide toxins produced by bacteria to kill competition of closely related species, are an alternative method to potentially treat these infections and alleviate the pressure MDR organisms poses on healthcare. Pseudomonas aeruginosa has been previously shown to secrete antimicrobial agents which inhibit other microorganisms, giving a competitive advantage within a mixed species community. In this study we evaluated P. aeruginosa strains isolated from various environmental (healthcare water) sources for antimicrobial activity against clinically relevant pathogens.

Materials/methods: Antibiotic susceptibility tests (AST) assays were performed using piperacillin-tazobactam, ceftazidime, imipenem, meropenem, aztreonam, amikacin, gentamicin, tobramycin, ciprofloxacin and piperacillin, to eliminate potential duplicate strains. A cross-streak method on an agar interface was used to determine the antimicrobial activity of 323 P. aeruginosa isolates against 10 type and clinical target isolates including: P. aeruginosa, Staphylococcus aureus, Escherichia coli, Enterococcus faecalis, Klebsiella pneumoniae. P. aeruginosa were exposed to UV radiation, low nutrient, low temperature or low-to-high temperature conditions to stress the isolates. P. aeruginosa isolates were cultured in broth to harvest the secreted molecule(s) by membrane-filtration (0.45um pore-size). Aliquots (65μL) of the filtrate were inoculated onto blank AST-discs to determine the antimicrobial activity when placed on a bacterial lawn of the target organisms.

Results: P. aeruginosa isolates (323) demonstrated secretion of antimicrobial molecules which inhibited the growth of at least one target bacteria. S. aureus (81.5% type strain, 74.2% Methicillin-resistant) and E. faecalis (32.9% type, 35.1% vancomycin-resistant) were particularly sensitive. Minimal activity was seen against K. pneumoniae strains (type, carbapenem-resistant and pan-resistant. P. aeruginosa isolates cultured under low nutrient (99) conditions showed a significant increase in activity towards carbapenem-resistant E. coli and carbapenem-resistant K. pneumoniae (p= 0.007 and 0.003 respectively).

Conclusions: Antimicrobial molecules secreted from P. aeruginosa can inhibit the growth of clinically relevant organisms. Environmental stress-induction may further enhance the inhibitory properties of P. aeruginosa strains against MDR bacteria. Antimicrobial molecules harvested from P. aeruginosa may have therapeutic clinical application.

**Candida auris** in a large healthcare system in South Florida: importance of active surveillance testing to prevent spread

Adriana Jimenez*,1,2, Kathleen Sposato1, Gemma Rosello1, Dennise De Pascale1, Javier Cardozo1, Olga Orozco1, Biagio De Pascale1, Octavio Martinez3,4, Veronica Salazar5, Kailynn Beronde5, Ana Vega5, Lilian Abbo1,6

1Jackson Health System, Infection Prevention and Control Department, Miami, United States, 2Florida International University, Robert Stempel College of Public Health and Social Work-Epidemiology Department, Miami, United States, 3Jackson Health System, Microbiology Department, Miami, United States, 4University of Miami, Miller School of Med., Pathology Department, Miami, United States, 5Jackson Health System, Pharmacy Department, Miami, United States, 6University of Miami, Miller School of Med., Division of Infectious Diseases, Miami, United States

**Background:** *Candida auris* (C. auris) is a multidrug-resistant yeast of urgent concern for public health that continues to spread globally. We describe the experience of a large healthcare system in Miami, Florida for early detection and control of *C. auris*.

**Materials/methods:** The healthcare system has two major-teaching hospitals (adult and pediatric), and two community hospitals (over 2250-licensed beds). After the first *C. auris* case was identified in the adult major-teaching hospital in May 2019, strategies were implemented in all hospitals for *C. auris* early detection and control: 1. Enhanced contact precautions and environmental disinfection with bleach-based products for the duration of admission for all confirmed cases; 2. Consecutive point-prevalence surveillance cultures (PPS) from axilla/groin in units with *C. auris* cases and in those where horizontal transmission was suspected; 3. One-time PPS in all adult ICUs; 4. Admission screening questionnaire to all patients at point of entry with screening cultures and contact precautions for those with risk factors until ruled out; 5. Referral to the Antibiotic Resistance Laboratory Network (ARLN) to confirm identification and susceptibility testing of clinical isolates reported using the VITEK 2 system. The MALDI-TOF system was updated September 2019 to allow on-site identification of *C. auris*.

**Results:** In total 753 screening cultures were collected between May – November 2019 from 620 patients. Of those, 670 swabs were PPS and 83 were admission screening cultures. In total 22 (3%) patients from two hospitals were positive in surveillance cultures. Seven (32%) were community-onset and 15 (68%) were hospital-onset (Figure) with horizontal transmission within one facility. Three (14%) patients also had *C. auris* isolated from clinical cultures: blood (2), urine (1), and sputum (1). Only two patients developed clinical infections (fungemia) and were successfully treated with micafungin for 14 days. The overall in-hospital mortality among all *C. auris* cases was 23%; moreover, these patients expired for reasons unrelated to *C. auris* infection.

**Conclusions:** *C. auris* remains uncommon in Miami, Florida. Only 3% of the surveillance cultures were positive and we successfully treated two infected patients. Horizontal transmission led to 68% of the cases. These findings emphasize that early detection, multidisciplinary communication, and effective infection prevention measures are crucial to prevent *C. auris* spread.

Abstract 4128

Analysis of resistance transmission among humans and livestock using microbiome profiling
Hyunjoo Pai$^{1,2}$, Mina Rho$^3$, Jieun Kim$^3$, Suk-Kyung Lim$^4$, Mi-Ran Seo$^5$, Bongyoung Kim$^5$

$^1$Hanyang University, Dept. of Internal Medicine, College of Medicine, Seoul, South Korea, $^2$Hanyang University, Dept. of Computer Science and Engineering, Seoul, South Korea, $^3$Hanyang University, Dept. of Internal Medicine, College of Medicine, Seoul, South Korea, $^4$Animal and Plant Quarantine Agency, Bacterial Disease Division, Gimcheon, South Korea, $^5$Hanyang University, Dept. of Internal Medicine, College of Medicine, Seoul, South Korea

Background: Increase of antibiotic resistance is a huge problem of public health. Globally 70% of antibiotics are used in agricultural field including animal industry. Objective of the study is to clarify the cycle of antibiotic resistance among human and livestock by using metagenomic sequencing of gut microbiome of human, pig, cow and chicken.

Materials/methods: Metagenomic whole gene sequencing was performed for 103 stool samples of human and 118 samples from livestock. As for qnrS1 and CTX-M genes, Escherichia coli containing each gene was isolated from stools of human and chicken and whole gene sequencing was performed using NGS method to analyze the phylogeny of the isolates and plasmid structure.

Results: Chicken presented the most similar pattern of gut resistome with human. Variable antibiotic resistance genes (ARGs) of variable antibiotic group showed zoonotic distribution in gut of human and livestock. TEM and CTX-M were the most popular among beta-lactam resistance genes, and qnrS1 most successfully resided among plasmid-mediated quinolone resistance genes in gut of human and chicken. Mobile element of qnrS1 constituted with 6 genes of qnrS1, 3 transposons and 1 plasmid gene (resolvase, ISKra4 family transposase ISKpn19, IS380 family transposase ISEc9 and plasmid pRiA4b ORF-3 family protein) identically in human and chicken microbiome. Meanwhile, 2 plasmids of E. coli selected from human and chicken respectively showed the identical structure consisting with 12 genes containing transposon genes and ARGs, which suggest the recent transfer of this plasmid between human and chicken. CTX-M looked also successful zoonotic ARGs, which appeared commonly in gut microbiome of human and chicken. Among 4 groups of CTX-M genes, CTX-M-1 gene was the most important zoonotic gene

Conclusions: ARGs are transferred among human and livestock and some ARGs are especially efficient in zoonotic transfer. This research was supported by a fund (2017N-ERS407-00) by Research of Korea Centers for Disease Control and Prevention.

Background: Streptococcus suis serotype 2 (S. suis 2) is an important swine pathogen and an emerging zoonotic agent for human. In a previous study, we reported a cell surface-exposed protein HtpsA, which confers protection in mice. In the present study, we constructed an isogenic mutant strain of htpsA and investigated its role in S. suis 2 development and virulence.

Materials/methods: Homologous recombination based method was used to construct an htpsA mutant of the S. suis 2 high virulent strain 05ZYH33. Gram staining observation and Transmission electron microscope (TEM) observation were performed to compare the morphological difference of the htpsA mutant and the wild type bacteria. Adhesion assay, phagocytosis assay and animal infection experiment were adopted to evaluate the involvement of htpsA in the virulence of S. suis 2.

Results: The results showed that the mutant strain ΔhtpsA forms shorter chains and smaller colonies comparing to the wild type strain. The mutant strain also lost typical encapsulated structures with reduced level of sialic acid content. Furthermore, the survival ratio in whole blood, the anti-phagocytosis ability to mouse macrophage cell RAW264.7 and the adherence ability to Hep-2 cell of ΔhtpsA all declined significantly comparing to the wild type strain. In addition, deletion of htpsA significantly attenuated the virulence of S. suis 2 in a mouse infection model. RNA-seq analysis revealed that 126 genes were differentially expressed between the ΔhtpsA and the wild type strains (28 up-regulated and 98 down-regulated). Among them, many down-expressed genes are involved in the carbohydrate metabolism. Some of the down-expressed genes encode evidenced virulence-associated factors.

Conclusions: Taken together, the results from this study demonstrated that htpsA is involved in the morphology development and pathogenesis of the highly virulent S. suis 2 strain 05ZYH33.

Fig. 1 Phenotypic analysis of the ΔhtpsA mutant strain.

[A] Growth caves of the ΔhtpsA and wild strains were measured spectrophotometrically at a wavelength of 600 nm. [B] Observation of the cellular morphology using gram staining and light microscopy. [C] Observation of capsular morphology by transmission electron microscopy of the ΔhtpsA and wild strains.

Abstract 4133

**Comparative effectiveness of empiric antistaphylococcal penicillins versus cefazolin in methicillin-susceptible Staphylococcus aureus bacteraemia**

Jaclyn Cusumano*1,2, Haley Appaneal1,3,4, Vrishali Lopes1, Kerry Laplante1,3,4, Aisling Caffrey1,3,4

1Providence VA Medical Center, Providence, United States, 2Long Island University, Brooklyn, United States, 3Brown University, Providence, United States, 4University of Rhode Island, Kingston, United States

**Background:** Treatment failure related to the cefazolin inoculum effect in MSSA bacteremia is theorized to occur during the initial period of empiric therapy. Previous comparative effectiveness studies of anti-staphylococcal penicillins (nafcillin or oxacillin) versus cefazolin for MSSA bacteremia only evaluated definitive therapy, when the bacterial inoculum has already diminished. Therefore, the potential impact of the cefazolin inoculum effect with empiric cefazolin treatment is still under debate.

**Materials/methods:** We conducted a national retrospective cohort study of MSSA bacteremia patients admitted to Veterans Affairs (VA) hospitals between January 2002 and October 2015. We included patients empirically treated with up to 4-days from initial positive blood culture with vancomycin plus nafcillin or oxacillin (VAN+NAF/OXA), or vancomycin plus cefazolin (VAN+CEF), and de-escalated to the respective beta-lactam monotherapy. Patients were excluded if death or discharge occurred within 48 hours of initial culture. The effect of empiric VAN+NAF/OXA was compared with VAN+CEF for time to 30-day mortality and discharge from the culture date, and time to 30-day readmission and 30-day *S. aureus* reinfection from the discharge date, using propensity score adjusted and matched Cox proportional hazards regression models.

**Results:** We identified 384 patients treated with VAN+NAF/OXA (n=248, 64.6%) or VAN+CEF (n=136, 35.4%). The risk of 30-day *S. aureus* reinfection was significantly higher in the VAN+CEF group [adjusted hazard ratio [HR] 0.25, 95% confidence interval [CI] 0.07-0.88; n=95 matched pairs, matched HR 0.13, 95% CI 0.02-0.999]. There were no differences in the other outcomes assessed.

**Conclusions:** Among patients with MSSA bacteremia empirically treated with nafcillin/oxacillin or cefazolin, in combination with vancomycin, and de-escalated to the respective beta-lactam monotherapy, there were no differences in mortality, readmission, or time to discharge. However, patients receiving the cefazolin empiric regimen had a higher likelihood of *S. aureus* reinfection within 30-days of discharge, supporting the hypothesized inoculum effect during initial empiric therapy.

Control of hospital-wide outbreak of OXA-48-producing Enterobacteriaceae outbreak

Moi Lin Ling*1, Molly How1, Kwee Yuen Tan1, Ewe Choon Lee1, Kwan Ki Karrie Ko1, James Heng Chiak Sim1

1Singapore General Hospital, Singapore, Singapore

Background: An increase in healthcare onset OXA-46 carbapenemase producing Enterobacteriaceae (CRE) from an average of 3 patients per month to 5 patients in September, and then 10 in October 2019 hospital alerted the Infection Prevention team of a 1750-bedded acute tertiary care of a cluster that needed investigation.

Materials/methods: The hand hygiene and environment hygiene compliance of all the wards were noted to be around 80-90% in the affected wards. 46 samples were taken from shared equipment, sink P traps and shower drains. Environmental cleaning of affected wards were immediately enhanced with 1000 ppm sodium hypochlorite twice daily and daily audits on hand hygiene and environment hygiene were conducted. P traps were changed for sinks in affected wards after samples were collected for culture. Besides usual cleaning and disinfection by ward staff in between use, the commodes were further cleaned down by Environmental Services staff daily. Decontamination of sink traps with 250mls 5000ppm sodium hypochlorite was done 3 times a week with random sampling done to check on clearance of OXA-48.

Results: Two samples from the 46 commodes and two samples from the 27 shower drains tested were positive for OXA-48. Following the decontamination of sink traps, weekly samples confirmed clearance of the OXA-48 isolates. Whole genome sequencing of the isolates from 18 patients and 3 environmental samples confirmed that they are of the same type. The number of OXA-48 patients has since returned to the baseline norm.

Conclusions: We have successfully controlled the outbreak using the approach of biofilm control in the P traps. However, more work needs to be done to determine the optimal schedule for sink trap decontamination to mitigate possibility of CRE colonization.

**CTX-M-15 and CTX-M-14 genes in UK Escherichia coli are found as often on the chromosome as they are on plasmids**

Abdulrahman Almusallam\(^1\), Dmitriy Babenko\(^2\), Jordan Mathias\(^3\), David Wareham\(^3\), Mark Alexander Toleman*\(^4\)

\(^1\)Cardiff University, Cardiff, United Kingdom, \(^2\)Karaganda Medical University, Karaganda, Kazakhstan, \(^3\)Blizard Institute, London, United Kingdom

**Background:** Several reports have described CTX-M genes in *E. coli* as being mostly plasmid and occasionally chromosomally encoded. We sought to determine the commonality of chromosome location by analysis of a large number of UK strains collected through a multi-centre project.

**Materials/methods:** 968 ESBL producing *E. coli* isolates were collected through a large multi-centre study from 5 UK regions in 2014. These included isolates from bacteraemias, faecal and sewage sources. All *E. coli* were analysed for chromosomal location by Pulsed Field Gel Electrophoresis combined by in-gel hybridization using \(^{32}\)P-labeled CTX-M-15 and CTX-M-14 radioactive probes. All isolates were whole-genome sequenced by illumina-miseq. A sub-group of 50 isolates were additionally sequenced using nanopore minion sequencing.

**Results:** Sequence analysis indicated that 534 isolates encoded CTX-M-15 and 83 isolates encoded CTX-M-14. PFGE analysis indicated that c. 50% of these resistance genes were chromosomally encoded and c. 40% were plasmid encoded with c. 10% of samples losing resistance genes during processing (fig 1). Isolates with chromosomally encoded resistance were found in numerous different *E. coli* ST and typically lacked additional plasmid copies of the gene. We determined chromosomal insertion sites for 30 isolates. Most insertions were ISEcP1 mediated with insertions into various different genes and intergenic spaces. The insertions ranged from 2971-11,384bp, appeared to have no bias for insertion site and all included the resistance gene and ISEcp1. Larger insertions contained additional plasmid genes. All ISEcP1 mediated insertions were flanked by 5bp direct repeats. Other common insertions (7/30) were IS26 mediated and of common sizes 8795 and 13104bp all in ST131 strains. These insertions were all with a hot spot in a molybedenum metabolism regulator gene and included both OXA-1 and aac6’1b-cr genes as well as other plasmid encoded genes.

**Conclusions:** Chromosomal carriage of CTX-M-15 and CTX-M-14 genes is a common occurrence in UK *E. coli* isolates belonging to many different ST groups. The observation that isolates with chromosomally encoded resistance typically lack additional plasmid copies suggests loss of plasmids subsequent to chromosomal targeting.

Risk factors and mortality for patients with bloodstream infections of Klebsiella pneumoniae during 2014-2018: clinical impact of carbapenem resistance in a large tertiary hospital of China

Jie Wei¹, Chang Haiyan¹, Yuxin Chen², Chao Wu*¹

¹Nanjing Drum Tower Hospital, Clinical College of Nanjing Medical University, Nanjing, China, ²Nanjing Drum Tower Hospital, Nanjing University Medical School, Nanjing, China

Background: Bloodstream infection (BSI) caused by Klebsiella pneumoniae (KP), especially Carbapenem-resistant Klebsiella pneumoniae (CRKP), results in high morbidity and mortality.

Materials/methods: In this retrospective cohort study, we examined 285 inpatients with BSI caused by KP in a tertiary hospital in China between 2014 and 2018, and 46 patients were infected with CRKP. All episodes of BSI caused by KP that occurred in hospitalized patients were enrolled. The outcome measured was death within 7 and 28 days of the first positive blood culture, respectively. Survivor versus non-survivor subgroups were analyzed in order to identify predictors of 28-day mortality due to KP BSI.

Results: We identified that hematological tumor (odds ratio [OR]: 8.359, [95% CI: 2.162-33.721], P=0.002), CRKP isolation (OR: 7.766, [95% CI: 2.796-21.576], P=0.001), chronic lung disease (OR: 5.020, [95% CI: 1.275-19.768], P=0.020), and septic shock (OR: 4.591, [95% CI: 1.686-12.496], P=0.003) were independent risk factors for the death of KP BSI. A 28-day mortality of KP BSI score ranging from 0 to 22 was developed based on the above 4 independent variables. Our scoring system revealed that the 28-day mortality were 9.14%, 35.29%, 38.10%, 75% and 100% for carriers with a score of 0, 5, 6-10, 11-13 and ≥14, respectively. Additionally, CRKP infection were independently associated with intensive care unit stay (OR: 5.506, [95% CI: 2.258-13.424], P=0.001), exposure to antifungals (OR: 4.679, [95% CI: 2.065-10.063], P=0.001), exposure to fluoroquinolones (OR: 2.892, [95% CI: 1.151-7.267], P=0.020), and the number of isolated bacterial species from the patient ≥ 3 (OR: 2.414, [95% CI: 1.306-4.463], P=0.005).

Conclusions: our study may be useful for the reduction of the mortality of patients with KP BSI and the prevention of developing CRKP BSI in hospitals.

Abstract 4143

**Laboratory evaluation of the BIOFIRE FILMARRAY pneumonia panel plus compared to standard-of-care testing at a private laboratory in Cape Town, South Africa**

Preneshni Naicker1,2, Laila Suleman*1, Fatima Khan3, Asheen Haripersad1, Jocelyn Hellig1, Edward Naicker4, Quinten Labuschagne1, Hushendree Naicker1, Frederika Van Der Merwe5, Mvuseleli Hlazo3, Tania Poole1, Simone Cass1, Justyna Wojno1, Adrian Brink1

1Lancet Laboratories, Cape Town, South Africa, 2University of Cape Town, Cape Town, South Africa, 3Life Healthcare, Cape Town, South Africa, 4ER consulting, Cape Town, South Africa

**Background:** Pneumonia causes significant mortality and morbidity worldwide. The standard method for the laboratory diagnosis of lower respiratory tract infections is culture, which has a long turnaround time (TAT), poor sensitivity and does not test for atypical bacteria and viruses. The Biofire® FilmArray® Pneumonia Panel plus (FA-PP) is a comprehensive syndromic testing molecular panel that provides rapid results for 34 targets. Our aim was to compare the FA-PP to standard-of-care testing.

**Materials/methods:** This was a prospective evaluation conducted in a private laboratory in Cape Town, South Africa. Residual sputum, tracheal aspirate and broncho-alveolar lavage specimens were tested in parallel with conventional culture and the FA-PP. Standard-of-care (SOC) testing includes culture as well as other tests that were performed on clinician order only (Biofire® FilmArray® RP2plus, Legionella urine antigen and blood cultures). Detection rates and TAT of the FA-PP were compared to culture. Percentage agreement between the FA-PP and SOC was assessed.

**Results:** Thirty* samples from unique patients were tested from August-November 2019. The FA-PP was positive in 80% (24/30) of samples (14 with bacteria only, 7 viruses only, 3 co-detections of bacteria and viruses). Co-detections for ≥2 bacteria occurred in 6 samples. The FA-PP detected 2 Mycoplasma pneumoniae and 1 Legionella pneumophila.

Culture was only positive in 53% (16/30) of samples. Detection of additional organisms on culture (n=9) were only those not included in the FA-PP (Candida species, Haemophilus species other than H. influenzae, Raoultella ornithinolytica). Bacterial detection of ≥10^7 on the FA-PP correlated best with culture-based reporting, especially in bacterial co-detections. Resistance mechanisms were detected in two samples.

The mean TAT for negative and positive cultures were 42 and 62 hours respectively, versus 2-hours for FA-PP. Overall agreement between FA-PP and SOC for at least one significant pathogen was 73% (22/30). Non-concordance was due to RP2plus not requested or the cultured organism was not included in FA-PP.

**Conclusions:** The FA-PP offers a rapid TAT and high yield of bacteria, atypical bacteria and viruses. The potential impact of this panel on antimicrobial stewardship, infection control and clinical factors needs to be evaluated in further studies.

Abstract 4144

In vitro activities of β-lactam antibiotics alone and in combination with sulbactam against Acinetobacter baumannii

Leilei Wang1, Renru Han1, Yuancheng Chen1, Zhiwei Huang1, Xuefei Zhang1, Fupin Hu1, Fan Yang*1

1Huashan Hospital, Fudan University, Shanghai, China

Background: Sulbactam, an inhibitor of β-lactamase, displays intrinsic activity against the Acinetobacter baumannii. This study aimed to evaluate the in vitro activities of β-lactam antibiotics alone and in combination with sulbactam at different ratios against Acinetobacter baumannii clinical strains.

Materials/methods: A total of 300 clinical isolates of A. baumannii were collected from 29 hospitals across China in 2018, including carbapenem-susceptible A. baumannii and carbapenem-resistant A. baumannii isolates. Minimum inhibitory concentrations (MICs) were determined by broth microdilution method. Amoxicillin, cefoperazone and imipenem were tested alone and in combination with sulbactam at different ratios of 1:1, 1:1.5, 1:2, 1:2.5 and 1:3. Sulbactam alone was also tested.

Results: MIC50 and MIC90 values for sulbactam were 32 mg/L and 64 mg/L, respectively. High resistant rates for imipenem, ampicillin and cefoperazone were observed (85.3%, 92.3% and 93%, respectively). A stepwise increase in the ratio of sulbactam to β-lactams led to a stepwise decrease in the β-lactams MICs and a stepwise increase in the susceptible rates. The susceptible rates for imipenem-sulbactam at the ratios of 2:1, 1:1, 1:1.5, 1:2, 1:2.5 and 1:3 remained at 13.7%, 14.3%, 14.3%, 15.0%, 15.7%, and 16.3%, respectively. The susceptible rates for ampicillin-sulbactam at the ratios of 2:1, 1:1, 1:1.5, 1:2, 1:2.5 and 1:3 were 12.3%, 14.3%, 20.3%, 28.3%, 51.3%, and 58.3%, respectively. Of note, the susceptible rates for cefoperazone-sulbactam at the ratios of 2:1, 1:1, 1:1.5, 1:2, 1:2.5 and 1:3 reached to 15%, 29.3%, 66.3%, 78.7%, 86.3%, and 91%, respectively.

Conclusions: The increasing proportion of sulbactam could enhance in vitro activity of imipenem-sulbactam, ampicillin-sulbactam and cefoperazone-sulbactam combinations against A. baumannii clinical strains, with cefoperazone-sulbactam as the most potent compound.
