Background: Meningitis is a devastating disease. The key to patient management is distinguishing bacterial causes, which need immediate antibiotic treatment, from clinical mimics, e.g. viral meningitis, which do not. The gold-standard for diagnosis is lumbar puncture (LP), microscopy and culture of the cerebrospinal fluid (CSF). However, LP can be delayed, or microbiological results inconclusive. Consequently, patients can be treated with unnecessary antibiotics until bacterial meningitis is excluded. One solution is to develop a blood test to rule-out bacterial meningitis.

Materials/methods: Host transcript analysis was undertaken in five phases to identify transcript that accurately distinguished between blood samples from bacterial meningitis patients and clinical mimics (n=600). Transcripts were retained based on accuracy. Initially (1), gene-expression data of patients from multiple countries with bacterial or viral meningitis, viral encephalitis, meningism, or invasive bacterial disease with meningitis were analysed (n=180). Next (2), high performing transcripts were re-tested via quantitative RT-PCR among adult UK meningitis patient samples (n=81); (3) translated into a multiplex PCR assay (n=91 samples); (4) the multiplex re-tested/refined (n=72 samples). Finally (5), the TRIM assay (based on five host transcripts) was tested, blind to sample classification, on a further set of adult UK meningitis patients (n=176). Samples were confirmed bacterial meningitis or clinical mimics [confirmed viral meningitis or meningism]. Confirmed cases had meningitis symptoms, CSF pleocytosis and detection of pathogen in CSF or blood. Meningism cases had meningitis symptom but no CSF pleocytosis.

Results: TRIM assay accuracy for correctly diagnosing bacterial meningitis from mimics was 87% (153/176). Excluding samples collected after five days of intra-venous antibiotic provision, sensitivity was 100% ([Streptococcus pneumoniae, Neisseria meningitidis, Haemophilus influenzae]) and specificity 90% (135/150). Accuracy was 98% (64/65) distinguishing confirmed bacterial from viral meningitis cases.

Conclusions: TRIM is the first syndromic blood test focussing on meningitis diagnosis and translated from gene-expression data to multiplex PCR assay. It potentially offers a highly sensitive test to rule-out bacterial meningitis. It remains accurate among antibiotic exposed patients. Test use could help clinicians rationalise treatment, reduce in-patient stay, lower hospital costs and lessen risk of antimicrobial resistance. We are validating TRIM in a large (>700 patients) European study.

Abstract 6916

Epidemiological and molecular characteristics of human parechovirus infection in children <6 months hospitalised with symptoms of sepsis-like illness: Milan 2015-2018

Laura Pellegrinelli, Sara Colonia Uceda Renteria, Cristina Galli, Anna Orlandi, Sandro Binda, Elena Pariani

1Department of Biomedical Sciences for Health, University of Milan, Milan, Italy, 2Virology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Human parechoviruses (HPeVs) are widespread pathogens belonging to the Picornaviridae family and currently divided into 19 genotypes. Although most HPeV infections cause self-limiting mild respiratory/gastrointestinal diseases, severe clinical manifestations, such as sepsis-like illness, have been reported, particularly in youngest children. The epidemiological and molecular characteristics of HPeV infections in children <6 months hospitalized with symptoms of sepsis-like illness were investigated.

Materials/methods: From January 1st, 2015, to December 31st, 2018, biological samples (cerebrospinal fluid samples and/or blood samples) were collected from 115 patients <6 months (median age: 20 days; inter quartile range: 32 days) hospitalized with symptoms of sepsis-like illness at a university and research hospital in Milan (Northern Italy). After extraction, HPeV RNA was detected by real-time RT-PCR (target 5'UTR) and a portion of HPeV VP3/VP1 junction (nt. 2159–2458) was sequenced for typing and molecular characterization.

Results: Overall, 13% (15/115) of patients with symptoms of sepsis-like illness tested HPeV-positive. Cumulatively, 14/15 (93.3%) HPeV cases were children <3 months and 10/15 (66.7%) children <1 month. 9/15 (60%) HPeV-positive cases were identified during the summertime (June-August). 10/15 (66.7%) HPeV-positive samples were molecularly characterized and all resulted HPeV type 3.

Conclusions: In this study, HPeV infection was identified in 13% of children <6 months with symptoms of sepsis-like illness. Almost all HPeV infections were identified in children <3 months during the summertime; all HPeV molecularly characterized were HPeV type 3 that is considered an emerging pathogen. Including HPeV molecular detection in routine diagnostic tests would allow estimating the burden of HPeV infection and improving clinical management of young patients.

Presenter email address: sarauceda@outlook.com
Background: The gold standard for pathogen detection in blood is the inoculation of blood culture (BC) bottles and subsequent identification of microbes using mass spectrometry (MS). Rapid identification of the causative pathogen, and possible inherent antibiotic resistances, is crucial for appropriate treatment of severe infections.

Rapid pathogen identification is hampered as: (1) certain bacterial species proliferate very slowly under BC conditions (e.g. Bacteroides spp., Propionibacterium acnes); (2) in mixed infections, faster proliferating species overgrow slower ones, which might then be missed; (3) treatment with antibiotics prior to blood draw prolongs/inhibits bacterial growth; (4) antibiotic resistances are determined by (time-consuming) plating.

This work compares pathogen identification from positive BC by state-of-the-art MS and Cube Dx' molecular test: LINA compact sequencing, which uses a diluted sample of BC directly in a PCR reaction. After the PCR pathogens are identified using Cube Dx' compact sequencing, covering 101 targets (bacterial-, resistance- and fungal genes).

Materials/methods: In total, 277 blinded BC samples (178 positive, 99 negative) were analysed at Unilabs by conventional culture and MS in parallel to LINA compact sequencing, respectively.

Results: Among the positive samples both methods identified identical bacterial species/genus in 166/178 cases (93%). Seventeen samples (~6%) yielded discordant results. In 3 cases compact sequencing did not report a bacterial species. Interestingly, in 4 positive samples, compact sequencing yielded a result whereas MS did not, and in 9 cases more than one species was detected – indicating that molecular diagnostics reveals mixed infections, even if one species might be predominant in culture. As an example, 3 samples contained bacteria of the Acinetobacter baumannii complex and Escherichia coli according to compact sequencing, where MS only detected E.coli.

Conclusions: Results for positive BC samples with LINA compact sequencing were obtained within 3 hours. LINA detected almost all positive blood cultures concordantly with current established methods resulting in a sensitivity of 98%. In addition, several mixed infections and slow growing bacteria were identified which were missed by MS, including Acinetobacter species which are highly relevant carriers of antibiotic resistance genes, resulting in a specificity of 88%.

Healthy carriage of colistin-, ESC- and carbapenem-resistant Enterobacterales in workers in Lebanese pastries

Ali Mir Hiba*1,2, Marwan Osman1, Jean-Yves Madec2, Monzer Hamze1, Marisa Haenni2

1Ecole Doctorale des Sciences et de Technologie, Faculté de Santé Publique, Université Libanaise, Laboratoire Microbiologie Santé et Environnement (LMSE), Tripoli, Lebanon, 2Université Claude Bernard Lyon 1 - ANSES, Unité d’Antibiorésistance et Virulence Bactériennes, Lyon, France

Background: In Lebanon, resistance to Extended-Spectrum Cephalosporins (ESC) and carbapenems in Enterobacterales have been reported in humans in the community, but not mcr-1-mediated colistin-resistance. Those resistances have also been reported in animals, the environment or along the food chain in this country.

Materials/methods: A longitudinal study was performed on 84 healthy adults working in three major pastries in North-Lebanon. All workers were sampled twice at a 6 months’ interval (t0 and t6). Resistant Enterobacterales were isolated on media supplemented with ceftazidime, ertapenem, and colistin, and identified by MALDI-TOF. Antibiotic susceptibility was determined by disc diffusion. Resistance genes were characterized using PCR and sequencing. Characterization of the bacterial clones (PFGE, phylogroups) and plasmids (PBRT, S1-PFGE and Southern hybridization) is ongoing. Selected isolates will be subjected to NGS.

Results: 32 workers (38.1%) and 26 (37.1%), from the first and second sampling, respectively, were susceptible to colistin, ESC and carbapenem. ESBLs were detected in 26 workers (30.9%) and 39 (55.7%) from the first and second sampling, respectively. The carbapenemase OXA-48 was identified in 3 workers (3.6%) from the first sampling only. Finally, the mcr-1 gene was detected in 5 and 1 E. coli from workers from the first and second sampling, respectively. Continuous ESC-R carriage was observed in 31 workers even though the same resistant Enterobacterales was very rarely found over the two samplings, suggesting a transient acquisition/loss dynamic. Molecular characterization of the collected bacteria is ongoing.

Conclusions: We report the first longitudinal study on ESBL/AmpC-, carbapenemase- and mcr-1-producing Enterobacterales carriage in the community in Lebanon. A persistent and high proportion of workers carrying ESC-resistant Enterobacterales (30.9% at t0 and 55.7% at t6) was highlighted but the individual carriage was transient. We also showed incidental carbapenemase producers and the emergence of mcr-1-positive colistin in the community. Cross-transfers of resistant Enterobacterales within pastries, including to foodstuff, is plausible. This highlights the peremptory necessity to reevaluate effective antimicrobial stewardship, enhance national surveillance systems and promote public awareness programs in order to limit the spread of AMR in Lebanon in a One Health perspective.

Abstract 6925

**ETEST Imipenem-relebactam for antimicrobial susceptibility testing of Enterobacteriaceae and Pseudomonas aeruginosa: performance results from a multi-centre study**

Claire Anglade*, Sheri Garrett¹, Jennifer Richards², Davies Leanne³, Carey-Ann Burnham⁴, Omai Garner⁵, Mandy Wootton⁶, Gilles Zambardi⁷, Diane Halimi⁷

¹bioMérieux, Marcy l’étoile, France, ²bioMérieux, Saint Louis, United States, ³University Hospital of Wales (SACU), Cardiff, United Kingdom, ⁴Washington University, Saint Louis, United States, ⁵University of California, Los Angeles, United States, ⁶University Hospital of Wales (SACU), Cardiff, United States, ⁷bioMérieux, La Balme les Grottes, France

**Background:** Imipenem/Relebactam (IPR), RECARBRIO brand name, is a combination of imipenem, a penem antibacterial, cilastatin, a renal dehydropeptidase inhibitor, and relebactam, a beta-lactamase inhibitor, indicated in patients 18 years of age and older with complicated urinary tract infections including pyelonephritis (cITU) or with complicated intra-abdominal infections (cIAI) caused by susceptible gram-negative bacteria. This study evaluated the performance of ETEST® IPR, a new gradient diffusion strip (FDA cleared but not yet CE marked) for determining antimicrobial susceptibility of Enterobacteriaceae and Pseudomonas aeruginosa as compared to CLSI M07 broth microdilution reference method (BMD).

**Materials/methods:** A population of 652 isolates including 477 Enterobacteriaceae (30 Citrobacter freundii, 103 Enterobacter cloacae/Enterobacter cloacae complex, 165 Escherichia coli, 30 Klebsiella aerogenes, 32 Klebsiella oxytoca and 117 Klebsiella pneumoniae) and 175 Pseudomonas aeruginosa were tested at 4 clinical trial sites, including one internal laboratory using ETEST® IPR and BMD. Results were analyzed in terms of essential (EA), category (CA) agreements, minor (mE), major (ME) and very major (VME) error rates using FDA breakpoints (Enterobacteriaceae: ≤1/4 (S), 2/4 (I) and ≥4/4 (R) µg/mL, Pseudomonas aeruginosa: ≤2/4 (S), 4/4 (I) and ≥8/4 (R) µg/mL).

**Results:** Results are summarized in Table 1. ETEST® IPR performance for Pseudomonas aeruginosa met FDA acceptance criteria for EA (≥90%), CA (≥90%), ME (≤3%) and VME (≤2%). For Enterobacteriaceae ETEST® IPR performances met FDA criteria for EA, CA and ME but not for VME with a rate of 2.3% (1/44). That percentage was only due to one Very Major Error with an E. coli isolate. Repeat testing of both ETEST® Imipenem/Relebactam and the reference method with this isolate showed acceptable category agreement between the two tests.

**Conclusions:** When compared to the reference method, results of this multicenter trial support the accuracy of ETEST® IPR for determining the MIC of Enterobacteriaceae and Pseudomonas aeruginosa in a clinical setting. As such, the new ETEST® IPR can be considered as substantially equivalent to BMD.

Abstract 6926

Towards an enhanced diagnosis of relapsing fevers by the use of dried blood spots

Emilie Talagrand-Reboul*, Pierre Boyer1, Antoine Grillon1, Cathy Bartel1, Lisa Baldinger2, Marine Engel2, Laurence Zilliox2, Benoît Jaulhac1,2, Nathalie Boulanger1,2

1 Strasbourg University, EA 7290-Early Bacterial Virulence: Lyme borreliosis Group, Strasbourg, France, 2 Hôpitaux Universitaires de Strasbourg, French National Reference Center for Borrelia, Strasbourg, France

Background: Relapsing fever borreliosis (RFB) are worldwide distributed vector-borne diseases. The biological diagnosis of RFB is hardly performed in some remote areas, mainly because the sampling and analysis of venous blood by microscopic examination or PCR require laboratory facilities. In the aim to enhance this diagnosis, we have evaluated the methodology of Dried blood spots (DBS).

Materials/methods: Firstly, one Balb/C mouse was infected with Borrelia duttonii CR2a by intraperitoneal injection and the spirochaetemia was followed by microscopic examination of Giemsa-stained blood smears. In parallel, capillary blood spots were directly made on Whatman MM3 paper. Blood was eluted and then submitted to a bacterial DNA extraction and, a pan-relapsing fever Borrelia real-time PCR was performed. Secondly, we applied the same method to human blood samples kept at -80°C, formerly tested negative (n=56) or positive for B. crocidurae (n=6) or B. hispanica (n=1). The DNA extractions were performed after 24h drying at +20°C-+30°C and 1-3 days later.

Results: In the mouse, we have observed a spirochaetemial peak 3-6 days post-infection, followed by a reversion of the bacterial load, and then a relapse at 9-10 days that was cleared on day 13. RF Borrelia DNA was successfully amplified from the DBS extracts during the course of mice bacteremia (2-6.10^7 spirochaetes/mL). For human blood samples, a total agreement was obtained between the DBS extraction and the whole blood direct extraction methods. The DBS-qPCR method reached a higher sensitivity (100%; CI95%=59-100%) than blood smear examination (50%; CI95%=18-88%). The results of qPCR were not different from 1-day or 14-day DBS. In all tested conditions, there was not inhibitory effect and no contamination between samples.

Conclusions: This study is the proof of concept for the diagnosis of RFB by the use of DBS. We showed that Borrelia DNA contained in the DBS retained its integrity after storage 14 days at +25°C, allowing a delay for transport to a laboratory. Given the simplicity of the preanalytical phase well adapted to tropical medicine, the DBS methodology may enhance the biological diagnosis of RFB, and, furthermore, may be associated with the malaria molecular diagnosis from DBS samples in some areas.

Abstract 6927

**Increasing rates of antimicrobial resistance in *Escherichia coli* and *Klebsiella sp.* bacteraemia are not associated with a proportional increase in mortality**

Adrian Crawford1, Aodhan Breathnach1,2, Peter Riley*1,2,3

1St George’s, University of London, True Blue, United Kingdom, 2St George’s University Hospitals NHS Foundation Trust, Department of Infection, London, United Kingdom, 3South West London Pathology, Medical Microbiology, London, United Kingdom

**Background:** Increasing antimicrobial resistance rates may lead to increased mortality as infections become harder to treat. At our large centre in London we reviewed all *Escherichia coli* and *Klebsiella sp.* bacteraemias over 18 years and examined the relationship of antimicrobial resistance to 30 day and 90 day all-cause mortality.

**Materials/methods:** Records of *E coli* and *Klebsiella sp.* bacteraemias were extracted from the laboratory database for the years 2001 to 2018. Records were de-duplicated to determine the number of individual bacteraemic episodes. A new positive blood culture more than 28 days since the last was classified as a new episode. Antimicrobial susceptibility results were analysed and isolates were classified as wild type (WT), resistant (R) or multiply-resistant (MDR).

**Results:** Over 18 years there were 3519 episodes of *E coli* bacteraemia of which 1106 (31%) were WT, 1647 (47%) were R and 766 (22%) were MDR. There were 1069 episodes of *Klebsiella sp.* bacteraemia of which 755 (71%) were WT, 68 (6%) were R and 246 (23%) were MDR. Annual rates of resistance increased for both organisms with a stronger trend in *E coli* compared to *Klebsiella sp.* *E.coli* bacteraemic episodes had a mean 30 day mortality of 1.7% compared to 2.1% for *Klebsiella sp.* and were 24% and 31% for 90 day mortality respectively. There was a small trend (approx. 5%) over the study period for reduction in 30 and 90 day mortality rates for *E coli* episodes whereas with *Klebsiella sp* there was a small trend for increasing mortality rates (approx. 2% for 30 day and 4% for 90 days).

**Conclusions:** Despite increasing rates of resistance in *E coli* and *Klebsiella sp.* bacteraemias there was no evidence of a proportional increase in mortality over an 18 year period and in fact mortality from *E coli* fell. This was surprising. There are many possible explanations including changing patient populations or changes in pathogenicity of the circulating organisms. At the same time, there have been advances in rapid diagnostic techniques, improved recognition and treatment of sepsis and following the introduction antimicrobial stewardship programmes better prophylactic, empirical and result-led antimicrobial usage.

Abstracts 2020

Abstract 6929

Toscana virus: clinical and biological studies based on 864 cases

Nazli Ayhan*1, Rémi Charrel1

1Unité des Virus Emergents [Aix-Marseille Univ–IRD 190–Inserm 1207–IHU Méditerranée Infection], Marseille, France

Background: Toscana virus is an arbovirus transmitted by sand flies within the Mediterranean area where it can cause febrile illness and neuroinvasive infections during the seasonal circulation period of the vector. Although it is an important cause of meningitis and encephalitis, it remains neglected.

Materials/methods: We searched global web-based resources [PubMed, Google Scholar, Web of Science] to collect all the Toscana virus case reports have been published since now. After gathering all the data, irrelevant publications were discarded. A total of 72 publications including 864 case reports of Toscana virus infection were collected. All the collected data were put in order based on country, year, sex, clinical signs, clinical presentation, biological signs, onset of symptoms. Clinical signs have been grouped in categories for further analysis. Additionally, imported case reports were categorized and analyzed separately.

Results: Sex ratio is 1.85. Since 1985, 864 human cases [834 autochthonous and 30 imported] were reported from inhabitants of Mediterranean countries and travelers who visited the region. More than 80% of the patients show manifestations of fever, headache, neck rigidity, Kernig's sign and nausea. Ocular, gastro-intestinal and cutaneous manifestations were reported between 40-80% of the cases. The neurological and muscular manifestations were identified in 27.6% and 22.6% of the patients, respectively. Manifestations as testicular pain/tenderness, hepatomegaly, incontinence, orthostatic hypotension represent less than 1% of the cases. There is one lethal case recorded after Toscana virus infection, who is a German tourist returning from a 3 week trip to Tuscany, up to now.

Conclusions: Toscana virus is currently the most important phlebovirus for public health which is transmitted by sand flies. Since Toscana virus is a neglected virus most of the cases caused by Toscana virus remain unidentified. Defining the most common manifestations and the characterization of Toscana virus can help physician and engage them to prescribe laboratory documentation when facing unexplained febrile illness in patient living in or returning from Toscana virus endemic regions. The population in Mediterranean area are at risk of Toscana virus infection which requires the increase of the awareness and the knowledge.

Presenter email address: nazliayhann@gmail.com
Abstract 6930

**Carbapenem-resistant *Acinetobacter baumannii* fitness in murine model is associated with 14-day mortality in humans**

**Abstract third-party references:** European Commission FP7 AIDA project [preserving old antibiotics for the future: assessment of clinical efficacy by a pharmacokinetic / pharmacodynamic approach to optimize effectiveness and reduce resistance for off-patent antibiotics], Grant Health-F3-2011-278348

**Background:** Mortality among patients with carbapenem-resistant *A. baumannii* (CRAB) infections is high. In the AIDA trial, 14-day mortality among patients with severe infections caused by CRAB was 37%. We examined whether *in vivo* bacterial fitness in a murine thigh infection model is associated with outcomes in patients with CRAB infections.

**Materials/methods:** Bacterial isolates were collected from patients in the AIDA trial with hospital-acquired pneumonia (HAP), bloodstream infection (BSI), or urinary tract infection caused by CRAB. We tested *in vivo* fitness of each CRAB strain using a neutropenic mouse thigh infection model. Fitness was defined based on the CFU count 24 hours after injection of an inoculum of 10^5 CFU per mouse, and was modeled as a binary variable [below vs. at or above the median]. The primary outcome was 14-day clinical failure, defined as failure to meet all criteria: alive; hemodynamically stable; improved or stable SOFA score; improved or stable oxygenation; and microbiological cure of BSI. The secondary outcome was 14-day all-cause mortality. We compared bacterial fitness and demographic and clinical variables between patients with and without clinical failure. We used backwards selection to build a multivariable logistic regression model of the association between fitness and clinical failure. We repeated this process for the 14-day mortality outcome.

**Results:** The sample included 266 patients with infection caused by CRAB. Bacterial fitness ranged from 5.23-10.08 logCFU/gram (median 8.78 logCFU/gram). High bacterial fitness was not significantly associated with the study primary outcome of clinical failure in bivariate or multivariable analysis that controlled for age, appropriate empiric therapy, and diabetes [OR 1.26, 95% CI: 0.66-2.39, p=0.48]. High fitness had a nearly significant association with 14-day mortality [OR 1.56, 95% CI: 0.95-2.57, p=0.08] in bivariate analysis, and was significantly associated with 14-day mortality when adjusting for age and Charlson score in the multivariable model [OR 1.82, 95% CI 1.07-3.09, p=0.03].

**Conclusions:** This study provides evidence that the CRAB fitness as measured in a murine infection model is an important determinant of CRAB infection 14-day mortality. Strain fitness may be an important factor to measure and control for in CRAB clinical trials.

Abstract 6932

**Xpert MTB/RIF Ultra: multi-centre evaluation of result “TRACE” in tuberculosis diagnosis**

Stefania Torri*1, Claudio Farina2, Paola Cichero3, Alessandra Lombardi4, Fulvia Marini5, Eugenio Sala6, Francesca Gurrieri7, Vanina Rognoni8, Carlo Federico Perno1, Ester Mazzola1

1 ASST Great Metropolitan Niguarda, Milano, Italy, 2 Ospedale Papa Giovanni XXIII, Bergamo, Italy, 3 San Raffaele Hospital, Milano, Italy, 4 Sacco Hospital, Milano, Italy, 5 Ospedale San Gerardo di Monza, Monza, Italy, 6 Ospedale Sant’Anna, Como, Italy, 7 University of Brescia-Spedali Civili, Brescia, Italy, 8 Azienda Socio Sanitaria Territoriale di Lodi, Lodi, Italy

**Background:** Xpert® MTB/RIF Ultra (Cepheid), an automated PCR for identification of **Mycobacterium tuberculosis** complex (Mtbc) and Rifampin (RIF) resistance [detection limit 11.8 UFC/mL], has higher sensitivity than Xpert® MTB/RIF [131 UFC/mL]. The improved sensitivity is also due to result “TRACE”, which corresponds to a lower detectable bacterial load.

According to the interpretation algorithm of GLI – Global Laboratory Initiative (WHO), the result “TRACE” should be considered as Positive in non-respiratory samples.

**Aim of this multicentric study was the correlation between result “TRACE” and diagnosis of Tuberculosis.**

**Materials/methods:** We analyzed 130 biological samples (92 respiratory, 38 non-respiratory) processed in 8 different Microbiology laboratories, which reported “TRACE” with Xpert® MTB/RIF Ultra.

For respiratory samples, explicative note “Mtbc genome detected at inferior limit of Sensitivity. New sample is required” was enclosed in the medical report.

For each biological sample with result “TRACE”, we recorded culture positivity for Mtbc or possible positivity for Mtbc in other samples, or anamnestic data of ongoing Tuberculosis therapy.

**Results:** Among 130 samples with result “TRACE”, 50 (38.5%) had positive culture for Mtbc (36 respiratory, 14 non-respiratory).

17 (13.1%) samples with negative culture belonged to patients with positive cultures for Mtbc in other clinical samples (7 respiratory, 10 non-respiratory) within three months.

31 (23.8%) samples with negative cultures belonged to patients with ongoing therapy for Tuberculosis diagnosis (21 respiratory, 10 non-respiratory).

32 (24.6%) samples with result TRACE had no microbiological or clinical confirmation of Tuberculosis (28 respiratory, 4 non-respiratory) for absent repetition of test on other samples.

Overall, result TRACE with Xpert MTB/RIF Ultra test for 98 (75.4%) of 130 examined samples is coherent with Tuberculosis diagnosis, while for 24.6% the diagnosis wasn’t confirmed or excluded for absence of second sample, as required by interpretative algorithm, and/or for lack of clinical information.

Regarding the different specimens, the concordance with Tuberculosis diagnosis was 69.5% for respiratory samples (64/92) and higher for non-respiratory samples: 89.5% (34/38).

**Conclusions:** Data show clinical relevance and reliability of reply “TRACE” in Tuberculosis diagnosis in respiratory samples and even more in non-respiratory samples, corroborating the indication of WHO-GLI to report as POSITIVE a result “TRACE” in non-respiratory samples.

**Presenter email address:** stefania.torri@unimi.it
Evaluation of the EUCAST rapid antimicrobial susceptibility testing directly from positive blood cultures for *Escherichia coli* and *Staphylococcus aureus* in a routine laboratory

Emma Jonasson*1, Per Rydström1

1Central Hospital, Växjö, Department of Clinical microbiology, Växjö, Sweden

**Background:** With increasing antibiotic resistance it is important with rapid and correct antimicrobial susceptibility testing results. The EUCAST method for rapid antimicrobial susceptibility testing (RAST) directly from positive blood cultures is now available on the EUCAST website. The aim of this study was to evaluate the performance of RAST for *Escherichia coli* and *Staphylococcus aureus* in our routine clinical laboratory.

**Materials/methods:** Clinical blood culture bottles inoculated with blood or other sterile body fluid between 1 August 2018 and 31 July 2019 were included in the study. Disk diffusion according to EUCAST RAST methodology was performed by routine staff on consecutive positive blood culture bottles [BACTEC Plus bottles, BD] with monocultures of *E. coli* (n=335) or *S. aureus* (n=196). Inhibition zones were read at one or several of the possible incubation times (4, 6 and 8h). Initially, inhibition zones were primarily read after 6h incubation but after 28 May 2019 the 4h reading was prioritised. EUCAST standard disk diffusion, interpreted according to EUCAST Breakpoint Tables version 9.0 (2019), was performed on all isolates and used as reference. Only one isolate per patient and sampling time was included in the analysis.

**Results:** More than 95% of all zones could be read after 4h incubation for both species (Table). Some isolates of *E. coli* and *S. aureus* were read at more than one reading time (8% and 7% respectively). ESBL-producing isolates (n=23) [resistant to cefotaxime and/or ceftazidime with standard methodology] were correctly categorised as such. All MRSA isolates (n=6) were either categorised as resistant (5/6) to cefoxitin or in the Area of Technical Uncertainty, ATU (1/6). The total number of errors was below 1.5% and there were no false susceptible results.

**Conclusions:** The EUCAST RAST method in a routine laboratory resulted in AST results after only 4h incubation for most of *E. coli* and *S. aureus* isolates. Error rates were low and there were no false susceptible results. Most of the isolates categorised in the ATU for *E. coli* were due to piperacillin-tazobactam and tobramycin and for *S. aureus* clindamycin (75% and 79% respectively).

**Table.** Theoretical and actual number of tests, the proportion of tests which could be read and interpreted after 4, 6 and 8 h, and the categorical errors with RAST at each reading time for *E. coli* and *S. aureus*.

For each table, data are presented as (letters relating to footnotes):

A. The theoretical number of tests = Total number of possible isolate-agent combinations.

B. Number of completed tests = Number of completed test after excluding missing data (e.g. disk dropped).

C. Readable zones = Number of tests with readable inhibition zones.

Abstract 6936

**Comparison of Illumina and nanopore sequencing methodologies for whole genome sequencing of influenza A virus from clinical isolates**

Judith Heaney*1, Dan Frampton2, Harriet Gliddon3, Matthew Byott1, Paul Grant1,4, Rachel Mckendry3, Eleni Nastouli1,5

1UCLH, Advanced Pathogen Diagnostic Unit, London, United Kingdom, 2University College London, Division of Infection and Immunity, London, United Kingdom, 3University College London, London Centre for Nanotechnology, London, United Kingdom, 4Health Services Laboratories, London, United Kingdom, 5University College London, Institute of Child Health, London, United Kingdom

**Background:** Influenza A virus remains a major global threat; causing significant patient mortality and morbidity as well as costly closure of hospital wards primarily due to seasonal influenza infections. Point-of-care tests rapidly identify viral subtype but have limited utility in tracing virus transmission or drug resistance in a healthcare setting. Minimising the time from sampling and reporting potential linkage between clinical isolates can aid clinical decisions; can inform both local and public health measures as well as reduce preventable nosocomial infections. Here, we compare whole genome sequencing methodologies of influenza A virus in terms of cost, speed and sensitivity. Illumina and Oxford Nanopore Technologies (ONT) sequencing platforms were compared for both H1N1 and H3N2 influenza A viruses.

**Materials/methods:** Full-length influenza A virus amplification was achieved using a two reaction RT-PCR for 24 known positive clinical isolates covering a range of viral loads (11 H1N1 and 13 H3N2). For Illumina sequencing, the Nextera® XT DNA library preparation kit with 1ng DNA input per sample was used and the generated library run on a MiSeq (V2 500 cycles reagent kit) taking approximately 45 hours. Sequence analysis was performed using an in-house de novo assembly pipeline. For ONT sequencing, 1µg DNA input per sample was used and the library prepared using the Ligation Sequencing Kit and associated protocols for native barcoding. For sequencing, a MinION flow cell was used and run for a total of three hours, base calling using MinKnow or guppy (ONT) with an in-house pipeline used to perform reference-based genome assembly.

**Results:** Across all samples concordance between MiSeq and MinION sequenced genomes was exceptionally good, generating consensus genomes with almost complete sequence and read-depth agreement. Nine of the 11 H1N1 pairs of genomes were identical, remaining samples differing by one and two nucleotides respectively. For the H3N2 samples the results were similar: five were identical and eight differed by less than five nucleotides.

**Conclusions:** Illumina and ONT sequencing methodologies performed equally well for influenza A whole genome sequencing. Therefore, time to results and scalability should be the influencing factors when determining the most applicable sequencing platform.

Abstract 6938

**Oral Chagas disease outbreak in the Brazilian Amazon: first report of an outbreak related to patauà fruit**

Martínez Lacalzada Miguel¹, Jorgue Augusto De Oliveira Guerra²³, Paula Bonates Bessa⁴, Katia Couceiro²⁴, Monica Hossanah²³, Aline Storino², Daniele Nahmias²⁴; Jose López¹, Karina Lopez¹, Debora Raysa Teixeira¹, Jessica Ortiz², Maria Das Graças Vale Barbosa Guerra.²

¹Hospital Ramón y Cajal, Department of Internal Medicine, Madrid, Spain, ²Fundação de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil, ³Faculdade Metropolitana De Manaus- FAMETRO, Manaus, Brazil, ⁴University of the State of Amazonas, Manaus, Brazil

**Background:** Acute Chagas disease (ACD) has a distinct epidemiological profile in the Amazon Region, with cases and outbreaks related to the ingestion of *Trypanosoma cruzi* contaminated food. For most reported outbreaks, epidemiologic investigations point to nonvectored transmission, implicating juices from local fruits contaminated with triatomine faeces or secretions from infected mammals.

**Materials/methods:** Descriptive study and outbreak investigation of the first ACD outbreak related to the local fruit patauà (*Oenocarpus bataua*) in a rural area of the Brazilian Amazon in September 2019. Clinical evaluation, epidemiological, entomological and microbiological survey were performed. Relative Risk and Attack Rate were calculated. Confirmed, suspicious and exposed cases were defined according to established criteria.

**Results:** During the study period we detected 41 exposed people, 16 (39%) were diagnosed as ACD confirmed cases. All of them were diagnosed by direct visualization of parasite in thick drop. 8 of them were women (50%), the mean age was 36,8 ± 16,1 years. The Attack Rate in individuals exposed to patauà was 50% (25% in non exposed), lethality 0% (0/16), a calculated Relative Risk (RR) of 1.9 and a mean incubation time of 11.5 days (range 7 – 15 days). 16/16 patients (100%) had fever, 12/16 (75%) myalgias, 8/16 (50%) rash, 7/16 (38%) abdominal pain, 6/16 (38%) headache and 2/16 (13%) diarrhea, none presented acute miocardiopathy. All confirmed patients referred consumption of patauà juice prepared with inadequate hygienic measures. Serologies, PCR and direct parasitological study with thick drop was carried out to all individuals who had ingested patauà juice (n=41). 9 specimens of *Rhodnius robustus* and *Rhodnius pictipes* were captured during entomological survey in patauà palm trees, no domiciliary infestation was detected.

**Conclusions:**

- Oral transmission of *T. cruzi* involving the patauà fruit is the most likely hypothesis for acute chagas disease in these patients.

- To date, this is the first report of an acute Chagas disease outbreak associated with consumption of patauà.

- This study highlights the increasing incidence of oral ACD in the Amazon Region and the need to improve prevention and education campaigns at rural areas of this region focusing on hygienic and better harvesting methods.

Abstract 6941

**Diagnostic evaluation of the new FluoroType MRSAfast assay for the detection of MRSA from clinical swab specimens**

Sandra Dargel¹, Birgit Herberth², Martin Eckart*², Vera Allerheiligen², Thomas Brodegger³;⁴

¹MEDILYS Laborgesellschaft mbH, Hamburg, Germany, ²Hain Lifescience GmbH, Nehren, Germany, ³MEDILYS Laborgesellschaft mbH, Molecular Genetics, Hamburg, Germany, ⁴Hain Lifescience GmbH, Nehren, Germany

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) infections are caused by a type of bacteria strains resistant to at least all beta-lactam antibiotics and are thus difficult to treat. By establishing screening measures for high-risk patients when admitted to hospital, MRSA carriers can be identified at an early stage. The new FluoroType MRSAfast VER 1.0 is a qualitative *in vitro* PCR test for fast detection of MRSA strains directly from clinical specimens including the methicillin resistance-mediating genes mecA and mecC.

**Materials/methods:** DNA extraction for PCR was performed with the SpheroLyse-Kit. The eluted DNAs were analyzed with the new FluoroType MRSAfast VER 1.0 on the FluoroCycler 12 and FluoroCycler XT and the FluoroType MRSA Ver 2.0 (Hain Lifescience). The swab was used for inoculation of BBL Trypticase soy broth bouillon (Becton Dickinson). The trypticase soy broth was incubated for 24 h and then used to inoculate selective culture and non-selective culture (CNA agar). Species identification by MALDI-TOF (MALDI Biotyper, Bruker Daltonics) was used to confirm appropriate selection of colonies prior to culture differentiation. Culture differentiation by GenoType MRSA VER 3.0 (Hain Lifescience) was performed from all positive cultures on selective and/or non-selective agar to confirm the presence or absence of MRSA and to allow the differentiation of mecA- or mecC-strains. MRSA history and additional culture results were also considered in results evaluation.

**Results:** 512 swabs were analysed. The inhibition rate of the MRSAfast assay was at least 0%. The sensitivity / specificity / positive predictive value / negative predictive value were 96.3% / 97.6% / 99.6% / 99.6% on the FluoroCycler 12 and 94.5% / 96.5% / 76.5% / 99.3% on the FluoroCycler XT compared to combined MRSA results.

**Conclusions:** The specifications resulting from the data in our FluoroType MRSAfast study are in line with the expectations of PCR-based tests for the screening of MRSA at risk patients to derive timely hygiene-relevant measures. The turnaround time is significantly reduced (approx. 1h for FluoroType MRSAfast PCR vs. 2h for FluoroType MRSA 2.0 PCR). This represents a clear advantage over the previous FluoroType MRSA Ver. 2.0 results in consistent performance in the test execution.

Abstract 6942

**Gut microbiome characterisation in irritable bowel syndrome patients following faecal microbiota transplant: a case report study**

Marius Surleac1, Simona Paraschiv*1, Catalin Gabriel Apostolescu1, Dan Otelea1

1National Institute of Infectious Diseases-Prof. Dr. Matei Baș, București, Romania

**Background:** Irritable bowel syndrome (IBS) is a multifactorial digestive disorder affecting up to 11% of the adult population. Recent studies suggested the role of bacterial, viral and parasitic infections in triggering IBS, therefore targeting microbiota represents a promising approach in IBS patients. In this study we present the case of two patients with IBS that underwent fecal microbiota transplant (FMT): sequential studies of gut microbiome pre and post-transplant are performed.

**Materials/methods:** Microbial DNA was extracted from stool samples of seven healthy donors and two IBS patients eligible for FMT. NGS 16S metagenomics (pair-end amplicon sequencing) protocol was performed by using MiSeq platform (Illumina) and MiSeq reagent kit v.3 (600 cycles). Following FMT, longitudinal samples from IBS patients were collected (day 3, 10 and 28 post-transplant) and analyzed in the same manner. The bacterial microbiome diversity was primarily characterized at Family, Genus and Species levels using BaseSpace app from Illumina dedicated software. An extensive analysis was further performed by using QIIME and mothur tools.

**Results:** The donor for FMT was selected for high diversity of beneficial bacteria families. Both IBS patients had a good clinical outcome post- FMT, with slight differences. By analyzing the microbiome longitudinal data in IBS patients we observed that bacterial families considered beneficial (*Blautia, Faecalibacterium, Roseburia, Lahnospira*) were transmitted from the donor to the recipient, replacing other bacteria that are frequently associated with IBS (*Ruminococcus, Enterobacter, Pseudomonas*). For some bacteria families the effect was stable while in other cases it was transient (some disappeared at day 28 post-FMT). In one IBS patient we observed a few bacterial families not seen in donor microbiota or pre-FMT sample suggesting the role of other factors in shaping the gut microbiome.

**Conclusions:** Gut microbiome characterization by NGS coupled with bioinformatics analysis represents an important tool in personalized medicine for IBS patients useful by selecting the adequate FMT donors and monitoring the post-transplant effects. Clinical improvement was associated with stable transfer of bacterial populations.

Hospital Universitari i Politècnic La Fe, Valencia, Spain, 4Hematology Service, Hospital Clínico Universitario, Institute for Research INCLIVA, Valencia, Spain, 5Department of Infectious Diseases, Hospital Universitari i Politècnic La Fe, Valencia, Spain, 6Microbiology Department, Hospital Universitari i Politècnic La Fe, Valencia, Spain, 7Department of Medicine, School of Medicine, University of Valencia, Valencia, Spain, 8Department of Microbiology, School of Medicine, University of Valencia, Valencia, Spain

Background: Intestinal acute Graft versus Host Disease (aIGvHD), is a frequent immune-related complication after allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT). Torque Tenovirus (TTV) DNA in plasma behaves as a surrogate marker for immune reconstitution in transplant recipients. Here, we assessed the potential value of TTV DNA quantitation in stool for predicting of aIGvHD in this setting.

Materials/methods: Retrospective, observational study including 86 undergoing allo-HSCT at two Hospitals in Valencia between July 2016 and July 2019. TTV DNA was quantified in plasma and stool specimens using a TaqMan real-time PCR targeting conserved UTR sequences. A standard curve was generated by spiking a TTV plasmid in stool samples at concentrations ranging from 10^6 copies to 10^3 copies/ml.

Results: Stool specimens obtained after transplant (median, 14 days; range, 6-23 days) were available from all patients. Baseline specimens were available from 71 patients. Fifteen patients had paired plasma samples. 31 (36%) patients had developed aIGvHD [III-IV] at a median of 43 days (15 to 178) after transplantation. TTV was undetectable in 24 (33.80%) and 36 (41.90%) of pre and post HSCT in stool samples, respectively, while only in 1 (6.66%) and 2 (1.33%) of plasma samples. No differences were found regarding baseline TTV levels between patients who either went on to develop aIGvHD or not [median 3.17 Log_{10} copies/ml [1 to 5.88] vs 2.57 [1 to 4.44], P=0.18]. TTV loads after allo-HSCT were lower in patients with aIGvHD [median <1 to 5.88] vs 2.49 [1 to 6.82], P=0.11. As for TTV kinetics, the majority of patients with aIGvHD [80.00%] had declining levels of TTV in stool [median of differences between post and pre HSCT TTV DNA of 3.93 Log_{10} [2.04 to 7.42], P=0.03] whereas most patients had decreasing TTV loads in plasma, regardless of the occurrence of aIGvHD. A correlation was found between TTV DNA load in plasma and stool samples obtained prior to but not after HSCT [\rho= 0.87, P<0.01].

Conclusions: Early kinetics of TTV DNA in stool samples may help to anticipate the occurrence of aIGvHD in Allo-HSCT patients.

Invasive CNS aspergillosis in non-neutropenic patients: a review of nine cases from North India

Nitin Gupta1*, Ankit Mittal1, Parul Kodan1, Netto George Mundadan1, Rohit Kumar1, Tirlangi Praveen Kumar1, Gagandeep Singh1, Dr. Imaculata Xess1, Prashant Ramteke1, Manish Soneja1

1All India Institute Of Medical Sciences, New Delhi, India

Background: Invasive aspergillosis involving the central nervous system (CNS) is a rare and difficult to manage entity with most of the available literature describing it in patients with malignancies or patients undergoing bone marrow transplant. We describe a series of nine patients with CNS aspergillosis from a tertiary care teaching institute in North India.

Materials/methods: All patients who had clinical and radiological features consistent with fungal CNS infection and showed the presence of septate hyphae on histopathology/microscopy and were either culture positive for Aspergillus spp. or had serum galactomannan positivity were diagnosed as CNS Aspergillosis. Clinical features, risk factors, diagnostic modalities, treatment details and outcome at last follow-up were recorded of all patients diagnosed with CNS aspergillosis.

Results: A total of nine patients with an average age of 38+/-12 years were diagnosed with CNS aspergillosis between July 2016 and June 2019. Four patients were known case of Type 2 Diabetes mellitus (DM), two patients were diagnosed with chronic granulomatous disease (CGD) on primary immunodeficiency work-up and one patient had a recent history of head injury. No risk factors were identified in three patients (Table 1). The median duration of symptoms at presentation at our hospital was six months (IQR-2-9 months). Four patients were diagnosed as sino-cerebral aspergillosis, two patients were diagnosed with skull-based osteomyelitis due to Aspergillus spp. and the rest of the three patients had isolated brain abscess. Culture was positive in three patients and serum galactomannan was positive in six patients. Extensive surgical debridement was done in three patients. All patients were treated with voriconazole therapy. All but one patient survived at the last follow-up. The average duration of last-follow up was 14 months (IQR-8-21.5 months). Two patients had complete resolution and voriconazole was stopped at the last follow-up and the rest of the patients were continued on voriconazole. Of the six patients who were continued on voriconazole, all but one had >50% radiological resolution on follow-up imaging.

Conclusions: Invasive aspergillosis should be suspected even in non-neutropenic patients with DM or CGD presenting with CNS manifestations.

German multi-centre study on standardised in vitro testing of ceftazidime-avibactam against extensively drug-resistant clinical Pseudomonas aeruginosa isolates from 2017-2019

Raphael Stauf*, Jacqueline Abel1, Ernst Molitor2, Gunnar Hischebeth2, Alexander Halfmann3, Sören Leif Becker3, Jörg Steinmann1

1Paracelsus Medical University, Institute for Clinical Hygiene and Medical Microbiology, Nuremberg, Germany, 2UKB University of Bonn, Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, 3Saarland University, Institute for Medical Microbiology and Hygiene, Saarbrücken, Germany

Background: Multidrug resistance is an emerging healthcare issue, especially concerning gram-negative bacteria such as P. aeruginosa. Activity of ceftazidime-avibactam has been studied on P. aeruginosa with derepressed AmpC, ESBL- and metallo-β-lactamase-producing and efflux-based resistance mechanism. There is a lack of commercially available reliable standardised testing methods for ceftazidime-avibactam and reliability of gradient diffusion or disk diffusion test remains questionable.

Materials/methods: Minimum inhibitory concentrations (MIC) of 186 clinical extensively-drug-resistant (XDR, resistance to all but 2 sentinel agents of antimicrobial agent classes) P. aeruginosa isolates of three university hospitals in Germany from various sites of infection were determined according to EUCAST guidelines. MERLIN MICRONAUT-S microdilution test plates containing ceftazidime-avibactam (0.125/4-128/4 mg/L) and meropenem (0.0625-128 mg/L) were used. Test plates were provided by Pfizer Pharmaceuticals Inc.. Growth was assessed via photometric read-out using MICRONAUT6 software. P. aeruginosa ATCC strain 27853 was included as quality control in each run. In addition, Liofilchem® MIC Test Strip for ceftazidime-avibactam was conducted for comparison (173/186) and isolates were tested for presence of carbapenemase by PCR (130/186).

Results: Overall, for ceftazidime-avibactam MIC range was 0.25->128 mg/L, MIC90 was 32 mg/L and MIC50 was 8 mg/L. According to clinical EUCAST 9.0 breakpoints, 116 isolates were reported as susceptible and 70 isolates were reported as resistant in automated reading. Most, but not all VIM-positive (31/130) isolates showed elevated MICs (MIC range 0.25-64 mg/L, MIC90 32 mg/L, MIC50 16 mg/L) in vitro. MIC Test Strip for ceftazidime-avibactam generally showed higher MICs (MIC90 64 mg/L, MIC50 32 mg/L) with essential agreement of 58.38% (101/173) and categorical agreement of 70.52% (122/173).

Conclusions: Overall, 62.36% of clinical XDR-P. aeruginosa isolates were tested susceptible for ceftazidime-avibactam by semi-automated microdilution in vitro, though efficacy of ceftazidime-avibactam has shown to be variable with high inter-isolate variance. With semi-automated EUCAST microdilution via MERLIN MICRONAUT-S plates, testing is quick and standardised, yet delivers significantly differing results in comparison to gradient diffusion test. As Liofilchem® MIC test strips are reported to overestimate resistance for up to 20% of XDR-P. aeruginosa isolates, semi-automated microdilution may represent an alternative for MIC-determination of ceftazidime-avibactam for XDR-P. aeruginosa isolates in a clinical setting.

Abstract 6946

Characterisation of *Mycoplasma pneumoniae* and *Chlamydia pneumoniae* infections in Palestinian children older than 5 years of age

Jane Jeries*1, Ahmad Neirokh1, Raneen Bakri1, Nader Handal1, Hiyam Marzouqa1, Musa Hindiyeh1

1Caritas Baby Hospital, Bethlehem, Palestine

**Background:** Worldwide, *M. pneumoniae* and *C. pneumoniae* are responsible for 3% to 43% of Community Acquired Pneumonia (CAP). *M. pneumoniae*; is the smallest self-replicating organism that belongs to a special class of bacteria called the “Mollificates” whereas *C. pneumoniae* is an intracellular bacterium that belongs to the family Chlamydiaceae. This study aimed at determining the epidemiology of *M. pneumoniae* and *C. pneumoniae* in Palestinian children. In addition, the types of antibiotics prescribed to the infected patients and macrolide resistance pattern of *M. pneumoniae* was also assessed.

**Materials/methods:** A retrospective study was conducted on 438 nasopharyngeal aspirates collected from hospitalized children older than 5 years of age between 2015-2018. All patients were hospitalized at Caritas Baby Hospital due to pneumonia. *M. pneumoniae* and *C. pneumoniae* detection relied on utilizing an in-house validated multiplex Real-Time Polymerase Chain Reaction (RT-PCR). All positive *M. pneumoniae* samples were screened for macrolides resistance by sequencing the 23S rRNA domain V at positions 2063, 2064 and 2617. Patient charts were reviewed to determine the type of antibiotic the patient received and comparisons were performed using the Chi-Squared test.

**Results:** Of the 438 NPA samples, 21 (4.8%) were positive for *M. pneumoniae*, while 6 (1.4%) were positive for *C. pneumoniae*. *M. pneumoniae* circulation was most prevalent in the spring season (P<0.001) mainly between the months of February and April, while *C. pneumoniae* had a sporadic months distribution. Overall, antibiotics were prescribed to 20 (74%) patients (P<0.001) of whom 12 (60%) received the macrolide azithromycin. In addition, 19 (70%) patients also received either a second or third generation cephalosporins. Sequence analysis of the *M. pneumoniae* 23S rRNA gene revealed that 3 (14%) patients’ isolates were mutated at position 2063 (A2063G) in domain V.

**Conclusions:** Similar to other parts of the World, *M. pneumoniae* and *C. pneumoniae* were prevalent in Palestinian children older than 5 years of age. Implementation of rapid detection techniques of *M. pneumoniae* and *C. pneumoniae* not only will help in proper prescription of macrolides, but will help in eliminating the usage of second or third generation cephalosporins used to manage patients respiratory infections.

**Presenter email address:** jane.jeries@cbh.ps
**Abstract 6951**

**In vitro activity of ceftaroline and ceftobiprole against Enterococcus faecalis recovered from infective endocarditis and/or bloodstream infections**

Raquel Rodríguez García¹, Isabel Costales¹, Angeles Rodríguez-Esteban¹, Mauricio Telenti¹, Enrique García¹, Javier Fernández*¹

¹Hospital Universitario Central de Asturias, Oviedo, Spain

**Background:** Enterococci are a major leading cause of infective endocarditis (IE) and a common cause of hospital-acquired bacteremia. Ceftaroline and ceftobiprole are two novel broad-spectrum cephalosporins with bactericidal activity against multidrug-resistant Gram-positive bacteria, including *Enterococcus faecalis*, and also against many Gram-negatives. However, there are not current clinical trials in which the use of these drugs has been investigated in the initial treatment of bacteremia or IE caused by *E. faecalis*.

The aim of this study was to evaluate the *in vitro* activity of ceftaroline and ceftobiprole against a collection of *E. faecalis* recovered from IE and bacteremia.

**Materials/methods:** All patients admitted to a tertiary hospital in Spain with the diagnosis of IE by *E. faecalis* between January 2015 and October 2018 were studied. The modified Duke criteria were applied for diagnosis. Also, we evaluated the patients with bacteremia by *E. faecalis* in a six-month period (March-December 2018). Bacterial isolates were recovered from blood and/or heart valve cultures which had been processed at the Clinical Microbiology Unit and identified by MALDI-TOF MS (Bruker Daltonik, Bremen, Germany) or by PCR amplification of the gene encoding 16S ribosomal RNA and subsequent sequencing. When bacterial growth was obtained, minimum inhibitory concentrations (MICs) of ceftaroline and ceftobiprole were determined by using E-test strips (Biomérieux, Marcy l’Étoile, France) and interpreted according to CLSI guidelines.

**Results:** 162 patients were diagnosed with IE during the study period. A total of 65 *E. faecalis* isolates (19 from IE and 46 from other source of bacteremia) were recovered and tested. Microbiological data, including MICs to ceftaroline and ceftobiprole are summarized in Figure 1.

**Conclusions:** Isolates recovered from IE and bacteremia confirm that ceftaroline and especially ceftobiprole have an excellent activity against *E. faecalis* (MIC₅₀ 0.75 and 0.5 µg/mL, respectively), despite the theoretical intrinsic resistance of this organism to cephalosporins. Our data confirm that, due to its broad spectrum, both of this antibacterial could be a good choice for the initial treatment of IE or bacteremia by *E. faecalis*, probably combined with ampicillin and replacing ceftriaxone (drug included in current IE guidelines), however further clinical experience is required.

**Figure 1:** *In vitro activity of ceftaroline and ceftobiprole against Enterococcus faecalis*

**Abstract 6953**

**Evolution of candidaemia epidemiology and outcomes over the last 10 years: a single-centre study**

Julien Battistolo*, Emmanouil Glampedakis, Lauro Damonti, Julien Poissy, Thierry Calandra, Jean-Luc Pagani, Philippe Eggimann, Pierre-Yves Bochud, Oscar Marchetti, Frederic Lamoth

1Infectious Diseases Service, Lausanne University Hospital, Lausanne, Switzerland, 2Intensive Care Unit, Centre Hospitalier Régional Universitaire de Lille, Lille, France, 3Intensive Care Unit, Lausanne University Hospital, Lausanne, Switzerland, 4Department of Medicine, Ensemble Hospitalier de la Côte, Morges, Switzerland

**Background:** Candidemia remains an important cause of morbidity and mortality in hospitals. Increased use of antifungal drugs has been associated with epidemiological changes of candidemia with a shift from *Candida albicans* to more resistant non-albicans Candida species. The management of candidemia has also evolved over the last decade with increased use of echinocandins exhibiting a broader spectrum and possibly better efficacy than fluconazole. The aim of this study was to analyze the evolution of the epidemiology and outcome of candidemia over the last decade in our institution.

**Materials/methods:** This was a single-center retrospective analysis comparing all candidemic episodes occurring in our hospital between 2004-2006 (period A) and 2014-2017 (period B). Data about characteristics of patients and infections, Candida species and antifungal susceptibility, antifungal treatment and outcome were collected.

**Results:** A total of 158 candidemic episodes were included (68 in period A and 90 in period B). During period B, candidemia occurred more frequently in the ICU (41% vs 19% p=0.003), in patients that were older (mean 68 vs 58 years old, p=0.006) and experienced more frequently mechanical ventilation (43% vs 25%, p=0.01) and septic shock (27% vs 7%, p=0.02) compared to period A. Mortality was significantly higher in period B (37% vs 18%, p=0.01). While most cases of period A (76%) were treated by fluconazole, caspofungin was the most frequent first-line antifungal therapy in period B (51%). There was no differences in the proportion of Candida spp. between the two periods with *C. albicans* remaining the predominant species (59% vs 56% in period A and B, respectively, p=0.74). Resistance rates to fluconazole and echinocandins remained low and stable over years.

**Conclusions:** Compared to historical cases (10 years apart), candidemia currently affects mainly ICU patients with severe underlying conditions and is associated with higher overall mortality rates. Despite increased echinocandin use, the Candida species distribution and susceptibility patterns remain unchanged in our institution.

Background: Metronidazole resistance is still a serious problem among anaerobic pathogens, especially in countries where antibiotics are misused. Its best described resistance mechanism is mediated by nim gene-insertion sequence (IS) element pairs which can be a matter of question, but most of the metronidazole-resistant clinical Bacteroides isolates do harbour them. Metronidazole resistance among Bacteroides strains is also a major concern along with the emergence of multidrug-resistant strains as well.

Materials/methods: 421 clinical Bacteroides strains were collected during 2006-2018 in Kuwait. Antibiotic susceptibilities were recorded by Etests and nim genes and IS elements were detected by PCR in metronidazole-resistant strains. Nim gene types were determined by nucleotide sequencing and the localization of the nim genes was determined by plasmid DNA isolation and Southern blotting. The genetic relatedness of the metronidazole-resistant Bacteroides strains was investigated by ERIC [Enterobacterial Repetitive Intergenic Consensus] PCR typing. Carbapenem resistance mechanisms were also analyzed using similar methods.

Results: Of the 421 Bacteroides isolates 12 proved to be metronidazole resistant (10 B. fragilis, 1 B. dorei and 1 B. thetaiotaomicron). All but one was nim gene-positive harbouring the nimE gene. Of these, 9 were activated by ISBf6 and 5.7, 8.3, ~10 and ~13 kb plasmids carried the nimE genes. Interestingly, 6 of the nim-positive strains were also cfiA-positive with 5 silent and with 1 phenotypic resistance. By means of ERIC PCR typing, the B. fragilis strains were not clonal.

Conclusions: The prevalence of metronidazole resistant Bacteroides strains is around 4% in Kuwait and it is mainly due to nimE gene and ISBf6-carrying plasmids that in our cases represented four molecular weight classes. Since most of the examined strains were also cfiA-positive therefore possible treatment options are severely restricted.

Monitoring outpatient antibiotic utilisation using sales and reimbursement data: a population-based comparison in France, 2012-2017

Nhung Trinh1,2,3, Jérémie Cohen1,3, Tim Bruckner4, Corinne Levy5, Pierre Chahwakilian6, Antoine Bessou2, Dejan Milic3, Robert Cohen5, Martin Chalumeau1,3, Magali Lemaitre6

1University of Paris, CRESS IMR 1153, Paris, France, 2IQVIA France, Courbevoie, France, 3Necker Hospital, Paris, France, 4University of California, Irvine, Program in Public Health, Irvine, United States, 5Association Clinique et Thérapeutique Infantile du Val de Marne, Créteil, France, 6Independent expert, Versailles, France

Background: To assess whether a retail sales database could be used to monitor antibiotic utilization in the outpatient setting.

Materials/methods: We extracted outpatient antibiotic retail sales data (IQVIA’s Xponent database) and individual reimbursement data from the National Health Insurance (SNDS database), France, 2012-2017. We compared monthly-aggregated estimates of antibiotic use (number of antibiotic prescriptions per 1000 inhabitants per day, PrID) and antibiotic consumption (number of DDDs per 1000 inhabitants per day, DID) between sales and reimbursement data. We used Pearson’s $r$ statistics and linear regression to study how well Xponent data correlated with SNDS data. Autoregressive integrated moving average transfer function models were used to assess the possibility of using Xponent data to predict SNDS values.

Results: We analyzed approximately 390 million antibiotic prescriptions, comprising nearly 3.5 billion DDDs. Overall, Xponent slightly overestimated SNDS data, by 1.4% in PrID (Figure) and 1.8% in DID on average, consistently across major ATC classes, individual antimicrobial agents, types of prescribers, and regions. There were 3.5% missing data on age in the Xponent database; Xponent slightly underestimated SNDS data when evaluating adult [-1.1% and -0.5% for PrID and DID, respectively] and children [-0.5% and -2.8% for PrID and DID, respectively] antibiotic utilization. Xponent and SNDS data were highly correlated, both for PrID ($r$ coefficient = 0.998, $p < 0.0001$) and DID ($r$ coefficient = 0.996, $p < 0.001$). Linear regression modeling confirmed the high degree of correlation between Xponent and SNDS data (slope = 0.973 and 0.976 for PrID and DID, respectively, both $p < 0.0001$). Transfer function modeling showed that Xponent data could predict SNDS values with low deviation (between 0 and -1.1%), and that there was no divergence between the two time series.

Conclusions: IQVIA’s Xponent retail sales data were highly consistent with reimbursement data and were able to accurately predict SNDS values. IQVIA’s Xponent database is suited for monitoring outpatient antibiotic utilization in France.

Genomic surveillance of carbapenemase-producing Enterobacterales over 5 years reveals transmission clusters of clones and plasmids and extensive diversity of bacterial species encoding carbapenemases

Catherine Ludden*1,2, Elaine Mcgrath3, Niall Delappe1, Wendy Brennan2, Beth Blane4, Julian Parkhill4, Martin Cormican3, Sharon Peacock4,6

1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2Wellcome Sanger Institute, Hinxton, Cambridge, United Kingdom, 3National CPE Reference Laboratory, University Hospital Galway, Galway, Ireland, 4Department of Medicine, University of Cambridge, Cambridge, United Kingdom, 5Department of Veterinary Medicine, University of Cambridge, Cambridge, United Kingdom, Clinical Microbiology and Public Health Laboratory, Public Health England, Cambridge, United Kingdom

Background: Carbapenemase-producing Enterobacterales (CPE) are a major public health concern in Ireland. Screening for CPE is extensive and the number of cases, in particular of colonization, detected has increased progressively. The frequency of multispecies outbreaks remains poorly understood. Here, we sought to identify the transmission of CPE clones and plasmids circulating in Ireland using genomic surveillance. In addition, we investigate sharing of carbapenemase-encoding plasmids within and between species.

Materials/methods: We performed whole genome sequencing on all isolates received by the National CPE Reference Laboratory in Ireland between August 2012 and July 2017. We sequenced 782 CPE from 33 Irish hospitals (371 Klebsiella spp, 198 E. coli, 117 Enterobacter spp, 64 Citrobacter spp, 6 Serratia spp, 3 Raoultella spp, 1 Leclercia adecarboxylata, 1 Morganella morganii and 1 Providencia stuartii). Species and multi-locus sequences types (ST) were identified and genome comparisons were performed within each species. Carbapenemase genes were identified and mobile elements encoding carbapenemases were compared within and between species.

Results: High bacterial diversity was observed for the 766 isolates for which an ST could be defined (237 STs). blaOXA-48, blaKPC and blaNDM genes were detected in 490, 189 and 73 isolates, respectively (96% of isolates overall). blaOXA-48, blaKPC and blaNDM were observed in 26/33, 12/33 and 21/33 of the study hospitals, respectively. Genome analyses revealed both local and national clonal expansion (>5 isolates/ST from 1 or more hospitals) of carbapenemase producing Citrobacter spp, Enterobacter cloacae, Enterobacter hormaechei, E. coli, K. grimontii, K. pneumoniae, K. pneumoniae quasipneumoniae and K. oxytoca. Long-read sequencing identified a highly similar (99% identity) blaOXA-48 plasmid in 6 different bacterial species.

Conclusions: We characterised CPE isolated in Ireland from 2012-2017 using whole genome sequencing. This highlighted diversity in bacterial species encoding carbapenemases, and widespread dissemination of CPE clones. A highly similar blaOXA-48 plasmid was observed in different bacterial species. Additional analyses are underway to determine whether other carbapenemases are encoded on mobile elements that are disseminated within and between species and being transferred between hospitals.

A model-based analysis identifies differences in phenotypic resistance between in vitro and in vivo: implications for translational medicine within tuberculosis

Oskar Clewe¹, Alan Faraj*¹, Yanmin Hu², Anthony Coates², Ulrika Simonsson¹

¹Uppsala University, Department of Pharmaceutical Biosciences, Uppsala, Sweden, ²St Georges, University of London, Institute for Infection and Immunity, London, United Kingdom

Background: Proper characterization of drug effects on Mycobacterium tuberculosis relies on the characterization of phenotypically resistant bacteria to correctly establish exposure-response relationships. The aim of this work was to evaluate the potential difference in phenotypic resistance in in vitro compared to murine in vivo models using colony forming unit (CFU) data alone or CFU together with most probable number (MPN) data following resuscitation with culture supernatant.

Materials/methods: Predictions of in vitro and in vivo phenotypic resistance i.e. persisters, using the Multistate Tuberculosis Pharmacometric (MTP) model framework was evaluated based on bacterial cultures grown with and without drug exposure using CFU alone or CFU plus MPN data.

Results: Phenotypic resistance and total bacterial number in in vitro natural growth observations i.e. without drug, was well predicted by the MTP model using only CFU data. Capturing the murine in vivo total bacterial number and persisters during natural growth did however require re-estimation of model parameters using both the CFU and MPN observations implying that the ratio of persisters to total bacterial burden is different in vitro compared to murine in vivo. The evaluation of the in vitro rifampicin drug effect revealed that higher precision in the persister drug effect was seen using CFU and MPN compared to CFU alone although drug effects on the other bacterial populations were well predicted using only CFU data.

Conclusions: The ratio of persistent bacteria to total bacteria was predicted to be different between in vitro and murine in vivo. This difference could have implications for subsequent translational efforts in tuberculosis drug development

Epidemiology and mortality of neonatal Group B streptococcal meningitis and sepsis in the Netherlands: a 30-year nationwide surveillance study

Merel Van Kassel*1, Dorota Jamrozy2, Samira Teeri1, Stephen Bentley2, Matthijs Brouwer1, Arie Van Der Ende1, Diederik Van De Beek1, Merijn Bijlsma1

1Academic Medical Centre, Amsterdam, Netherlands, 2Wellcome Sanger Institute Sulston Building, Hinxton, United Kingdom

Background: Group B streptococcus (GBS) is the most common cause of invasive neonatal disease. We assessed the molecular epidemiology, incidence and mortality of neonatal GBS sepsis and meningitis in the Netherlands over 30 years and compared strain characteristics of meningitis with sepsis cases.

Materials/methods: We performed this nationwide surveillance study with data from neonatal (0-3 months of age) invasive disease cases between 1987 to 2016, from the Netherlands Reference Laboratory for Bacterial Meningitis. Serotyping was performed by latex agglutination. Capsule- and multi locus sequence types were determined using whole genome sequence data. Outcome data was obtained through the Municipal Personal Records Database.

Results: 1396 episodes in 1386 patients were identified, of which 177 (13%) were cultured from CSF, 344 (25%) from CSF and blood, and 875 (63%) from blood only. For meningitis, mean annual incidence was 0.09 (95%CI 0.08-0.10) per 1000 live births and remained stable over time (b=0.009, p<0.001; Figure 1). However, the annual incidence of sepsis only cases increased during the observation period (b=0.009, p<0.001) from a mean incidence of 0.07 per 1000 live births in the first decade to 0.26 per 1000 live births from 2006-2016. Late onset disease was associated with meningitis (p<0.001). Serotype III (62%) and sequence type (ST) 17 (34%) predominated in both sepsis and meningitis. Serotype III was identified among 26 STs, mostly ST17 (54%) and ST19 (24%). ST17 was associated with late onset, even after correcting for serotype and meningitis (OR 1.7 95%CI 1.30-2.33). Incidence of ST17 increased in sepsis (b=0.003, p<0.001). ST17 also increased in meningitis (b=0.001, p=0.090), when ST19 concurrently declined (b=-0.001, p<0.001). Mortality rate was 8% (27/323) in meningitis cases and 6% (39/656) in sepsis cases (p=0.175). Serotype Ib was associated with mortality in neonatal meningitis (OR 8.78 95%CI 1.92-40.05) compared to serotype III, even after correcting for multiple testing.

Conclusions: Hypervirulent strain ST17 increased overall, resulting in an increase in incidence of sepsis. Due to declining rates of other STs the overall incidence of meningitis remained stable.
Abstract 6969

**Experience of 319 post-surgical abscesses: focus on empiric antifungal therapy**

Eleonora Taddei*1, Francesca Giovannenze1, Emanuela Birocchi1, Rita Murri2, Lucia Cerolini1, Francesco Taccari1, Roberto Cauda1,2, Massimo Fantoni2

1Catholic University of Rome Fondazione Policlinico Gemelli IRCCS, Rome, Italy, 2Fondazione Policlinico Gemelli IRCCS, Rome, Italy

**Background:** Post-surgical abscesses are serious intra-abdominal infections (IAIs). Fungal etiology is less frequent than bacterial but associated with severe prognosis and difficult to establish due to inadequate sampling and polymicrobial cultures. Empiric antifungal therapy of IAIs must sometimes be considered, but guidelines in this regard are based on poor evidence. This work aimed to analyze the factors associated with the administration of empiric antifungal therapy in a real-life cohort of post-surgical IAIs and the impact of empiric antifungal therapy on patients’ outcome.

**Materials/methods:** We conducted a retrospective chart review in a tertiary level hospital in Italy for years 2013-2018. Adult patients with post-surgical abscesses who had been cared for by our ID consultation service were included. We excluded ICU and Hematology patients, intra-hepatic abscesses, extra-peritoneal collections and IBD cases. Empiric therapy was defined as administered within forty-eight hours from presentation. Freshly drawn percutaneous specimens or surgical specimens only were considered for etiology determination.

**Results:** Three-hundred nineteen post-surgical IAIs were retrieved (males 55.8%). Forty-six patients (14.4%) received empiric antifungal therapy (azoles 65.2%). *Candida* was isolated in 34 (10.7%) cases, all polymicrobial: 17 *C.albicans*, 10 *C.glabrata*, 2 *C.tropicalis*, 1 *C.incospicua*, 4 more than one species. One candidaemia by *C.tropicalis* was observed. Among 46 patients who received empirical antifungal therapy *Candida* was isolated in 11 cases, in 18 cases abdominal samples were not obtained, 15 had negative cultures 2 grew bacteria. On multivariate analysis, upper GI surgery, urgent surgery and re-intervention within 30 days were associated with empiric antifungal therapy. Pancreas or biliary tract surgery was associated with *Candida* isolation on univariate analysis. Among 34 fungal isolates, 11 patients received empiric antifungal therapy. Survival analysis showed an advantage against composite adverse outcome of death or IAI relapse when empiric therapy was administered (OR 0.11, p=0.05).

**Conclusions:** Criteria for empiric antifungal therapy administration in IAIs are not well-established and evidence from the literature is weak. Classic risk factors seem not to intercept all patients with *Candida* infection. Empiric therapy could provide an advantage in survival, thus better definition of criteria to guide empiric therapy should be defined through further studies.

¹Hospital Clínico Universitario, Institute for Research INCLIVA, Valencia, Spain, ²Hematology Department, Hospital Universitari i Politècnic La Fe, Valencia, Spain, ³Microbiology Department, Hospital Universitari i Politècnic La Fe, Valencia, Spain, ⁴Hematology Service, Hospital Clínico Universitario, Institute for Research INCLIVA, Valencia, Spain, ⁵Department of Infectious Diseases, Hospital Universitari i Politècnic La Fe, Valencia, Spain, ⁶University of Valencia / Hospital Clínico Universitario, School of Medicine, Department of Microbiology / Institut for Research INCLIVA, Valencia, Spain, ⁷Department of Medicine, School of Medicine, University of Valencia, Valencia, Spain, ⁸Department of Microbiology, School of Medicine, Shoal of Medicine, University of Valencia, Valencia, Spain

**Background:** *Pneumocystis jirovecii* (PJ) causes life-threatening pneumonia (PJP) in patients with underlying immunological disorders. Diagnosis of PJP relies on direct examination of bronchoalveolar fluid. Real-time PCR assays display increased sensitivity in comparison with microscopy; nevertheless, a positive PJ DNA PCR result in the absence of positive microscopy remains challenging, since because it may merely reflect carriage rather than infection.

**Materials/methods:** Retrospective, two-center study including 192 hematological patients (105 undergoing hematopoietic stem cell transplantation) who presented with clinical signs of pneumonia. All the respiratory tract specimens (BAL, sputa, and tracheal aspirates) were obtained and processed following routine procedures (including bacterial, fungus [extends galactomannan] and viruses examination). For PJ detection the RealCycler PJIR kit® (Progenie-Molecular, Spain) was used.

**Results:** The study included 219 episodes of pneumonia from 192 patients. In transplant patients (n=105, [allo-HSCT; n=86]), these episodes occurred at a median of 227 days after transplantation (0 to 3,231 days) and in non-transplant patients (n=87) at a median of 62 days after diagnosis (-8 to 5,326 days).

All specimens were negative by direct examination for PJ, while 27 displayed positive results by PCR (Bronchoalveolar lavage [BAL], n=18, sputa, n=7, and tracheal aspirate, n=2). Twenty-four out of these 27 patients were treated with Trimethoprim/Sulfamethoxazole. In twelve samples, PJP was the most probable diagnosis, of which 8 were non-transplant patients. Patients not undergoing anti-PJ prophylaxis were more likely to display a clinically significant PJ PCR result (P=0.04). Overall, higher serum levels of LDH was observed for patients with PJP (P=0.15). Corticosteroid use was equivalent across two groups.

Co-detection of other microorganisms was documented in 17 out of 27 specimens, mostly respiratory viruses, and was significantly lower (P=0.001) in patients with PJP when compared to those colonized by PJ. (OR= 0.02; 95%CI, 0.002-0.26).

When only considering BAL specimens, PCR C₅₇₃ were significantly lower in patients with PJP (median, 29.0 [26.4-34.7] vs. median 34.6 [30.0-41.0]; P=0.04).

**Conclusions:** Absence of co-detection of other microorganisms in respiratory specimens along with a low PJ PCR C₅₇₃ result may help to ascertain the clinical significance of PJ detection in hematological patients.

**Presenter email address:** eliseo.al.vi@gmail.com
Individuals at risk of developing rheumatoid arthritis possess a unique microbiome

Christopher Rooney*, Suparna Mitra, Kulveer Mankia, Ines B. Moura, Paul Emery, Mark H. Wilcox

1University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom, 2Leeds Teaching Hospitals NHS Trust, Great George Street, Leeds, UK, Microbiology, Leeds, United Kingdom, 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Individuals with newly diagnosed rheumatoid arthritis (RA) have a distinct microbiome when compared with healthy controls. However, little is known as to when these microbiome perturbations begin or indeed if they predate the onset of arthritis. RA is now recognised as an endpoint of a disease continuum encompassing genetic risk and development of autoantibodies, which may occur years before symptoms develop. Using a prospective ‘at-risk’ cohort of individuals positive for Anti-Citrullinated Peptide Antibodies (ACPA) with musculoskeletal symptoms but without arthritis, we investigated for the presence of a gut dysbiosis before the onset of RA.

Materials/methods: The gut microbiomes of 25 ACPA positive individuals were compared with a publically available control population using 16S rRNA sequencing, matched for rRNA V4 amplification region, sequencing technique, and approximately for age, gender, diet and ethnicity. Median interval between sample collection and analysis was 9 months. Data were quality controlled and annotated (Cutadapt, QIIME, RDP). OTU files were imported in MEGAN for further analyses. R was used for graphics.

Results: There were significant differences \( p=0.01 \) at family level in gut microbiome of ACPA positive individuals when compared with the control population. Five individuals progressed to RA in between sample collection and analysis. This progressor population displayed decreased microbiome diversity (Shannon/Simpson) when compared with non-progressors. Clustering of the progressor samples was observed on a phylogenetic network created using a pair-wise similarity network (Goodall’s index).

Conclusions:
ACPA positive at-risk individuals have a distinct microbiome when compared with healthy controls. The presence of decreased diversity and clustering suggests that distinct taxa may be involved in the development of RA and warrants further investigation.

Abstract 6975

Prevalence of fosfomycin resistance among Escherichia coli and Enterococcus faecalis isolates causing urinary tract infection in 34 primary care units in Brazil

Inneke Marie Van Der Heijden* 1, Alexandre José Natario 1, Claudia Giorgia Bronzatti Rodrigues 1, Registila Libania Beltrame 1, Fernando Luiz Affonso Fonseca 1, Silvia Figueiredo Costa 2

1Health Center University ABC, Health Center University ABC, Sao Andre, Brazil, 2University of Sao Paulo - FMUSP - LIM49, University of Sao Paulo - FMUSP - Hospital de Clinicas, Sao Paulo, Brazil

Background: Urinary tract infection (UTI) is one of the causes that often leads men and, specially, women to seek treatment at health units. Fosfomycin has been widely used in the treatment of lower uncomplicated UTI because of its excellent performance against Escherichia coli and Enterococcus faecalis. The aim of this study was to evaluate the prevalence of fosfomycin resistant Escherichia coli and Enterococcus faecalis strains recovered from patients attended at 34 primary care units in Brazil.

Materials/methods: We performed a retrospective study using the data obtained from laboratory records from January to September 2019. One sample by patients was including, and demographic variables such as age and gender were evaluated. The isolates were identified using BD Phoenix system and the susceptibility testing for fosfomycin were done by disk-diffusion technique using the breakpoints values according to CLSI standards.

Results: During the study period 39,958 urine cultures were performed at 34 primary care units (city of Sao Bernardo, Brazil). These samples were obtained by midstream technique and cultured at the clinical microbiology laboratory of the Health Center University ABC; a total of 6,676 (16.7%) urine cultures were positive and Escherichia coli and Enterococcus faecalis were isolated in 3,416 patients. The average age of these patients was 50.3 years (median 53 years) and 89.5% were female. Among these, 460 patients collected more than one urine sample. A total of 3,972 isolates were recovered being 3,478 (87.6%) E. coli and 494 (12.4%) E. faecalis. The fosfomycin resistance was observed in 45 isolates (1.1% E. coli and 1.4% E. faecalis). Resistant strains were observed in 44 patients with average 56.6 years old (median 64 years) and 79.5% occurred in women. Only one patient had 2 isolates resistant to fosfomycin in different episodes of UTI.

Conclusions: Fosfomycin resistance is still very uncommon among E. coli and E. faecalis causing UTI in patients attending at primary care units in patients. Thus, this drug can be used as a first choice of treatment for uncomplicated UTI in this setting. Strains resistant to fosfomycin were observed in cases of UTI mainly in women and in older patients.

Presenter email address: innekemicro@yahoo.com.br
Characterisation of virulence in KPC-2-producing *Klebsiella pneumoniae* CG258 from an outbreak in high complexity hospital in Brazil

Thais Rezende*, Carlos Morais†, Jussimara Monteiro§, Cely Abboud¶, João Carlos Setubal¶, Antônio Pignatari†, Carlos Kiffer†

†University Federal de São Paulo – Unifesp, São Paulo, Brazil, ‡University of São Paulo, São Paulo, Brazil, §AFIP – Associação Fundo de Incentivo à Pesquisa, São Paulo, Brazil, ¶Instituto Dante Pazzanese de Cardiologia, São Paulo, Brazil

**Background:** *Klebsiella pneumoniae* is an important opportunistic pathogen often associated with nosocomial infections. The capsular serotype, lipopolysaccharide, iron-scavenging systems, and fimbrial and non-fimbrial adhesins are some of the main factors implicated in the virulence of *K. pneumoniae* strains. In this study, we characterize through Whole Genome Sequencing (WGS) the capsular polysaccharide (CPS) and virulence characteristics in *Klebsiella pneumoniae* carbapenemase producing (KPC-KP) strains isolated from a Brazilian Hospital outbreak.

**Materials/methods:** A total of 11 KPC-KP isolates out of 88 isolates identified at a hospital in the city of São Paulo, Brazil were submitted to the WGS. This eleven isolates were assigned to clonal lineages by Pulsed Field Gel Electrophoresis (PFGE). Capsule typing genes (wzy sequencing and wzc), virulence factors of these strains were determined by biofilm formation, virulence genes including clpK, entB, ybtS, mrkD, ycfM, fimH, rmpA, ailS, iutA, kfu, wcaG, aerobactin, fecIRA, shiF, magA e pagO and Galleria Mellonella infection model.

**Results:** Four different STs were found among the 11 KPC-KP strains: 6 belonged to ST437; 3 to ST11; 1 to ST340 and 1 to ST101. Based on the DNA sequences of the wzy and wzc gene, these 11 strains were classified as capsular type K36 (n=5), all belonging to representatives of ST437; K161 (n=1) belonging to ST437; K64 (n=3) all representatives of the ST11 study; K107 (n=1) belonging to ST340, K17 (n=1) ST101. Biofilm formation was found in all isolates, and two ST437 isolates, one from blood culture and the other from the sternum secretion, showed a high adhesion to plaque. All 11 strains had the virulence genes entB, mrkD, ycfM, fimH followed by clpK in 10 strains, traT in 4, ybtS in 3, kfu in 1. The Galleria Mellonella infection model, showed that only 1 representative of ST11 killed 73.3% of the larvae within 24 h.

**Conclusions:** KPC-KP strains exhibited variability in traits associated with virulence. Therefore, the emergence of resistant KPC-KP strains associated with virulence factors in blaKPC-2 biofilm producing strains contributes to this pathogen causing infections, leading to its rapid expansion and persistence in the hospital environment.

Abstract 6979

**Zika virus: a global health threat and current situation in Pakistan**

Khekashan Imtiaz1, Joveria Farooqi1, Dhani Prakoso2, Kelli Barr3,4, Maureen Long5, Erum Khan*6

1Aga Khan University, Karachi, Karachi, Pakistan, 2University, Gainesville, United States, 3University, Waco, United States, 4Baylor University, Waco, United States, 5University Hospital, Gainesville, United States, 6University Hospital, Karachi, Pakistan

**Background:** Zika virus (ZIKV) is an emerging mosquito borne virus, which belongs to the family flaviviridae. It was first reported from a sentinel rhesus monkey in a Ugandan forest in 1947. The first human case of ZIKV was identified in Central Java, Indonesia in 1977, since then there has been several reports of ZIKV spread in Asia, Africa and Latin America. This dissemination of ZIKV around the globe makes it a serious health concern and has been declared by WHO as a state of ‘international emergency’ in February 2016.

**Materials/methods:** A cross-sectional, observational study was performed to identify flavivirus other than dengue as cause of acute febrile illness (AFI) including ZIKV. Patients were recruited at basic health units and or district hospitals at five different sites of the Sindh region of Pakistan. Serum samples of patients tested negative for dengue virus infection (using Pan Bio Rapid Detection kit for NS1-antigen, InBios ELISA kit for IgM antibodies and real time PCR (RTPCR) were selected for ZIKV testing using InBios ELISA kit for IgM antibodies and RTPCR and PRNT testing.

Nine hundred and ninety-five (n=995) patients were recruited over period of one year (April 2015 to December 2016).

**Results:** Of 995 tested 521 (52.36%) were found to be negative for dengue using all tests mentioned above. These samples were also tested negative for West Nile Virus (WNV), Japanese Encephalitis Virus (JEV) IgM antibodies. These samples were then tested for Zika Virus IgM using InBios ZIKV Detect™ 2.0 IgM Capture ELISA kit, 5.72% (n=57) were positive for Zika Virus IgM, these samples were considered presumptively positive for ZIKV. Confirmatory PRNT tests and PCR testing is in process. This is the first ever report of ZIKV activity from Pakistan.

**Conclusions:** In this study, we would like to share the demographic and clinical details of patients confirmed positive cases for ZIKV based on PRNT result.

Abstract 6982

**Determination of prevalence of *Chlamydia trachomatis* in pregnant women between 15 to 25 years old at Hospital Universitario La Paz, Madrid, Spain**

Bartolomé Gómez Arroyo*, Patricia González Donapetry¹, Celia Fabra Garrido¹, Marta Dorado Criado¹, Carolina González Arboleya¹, Elena Merino San Martín¹, Cristina Calvo Rey¹, María De La Calle Fernández-Miranda¹, Inmaculada Quiles¹, Julio García Rodríguez¹

¹University Hospital La Paz, Madrid, Spain

**Background:** *Chlamydia trachomatis* is one of the most commonly reported sexually transmitted diseases, it mostly affects sexually active young women. The newly born infants of infected mothers could be infected when passing through the birth canal. The aim of this study is to know the prevalence of *C. trachomatis* in pregnant women aged between 15 and 24 years and to obtain data about vertical transmission.

**Materials/methods:** We collected urine samples from pregnant women between 15 and 24 years old who gave birth in Hospital Universitario La Paz (Madrid, Spain) before delivery or in the immediately postpartum period, in a period of 7 months from November 2018 to June 2019. We performed a nucleic acid amplification test by real time PCR multiplex (BD-Max, Becton Dickinson) which detects *C. trachomatis*, *Neisseria gonorrhoeae* and *Trichomonas vaginalis*. Urine and respiratory samples were collected from all the infants of infected women. Conjunctival samples were also collected from those newborn who presented conjunctivitis signs.

**Results:** We analized a total amount of 136 urine samples and 31 of them showed a positive result. *C. trachomatis* was detected in 25 patients (18.38 %), *N. gonorrhoeae* in 4 patients (2.94%) and *T. vaginalis* in 5 (3.67%). In three patients with a positive result for *C. trachomatis* a mixed infection was detected (2.20%), in one case with *N. gonorrhoeae* (0.73%) and on the other two with *T. vaginalis* (1.47%). To this moment a total of 20 infants have been studied out of the 31 mothers that tested positive. In the newly born group 5 patients received a positive test.

**Conclusions:** We observed that there is a high prevalence of *C. trachomatis* infection among the population we studied, and that there is also the risk to transmit the infection to the newborn. Although perinatal transmission have been investigated in few recent publications, in Europe some studies have shown that the prevalence of *oftalmia neonatorum* is around 15%. For all that we consider that it will be usefull to perform a screening test for this microorganisms in pregnant women between 15 and 24 years old.

Influence of extracorporeal membrane oxygenation on the pharmacokinetics of ceftolozane/tazobactam

Camille Mane*, Clément Delmas, Jean Porterie, Patrick Verwaerde, Géraldine Jourdan, Didier Concordet, Bertrand Marcheix, Georges Bernard, Stephanie Ruiz, Peggy Gandia

1INTHERES, Université de Toulouse, INRA, ENVT, Toulouse, France, 2Toulouse University Hospital, Toulouse, France, 3IMC2, UMR-1048, INSERM, Toulouse, France, 4Alfort School of Veterinary Medicine, UPEC/IMRB-Inserm U955, Maisons-Alfort,, 5Toulouse School of Veterinary Medicine, Stomalab UMR 5273 CNRS/UPS - EFS - ENV - INSERM U1031, Toulouse, France

Background: Extracorporeal Membrane Oxygenation (ECMO) is increasingly used in Intensive Care Unit and can modify drug pharmacokinetics and possibly lead to under-exposure associated with treatment failure. Ceftolozane/tazobactam is an antibiotic combination used for complicated infections in critically ill patients. Launched in 2015, sparse data are available on the influence of ECMO on its pharmacokinetics. The objective of the current study was to determine the influence of ECMO on the pharmacokinetics of ceftolozane-tazobactam.

Materials/methods: An ex vivo model (closed-loop ECMO circuits primed with human whole blood) was used to study adsorption during 8-hour interdose intervals over a 24-hour period (in all 3 ceftolozane/tazobactam injections) with 8 samples per interdose intervals. Two different dosages of ceftolozane/tazobactam injection were studied and a negative control (whole blood in a glass tube with one ceftolozane/tazobactam injection and adsorption study over 24 hours) was performed. An in vivo porcine model was developed with a 1-hour infusion of ceftolozane-tazobactam and concentration monitoring for 11 hours. Pigs undergoing ECMO were compared with a control group. Pharmacokinetic analysis of in vivo data (non-compartmental analysis using PK-solver and non-linear mixed effects modelling using MONOLIX®) was performed to determine the influence of ECMO.

Results: With the ex vivo model, concentrations ranged from 20 to 180 mg/l and from 10 to 75 mg/l for ceftolozane and tazobactam respectively. Height-hour variations in concentration ranged from -5.73% to 1.26% and from -12.95% to -2.89% for ceftolozane and tazobactam, respectively. The in vivo pharmacokinetic exploration showed that ECMO induces a significant decrease of 37% for tazobactam clearance without significant modification in the pharmacokinetics of ceftolozane, probably due to a small cohort size.

Conclusions: Considering that the influence of ECMO on the pharmacokinetics of ceftolozane and tazobactam is not clinically significant, normal ceftolozane and tazobactam dosing in ICU patients should be effective for patients undergoing ECMO.

Genomic analysis of invasive Streptococcus pyogenes isolated in 2013 and 2018 from Hungary

Katalin Kristóf1, Petronella Farkas1, Miklós Iván1, Erika Ungvári2, Timea Erdős2, Akos Toth*2

1Semmelweis University, Budapest, Hungary, 2National Public Health Center, Budapest, Hungary

Background: Most of the severe invasive infections has been caused by several emm types of Streptococcus pyogenes (emm1, emm12, emm28, emm3, emm4 and emm89) in Europe. In 2005 emm1 was the prevalent type among invasive S. pyogenes isolates in Hungary. Since 2012 the number of invasive S. pyogenes cases among patients older than 25 years has steadily increased. The aim of the study was to perform genomic analysis of such isolates collected in 2013 and 2018 in order to compare their genetic background and relationships.

Materials/methods: We investigated 39 selected S. pyogenes isolates (14 from 2013, 25 from 2018) from invasive samples of patients older than 25 years originated from 13 Hungarian hospitals by whole genome sequencing on Illumina MiSeq. Clonal relationships were investigated by emm-typing and core genome (cg)MLST (SeqSphere+ [Ridom]). A bioinformatic pipeline was generated based on 60 genes associated with virulence and 18 genes associated with resistance. Antibiotic susceptibility tests were performed by gradient MIC tests and interpreted using EUCAST guidelines.

Results: Rates of antimicrobial resistance were: erythromycin 5.1%, clindamycin 2.6%, tetracycline 23.1% and levofloxacin 5.1%, which could be also predicted by resistome analysis. Thirteen emm types were detected, of these in 2013 emm28 (28.6%) and emm1, emm3, emm117 (each 14.3%), while in 2018 emm59 (24%), emm1 (20%), emm3 and emm81 (each 12%) were prevalent. The tetracycline resistance was significantly associated with emm59. According to cgMLST, all six emm59/ST172 isolates originated from six hospitals in 2018 could be assigned to one cluster, while clonal relationship between eight emm1/ST28 isolates was unlikely. Four minor clusters from different STs could be also observed. All isolates harboured genes encoding hyaluronic acid capsule (hasA-B-C), DNAse (spd), hyaluronidase (hyl), streptolysin O (slo), NADase (nga), exotoxin B and G, and adhesins (fbp54, lmb). Among the emm1/ST28 isolates 54-56% of investigated virulence factors could be detected, while among emm59/ST172 isolates only 37%. The most frequent emm-type/exotoxin-profile combinations were emm1/A-B-C-G-J-smeZ (20.5%) and emm59/B-G-J-smeZ (15.4%).

Conclusions: Our results suggested that the emm59/ST172 with tetracycline resistance appeared clonally in geographical distant parts of Hungary and became a prevalent type among invasive S. pyogenes population in 2018.

Clinical outcomes in patients receiving high vs standard dose caspofungin in the treatment of Candida intravascular infections

Galyna Clous*1, Kelci Coe1, Lynn Wardlow1, Christine Hanks1, Zeinab El Boghdadly1, Erica Reed1

1The Ohio State University Wexner Medical Center, Columbus, United States

Background: Echinocandin antifungals are an important therapeutic option in the management of Candida infections. The 2016 Infectious Diseases Society of America Guidelines recommend high dose (HD) caspofungin (150 mg daily) for treatment of Candida intravascular infections (CINs), including endocarditis and implantable cardiac device infections. In vitro studies have shown reversal of fungal growth inhibition at high doses of echinocandins. Clinical implications of this paradoxical effect among Candida species is unknown. The aim of this study is to compare clinical outcomes associated with HD vs standard dose (SD) (50 mg) caspofungin therapy in patients with CINs.

Materials/methods: This was a single-center, retrospective cohort of inpatients with CINs from Jan 2012 to October 2018 who received caspofungin for a minimum of 48 hours. Data collected included baseline clinical characteristics, echinocandin dose received and adverse events (ADEs). Patients receiving HD vs SD caspofungin were compared. The primary outcome was treatment failure necessitating a change of antifungal therapy. Secondary outcomes included all-cause in-hospital and 90-day mortality and 90-day infection relapse. The Wilcoxon Rank Sum test, Pearson chi-squared test, and Fisher’s exact test were utilized as appropriate.

Results: There were 44 eligible patients with CINs, of which 28 (64%) received HD caspofungin and 16 (36%) received SD caspofungin. There were no significant differences in the baseline clinical characteristics. The most common indications were Candida endocarditis (36, 82%) and cardiac device infection (8, 18%). Candida albicans was the predominant species (15, 34%). The caspofungin dose did not affect time to microbiological clearance (p=0.91), with a median of 3 candidemia days in both groups. There was no difference in treatment failure with HD vs SD caspofungin therapy (29% vs 19%, p=0.72). All-cause in-hospital mortality (18% vs 13%, p=1.00) and 90-day mortality (11% vs 25%, p=0.24) were also similar. None of the patients had 90-day infection relapse. The most common ADE was hepatotoxicity, but there was no significant difference between the HD and SD caspofungin groups.

Conclusions: SD caspofungin therapy had similar outcomes and tolerability compared to HD caspofungin therapy for CINs. Further studies are warranted to evaluate the safety and efficacy of HD caspofungin.

Dalbavancin use in the United Kingdom: a multi-centre, retrospective evaluation of real-world use of an extended dosing interval lipoglycopeptide

Ritchie Neil1, Katharine Cartwright2, John Cunniffe3, Sally Curtis4, Chris Durojaie5, David Enoch6, Sharon Falconer7, Achyut Guleri8, Robert Laing7, Andrew Seaton1, Harriet Sharp4, Liz Sheridan9, Simon Tiberi10, Beth White1

1Queen Elizabeth University Hospital, Glasgow, United Kingdom, 2Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom, 3Wirral University Teaching Hospital NHS Foundation Trust (WUTH), Birkenhead, United Kingdom, 4Brighton & Sussex University Hospitals NHS Trust, Brighton, United Kingdom, 5University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom, 6Addenbrooke’s Hospital, Cambridge, United Kingdom, 7Aberdeen Royal Infirmary, Aberdeen, United Kingdom, 8Blackpool Teaching Hospitals, Blackpool, United Kingdom, 9Poole Hospital, Poole, United Kingdom, 10Barts Health NHS Trust, London, United Kingdom

Abstract 6994

Background: Dalbavancin is a lipoglycopeptide antibiotic, highly active against gram positive organisms with a prolonged half-life permitting an extended dosing interval. It is licenced for the treatment of acute bacterial skin and skin structure infection (ABSSSI) but data supporting use in other conditions are limited.

Materials/methods: a multicentre, service evaluation recording all use of dalbavancin in 10 UK centres.

Results: 269 patients received 409 doses of dalbavancin. Dalbavancin was well tolerated with 11 adverse effects recorded (4% of patients). One patient died within 72 hours of drug administration. The most common indications for dalbavancin were ABSSSI (45%), osteomyelitis/septic arthritis (21%), prosthetic joint and orthopaedic device related infection (12%), infective endocarditis (11%) and sepsis in people who inject drugs (PWID) (7%). The most common reasons for selecting dalbavancin were practical difficulties with OPAT (35%), PWID (26%), OPAT capacity (18%) and IV access difficulties (5%).

In 122 cases of ABSSSI, dalbavancin was administered after a median 1 day of antibiotic therapy (range 0-16). 75% received 1500mg and the remaining 25% received 1000mg of dalbavancin ± 500mg a week later. 4 patients (3%) with ABSSSI were readmitted to hospital and 10 patients (8%) received a further dose of dalbavancin after 2 weeks because of an ongoing need for IV antibiotics. 1 patient failed to respond.

Dalbavancin given for other indications was associated with greater duration of prior therapy (median 7 days, range 0-200). Bacteraemia was recorded in 63/147 (43%) of patients with 45 (31%) having Staphylococcus aureus bacteraemia (SAB). 41 patients including 12 with bacteraemia (9 SAB) received < 48 hours of treatment prior to receiving dalbavancin usually to treat osteoarticular infection (61%) or other deep-seated infections in PWID (24%). In this group, outcomes were generally favourable with 2/41 patients reported to have experienced treatment failure and 1/41 being readmitted to hospital with a presumed febrile reaction to dalbavancin. In 106 cases given > 48 hours of antibiotics prior to dalbavancin, 6 (5%) experienced treatment failure.

Conclusions: Dalbavancin was safe and well tolerated. In ABSSSI, dalbavancin was typically administered within 24-48 hours whereas in other infections, dalbavancin was usually given after initial treatment with alternative agents.

Abstract 6997

Distinct augmenting contribution of hyperbaric oxygen therapy to neutrophil function and antibiotic efficacy against Staphylococcus aureus

Franziska Angelika Schwartz*, Lars Jackie Christophersen1, Peter Østrup Jensen1, Christian Johann Lerche1, Claus Moser1
1Rigshospitalet, Clinical Microbiology, København, Denmark

Background: Staphylococcus aureus (SA) is known to cause severe endovascular infections such as infective endocarditis (IE), in which it accounts for up to 40% of cases. As mortality rates are high, clinical management of left-sided SA IE remains challenging. Previously, we showed that hyperbaric oxygen therapy (HBOT) enhances the effect of tobramycin-treatment in a rat model of left-sided IE. Since the mechanism of HBOT is not clarified, the present in vitro study aimed at investigating the contributing anti-SA mechanisms of HBOT on direct bacterial killing, antibiotic potentiation and polymorphonuclear leukocyte (PMN) enhancement.

Materials/methods: SA (1.25x10⁷ CFU/mL) was exposed to isolated human PMNs (1.25x10⁶ PMN/mL from one healthy individual), tobramycin (0.007 µg/mL; MIC = 0.125 µg/mL) and ciprofloxacin (0.03 µg/mL; MIC = 0.25 µg/mL). HBOT was used in humanized exposure (100 % O₂, 2.8 bar, first 90 minutes of the assay). Bacterial survival and growth were observed after 4 hours by quantitative bacteriology and optical density (OD₆₀₀nm) measurements. For measuring PMN functionality, 100 µL whole blood was stimulated with 1.67 mM phorbol myristate acetate or 3x10¹⁰ CFU/mL SA and exposed to normoxic and normobaric conditions or HBOT for 40 minutes at 37 °C. Intracellular ROS-production was measured as mean fluorescence intensity by means of dihydrorhodamine analysis in a flow cytometer.

Results: We established an in vitro assay of SA infections and showed that HBOT exhibits significant direct anti-staphylococcal effects (32% killing, p=0.0002). Furthermore, HBOT increased the functionality of PMNs 18 % in general (p=0.0004) and 15 % in response to SA (n.s). Finally, HBOT showed an additive effect as 35 % additional killing to sub-MICs of tobramycin (p=0.006) and 57 % additional killing of ciprofloxacin (p=0.0001).

Conclusions: The present in vitro study provides evidence that HBOT has differential beneficial mechanisms mediating its anti-SA effects in infections. Despite the direct effect, it enhances the host-immune response and improves the oxygen-dependent antibiotic killing by tobramycin and ciprofloxacin. This observation can help to improve the clinical management of severe SA infections with adjunctive HBOT by augmenting the host immune response and optimizing the efficacy of antibiotic treatments.

**Abstract 6998**

**Performance of the Accelerate Pheno system in a tertiary care hospital in Germany**

Benjamin Berinson*1, Flaminia Olearo1, Anna Both1, Martin Aepfelbacher1, Holger Rohde1

1University Medical Center Hamburg-Eppendorf, Institute of medical Microbiology, Virology and Hygiene, Hamburg, Germany

**Abstract third-party references:** Accelerate Diagnostics

**Background:** The number of multidrug-resistant Gram-negative bloodstream infections (BSI) has dramatically increased the problems faced, when treating a hospitalized patient. In recent years, many attempts have been undertaken to enhance antibi-otic management and reduce the turnaround time for reporting of the antimicrobial susceptibility profile (AST) of the identified organism to improve clinical outcome for patients. The Accelerate Pheno System (ACC) provides ID and AST results in 7 hours, directly from positive blood culture. We aimed to evaluate the analytical performance of ACC for Gram-negative BSI in a tertiary care hospital.

**Materials/methods:** The ACC was implemented at the University Hospital of Eppendorf (Germany) and compared to Standard of care (SOC; Vitek2). Categorical agreement (CA, results with the same interpretation), rates of very major errors (VME, proportion of resistant isolates by SOC, tested susceptible by ACC), major errors (ME, susceptible isolates by SOC, resistant by ACC), minor errors (mE, intermediate isolates by SOC, resistant or susceptible by ACC) and area of technical uncertainty (ATU) were analyzed.

**Results:** 75 blood cultures with Gram-negative isolates as a causative agent were prospectively measured with the ACC. The most commonly identified organisms were *E. coli* (36), *K. pneumoniae* (8) and *Pseudomonas aeruginosa* (5). 938 AST results were available by the ACC. Overall CA was 98.3%. mE rate was 0.64%, ME rate was 0.1%, VME rate was 0.53% and 0.42% were in the ATU. In 10 cases of mono-microbial infections the ACC could not identify the causative bacterium. Four poly-microbial blood cultures were measured, of which two were correctly identified, in one case the ACC identified one of two organisms and failure to identify any organism occurred in one case. In 7/61 (11.5%) cases, the ACC correctly identified the causative organism, but failed to create an AST record.

**Conclusions:** ACC can help to quickly identify a causative organism of a BSI directly from the positive blood culture and perform a rapid AST, reducing the turnaround time. ACC should be initiated within 8 hours of blood culture positivity, therefore laboratories must consider workflows and integration into a structured antimicrobial stewardship program to ensure maximal benefit for the patients.

Identification by proteomic (MALDI-TOF MS) of non-tuberculous mycobacteria from liquid medium in clinical practice

Rocio Sainz Rodriguez1, Maria Concepcion Mediavilla Gradolph2, Fernández Ana María1, Begoña Palop*1, Ana Correa2, Mªpilar Bermúdez Ruiz1

1Hospital Regional Universitario de Málaga, Servicio de Microbiología, Málaga, Spain, 2Hospital Costa del Sol, Servicio de Microbiología, Marbella, Spain

Background: The use of MALDI-TOF MS for the identification of non-tuberculous mycobacteria (NTM) in solid medium has proven to be very useful and allow good discrimination at the species level. To reduce the response time we would need to be able to identify the NTM directly from the liquid medium. The objective of our study was to compare the results obtained by identifying the NTM with MALDI-TOF MS of liquid medium and those obtained by Genotype ® Mycobacterium CM / AS. (Hain Lifescience, Germany).

Materials/methods: From November 1, 2018 to March 31, 2019, we studied 31 cultures of positive clinical samples for NTM in Bactec Mycobacteria Growth indicator tubes (MGIT, Becton Dickinson), making the identification by MALDI-TOF MS from liquid medium. For the identification, we used the extraction procedure described by B. Rodriguez Sanchez, 2018, using the Mycobacteria library 4.0 database. The cultures were sent to the reference center of the Costa del Sol Hospital (Marbella) for the realization of reverse hybridization Genotype ® Mycobacterium CM / AS.

Results: We worked with 31 MGITs, of which 29 (93.5%) were correctly identified. In 27 samples, the results coincided with those obtained using Genotype® Mycobacterium CM / AS [M.chimaera intracellulare-group M. lentiflavum, M. mucogenicum phoacaicum group, M. chelonae, M. lentiflavum, M. fortuitum, M. avium and M. gordonae]. Two cases identified as M. canariasense / cosmeticum and M. elephantis, not being in the Genotype ® Mycobacterium CM / AS database, were sent to the National Center for Microbiology, where they confirmed the identification.

Of the 29 identifications made, 13 were obtained with a score > 2,000, 13 with a score between 2,000-1,700 and 3 with <1,700. In two samples, no protein peaks were obtained and identification was not possible.

Conclusions: MALDI-TOF MS is a useful technique for the rapid, reliable and cost-effective identification of non-tuberculous Mycobacteria from liquid medium, presenting a high concordance with the reference method. The spectrum of identified species is not very extensive, it would be necessary to increase the number of samples in order to evaluate the ability to identify other species.

Presenter email address: bpalop@hotmail.com
**Evaluation of the interactions of polymyxin B in combination with aztreonam, minocycline, meropenem and rifampicin against NDM- and OXA-48-like producing Escherichia coli**

Anna Olsson*1, Marcus Hong1, Hissa Al Farsi2, Christian Giske3, Pernilla Lagerbäck1, Thomas Tängdén1

1Uppsala University, Department of Medical Sciences, Uppsala, Sweden, 2Karolinska Institute, Department of Laboratory Medicine, Division of Clinical Microbiology, Stockholm, Sweden, 3Karolinska University Hospital, Department of Clinical Microbiology, Solna, Sweden

**Background:** The prevalence of infections with multidrug-resistant Gram-negative bacteria is steadily increasing. Combination therapy is used to enhance the efficacy of the available antibiotics. However, there is a paucity of data on which combinations are most effective, mechanisms of synergistic interactions and associations between the susceptibility to specific combinations and the presence of resistance genes. This study aimed to determine the in vitro effects of polymyxin B combinations against Escherichia coli producing NDM and OXA-48-like carbapenemases.

**Materials/methods:** Time-lapse microscopy was used to screen the antibacterial activity of polymyxin B in combination with aztreonam, meropenem, minocycline and rifampicin at multiple drug concentrations against 20 clinical isolates of NDM (n=13), OXA-48-like (n=5) and NDM and OXA-48-like-producing (n=2) E. coli. After 24 h the samples were spotted on agar with and without 4x MIC polymyxin B to assess resistant subpopulations. The strains were characterized by MIC determination according to EUCAST guidelines and whole genome sequencing to detect antibiotic resistance genes and genes involved in efflux.

**Results:** A synergistic and bactericidal effect was found with polymyxin B and minocycline against 11 of the 20 strains and with polymyxin B and rifampicin against 9 strains. Synergy was less frequently observed with combinations including aztreonam (3 of 20) and meropenem (2 of 20). Bacterial growth >2 log10 CFU/mL on 4x MIC polymyxin B was only detected in 3 of 1600 24-h samples, suggesting very little resistance development. In addition to the carbapenemases, all strains carried other β-lactamase genes, most commonly blaCTX-M-15 and blaTEM-1B. Tetracycline resistance genes were present in all but two strains. The tet(B) gene and a wild-type soxR gene were correlated with synergy of polymyxin B plus minocycline and no synergy was found for polymyxin B in combination with aztreonam or meropenem against any of the strains carrying blaCTX-M-15.

**Conclusions:** Combinations of polymyxin B and minocycline or rifampicin were most effective showing synergistic and bactericidal effects against approximately half of the tested NDM and OXA-48-like-producing E. coli. Potential associations between synergistic interactions and resistance genes were found, which could be of interest in the future search for promising combination therapies.

Abstract 7005

Long-term impact of an antimicrobial stewardship programme implemented in a tertiary care Greek hospital on antibiotics consumption and on the incidence of carbapenem-resistant Gram-negative pathogens: an interrupted time-series analysis

Antonios Markogiannakis1, Michail Samarkos1,2, Maria Gamaletsou*1,2, Ioannis Deliolanis3, Nikolaos Pantazis4, Fotinie Ntziora1, M. Psichogiou1,2, Giannoula Rentziou1,2, Eugenia Malliarou1,2, Dimitrios Bassoulis1,2, Eirini Iliadi1,2, Nikolaos Sypsas1,2

1General Hospital of Athens “Laika”, Athens, Greece, 2Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: During the last decade the prevalence of Carbapenem-resistant (CR) Gram-negative pathogens (GNP) has dramatically increased in Greek hospitals. Our aim was to evaluate the impact of an antibiotic stewardship program (ASP) implemented in a 535-bed tertiary-care hospital on the consumption of 3 classes of protected antibiotics (PrA, i.e. carbapenems, colistin, tigecycline) on the incidence of CR isolates of three major GNP: Klebsiella pneumoniae (KP), Pseudomonas aeruginosa (PA) and Acinetobacter baumannii (AB).

Materials/methods: A prospective audit with feedback ASP targeted specifically to three PrA was evaluated by comparing a pre-interventional period (PP) (January 2014-October 2016) to the interventional period (IP) (November 2016-September 2019). A total of 653 CR blood isolates belonging to the 3 GNP during the two study periods were included. The incidence rate of carbapenem-resistance was calculated as number of carbapenem-resistant isolates/1000 patient-days (PD). Antibiotic consumption was expressed as Defined Daily Doses (DDDs)/100 PD. Statistical analysis was performed using interrupted time-series models.

Results: A statistically significant reduction in the consumption of all 3 classes of PrA between PP and IP, was observed. The most significant decline was observed in carbapenem consumption with a change at intervention period of -10.3 DDD/100 PD (p<0.001; Figure 1A). Regarding the incidence rate of carbapenem-resistant GNP, a prominent reduction was observed among CR KP isolates, in which the increasing, but non-significant pre-intervention trend, turned to a significantly (p=0.042) decreasing trend after the intervention (Figure 1B). A less evident, not statistically significant decreasing trend was recorded in the incidence of CR PA and AB isolates. Both total in-hospital crude mortality and mean length of hospital stay, which were used as quality indicators, were not significantly affected.

Figure 1: Observed values and model predictions of (A) carbapenem consumption (DDD/100PD), (B) incidence in KP CR isolates/1000 patient-days. Solid lines represent predicted value from interrupted time-series analysis models

Conclusions: After almost three years of successful and safe implementation of an ASP program, in a hospital with high resistance rates, a decreasing trend in the incidence of CR GNP was recorded. This tendency was most apparent for CR KP isolates.

Abstract 7006

**Genome wide mutations in a clinical Escherichia coli isolate with a DNA mismatch repair gene defect after exposure to remnants of a phagemid-containing Escherichia coli**

Joep Stohr*1,2, Marjolein Kluytmans - Van Den Bergh1,3,4, Carlo Verhulst1, John W. A. Rossen1, Jan A. J. W. Kluytmans1,2,3,4

1Amphia Hospital, Breda, Netherlands, 2Elisabeth-TweeSteden Hospital, Tilburg, Netherlands, 3Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 4Amphia Academy Infectious Disease Foundation, Breda, Netherlands, 5University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

**Background:** In a recent proof-of-concept study, we have shown that exposure of a clinical amoxicillin-susceptible *Escherichia coli* isolate to remnants of a disinfectant-treated *E.coli* K-12 strain, containing a pBluescript KS(-) phagemid, resulted in the development of amoxicillin resistance. The genomes of these isolates were screened for mutations and DNA mismatch repair (DMMR) gene defects.

**Materials/methods:** Short-read sequence data (Illumina) of the amoxicillin-susceptible *E.coli* isolate (EUR1) and twelve of its amoxicillin-resistant mutant isolates (EUR1M1 - EUR1M10, EUR1S1, EUR1S2) were analysed. De novo assembly was performed with CLC Genomics Workbench v11 (Qiagen), followed by whole-genome multilocus sequence typing (wgMLST) with Ridom SeqSphere+ v5.1.0 (Ridom). Twenty-eight DMMR genes were detected in and extracted from the genomes using BLAST v2.6.0. and Biopython v1.73. Extracted genes were translated with Biopython v1.73 and aligned against translated DMMR genes of 18 *E. coli* isolates with the same sequence type from a publicly available database (PREJB15226) using Vector NTI Advance 11 software (ThermoFisher Scientific). Assembled genomes were uploaded to the online bioinformatics tools ResFinder v3.2.0. and PointFinder v3.1.0 (CGE).

**Results:** The EUR1 isolate belonged to ST73. The number of wgMLST allele differences between the amoxicillin-susceptible and –resistant isolates ranged from 21 (0.59%) to 69 (1.96%) alleles. In total, 526 mutations were detected in 517 mutated alleles. Of those, 505 (96%) were transitions (96%), of which 294 (58%) were G:C>A:T transitions. Out of 517 mutated alleles, 56 alleles (11%) were mutated in more than one amoxicillin-resistant isolate. The EUR1 isolate harboured a MutL gene amino acid sequence that was different from the *E. coli* ST73 isolates from the publicly available database and lacked a vsr gene. This specific MutL sequence and vsr gene absence are known to be associated with a constitutive increased mutational phenotype. In contrast to the amoxicillin-susceptible isolate, all amoxicillin-resistant mutants harboured mutations in the promoter of the chromosomal AmpC (cAmpC) gene, associated with AmpC hyperproduction (Figure 1).

**Conclusions:** Exposure of an *E. coli* isolate with a MutL gene defect and no vsr gene to remnants of a phagemid-containing *E. coli* was associated with genome wide mutations, among which mutations in the cAmpC promoter that resulted in beta-lactam resistance.

**Figure 1 Mutations in cAmpC promoter/attenuator region of amoxicillin-susceptible and -resistant isolates.**

Pleuromutilin resistance in methicillin-resistant *Staphylococcus aureus* at the human-animal interface, Denmark

Jesper Larsen*1;1, Andreas Petersen1, Raphael Sieber1, Anders Rhod Larsen1, Ute Sönksen1

1Statens Serum Institut, København, Denmark

**Background:** Since 1979, pleuromutilins have been widely used in veterinary medicine and account for 10-15% of all antimicrobials used in the Danish pig production system. In Denmark, pleuromutilins have not yet been marketed for clinical use in humans, although they were recently approved in the EU and USA. In this study, we used whole-genome sequencing and bioinformatics analysis to evaluate the activity of pleuromutilins against: 1) livestock-associated methicillin-resistant *Staphylococcus aureus* clonal complex 398 (LA-MRSA CC398), which was present in 88% of Danish pig farms and accounted for 17% (256/1,478) of all human MRSA infections in 2018; 2) the predominant human-origin MRSA (HO-MRSA) clones circulating in Denmark.

**Materials/methods:** The study included 444 LA-MRSA CC398 isolates collected from pigs (n=288) and patients (n=156) and 726 HO-MRSA isolates representing CC5, CC6, CC8, CC22, CC30, and CC80. All 1,170 MRSA isolates were whole-genome sequenced and investigated for pleuromutilin resistance genes and amino acid substitutions in ribosomal protein L3.

**Results:** In total, 70% of the LA-MRSA CC398 isolates from pigs and 76% of the LA-MRSA CC398 isolates from patients were genotypically resistant to pleuromutilins, of which 94% and 88% carried *lsa* on mobile genetic elements, respectively. In comparison, only one of the 726 HO-MRSA isolates was genotypically resistant to pleuromutilins due to the presence of the *vga* gene. The plasmid-borne *cfr* gene conferring cross-resistance to pleuromutilins and linezolid was not detected in any of the isolates.

**Conclusions:** Our findings showed that pleuromutilin resistance is widespread in LA-MRSA CC398 isolates from pigs and humans, supporting that use of antimicrobials in animals can (co-)select for resistance in zoonotic bacteria. There is currently no evidence for transfer of *lsa* from LA-MRSA CC398 into HO-MRSA, but this might change if pleuromutilins become available for clinical use in humans. Thus, the applicability of pleuromutilins as anti-MRSA drugs will depend on the relative disease burden of LA-MRSA CC398 in a given area and the transferability of pleuromutilin resistance between LA-MRSA CC398 and HO-MRSA. The results highlight the usefulness of integrated surveillance of antimicrobial consumption and resistance at the human-animal interface when assessing the efficacy of antimicrobials in human and veterinary medicine.

Abstract 7009

The role of using the UBU (Urethritis Basic Unit) and the FVU (First-Void Urine) in the quick diagnosis and adjustment of treatment in urethritis

Tania Martín Peñaranda*, Idoia De La Caba1, David Grandioso Vas1, Marta Gómez Ruiz De Arbulo1, Pedro Idigoras1

1Biodonostia, Infectious Diseases Area, Respiratory Infection and Antimicrobial Resistance Group; Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Microbiology Department, 20014 San Sebastian, Spain., Donostia, Spain

Background: Urethritis is a common infection in men which can benefit from rapid diagnosis and selected treatment.

Materials/methods: Data from 100 patients with urethritis were collected in a prospective study conducted in a Sexually Transmitted Infections (STI) Clinic based in a Microbiology Laboratory. A urethral swab and a first-void urine (FVU) sample were taken from all patients. In most patients, a STI serology and in some of them, a pharynx, anal, glans or/and skin's lesions samples were also performed. While examining the patient, a small extension of Gram staining of the urethral swab was performed, which allowed viewing what we call UBU (Urethritis Basic Unit), which represents a picture of the state of the urethral mucosa, as well as flow cell cytometry counting from the FVU. Having this quick information in addition to clinical and epidemiological data, allowed treating patients with an accurate approach to the underlying cause of urethritis before leaving the STI Clinic. Additionally, traditional culture and PCR (STI, Seegene) were performed.

Results: The etiological diagnosis was established in 92/100 patients: 31 Chlamydia trachomatis (33.7%), 31 Neisseria gonorrhoeae (33.7%), 20 Ureaplasma urealyticum (21.7%), 14 Mycoplasma genitalium (15.2%), 4 Haemophilus influenzae (4.3%), 1 Haemophilus parainfluenzae (1%), 3 herpes simplex virus type 1 (3.2%), 1 herpes simplex virus type 2 (1%) and 2 adenovirus (2.2%). Discrepancies between urethra and urine leukocyte counting were found in 21 samples, finding <5 leukocytes/field in urethra's Gram staining and higher counting in FVU flow cytometry. All gonococcal urethritis were detected by microscopy observing gram-negative diplococcus in the urethral swab (and therefore, treated with intramuscular ceftriaxone). 39 patients suspected of infection with a non-gonococcal urethritis received 1 g. of azithromycin. There were 7 suspicions of viral urethritis and 6 were confirmed. Only one of the viral infections was initially treated with azithromycin because of polymorphonuclear predominance.

Conclusions: The proximity between a STI Clinic and a Microbiology laboratory, allows using quick techniques to optimize choosing a better treatment adjusted to etiological suspicion. The use of FVU allowed detecting urethritis which weren’t detected after microscopy observation of the urethra’s Gram staining following classic urethritis diagnosis criteria.

Abstract 7011

**Evaluation of T2MR in a Greek university intensive care unit**

Evangelia Douka*, Ioannis Papachatzakis1, Charikleia Vrettou1, Eleftheria Mizi1, Efstatia Perivoliotis2,3, Spiros Zakynthinos1

1 First department of Critical Care Medicine, University of Athens, Evangelismos General Hospital, Athens, Greece, 2 Microbiology Department, Evangelismos General Hospital, Athens, Greece, 3 Evangelismos General Hospital, Microbiology Department, Athens, Greece

**Background:** T2 Magnetic Resonance (T2MR) is a novel method of detecting ESKAPE pathogens in blood specimens. T2MR test is a fully automated procedure which amplifies microbial cell-associated DNA using a thermostable polymerase and target-precific primers and detects signals by amplicon-induced agglomeration of superparamagnetic particles and T2 magnetic resonance. We aim at evaluating the performance of this method in an ICU population.

**Materials/methods:** This is a prospective observational study that took place in a 35 bed university ICU were surveillance data report 40 % ESCAPE pathogens in BCs. Inclusion criteria were age >18 y.o., and clinical suspicion of a new bloodstream infection. Patients who were unsalvageable were excluded. A sample for T2MR and a blood culture (BC) sample were collected simultaneously from all patients. The T2MR test was run according to the manufacturer’s guidelines and the blood cultures were processed according to the hospital standard procedures.

**Results:** 26 patients were included in the study. The results of the T2MR and BCs are presented in the Table. In 20 cases the results of T2MR were in concordance with the BCs. In the remaining 6 cases, the BCs were negative while the T2 MR detected one or more ESKAPE pathogens. There were no false negative results. Mean time to culture positivity was 84 hours while mean time to T2MR result was 3.5 hours. The negative predictive value of T2MR was 100%

(+): ESKAPE pathogen detected  
(-): Escape pathogen not detected

**Conclusions:** T2MR detects more pathogens than BCs and provides a quicker detection time that could shorten the time to targeted therapy. The number of positive T2MR cases with negative BCs can be attributed to the high sensitivity of T2MR compared to the gold standard (BCs).

Abstract 7018

Clinical evaluation of ChromaCode’s HDPCR tick-borne pathogen panel
Lauren Petersen*, Joel Lefferts1, Gregory Tsongalis1

1Dartmouth-Hitchcock Medical Ctr, Lebanon, United States

Abstract third-party references: ChromaCode Inc.

Background: The number of reported tick-borne illness cases in the US has been increasing steadily since the 1990s. In addition to carrying the causative agent of Lyme disease, Borrelia burgdorferi, the Ixodes scapularis tick can carry other pathogenic microorganisms including Anaplasma, Ehrlichia, Babesia, and other Borrelia species. These non-Lyme infections can present similarly with a range of severity from asymptomatic to an acute febrile, flu-like illness, occasionally resulting in fulminant multi-organ failure. While clinical guidelines dictate that Lyme disease is best diagnosed with serologic testing, acute illness with the remaining tick-borne pathogens is optimally detected from whole blood using nucleic acid amplification testing within the first few weeks of symptom onset.

Materials/methods: To address this need, we evaluated the HDPCR™ Tick-Borne Pathogen (TBP) Panel from ChromaCode (Carlsbad, CA). It is a qualitative assay which uses qPCR to detect nine pathogens that cause disease (Anaplasma phagocytophilum, Ehrlichia chaffeensis, Ehrlichia ewingii, Ehrlichia muris eauclairesis, Rickettsia spp., Babesia microti, Borrelia miyamotoi, and Groups #1 and #2 of Borrelia) in one reaction and uses cloud-based analysis software for reporting results. We compared the ChromaCode panel to our own laboratory-developed test (LDT) that uses qPCR to detect the four non-Lyme pathogens most likely to cause acute tick-borne illness in New England (A. phagocytophilum, E. chaffeensis, B. microti, and B. miyamotoi).

Results: One hundred and fifteen clinical samples were tested on the TBP panel. Seventy samples, which were obtained from either ARUP Laboratories, The Mayo Clinic, or the Dartmouth-Hitchcock Microbiology Laboratory, were positive for either A. phagocytophilum, E. chaffeensis, B. burgdorferi or B. microti. The remaining 45 samples were clinical samples containing other bacteria or viruses as well as samples taken from patients with no suspected tick-borne illness. There was 98.3% positive agreement in results between ChromaCode’s TBP panel and with our qPCR assay. The two discrepancies were in samples where the LDT detected A. phagocytophilum however the TBP panel reported a co-infection of Rickettsia spp. and E. muris eauclairesis in both samples.

Conclusions: The ChromaCode TBP panel was straightforward, easy to use, and the cloud-based analysis software made results easier to obtain than our LDT.

Interplay between genetic disorders and gut microbial community: Rubinstein-Taybi syndrome as a model

Giulia Bassanini1, Elisabetta Di Fede1, Elisa Adele Colombo1, Camilla Ceccarani1, Emerenziana Ottaviano1, Valentina Massa1, Cristina Gervasini1, Elisa Borghi*1

1Università degli Studi di Milano, Department of Health Sciences, Milan, Italy

Background: Rubinstein-Taybi syndrome (RSTS) is a genetic disorder affecting 1 out of 125,000 newborns characterized by intellectual disability, skeletal and gastrointestinal anomalies and growth deficiency. RSTS is caused by mutations in the genes CREBBP, encoding for CBP protein, or EP300, encoding for p300 protein. As CBP and p300 are lysine acetyl-transferases, RSTS patients show an imbalance between histone acetylation and deacetylation. Preclinical studies have shown that histone deacetylase inhibitors (HDACi) may attenuate the chromatin impairment improving the phenotype. As microbial-derived short-chain fatty acids, especially butyrate, display HDACi activity, the aim of this study was to assess the endogenous level of butyrate and the relative abundance of butyrate-producing taxa in a RSTS cohort.

Materials/methods: We enrolled 23 RSTS patients and 16 healthy siblings (HC), as control group to minimize environmental factors having a well-recognized role on gut microbiota. We assessed dietary intake and performed gut microbiota analysis by next-generation sequencing using V3–V4 hypervariable 16S rRNA genomic region. Fecal SCFAs were quantified by gas chromatography. Exogenous HDACi effect on acetylation of lymphoblastoid cell lines (LCLs) derived from RSTS patients was assessed by Alpha LISA technology.

Results: The biodiversity of gut communities (alpha-diversity) was similar for all the assessed metrics (Observed species, chao1, Shannon index, PD-whole tree) between RSTS and HC. Conversely, a clear difference among HC and RSTS subjects was highlighted in beta-diversity analyses, as both unweighted and weighted Unifrac distances revealed a significant separation between groups (p=0.022 and p=0.013, respectively). We found several significant differences in taxa relative abundance between groups across all phylogenetic levels. In particular, RSTS were depleted in major butyrate-producing genera Faecalibacterium and Roseburia. Fecal SCFA concentrations were similar except for butyrate that was found reduced in RSTS. Sodium butyrate (HDACi) appeared to restore acetylation levels in RSTS LCLs.

Conclusions: Despite sharing diet habits and the environment, RSTS gut microbiota is depleted in major butyrate-producing taxa, resulting in a decreased butyrate production. Deepening our knowledge of RSTS gut microbiota alterations could offer new hints to explore strategies aimed at restoring a normal microbial community, and potentially improving some co-morbidities associated to RSTS, such as gastrointestinal discomfort.

**Evolutionary trajectories of carbapenemase-producing Escherichia coli**

Rafael Patino-Navarrete1, Isabelle Rosinski-Chupin1, Nicolas Cabanel1, Lauraine Gauthier2, Julie Takissian2, Jean-Yves Madec3, Monzer Hamze4, Remy Bonnin2, Thierry Naas2, Philippe Glaser*1

1Institut Pasteur, Paris, France, 2Faculty of Medicine of University Paris-Sud, Le Kremlin-Bicêtre, France, 3ANSES, Lyon, France, 4Université Libanaise, Faculté de Santé Publique, Tripoli, Lebanon

**Background**: Carbapenem-resistant Enterobacteriaceae are considered by WHO as "critical" priority pathogens for which novel antibiotics are urgently needed. The dissemination of carbapenemase-producing Escherichia coli (CP-Ec) in the community is a major public health concern. However, the global molecular epidemiology of CP-Ec isolates remains largely unknown as well as factors contributing to the acquisition of carbapenemase genes.

**Materials/methods**: We first analyzed the whole-genome sequence and the evolution of the E. coli sequence type (ST) 410 and of its disseminated clade expressing the carbapenemase OXA-181. We reconstructed the phylogeny of 19 E. coli ST enriched in CP-Ec and corresponding to a total of 2026 non-redundant isolates. Using the EpiCs software, we determined the significance of the association between specific mutations and the acquisition of a carbapenemase gene and the most probable order of events. The impact of the identified mutations was assessed experimentally by genetic manipulations and phenotypic testing.

**Results**: In 13 of the studied STs, acquisition of carbapenemase genes occurred in multidrug resistant lineages characterized by a combination of mutations in ftsI encoding the penicillin binding protein 3 and in the porin genes ompC and ompF. Mutated ftsI genes and a specific ompC allele related to that from ST38 inducing reduced susceptibility to diverse β-lactams spread across the species by recombination. We showed that these mutations precede in most cases the acquisition of a carbapenemase gene. The ompC allele from ST38 might have contributed to the selection of CP-Ec disseminated lineages within this ST. On the other hand, in the pandemic ST131 lineage, CP-Ec were not associated with mutations in ompC or ftsI and show no signs of dissemination.

**Conclusions**: Lineages of CP-Ec have started to disseminate globally. However, their selection is a multistep process involving mutations, recombination, acquisition of antibiotic resistance genes and selection by β-lactams from diverse families. This process did not yet occur in the high-risk lineage ST131.

**Abstract 7028**

**Reliable HCV genotyping and resistance associated substitutions identification by a new next-generation sequencing approach**

Jenny Antonello¹, Diego Corradini¹, Mauro Simonato¹, Alessio Polacchini¹, Serena Tiozzo¹, Alice Renesto¹, Anna Gani*¹, Dino Paladin¹, Mose Favarato²

¹AB ANALITICA, Padova, Italy, ²UOC Laboratorio Analisi, AULSS 3 Serenissima, Venezia, Italy

**Background:** Hepatitis C virus (HCV) is an RNA virus causing 4 million of new infection worldwide. Liver disease and hepatocellular carcinoma can be consequences of chronic infection by HCV. The aim of World Health Organization (WHO) is the eradication of the virus by 2030. Pangenotypic Direct Antiviral Agents [DAA] were FDA approved in 2016 and increasingly used for all HCV genotypes treatment. High variability as well as strong mutation rate of HCV can lead to the appearance of Resistance Associated Substitutions [RASs]. Furthermore, different strains of HCV virus can co-exist in the same host originating a coinfected. Hence the importance to develop a single kit able to characterise all HCV strains and RASs.

**Materials/methods:** We developed a new NGS workflow for detection of both genotypes and RAS on HCV. V-Seq HCV system allows to identify genotypes 1-7 and to detect RASs for genotypes 1a and 1b by sequencing HCV regions 5UTR, CORE, NS3, NS5A and NS5B. RNA from 153 HCV positive samples were tested. All samples used for the validation were previously genotyped with a reference method. The validation was performed in AB ANALITICA and in Molecular Biology Unit of Venice Hospital. Diagnostic sensitivity/specificity, Limit of Detection (LoD) and precision were evaluated.

**Results:** All samples analysed were correctly genotyped with a median coverage of more than 90% (100X) on target regions. The diagnostic sensitivity and specificity were respectively 98% and 100% with a LoD of 200IU/mL for genotype 1-4 and 500IU/mL for genotype 5-6. The reproducibility was more than 95%. RASs identification, evaluated with proficiency testing samples, were concordant with the expected results. Coinfection and recombinant genotypes were correctly identified in the 100% of cases.

**Conclusions:** V-Seq HCV device is a powerful tool able to correctly recognize HCV genotypes, coinfections and recombinants, with the capability to identify samples at low viral load. The most important RASs described by the major international HCV guidelines were recognized by the kit. V-Seq HCV can improve the HCV treatment leading to a personalized medicine. Similar approach will be used for other pathogens such as CMV or HIV.

Abstract 7031

Impact of the FilmArray Blood Culture Identification Panel (BCID) compared to VITEK-MS and the VITEK-2 ID/AST instrument in the diagnosis and management of bloodstream infections in a 24-hour laboratory setting

Ross Davidson*, David Haldane, Jason Leblanc, Ian Davis, Zafar Hussain, Glenn Patriquin, Hilal Alsidairi, Todd Hatchette
1Halifax, Nova Scotia Health Authority, Halifax, Canada

Background: The rapid identification and reporting of blood-borne isolates allows physicians to promptly manage their patients with the most appropriate antimicrobial therapy, aimed at improving patient outcomes. Technologies, such as the FilmArray® Blood Culture Identification Panel (BCID), incorporate a multiplex PCR amplification and detection system allowing the identification of 24 pathogens and 3 antimicrobial resistance markers. We evaluated the BCID1 panel in a 24-hour laboratory prospectively against the Vitek-MS® and retrospectively against the Vitek-2® ID/AST instrument.

Materials/methods: Blood cultures identified as positive (BD Bactec®) were plated onto appropriate media and gram stained. Bottles with visible bacteria on gram stain were processed using the BCID1. Simultaneously, a direct, or, where necessary, re-processed identification after 6 hours of growth detection technique using the Vitek-MS® was performed. Technologists relayed the results to the wards in the first half of the study (268 patients), microbiologists discussed positive results with physicians in the second half of the study (265 patients).

Results: Five hundred thirty-three unique patients (blood cultures) were analyzed. Mean time to identification for the BCID-1 was 1.39 hours. In comparison, mean identification times for the Vitek-MS® and Vitek-2® were 1.7 - 10.4 hours (direct and indirect) and 25.5 hours respectively. The BCID-1 correctly identified 91% (485/533) of all isolates (8% of isolates not found in the BCID database). Vitek-MS® identified approximately 80% of gram negatives and 60% of gram positives by direct detection, the remaining isolates required a minimum of 6 hours growth prior to identification. Thirty-three percent of all blood-borne Staphylococci were methicillin resistant. The one-hour identification and detection of mecA by BCID-1 resulted in a statistically significant reduction in empiric vancomycin use during the study period. Compared to historic controls, physicians used less piperacillin-tazobactam and carbapenems empirically when results were discussed with a microbiologist. Twenty-eight percent of cultures were polymicrobial. The BCID-1 correctly identified all isolates in 86% (24/28) of cases including one case with 8 pathogens.

Conclusions: The BCID-1 is a rapid detection system that identified 91% of blood-borne pathogens an hour from detection. It is an effective tool in antimicrobial stewardship resulting in more appropriate managements of patients.

**Abstract 7032**

**Rapid syndromic panel for the diagnosis of infectious meningitis and encephalitis: a systematic review and meta-analysis of accuracy**

Giulia Menchinelli*, Brunella Posteraro¹, Maurizio Sanguinetti², Teresa Spanu², Giulia De Angelis¹

¹Università Cattolica del Sacro Cuore, Rome, Italy, ²Fondazione Policlinico Universitario A.Gemelli IRCCS, Rome, Italy

**Background:** Infectious meningitis and encephalitis are potentially life-threatening diseases, in which rapid identification of the responsible microorganism is imperative. Therefore, recent guidelines recommend the use of molecular tests for rapid detection of pathogens directly from cerebrospinal fluid (CSF). FilmArray® meningitis/encephalitis (ME) panel (BioMérieux) is a syndromic panel largely used in clinical laboratory practice for the direct detection of 14 pathogens (6 bacteria, 7 viruses and 1 yeast) in CSF samples. The aim of this study was to systematically review and summarize the literature evidence about the diagnostic accuracy of the FilmArray® ME panel.

**Materials/methods:** We searched PubMed up to November 1, 2019 to identify studies reporting on the diagnostic accuracy of the FilmArray® ME panel in comparison with conventional methods (i.e. based on microscopy, culture and/or PCR). Two reviewers independently selected articles, extracted data and performed a quality assessment. We generated a bivariate random-effects model to obtain pooled sensitivity and specificity estimates. The R software 3.6.0 (mada package) and Microsoft Excel software 1.30 were used for statistical analysis.

**Results:** We selected 23 articles from 567 search records, including 6931 CSF samples tested by the FilmArray® ME panel and conventional methods for 63,967 results in total. Overall pooled sensitivity and specificity were 84.9% (95% confidence interval [CI], 74.4–91.5) and 99.5% (95% CI, 98.9–99.8), respectively. Pooled sensitivity was higher for bacteria (91.6%; 95% CI, 86.4–94.9) than for virus (90.2%; 95% CI, 86.0–93.3) and Cryptococcus (52.4%; 95% CI, 28.1–75.7). By single targets, pooled sensitivities ranged from 72.5% (95% CI, 59.5–82.5) for herpes simplex virus 1 to 92.0% (95% CI, 87.3–95.1) for enterovirus. Pooled specificities were higher than 98.0% for all the targets. Additionally, cumulative positive predictive values ranged from 58.3% (95% CI, 51.5–64.7) for human herpesvirus 6 to 100% for both *Listeria monocytogenes* and paraechovirus.

**Conclusions:** Based on these findings, the FilmArray® ME panel is an accurate tool for the laboratory diagnosis of the most common aetiologic agents of meningitis/encephalitis worldwide.

**Presenter email address:** menchygiu@gmail.com
Evaluation of IP-10 as a potential biomarker for the diagnosis of latent tuberculosis infection in vulnerable populations at high risk of TB

Linda Petrone1, Assunta Navarra2, Elisa Petruccioli1, Valentina Vanini1, Tonino Alonzi1, Carmela Pinnetti3, Umberto Massafra4, Gianpiero Baldi5, Fabrizio Cantini6, Fabrizio Palmieri3, Andrea Antinori3, Delia Goletti*1

1 Translational Research Unit, Department of Epidemiology and Preclinical Research, National Institute for Infectious Diseases Lazzaro Spallanzani–IRCCS, Rome, Italy, 2 Department of Epidemiology and Preclinical Research, National Institute for Infectious Diseases Lazzaro Spallanzani–IRCCS, Rome, Italy, 3 Department of Clinical and Clinical Research, National Institute for Infectious Diseases Lazzaro Spallanzani–IRCCS, Rome, Italy, 4 Department of Internal Medicine, S. Pietro Fatebenefratelli Hospital, Rome, Italy, 5 Rheumatology Unit, San Paolo Hospital, Civitavecchia, Rome, Italy, 6 Department of Rheumatology, Hospital of Prato, Prato, Italy

Background: HIV-infection and biologic drugs therapies increase the risk of progression to active tuberculosis (TB). Latent TB infection (LTBI) identification is needed to propose preventive therapy thus reducing TB reservoir. The QuantiFERON-TB Gold Plus (QFT-Plus) is a test for LTBI diagnosis, in which a new tube containing peptides stimulating both CD8- and CD4-T-cells has been added. Alternative biomarkers to interferon-γ (IFN-γ) as interferon-γ inducible protein 10 (IP-10) have been proposed. IP-10 evaluation in the QFT-Plus of LTBI subjects with HIV infection or with rheumatic disorders has never been performed. We aimed to evaluate IP-10 accuracy in QFT-Plus for LTBI diagnosis in these fragile populations.

Materials/methods: QFT-Plus was performed in 85 individuals: 13 HIV-infected, 16 co-infected TB-HIV and 22 co-infected LTBI-HIV; 34 LTBI subjects with rheumatic diseases (R-LTBI) were also included. IP-10 results were analyzed and compared to the IFN-γ-QFT-Plus. Active TB was defined by microbiological means, LTBI by a positive QFT or by radiological lesions suggestive of a previous TB exposure.

Results: TB-HIV and LTBI-HIV co-infected subjects were all positive to IFN-γ-QFT-Plus while only 2/34 R-LTBI subjects scored positive to IFN-γ-QFT-Plus. IP-10 levels are increased in TB1 and TB2 tubes in TB patients compared to TB-HIV co-infected and HIV-infected subjects only; moreover, IP-10 is significantly increased in TB1 and TB2 tubes in LTBI subjects compared to HIV-LTBI [p<0.0001] co-infected subjects and to R-LTBI [p=0.006] co-infected subjects and to R-LTBI [p>0.0001], with the lowest levels in this last population. Based on a previously identified IP-10 cut-off of 1174 pg/mL for TB1 and 928.8 pg/mL for TB2, 19/22 (86.4%) and 21/22 (95.5%) LTBI-HIV co-infected subjects scored positive to TB1 and TB2 respectively. Regarding R-LTBI, 17/34 (50.0%) and 18/34 (52.9%) subjects scored positive to IP-10 in TB1 and TB2 respectively. However, when R-LTBI were stratified based on the IFN-γ-QFT-Plus results, 3/13 (23.1%) subjects with a negative IFN-γ-QFT-Plus but showing radiological lung lesions associated with past TB exposure, scored positive to IP-10.

Conclusions: These results suggest that the IP-10 evaluation may be proposed as an alternative biomarker to IFN-γ in subjects scored QFT-negative, but at high risk of TB based on origin and/or reported exposure to M. tuberculosis.

Presenter email address: delia.goletti@inmi.it
Evaluation of Biofire Filmarray Pneumonia for the detection of pathogen bacteria in respiratory infections

Mªpilar Bermúdez Ruiz¹, Miriam Valverde Troya¹, Fernández Ana María¹, Concepción Mediavilla¹, Begoña Palop*¹, Inmaculada De Toro Peinado¹

¹Regional University Hospital in Malaga., Málaga, Spain

Background: The objective of this study is to evaluate the usefulness of Biofire Filmarray Pneumonia Panel (BioMérieux, France) for detection of pathogenic bacteria in patients with community and nosocomial respiratory infections.

Materials/methods: From October-2018 to October-2019, we studied respiratory samples from 60 patients prospectively: 6 children and 54 adults. Only one sample per patient was included: 32 sputum, 20 BAS and 8 BAL. The results obtained with Biofire Filmarray Pneumonia Panel (BFP) were compared with those obtained in the conventional culture and Real Cycler® Molecular Progenie PCR (RCPM) for Legionella pneumophila and Mycoplasma pneumoniae/Chlamydia pneumoniae.

Results: Of the 60 samples processed, 23 samples obtained negative results with BFP, with no pathogen found in the culture. We detected a bacterial pathogen with BFP in 37 samples, some of them in coinfection: 10 H.influenzae, 8 S.pneumoniae, 6 P. aeruginosa, 4 S.aureus, 3 M.catarrhalis, 7 enterobacteria, 2 Legionella pneumophila, 2 Mycoplasma pneumoniae y 1 Chlamydia pneumoniae. In 16 of these cases, the same bacteria was detected in the culture (43.2%), with a difference of 1-2 logarithms less between the CFU isolated in the culture respect to the copies/ml in BFP. In the 21 samples with no pathogens isolated in culture, the following microorganisms were detected with BFP: 8 H.influenzae, 6 S.pneumoniae, 5 S.aureus, 3 P. aeruginosa, 3 K. pneumoniae, 2 M.catarrhalis, 1 K. oxytoca and 1 E. coli. 13 of these 21 samples corresponded to patients who had received antibiotic treatment in the previous 24 hours (61.9%). Legionella pneumophila was detected in two samples, the result of the culture, the RCPM and the detection of antigen in urine being negative. Mycoplasma pneumoniae was detected in two samples and Chlamydia pneumoniae in one sample, the three cases being confirmed by RCPM. There was no culture with pathogenic microorganisms not detected with BFP.

Conclusions: BFP panel seems to be a useful tool for the etiological diagnosis of respiratory infections, improving sensitivity and rapidity against the culture, especially in patients who have received previous antibiotic treatment. Correlation studies with culture counts are necessary to establish cut-off points in the quantification of BFP that allow us to manage this new tool.

Efficiency of phototherapy as a non-conventional antimicrobial strategy against selected Gram-negative bacteria in planktonic and biofilm models

Heba Kamal*1, Noha Farag1, Salma Tammam1, Mohamed El-Azizi1

1GUC (German University in Cairo), Cairo, Egypt

Abstract third-party references: German University in Cairo

Background: Antibiotic resistance in bacteria has emerged as a critical and devastating problem that challenges modern healthcare system. Searching for alternative non-conventional antimicrobial agents is crucial nowadays. Photothermal therapy implementing gold nanoparticles as photosynthesizers is gaining attention as a new strategy for combating antibiotic resistance. Gold nanorods (GNRs), have several advantages including biocompatibility and superior capability of heat release due to their high surface plasmon resonance. The aim of the current study is to investigate the efficacy of GNRs coupled with laser irradiation against *P. aeruginosa*, *E. coli* and *S. typhi*, in planktonic and biofilm models.

Materials/methods: Gold nanorods were synthesized using seed-mediated method with an average aspect ratio of 3.43 (±0.21) and biofunctionalized by cross linking to a phage peptide that selectively binds to gram negative bacteria. The efficacy of gold nanorods at concentrations 10, 100, 500 and 1000uM against the selected bacteria, was investigated in planktonic and biofilm models by incubation for 90 minutes followed by near infrared (NIR) laser irradiation for 6 minutes at 500mW. The cytotoxicity of GNRs on mammalian fibroblasts was assessed by MTT assay. Transmission Electron Microscopy was also done to investigate the possible killing mechanism.

Results: Our results showed that gold nanorods coupled with laser irradiation significantly killed all the bacteria tested in both planktonic and biofilm model as compared to gold nanorods alone. Peptide tagged GNRs had significantly higher killing activity compared to untagged GNRs. No significant change in cellular viability was observed in irradiated fibroblasts. TEM showed accumulation of GNRs on bacterial cell surface, rupture of cell membrane and release of cytoplasmic content following irradiation.

Conclusions: The current study is one of very few which uses a peptide as a targeting agent on gold nanorods to photothermally kill bacteria. Gold nanorods coupled to NIR laser irradiation has shown promising results by being able to totally eliminate bacteria such as *P. aeruginosa*, *S. typhi* and *E. coli* in planktonic and biofilm model. This could offer an non-conventional antimicrobial agents alternative to the antibiotics to treat infections caused by antibiotics-resistant bacteria.

Abstract 7039

**SynAST, a reliable in vitro synergy test as support for New Delhi metallo-beta-lactamase Klebsiella pneumoniae infection therapy**

Alessandro Leonildi*, Cesira Giordano1, Enrico Tagliaferri2, Marco Falcone3, Giusy Tiseo4, Simona Barnini2, Francesco Menichetti2

1Azienda Ospedaliero Universitaria Pisana, U.O. Malattie Infettive, Pisa, Italy, 2Azienda Ospedaliero Universitaria Pisana, U.O. Microbiologia Ospedaliera, Pisa, Italy, 3Azienda Ospedaliero Universitaria Pisana, U.O. Malattie Infettive, Pisa, Italy, 4Azienda Ospedaliero Universitaria Pisana, U.O. Malattie Infettive, Pisa, Italy

**Background:** New Delhi metallo-beta-lactamase producing *Klebsiella pneumoniae* (NDM-Kp) is increasingly reported in Europe and represents a clinical challenge because of limited available treatment options. Combination therapy with aztreonam plus extended-beta-lactamase, ESBL, inhibitor is required against NDM-Kp and new methods to demonstrate its efficacy are needed. The aim of this study is to propose a reliable and easy in vitro synergy test named SynAST.

**Materials/methods:** Twenty bloodstream isolates of NDM-Kp, co-expressing CTX-M bla1 ESBL, were tested by SynAST, a micro-dilution method adapted to a commercial plate (DKMGN, Thermo Fisher Scientific, MA, USA). Briefly, 100 µL of a 0.5 McFarland suspension was inoculated in 10 mL of cation adjusted Mueller-Hinton Broth; 200 µL of this suspension was added to the wells containing aztreonam obtaining a concentration range of 0.125-4 µg/mL. After aztreonam resuspension, 50 µL were distributed from these wells to those containing piperacillin/tazobactam, amoxicillin/clavulanate and ceftazidime/avibactam, with beta-lactamase inhibitor concentrations fixed at 4 µg/mL, 2 µg/mL and 4 µg/mL, respectively. Minimum inhibitory concentration (MIC) of aztreonam/ beta-lactamase inhibitor combinations was determined after an overnight incubation at 37°C. Clear wells were subcultured to obtain minimum bactericidal concentrations (MBC) values. We considered as synergistic those aztreonam/ ESBL-inhibitor combinations which reduced aztreonam MIC below EUCAST clinical breakpoint (1 µg/mL). SynAST results were confirmed by the validated gradient-test superposition method.

**Results:** All the strains were resistant to aztreonam (MIC > 32 µg/mL), piperacillin/ tazobactam, amoxicillin/ clavulanate and ceftazidime/ avibactam (MIC > 32, 64,16 µg/mL, respectively). The combination of aztreonam plus ceftazidine/ avibactam was synergistic [MIC and MBC of aztreonam were ≤0.125 µg/mL for 20/20 strains]. Also in presence of amoxicillin/ clavulanate MIC and MBC of aztreonam were reduced below the clinical breakpoint [0.25 µg/mL for 1/20 strain and ≤0.125 µg/mL for 19/20 strains]. No synergistic activity was observed when aztreonam was added to piperacillin/ tazobactam [MIC > 4 µg/mL for 20/20 strains].

**Conclusions:** SynAST can easily be used to test the synergism between aztreonam and beta-lactamases inhibitors; it also provides information about MBC values, clinically relevant in severe infections, especially in compromised patient. SynAST could support clinicians to select the most appropriate therapy for NDM-Kp infections.

Abstract 7040

Single-locus-sequence-based typing of the mgpB gene reveals transmission dynamics in Mycoplasma genitalium

Miguel Fernández-Huerta*1, Judit Serra Pladevall2, Juliana Esperalba1, Albert Moreno-Mingorance1, Candela Fernández Naval1, María Jesús Barberá1, David Aparicio1, Óscar Q. Pich1, Tomás Pumarola-Suñé1, Jorgen Skov Jensen4, Mateu Espasa3

1Vall d’Hebron University Hospital, Barcelona, Spain, 2IBMB-CSIC, Parc Científic, Barcelona, Spain, 3Parc Taulí University Hospital, Sabadell, Spain, 4Statens Serum Institut, Copenhagen, Denmark

Background: The sexually transmitted infection (STI) Mycoplasma genitalium (MG) is a major problem worldwide, especially after demonstrating a marked propensity to develop antimicrobial resistance. Since very few treatment options exist, clinicians face an important challenge in the management of the infection. In this scenario, little is known regarding the transmission dynamics of MG and the epidemiology of antimicrobial resistance.

Materials/methods: A total of 70 samples from 66 asymptomatically MG-infected individuals were prospectively collected at a point-of-care service for rapid STI screening in Barcelona, Spain, between October 2017 and January 2018, as part of a parent study. Of them, 57 from 54 participants were suitable for molecular epidemiology studies using the mgpB-based single-locus-sequence-based typing system. The genotypic profiles were complemented with information regarding gender/sexual conduct, infection site, HIV serostatus, and the presence of antibiotic resistance-associated mutations in the 23S rRNA and the parC genes, respectively.

Results: Overall, 32 different sequence types (STs) were described among the 54 infected individuals. None of the STs was identical with the reference ST_G37. The phylogenetic dendrogram is shown in figure 1. The major genotypic cluster 1 is mainly comprising infections occurring in women and heterosexual men (MSW) [11/17; 64.7%], while major cluster 2 is mostly grouping infections in men who have sex with men (MSM) and bisexual men (MSMBI) [31/37; 83.8%]; p < 0.001. This correlation between sexual behaviour and genotype is translated into the structuration of well-defined epidemiological clusters, and may suggest the presence of two independent sexual networks with little connectivity between them. Also, in accordance with other investigations, our study demonstrates the multiclonal feature of the emergence of antibiotic resistance in MG to both macrolides and fluoroquinolones.

Conclusions: The study provides further evidence regarding the transmission dynamics and the structure of sexual networks in MG infection. Furthermore, the investigation demonstrates the multiclonal selection and spread of antibiotic resistance in MG, and assesses the specific allodemic situation of macrolide resistance among MSM.

Figure 1. Abbreviations: MSM, men who have sex with men; MSMBI, bisexual men; MSW, men who have sex with women; HIV, Human Immunodeficiency Virus; ND, not determined; MXD, mixed genotypes.

Abstract 7041

**Seroprevalence of Bordetella pertussis in Tunisian adults**

Naija Habiba*1,2, Molka Osman1, Abir Mbarek1, Mohamed Ben Moussa1

1The military hospital in Tunis, Microbiology department, Tunis, Tunisia, 2Université de Tunis El Manar, Faculty of Medicine of Tunis, Tunis, Tunisia

**Background:** Pertussis, an infectious disease caused by *Bordetella Pertussis*, is still a public health problem in many countries despite high vaccination coverage rates. Its current reservoir is represented by adults with undiagnosed pertussis, with the risk of contamination of unvaccinated children, in whom pertussis can be serious or even fatal. In Tunisia, although pertussis vaccine is part of the vaccination schedule, the adult booster dose is not current. The purpose of this study was to estimate the seroprevalence of pertussis in Tunisian adults.

**Materials/methods:** It was an epidemiological, cross-sectional study conducted in adults recruited from the laboratory department of the military hospital of Tunis in marsh 2019 in whom we practiced a serological test for pertussis. We used the EUROLINE kit for a qualitative study of IgG antibodies against Pertussis toxin (PT) and Adenylate Cyclase toxin (ACT) antigens of *Bordetella pertussis* according to the manufacturer’s instructions.

PT: specific for *Bordetella Pertussis*, its antibodies (anti-PT) are detectable both after infection and vaccination.

ACT: secreted by *Bordetella Pertussis* and *Bordetella Parapertussis*, its antibodies can be an indication of a naturally acquired infection.

**Results:** A total of 200 adults [57.5% female; mean age 42.9±15.6 years] were enrolled. Seventy-seven point five percent were from urban area and 33.2% were smokers. None of the subjects had received pertussis vaccination in the last five years. More than half of the subjects (56.0%) reported a cough in the last 12 months, 90.2% of which lasted more than 14 days and required hospitalization in six cases. A total of 33 (16.5%) subjects were seropositive for anti-PT IgG. Only 12 (6.0%) adults were vaccinated. The prevalence of anti-ACT antibodies was 43.0% indicating a naturally acquired infection. We didn’t find any significant relationships between increased rates of seropositivity and age, sex or smokers.

**Conclusions:** Our study highlights the low prevalence of anti-PT antibodies in Tunisian adults, despite the fact that pertussis vaccination is part of the vaccination schedule. This requires a greater awareness of the need to introduce a booster dose for pertussis in adulthood, to confer immunization against it and prevent its transmission to vulnerable infants.

Abstract 7042

Introduction and spread of the novel GII.P16 pandemic recombinant norovirus in Italy detected by a newly designed PCR primer pair

Giovanni Giammanco1, Noemi Urone1, Floriana Bonura1, Chiara Filizzolo1, Leonardo Mangiaracina1, Celestino Bonura1, Vito Martella2, Simona De Grazia1

1Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy. 2Bari, Department of Veterinary Medicine, Aldo Moro University, Bari, Italy

Background: Noroviruses (NoVs) are a leading cause of acute gastroenteritis across all ages, causing 685 million cases/year. They are classified in 7 distinct genogroups (GI-GVII). Genogroups I, II and IV are able to infect humans and have been further divided in more than 30 genotypes based on polymerase (ORF1) and capsid protein (ORF2) sequences. New NoV genotypes combinations and variants continuously emerge resulting in epidemics and sometimes global pandemics.

Materials/methods: From January 2016 to December 2017, 251/1185 (21.2%) stool samples collected from children hospitalized with acute gastroenteritis at the “G. Di Cristina” Children’s Hospital in Palermo, Italy, were detected NoV-positive by Real-time PCR, targeting ORF1/ORF2 junction. NoV dual-typing was performed by sequencing two genomic portions, encompassing region A-B of ORF1 (pol) and regions C-D of ORF2 (cap), using JV12A/JV13B and COG2F/G2SKR primers, respectively. Concomitantly, ORF1 was amplified with new degenerate primers JV12Y/JV13RN, designed using a dataset of ORF1 sequences belonging to all NoV genotypes.

Results: With standard protocols pol genotyping was obtained for 56/251 (22.3%) NoV-positive samples. Lacking ORF1 fragment amplification, partial ORF2 genotyping was obtained for 47 GII.2 and 42 GII.4 strains. ORF2 phylogenetic analysis showed that these strains were strongly correlated to the new recombinant GII.P16_GII.2 and GII.P16_GII.4, spreading worldwide since 2016. When a wide panel of complete NoV ORF1 sequences was retrieved from GenBank and aligned with JV12A/JV13B primers sequences, GII.P16 sequences showed multiple nucleotide mismatches with the PCR primers used. Therefore, degenerate primers JV12Y/JV13RN were created. The use of JV12Y/JV13RN degenerate primers allowed to obtain the missing ORF1 sequences and to confirm the circulation of GII.P16_GII.2 and GII.P16_GII.4 recombinant strain in Palermo since September and December 2016, respectively.

Conclusions: From 2016, new recombinant NoV variants are spreading in Italy but an update of PCR protocols was necessary to amplify ORF1 diagnostic fragments of GII.P16 genotype strains. A continuous update of the methods used their detection is essential for molecular surveillance of NoVs, for monitoring emerging strains and to study the impact of NoV disease on public health.

First vector-borne cases of Zika virus diseases in Europe: a seroprevalence survey
Harold Noël1, Florian Franke2, Guillaume Durand3, Juliette Paireau5, Sandra Giron2, Gilda Grard3, Pascal Chaud2, Anne Decoppet6, Simon Cauchemez5, Marie-Claire Paty1, Henriette De Valk1

1Santé publique France, Saint-Maurice, France, 2Santé publique France, Marseille, France, 3Institut de Recherche Biomédicale Des Armées, French National Reference Laboratory for Arboviruses, Marseille, France, 4Unité des Virus Emergents, [UVE: Aix-Marseille Univ – IRD 190 – Inserm 1207 – IHU Méditerranée Infection], Marseille, France, 5Institut Pasteur, Mathematical Modelling Of Infectious Diseases Unit, Paris, France, 6Regional Health Agency of Provence-Alpes-Côtes d’Azur, [ARS Paca], Marseille, France

Background: Zika virus (ZIKV) is a flavivirus in the family Flaviviridae, primarily transmitted to human by Aedes mosquitoes. ZIKV was responsible for major outbreaks of eruptive illness, neurological complications and adverse pregnancy and birth outcomes in 2016 in the Americas. In October 2019, the three first cases of vector-borne ZIKV disease acquired in Europe were detected in a neighbourhood in Hyères, southern France, with symptom onset within 8 consecutive days in the first half of August. Since the majority of ZIKV infections remain subclinical, several cases may have gone unnoticed. We conducted a seroprevalence study within 200m-radius around the focus, nearly the expected flight range of 90% of the local vector mosquito, to determine the extent of ZIKV transmission in Hyères.

Materials/methods: We collected capillary blood from all consenting inhabitants over 2 years old, and information on their medical and travel histories, and exposure to mosquito bites.

Laboratory tests are currently pending. Recent infections will be identified using IgM and IgG anti-ZIKV ELISA, followed, when positive, by neutralisation tests on serum against ZIKV, dengue virus 1–4 and West Nile virus. The prevalence estimator will be calculated using recent reference demographic data. Spatial clustering of Zika cases within the affected neighbourhood will be quantified at various distance ranging from 0 to 200m as the risk of two cases living with a distance range relative to two non-infected individuals living within the same distance. We will develop a statistical model to characterize the spread of ZIKV in this population and reconstruct the most likely transmission tree.

Results: We surveyed 60% (89/150) of the households of the study area and tested 67% (172/257) of the eligible inhabitants. Our study will provide an estimate of the prevalence of ZIKV infection in the affected population. The spatial analysis should contribute to assessing the distance over which infected mosquitoes spread ZIKV. We will estimate the proportion of subclinical cases and their contribution and place to the transmission tree.

Conclusions: This study should characterise the potential for ZIKV spread and outbreaks in temperate regions and to guide efficacious control interventions.

Abstract 7045

**Analysis of the practices of the multidisciplinary consultation meeting on infectious endocarditis**

Léo Sauvat*1, Marion Rosburger2, Aurélien Mulliez2, Frédéric Robin4, Mehdi Farhat1, Guillaume Clerfont2, Magali Vidal1

1University Hospital of Clermont-Ferrand, Infectious and Tropical Diseases Unit, Clermont-Ferrand, France, 2University Hospital of Clermont-Ferrand, Cardiology Department, Clermont-Ferrand, France, 3University Hospital of Clermont-Ferrand, Department of Clinical Research and Innovation, Clermont-Ferrand, France, 4University Hospital of Clermont-Ferrand, Bacteriology Unit, Clermont-Ferrand, France, 5University Hospital of Clermont-Ferrand, Cardiovascular Surgery Department, Clermont-Ferrand, France

**Background:** Infectious endocarditis is associated with a severe prognosis with a mortality rate of 30% at one year projection. The latest recommendations of European Society of Cardiology (ESC) in 2015 put the multidisciplinary consultation meeting (MCM) “infectious endocarditis” at the heart of endocarditis management.

**Materials/methods:** This unicentric retrospective study analyses the patient files presented at MCM and hospitalized or transferred to the Clermont-Ferrand University Hospital in 2017.

**Results:** One hundred and seventy-seven patients were included in this study and 35 excluded (of which 24 were hospitalized in peripheral hospitals only). MCM identified 98 patients with the diagnosis of endocarditis in which 20 had the mention of probable/possible endocarditis. After deliberation, seventy-nine patients did not ultimately have endocarditis. *Staphylococcus aureus* was the most frequent bacteria (27%) involved in the cases submitted. The main relevant characteristics of the 2 groups are described in table I. Concerning files analysis by MCM, review of the cardiac ultrasound confirmed the diagnosis of endocarditis for 7 patients and invalidated it for 10. The proposal for additional examen was made for 14 patients (64%). Their results confirmed the diagnosis of endocarditis for 13 patients and invalidated it for 9 patients. Only 96 patients presented (54%) had a brain imagery. Seventy-three patients with endocarditis (75%) had a post-hospitalisation consultation achieved by a cardiologist or an infectiologist in the hospital.

**Table I:** Main relevant characteristics of endocarditis and excluded endocarditis groups

**Conclusions:** This study shows that the expertise of the multidisciplinary team is required to adapt the modified Duke criteria by ESC for each patient. Moreover, clear quality control of MCM must be done to improve the management of infectious endocarditis.

**Background:** Tuberculosis [TB] is the leading infectious cause of death in the world. It is caused by Mycobacterium tuberculosis [Mtb]. Low treatment adherence promotes the emergence of multi-drug resistant Mtb. Immunomonitoring of TB treatment is a promising prognostic option because signs of immune reversion are thought to occur earlier than signs of microbiological clearance. We are investigating blood-based immune biomarkers of TB treatment response in patients from high burden countries, using a putative mycobacterial recall antigen: recombinant Mtb heparin-binding hemagglutinin expressed in Mycobacterium smegmatis [rmsHBHA].

**Materials/methods:** We enrolled non-immunocompromised adults presenting with microbiologically confirmed pulmonary sensitive or resistant TB in Bangladesh, Georgia, Paraguay, Lebanon, and Madagascar. Patients were followed up after 2 months of treatment, at the end of therapy, and 2 months afterwards when possible. Sputum and blood samples were collected. After in vitro whole blood stimulation by rmsHBHA and conventional QuantiFERON-TB Plus antigens, plasma and white blood cells were separated, cryopreserved, and shipped to France. Plasmatic IFN-γ response to stimulation was assessed by ELISA. Leukocytes were analyzed by mass cytometry, and supervised and unsupervised analyses were performed. Immunological results were evaluated over the course of treatment and compared to clinical and microbiological data.

**Results:** Between December 2017 and October 2019, 172 patients were recruited. IFN-γ ELISAs were performed for 79 patients having finished treatment. A significant increase of IFN-γ response to rmsHBHA stimulation was observed during treatment (p<0.01). CyTOF analyses were performed for 11 patients. A significant increase in the overall proportion of rmsHBHA stimulated T-cells was observed after 6 months of treatment (p<0.01). In Mtb-specific CD4+ T-cells, a significant decrease in the proportion of CD40L+ and CD69+ cells was observed (p<0.05). Consistently, unsupervised analyses revealed a significant decrease in clusters of memory CD4+ cells (CCR7CD45RA+CD69CD40L–HLA-DR+) co-expressing CD69, CD38, CD40L, and HLA-DR.

![Plasmatic IFN-γ response to mycobacterial stimulation.](image)

T0: inclusion. T1: T0+ 2 months. T2: end of treatment (6 to 9 months).

Data are presented as median + interquartile range. Each grey dot represents a value for one patient. ****: p<0.001. *: p<0.01 (Friedman’s test with Wilcoxon-Nemenyi-McDonald-Thompson’s post-hoc test).
Abstracts 2020

Conclusions: rmsHBHA is a good recall antigen for in vitro T-cell activation testing, and a promising biomarker for prediction of successful TB treatment. The proportion of rmsHBHA-stimulated activated CD4+ T-cells decreased significantly over treatment course. In-depth investigations will be performed in parallel with NGS and pharmacokinetics data to uncover more exhaustive trends.

Abstract 7047

**Dispersal of microbes to hospital surfaces following two hand drying methods: paper towels or a jet air dryer**

Ines B. Moura*1, Duncan Ewin1, Mark H. Wilcox1,2

1University of Leeds, Leeds, United Kingdom, 2Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

**Background:** Hand drying is important to minimise microbial spread, noting pathogen survival on environmental surfaces and opportunities for transmission and spread. We investigated whether there are differences in extent of microbe transmission, according to hand drying method, beyond the toilet/washroom to the hospital environment.

**Materials/methods:** Four volunteers simulated contamination of hands/gloved hands using a bacteria-free preparation of bacteriophage (phage PR772; ATCC® BAA-769-B1) at 10⁷ pfu/ml. Hands were dried using either paper towels (PT) or a jet dryer (JD). Each volunteer wore an apron, to enable measurement of body/clothing contamination during drying. Hand drying was performed in a hospital public toilet and, after exiting, samples were collected from public and ward areas. Environmental/surface sites (n=11) were sampled following contact with hands or apron. Samples were analysed by real-time PCR targeting the P3 gene of phage PR772 (results expressed as copies/µl).

**Results:** Both JD and PT methods significantly (p<0.05) reduced phage contamination of hands (2.2 and 3.3 log₁₀ copies/µl, respectively, Figure). For 10/11 surfaces, significantly greater environmental contamination (p<0.05) was detected after JD versus PT use. All surfaces sampled following JD use showed phage contamination, compared with 6 surfaces after PT use. Average surface contamination following hand contact was >10-fold higher after JD versus PT use (4.1 vs 3.0 log₁₀ copies/µl). Phage dispersal to apron/clothing was 3.5 and 2.8 log₁₀ copies/µl with JD and PT, respectively. Phage transfer from body to environmental surfaces was detected only after JD use (average 3.2 log₁₀ copies/µl).

**Conclusions:** There are clear differences, according to hand drying method, in the residual microbial contamination of the subject’s hands and body. Crucially, these differences in contamination translate into significantly greater levels of microbe contamination after JD vs PT use from hands and body beyond the toilet/washroom. As public toilets are used by patients, visitors and staff, the hand drying method chosen has the potential to increase [JD] or reduce [PT] pathogen transmission in hospital settings.

**Figure:** Real-time PCR results for gene P3 of bacteriophage PR772 detection on environmental samples. Green bar represents 10⁷ pfu/ml stock solution used for hand contamination. Changes are presented as logarithms to achieve normal distribution.

**Presenter email address:** i.b.moura@leeds.ac.uk
**Colistin hetero-resistant Klebsiella pneumoniae and Escherichia coli blood isolates**

Ümran Lister1, Ekin Kirbaş*1, Asiye Bıçakçılı1, Banu Sancak1

1Hacettepe University Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey

**Background:** The increase of multidrug-resistant Enterobacteriaceae led to increased use of colistin as a treatment of last resort. The emergence of colistin heteroresistance (HR) in Enterobacteriaceae may pose a threat to the prognosis of patients following colistin treatment.

In this study, we investigated the prevalence of colistin HR in *Klebsiella pneumoniae* and *Escherichia coli* blood isolates.

**Materials/methods:** A total of 301 *K. pneumoniae* and *E. coli* blood isolates recovered from hospitalized patients between January 2016-August 2018 were included in the study. In vitro antimicrobial susceptibility testing was performed using the broth microdilution method (BMD). Colistin HR was detected by population analysis profiles (PAP). For investigation of colistin HR, we selected the ones with colistin MICs ranging from 1 to 2 µg/ml (*n* = 111). Heteroresistance was considered if the antibiotic concentration exhibiting the highest inhibitory effects was at least 8-fold higher than the highest noninhibitory concentration.

**Results:** Of 301 *K. pneumoniae* and *E. coli* blood isolates, 60 isolates (20%) were found as resistant to colistin by BMD method. Among 301 blood isolates, 241 were detected susceptible to colistin by BMD. The MIC values of isolates were ≤0.06 (*n* = 1), 0.25 (*n* = 11), 0.5 (*n* = 118), 1 (*n* = 99) and 2 µg/ml (*n* = 12). The overall incidence of colistin heteroresistance was 21.2% (*n* = 64).

**Conclusions:** Despite its favorable bacterial killing, the high prevalence of colistin resistance and heteroresistance in *K. pneumoniae* and *E. coli* isolates found in this study. These results clearly demonstrate that heteroresistance could lead failure of this antibiotic in vivo.

For detection of HR, the gold standard is PAP analysis which is cumbersome and unsuitable for routine use in clinical laboratories. Therefore, the high incidence of colistin heteroresistance may raise concern about the choice of antimicrobial susceptibility testing methods to assess HR, as the prevalence of colistin-resistant isolates is widely underestimated.

Effect of brincidofovir on adenovirus and cellular transcriptome profile

Maud Salmona*, Linda Feghoul1, Séverine Mercier-Delarue1, Elise Diaz1, Alex Armero1, Jacques Dutrieux2, Jerome Le Goff3

1Hospital Saint-Louis AP-HP, Paris, France, 2Institut Cochin, INSERM U1016 – CNRS UMR 8104, Paris, France

Background: Brincidofovir, a lipidic conjugate of cidofovir, is currently used off-label for the treatment of severe human adenovirus (HAdV) infections. Its mechanism of action is the inhibition of DNA polymerase by DNA elongation termination. In order to determine whether brincidofovir present other mechanisms, the impact of brincidofovir on cellular and viral transcriptome was investigated by RNAseq.

Materials/methods: We tested four conditions: lung epithelial cells mock infected (A549), A549 cells infected with HAdV C5 (ADV), A549 cells infected with HAdV C5 and treated with brincidofovir (ADV+BCV), and A549 cells mock infected with brincidofovir treatment (BCV). Cellular mRNAs were extracted and sequenced on a NextSeq 72 hours after infection. The sequences were aligned on the human and adenovirus C5 genomes. Differentially expressed genes (DE) were selected (corrected p-value<0.05 and fold change>2) and then used in ontological analysis.

Results: The brincidofovir treatment decreased significantly the overall viral transcription (ADV+BCV vs ADV). However, after normalization with the number of viral reads aligned, brincidofovir treatment was associated with an overexpression of the HAdV early genes E1A and E4 and of the late gene L1 and with a decreased expression of several structural genes (L2 pV, L3 PVI, L4 100K and pVIII and L5 PVI) and of one early gene E3 12.5K. The most significant alterations of the cellular transcriptome were observed with brincidofovir treatment; 555 DE genes for ADVBCV vs ADV, 374 for BCV vs A549 and 113 for ADV vs A549. In non-infected cells, brincidofovir treatment showed a significant inhibition of the biological function “viral replication”, including 25 dysregulated genes. The putative upstream regulators of those genes are NOS2, the cytokine TNFSF10, the PI3K family and the STAT3 transcription regulator. A large overlap of DE genes (218) was found between ADVBCV vs ADV and BCV vs A549, suggesting that the profile of cellular expression after brincidofovir treatment was maintained even after HAdV infection.

Conclusions: Our results suggest indirect antiviral action of brincidofovir by interaction with cellular signalling pathways. Further research is needed to better understand the cellular interactome of brincidofovir and its importance in the treatment of viral infections.

One Health in practice: longitudinal screening of antibiotic residues, antibiotic resistance genes and zoonotic bacteria in soils fertilised with pig manure

Marc Heyndrickx*1, Tina Van Den Meersche1, Els Daeseleire1, Els Van Coillie1, Geertrui Rasschaert1

1Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Melle, Belgium

Background: Fertilization with animal manure is one of the main routes responsible for the introduction of antibiotic residues, antibiotic resistance genes and zoonotic bacteria into the environment. In the context of One Health, it is not well known which contribution is exerted by the agricultural environment for the dissemination of antibiotic residues, antibiotic resistance genes and zoonotic pathogens.

Materials/methods: Five agricultural fields were sampled at five consecutive time points in Flanders (Belgium), starting before fertilization up to harvest. Quantification of antibiotic residues in manure and soil samples were performed through Liquid chromatography-mass spectrometry. The abundance of nine antibiotic resistance genes belonging to three antibiotic classes and the 16S rRNA gene were quantified using qPCR. Detection of Salmonella and Campylobacter and enumeration of E.coli was performed through standard bacteriological cultivation.

Results: Low concentrations of antibiotic residues could be observed in the soils until harvest. The antibiotic resistance genes studied were already present in the soil environment prior to fertilization but after fertilization with pig manure an increase in relative abundance was observed for most of them, followed by a decline back to background levels by harvest-time on all of the fields studied [see graph for tetM gene as example]. No apparent differences regarding the presence of antibiotic resistance genes in soils were observed between those fertilized with manure that either contained antibiotic residues or not. It seems that fertilization with animal manure directly adds resistance genes to the soil and that this mechanism may be more important than possible selective pressure in soil-dwelling bacteria exerted by antibiotic residues present in the manure. The results also indicate that zoonotic bacteria detected in the manure could be detected in the soil environment directly after fertilization, but not after one month.

Conclusions: To the best of our knowledge, the present study is the first to assess a multitude of antibiotic residues as well as resistance to several classes of antibiotics in pig manure and in fertilized soil over time. This is also the first study to report environmental resistance data for Flanders, Belgium, a region with an intensive pig industry.

Abstract 7061

**Meningococcal disease-associated prophage-like elements are present in Neisseria gonorrhoeae and some commensal Neisseria sp.**

Barakat Al Suwayyid, David Speers, Michael Wise, Geoffrey Coombs, Charlene Kahler

1University of Western Australia, Perth, Australia, 2PathWest Laboratory Medicine WA, Perth, Australia, 3Murdoch University, Perth, Australia

**Background:** Neisseria sp. possess four clades of filamentous prophages, termed Nf1 to 4. A filamentous bacteriophage from the Nf1 clade termed Meningococcal Disease Associated phage (MDA φ) is associated with clonal complexes of Neisseria meningitidis that cause invasive meningococcal disease. Nf2, 3 and 4 clades of prophage are most closely associated with Neisseria gonorrhoeae. Recently we recovered an isolate of Neisseria gonorrhoeae (ExNg63) from a rare case of gonococcal meningitis, and found that it possessed a region with 90% similarity to Nf1 prophages, specifically the meningococcal MDA φ. This led to the hypothesis that the Nf1 prophage may be more widely distributed in amongst other Neisseria sp.

**Materials/methods:** A collection of 91 reference genomes representing 17 commensal Neisseria sp. and 44 closed genomes of N. meningitidis and 28 closed genomes of N. gonorrhoeae was interrogated for the presence of intact Nf prophage regions by NCBI Blast and by the annotation in the PubMLST database. Intact phage genomes were aligned using MAFFT alignment tool. Maximum likelihood phylogenetic trees were constructed using MEGA7 with 500 bootstrap replicates. hierBAPS was used to define genetic population groups of prophages using the aligned sequences. Bayesian Evolutionary Analysis by Sampling Trees (BEAST) v 1.8.3 was used to infer time measured phylogeny of a dated subset of forty one Nf1 sequences.

**Results:** 160 filamentous prophages were identified in the reference genome collection. Maximum likelihood phylogeny and population structure analysis using hierBAPS revealed Nf1-like prophages in N. gonorrhoeae, N. Lactamica, N. cinerea and N. polysaccharea. In N. gonorrhoeae, Nf1 prophages had a restricted distribution amongst a few sequence types, but notably was present in all representatives of ST1918. A timed phylogeny inferred that N. meningitidis was the donor of the Nf1 prophages in N. lactamica and N. gonorrhoeae.

**Conclusions:** Nf1 prophage is present in N. gonorrhoeae and some human commensal Neisseria sp. Further work is required to determine whether Nf1 prophages are active and can act as accessory colonization factors in these species.

Abstract third-party references: Supported by the German Center for Infection Research (DZIF)

Background: Estimation of burden of bloodstream infections (BSIs) is limited by time of assessment (commonly in-hospital mortality) and lack of adjustment by appropriateness of antibiotic therapy. The aim of this study was to determine short-term and long-term survival patterns among patients with BSIs receiving appropriate empiric and targeted antibiotic therapy.

Materials/methods: BLOOMY.COM is a 24-month prospective cohort study conducted at 6 german universities hospitals. All adult patients with BSI caused by Staphylococcus aureus, Enterococcus spp., Escherichia coli, Klebsiella spp., Enterobacter spp., Pseudomonas aeruginosa, or Acinetobacter baumannii and receiving appropriate therapy were included. Appropriate therapy definition was based on sensitivity pattern of the isolate. Demographic, microbiological, and clinical data were collected at defined time points throughout hospitalization and at month-6 after discharge. Primary outcomes were crude short-term and long-term mortality at month-6. Risk analyses included age, gender, BMI, ICU stay, etiology, BSI focus, and mode of acquisition. Mortality rates were calculated per 1,000 patient-days (PD).

Results: The cohort included 2289 patients, 278.025 patient-days of follow-up. Patients were predominantly male [1432, 63%] with a median age of 68 (IQR:58-77). E. coli [799, 35%] and S. aureus [580, 25%] were the most common etiology. The mortality rate was 3.0 overall (95%CI 2.4-3.98)/1000 PD (risk:36.4%); 28.6 at day-3 (22.7-38.2)/1000PD (8.6%); 9.6 at day-14 (6.7-15.5)/1000PD; 4.9 at day-28 (3.4-7.7)/1000PD (6.1%); and 1.6 at month-6 (1.3-2.1)/1000PD (20.1%). 3-day mortality varied greatly by risk population and was highest in patients with ICU admission at BSI diagnosis (mortality rate: 86.0), respiratory focus (80.0), vancomycin-resistant enterococci (VRE) BSI (50.3). Patients with carbapenem-resistant Enterobacteriales BSI (5.5), VRE BSI (3.9), metastatic cancer (3.9), methicillin-resistant S. aureus (2.9), and BMI <20 kg/m2 (2.7) had the highest long-term mortality rate.

Conclusions: Assessment of burden of BSIs is complex and cannot be limited to in-hospital mortality. Results of this study might inform burden studies on the importance of accounting for focus of infection, etiology (both sensitive and resistant strains), and comorbidities to perform appropriate cost-effectiveness analyses and plan public health interventions. Kaplan-Meier-curves for mortality among BSI patients according to focus of infection:

Abstract 7069

**Impact of letermovir and associations of antivirals in vitro and in ex vivo first-trimester placenta model**

Deborah Andouard*1,2, Brice Gastineau1,3, Chaharazed El Hamel Bellili4, Sebastien Hantz1,3,5, Sophie Alain1,3,5

1University of Limoges, INSERM U1092, Limoges, France, 2University Hospital Limoges Dupuytren Hospital, Reference center for Herpesviruses, Limoges, France, 3University of Limoges, Univ Limoges, Limoges, France, 4Limoges University Hospital, CB-HME, Collection Biologique Hôpital de la Mère et de l’Enfant, Service de pédiatrie, CHU Limoges, Limoges, France, 5National Reference center for Herpesviruses, Limoges University Hospital, Limoges, France

**Background:** Human cytomegalovirus (HCMV) is the first cause of viral congenital disabilities. There is a lack of therapies available to pregnant women. Letermovir showed good efficacy and low toxicity in vitro and in CMV prophylaxis. We thus test this antiviral drug in a placenta model to assess toxicity and antiviral efficacy.

**Materials/methods:** We performed in triplicate toxicity and antiviral assays for efficacy (EC50) in various cell lines (MRC-5, ARPE-19, U373 and HUVECs) and in 1st trimester placental villi explants from CMV-seronegative women. Cytotoxicity (CC50) was checked using a range of concentrations from 0.5mM to 5µM, and a DMSO control. To evaluate placenta viability, we quantified β-HCG in explants supernatants at day 4, 7, 10 and 13-post treatment.

We infected placenta explants with fibroblastic or endotheliotropic strains: AD169, TB40E and VHLE (MOI of 1). After 5 days of infection, letermovir was added at concentrations of 0,4, 4, 6.1 and 40nM. We harvested explants at day 5 post-treatment and measured CMV viral load in villi by CMV/albumin quantification qPCR.

We associated LTV with different anti-HCMV compounds: Ganciclovir (GCV), Cidofovir (CDF), Foscarnet (FOS), Maribavir (MBV) and Aciclovir (ACV) and test the combinations in MRC-5, against AD169. Effect of combination [Synergism, additive or antagonism] was determined with Compusyn © software.

**Results:** LTV shows no toxicity in vitro at tested concentrations. EC50 was 0.92 nM against AD169 in MRC-5 cells, and 1.34 nM against TB40E in ARPE-19. In vitro associations, showed an additive effect with GCV, ACV and MBV, and a light synergy with CDF and FOS. The different associations showed no toxicity. We didn’t reach CC50 in treated placenta, neither in DMSO control placenta. Letermovir antiviral efficacy was dependent of placenta and viral strain: EC50 was 31 nM for AD169, 25 nM for TB40E and 11 nM for VHLE.

**Conclusions:** The good antiviral efficacy of low concentration of letermovir in placenta, although depending on viral strain is encouraging. Moreover, the molecule showed no significant toxicity at the tested concentrations. In vitro associations with conventional anti-HCMV therapies are promising for further trials in placental model, particularly for ACV which is well-tolerated during pregnancy.

Public health impact of the introduction of a high dose quadrivalent inactivated influenza vaccine in France

Mafalda Costa1, Florence Bianic1, Nathalie Largeron2, Fabian Alvarez2, Marie-Cécile Levant2, Mathieu Uhart*2

1Syneos health, London, United Kingdom, 2Sanofi, Lyon, France

Background: Influenza epidemics are annually responsible for a substantial public health and economic burden especially in adults 65 years of age and older (seniors). The need for improved vaccines and higher coverage rate in this age group is a public health priority. A High Dose quadrivalent influenza vaccine (QIV HD) is currently being evaluated at EU level and should be approved in 2020 in France. The high-dose vaccine is supported by a substantial body of clinical and economic evidence demonstrating benefit over standard dose vaccines currently used in France. The objective of this study is to estimate the public health benefits associated with the introduction of QIV HD in France.

Materials/methods: A static decision tree model was used to compute influenza cases, general practitioner (GP) visits, hospitalizations, and deaths during one influenza season. The current situation – vaccination of seniors with QIV SD at 50% VCR was compared to two alternative scenarios: switching to QIV HD in seniors at the current VCR, switching to QIV HD in seniors and increasing VCR to the official target of 75%.

Results: Vaccinating seniors with QIV HD compared to QIV SD would prevent on average 57,208 influenza cases, 13,704 GP visits, 1,728 hospitalizations and 764 deaths each season compared to the current situation. Reaching a 75% VCR with QIV HD would prevent 204,012 influenza cases, 48,869 GP visits, 6,161 hospitalizations and 2,725 deaths each season compared to the current situation.

Conclusions: The introduction of QIV HD in France could have a substantial public health impact by maintaining the older adults healthy and active and relieving unnecessary clinical and socioeconomic burden from French healthcare systems.

**Abstract 7075**

**Haemophilus influenzae/parainfluenzae as triggers of urethritis in men: risk factors and characteristics of this emerging problem**

Leticia Fontan¹, Ayla Yarci Carrión¹, Eva Navarro Lara¹, Nelly Daniela Zurita Cruz¹, Laura Cardeñoso*¹, Alicia García¹

¹Hospital de La Princesa, Madrid, Spain

**Background:** Both *Haemophilus influenzae* and *Haemophilus parainfluenzae* are colonisers of the upper respiratory tract. Transmission of oropharyngeal commensal flora to the urethra via insertive oral sex is recognised as a mode of transmission of several pathogens including *Haemophilus spp.* The aim of this study was to describe the characteristics of the urethritis possibly caused by *H. influenzae/parainfluenzae*.

**Materials/methods:** A retrospective study with all positive urethral samples for *H. influenzae/parainfluenzae* isolated from adult men between January 2019 and September 2019 was performed. Those whose samples were requested from primary heath care centers (PHCCs) were excluded for the lack of enough information. The identification was made by MALDI-TOF and the antibiogram by disk diffusion.

**Results:** In that period the urethritis were: gonococcal 28% (n=136), non-gonococcal 72% (n=350). *H. influenzae/parainfluenzae* were isolated in 13.7% (n=67). Finally we studied 30 patients (not requested from PHCCs) of which 3 had *H. influenzae* and 27 had *H. parainfluenzae*. From these strains of *Haemophilus* we studied the resistance to the following antibiotics: amoxicillin-clavulanic acid (10.3%), cefotaxime (0%), levofloxacin (13.7%), cotrimoxazole (24.1%).

To elucidate how many of these 30 patients actually had *Haemophilus influenzae/parainfluenzae* urethritis, those with more than one isolation and those without the characteristic symptoms of urethritis were excluded. Therefore, we considered that only 15 patients actually had *Haemophilus* urethritis. From these patients (average age 34 years old), we found the following symptoms: urethral discharge 40% (n=12), dysuria 36.6% (n=11), erythema 16.6% (n=5), meatus inflammation 6.6% (n=2). We also studied the next data:

<table>
<thead>
<tr>
<th></th>
<th>Yes</th>
<th>No</th>
<th>Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSM</td>
<td>5</td>
<td>4</td>
<td>6</td>

<td>5</td>
<td>2</td>
<td>8</td>
</tr>
<tr>
<td>HIV</td>
<td>4</td>
<td>11</td>
<td>0</td>
</tr>
</tbody>
</table>

Conclusions: According to our results, the most frequent symptoms in patients with *Haemophilus influenzae/parainfluenzae* urethritis are urethral discharge and dysuria. A high percentage of the strains in our environment are susceptible to cefotaxime. As such, we conclude that third generation cephalosporins are a good option as an empirical treatment. Non-safe oral sex practices and MSM could be risk factors for acquire this opportunistic pathogen. More studies with larger sample size are needed to link *Haemophilus spp.* with urethritis.

Abstract 7077

Trends of antibiotic consumption in German hospitals from 2015-2018

Birgitta Schweickert*1, Marcel Feig1, Marc Schneider1, Karin Groeschner1, Michael Behnke2, Luis Alberto Pena Diaz2, Petra Gastmeier2, Muna Abu Sin1, Doreen Richter1, Hans-Peter Blank1, Hartwig Wehrmeyer1, Alexandra Hoffmann1, Tim Eckmanns1

1Robert Koch-Institut, Department for nosocomial infections and surveillance of antimicrobial resistance and antimicrobial consumption, Berlin, Germany, 2Charité University Medicine Berlin Campus Benjamin Franklin, Institute for Hygiene and environmental medicine, Berlin, Germany

Background: The Antibiotic Consumption Surveillance (AVS)-system has been built up by the national public health institute in cooperation with the national reference center for surveillance of nosocomial infections in order to serve the hospitals in monitoring antimicrobial consumption and to support antibiotic stewardship activities. Trends in antibiotic consumption from the years 2015 to 2018 are presented.

Materials/methods: The calculation of antibiotic consumption values is based on the ATC (Anatomical Therapeutic Chemical)/DDD (Defined Daily Dose) method of WHO (ATC/DDD-version 2019). Target value is the antibiotic consumption density (CD) expressed in DDD per 100 patient days (PD). The data of systemically applied antibiotics (A07AA, J01, J04AB02, P01AB01) are presented as medians and interquartile range. The analysis results rely on the data submission of general acute care hospitals from the years 2015-2018 and represent sequential cross-sectional analyses. Trend analysis was performed by linear regression and a p-value of <0.05 was considered as significant.

Results: From 2015 to 2018 the number of participating hospitals increased from 103 to 209 hospitals. The median of total antibiotic consumption shows a decrease from 55.1 DDD/100 PD in 2015 to 51.2 DDD/100 PD in 2018. Analysis of the different antibiotic groups reveals a significant decline of the CD of cephalosporins from 17.4 DDD/100 PD to 12.1 DDD/100 PD, which is primarily due to a decrease of second generation cephalosporins while third generation cephalosporins remained nearly constant. A decrease can also be observed for macrolides, fluoroquinolones, imidazoles, sulfonamides/trimethoprim and glycopeptides. In contrast, the group of penicillins shows an increase from 14.0 DDD/100 PD to 16.2 DDD/100 PD which includes a rise of penicillins combined with beta-lactamase inhibitor as well as small-spectrum penicillins (Table 1). The results have been confirmed by analyzing a subgroup of hospitals providing data continuously from 2015 to 2018.

Conclusions: The surveillance data show a slight decrease of total antimicrobial consumption in German hospitals primarily driven by a decline of the use of second generation cephalosporins, which is partly compensated by an increase of penicillins. The data may indicate an effect of antibiotic stewardship activities and encourage for further enforcement and continuation of efforts.

Abstract 7078

**Synergistic activity of a three-drug combination against clinical isolates of Mycobacterium abscessus complex**

Mariana Fernandez1, Maria Rosa Monte1, Angely Roman1, Elena Portell Buj2,3, Alexandre López2,3, Griselda Tudó1,2,3, Julià Gonzalez1,2,3

1Hospital Clinic de Barcelona, Barcelona, Spain, 2University of Barcelona, Barcelona, Spain, 3ISGlobal, Barcelona, Spain

**Background:** Infections by nontuberculous mycobacteria (NTM) are increasing, affecting mainly patients with chronic pulmonary disease, being bronchiectasis the most frequent. *M. abscessus* complex (MAB) and *M. avium* complex are the most common NTM in these patients. To start treatment is a difficult decision, since to differentiate between contamination and infection is complicated and the response to antibiotic treatment is not optimal. The guidelines recommend the use of combinations including 3-4 drugs. The objective of this study was to test the activity of two combinations (including two and three drugs) against clinical isolates of MAB using an *in vitro* microdilution model.

**Materials/methods:** Ten clinical isolates of MAB were recovered from patients with bronchiectasis. A previous drug sensitivity testing (DST) showed that 6 were susceptible to clarithromycin and 4 had inducible resistance. The isolates were tested against amikacin, tigecycline and clarithromycin, using Mueller-Hinton (+cat) broth. The range of concentrations were 16 to 0.125 µg/mL for amikacin and clarithromycin and 1 to 0.0005 µg/mL for tigecycline. The combinations tested were amikacin-tigecycline (AT) and amikacin-tigecycline-clarithromycin (ATC). The range of concentrations were the same than for drugs alone. Plates were incubated at 30°C and the MIC results were obtained at 3 days. MBC was determined by subculturing the 4 higher concentrations to MIC and incubating them 3 additional days.

**Results:** Table 1 shows the results. The combination AT shows a MIC90 lower than the MIC90 for individual drugs, although not significant (decreasing one dilution). The combination ATC obtained a MIC90 decreasing two dilution, then individual drug. This combination showed synergism for 7/10 isolates tested. MBC90 for AT and ATC increased one dilution with respect to the MIC90.

**Conclusions:** Both combinations showed better activity than drugs alone. The combination amikacin-tigecycline-clarithromycin showed *in vitro* synergism against *M. abscessus*, compared to the individual activity of the drugs.

Table 1. Activity of individual drugs and combinations against *M. abscessus*.

Detection of the novel variant of NDM-type metallo-β-lactamase: significance of D130N amino acid substitution

Polina Starkova*1,2, Ofeliia Sulian1,3, Daria Likholetova1,4, Vladimir Ageevets1, Irina Lazareva1, Julia V. Sopova5,6, Sergey Sidorenko1,7

1Pediatric Research and Clinical Center for Infectious Diseases, St. Petersburg, Russian Federation, 2National Research Institute of Information Technologies, Mechanics and Optics, Saint Petersburg, Russian Federation, 3Saint-Petersburg State Academy of Veterinary Medicine, Saint Petersburg, Russian Federation, 4Saint Petersburg State University, Sankt-Peterburg, Russian Federation, 5Laboratory of Genetic Models of Human Diseases, Saint Petersburg Branch of Vavilov Institute of General Genetics, Saint Petersburg, Russian Federation, 6Department of Genetics and Biotechnology, Saint Petersburg State University, Saint Petersburg, Russian Federation, 7Department of Medical Microbiology, North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation

Abstract third-party references: The Russian Science Foundation (grant number 18-75-10117) supported this work

Background: To date 28 variants of NDM-type carbapenemase have been identified. NDM-type metallo-β-lactamase (MBL) positive Klebsiella pneumoniae isolate 1970_kpn was recovered from the urine of male patient in oncology center. Molecular analysis presented in the current study revealed the new variant of NDM-type metallo-beta-lactamase.

Materials/methods: The isolate 1970_kpn was sequenced on Illumina MiSeq platform (NexteraXT libraries, 300-bp paired-end reads), followed by de novo assembly using the SPAdes v.3.10.0 algorithm. The 1139 bp DNA fragment carrying NDM-type MBL and its own promoter was amplified, and cloned in pJET1.2 cloning vector. The chemical transformation was performed with XL10-Gold Escherichia coli strain. The same manipulations were performed with blaNDM-1 gene from validated clinical strain as a control. Sanger sequencing was used to confirm the cloned inserts. Antimicrobial susceptibility testing of transformants was performed by broth microdilution method according to the EUCAST recommendations to imipenem, meropenem, aztreonam, ceftazidime and piperacillin/tazobactam.

Results: NGS sequencing revealed that isolate 1970_kpn belongs to ST147 and carries new variant of NDM-type MBL. The contig with new blaNDM was deposited in GenBank - accession number MN624980. New blaNDM variant differed from blaNDM-1 by single amino acid substitution [AAS] – D130N [G→A]. Similar AAS is presented in NDM-7 and NDM-19. However, additional AAS are presented in above-mentioned enzymes: M154L – in NDM-7 and M154L + A233V – in NDM-19. Phenotypes of NDM-1 and new variant transformants are presented in Table and it is obvious that MIC’s of carbapenems against both transformants are similar. We can speculate that though D130N AAS did not provide significant evolutionary advantages it may be an important point in the emergence of new types of NDM. Alternative scenario of D130N acquisition as secondary mutation in NDM-type enzymes cannot be excluded.

Conclusions: D130N amino acid substitution plays significant role in the evolution of NDM-type MBL’s.

Abstract 7081

Characterisation of ZIKV NS1 protein and development of ZIKV-specific monoclonal antibodies for rapid diagnosis

Hye-Yeon Kim*, Sangmi Jun1, Edmond Changkyun Park1, Seung Il Kim1

1Korea Basic Science Institute, Cheongju, South Korea

Background: Zika virus (ZIKV), a member of the flavivirus, was declared a global public health emergency and causes microcephaly and other neurological diseases. Zika virus has a single-stranded positive-sense RNA genome and viral proteins consist of three structural proteins (capsid, membrane and envelope) and 7 non-structural proteins (NS1, NS2A, NS2B, NS3, NS4A, NS4B and NS5). Non-structural protein 1 (NS1) plays a crucial role in the early stage ZIKV infection and NS1 protein is a potential diagnostic marker.

Materials/methods: The gene coding for the NS1 protein of ZIKV was synthesized and cloned into bacterial expression vector. Recombinant NS1 proteins were purified, characterized and used for the development of monoclonal antibodies for rapid diagnosis of ZIKV. The purified recombinant ZIKV NS1 proteins were characterized by size-exclusion chromatography (SEC), circular dichroism (CD) spectroscopy and multi-angle light scattering (MALS). ZIKV-specific monoclonal antibodies were selected using dot blot assay with ZIKV NS1 protein expressed in mammalian cells.

Results: To validate the folding of ZIKV NS1 recombinant protein after purification, its secondary structure was determined by CD spectroscopy and its oligomeric state was confirmed by SEC and MALS. This indicates that the purified recombinant ZIKV NS1 protein is well-folded and forms a dimer in solution. A large number of monoclonal antibodies were produced and the binding of ZIKV NS1 and antibody was verified by dot blot experiments. We selected two monoclonal antibodies for lateral flow assay (LFA) and development of rapid diagnostic test (RDT) kit for point-of-care is in progress.

Conclusions: In this study, we purified recombinant ZIKV NS1 proteins and developed ZIKV-specific antibodies. Characterization of recombinant viral antigen protein and production of virus-specific monoclonal antibodies are useful for both the early diagnosis of viral infection and biophysical studies of viral antigens and virus-specific antibodies.

Abstract 7082

Use of short- and long-read sequencing for the identification of antimicrobial resistance genes from pig oral fluid samples

Leonard Schuele*1, Giuseppe Fleres1, Katrin Strutzberg-Minder1, Christopher Erdmann2, Claudia Lambrecht1, Jürgen Harlizius3, Sabine Schütze1, Sandra Löbert3, Natacha Couto1, John Rossen4

1University of Groningen - University Medical Center Groningen, Groningen, Netherlands, 2IVD Gesellschaft für Innovative Veterinärmedizin mbH, Seelze, Germany, 3Landwirtschaftskammer Nordrhein-Westfalen, Bad Sassendorf, Germany, 4University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: Antibiotic resistance driven by antibiotic overuse and bacterial evolution is a global problem not only in healthcare, but also in agriculture and the meat industry. Detection of the genes causing resistance is key to prevent further spread and to treat patients and animals suffering from an infection in the most optimal way. Shotgun metagenomic sequencing (SMg) has the potential to detect all antimicrobial resistance genes (ARG) and the possible transmission of ARG through horizontal gene transfer between different individuals. Here we report the presence and expression of ARG in pig oral fluid (OF) samples.

Materials/methods: Nucleic acids were extracted using MagMAX nucleic acid purification Kits from OF samples obtained from ropes. For long read sequencing (LRS), libraries were generated using the Rapid Barcoding Kit and sequenced on a FLO-MIN106 R9.4 flow cell. For short read sequencing (SRS), libraries were generated using the KAPA HyperPlus kit and sequenced on a NextSeq. SRS reads were trimmed and assembled using CLC workbench. MinION data was basecalled with Albacore, demultiplexed with Porechop, assembled with Flye and polished twice with Medaka. Finally, the LRS assembly was polished with MaxBin2 and annotation using PATRIC.

Results: Overall, we detected 32 different ARG conferring resistance to 9 different antibiotic classes (Table 1). Five ARG were actively being expressed. A novel IncQ plasmid of 18156 bp containing the MCR 1.1 gene, insertion sequence 26 and the gene encoding for the HicAB toxin-antitoxin was detected. MCR was detected both on a DNA and RNA level, with metagenomic binning and BLAST identifying E. coli as the most probable host. Other ARG were detected on plasmids, phages and in the chromosome and were frequently flanked by mobile genetic elements.

Conclusions: We show the potential of combining long and short read sequencing to not only detect, but also characterize ARG directly from samples. In addition, OF sampling has the potential for broad microbial screening in pig farms on the herd level.

Table 1: AMRFinder results of sample S.3. Cutoffs: Coverage >80%, identity >95%. ARG present on multiple alleles are presented in bold and expressed ARG are represented in blue.

Abstract 7083

**Changing the hospital microbiome: a cluster-randomised controlled trial to analyse the influence of environmental cleaning on hospital-acquired infections using disinfectant, soap or probiotic agents**

Rasmus Leistner*1, Britta Kohlmorgen1, Jennifer Golembus1, Desiree Gruh1, Elke Lemke1, Bastian Raguse2, Gregor Zakonsky2, Petra Gastmeier1

1Charité Universitätsmedizin Berlin, Institute of Hygiene and Environmental Medicine, Berlin, Germany, 2Charité Universitätsmedizin Berlin, Charité Facility Management, Berlin, Germany

**Background:** Environmental cleaning is an important pillar of hospital infection prevention and control. However, in international and even national comparisons different substances are used for identical indications. Besides disinfecting agents and soap-based cleaning substances, a new type of agent was introduced recently: probiotic agents. In order to assess the effect of those different cleaning agents we designed an experimental study.

**Materials/methods:** From June 2017 to August 2018 we performed a 3-armed cluster-randomized-controlled trial. In each arm a different cleaning agent was employed in the routine maintenance cleaning (disinfection, soap, probiotic). The setting was the main building of Charité Universitätsmedizin Campus Mitte including 18 wards of different non-ICU disciplines. A hospital-acquired infection (HAI) was diagnosed if a patient had a clinically relevant pathogen in a microbiology specimen and fulfilled the criteria of CDCs HAI definition. The latter was based on the review of the patients’ files.

**Results:** Altogether, we analyzed about 17,702 patients (between 5,905 and 6,127 in each arm) with similar underlying diseases, age and gender in each arm. The hand hygiene compliance on all wards was between 50% and 66%. We found an overall HAI incidence of 1.7% [1.9% for probiotic cleaning, 1.5% for disinfection cleaning and 1.6% for soap-based cleaning]. The 95% confidence intervals of the three arms overlapped largely showing no relevant difference. The most common HAIIs were UTI [31.8%], BSI [22.6%], SSI [19.2%], LRTI [8.3%]. The most commonly detected pathogens were *E. coli* [32.8%], *S. aureus* [14.2%], *Enterococcus spp.* [32.8%], coagulase-negative staphylococci [8.8%], *Klebsiella spp.* [8.1%], *C. difficile* [6.4%], *P. aeruginosa* [4.1%]. There was no clinical detection of one of the used probiotic species (*Bacillus subtilis, Bacillus pumilus, Bacillus megaterium*).

**Conclusions:** In this RCT the measured rate of hospital-acquired infections did not depend on the agent that was used for environmental cleaning. However, each cleaning agent offers different advantages that could trigger their deployment.

**Enterococcal bacteraemia: epidemiology, clinical characteristics and causes of inappropriate treatment**

Gemma Grau Gómez*1, Lucía Boix-Palop1, María Lopez1, Ursula Masats1, Mariona Xercavins Valls1, Beatriz Dietl Gómez-Luengo2, Esther Calbo Sebastian1

1Mútua Terrassa University Hospital, Terrassa, Spain

**Background:** The frequency of enterococcal blood stream infections is rising due to the increasing aging and comorbidities prevalence among general population.

The aim of this study was to assess the epidemiological and clinical characteristics and outcomes of enterococcal blood stream infections (E-BSI) and to evaluate the causes of inappropriate empirical antibiotic treatment (EAT).

**Materials/methods:** Design: Observational retrospective study. Setting: Acute care hospital. Period: January 2017-December 2018. Patients: All consecutive EB-foci were included. The EAT appropriateness was evaluated (appropriate EAT was defined as the use of an antibiotic with in vitro activity). Variables: demographic and clinical characteristics, appropriateness of EAT and outcomes.

**Results:** Eighty-two E-BSI were identified, representing 7.2% of global BSI episodes, 40 (48.8%) caused by *E. faecalis* and 42 (51.2%) by *E. faecium*. Median age was 68y, 60 (73.2%) cases were men. Median Charlson index was 2. Ten (12.2%) E-BSI were community-acquired, 39 (47.6%) hospital-acquired and 33 (40.2%) health-care related. The most prevalent sources of infection were urinary (20 [24.4%]) and abdominal-biliar (34 [41.5%]). In-hospital mortality was 28%.

We compared E-BSI that received appropriate-EAT (35 [42.7%]) with those with inappropriate-EAT (47 [57.3%]). Urinary focus (13 [34.3%] vs 8 [17%], p=0.07), Pitt Index >3 (5 [14.3%] vs 1 [2.1%], p=0.06) and control of the infectious focus (39 [82.9%] vs 28 [59.6%, p=0.03) were more common among patients with appropriate-EAT, whereas the identification of *E. faecium* (12 [34.3%] vs 30 [63.8%], p=0.008), vascular focus (5 [10.3%] vs 0, p=0.07), oncologic patients (8 [17%] vs 1 [2.9%, p=0.07) and continuous bacteremia (6 [13%] vs 1 [2.9%, p=0.01) were more frequent among patients with inappropriate-EAT. There were no differences in duration of antibiotic treatment, days of hospitalization or in-hospital mortality.

**Conclusions:** Almost one third of patients with E-BSI dies during admission. E-BSI are mostly health-care related. More than a half cases are produced by *E. faecium*. The risk of inappropriate-EAT was higher among patients with E-BSI due to *E. faecium*, in oncologic patients and in those with vascular focus. It is important to identify patients at risk of receiving inappropriate-EAT.

Colistin hetero-resistance in Acinetobacter baumannii blood isolates
Ekin Kirbaş*, Umran Liste1, Cumhur Özkuyumcu1, Banu Sancak2

1Hacettepe university faculty of medicine, Ankara, Turkey, 2Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Colistin is used as drug of last resort for the treatment of infections caused by multidrug-resistant Gram negative bacteria. Together with the increased usage, colistin resistance and heteroresistance (HR) have been described in Acinetobacter baumannii. The inability to detect HR by routine diagnostic testing results in strains being misclassified as susceptible.

The aim of this study was to evaluate the presence of resistance and heteroresistance to colistin in A. baumannii blood isolates.

Materials/methods: A total of 169 A. baumannii blood isolates recovered from hospitalized patients between January 2014 and April 2018 were included in the study. Minimum inhibitor concentrations (MICs) were determined by broth microdilution method (BMD). For detection of HR, population analysis profiling (PAP) was applied. For investigation of colistin HR, we selected either the isolates which colonies were observed within the inhibition zone of colistin gradient test (n=7) [Etest, BioMérieux, France] or the ones with colistin MICs ranging from 1 to 2 μg/ml (n=68) Heteroresistance was considered if the antibiotic concentration exhibiting the highest inhibitory effects was at least 8-fold higher than the highest noninhibitory concentration.

Results: Among 169 A. baumannii blood isolates, 48 isolates (28.4%) were found as resistant to colistin by BMD method. The overall incidence of colistin heteroresistance was 27.2% (n=46). HR detected in %55.8 (n=29) of 52 isolates which had colistin MICs of 1 μg/ml and %76.2 (n=16) of 21 isolates which had colistin MICs of 2 μg/ml.

Conclusions: In this study, we found high HR incidence among colistin susceptible A. baumannii blood isolates. The frequency of HR was MIC dependent. The number of solates demonstrating heteroresistance increases with increasing colistin MICs.

The rates of colistin HR can vary according to the center, isolation source and treatment of colistin. Therefore investigation of HR is very important for understanding of clinical implications of this phenomenon.

Cross-reactivity of antigenic enterococcal proteins against *Staphylococcus aureus* for the development of a vaccine to fight Gram-positive ESKAPE pathogens

Felipe Romero-Saavedra*1, Diana Laverde1, Johannes Huebner1

1Dr. von Hauner Children’s Hospital, Ludwig Maximilian University of Munich, Munich, Germany

Abstract third-party references: Supported by European Union’s Horizon 2020 research and innovation programme for funding work on this topic under the Marie Skłodowska-Curie grant agreement BactiVax No. 860325

**Background:** The ESKAPE bacteria are pathogens of great clinical concern. These bacteria are major causes of nosocomial infections worldwide being able to escape the bactericidal action of many antimicrobial agents. Despite efforts targeted at these organisms, few novel antimicrobials are available, and therapeutic options remain limited. Therefore, non-antibiotic alternative treatments such as vaccines are valuable approaches to fight these diseases. Gram-positive ESKAPE pathogens (*i.e.* *Enterococcus faecium* and *Staphylococcus aureus*) possess similar components in their cell wall envelope that could be targeted by these immunotherapies. We have previously described cell-wall associated *E. faecium* proteins able to raise opsononic and protective antibodies against enterococci1–3 especially *Enterococcus faecium*, are well-known pathogens of hospitalized patients and are frequently linked with resistance against multiple antibiotics, which compromises effective therapy. Rabbit immune serum raised against heat-killed *E. faecium* E155, a HiRECC clone, was used in an opsonophagocytic assay, an inhibition assay and a mouse bacteraemia model to identify targets of opsonic and protective antibodies. Serum against whole heat-killed bacteria was opsonic and recognized a protein of about 72 kDa that was abundantly secreted. This protein, identified as SagA by LC-ES-MS/MS, was expressed in *Escherichia coli* and purified. Rabbit serum raised against the purified protein showed opsonic killing activity that was inhibited by almost 100% using 100 µg purified protein ml⁻¹. In this study, we evaluated antibodies targeting these immunogenic *E. faecium* proteins for their ability to cross-react with *S. aureus*.

**Materials/methods:** We performed *in silico* analysis to determine whether the previously immunogenically characterized *E. faecium* proteins have homologies in *S. aureus*. In addition, *in vitro* assays mimicking the protective immune responses were performed to determine if antibodies directed against the selected proteins mediate opsonophagocytosis of *S. aureus*. To this end, sera before and after immunizations with the proteins were compared in opsonophagocytic assays (OPA).

**Results:** Bioinformatic analysis showed that, previously characterized *E. faecium* proteins have homologies between 36 and 74% in *S. aureus*. The zinc ABC transporter substrate-binding lipoprotein (AdcAₕ), low-affinity penicillin-binding 5 (PBP5), manganese ABC transporter substrate-binding lipoprotein (PsaAₕ), peptidyl-prolyl cis-trans isomerase (PpiC) and secreted antigen A (SagA) proteins were selected to be tested in OPA. Sera raised against three out of the five selected proteins (*i.e.* AdcA, PpiC, and SagA) showed more than 40% killing activity against different *S. aureus* strains.

**Conclusions:** AdcAₕ, PpiC, and SagA are promising protein antigens that could be used alone or conjugated to bacterial polysaccharides to develop a vaccine against the Gram-positive ESKAPE pathogens. Currently, the protective efficacy of the antibodies against *S. aureus* is being tested. Moreover, identification of the specific cross-reactive epitopes could lead to a more potent formulation.

Abstract 7093

Evaluation the presence of leukocytes and bacterial communities of sputum from cystic fibrosis patients

Fabiana Volpato*, Daiana Lima Morales, Pabulo Rampelotto, Paulo Maróstica, Afonso Barth

Hospital de Clínicas de Porto Alegre, Federal University of Rio Grande do Sul, Porto Alegre, Brazil

Abstract third-party references: Supported by: INPRA (Instituto Nacional de Pesquisa em Resistência Antimicrobiana), FIPE/HCPA

Background: Cystic Fibrosis (CF) is a recessive genetic disease, which affects mainly the respiratory tract of patients causing chronic and persistent bacterial infection of the airways. The lungs of CF patients can be colonized by a complex of microbial communities. It is consider that the composition of these communities may be relate to the CF lung disease progression. The aim of this study was to correlate the diversity of the bacterial communities with the presence or absence of leukocytes in sputum samples from CF patients.

Materials/methods: In order to evaluate the microbiome of the sputum of the CF patients we performed 16S rRNA sequencing using the Illumina MiSeq platform. Eleven CF sputum were submitted to DNA extraction with QIAamp DNA Mini Kit (QIAgen, Valencia CA), with proteinase K pre-treatment (60 minutes at 56°C), followed by bead-beating with zirconia/silica beads in a FastPrep 24 5G system (Qbiogene, CA), for 10 seconds at 6.0 m/sec (repeated 3 times). The 16S rRNA gene library was prepared according to 16S Metagenomic Sequencing Library Preparation Illumina protocol, using V5V6 region. A set of sputum was evaluate in triplicate in order to evaluate the reproducibility of the technique. The presence or absence of leukocytes was evaluate using a differential slide counting of sputum smears stained with May-Grunwald-Giemsa. Alpha diversity measures were calculate based on OTU counts rarefied to the minimum sample size.

Results: The triplicate analysis presented homogeneous results indicating reproducibility of our methods for DNA extraction, amplification and sequencing. The metagenomics analysis indicated that the microbiome profile is particular of each patient. It was also possible to observe that the absence of leukocytes was associated to the heterogeneity of the sputum microbial community. In fact, the less diverse bacterial communities were related to an increase number of leukocytes \( p= 0.004329 \).

Conclusions: This study results indicated that the presence of leukocytes in a sputum sample are directly correlate to a homogeneous bacterial community. Further studies are necessary to evaluate other inflammatory markers, which will give a better understanding of the relationship between bacterial infection and host responses in CF patient.

Abstract 7094

Rapid distinction of capsulated Acinetobacter baumannii using a density gradient method

Hadas Kon1, Nadya Rakovitsky1, David Schwartz1, Yehuda Carmeli1,2, Jonathan Lellouche*1

1National Laboratory for Antibiotic Resistance and Investigation of Outbreaks in Medical Institutions, Ministry of Health, Israel; National Institute for Antibiotic Resistance and Infection Control, Ministry of Health, Israel, Tel-Aviv, Israel, 2Sackler Faculty of Medicine, Tel Aviv University, Ramat-Aviv, Israel, Tel-Aviv, Israel

Background: Gram-negative bacterial capsules are associated with hypervirulence and overproduction of extracellular polysaccharide matrix, resulting in a mucoidic phenotype. Capsule production confers antiphagocytic and antibacteriolytic activity and immune evasion. Recently, fatal clinical cases involving capsulated carbapenem-resistant A. baumannii (CRAB) were reported in Israel. A rapid screening tool to identify capsulated isolates is needed. We present a simple method to distinguish A. baumannii based on capsule size.

Materials/methods: The sample consisted of 46 CRAB clinical isolates: 21 mucoid and 25 non-mucoid. Mucosity was determined by visual inspection after overnight incubation at 35±2°C on blood agar. Our method is based on migration of bacterial cells through a gradient matrix composed of colloidal silica particles of 15–30nm suspended in phosphate buffer saline. To determine the optimal number of layers and the silica concentrations (density of each layer) needed to obtain separation of capsulated from non-capsulated isolates, several combinations with a range of concentrations (20-80% V/V) were evaluated. Each test was performed by centrifugation of an aliquot (600µl) of the bacterial culture for 30 minutes at 3,000xg. Results were read by visual inspection. To eliminate subjectivity, we normalized a quantitative value (Rt-OD600) based on the ratio of optical density values (at 600nm) of the top and bottom layers. Capsule thickness was confirmed for five isolates by transmission electron microscopy and lipopolysaccharides (LPS) quantification. A highly mucoid (string test positive) Klebsiella pneumoniae was used as a positive control and a non-mucoid A. baumannii (ATCC19606) as a negative control.

Results: A set of two layers with silica concentrations of 30% (upper layer) and 50% (bottom layer) V/V was optimal. Twenty-three of the 46 isolates migrated to the lower layer (Rt-OD600 range: 0.0-1.5), while the other 50% remained in the upper layer (Rt-OD600 range: 4.2-75.9). Two isolates with a non-mucoid phenotype by visual inspection were detected as capsulated. Mean capsule thickness was 58±2nm for non-mucoid isolates and 103±20nm for mucoid capsulated isolates. ATCC19606 had no visible capsule. LPS concentration was 2.20ng/10⁸CFU for non-mucoid isolates, 2.22ng/10⁸CFU for mucoid isolates, and 1.92ng/10⁸CFU for ATCC19606.

Conclusions: We validated a rapid tool to screen for the presence of capsulated CRAB.

Is there any association between microbiological variables and toxigenic *Clostridioides difficile* infection (CDI) in a tertiary hospital?

Ledicia Alvarez Paredes¹, Cristina Labayru Echeverría¹, María Andrés Franch², María Ángeles Mantecón*¹, Cristina Losa Pérez¹, María Ortega Lafont¹, Eleda Coletta¹, Gregoria Megías Lobon¹

¹Hospital Universitario de Burgos, Burgos, Spain

**Background:** According to several studies, specific microbiological factors can be related to poor outcome in CDI patients. The objective of the study was to analyze the documented microbiological factors and to assess its relationship with CDI.

**Materials/methods:** Between September 2013 and December 2018, patients >2 years old with unexplained and new-onset ≥3 loose stools in 24 h were included. Microbiological diagnosis of toxigenic strains was confirmed by real time PCR (Xpert® *C. difficile*) in stool samples. Microbiological risk factors associated to a severe episode or recurrence were analysed. Recurrence is defined as a relapse of CDI symptoms within 2 - 8 weeks of successful treatment of the initial episode. Clinical definition was categorised according to current guidelines. To assess possible differences between variables, Chi-square and U-Mann Withney were performed.

**Results:** 250 patients were included. The presence of binary toxin was detected in 58 (23%) of them. In 5 patients 027 ribotype was detected. Association between toxin B Ct (cycle threshold) and recurrence was found to be statistically significant. Additionally, when Ct were categorised according with a multicenter study (*Reigadas et al, Anaerobe. 2019 Jul 26:102079*), the association remained. (Table 1).

**Conclusions:** According to other authors, Ct, as a surrogate for the amount of toxin in the sample, could be a predictor of poor outcome in CDI patients. In our number of cases, toxin B Ct, might be a strong marker associated with recurrence. Microbiological factors will be included in robust scores that allow predicting recurrence.

Abstract 7098

Antibiotic resistance pattern and prevalence in occupied Palestinian territories (oPt): evidence for guiding empiric antibiotic therapy

Dina Nasser1, Fortunato Morabito1, Tahreer Taha2, Hammam Rjoup2, Musa Hindiyeh2, Ali Sabateen*2

1Augusta Victoria Hospital, East Jerusalem, Palestine, 2Augusta Victoria Hospital, East Jerusalem, Palestine

Background: The emergence of carbapenem and colistin resistant Klebsiella pneumonia in the oPt has complicated patients’ treatment and increased the risk of health care associated infections. The study aimed to investigate the burden of ARO colonization and differences in prevalence among oPt districts.

Materials/methods: A retrospective analysis of the ARO surveillance program at Augusta Victoria Hospital (AVH) targeting nasal and anal cultures of newly admitted patients has been carried out. The target group comprised 968 adult and pediatric oncology patients admitted between January and August 2018. All patients referred from other hospital or with a history of ARO on prior admission were included. Samples were microbiologically processed according to the American Society for Microbiology standard guidelines to isolate bacterial pathogens. Antimicrobial resistance was identified following the Clinical and Laboratory Standard Institute standards. Statistical analysis (Odds ratios) compared the prevalence of colonization in samples from specific districts, focusing on the Gaza Strip (GS) and the West Bank (WB). Comparison between groups was performed using the Chi-Squared test and the corresponding P-value.

Results: Overall 2,708 screening swabs were collected (1265 nasal and 1443 anal samples), 36% of samples came from GS patients. Anal swabs’ analysis revealed that 71% of the GS samples and 55% of the WB samples were AROs. There was a significantly higher prevalence (P<0.001) of 3rd generation cephalosporin-resistant (3GCR) bacteria in GS 56% (95%CI 52-60) compared to 43% (95%CI 40-66) from WB, and a significantly higher prevalence (P<0.001) of carbapenem-resistant Enterobacteraceae (CRE) from the GS (5.3%, 95%CI 3.7-7.5) compared to 1.9% (95%CI 1.2-2.5) in WB. The odds of having 3GCRs (OR 1.7, 95%CI 1.4-2.1) and CRE (OR 2.9, 95%CI 1.6-5.4) in GS is significantly higher than WB (P<0.001). Nasal swabs indicated there was a significantly higher prevalence of methicillin-resistant Staphylococcus aureus (MRSA) in GS compared to WB samples (GS: 11.9%, 95%CI 9.1-15 versus WB: 7.3%, 95%CI 5.7-9.4; P=0.009).

Conclusions: These results suggest an overall elevated anal colonization of AROs (3GCS, CREs and MRSA) among GS patients seem to be at higher risk of having. Introducing antimicrobial stewardship programs will help in reducing the spread of resistant bacteria in the oPt.

Spectrum overly broad and duration too long: an assessment of appropriateness of antimicrobial prescriptions in older patients admitted to an Australian tertiary teaching hospital

Lemlem Gebremichael1, Renuka Visvanathan2, Morgyn Warner*2,3

1University of South Australia City West Campus, Adelaide, Australia, 2The Queen Elizabeth Hospital, Woodville South, Australia, 3The University of Adelaide, Adelaide, Australia

Background: Elderly patients are at higher risk of infections and are prescribed more antimicrobials compared to younger patients. As the prevalence of infections, polypharmacy, and comorbidities increases, inappropriate antimicrobial prescribing also increases. We evaluated antimicrobial prescribing in elderly patients admitted to a South Australian tertiary hospital to identify targets for improvements in antimicrobial prescribing.

Materials/methods: Antimicrobial prescriptions in 280 patients admitted to the Geriatric Evaluation and Management Unit (GEMU) of The Queen Elizabeth Hospital between December 2017 and June 2018 were evaluated using a national antimicrobial prescribing survey tool. Appropriateness of antimicrobial prescriptions was assessed using Australian therapeutic guidelines recommendations.

Results: Of the 280 GEMU patients, 142 (50.7 %) were prescribed at least one antimicrobial. The mean age of antimicrobial-prescribed patients was 84.2 ± 7.0 years. 342 antimicrobial prescriptions were assessed for appropriateness. The most common documented indications for antimicrobials were cystitis (n = 118, 34.5 %), and empiric therapy for community-acquired pneumonia (n = 34, 10.8 %). Twenty-eight (23.7 %) cystitis, and 10 (27.0 %) community-acquired pneumonia prescriptions were assessed as inappropriate. Indications of 341 (99.7 %), and review or stop date of 337 (98.5 %) prescriptions were documented. The most commonly prescribed antimicrobials were amoxicillin-clavulanic acid (n = 67, 19.6 %), and cephalexin (n = 45, 13.2 %). The most common inappropriately prescribed antimicrobials were amoxicillin-clavulanic acid (n = 34, 50.7 %), and ciprofloxacin (n = 4, 36.4 %). Overall, 178 (52.0 %) prescriptions were compliant with guidelines, while 96 (28.1 %) were non-compliant. 261 (76.3 %) prescriptions were deemed appropriate, and 80 (23.4 %) inappropriate; with the main reasons for inappropriateness being incorrect duration (n = 129, 37.7 %), and prescription of overly broad-spectrum antimicrobials (n = 54, 15.8 %).

Conclusions: Usage of broad spectrum antibiotics for an excessive duration was common in this elderly patient cohort, with suboptimal adherence to national prescribing guidelines. A low threshold to empirically treat for infection without clear infective symptoms and diagnostic uncertainty were likely important drivers of inappropriate prescribing in this group; needs for antibiotics should be weighed against the risk of adverse effects and the development of antibiotic resistance.

Impact of the inpatient infectious disease consultations at a tertiary care university hospital

Jacques Choucair*1, Danielle Jaafar1, Marie Chedid1, Elie Haddad1, Gebrael Saliba1, Rami Waked1

1Université Saint Joseph - Campus des Sciences Médicales CSM // University Saint Joseph - Medical Science Campus, Bayrut, Lebanon

Background: The purpose of this study is to report the value of infectious disease consultation in the inpatient setting.

Materials/methods: This is a prospective cohort study that took place in a tertiary care university hospital. During the period from April to June 2016, 224 cases of patients receiving antibiotics in the hospital with the request of an infectious diseases' consultation, were evaluated. The following variables were assessed: the referring department, purpose of the consultation, the antibiotic used before the infectious diseases consultation was requested, the antibiotic modifications (changing the type, dose or range of the antibiotic when applicable), the duration of antibiotic use (decreased or increased), whenever the antibiotic usage was switched to a mono or bi-therapy.

Results: The most frequent requesting departments were oncology (23.2%) and urology (21.4%). The purpose of the consultations was diagnostic (29%), therapeutic (41%), both diagnostic and therapeutic (21%) and prophylactic (9%). An infectious diseases consultation was given at a rate of 4.9 consultations per 100 hospitalized patients. Consequently, there was no indication for the antibiotic treatment in 11.6% of cases, antibiotherapy was discontinued in 14.7% of cases and modified in 25.4% of cases. Adjusting the antibiotic dosage was done in only one case. Carbapenem antibiotics were discontinued in 31.6% of cases and Quinolones discontinuation accounted for 22.7% of cases. Prolonging or shortening the duration of antibiotherapy was carried in 7 and 13 cases respectively. Changing the treatment to a monotherapy was performed in 54.1% (13 out of 24 cases). Antibiotic was already started in 132 cases (59%) before an ID consultation was requested.

Conclusions: Infectious disease consults contributed to the optimization of the diagnostic and therapeutic approaches for suspected or established infections in hospitalized patients. Furthermore, the de-escalation and interruption of the antibiotherapy are essential to reduce bacterial resistance.

Clinical management of serious infections attributable to carbapenem-resistant Gram-negative pathogens in Spanish hospitals

Ricardo Ferrer1, Jorge Calvo-Montes1, Emilio Maseda1, Miguel Salavert1, Germán Bou Arevalo1, Jazmin Diaz-Regañon4, Diego Lopez2, Virginia Lozano6, David Gómez-Ulloa5, Raquel Fenoll7, Emilio Sánchez7, Eilish Mccann*8

1Vall d’Hebron University Hospital, Barcelona, Spain, 2Marqués de Valdecilla University Hospital, Santander, Spain, 3University Hospital La Paz, Madrid, Spain, 4Hospital Universitaria y Politécnica de La Fe, Valencia, Spain, 5Hospital Universitario La Coruña, La Coruña, Spain, 6Merck Sharp & Dohme, Madrid, Spain, 7IQVIA Real World Solutions, Barcelona, Spain, 8Merck & Co., Inc., Kenilworth, NJ, United States

Background: The treatment of Gram-negative (GN) infections is a major and growing challenge as bacteria become increasingly resistant to commonly used antibiotics. The objective of this study was to characterize the clinical management of patients diagnosed with complicated urinary tract infections (cUTI), complicated intra-abdominal infections (cIAI), or hospital-acquired/ventilator-associated bacterial pneumonia (HABP/VABP) due to carbapenem-resistant (CR) GN bacteria in Spain.

Materials/methods: Hospitalized adults with a diagnosis of cUTI, cIAI, or HABP/VABP caused by CR GN pathogens from February 2015–July 2017 were consecutively enrolled from five hospitals in Spain (all >600 beds). Patient characteristics, medical history in the year prior to index hospitalization, and treatment patterns were abstracted from patient records in a retrospective chart review.

Results: 100 patients were included: mean age 65.9 years, 70% male. In the year before index admission, over half (52%) received antibiotics, most frequently penicillins (n=35, 67.3%), 58% were previously admitted to hospital, and 57% underwent invasive procedures. Most index infections were hospital-acquired (71%) and the most common index infections were HABP/VABP (47%), cUTI (42%), and cIAI (6%). K. pneumoniae was most frequently implicated (51% of patients) followed by P. aeruginosa (44%). 63 isolates were tested for carbapenemase type (isolates could be tested multiple times); 45 (71.4%) were OXA-producers, 3 (4.8%) VIM, and 15 (23.8%) ‘other’. The most common therapies given immediately after culture collection were carbapenems (21%), penicillins (15%), and macrolides (8%). Immediately prior to susceptibility results the most common were carbapenems (41%), colistin (20%), aminoglycosides (19%), and penicillins (19%). After test results were available, patients received carbapenems (41%), colistin (28%), and aminoglycosides (27%). Treatment patterns for patients receiving carbapenems at any timepoint (n=57) are shown in Figure 1.

Conclusions: Carbapenems are frequently used to treat cUTI, cIAI, HABP/VABP caused by CR GN bacteria in Spanish hospitals. Carbapenem use, particularly in combination with other agents, persists after confirmation of carbapenem resistance. New agents which restore bacterial susceptibility to carbapenems will support this prescribing behavior and provide an alternative to colistin use, which was seen to increase over the course of the treatment period.

Presenter email address: eilish.mccann@merck.com
Abstract 7108

**Microdiversity of Enterococcus faecalis isolates from infective endocarditis**

Guilhem Royer1, Lolita Roisin2, Stéphane Lo1, Demontant Vanessa1, Herve Jacquier1, Raphael Lepeule1, Vincent Fihman1, Pascal Lim1, Christophe Rodriguez1, Paul-Louis Woerther1

1Hôpital Henri-Mondor Ap-Hp, Créteil, France, 2Créteil Medical School, Créteil, France, 3Hospital Lariboisiere, Paris, France

**Background:** Infective endocarditis (IE) due to *Enterococcus faecalis* are severe infections which relapse in almost 10% of cases, despite effective antimicrobial therapy. We recently hypothesized that treatment failure could be linked with the selection of isolates lacking the virulence factor Ebp. Ebp is a protein belonging to microbial surface component recognizing adhesive matrix molecules, and is an important target of the host’s immune system. For that reason, deletion of Ebp may be involved in immune evasion. In order to evaluate the frequency Ebp deletions in IE, we analyzed the microdiversity within 5 heart valves from patients with IE due to *E. faecalis*.

**Materials/methods:** Five heart valves from patient with *E. faecalis* IE were inoculated onto Polyvitex agar plates for 48h under aerobic, anaerobic and microaerophilic atmospheres. A total of 9 isolates (3 for each condition) per patient were selected according to the macroscopic aspect. The resulting 45 isolates were sequenced by Illumina. We analyzed the sequence type, the resistance and virulence genes (Resfinder and VFDB) of the isolates. Moreover, we searched for SNPs and large deletions between all pairs of isolates among each patient using Breseq.

**Results:** All isolates from each patient belonged to the same ST. However, the precise comparison of the isolates identified differences ranging from a few SNPs to large deletions of thousands of bases particularly for two patients. As expected, we found a 15 000 bp deletion involving the virulence factor ebpA/B/C and srtC into 2 of 9 isolates from a first patient. We also detected a deletion of more than 40 000 bp which probably results from a phage excision into 1 of 9 isolates in a second patient. Interestingly, the genetic analysis of this phage showed the presence of the *pblA* and *plbB*-like genes implicated in adhesion to human platelets.

**Conclusions:** Although poorly described, the bacterial microdiversity seems to be frequent during IE due to *E. faecalis*. The deletion of important genetic determinants such as ebp that we previously observed or other determinants such as gene *pblA* and *plbB*-like genes involved in adhesion to human platelets could allow immune evasion and facilitate IE relapses.

**Presenter email address:** guilhem.royer@gmail.com
Abstract 7109

Genomic characterisation of CTX-M-15/DHA-1/OXA-48-producing Klebsiella pneumoniae of ST15/ST11/ST307 lineages from companion animals in France

Raquel Garcia Fierro1, Antoine Drapeau1, Melody Dazas1, Estelle Saras1, Edouard Hirchaud1, Carla Parada Rodrigues1, Sylvain Brisse1, Jean-Yves Madec1, Marisa Haenni1

1Unité Antibiorésistance et Virulence Bactériennes, Université Claude Bernard Lyon 1, ANSES, Lyon, France, 2Viral Genetic and Biosecurity Unit, BP53, ANSES Ploufragan-Plouzané-Niort Laboratory, Ploufragan, France, 3Biodiversity and Epidemiology of Bacterial Pathogens, Institut Pasteur, Paris, France

Background: Dissemination of multi-drug resistance (MDR) is a worldwide problem in both human and veterinary medicine. Among MDR bacteria, WHO considered extended spectrum β-lactamase (ESBL)-producing Klebsiella pneumoniae as a major global concern. Recently, ESBL- and carbapenemase-producing Enterobacterales have been increasingly isolated from companion animals, stressing their potential role as a reservoir for humans. In this study, molecular features of ESBL- and carbapenemase-producing K. pneumoniae isolates recovered from companion animals in France were investigated.

Materials/methods: Between 2010 and 2018, 116 K. pneumoniae isolates collected in France from diseased companion animals (mostly dogs (n=65) and cats (n=35)) were included in the study based on phenotypic ESBL isolation/testing. Antimicrobial susceptibility was tested using disk diffusion. Clonal relatedness was assessed by PFGE and Multi-Locus Sequence Typing (MLST). ESBLs and carbapenemases genes were detected by PCR and sequencing. S1-PFGE, Southern blotting and PCR-based replicon typing (PBRT) were performed for plasmid characterization. For phylogenetic purposes, all isolates were whole-genome sequenced using the NovaSeq technology and genomic analyses were performed through appropriate bioinformatics tools.

Results: Among the 116 K. pneumoniae isolates analysed, 62 isolates (53.4%) carried the ESBL gene blaCTX-M-15. Most isolates harbouring blaCTX-M-15 belonged to the Sequence Type ST15 (n=17) or ST307 (n=11), while the remaining blaCTX-M-15-positive isolates showed a great diversity of STs. Three K. pneumoniae isolates belonging to ST15, ST48 and ST37 co-harboured the blaCTX-M-15 and blaOXA-48 genes. The AmpC β-lactamase gene blaDHA-1 was identified in 54 (46.5%) isolates, for which thirty-five belonged to ST11. Besides, nine ST11 isolates co-harboured the blaOXA-48 gene. Results from S1-PFGE showed that blaCTX-M-15 was mostly carried by IncFIIk plasmids, whereas blaOXA-48 was mainly harboured by IncR plasmids. The blaOXA-48 gene was systematically carried by IncL plasmids. Phylogenetic analysis using Illumina data is ongoing.

Conclusions: This study showed the predominance of two ESBL-producing K. pneumoniae lineages spreading in cats and dogs in France, i.e. ST15 blaCTX-M-15 and ST11 blaOXA-48. Notably, we also identified the emergence of the human-related ST307 blaCTX-M-15 K. pneumoniae lineage and the circulation of OXA-48-positive K. pneumoniae isolates.

Abstract 7110

Extending the NeuMoDx CTNG test to liquid-based cytology specimens: a performance evaluation

Lijie Gong*, Caly Lounds¹, Mark Olson¹, Elizabeth Craig¹, Catherine Couture¹, Michelle Mastronardi¹, Betty Wu¹, Sundu Brahmasandra¹

¹NeuMoDx Molecular, Ann Arbor, United States

Background: Detection of infection using a variety of specimen types in symptomatic and asymptomatic subjects is critical to effectively combat the spread of Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) infection. The NeuMoDx CTNG Test is currently CE/IVD certified for use with neat urine and endocervical/vaginal swab specimens. The goal of this study was to demonstrate performance of the NeuMoDx CTNG Test in liquid-based cytology specimens. Effective implementation of the NeuMoDx CTNG Test in such specimens would enable rapid & effective screening of women during their routine Pap exam. Results of performance verification of the NeuMoDx CTNG Test in ThinPrep® liquid-based cytology specimens are presented here.

Materials/methods: A risk-analysis was performed considering the differential characteristics of cytology specimens, and specific analytical & clinical studies deemed essential to demonstrating the performance of the NeuMoDx CTNG Test in Thin Prep specimens were executed including Limit of Detection (LoD), interference testing, specimen stability on-board the system, and pilot method comparison. Testing was performed using 550 µL specimen volume.

Results: The NeuMoDx CTNG Test demonstrated an LoD of 20 EB/mL for CT and 5 cells/mL for NG in Thin Prep medium with excellent inclusivity across the 15 CT serovars and 20 NG isolates. The sensitivity of each target (CT or NG) was maintained in the presence of high target concentration (~1E6 cells/mL or EB/mL) of the other target (NG or CT) demonstrating the robustness of the assay. Turnaround time was only 60 minutes and specimens were stable for at least 8 hours on board the System. No adverse effect on the detection of low target levels was observed in the presence of common interfering agents. The included Sample Process Control was an excellent monitor of sample processing efficacy and demonstrated its ability to also monitor for inhibition in these specimens. Finally, the pilot method comparison study performed using a combination of clinical and contrived specimens demonstrated excellent correlation to the results obtained using the reference FDA-cleared assays (with ThinPrep specimen indication) for CT/NG.

Conclusions: The NeuMoDx CTNG Test was demonstrated to be effective for detection of CT and NG directly from Thin Prep specimens.

Bezlotoxumab in real-life treatment of Clostridioides difficile infections in a tertiary centre in Spain

Maria Olmedo Samperio1,2, Martha Kestler Hernandez*1,2,3, Maricela Valerio Minero1,2, Marina Machado1,2, Ana Alvarez-Uria1,2, Belén Padilla1, Patricia Muñoz1,2,3, Emilio Bouza2,3

1Gregorio Marañón Hospital, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3Complutense University of Madrid, Madrid, Spain

Background: Recently the Spanish public health system has approved the use of Bezlotoxumab for CDI patients, who meet the following criteria: 1) Immunosuppressed patients (oncological, or transplanted), 2) patients with hypervirulent strains and 3) patients older than 65 years of age with one of the following: a) severe CDI episode (WBC count ≥15,000 cells/mm$^3$ or Cr ≥1.5 x baseline); b) previous episode in the last 6 months, or c) persistent diarrhea after 5 days despite adequate treatment. Our aim was to assess the use and effectiveness of the drug in real-life.

Materials/methods: Ongoing prospective study in a tertiary care center with a very active C. difficile program including a registry of cases and a bedside intervention in which all the cases are evaluated daily by an infectious disease specialist. Patients treated with Bezlotoxumab were compared to a cohort of 84 patients who survived a CDI, had risk of recurrence and were treated by our group before the drug was commercially available in our country. These control patients frequently received vancomycin tapering and sometimes with Fecal Microbiota Transplantation. Recurrence was defined as a second episode between 15-60 days after the initial episode.

Results: From January to October 2019, a total of 297 patients with CDI were evaluated and 20 (6.7%) met the Bezlotoxumab financing criteria of the public health system. Patients had a median age of 68.5 years and 18 (90%) were immunosuppressed {4 (20%) solid organ transplant recipients; 6 (30%) solid tumor and 3 (15%) cirrhosis}. As for CDI severity 2 (15%) were severe, 7 (35%) were severe-complicated and 10 (50%) were considered mild. Only one case (5%) was due to ribotype 027.

During the episode treated with Bezlotoxumab, 17 out of the 20 patients received vancomycin as concomitant treatment and 3 received fidaxomicin. Two patients treated with Bezlotoxumab died of non-related causes. When compared with the control cohort the recurrence rate was 3/18 (16.6%) vs 27/84 (32.1%), p=0.25

Conclusions: Preliminary experience with Bezlotoxumab in our institution was associated with a very good tolerance and a reduction in the incidence of recurrent episode of CDI.

A new approach for the quantification of clinical samples viral load based on virtual qPCR standard curves

Anna Gani1*, Nicola Paccagnella1, Diego Corradini1, Claudia Savio1, Alessio Polacchini2, Dino Paladin2, Riccardo Costacurta1

1AB ANALITICA, Padova, Italy

Background: Quantification of clinical samples viral load in qPCR traditionally requires the presence of a calibrated standard curve in every run. The innovative V-Quant System (AB ANALITICA) allows the viral load quantification using a specific virtual standard curve (VSC), included in the AB V-Quant Software. The VSC is calculated based on dataset of standard curves and it is pre-loaded on software database. In this way, the user do not need to run standard curve. This approach permits to reduce costs associated with including standard curves on every qPCR run, increasing the number of available tests, and to save time during the plate set up and results analysis.

Materials/methods: V-Quant CMV device consists of a qPCR kit and the correlated software for the interpretation and quantification of Cytomegalovirus (CMV). 319 Samples (218 CMV positive and 101 CMV negative), previously identified with a reference IVD method or belonging to QCMD panels, were tested. The samples have been quantified in parallel using a real quantification standard included in the qPCR runs and by using the AB V-Quant Software. Furthermore, diagnostic sensitivity and specificity, Limit of Detection (LoD) and precision of the device have been evaluated.

Results: The quantifications of CMV loads obtained with the real standards have been compared with the quantification obtained with the virtual one. The mean difference stands around 0.1 Log10 copies/mL, which is far from the commonly recognized limit value of 0.5 Log10 copies/mL. As for the performances, the device shows a diagnostic sensitivity and specificity around 99 %, a LoD of 5 viral genome copies/reaction and a precision percent coefficient of variation below 5%.

Conclusions: The V-Quant System demonstrate to be a reliable tool for the quantification of clinical samples viral load without including the traditional quantification standards in qPCR runs by saving the diagnostic costs. Similar assays for other clinically relevant pathogens are under development.

Global assessment of neonatal sepsis incidence and case fatality

Carolin Fleischmann-Struzek*¹, Felix Reichert²,³, Alessandro Cassini⁵, Thomas Harder¹, Niranjan Kissoon⁶,⁷, Konrad Reinhart¹,⁸,⁹, Benedetta Allegranzi⁵, Tim Eckmanns²

¹ Jena University Hospital, Center for Sepsis Control and Care, Jena, Germany, ² Robert Koch Institute, Department of Infectious Disease Epidemiology, Berlin, Germany, ³ Robert Koch Institute, Postgraduate Training for Applied Epidemiology (PAE), Berlin, Germany, ⁴ ECDC, European Programme for Intervention Epidemiology Training (EPIET), Stockholm, Sweden, ⁵ World Health Organization HQ, Infection Prevention and Control Hub, Integrated Health Services, Geneva, Switzerland, ⁶ University of British Columbia, Vancouver, Canada, ⁷ British Columbia Children’s Hospital, Vancouver, Canada, ⁸ Charité Universitätsmedizin, Department of Anesthesiology and Operative Intensive Care Medicine (CCM, CVK), Berlin, Germany, ⁹ Berlin Institute of Health, Berlin, Germany

Abstract third-party references: World Health Organization

Background: Neonates are at major risk for sepsis, which is the common final pathway of death from infection. Data on sepsis incidence in this age group is scarce. We assessed the global burden of neonatal sepsis by updating and expanding a systematic review and meta-analysis (Fleischmann-Struzek Lancet Respir Med 2016).

Materials/methods: We searched 13 electronic databases for studies on the population-level incidence of neonatal sepsis. We included studies that used a clinical sepsis definition, e.g. the 2005 consensus definition (Goldstein Pediatr Crit Care Med 2005), or relevant ICD-codes. The search of the original systematic review was updated for studies published between 05/2016-05/2019 and complemented by a search targeting studies from low- and middle-income-countries (LMIC) published between 01/1979 and 05/2019. We performed a random-effects meta-analysis on sepsis incidence and case fatality and estimated between-study heterogeneity based on the I² statistic.

Results: 4,729 abstracts were identified, of which 18 met the inclusion criteria. Adding these studies to the 8 studies of the original review, we meta-analyzed 26 studies. The majority of these studies originated from middle-income-countries, predominantly from the South-East-Asian Region. We estimated a pooled incidence of 2876.9 [95% CI, 1924.3; 4280.5] neonatal sepsis, 1903.2 [979.5; 3665.4] early-onset sepsis (EOS) and 1026.7 [271.5; 3802.7] late-onset sepsis (LOS) cases per 100,000 live births. We observed large between-study heterogeneity. The pooled estimate for community-based studies was more than twice as high as for hospital-based studies. Stratified by WHO regions, we found that the highest pooled incidence of neonatal sepsis in the African Region was two-fold higher than in the Pan-American Region, where the lowest incidence was observed [5243.6 [2504.6; 10,650.6] vs. 2461.2 [857.1; 6859.6]/100,000 live births]. An estimated 16.4% [9.8%; 26.1%], 9.1% [2.1%; 32.5%] and 17.7% [10.3%; 28.7%] of neonatal sepsis, EOS and LOS patients died, respectively.

Conclusions: Although neonatal sepsis is common and often fatal, its incidence in most countries remains unknown. Further epidemiological research is needed to address this gap, particularly using community-based designs, as estimates from hospital-based studies seem to miss sepsis cases occurring outside the hospital and therefore, are likely to underestimate the burden of neonatal sepsis.

Clinical outcomes in oncological patients with *Clostridioides difficile* infection in Catalonia: a cohort study

Esther Calbo Sebastian*, Gonçalo Carvalho Rodrigues2, Nieves Sopena3, Sergi Hernández2, Laia Castella1, Rafael Pérez-Vidal1, Jordi Cuquet2, Ana Conde1, Mariló Marimón1, Joan Espinach2, Marta Andrés-Santamaria1, Purificación Martos10, Enric Limón21

1Hospital Universitari Mútua Terrassa, Terrassa, Spain, 2VINCat Nosocomial Infection Surveillance in Catalonia, Catalonia Health Department, Barcelona, Spain, 3Hospital Germans Trias i Pujol, Badalona, Spain, 4Althaia Xarxa Assistencial Universitaria de Manresa, Manresa, Spain, 5Hospital General de Granollers, Granollers, Spain, 6Hospital de Moisés Broggi, Barcelona, Spain, 7Hospital Universitari General de Catalunya, Barcelona, Spain, 8Fundació Hospital Sant Joan de Déu de Martorell, Martorell, Spain, 9Hospital de Terrassa, Terrassa, Spain, 10Hospital Universitari de Bellvitge, Barcelona, Spain, 11University of Barcelona, Barcelona, Spain

**Background:** Oncological patients suffer high rates of *C. difficile* infection (CDI) due to the frequent presence of risk factors such as recurrent hospitalizations, immunosuppression, antibiotic use, chemotherapy and the use of enteral and parenteral nutrition. Data on specific risk factors and clinical outcomes of CDI in this group of patients are scarce. The aim of this study was to evaluate clinical outcomes (clinical cure, recurrence and mortality) in a cohort of oncologic patients with CDI in Catalonia.

**Materials/methods:** Prospective observational study in 28 hospitals participating in the VINCat program (Infection Control and Antimicrobial Stewardship Catalan Program), which represent 46% of all adult acute hospital beds. Cases were defined as oncological adult patients visited during 2018 in the participating hospitals who meet the case definition of CDI. Colonized and asymptomatic patients (even if they carried a toxin-producing strain), patients with previous CDI episodes or those admitted to specific convalescent and palliative care units were excluded. Comorbidities, CDI specific treatment and evolution at discharge and after 90 days were recorded for each case.

**Results:** During the study period 122 cases were included, 58.2% were male and the mean age was 71.6 years. After 90 days follow-up the evolution of cases was: 81 cases (66.4%) were cured; 17 cases (13.9%) had a recurrent CDI (rCDI), and 24 cases (19.7%) died. From the 122 cases, 2 (2.5%) developed megacolon and 3 (3.7%) required intensive care unit admission. The proportion of cure was higher when cases were treated with vancomycin vs metronidazole (78.1% vs 64.7%). From cases treated with metronidazole, those with active chemotherapy showed a statistical significant lower proportion of cure (47.6% vs 76.7%, p=0.033). No comorbidities present in cases were associated with a higher frequency of mortality or rCDI.

**Conclusions:** A fifth of the oncological patients presented an rCDI at 90 days. Metronidazole was clearly inferior to vancomycin in this population, especially in patients with active chemotherapy. Despite the lack of severity at the onset of the CDI, the mortality at the end of the follow-up was high, suggesting that the CDI has a great impact on the health status of oncological patients.

Detection of unexpected emerging extensively drug-resistant bacteria: experience of a French university hospital, 2012-2018

Nagham Khanafer*1,2, Xavier Jarrige*, Delphine Hilliquin1,2, Claire De Bastiani1,2, Olivier Dauwalder3, Elodie Munier-Marion1, Philippe Vanhems1,2

1Hopital Édouard Herriot, Lyon, France, 2Université Lyon 1, Lyon, France, 3Hopital La Croix-Rousse - HCL, Lyon, France

**Background:** One control measure to manage the spread of emerging extensively drug-resistant (eXDR) is based on early identification of carriers and spread evaluation from carriers by screening contact patients (CP). The incidence of colonization by eXDR has increased, and it is not unusual to detect in CP an eXDR different from those isolated in index patients. The objective of this study is to describe the frequency of detection of unexpected eXDR in a French university hospital.

**Materials/methods:** An eight-year prospective study was conducted in a French university hospital. Until November 2017, CP were those shared the same ward with the index patient for at least 24 h. Since December 2017, the definition was modified and patient was considered as contact if the index patient was not under additional precautions. Secondary case was defined by the discovery of the same bacterial species and resistance mechanism as the index case. Unexpected eXDR was considered if species or resistance mechanism were different from those in index case.

**Results:** Between 2012 and 2018, the number of eXDR carriers has increased 11-fold (table 1). The first case of unexpected discovery of eXDR occurred in 2015, followed by 4 cases in 2016, 4 in 2017 and 11 in 2018 (P<10<sup>-3</sup>).

**Conclusions:** The unexpected discovery of eXDR other than those being researched is a growing phenomenon. These data suggest a higher than expected dissemination of eXDR carrying and probably an underestimated prevalence in France. Further investigations are needed to confirm this epidemiological trend and to evaluate the efficacy of actual strategy to manage eXDR.

**In vitro activity of novel propionohydrazide derivatives BG-354 and KTU-341 against multidrug-resistant Candida auris**

Povilas Kavaliauskas*1,2, Birute Grybaite3, Kazimieras Anusevicius3, Vytautas Mickevicius1, Rita Plančiūnienė4, Ramune Grigaleviciute1, Thomas J. Walsh1, Ruta Petraitiene1,2, Vidmantas Petraitis1,2

1Weill Cornell Medicine of Cornell University, New York, United States, 2Institute of Infectious Diseases and Pathogenic Microbiology, Prienai, Lithuania, 3Kaunas University of Technology, Department of Organic Chemistry, Kaunas, Lithuania, 4Institute of Microbiology and Virology, Lithuanian University of Health Sciences, Kaunas, Lithuania, 5Lithuanian University of Health Sciences, Biological Research Center, Kaunas, Lithuania

**Background:** Candida auris (C. auris) is an emerging multidrug-resistant fungal pathogen responsible for increasing morbidity and mortality worldwide. Increasing numbers of outbreaks caused by C. auris, limited treatment options, and emergence of resistance require urgent development of new therapeutics. We therefore aimed to investigate in vitro antifungal activity of novel propanohydrazide derivatives BG-354 and KTU-341 against clinical isolates of C. auris.

**Materials/methods:** Antifungal activity of BG-354 and KTU-341 was evaluated against a panel of C. auris (n=15) and C. albicans (n=5) isolates using broth microdilution methods as described by CLSI. Activity against C. auris biofilm integrity and viability was also evaluated using a crystal violet assay and measured by spectrophotometry.

**Results:** BG-354 and KTU-341 demonstrated antifungal activity against multi-drug resistant C. auris (n = 15) and pan-susceptible C. albicans (n = 5) isolates with EC_{50} of 5.38 µM and 5.89 µM, respectively. BG-354 and KTU-341 demonstrated selective antifungal activity against C. auris as measured by MIC (10.7 µM and 11.7 µM respectively) but showed no significant effect against C. albicans. Both BG-354 and KTU-341 demonstrated fungicidal activity with MFC of 10.7-21.4 µM for BG-354 and 23.4 µM for KTU-341. After 24 hour of incubation, BG-354 significantly reduced C. auris biofilm integrity in comparison to growth controls (OD_{570nm. 1.032 vs. 0.448, p<0.05}). More studies are needed better understand antimicrobial activity, safety, synergistic relationship, and therapeutic potency of propionohydrazide derivatives.

**Conclusions:** Novel propionohydrazide derivatives BG-354 and KTU-341 demonstrated favorable activity against multidrug-resistant C. auris making this class as selective and pathogen-directed antifungals.

An epidemiological overview of intestinal parasitoses in a non-endemic setting: a comparison between Italians and immigrants from developing countries during the years 2011-2018

Adriana Calderaro*, Sara Montecchini*, Mirko Buttrini*, Sabina Rossi1, Federica Motta1, Giovanna Piccolo1, Marco Maria Antonaci1, Maria Loreana Dell’anna1, Maria Cristina Arcangeletti1, Carlo Chezzi1, Flora De Conto1

1University of Parma, Department of medicine and surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Virology, Parma, Italy, 3University Hospital of Parma, Unit of Clinical Microbiology, Parma, Italy

Background: Intestinal parasites are now being diagnosed with increasing frequency in industrialized countries probably as a consequence of the globalization of the food supply, of the immigration/adoption from endemic regions, and of travels through the same areas.

This study reports the investigation of imported intestinal parasitoses in Parma, Italy, a non-endemic setting, during 2011-2018 with a comparison between those revealed in Italians and in immigrants from developing countries.

Materials/methods: In our laboratory, from 2011 to 2018, conventional diagnosis of intestinal parasitosis (microscopic examination of fresh/concentrated faeces and cultivation in Robinson’s medium) was performed on 20,978 faecal samples belonging to 13,596 patients, all presenting with the clinical suspicion of intestinal parasitosis; the foreigner patients included in the study were from developing countries, mainly from Sub-Saharan Africa. Real-time PCR assays for the differentiation of Entamoeba histolytica and E. dispar and for the detection of Dientamoeba fragilis were also used when clinical manifestation and/or risk factors for parasitic infections were reported, and/or when diagnostic stages of intestinal parasites were detected by microscopy.

Results: Intestinal parasitosis was diagnosed in 2671 patients (19.6%), about half of whom were immigrants from developing countries. For 15% of Italians and 36.2% of Foreigners at least one intestinal parasite was detected. The most common intestinal protozoa detected were Blastocystis hominis, D. fragilis and Giardia intestinalis, while the most prevalent helminths were Strongyloides stercoralis, Enterobius vermicularis, and Taenia saginata. A total of 204 (71%) helminthic infection was revealed in Foreigners. For 2.6% of Italians and 13% of Foreigners a mixed infection was found. The total of 663 mixed infections (co-infection by protozoa, helminths and/or by protozoa and helminths) detected, 380 were revealed in Foreigners.

Conclusions: The data presented confirm the importance of suspecting parasitic infections together with the use of appropriate diagnostic tools even in non-endemic areas, where, besides autochthonous intestinal parasites, imported ones are frequently diagnosed. The probability to reveal the presence of such agents increase also as a result of the high number of “forced migrants” coming during recent years from their origin countries afflicted by inadequate sanitation and poor hygiene conditions.

Modulating the microbiota of the hospital environment by microbial cleaning: impact on infections and antimicrobial resistance

Maria D’accolti1, Irene Soffritti1, Luca Lanzoni2, Matteo Bisi2, Antonella Volta2, Sante Mazzacane2, Elisabetta Caselli*1

1University of Ferrara, Department of Chemical and Pharmaceutical Sciences, Ferrara, Italy, 2University of Ferrara, CIAS, Ferrara, Italy

Background: Healthcare–associated infections (HAIs) are a global concern, whose major causes include the persistent microbial contamination of the hospital environment, and the growing antimicrobial-resistance (AMR) of HAI-associated microbes. The control of contamination has been so far addressed by the use of chemical-based sanitation, which however does not prevent recontamination, have a high environmental impact and can select resistant microbes. Inspired by the studies on the human microbiome and by the recent acquisitions on the built-environment microbiomes, we set-up a microbial-based sanitation (MBS), testing the possibility to modulate the hospital microbiome by a biological approach based on competitive exclusion. Specific elimination of peculiar pathogens by bacteriophage application was also tested.

Materials/methods: MBS was tested in 10 healthcare settings, for 1-6 months, by substituting conventional chemical-based cleaning procedures with the microbial system. In the study including 6 Italian public hospitals and 5 Italian Universities the hospital bioburden and healthcare-associated infection (HAI) incidence were simultaneously analyzed for 18 months. Environmental contamination was examined by microbiological and molecular methods, including characterization of the resistome of the contaminating population. In parallel, rate of HAI onset and therapy costs were evaluated. The impact of bacteriophage addition on specific contaminants was also evaluated.

Results: Over 40,000 environmental samples were analyzed and about 12,000 patients surveyed. The MBS system was shown to induce a stable remodulation of hospital microbiota, obtaining a stable control of both bioburden (-80% pathogen load on treated surfaces compared to conventional disinfectants) and AMR (up to -99% of resistance genes in the residual contaminants). Microbiome modulation was associated with a significant reduction of HAIs (-52%) and of associated therapy costs (-75%). Bacteriophage treatment in addition to probiotic sanitation determined a further reduction (>90%) of targeted bacteria in less than 24 hours.

Conclusions: Collected data highlight the possibility to modulate hospital microbiota and suggest that microbiota remodulation can be associated with a consistent reduction of associated HAIs. The results thus suggest that such systems, based on the microbiome balance principles, might be considered as one of the tools for AMR and infection prevention and control.

Abstract 7133

**Diagnostic performance of two novel semi-quantitative cryptococcal antigen assays**

Caleb Skipper*, Kiiza Tadeo*, Emily Martyn†, David Meya†, Bosco Kafufu†, Josh Rhein†, David R. Boulware†

†University of Minnesota, Minneapolis, United States, †Infectious Diseases Institute, Kampala, Uganda

**Introduction:** Early cryptococcal disease can be detected via circulating antigen in blood before fulminant meningitis signs develop—where early antifungal therapy improves survival. Serum cryptococcal antigen (CrAg) titer predicts meningitis probability and outcome with fluconazole preemptive therapy. Two new semi-quantitative CrAg lateral flow assays have been developed but with undefined diagnostic performance.

**Materials/Methods:** Cryopreserved serum samples from 100 HIV+ Ugandans obtained as part of a prospective CrAg-screening cohort were tested in duplicate for cryptococcal antigen by the CrAg-SQ (IMMY) and CryptoPS (Biosynex) lateral flow assays. The tests were retrospectively run and read by two independent, trained readers. Inter-reader discrepancy was adjudicated by a third reader, as a tiebreaker. Diagnostic performance was measured using the FDA-approved CrAg LFA (IMMY) as a reference standard via McNemar’s test.

**Results:** Of 100 samples, 57 were CrAg+ by the CrAg LFA reference standard. By CrAg-SQ, 57 were positive, with 98% sensitivity (56/57) with 98% specificity (42/43) (P=.99). The CrAg-SQ false negative had a titer <1:5; while the false positive yielded a 1+ result. By CryptoPS, 53 were positive, with 88% sensitivity (50/57) and 93% (40/43) specificity (P=.34). The CryptoPS false negatives included samples with titers <1:5 (n=6) and 1:30 (n=1). The median CrAg titer values for the CrAg-SQ LFA at 2+ was 1:40 and at 3+ was 1:320. The median CrAg titer values for the CryptoPS at positive was 1:40 and at strong positive was 1:320. In assessing inter-reader variability, 14 incidents of reader discrepancy occurred for the CrAg-SQ (for grade of positivity) versus 10 incidents for CryptoPS. Qualitative reads were 97% concordant for CrAg-SQ and 96% concordant for CryptoPS.

**Conclusions:** The new semi-quantitative CrAg LFAs allow for a rapid estimation of titer level in easy-to-perform platforms, providing the potential to stratify clinical risk, and therefore determine clinical management. The CrAg-SQ demonstrated better qualitative sensitivity and specificity over CryptoPS in comparison to the reference standard. Both tests could delineate a low titer versus a higher titer [considering a 1:160 breakpoint]. The exact grade of CrAg-SQ does have some subjectivity with inter-reader variability; however, qualitative reads were generally concordant for both assays.

**Risk factors for prosthetic joint infections caused by Gram-negative bacteria: experience at an infectious disease referral centre**

Sara Tedeschi*, Livia Pancaldi, Nicolò Rossi, Eleonora Zamparini, Maria Pia Neri, Massimiliano De Paolis, Alberto Corrado Di Martino, Pierluigi Viale

1Policlinico Sant’Orsola-Malpighi - Alma Mater Studiorum University of Bologna, Infectious Diseases unit, Bologna, Italy, 2Rizzoli Orthopedic Institute, Bologna, Italy

**Background:** In recent years, a significant increase of prosthetic joint infections caused by Gram-negative bacteria (GNB-P JIs) has been described. Currently, in the absence of a pre-operative aetiological diagnosis, a broad-spectrum antimicrobial therapy is used for patients undergoing surgical treatment of P JIs, pending the results of intra-operative cultures. This strategy may lead to a widespread use of GNB-coverage, increasing resistance selections and costs.

The aim of our study is to identify the risk factors for GNB-P JIs, in order to select patients who would really benefit from an empirical GNB-coverage.

**Materials/methods:** Observational, single-centre, retrospective study (June 2010-December 2018) on patients at their first episode of hip or knee PJI, managed at a referral centre for P JIs in Italy.

**Results:** We enrolled 322 consecutive patients, 33 (10.2%) having a GNB-PJI. We found a trend toward increased incidence of GNB-PJI over time, that did not reach statistical significance (8.7% in 2011, 11% in 2012, 9% in 2013; 5% in 2014; 15% in 2015; 17% in 2016; 18% in 2017, 15% in 2018, p=0.48). A pre-operative synovial fluid culture was obtained in 110 patients (34%), and it was positive in 71 (64.5%); after surgery, 224 patients (69.5%) received a broad-spectrum antibiotic therapy with GNB-coverage.

At multivariate logistic regression analysis, an early infection [aOR 2.73, 95%CI 1.10-6.82, p=0.03] and the presence of a sinus tract both in early and delayed infections [aOR 2.46, 95%CI 1.14-5.33, p=0.03] were independently associated with GNB-P JIs.

**Conclusions:** To identify risk factors for GNB-PJI may reduce the use of empirical GNB-coverage when treating P JIs without a pre-operative aetiological diagnosis. GNB-PJIs are still uncommon, so large multicentre studies are urgently needed to address this issue.

Development of a ery-C recombinant protein-based ELISA approach for differentiating brucellosis infected cattle from vaccinated ones

Waleed Abdelwahab*1,2, Marwa Salah El-Din Diab3,4, Ayman Amin Samy5, Jakeen Abd Elhalim Eljaky6

1Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Central Laboratory for Evaluation of Veterinary Biologics. Abbasaia (CLEVB), Cairo, Egypt, 2Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Abassia, Egypt, 3Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Abassia, Egypt, 4Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Ministry for Agriculture and Land Reclamation — Agriculture Research Center (ARC), Cairo, Egypt, 5National Research Center (NRC), Microbiology Department, Dokki, Giza, Arab Republic of Egypt (ARE), National Research Center (NRC), Microbiology Department, Giza, Egypt, 6Faculty of Veterinary Medicine, Cairo University Cairo, Arab Republic of Egypt (ARE), Department of Microbiology, Giza, Egypt

Introduction: Serological tests used for diagnosis of bovine brucellosis are usually depending on smooth lipopolysaccharides (S-LPS) as a diagnostic antigen for most of serological tests (mainly ELISA) which usually gives false positive reactions with sera of S19 vaccinated cattle. The eryC gene is absent in Brucella abortus S19 only but it is present and functional in all other Brucella strains. Aim: according to previous facts, this study aimed to develop and evaluate a diagnostic kit for accurate diagnosis of bovine brucellosis able to differentiate between vaccinated and infected cattle and exclusion of false positive cases. The present study evaluated antibody responses of brucellosis infected and S19 vaccinated cattle to purified recombinant EryC protein in an indirect enzyme-linked immunosorbent assay (I-ELISA) as an alternative diagnostic antigen.

Materials/methods: In this study, 114 samples of naturally infected, 78 sera from S19 vaccinated cattle and 25 sera samples from Brucella free cattle were used after screening with Rose Bengal test. Sera samples were tested with I-ELISA using S-LPS and periplasmic proteins as a coating antigen [a gold standard test] also with I-ELISA using ery-C protein as a coating antigen.

Results: The results revealed that in case of sera of naturally infected cattle, sero-positivity was 94.7%, 100%, 100% and 100% with EryC-ELISA, LPS-ELISA, periplasmic-ELISA and Rose Bengal test, respectively. Where in case of sera of S19 vaccinated cattle, all samples were negative when tested with EryC-ELISA while in case of LPS-ELISA, periplasmic-ELISA and rose Bengal test, the sero-positivity was 92.3%, 84.6% and 100%, respectively. Sera samples from Brucella free cattle react negatively with all types of coating antigens.

Conclusions: It could concluded that the EryC protein could be used in serological tests for diagnosis of bovine brucellosis and differentiation between infected and Brucella abortus S19-vaccinated cattle but further studies are demanded to be performed on large scale accompanied with bacteriological isolation to detect the sensitivity and specificity of this protein as a diagnostic antigen and also for validation.

Dipreca, Santiago, Chile, 15Clínica Santa María, Santiago, Chile

Abstract 7138

Background: Ceftaroline (CPT) is a cephalosporin active against MRSA. Previous data suggest that the E-test® underestimates MIC values and that disk diffusion (both CLSI 30µg and EUCAST 5µg) performs poorly compared to broth microdilution (BMD), with categorical concordances (CC) of 51%, 55%, and 36%, respectively. This data make the evaluation of other methods necessary. The aim of the study was to compare CPT susceptibility testing determined by two automated systems, Phoenix-100™ (Becton Dickinson) and Vitek®2 XL (bioMérieux), with results from BMD in clinical isolates of MRSA.

Materials/methods: In vitro activity of CPT was evaluated in 320 clinical MRSA isolates collected between 1999-2018, in nine hospitals in Santiago, Chile. Identification was confirmed by MALDI-TOF MS. BMD was performed following CLSI-2019 guidance. Susceptibility for Phoenix-100™ and Vitek®2 was performed according to the manufacturer’s instructions, using the PMIC/ID 89 panel and AST-GP78 cards, respectively. CC, categorical agreement (CA), essential agreement (EA), minor errors (ME), and major errors (VME) were evaluated. Susceptibilities were analyzed using CLSI-2019 breakpoints.

Results: The MIC50/MIC90 by BMD was 2 μg/mL. No CPT-resistant (i.e. MIC >8µg/mL) strains were found, but 206/320 (64%) strains were categorized as susceptible dose-dependent (SDD) with an MIC between 2-4µg/mL (previously reported). For Phoenix-100™, the MIC50/MIC90 was 2µg/mL; 69/320 (22%) strains were classified as CPT-susceptible (MIC <2µg/mL), 218/320 (68%) as SDD (MIC = 2µg/mL) and 33/320 (10%) could not be cataloged, since the highest concentration of CPT included in PMIC/ID 89 panel is ≥4µg/mL. For Vitek®2, the MIC50/MIC90 were 0.5/2 µg/mL respectively, 192/320 (60%) strains were classified as CPT-susceptible and 128/320 (40%) as SDD. The CA, EA and mE between Phoenix-100™ and BMD were 81-98-19%, respectively. The CA, EA and mE between Vitek®2 and BMD were 64-98-30%, respectively. No ME and VME could be detected.

Conclusions: The Phoenix-100™ system showed good performance; however, the percentage of mE was unacceptable. Modifications of CLSI 2019 cut-off values did not allow the classification of 10% of the strains. Vitek®2 severely underestimated CPT MICs and its routine use in clinical MRSA isolates needs further evaluation.

Abstract 7139

A comparative phenotypic study of aggregate versus non-aggregate Candida auris isolates

Patrice Lepape*, José Y. Rodríguez2, Estelle Robert3, Isabelle Ourliac Garnier2, Marjorie Albassier1, Pierre Bonnet2, Andres Ceballos4, Claudia Marcela Parra Giraldo4, Carlos Arturo Alvarez5

1University of Nantes, EA1155 IICiMed Department of Parasitology and Medical Mycology, Nantes, France; 2Centro de Investigaciones Microbiológicas del Cesar, Valledupar, Colombia; 3University of Nantes, EA1155 IICiMed Department of Parasitology and Medical Mycology, Nantes, France; 4Pontificia Universidad Javeriana, Bogota, Colombia; 5Universidad Nacional de Colombia, Bogota, Colombia

Background: Candida auris, first reported in Japan in 2009, has recently emerged on five continents and it is considered a serious global health threat. Due to a particular persistence on a large range of surface types, this Candida species has been associated with outbreaks in healthcare settings.

Materials/methods: Candida auris isolates collected during an outbreak in Colombia were identified by MALDI-TOF analysis and ribosomal DNA (rDNA) gene sequencing targeting ITS1 regions. Aggregative and non-aggregative C. auris isolates were selected for a comparative phenotypic study including sterol composition, cell wall characterization, stress resistance, biofilm-forming capacity on catheter pieces and pathogenicity in a Galleria mellonella insect model.

Results: C. auris isolates with aggregating phenotype have a greater biofilm-forming capacity. This capacity is even higher if the medium contained glucose as in EUCAST method. In the latter medium, the biofilm formed by this phenotype is superior to that formed by C. albicans. Aggregating strains are more sensitive to heat stress while they are more resistant to osmotic shock. In contrast, there is no difference in sterol composition. Finally, in the in vivo Galleria mellonella model, aggregating phenotype isolates have a lower virulence than those of non-aggregating phenotype (Figure 1).

Figure 1: The virulence of Candida auris strains in Galleria mellonella larvae at 37°C. Non-aggregate (red) and aggregate (green) strains.

Conclusions: Our data suggest that using the Galleria mellonella infection model, non-aggregating C. auris strains exhibit higher pathogenicity which could be related to resistance to heat stress.

Abstract 7141

Real-world treatment patterns observed in patients with carbapenem-resistant Gram-negative infections in Italian hospitals

Emanuele Durante Mangoni1, Claudio M. Mastroianni2, Pierluigi Viale3, Matteo Bassetti4, Rita Citton5, Raquel Fenoll6, Montse Roset7, Eilish Mccann*7

1University of Campania ‘L. Vanvitelli’, Monaldi Hospital, Naples, Italy, 2Policlinico Umberto I, Roma, Italy, 3AOU Policlinico S. Orsola-Malpighi, Bologna, Italy, 4University of Genova and Ospedale Policlinico San Martino, Genova, Italy, 5Merck Sharp & Dohme, Rome, Italy, 6IQVIA Real World Solutions, Barcelona, Spain, 7Merck & Co., Inc., Kenilworth, NJ, United States

Background: Antibiotic resistance is highly prevalent in Italy. The increase in resistance has made the treatment of bacterial infections very challenging. The study aimed to describe the current clinical management of complicated urinary tract infections (cUTI), complicated intra-abdominal infections (cIAI), and hospital-acquired/ventilator-associated bacterial pneumonia (HABP/VABP), specifically infections attributable to carbapenem-resistant (CR) Gram-negative (GN) bacteria

Materials/methods: Four Italian hospitals participated in a retrospective chart review in which hospitalized adults with cUTI, cIAI, or HABP/VABP caused by CR GN pathogens between February 2015 and July 2017 were consecutively enrolled; their records were evaluated for baseline characteristic, medical history, and details of antibiotic treatment.

Results: 100 patients were included (the majority were male [64%], mean age: 64.1 years). In the 12 months prior to index admission, 57% had prior hospital admissions, 45% had prior invasive procedures, and 32% were treated with antibiotics, most commonly penicillins [n=24, 63.2%]. HABP/VABP was the most common infection type [56%], followed by cUTI [34%] and cIAI [10%]; the majority of index infections were hospital-acquired [78%]. Klebsiella pneumoniae was the most commonly isolated pathogen [66%]. Acinetobacter baumannii and Pseudomonas aeruginosa were detected in 23% and 12% of patients, respectively. 34 isolates [all K. pneumoniae] were tested for carbapenemases and all were found to be Klebsiella pneumoniae carbapenemase (KPC)-producers. Prescribing choices were evaluated immediately after culture collection [most common: carbapenems [19%], colistin [14%], and penicillins [14%]), immediately prior to susceptibility test results [carbapenems [44%], colistin [25%], and penicillins [17%]), and after test results were available [carbapenems [68%], colistin [61%], macrolides (16%), and aminoglycosides [16%]]. Carbapenems were typically given as part of combination therapy. Antibiotic treatment patterns for 67 patients who received carbapenems are presented in Figure 1.

Figure 1. Sankey diagram of treatment patterns for patients treated with carbapenems.

Conclusions: Carbapenem use was detected at every stage of the treatment period (pre- and post-susceptibility test results confirming carbapenem resistance), indicating the importance of this antibiotic class for the management of serious GN infections. The detection of KPC production in every tested isolate demonstrates that activity against this resistance mechanism should be considered when making treatment selections in Italy.

Background: A rapid, sensitive and specific method is essential for the diagnosis of histoplasmosis in laboratories with limited resources and also in regions that lack experience in the management of these patients. The diagnostic accuracy of different techniques using serum as a non-invasive sample has been evaluated. Techniques based on the detection of antibodies, antigens and DNA have been tested.

Materials/methods: Sera samples from patients with proven and probable histoplasmosis were analyzed (40). Four techniques were used. Histoplasma GM EIA test kit (IMMY, Palex), not used to date in serum, Platelia™ Aspergillus Ag (Bio-Rad), “ID Fungal Antibody System” kit (IMMY, Palex) and a Real time PCR method (RT-PCR) previously described (Gago et al., 2014). For Histoplasma GM EIA test kit, sera samples were pretreated and a cutoff of ≥0.2 ng/ml was used to determine positivity, according to the manufacturer´s recommendations.

Results: Analysis of the results was performed taking into account the clinical picture and the immune status of patients. Sensitivity of GM EIA test kit in patients with Aids and a disseminated disease was 94% and in immunocompetent patients was 66%. Detection of antibodies by ID antibody System was positive in 84% of immunocompetent patients and 68% HIV+ patients. Platelia™ Aspergillus Ag had a low performance in both groups (38% S in HIV+ and 21% S in HIV-) and finally RT-PCR obtained moderate results being more useful for immunosuppressed patients (47% S in HIV+ vs 26% S in HIV-).

Conclusions: i) Sera samples could be used to a rapid diagnosis of histoplasmosis but their performance depends on the clinical picture of the patient and the technique used. ii) GM EAI test kit seems to be a suitable option in disseminated disease. More validation studies are required. iii) The ID technique is useful to detect H. capsulatum antibodies in immunocompetent patients. iv) RT-PCR showed a moderate performance, being better option for the detection of histoplasmosis disseminated in HIV+ than in immunocompetent travelers. v) Further studies are warranted including control patients and patients with other invasive fungal infections to evaluate the specificity of these techniques and their usefulness.

Abstract 7143

Molecular detection of mutations involved in *Helicobacter pylori* antimicrobial resistance in Ecuador

Jeannete Zurita*123, Gabriela Sevillano1, Vicente Penaherrera1, Manuel Echeverria3, Camilo Zurita2, Ariane Paz Y Mino2, Hugo Navarrete1, Helicobacter Pylori Working Group3

1Pontificia Universidad Católica del Ecuador, Quito, Ecuador, 2Unidad de Investigaciones en Biomedicina. Zurita&Zurita Laboratorios, Quito, Ecuador, 3Hospital Vozandes, Quito, Ecuador

Background: *Helicobacter pylori* (HP) infection is one of the most common chronic bacterial infections. Eradication of HP infection has been proven to reduce the incidence of gastric cancer. The efficacy of the HP eradication treatment has decreased dramatically because of antibiotic resistance. The most recent international consensus reports recommend the selection of treatment based on local resistance patterns, however, HP testing is rarely performed. In this study, we analyzed the prevalence of HP and main mutations involved in resistance.

Materials/methods: A total of 330 gastric biopsies of older than 18 years’ Ecuadorian patients were analyzed. PCR and sequencing were performed to amplify the regions *rdxA* (metronidazole [MTZ] resistance), *23S* ribosomal RNA (rRNA) [clarithromycin (CLA) resistance], *gyrA* (levofloxacin [LVX] resistance), *pbp1A* (amoxicillin [AMX] resistance) and *16S* rRNA regions (detection of infection) of HP. The mutations were determined using the MEGA 7. HP 26695 [access number CP003904.1] was reference strain. The biopsies were collected between March and September 2019.

Results: The prevalence of HP was 67.87% (224/330). The antimicrobial resistance rates associated with mutations are shown in Figure 1. The main mutations for CLA were A2142G and A2143G in the *23S* rRNA gene. For LVX were N87I, N87K, D91N, D91G, D91Y in the *gyrA* gene. For MTZ were D50E, S88P, H97T, M56V, M56I, R16H, A118T, R90K, G98S, L62V in the *rdxA* gene and for AMX were N562Y, T593A, G595S, V374L, N504D in *pbp1A* gene.

Conclusions: HP is present in a high percentage (67.82%). The high resistance of HP to metronidazole, clarithromycin and levofloxacin found in this study requires systematic monitoring to optimize the selection of treatment regimens. Clarithromycin-containing regimens are no longer suitable for unconditional empiric use because of resistance rates (43%). A limitation of this study was that sensitivity tests were not performed in parallel, only searching for mutations in genes and as in the case of AMX, MTZ, there are still no specific mutations that correlate the genotype with the phenotype, as in the case of LVZ, CLA.

Figure 1. Antimicrobial resistance rates in HP associated with mutations for metronidazole (MTZ), clarithromycin (CLA), levofloxacin (LVX) and amoxicillin (AMX).

Abstract 7144

Blue-Carba complete

Aline Valerio Lima¹, Darlan Augusto Da Costa Rocha¹, Keila De Oliveira Lima¹, Suely Sampaio¹, Jorge Luiz Mello-Sampaio*¹

¹Universidade de São Paulo, São Paulo, Brazil

Abstract third-party references: Fleury Medicine and Health, Universidade de São Paulo - School of Pharmacy

Background: The Blue-Carba test is a rapid, low cost test for carbapenemase detection but does not allow the differentiation between metallo-β-lactamases (MBL) and serine carbapenemases. With the introduction of ceftazidime-avibactam (CAZ-AVI) in clinical use it is critical to rapidly detect and differentiate these two carbapenemase groups.

Materials/methods: Blue-Carba complete (BCC) consisted of four microplate wells: 1 - 0.4 mg/ml bromothymol blue in water pH 6.8; 2 - 6mg of imipenem/cilastatin in bromothymol blue solution [BTB]; 3 - 6mg/ml of imipenem/cilastatin plus 0.55mg/ml of DPA in BTB; 4 – 6mg of imipenem/cilastatin plus 5mg/ml of CAZ-AVI, both commercial products for injection in BTB. A total of 163 strains, mostly Enterobacterales, previously characterized by PCR and spectrophotometric imipenem hydrolysis [54 NDM-1; 7 SMP-1; 41 KPC-2; 10 KPC-2+NDM-1; GES-20, IMP-1, VIM-1, BKC-1, one of each; 8 OXA-carbapenemases; 39 non-carbapenemase producers] were cultured on CPS-Elite, Mueller-Hinton and Sheep blood agar. BCC tests were incubated in ambient air at 36°C. Readings were performed after 15, 30, 60 and 120 min. Positive and negative concordance values were calculated using spectrophotometry and PCR as the gold standards.

Results: Concerning NDM-1 producers, 44/54, 52/54 and 54/54 were identified as metallo-β-lactamase producers [no color change in the wells containing imipenem plus DPA] after 30, 60 and 120 min, respectively. There was 100% positive concordance with PCR. For KPC-2 producers, 41/41 strains were identified as serine-carbapenemase producers [no color change in the wells containing imipenem plus CAZ-AVI] after 30 min of incubation. There was 100% positive concordance with PCR for blaKPC. None of OXA-type carbapenemases producers were positive in the well containing imipenem only. Most (6/10) of the strains co-producing KPC-2 and NDM-1 were identified [color change to yellow in the wells containing imipenem plus CAZ-AVI and in the wells containing imipenem plus DPA] after 30 min and all were identified after 60 min; consequently there was 100% positive concordance for KPC-2 plus NDM-1 co-producers. All strains negatives for carbapenemases showed a negative result in BCC test, resulting in 100% negative concordance.

Conclusions: The Blue-Carba complete can differentiate serine-carbapenemase producers from metallo-β-lactamase producers and identify co-production of these carbapenemases.

Abstract 7145

**Invasive pneumococcal disease in children: the risk of a moving target**

Mary Corcoran*, Jolita Mereckiene, Stephen Murchan, Suzanne Cotter, Robert Cunney, Hilary Humphreys

1CHI at Temple Street, Irish Meningitis and Sepsis Reference Laboratory, Dublin, Ireland, 2Health Protection Surveillance Centre, Dublin, Ireland, 3Beaumont Hospital, Royal College of Surgeons of Ireland, Dublin, Ireland

**Background:** Invasive pneumococcal disease (IPD) causes life-threatening illnesses including meningitis and bloodstream infections. The highest disease incidence is associated with young children and older adults. Seven and 13-valent pneumococcal conjugate vaccines (PCV7/PCV13) were introduced into the Irish paediatric schedule in 2008 and 2010 to target the predominant serotypes. The aims of this work were to evaluate the effectiveness of PCVs in reducing paediatric IPD, examine potential vaccine-failures and identify emerging replacement-serotypes in the post-PCV era.

**Materials/methods:** Cultures submitted from children <16 years of age from July 2007 to June 2018 were assessed by serotyping and antimicrobial susceptibility testing. Whole genome sequencing was performed on strains of interest.

**Results:** The number of paediatric IPD cases decreased by over 50% since the introduction of PCVs. The most substantial reductions were in the numbers of PCV7/PCV13 serotypes in children aged <2 years, a 97% decline (incidence rate ratio [IRR]:0.03, 95% confidence interval [CI]:0.00-0.21, p=0.0005), and a 78% decline (IRR:0.22, 95%CI:0.05-1.04, p=0.0558), respectively. There was an increase in non-PCV13 serotypes during the same period (IRR:2.82, 95%CI:1.02-7.84, p=0.0463), with similar trends observed for older children. The predominant serotypes included 23B,15B/C,22F,33F,12F,24F,38,10A,15A,9N,11A and 35B, with variability within each age group and year. There were no clear vaccine replacement serotypes; instead a number of different serotypes emerged and were non-susceptible to antimicrobials.

Of sixteen vaccine failures/breakthrough identified, ten cases received all three doses of PCV, while six were mixed schedule or incomplete due to age. Most failures/breakthroughs (n=10, 63%) were serotype 19A and resistant to antimicrobials. Serotype 19A isolates were associated with a virulent clonal complex, CC320, but displayed considerable genetic divergence in comparison to strains reported elsewhere.

**Conclusions:** Reducing the incidence of IPD is more challenging as the number of non-PCV13 serotypes has expanded and are now less susceptible to antimicrobials. Consequently, higher valency or broader target vaccines are required to further prevent IPD.

Abstract 7146

The burden of nosocomial pneumonia caused by Pseudomonas aeruginosa and Staphylococcus aureus for ventilated patients in European intensive care units: a weighted multi-state analysis

Maja Von Cube*1,2, Tobias Bluhmki3, Klaus Kaier1, Frangiscos Sifakis4, Omar Ali5, Jafri S Hasan5, Fleur Paling6, Jan A. J. W. Kluytmans6, Surbhi Malhotra-Kumar7, Jan Beyersmann3, Martin Wolkewitz1

1Faculty of Medicine and Medical Center - University of Freiburg, Institute of Medical Biometry and Statistics, Freiburg, Germany, 2University of Freiburg, Freiburg Center for Data Analysis and Modeling, Freiburg, Germany, 3University of Ulm, Ulm, Germany, 4Boehringer Ingelheim Pharmaceuticals, Ridgefield, United States, 5AstraZeneca, Microbial Sciences, BioPharmaceuicals R&D, Gaithersburg, United States, 6University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 7University of Antwerp, Antwerp, Netherlands

Abstract third-party references: On behalf of COMBACTE-MAGNET Consortium

Background: Nosocomial pneumonia (NP) remains a major complication for ventilated patients in European intensive care units (ICUs). Among the most common causative agents are Pseudomonas aeruginosa (PA) and Staphylococcus aureus (SA).

Materials/methods: The prospective, observational, multi-center cohort study ASPIRE-ICU provides detailed information on the consequences of NP for eleven European countries. Patients in the sample (n=1929) are matched according to SA colonization status at ICU admission (50% SA-colonized). This study sample is embedded within a large surveillance population (n=9841) of which baseline characteristics are available. Additional detailed clinical and pathogen-specific variables as well as follow-up information beyond hospital discharge up to 90 days is collected for the matched sample.

Using up-to-date statistical methods, we investigate the burden of PA NP and SA NP. Multistate methodology is used to account for the time-dynamics of subsequently occurring events. Moreover, weights based on the information available from the surveillance population are calculated in order to make the matched sample representative of the surveillance population. The weighted sample is used to analyze 90-day mortality as well as extra length of ICU and hospital stay. The weighted multistate model analysis allows us to draw conclusions from the matched sample for the complete surveillance population.

Results: PA NP (n=46) was associated with increased length of stay in the ICU (8 extra days, 95%-CI: [3;24]) and 90-day mortality (adjusted weighted hazard ratio=1.88, 95%-CI: [1.05;3.36]). Subsequent hospital stay after ICU discharge was not found to be affected by PA NP (4 extra days, 95%-CI: [-1;9]). In contrast, no association between SA NP (n=131) and ICU-length-of-stay was detected (0 extra days, 95%-CI: [-4;4]). However, subsequent hospital stay was significantly increased (9 extra days, 95%-CI: [1;17]). Effects on 90-day mortality were not significant (adjusted weighted hazard ratio=1.36, 95%-CI: [0.90;2.06]).

Conclusions: PA NP remains a major complication for ventilated patients in the ICU with severe consequences. While SA NP was neither found to be associated with increased length of ICU stay nor with 90-day mortality, subsequent hospital stay was significantly increased. For cost calculations follow-up beyond ICU discharge provides important additional information on the economic burden of NP SA.

Abstract 7148

Real-world treatment of patients diagnosed with serious infections due to carbapenem-resistant Gram-negative pathogens in Greek hospitals

Dimitrios Georgopoulos1, Asimina Safarika2, Eleni Ischaki3, Effrosyni Filoutsou4, Konstantinos Mantzarlis5, Dimitrios Athanasopoulos6, Raquel Fenoll7, Emilio Sánchez7, Eilish McCann*8

1University Hospital of Crete, Crete, Greece, 2National and Kapodistrian University of Athens, Athens, Greece, 3General Hospital of Athens Evangelismos, Athens, Greece, 4National and Kapodistrian University of Athens, Medical School, General Hospital for Chest Diseases ‘I Sotiria’, Athens, Greece, 5University Hospital of Larissa, Larissa, Greece, 6Merck Sharp & Dohme, Athens, Greece, 7IQVIA Real World Solutions, Barcelona, Spain, 8Merck & Co., Inc., Kenilworth, NJ, United States

Background: Gram-negative (GN) infections which are resistant to key antibiotic classes pose a major threat to patients and clinicians. This issue is especially acute in southern European countries, including Greece. Our study objective was to characterize the real-world treatment of carbapenem-resistant (CR) GN complicated urinary tract infections (cUTI), complicated intra-abdominal infections (cIAI), and hospital-acquired/ventilator-associated bacterial pneumonia (HABP/VABP).

Materials/methods: Hospitalized adults with cUTI, cIAI, or HABP/VABP caused by CR GN pathogens between February 2015-July 2017 were consecutively enrolled from five participating hospitals across Greece. Baseline characteristics, medical history in the 12 months preceding index hospitalization, and treatment patterns were retrospectively reviewed through chart abstraction.

Results: 100 patients were identified from the five hospitals, with a mean age of 66.2 years; most (72%) were male. Index infections were largely hospital-acquired (90%) and the most common index infection types were HABP/VABP (81%), cIAI (10%), and cUTI (7%). A. baumannii was the most common pathogen identified (64%) - K. pneumoniae and P. aeruginosa were isolated in 37% and 9% of patients, respectively. After culture collection the most common antibiotics were carbapenems (43%), colistin (29%), glycopeptides (16%); prior to susceptibility test results: colistin (65%), carbapenems (57%), aminoglycosides (23%); post-susceptibility test results: colistin (79%), carbapenems (46%), tigecycline (39%). The majority of carbapenem use was as part of combination therapy. Antibiotic treatment patterns for patients who received carbapenems (n=71) are shown in Figure 1. Enrolled patients demonstrated considerable comorbidity in the pre-index period; in the year prior to index admission, 43% of patients received antibiotics, most commonly fluoroquinolones (n=20, 46.5%), 51% were admitted to hospital, and 37% had undergone prior invasive procedures.

Figure 1. Sankey diagram of treatment patterns for patients treated with carbapenems.

Conclusions: Carbapenems were the most commonly used empiric treatment, with continuing use observed just prior to, and after, susceptibility test results. High levels of colistin usage was observed in this cohort which may be linked to the high antibiotic resistance levels in Greece. The comorbid nature of these patients and the toxicity concerns associated with colistin suggest a need for alternative therapies which are efficacious against resistant pathogens and with improved tolerability profiles.

Early, potent and sustained virus-specific antibody-dependent complement-mediated inactivation activity in HIV-2 infection

Gulsen Ozkaya Sahin*1,2, Sara Karlson3, Fredrik Mansson2,4, Joakim Esbjornsson2,3, Malik Sallam2,6,7, Patrik Medstrand1,2, Hans Norrgren8, Marianne Jansson9

1Region Skåne, Laboratory Medicine, Clinical Microbiology, Lund, Sweden, 2Lund University, Department of Translational Medicine, Malmö, Sweden, 3Lund University, Systems Virology, Department of Translational Medicine, Lund, Sweden, 4Skåne University Hospital, SUS, Malmö, Department of Infectious Diseases, Malmö, Sweden, 5University of Oxford, Nuffield Department Medicine, Oxford, United Kingdom, 6The University of Jordan, Department of Pathology, Microbiology and Forensic Medicine, Amman, Jordan, 7The University of Jordan, Department of Clinical Laboratories and Forensic Medicine, Amman, Jordan, 8Skånes universitetssjukhus Lund, Department of Infectious Diseases, Lund, Sweden, 9Lund University, Department of Laboratory Medicine, Malmö, Sweden

Background: Despite significant improvements in therapy, the HIV/AIDS pandemic remains globally an important threat to public health. While there is hope that elimination of proviral HIV-1 DNA can be achieved, several approaches to reach a functional cure [control of HIV-1 replication in the absence of antiretroviral therapy] are also under investigation. HIV-2 is known to be less pathogenic than HIV-1, translating into slower disease progression. HIV-2 infection, therefore, represents a natural model for studies on HIV functional cure. In the present study, we examined longitudinally antibody-dependent complement-mediated inactivation (ADCMI) during the course of HIV-2 infection.

Materials/methods: Swedish teams, in collaboration with Guinea-Bissau, initiated in 1990 a police cohort, from which longitudinal plasma samples have been collected. In this study longitudinal plasma samples obtained between 1992 and 2010 (median four time points per subject) from seven HIV-2 seroincident individuals (median follow-up 14 years) were studied. Neutralizing and ADCMI activities of plasma were determined using a plaque reduction assay with GHOST(3)-CCR5 cell line. Pooled human AB serum was the source of complement. The cut-off for neutralization was 30% reduction in the number of plaques. For determination of the magnitude of neutralizing activity and ADCMI plasma samples were tested against three HIV-2 isolates.

Results: ADCMI developed at 6-13 months after estimated time of infection and plasma titers raised to 1:10 000-1:100 000 000 after five years and were thereafter sustained against tested HIV-2 isolates throughout the follow-up period. Moreover, complement enhanced plasma neutralizing activity 10-1000 times, depending on which HIV-2 isolate tested against.

Conclusions: This study represents the first longitudinal HIV-2 infection study of ADCMI, from early infection to years of follow-up, and shows that ADCMI develops earlier and to higher titers than that previously described for HIV-1. This suggests that complement may contribute to the relative benign outcome of an HIV-2 infection.

Abstract 7152

**Sepsis-3: a prospective clinical study of the clinical diagnosis and blood culture performance**

David Yu1, David Unger2, Åsa Parke3, Christian Unge3, Claes Henning4, Jonas Sundén-Cullberg3, Kristoffer Strålin3, Volkan Özenci*1

1Karolinska Institutet Campus Huddinge, Department for Laboratory Medicine, Stockholm, Sweden, 2Karolinska Institute, Stockholm, Sweden, 3Karolinska Institutet Campus Huddinge, Department of Medicine, Stockholm, Sweden, 4Southern Älvsborg Hospital, Clinical Microbiology Laboratory, Borås, Sweden

**Introduction:** Microbiological diagnosis of sepsis is crucial for appropriate treatment of patients with sepsis. Blood cultures (BC) are the gold standard method in sepsis. The performance of BC in detection of microorganisms in patients with the recently defined sepsis-3 definition has scarcely been studied.

**Aims:** The primary aim of the study was to analyze the association of clinical sepsis-3 diagnosis with BC results in patients who were identified through a sepsis alert system. Secondary aims were to describe the clinical characteristics in BC positive vs. BC negative sepsis.

**Materials/methods:** Patients that were treated according to a sepsis triage model were included prospectively in the emergency department. In total six blood culture bottles were collected from each patient that fulfilled the criteria for triage. BC were defined as having clinically relevant growth, contaminant growth or no growth by standard methods. The clinical and laboratory data were collected from patient journals and the laboratory information system. Foci of infection included in the study were: upper respiratory tract, lower respiratory tract, urinary tract, abdominal, skin/soft tissue/joint/skeletal, central nervous system and others. Correlation between the clinical diagnosis of sepsis and BC results were analyzed using Pearson's χ²-test.

**Results:** 652 suspected sepsis episodes were studied, the final analysis included 549 episodes. 387/549 (70.5%) episodes fulfilled sepsis-3 criteria. BC were positive in 140/387 (36.1%) episodes with sepsis. In patients without sepsis, BC were positive in 30/162 (18.5%) episodes (p < 0.001). In patients with sepsis, the BC positivity rates were correlated to infection focus. Patients with urinary tract infections (49.8%) had higher BC positivity rates compared to lower respiratory tract infections (31.4%) (p < 0.001).

**Conclusions:** BCs had low performance in detection of relevant clinical growth in patients with sepsis and could detect microorganisms in only 36% of the episodes. A higher proportion of positivity was detected in patients with sepsis compared to patients without sepsis. Urinary tract focus had the highest association with BC positivity.

**Comparative effectiveness of ceftolozane/tazobactam versus aminoglycosides or polymyxins in multidrug-resistant *Pseudomonas aeruginosa* infections**

Aisling Caffrey\(^1,2,3,4,\) Emily Piehl*\(^1,2,\) Vrishali Lopes\(^1,\) Laura Puzniak\(^5,\) Kerry Laplante\(^1,2,3,6\)

\(^1\)Providence Veterans Affairs Medical Center, Rhode Island Infectious Diseases Research Program, Providence, United States, \(^2\)University of Rhode Island, College of Pharmacy, Kingston, United States, \(^3\)Providence Veterans Affairs Medical Center, Center of Innovation in Long-Term Support Services, Providence, United States, \(^4\)Brown University, School of Public Health, Providence, United States, \(^5\)Merck & Co., Inc., Kenilworth, United States, \(^6\)Warren Alpert Medical School of Brown University, Division of Infectious Diseases, Providence, United States

**Background:** *Pseudomonas aeruginosa* infections are challenging to treat, due to multi-drug resistance (MDR) and the complexity of the patients affected by these serious infections. As new antibiotic therapies come to market, limited data exists about the effectiveness of such treatments in clinical practice among varied clinical populations. The objective of our study was to assess the comparative effectiveness of ceftolozane/tazobactam (C/T) compared with aminoglycosides or polymyxins in MDR *Pseudomonas aeruginosa* infections in Veterans Affairs (VA) hospitals.

**Materials/methods:** This retrospective cohort study included VA hospitalized patients with positive MDR *P. aeruginosa* cultures between January 2015 and April 2018. Inclusion criteria were 1) treated with C/T versus aminoglycosides or polymyxins for ≥48 hours, without overlapping therapy between C/T and aminoglycosides or polymyxins for >48 hours and 2) isolates were susceptible to the treatment of interest (C/T and aminoglycosides/polymyxins). Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were calculated using automatic stepwise logistic regression for inpatient mortality, 30-day mortality, 30-day readmission, persistent positive culture, and microbiological eradication.

**Results:** We included 57 patients treated with C/T compared with 155 patients treated with aminoglycosides/polymyxins for MDR *P. aeruginosa* infections. Patients treated with C/T were younger (mean age 67.5 vs 71.1, p=0.03), and had a higher comorbidity burden prior to hospitalization [median Charlson 5 vs 3, p=0.01], as well as higher rates of spinal cord injury (38.6% vs 21.9%, p=0.02), *P. aeruginosa* positive bone/joint cultures (12.3% vs 0.7%, p<0.0001), and positive *P. aeruginosa* cultures in the 30 days prior to admission (54.4% vs 38.7%, p=0.04). Median time to initiation of the treatment of interest from culture was 3 days for both groups. Inpatient mortality was significantly lower in the C/T group compared with aminoglycosides/polymyxins (15.8% vs 27.7%, aOR 0.39, 95% CI 0.16-0.93) adjusting for prior positive *P. aeruginosa* culture, treating specialty, and previous antibiotics exposures prior to the initiation of the treatment of interest. There were no significant differences observed for the other outcomes assessed.

**Conclusions:** In hospitalized patients with MDR *P. aeruginosa*, the risk of inpatient mortality was 61% lower among patients treated with C/T compared with those treated with aminoglycosides or polymyxins.

Background: Carbapenem resistance is increasing, particularly in southern Europe. This study characterized how patients with serious infections [complicated urinary tract infections [cUTI], complicated intra-abdominal infections [cIAI], and hospital-acquired/ventilator-associated bacterial pneumonia [HABP/VABP]] attributable to carbapenem-resistant [CR] Gram-negative [GN] bacteria are treated and the outcomes of treatment.

Materials/methods: Retrospective chart review in 300 patients from 14 Spanish, Italian, and Greek hospitals. Adult patients were enrolled consecutively if hospitalized with cUTI, cIAI, or HABP/VABP caused by CR GN pathogens from February 2015 to July 2017. Baseline patient characteristics, treatment patterns, and clinical outcomes [clinical cure, death/discharge] were abstracted. Univariate/multivariate cox regression models were performed to determine significant predictors of observed outcomes.

Results: In the included cohort, most infections were hospital-acquired (79.7%) and the most common infection types were HABP/VABP (61.3%), cUTI (27.7%), cIAI (8.7%); the remainder were mixed infections. Klebsiella pneumoniae was the most common pathogen (51.3%), followed by Acinetobacter baumannii (30.0%) and Pseudomonas aeruginosa (21.7%). Overall, 46.7% of patients reported clinical cure; rates ranged from 34.6% [cIAI] to 73.5% [cUTI]. Median time from culture collection to clinical cure was 16 days (11-24 days). On the date of discharge, 50.7% of patients were deceased; median time from culture collection to death was 27 days (12-84 days). Having cUTI was a predictor of clinical cure [hazard ratio [HR]: 1.728, 95% confidence interval [CI]: 1.172, 2.548, p=0.0057]; colistin use was inversely associated with clinical cure [HR: 0.625, 95% CI: 0.429, 0.912, p=0.0148]. cIAI [HR: 1.068, 95% CI: 1.011, 1.127, p=0.0177], receiving more drugs post-antibiogram availability [HR: 1.096, 95% CI: 1.052, 1.142, p=0.0001], and receiving carbapenems [HR: 1.583, 95% CI: 1.096, 2.287, p=0.0143] were all significantly associated with death.

Conclusions: cUTI, cIAI, and HABP/VABP attributable to CR GN infections were fatal in just over half of included patients. Infection type and antibiotic choices were predictive of outcomes, specifically, colistin and carbapenem use were associated with poor clinical outcomes. The trend between treatment decisions and outcomes warrants further exploration; patients identified as candidates for carbapenem or colistin therapy may benefit from newer treatments with enhanced activity against carbapenem-resistant pathogens and improved toxicity profiles.

Abstract third-party references: On behalf of the contributing members of the SHARED database

Background: Hepatitis C patients who failed Direct-Acting Antivirals (DAA) often selected viruses with drug resistance-associated substitutions (RAS), which limits treatment options. High response rates from DAA therapy make it challenging to study HCV drug resistance. SHARED, the Surveillance of Hepatitis C Antiviral Resistance, Epidemiology and Methodology, is an international consortium with the goal of better understanding and avoiding HCV drug resistance and transmission through the development, application, and sharing of HCV genomic data, methods, software and technologies. Our aim was to characterize HCV resistance after unsuccessful DAA in real-world settings.

Materials/methods: HCV sequences and clinical data from >1900 DAA-failures were collected from 17 countries. Variants within NS3, NS5A, and NS5B were examined for resistance-associated substitutions (RAS) at positions according to the 2018 EASL guideline.

Results: Of the 1543 patients who failed NSSA inhibitor (NS5AI)-containing regimens, 83% selected RAS following therapy. Notably, 63% of patients with RAS had intricate patterns with ≥2 NSSA RAS suggesting a high level of resistance. In the 244 patients treated with a combination of NS5AI and protease inhibitor (PI), 63% had RAS in both drug-targets, and only 6% failed with no RAS. There was no difference in the frequencies of RAS selected between the first-generation NS5AI+PI regimens versus glecaprevir/pibrentasvir after treatment failure. The prevalence of NS5A-RAS was lower in genotype (GT) 1a (77%) but higher in GT2 (100%) and GT4 (99%). Each genotype/subtype had distinct RAS patterns, usually at positions 28, 30, 31, and 93. In general, GT2a virologic failures selected L31M while non-GT2 selected T24S+F28C; none of them harbored Y93H. In GT3, Y93H was most prevalent (61%) followed by mutations at position 62 (45%) and A30K/S (17%). Intriguingly, all GT3b/g harbored A30K+L31M mutations without Y93H. Overall, the prevalence of an unfit sofosbuvir mutation, S282T, was low in GT1a (2%), GT1b (1%), GT2 (3%) and GT3 (1%), but high in GT4 (18%).

Conclusions: SHARED is currently gathering a critical mass of data from virological failures worldwide, including uncommon GT and subtypes, to characterize the modality of DAA failure comprehensively. This information provides valuable insight to optimize rescue treatment options and to track resistant virus transmission.

Abstract 7159

Rapid reduction in rotavirus gastroenteritis in children aged 0-59 months following the introduction of universal rotavirus vaccination in Palestine

Musa Hindiyeh*1, Wolfgang Rennert2,3, Ruba Khalawi1, Abed Issa1, Asad Ramlawi4, Hiyam Marzouqa1

1Caritas Baby Hospital, Bethlehem, Palestine, 2Georgetown University, Washington, United States, 3Rostropovich Vishneskaya Foundation, Washington, United States, 4Palestine Ministry of Health, Ramallah, Palestine

Background: Universal vaccination with a monovalent rotavirus vaccine (Rotarix GSK) was introduced in Palestine in May-2016 in collaboration between Palestine Ministry of Health and the Rostropovich & Vishneskaya Foundation (RVF). In November-2018 it was switched to the newly approved monovalent vaccine, Rotavac (Bharat Biotech) to foster program sustainability with the support of RVF. The study aims to examine the changes in rotavirus gastroenteritis hospitalizations following the introduction of universal rotavirus immunization among children aged 0-59 months.

Materials/methods: An ongoing laboratory-based surveillance of RVGE was launched in January-2016 till October 2019 among children aged 0-59 months living in Bethlehem and Hebron regions. Stool samples were collected from children hospitalized for gastroenteritis and analyzed for rotavirus antigen by immunochromatography. The year 2016 was considered as the reference period.

Results: Overall, 3341 hospitalizations for gastroenteritis occurred during 2016-March 2019. The median age of the patients was 7 months. Rotavirus tested positive in 709 (21.2%) samples. Rotavirus positivity was 389/1317 (29.5%), 149/889 (16.8%), 129/917 (14.1%) and 42/218 (19.2%) in 2016, 2017, 2018 and 2019 respectively. The number of hospitalizations for all-cause gastroenteritis decreased by 32.5% and 30.4% in 2017 and 2018, respectively compared to 2016. The corresponding reduction (p<0.001) in the percentage of rotavirus positive tests was 43.3% (95% CI 31.3, 54.8), and 52.4% (95% CI 40.9, 63.5). This reduction (p<0.001) was of stronger magnitude in infants aged 0-11 months: 62.0% (95% CI 46.4, 76.9) in 2017 and 59.2% (95% CI 43.9, 74.0) in 2018. In toddlers aged 12-23 months the respective reduction (p<0.05) was 22.9% (94% CI 1.9, 43.1) and 53.2% (95% CI 32.3, 72.1). In children aged 24-59 months, a small and non-significant reduction was documented: 28.5% (95% CI 1-3, 56.6) and 18.0% (95% CI 12.8, 47.4), in 2017 and 2018, respectively.

Conclusions: The introduction of universal immunization with a monovalent vaccine was followed by a rapid and significant reduction in rotavirus hospitalizations in children aged 0-59 months in Palestine. Preliminary data suggest that there is no difference between the clinical impact of Rotavac vaccine and the previously used Rotarix.

Abstract 7161

**Light scatter AST for positive blood cultures, how impactful on antimicrobial therapy management of septic patient?**

Antonio Curtoni*, Davide Ghibaudo1, Luigi Imperatore1, Caterina Veglio1, Gabriele Bianco1, Silvia Corcione3, Silvia Scabini3, Cristina Costa1, Luca Scaglione4, Francesco G. De Rosa3, Rossana Cavallo1

1University of Turin, Department of Public Health and Pediatrics, Microbiology and Virology Unit, Turin, Italy, 2University of Turin, Department of Medical Sciences, Internal Medicine 3, Turin, Italy, 3University of Turin, Department of Medical Sciences, Infectious Diseases, Turin, Italy, 4City of Health and Sciences of Turin, Teaching Hospital Molinette, Department of General and Specialistic Medicine, Internal Medicine 5, Turin, Italy

**Background:** Improving blood culture turnaround time (TAT) is pivotal in the management of septic patients. Faster reporting of results can significantly impact on patients’ outcomes and costs associated to inappropriate antimicrobial therapy.

**Materials/methods:** Positive blood cultures have been consecutively screened, and 50 septic patients have been enrolled so far. Each sample was processed according to the standard protocol (SP) consisting of preliminary ID by MALDI-TOF MS and preliminary AST both performed on short-term colony incubation, and definitive AST on isolated colony. A rapid protocol (RP) consisting of light scatter technology (ALFRED 60AST) direct AST from positive monomicrobial blood cultures coupled to ID by MALDI-TOF MS was tested, by choosing the appropriate antibiotic panel after Gram stain results. Clinicians were presented with the RP and SP results and interviewed to assess the potential impact of the RP results on the antimicrobial therapy management.

**Results:** The RP instrument TAT was significantly lower than that of the preliminary SP (6h 31’ vs 19h 12’ – p<0.001), and even more so was the real-life TAT (7h 31’ vs 26h 27’ – p<0.001). Overall concordance between RP and definitive SP was 93.4% (Cohen K 0.82 – excellent concordance) and no very major errors were found. The concordance between antimicrobial therapy decisions based on RP and PSP results was 91.7% (Cohen K 0.79 – good concordance). Based on RP results, there would have been 22.9% antibiotic therapy changes one day earlier. In 8.3% of cases, therapy management decisions were not concordant, half of which were motivated by antibiotics not tested in the RP.

**Conclusions:** The results represent a halfway analysis of an ongoing study that is designed to reach a sample size of 100 patients. The RP TAT is considerably lower than the SP TAT, and its diagnostic accuracy is excellent. The preliminary data suggest that rapid reporting of AST results could benefit more than 1 out of 5 patients thanks to changes of the empirical antibiotic therapy to a targeted one with one day in advance.

Background: Gram-negative (GN) bacterial infections are known to be clinically burdensome, particularly when the causative pathogens are resistant to antibiotics. This study characterizes the economic burden by describing the healthcare resource use (HCRU) associated with serious carbapenem-resistant (CR) GN infections in three southern European countries.

Materials/methods: HCRU, including length of stay (LOS), procedures, and readmissions, was assessed in 300 hospitalized adult patients with complicated urinary tract infections (cUTI), complicated intra-abdominal infections (cIAI), and hospital-acquired/ventilator-associated bacterial pneumonia (HABP/VABP) caused by CR GN pathogens from February 2015-July 2017, identified through a retrospective chart review conducted in 14 hospitals in Spain, Italy, and Greece.

Results: Patients had HABP/VABP (61.3%), cUTI (27.7%), cIAI (8.7%), or mixed infections (2.3%). Patients were most often admitted to medical wards (53.7%). Median LOS from admission to discharge was 39.5 days (interquartile range: 23-67 days), varying from 33.5 days (cIAI) to 41.0 days (HABP/VABP); from culture collection to discharge median LOS was 21.0 days [12-42 days]. 64.3% of patients spent time in the intensive care unit (ICU) during their hospitalization. Median ICU LOS was 27.0 days [13-47 days] from admission, and 7 days [0-18 days] from culture collection date. During index hospitalization, the most frequently performed tests were blood cell counts (in 92.7% patients, mean: 13 per patient), biochemistry tests (88.0%), and blood cultures (87.0%). The most common invasive procedures were vascular catheterization (33.7%), mechanical ventilation (18.3%), and urinary catheterization (16.3%). 143 patients had readmission data for six months post-discharge: 57 (39.9%) were readmitted. The cause of readmission was recurrence of infection for 10 (16.7%) of the 69 reported readmissions. Median time from discharge to readmission was 32.0 days [5-70 days]; mean LOS once readmitted was 4.9 days. 16.3% of discharged patients reported outpatient or emergency visits in the six months post-discharge, most commonly under the care of a specialist.

Conclusions: cUTI, cIAI, and HABP/VABP caused by CR GN infections were associated with substantial HCRU, including LOS and ICU LOS, procedures, and readmissions. These data highlight the considerable financial burden associated with these infections and highlight the urgent need for enhanced clinical management of these difficult-to-treat infections.

Genomic features involved in intra-hospital transmission of *Pseudomonas aeruginosa*

Jan Liese1, Madeleine Desch1, Silke Peter1, Ralf Eggeling1, Nico Pfeifer1, Matthias Willmann*1

1University of Tuebingen, Tuebingen, Germany

**Background:** *Pseudomonas aeruginosa* causes life-threatening nosocomial infections. Moreover, it is known to easily spread within hospitals, particularly during long-term outbreaks. However, little is known about the genomic and phenotypic features of successful outbreak strains since outbreaks are usually only detected when multidrug resistant strains are involved.

**Materials/methods:** We performed whole genome sequencing of 650 *P. aeruginosa* strains from 384 patients collected during active screening at our hematology department at the University Hospital Tübingen, Germany. We included the first isolate of all patients regardless of their antimicrobial susceptibility pattern. Further strains from the same patient were included when they differed in their antimicrobial susceptibility profile or were isolated from different specimen collection sites. Room occupation and transfer data from each patient was extracted from the clinical database system.

**Results:** Maximum likelihood phylogeny revealed 187 clusters of various sizes including strains from one or more patients. We determined likely transmissions for each cluster based on genetic and epidemiological links. In linear regression models, the number of transmissions was associated with direct contact days (standard coefficient 15.53, p = 0.06) and indirect contact days (standard coefficient 14.79, p = 0.03). Based on this data, we determined a weighted transmission efficacy for each cluster and found 9 clusters having a high transmission efficacy and 44 clusters having a low transmission efficacy, together comprising of 423 strains (65% of all strains). A group of four genes was found to be significantly enriched in the high transmission clusters (OR 119.94, FDR = 3.15 x 10^-49, sensitivity = 78.19%, specificity = 97.07%).

**Conclusions:** Our study shows a strong relationship between number of patient contacts and transmission counts, suggesting that transmission events are clearly driven by the hospital setting and logistics. Furthermore, our data suggest that genomic features of *P. aeruginosa* strains contribute significantly to intra-hospital transmission and could be used as biomarkers indicating strains with high transmission risk.

Within host genetic comparison of *Escherichia coli* strains isolated from patients with urosepsis

Aline Cuénod*1;2, Jessica Agnetti1;2, Helena Seth-Smith1;2;3, Olivia Grüninger1, Josiane Reist1, Sarah Tschudin-Sutter4;5, Stefano Bassetti6, Nicholas Thomson7;8, Adrian Egli1;2

1University of Basel, Applied Microbiology Research, Department of Biomedicine, Basel, Switzerland, 2University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 3Swiss Institute for Bioinformatics, Basel, Switzerland, 4University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 5University of Basel, Department of Clinical Research, Basel, Switzerland, 6University Hospital Basel, Division of Internal Medicine, Basel, Switzerland, 7Wellcome Trust Sanger Institute, Parasites and Microbes, Hinxton, United Kingdom, 8London School of Hygiene and Tropical Medicine, Department of Pathogen Molecular Biology, London, United Kingdom

**Background:** *E. coli* is the most common cause of urinary tract infections (UTIs) and urosepsis worldwide. Whether these infections are caused by single clonal strains ascending the urinary tract, or whether more diverse *E. coli* populations are involved in these severe infections is not yet fully understood. In this project we assess the genetic diversity between *E. coli* strains isolated from paired blood or urine samples.

**Materials/methods:** We isolated and whole genome sequenced *E. coli* strains (*n*=129) from 63 patients with urosepsis. We compared the genomic sequences of strains isolated from the bloodstream (*n*=63) to strains isolated from the urinary tract (*n*=66) of the same patient. The samples were compared in terms of Average Nucleotide Identity (ANI), whole genome single nucleotide polymorphisms (SNPs) and for differences in gene content. In a subset of patients, we picked ten random colonies from blood and urine culture plates to assess the genomic diversity within the patient samples.

**Results:** We found that in 86% of patients with urosepsis (*n*=54/63), the *E. coli* isolates from blood and urine were closely related with >99.5% ANI (median number of SNPs=4; interquartile range=1-13) whereas in 14% of patients with urosepsis (*n*=9/63), the bloodstream isolated *E. coli* strains shared <99.5% ANI (median number of SNPs=79,631; interquartile range=31,189-82,557) to those isolated from the urine of the same patient. As a next step we assess the diversity of *E. coli* strains in urine and bloodstream samples of ten urosepsis cases, by comparing ten randomly picked colonies per sample material.

**Conclusions:** These findings suggest for patients with urosepsis with distantly related *E. coli* strains isolated from urine and blood, multiple *E. coli* strains may ascend the urinary tract to cause UTI. Assessing the diversity of *E. coli* strains in urine and bloodstream samples could increase our understanding and anticipation of disease progression.

![Core genome phylogeny of *E. coli* strains isolated from bloodstream (*n*=63) and urinary samples (*n*=66). Distantly related strains of the same clinical case are labeled with the case ID.](image-url)
Co-production of two types of carbapenemases in Enterobacterales from Poland
Elzbieta Literacka*1, Radosław Izdebski2, Anna Baraniak1, Paweł Urbanowicz2, Małgorzata Herda1, Katarzyna Malinowska3, Borota Żabicka1, Waleria Hryniewicz1, Marek Gniadkowski2
1National Medicines Institute, Department of Epidemiology and Clinical Microbiology, Warsaw, Poland, 2National Medicines Institute, Department of Molecular Microbiology, Warsaw, Poland

Background: Since the first identification of carbapenemase-producing Enterobacterales (CPE), VIM-2 positive isolate, in Poland over decade, various types of carbapenemases including VIM, IMP, KPC, NDM, OXA-48-like and GES-5 have been recognized by the National Reference Centre for Susceptibility Testing (NRCST). Recently, the major CPE problem is NDM-producing Klebsiella pneumoniae, which continues its dissemination in the country since 2013. Here we present the first Polish strains coproducing of two different types of carbapenemases.

Materials/methods: A total of 26 Enterobacterales isolates: K. pneumoniae [n=20], Klebsiella oxytoca [n=3], Enterobacter cloacae cpx. [n=2], Escherichia coli [n=1] collected by NRCST were examined. The strains were isolated in 13 microbiological centers, 6 cities: Warsaw, Łódź, Lublin, Cracow, Rybnik and Grodzisk Mazowiecki. Species were identified by Vitek2 (bioMérieux). Carbapenemase detection was carried out by Carba NP and CIM tests, and phenotypic methods. blaNDM, blaVIM, blaKPC, blaOXA-48-like genes were identified by PCR. Susceptibility of isolates was tested by MIC Test Strips (Liofilchem) and the results were interpreted according to the EUCAST guidelines. Whole genome sequencing (WGS) was performed for the 23 isolates using the Illumina MiSeq.

Results: The first strain coproducing of two carbapenemases - K. pneumoniae NDM/KPC emerged in Warsaw in 2016. Since then, the following pairs of carbapenemases have been confirmed in 25 other isolates: NDM/KPC (Warsaw, n=2; Rybnik, n=7), KPC/VIM (Warsaw, n=5; Cracow, Lublin, n=1), KPC/OXA-48 (Cracow, n=4; Łódź n=1), NDM/VIM (Warsaw n=2; Łódź, Lublin, n=1), NDM/OXA-48 (Grodzisk Mazowiecki, n=1). NDM/KPC-producing K. pneumoniae isolates discovered in Rybnik represented the hyperepidemic clone ST23, while strains isolated in Warsaw - ST11. KPC/OXA-48-producing K. pneumoniae belonged to two STs: ST512 and ST395 which was previously observed in Cracow in strains with OXA-48. KPC/VIM E. cloacae and K. oxytoca isolates were classified as ST96 and ST145 respectively, both STs were observed previously in Poland in VIM-producing Enterobacterales. The studied strains showed multidrug-resistance patterns. A more detailed analysis of the genetic context of the carbapenemase encoding genes is currently underway.

Conclusions: Our research has revealed the occurrence of Enterobacterales coproducing of two carbapenemases in different type combinations. This new phenomenon is observed in Poland since 2016.

Genomic analysis of Group B streptococci colonising pregnant women in Portugal reveals the emergence of novel genetic lineages resulting from capsular switching

Elisabete Raquel Ferreira Martins1, Rui Pedrosa2, José Melo-Cristino2, Mario N. Ramirez*2

1Instituto de Medicina Molecular (IMM), Instituto de Microbiologia, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal, 2Faculty of Medicine, University of Lisbon, Instituto de Microbiologia, Instituto de Medicina Molecular, Lisboa, Portugal

Background: Diversification of group B streptococci (GBS) clones causing invasive disease has been reported, together with emerging resistance within previously stable genetic backgrounds. Our aim was to use high throughput sequencing (HTS) to characterize the genetic lineages circulating among GBS colonizing pregnant women and to compare them with those causing neonatal infections in Portugal.

Materials/methods: GBS isolates (n=252) recovered from vaginorectal swabs of pregnant women (35-37 weeks gestation) in three hospitals in the Lisbon metropolitan area were sequenced (Illumina, San Diego, CA, USA) and analyzed by both mapping and de novo assembly approaches. Capsular serotypes, multilocus sequence typing (MLST) and antimicrobial resistance determining genes were extracted from the genomes.

Results: Serotype Ia was the most frequent (24%), mainly representing ST23 and ST24 and respective single-locus variants (SLVs). In ST24 a novel serotype combination - V/ST24 – was found (39%), possibly resulting from capsule switching. Serotype III accounted for 21% of the isolates, mostly representing the hypervirulent CC17 clone, including one isolate carrying multiple resistant determinants. Serotypes V (19%) and Ib (14%) represented mostly CC1, a lineage previously almost exclusively expressing serotype V. All Ib/CC1 isolates carried the ermB gene, accounting for the majority of isolates carrying macrolide resistance determinants within CC1 (66%). In total sixty isolates (24%) contained a macrolide resistance gene and a tet gene (mostly tetM, 95%) was found in 87% of the isolates.

Conclusions: In the past years, the emergence and expansion of the Ib/CC1 lineage, which we showed to have emerged from recombination of a large genomic region including the capsular locus, has been mostly restricted to non-pregnant adult disease. This lineage has been the major driver of the increase in macrolide resistance in Portugal, despite decreases in consumption. While only a small number of cases were found among neonatal infections, the expansion of Ib/CC1 lineage among GBS colonizing pregnant women, together with novel serotype/genotype combinations identified by genomic analyses, may be a harbinger of a shift in the serotypes and clones causing neonatal disease, which may impact the vaccine formulations currently under development.

Abstract 7169

Detection of antibodies to hepatitis C virus using the Ortho VITROS: evaluation of the signal-to-cutoff ratio

Giuseppina Colomba, Noemi Urone, Chiara Mascarella, Donatella Ferraro

1Palermo, University of Palermo, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties. "Giuseppe D’Alessandro", Palermo, Italy

Background: Diagnosis of HCV infection is based on the detection of HCV specific antibodies (HCV-Ab) and serum HCV genome (HCV RNA). HCV-Ab chemiluminescence immunoassays are characterized by higher specificity compared to enzyme immunoassay methods, but a false positive results are possible specially in low-prevalence population. Several studies have shown that the use of signal / cut off ratio (S/Co) may reduce false positive results and they have correlated higher S/Co values to persistent HCV infection. The aim of this study is to correlate patients HCV-Ab absorbance values to HCV viremic status, in order to understand the clinical significance of S/Co ratio and reduce the use of second level tests.

Materials/methods: HCV antibodies results from 12901 serum samples, collected from January 2018 to July 2019, tested by Vitros ECi Anti-HCV assay (Ortho-Clinical Diagnostics), were extrapolated from the management system of a tertiary hospital. A part of HCV-Ab Vitros S/Co ≥1 positive samples (65/501) were re-tested using the LIAISON® XL murex HCV Ab assay (DiaSorin). Furthermore, the correlation between HCV-Ab S/Co ratio results and HCV RNA detection by CobasAmpli/Prep CobasTaqman (Roche) have been analyzed for 356 HCV-Ab positive samples

Results: Among 12901 samples, 501 (3.8%) samples have been resulted positive (Vitros S/Co ≥1) for anti-HCV, S/Co ratio resulted high (≥ 20) in 257/501 (51.3%) positive samples, intermediate (10 ≥ - <20) in 76 (15.1%), low (5 ≥ - < 10) in 35 (6.9%) and very low (≥ 1 - <5) in 133 (26.5%). Fifty/133 samples with very low S/Co have been re-tested with LIAISON and 32/50 of them resulted HCV-Ab negative (LIAISON, S/Co < 1). These samples have been confirmed as HCV-Ab Vitros false positive because they also resulted HCV-RNA negative. We demonstrated the correlation between high S/Co ratio and patients viremic status, 252/257 (98%) samples with S/Co ≥ 20 resulted HCV-RNA positive (> 100.000 UI/ml). Instead, only 30% and 18% of samples with intermediate to low S/Co ratio are also result HCV-RNA positive

Conclusions: Anti-HCV S/Co value definition, specific assay, allows to define false positive samples and therefore reduce the use of supplementary testing

Clinical characteristics and outcome of patients with plasmid-borne AmpC β-lactamase-producing Klebsiella pneumoniae bacteraemia at a tertiary medical centre

Ying-Chi Huang*1,2, Sheng-Hua Chou2, Yi-Hsiang Cheng2, Yi-Tsung Lin1,2

1Taipei Veterans General Hospital, Taipei, Taiwan, 2National Yang-Ming University, Emergency and Critical Care Medicine, Taipei, Taiwan

Abstract third-party references: Institute of Emergency and Critical Care Medicine, National Yang-Ming University, Taipei, Taiwan, Division of Infectious Diseases, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Third-generation-cephalosporin-resistant (3GCR) Klebsiella pneumoniae infections are associated with significant morbidities and mortalities worldwide. Extended-spectrum β-lactamases (ESBL) and plasmid-borne AmpC β-lactamases are major resistance mechanisms in 3GCR K. pneumoniae. Carbapenem are considered the most effective therapeutic option for patients with ESBL-producing K. pneumoniae infections, but carbapenem-sparing regimens were proposed recently. However, the treatment regimens for 3GCR K. pneumoniae bacteraemia with plasmid-borne AmpC β-lactamases were rarely reported in the literature. We aimed to study whether non-carbapenems are suitable agents for bacteraemia caused by 3GCR K. pneumoniae with plasmid-borne AmpC β-lactamases.

Materials/methods: This single-centre, retrospective study enrolled 124 adult inpatients with 3GCR K. pneumoniae bacteraemia from January 2016 to September 2018. 3GCR K. pneumoniae strains were determined for genes coding for ESBL (including SHV, TEM, CTX-M) and plasmid-borne AmpC β-lactamases (including DHA and CMY) by PCR. Clinical characteristics of these patients infected with 3GCR K. pneumoniae strains were demonstrated and we further compared carbapenem and non-carbapenem regimens in patients infected with plasmid-borne AmpC β-lactamases-producing K. pneumoniae bacteraemia.

Results: Among 124 patients with 3GCR K. pneumoniae bacteraemia, 42 (33.9%) isolates harboured only plasmid-borne AmpC β-lactamases, 45 (36.3%) harboured only ESBL, 33 (26.6%) harboured both ESBL and plasmid-borne AmpC β-lactamases, and the remaining 4 isolates had unknown resistant mechanism. All strains with plasmid-borne AmpC β-lactamases were DHA-1-producing strains. The 14-day mortality of DHA-1-producing K. pneumoniae bacteraemia was similar to that of ESBL-producing strains (9.5% vs 15.6%, p=0.398). Thirty-seven patients with exclusive DHA-1-producing K. pneumoniae bacteraemia received appropriate antibiotics, including 19 patients with carbapenem and 18 with non-carbapenem group (5 with cefepime, 2 with piperacillin/tazobactam, 5 with fluoroquinolone, 3 with cefoperazone/sulbactam and 3 with ceftiraxone). There’s no difference in 14-day mortality and 28-day mortality between carbapenem and non-carbapenem treatment (5.3% vs 0%, p=0.324, 15.8% vs 0%, p=0.079). The time to clinical success was also similar between the group with carbapenem and those with non-carbapenem treatment [3 (2-6) vs 4 (2-5) days, p=0.613].

Conclusions: The 14-day mortality of patients infected with plasmid-borne AmpC β-lactamases K. pneumoniae strains was similar to those with ESBL-producing strains. Non-carbapenem regimes was as effective as carbapenems in the treatment of DHA-1-harbouring 3GCR K. pneumoniae bacteraemia.

Abstract 7172

Hetero-resistance to colistin in *Stenotrophomonas maltophilia* isolates: challenges in colistin susceptibility testing

Ümran Liste\(^1\), Asiye Bıçakçıgil\(^1\), Cumhur Özkuyumcu\(^1\), Banu Sancak\(^*1\)

\(^1\)Hacettepe University Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey

**Background:** Colistin is one of the last –line antibiotic used for multidrug-resistant Gram negative bacilli. The increasing use of colistin has led to emergenge of resistant and heteroresistant isolates. The heteroresistance (HR) raised a diagnostic and therapeutic dilemma for clinicians because HR isolates could be misclassified as susceptible by routine diagnostic testing.

The aim of this study was to determine colistin heteroresistance in *Stenotrophomonas maltophilia* clinical isolates.

**Materials/methods:** A total of 212 *S. maltophilia* clinical isolates recovered from hospitalized patient between December 2015-April 2018 were included in the study. The colistin MICs were determined by both broth microdilution method (BMD) and gradient test (bioMérieux Etest). All tests were repeated twice. Heteroresistance was suspected if incompatible results were detected between BMD and gradient test or when colonies were observed within the inhibition zone of colistin gradient test. Heteroresistance was confirmed by applying population analysis profile (PAP) method. Heteroresistance was considered if the antibiotic concentration exhibiting the highest inhibitory effects was at least 8-fold higher than the highest noninhibitory concentration.

**Results:** Of the 212 *S. maltophilia* isolates, 54 (25.5%) were found as heteroresistant to colistin by PAP. In all of the HR isolates, category differences was detected with BMD test between two runs.

**Conclusions:** The results of this study shows that colistin susceptibility testing remains a challenging issue for routine microbiology laboratories. Although the recommended method is BMD, it cannot detect heteroresistance. The rate of colistin HR in *S. maltophilia* was found high in this study. In *vitro* and in *vivo* studies involving more isolates are needed to determine the true clinical outcome of HR to colistin.

**Abstract 7173**

**Therapeutic equivalence between brand name antibiotics versus generics: a systematic review and meta-analysis**  
André Cotia*1, Icaro Boszczowski1,2, Jessica Matuoka2, Mariana Barbosa2, Haliton Oliveira2  

1Clinical Hospital, University of São Paulo, São Paulo, Brazil, 2Hospital Alemão Oswaldo Cruz, São Paulo, Brazil

**Abstract third-party references:** Hospital Alemão Oswaldo Cruz, Universidade de São Paulo

**Background:** The use of generic drugs (GD) as an alternative to reference brand-name drugs (BD) is justified by the reduction in costs. Regulatory authorities authorize the clinical use of GD based on bioequivalence studies, which is the evaluation of single-dose pharmacokinetics in vitro or in healthy patients. There is little data on a therapeutic equivalence between BD and GD antimicrobials.

The objective was to synthesize and analyze the available evidence regarding the efficacy and safety of generic antibiotics compared with their original formulations.

**Materials/methods:** A systematic review of the literature was conducted in Medline (Pubmed) and Embase and validated through Epistemonikos and Scholar Google. The last search was in March 27th, 2019.

**Results:** The literature search retrieved 1179 unique studies. At the end of the selection process, 8 studies were included in this review. 1 was an RCT and 7 were non-randomized studies of intervention, totaling 11787 participants: 8522 received generic antibiotics and 3625 received the original formulation. Microbiological cure was reported in 6 studies that included a total of 2372 individuals. Overall, no significant differences were observed between the generic and original formulation groups (OR=0.89, 95% CI: [0.61-1.28]). However, in this analysis, there was significant heterogeneity (I²=70%, p=0.005).

Drugs contain pharmaceutical solids that may exist in different conformations in the crystal structure, which may interfere with the processability of the drug, and slight differences in production processes can cause distortions in therapeutic equivalence. The efficacy and safety of GD products are ensured by relying on the scientific principles of bioequivalence studies.

Nevertheless, there may be distinct differences in terms of outcome and adverse events when used in a clinical setting. The validity of current bioequivalence criteria depends on the existence of a clear relationship between active metabolite concentration, therapeutic efficacy, and tolerability.

In this review, most studies had an observational design that resulted in considerable heterogeneity. The length of follow up, participant characteristics, and sites of infection were different between studies.

**Conclusions:** It is not possible to contraindicate the use of GD, but we must maintain a surveillance posture in their use. Evidence of therapeutic equivalence is weak.

Abstract 7174

**Sub-inhibitory concentrations of beta-lactam, aminoglycoside and polymyxin antibiotics induce differential proteomic responses in Pseudomonas aeruginosa**

Bart S. Jongers1,2, Kenny Bielen1, An Hotterbeekx1, Evy Timmerman1, Christine Lammens1, Herman Goossens1, Surbhi Malhotra-Kumar1, Samir Kumar-Singh1

1University of Antwerp, Antwerp, Belgium, 2Gent University, Gent, Belgium

**Background:** *P. aeruginosa* is one of the main causes of hospital-acquired pneumonia associated with high mortality and morbidity. Growing evidence suggest that select antibiotics such as imipenem/carbapenems induce biofilm formation and have clear influence on colony composition. Moreover, organisms recovered from respiratory samples from hospital-acquired pneumonia patients are polymicrobial, however, the microbial diversity is reduced in presence of *P. aeruginosa*. We questioned whether sub-MIC challenge of common empirically prescribed antibiotics induce upregulation of specific responses including those capable of killing non-pseudomonal bacteria.

**Materials/methods:** Four strains of *P. aeruginosa* (PAO1, ATCC27853, and 2 clinical isolates) were challenged for 5 hours with 1/4 MIC of imipenem or tobramycin and both cytosolic and secreted proteins were studied using TMT-tagged mass spectrometric analyses. We further validated these findings by qPCR.

**Results:** Proteomic analyses showed that imipenem pressure significantly increased expression of AlgR and AlgC (1.6–1.8 fold, P < 0.05), while B-type flagellin protein was reduced (1.5 folds, P = 0.08) indicating a switch to biofilm formation. Imipenem also significantly induced expression of main T6SS structural components, Hcp1 (2.3 fold, P < 0.05) and ClpV1 (1.6 fold, P = 0.07). Hcp1 was also significantly upregulated in secreted fraction (5.8 fold, P < 0.01), indicating an activated T6SS. Tobramycin induced a significant increase of several components of branched chain amino acid (BCAA) metabolism such as lipoamide acyltransferase component (BkdB) (2.2 fold, P < 0.01), LpdV, a dihydrolipoyl dehydrogenase, (1.9 fold, P < 0.01), MmsA and MmsB (2.4 fold, P < 0.001 and 2.5 fold, P < 0.01 respectively). Displaying a shift in metabolism towards BCAA catabolic processes.

**Conclusions:** This study identified unique pathways upregulated as a consequence of subinhibitory concentrations of antibiotics thus gaining further insight in the potential resistance mechanisms and cellular physiology. The significance of our research is in identifying the proteomic changes occurring in different *P. aeruginosa* isolates when stressed with sub-inhibitory concentrations of different antibiotic classes, conditions that are also known to occur in patients. The specific pathways identified here could be co-targeted along with already existing antibiotics for treatment purposes.

Implementing an antibiotic stewardship programme without increasing the surgical site infection rate in a highly antibiotic-resistant setting

Wael Harb¹, Farah Mansour¹, Jamil Mourad¹, Miguel Trelles¹, Anita Williams*²

¹MSF Bar Elias Hospital Project, Médecins Sans Frontières - Operational Centre Brussels, Bar Elias, Lebanon, ²Luxembourg Operational Research (LuxOR) Unit, Médecins Sans Frontières - Operational Centre Brussels, Luxembourg, Luxembourg

Abstract third-party references: Médecins Sans Frontières Luxembourg

Background: The Bar Elias Hospital, along the road from Damascus to Beirut, in the Bekaa Valley, Lebanon, was started in October 2018 in response to the minor general surgical and chronic wound care needs of populations in the surrounding areas. Excessive prescription of broad-spectrum antibiotics is typical practice in Lebanon. For this reason, priority was set on establishing an Antibiotic Stewardship Program (ASP) and a surgical site infection (SSI) surveillance system to guarantee rational antibiotic use whilst ensuring the SSI rate did not increase. This report shares the lessons learnt in implementing an ASP and SSI surveillance system in this context.

Materials/methods: Preparation for implementing the ASP began before the hospital was opened. Staff were trained on ASP on initiation of employment. Tools for monitoring the pre- and post-operative prophylaxis, antibiotic prescriptions and SSI monitoring are used and data is collected in an Excel database. The ASP Committee was established in October 2018 and includes the Deputy Medical Director, Pharmacist, Health Promoter, Laboratory Manager, Nurse Responsible, Medical Manager and Data Manager. Modified AWaRe classifications were used to limit access to antibiotics. For the SSI surveillance system, monitoring during follow-up visits was performed, along with outpatient department nurses contacting patients by phone 30 days after surgery.

Results: During the first 12 months of operation, 420 surgeries were performed; 326 clean surgeries (Class I Altmeier) and 94 clean-contaminated (Class II Altmeier) were performed. There was 99.7% compliance with guidelines for pre-prophylactic antibiotics during anaesthesia; however one case received a restricted antibiotic without appropriate approval. Four percent (13) of clean surgeries received post-surgical prophylaxis in conflict to guidelines, whilst 69% (65) of clean-contaminated surgeries received post-surgical prophylaxis in concordance with guidelines. Of the 326 clean surgeries performed, there was one SSI case reported, whilst there were no cases of SSI reported for the 94 clean-contaminated surgeries.

Conclusions: The results from the initial 12 months of this program are promising, and indicate that an ASP and SSI surveillance system can be employed in a culture of high antibiotic prescribing activity. There was no indication that the application of an ASP affected the SSI rate.

Genomic surveillance of *Bordetella* pertussis in Austria

Adriana Cabal Rosel*1, Daniela Schmid2, Markus Hell1, Elisabeth Mustafa3, Johannes Möst4, Eva Leitner4, Franz Allerberger2, Werner Ruppitsch2

1Austrian Agency for Health and Food Safety [AGES], Division of Public Health, Vienna, Austria, 2Austrian Agency for Health and Food Safety [AGES], Division of Public Health, Vienna, Austria, 3Medizinisch-chemisches Labor Medilab, Clinical microbiology and hygiene- dep., Teaching Lab of the Paracelsus Medical University, Salzburg, Austria, 4MB-LAB, Mikrobiologisches Labor, Innsbruck, Austria, 5Diagnostic & Research Institute of Hygiene, Microbiology and Environmental Medicine, Medical University of Graz, Graz, Austria

**Background:** Pertussis is a respiratory disease affecting mostly children and reemerging since the introduction of the acellular vaccines (ACVs) in the 90s. Strains that differ from the vaccine strain are a possible explanation for its increase worldwide. In Austria, the pertussis incidence in 2018 almost doubled in comparison to 2017. To explain this, we aimed at setting up an isolate-based surveillance system that complemented the case-based surveillance system, in order to characterize the collected isolates through whole genome sequence-based typing and to compare them with the vaccine strain.

**Materials/methods:** The surveillance system consisted of several microbiology laboratories servicing GPs and pediatricians in different Austrian provinces. Nasopharyngeal swabs for PCR and culture were collected from each pertussis case from May 2018 onwards. In the recovered isolates we identified 1) variants and mutations in the genes used as vaccine antigens (*ptxP, ptxS1, prn, fim2, fim3 and fhaB*) 2) genetic profiles, defined as the combination of the vaccine antigens genes 3) a new core genome Multi Locus Sequence Typing (cgMLST) scheme, comprising 2,938 genes, to detect clusters and assess the genetic relatedness among the isolates.

**Results:** Since May 2018, 60 isolates from 60 pertussis were recovered, being half of those vaccinated. Five genetic profiles were detected being the most frequent *ptxP3/ptxS1A/prn2/fim2/fim3-1/fhaB1*. None of them had the vaccine strain antigen profile. In addition, 42% of the isolates presented mutations in the *prn* gene causing pertactin deficiency, mostly originating from cases living in the same district, and more than the half of those were vaccinated. cgMLST revealed low variability among the clinical isolates (0-22 alleles), which was even lower (0-3) when intra-household transmission was confirmed, and high variability between the vaccine strain and the clinical isolates (>120 alleles). With a preliminary cluster threshold of ≤6 alleles, we identified 7 clusters. One of those grouped almost all pertactin-deficient isolates.

**Conclusions:** In conclusion, the circulating strains in Austria are different from the vaccine strain, being pertactin-deficient strains frequent, especially among vaccinated. cgMLST facilitated linking clusters with epidemiological data and therefore, we recommend its use together with vaccine genes typing to alert on *B. pertussis* outbreaks.

Abstract 7180

One Health investigation of Chlamydia psittaci in Denmark in 2019
Randi Føns Petersen1, Søren A. Uldum2, Øystein Angen2

1Statens Serum Institut, Dept. of Bacteria, Parasites and Fungi, København S, Denmark, 2Statens Serum Institut, København S, Denmark

Background: Ornithosis or psittacosis caused by Chlamydia (C.) psittaci is a zoonosis primarily transmitted from birds. Ornithosis is often regarded as sporadic events, and cases are rarely investigated by molecular or epidemiological analysis. Since the beginning of 2019 both the human and veterinary diagnostics of C. psittaci has been performed at Statens Serum Institut (SSI)/Dansk Veterinær Konsortium (DK-VET), allowing investigation of infections in a one-health perspective. This has provided excellent insight into an outbreak-situation of C. psittaci in Northern Zealand in the summer 2019

Materials/methods: The owner of a large private homing pigeon flock in Northern Zealand was hospitalised with pneumonia. Atypical pneumoniae was suspected and C. psittaci was detected by PCR on a sputum sample. Samples were collected from the trachea of the pigeon flock (30 birds) owned by the patient, and as these were found positive, 31 contact flocks were sampled and analysed. A total of 961 swab samples from the pigeons were collected and pooled 3 by 3 into 329 sample

At SSI a new C. psittaci specific qPCR was designed. A database was constructed based on all available Chlamydia assemblies from the NCBI RefSeq genomic database (ftp://ftp.ncbi.nlm.nih.gov/genomes/refseq/bacteria), in order to identify genes unique to C. psittaci. The target was chosen to include a psittaci-specific region. This region is absent in C. abortus as well as other closely related Chlamydia species.

Results: Ornithosis was laboratory confirmed in the hospitalised index patient. Six out of 10 pooled samples from his pigeon flock were confirmed C. psittaci positive, and a total of 40 samples were C. psittaci positive (12%) from 12 flocks (36%) of the 31 investigated contact flocks.

Conclusions: As 36% of the contact flocks were found positive, the question is raised whether there is a large silent pool of C. psittaci infected birds in Denmark that can cause a continuous spread of the infection, and cause cases of ornithosis in humans. The co-localization of the C. psittaci diagnostics for both humans and animals, supplemented with molecular identification and epidemiological analysis gives us the opportunity to investigate a potential C. psittaci reservoir in Denmark

Abstract 7182

The impact of H-NS-like protein on IncX3 plasmid dissemination and stability

Liu Baomo*1, Chao Zhuo1, Lili Shui1, Yingyi Guo1

1the First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: IncX3-type plasmids largely mediate the dissemination of NDM genes in China. IncX3 plasmid could stabilize in host strains for 1000 generations and bring host advantage to the strain. It remains unclear which protein can regulate bla_{NDM}-bearing IncX3 plasmids adapting to new hosts and further spreading in this bacterial family. We focus on a DNA stabilized protein H-NS-like protein harbored by the IncX3 plasmid backbone and explore its role in plasmid stability.

Materials/methods: After knocking down IncX3 plasmid-encoded hns gene, we used conjugation experiments to evaluate the difference of conjugation frequency of parent strain and hns-knocking-down strain at different temperatures. Then we estimated the expression levels of different pilX genes. Plasmid stability in host was tested by serially passaging for 10 days. Mice infection models were employed to check strains virulence.

Results: Under different temperatures, IncX3 from parent strain J330 could transfer to Ec600 at 37°C with highest conjugation frequency. (6.22X10^{-5} for 25°C, 3.34X10^{-5} for 30°C, 1.19X10^{-4} for 37°C, 4.57X10^{-5} for 42°C). Plasmid-encoded HNS-like protein could decrease conjugation frequency at different temperature. Transcription of several pilX genes (pilX4, 5, 9 10, conjugation-related genes) from IncX3 are upregulated in cells depleted of H-NS-like proteins. Plasmid stability test showed that HNS-like protein could decrease the percent of strains maintaining IncX3 plasmid(at day 10, 0.71% for J330 vs 3.93% for strains losing plasmid-encoded hns). J330 could not infect balb/c mice successfully, so the impact of HNS-like protein on strain virulence is unclear.

Conclusions: Plasmid-encoded HNS-like protein could repress plasmid tranfer between the same species at different temperature, as well as the plasmid stability. The actual role of HNS-like protein in strain virulence could not be detected and IncX3 plasmid is a resistance plasmid more than a virulence plasmid.

Abstract 7189

**Neuraminidase antibody response in a population vaccinated with split and adjuvant influenza vaccines**

Jose Manuel Mendez Legazá1, Iván Sanz1, Raúl Ortiz De Lejarazu1, Laura Sanchez De Prada*1

1Hospital Clínico Universitario de Valladolid, Valladolid, Spain

**Background:** Current licensed seasonal influenza vaccines (SIV) are only standardised for the hemagglutinin protein. Even so, clinical studies demonstrate that those vaccines contain immunogenic amounts of neuraminidase (NA), but the contribution of its immunogenicity to vaccine efficacy is currently not well studied. This study analyzes the increase in antibodies titers against the NA of different A(H1N1) viruses after SIV administration in two different age groups.

**Materials/methods:** The study included 160 pre and post-vaccination sera from adults [G1 = 80; 15-64yrs] and ≥65 years [G2 = 80], vaccinated with split and adjuvant influenza vaccine (AIV) against subtype A(H1N1)pdm09, respectively. Anti-neuraminidase antibodies (NAI) analysis was performed by using enzyme-linked-lectin-assay (ELLA) against five seasonal influenza strains of subtype A(H1N1) and the A/California/07/2009 strain of subtype A(H1N1)pdm09. Geometric means of NAI titers (GMTs) were analyzed. The increase of GMTs after vaccination (RIC) was compared according to the type of vaccine administered (α=0.05).

**Results:** Both split and AIV increased the titers of homologous and heterologous NAI against all influenza strains analyzed. The pre- and post-vaccination GMTs as well as the statistical comparison in the RIC according to the type of vaccine administered are described in Table 1.

Table 1. GMTs pre and post-vaccination and RIC of the NAI titers according to the seasonal influenza vaccine (SIV).

**Conclusions:** Our results showed the homologous and heterologous humoral response against neuraminidase influenza viruses after vaccination. Split vaccine induced a greater increase in the NAI titers with respect to the AIV against A/Weiss/43 and A/FM/1/47 strains. This difference seems to be linked to the fact that the population ≥65 years that received the adjuvant type vaccine had already very high NAI titers prior to vaccination against these two strains. Not only the type of vaccine administered seems relevant in the response to neuraminidase, but also the immunity previously acquired against the first infections during the life of an individual.

Abstract 7191

**Epidemiology and outcomes of respiratory syncytial virus Infection in haematopoietic cell transplant recipients: findings from a multinational respiratory viral infection consortium (RVIC)**

Dimpy Shah1, Mirella Salvatore2, Khush Patel3, Michael Satlin4, Sherif Mossad5, Jennifer Horan6, Cameron Wolfe7, Michele I. Morris8, Jose Camargo9, Maheen Abidi1, Pearlie Chong5, Donald Vinh9, Jesse Papenburg5, Behyar Zoghi10, Lakshmi Kannikanan1, Cinthya Silva11, Nelson Hamerschlag11, Sajjad Shete1

1University of Texas Health San Antonio, San Antonio, United States, 2Weill Cornell Medicine, New York, United States, 3University of Texas MD Anderson Cancer Center, Houston, United States, 4Cleveland Clinic, Cleveland, United States, 5Duke University, Durham, United States, 6University of Miami Miller School of Medicine, Miami, United States, 7University of Colorado, Denver, United States, 8University of Texas Southwestern, Dallas, United States, 9McGill University, Montreal, Canada, 10Methodist, San Antonio, United States, 11Hospital Israelita Albert Einstein, Sao Paulo, Brazil

**Background:** Respiratory syncytial virus (RSV) is a common infection with serious consequences in immunocompromised cancer patients especially in recipients of hematopoietic cell transplant (HCT). Due to the seasonal nature, limited resources, and non-standard reporting practices, the studies examining these infections have been limited to single, large, cancer centers. We aimed to establish a multinational respiratory viral infection consortium (RVIC) of 11 cancer centers from US, Canada, and Brazil to study RVI in HCT recipients.

**Materials/methods:** We employed consensus-based data collection instruments and trained data entry personnel to collect demographics, risk factors, diagnosis, treatment, and outcomes of all HCT recipients with laboratory confirmed RSV infections diagnosed between January 2010 and December 2016 in a comprehensive data repository and performed descriptive statistical analyses on completed records.

**Results:** Of the 325 HCT recipients, majority were non-Hispanic white (66%), males (56%) with a median age of 57 years (range: 18 – 79 years) presenting with a community acquired (90%) RSV infection of the upper respiratory tract (80%). Patients had undergone autologous HCT (33%) or allogeneic HCT matched related [21%], matched unrelated [23%], mismatched donor [4%], cord [15%], and haploidentical [4%] and most were in complete or partial remission (78%) of acute myeloid leukemia [27%] or multiple myeloma [24%] at the time of RSV diagnosis. Acute (13%) or chronic (19%) graft versus host disease was common and treated with more than >2mg/kg/week of systemic corticosteroids in 36% of patients. RSV was mainly detected by nasal wash (43%) or swab (51%) and progressed from URI to LRI in 12%. Both oral (53%) and aerosolized (47%) ribavirin-based antiviral therapy using a continuous (21%) or intermittent schedule (79%) over a median duration of 10 days (range: 1 to 28 days) was administered in 64% of the study cohort for URI or LRI. Burden of RSV included need of hospitalization (32%), ICU admission (15%), mechanical ventilation (8%), and RSV-associated death (15%).

**Conclusions:** RSV remains a common and significant infection in HCT recipients with substantial burden on patient and cancer centers. RVIC has been a successful endeavor in bringing together a multinational, multidisciplinary team to study RSV in this vulnerable population.

Abstract 7192

Plazomicin activity against carbapenemase-producing Enterobacterales carrying aminoglycoside-modifying enzymes from European and United States hospitals

Mariana Castanheira*, Timothy Doyle¹, Rodrigo E. Mendes¹, Jaideep Gogtay², Helio S. Sader¹

¹JMI Laboratories; North Liberty, United States, ²Cipla Ltd, Mumbai, India

Abstract third-party references: This study was performed by JMI Laboratories and supported by Cipla Ltd., which included funding for services related to preparing this abstract.

Background: Plazomicin is a next-generation aminoglycoside recently approved by the United States (US) Food and Drug Administration (FDA) for complicated urinary tract infections, including acute pyelonephritis caused by certain Enterobacterales species. We evaluated the activity of plazomicin and clinically available aminoglycosides against CPE isolates collected in European and US hospitals that also carried AMEs.

Materials/methods: Among 7,913 Enterobacterales isolates collected in European and US hospitals during 2017-2018 and susceptibility tested by CLSI reference broth microdilution methods, 280 were carbapenem-resistant Enterobacterales (CRE; CLSI criteria). These isolates were submitted to whole genome sequencing and data analysis to detect β-lactamases, AMEs and 16S rRNA methyltransferases (RNAmet).

Results: A total of 232 (82.9% of CRE and 2.9% overall) CPEs were identified among the 280 CRE isolates. These isolates carried genes encoding KPC-2, KPC-3, NDM-1 and OXA-48-like enzymes (48, 64, 29 [6 producing OXA-48] and 19 isolates, respectively). RNAmet that encode resistance to all aminoglycosides, including plazomicin (US FDA breakpoint) were detected in 66 (28.4%) CPE isolates. All but 1 of these isolates was from Europe and armA was the most common RNAmet (56 isolates). Among the 166 isolates that did not carry RNAmet, 110 harbored AMEs (91 from Europe and 19 from US). Among the most common AME genes that modify clinically important aminoglycosides were aac(6’)-Ib [57 isolates], aac(6’)-Ib-cr [41] and aac(3)-Ila [39]. Amikacin and gentamicin were only active against 40.9% and 43.6% of these isolates (EUCAST breakpoints), respectively. Plazomicin inhibited 97.3% of the CPE isolates carrying AME genes at the US FDA approved breakpoints. Gentamicin displayed greater activity against Enterobacterales isolates when compared to US isolates (47.3% and 26.3%, respectively), but the activity of amikacin (40.7%/42.1% susceptible [Europe/US]) and plazomicin (100.0%/96.7%) was similar for both regions. Tobramycin had limited activity against these isolates (<2.0% susceptible). Only 1 NDM-1-producing Providencia stuartii from Romania carried the gene aac(2’)-Ia, which encodes the AME that modifies plazomicin.

Conclusions: Plazomicin displayed greater in vitro activity when compared to amikacin and gentamicin against CPE isolates that do not carry RNAmet and its activity is not affected by commonly detected AMEs in US and European hospitals.

Validation of three MicroScan antibiotic susceptibility testing microplates designed for low-resource settings

Jean-Baptiste Ronat*1, Saoussen Oueslati2, Alessandra Natale1, Olivier Vandenberg3, Jan Jacobs4, Thierry Naas2

1Doctors Without Borders, Paris, France, 2Bicetre Hospital AP-HP, Le Kremlin-Bicêtre, France, 3CHU Saint-Pierre, Bruxelles, Belgium, 4Institute of Tropical Medicine Antwerp, Antwerpen, Belgium

Abstract third-party references: Médecins Sans Frontières

Background: The Mini-lab is a Médecins Sans Frontières (MSF) project for the development of an all-in-one clinical bacteriology laboratory (CBL) deployable in low-resource settings (LRS). AST is essential in CBL, to improve patient treatment and limit the emergence of antimicrobial resistance. Three microplates were designed by choosing a list of antibiotics based on bloodstream infection (BSI) pathogens, MSF field needs, surveillance and public health importance. MicroScan lyophilized broth microdilution plates (Beckman Coulter Inc., Sacramento, USA) were chosen, co-developed and tested as they provide standardized, long shelf life, robust and easy-to-use by none-expert microbiology technicians.

Materials/methods: The MSF MicroScan Gram Pos microplate (C32698) for Staphylococcus and Enterococcus species, MSF MicroScan Gram Neg microplate (C32699) for Gram-negative bacilli and MSF MicroScan Fastidious microplate (C32700) for Streptococcus and Haemophilus species were validated with frozen isolates from routine clinical laboratories and challenging isolates coming from low resource settings, following ISO20776-2:2007 guidance. In total, 123 Gram-positive isolates (representing 7 different Gram-positive species), 157 Gram-negative isolates (representing 15 different gram-negative species), and 107 fastidious isolates (representing 8 different fastidious species), were tested. The three microplates were tested against EUCAST V9 recommended Disc diffusion, gradient diffusion method (E-test) or standard micro-broth dilutions.

Results: From the 16 antibiotics present on the three panels for treatment orientation all of them had a percentage of Category Agreement (CA) above 90% and major (MAJ) and very major error (VMJ) below 3%. On the MSF MicroScan Gram Pos panels for Staphylococcus spp, penicillinase-stable beta-lactams indicators had a CA of 99%, inducible clindamycin had a CA of 100%, while for Enterococcus spp, high-level aminoglycoside resistance indicators had a CA of 96% with only 2% MAJ and VMJ. On the MSF MicroScan Gram Neg panels, Extended Beta Lactamase, colistin and carbapenem indicators had presented a CA of 99%, 98% and 100% respectively for all species.

Conclusions: The 3 MSF MicroScan AST microplates was to that excellent performances with the clinical isolates from LRS and also other including pathogens such as Non-typhi Salmonella, Streptococcus pneumoniae and Haemophilus influenza. These often cause BSI in LRS but have been rarely tested on these microplates.

Abstract 7196

Characterisation of Group B streptococci (GBS) colonising pregnant women in Belgium, 2018: antimicrobial susceptibility profile and distributions of capsular-types, pili-types and sequence-types

Cécile Meex*1, Solène Douillez1, Amélie Kinet1, Rosalie Sacheli1, Pierrette Melin1

1University Hospital of Liège, National Reference Center Streptococcus agalactiae, Clinical Microbiology, Liège, Belgium

Background: To update the knowledge of key epidemiological features of group B streptococcus (GBS) colonizing pregnant women’s vagina and/or rectum is important in the process of development of a vaccine to prevent GBS neonatal disease. As in 2013, the Belgian National Reference Center Streptococcus agalactiae (NRC) renewed in 2018 an epidemiological surveillance study.

Materials/methods: GBS strains isolated from pregnant women’s vagino-rectal swabs were sent to the NRC between October 2017 and March 2018 by laboratories of the Belgian sentinel network and of Luxembourg. Five isolates were expected per laboratory. For each strain, the capsular-poly saccharide (CPS) type and the pili-type were determined by multiplex-PCR. The antimicrobial susceptibility testing was performed according to EUCAST criteria by disk-diffusion and broth-microdilution. Multiple-Locus Sequence-Typing (MLST) was performed on serotype III strains and the gene hvgA was detected by PCR.

Results: A total of 228 strains of GBS have been sent from 46 laboratories. Serotype III, Ia and V were the 3 predominant serotypes, representing 25%, 23.7% and 23.7% of the cases, respectively, followed by serotype II in 14.47% of the cases. All GBS strains expressed at least one of the three pili proteins, with the couple Pi1, Pi2a being predominant (51.75%). All strains remained susceptible to penicillin. The resistance rates to erythromycin and clindamycin were 27.63% and 24.56%, respectively. Among these macrolides/lincosamides resistant GBS, the constitutive resistance phenotype was predominant [56.06%] and ErmB and ErmTr were the most frequent detected genes, in 37.88% and 27.27% of cases, respectively. The most prevalent sequence-type among serotype III GBS was ST17 in 40.35% of cases.

Conclusions: Among GBS isolated from colonized pregnant women in Belgium in 2018, we observed, compared to our previous 2013 data, an increase of serotypes Ia and V, being now practically equal to serotype III. On the other hand, pili distribution and MLST profiles among type III strains were quite similar. All the strains remained totally susceptible to penicillin and the resistance rate to macrolides and lincosamides was stable compared to 2013.

Abstract 7200

Dynamic interactions between methicillin-resistant *Staphylococcus aureus* and methicillin-sensible *Staphylococcus aureus* contamination of the near patient and extended environment and patient colonisation revealed by whole genome sequencing in a tertiary referral hospital

Peter Kinnevey1, Aoife Kearney1, Megan Earls1, Toney Poovelikunnel1, Grainne Brennan1, Anna Shore1, Hilary Humphreys1,2, David C. Coleman1

1Dublin Dental University Hospital, Dublin, Ireland, 2Beaumont Hospital, Dublin, Ireland, 3St. James’s Hospital, Dublin, Ireland

**Background:** The transmission dynamics of methicillin-susceptible *S. aureus* (MSSA) and methicillin-resistant *S. aureus* (MRSA) between patients, their near environment and extended-environmental sites on nine wards of a tertiary referral hospital was investigated using whole-genome sequencing (WGS) during a non-outbreak period.

**Materials/methods:** Nasal-swab and oral rinse samples were obtained from consenting patients over three collection phases, 2017-2019. Samples were also taken from patient lockers, bedframes and mattress using sterile-neutralisation swabs. Air samples (500 L) were taken in each ward using an air sampler (Oxoid/Thermo Scientific). All samples were cultured on MRSAselect and SAselect chromogenic agars (Colorex) with methicillin-resistance confirmed using 30-μg cefoxitin disks (Oxoid). Additional MRSAselect and SAselect contact plate samples were taken from frequent hand-touch sites. Representative patient and environmental isolates selected on their antibiogram susceptibility profiles underwent Illumina whole-genome sequencing (WGS) and whole-genome multilocus-sequence typing (wgMLST; BioNumerics). Isolates exhibiting <24 wgMLST allelic differences were deemed related.

**Results:** MRSA and MSSA were recovered from 27/388 (6.9%) and 129/388 (33.2%) patients, respectively. A total of 1164 samples from near-patient environment sites yielded 13 MRSA and 58 MSSA corresponding to 57/388 (14.7%) near-patient environments. Air samples from 445 locations yielded 23 MRSA and 65 MSSA, whereas 21 MRSA and 73 MSSA were recovered from 1110 samples from frequent hand-touch sites. WGS was undertaken for environmental isolates associated with 29/57 near-patient environments including 12 colonised and 17 uncolonised patients whose near environments yielded MRSA or MSSA. Relatedness determined by wgMLST analysis was detected in 4/12 instances between pairs of isolates recovered from a colonised patient and their near environment. Isolates from the remaining eight colonised patients were unrelated to isolates from their near environment. Isolates recovered from air or additional environmental sampling were unrelated to patient isolates recovered from the 29 patients or near environments.

**Conclusions:** Considerable contamination of patients’ near and extended ward environment sites with MRSA and MSSA was detected. WGS identified patients as the likely source of near-environmental site contamination in 4/29 (13.8%) instances, implying another source of contamination in the majority of cases. This underpins the importance of regular decontamination and cleaning of ward surfaces in the acute setting.

Plasticity in a bacterial global regulator drives the switch to antibiotic resistance and virulence

Annapaula Correia1, Emma Manners1, Benjamin Evans*,1, Jacob Malone2,3, Justin O’grady1,4, Sergio Arminu1, Manuela Usai1, Stuart Mcmillan5, Gemma Kay1,4, Claire Hill1,4, Padhmanand Sudhakar4,6, Emma Meader7, Katarzyna Schmidt7, Tamas Korcsmaros4,6, Andrew Desbois5, Lisa Crossman1,3,8, John Wain1,4, Gemma Langridge1,4

1University of East Anglia, Norwich Medical School, Norwich, United Kingdom, 2John Innes Centre, Norwich, United Kingdom, 3University of East Anglia, School of Biological Sciences, Norwich, United Kingdom, 4Quadram Institute, Norwich, United Kingdom, 5University of Stirling, Institute of aquaculture, Stirling, United Kingdom, 6Earlham Institute, Norwich, United Kingdom, 7Norfolk and Norwich University Hospital, Microbiology Department, Norwich, United Kingdom, 8SequenceAnalysis.co.uk, Norwich, United Kingdom

Background: The ability to adapt rapidly to a changing environment is key for bacteria to be able to survive the ever-changing conditions they are exposed to. The inducible MexEF-OprN efflux pump, involved in antibiotic resistance, substrate import, toxin export and quorum sensing, is regulated by the global transcriptional regulator MexT, which is suppressed by MexS. Mutations in mexT and mexS in P. aeruginosa are associated with changes in antibiotic sensitivity and virulence. We investigated why such mutations arise so frequently and assessed their phenotypic impact.

Materials/methods: 151 clinical and environmental P. aeruginosa isolates were collected and sequenced. Strain PAO1 was used to construct a strain with an 8bp deletion in mexT (PAΔ) and select for a ciprofloxacin resistant strain with a mutation in mexT (PAn). All strains had MICs of ciprofloxacin, chloramphenicol and imipenem determined. Antibiotic-resistant mutants and subsequently antibiotic-sensitive revertants were selected from 33 strains in vitro, and sequenced. The strains PAO1, PAΔ and PAn underwent transcriptomics, virulence assays in Galleria mellonella, and metabolic phenotyping of 626 compounds.

Results: Analysis of strains PAO1, PAΔ, PAn, and in vitro selected strains, showed that P. aeruginosa switches from an antibiotic-sensitive to an antibiotic-resistant phenotype through MexT-induced increased efflux due to inactivating mutations in mexS. Transcriptomics showed altered expression of 1/6th of the genome (~900 genes) in the MexT-active/MexS-inactive strains PAΔ and PAn relative to PAO1, including reduced expression of virulence-related genes. Strains PAΔ and PAn were less virulent than PAO1 in the G. mellonella infection model, and were less metabolically active. In the absence of selective pressure, antibiotic-resistant strains reverted to sensitivity through mutations in mexT rather than a reversion to the ancestral genotype (i.e. reactivation of mexS).

Conclusions: Exposure to antibiotics selects for a loss of homeostatic control of efflux, which is not regained upon removal of antibiotic selection. This suggests that an evolutionary ratchet drives bacteria towards switching between an antibiotic-resistant but less virulent phenotype and an antibiotic-sensitive virulent phenotype, but does not enable a return to the ancestral state. This then enables subsequent unrelated antibiotic resistance mutations to produce strains that are simultaneously highly resistant and virulent.

Abstract 7205

**Evaluation of Myco-TB TM kit for decontamination of urine and stool specimens to detect mycobacteria**

Roberta Grossi*, Angela Careddu1, Rosario Nicotra2, Maurizio Sanguinetti1,2, Michela Sali1,2

1Dipartimento di Scienze di Laboratorio e Infettivologiche, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy, 2Istituto di Microbiologia, Università Cattolica del Sacro Cuore, Rome, Italy

**Background:** During the last decade, remarkable progress has been made in the diagnostics of pulmonary tuberculosis; however, diagnostic challenges in extra-pulmonary tuberculosis (EPTB) remain to be addressed. Diagnosis of EPTB is difficult due to the pauci-bacillary nature of disease. Most of the extra-pulmonary specimens (such as body fluids, aspirates, pus, urine and stool) need decontamination but certain decontaminating agents eliminate a substantial number of mycobacteria together with the contaminants, while others are too weak to destroy them. The resulting consequence is a costly delay in detecting the tubercle bacilli thereby slowing down the process of initiation of therapy. The aim of this study was to evaluate Myco-TB TM (Copan Italia, Brescia) in sample pretreatment, compared to the N-acetyl-L-cysteine–sodium hydroxide (NALC-NaOH) decontamination and fluidization method, for the detection of the *Mycobacterium tuberculosis* complex (MTBC) and Non Tuberculous Mycobacteria (NTM) in urine and stool specimens.

**Materials/methods:** A total of 120 urine and 90 stool specimens has been collected from clinically suspected cases of EPTB. Each sample has been divided into two equal parts and decontaminated by using the ready-to-use kit Myco-TB TM kit and classical NALC-NaOH decontamination protocol then investigated using Ziehl-Neelsen method, the Lowenstein-Jensen culture and the Real-Time PCR Anyplex MTB/NTM test.

**Results:** Stool and urine treated with Myco-TB system shown a significant reduction in bacteria load compared to NALC-NaOH decontamination (reduction of 11% for urine and 20% for stool). The Anyplex MTB/NTM test underlined an improvement in for samples treated with Myco-TB system. Furthermore, no contamination was detected following the treatment with this innovative system.

**Conclusions:** Our findings suggest that Myco-TB is an effective and faster decontamination tool for extrapulmonary clinical specimens as urine and stool. Particularly, this approach allows to reduce microbial contaminants and to efficiently remove inhibitors for molecular assays increasing the specificity and significantly reducing the invalid tests.

Abstract 7208

Long-lasting outbreak of *Serratia marcescens* in a veterinary hospital due to contaminated chlorhexidine

Nicolas Keck1, Antoine Dunié-Mérigot1, Melody Dazas1, Edouard Hicchaud4, Stéphanie Laurence1, Béatrice Gervais1, Jean-Yves Madec2, Marisa Haenni*3

1Laboratoire Départemental Vétérinaire de l’Hérault, Montpellier, France, 2Centre Hospitalier Vétérinaire Languedocia, Montpellier, France, 3Université de Lyon – Anses site de Lyon, Unité Antibiorésistance et Virulence Bactériennes, Lyon, France, 4ANSES Ploufragan-Flouzané-Niort Laboratory, Viral Genetic and Biosecurity Unit, Ploufragan, France

**Background:** Companion animals can be infected or colonized by bacteria, some of them representing both an animal and public health issue. These bacteria can spread within veterinary settings and cause Healthcare-Associated Infections (HAI) with various epidemiological facets. Our aim was to characterize the long-term occurrence of HAI due to *S. marcescens* in a French veterinary hospital.

**Materials/methods:** The study was conducted from September 2009 to September 2018 on 66 animals (45 dogs, 19 cats, 2 rabbits) from which one *S. marcescens* isolate was collected. Identification was performed using MALDI-TOF and antimicrobial susceptibility was tested by disc diffusion. All isolates were typed by XbaI-PFGE and five representative isolates were whole-genome sequenced using the NovaSeq technology.

**Results:** Epidemiological data unambiguously indicated that 32 isolates were HAI cases, mostly associated with surgical site infections. *S. marcescens* isolates were also found as surgical site colonizers without infection (n=22). The monthly incidence of *S. marcescens* isolation showed two clusters (September to December 2009, and March 2014 to September 2018) belonging to two distinct PFGE profiles. All isolates showed the intrinsic antibiotic resistance profile of this bacterial species. In January 2019, a large environmental sampling of the clinic demonstrated that *S. marcescens* was only present in 1% chlorhexidine impregnated gauze tubes, and that these environmental isolates shared exactly the same PFGE profile as animal isolates, which was further confirmed by the NGS data. All animal *S. marcescens* isolates also showed high MIC values for chlorhexidine (128 mg/L). Chlorhexidine tubs were banned from the hospital and disinfection gauzes are now prepared instantly.

**Conclusions:** This study reports the first long-term occurrence of HAI due to *S. marcescens* in a veterinary hospital due to contaminated chlorhexidine. The mode of transmission was undoubtedly direct inoculation of the bacteria onto the surgical site during skin disinfection procedures. The absence of any detection of *S. marcescens* between 2009 and 2014 is most likely due to the relocation of the clinic in new premises at the end of 2009, but without changes in hygiene procedures. Measures have now been taken and no *S. marcescens* was found at the time of writing (6 months).

Abstract 7210

Brucellosis in different types of transplantation
Mohammad Mahdi Rabiei1, Fariba Imanzadeh1, Ilad Alavidarazam*1,2, Shervin Shokouhi1

1Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Clinical Research Development Center, Loghman Hakim Hospital Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background: Brucellosis, a bacterial disease caused by Brucella species, is one of the most important zoonotic diseases worldwide. Brucella can affect all organs of the human body and has different and numerous manifestations. It is an intracellular microorganism with particular immunologic response, which is different from other intracellular bacteria. In addition, it is less likely to theoretically transmit through various organs in body. The behavior and manifestations of Brucella in transplant recipients has not yet been comprehensively studied. The purpose of this study was to evaluate brucellosis in all types of transplant patients.

Materials/methods: Total cases of brucellosis in transplant patients with no time and language limitations were searched and retrieved using the following keywords: Brucella, Brucellosis, Transplant, and Transplantation through medical databases, including Google Scholar, Scopus, PubMed, and SID. All clinical features, including the time of transmission (before, during, and after transplantation), considered treatments and patients’ outcomes were investigated.

Results: Fifteen cases reported in 15 studies (out of 777 studies) were retrieved. Kidney (46.6%), liver (26.6%), and hematopoietic stem cell transplantation (HSCT) (13.3%) were the most reported types of transplantation. The majority of cases were related to the Middle East countries, including Turkey (five studies), followed by Saudi Arabia (4 studies) and Iran (2 studies). The presentation of brucellosis in 40% of the patients has been occurred in the early post-transplantation period, whereas in 60% of the cases it was late-onset. Transmission by donor had been reported in rare cases of HSCT. The most clinical features of the disease were fever (80%), headache (33.3%), musculoskeletal pain (33.3%), and sweating (26.6%).

Conclusions: Brucellosis in transplant recipients seems to be uncommon even in the endemic regions. However, rare cases could be transmitted through bone marrow transplantation and transfusion. Precise screening and meticulous supervision during and after transplantation can lead to a reduction in the frequency of brucellosis.

Presenter email address: ilad13@yahoo.com
**Background:** The plasma exposures of posaconazole improve with the newer formulations of intravenous (IV) injection and delayed-release tablet. The targeted plasma concentrations (Cp) of posaconazole are >700 ng/mL for prophylaxis and >1250 ng/mL for treatment. Lack of consensus on the upper limit of therapeutic range but 1830, 2000, or 3750 ng/mL was proposed to prevent hepatotoxicity. This study aimed to compare posaconazole Cp between IV and tablet and to explore the association between Cp and hepatotoxicity.

**Materials/methods:** This retrospective study enrolled adult patients who received IV posaconazole in a 2600-bed medical center in Taiwan between December, 2018 and September, 2019. The use of posaconazole IV and tablet formulations and trough Cp were evaluated. Liver function tests such as ALT, AST, ALP, GGT and bilirubin were documented. Nonparametric tests were applied due to small sample size. Statistical analyses were conducted with SPSS with a two-tailed $\alpha$ value of 0.05 as statistical significance.

**Results:** Twenty-eight patients receiving IV posaconazole were included and all of them had haematological malignancies. Their median age was 53.3 years old (range: 22-74) and more females (18/28, 64.3%) in the study. There were 23 patients (82.1%) on posaconazole for prophylaxis. The overall median posaconazole Cp was 1100 ng/mL (range 160-3480). No significant difference of Cp was observed between IV (1310 ± 747 ng/mL) and tablet (1240 ± 742 ng/mL). Approximately 25% of Cp failed to achieve targets: 13/77 Cp (16.9%) on prophylaxis with 1 breakthrough invasive fungal infection and 16/39 on treatment (41.0%). Elevations of ALT and bilirubin were the most frequent laboratory abnormalities. Although ALT elevation was generally mild, there was a significant association between increased ALT and individual posaconazole Cp >1830 ng/mL (P=0.02). Increase of direct bilirubin was associated with average Cp >2000 ng/mL in therapy courses (P=0.005).

**Conclusions:** Similar distribution of posaconazole Cp in IV and tablet formulations was demonstrated in this study. One fourth of patients had sub-therapeutic Cp. Elevation of liver enzymes most likely occurred when Cp >1830 ng/mL. Clinicians should consider monitoring of Cp during IV and tablet posaconazole therapy to improve effectiveness and safety.

Abstract 7212

Detection of Zika and Chikungunya viruses circulation in Pointe Noire district (Republic of Congo) during the 2019 Chikungunya outbreak

Claudia Fortuna1, Francesco Severini1, Michela Menegon1, Marco Di Luca1, Giulietta Venturi1, Aubierge Victoire Kimpamboudi Matondo2, Justin Imboua3, Medard Saint Gauhy3, Christian Boungou4, Amedeo Suardi4, Filippo Uberti5, Giovanni Rezza1

1Istituto Superiore di Sanità, Rome, Italy, 2Ministère de la Santé – Direction Departementale de la Santé de Pointe Noire, Pointe Noire, Congo, 3Ministère de la Santé – Departement de la Santé de Pointe Noire, Pointe Noire, Congo, 4ENI, Pointe Noire, Congo, 5ENI, Milano, Italy

Background: On 9 January 2019, the health authorities notified to the WHO and outbreak of chikungunya in the Republic of Congo. A risk assessment was carried out by the Italian Istituto Superiore di Sanità in collaboration with ENI and the Department of Health of Pointe-Noire to evaluate the potential exposure to chikungunya virus (CHIKV) and other vector-borne virus infections.

Materials/methods: Mosquitoes were collected in different sites of the urban and sub-urban area of Pointe-Noire, which was considered the epicenter of the outbreak, to detect the possible presence of CHIKV and other arboviruses. Field collected mosquitoes were identified, pooled and analyzed by real-time RT-PCR for the presence of genome of Zika, dengue, chikungunya, West Nile, Usutu, Yellow fever, Rift Valley, and Japanese encephalitis viruses. Culex was the most commonly detected genus.

Results: The identification of some mosquito species and full genome analysis of virus isolates are in progress. However, preliminary analyses showed the positivity of 3 Culex quinquefasciatus mosquito pools to Zika virus (ZIKV). Furthermore, molecular tests performed on the blood of a symptomatic child showed a double infection by CHIKV and ZIKV. The girl lived in the same district of Pointe-Noire where the ZIKV positive Culex mosquitoes were collected.

Conclusions: Our results show the circulation in the region, beside CHIKV, also of ZIKV, and highlight the possible role of the genus Culex in the transmission of ZIKV. The low level detection of Aedes spp. mosquitoes was probably due the limited number of typical Aedes larval breeding sites compared to other more suitable for Culex species in the dry season.

Abstract 7214

First case of osteomyelitis caused by hypervirulent Klebsiella pneumoniae spread within a family in Korea

Jeong Dong Chae*, Chang-Hun Lee¹, Won Ho Choe¹, Hyo Young Lee¹, Yong-Hak Sohn²

¹Eulji University Eulji Hospital, Eulji University Eulji Hospital, Seoul, South Korea, ²Seegene Medical Foundation, Seoul, South Korea

Background: A new “hypervirulent” K. pneumoniae (hvKP) with hypermucoviscosity has emerged as a clinically significant pathogen causing highly invasive infections, such as liver abscesses, in both healthy and immunocompromised individuals. We present a case of osteomyelitis due to hypervirulent K. pneumoniae spread within a family reported in Korea.

Materials/methods: We characterized two isolates from blood sample of patient and stool sample of husband for their antimicrobial susceptibility, VITEK-2 system and genetic relatedness using capsular typing, multilocus sequence typing (MLST). Whole genome sequencing and comparative genomics analysis of strains of K. pneumoniae were determined by MiSeq (300bp paired end) by (Chunlab, Seoul, Korea).

Results: Both isolates were susceptible to all antibiotics except for ampicillin and showed hypermucoviscosity by a positive string test. K. pneumoniae isolates found to be a K1 serotype, sequence type 23 (ST23). Comparative genomics analysis presented with a phylogenetic tree analysis (Fig. 1.) and Venn diagram. A phylogenetic tree shows that two isolates of this case are closely related to liver abscess isolate in Taiwan and femoral bone isolate in United States. Carbapenem-resistant K. pneumoniae strain and carbapenem-resistant hypervirulent K pneumoniae strains in China are closely related. Venn diagram depicts the comparative Venn diagram of 6 hypervirulent K pneumoniae sharing a lot of genes (4475) and two isolates of this case are closely related than other isolates.

Conclusions: we report a first case of osteomyelitis caused by hypervirulent Klebsiella pneumoniae spread within a family in Korea. Microbiologists and clinicians need to become more aware of the possible severity of infections caused by this strain of K. pneumoniae.

Evaluation of the Revogene Carba C assay for detection and differentiation of carbapenemase-producing bacteria
Delphine Girlich¹, Marine Laguide¹, Laurent Dortet¹, Thierry Naas*¹²

¹Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, ²Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: Rapid confirmation of carbapenemase production (CP) is essential not only for an effective therapy, but also for the prompt implementation of infection control measures in order to prevent CP-Enterobacterales (CP-E) dissemination. We have evaluated the performance of the novel, real-time PCR-based Revogene® Carba C Assay for the detection of blaKPC, blaNDM, blaVIM, blaOXA-48-like, and blaIMP genes.

Materials/methods: Revogene® Carba C Assay is a multiplex nucleic acid-based in-vitro diagnostic test that runs on the microfluidic Revogene platform (Meridian Bioscience, Cincinnati, OH, USA) and intended for CP-E detection from cultured colonies. It was evaluated on colonies of 120 well-characterized Enterobacterales with reduced susceptibility to carbapenems, on 50 MDR Pseudomonas aeruginosa (Pa) and 40 MDR Acinetobacter baumannii (Ab).

Results: The GenePOC™ Carba Assay’s performances were high as it was able to detect the five major carbapenemases in Enterobacterales with nearly 100% sensitivity, except for OXA-48 with 97.4%, as one distantly related variant OXA-535, was not detected. All double and triple carbapenemase producers were detected. When extrapolating the results to the French CP-E epidemiology between 2012-2018, the Revogene® Carba C Assay would have detected 99.3% of the 9624 CPEs sent to the F-NRC, missing 69 CPEs [2 GES-5; 10 OXA-23; 2 TMB-1; 1 SME-4; 54 IMI, 1 FRI].

Similarly, when extrapolating the results to the French epidemiology of CP-Pa it would have been able to detect 94% of them, missing only one DIM, 11 GES-variants and two rare IMP variants [IMP-31 and IMP-46]. However, only 15.9% of CP-Ab could be detected, as the most prevalent carbapenemase in that species is OXA-23.

Conclusions: The Revogene® Carba C Assay showed excellent sensitivity and specificity for the five most common carbapenemases, including IMP variants that are not detected by all molecular assays. It is well adapted to the CP-E and CP-Pa epidemiology of many countries worldwide. Its simplicity and short turnaround time make it suitable for use in the routine microbiology laboratory. It can provide results from colonies that grew on MH but also from selective screening media. This assay needs now to be evaluated directly on clinical samples.

Presenter email address: thierry.naas@aphp.fr
In vitro activity of delafloxacin against highly-levofloxacin-resistant invasive isolates of Streptococcus pneumoniae

Emilia Cercenado*, Cristina Loras1, Alejandro Cobos1, Juan Carlos Sanz1

1University Hospital Gregorio Marañón, Servicio de Microbiología, Hospital Gregorio Marañón, Madrid, Spain, 2Hospital Universitario de Getafe, Getafe (Madrid), Spain, 3Laboratorio Regional de Salud Pública, Madrid, Spain

Background: The emergence of multidrug-resistant non-PCV-13 Streptococcus pneumoniae isolates causing invasive disease is a cause of concern. Delafloxacin is a new anionic fluoroquinolone equally potent against topoisomerase IV and DNA gyrase, with high intracellular penetration and enhanced bactericidal activity under acidic conditions. We studied the activity of delafloxacin against highly-levofloxacin-resistant invasive strains of Streptococcus pneumoniae.

Materials/methods: A total of 114 highly-levofloxacin-resistant (MIC >32 mg/L) S.pneumoniae invasive isolates received at a Reference Laboratory from March 2008 to June 2019 were studied. The origins were blood (n=109), pleural fluid (n=3), cerebrospinal fluid (n=1) ascitic fluid (n=1). Capsular serotypes were analysed by the Pneumotest-Latex and by the Quellung reaction using commercial antisera (Statens Serum Institut, Copenhagen, Denmark). Delafloxacin, levofloxacin, penicillin, cefotaxime, erythromycin, and vancomycin MICs were determined by the gradient diffusion method (Etest®; bioMerieux, France).

Results: The distribution of serotypes/serogroups were 8 (n=60), 19V (n=22), 4 (n=12), 15A (n=9), 19A (n=2), 33 (n=2), 31 (n=1), 11A (n=1), 12F (n=1), 15C (n=1), 18C (n=1), 35B (n=1) and 35F (n=1), being 87.7% non-PCV-13 serotypes. A total of 47 (41.2%) isolates were penicillin non-susceptible (MIC>0.06 mg/L), 27 (23.7%) were cefotaxime non-susceptible (MIC>0.5 mg/L), and 80 (70.2%) were erythromycin resistant (MIC>0.5 mg/L). Delafloxacin MIC50 and MIC90 (mg/L) values against the 114 levofloxacin-resistant isolates were 0.06 and 0.19, respectively, (range 0.01 - 1.0 mg/L). All isolates were susceptible to vancomycin. MIC distributions for delafloxacin against the pneumococcal strains is shown in the table.

Conclusions: This study shows that delafloxacin is a very active agent against multi-drug resistant invasive isolates of S.pneumoniae including highly-levofloxacin-resistant isolates, being at least >32-fold more potent than levofloxacin. The potency of delafloxacin makes it a good addition to the therapeutic arsenal for the treatment of multidrug resistant pneumococci.

Table. Antimicrobial activity of delafloxacin tested against highly-levofloxacin-resistant (MIC>32 mg/L) S. pneumoniae.

| Number and cumulative % of isolates inhibited at delafloxacin MIC (mg/L) of: | 0.01 | 0.02 | 0.03 | 0.04 | 0.05 | 0.06 | 0.09 | 0.12 | 0.19 | 0.25 | 0.38 | 0.50 | 0.75 | 1 |

Abstract third-party references: Supported by Department of Anesthesiology and Intensive Care, University of Leipzig Medical Center, Leipzig, Germany, On behalf of Dr. Philipp Simon

Background: Antibiotics are often administered at a fixed dose, often without taking into account essential individual pharmacokinetic influencing factors. Obesity influences the pharmacokinetics of antibiotics due to changes in distribution volumes, blood flow and elimination rate. Underdosing of antibiotics promotes the development of multi-resistant bacteria in addition to severe consequences for individual patients. In this clinical study, perioperative antibiotic prophylaxis prior to abdominal surgery was used as a clinical-pharmacological model for the single administration of antibiotics. We investigated the hypothesis that meropenem plasma and subcutaneous interstitial space fluid (ISF) exposure in obese patients are lower compared to non-obese patients.

Materials/methods: The study was approved by the local Ethics Commission and the Federal Institute for Drugs and Medical Devices of Germany (EudraCT No. 2012-004383-22). We included patients prior to elective abdominal surgery with BMI ≥ 35 kg/m² or 18.5 ≤ BMI ≤ 30 kg/m² matched for age and sex. An intravenous bolus of 1000 mg meropenem was infused for 30 min starting 60 min prior to skin incision. The determination of meropenem concentration in ISF was performed by microdialysis via catheters placed subcutaneously in both upper arms, preoperatively. Catheters were calibrated by retrodialysis. Serial blood and tissue samples were collected in fractions from 0.5 to 8 h after infusion and meropenem was determined in the samples by HPLC and UV detection. Noncompartmental analysis was performed in R 3.6.0 and the PKNCA package (v0.9.1). P-value < 0.05 was considered statistically significant.

Results: 30 patients were included (15 obese BMI = 49 ± 11 kg/m²; 15 non-obese BMI = 24 ± 2 kg/m²). In contrast to plasma, meropenem concentrations in ISF in the obese group (Figure 1) were lower than in the non-obese group with significantly lower maximum concentrations (median Cmax 11.9 vs. 18.0 mg/L, p = 0.011). The distribution volume in the obese group was higher (25.9 vs. 22.9 L, p = 0.013), the half-life longer (1.6 vs. 1.3 h, p = 0.014) and clearance comparable (12.5 vs. 10.9 L/h, p = 0.41).

Conclusions: During the first hours after single administration of meropenem obese patients had significantly lower ISF concentrations. Depending on different MICs this may have an effect on target attainment. Therefore further analyses are necessary.

Figure 1: Concentration-time-curves (mean ± standard deviation) of meropenem in plasma and interstitial space fluid (ISF) of subcutaneous adipose tissue; dashed lines show relevant MIC for meropenem (EUCAST breakpoints 2019)

Abstract 7219

Positive respiratory viral panel results moderately shorten antibiotic duration in patients with presumed respiratory tract infections

J. Emily Von Bulow¹, Leah Rodriguez¹, Sara Lee¹, Kaede Ota Sullivan²,³, Jason Gallagher¹,²
¹Temple University School of Pharmacy, Philadelphia, United States, ²Temple University Hospital, Philadelphia, United States, ³Lewis Katz School of Medicine at Temple University, Philadelphia, United States

Background: Respiratory viral panels (RVPs) can detect multiple viral pathogens and give clinicians diagnostic confidence to discontinue antibiotics. However, relatively little is known about how these tests influence antibiotic prescribing in hospital settings.

Materials/methods: This was a retrospective chart review of patients who had RVPs performed while receiving antibiotics. Hospitalized adults receiving antibiotics at the time of the RVP were included. Exclusion criteria included ICU care, solid organ transplantation (SOT), positive RVP for influenza, positive bacterial cultures, and antibiotic administration for other bacterial infection or prophylaxis. A multivariate linear regression model was created to investigate associations with longer antibiotic use after the RVP result.

Results: 2587 patients were screened and 451 met inclusion criteria; 249 in the positive RVP group and 252 in the negative RVP group. Primary reasons for exclusion were SOT, ICU, and influenza diagnosis. No significant differences existed between groups. Of the patients with a positive RVP, rhinovirus was isolated in 156 (64.5%), followed by metapneumovirus (35, 14.9%) and RSV (32, 13.3%).

Table. Characteristics of patients by test

<table>
<thead>

<td>3.8 (2.4)</td>
<td>3.6 (2.4)</td>
<td>3.7 (2.4)</td>
</tr>
<tr>
<td>Antibiotics discontinued within 24 hours of RVP, n [%]</td>
<td>109 (43.8)</td>
<td>93 (46)</td>
<td>202 (44.8)</td>
</tr>
</tbody>
</table>

On multivariate analysis, factors that were significantly associated with longer antibiotic duration after RVP were length of stay (0.22 days, p=<0.0001), immunocompromised state (0.32 days, p=0.001), and a PMH of asthma (0.2 days, p=0.0355). A positive RVP was associated with a shorter duration of antibiotics after the test result (0.22 days, p=0.0133).

Conclusions: Positive RVP results were associated with a moderately shorter duration of antibiotics. More rapid assays may hasten time to discontinuation of unneeded antibiotics.

Abstract 7220

**Graphene oxide-linezolid combination as potential new anti-TB treatment**

Flavio De Maio¹², Valentina Palmieri³⁴, Alessandro Salusti³, Giordano Perini³, Ivana Palucci¹², Michela Sali¹², Maurizio Sanguinetti¹², Marco De Spirito¹⁴, Giovanni Delogu²⁵, Massimiliano Papi³⁴

¹Fondazione Policlinico Universitario A. Gemelli, IRCCS, Institute of Microbiology, Rome, Italy, ²Università Cattolica del Sacro Cuore, Institute of Microbiology, Rome, Italy, ³Università Cattolica del Sacro Cuore, Institute of Physics, Rome, Italy, ⁴Fondazione Policlinico Universitario A. Gemelli, IRCCS, Institute of Physics, Rome, Italy, ⁵Mater Olbia Hospital, Olbia, Italy

**Background:** Tuberculosis (TB) remains one of the most alarming worldwide infectious disease and there is an urgent need for improved drugs and treatments, particularly for the emergence and spread of drug-resistant Mycobacterium tuberculosis (Mtb) strains. New nanotechnologies based on carbon nanomaterials are now being considered to improve anti-TB treatments and graphene oxide (GO) showed interesting properties as anti TB drug. GO preferentially accumulates in the lungs and it is quickly degraded by macrophagic peroxidases. Additionally, it has a high drug loading capacity and intrinsic antibacterial properties. GO can trap Mycobacterium smegmatis and Mtb in a dose-dependent manner, reducing entry of bacilli into macrophages, but not much is known about interaction with anti-TB drugs.

**Materials/methods:** Combination of anti-TB drugs and GO anti-mycobacterial properties have been evaluated on Mtb H37Rv by using a modified synergy checkerboard assay. Isoniazid (INH), Amikacin (AMK) and Linezolid (LZD) have been selected and minimal inhibitory concentration (MIC) assessed in presence of GO. Murine macrophages (J774) were used as in vitro infection model, and colonies forming units (CFUs) were evaluated at 4 hours and 24 hours post infection.

**Results:** Synergy checkerboard assay highlighted different activity of the GO when incubated with INH, AMK or LZD. Interestingly, INH and AMK activity inversely correlated with GO concentrations. Conversely, LZD MIC was reduced when GO was co-administered. We studied the interaction between GO and the selected anti-TB drugs observing a strong interaction with INH and LZD. GO-INH/AMK interaction, and not GO-LZD, promoted a significant aggregation in solution. Combinations of GO and LZD were tested in an in vitro infection model highlighted a higher anti-TB activity than the single compounds at four hours post infection. Surprisingly, a capacity to reduce CFUs were still observed when GO-LZD was administrated 4 hours post infection and CFUs evaluated at 24 hours.

**Conclusions:** GO-LZD co-administration is potentially a new promising anti-TB treatment at the forefront in fighting emerging antibiotic resistant Mtb strains. Importantly, LZD is suggested to treat MDR-TB together with fluoroquinolones and bedaquiline. Even though other studies are needed, this innovative pharmacological approach leads to reduce treatment periods and decrease or mitigate antibiotic adverse effects.

Abstract 7221

Regional outbreaks of Enterobacter cloacae complex NDM-1 in Poland, 2015-19

Radosław Izdebski*, Paweł Urbanowicz1, Marta Biedrzycka1, Dorota Zabicka1, Elżbieta Literacka1, Waleria Hryniewicz1, Marek Gniadkowski1

1National Medicines Institute, Warsaw, Poland

Background: Since 2011 Poland has recorded NDM-producing Enterobacteriaceae, including large Klebsiella pneumoniae ST11 NDM-1 multi-regional outbreak, approaching rapidly to endemic situation, and much smaller regional outbreak of K. pneumoniae ST147 NDM-1 imported in 2015 from Tunisia. Here we extend our previous observations, by presenting two regional dissem-
inations of Enterobacter cloacae complex NDM-1 based on the WGS data.

Materials/methods: The study comprised 82 unique NDM-positive E. cloacae complex isolates, since the first identification in October 2015 till the end of August 2019. NDMs were detected by CarbaNP and PCR, followed by sequencing. All isolates were
typed by MLST. Polymorphism of blaNDM-carrying Tn125-like elements was assessed by PCR-mapping. Twenty-seven isolates
representing the temporal and geographical scale of the outbreak, as well single K. pneumoniae and Escherichia coli NDM-posi-
tive isolates co-identified with E. cloacae complex in the same materials were subjected to WGS by Illumina MiSeq. The polymor-
phism of blaNDM-carrying Tn125-like elements was re-analysed using the DNASTAR software. Resistomes of the isolates were
determined using ResFinder.

Results: The MLST analysis revealed 7 profiles: ST89 (n=59), ST146 (n=16), ST114 (n=2), ST1303 (n=2), ST56 (n=1), ST198 (n=1) and ST231 (n=1). Five Tn125 derivatives were found, with the most numerous comprising 2994bp fragment from the up-
stream ISAba125 3' end (253bp) to the 5' part of the tat gene (806bp) characteristic for K. pneumoniae/ST11/NDM-1 outbreak
(n=71) and 5353bp element from 253bp 3'end of tnpA ISAba125 to 1250 5'end of groEL typical for “Tunisian” K. pneumoniae/
ST147/NDM-1. “Endemic” variant of Tn125 was detected among ST89 (n=8), all ST146, ST1303 (n=2), ST114 (n=1) and ST198
(n=1), whereas “Tunisian” only in ST89 (n=8). K. pneumoniae and E. coli NDM-positive isolates represented identical Tn125
polymorphs as co-morbid E. cloacae complex isolates, revealing horizontal transfer between species. Analysis of resistomes
of two main clones, ST89 and ST146, showed very similar profiles within groups, with ST146 possessing much less acquired
resistance genes.

Conclusions: The results documented horizontal transfer of Tn125 polymorphs from K. pneumoniae ST11 and ST147, followed
by clonal dissemination of two E. cloacae complex clones in Poland: ST89, recently described as E. hormaechei ssp. steiger-
waltii, and ST146.

Development of two new techniques based on real-time PCR for the detection of Candida auris in clinical settings
Leticia Bernal Martinez*1, Ana Cecilia Mesa1, Laura De Francisco1, Alicia Gomez Lopez1, María José Buitrago1
1Carlos III Health Institute, Majadahonda, Spain

Background: Candida auris is an emerging fungal pathogen associated with nosocomial outbreaks and high mortality rates. This species is often misidentified as it is phylogenetically close to other Candida spp. In order to improve their detection in clinical settings, specific primers and probes for C. auris were designed and included in a multiplex real-time PCR (MRT-PCR) technique previously described (Fortun et al., 2014). The assay was standardized and validated with strains and sera samples spiked with DNA. A technique based in High Resolution Melting (HRM) was also developed to fast identify clinical strains.

Materials/methods: For MRT-PCR assay, Beacon Designer 9.1 software (Premier Biosoft,) was used to design specific primers and a molecular Beacon probe targeting rDNA region. The technique was optimized and included in a previous assay that detected C. glabrata, C. krusei and C. guilliermondii. Sensitivity, specificity and reproducibility were determined: i) Standard lines were constructed by using 5 repetitions of dilutions of genomic DNA from 1 ng to 1 fg / µl of each pathogen, ii) specificity was tested including other fungal species and human DNA. Validation was performed by using clinical strains and sera samples spiked with different DNA amounts (10ng to 200 fg). For HRM assay the ITS2 region of the rDNA was amplified using the universal primers ITS3 and ITS4. Six species of Candida spp. close-related to C. auris were included in the HRM assay.

Results: The MRT-PCR assay presented a high reproducibility detecting up to 100 fg of DNA/µl of sample. No cross-reaction was detected when other fungal species were included in the assay. Coefficient of variation was 3 %. The technique detected all strains included (7/7) and all sera samples (7/7). The analysis of HRM allowed to discriminate the six species included in the assay.

Conclusions: 1) The new MRT-PCR assay that detects four species of the genus Candida including C. auris presented a high sensitivity, reproducibility and specificity, although further validation will be required. 2) The method developed to identify C. auris based on HRM, was able to discriminate the species included and it could be a simple tool to identify this emerging species.

Abstract 7229

**Antibiotic resistance and efflux pump inhibitor effect in Acinetobacter baumannii strains isolated from Cajamarca, Peru**

Isaac Alberto Pena Tuesta¹, Wilmer Silva Caso¹, Nicolas Lopez-Chegne², Miguel Angel Aguilar Luis¹,³, Hugo Carrillo-Ng¹,³, Jorge Bazan-Mayra¹, Victor Zavaleta Gavidia¹, Saul Levy Blitcähtein¹,³, Juana Del Valle-Mendoza¹,³

¹Universidad Peruana de Ciencias Aplicadas, Research and Innovation Centre of the Faculty of Health Sciences, Chorrillos, Peru, ²Regional Hospital of Cajamarca, Cajamarca, Peru, ³Instituto De Investigación Nutricional, La Molina, Peru, ⁴DIRESA Cajamarca, Laboratorio Regional de Cajamarca, Cercado de Lima, Peru

**Abstract third-party references:** Universidad Peruana de Ciencias Aplicadas, Instituto de Investigación Nutricional

**Background:** Acinetobacter baumannii is a nosocomial pathogen that thrives alarmingly in intensive care units due to its ability to adapt and develop mechanisms of antibiotic resistance. Recent studies in Peru show that most infections are caused by multi-resistant (MDR) and extremely resistant (XDR) strains of this pathogen. Efflux pumps represent an important mechanism for resistance development on this bacteria.

**Materials/methods:** In this study, the antibiotic susceptibility of 47 A. baumannii strains isolated from Cajamarca, Peru were evaluated. Antibiotic susceptibility was assessed by disk diffusion on Mueller-Hinton agar plates, following the Clinical and Laboratory Standards Institute (CLSI) guidelines for the following antibiotics: ampicillin-sulbactam, piperacillin-tazobactam, cefotaxime, cefazidime, cefepime, gentamicin, amikacin, levofloxacin, doxycycline, tetracycline, meropenem, imipenem, trimethoprim-sulfamethoxazole and colistin. The effect of phenylalanine-arginine B-naphthylamide on the Minimum Inhibitory Concentration [MIC] of levofloxacin, tetracycline and amikacin was determined based on a 4-fold or greater reduction as the criterion for significance.

**Results:** All the isolates were resistant to at least one antibiotic agent in three or more categories. One isolate (2.13%) proved to be resistant to all the antibiotics tested and was classified as pan-drug-resistant (PDR) and 25 isolates (53.19%) presented an XDR phenotype, the majority being susceptible to colistin. The remaining 21 isolates (44.68%) were considered MDR. After phenylalanine-arginine B-naphthylamide addition: 8.51% of the isolates (4/47) showed a significant reduction with levofloxacin, 59.57% (28/47) with tetracycline and 31.91% (15/47) with amikacin.

**Conclusions:** Acinetobacter baumannii strains demonstrated MDR and XDR profiles of antibiotic resistance, which is an important nosocomial and public health concern. The addition of the efflux pump inhibitor PABN resulted in a reduction of the non-susceptibility for levofloxacin, tetracycline and amikacin. Efflux pump inhibitors may be useful as adjunct therapy for this pathogen if they significantly improve antimicrobial susceptibility in further larger studies and prove to be safe.

Abstract 7231

**Evaluation of T2MR for the diagnosis of bloodstream infections in paediatric patients**

Barbara Lucignano¹, Livia Mancinelli¹, Manuela Onori¹, Marilena Agosta*, Enrico Masiello², Laura Lancella¹, Andrea Onetti Muda³, Paola Bernaschi⁴

¹Bambino Gesù Children’s Hospital - IRCCS, Microbiology Unit, Laboratory Department, Rome, Italy, ²Bambino Gesù Childrens’ Hospital - IRCCS, Pediatric and Infectious Diseases Unit, Rome, Italy, ³Bambino Gesù Children’s Hospital - IRCCS, Laboratory Department, Rome, Italy, ⁴Bambino Gesù Childrens Hospital IRCCS, Microbiology Unit, Rome, Italy

**Background:** Bloodstream infection (BSI) is one of the major sources of mortality among hospitalized patients. A prompt and appropriate antibiotic therapy is critical to reduce morbidity and address a favorable clinical outcome. Cultural methods are the "gold standard" although they require too long times.

The molecular technology T2 magnetic resonance (T2MR) uses two diagnostic panels (T2Candida and T2Bacteria) to detect yeasts and bacteria directly from whole-blood samples within 3-5 hours, in a fully automated process.

Objective of the study is to evaluate the T2MR for rapid detection of pathogens in blood samples of paediatric patients with suspected BSI. Results were compared with those of blood culture (BC) and with the LightCycler Septifast test, a PCR Real-Time for the identification of bacterial and fungal DNA.

**Materials/methods:** A total of 226 paediatric patients, admitted to the Bambino Gesù Children's Hospital from May 2018 to November 2019, were included in the study and blood samples were contextually analyzed for T2Bacteria and/or T2 Candida, BC and Septifast. The recommended minimal blood volume samples for T2 testing is 3 ml. When less volume was occurring, samples were diluted or loading was performed through direct pipetting of whole blood directly onto the T2 cartridge.

**Results:** For T2Bacteria a 76% overall PPA was detected and a NPA of 95%. For T2Candida panel PPA was 100% and NPA 98%. Statistical analysis was elaborated for T2 bacteria including only not diluted samples and an increase of sensitivity and specificity was obtained (PPA 83%; NPA 96%). A total of 70/282 (25%) samples provided discordant results due to these possible reasons: BC and Septifast not performed or with discordant result. A T2 positive result, not confirmed by BC and Septifast, was evaluated in conjunction with clinical presentation and/or other laboratory markers.

**Conclusions:** T2MR assay can be used to efficiently diagnose BSI caused by bacteria and yeasts from paediatric specimens. This technology shows a significantly faster time to identify microorganisms than a culture-dependent system and this could result in improved time to appropriate pharmacological therapy.

**Presenter email address:** marilena.agosta@gmail.com
Characteristics of the initial phase of tick-borne encephalitis
Petra Bogovic*, Stanka Lotric-Furlan¹, Katarina Ogrinc¹, Tatjana Avsic², Franc Strle¹

¹University Medical Centre Ljubljana, Department of Infectious Diseases, Ljubljana, Slovenia, ²Medical Faculty, University of Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia

Background: TBE usually has a biphasic course. Reliable information on the initial phase is limited. Recognition that febrile illness was the initial phase of TBE typically occurs only after the onset of the second, meningoencephalitic phase of the disease and development of antibodies to TBE virus (TBEV). In the initial phase the infection can be confirmed by the presence of TBEV in serum but this is not a routine diagnostic approach.

Materials/methods: 98 patients, seen at the initial and second phase of TBE at our centre during 2003–2019, in whom infection with TBEV was identified with PCR in the initial phase serum specimens, qualified for the present report. The samples were obtained either during a prospective study on the etiology of febrile illness after a tick bite (78 patients, 80%) or represented remnants of the samples collected as a part of routine diagnostic testing of a patient with a febrile illness in whom TBE later developed (20 patients).

Results: Of 98 patients (median age 51, IQR 39–61 years), 47 (48%) were males. The most common signs/symptoms were malaise/fatigue [98% of patients], fever [89%; the highest temperature 38.5 (38.0–39.0) ºC], headache [86%], myalgias [54%], arthralgias [43%], gastrointestinal symptoms [46%; nausea/vomiting 38%, mild diarrhea 16%], and respiratory symptoms [18%; sore throat 10%, cough 10%]. 88% of patients had leukopenia, 51% thrombocytopenia, and 60% at least one abnormal liver function test result. IgM antibodies to TBEV in serum were present in 2 patients, none was IgG positive. Duration of the initial phase of TBE was 7 (6–8) days. 37 (38%) patients were hospitalized for median 3 (1–5) days.

Of 78 patients who were included in the prospective study and systematically followed for ≥2 months, 5 (6%) did not develop any further symptoms, 5 had mild and unimpressive symptoms potentially suggesting nervous system involvement but did not undergo CSF examination, while 68 (87%) patients developed clear-cut neurologic involvement associated with CSF pleocytosis. All the patients seroconverted.

Conclusions: The initial phase of TBE may be quite severe. A large majority of patients with initial phase of TBE later develops meningoencephalitis.

Nasal colonisation with *Staphylococcus aureus* is a risk factor for ventricular assist device infection in the first year after implantation: a single-centre cohort study

Dennis Nurjadi*1, Katharina Last1, Sabrina Klein1, Sebastien Boutin1, Bastian Schmack2, Florian Mueller2, Klaus Heeg1, Arjang Ruhparwar1, Alexandra Heininger1, Philipp Zanger1,4

1Heidelberg University Hospital, Department of Infectious Diseases, Heidelberg, Germany, 2Heidelberg University Hospital, Department of Cardiac Surgery, Heidelberg, Germany, 3Essen University Hospital, Department of Cardiac Surgery, Essen, Germany, 4Heidelberg University Hospital, Heidelberg Institute of Global Health, Heidelberg, Germany

**Background:** *S. aureus* nasal colonization is a risk factor for the acquisition of post-operative wound infections. *S. aureus* infections in patients with implanted ventricular assist device (VAD) have detrimental effect on the overall morbidity and mortality. In this study we prospectively investigated *S. aureus* nasal colonization as the source of endogenous infections in this vulnerable patient group with a special focus on the onset of *S. aureus* infection. Better knowledge on the temporal component of *S. aureus* infection dynamics in VAD patients may provide the necessary evidence for optimized preventive interventions.

**Materials/methods:** Single-center, prospective cohort study (n=49) to (i) evaluate the risk of *S. aureus* nasal colonization for VAD-related *S. aureus* infection in patients with implanted VAD and (ii) determine the time to infection onset after implantation. Patients admitted for VAD implantation were screened for *S. aureus* colonization prior to surgical intervention with follow-up until heart transplant, death or end of study period. Endogenous infections were confirmed by WGS.

**Results:** Among 49 patients (17 colonized, 32 non-colonized), *S. aureus* VAD-infections by *S. aureus* occurred after 60 days post-implantation. Those colonized with *S. aureus* were at a significantly higher risk of acquiring VAD-related *S. aureus* infections compared to non-carriers (9/17, 52.9% vs. 4/32, 12.5%, P=0.005; IRs 2.81 vs. 0.61/1000 pdys; IRR 4.65, 95% CI 1.30-20.65, P=0.009). 75% (6/8) of paired *S. aureus* samples from colonized patients with VAD-infection showed concordant core genomes.

**Conclusions:** In patients with durable VAD, *S. aureus* nasal colonization is a source of endogenous infection throughout the first year after device-implantation, affecting mostly the driveline, and accounting for about half of VAD-infections. Due to the late infection onset, VAD-patients may still benefit from post-operative decolonization if pre-operative decolonization could not be performed. Our findings suggest that decolonization strategies may need to be adapted and optimized for this patient group to accommodate for late onset of infection.

Abstract 7237

One-year evaluation of Genelead VIII combined to Deeplex-MycTB to detect rapidly the genotype and the resistance profile of Mycobacterium tuberculosis complex directly from clinical samples

Isabelle Bonnet*1,2, Sabrina Goumghar1, Gérald Millot1, Jérémy Jaffré1,2, Alexandra Aubry1,2, Jerome Robert1,2, Wladimir Sougakoff1,2

1APHP, Laboratoire de Bactériologie-Hygiène, Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux (CNR-MyRMA), Paris, France, 2Sorbonne Universités, Inserm, Centre d’Immunologie et des Maladies Infectieuses (CIMI-Paris), UMR 1135, Paris, France

Background: For quickly starting suitable treatment to increase the chance of cure and reduce transmissibility of the disease, early and accurate identification of complete tuberculosis (TB) drug resistance profile is needed. The Genelead VIII is a new all-in-one system that extracts and detects Mycobacterium tuberculosis complex (MTBC) DNA from clinical samples. Deeplex-MycTB is based on the next-generation sequencing of PCR fragments amplified from extracted DNA and can predict the genotype and the resistance profile of 13 anti-tuberculous drugs. This study reports a one-year routine evaluation of the coupling of these two technologies applied directly to clinical samples.

Materials/methods: 52 clinical samples, with a positive (N=35) or a negative (N=17) microscopic examination, were tested from May 2018 to June 2019 in the French National Reference Center for Mycobacteria (CNR MyRMA). The results were compared (i) with the culture for Genelead VIII, and (ii) with the standard genotypic and phenotypic drug susceptibility testing for Deeplex-MycTB. When a spoligotype was shared by at least two strains, the MIRU-VNTR typing was performed for these strains.

Results: Overall, the combination of Genelead VIII to Deeplex-MycTB identified MTBC and drug resistance in 27 of the 35 (77%) smear positive- and 3 of the 17 (18%) smear negative samples. The Genelead VIII results were fully concordant with those of the culture for smear-positive samples and were 65% concordant for the tests carried out on smear-negative samples. The Deeplex-MycTB assay following Genelead VIII extraction gave interpretable results in 52% of the tests done in the study. Most of the failed tests corresponded to samples with a negative microscopic examination or less than 1 AFB per field. Deeplex-based drug susceptibility predictions were 83% concordant with the phenotypic method, and 91% with the genotypic ones. The median time to obtention of full results from clinical samples was 8 days.

Conclusions: The combined approach Genelead VIII-Deeplex-MycTB represents real progress for quickly identifying (8 days) MTBC and for determining the drug resistance profiles of M. tuberculosis directly from clinical samples. This tool could be very helpful, especially for choosing the most suitable therapeutic regimen to treat multidrug- and extensively drug-resistant TB.

Background: Viral metagenomics next-generation sequencing (mNGS) enables the comprehensive characterization of viral communities in clinical samples. Despite a wide range of potential applications, several hurdles need to be overcome before its implementation in clinical lab. In particular, reagent contaminations (kitome) may critically impair the interpretation of the results. A growing number of studies have developed methods to address this issue, but mainly evaluated for the identification of bacterial contaminants. In this study, we aimed to compare various approaches for the detection of viral contaminants in mNGS data.

Materials/methods: We used a data set corresponding to 236 plasma samples, prospectively collected from multiple myeloma patients. These samples were sequenced in 19 batches using a validated mNGS protocol. One no-template control (NTC) per batch was also processed through the complete workflow. The detection of viral contaminants was performed through (1) the batch effect analysis [2] the comparison of viral abundances between NTC and clinical samples with DESeq2 and [3] Decontam package which includes two methods; one is based on the relationship between read counts and biomass and the second is based on the comparison of the prevalence between NTC and patient samples.

Results: We found that the batch effect approach and methods of the Decontam package identified at random the contaminant status of viral families or genera. Conversely, the differential approach comparing viral abundances between clinical samples versus NTC provided much better classification performances. This classification was based on three criteria, including fold change, significance and background noise. Using these criteria, we generated a list of potential contaminants that mainly derived from bacteriophages or plant viruses. Interestingly, some of these contaminants were found differentially abundant between patients and could have been misinterpreted as clinically relevant.

Conclusions: To our knowledge, this is the first study assessing different computational methods for the kitome identification in viral metagenomic data. Our data highlight that specific approaches are needed to detect viral contaminants and should be systematically applied to avoid clinical misinterpretation.

Candida auris compared to other Candida spp. candidaemia: a two-year experience in a Spanish tertiary hospital

Juan Vicente Mulet*1, Nuria Tormo1, Carme Salvador1, Reme Guna1, Maríà Martínez-Serrano1, Roberto Olmos1, Begoña Fuster1, Manuel Belda1, Concepción Gimeno Cardona1

1Consorci Hospital General Universitari de Vallència, València, Spain

Background: Candida auris is a novel Candida species, first reported in Japan in 2009, which is associated with nosocomial outbreaks, especially in intensive care units. In our setting, a 500-bed tertiary hospital, there is an ongoing C. auris outbreak since September, 2017; and, despite the implementation of different control measures (e.g. periodic screening for C. auris colonization), we still report cases. The aim of this study is to describe the characteristics of patients with C. auris compared to other Candida spp. candidaemia episodes.

Materials/methods: Candida species were isolated by our routine laboratory procedure. Briefly, blood samples are incubated in BD Bactec® FX for 14 days. When the sample flags positive, and the gram stain reveals the presence of yeasts, subculture is performed in Sabouraud-Chloramphenicol. Candida isolates are further identified by MALDI-TOF (Bruker®) and susceptibility testing is carried out. Demographic and clinical relevant data were retrospectively collected in a 2-year period of all candidaemia episodes from the beginning of the C. auris outbreak (September 2017 to September 2019).

Results: The main results of the study are shown in the table below. Among all clinical underlying conditions, digestive disease/abdominal surgery was selected for being the most frequent. Some patients were infected by two or more different species simultaneously or in the same hospitalization period.

<table>

</tr>
</tbody>
</table>

*C.albicans [36/91, 39.6%], C.glabrata [18/91, 19.8%], C.parapsilosis [8/91, 8.8%], other species [13/91, 14.3%].

Conclusions: C. auris is the second cause of candidaemia following C. albicans two years after the outbreak started [33.0%]. Most patients had an underlying condition of digestive disease. This is especially important in C. auris, reaching 70.0%. C. auris seemed to cause less mortality at day 30 than other Candida spp. This could be related to the younger age of patients affected by C. auris.

Dengue virus infects HBMEC cell model and regulates proteins related to the blood-brain barrier function

Jianhai Yu*, Xiaoen He¹, Xuling Liu¹, Wei Zhao¹

¹Southern Medical University, Guangzhou, China

Background: The clinical characteristics of dengue are changing, and neurological manifestations in dengue cases with fatal outcomes are being reported more frequently, although dengue was long regarded as a non-neurotropic virus. Although dengue antigen has been detected with different laboratory techniques in the brain, it is still not completely understood how dengue virus (DENV) gains entry into the CNS.

Materials/methods: Human brain microvascular endothelial cells (HBMEC) cell model was used to study the mechanism of DENV crossing the blood-brain barrier. We identified the susceptibility of four serotypes of dengue virus to HBMEC cells, and applied transcriptome sequencing to find genes that were differentially expressed when HBMEC cells were infected with DENV3. Finally, the dynamic changes of proteins with different gene expression were detected to verify key regulatory proteins related to the blood-brain barrier function.

Results: All four serotypes of DENV are susceptible to HBMEC cells, of which DENV3 is the strongest. DENV persistent virus replication was observed after infection, accompanied by CPE. Infection of the CNS by DENV3 may correlate with the expression of specific chemokines, tight junction proteins (TJPs), and cell adhesion molecules (CAMs). The expression of GM-CSF, GRO-α, MCP-2, MIG, and RANTES shown significant increase, especially RANTES increased by 1.5 fold at day 1 after MOI-5 infection, and remained significantly high at days 2 and 3 compared to uninfected cells. As the TJP, the expression of ZO-1 and claudin-1 sharply increased at day 1, and declined to near baseline levels at day 2. It is worth noting that, we did observe an obviously increase in VCAM-1 transcripts at post infection, while no significant increase in CAM expression was observed in control cells. However, the increase in VCAM-1 protein levels was not observed.

Conclusions: DENV manifests strong infectivity in blood-brain barrier-associated HBMEC cell model. Dynamic changes in protein, such as RANTES for specific chemokines, ZO-1 and claudin-1 for TJPs, and VCAM-1 for CAMs, imply that DENV infection of HBMECs could destroy the integrity of the BBB, which facilitate the entry of cell-free virus into the CNS.

Abstract 7246

Epidemiology, risk factors and treatment of anaerobic bloodstream infections: a 7-year study

Ruth Figueroa-Cerón¹, Mikele Macho², Ander Gonzalez Sarria²*, Cristina Aspichueta², Mikel Urrutikoetxea-Gutierrez², Felicitas Elena Calvo Muro², Jose Luis Diaz De Tuesta²

¹Basurtuko unibertsitate ospitalea, Osakidetza, Bilbo, Spain, ²Basurtuko unibertsitate ospitalea, Osakidetza, Bilbo, Spain

Abstract third-party references: University Hospital Basurto

Background: Anaerobic bacteria can cause life threatening bloodstream infections. Anaerobic bloodstream are rare, but have high mortality. The objective of this study is to describe the epidemiology of bloodstream anaerobic infections from blood culture, clinical risk factors and the use of empirical treatment over 5 years, between January 2014 and January 2019, at a tertiary care hospital with 680 beds.

Materials/methods: Retrospective and descriptive study of patients with bloodstream infections. Between January 2014 and December 2018, blood cultures bottles were submitted 42,607 for analysis from 25,565 patients. The medical records of patients with positive blood cultures, microbiological data of the isolates and the epidemiological, clinical and therapeutic variables of the patients have been reviewed.

Results: 79 clinical cases of true anaerobic bacteremia were identified. The mean age was 68.53 years (range 30-90), 40 were male and 39 were female. The majority 46 (58.22%) had at least one comorbidity, and 10 (12.65%) had two or more comorbidities, in 33 (71.73%) of the cases it was a neoplasm. The main focus of bacteremia was abdominal (70.87%), followed by skin and soft tissues (21.51%). The most frequently isolated anaerobes were the following: Bacteroides fragilis (35.44%), Bacteroides thetaiotaomicron (20.25%), Bacteroides spp. (7.59%), Clostridium perfringens (6.32%), Clostridium septicum (3.79%), Parabacteroides distasonis (1.26%), Prevotella spp. (1.26%), Fusobacterium nucleatum (2.53%) Finegoldia magna spp. (1.26%), Peptostreptococcus (1.26%). The most commonly used empirical antibiotic treatment was Piperacillin / Tazobactam in 46.83% of the cases, followed by amoxicillin / ac. clavulanic 13.92% and ertapenem 7.59%. Mortality was 20 (25.31%) directly related to bloodstream infections.

Conclusions: Cancer patients have a greater predisposition for anaerobic bloodstream infections (71.73%). The prevalence of Bacteroides spp. (63%) and Clostridium spp. (10%) may reflect the dominance of intra-abdominal sepsis in anaerobic bloodstream infections. In most cases the empirical antibiotic treatment was adequate.

Abstract 7247

**Delivering antibiotics locally to biofilms by targeted drug delivery and prodrug therapy**

Rikke Louise Meyer*1, Raoul Walther2, Signe Maria Nielsen1, Pernille Ommen Andersen1, Line Hansen1, Rikke Christiansen2, Hieu Quang1, Jørgen Kjems1, Alexander Zelikin2

1Aarhus University, Interdisciplinary Nanoscience Center, Aarhus C, Denmark, 2Aarhus University, Department of Chemistry, Aarhus C, Denmark

**Background:** Antibiotic treatment of biofilm infections often fail because the dose that can be administered safely is insufficient to eradicate the biofilm, which contains antibiotic-tolerant persister cells. We hypothesize that treatment will be more effective if drugs are delivered or synthesized at the site of infection, leading to a high local concentration with minimal side effects. We aimed at delivering a high local dose of antibiotics through two different approaches: i) targeted delivery of encapsulated antibiotics, and ii) local drug synthesis through prodrug therapy.

**Materials/methods:** Targeted drug delivery uses drug encapsulation, accumulation in the biofilm, and a triggered burst release. We encapsulated vancomycin and rifampicin in temperature-sensitive liposomes decorated with aptamers that bind specifically to *Staphylococcus aureus*. Accumulation, drug release, and kill efficiency was quantified on *S. aureus* biofilms in vitro.

Prodrug therapy uses immobilized enzymes (glucuronidase) to convert non-toxic glucuronide prodrugs to the active drug. We developed a novel method for synthesizing glucuronide prodrugs, opening the door for antimicrobial prodrug therapy for the first time. We immobilized the catalyst (β-glucuronidase) in a layer-by-layer coating on titanium implants. Glucuronide prodrugs of moxifloxacin was administered in solution, and the effect on *S. aureus* viability and biofilm formation was quantified.

**Results:** Aptamer-targeted liposomes accumulated in *S. aureus* biofilms, resulting in eradication of biofilms in vitro, while non-targeted liposomes were less effective. Although this result is promising, the burst release offers little control over dosage and exposure time. We therefore proceeded with prodrug therapy. The embedded enzyme continuously converted the inactive moxifloxacin prodrug to active moxifloxacin at the implant surface, which prevented biofilm formation, even under continuous flow where the synthesized drug could not accumulate locally.

**Conclusions:** Targeted drug delivery and pro-drug therapy enable local antibiotic therapy. The exposure time and concentration is better controlled in prodrug therapy, and we believe that our encouraging results will pave the way for implementing more potent drugs that target persister cells in treatment of biofilm infections.

Etiological structure of exanthema subitum in children of younger age

Olga Silveystrova1, Elvira Domonova1, Olga Shipulina1, Elmira Samitova2, Irina Khegai2

1Central Research Institute of Epidemiology, Moscow, Russian Federation, 2Z.A. Bashlyaeva Children’s City Clinical Hospital of Moscow Health Department, Moscow, Russian Federation

Background: Exanthema subitum is a common disease of early childhood caused by a primary infection with Human betaherpesvirus 6B and less frequently by Human betaherpesvirus 7 (HHV-7). 90% of cases occurring in children younger than two years old. In some cases inaccurate diagnosis and subsequent inadequate treatment at the beginning of the disease often lead to the development of undesirable complications requiring longer-term hospital treatment.

Materials/methods: The study involved 47 patients with primary infection, which were hospitalized at the infectious department of the children’s city hospital in Moscow: 24 male and 23 female with median age 12 months (ranged 6 – 36 months). DNA of Human betaherpesvirus 6A/B (HHV6-A/B), HHV-7, Human gammaherpesvirus 4 (EBV), Human betaherpesvirus 5 (HCMV), Human alphaherpesvirus 3 (VZV), Human alphaherpesvirus 1/2 (HSV-1/2), Primate erythroparvovirus 1 and RNA of Rubella virus, Enterovirus spp. in samples of whole blood were detected using qualitative or quantitative real-time PCR assays.

Results: 97.9% (46/47) children had a fever of 37.6 – 40.1 ºC. Most of them (76.6% (36/47) cases) had a small, rose-pink or red papules. Febrile seizures were observed in 4.3% (2/47) cases. HHV-6A/B DNA was detected in whole blood in 68.1% (32/47); HHV-7 – 17.0% (8/47); HHV6-A/B and HHV-7 co-infection – 8.5% (4/47); HHV-6A/B and EBV – 6.4% (3/47) cases. The concentration of HHV-6A/B DNA was 1.68–2.97 (median 2.20); HHV-7 – 1.95–3.28 (median 2.53) log10 copies/10^6 cells. Another viruses was not detected.

Conclusions: We have obtained data on etiological interpretation of exanthema subitum in children of younger age. HHV6-A/B was found in whole blood in 83.0% [39/47, 95% CI 69.86 – 91.11] cases, HHV-7 – in 25.5% [12/47, 95% CI 15.25 – 39.51]. 14.9% [7/47, 95% CI 7.41 – 27.69] patients had multiple concurrent viremia events.

The effects of introduction of a syndromic PCR sputum testing in intensive care unit pneumonia patients in a tertiary trauma centre

Diana Kluczna*, Phillipa Burns1, Deborah Wearmouth2, Patrick Lillie3

1Hull University Teaching Hospitals NHS Trust, Kingston-upon-Hull, United Kingdom

**Background:** Pneumonia is one of the most common diagnoses in ICU and carries up to 50% mortality rates. It is also associated with high healthcare costs. Microbiological diagnosis allows targeting of antimicrobial therapy and has been shown to improve patient outcomes. Standard culture of sputum samples has limitations due to time required to obtain results. BioFire offers a syndromic panel of multiplex PCR to identify pathogens rapidly. It is currently unknown if this molecular diagnostic test improves patient outcomes or what effect it has on pneumonia management.

**Materials/methods:** The study analysed notes of pneumonia patients admitted to ICUs in Hull hospitals between 1st August and 31st December 2018 and 2019, before and after the introduction of BioFire testing. The primary outcome of this observational study was the length of ICU stay and the secondary outcomes included the following: 1) ventilation duration, 2) mortality, 3) number of antibiotics before and after microbiological testing, 4) time from sample collection to a) management change, b) extubation and c) discharge from ICU.

**Results:** The review of all sputum samples received in the laboratory during the set time period in 2018 identified 120 patients with radiologically confirmed pneumonia. So far, 78 patients have been identified in the 2019 period. Although there was no reduction of median ICU stay duration, a reduction of prolonged ICU stay frequency was observed in 2019 in comparison to 2018 (61.5% and 65% respectively). We observed a reduction in number of antibiotics prescribed per patient following microbiology results in both groups. This reduction occurred sooner in 2019 group, within 1.2 days, compared to 3.3 days in 2018 group from the time of sample collection (p<0.001). There was a reduction in time from sample collection to extubation of 3.4 days and to ICU discharge of 5.4 days in 2019 compared to 2018 group. We also observed a reduction in mortality rates within 30 days of ICU discharge (28.3% vs 24.4% in 2018 and 2019 groups respectively, p<0.05).

**Conclusions:** Rapid molecular diagnostics allows adjustment of antimicrobial therapy and has potential for improving patient outcomes.

Ultra high-resolution mass spectrometry database improves identification of clinical yeasts from blood cultures by the Acrion system

Azadeh Jamalian*1,2, Joanna Freeke1,2, Ivan Moser2, Herdis Friedrich3, Juha Knuuttila3, Anssi Rantakari3, Jemiina Salo3, Karita Haapasalo-Tuomainen3, Benjamin Stielow1,2, Sybren De Hoog2,4

1Thermo Fisher Scientific, Microbiology Mass Spectrometry, Landsmeer, Netherlands, 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands, 3Thermo Fisher Scientific, Microbiology Mass Spectrometry, Helsinki, Finland, 4Radboud University Medical Center, Nijmegen, Netherlands

Background: Bloodstream infections caused by yeasts can lead to devastating complications and markedly increase the costs of hospital care and is a big challenge as a life-threatening condition with increasing prevalence. Mortality remains high, especially when effective antifungal drug therapy is not promptly administered. Consequently, rapid and accurate identification of the causative organism is critical for successful treatment. Bloodstream yeast species are frequently identified by MALDI-ToF in the clinical laboratory. Due to their cell wall structure and low cell count they give higher quality identifications when the samples are prepared with manual purification, sub-culturing on a plate and lysis steps either offline or on the MALDI-ToF plate. This poster demonstrates the performance of bloodstream yeast identifications using a novel integrated high resolution mass spectrometry system and a spectral database containing a diverse range of bloodstream clinical yeasts.

Materials/methods: A novel workflow applying high resolution accurate mass spectrometry (HRAM MS) was applied to identify bloodstream yeast infections. The protein extracts from each species were introduced to the mass spectrometer in Acrion™ system. Mass spectra were evaluated for the individual protein masses detected. Different identification approaches were compared.

Results: A comprehensive HRAM MS database covering 22+ clinical yeast species causing bloodstream infections has been developed. In the highly automated workflow in Acrion™ system, hands on time for the sample preparation is limited to pouring directly from the positive blood culture bottle such that user handling variability is thereby reduced, and a second culturing step is not needed. The high resolution mass spectrometry analysis yields good performance and identification of challenging yeast taxa.

Conclusions: Applying the proposed rapid and user-friendly workflow in Acrion™ system and benefiting from high resolution Orbitrap™ mass spectral data in the database significantly improved identification of yeast species from blood culture including challenging taxa.

Epidemiology, characteristics and outcomes of bacteraemia and endocarditis caused by Staphylococcus aureus in cancer patients

Sara Grillo1,2, Guillermo Cuervo*1,2, Julia Laporte Amargos1,2, Manel Tuells Morales1, Inmaculada Grau1,2, Dàmaris Berbel Palau1,2, Carlota Gudiol1,2,3, Jordi Carratalà1,2,4, Miquel Pujol1,2

1Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain, 2IDIBELL, L’Hospitalet de Llobregat, Spain, 3Institut Català d’Oncologia - ICO, L’Hospitalet de Llobregat, Spain, 4University of Barcelona, Barcelona, Spain

Background: Cancer patients with Staphylococcus aureus bacteraemia (SAB) could have different clinical characteristics, risk of endocarditis and outcomes than the general population.

Materials/methods: Retrospective multicentre cohort study of consecutive patients with SAB admitted in two tertiary hospitals in Spain, from January 2011 to December 2017. Patients with active cancer (PAC) were defined as patients with recently diagnosed solid cancer or haematologic malignancy, who underwent chemotherapy/radiotherapy within the prior 3 months or who had metastatic cancer. SAB and S. aureus endocarditis in PAC were compared with patients without cancer (PWC).

Results: Among 789 episodes of SAB, 217 (27.5%) occurred in PAC. Compared to PWC, PAC were younger (mean age 59.5y vs 66.6y, p<.001), had less comorbidities such as cardiopathy (11.5% vs 39.9%, p<.001), diabetes mellitus (13.8% vs 36.7%, p<.001) and chronic renal failure (8.3% vs 29.6%, p<.001). They had less often osteoarticular prostheses than PWC (3.2% vs 10.3%, p<.001). PAC had less commonly community-acquired SAB (6.9% vs 26.6%, p<.001). Catheter-related SAB (39.6% vs 26.4%, p<.001) and skin and soft tissues infection (18.4% vs 12.9%, p<.001) were more common in PAC, whereas they presented less frequently osteoarticular infection (3.2% vs 14.0%, p<.001) and endocarditis (2.3% vs 8.7%, p<.001). Thrombocytopenia was more commonly observed in PAC (30.9% vs 0.3%, p<.001) but it was not significantly associated with a lower risk of endocarditis. Septic shock at presentation (12.0% vs 17.3%, p=.040) and septic embolisms (8.3% vs 29.2%, p<.001) were less frequent in PAC. Overall, methicillin-resistant SAB was observed in 177 patients (22.5%), without differences between groups. Thirty-day mortality was also similar between groups (24% vs 20.8%, p=.245). Independent risk factors for 30-day mortality in PAC were unknown source of infection (OR 2.89, 95%CI 1.10-7.55, p=.030), septic shock (OR 5.29, 95%CI 1.87-15.0), and persistent bacteraemia (OR 4.34, 95%CI 1.70-11.08, p=.002).

Conclusions: Endocarditis in PAC with SAB was less frequently observed than in PWC. Relevant differences in the sources of SAB, baseline comorbidities and site of acquisition could explain the different risk observed between both populations. Thirty-day mortality was high in both groups of patients.

Abstract 7253

Performance evaluation of the new automated chemiluminescent immunoanalyser-based interferon-gamma releasing assay in comparison with the QuantiFERON-TB Gold Plus to detect latent tuberculosis infection

Hanaa Benmansour*, Sophie Boyer2, Estelle Bernard2, Faïza Mougari1, Emmanuel Lecorche1, Jean Francois Gehanno3, Stephanie Pramil4, Martine Pestel-Caron2, Emmanuelle Cambau1

1APHP Hôpital Lariboisière, Centre national de référence des mycobactéries et résistance aux antituberculeux, Paris, France, 2Centre hospitalo-universitaire, Service de Microbiologie, Rouen, France, 3Centre hospitalo-universitaire, Médecine de travail, Rouen, France, 4Centre hospitalo-universitaire, Centre de Lutte Antituberculeuse, Rouen, France

Background: laboratory diagnosis of latent tuberculosis infection (LTBI) is performed with interferon-gamma release assays (IGRAs). We compared the performance of a new automated chemiluminescent immunoanalyzer-based IGRA test (CLIA-IGRA; LIAISON, DiaSorin, Italy) with the commonly used QuantiFERON-TB Gold (Qiagen, Germany) Plus performed on two ELISA instruments, the Dynex DS2 (Qiagen) and ETIMAX-3000 (DiaSorin, Italy).

Materials/methods: 50 healthcare workers (HCWs), 50 TB contact subjects and 200 patients were consecutively enrolled in two University hospitals from June to October 2019. They were tested by the two assays per the manufacturers’ protocols and results were compared qualitatively as positive, negative and indeterminate results.

Results: ELISA-QFT-Plus and CLIA-IGRA detected 18% (54/300) and 19.3% (58/300) positive samples, respectively. CLIA-IGRA demonstrated 98.4% positive and 97.7% negative percentage agreement with ELISA-QFT-Plus, with a Cohen’s kappa value of 0.95 (strong agreement).

In addition, 13 samples were indeterminate with both tests. With regard to the threshold of 0.35 UI/mL, discordant results were detected in 6 subjects (2%). 5 samples were ELISA-QFT-Plus(-)/CLIA-IGRA(+) and one provided ELISA-QFT-Plus(+)/CLIA-IGRA indeterminate results. However, taking into account the range of uncertainty of measure published as 0.2-0.7 UI/mL, only 1 sample was really discordant: an ELISA-QFT-Plus(+)/CLIA-IGRA indeterminate with a high IFN-γ level (7.25) in the Nil tube. IFN-γ values between ELISA-QFT-Plus and CLIA-IGRA showed a strong correlation between TB1 and TB2 tubes (Pearson’s correlation coefficients 0.93 and 0.96 respectively). Of note, the rate of positive test for HCWs was 8% whereas it was 34% for people presenting for TB contact investigation or screening for recent immigration (all foreign-born from high endemic countries). For patients hospitalized for immunosuppression patients, or waiting for immunosuppressive therapy or with TB suspicion, the positivity rate was 18.4%

Conclusions: CLIA-IGRA showed similar performances as QFT-Plus whatever the indication of the test. CLIA-IGRA represents a useful reliable alternative tool of ELISA-based IGRA, especially in large-scale LTBI screening because of ease-of-use and automation.

Genomic and phenotypic diversity of carbapenemase-producing Enterobacteriaceae isolates from bloodstream infections: a multi-centre epidemiological, microbiological and genetic study in China

Beiwen Zheng*1, Hao Xu1, Yonghong Xiao1

1Zhejiang University, Hangzhou, China

Background: Globally, carbapenemase-producing Enterobacteriaceae (CPE) isolates are recognized as one of the most severe threats to public health due to their association with hospital outbreaks and high mortality. However, the population structure and genomic characteristics of CPE among bloodstream infections (BSIs) are largely unknown. We report the first comprehensive survey on the prevalence of CPE in patients with BSIs in China and present a detailed genomic framework for CPE isolates based on whole genome sequencing (WGS).

Materials/methods: In this study, we included patients with clinically significant BSIs due to Enterobacteriaceae isolates recruited from 26 sentinel hospitals in China (2014-2015). CPE isolates were microbiologically and genomically characterized, including susceptibility profiles, molecular typing, phylogenetic features and genetic context analysis of carbapenemase-encoding genes.

Results: Of the 2,569 BSI Enterobacteriaceae isolates enrolled, 42 (1.6%) were carbapenemase-positive. Moreover, 1,111 (49.6%) extended-spectrum β-lactamase (ESBL)-producing isolates were identified in Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, and Klebsiella oxytoca (n = 2,242). WGS analysis uncovered the clonal spread of ST11 KPC-2-producing Klebsiella pneumoniae and ST167 NDM-5-producing Escherichia coli in our collection. Plasmid analysis revealed that carbapenemase-encoding genes were located on multiple plasmids. A high prevalence of biofilm-encoding type 3 fimbriae clusters and yesiniabactin-associated genes was observed in K. pneumoniae isolates.

Conclusions: Our study demonstrates the high prevalence of ESBLs and wide dissemination of CPE among BSI isolates in China, which represent real clinical threats. The clonal spread of KPC-2-producing K. pneumoniae ST11 and NDM-5-producing E. coli ST167 needs to be closely monitored.

Abstract 7257

**Persuasive antimicrobial stewardship intervention in the context of a KPC outbreak: a controlled interrupted time-series analysis**

Nuno Rocha Pereira*1,2, Paulo Figueiredo1,2, Sofia Correia3, Shirin Shahriari1, João Neves1,2, José Teixeira1, José Artur Paiva1,2, Carlos Alves1, Ana Azevedo1,2

1Centro Hospitalar Universitário São João, Porto, Portugal, 2Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal, 3Instituto de Saúde Pública da Universidade do Porto (ISPUP), Porto, Portugal

**Background:** Antimicrobial resistance is a major public health threat. Antimicrobial stewardship (AMS) is one of the key strategies to overcome resistance, but robust evidence on the effect of specific interventions is lacking. We report an interrupted time series (ITS) analysis of a persuasive AMS intervention implemented during a KPC producing *Klebsiella pneumoniae* outbreak.

**Materials/methods:** A controlled ITS for carbapenem consumption, total antibiotic consumption and antibiotic-free days, between January 2012 and May 2018 was performed, using segmented regression analysis. The AMS intervention was implemented in the Vascular Surgery ward starting on April 2016 in the context of a KPC outbreak and included two strategies, diabetic foot infection treatment institutional guideline and prospective audit and feedback. The General Surgery ward was taken as a control group. Data were aggregated by month for both wards, including 51 pre-intervention and 26 intervention points.

**Results:** The AMS intervention produced a level change in carbapenem consumption of -9.92 DDDs/100 patient-days accompanied (Figure 1) by a reduction of total antibiotic consumption and an increase of 4% in antibiotic-free days in Vascular Surgery ward. These differences were not apparent in the control group. No differences in mortality or readmission rates between pre-intervention and intervention periods were noticed in any of the groups.

**Conclusions:** Persuasive AMS interventions on top of previously implemented restrictive interventions can reduce carbapenem consumption and increase antibiotic-free days. Starting persuasive AMS interventions in an outbreak setting does not compromise the sustainability of the intervention.

Suitability of ceftolozane/tazobactam (ZERBAXA) via continuous infusion in outpatient parenteral antimicrobial chemotherapy (OPAT)

Felicity Drummond¹, Conor Jamieson*¹, Laima Ozolina², Alan-Shaun Wilkinson²

¹The British Society for Antimicrobial Chemotherapy, Birmingham, United Kingdom, ²BioPharma Stability Testing Laboratory, Nottingham, United Kingdom

Abstract third-party references: On behalf of Members of the BSAC Working Group for Drug Stability Testing

Background: Ceftolozane/tazobactam is a broad-spectrum cephalosporin/beta-lactamase inhibitor combination with activity against a range of pathogens including expanded spectrum beta-lactamase (ESBL) producing strains of Enterobacteriaceae and multi-drug resistant strains of Pseudomonas aeruginosa. It is given three times daily, making it unsuitable for OPAT services at this dose frequency. This study assessed the stability of ceftolozane/tazobactam via continuous 24-hour infusion in two different commercially available elastomeric devices 1) FolFusor LV10 (Baxter Healthcare) and 2) Easypump® II (B.Braun), in accordance with the UK National Health Services Yellow Cover Document (YCD) standards.

Materials/methods: Ceftolozane/tazobactam was diluted in 0.9% w/v saline, pH 7.0 at two therapeutic concentrations of the drug combination (5 mg/mL and 20 mg/mL). Devices were refrigerated at 2-8°C for 8 days, followed by a 3-hour warm up period at room temperature and a simulated infusion period up to 24 hours at 32°C. Concentrations of ceftolozane/tazobactam were determined using a stability indicating HPLC-DAD method developed for use in this study. Testing was carried out in triplicate at five timepoints.

Results: Results indicate ceftolozane is less chemically stable than tazobactam. At 12 hours the concentration of ceftolozane remaining was within the 95% YCD limit; at the end of the 18-hour testing period the concentration remaining for ceftolozane had marginally dropped below the 95% limit; the concentration was a minimum of 93.78±0.19% remaining after 24 hours.

Conclusions: HPLC-DAD assay results from this study show that ceftolozane, while relatively stable at fridge temperature, undergoes degradation during the administration “in-use” period at 32°C. Tazobactam, in contrast to ceftolozane, remains relatively stable even at 32°C. Depending on the acceptance criteria applied, the data supports a shelf life assignment of between 12-24 hours “in use period” at 32°C after storage for up to 8 days in fridge (2-8°C), following a three hour warm up period for ceftolozane/tazobactam solutions in both elastomeric devices tested, within the concentration range of 5-20 mg/mL.

Abstract 7261

Prospective evaluation of BinaxNOW for rapid identification of Streptococcus pneumoniae from positive blood culture bottles

Klemen Žnidar*, Damjana Tratnik, Mateja Pirs, Manica Mueller-Premru

1Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia

Background: BinaxNOW Streptococcus pneumoniae is a rapid immunochromatographic test (BNT-SP) for detection of pneumococcal antigen in urine and cerebrospinal fluid to aid rapid diagnosis of pneumococcal pneumonia and meningitis in conjunction with cultivation. The main drawback of BNT-SP is potential cross-reactivity with viridans streptococci (particularly S. mitis group) as well as some Enterococcus species. While rapid identification of S. pneumoniae from positive blood culture (BC) has important clinical impact, the usefulness of rapid identification methods such as MALDI-TOF is lacking. The aim of our prospective study was to determine the usefulness of BNT-SP performed on positive BC and the frequency of false positive results due to cross-reactivity.

Materials/methods: Positive BCs from 1.1.2018 until 31.7.2019 were included in the study. BNT-SP was performed when Gram positive cocci in chains were observed in the Gram stain and direct MALDI-TOF test did not reliably identify bacterial species. BNT-SP was performed by collecting 10 drops of blood from the positive BC bottle into a tube. A swab was dipped into the tube, then inserted into the test card and reagent added. After 15 minutes the test result was interpreted visually. The results of BinaxNOW were compared to the results of overnight culture, S. pneumoniae was identified using optochin or bile solubility test, other bacterial species were identified using MALDI-TOF.

Results: In total 119 BCs were included in the study. BinaxNOW was positive in 95 cases, in 94 (98.9%) of them S. pneumoniae was isolated from overnight culture, in one case S. mitis was isolated. In the remaining 24 cases BinaxNOW was negative and bacterial species other than S. pneumoniae were isolated from overnight culture, in 19/24 cases other streptococci and 5/24 enterococci. Sensitivity was 100%, with good specificity 96.0%, positive 98.95% and negative predictive value 100%.

Conclusions: The results of our prospective study show very low rate of false positive results due to cross-reactivity with S. mitis, however, only two S. mitis were isolated among 119 isolates and no cross-reactivity with other species was detected. Our study has demonstrated that BinaxNOW is a valuable addition to rapid identification of S. pneumoniae bacteremia.

Evaluation of the whole blood spot on plasma separation card as a sample type for serological screening for hepatitis B and hepatitis D infection

Fernando Velasquez1, Ariadna Rando Segura1, Paula Salmerón1, Unai Aldama2, Adrian Najarro1, Angels Esteban2, Gerard Ruiz2, Mar Riveiro-Barciela3, Maria Buti3, Ed G. Marins4, Francisco Rodriguez-Frias4

1Vall d’Hebron University Hospital, Microbiology department, Barcelona, Spain, 2Vall d’Hebron University Hospital, Biochemistry department, Barcelona, Spain, 3Vall d’Hebron University Hospital, Internal medicine department, Barcelona, Spain, 4Roche Molecular Systems, Inc, Pleasanton, United States

Background: Viral hepatitis elimination is one of the WHO objectives; this includes increasing diagnosis rate of hepatitis B. Access to a laboratory is not always possible, especially in remote areas, and certain regions with special populations, in these scenarios a method to stock and transport blood samples for long periods and distances can be useful to bring near the laboratory based assays. Dried blood spots have been found useful to evaluate viral load of HCV an HIV, however there isn’t a wide experience using this sample to perform serological assays which is the first step in the diagnosis of viral hepatitis. The aim of this study was to evaluate the performance of the Cobas Plasma Separation Card (PSC) as alternative sample for serological testing compared to serum.

Materials/methods: We recovered whole EDTA venous blood from clinical samples with positive (n=101) and negative HBs (n=81). All samples HBs positive with anti-HDV results (n=24) were also tested for this assay. PSC samples were prepared by spotting 140µL of whole EDTA venous blood and drying it at room temperature over a minimum of 4 days. One spot of each PSC was eluted in 600µL of Elecsys universal diluent, incubated at 37ºC over one night and centrifuged at 3000rpm over 10min. Serum and PSC eluted samples were analyzed by elecsys HBs II and elecsys anti-HBc in cobas 8000 system (Roche, Switzerland) and XL MUREX anti-HDV in Liaison (DiaSorin, Italy). The results were compared by paired.

Results: Sensitivity of PSC compared to serum for HBsAg was 97.0% (n=101; 95% CI: 91.6 - 99.4%), for anti-HBc was 98.9% (n=94, 95% CI: 94.2 to 100%) and 43.75% (n=23, 95% CI: 38.5 to 80.3%) in HBsAg positive and HBsAg negative (solved hepatitis B) cases, respectively. For anti-HDV sensitivity was 100% (n=7, 95% CI: 59.0 to 100%). Specificity for all tests was 100%.

Conclusions: PSC demonstrated a good concordance with standard serum samples as an alternative sample type for serological testing used for screening of HBV and HDV infection. These results support the feasibility of PSC as an alternative sample for serological screening of patients in resource limited settings.

Abstract 7264

A broad-spectrum bacterial gyrase inhibitor with a novel scaffold

Aurélie Vassort*1, Daniel Kohnhaeuser2, Mark Broenstrup2, Andreas Kirschning3, Katarina Cirnski4, Jennifer Herrmann4, Rolf Mueller4, Michael Mourez1, David Corbett5, Sylvie Sordello5

1Evotec ID, Marcy l’Etoile, France, 2Helmholtz Centre for Infection Research, Braunschweig, Germany, 3Leibniz Universität, Hannover, Germany, 4Helmholtz Institute for Pharmaceutical Research Saarland, Saarbrücken, Germany, 5Evotec, Cheshire, United Kingdom

Background: There is an alarming scarcity of novel chemical matter with bioactivity against multidrug-resistant Gram-negative bacterial pathogens. Studying natural products arguably remains the most fruitful strategy to discover novel antibiotic lead structures, since more than 80 % of marketed antibiotics are secondary metabolites found in nature or derivatives thereof. In 2014, we identified cystobactamids as novel myxobacterial natural products that exhibit potent broad-spectrum antibacterial properties through the inhibition of bacterial topoisomerases. We accomplished the full chemical synthesis of these natural products and embarked into a medicinal chemistry and biological profiling program to advance cystobactamid leads to pre-candidates.

Results: Cystobactamids exhibit an unusual chemical structure, composed of oligomeric para-aminobenzoic acid moieties. Medicinal chemistry optimization has enabled some improvements in the spectrum coverage, which comprises some clinically important Gram-negative and Gram-positive pathogens (MIC90 on Escherichia coli of 0.06 µg/mL, n=12; MIC90 on Acinetobacter baumannii of 1 µg/mL, n=13; MIC90 on Staphylococcus aureus of 0.25 µg/mL, n=14), with some existing gaps currently being addressed (most notably Klebsiella pneumoniae and Proteus mirabilis). Although fluoroquinolones (FQ), albicidin and cystobactamids share the same molecular targets (GyrA/ParC subunits of topoisomerases), no cross-resistance is observed with the current frontrunners. In some species we observed rapid emergence of resistance in vitro through off target mutation. However, in vitro and in vivo efficacy data indicate that this liability may be overcome by adequate dosing of the compound. Indeed, in a mouse model of thigh infection by Escherichia coli the frontrunner led to three log kill of bacterial loads when administered intravenously at 40 mg/kg/day. The physico-chemical and ADMET profiles of the frontrunners are also acceptable at this stage.

Conclusions: Taken together, these data suggest that cystobactamids are promising lead structures, and more broadly that there is still a chemical space to identify novel broad-spectrum gyrase/topo-isomerase antibiotics against infections caused by Gram-positive and Gram-negative bacterial pathogens.

Rapid diagnostics of bloodstream infections using sybodies and nanobodies as capturing agents

Lea Huber1, Michèle Sorgenfrei*, Remy Melissa2, Hans-Anton Keserue3, Peter Michael Keller2, Markus Seeger1

1University of Zurich, Institute of Medical Microbiology, Zurich, Switzerland, 2University of Bern, Bern, Switzerland, 3rqmicro, Schlieren, Switzerland

Background: Sepsis caused by bloodstream infections (BSIs) affects 18 million people world-wide every year and has unacceptably high mortality rates of 10-20% in Western countries. BSI diagnostics typically takes several days which forces clinicians to treat sepsis patients with empiric broad-spectrum antibiotics. However, cephalosporin- and carbapenem-resistant Escherichia coli, Klebsiella pneumoniae and Pseudomonas aeruginosa are often treated with inadequate antibiotics. We aim to drastically shorten the routine BSI diagnostics by extracting pathogenic bacteria from blood using single domain antibody fragments, called nanobodies to omit long-lasting blood cultures necessary for BSI diagnostics.

Materials/methods: Nanobodies from immunized alpacas and synthetic nanobodies (sybodies) were raised against non-essential but highly conserved outer membrane proteins (OMPs) of E. coli, K. pneumoniae and P. aeruginosa, namely OmpX, OmpA and OmpF [E. coli], OmpA [K. pneumoniae] and OprF [P. aeruginosa]. Enriched pools were then deep-mined using our recently developed NestLink technology to identify nanobodies and sybodies binding to OMPs in the native outer membrane context of the respective pathogens. Target binding was verified by cellular binding assays using fluorescently labelled nanobodies and sybodies, complex runs using size exclusion chromatography, and FACS.

Results: Nanobodies and sybodies were first selected against purified OmpX [E. coli], OmpA [K. pneumoniae] and OprF [P. aeruginosa]. In case of OmpX, enrichment of both nanobodies and sybodies turned out to be difficult. Therefore, nanobodies against OmpA and OmpF [E. coli] were raised, which are less conserved than OmpX, but both are necessary to achieve coverage of all E. coli strains. Binding various E. coli strains in a cellular context was shown by the above mentioned methods. Finally, nanobodies and sybodies binding to OmpA [K. pneumoniae] and OprF [P. aeruginosa] were successfully enriched and will be further analysed.

Conclusions: We have established an elaborate platform to generate binders that recognize highly conserved OMPs in their native context of the outer membrane of gram-negative pathogens. These binders will be further developed to capture these bacteria directly from blood samples of patients suffering from life-threatening BSIs. Thereby, time-consuming blood culturing is omitted, allowing for rapid antibiotic susceptibility testing.

Abstract 7268

**Novel taxonomic and functional cervical microbiome biomarkers of persistency and histological progression to CIN2+ in women infected with high risk human papilloma virus**

Thomas Iftner1, Frank Stubenrauch2, Angelika Iftner1, Matthias Willmann*

1University of Tuebingen, Tuebingen, Germany

**Background:** Predictors of viral persistence and development of prestage cancer in high risk human papillomavirus (HR HPV) infected women would allow better risk stratification in cervical cancer screening.

**Materials/methods:** Previously a prospective German cohort of 10,040 women was established and 411 test-positive (HPV and/or cytology) women were followed for up to six years with yearly intervals. Shotgun metagenomics from the first cervical smear taken at the baseline was performed in 100 HR HPV infected women. Of these, 43 women showed a persistent HR HPV infection with the same HR HPV type (> 24 months) including 10 women who developed histological progression to CIN2+. The remaining 57 women had cleared their infections spontaneously within 24 months.

**Results:** Potential biomarkers for persistent HR HPV infection and histological progression to CIN2+ were identified using a univariate Wilcoxon rank sum test followed by multivariate logistic regression. Different machine learning classifiers built from six taxonomic and functional biomarkers allow to stratify women with a high risk of persistent HR HPV infection (OR=2.77; p=0.03) from those that cleared spontaneously (ROC-AUC 0.96 - 1.0). The six biomarkers are the relative abundance of three bacterial taxa (2 genera: Catenulispora, Oleiphilus; 1 phylum: Chlamydiae), the relative abundance of two metabolic microbial pathways (UDPNAGSYN-PWY, PWY-621), and the relative abundance of the fungal genus Aureobasidium. Furthermore, we trained machine learning classifiers on prediction of a high risk for incident CIN2+ (OR=15.5, p = 0.001) based on the relative abundance of two bacterial taxa (2 genera: Leisingera, Devosia), the relative abundance of a metabolic microbial pathway (PWY-2941), and the relative abundance of the two fungal genera Thermothelomyces und Marssonina (ROC-AUC 0.77 - 1.0). All biomarkers were further investigated using a Ward-cluster analysis that demonstrated excellent discrimination of the respective groups.

**Conclusions:** Applying machine learning algorithms to shotgun metagenomics data from cervical smears in women infected with HR HPV seems to enable prediction of the establishment of persistent HPV infections and more important an increased risk of incident CIN2+.

Abstract 7269

**Large diffusion of Optra- and Poxta-producing linezolid-resistant Enterococcus spp. among healthy children from rural communities of the Bolivian Chaco**

Ilaria Baccani1*, Alberto Antonelli1, Mario Tortorella1, Tiziana Di Maggio2, Michele Spinicci1, Marianne Strohmeyer3, Francesca Mariotti1, Herlan Gamboa Barahona4, David Rojo Mayaregua5, Veronica Poma5, Lucia Pallecchi2, Alessandro Bartoloni3, Gian M. Rossolini1

1University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy; 2University of Siena, Department of Medical Biotechnologies, Siena, Italy; 3Careggi University Hospital, Infectious and Tropical Diseases Unit, Firenze, Italy; 4Universidad Rene’ Moreno, Facultad Politecnica del Chaco, Camiri, Bolivia; 5Escuela de Salud Tekove Katu, Gutierrez, Bolivia

**Background:** The spread of antimicrobial resistance is increasing worldwide in both healthcare and veterinary field. Since now, little is known about the prevalence of oxazolidinone resistant enterococci bacteria among healthy children in rural communities. In this study, a surveillance was set up for the colonization by oxazolidinone and phenicol resistant Enterococcus spp. in two communities of the bolivian Chaco.

**Materials/methods:** 100 faecal samples obtained from healthy children from two rural communities of the bolivian Chaco (Ivamirapinta and Palmarito) in 2018 were studied. The samples were grown on selective plates for enterococci [Columbia CNA Agar with 5% Sheep blood] supplemented with 16 mg/L of florfenicol. Each colony characterized by a different morphology was isolated and identified by MALDI-TOF mass spectrometry. Each isolate was subjected to Real-Time PCR in order to detect the most common acquired oxazolidinone resistance genes (optra, poxta, cfr, cfr (B)), and RAPD (Random Amplification of Poly-morphic DNA) PCR was executed to detect the clonal relatedness of isolates from the same patient. Antimicrobial susceptibility testing for ampicillin, florfenicol, linezolid and vancomycin was performed by reference broth-microdilution method according to ISO 20776:1-2006, and interpreted according to EUCAST clinical breakpoints (when available).

**Results:** 59 samples yielded some growth on the selective medium and 83 different morphologies were detected. 75 isolates resulted positive for optra gene (including 64 Enterococcus faecalis, 8 Enterococcus faecium, one Enterococcus hirae, one Enterococcus casseliflavus and one Vagococcus spp.) and 8 for poxta gene (6 Enterococcus faecium, one Enterococcus gallinarum, and one Enterococcus hirae). The results confirmed a high MIC to florfenicol (>8 mg/L) for the 95% of the isolates. Additionally, 89% of the samples were also linezolid resistant, whereas only few of them showed ampicillin resistance (5%) or vancomycin resistance (2%, only E. gallinarum and E. casseliflavus isolates).

**Conclusions:** An unexpected high prevalence of antibiotic resistant enterococci carrying the optra and poxta resistance genes were detected among healthy children in two rural communities. The possible causes of this diffusion of oxazolidinone and phenicol resistance genes among enterococci are still unknown and this study highlights the importance of future surveillance studies at veterinary, environmental and clinical level in Bolivia

Abstract 7271

Genetic mutations in drug-resistant paediatric tuberculosis: experience from a paediatric tertiary care centre in north India

Prerna Khurana*, Karnika Saigal¹, Arnab Ghosh¹

¹Chacha Nehru Bal Chikitsalaya, Delhi, India

Background: The emergence of multidrug-resistant MDR-TB and extensively drug-resistant XDR-TB are serious threats to global TB control. Molecular tests like GenoType MTBDRplus has revolutionized MDR-TB diagnosis by rapid detection of resistance, leading to early and appropriate management of DR-TB. Information about common mutations imparting resistance to Rifampicin and isoniazid helps in understanding the disease epidemiology in various regions.

The study was conducted to determine the genetic mutation in drug resistant tuberculosis in children less than 12 years with pulmonary or extrapulmonary tuberculosis.

Materials/methods: Retrospective analysis was done over a period of 54 months from January 2015 to June 2019 to study the resistance pattern and mutations present in DR-TB in children less than 12 years with suspected pulmonary or extrapulmonary tuberculosis using Hain’s GenoType MTBDRplus VER 2.0.

Results: Over a period of 54 months, samples from 3461 patients with suspected TB were received for MGIT culture, out of which, 347 were positive for Mycobacterium tuberculosis. 250 of these 347 isolated were tested for drug resistance by Hain’s GenoType MTBDRplus VER 2.0. 61.1% were sensitive to isoniazid and rifampicin while 38.9% were DR-TB (38 out of 250). Out of these 38, 22 were MDR TB, 13 were isoniazid monoresistant (34.2%) and 3 were rifampicin monoresistant. The most common genotypic resistance for rifampicin was absence of rpoB WT8 band and presence of rpoB MUT 3 band (88%). 84.6% of the INH monoresistant isolates showed high level isoniazid resistant. All these isolates showed presence of katG MUT 1 band. On comparing Hain’s GenoType MTBDRplus VER 2.0 with Xpert MTB/Rif Assay, most common mutation for rifampicin resistance at SS31L which can be detected by Xpert MTB/Rif Assay [probe E]. However, two cases with rifampicin resistance had mutation in codon region 509-513 and 513-519 which could be missed by Xpert MTB/Rif Assay.

Conclusions: We cannot solely rely on Xpert MTB/Rif Assay for detection of drug resistance due to the risk of missing the isoniazid monoresistance. The higher frequency of mutation in codons of rpoB (SS31L) and katG (S315T) gene may help to design simple, new and less expensive molecular techniques to use in peripheral laboratories.

Abstract 7273

Comparison of Candida PCR and blood culture results in high-risk patients with candidaemia in the intensive care unit

Tugce Simsek Bozok1, Ferit Kuscu1, Taylan Bozok2, Suheyla Komur1, Aslihan Ulu1, Ayse Seza Inal1, Behice Kurtaran1, Filiz Kibar1, Yesim Tasova*1

1Cukurova University Faculty of Medicine, Adana, Turkey, 2Adana City Hospital Complex, Adana, Turkey

Background: Candida isolates are responsible for 70 to 90% of invasive fungal infections in intensive care units. Early diagnosis and treatment is important in candidemia. Improper diagnosis and treatment can significantly increase mortality and morbidity. The aim of this study was to investigate the feasibility of Candida PCR as a rapid diagnostic method in patients with suspected candidiasis in intensive care units.

Materials/methods: Ninety patients with a high risk of candidiasis were evaluated prospectively in our study. Urine, perineum, axilla, tracheal aspirate culture and 2 sets of blood cultures were obtained from the patients. In Candida multiplex PCR ITS1, ITS2, ITS2D, CA3, CA4 primers were used. In Candida real-time PCR species-specific primers were used to distinguish species.

Results: 41 (45.5%) of the patients were female and 49 (55.5%) were male. The mean age of the patients was 58.1 (± 18.4) years. The blood culture was positive only for 3 (3.3%) patients. Candida multiplex PCR and Candida real-time PCR were positive in 17 (18.9%) patients. Candida species found in the blood culture and PCR test were compatible with each other (Table). PCR was significantly more positive than the blood cultures (p=0.006). The difference in candida score between patients with PCR positive and PCR negative was statistically significant (p=0.015).

Conclusions: In our study, we found that the probability of detecting candidemia with PCR was higher. Therefore, it can be seen that molecular methods should be used in the diagnosis especially in patients with high risk of candidiasis.

**Abstract 7274**

**In vitro activity of cefiderocol, a siderophore cephalosporin, against multidrug-resistant isolates of Gram-negative bacilli from France**

Saoussen Oueslati¹, Laurent Dortet¹, Thierry Naas*¹,²

¹Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France; ²Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France

**Background:** Antimicrobial resistance has reached in many countries an extremely worrying situation, threatening the achievements of modern medicine and requiring urgently novel antibiotics to cope with this problem. Here, we have evaluated the in vitro activity of cefiderocol (S-649266), a novel siderophore cephalosporin against Multidrug resistant Gram-Negative Bacilli from France.

**Materials/methods:** The in vitro activity of cefiderocol was determined against a collection of carbapenem-resistant clinical isolates of Enterobacteriaceae \(n = 220\), multidrug-resistant (MDR) Acinetobacter baumannii \(n = 52\), MDR Pseudomonas aeruginosa \(n = 51\), Stenotrophomonas maltophilia \(n = 15\), and Burkholderia cepacia \(n = 10\) using the Clinical and Laboratory Standards Institute (CLSI) standard broth microdilution method. Iron-Depleted cation-adjusted Mueller-Hinton broth (ID-CAMHB), used to test cefiderocol while for all the other antimicrobial agents (ceftolozane-tazobactam, cefepime, ceftazidime, ceftazidime-avibactam, aztreonam, meropenem, amikacin ciprofloxacin, colistin, and tigecycline) were tested using CAMHB. MIC breakpoints were those of EUCAST or CLSI in case they were not available at EUCAST.

**Results:** The concentration of cefiderocol inhibiting 90% \(\text{MIC}_{90}\) of isolates of carbapenem-nonsusceptible Enterobacterales was 4 \(\mu\)g/ml; cefiderocol MICs ranged from 0.03-64 \(\mu\)g/ml, and 93.0% \(\text{MIC}_{90}\) of isolates demonstrated cefiderocol MICs of \(\leq 4 \mu\)g/ml. The MIC90s for cefiderocol for MDR A. baumannii, MDR P. aeruginosa, and S. maltophilia were 64, 2, and 0.06 \(\mu\)g/ml, respectively, with 81% \(\text{MIC}_{90}\), 100% \(\text{MIC}_{90}\), and 100% \(\text{MIC}_{90}\) of isolates demonstrating cefiderocol MICs of \(\leq 4 \mu\)g/ml. Cefiderocol MIC90 for B. cepacia were 1 with MICs ranging from 0.003 to 8 \(\mu\)g/ml. Cefiderocol was the most active antibiotic against these MDR Gram negative bacilli.

**Table 1: Antibiotic susceptibility of the 348 tested XDR isolates**

**Conclusions:** Cefiderocol demonstrated potent in vitro activity against a collection of highly drug resistant Gram-negative bacteria (Enterobacteriales, MDR A. baumannii, MDR P. aeruginosa, S. maltophilia, and B. cepacia isolates) as >93% of all \(320/348\) isolates tested had cefiderocol MICs of \(\leq 4 \mu\)g/ml. Interestingly 100% of the tested \(P. aeruginosa\) isolates being mostly susceptible only to colistin had cefiderocol MICs of \(\leq 4 \mu\)g/ml.

Management of MDR-TB cases: roadmap towards TB elimination in Italy

Valentina Marchese*1, Beatrice Formenti1, Giovanni Sotgiu2, Gabriele Pinsi3, Alberto Matteelli1

1University of Brescia, Institute of Infectious and Tropical Diseases, WHO Collaborating Centre for TB/HIV coinfection and TB elimination, Brescia, Italy, 2 University of Sassari, Clinical Epidemiology and Medical Statistics Unit, Dept of Medical, Surgical and Experimental Sciences, Sassari, Italy, 3University of Brescia and ASST Spedali Civili General Hospital, Microbiology and Virology Unit, Brescia, Italy

Background: Drug-resistance poses a major threat to global progress to end tuberculosis. In 2017 558,000 new cases of multidrug-resistant tuberculosis (MDR/RR-TB) emerged globally. In 2018 a total of 170 cases of MDR/RR-TB were notified in Italy, an incidence of 0.28 cases per 100,000 population. The WHO End TB Strategy aims at strengthening the capacity to manage the MDR-TB cases, providing new models for the implementation of out-patient management and shorter regimens.

Materials/methods: Findings of a two year (April 2017 - April 2019) observational study on the pilot implementation of four interventions for MDR TB management at the Infectious Disease Department of ASST Spedali Civili of Brescia. The project was funded by the Italian Ministry of Health. The intervention consisted on shorten definition of sensitivity pattern in MDR-TB strains through whole genome sequencing (WGS); adoption of shorter regimen (following the WHO criteria); MDR-TB out-patient treatment as initial care in the intensive phase whenever possible; treatment of MDR-TB contacts using fluoroquinolone containing regimens.

Results: Eleven MDR-TB cases were observed (1 XDR-TB, 1 PRE XDR-TB, 1 RR-TB). Four cases had extra-pulmonary TB (kidney; pleura; lymph node; miliary), two cases had HIV co-infection and one patient was under chronic immunosuppression due to Chron’s disease. The average time between Xpert positivity to MTB-RIF and start second line TB treatment based on WGS result was 10 days. MDR-TB patients treated ab-initio in out-patient setting were 2 out of 7 eligible (28%): (contraindications in XD; PRE XDR; cerebral location; social reasons). Of the 11 patients 7 had a resistance pattern not compatible with shorter regimen and one had TB meningitis. Of the 3 eligible cases, shorter regimens were started in 2 (66%). Among 20 identified MDR-TB contacts 3 received fluoroquinolone based preventive therapy (15%). Reasons for no treatment was mostly clinician preference. Treatment was completed by 1/3 contacts (treatment interruption due to side effects).

Conclusions: Selection of second line regimens based on WGS results in TB cases with rifampicin resistance measured through rapid test is feasible in this setting. The proportion of MDR-TB cases who are eligible and adopt shorter regimens according to current WHO guidelines is very limited.

Abstract 7282

Genetic variability of Trypanosoma cruzi, in clinical samples from Latin American immigrant patients, living in Barcelona, Spain

Maykon Tavares De Oliveira*, Elena Sulleiro Igual1, Aroa Silgado Gimenez1, Marta De Lana1, Bianca Zingales2, João Santana Da Silva3, José Antônio Marin-Neto4, Israel Molina1

1Vall d’Hebron University Hospital, Barcelona, Spain, 2Universidade Federal de Ouro Preto - UFOP, Ouro Preto, Brazil, 3University of São Paulo, São Paulo, Brazil, 4Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil

Abstract third-party references: Vall d’Hebron Research Institute (VHIR), São Paulo Research Foundation - FAPESP

Background: Chagas disease (ChD) has as its etiological agent the hemoflagellate protozoan denominated Trypanosoma cruzi. The species has a genetic structure that allows subdivision into six distinct DTUs (TcI to TcVI) and TcBat, which has shown differences in geographical distribution, biological properties and drug susceptibility. The predominance of TcII, TcV and TcVI DTUs is known in several regions of Latin America, associated with both the domestic and wild, Chagas Disease cycle. However, little is known about the circulation of different T. cruzi genotypes in Latin American chagasic immigrants living in the European continent. Thus, it was intended with this work, to verify the genotypes of parasites present in patients with ChD attended in Universitary Hospital Vall d’Hebron, Barcelona - Spain.

Materials/methods: 116 chronic chagasic patients with positive serology (residents in Barcelona, Spain), with different nationalities were included in this study. It was collected 5ml of blood in Guanidine/EDTA eluate, for subsequent DNA extraction, to evaluate the parasite load and molecular characterization of the parasites in their appropriate DTUs. Genotyping was performed using conventional multilocus PCR and Nested PCR, using amplification of different genes (SLIRac, SLIR, 24Sα rDNA and A10). Parasite loading was performed according to standard protocol in our laboratory, using a standard curve containing epimastigote forms of T. cruzi, SO3cl5 strain (DTU/TcV).

Results: An extremely low bloodstream parasitic load was observed in all 116 chronic patients included in the study, with an average of approximately 10fg of T. cruzi DNA in each patient sample. Regarding genotyping, we found the presence of TcV DTU in Bolivian patients, as reported in the specific literature, in addition to the presence of TcII/TcVI, TcII/TcV/TcVI genotypes in patients of different nationalities.

Conclusions: We can conclude from these data that the parasitic loads in all evaluated patients are really low, and that the genotypes found are very variable due to the different geographical origins of each patient. Thus, by better understanding the genetics of the circulating parasite, it is possible to perform control measures, treatment and clinical intervention with greater efficiency, bringing improvements to patients.

Abstract 7283

Two-year experience of meningitis/encephalitis multiplex PCR assay on cerebrospinal fluids in comparison with conventional methods: advantages and disadvantages

Adriana Calderaro1, Mirko Buttrini1, Monica Martinelli*2, Sara Montecchini3, Silvia Covan1, Alberto Ruggeri2, Marco Maria Antonaci2, Francesca Casula2, Maria Loretana Dell’Anna2, Sandra Larini2, Francesca Ferraglia1, Federica Pinardi1, Paolo Montagna2, Maria Cristina Arcangeletti1, Flora De Conto1, Carlo Chezzi1

1University of Parma, Department of medicine and surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Microbiology, Parma, Italy, 3University Hospital of Parma, Unit of Clinical Virology, Parma, Italy

Background: Central nervous system (CNS) infections, including meningitis and encephalitis, are associated with significant morbidity and mortality; rapid and accurate detection of pathogens in the cerebrospinal fluid (CSF) can improve clinical care. The aim of this two-year study was to prospectively evaluate the multiplex PCR FilmArray Meningitis and Encephalitis Panel (FA-MEP, BioFire Diagnostics/bioMérieux) for the rapid (1 h) and simultaneous detection in CSF of 14 life-threatening agents (6 bacteria, 7 viruses and 1 yeast) in comparison with the reference methods currently used in case of CNS infection suspicion.

Materials/methods: A total of 173 CSFs (November 2017-November 2019) belonging to as many patients were analyzed by FA-MEP in comparison with the reference methods for bacteria, including the mandatory direct microscopic examination (DME) and the identification by MALDI-TOF MS from either agar or liquid conventional cultures. For virus confirmation, when a FA-MEP positive result for virus was obtained, the samples were submitted to agent specific PCRs (except for paraechovirus not routinely detected).

Results: The FA-MEP gave a positive result in 24 cases (13.9%), in 23 cases (95.8%) for a single agent (5 Streptococcus pneumoniae, 3 Haemophilus influenzae, 2 Neisseria meningitidis, 1 Streptococcus agalactiae, 7 enterovirus, 2 human herpesvirus 6, 2 varicella zoster virus and 1 paraechovirus) and in 1 case (4.2%) for H. influenzae in combination with cytomegalovirus. The FA-MEP positive results were concordant, with regard to the agents recognized by the molecular assay, with those obtained by the reference methods in all cases (83.3%) except in 4 culture-negative cases: 2 samples containing S. pneumoniae (DME-positive for Gram positive cocci, patients under antibiotic therapy) and 2 DME-negative samples containing S. pneumoniae and H. influenzae, respectively. In addition, the reference bacterial methods gave positive results in 12 CSFs, all agents not targeted by FA-MEP.

Conclusions: This study suggests that FA-MEP, despite high costs, can have comparable diagnostic yield and more rapid time-to-diagnosis than conventional methods in patients with suspected CNS infection and proves the potential for significant clinical impact including optimization of antimicrobial therapy and reduction of unnecessary use. However, for the definitive diagnosis reference methods remain mandatory for both bacteria and viruses.

Abstract 7284

An evaluation to assess the performance of the Fungiplex Aspergillus real-time PCR and the Fungiplex Aspergillus Azole-R IVD real-time PCR Kits following the implementation of an extraction control

Julie Green*

1Bruker Microbiology and Diagnostics, Glasgow, United Kingdom

Background: This Performance Evaluation was designed to test contrived samples spiked into serum, plasma and BAL material to assess the impact of a new extraction control on the limit of detection of the Fungiplex Aspergillus and Fungiplex Aspergillus Azole-R IVD Real-Time PCR Kits and to ensure sensitivity was unaffected by this change.

Materials/methods: Simulated samples were prepared and analysed by the clinical evaluators. Samples prepared in serum, plasma and BAL were spiked with specific concentrations of Aspergillus fumigatus or Aspergillus terreus genomic DNA prior to extraction. Aspergillus fumigatus wild type strains were used as well as resistant strains containing DNA mutations TR34 and TR46 in the Cyp51A gene. Samples were prepared in replicates of five and negative controls were included for each sample type.

Results: When tested with the Fungiplex Aspergillus IVD Real-Time PCR Kit, the limit of reproducibility for Aspergillus fumigatus and Aspergillus terreus samples was 5 ge (genome equivalents). No difference in sensitivity was observed when the results from two different extraction platforms were compared, however, on average the resultant Ct (cycle threshold) values were 1.2 cycles higher when the EZ1™ platform was used.

When tested with the Fungiplex Aspergillus Azole-R IVD Real-Time PCR Kit, the limit of reproducibility for Aspergillus fumigatus samples containing mutations TR34 and TR46 was 50 ge. This higher limit of reproducibility was expected as the Cyp51A gene is single copy. The limit of reproducibility was consistent between all sample types, where in a previous study, without an extraction control, the limit of reproducibility had been reported between 50 and 75 ge depending on which sample type was used.

Conclusions: 100% sensitivity was reported for the Fungiplex Aspergillus Kit when analysing Aspergillus samples at 5 ge and for the Fungiplex Aspergillus Azole-R Kit when analysing resistant strains at 50 ge. The sensitivity is not dependent on sample type and the new extraction control implemented in these products did not affect the performance of either Kit. Data has shown that results from this study are equivalent, and in some cases, superior to previous studies performed.

Abstract 7285

Multimodal analysis of *Escherichia coli* isolates from patients and carriers with EPISEQ CS, a next-generation sequencing service for epidemiological surveillance

Katleen Vranckx*1, Klara De Rauw1, Katrien De Bruyne1

1Applied Maths NV, Data Analytics Department bioMérieux, Sint-Martens-Latem, Belgium

Abstract third-party references: bioMérieux

**Background:** In hospital environments, the presence of antibiotic resistant and/or virulent strains are of particular concern. In this work, we present a new, fast and high-resolution multimodal epidemiological analysis of WGS data with bioMérieux EPISEQ® CS that easily provides information on the relatedness, resistance and virulence of strains.

**Materials/methods:** We analyzed WGS data of 22 *E. coli* publically available isolates from either patients with symptoms typical of an *E. coli* infection and asymptomatic carriers. This online application starts from raw reads with de novo assembly, and allows a multimodal approach for epidemiological surveillance including phylogenetic analysis based on whole genome multi-locus sequence typing (MLST), 7-gene MLST, resistome and virulome analysis.

**Results:** After upload of the metadata and fastq.gz files, EPISEQ® CS allowed the analysis of the 22 *K. pneumoniae* isolates with a turnaround time of just over one hour. The analysis outcome provides insight in the quality of the different steps in the pipeline, and clustered all isolates together in the final phylogenetic tree. Five different STs were detected in the set, and four clusters of related strains, two clusters from asymptomatic carriers, one cluster of symptomatic patients and one mixed cluster. The virulome shows the unique presence of stx2 in the cluster of patients, confirming current knowledge on this virulence factor. The strains in the mixed cluster have an identical resistome and virulome suggesting a recent transmission even between carrier and patient.

**Conclusions:** As WGS is also becoming feasible to smaller clinical laboratories, there is a need for automated and standardized analysis of these data. EPISEQ® CS is a fast, high-resolution, easy-to-use and automated WGS application, providing phylogenetic analysis, typing and resistome analysis. The phylogenetic analysis next to the quality information and uploaded metadata provides a useful overview to detect and allow the analysis of possible transmission events and will enhance rapid and accurate epidemiological surveillance in clinical environments.

Comparison of humoral response against both haemagglutinin and neuraminidase after seasonal influenza vaccination

Jose Manuel Mendez Legaza1*, Iván Sanz1, Raúl Ortiz De Lejarazu1, Laura Sanchez De Prada1

1Hospital Clínico Universitario de Valladolid, Valladolid, Spain

Background: Vaccine serological efficacy is performed by analysing the production of antibodies against haemagglutinin (HA). However, seasonal influenza vaccines (SIV) have a non-standardized amount of neuraminidase (NA) and also its immunogenicity to the serological efficacy of the vaccine is not evaluated. The objective of the study is to analyze and compare anti-Neuraminidase (NAI) and anti-Hemagglutinin (HAI) antibodies response after seasonal influenza vaccination.

Materials/methods: Retrospective observational analysis of pre and post-vaccination sera from 160 vaccinated individuals, distributed in two age groups: adults (G1=80;15-64yrs) and elderly (G2=80≥65 years). Both groups received SIV that included the A/California/07/2009 strain of subtype A(H1N1)pdm09. HAI and NAI serological response was analyzed against five influenza strains of seasonal subtype A(H1N1) (A/PR/8/1934; A/Weiss/1943; A/FM/1/1947; A/Brazil/11/1978; A/Brisbane/59/2007) and the A/California/07/2009 strain of subtype A(H1N1)pdm09. Seroconversion rate (SCR) and Increment Ratio (RIC) of HAI and NAI titers against different analyzed influenza strains were compared according to age group. SCR was defined as an increase of at least four times the titres between pre and post-vaccination serum.

Results: Mean age of young-adults was 51.0 years (CI95%:48.2-53.4) and 78.6 years (CI95%:76.6-80.6) in elderly. Seasonal vaccination increased HAI and NAI titers against all influenza strains analyzed in both age groups. The highest SCR of HAI and NAI was observed in elderly against A/California/07/2009 strain. RIC against seasonal subtype A(H1N1) strains ranged from 1.3 to 36.3%. Statistical comparison between SCR and RIC of HAI and NAI titers is described in Table 1.

Table 1. SCR and RIC of HAI and NAI titers against different influenza strains in adults and elderly.

</tbody>
</table>

Conclusions: Results of our study show that SIV against subtype A[H1N1]pdm09 induced a similar serological response of HAI and NAI antibodies in adults and elderly. However, compared to some older A[H1N1] strains, seasonal vaccination induced a significantly greater heterotypic response in terms of NAI antibodies. This increased NAI response occurred despite the fact that the seasonal vaccine does not contain a standardized amount of neuraminidase.

Dissemination of OXA-244-producing *Escherichia coli* in Germany

Jörg B. Hans1, Bernd Neumann2, Rolf Kramer3, Katrin Kremer3, Sebastian Haller3, Niels Pfennigwerth1, Annicka Reuss3, Yvonne Pfeifer2, Guido Werner2, Tim Eckmanns3, Sören G. Gatermann1

1Ruhr-Universität Bochum, National Reference Centre for Multidrug-resistant Gram-negative Bacteria, Department for Medical Microbiology, Bochum, Germany, 2Robert Koch Institute, Wernigerode, Germany, 3Robert Koch Institute, Berlin, Germany

**Background:** Because of their enzyme-mediated antibiotic resistance, carbapenemase-producing Enterobacterales (CPE) are of major public health concern. For diagnostic laboratories in Germany, the National Centre for Multidrug-resistant Gram-negative Bacteria (NRC) provides the cost-free phenotypic and genotypic identification and characterization of carbapenemases. From 2017 to 2019, an annually increasing number of OXA-244-producing *Escherichia coli* prompted the Robert Koch Institute (RKI) to initiate detailed investigations.

**Materials/methods:** Between January 2017 and mid-August 2019, a total of 255 OXA-244-producing *E. coli* isolates from 86 diagnostic laboratories were identified at the NRC, of which 150 isolates were successively subjected to whole genome sequencing (Illumina). We performed *in silico* multi-locus sequence typing (MLST), core genome (cg)MLST and high-resolution SNP analyses.

**Results:** Sequencing of 150 OXA-244-producing *E. coli* isolates identified a total of 16 different sequence types (ST). The majority of isolates (n=102) belonged to ST38, for which results of cgMLST and SNP-based mapping analyses revealed close genetic relatedness, particularly among 63 isolates segregating into a distinct cluster. Distribution of these ST38 *E. coli* isolates was not geographically restricted. Detailed *in silico* analyses showed cluster-specific resistance gene patterns and chromosomal integration of \( \text{bla}_{\text{OXA-244}} \) in all 150 isolates. However, \( \text{bla}_{\text{OXA-244}} \) was found to be integrated at different sites of the chromosome dependent on the clonal background.

**Conclusions:** Here we present a country-wide spread of OXA-244-producing *E. coli* in Germany that is predominantly driven by ST38 variants. Continuous characterization of newly identified isolates and complementary sequencing approaches are needed to identify routes of transmissions as well as the underlying mechanisms leading to the chromosomal plasticity of the \( \text{bla}_{\text{OXA-244}} \) gene.

Abstract 7291

Comparative evaluation of the effectiveness of prophylactic agents based on bacteriophages, liquid soap and skin antiseptics for hand disinfection

Nikita Krivonosov1*, Iren Grigoryan2, Alexey Gordeev3, Alina Melkumyan3, Priputnevich Tatiana3

1Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Moscow, Russian Federation, 2Moscow State University of Medicine and Dentistry, Moscow, Russian Federation, 3National Medical Research Center for Obstetrics, Gynecology and Perinatology named after Academician V.I.Kulakov of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

Background: Comparative evaluation of the effectiveness of prophylactic agents based on bacteriophages, liquid soap and skin antiseptics for hand disinfection.

Materials/methods: The study included 22 students. According to the method of how the students’ hands were disinfected, they were divided into 3 groups. Group I treated hands with soap (n=7), Group II - with skin antiseptic (n=7), and Group III - with gel containing a bacteriophage (n=8). Students’ hands were evaluated on the subject of microbial colonization of the palmar surface before and after treatment with smear imprints on the surface of Petri dishes (d=140) containing blood agar (Oxoid, Great Britain). Grown colonies on blood agar before and after the treatment were counted. Identification of the isolated microorganisms was carried out using Autoflex III mass spectrometer (Bruker Daltonics, Germany).

Results: Before washing and the treatment, all students’ hands were colonized by a large number of microorganisms. After treatment of hands in Group I (liquid soap) and Group II (gel with antiseptic) an increase in colonization by microorganisms post-treatment was observed in 57.1%. 42.9% however demonstrated a reduction in the number of microbes on the surface of the hands. In Group III (bacteriophage gel) 50% of cases showed a significant decline in the number of bacteria grown on Petri dishes. Bacteria belonging to 15 genera were isolated from the surface of the hands as follows: Staphylococcus aureus, Staphylococcus spp., Bacillus spp., Moraxella spp., Micrococcus luteus, Acinetobacter spp., Brevundimonas diminuta, Pseudomonas spp., Kocuria spp., Bergeyella spp., Lactobacillus spp., Enterococcus spp., Corynebacter spp., Brevibacillus spp., Paenibacillus spp., Bacteroides spp.

Conclusions: The main microorganisms colonizing the hands of the students were Staphylococcus spp., Bacillus spp., Micrococcus luteus, Acinetobacter spp., Kocuria spp., Lactobacillus spp. 13 participants (59.1%) carried S.aureus on their hands surface. It has been demonstrated that the treatment with bacteriophage gel is more effective compared to the treatment of hands with liquid soap and gel with antiseptic. Since 12 children had in fact an increase in the number of microbes after the treatment compared with the original colonization on their dirty hands, pupils were given recommendations on effective hand washing.

Presenter email address: n_krivonosov@oparina4.ru
Emergence of Klebsiella quasipneumoniae carrying New Delhi metallo-β-lactamase (blaNDM-1) gene in a Brazilian hospital

Bruno Boettger*1, Antonio Pignatari1

1Unifesp-SP, São Paulo, Brazil

Background: Klebsiella pneumoniae carbapenemase-resistant carrying the blaKPC gene is highly prevalent in some Brazilian hospitals. Recently, isolates of K. pneumoniae carrying blaKPC gene have been described in Brazil. K. pneumoniae were phylogenetically described in four groups (KpI, KpII-A, KpII-B and KpIII), but recently the KpII and KpIII groups were reidentified as K.quasipneumoniae and K.variicola. K.quasipneumoniae can be as virulent as K.pneumoniae carrying and spreading antimicrobial resistance genes. The aim of this study is to characterize through the whole genome sequence (WGS) isolates carrying the blaNDM-1 gene.

Materials/methods: We studied eight isolates of K.pneumoniae carrying blaNDM-1 causing infection in a Brazilian tertiary hospital located in the city of São Paulo in the period of 18/01/2018 – 05/07/2019. They were isolated from bone fragment, blood, catheter, rectal swab and urine. The WGS was performed in an Illumina® MiSeq 2x250 bp platform with paired-end mode. Sequences were assembled using Newbler 3.0 and Ray 2.3.1 software. Automatic annotation was performed using Prokka software, and manual validation was performed using NCBI Blast and the website bigsdb.web.pasteur.fr/klebsiella and genomicepidemiology.org/.

Results: The ribosomal multilocus sequence typing (rMLST) analyzes showed four K.quasipneumoniae isolates; these findings were confirmed by identifying the bla_oxa gene considered chromosomal in this species. In addition, the presence of blaKOP-A and blaKOP-B was used to characterize the subspecies K.quasipneumoniae subsp. quasipneumoniae in two isolates and K.quasipneumoniae subsp. similipneumoniae in another two. All isolates had a multidrug resistance profile including bla TEM-1A, blaCTX-M-15, blaNDM-1, and oxacillinase blaOXA-9, were detected in three isolates. All isolates were susceptible to amikacin and polymyxin B. Through Multilocus Sequence Typing (MLST), we found ST-735 [2] and ST-334 [1]. Single nucleotide Polymorphisms (SNPs) analysis showed that the two K.quasipneumoniae subsp. quasipneumoniae were identical and the two K.quasipneumoniae subsp. similipneumoniae were related.

Conclusions: Extensively drug-resistant K.quasipneumoniae carrying several antimicrobial resistance genes, including metallo-β-lactamase blaNDM-1 is present at this hospital warranting a surveillance in other Brazilians hospitals.

Bacteriocin production in *Staphylococcus aureus* CC398 and CC130 lineages, potential strategies to antimicrobial resistance

Rosa Fernández Fernández¹, Paula Gómez¹, Laura Ruiz¹, Myriam Zarazaga¹, Carmen Torres*¹

¹University of La Rioja, Logroño, Spain

**Background:** *Staphylococcus aureus* (*S. aureus*) frequently colonize the skin and mucous membranes of humans and animals, also being an opportunistic pathogen. Recently, the *S. aureus* genetic lineages CC398 (mostly the livestock-associated methicillin-resistant MRSA) and CC130 (mostly the MRSA containing the mecC gene, frequent in wild animals) have gained public health relevance. Moreover, bacteriocins are antimicrobial peptides secreted by bacteria, with ecological and biotechnological implications. The objective was to determine the bacteriocin production (BP) in CC398 and CC130 strains of different origins with antimicrobial activity against indicator bacteria of public health significance and characterize at genomic level BP-strains.

**Materials/methods:** 43 *S. aureus* isolates CC398 (*n*=25) and CC130 (*n*=18) from (red-deer, magpie, vulture, rabbit, stork, small-mammals, chicken, goat, sheep, water and human) were included in the study. Isolates were methicillin-susceptible *S. aureus* (MSSA, 80% in CC398 and 28% in CC130) and MRSA (20% in CC398 and 72% in CC130, both mecC/meca). All 43 strains were tested for BP by the spot-in-the-lawn method against 19 indicator bacteria (different genera/species), including multi-drug-resistant (MDR) bacteria and relevant pathogens, including zoonotic ones. The presence of bacteriocin related genes was studied in the whole-genome-sequence of the 43 strains (previous studies), using the programs Bagel4 and Geneious.

**Results:** Only one of the 43 *S. aureus* tested showed BP. This BP-strain (C5802, of water origin) was MSSA-CC130-t843 and showed an intense antimicrobial activity against 74% of bacterial indicators tested including MRSA, *Streptococcus suis* and *Listeria monocytogenes*, among others. Bagel4 analysis revealed the presence of possible bacteriocins, mainly sactipeptides and the putative bacteriocin (lactococcin 972, accession nº PF09683). Sequence alignment between the reference sequence (accession nº WP_000726502), the BP-strain and other isolate genetically similar (CC130, t843, MRSA), revealed that all of them have the same nucleotidic/aminoacidic sequence and identical genetic environment. *S. aureus* strain C5802 contained only the resistance gene *blaZ*, and the virulence genes *lukME*, *lukED*, *etD2*, *hlgAB*, *hlgCB*, *edinB*, *splA/B*, *aur*.

**Conclusions:** BP is an unusual character in *S. aureus*; nevertheless, the detection of a BP-strain MSSA-CC130, with low resistance gene content but intense inhibitory action against zoonotic and MDR bacteria, open new therapeutic and biotechnological futures strategies.

Abstract 7302

Streptococcus suis infection: a series of 37 cases from a community-based hospital, Thailand
Subencha Pinsai1*

1 Chao Phraya Aphaiphubet Hospital, Tambon Tha Ngam, Thailand

Background: Streptococcus suis (S. suis) is a gram-positive bacterial pathogen which can cause severe infections in human, including meningitis, and septicemia resulting in serious complications. This study is aimed to describe the clinical features and determine the risk factors for mortality of this life-threatening.

Materials/methods: We conducted a retrospective cohort study among patients diagnosed with culture-confirmed S. suis infection in a community-based hospital in eastern of Thailand from 1 January 2017 to 31 October 2018. All patients’ demographic data, diagnosis, and treatment were retrieved. Median with interquartile range (IQR) and frequency (%) were used to describes patients’ characteristics. Risk factors for mortality were determined by logistic regression analysis.

Results: Thirty-seven patients (22 men and 15 women, mean age 57 years) with S. suis infection were identified. The most common risk of S. suis infection was eating undercooked pork (72.4%). Blood cultures were confirmed S. suis in 36 (97.3%) patients. Clinical presentations included acute meningitis (48.6%), sepsis (21.6%), endocarditis (10.8%). 29.7% were presented with septic shock at the emergency department. Hearing loss was observed in 8.1% and was associated with meningitis. The overall mortality rate was 16.2%. On univariate analysis, acute respiratory failure and septic shock at the emergency department was significantly correlated with a high mortality rate.

Conclusions: S. suis infection is common in Eastern of Thailand, commonly presents with acute meningitis or sepsis. The mortality rate is high. The risk factors for mortality are septic shock and acute respiratory failure at emergency department. High suspicion and early detection are essential and could lead to a successful clinical outcome. The public health educations are crucially needed.

Post-artesunate delayed haemolysis presenting with positive direct antiglobulin test: are steroids a therapeutic option?
Tommaso Ascoli Bartoli*, Luciana Lepore1, Alessandra D’abramo1, Angela Corpolongo1, Andrea Mariano1, Nazario Bevilacqua2, Maria Letizia Giancola1, Claudia Palazzolo1, Laura Scorzonelli1, Pierre Buffet2, Emanuele Nicastri1
1Lazzaro Spallanzani Hospital, Roma, Italy, 2 Paris Descartes Université, Paris, France

Background: After the widespread introduction of artesunate as first-line severe malaria treatment, several cases of "post-artesunate delayed hemolysis" (PADH) have been reported. PADH is defined as a drop >10% of the hemoglobin level, combined with hemolysis blood markers, occurring more than 7 days after the start of intravenous artesunate. PADH pathophysiology is thought to be related to the "pitting" phenomenon and the synchronous delayed removal of once-infected erythrocytes, spared during the parasite killing. However, few PADH cases presenting with positive direct antiglobulin test (DAT) have been reported, suggesting a possible autoimmune pathogenesis. We reviewed published PADH episodes that explicitly included the results of DAT.

Materials/methods: PubMed database was investigated using a string of MeSH terms ("hemolysis" OR "anemia, hemolytic") AND ("artemisinins" OR "artemisinine" OR "artesunate" OR "artemether" OR "artemether, lumefantrine drug combination" OR "dihydroartemisinin") and all the articles published before October 31, 2019 were reviewed. Titles and abstracts were independently screened by two Infectious Diseases specialists and data regarding patients diagnosed with PADH, for whom DAT had been performed, were extracted. Uni- and multivariate analysis of features potentially related to DAT results were performed using SPSS. Mann-Whitney U-test and Fisher’s exact test were respectively used to analyze continuous and categorical variables, while multivariate logistic regression was used to detect features independently associated with outcomes.

Results: Twenty-two studies reporting 39 PADH cases were included: 13 patients (33.3%) were women, median age was 44 years (IQR: 24.5-51.5), median baseline parasitemia was 20.8% (IQR: 11.2-30.0) and DAT was positive in 17 cases (45.5%). Upon univariate analysis, DAT positive patients were older (49.5 vs 31; p=0.01), had higher baseline parasitemia (27% vs 17%; p=0.03) and were more commonly treated with systemic steroids (11 vs 3 patients, p=0.003). Upon multivariate analysis, steroids use was independently associated to positive DAT result (p<0.01).

Conclusions: In this case series focused on immunohematological results, almost half of severe malaria cases with PADH had a positive DAT. Whether the positivity of DAT contributes to anemia and whether the use of steroids is justified requires prospective studies.

Amikacin or colistin monotherapy for complicated urinary tract infections by extensively drug-resistant 
Pseudomonas aeruginosa

Inmaculada López Montesinos1, Silvia Gómez-Zorrilla1, Nuria Prim1, Daniel Echeverría-Esnal3, Maria Pilar Gracia-Arnillas1, M. Milagro Montero1, Luisa Sorlí2, Eduardo Padilla1, Santiago Grau1, Juan F. Horcajada1

1Hospital del Mar, Barcelona, Spain

Abstract third-party references: On behalf of PROA-PSMAR group

Background: To compare the performance of amikacin/colistin monotherapy with other antibiotic regimes in treating complicated urinary infections (cUTI) caused by extensively-drug-resistant (XDR) Pseudomonas aeruginosa (PA).

Materials/methods: Study performed at a 450-bed teaching hospital from 2012 to 2018. All consecutive adult patients with XDR-PA monomicrobial urinary-culture and diagnosed of cUTI were retrospectively reviewed. XDR phenotype was defined according to Magiorakos et al. Clinical failure was considered if: persistence/worsening of infection signs/symptoms, modification of antibiotic therapy or death.

Results: 281 cases with XDR-PA were identified; 133 asymptomatic bacteriuria/non-cUTI and 91 polymicrobial cultures. Overall, 57 cUTI episodes were included. Most XDR-PA were susceptible to amikacin 35 (61.4%) and colistin 57 (100%). History of urinary catheter 34 (59.6%), recurrent UTI 30 (52.6%), benign prostatic hyperplasia 19 (33.3%) and urologic malignancy 13 (22.8%) were frequent. The most frequent antibiotic regimens were: amikacin/colistin 26 (45.6%), amikacin/colistin+carbapenem 13 (22.8%), antipseudomonal-cephalosporins 6 (10.5%) and amikacin/colistin+aztreonam 4 (7%). Median days of treatment: 10 (IQR 7-13.5). Table below summarizes main differences between patients treated with amikacin/colistin alone vs other treatments (including combinations with either of these).

In a logistic-regression model, amikacin/colistin monotherapy was associated with neither clinical failure nor in-hospital mortality. Urologic malignancy (OR 6.44, 95%CI, 1.03-40.3) and prior renal disease (OR 5.39, 95%CI, 1.02-25.6) were independent predictors of clinical failure whereas a high SAPS-II (OR 1.09, 95%CI, 1.01-1.19) was independently associated with in-hospital mortality.

Conclusions: Amikacin/colistin monotherapy showed good efficacy and safety profiles in treating cUTI by XDR-PA.

Impact of porin deletions on the in vitro antimicrobial activity of cefepime-taniborbactam (formerly cefepime/VNRX-5133) in Klebsiella pneumoniae

Tsuyoshi Uehara*, Salvador Vernacchio1, Brittany Miller1, Cassandra Chatwin1, Greg Moeck1, Christopher Burns1, Daniel Pevear1, Denis Daigle1

1VenatoRx Pharmaceuticals, Inc., Malvern, United States

Background: Taniborbactam (formerly VNRX-5133) is an injectable, cyclic boronate β-lactamase inhibitor that inhibits all classes of β-lactamases and restores antibacterial activity of cefepime against Enterobacterales and P. aeruginosa producing both serine-β-lactamases and metallo-β-lactamases. A Phase 3 trial of the cefepime-taniborbactam combination is currently ongoing in patients. Herein, we report the mechanisms of resistance to cefepime-taniborbactam in Klebsiella pneumoniae, and evaluate the impact of deletion of porin genes (ompK35, ompK36 and ompK35/ompK36) and/or the master regulator gene ramA on the activity of cefepime-taniborbactam in K. pneumoniae isogenic strains.

Materials/methods: Minimum inhibitory concentrations (MICs) were determined by broth micro-dilution following CLSI methods. Isolation of mutants less susceptible to cefepime-taniborbactam was performed by selection of K. pneumoniae strains producing NDM-1. Whole genome sequencing was used to identify the mutation sites. Klebsiella pneumoniae isogenic strains lacking OmpK35, OmpK36 and/or RamA, and/or expressing KPC-3 β-lactamase were obtained from Kemyth Biotech.

Results: Selection of K. pneumoniae with cefepime-taniborbactam yielded less susceptible mutants. Genome sequencing revealed a deletion of 2 base pairs in the ompK36 gene that caused frameshift at the codon 159 in one of the mutants, and also lack of OmpK35 in the parent and mutant strains. Because deletion of the OmpK35 and OmpK36 porins reduces permeability to antibiotics, we examined whether porin deletions affected the activity of the β-lactamase inhibitors. The MIC results showed that deletions of the porins reduced the activities of cefepime synergistically with KPC-3. However, restoration of the cefepime activity by the addition of taniborbactam, were not affected significantly by deletion of the porins. Furthermore, the deletion of the two major porins reduced the susceptibility to ceftazidime-avibactam and meropenem-vaborbactam.

Conclusions: In K. pneumoniae, OmpK35 and OmpK36 were the major porins for penetration of cefepime through the outer membrane into the periplasm. By contrast, taniborbactam does not show a strong dependence on OmpK35 or OmpK36 for periplasmic accumulation.

Abstract 7311

Measuring the impact on turnaround time by implementation of a new fully-automated random, continuous-access molecular platform in a large microbiology department

Laura Martínez García*1, Mario Rodríguez1, Concepción M. Rodríguez2, Beatriz Romero2, Rafael Canton Moreno2, Juan Carlos Galán1

1Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación sanitaria (IRYCIS). CIBER en Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, 2Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación sanitaria (IRYCIS), Madrid, Spain, 3Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación sanitaria (IRYCIS). Red Española de Investigación en Patología Infecciosa (REIPI), Madrid, Spain

Abstract third-party references: Abbott Molecular

**Background:** Availability of automated platforms for accurate molecular diagnosis and rapid turnaround time is key to provide an adequate and timely treatment and consequently to reduce transmission rates. The Abbott Alinity m system (Alinity m) is utilizing proprietary ReadiFlex technology, when processing time across different assays is synchronized. This study aimed to evaluate the impact on the reduction of turnaround time after Alinity m implementation, comparing the Alinity m workflow to the current molecular methods used in a tertiary hospital with >30,000 molecular tests per year for HIV/HBV/HCV/HPV and STIs.

**Materials/methods:** Every day, all samples for HIV, HBV, HCV quantification, HPV detection, and STI diagnosis arriving in the laboratory were registered, stored and tested by the routine methods (kPCR for HIV, c6800 for HBV/HCV, c4800 for HPV, and Seegene for STI) and by Alinity m. Two times were evaluated in the comparative study: total turnaround time (from sample arrival to result reporting) and onboard time (from onboard sample registration for Alinity m or start processing for routine methods to result reporting). Two times were measured specifically for Alinity m: time from sample aspiration until result reporting, and processing time for urgent samples.

**Results:** Total turnaround time was analyzed for 860 samples. Fifty percent of samples results were reported within 3 (HBV, HCV, and HPV), 4 (STI) and 7 days (HIV) using the routine methods, while Alinity m reported 100% of the results within 10h. Moreover, 1,229 samples were included into the comparative evaluation of the onboard time. The time until completion of 95% of results was 7:30h for routine methods compared to only 4:15h for Alinity m (including time between sample aspiration and result reporting which was <2h in 100% of the samples). The onboard time for prioritized urgent samples on Alinity m was ≤2:45h.

**Conclusions:** The Alinity m system allows rapid result reporting. It reduces the turnaround time on board by faster sample processing, ReadiFlex technology, and truly random access, compared to the routine methods. The implementation of the Alinity m system in molecular diagnostics could optimize the workload/day and the workflow by avoiding sorting, freezing and thawing steps.

Impact of antibiotic stewardship strategies for Clostridioides difficile infection

Vincent Bérot*, Pascaline Choinier¹, Laurence Drieux-Rouzet², Jerome Robert², Helga Junot³, Alexandre Bleibtreu¹

¹University Hospitals Pitié Salpêtrière - Charles Foix, Infectious and Tropical diseases departement, Paris, France, ²University Hospitals Pitié Salpêtrière - Charles Foix, Microbiology Departement, Paris, France, ³University Hospitals Pitié Salpêtrière - Charles Foix, Central Pharmacy, Paris, France

Abstract third-party references: Diftec network

Background: Clostridioides difficile infection (CDI) remains a frequent and severe complication for inpatients. In 2017, metronidazole prescription counted for more than 70% of CDI treatment in our institution. Local guidelines diffused in May 2018 put oral vancomycin or fidaxomicin (OVF) as first-line treatment for CDI instead of metronidazole. Impact of different antimicrobial stewardship (ASM) strategies towards antibiotic prescription for CDI and its clinical outcomes is undescribed. Our objective is to compare 3 different stewardship periods for CDI management in a tertiary universitary hospital in France.

Materials/methods: All patients with a CDI bacteriologically diagnosed on stool samples were included prospectively from Jan. 1st 2018 to July 31st 2019. Patients whose first documented-on-place episode was a second or more relapse were excluded. Three phases were defined according to stewardship strategies: free prescription (P1, from Jan. 1st to April 30th 2018), local guidelines by printed and numeric flyer (P2, from May 1st to Oct. 30rd 2018) and systematic intervention of the ASM team (from Nov 1st 2018 to July 31st 2019). Primary endpoint was OVF prescription as first-line treatment. Secondary endpoints were mortality and recurrence rates after 90 days and OVF prescription for first relapse.

Results: 213 CDI episodes – 171 first episodes (E1), 31 first relapses (R1), 11 further relapses - were recorded in 232 patients (median age: 67.3 years old (IQR= [56.8-76.5]), 105 female) 16 patients during P1, P2=69 and P3=101. Sixty-four episodes (30.0%) were severe or complicated according to ESCMID definition (P1=46.7%, P2=28.6%, P3=30.2%). We did not show significant difference between different ASM periods for OVF prescription as first-line treatment (P1=85.7%, P2=81.8%, P3=80.2%, p=0.87). In the 171 E1 patients, 17.0% relapsed and 20.4% died before 90 days. We did not show significant difference for relapses or global mortality (p=0.52 and 0.42 respectively).

Conclusions: With more than 80% of adapted prescription during the study periods antibiotics management for CDI is almost adapted to local and international guidelines. We could not show significant impact of our strategies evaluated by improvement of accordance between practice and guidelines for CDI infection by active stewardship compared to free or guided prescription.

Abstract 7314

Molecular characterisation of 15 strains of OXA-181-producing Klebsiella pneumoniae in Spain
Nona Romaní Rodés*1, Albert Moreno-Mingorance1, María Dolores Quesada1, Nieves Larrosa2, Montserrat Gimenez1, Juan Jose González-López2

1Hospital Germans Trias i Pujol, Badalona, Spain, 2Hospital Universitari Vall d’Hebron, Barcelona, Spain

Background: OXA-181 was suggested to be originated in India, from where it has spread worldwide causing sporadic cases. However, there are no cases of clonal dissemination of OXA-181-producing Enterobacteriales reported in Spain. Our objective is to characterize these isolates by using molecular methods and to determine their epidemiological relatedness.

Materials/methods: Retrospective revision and characterization of all OXA-181-producing Enterobacteriales isolated in our hospital between June-2018 and August-2019. OXA-181-producing isolates were identified by in-house PCRs or LAMP-based assay (EazyplexCRE®). Whole genome sequencing (WGS) was used in certain isolates to perform MLST and cgMLST by Ridom software and SNP analysis by SNIPPY pipeline. Antimicrobial resistance markers were identified by Resistance Gene Identifier (version 4.2.2), virulence determinants by VFanalyzer and plasmid incompatibility groups by the PlasmidFinder 2.0 web-based tool. A subset of 23 ST147 Klebsiella pneumoniae (Kp) isolates were additionally used for an in silico comparison of antimicrobial resistance genes, plasmid carriage and typing.

Results: We identified fifteen OXA-181 Kp isolates from urine (11), rectal swab (2), blood (1) and wound (1). Five episodes were considered hospital-acquired infections without epidemiological relationship, 1 healthcare-associated infection and 9 community-acquired infections, with no apparent epidemiological relationship. WGS of 10 isolates revealed that all belonged to ST147. Typing analysis revealed that they only showed 0-1/2513 alleles of difference by cgMLST and 5 variable positions (range 0-5) by SNP analysis. All carried bla_{OXA-181}, bla_{CTX-M-15}, dfrA14, aph[6]-Id, aph[3’]-Ib and amino acid substitutions in GyrA (S83I), ParC (S80I) and MarR (S3N). All presented enterobactin and yersiniabactin siderophores and carried IncFII, IncFIB, IncR, ColKP3, Col440I and Col440III plasmid incompatibility group. Maximum likelihood comparison with isolates belonging to ST147 lineage revealed that they were genetically closer to previously described bla_{OXA-181} isolates identified in Oman, Canada and United Arab Emirates (range 34-50 polymorphic sites) than previously isolates detected in Spain non-OXA-181-producers (range 117-176 polymorphic sites).

Conclusions: Genomic characterization of the OXA-181-producing Kp isolated in our hospital suggests that clonal dissemination of a ST147 strain has been produced, although no epidemiological relationship has been evidenced among the patients. As far as we know this represent the first clonal dissemination of OXA-181-producing Kp isolates in Spain.

Assay for screening of Enterococcus faecium susceptibility to the disinfectant Sodium Dichloroisocyanurate plus detergent

Bolette Skive**, Anette M. Hammerum², Henrik Hasman³, Mette Pinholt³, Christian Stab Jensen³, Inge Jenny Dahl Knudsen⁴, Anne Vinther Kjerulf², Hanne Ingmer⁵

¹University of Copenhagen, Faculty of Health and Medical Sciences, Department of Veterinary and Animal Sciences, Frederiksberg C, Denmark, ²Statens Serum Institut, København, Denmark, ³Hvidovre Hospital, Hvidovre, Denmark, ⁴Rigshospitalet, København, Denmark, ⁵University of Copenhagen, Faculty of Health and Medical Sciences, Frederiksberg C, Denmark

Background: Nosocomial infections caused by hospital-associated clones of Enterococcus faecium have increased globally over the last decades. Enterococci are intrinsically resistant to a number of first-line antibiotics, which makes treatment challenging. Vancomycin is an important drug for the treatment of severe E. faecium-infections, but in Denmark, there has been an alarming increase in the proportion of invasive cases with vancomycin-resistant E. faecium (VREfm) and vancomycin-variable E. faecium (VVEfm) from 0.5% in 2008 to 12% in 2018.

This study investigated whether different hospital clones of E. faecium could survive exposure to relatively high concentrations of Sodium Dichloroisocyanurate plus detergent (NaDCC Plus), possibly contributing to difficulties controlling VREfm/VVEfm outbreaks. Furthermore, we compared to survival of non-hospital isolates.

Materials/methods: 59 Danish clinical isolates divided into six representative groups (hospital-associated “outbreak” clones [VREfm and VVEfm], hospital-associated VREfm of less common ST/CT types, hospital-associated, human community-associated or animal community-associated vancomycin-sensitive E. faecium [VSEfm]) were included. Screening was performed in 96-well plates containing disinfectant in increasing concentrations [50 to 1000 ppm]. Isolates, grown in brain hearth infusion broth [BHI broth] overnight at 37 °C, were diluted to a final concentration of 10⁵ bacteria per well. Exposed to NaDCC Plus. After 10 minutes, the disinfectant was inactivated by adding a neutralizing agent. Plates were spun down, washed with 0.9% NaCl-water and spun down again. The supernatants were discarded and BHI broth was added. Plates were incubated overnight at 37 °C and each well was checked for growth or no growth.

Results: Growth indicated survival of theoretically at least one bacterium. No growth indicated eradication of the inoculum. The average concentration of disinfectant resulting in growth for the 59 isolates was 398 ppm [SD ± 74 ppm]. When the data was grouped into the six groups, according to the classification described above, no statistically significant differences between groups were found.

Conclusions: The results indicate that E. faecium could survive exposure to relatively high concentrations of NaDCC Plus, which could be of concern regarding disinfection in hospital settings. “Outbreak” clones were not less susceptible to NaDCC Plus compared with other E. faecium clones.

Abstract 7317

The role of microbiological surveillance in ensuring the safety of endoscopes reprocessing

Benedetta Tuvo1*, Costanza Bisordi1, Guglielmo Arzilli1, Giuditta Scardina1, Giacomo Visi1, Virginia Casigliani1, Lorenzo Cosco1, Angelo Baggiani1, Beatrice Casini1

1University of Pisa, Department of Translational Research and NTMS, Pisa, Italy

Background: Failure in reprocessing of thermolabile flexible endoscopes has been reported as one of the top ten most important threats to patient health. Microbiological surveillance may be used to identify systematic errors in reprocessing or damaged endoscopes and equipment. Implementation of a microbiological surveillance of endoscope reprocessing is appropriate to detect early colonization and biofilm formation in the endoscope and to prevent contamination and infection in patients after endoscopic procedures.

Materials/methods: The study was conducted in two digestive endoscopy centers of a teaching hospital (29,000 endoscopies/year, of which 550 ERCP). Microbiological surveillance was performed according to the "Duodenoscope Surveillance Sampling and Culturing Protocols" protocol, CDC, 2018, with slight modification. Duodenoscopes were sampled monthly, automatic washer-disinfectors and endoscopes every three months and the medical cabinet twice a year

Results: In the 9 months of surveillance, 43 endoscopes were sampled (13 colonoscopes, 9 gastroscopes, 19 duodenoscopes and 2 echoendoscopes), 12 washer-disinfector machines and 8 medical cabinets. The analyzes were conducted both on the outer surfaces (valve ports, distal end, bridge elevator) and each endoscope channel. High microbial count were detected in 6% (9/154) of valves, with >100 CFU in 3 valves; E. coli was isolated on a bioptic valve of a gastroscope and of a colonoscope, while K. pneumoniae was isolated from the bridge elevator of a duodenoscope.

39% (17/43) of the internal channels of the endoscopes resulted contaminated; E. cloacae were isolated in 10% (2/19) of duodenoscopes, P. aeruginosa in 15% (2/13) of colonoscopes and in 11% (1/9) of gastroscopes. K. pneumoniae was identified in 10% (2/19) of duodenoscopes and NDM-producing K. pneumoniae was isolated in 22% (2/9) of gastroscopes, after the use on a colonized patient. The inlet and final rinsing water of washer-disinfectors resulted always conformed to the parameters required by National low D.Lgs. 31/2001 and by ISO 15883-4, as medical cabinets to the limits required by ISO 16442.

Conclusions: Implementation of a microbiological surveillance of endoscope reprocessing is appropriate to detect early colonization and biofilm formation in the endoscope and to prevent contamination and infection in patients after endoscopic procedures.

Type I interferon in viral and bacterial infections in children
Antoine Ouziel1, Sébastien Viel1, Lucille Boisselier1, Philippe Rebaud1, Romain Basmaci2, Nina Droz3, Tiphanie Sinhoux1,4, Behrouz Kassai-Koupai1,5, Alexandre Belot1, Fabien Subtil1, Sylvie Pons1, Karen Brengel-Pesce1, Yves Gillet1, Etienne Javouhey1, Trouillet-Assant Sophie2

1Hôpitaux Civils de Lyon, Lyon, France, 2Hôpitaux Civils de Lyon, Joint unit Hospices Civil de Lyon/Biomérieux, Pierre-Bénite, France, 3Hôpital Nord-Ouest, CH de Villefranche-sur-Saône, Gleizé, France, 4Hôpital Louis-Mourier, APHP, Colombes, France, 5Université de Lyon and Hospices Civils de Lyon, Centre d’Investigation Clinique, 1407 Inserm, UMR 5558, LBME, CNRS Lyon, Lyon, France

Background: Type I interferons (IFNs) are involved in the antiviral response and in the pathophysiology of some autoimmune disease such as type I interferonopathies. Secreted at femtomolar concentrations during course disease, detection of type I IFN in these patients remains challenging. This issue has led several groups to develop an alternative strategy for the detection of this group of cytokines. Based on quantification of expression of IFN-stimulated genes, blood transcriptional IFN signatures have been developed and are currently used for the screening of patients with interferonopathies.

Distinguishing between bacterial and viral infections etiologies in febrile patients remains challenging, especially in children. Misdiagnosis of disease etiology are responsible of inappropriate antibiotic prescription. We hypothesized that specific host biomarkers for viral infections, like type I-IFN, could help clinicians decisions and limit antibiotic overuse.

Materials/methods: This is an ancillary study of the prospective multicentric protocol ANTOINE (NCT03163628). Paxgene® tubes and serum were collected from febrile children aged from 7 days to 36 months with proven viral (n=17) or bacterial (n=33) infection admitted in pediatric emergency departments in France. We have assessed the performance of IFN signature calculated using Nanostring® technology and plasma IFNα quantified by digital ELISA technology (Quanterix®).

Results: Serum level of IFNα were below the quantification threshold (30fg/mL) for 6% (1/17) and 67% (22/33) of children with proven viral and bacterial infection respectively. IFNα levels were significantly higher in viral compared to bacterial infection (median [IQR] 511.2 [559; 1014.1] and 132 [37; 3708] fg/mL respectively, p<0.001). We noticed a strong correlation between serum IFN-α concentrations and IFN score (r=0.83 [CI 0.75, 0.89]). Both serum level IFN-α and IFN score robustly discriminated (AUC 0.88 [CI 0.78, 0.99] and 0.85 [0.72, 0.97] respectively) between viral and bacterial infection in febrile children.

Conclusions: Our study suggests that measurement of IFNα femtomolar concentrations as well as IFN signature could offer new perspectives for improving diagnosis and limiting antibiotic overuse in febrile children. Our patient recruitment and investigations are still ongoing to ultimately confirm if these markers could become key biomarkers in the decision-making process of clinicians dealing with febrile children.

Abstract 7320

**Antimicrobial activity, synergy and toxicity of a new gold(III) complex (AuC2) against multidrug-resistant pathogens with no detectable resistance**

Carlos Ratia1, Virgilio Cepas Lopez1, Raquel Soengas2, Yuly López Cubillos1, María Velasco De Andrés1, María J. Iglesias1, Francisco Lozano3, Fernando López-Ortiz2, Sara Maria Soto*1

1ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona Institute For Global Health (ISGlobal), Barcelona, Spain, 2CIAIMBITAL Research Centre - Universidad de Almería, CIAIMBITAL, Almería, Spain, 3Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

**Background:** The worldwide emergence and spread of infections caused by multidrug-resistant (MDR) bacteria endangers the efficacy of current antibiotics in the clinical setting. The lack of new antibiotics in the pipeline points the need of developing new strategies. Gold(III) complexes could be a promising alternative due to their antibacterial activity. We evaluate the effectiveness of a gold(III) complex alone and in combination with antibiotics against MDR clinical isolates as well as its in vitro and in vivo toxicity.

**Materials/methods:** Susceptibility of gold(III) complex (AuC2) was assessed in planktonic and biofilm growth, by both microdilution and crystal violet staining respectively, against MDR strains of Pseudomonas aeruginosa, Methicillin-resistant Staphylococcus aureus, Stenotrophomonas maltophilia, Acinetobacter baumannii, and Escherichia coli. Antimicrobial interactions in vitro were determined by the checkerboard method. Point-of-resistance studies were determined by 30-daily sequential passages in sub-MIC concentrations of AuC2. Cytotoxicity assays were performed in HepG2 and THLE-2 cell lines by MTT assay and hemolysis detection in human erythrocytes. For acute toxicity in vivo, CD1 female mice were treated by single intravenous 2.5 mg/Kg doses, toxicity signs were monitored for 14 days after treatment and Organ Weight/Body Weight (OW/BW) coefficients were calculated to assess organ toxicity.

**Results:** Susceptibility studies in planktonic and biofilm state showed high efficacy of AuC2, markedly against MRSA, presenting MIC=0.125-0.25 mg/L and MBIC=0.5-1 mg/L. Drug interaction checkerboard method showed a synergistic effect of AuC2 when combined with colistin or aminoglycosides in all MDR gram-negative strains tested. No resistant mutants were obtained after 30 days of sequential cultures. No hemolysis or cytotoxicity was detected at AuC2 therapeutic concentrations. Mice showed no significant weight loss or other toxicity signs within the 14 days post-treatment. No statistically different BW/BW values were obtained when compared to the untreated control.

**Conclusions:** Newly described gold(III) complex AuC2 has shown antimicrobial activity against MDR pathogens, specially MRSA strains in planktonic and biofilm state. Its potent synergistic effect combined with colistin or aminoglycosides in gram-negatives, its inability to produce resistant mutants, as well as its low in vitro and in vivo toxicity, makes it a promising candidate in the fight of antimicrobial resistance.

Abstract 7321

The 2017 epidemic of pulmonary plague in Madagascar
Julia Ratomaharo*1,2, Rabezanahary Andriamihaja3, Lucien Razafindrakoto4, Rivo Rakotoarivel05, Mamy Randria6, Danielle Vololontiana7

1Hôpital Privé d’Athis-Mons - Site Caron, Service de Pneumologie, Athis-Mons, France, 2Hôpital Privé d’Athis-Mons - Site Caron, Pneumologie, Athis-Mons, France, 3Toamasina, Toamasina, Madagascar, 4Toamasina, CHU Toamasina, Toamasina, Madagascar, 5Fianarantsoa, universite, Fianarantsoa, Madagascar, 6universite Antananarivo, CHU Befelatanana, Antananarivo, Madagascar, 7University of Antananarivo, CHU Befelatanana, Antananarivo, Madagascar

Abstract third-party references: pneumalgia

Background: Plague, Yersinia pestis (YP), is a zoonotic infection of rodents, transmitted to humans by flea. Plague is a reportable disease that is endemic to Madagascar with bubonic plague being the most common seasonal manifestation. In 2017 an unexpected epidemic of pulmonary plague (PP), a rare clinical form, occurred in Madagascar involving 2348 patients (791 cases of pulmonary plague (22% confirmed, 34% probable and 44% suspected), 341 cases of bubonic plague, a case of septicemic plague and 215 cases of unspecified type. There were 202 deaths during this epidemic. Confirmed, probable or suspected plague cases were reported to WHO by the Malagasy Ministry of Public Health. This epidemic of pneumonic plague raised many questions and issues related to diagnosis, treatment and prophylaxis, socio political and cultural aspects some of which remain unanswered. We report a summary of the challenges that local healthcare professionals faced during this unprecedented outbreak.

Materials/methods: Symptoms were frequently severe with brutal onset, high fever, profound deterioration of the general condition. Severe respiratory signs were observed: cough, hemoptoid sputum, chest pain, cyanosis. Without treatment death occurred in 1-3 days in 100% of the cases. Confirming the diagnosis was challenging and relied on culture for YP, rapid diagnostic test detecting F1 capsular antigen, detection of antibodies. Testing was performed at the Laboratoire Central de la Peste which led to delays in getting results to clinicians.

Results: Additionally, the RDT proved to have inadequate sensitivity for pneumonic plague. Treatment was with intramuscular streptomycin which was poorly tolerated by patients. Supplies (gloves, gowns and surgical masks) required for infection control measures were not readily available and waste disposal was a major challenge. Communication between hospitals proved to be challenging. Protection rules and special burial protocol were applied leading to a big source of conflict with the patient’s families.

Conclusions: YP remains a major public health problem in Madagascar and the pneumonic plague outbreak presented numerous challenges to clinicians and healthcare workers charged with identifying and controlling outbreaks. Improving the health infrastructure with basic supplies is critical for those at the front line.

Recruiting donors for faecal microbiota transfer: a one year experience

Andrea Aira1, Veronica Rico Caballero1, Elisa Rubio Garcia1, Climent Casals-Pascual1,2, Alex Soriano1,3

1Hospital Clinic de Barcelona, Barcelona, Spain, 2ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, 3Universitat de Barcelona / IDIBAPS, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

Background: Prior to performing fecal microbiota transfer (FMT), eligible donors undergo comprehensive screening to prevent potential infectious and non-infectious disease transmission. The difficulties to find eligible relatives from which to obtain stool samples can be solved by using universal screened donors, which can also increase the cost-effectiveness of the procedure. The aim of the study was to evaluate the success of finding eligible donors in our hospital.

Materials/methods: University students were informed and received a prescreening questionnaire about lifestyle habits, medical history and general health conditions to identify any exclusion criteria. Those who met the inclusion criteria were called for a personal interview in which they received detailed information, signed the informed consent and were subjected to medical examination, blood and fecal analyses. Any major alteration implied their exclusion and those qualified as donors were asked to avoid eating common allergens within 5 days prior to stool donation. They received a donation bag containing the necessary material for sample collection and a second questionnaire to report any change in their health status between screening and donation day. The samples were collected within 4-6 hours before being delivered to our laboratory. Donors provided samples during the following 2 weeks after screening.

After their participation, all volunteers received an economic compensation. Donors were asked to fill in a satisfaction questionnaire to obtain information about their experience during the recruitment process.

Results: Table 1. Results from stool donors screening and their characteristics.

<table>
<thead>
<tr>
<th>Invited to participate</th>
<th>Pre-screening survey</th>
<th>Blood and stool screening</th>
<th>Bring valid sample</th>
<th>Mean Age</th>
<th>Gender</th>
<th>Mean BMI</th>
</tr>
</thead>

<td>64.29% female</td>
<td>21.21kg/m² (range 18.6-24.9 kg/m²)</td>
</tr>
</tbody>
</table>

The satisfaction questionnaire showed that 62.5% (n=10) of respondents knew about FMT prior to participating in our study although the same percentage didn’t know about stool donation. Only 31.25% (n=5) would repeat as donors without receiving any remuneration.

Conclusions: The eligibility success in this population was 22%, showing higher rates than other studies. Although general population is not aware of FMT, university students showed interest in being stool donors favored by economic motivation.

Abstract 7328

Mupirocin exposure in the preceding year is associated with mupirocin resistance among methicillin-resistant *Staphylococcus aureus* in a tertiary care hospital in the United States of America

Edward Drehs*, Lauren Holt, Seetha Lakshmi, Joshua Kalter, Abel Abraham, Kimberly Atrubin, Peggy Thompson, Suzane Silbert, Ambuj Kumar

University of South Florida, Division of Infectious Diseases, Tampa, United States, *Morsani College of Medicine, Tampa, United States, Morsani College of Medicine, Department of Internal Medicine, Tampa, United States, Tampa General Hospital, Tampa, United States

Abstract third-party references: University of South Florida, Department of Infectious Diseases, Tampa General Hospital

Background: Methicillin-resistant *Staphylococcus aureus* (MRSA) infections are associated with increased morbidity and mortality in nosocomial settings. Active surveillance and decolonization with mupirocin are vital components of MRSA control strategy. Emergence of mupirocin resistance (MR) poses an increasing threat to MRSA control efforts. Hence, this study aims to identify risk factors for emergence of MR among MRSA isolates in a 1040 bed tertiary care academic center in the United States of America.

Materials/methods: We conducted a retrospective cohort study. All consecutive hospitalized patients who screened positive for MRSA from May to August 2019 were eligible for inclusion. We tested for MR among MRSA culture positive isolates and reviewed risk factors for development of MR. The association between MR and risk factors was assessed using binary logistic regression and summarized as odds ratios (OR) along with 95% confidence intervals (CI). Statistical analyses were carried out using IBM SPSS software.

Results: A total of 326 MRSA positive samples were obtained during the study period. Of these, 235 patients had MRSA that were culture proven, and were tested for mupirocin susceptibility. MR was seen in 38.7% of the patients. Patients with mupirocin sensitive and resistant strains were similar in gender, location of transfer (hospital to hospital transfer, transfer from rehab facilities), presence of diabetic ulcers and chronic skin disorders. Following risk factors for mupirocin resistance were associated with MR: pressure ulcers (OR: 2.53, 95% CI 1.25-5.14; p=0.01), nursing home placement prior to admission (OR 2.48, 95% CI 1.01-6.07; p=0.047), mupirocin exposure within one year of admission (OR 7.01, 95% CI 3.90-12.59; p<0.001), age >59 years (OR 2.77, 95% CI 1.6-4.8; p<0.001) and intranasal mupirocin administration within one year (OR 6.58, 95% CI 3.68-11.78; p<0.001).

Conclusions: Prior mupirocin exposure within one year of admission poses increased risk of MR. Further investigation is needed to understand the effect of pressure ulcers and prior nursing home placement on the emergence of MR. These findings warrant early testing strategies for detection of MR and use of alternative decolonization strategies in patients with high risk for MR.

Comparing the financial burden of hospitalised patients within the same Diagnosis Related Groups (DRGs) with and without an infection: a multi-centre evaluation in the USA

Laura Puzniak¹, Kalvin Yu*², Vikas Gupta²

¹Merck & Co., Inc., Kenilworth, United States, ²Becton, Dickinson and Company, Franklin Lakes, United States

Abstract third-party references: This study is supported by Merck & Co., Inc., Kenilworth, NJ, USA

Background: Slow uptake of new antimicrobials may be due to perceived higher cost relative to generic comparators. We compared the mortality and financial outcomes of similar hospitalizations that did or did not have an infection to determine the attributable total cost of an infection.

Materials/methods: We analyzed 92 hospital’s microbiology, general laboratory, antimicrobial orders and administrative data from 10/2015-7/2018 [BD Insights, Franklin Lakes, NJ USA]. Infection positive was defined as adult [≥ 18 yrs] admissions prescribed ≥ 72 hours of antibacterial therapy meeting the following: 1) infection ICD10 code [pneumonia, sepsis, urinary tract infections, skin/wound infection, or intra-abdominal infection] regardless of culture, 2) no infection ICD10 code but culture collected. Admissions with a length of stay (LOS) ≥ 3 days not meeting infection criteria and no antimicrobials prescribed was classified as no infection. We evaluated hospital mortality, LOS, intensive care unit (ICU) LOS, hospital cost, payment, and gain/loss per case within each non-infection diagnosis related group (DRG) that included an infection in the same DRG but without infection. Pair-wise comparisons were analyzed using t tests followed by Cohens d for the effect size.

Results: Across 704,559 total admissions, 303,650 met the study criteria. Of these, there were 133,423 with an infection and 170,227 without an infection. The DRG adjusted outcomes were significantly higher with versus without infection as follows: avg. additional LOS (4.5 days, p < 0.0001); avg. additional ICU LOS (1.3 days, p < 0.0001); avg. hospital cost ($10,953, p < 0.0001); avg. additional loss (-$3,087, p < 0.0001). Outcome differences varied by DRG type. The top 10 DRGs with infection in frequency are in table below.

</tbody>
</table>

Conclusions: The financial burden of admissions with an infection are significantly greater than the same DRGs without an infection. It is important to identify these groups with high risk of infection and high resource utilization that may be in need of treatment optimization. The cost of appropriate use of newer antimicrobials could be offset if there are benefits derived from decreased resource utilization in these patient groups.

**Abstract 7331**

**Limited value of fluorescence in situ hybridization for the detection of *Coxiella burnetii* in tissue samples of patients with chronic Q fever.**

Sheila Bianca Buijs*, Tim Jensen², Mirjam Hermans³, Mette Boye⁴, Peet Nooijen¹, Andy I.M. Hoepelman¹, Chantal Bleeker-Rovers³, Jan Jelrik Oosterheert¹, Peter Wever³

¹UMC Utrecht, Utrecht University, Utrecht, Netherlands, ²Technical University of Denmark, National Veterinary Institute, Kgs. Lyngby, Denmark, ³Jeroen Bosch Ziekenhuis, ’s-Hertogenbosch, Netherlands, ⁴Norwegian Veterinary Institute, Oslo, Norway, ⁵Radboud University Medical Center, Radboud Expert Center for Q Fever, Nijmegen, Netherlands

**Background:** Chronic infection with *Coxiella burnetii* is notoriously difficult to diagnose and is based on a combination of clinical, microbiological and radiologic characteristics. When *C. burnetii* is detected in blood or tissue, the diagnosis is considered proven. However, culturing *C. burnetii* is time-consuming and only possible in a biosafety level 3 lab, and polymerase chain reaction (PCR) on formalin-fixed tissue samples lacks sensitivity. Fluorescence in situ hybridization (FISH) is a promising technique, but its diagnostic value alone or in comparison to PCR has not been determined. We evaluated the diagnostic value of FISH for the detection of *C. burnetii* in formalin-fixed tissue samples.

**Materials/methods:** *C. burnetii* FISH and *C. burnetii* PCR were performed on formalin-fixed tissue samples from Dutch chronic Q fever patients collected during surgery or autopsy. A positive percentage agreement was calculated. Patient and disease characteristics were collected from electronic medical records.

**Results:** From 19 chronic Q fever patients, 27 tissue samples were available: 19 (70%) vascular walls, three (11%) tissues surrounding prostheses, two (7%) placentas, two (7%) lung tissues, and one (4%) heart valve were examined by both FISH and PCR. Of 24 PCR positive samples, 9 (37.5%) were also FISH positive. Two PCR negative tissues, both placentas, were FISH positive. FISH positive and negative results had similar time before fixation (<1h, 63.6% vs. 66.7%, p=0.41), PCR CT values (mean, 21.68 vs. 24.94, p=0.39), similar treatment during retrieval of samples (27.3% vs. 20.0%, p=0.21), *C. burnetii* PCR serum positivity (45.5% vs. 60.0%, p=0.50), and phase II IgG titers during retrieval of samples (mean, 2,048 vs. 4,096, p=0.12). Sampling error might have occurred given discordant FISH results in tissue sections from one patient obtained at the same moment.

**Conclusions:** As compared to PCR, FISH had a positive agreement percentage of 37.5%. Given the FISH positive results in PCR negative placentas, FISH does seem to have an additional value in combination with PCR and remains an interesting technique to further examine in patients with chronic Q fever.

Abstract 7336

An innovative model to analyze anti-biofilm immune response in vivo
Léo Sauvat*, Aizat Abdul Hamid1, Christelle Blavignac2, Frédéric Laurent3, Olivier Lesens4, Pascale Gueirard1

1Clermont Auvergne University, Laboratoire Microorganismes : Génome et Environnement, UMR CNRS 6023, Clermont-Ferrand, France, 2Clermont Auvergne University, Centre Imagerie Cellulaire Santé, Clermont-Ferrand, France, 3Université Claude Bernard Lyon 1, Centre International de Recherche en Infectiologie (CIRI), UMR CNRS 5308, Lyon, France, 4University Hospital of Clermont-Ferrand, Infectious and Tropical Disease Unit, Clermont-Ferrand, France

Background: Due to its ability to form biofilms, *Staphylococcus aureus* (*S. aureus*) is responsible for an increasing number of infections on implantable medical devices with a high mortality rate. In order to simulate this, a mouse model of infection consisting of microbeads coated with *S. aureus* biofilm has been developed to analyze the dynamics of anti-biofilm inflammatory responses by intravital imaging.

Materials/methods: *In vitro*, silica microbeads were coated by a biofilm of *S. aureus* (fluorescent strain SH1000 mCherry+). Then, biofilm was injected intradermally into the ear tissue of LysM-EGFP transgenic mice (fluorescent polymorphonuclear neutrophils and macrophages). Different kinds of inocula were compared: microbeads coated by biofilm, a mixture of microbeads and planktonic bacteria, microbeads alone. The inflammatory responses in ear tissue were studied in real time by confocal microscopy at early (4h) and late time point (24h) after injection. The displacement properties of immune cells (average velocity, trajectory linearity) were analyzed.

Results: *In vitro*, we confirmed coating of microbeads by biofilm by labeling matrix components and observing biofilm ultrastructure at the microbeads surface by scanning electron microscopy. In vivo, the global analysis of inflammatory responses showed a massive recruitment of EGFP+ cells between early and late time points. Observation of cell recruitment in real time at the injection site revealed a difficult access to biofilm bacteria for immune cells. At 4h, the average velocity of cells after infection was decreased for planktonic and biofilm forms compared to control mice (p < 0.01). In tissue areas with direct contact between immune cells and bacteria, the average cell velocity and linearity were decreased regardless of the form (p < 0.001 and p < 0.05 respectively). At 24h, we observed a decrease in the mean velocity for both bacterial forms in direct contact with bacteria (p < 0.05).

Conclusions: This original model provides an innovative way to analyze the specific immune responses against biofilm infections on medical devices. It paves the way for live evaluation of the effectiveness of immunomodulatory therapies combined with antibiotics.

Abstract 7339

**Multidrug-resistant A. baumannii beyond colistin era: in vitro synergy of ceftazidime/avibactam in combination with antibiotics**

Helen Moraitou1, Vassiliki Perdiou1, Magdalini Makarona1, Anna Mavrommati1, Konstantinos Pontikis1, Sophia Triantafyllou1, Maria Voutou1, Theopoula Kiousi2, Simona Karabela2

1Athens, Sotiria General Hospital of Chest Diseases, Athens, Greece, 2Athens, Athens, Greece, 3Athens, ICU, 1st Dept of Respiratory Medicine, University of Athens, Athens, Greece

**Background:** Multi-drug resistant (MDR) A. baumannii presents a global threat for hospital-acquired infections and colistin-resistance is rapidly evolving in the hospital setting. A number of patients, especially in ICU, are co-infected by other MDR organisms, mainly K pneumoniae. This study investigates the possible in vitro synergy effect of ceftazidime/avibactam, which is a potent compound for KPC+ K pneumoniae, with colistin, tigecycline and fosfomycin against MDR A. baumannii strains.

**Materials/methods:** Forty MDR A. baumannii strains, resistant to carbapenems and colistin were included in the study. Strain identification and antibiotic susceptibility was originally performed by Vitek2 system (bioMerieux) and susceptibility to colistin tested by broth dilution method (ComASP Colistin, Liofilchem srl) according to EUCAST guidelines. All strains were screened for MIC by E-test (Liofilchem srl), against colistin (COL), fosfomycin (FOS), tigecycline (TIG) and ceftazidime/avibactam (CAZAVI) and the in vitro synergistic effect of combinations COL+CAZAVI, FOS+CAZAVI, TIG+CAZAVI was determined by E-test cross onto Muller Hinton agar plates (Oxoid), according to published methods. All strains were clinical isolates from blood, bronchial secretion or pus cultures, collected from January to October 2019. Synergy effect of all antibiotic combinations was calculated using the Fractional Inhibition Concentration index formula (MIC\(AB\)/MIC\(A\) + MIC\(BA\)/MIC\(B\)) and result was interpreted as: Synergy < 0.5, Additive 0.5-1.0, Indifference >1.0 - <4.0 and Antagonism >4.0.

**Results:** All strains were resistant to colistin both by broth dilution method and E-test, with MICs ranging from 4 to 64 mg/l, as well to CAZAVI with MICs from 12 to 32 mg/l. MICs to FOS were ranging from 1 to 64 and TIG from 0.50 to 16.

**Conclusions:** The findings of this study suggest that a significant synergy effect is observed with all tested combinations of CAZAVI. The combination with no antagonism effect was COL+CAZAVI, whereas FOS+CAZAVI showed the most antagonism effects. There is an indication of testing for synergy all MDR A. baumannii strains, even colistin-resistant ones, as there are high possibilities of achieving a synergistic effect.

Abstract 7340

Genomic insights into the dynamic of OXA-48-producing Enterobacterales in a veterinary hospital

Marisa Haenni1*, Henri-Jean Boulouis1, Chatre Pierre1, Edouard Hirchaud2, Jean-Yves Madec1

1Université de Lyon – Anses site de Lyon, Unité Antibiorésistance et Virulence Bactériennes, Lyon, France, 2Ecole Nationale Vétérinaire d’Alfort, BioPôle, Unité de Bactériologie, Maisons-Alfort, France, 3ANSES Ploufragan-Plouzané-Niort Laboratory, Viral Genetic and Biosecurity Unit, Ploufragan, France

Background: Carbapenem-resistance is still rare in Europe in animals due to the prohibition of carbapenem use in the vet sector. There are nevertheless a few specific exceptions, including the VIM-1 spread in the food chain in Germany and the sporadic detection of OXA-48 throughout Europe in companion animals. In this study, we characterized the dynamics of resistance to carbapenems in Enterobacterales in dogs in a French veterinary hospital.

Materials/methods: Between February and May 2017, 124 healthy dogs admitted for non-infectious surgery at a veterinary hospital in Paris were sampled on their arrival (t0) and when they left (t4). Environmental samples within the hospital were also taken. Bacteria were isolated on selective media for the detection of carbapenem-resistant Enterobacterales. Identification was performed by Maldi-TOF. Non-duplicate isolates were characterized by antimicrobial susceptibility testing (disc diffusion) and whole-genome sequencing (NGS) using the NovaSeq technology. Analyses were performed using the CGE website.

Results: Fifteen OXA-48-producing Enterobacterales were identified: one Citrobacter freundii, 3 Klebsiella pneumoniae, 4 Escherichia coli and 7 Enterobacter cloacae. Six E. cloacae originated from the environment within the hospital. One OXA-48-positive dog arrived and left with the same OXA-48-producing K. pneumoniae, whereas a second one entered with an OXA-48-producing E. coli that was not detected when the dog left. Three additional dogs most probably acquired OXA-48 during their stay in the hospital, of which two animals presented respectively two and three OXA-48-producing Enterobacterales. A wide genetic diversity was observed except for K. pneumoniae, which all belonged to the sequence type [ST]11. All blaOXA-48 genes were carried by an IncL plasmid.

Conclusions: OXA-48-producing Enterobacterales were resident, transient and/or acquired in the veterinary hospital. NGS data suggest a complex dynamic of OXA-48 clonal and plasmid spread, and most likely highlight E. cloacae as a local reservoir of carbapenem-resistance. Since one dog left with the same OXA-48-positive E. cloacae recurrently identified in the environment, a direct transmission is also plausible. Two dogs presented several OXA-48-producing Enterobacterales, proving the high mobility of the OXA-48/IncL plasmid. In the absence of carbapenem prescription, such a significant OXA-48 epidemiology remains unclear but of major public health concern.

Regional dissemination of Klebsiella pneumoniae ST147 NDM-1 in Poland

Marta Biedrzycka1, Radosław Izdebski*, Anna Baraniak1, Monika Machulska1, Paweł Urbanowicz1, Dorota Żabicka1, Elżbieta Literacka1, Waleria Hryniewicz1, Marek Gniadkowski2

1National Medicines Institute, Warsaw, Poland

Background: Since 2011 the large countrywide Klebsiella pneumoniae ST11 NDM-1 outbreak has been observed in Poland, with rate growing exponentially year by year, reaching over 2000 cases in 2018 and over 7000 affected patients in total. In March 2015 three Polish nationals were seriously injured in terrorist attack in the Bardo National Museum located in Tunis, Tunisia, and after surgical intervention on place they have been transported to hospital in Warsaw. From all three patients K. pneumoniae blaNDM-1 gene localized in Tn125 derivative and represented ST147 were detected at admission. Here we present contribution of ST147 in NDM-1 outbreak in Poland from first isolation till the end of 2017 providing molecular data, including the whole-genome sequencing (WGS) results.

Materials/methods: The study comprised 4504 unique NDM-positive K. pneumoniae isolates identified between April 2015 and December 2017. NDMs were detected by CarbaNP and PCR. Polymorphism of blaNDM-carrying Tn125-like elements, being a screening molecular marker, was assessed by PCR-mapping. Isolates representing variant Tn125F, characteristic for ST147 from Tunisia, were subjected to further analysis. All Tn125F-variant isolates were typed by PFGE and randomly by MLST. Seventeen K. pneumoniae ST147 NDM-1 outbreak isolates were subjected to WGS by Illumina MiSeq. Their sequences were analyzed by cgMLST and compared with 23 international ST147 isolates of the Institut Pasteur Klebsiella MLST database.

Results: One hundred and five K. pneumoniae isolates with Tn125F-variant, containing 5353bp fragment harbouring blaNDM-1 from 253bp 3’end of tnpA ISaba125 to 1250bp 5’end of groEL, were analysed. The material were collected in 24 medical centres in 13 cities in 2015 (n=9), 2016 (n=13) and 2017 (n=83), including one centre in Warsaw with 70 cases. All isolates represented single PFGE type and were classified to ST147. Based on WGS the outbreak ST147 isolates formed a separate cluster of closely-related genotypes, differing in 1-7 locus each at all 629 target loci.

Conclusions: The results documented the progressing spread of K. pneumoniae ST147 NDM-1 in Poland, with serious problem in one centre in Warsaw, being far behind of endemic K. pneumoniae ST11 NDM-1.

Abstract 7342

10 years surveillance of West Nile virus neuroinvasive disease
Corneliu Petru Popescu*1,2, Simin Florescu1,2, Mihaela Zaharia1,2, Delia Stanciu1, Melinte Violeta1,2, Valentina Simion1,2, Cristiana Cristea1,2, Bianca Voinescu1, Elena Nedu1, Filofteia Cojanu Baniciu1,2, Olivia Burcos1, Adelina Dogaru1, Alma Gabriela Kosa1, Daniel Codreanu1,2, Gratiela Tardei2, Manuela Nica1,2, Emanoil Ceausu1, Simona Maria Ruta1,2

1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, 2Dr Victor Babes Clinical Hospital of Infectious and Tropical Diseases, Bucharest, Romania, 3Ştefan S. Nicolau Institute of Virology, Bucharest, Romania

Abstract third-party references: The research was funded through CCCDI-UEFISCDI project PN-III-P1.2-PCCDI-2017-0005/2018.

Background: During the last 10 years have been observed major changes in West Nile virus human infections, with spread in new regions and increasing mortality.

Materials/methods: We analyzed patients hospitalized with West Nile virus neuro-invasive disease (WNND) in a tertiary infectious diseases hospital from May 2010 to November 2019, in order to characterize patients and to identify the prognostic factors associated with the severe outcome of patients.

Results: In this period, a total of 115 cases of WNND, median age 64 years, 51.3% males, were hospitalized with the overall mortality rate at discharge 2.1% (25 patients). Most cases have been in the years 2016 (15 cases), 2017 (23 cases), 2018 (41 cases) and 2019 (22 cases). All deaths were recorded during 2016-2019. In addition other 3 patients died in first month of follow-up after discharge [3.33% from survivors at discharge]. The median age of deceased patients was significantly higher than that of survivors [78 years (IQR 75.0-84.5) vs 64 years (IQR 50-77.25), p<0.001]. Average days of hospitalization was 16.3 days [from 1 to 64 days]. Long rank test (Mantel-Cox) indicates significant differences between the days of hospitalization depending on the clinical forms. Deceased patients had clinical forms of meningo-encephalitis (72%) or encephalitis (28%), and associated several cardio-vascular co-morbidities: ischemic heart disease (80% vs. 34.4%), arterial hypertension (80% vs. 57.8%) or congestive heart failure (28% vs. 8.9%). Clinical signs associated with severe prognosis were coma (92% vs. 23.3%), Glasgow coma score [9.16 (IQR 7.89-10.43) vs. 13.39 (IQR 12.89-13.89)], change in consciousness [100% vs. 51.1%], obtundation [96% vs. 37.8%], disorientation [96% vs. 66.7%] and speech disorders [76% vs. 35.6%], 70% of deceased patients died in the first 20 days after hospital admission [Figure]. Of all survivors at discharge 51 (44.3%) had sequelae and at one month follow-up still had sequelae 47 patients (40.8%). The most frequent sequelae were weakness, tremor of the extremities and ataxia.

Conclusions: Severe outcome of WNND is associated with age, cardio-vascular co-morbidities and several neurological signs. WNND remains an important cause of morbidity and mortality with long length of stay in hospital with re-emergence in our region.
Abstract 7351

**OXA-48 producing Klebsiella pneumoniae in non-hospitalised elderly patients in Zagreb, Croatia**

Jasmina Vranes*1, Sandra Suto2, Branka Bedenic3, Ana Milnaric-Dzepina4, Saša Likić5, Sara Kibel1, Jasna Knezevic1, Maja Anusic2, Vladimira Ticic2, Andrea Grisold6

1Teaching Institute of Public Health “Dr. Andrija Stampar” and Zagreb University Medical School, Zagreb, Croatia, 2Teaching Institute of Public Health “Dr Andrija Stampar”, Zagreb, Croatia, 3University Hospital Zagreb and Zagreb University Medical School, Zagreb, Croatia, 4School of Medicine, University of Zagreb, Zagreb, Croatia, 5University Hospital Osijek, Osijek, Croatia, 6Institute of Hygiene, Microbiology and Environmental Medicine, University of Graz, Graz, Austria

**Background:** During 2016 epidemic spread of OXA-48 positive *Klebsiella pneumoniae* strains from northwest to other regions of Croatia was noticed. In the early stage of dissemination only hospitals were affected, but during the last three years spread to the long-term care facilities was observed. The aim of this research was to analyse 98 *K. pneumoniae* strains positive for OXA-48 carbapenemases isolated from urine of non-hospitalized elderly patients from 2016-2018 in Zagreb.

**Materials/methods:** Antimicrobial susceptibility profiles and production of carbapenemases were assessed phenotypically. PCR was used to detect genes encoding extended-spectrum β-lactamases (ESBLs), plasmid-mediated AmpC β-lactamases, carbapenemases of class A, B and D, and qnr encoding fluoroquinolone resistance. Transferability of cefotaxime resistance was tested by conjugation using *E. coli* J53 resistant to sodium azide. Ertapenem resistance was transferred to recipient strain by transformation.

**Results:** The isolates were uniformly resistant to amoxicillin alone and combined with clavulanic acid, piperacillin/tazobactam, cefazoline and cefuroxime. Colistin resistance was observed in only two strains. Fifty five isolates (56%) were phenotypically positive for ESBLs. ESBL-positive isolates exhibited resistance to expanded-spectrum cephalosporins, cefepime, gentamicin and ciprofloxacin. Fourteen out of 32 ESBL-positive organisms tested harboured CTX-M-15 β-lactamase, and 12 TEM-1. PCR revealed OXA-48 class D carbapenemase as the sole carbapenem-resistance mechanism. The transformants were positive for blaOXA48 genes and harbouring L plasmid. Out of 98 strains tested 54 (55%) were isolated from long long-term care facilities patients. Those isolates exhibited significantly lower rates of additional ESBL positivity than isolates collected from 44 elderly outpatients (p<0.01). Moreover, they showed very low MICs of both imipenem and meropenem with the majority of isolates being in the susceptible range (MIC< 2mg/L).

**Conclusions:** OXA-48 producing *K. pneumoniae* isolates from long-term care facilities patients were predominantly non ESBL-positive, like isolates from hospitalised patients in Zagreb, suggesting transmission from hospitals. CTX-M-15 was the dominant type of ESBL coproduced by OXA-48 positive strains from outpatients. OXA-48 was the sole carbapenemase detected in isolates from geriatric non-hospitalized population in Zagreb.

Speeding up identification and antimicrobial susceptibility testing of bacteria from positive blood cultures by the use of Alifax HB&L system

Yao Wang1*, Yuanji Dai2, Dingding Li2, Hongli Sun2, Ying Zhao2, Yingchun Xu2

1Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Science, Beijing, China, 2Peking Union Medical College Hospital, Peking Union Medical College, Beijing, China

Background: Rapid identification and antimicrobial susceptibility testing (AST) of the causative agents of bloodstream infections can lead to prompt appropriate antimicrobial therapy and decrease the mortality rate of patients. In this study we evaluate the workflow of combination of Alifax HB&L system with MALDI-TOF MS and VITEK 2 Compact system on how it can speed up the identification (ID) and AST of bacteria from positive blood cultures (BC).

Materials/methods: Two hundred and eighteen positive BC from BACTEC FX system (BD) were tested. After subculture onto agar plate, isolates were identified by VITEK MS (bioMérieux) and AST was performed by VITEK 2 Compact (bioMérieux), which were used as reference methods.

15 μl of positive monomicrobial BC, which was confirmed by Gram stain, was inoculated in the HB&L culture kit vial and incubated tilled the 1.00±0.25 McFland. Two tubes of 1 ml positive broth were centrifuge at 13,000 rpm for 5 min. Discard the supernatant and wash with 300 μl of distillate water. Vortex and centrifugate at 13,000 rpm for 5min. Spot the pellet onto target slide and identified by VITEK MS. Prepare the pellet into 0.5 McFland suspension and perform AST by VITEK 2 Compact using N334, N335 or P639 cards.

Results: In the 218 positive BC, 216 (99.1%) were reported positive by Alifax HB&L. Compared to the reference method, 212 (97.3%) were identified correctly. Four samples were reported as no identification. By Alifax HB&L, 92.4% positive BC can be tested by direct identification and AST within 4h. For Enterobacteriaceae (n=87), Acinetobacter baumannii (n=11), Pseudomonas aeruginosa (n=65) and Enterococcus (n=39), the percentages of CA/E/A/VME/ME were 96.5%/97.3%/1.5%/0%/0.8%, 95.0%/94.2%/0%/0.8%, 95.2%/91.7%/3.1%/1.0% and 98.1%/96.8%/0%/0.3%, respectively. The concordance rate of ESBL, methicillin resistant Staphycoccus, inducible clindamycin resistance and gentamicin high Level were 98.6%, 94.1%,100% and 100%, respectively.

Conclusions: Alifax HB&L system can shorten the TAT for BC with accurate ID and AST results, which would help clinicians to promptly confirm or adjust the antimicrobial therapy for patients with BSI.

Abstract 7358

Caco-2 permeability assessment and in vivo pharmacokinetics of VRT001-C (oral ceftriaxone)

Saransh Chaudhary*,1 Dilip Roy1, Anand Sachdeva1, Anurag Payasi2, Anmol Aggarwal1

1Venus Medicine Research Centre, Baddi, India

Background: Ceftriaxone, a BCS Class III drug, is a widely used broad-spectrum cephalosporin antibiotic that is only available in parenteral formulation due to its polar nature and poor permeability in the small intestine. Stealth Targeted Nanoparticles (STN) is a platform technology that uses polymeric nanocarriers, appended with a highly specific targeting ligand, for increased drug uptake in the small intestine. In this study, we report the Caco-2 permeability and in vivo pharmacokinetics of VRT001-C [a formulation of ceftriaxone developed using STN] after intraduodenal (ID) administration in mice. ID administration was preferred over oral to have a better assessment of intestinal permeability.

Materials/methods: Caco-2 study was conducted in accordance with ICH guidelines. Caco-2 cells were obtained from ATCC. 10μM concentration of either VRT001-C or ceftriaxone control was added to apical/basolateral chamber and samples from both chambers were collected at 0 and 120 mins to assess permeability and efflux. Collected samples were analysed using LCMS-MS. For the PK study, 72 healthy swiss albino mice (25-30g, both sex) were fasted overnight and divided into two groups. One group received ceftriaxone control [200 mg/kg given IV; n=18] and the second group received VRT001-C [200mg/kg given ID; n=54]. After a single dose of either drug, plasma samples were withdrawn at various time points up to 12hrs and drug concentration was analysed using a validated HPLC method. PK parameters were calculated using noncompartmental analysis.

Results: In Caco-2 assay, VRT001-C observed a 44-fold greater absorption than the ceftriaxone control, as evidenced by their apparent permeability coefficients [apical to basolateral] of 38.90*10^-6 cm/s and 0.88*10^-6 cm/s respectively. These results corroborated with the in vivo study, with VRT001-C group reporting a mean bioavailability of 55% [AUC0-inf of 229.49±38.3 mg/L·h vs. 419.25±5.36 mg/L·h]. Half-life of the drug was longer in the VRT001-C group [3.67 hrs vs. 0.82 hrs].

Conclusions: Both in vitro and in vivo results reflect high intestinal permeability of VRT001-C. Further, as ceftriaxone exhibits time-dependent killing, a longer half-life can improve the pharmacodynamic activity by prolonging the therapeutic window. Overall, these results encourage the further development of VRT001-C.

Abstract 7362

Evaluation of the RESIST-4 O.K.N.V. K-SeT test for the detection of carbapenemase production in Enterobacterales

Annamaria Both1, Laura Jánvári2, Adrienn Hanczvikkel2, Akos Toth*2

1Szent István University, Budapest, Hungary, 2National Public Health Center, Budapest, Hungary

Background: The emergence of antibiotic resistance in bacteria poses an increasing threat to healthcare worldwide. The production of carbapenemases is an especially dangerous mechanism that is spreading especially among Enterobacterales species. Due to the severity and mortality rates associated with infections caused by carbapenemase producing Enterobacterales (CPE), it is crucial to rapidly detect and identify the type of carbapenemase. The goal of this study was to evaluate the RESIST-4 O.K.N.V. K-SeT, which is a newly developed ready-to-use immunochromatographic test kit. The test is based on an reaction that can directly detect the four most prevalent carbapenemases (OXA-48-like, KPC, NDM and VIM) within 15 minutes. The aims of the study were to determine the sensitivity and specificity of the test and to compare the results with different methods capable of identifying carbapenemases.

Materials/methods: The RESIST-4 O.K.N.V. K-SeT [Coris BioConcept], Carbapenemase Nordmann-Poirel [CarbaNP] and Modified Carbapenemase Inactivation Method (mCIM) tests were conducted using 96 Enterobacterales isolates previously characterized by PCR originated from Hungarian hospitals, each of which were resistant to at least one carbapenem. Most of the isolates were CPE isolates, which included OXA-48-like [n=17], KPC [n=10], NDM [n=18], VIM [n=28] and NDM+OXA-48-like [n=2] producers, while the remaining non-CPE were ESBL and/or AmpC producers [n=21].

Results: The overall sensitivity/specificity values were 85.3%/100% for the RESIST-4 O.K.N.V. K-SeT, 93.3%/100% for the CarbaNP and 95.9%/98.6% for the mCIM, respectively. For the detection of OXA-48-like, sensitivity/specificity values were 89.5%/100%, 78.9%/100% and 89.5%/98.7%, respectively. In the case of KPC isolates, the values were 100%/100%, 100%/100% and 100%/98.8%. For the NDM enzyme, values were 95%/100%, 100%/100% and 100%/98.6%. And lastly, for the detection of VIM, sensitivity and specificity of the three tests were 71.4%/100%, 96.4%/100% and 96.3%/98.5%.

Conclusions: The RESIST-4 O.K.N.V. K-SeT showed good sensitivity and excellent specificity values overall and proved to be a highly efficient tool for the detection of the four carbapenemases. The lower sensitivity for detection of VIM-producers could be explained by the higher frequency of Klebsiella pneumoniae with mucoviscous phenotype and probably low level production of VIM-4-type carbapenemase. Thus modification of protein extraction method could be advised.

Abstract 7368

**Faster and more sensitive diagnostics of Shigella by Shigella specific PCR and improved culture**

Christoffer Lindsten†1, Hanna Wirdelius‡, Daniel Palmér‡, Frida Mårtensson†, Annika Ljung‡, Peter Nilsson†

1Hallands hospital Halmstad, Clinical Microbiology, Halmstad, Sweden, 2Sahlgrenska University Hospital, Clinical Microbiology, Gothenburg, Sweden

**Background:** *Shigella* is known to cause gastroenteritis with symptoms varying from mild diarrhea to colitis and dysenteria. Traditionally diagnosis is based culture but in recent years PCR-methods are becoming more common. The PCR targets used to detect *Shigella* in faeces (eg ipaH) are shared with enteroinvasive *E. coli* (eiec), hence discrimination between *Shigella* and eiec by PCR in the fecal sample is not possible. Attempts to culture *Shigella* often fails, typically 70-80 % of PCR-positive samples remains culture negative. In Sweden and many other countries *Shigella* is a notifiable disease but eiec not. Treatment with antibiotics is often recommended for *Shigella* infection but not for eiec. The unsatisfactory diagnostic result therefore poses a clinical problem.

**Materials/methods:** A new strategy for detecting *Shigella* in fecal samples was established, based on a novel *Shigella* specific PCR and a modified protocol for *Shigella* culture. The primers described by Kim et al, proposed to be specific for detection of *Shigella*, were combined with newly designed TaqMan probes in a triplex real time PCR method for detection of *Shigella* species. In an attempt to increase the outcome of *Shigella* culture a new routine was introduced. The fecal sample was diluted to a suitable concentration and spread over the whole surface of the agar plate resulting in many more free lying bacterial colonies for inspection and further analysis. This new strategy was applied to faecal samples positive for *Shigella*/eiec (ipaH). The result of *Shigella* specific PCR and the improved culture method was compared and the overall result of the new strategy was compared with historical results from diagnostic outcome of traditional methods.

**Results:** The combined result of modified culture and *Shigella* specific PCR increased the detection of *Shigella* from 20-30 % (historical data) to 52 % of the ipaH positive samples. The average time for a positive result was shortened by at least 3 days due to faster result from *Shigella* specific PCR.

**Conclusions:** The here described protocol for detecting *Shigella* in fecal samples increased the diagnostic outcome and decreased the time to result substantially.

**Presenter email address:** christoffer.lindsten@regionhalland.se
Impact of a multimodal intervention on non-sterile glove use in the intensive care unit

Laura Cadenau*1, Mireille Dekker1, Rosa Van Mansfeld1

1Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands

Background: Incorrect use of non-sterile gloves increases the risk of cross contamination. We sought to explore and improve compliance with the glove use protocol in the ICU of our University hospital.

Materials/methods: Direct observations of the use of non-sterile gloves were performed. Incorrect use was defined as missing glove switches and missed hand hygiene moments that can lead to contamination of the patient or the hospital environment. The multimodal intervention included feedback of the audit results, visual reminders in the workplace and an interactive lecture for all health care workers targeting hand hygiene moments and indications for glove use or switch. After two months observations were repeated.

Results: In total, 195 observations were performed. Non-sterile gloves were used during 160 patient care episodes and in 147 moments glove use was appropriate. Switching gloves when needed (n=57) occurred in 38.6% (95%CI, 27.1-51.6). Hand hygiene compliance was 38.6% (95%CI, 28.8-49.3) before glove use and 18.2% (95%CI, 7.3-38.5) during a switch. Two months after the intervention the compliance of switching gloves when needed was 50% (95%CI, 37.9-62.1). Hand hygiene compliance before glove use was 48.4% (95%CI, 36.3-60.4). Other hand hygiene moments did not change. The overall risk of contaminating the patient or the patient surroundings was 47% (95%CI, 36.6-57.6) before and 39.1% (95%CI, 28.1-51.3) after the intervention.

Conclusions: Non-sterile gloves are used in most patient care episodes by nurses caring for patients on the ICU. Failure to change gloves when necessary and not applying hand hygiene before and in between glove use appear to be the biggest risks for transmission of microorganisms to the patient and the hospital environment. Our multimodal approach did not significantly increase compliance of correct use of non-sterile gloves, although a positive trend was achieved in switching gloves appropriately. The risk of contaminating the patient or the environment did not improve significantly, although a positive trend was achieved in adherence to the glove use protocol. Although the low number of observations might impede these results, investigating the underlying causes of non-compliance and barriers is needed to adjust the program to achieve clinical relevant effects.

Abstract 7370

Gut microbiota of full-term and late preterm newborns in Moscow

Priputneva Tatyana¹, Elena Isaeva¹, Vera Muravieva³, Alexey Gordeev*¹, Alina Melkumyan¹, Lyudmila Lyubasovskaya³, Mikhail Mesyan¹, Leila Timofeeva¹, Vector Zubkov¹, Gennadiy Sukhikh¹

¹National Medical Research Center for Obstetrics, Gynecology and Perinatology named after Academician V.I. Kulakov of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

**Background:** It is obvious that gut microbiome has important meaning in establishment of life-critical systems of newborns. The aim of the study was to assess the formation of the gut microbiota of full-term and late premature newborns.

**Materials/methods:** Fecal samples of 50 healthy full-term newborns (25 were born by vaginal delivery and 25 – by Caesarean section) and 51 babies with gestational age 34-37 weeks (25 were born by vaginal delivery and 26 – C-section) were investigated by culturomics and mass-spectrometry at 1st, 7th and 30th day of life. Most of them were given by breast milk or mixed feeding. Preterm babies were given by probiotics (lactobacilli and bifidobacteria).

**Results:** Meconium was sterile in 58% of babies, more often in C-section groups. In other groups microbiota was isolated in a low titer and mainly represented by gram-positive cocci. Anaerobes and lactobacilli were found in rare cases in vaginal delivery groups. At 7th day levels of all microorganisms have riced up to $10^{10-12}$ CFU/g. Lactobacilli and bifidobacteria have found in vaginally delivered newborns more often (up to 70% and 50%, respectively). The relative high frequency of the occurrence in preterm babies may be define of more application of probiotics. Bacteroids at high titer were isolated in all children except preterm C-section babies. Large frequency and species diversity in vaginal delivery babies were shown as compared with C-section newborns (8%). Clostridia were isolated approximately with equal frequency (11-20%) in all newborns. At 30th day the frequency of lactobacilli did not change essential as compared with first week. Bacteroids frequency have riced substantial in vaginal delivery babies and did not changed in full-term C-section. Among preterm C-section babies bacteroids were isolated only in two newborns. Clostridia were more often isolated in C-section babies with 1.5 times more often in preterm newborns.

**Conclusions:** Thereby, there is delay in development of microbiome of preterm infants and full-term C-section babies as compared with full-term vaginally delivery children. This is especially noticeable by low frequency of gut colonization by bacteroids and higher – by clostridia, that do not include in probiotics and mixes formula in contrast to lactobacilli and bifidobacteria.

**Presenter email address:** gordeew@vega.protres.ru
Impact of calmodulin inhibition by fluphenazine on susceptibility, biofilm formation and pathogenicity of caspofungin-resistant Candida glabrata

Andres Ceballos1, Daniela Amado1, Estelle Robert2, Claudia Marcela Parra Giraldo1, Patrice Lepape*2

1Pontificia Universidad Javeriana, Bogota, Colombia, 2University of Nantes, EA1155 IICiMed. Department of Parasitology and medical Mycology, Nantes, France

Abstract third-party references: ECOS Nord

Background: In recent decades, Candida glabrata has emerged as a frequent cause of life-threatening fungal infection. In C. glabrata, echinocandin resistance is associated with mutations in fks1/ fks2 [β-1,3-glucan synthase]. The calmodulin/calci-neurin pathway is implicated in response to antifungal stress and calcineurin gene disruption specifically reverses Fks2-mediated resistance of clinical isolates. We evaluated the impact of calmodulin inhibition by fluphenazine on two caspofungin-resistant Candida glabrata isolates.

Materials/methods: Candida glabrata isolates were identified by ITS1/ITS4 sequencing and the echinocandin target FKS1/ FKS2 genes were sequenced. Susceptibility testing of caspofungin in presence of fluphenazine was performed by a modified CLSI microbroth dilution method. Effect of fluphenazine/caspofungin combination on heat stress (37°C or 40°C), oxidative stress (0.2 and 0.4 mM menadione) and on biofilm formation (polyurethane catheter) was analyzed. A Galleria mellonella model using 1x10⁹ UFC/mL blastospores were developed to evaluate the impact of this combination on larva survival.

Results: The F659del was found in FKS2 gene of both resistant strains. In these clinical isolates fluphenazine increases susceptibility to caspofungin and reduces their thermotolerance. Furthermore, fluphenazine/caspofungin combination significantly impairs biofilm formation in an in vitro polyurethane catheter model. All these features could participate in the increasing survival of infected Galleria mellonella after combination treatment in comparison to caspofungin alone.

Conclusions: In a repurposing strategy, our findings confirm that calmodulin could provide a relevant target for life-threatening fungal infectious diseases.

Evolution of teicoplanin susceptibility pattern of *Staphylococcus aureus* and coagulase-negative *Staphylococcus* spp. related to orthopaedic infections

Priscila Oliveira¹, Vladimir Carvalho¹, Angelica Anjos¹, Jordana Araujo⁺, Caroline Panico², Thiago Vitoriano², Luiz Alves Silva Neto³, Igor Marinho³, Vanessa Amorim³, Flávia Rossi³, Ana L. Munhoz³

¹University of São Paulo, Sao Paulo, Brazil, ²Federal University Of Goiás - Campus Aparecida De Goiânia, Goiania, Brazil

**Abstract third-party references:** University of Sao Paulo

**Background:** *Staphylococcus aureus* and coagulase negative *Staphylococci* (CoNS) infections are highly associated with biofilm formation, which is a major concern in orthopedic implants because of its implications in antibiotic resistance. Glycopeptides, including teicoplanin, have often been used in empirical and rational therapy in infections caused by these species. Long-term use of glycopeptide antibiotics can be related to emergence of resistant strains.

**Materials/methods:** Retrospective observational study that included all isolates of *S. aureus* and CoNS regarded as causative agents of surgical site infections (SSI) related to orthopedic procedures at a reference hospital in São Paulo, Brazil. Diagnosis of SSI followed criteria defined by the Centers for Disease Control and Prevention (CDC). Isolates were obtained from culture of bone and deep soft tissues specimens, collected following extensive removal of devitalized tissues during surgical debridement procedures as part of infection treatment. Positive samples were identified through automated VITEK2 and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry systems. Antibiotic susceptibility testing was done using the VITEK2 system. Breakpoints used in categorical interpretation for teicoplanin were those effective each year according to the Clinical and Laboratory Standards Institute (CLSI) M100 document. Cumulative antibiograms were performed in accordance with CLSI standards.

**Results:** From 2011 to 2018, 209 isolates of *S. aureus* and 179 isolates of CoNS were related to cases of SSI following orthopedic procedures. Among *S. aureus* isolates, teicoplanin susceptibility remained at 100% throughout the study period. For CoNS, however, there was a wide variation in susceptibility values observed, which reached a minimum of 43% in 2014. The trend line for the entire observed period shows the progressive decrease in susceptibility.

**Conclusions:** During the period of this study, an important variation of CoNS susceptibility to teicoplanin was observed, with a tendency to decrease in the global evaluation. The same phenomenon was not observed for *S. aureus*, showing a dissociation in the susceptibilities of different species of *Staphylococcus* spp. against this glycopeptide that needs to be taken into consideration in clinical practice.
Abstract 7380

**Improved NG-test Carba5 assay for the detection of previously undetected IMP-variants**

Herve Volland*1, Delphine Girlich1, Marine Laguide2, Virginie Paris3, Maxime Laroche1, Saoussen Oueslati2, Laurent Dortet1, Patrick Plésiat1, Stéphanie Simon1, Thierry Naas2,5

1CEA Saclay - Porte Nord, Saclay, France, 2Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 3NG Biotech, Guipry, France, 4University of Franche-Comté, Besançon, France, 5Bicètre Hospital AP-HP, Le Kremlin-Bicêtre, France

**Background:** The NG-Test Carba5 immunochromatographic assay (ICA) (NG Biotech, Guipry, France) accurately identifies the five most widespread carbapenemase families in Enterobacterales (CPEs) (KPC, NDM, VIM, IMP and OXA-48-like enzymes). In a recent study Potron et al. has identified IMP variants (IMP-13 clade (IMP-13 and IMP-37), IMP-14, IMP-15, IMP-18 clade (IMP-18 and IMP-71) and IMP-63) mostly encountered in *P. aeruginosa*, were not detected by the NG-Test Carba5. Here we have evaluated the NG-Test Carba5v2, with additional antibodies for detection of all IMP-variants.

**Materials/methods:** Monoclonal antibodies (mAbs) derived from IMP immunized mice were further tested against IMP-13. The NG-Test Carba5v2 tests (strip + cassette) were manufactured by NG Biotech using the IMP-13-selected mAbs and evaluated on a collection of 147 GNB (134 carbapenemase-producers (CP) including 31 IMP variants corresponding to the different branches of the IMP phylogeny and 13 non-CPs). Results were compared to those obtained with the NG-Test Carba5v1.

**Results:** Both versions of the NG-Test Carba5 gave similar results except for IMP, suggesting that the novel IMP- mAbs did not interfere with the other target. The NG-Test Carba5v2 allowed the detection of 100% of the IMP-variants tested (n=31/31), unlike NG-Test Carba5 that detected only 67% (n=21/31). The NG-Test Carba5v2 identified all VIM- (n=12), and NDM- (n=14) producers with no false- result. All OXA-48 carbapenemase variants were correctly identified, even the distantly-related OXA-535 variant. However, as already shown OXA-163 and OXA-405, two OXA-48 variants lacking carbapenemase activity were also detected. Two/19 (10%) KPC-producers were not detected. They corresponded to KPC-31 and KPC-33, two rare D179Y variants of KPC-3, known to be responsible for ceftazidime/avibactam resistance and for not being detected using ICA. All 13 non-CPs and the 13 isolates producing a non-targeted carbapenemase (different from the 5 main) gave negative test results demonstrating excellent specificity.

**Conclusions:** All tested IMP-variants were accurately detected, without impairing detection of the other carbapenemases. Thus NG-Test Carba5v2 is now well adapted to countries with high IMP-prevalence and to the epidemiology of CP-*P. aeruginosa* where IMPs are mostly detected.

Abstract 7381

**Performance evaluation of a new screening and viral load monitoring HIV-1 assay on the NeuMoDx molecular system**

Andrew Narwold1, Catherine Couture*1, Hui Lin Lee1, Jonathan Bezenah1, Crystal Nguyen1, Cameron Butcher1, Michelle Mastronardi1, Betty Wu1, Sundu Brahmasandra1

1NeuMoDx Molecular, Ann Arbor, United States

**Background:** As no cure exists for HIV-1 infection, current treatment regimen requires characterizing HIV-1 viral loads in infected patients to monitor disease progression and efficacy of anti-retroviral therapies. The NeuMoDx HIV-1 Quant Assay is a novel fully automated, “sample to result” in-vitro diagnostic test specifically designed for the accurate detection and quantitation of HIV-1 RNA with broad variant coverage including group O, P and the major CRFs directly from plasma. The NeuMoDx Molecular Systems allow the flexibility to use either primary blood tubes or secondary tubes, with options for qualitative reporting for screening purposes, or quantitative reporting for viral load monitoring.

**Materials/methods:** The objective of this study was to characterize performance metrics including analytical sensitivity and specificity, linearity, precision, inclusivity, turnaround time, as well as quantitative correlation to FDA-approved/CEIVD-certified reference tests. Analytical sensitivity was determined using a calibrated WHO Standard HIV-1 reference material and the quantitation limits (LLoQ/ULoQ) were determined using the Total Analytical Error (TAE) ≤1.0 criterion. Secondary standards traceable to the Calibrated WHO Standard were used for the rest of the analytical testing.

**Results:** The NeuMoDx HIV-1 Quant Assay demonstrated a limit of detection (LoD) and a lower limit of quantitation (LLoQ) of 35 IU/mL (equivalent to ~12 copies/mL) in plasma. Excellent linearity was demonstrated across a ~7-log dynamic range (R²>0.99) with ULoQ of 7.7 Log10 IU/mL. The assay showed equivalent detection across all HIV-1 groups M-P, subtypes (A, C-H) and CRFs, and provided extremely accurate results with a time to first result of ~85 minutes. Excellent within-lab precision was demonstrated in a multi-day study across 3 instruments including both NeuMoDx 96 and NeuMoDx 288 Molecular Systems. No cross-reactivity or interference was observed against a panel of phylogenetically similar or co-habiting pathogens. An in-house method correlation study confirmed excellent linear correlation (R²>0.95) and minimal bias [<0.5 Log] relative to reference test results. Finally, all reagents used in the study were stable at ambient conditions and demonstrated in-use shelf life of >14 days.

**Conclusions:** The NeuMoDx HIV-1 Quant Assay provides a rapid, easy-to-use, rapid, and automated method for sensitive HIV-1 screening and accurate viral load monitoring.

Abstract 7382

**Carbapenem hetero-resistance in blood isolates of OXA-48-producing Klebsiella pneumoniae and Escherichia coli**
Asiye Bıçakçılıg1, Banu Sancak*1

1Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Carbapenem-resistant Enterobacteriaceae have become an important problem during the last decade. The major mechanism which lead to carbapenem resistance is the production of carbapenemase enzymes such as KPC, OXA-48, NDM, VIM and IMP. Heteroresistance concept is another important issue about carbapenem resistance. Although, the mechanism of heteroresistance is not fully understood, it is thought to be effective on treatment success. The aim of this study is to determine carbapenem resistance and heteroresistance in Klebsiella pneumoniae and Escherichia coli blood isolates.

**Materials/methods:** A total of 301 Enterobacteriaceae (105 E.coli and 196 K.pneumoniae) blood isolates which were recovered in University Hospital of Hacettepe in the period from January 2016 to August 2018, were included in the study. Carbapenem resistance was evaluated by using gradient test, disk diffusion test, sensititre microdilution test and Phoenix automated systems. Polymerase chain reaction (PCR) was used for the detection of the KPC, VIM, IMP, NDM-1 and OXA-48 gene regions. Carbapenem heteroresistance was investigated with the disk diffusion method and gradient test (Etest, bioMérieux, Fransa). Heteroresistance was suspected when colonies were detected in the Etest/disk diffusion inhibition zone. It was confirmed by applying population analysis profile (PAP).

**Results:** Resistance or decreased susceptibility to carbapenems was detected in 160 blood isolates by at least one method. The presence of at least one carbapenemase gene were detected in 147 (91.8%) of the isolates that were intermediate or resistant to carbapenem. OXA-48 (142/160; 88.7%) was the most common carbapenemase enzyme, following by NDM-1 (14/160; 8.7%), VIM (5/160; 3.1%) and KPC (1/160; 0.6%). IMP enzyme was not observed in any of the isolates. In this study carbapenem heteroresistance was confirmed by PAP in 21 (16 K.pneumoniae and 5 E.coli) (6.9%) isolates. In 18 (85.7%) of these isolates OXA-48 enzyme was obtained.

**Conclusions:** The clinical significance of heteroresistance is still unknown. Therefore, there is a great need for studies involving larger numbers of isolates to determine the clinical effect of heteroresistance to carbapenems and the likelihood that the resistant subpopulations of carbapenem susceptible isolates will become fully resistant under drug action.

Abstract 7383

Association of IL-27 and STAT3 genetic polymorphism on the susceptibility of tuberculosis in western Chinese Han population

Mengjiao Li*, Lin Jiao1, Wang Min Jin2, Hao Bai2, Qian Wu2, Xuerong Chen2, Binwu Ying3

1West China Hospital of Sichuan University, Chengdu, China, 2West China Hospital of Sichuan University, Chengdu, China, 3West China Hospital of Sichuan University, Chengdu, China

Background: Host immune response has a pivotal role in latent tuberculosis infection and active tuberculosis. Interleukin-27 plays both pro-inflammatory and anti-inflammatory activities in infectious diseases via STAT1/STAT3 mechanism, as well as malignant tumor and autoimmune disease. To investigate the association of single nucleotide polymorphisms (SNPs) of IL-27 and STAT3 on the susceptibility of tuberculosis, we conducted a large size of case-control study in western Chinese Han population.

Materials/methods: A total of seven SNPs were genotyped by using multiplex ligation detection reaction method in 900 patients with tuberculosis and 1534 healthy controls.

Results: Variants of three SNPs (rs181206, rs17855750, rs26528) within IL-27 gene, the genotype and allele frequencies of rs17855750 were significantly different (p = 0.013, p = 0.004, respectively). Subjects carrying C allele for rs17855750 showed a decreased tuberculosis risk (OR=0.75, 95% CI=0.62-0.91, p = 0.004). Genetic modal analysis revealed that dominant modal was associated with decreased TB risk (OR=0.74, 95% CI=0.60-0.92, p=0.042). Haplotype of A-C-G (representing rs181206, rs17855750 and rs26528) showed a reduced risk to TB (OR=0.79, 95% CI=0.65-0.96, p=0.017). There were no significant differences between TB cases and healthy controls in the variants of four SNPs (rs1053005, rs2293152, rs744166, rs4796793) within STAT3 gene.

Conclusions: The polymorphisms of IL-27, rs17855750, but not rs181206 and rs26528, plays a protective role on the susceptibility to TB.

Loop-primer endonuclease cleavage loop-mediated isothermal amplification technology for singleplex or multiplex target detection and single-nucleotide polymorphism identification

Owen Higgins*1, Terry Smith1

1National University of Ireland, Galway, Galway, Ireland

Background: Loop-mediated isothermal amplification (LAMP) provides effective infectious disease pathogen detection and is compatible with inexpensive instrumentation for use in disease-prevalent developing regions. However, simultaneous multiple-target detection and single nucleotide polymorphism (SNP) identification, essential properties of nucleic acid diagnostics, is difficult to achieve using LAMP. This study introduces Loop-Primer Endonuclease Cleavage (LEC)-LAMP, a singleplex or multiplex LAMP technology with single-base specificity for variable SNP identification. We developed a singleplex LEC-LAMP assay demonstrating single-target detection and SNP identification, and further evaluated this assay in terms of analytical specificity, sensitivity and clinical application. Modified versions of this assay were subsequently used to demonstrate single-tube wild-type and mutant allele differentiation, and simultaneous multiple-pathogen detection.

Materials/methods: Target templates used to exemplify this technology were bacterial meningitis pathogens, Neisseria meningitidis, Streptococcus pneumoniae and Haemophilus influenzae, and synthetic DNA templates containing SNPs. Single-target detection and SNP identification was demonstrated using a singleplex LEC-LAMP N. meningitidis assay. The analytical specificity of this assay was established using a panel of bacterial reference strains and limit of detection (LOD) was determined using Probit analysis. Clinical application of this assay was evaluated using DNA from blood and cerebrospinal fluid samples of confirmed bacterial meningitis cases. Modified versions of this singleplex assay were developed to demonstrate differentiation of wild-type and mutant allele templates using an allele-specific (AS) LEC-LAMP N. meningitidis assay, as well as simultaneous multiple-target detection using a multiplex LEC-LAMP N. meningitidis, S. pneumoniae and H. influenzae assay.

Results: The singleplex LEC-LAMP N. meningitidis assay demonstrated complete analytical specificity, a LOD of 3.1 genome copies per reaction, and 100% diagnostic specificity and sensitivity for all clinical samples tested. The single-base specificity of this assay indicated effective variable SNP identification within a specific 6 base region. The AS LEC-LAMP assay successfully demonstrated single-tube wild-type or mutant allele differentiation, and the multiplex LEC-LAMP assay successfully demonstrated simultaneous detection of all bacterial targets in a single reaction.

Conclusions: LEC-LAMP is the first report of a single-tube, real-time, multiplex LAMP method with variable SNP identification capabilities, providing state-of-the-art transferable isothermal nucleic acid amplification technology for POC infectious disease diagnostics.

Utility of Xpert Carba-R in identifying carbapenem resistance in blood culture isolates in critically ill patients
Vidya Krishna*, Rakshith Vimal Kumar¹, Sekar Uma²

¹Sri Ramachandra Institute of Higher Education and Research, Chennai, India

**Background:** Xpert® Carba R (Cepheid, Sunnyvale, USA) is a real-time PCR test for the detection and differentiation of carbapenemase producing genes like KPC, NDM, VIM, OXA-48 and IMP in under 60 minutes. It is used for detection of colonization with carbapenem resistant gram negative organisms (CROs) in rectal swabs or feces to enable early isolation of such patients. However, there are fewer studies on the use of Xpert® Carba R to identify CROs in blood culture isolates to enable early identification to guide empiric treatment with Polymyxins. We aimed to study the utility of Xpert® Carba R to identify CROs in gram negative blood culture isolates.

**Materials/methods:** Retrospective study of cases in whom Xpert® Carba R had been done on gram negative blood culture isolates during the period between September 2018 till October 2019.

**Results:** Xpert® Carba R was done on 31 critically ill patients in the study period. Of the 32 blood culture isolates, 20 were Carbapenem Resistant Enterobacteriaceae (CRE) [E. coli 8, Kleb. species 12]. Sensitivity and specificity of Xpert® Carba R to detect carbapenem resistance was 67% and 78% in all isolates, and 85% and 75% respectively, in CRE. In concordant cases, average turnaround time for Xpert® Carba R was 2 days vs. culture at 3.75 days. Resistance genes in CRE were OXA 48 (8), NDM (3) and both (3).

**Conclusions:**
1. Xpert® Carba R detects carbapenem resistance in CRE earlier and faster in critically ill patients and can help guide empiric therapy.
2. OXA-48 was the commonest carbapenamase detected in this series.
3. It did not detect any resistance in non-enterobacteriaceae in this series.

**Echinocandin blood and peritoneal concentration in patients with Candida peritonitis**

Jesus Fortun Abete*, Alicia Gomez Lopez², Francesca Gioia³, María José Buitrago²

¹Hospital Ramón y Cajal, Madrid, Spain, ²CNM, ISCIII, Majadahonda, Madrid, Spain

**Background:** Echinocandin pharmacokinetics-pharmacodynamics (PK/PD) during abdominal candidiasis has not been evaluated systematically. Recently it has been announced the development of resistance to echinocandins especially in patients with candida peritonitis related to sub-optimal levels at peritoneum. The aim of this study was to describe the PK of echinocandins in patients with candida peritonitis (CP).

**Materials/methods:** Methods. Peritoneal and serum concentrations of anidulafungin (AND) micafungin (MCF) and caspofungin (CAS) were analyzed in 23 surgical patients with suspected candida peritonitis. After four days of starting therapy, serum [S] and peritoneal fluid [PF, through peritoneal drainage] were collected at baseline, 1 h, 6 h, 12h and 24 h of echinocandins administration. The PK/PD analysis was performed by using a non-compartmental approach [PKsolver, excel plug-in].

**Results:** The three echinocandins showed large interindividual variability in this study. Table shows the main PK parameters obtained in serum and peritoneal fluid.

**Conclusions:** We found that peritoneal exposure of echinocandins were a small fraction of that in blood. Using therapeutic doses, the minimal peritoneal concentrations were 0.64, 0.66 and 0.24 mg/L for AND, MCF and CAS in this study. Peritoneal exposures were above the MIC₉₀ for most of the *Candida* species responsible of CP. However, it is likely that Candida FKS mutations can emerge within the abdominal cavity in the face of prolonged subinhibitory echinocandin concentrations. Further researches including sanctuary compartments are needed to provide evidence for the development of candida resistance.

Abstract 7389

Clinical management of alveolar echinococcosis in Germany: a retrospective cohort study of 275 patients

Lynn Peters*1, Johannes Bloehdorn1, Sanne Burkert1, Julian Schmidberger2, Andreas Hillenbrand3, Tilmann Gräter4, Martina Furitsch5, Thomas Barth6, Nina Eberhardt7, Ambros Beer7, Doris Henne-Bruns2, Wolfgang Kratzer2, Beate Grüner1

1University Hospital Ulm, Division of Infectious Diseases, Department of Internal Medicine III, Ulm, Germany, 2University Hospital Ulm, Department of Internal Medicine I, Ulm, Germany, 3University Hospital Ulm, Department of General and Visceral Surgery, Ulm, Germany, 4University Hospital Ulm, Department of Diagnostic and Interventional Radiology, Ulm, Germany, 5University Hospital Ulm, Institute of Microbiology and Hygiene, Ulm, Germany, 6University Hospital Ulm, Institute of Pathology, Ulm, Germany, 7University Hospital Ulm, Department of Nuclear Medicine, Ulm, Germany

Background: Alveolar echinococcosis (AE) is a progressive parasitic disease caused by the larval stage of Echinococcus multilocularis. Surgical resection is the only curative treatment, however, most patients are not eligible due to the advanced stage. Limited treatment options, treatment failure and severe side effects remain a challenge in the management of AE.

Materials/methods: This retrospective cohort study included 275 patients presenting at the University Hospital Ulm from 2011 to 2018. Descriptive statistics included demographics, stage of disease, initial symptoms, treatment options, side effects and complications. Adverse outcomes (follow-up at least one year, n = 242), risk and protective factors were analysed using regression models adjusting for confounders.

Results: Incidence rates increased over the years (21 patients in 2011, 43 patients in 2018). Median age at diagnosis was 55 years, 55% were female. When diagnosis was established, more than 60% reported no specific symptoms, yet 62% presented in an advanced stage (P3 or P4 according to PNM classification). While 29% underwent curative surgery, AE was inoperable in the majority (57%) and hence treated with benzimidazoles (BMZ). Within this group, 9% received a structured treatment interruption (STI), i.e. the termination of BMZ therapy with sustained follow-up. A follow-up period of 803 cumulative patient-years was monitored. While 26% of patients were cured, 71% were stable (with or without BMZ) and 3% suffered from progressive disease. Risk factors for adverse outcomes included advanced stage, vascular and biliary complications, BMZ toxicity and relapse after STI. Surgical treatment was identified as protective.

Conclusions: We noticed an increasing incidence of AE cases due to either increased awareness, infection rates or alterations in immune response. Curative surgery was strongly associated with a favourable outcome. BMZ allowed for a long-term stable disease. However, cases with non-response to BMZ or BMZ toxicity resulted in adverse outcomes with complex clinical management. In carefully selected patients, a STI can present an valuable alternative to life-long BMZ treatment. Due to increasing incidence, high treatment costs and possible complications, a screening in high risk groups to identify AE in early stages seems reasonable and probably cost-effective.

Clinical features and outcomes of patients with Elizabethkingia meningoseptica infection: an emerging pathogen

Nosheen Nasir*, Abdullah Umair¹

¹Aga Khan University Hospital, Pakistan, Karachi, Pakistan

Background: Elizabethkingia meningoseptica, formerly known as Chryseobacterium meningosepticum, is a non-motile, non-fastidious, catalase and oxidase-positive, aerobic, glucose-non-fermentative Gram-negative bacillus. It is an important emerging opportunistic bacterium that primarily occurs in nosocomial settings. Given its ubiquitous nature, arsenal of multi-drug resistant genes, and affinity to infect primarily the immunosuppressed; it is paramount that more resources be devoted to study this emerging pathogen. It is also unclear as to which treatment regimen is most effective and what are the factors associated with adverse outcomes. The aim of this study is to describe the clinical features and outcomes of Elizabethkingia meningoseptica infections in a tertiary care center at Karachi, Pakistan.

Materials/methods: We conducted a retrospective case series on all patients identified to have any clinical culture specimen positive for Elizabethkingia meningoseptica over a period of 6 years between 2014 and 2019 at the Aga Khan University Hospital Karachi. Data was collected on a structured proforma on patient demographics and clinical factors. Descriptive analysis was performed for demographic features with median and IQR reported for quantitative variables such as age and lengths of hospital stay and frequencies (percentage) for qualitative variables such as gender, co-morbid conditions and mortality. All p value ≤0.05 will be taken as significant.

Results: Sixteen patients with E. meningoseptica were identified. The median age was 35 years with 44% males and 56% females. The most common co-morbidities were diabetes (31%) and hypertension (37.5%). 56% (n=9) had bacteremia with E. meningoseptica. Among other sites of infection, three had urinary tract infection, n=3 had meningitis and one had pneumonia. 61% (n=8) had monomicrobial growth whereas 38% had polymicrobial growth in culture. 56% required intubation and mechanical ventilation. E. meningoseptica was sensitive to beta lactam and quinolones in 68%. Three of the E.meningosepticum isolates were extensively drug resistant with sensitivity only to minocycline. Four out of 16 patients died and median length of hospital stay was 13 days.

Conclusions: E. meningosepticum is an emerging nosocomial infection and associated with good survival especially if isolates are susceptible to quinolones and can be treated with them.

1Manipal Academy of Higher Education, Kasturba Medical College, Manipal, Manipal, India, 2Central Soil Salinity Research Institute, Karnal, India, 3Medical University of Graz, Graz, Austria

Background: India is a recognized endemic region for melioidosis. However, there are no data on the environmental occurrence of *B. pseudomallei* from the country. Environmental surveillance is crucial to assess the risk of infection to humans and animals in different parts of the country. The study aimed to determine the environmental prevalence of *B. pseudomallei* in the vicinity of cases of melioidosis diagnosed in India and to further understand the effect of various physicochemical properties of soil on the presence of the pathogen in the environment.

Materials/methods: We performed environmental sampling close to the home of melioidosis patients from July 2016 – November 2018. A total of 1204 soil samples at 20 sites were screened for *B. pseudomallei* by using a recently developed quantitative real-time PCR including *B. pseudomallei* specific qPCR target. Further, the various physicochemical factors such as pH, conductivity, Salinity and levels of micronutrients such as Iron, Phosphorous, Manganese, Sodium, Potassium, Copper were determined in subset of samples (N= 120).

Results: So far, our molecular analysis revealed 30.2% (374/1228) of soil samples, including samples from all different sampling-sites to be *B. pseudomallei*-positive. However, the number of qPCR positive samples varied significantly between sites and time of the year, with the highest positivity rate detected in samples taken during the rainy season (47.5%). Presence of *B. pseudomallei* was negatively associated with presence of Iron ($p <0.001$) and Manganese ($p =0.02$). Further on multivariable logistic regression model, the presence of *B. pseudomallei* was negatively associated with Iron (OR: 0.98; CI: 0.97-0.99; $P=0.001$).

Conclusions: Our molecular approach proved to be a valuable tool to detect *B. pseudomallei* in the environment in southwest India. Our study suggests that *B. pseudomallei* survive in nutritionally deprived environment with lower levels of micronutrients. Such studies might help to develop a pragmatic framework of a wide network for monitoring and evaluating the environmental exploration of the bacteria in the nation. Targeting the overall population at an initial stage might be challenging, in such a scenario identifying the areas of risk would be a beneficial approach to increase the case detection.

Abstract 7394

Performance evaluation of a novel *Trichomonas vaginalis* and *Mycoplasma genitalium* assay in urine and swab specimens

Caly Lounds1,2, Lijie Gong*,1, Aaron Ripley1, Elizabeth Strand1, Cameron Butcher1, Will Marshall1, Michelle Mastronardi1, Betty Wu1, Sundu Brahmasandra1

1NeuMoDx Molecular Inc, Ann Arbor, United States

**Background:** *Trichomonas vaginalis* (TV) is the most widespread, non-viral sexually transmitted infection accounting for nearly half of all curable STIs globally with infection rates as high as 26% among STD clinical patients. In addition, only 30% of TV infections are symptomatic, making consistent & easy detection a critical component of patient management and infection control. *Mycoplasma genitalium* (MG) is a well-known cause of male urethritis as well as a major cause of clinical cervicitis in women. As culture techniques for MG are egregiously slow (sometimes taking up to 6 months), nucleic acid amplification testing is highly preferable for prompt diagnosis. The NeuMoDx TVMG Assay is a rapid, duplex test enabling the simultaneous detection of both pathogens from a single urine or swab specimen in a "sample-to-result" mode on the NeuMoDx molecular systems.

**Materials/methods:** Studies were performed to characterize relevant analytical parameters of the NeuMoDx TVMG Assay including sensitivity, inclusivity, exclusivity, and impact of interfering substances. Additionally, an in-house method correlation study was performed to assess concordance with a reference test using a combination of prospectively collected and archived clinical specimens.

**Results:** The NeuMoDx TVMG test demonstrated a Limit of Detection of 0.025 cells/mL for TV and 8.4 copies/mL for MG for urine and 0.04 cells/mL for TV and 15 cp/mL for MG in vaginal swabs with excellent inclusivity across an additional five TV variants (including two metronidazole resistant strains) and four MG variants. Over 80 phylogenetically similar or co-habiting pathogens were assessed for cross-reactivity and interference, with no adverse results observed. A panel of potentially interfering endogenous and exogenous substances, commonly associated with swab and urine samples, were tested in the presence of low levels of TV and MG targets and were shown to have no adverse effect on the quality of results. An in-house method comparison study showed excellent concordance (>95%) with FDA-cleared reference tests for both targets.

**Conclusions:** The NeuMoDx TVMG Assay provides an easy to use, reliable, low-cost and rapid method of detection of TV and MG directly from urine or swab specimens with no need for special preservatives or cumbersome storage requirements

Abstract 7400

Pharmacokinetics of amikacin and gentamicin in the setting of burn patients with Gram-negative bacterial infections
Silvia Corcione*, Amedeo De Nicolò, Anna Pensà, Francesco Vladimiro Segala, Giovanni Di Perri, Maurizio Stella, Antonio D’avolio, Francesco G. De Rosa

1Department of medical sciences, infectious diseases, University of Turin, Turin, Italy; 2Department of Medical Sciences, infectious Diseases, University of Turin, Turin, Italy; 3Burn Unit, CTO Hospital, AOU Città della Salute e della Scienza, Turin, Italy

Abstract third-party references: University of Turin

Background: Aminoglycosides (AG) pharmacokinetic (PK) is variable in critically ill patients, including patients with severe burn injuries, requiring frequent dose changes to achieve therapeutic antibiotic concentrations. Our aim is to prospectively describe the PK and pharmacodynamic (PD) parameters of AG in a cohort of burn patients.

Materials/methods: This was a prospective study on the PK/PD of amikacin (AMK) and gentamicin (GEM) in severe burn patients admitted in a regional referral center in Turin, Italy. Antibiotics were prescribed at the standard doses usually for gram negative bacterial infections. Target PK/PD ratio was defined as a $C_{\text{max}}$ above 8 x highest MIC. Samples were performed immediately before the antibiotic administration (T0) and at the end of the infusion (T1).

Results: Four patients in the AMK and GEM group were enrolled in the study. The most common sites of infection were bloodstream (5; 62.5%) and lungs (4; 50%). The most frequently isolated bacteria were Pseudomonas aeruginosa, followed by Klebsiella pneumoniae and Acinetobacter baumannii. The administration of standard doses of AMK (15-20mg/kg) or GEM (3-5 mg/kg) never achieved the target peak concentration of 60mg/L and 30mg/L, respectively (Table 1). At the standard dosage, the PK/PD target of $C_{\text{max}} > 8 \times$ highest MIC was reached for 8 (53.3%) out of 15 isolated pathogens. No Acute Kidney Failure (AKI) was reported during aminoglycosides treatment. We observed that standard dose of AMK and GEM in burnt population never achieved the target peak concentration of 60 mg/L and 30 mg/L, with low mean $C_{\text{max}}$ (33.1 and 14.3 mg/L, respectively).

Conclusions: in a population of septic burn patients, standard dosing of AG most often leads to unsatisfactory plasma concentrations, below the pk/pd target of efficacy. The use of elevated dosages along with TDM may help to optimized the treatment.

Table 1. S.D.: standard deviation; GEM: gentamicin; AMK: amikacin; BMI: body mass index; M: male; F: female; TBSA: total burn surface area; RBS: revised BAUX score; CVVH: continuous veno-venous hemofiltration; MIC: minimum inhibitory concentration; C: concentration

Abstract 7401

Evaluation of the whole blood spot on plasma separation card as a sample type for hepatitis B virus viral load quantification on the COBAS 6800 system

Fernando Velasquez*, Ariadna Rando Segura1, Paula Salmerón1, Unai Aldama2, Angels Esteban2, Adrian Najarro2, Gerard Ruiz2, Mar Riveiro-Barciela3, Maria Buti3, Ed G. Marins4, Francisco Rodriguez-Frias2

1Vall d’Hebron University Hospital, Microbiology department, Barcelona, Spain, 2Vall d’Hebron University Hospital, Biochemistry department, Barcelona, Spain, 3Vall d’Hebron University Hospital, Internal medicine department, Barcelona, Spain, 4Roche Molecular Systems, Inc, Pleasanton, United States

Background: Viral hepatitis elimination is one of the WHO objectives; increasing diagnosis of hepatitis B is one of the main tools to achieve it. Viral load is necessary to aid in the management of patients with hepatitis B virus (HBV) infection, facilitate sample transportation over long distances and in harsh environmental conditions is a useful method to achieve optimal laboratory results in samples from populations with suboptimal infrastructure or special characteristics that hinder a proper diagnosis. Dried blood spots from whole blood samples have been found useful to evaluate viral load of HCV an HIV, however there is no experience using this kind of sample to perform HBV viral load monitoring.

The aim of this study was to evaluate the performance of the PSC as alternative sample type for HBV viral load quantification compared to plasma.

Materials/methods: We recovered whole EDTA venous blood from clinical samples with positive HBs and HBV viral load determination. PSC samples were prepared by spotting 140µL of whole EDTA venous blood and drying it at room temperature over a minimum of 4 days. One spot of each PSC was eluted by incubating at 56ºC with Specimen Pre-Extraction Reagent for 10min at 1100rpm on a preheated thermo-shaker. Plasma EDTA direct samples and PSC eluted samples were analyzed by cobas HBV Test in cobas 6800 system (Roche, Switzerland) and results were compared by paired.

Results: Correlation between PSC and plasma samples was linear [slope=-1.14, intercept=0.81, R²=0.90]. For these samples, the mean viral load difference between plasma and PSC samples was -1.81 log10IU/mL (95%CI: -2.22 to -1.40). Detection for PSC >1000IU/mL occurred in all samples tested with PSC.

Conclusions: Using PSC as an alternative sample type demonstrated a linear correlation to plasma viral load when tested with cobas HBV test, indicating that a correction factor could be applied to better align the PSC and plasma viral load. All samples with a viral load >1000IU/mL were detected with PSC. These results support the feasibility of PSC as an alternative sample type for detection and viral load monitoring of HBV.

Increasing importance of reservoir hosts in viral infections: Hantavirus infection in rodents in East Anatolia of Turkey

Mehmet Özkan Timurkan*, Hakan Aydin

1 Atatürk University, Faculty of Veterinary Medicine Department of Virology, Erzurum, Turkey

Background: Hantaviruses are emerging pathogens that have a significant impact on human health. Hantaviruses cause two important life-threatening diseases including hemorrhagic renal syndrome (HFRS) and fever pulmonary syndrome (HPS, also known as Hantavirus cardiopulmonary syndrome). Hantaviruses are not transmitted by arthropods, but mechanically can spread. Hantavirus can be transmitted by inhalation of feces and urine of rodents. Dobrava-Belgrade and Puumala hantaviruses have previously been reported from Anatolia, in rodents in case reports and occasional outbreaks. This study was performed for the purpose of molecularly screening of rodents as possible reservoirs for hantavirus in East Anatolia, Turkey.

Materials/methods: In this survey for rodent-borne hantaviruses, 498 small rodents representing different genera were trapped in Turkey (Erzurum city and all districts in and around) from May-2016 to Oct-2016 and screened for hantavirus RNA by reverse transcription–polymerase chain reaction (RT-PCR).

Results: Rodents were identified morphologically as Microtus spp., Apodemus spp., Mesocricetus spp. and Cricetinae spp. tissues (lung, liver, spleen, kidney) from all rodents were screened by RT-PCR. In 24/498 (4.8%) of the scanned tissues, PCR products of the expected size for Hantavirus were obtained. Geographically, the city of Erzurum, where the study is made, consists of 20 different districts. Positivity was detected in 10 different districts (Figure 1).

Conclusions: This is the first comprehensive study in our region. This report describes important information of the circulation of hantavirus and its potential reservoir in East Anatolia of Turkey. When the identified location are examined, it can be seen that the disease is a bridge between east and west in this disease (Figure 1). As a result, hantavirus is an important pathogen in terms of public health. The region we are conducting our study is quite suitable for rodents which are the reservoir of the hantavirus. These data indicate that hantavirus poses a risk in our region and the necessary precautions should be taken. In the future studies need to be investigating the alternative hosts of Hantavirus, zoonotic aspects of the disease, and rodent-human contact in this region.

Figure 1. Representation of Hantavirus detected regions on the map in Erzurum, Turkey.

Abstract third-party references: McMaster University, University of Botswana, Botswana-UPenn Partnership, FIND

Background: The mortality and morbidity attributable to bacterial sepsis can be mitigated by timely, appropriate antimicrobial therapy; determination of what is ‘appropriate’ is dependent on pathogen identification and susceptibility. In resource-limited settings, manual blood culture systems are often utilized, followed by traditional manual microbial identification methods, which often greatly delays definitive results. Novel molecular assays, such as the FilmArray (FA) BCID panel (bioMérieux, France), can identify pathogens present in culture almost immediately, potentially facilitating earlier initiation of optimal antibiotic treatment. The objective of this study was to explore the use of the FA BCID panel at Princess Marina Hospital (PMH), a tertiary care centre in Botswana, as an add-on to the standard processing of positive blood cultures.

Materials/methods: Positive blood cultures from PMH inpatients, incubated using the manual Oxoid Signal system (Thermo Fisher, UK), were randomized 1:1 to standard PMH microbiologic processing (control arm) or standard processing plus FA BCID testing (intervention arm). The results of both were compared to the MicroScan WalkAway (Siemens, USA) automated system at a separate, accredited, hospital. If the FA BCID identified a pathogen, specific antimicrobial(s) were also recommended to the clinical team.

Results: Between May 2018-Nov 2019, 279 participants were enrolled, the case-fatality rate in these inpatients with bacteraemia was 20%. FA BCID results were available on the day of enrolment, with a median time-to-result of 4.8 hours (IQR 3.9-6.8h); standard testing results were available at a median of 55 h (IQR 51-66h). 54% of cultures grew isolates judged to be contaminants. In the intervention arm, there were 15 specimens (5%) that were misidentified only by standard processing, 2 (0.7%) that were misidentified only by FA BCID, and 2 (0.7%) that were misidentified by both FA BCID and standard workup. 8 specimens (3%) tested by FA BCID grew isolates that were not targeted by the panel, but only 2 (0.7%) of these were pathogenic (Burkholderia cepacia, Aeromonas caviae); both of these were misidentified by standard PMH testing.

Conclusions: In a referral hospital in a resource-limited setting, FA BCID testing provided identifications much more rapidly and more accurately than standard microbiologic processing.

Abstract 7406

External quality assessment panel on detection of carbapenem-resistant Gram-negative pathogens within the NeoOBS study
Tuba Vilken*1

1University of Antwerp, Laboratory of Medical Microbiology, Wilrijk, Belgium

Abstract third-party references: NeoOBS Study Team

Background: An external quality assessment (EQA) was carried out to reflect the performance of the laboratories involved in a neonatal observational study (NeoOBS) looking at mortality risk factors in hospitalised infants less than 60 days of age who are being treated for significant sepsis. NeoOBS is funded by the Global Antibiotic Research and Development Partnership (GARDP).

Materials/methods: Twenty well-characterized Gram-negative isolates were sent blinded to 16 global labs taking part in the NeoOBS study, located across Africa, Asia, Europe and South America between May and August 2019. The panel included both carbapenem-resistant and susceptible strains (Table 1). Labs were asked to perform identification and antimicrobial susceptibility testing (AST) using their local routine procedures. Results were collected via two online questionnaire forms which were built to capture data on the detection methods used, as well as on the identification and susceptibility data for each of the 20 strains. After submitting the results, labs were given feedback and were asked to repeat some of the strains, if necessary.

Results: Fifteen labs reported results by 11 November 2019. The most commonly used routine methods for identification were Vitek (60%) and conventional biochemical tests (30%). Gram-stain was also used by 40% of the labs. All labs used either disc diffusion or gradient MIC testing methods to perform antimicrobial susceptibility testing. The majority of the labs (93%) interpreted the AST results according to the CLSI guidelines. Five labs (33%) reported all strains correctly. Every strain was identified correctly by 2/3 of the labs and the remaining labs mis-identified only one isolate. The susceptibility results of 5 labs (33%) matched fully the baseline results. The success rate of the other 10 labs varied between 70% and 95%. After results re-submission, the number of labs that reported all results correctly increased to 7 (47%).

Conclusions: The EQA panel allowed us to assess the capabilities of participating labs for detection of carbapenem resistance. Based on the results we were able to highlight certain carbapenem-resistant phenotypes that could be challenging for some of the labs in the NeoOBS study.

Abstract 7410

Evaluation of in vitro susceptibility and molecular resistance mechanisms to ceftazidime-avibactam in clinical isolates of Pseudomonas aeruginosa from five Latin American countries

Elsa De La Cadena1, Tobias Appel1, María Fernanda Mojica1,2,3, Juan Carlos García-Betancur1, Christian Pallares1, María V. Villegas1

1Grupo de investigación en Resistencia Antimicrobiana y Epidemiología Hospitalaria, Universidad El Bosque, Bogotá, Bogotá, Colombia, 2Department of Infectious Diseases, School of Medicine, Case Western Reserve University, Cleveland, United States, 3Research Service, Louis Stokes Veterans Affairs Medical Center, Cleveland, United States

Background: Ceftazidime/avibactam (CZA) is the combination of a third-generation cephalosporin and a non-β-lactam β-lactamase inhibitor capable of inactivating class A, class C and several class D β-lactamases, without activity against metallo-β-lactamases (MBL). Resistance mechanisms to CZA in P. aeruginosa (Pae) are diverse, and resistance has been reported even before the introduction of CZA into the clinic. The aim of this study was to identify the susceptibility and molecular mechanisms responsible for the in vitro resistance to CZA in a group of clinical Pae strains from Latin America.

Materials/methods: Clinical isolates of Pae (n=504) were collected between 2016 and 2017 in Argentina, Brazil, Chile, Colombia, and Mexico. Minimum inhibitory concentrations to CZA were determined by standard broth microdilution and interpreted according to CLSI M100-S28 breakpoints. Production of carbapenemases in Pae isolates displaying resistance to CZA was assessed by carba-NP followed by PCR to detect blaKPC, blaNDM-1, blaVIM, blaIMP, and blaSPM-1. Illumina whole-genome sequencing (WGS) was performed for 30 isolates in which resistance to CZA was not mediated by MBL. The presence of mutations of several genes involved in regulation of MexAB-OprM (mexR, nalC, or nalD), mutations leading to AmpC hyperproduction and ftsI (PBP3) was compared with PAO1, was evaluated.

Results: Overall, 28.5% (144/504) of all clinical isolates of Pae were resistant to CZA. Table 1 summarizes the results obtained by PCR and WGS. In 27.1% of the CZA resistant isolates, at least one MBL was detected. In all of the 30 isolates, which underwent WGS, mutations in MexAB-OprM regulator genes were observed, most frequently a G71E substitution in NalC (66.7%), followed by V126E substitutions in MexR (26.7%). Furthermore, amino acid substitutions in PBP3 and the AmpC/AmpD system were observed in 36.7% and 20% of CZA resistant isolates, respectively.

Conclusions: Susceptibility of Pae isolates to CZA was high. Further studies are warranted to establish the role of the novel substitutions found in many isolates, which were CZA resistant and did not harbor MBL or previously reported mutations.

Table 1. Molecular analysis of CZA resistant strains

| Country | Number of CZA resistant isolates | blaKPC | blaNDM-1 | MexR/Amr | MexR/Amr-NalC/NalD | ftsI/Amr | PBP3

Abstract 7412

**Fourier-transform infrared spectroscopy for bacterial typing and real-time outbreak analysis**

Jonathan Lellouche*1, Nadya Rakovitsky1, Sammy Frenk1, David Schwartz1, Hadas Kon1, Shirin Abramov1, Polet Elmalih1, Yehuda Carmeli1,2

1National Laboratory for Antibiotic Resistance and Investigation of Outbreaks in Medical Institutions, National Institute for Antibiotic Resistance and Infection Control, Ministry of Health, Tel-Aviv, Israel, 2Sackler Faculty of Medicine, Tel Aviv University, Ramat-Aviv, Israel, Tel-Aviv, Israel

**Background:** Outbreaks of multidrug-resistant organisms or cases in which suspicious resistance patterns emerge over a short time demand quick information at the strain level. Typing of bacterial strains can aid in outbreak investigation when classical epidemiological methods are inconclusive. Typing can reveal clonality and possible routes of transmission, and can link clinical isolates to environmental reservoirs. Recently, a new automated system for characterization of bacterial strain typing was commercialized. This system is based on FT-IR spectroscopy and performs same-day strain typing. Here, we summarize the advantages and the limitations of using this system for real-time outbreaks investigations.

**Materials/methods:** This study included specimens collected during seven outbreaks in Israeli hospitals in 2018-2019. The investigations involved different microorganisms: A. baumannii, MRSA, VRE, P. aeruginosa, ESBL-producing K. pneumoniae, IMI-producing E. cloacae and S. marcescens. Typing was performed using an FT-IR spectroscopy-based system (Bruker, Germany) and hierarchical cluster analysis was generated using OPUS 7.5 software (Bruker, Germany). We compared FT-IR results to results of genomic fingerprinting methods using DNA amplification (REP/BOX/ERIC-PCR and blaOXA-51LIKE typing), spa typing, and genome-based sequencing (cgMLST and core genome alignment). Typeability, discriminatory power (Simpson Index of diversity), and the influence of the cut-off value were evaluated.

**Results:** In each outbreak, the analysis based on FT-IR spectroscopy confirmed the presence of a predominant clone and concurred with epidemiological findings. In three outbreaks (of P. aeruginosa, S. marcescens and MRSA), there was complete concordance between FT-IR and REP-PCR, BOX-PCR and spa typing, respectively. In 2 outbreaks (A. baumannii and VRE) there was partial concordance between FT-IR and blaOXA-51LIKE and BOX-PCR typing, respectively. FT-IR was overdiscriminatory in analyzing an ESBL-producing K. pneumoniae outbreak when compared to cgMLST and core genome alignment. FT-IR had a discriminatory power >0.7 in each outbreak. The discrepancies observed between FT-IR spectroscopy and other typing methods would not have affected outbreak interpretation or management.

**Conclusions:** Because of its technical simplicity, short turn-around time, and low cost, FT-IR biotyping has the potential to become an essential tool for outbreak investigation.

Abstract 7413

**Education for diagnostic stewardship needs fresh approaches in the digital era: lessons from an attempt to reduce inappropriate urine cultures**

Alicia Xin Yu Ang*

1National University Health System, Singapore, Singapore

**Background:** Inappropriate urine cultures can result in inappropriate treatment of asymptomatic bacteriuria, promoting antimicrobial resistance, increasing length of hospital stay, adverse drug reaction and possible missed diagnoses. We embarked on a series of interventions in a tertiary hospital in Singapore to reduce inappropriate urine cultures in hospitalised patients.

**Materials/methods:** Gap analysis identified that root causes of inappropriate urine culture orders included convenience of urine cultures, and lack of knowledge regarding indications for urine cultures, and consequences of inappropriate urine cultures. All urine culture orders were audited via electronic medical records review by trained reviewers, and deemed inappropriate if sent in the absence of any symptoms of urinary tract infection, unless they were in pregnancy or before a urological procedure. The interventions and continuous audit spanned 1 February to 1 November 2019. Initial interventions planned for 1 February to 30 June 2019 included educational efforts during hospital-mandated training sessions for junior doctors, and nurses questioning doctors on the indication of urine culture at the point of urine collection.

**Results:** At baseline in February 2019, 40.5% of urine cultures were inappropriate. Interventions planned between 1 February to 30 June 2019 could not be effectively carried out. Hospital-mandated training sessions had poor attendance, with limited presence even for doctors who signed in. Nurses were overwhelmed with reminder fatigue and could not undertake the additional task of questioning doctors at the point of urine collection. The rate of inappropriate urine cultures was 33.3%, 39.0%, and 35.7% in March, April and May 2019 respectively. New educational interventions were designed, including daily text reminders to junior doctors, and e-posters on ward computers used for electronic ordering. The prevalence of inappropriate urine cultures dropped to 32.6%, 28.6% and 21.1% in September, October and November 2019 respectively.

**Conclusions:** Diagnostic stewardship can improve patient care. Our experience suggests that utilising digital platforms in place of traditional means of education via face-to-face contact may be more effective in reaching out effectively to doctors.

Abstract 7416

**Preliminary evidence of absence of cystic echinococcosis in the Dibrugarh district of Assam state, North-East India**

Rahul Taye Gam1, Ishan Phukan2, Souvik Deb2, Abha Saikia2, Plabita Sharma2, Nabanita Nirmoliya2, Baruah Rupali2, Tommaso Manciulli*3,4

1King George's Medical University, Department of Community Medicine and Public Health, Lucknow, India, 2Assam Medical College, Department of Community Medicine, Dibrugarh, India, 3University of Pavia, PhD School of Experimental Medicine, Pavia, Italy, 4University of Pavia, Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, Pavia, Italy

**Background:** Cystic Echinococcosis (CE) is a cosmopolitan zoonosis caused by the tapeworm *Echinococcus granulosus*. In India, the disease has been estimated to have a significant socioeconomic impact. However, exact data on the epidemiology of the disease are lacking. We present findings from a cross-sectional ultrasound-based survey conducted to evaluate the prevalence of CE between March and April 2019 in rural communities in the state of Assam, North-East India.

**Materials/methods:** In the absence of published data on the presence of CE cases in animals and humans in the studied area, seven villages from the Dibrugarh district where randomly selected from communities where pastoral activities with goats are commonly carried out. Residents aged 5 to 90 years were invited to undergo a free ultrasound examination of the abdomen to check for the presence of CE cysts and stage lesions according to the WHO-Informal Working Group on Echinococcosis (WHO-IWGE) classification of CE cysts. A commercial Rapid Diagnostic Test (VIRAPID HYDATIDOSIS, Vircell, Spain) was performed using sera of patients with possible CE lesions.

**Results:** A total of 1464 participants were enrolled, 629 were female (42.91%). The median age was 35 (range 5-90, IQR 20). Only two patients (0.13%) presented with possible CE cystic lesions in the liver and the spleen respectively. Both lesions were found in patients who were over 60 years old, were solid with well-defined margins and no liquid component (possible CE5) and were negative at serology testing.

**Conclusions:** Our preliminary data suggest CE to be absent or at least very scarcely present in humans in the studied area, as we found no patient carrying cysts with pathognomonic signs detectable by ultrasound. Our results suggest the lack of an ongoing active CE transmission. This is most likely due to the scarcity of sheep raising activities in the region, as while other potential hosts such as goats and cows are present, sheep are known to be the most fertile intermediate host for *Echinococcus granulosus*. Physicians dealing with patients from this area carrying suspect CE lesions should carefully consider other differential diagnoses.

Abstract 7419

Therapeutic drug monitoring of isavuconazole in patients undergoing antifungal therapy in Denmark

René Jørgensen*, Malene Risum1, Maiken C. Arendrup1,2,3

1Statens Serum Institut, Department of Bacteria, Parasites and Fungi, Unit of Mycology, København, Denmark, 2Copenhagen University Hospital, Rigshospitalet, Department of Clinical Microbiology, København, Denmark, 3Copenhagen University, Department of Clinical Medicine, København, Denmark

Background: Isavuconazole is the newest approved broad-spectrum triazole antifungal agent. It is found non-inferior to voriconazole in the treatment of invasive aspergillosis and to have an effect on mucormycosis similar to amphotericin B. The pharmacokinetic features of isavuconazole identified during clinical development did not provide a clear need for therapeutic drug monitoring (TDM). Nevertheless, a recent study recommended a relatively narrow therapeutic range between 2.5 and 5 mg/L. We have monitored the serum levels since 2017 and present the results of isavuconazole TDM at Statens Serum Institut, Denmark

Materials/methods: Blood samples referred for isavuconazole TDM March 2017 to August 2019 were included. The serum concentration levels were determined by fluorescent detection on a UHPLC using an azole TDM kit from ChromSystems adapted and validated for isavuconazole determination [Jørgensen et al., 2017]. The therapeutic index aimed for was initially 2-10 mg/L, but recently adjusted to 2.5-5 mg/L. For invasive Aspergillus flavus infections a trough level ≥4 mg/L is recommended (due to a two-fold higher MIC compared to that for A. fumigatus) and in mucormycosis a trough level well above the individual MIC was preferred until fungal control.

Results: A total of 244 isavuconazole serum concentrations from 30 patients were analysed. The group of patients included 15 females/15 males with a median age of 59.5 years ranging from [7-80 years]. The median value of isavuconazole concentration in all patients was 4.5 mg/L range [0.0 – 15.4 mg/L]. The patients were divided into four disease groups, haematology (non-Mucorales), haematology (Mucorales), pulmonary disorders and other with median values of 4.1, 5.3, 4.3 and 2.2 mg/L, respectively, but with noticeable inter and intra patient variability (Fig. 1).

Conclusions: Although observing a median value of 4.5 mg/L, well within the recently recommended therapeutic range, the range of measured serum levels is very broad for all patient groups. This may in part be explained by variations in administration, sampling and influenced by drug-drug interactions. We recommend a targeted antifungal treatment according to species identification. Consequently, the serum levels for mucormycosis patients are higher compared to other patient groups although significant interpatient variability is seen for all groups.

Abstract 7420

Implementation of intravenous artesunate for severe malaria in France: analysis of outcome in 1391 patients

Camille Roussel1,2, Papa Alioune Ndour1,2, Eric Kendjo3,4, Sébastien Larréché5, Ayda Taieb1, Benoît Henry1,2,6, Bénédicte Lebrun-Vignes7, Charlotte Chambrion1,2, Nicolas Argy3,8, Sandrine Houze3,8, Oussama Mouri3,10, David Courtin4, Adela Angoulvant11,2, Hervé Delacour8, Frederick Gay3,10, Jean-Yves Siriez3, Martin Danis3, Fabrice Bruelle1, Olivier Bouchaud4, Eric Caumes3,4,16,17, Renaud Piarroux3,4,10, Marc Thellier3,4,10, Stéphane Jauréguiberry3,4,16,17, Pierre Buffet*1,2,3

Background: Intravenous artesunate has been deployed in Europe and in the USA through a diversity of distribution programs. Its efficacy and safety have been analyzed in observational studies relatively limited in size.

Materials/methods: We collected outcome features in patients treated with intravenous artesunate during the first seven years [from May 2011 through December 2017] of a national implementation program through the French National Drug Agency. Data were collected from the national pharmacovigilance system and by the Malaria National Reference Center.

Results: Artesunate distributed in local hospitals became the most frequent treatment for severe malaria in France in 3 years. In 2017, 71.4% of severe malaria patients were treated with IV artesunate. 1391 patients with severe (1370) or uncomplicated (21) malaria were treated during the study period. Death rate was estimated at 4.1% from patients with reported outcome (41/1011). Median (IQR) length of stay in the hospital and in ICU were 6 (4-8) and 2 (1-4) days respectively. Treatment failure was recorded in 27 patients but resistance-associated mutations in the parasite Kelch-13 gene were not observed. Main reported adverse events were anemia and/or hemolysis (136 cases), cardiac events (24), elevations of liver enzymes (23), and kidney failure (15). No increase in adverse events incidence was noted in children, over or under-weighted, HIV-positive patients or during pregnancy. Incidence of post-artesunate delayed hemolysis (PADH) was 42.8% when specifically assessed in a sub-cohort of 98 patients, and was twice higher in patient of European origin than in patients of African origin (57.9% vs 29.2%, p<0.0009). Compared to the general population, higher mortality rate and prolonged stay in the hospital [total and in ICU] were observed in patients with initial parasitemia > 10%, age >50 years and European origin; mortality was lower in children <15 years [1.0%] and in patients of African origin. Conversely, mortality rate was similar in the general population and in over- or under-weight, HIV-positive patients or pregnant women.

Conclusions: Artesunate was rapidly deployed on a nation-wide scale and confirmed its superior clinical benefit in the general population and main subgroups, justifying a wide implementation in imported severe malaria.

Infections associated with kinase and antiapoptotic Bcl-2 inhibitors in a cohort of real-life haematological patients

Estela Moreno1, Pedro Puerta1, Nicole Garcia-Pouton1, Veronica Rico Caballero1, Celia Roig1, Carlos Castillo1, Cristina Helguera1, Mariana Chumbita1, Celia Cardozo1, Tycho Stephan Baumann1, Eva Giné1, Julio Delgado1, Juan Correa1, Valentín Ortiz-Maldonado1, Alex Soriano1, Carolina Garcia Vidal1

1Hospital Clínic, Barcelona, Spain, 2Hospital General Universitario de Castellón, Castellón, Spain, 3Hospital Universitario de Gijón, Gijón, Spain

Background: Ibrutinib, idelalisib and venetoclax are novel oral agents for the treatment of hematologic neoplasias that have changed the landscape of hematology, but the knowledge of potentially associated infectious complications is scarce. We aimed to describe the incidence and epidemiology of infections in a current cohort of real-life treated patients.

Materials/methods: Retrospective descriptive study of the patients treated with ibrutinib, idelalisib or venetoclax in a tertiary center from June 2014 to September 2019. According to our hospital protocols, patients with idelalisib received prophylaxis with cotrimoxazole after March 2016 and also patients treated with ibrutinib if they had received 3 or more prior lines of therapy or concomitant corticosteroid therapy, after September 2018.

Results: A total of 167 patients were analyzed: 123 received ibrutinib, 17 idelalisib and 27 venetoclax. Median age was 72 years (IQR 62-78) and 67.1% were male. Underlying disorders were chronic lymphocytic leukaemia (89, 53.3%), non-Hodgkin lymphoma (55, 32.9%) and acute leukemia (22, 13.2%). Overall, 53 (31.7%) patients had at least one episode of microbiologically documented infection, and 110 different isolates were reported: 72.7% bacterial, 20.9% viral and 6.4% fungal. Patients receiving ibrutinib had a lesser risk of infection, while this risk was higher in those receiving venetoclax (p=0.001 each). Acute leukemia patients had a higher risk of infection (p=0.048) and those having received at least two previous lines of therapy for their baseline disease and those receiving corticosteroids had a non-significant trend for increased risk of infection (p=0.262 and p=0.121, respectively). In multivariate analysis, acute leukemia (OR 2.933, CI 1.154-7.456) and use of corticosteroids (OR 2.514, CI 1.048-6.033) were independently associated with higher risk of infection.

Conclusions: Patients with hematologic neoplasias treated with kinase and antiapoptotic protein Bcl-2 inhibitors face a high incidence of infection, especially those with acute leukemia and corticosteroids use. These results are important in order to establish preventive approaches.

Abstract 7422

Comparison of PCR assays for detection of Echinococcus multilocularis from human formalin-fixed paraffin-embedded tissue preparations

Jenny Knapp1, Franck Monnien2, Sophie Felix3, Demonmerot Florent4, Bruno Heyd5, Carine Richou6, Solange Bresson Hadni4, Laurence Millon*7

1Parasitology-Mycology department, University Hospital of Besançon, France, France, 2Pathology Department, University Hospital of Besançon, Besançon, France, 3Pathology Department, University Hospital of Besançon, Besançon, France, 4National Reference Center Echinococcosis, University Hospital of Besançon, Besançon, France, 5Digestive surgery Department, University Hospital of Besançon, Besançon, France, 6Hepatology department, University Hospital of Besançon, Besançon, France, 7University Hospital of Besançon, Parasitology-Mycology department, National Reference Center Echinococcosis, Besançon, France

Background: Molecular identification and pathology examination performed on lesions are the two pathways for confirmation of alveolar echinococcosis in patient. Molecular diagnosis can be performed on various samples containing parasite DNA, such as tissue, biopsy, liquid, or formalin-fixed paraffin-embedded preparation (FFPE). The present study aims to assess molecular diagnosis on FFPE samples.

Materials/methods: Molecular diagnosis was tested from 30 alveolar echinococcosis lesions isolated after surgery from 1997 to 2018 and included in paraffin, in order to test the best PCR conditions from different published DNA targets. DNA was extracted twice with commercial kit. Eleven PCR assays were tested, which targeted four mitochondrial genes (NADH1, COX1, 12S-rrnS-rRNA and 16S-rrnL-rRNA), and generated PCR products from 84 to 529 bp.

Results: Except for few samples (from 1997 and 2000), the PCR results were better for FFPE samples less than 10 years old. PCR was successful for half of the tested samples when the size of the PCR product was below 250 bp. The PCR targeting part of the 16S-rrnL-rRNA (84 bp) was the most successful PCR and allowed us to amplified 75% (22/30) of the FFPE preparations tested. When quantitative PCR technique was used, the target was amplified in 90% of the samples.

Conclusions: Retrospective molecular studies performed on FFPE preparations is a key point in epidemiology of rare or emerging diseases as alveolar echinococcosis. Methods of FFPE preparation have changed this last decade and have impact on DNA conservation. In FFPE, DNA can be partially degraded and the use of short PCR targets is essential. Quantitative PCR, instead of conventional PCR, could be performed to increase the sensitivity, especially in retrospective FFPE studies. Confirmation by sequencing requires appropriate DNA target size, with PCR products about 200 bp.

Abstract 7423

Unexpected genomic variability among Enterobacterales causing bloodstream infections in European neonates and infants less than 90 days

Laura Folgori*, Aurora Piazza1, Francesco Comandatore1, Adam Witney1, Yingfen Hsia1, Neal Russell1, Kenneth G. Laing3, Irene Monahan3, Matteo Perini2, Gian Vincenzo Zuccotti4, Timothy Planche1, Paul Heath1, Mike Sharland1

1St George’s, University of London, Institute for Infection and Immunity, London, United Kingdom, 2University of Milan, Sky Net UNIMI Platform - Pediatric Clinical Research Center Romeo ed Enrica Invernizzi, Dipartimento di Scienze Biomediche e Cliniche Luigi Sacco, Milan, Italy, 3St George’s University of London, Institute of Infection and Immunity, London, United Kingdom, 4Ospedale dei Bambini V. Buzzi, University of Milan, Department of Pediatrics, Milan, Italy

Background: Mortality in neonates with Gram-negative bloodstream infections (BSIs) has remained unacceptably high over the last decade (10-15%), despite improvements in neonatal care. This was a case-series study including European infants with culture-proven sepsis caused by Enterobacterales to investigate significant determinants of neonatal mortality.

Materials/methods: 92 strains were isolated from 90 infants <90 days with proven Enterobacterales BSIs from six European countries between 2010-2015. Patient-level clinical data, treatment and 28-day outcome were available. Bacterial isolates from blood were identified by MALDI-TOF mass spectrometry and antibiotic susceptibilities obtained with disk diffusion tests (EUCAST guidelines 2019). Strains were further characterised by Whole-Genome Sequencing (Illumina MiSeq platform).

Results: Among the 92 bacterial isolates (UK: 50; Estonia: 21; Greece: 11; Italy: 7; Lithuania: 2; Spain: 1) the majority were Escherichia coli (37/92), Enterobacter spp. (25/92), Klebsiella spp. (20/92), Serratia spp. (9/92), and Proteus mirabilis (1/92). 28% (26/92) isolates were multi-drug resistant and 21% and 19% were resistant to 3rd-generation cephalosporins and gentamicin, respectively, while 99% were susceptible to amikacin and meropenem and 93% to piperacillin/tazobactam and ciprofloxacin. Twenty-five isolates harboured blaTEM-type genes, two non-Klebsiella spp strains the blaSHV-type determinant, and two E. coli strains the blaCTX-M-type genes. One K. pneumoniae Sequence Type (ST) 17 carried blaVIM-12 gene, and two Enterobacter asburiae (ST484) the mcr-9 determinant. A total of fifty different STs were found, with ST131 and ST90 as the most frequent in E. coli and Enterobacter cloacae, respectively. E. coli strains showed the highest mean number of virulence genes [105 vs <65 in the other species overall], mainly those involved in fimbriae production. The fatality-rate among the cohort was 21% (19/90).

Conclusions: The fatality-rate was higher than that reported in literature, with potential confounders being the high proportion of pre-terms and/or comorbidities. Genomic analyses revealed an unexpected genetic variability among the isolates, in terms of the number of STs and resistome/virulome composition, compared to the published adult literature. This could be due to age-specific factors, such as pathogenetic and immunological mechanisms, which should be further investigated to develop a tailor-made therapeutic strategy. This genetic heterogeneity needs to be confirmed in global neonatal sepsis cohorts.

Presenter email address: laura.folgori@gmail.com
Evaluation of ResistancePlus GC assay for the detection of Neisseria gonorrhoeae and markers associated with ciprofloxacin-susceptibility and resistance

Paula Salmerón*, Patricia García1, M.Belén Viñado1, Beatriz Romero1, Javier Colomina Rodríguez1, Glaila Martínez2, Gloria Martín-Saco1, Noemi Sanchez Oliver3, Eva Alcoceba1, Laura Villa3, Aurora Torreblanca4, Tomás Pumarola-Suñé5, Yannick Hoyos-Mallecot1, Judit Serra Pladeval1

1Vall d’Hebron University Hospital, Microbiology Department, Barcelona, Spain, 2Hospital Ramón y Cajal, Madrid, Spain, 3Hospital clínico de valencia, Valencia, Spain, 4University Public Hospital of La Ribera, Alcira, Spain, 5Hospital Universitario Miguel Servet, Zaragoza, Spain, 6Hospital de Valme, Seville, Spain, 7Hospital Universitario Son Espases, Palma, Spain, 8Hospital Universitario Central de Asturias, Oviedo, Spain, 9Hospital de Cabueñes, Gijón, Spain

Background: Most European guidelines recommend ceftriaxone 500 mg intramuscular as a single dose together with azithromycin 2 g oral as a single dose for empirical treatment of uncomplicated gonorrhoea. Ciprofloxacin is an option if antimicrobial susceptibility test results are available before treatment.

The aim of this study was to evaluate the ResistancePlus GC assay (SpeeDx Pty Ltd) for the simultaneous detection of Neisseria gonorrhoeae (GC) and gyrA S91 markers of susceptibility (Wild Type) and resistance (S91F) to ciprofloxacin from clinical samples and GC isolates

Materials/methods: Performance was assessed on 150 GC strains and 97 GC-positive clinical samples (positive culture and Seegene Allplex STI Essential Assay). The gonococcal DNA extraction was performed using NucliSens easyMAG (bioMérieux, France) and Seegene Allplex STI Essential Assay (Seegene, Seoul, Korea) from isolates and clinical samples, respectively. Amplification and detection were performed using the LightCycler 480 II instrument (Roche, Spain).

Results were compared with phenotypic resistance profiles determined by gradient diffusion technique (E-test) using EUCAST breakpoints.

Results: Both GC strains and GC-positive clinical samples were correctly detected by the ResistancePlus GC (beta) assay. The test demonstrated a 100% sensitivity for GC detection. E-test results determined that 60.8% of clinical samples were resistant to ciprofloxacin and we observed a 100% concordance between the phenotypic-based susceptibility data and the detection of the S91F mutation or S91 Wild Type respectively. No isolates provided an indeterminate result for gyrA detection.

Conclusions: The ResistancePlus GC (beta) assay is an appropriate assay for simultaneous detection of N. gonorrhoeae and markers of susceptibility and resistance to ciprofloxacin in gyrA gene directly from clinical samples or GC isolates. Therefore, this assay could be implemented in a healthcare laboratory as a routine technique for the rapid detection of GCs as well as its ciprofloxacin susceptibility. Consequently, ciprofloxacin could be used for gonorrhea treatment in order to improve antibiotic stewardship and conserve extended-spectrum cephalosporins.

Conflict of interests: SpeeDx Pty Ltd supplied all the reagents for molecular testing.

Molecular epidemiology and spatiotemporal analysis of carbapenem-resistant Enterobacteriaceae among network hospitals in southern Thailand

Sarunyou Chusri*, Thanaporn Hortivakul1, Kalyarat Kaewnirat1, Arnon Chukamnerd1, Kachornsak Silpapojakul1

1Faculty of Medicine, Prince of Songkla University, Kho Hong, Thailand

**Background:** Carbapenem-resistant Enterobacteriaceae (CRE) become a worldwide concern in nosocomial infections. The data epidemiology, risk factors, and outcomes of CRE infections among hospitalized patients are still insufficient.

**Materials/methods:** We prospectively collected data of inpatients in network hospitals (1 university hospital, 3 referral centers and 5 provincial hospitals) who infected and colonized with CRE from October 2018 to September 2019. Thus we also investigated for the environmental contamination of these organisms in those studied hospitals. Carbapenemase genes were identified and sequencing was used to obtain a complete genetic context of the plasmid-harboring those genes. A spatiotemporal analysis was performed by admission ward, hospitals, time of infection and similar groups of genes and plasmids.

**Results:** There were 1096 isolates of CRE identified among 985 patients. *Klebsiella pneumonia* is the most common species accounting to 51% following with *Escherichia coli* (28%). Only 25 patients (with 25 isolates) accounting 2 % was identified with community-acquired infection. The only one significantly risk factor is previous use of carbapenems [OR 2.3 [1.9-5.8], P = 0.031]. Among K.pneumoniae and E.coli, the MIC50 and MIC90 of both imipenem and meropenem were 32 µg/ml and 64 µg/ml, respectively. Nine hundred and ninety-seven (91%) isolates were positive for *bla_

**Conclusions:** CRE transmitted both within hospitals and between hospitals in the network. The data served the better understanding to control the spreading of these organisms.

Genital tuberculosis in a low prevalence setting: an unsuspected cause of infertility and severe gynaecological disease

Maria Cristina Veintimilla Yanez*, Cristina Rodriguez Grande, María Jesus Ruiz Serrano, Ana Alvarez-Uria, Beatriz Alvarez Romasanta, Belén Padilla, Patricia Munoz, Paloma Gijón, Dario Garcia De Viedma

1Clinical Microbiology and Infectious Diseases Department, Hospital General Universitario Gregorio Marañón, Madrid, Spain, 2Clinical Microbiology and Infectious Diseases Department, Hospital General Universitario Gregorio Marañón. Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Background: Genital tuberculosis is an unusual site of extra-pulmonary tuberculosis, usually with a non-specific clinical presentation and thus underdiagnosed. However, a correct diagnosis is mandatory to avoid infertility. Our aim was to define clinical characteristics of female genital tuberculosis (FGTB), population at risk, sequelae and genotypic features of the strains involved, in a city with a low-rate of tuberculosis around 10/100,000 people.

Materials/methods: Retrospective study in a tertiary care Hospital from January-2003 to August-2019. All tuberculosis cases were evaluated and cases with FGTB were included. Clinical records were reviewed. The isolates were analyzed by MIRU-VNRT to assign their genotypes, analyze potential clusters, determine the lineage and evaluate possible polyclonal infections.

Results: During study period, a total of 1804 tuberculosis cases were identified. Five of them (0.3%) corresponded to FGTB. All cases were from migrant women: Dominican Republic [3], El Salvador [1] and Ecuador [1], median age was 31-years (range:20-60). Three patients had infertility upbringing. The most frequent symptom were abdominal pain and fever [3]. Diagnosis was performed by PCR MTB-GenXpert and culture on biopsy specimens (endometrial, fallopian tube and placenta). All isolates were susceptible to first-line anti-TB drugs. Three patients had a disseminate tuberculosis (pulmonary and genital). However, two cases required treatment adjustment due to adverse effects. Two pregnant patients required intensive unit care due to severe respiratory failure, and one of them died; 80% responded to treatment. Histopathology assessment contributed only in one case. Genotypic analysis determined that the strain involved in each case was different and all corresponded to lineage (Euro-American). In one case, a polyclonal infection involving two variants was detected in the respiratory specimen. For the cases with respiratory and extra-respiratory involvement, no clonal compartmentalization was observed.

Conclusions: Genital tuberculosis in Madrid is uncommon and under diagnosis disease because of its low suspicion. It should be considered as potential diagnosis especially in patients with pelvic inflammatory disease symptoms and migrants from endemic tuberculosis countries, and maybe associated to severe disease leading to infertility and even death. This presentation did not involve a specific strain; one polyclonal infection, likely due to diagnostic delay, was identified.

Abstract 7433

Antimicrobial resistance among bacteria causing asymptomatic bacteriuria in pregnant women, rural Burkina Faso
Issa Guiraud1, Marjan Peeters2, Achille Massa Bonko1, Garba Zakaria1, Karama Ibrahima1, Annelies Post1, Palpouguini Lompo*1; Sien Ombelet2,4, Salou Diallo1, Joel Bognini1; Kabore Berenger1; Quirijn De Mast3, Andre Van Der Ven1, Halidou Tinto1, Jan Jacobs2,4
1 Nanoro Department, Clinical Research Unit of Nanoro, Nanoro Department, Burkina Faso, 2 Institute of Tropical Medicine Antwerp, Antwerp, Belgium, 3 Radboud University Medical Center, Nijmegen, Netherlands, 4 Katholieke Universiteit Leuven, Leuven, Belgium

Background: To determine antimicrobial resistance (AMR) in a rural community in sub-Saharan Africa, we assessed healthy pregnant women for asymptomatic bacteriuria.

Materials/methods: From 2016 to 2018, we recruited consenting pregnant women attending antenatal clinics in Nanoro district, Burkina Faso. Urine routinely sampled for glucose and protein testing was inoculated on-site on the Uricult system (LifeSign). Bacteria growing in quantities ≥10^4 colony (CFU) forming units/ml were processed for identification and antibiotic susceptibility testing (AST, disk diffusion according to CLSI-M100-S29). Skin bacteria, non-fermentative Gram-negative rods and bacteria from mixed flora (≥3 species) were considered as contaminants. For comparison, AST results from clinical isolates obtained from a diagnostic accuracy study in Nanoro [2017 – 2018] were used (ClinicalTrials.gov, NCT02669823). Multidrug resistance was defined as resistance to ≥3 antibiotic classes.

Results: On 6018 participating women, 92 (1.5%) had urine cultures grown at quantities ≥10^4 CFU/ml, and 132 (2.2%) had quantities ≥10^5 CFU/ml, meeting the criteria of asymptomatic bacteriuria. Among a total of 238 isolates, the top-3 pathogens included Escherichia coli (71.0%), Klebsiella pneumoniae (13.5%) and Staphylococcus aureus (9.2%). Proportions of susceptibility and MDR for the urine and clinical isolates were as follows:

<table>
<thead>
<tr>
<th>Pathogen</th>

Klebsiella pneumoniae (n=36) isolates were susceptible to cotrimoxazole (66.7%), ciprofloxacin (94.4%), ceftriaxone (97.2%) and gentamicin (100%), with only 2.8% MDR. Results were similar for isolates grown in quantities ≥10^4 CFU/ml versus ≥10^5 CFU/ml.

Conclusions: AMR rates of Escherichia coli from the urinary tract in healthy pregnant women were considerably lower compared to AMR rates in clinical isolates. Integration of urine culture in the routine of antenatal care in a rural setting in sub-Saharan Africa proved to be feasible and effective and can be used as a proxy for monitoring community AMR in remote areas.

Hospital outbreak of *Klebsiella pneumoniae* producing GES-1 or GES-5 β-lactamases in Poland

Elzbieta Literacka1, Radoslaw Izdebski2, Dorota Zabicka1, Anna Baraniak1, Pawel Urbanowicz2, Iwona Zaka1, Iwona Sowa-Sierant1, Malgorzata Herda1, Katarzyna Malinowska1, Waleria Hryniewicz2, Marek Gniadkowski2

1National Medicines Institute, Department of Epidemiology and Clinical Microbiology, Warsaw, Poland, 2National Medicines Institute, Department of Molecular Microbiology, Warsaw, Poland, 3University Children’s Hospital, Department of Clinical Microbiology, Cracow, Poland

**Background:** The first representative of the GES family (GES-1) was identified in France in 1998 in the clinical strain of *Klebsiella pneumoniae*. Among the variants of GES β-lactamases described so far are both ESBLs, e.g. GES-1, and carbapenemases, e.g. GES-5, which is the most commonly identified carbapenemase in the world from the GES family. Here we extend our previous ECCMID report, by incorporating all GES-producing isolates from Poland and providing new molecular data.

**Materials/methods:** This work covered 12 clinical *K. pneumoniae* strains: 11 from Cracow isolated in 2017 (n=1), 2018 (n=8), 2019 (n=2) and 1 from Bytom identified in 2019. The strains were from new-borns and infants up to 6 months hospitalized in intensive care and cardiology wards. All strains were obtained by the National Reference Centre for Susceptibility Testing to carbapenemase confirmation. Species identification was performed by Vitek2 (bioMérieux). Carbapenemase activity was studied by phenotypic methods, including CIM test. The presence of the *bla*GES genes were confirmed by PCR. MICs were determined using antibiotic strips (Liofilchem) and the results were interpreted according to the EUCAST guidelines. All isolates were subjected to whole genome sequencing (WGS) by Illumina-Miseq.

**Results:** The first *K. pneumoniae* strain producing GES-5 in Poland was isolated in Cracow in 2017. Molecular studies revealed the presence of *bla*GES-5 on the plasmid pKRA-GES-5 (25.004bp), belonging to the IncP6 family. *bla*GES-5 was identified within class 1 integron - In1525. Afterwards, *bla*GES genes were identified by PCR in the next 11 *K. pneumoniae*. WGS analysis confirmed *bla*GES-5 in two and *bla*GES-1 in eight isolates from Cracow. *bla*GES-1 was also present in strain from Bytom. In all cases *bla*GES were located on the plasmid pKRA-GES-5 within In1525. All strains represented ST45 and were indistinguishable in cgMLST. In the studied genomes a total of 24 SNPs was identified with 7-17 SNPs in comparison with isolate from 2017. All GES-5-producing strains were resistant to carbapenems and they were positive in CIM test.

**Conclusions:** This study showed the first hospital outbreak of *K. pneumoniae* ST45 producing GES-1 or GES-5 in Poland with *bla*GES localised on plasmid pKRA-GES-5.

**Presenter email address:** e.literacka@nil.gov.pl
Long lasting outbreak of severe Mycobacterium chimaera infection among cardiac surgery patients operated with contaminated heater-cooler devices: Italy, 2010 to 2019

Michela Sabbatucci1, Antonella Campanale2, Roberto Cagarelli3, Antonino Di Caro4, Savina Ditommaso5, Lucia Lispi2, Vinicio Manfrin6, Francesco Paolo Maraglino4, Mauro Mazzolani2, Maria Luisa Moro8, Giuseppina Napoletano6, Elena Narne3, Pietro Ragni8, Roberto Raso11, Francesca Russo9, Carlo Silvestre12, Carla Maria Zotti5, Stefania Iannazzo2

1Istituto Superiore di Sanità, Rome, Italy, 2Ministero della Salute, Rome, Italy, 3Regione Emilia-Romagna, Modena, Italy, 4 INMI Lazzaro Spallanzani, Rome, Italy, 5Università di Torino, Torino, Italy, 6Regione Veneto, Venezia, Italy, 7Azienda USL Imola, Imola, Italy, 8Agenzia Sanitaria e Sociale Regione Emilia-Romagna, Modena, Italy, 9Azienda Zero, Padova, Italy, 10AUSL Reggio Emilia, Reggio Emilia, Italy, 11Servizio di riferimento regionale di Epidemiologia per la sorveglianza, la prevenzione e il controllo delle malattie infettive (SEREMI), Alessandria, Italy, 12Ospedale Molinette, Torino, Italy

Background: Mycobacterium chimaera is a non-tuberculous Mycobacterium (NTM) belonging to the Mycobacterium Avium Complex (MAC) species. It is spread in the environment ubiquitously and harmless for healthy subjects, while vulnerable patients may develop severe infections. We report a long lasting outbreak of M. chimaera infection related to contaminated heater-cooler devices (HCD) used during open chest surgery interventions in Italy, between January 2010 and October 2019.

Materials/methods: We collected data since 2010 retrospectively, from the mandatory surveillance of human infections due to NTM, regulated by Ministerial Decrees 15/12/1990 and 29/7/1998. We adopted the case definition indicated by the European Centre for Disease prevention and Control (ECDC) referring to clinical and exposure criteria.

Results: We identified 36 lab-confirmed cases (median age: 66y, range: 35-82y; 91.4% male), included 21 death. Cases were notified from North (91.7%) and South (8.3%) Italy. Two cases were diagnosed in 2015, 6 in 2016, 8 in 2017, 6 in 2018, 11 in 2019 [3 dates were missing]. The median time between surgery and diagnosis was 3y. Mostly, patients referred fever (10.8%), leukopenia/thrombocytopenia (9.5%), night sweats (8.2%), endocarditis (8.1%), hepatitis (8.1%), asthenia (6.8%), weight loss (6.8%), nephritis (6.8%), multiple granulomas (6.8%), pulmonary involvement/pneumonia (5.4%), splenomegaly (5.4%), nausea (4.1%). Mostly, contaminated HCD were located in the North (84.6%), while 13.8% in the Centre and 1.6% in the two islands. Phylogenetic analysis is ongoing.

Conclusions: The different geographical distribution of cases and contaminated HCD possibly relay to a greater use of these devices and/or compliance in the notification flow procedures in Northern healthcare settings compared to those in other regions. We gave information to aware clinicians and general practitioners to guarantee patient safety and follow-up, together with the device cleaning and decontamination procedures spread by the Manufacturer. We recommend increased collaboration among all the actors at local and regional level to improve both case and HCD notifications in order to operate adequate and prompt health interventions. The correct cleaning, disinfection and maintenance procedures are key routine actions to guarantee appropriate HCD functioning and patient safety, avoiding spreading of infectious agents through the aerosol generated from the heating water contained in HCD.

Abstract 7441

**Evaluation of *Stenotrophomonas maltophilia* non-susceptibility and associated risk factors: a multi-centre analysis**

Christopher Bland¹, Noah White², Jason Lin², Jamie Wagner³, Kayla Stover⁴, Brandon Bookstaver⁴, Daniel Chastain⁵*, Hannah Matson⁶, Madalyn Motes⁷, Bruce Jones⁸

¹University of Georgia College of Pharmacy, Savannah, United States, ²Memorial Health University Medical Center, Savannah, United States, ³University of Mississippi School of Pharmacy, Jackson, United States, ⁴University of South Carolina College of Pharmacy, Columbia, United States, ⁵University of Georgia College of Pharmacy, Albany, United States, ⁶Huntsville Hospital, Huntsville, United States, ⁷Prisma Health, Columbia, United States, ⁸St. Joseph’s/Candler Health System, Savannah, United States

**Background:** *Stenotrophomonas maltophilia* is a lactose, nonfermenting gram-negative organism with few treatment options due to intrinsic resistance to most antimicrobials. Trimethoprim-sulfamethoxazole (TMP-SMX) and levofloxacin have traditionally high rates of *in vitro* susceptibility and are considered first line agents for *S. maltophilia*, with tigecycline, ceftazidime, and polymyxins also showing activity. Little is known regarding the prevalence of *S. maltophilia* non-susceptibility among these commonly used agents as well as potential risk factors associated with resistant isolates.

**Materials/methods:** A retrospective, multicenter analysis was performed at 5 centers in the southeastern United States. Inpatients that had a positive culture with susceptibility results between October 2015 - September 2018 were evaluated. The first isolate per patient per year was included. The primary outcome was the prevalence of non-susceptible isolates among any agent tested with typical activity vs. *S. maltophilia*. Intermediate and resistant results were grouped together and considered non-susceptible for evaluation. The secondary outcome was factors associated with *S. maltophilia* non-susceptibility based on historical risk factors associated with Pseudomonas species resistance. Data collected included baseline demographics, culture and susceptibility results, and clinical outcomes. Statistical analysis was performed using SPSS software, version 26.0 (IBM). Categorical data were analyzed using the Chi-square or Fisher exact test, and continuous data were analyzed using the Student t-test or Mann-Whitney U test, as appropriate. An alpha of ≤0.05 was deemed statistically significant.

**Results:** A total of 325 isolates met inclusion and exclusion criteria and were included in the study. Most isolates (76.3%) were sputum/respiratory cultures. Non-susceptibility was present in 43/325 (13.2%), 53/324 (16.4%), and 105/172 (61%) to TMP-SMX, levofloxacin, and ceftazidime, respectively. In centers that tested tigecycline, non-susceptibility was present in 11/16 (68.8%) isolates. The only factor predictive of non-susceptibility was isolation from a urine culture (13.3% vs. 5.4%; p=0.014). Presence of mechanical ventilation (37.7% vs. 21.5%) and ICU admission (35.3% vs. 18.4%) were predictive of susceptibility to these agents (p<0.001).

**Conclusions:** *S. maltophilia* non-susceptibility had a prevalence of almost 50% to at least one first-line or commonly used agent. Further research should evaluate national/international prevalence of, as well as risk factors associated with non-susceptibility, as treatment options are limited.

Abstract 7450

**Resistance to azithromycin in *Mycoplasma genitalium* from patients of a tertiary hospital from Madrid, Spain**

Paloma García Clemente¹, Virginia Guedez López¹, Sergio Román Soto*¹, Jose Ignacio Bernardino¹, Elena Sendagorta¹, Inmaculada Quiles¹

¹University Hospital La Paz, Madrid, Spain

**Background:** *Mycoplasma genitalium* (MG) is an etiological agent of sexually transmitted diseases, increasingly diagnosed thanks to the new commercial PCR assays. MG is associated mainly with nongonococcal urethritis, cervicitis, pelvic inflammatory disease and proctitis. Azithromycin is recommended for empirical treatment but some studies report significant rates of macrolide resistance suggesting that selection for resistance may be widespread. Our aim is to study the prevalence and characteristics of azithromycin resistance in *Mycoplasma genitalium* at La Paz-Cantoblanco-Carlos III University Hospital, a tertiary care hospital from Madrid, Spain.

**Materials/methods:** Between April 2018 and November 2019, we collected clinical samples from patients with symptoms of nongonococcal urethritis, infertility, pelvic inflammatory disease and proctitis that were positive for MG by Mycoplasma-Ureaplasma – QSR for BD MAX™ (BioGX), a real-time multiplex PCR-assay that detects *M. genitalium*, *M. hominis*, *Ureaplasma urealyticum* and *U. parvum*. The macrolide-resistance study was performed with Allplex™ MG & AzI R assay (Seegene), a real-time multiplex PCR-assay that detects MG and six azithromycin resistance mutations in the 23S rRNA gene: A2058G, A2058T, A2058C, A2059G, A2059T and A2059C.

**Results:** Seventy-one clinical samples were MG positive by BD MAX™: 27 urines, 42 rectal swabs and 2 semen. Fifty-three percent of the clinical samples had azithromycin resistance mutations detected with Allplex™ (38/71). The mutations detected were: 40% (15/38) A2058G, 34% (13/38) A2058T and 26% (10/38) A2059T.

**Conclusions:** The data obtained in our study indicate a high resistance rate compared to other studies in Spain. This situation makes it necessary to implement resistance detection assays for *M. genitalium* to facilitate the optimization of antibiotic treatment in these patients and potentially reduce the transmission of resistance.

Abstract 7451

Prospective surveillance of multidrug-resistant Gram-negative bacteria in a UK intensive care unit using whole genome sequencing

Hayley Wilson*1, Fahad Khokhar1, Ben Warne1, Rory Carpenter1, James Bryan1, Petra Polgarova3, Nicholas Brown4, David Enoch4, Charlotte Summers1, Gordon Dougan1, Julian Parkhill5, Estee Torok1

1University of Cambridge, Department of Medicine, Cambridge, United Kingdom, 2Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom, 3Cambridge University Hospital NHS Foundation Trust, John V Farman Intensive Care Unit, Cambridge, United Kingdom, 4Public Health England, Clinical Microbiology and Public Health Laboratory, Cambridge, United Kingdom, 5University of Cambridge, Department of Veterinary Medicine, Cambridge, United Kingdom

Background: The prevalence of multidrug-resistant Gram-negative bacilli (MDRGNB, defined as resistance to 3 or more antibiotic classes) is increasing globally. In 2017 ECDC estimated that 8.3% of patients staying in an intensive care unit (ICU) for more than two days acquired at least one healthcare associated infection (HCAI). Routine surveillance for MDRGNB differs between different units, hospitals and countries, reflecting uncertainty about best practice. The impact of asymptomatic carriage of MDRGNB on rates of HCAI is unclear.

Materials/methods: We conducted a six-month prospective surveillance study for ESBL-producing and/or carbapenem-resistant Gram-negative bacteria in an adult ICU in the United Kingdom. Samples were collected from multiple sites (respiratory, urine, stool / rectal swabs, wound swabs) from all participants on admission, weekly, and on discharge from the ICU. Samples were cultured on selective media (Brilliance ESBL and chRomeID Carba/Smart) and underwent identification (MALDI-TOF MS), antimicrobial susceptibility testing (Vitek2) and whole-genome sequencing (illumina HiSeq).

Results: Between June and December 2016 461 participants were recruited. 14.1% were positive for MDRGNB on admission to ICU; 11.2% carried MDRGNB in their stool. The most frequently identified organisms were Pseudomonas aeruginosa (41.4%), Escherichia coli (24.1%) and Klebsiella pneumoniae (15.5%). 8.8% of patients acquired MDRGNB during their ICU stay. Whole-genome sequencing identified epidemic lineages and genomic populations consistent with UK national data. An outbreak of carbapenem-resistant K. pneumoniae was identified by surveillance, which would have been missed on routine diagnostic testing. A distinct lineage of ESBL-producing E. coli was identified in hepatology patients.

Conclusions: Asymptomatic carriage and infections with MDRGNB in ICU patients were higher than previously reported. The majority of patients were colonised on admission to ICU. Transmission between patients was minimal, suggesting effective infection control practices on ICU. We rapidly identified and controlled an outbreak of carbapenem-resistant K. pneumoniae. WGS data provided rapid, high resolution information during the outbreak. Distinct lineages of MDRGNB in particular patient groups may indicate target populations for more frequent surveillance. These findings have potential implications for infection control strategies and interventions.

Goretti Hospital, Latina, Italy, 6Infectious Disease Unit, Department of Biomedical and Clinical Sciences L. Sacco, University of Milano, Italy, 7Infectious Diseases Unit, Ospedale di Busto Arsizio, Varese, Italy, Milan, Italy, 8Infectious Diseases Unit, Ospedale San Gerardo, Monza, Italy, 9Infectious Diseases Unit, University Hospital of Verona, Verona, Italy, 10Department of Public Health and Infectious Diseases, Azienda Ospedaliero-Universitaria Policlinico Umberto I, Sapienza University, Rome, Italy, 11Infectious Diseases Department, University Hospital of Verona, Verona, Italy, 12Department of Medical Sciences, University of Turin, Amedeo di Savoia Hospital, Turin, Italy, 13Department of Infectious Diseases, Galliera Hospital, Genova, Italy, 14Infectious Disease Unit, Department of Biomedical and Clinical Sciences L. Sacco, University of Milano, Milan, Italy

Background: Italian guidelines for the management of people living with HIV (PLWH) indicate screening for latent tuberculosis infection (LTBI) in those recently diagnosed with HIV. The Italian Society of Infectious and Tropical Diseases performed a survey on the current practice and yield of LTBI-screening [tuberculin skin test (TST) or QuantiFERON TB Gold-In tube (QFT-IT), QuantiFERON TB Plus (QFT-P)] in recently diagnosed PLWH in Italy. Primary endpoint was the LTBI prevalence. Secondary endpoints included rate and features of LTBI-screening (compared to other suggested screening test for HCV and HBV), the rate of offer and acceptance of TB-preventive therapy and its outcome.

Materials/methods: We retrospectively enrolled recently diagnosed PLWH from 9 centres, from January 2016 to December 2017. We used binary logistic regressions and multinomial logistic regressions to identify factors associated with LTBI-screening [by TST, QFT or both] and QFT-results respectively.

Results: Among the 801 participants, 774 patients were included [after excluding active TB]. LTBI tests was significantly more frequently executed in foreign vs Italian born [OR:2.52, p<0.001], AIDS diagnosis [OR: 1.81, p=0.013] and in case of CD4 count <100 cells/mm³ vs CD4≥500 cells/mm³ [OR: 2.30, p=0.059]. HBV and HCV tests were done in 98% of the patients and this was significantly different compared to LTBI-screening that was done in 65.5% [p<0.001]. LTBI was diagnosed in 32 subjects (6.5%) of the 495 patients evaluated by QFT. Positive QFT-results were significantly associated with being foreign [RRR 23.32, p<0.001], high CD4 T-cell count (100 cell/mm³ increments RRR 1.26, p<0.001) and low HIV-RNA load (log10 copies/ml increments RRR 0.59, p=0.003). Indeterminate results were significantly associated with old age [10 year increments RRR 2.08, p<0.001], low CD4 T-cell count (100 cells/mm3 increments RRR 0.09, p<0.001), high HIV-RNA load (log10 copies/ml increments RRR 2.23, p=0.006) and AIDS diagnosis [RRR1768 p<0.001]. Sixteen LTBI-subjects started LTBI treatment and 8 completed it.

Conclusions: In a low prevalence country LTBI was found in a minority of newly diagnosed PLWH. LTBI-screening is not consistently performed in PLWH in Italy and preventive-TB-therapy is not offered to all LTBI. Next updated national guidelines need to consider these observations.

Abstract 7454

**Epidemic clonal lineages of Enterobacteriales producing VIM-type carbapenemases in Poland, 2013-18**

Radosław Izdebski*, Dorota Zabicka, Elżbieta Literacka, Paweł Urbanowicz, Anna Baraniak, Waleria Hryniewicz, Marek Gniadkowski

1National Medicines Institute, Warsaw, Poland

**Background:** Carbapenemase-producing Enterobacteriales (CPE) with MBLs of the integron-encoded families VIM and IMP have been recorded in Europe from 2001 and in Poland from 2006. The analysis of all 121 VIM/IMP CPE isolates from 2006-12, revealed their striking specificity, with prevailing organisms *Enterobacter cloacae* cpx (~53%), mainly *E. hormaechei* clones ST90 and ST89, and *Klebsiella oxytoca* (20%), mainly ST145. Here we present a remarkable increase of VIM/IMP CPE cases in 2013-18 with detailed species distribution.

**Materials/methods:** 623 non-duplicates VIM/IMP CPE isolates confirmed by the National Reference Centre for Susceptibility Testing (NRCST) in Warsaw from 2013-18 were analyzed. The isolates were derived from various infections or colonization cases in 180 hospitals all over the country (16/16 administrative regions). Species identification were confirmed by the VITEK 2 system (bioMérieux, France). In all isolates the MBL production was detected biochemically by the Carba NP test, and phenotypically by the EDTA double-disk synergy test. The *bla*\_vim\_ and *bla*\_imp\_like genes were detected by PCRs.

**Results:** Following 2012, the NRCST has been observing continuous significant increase in numbers of VIM/IMP CPE in Poland, from 36 isolates in 2013, 78 in 2014, 63 in 2015, 89 in 2016, to 174 cases in 2018. Altogether, 623 VIM/IMP CPE cases were confirmed, representing 12 taxa with the most numerous being: *E. cloacae* cpx (n=231), *Klebsiella pneumoniae* (n=168), *Citrobacter freundii* cpx (n=69), *K. oxytoca* (n=64), *Escherichia coli* (n=58) and *Serratia marcescens* (n=16) followed by *Morganella morganii* (n=5), *Citrobacter braakii* (n=3), *Proteus mirabilis* (n=3), *Klebsiella aerogenes* (n=2), *Citrobacter farmeri* (n=1) and *Enterobacter asburiae* (n=1). PCR analysis revealed a total predominance of VIM types with over 98% (n=614) of the isolates, and marginal contribution of IMP-like MBLs (n=9).

**Conclusions:** Comparison with the first phase of VIM/IMP CPE dissemination (2006-12), apart from the increasing tendency, showed a remarkable change in the species distribution. In 2018 *K. pneumoniae* became the leading species, probably as a result of several dynamic regional outbreaks, like in Lubelskie (45 isolates in 2018). If to consider all species, some regions (and specific hospitals) have been arenas of extensive VIM CPE expansion, like Mazowieckie (n=129), Łódzkie (n=91) or Pomorskie (n=69).

Abstract 7457

Prevalence and molecular characteristics of Staphylococcus aureus carrying Panton-Valentine leukocidin genes isolated from patients accessing at emergency department in 2016-2018 period

Alessia Lai*, Annalisa Bergna, Sara Rimoldi, Annalisa Ridolfo, Maria Rita Gismondo, Claudia Balotta, Massimo Galli, Gianguglielmo Zehender

1University of Milan, Department of Biomedical and Clinical Sciences ‘L. Sacco’, Milan, Italy, 2L. Sacco University Hospital, Clinical Microbiology Virology and Diagnosis of Bioemergency, Milan, Italy, 3ASST Fatebenefratelli Sacco University Hospital, Department of Infectious Diseases, Milan, Italy

Background: Panton-Valentine leukocidin (PVL) represents a key determinant of community-acquired methicillin-resistant S.aureus (CA-MRSA) virulence, although not all CA-MRSA produce PVL and its presence is recently found also in hospital–acquired MRSA (HA-MRSA). HA and CA infections due to PVL-positive methicillin-susceptible S.aureus (MSSA) have also been described with clinical characteristics similar to that produce by PVL-positive MRSA suggesting that PVL-positive MSSA may be reservoirs for PVL-positive MRSA via the integration of the Staphylococcal Cassette Chromosome mec (SCCmec) mobile elements. We aimed at determining the frequency of PVL genes in S.aureus isolates collected from clinical samples at the emergency department in Milan, during the 2016-2018 period.

Materials/methods: The identification of the bacterial species and the antibiotic susceptibility were performed by MALDI-TOFF and VITEK.2, respectively. Samples were tested for the presence of PVL gene using RT-PCR. Whole genome sequencing was performed on PVL-positive isolates.

Results: We analyzed 25 stains carrying PVL genes (15 MSSA and 10 MRSA). We identified 14 different STs: the most frequent was ST512 (16%) followed by ST18 and ST1472 (12% each). The SCCmec typeIVa was the most frequent. In the minimum spanning tree we identified 3 distinct groups without common alleles with others: group A involving exclusively ST152, group B encompassing ST10, ST30, ST121 and ST1472, and group C including other STs. A median of 2.8 resistance genes were detected for 6 different classes of antibiotics. Most frequent detected genes were blaz (88%) and mecA (40%). By integrating phenotypic and genotypic data only one isolate showed a full sensitive profile. A median of 49 virulence genes was detected; MRSA isolates had more virulence genes compared to MSSA (53.6 vs. 46.5, p=.013).

Conclusions: Our data showed a high frequency of PVL in the MSSA strains which, despite their sensitivity to antibiotics, may have a high pathogenetic potential. The MRSA strains characterized showed the typical genetic characteristics related to CA infections such as a high number of virulence genes and a marked heterogeneity, representing a potential source of exchange of genetic material for the strains associated with hospitalization.

Alarming high occurrence of multidrug resistance of *Mycoplasma genitalium* in a cohort of men who have sex with men using pre-exposure prophylaxis in Belgium (Be-PrEP-ared study)

Irin De Baetselier1, Chris Kenyon1, Hilde Smet1, Vicky Cuylaerts1, Kristien Wouters1, Marie Laga2, Bea Vuylsteke2, Tania Crucitti3

1Institute of Tropical Medicine Antwerp, Department of Clinical Sciences, Antwerpen, Belgium, 2Institute of Tropical Medicine Antwerp, Department of Public Health, Antwerpen, Belgium, 3Centre pasteur du Cameroun, Yaounde, Cameroon

**Background:** Increasing antimicrobial resistance in *Mycoplasma genitalium* (Mg) has been described in men who have sex with men (MSM). We report on the occurrence of macrolide and fluoroquinolone resistance associated mutations (RAMs) in a cohort of MSM using pre-exposure prophylaxis in Belgium (Be-PrEP-ared study).

**Materials/methods:** Mg detection in urine, anorectal and pharyngeal (U-A-P) samples was performed every three months for 1.5 years using real-time PCR in 179 participants. Remnant specimens were genotyped via Sanger sequencing. RAMs were detected in the 23S rRNA which corresponds to high level resistance to azithromycin. Furthermore, quinolone resistance determining regions (QRDR) of the *parC* gene and the *gyrA* gene were sequenced to detect mutations conferring resistance to fluoroquinolones.

**Results:** At baseline, the prevalence of Mg was 19.3% (n=31). At follow-up, 139 additional Mg infections were detected (33.5% U; 59.4% A; 7.1% P). Genetic resistance data is available for 116 samples and is presented in Table 1. Only nine samples (7.8%) did not present any mutation. Macrolide resistance mediating mutations were detected in 90.5% of the samples (n=105). Mutations conferring resistance to fluoroquinolones were found in almost 45% (n=51). A total of four gyrA alterations were found (all anorectal samples), two of them coincided with a ParC mutation. The most frequent mutation of the QRDR of the ParC gene was S83I (n=27/49; 55.1%), followed by P62S (n=8/49; 16.3%).

Multidrug resistant strains were found in more than 40% of the samples (n=49; 42.2%) and were almost equally detect in the anorectum (41.3%) and urethra (44.9%).

Of those multidrug resistant cases, only eight (16.3%) presented symptoms. We linked 15 mutations to possible treatment failures; 11 with azithromycin (7/11 A2058G and 4/11 A2059G) and four with moxifloxacin (three S83I and one V112V).

**Conclusions:** The high rate of macrolide and fluoroquinolone resistance in Mg among MSM using PrEP demands attention. Nearly half of all Mg infections were multidrug resistant to azithromycin and moxifloxacin which are the first and second line treatment of Mg. Most of the cases were asymptomatic. Detection and treatment of asymptomatic cases of Mg among MSM will do more harm than good and should be avoided.

Ugandan increase in malaria cases is reflected in imported cases to Norway of which surprisingly many have mixed infections identified by PCR

Hanne Brekke*, Cathrine Fladeby¹, Gunilla Løvgården¹, Frank Olav Pettersen¹,³, Lumnije Dedi¹, Fredrik Müller¹,³

¹Oslo University hospital Ullevål, Department of Medical Microbiology, Oslo, Norway, ²Oslo University hospital Ullevål, Department of Infectious diseases, Oslo, Norway, ³University of Oslo Faculty of Medicine, Oslo, Norway

Background: In August 2019 the Ugandan ministry of health reported a 40% increase in malaria cases since June 2018. In the same time period, we have noticed an increase in malaria cases imported from Uganda.

At Oslo University Hospital malaria is initially diagnosed by rapid diagnostic tests (RDT) and microscopy. In addition, the Department of Microbiology offers a nationwide service for species-specific Plasmodium PCR to confirm suspected malaria cases and identify Plasmodium species, and mixed infections.

Materials/methods: EDTA blood samples were analyzed by in-house real-time PCR targeting the five human pathogen Plasmodium species. PCR-data from patients analyzed for Plasmodium infections in the period 2017 until November 2019 were collected.

Results: A total of 220 patients with suspected or confirmed malaria were analyzed at our department in the given time period. Of these, 75 patients had been residing in Uganda and 63 patients were PCR positive for malaria. A major part of patients infected in Uganda were Plasmodium falciparum positive of which 28.2% were mixed infections. None of these mixed infections were identified by microscopy.

Table 1

Conclusions: Malaria is a potentially fatal infection, and correct diagnosis is important to provide adequate treatment. In 2019 we have noticed an increased number of malaria infections from Uganda, and a significant proportion of these are double and even triple infections. We urge our colleagues to be aware of the current situation and recommend PCR testing as a supplement to primary diagnostic in order to detect mixed Plasmodium infections in this patient group.

**Abstract 7461**

**The antimicrobial role of a commonly used mucolytic agent in Chlamydia pneumoniae infection**

Dávid Kókai1, Dóra Paróczai1,2, Dézso Virok1, Valeria Endresz1, Katalin Burian*1,3

1 University of Szeged, Department of Medical Microbiology and Immunobiology, Szeged, Hungary, 2 University of Szeged, Department of Pulmonology, Deszk, Hungary, 3 University of Szeged, Department of Clinical Microbiology, Szeged, Hungary

**Background:** Chlamydia pneumoniae (Cpn) is an obligate intracellular bacterium, with characteristic biphasic lifecycle, causing respiratory infections. It is thought to be responsible for approximately 10% of community-acquired pneumonia cases. Ambroxol (Ax) is a widely used drug in the treatment of respiratory infection due to its effect on mucus viscosity. Ax-treatment showed anti-chlamydial activity *in vitro* on A549 cells, however, this effect was not observed *in vivo* in Cpn-infected mice when human equivalent dose of Ax was applied. In this study, our aim was to examine whether an increased dose of Ax could influence the growth of Cpn *in vivo*.

**Materials/methods:** Balb/c mice were infected with Cpn intranasally and treated with higher dose of Ax than the commonly used human equivalent dose. The recoverable Chlamydia inclusions from the mouse lungs and the growth rate *in vitro* were detected by an indirect immunofluorescent assay. The seroconversion of mice, IFN-γ and IL-6 quantity in the lungs were tested with ELISA. Furthermore, the relative mRNA expression of IL-12, IL-23, IL-17-{A,F}, IFN-γ, IDO-{1,2}, surfactant-proteins [SP-A1,B,C,D] in the lungs were analysed with RT-qPCR. Moreover, *in vitro* apoptotic assay on A-549 cells was carried out with fluorescence-activated cell sorting.

**Results:** The Ax-treatment of mice resulted in a significantly lower [2.3-times] Cpn load in the lungs and a higher Cpn specific IgM seropositivity rate. The mRNA expression level of surfactant proteins [SP-A1, B, C,D], IL-12, IL-23, IL-17-[A,F] and IFN-γ was elevated in the Ax-treated mice compared to that in the non-treated group. The quantity of IFN-γ on protein level was significantly higher in the Ax-treated group of mice. Based on the *in vitro* results, the antimicrobial activity of Ax affects the early phase of the infection and it increases the apoptosis of the cells. Furthermore, the SP-A1 showed significant anti-chlamydial effect in *in vitro* conditions.

**Conclusions:** According to our results, the higher dose of Ax-treatment had beneficial effect during Cpn infection by increasing the bacterial clearance from the mice. The antimicrobial effect of Ax treatment is complex and might be due to the increased expression of inflammatory cytokines and surfactant proteins and the apoptosis of infected cells.

Abstract 7466

**Very good results for the use of the RAST methodology and for identification of agents of sepsis directly from the blood cultures by MALDI-TOF to optimise antibiotic therapy**

Jesus Mamani Pariona1, Flavio Oliveira2, Patricia Scotoni3, Tania Zaccariotto1, Nilton Lincopan4, Carlos Levy*2

1Universidad Nacional Mayor de San Marcos, Cercado de Lima, Peru, 2State University of Campinas, Faculty of Medical Sciences, Campinas, Brazil, 3Hospital de Clinicas State University of Campinas, Faculty of Medical Sciences, Campinas, Brazil, 4State University of Sao Paulo, Instituto de Ciencias Biomédicas II, Sao Paulo, Brazil

**Background:** Rapid blood cultures identification and antibiotic susceptibility profile are of the main microbiological informations for appropriate management of sepsis.

**Materials/methods:** We evaluated the performance of the Rapid Antimicrobial Susceptibility Testing (RAST) proposed by the European Committee on Antimicrobial Susceptibility Testing (EUCAST), for blood cultures with the direct identification of the agents by MALDI-TOF (Bruker®) with the Bruker’s methodology, in an University and Reference Hospital in Brazil. We followed all the procedures of version 1.1 RAST EUCAST May 2019. We compared the results with the PHOENIX BD® antimicrobial susceptibility test and we also included the comparison of the screening for carbapenemase with the Blue–Carba test and final confirmation by BDMAX® resistance panel.

**Results:** From July first to 25 November 2019, 176 blood samples were included and the antibiogram completed and compared. For *E.coli* (n=35), *K. pneumoniae* (n=50), *S. aureus* (n=38), *S. pneumoniae* (n=9), *P. aeruginosa* (n=13) and *A. baumannii* (n=15) the performance of ≥90% of correct results was achieved since the 6hs reading. Only for *E. faecalis* (n=12) and *E. faecium* (n=4) the results were around of 70% of correct results on 4, 6 and 8hs reading. The VME was acceptable for *E. coli* and *K. pneumoniae* for 6 and 8hs, *S. aureus* and *S. pneumoniae* for 4, 6 and 8hs, *P. aeruginosa* for 8hs. *E. faecalis* no VME, but ME 5% for 4hs and *E. faecium* no VME but 5% ME in all the readings. For *A. baumannii* we get no so good results: VME of 5.7% at 4, 6 and 8hs. The screening of carbapenemase when compared with Blue-Carba for 6 and 8hs was respectively: sensibility 90/100%, specificity 95/90%, VPP 86/77% and VPN 97/100%. The Blue carba results were confirmed by BDMax®. The polymicrobial blood cultures occurred in 5%, and the MALDI-TOF detected only the predominant bacteria, and the Gram stain did not helped to detect the mixture.

**Conclusions:** The RAST methodology is easy, fast, with good accuracy and very useful for the antibiotic therapy choice for bacteremia and septic patients. The inclusion of MALDI-TOF and a rapid carbapenemase test like Blue-Carba can improve these critical informations.

Abstract 7470

**Malaria outbreak response in a nomadic pastoralist setting, Kenya 2019**

Robert Rono*1

1Marigat Sub County Hospital, Baringo County, Kabarnet, Kenya

**Background:** On 22nd August 2019, Baringo County health department, Kenya notified of a suspected malaria outbreak. As at 26th August 2019, a total of 301 cases had been line-listed with six deaths (CFR=2.0%), all under the age of five years. We carried out response activities to investigate the suspected outbreak with the specific objectives to confirm, determine the magnitude and describe the epidemiology of the suspected cases. We also proposed and initiated appropriate public health actions.

**Materials/methods:** The outbreak epicenter was in Tirioko ward, Baringo county. A suspect case was defined as a case presenting with fever (axillary temperature ≥ 37.5°C), chills, malaise, headache or vomiting at examination or 1–2 days prior. A laboratory confirmed case was a suspect case with detection of *Plasmodium* species by either rapid diagnostic antigen or detection of malaria parasites by microscopy. Collected data was cleaned and analyzed using Microsoft Excel software’s and Epi info 7.2 software (CDC Atlanta, GA). Descriptive statistics was performed using means and medians for continuous variables and frequency and proportions for categorical variables.

**Results:** A total of 1242 cases were line listed with 8 deaths (CFR=0.6%). Females were 697 (56.1%) with those <5 years old being 424 (34.1%). Of the sixty three (63) laboratory samples collected, RDT positives were 40 (63.4%) and Microscopy positive were 28 (44.4%). Additional arboviral screen testing yielded 2/13 (15.3%) positives for Dengue fever. All were negative for Chikungunya, Riftvalley fever, Yellow fever, West Nile fever and Crimean Congo hemorrhagic fever. We observed that the epicenter was poorly served by health facilities, social amenities and experienced security incidents occasion by cattle rustling. Short rains had been experienced a month prior and pools of water were evident in the environment. Additionally, the communities did not always use mosquito nets due to their temporary housing structures.

**Conclusions:** We recommended the establishment and operationalization of a health facilities in the region. Additionally, strengthen Integrated Disease Surveillance and response activities to proactively mitigate future outbreaks. There is also a need to customize malaria social behaviour change communication to fit the community’s nomadic lifestyle

Abstract 7471

**Evaluation of fungi isolates from cystic fibrosis adult patients in a tertiary hospital of Madrid, Spain**

Arturo Manuel Fraile Torres*1, Leticia Fontan1, Sara Gómez De Frutos1, Tamara Soler Maniega1, Teresa Alarcon Cavero1, Rosa M. Girón2, Laura Cardeniioso1, Buenaventura Buendía1

1Microbiology Department, University Hospital of La Princesa, Madrid, Spain, 2Neumology Department, University Hospital of La Princesa, Madrid, Spain

**Background:** There is a great variability in the clinical manifestations of the respiratory fungal diseases in patients with cystic fibrosis (CF). The role of fungi isolations from these patients, is sometimes uncertain, specially, in the context of the emerging fungi and the new methods of identification. We aimed to assess the epidemiological data, of fungi isolations, in adult CF patients.

**Materials/methods:** Data of fungal isolates from sputum samples of adult patients with CF from the University Hospital of La Princesa, were collected retrospectively. Six year (November 2013 to November 2019) of fungal cultures, and epidemiological data were analyzed.

Sabourdau dextrose agar with chloramphenicol was used as growth medium. Fungal identification, was performed by at least one of the following techniques: lactophenol blue stain [optical microscopy], MALDI-TOF MS [Bruker], and chromogenic medium. Patient data, were collected from their medical records.

**Results:** 2773 sputum samples of 130 patients [medium age 28 years, 51.1% males] were analyzed. 1240 [44.7%] of these samples, from 92 [70.8%] patient [medium age 28 years, 50.3% males] were positive for fungi culture, of wich, 353 [28.5%] where positive for two or more fungi.

The global fungi identification data were:

- **Candida** sp. [44.1%], from wich, main species: *C. parapsilopsis* [44.2%], *C. albicans* [27.7%], *C. lusitaniae* [19.9%].
- **Aspergillus** sp. [29.9%]; main species: *A. fumigatus* complex [78.6%], *A. flavus* complex [13.1%], *A. terreus* complex [5.7%].
- **Scedosporium apiospermum complex** [14.6%], *Lomentospora prolificans* [6.4%], *Exophiala dermatitidis* [3.1%] and other species (*Fusarium* sp., *Paecilomyces* sp., *Penicillium* sp., *Aureobasidium pullulans*, and *Trichoderma* sp.) [1.9%].

Annual data evolution are summarized in the following graphic:

Regression line for **S. apiospermum** \( r=0.93 \)

**Conclusions:** *Candida* sp., *Aspergillus* sp., and *S. apiospermum complex*, were the most prevalent fungi, being consistent data with the literature. The data evolution by year, seems to indicate an ascendant trend for *S. apiospermum complex*. Further studies are needed to track epidemiological evolutions and to deepen the role played by these fungical isolates in the patient’s clinic.

Clinical spectrum of infections by new members of the Staphylococcus aureus complex
Alicia Xin Yu Ang*, Ka Lip Chew

1National University Health System, Singapore, Singapore

Background: Staphylococcus argenteus and Staphylococcus schweitzeri are new members of the Staphylococcus aureus complex that were first described in 2015. Differentiation of these species from Staphylococcus aureus in routine diagnostic microbiology reports is not recommended by the ESCMID Study Group for Staphylococci and Staphylococcal Diseases. One of the reasons is to minimise misinterpretation of these new species as non-pathogenic. Given limited clinical reports of this new species, this study was performed to review the clinical features of patients from whom clinical isolates of Staphylococcus argenteus or Staphylococcus schweitzeri were detected.

Materials/methods: Laboratory records between 1 April to 31 July 2019 were reviewed to identify potential Staphylococcus argenteus and Staphylococcus schweitzeri based on matrix-assisted laser desorption/ionization (MALDI-TOF) score >2.000 on Bruker Biotyper (BD, Bremen, Germany) following upgrade to the latest software version. Susceptibility testing was routinely performed using Vitek 2 (bioMérieux, Marcy l’Etoile, France) and interpreted according to EUCAST breakpoints. Only clinical samples were included. Screening samples for epidemiology were excluded. Electronic medical records of patients were retrospectively reviewed.

Results: 38 methicillin-susceptible isolates were identified from non-duplicate patients. Majority (27/38, 71.1%) of the samples were associated with skin and soft tissue infections, including post-operative wound infections. Two of these cases were associated with bacteraemia. Other sites include nasal swabs of patients with bacterial sinusitis (2/38, 5.3%), empyema (1/38, 2.6%), urinary tract (2/38, 5.3%), nasal swab (1/38, 2.6%), and female genital tract (1/38, 2.6%). High susceptibility rates were seen to most tested antimicrobials, including trimethoprim-sulphamethoxazole (38/38, 100%), erythromycin (34/38, 89.5%), clindamycin (34/38, 89.5%), quinupristin-dalfopristin (38/38, 100%), minocycline (37/38, 97.4%), gentamicin (35/38, 92.1%), ciprofloxacin (37/38, 97.4%).

Conclusions: The spectrum of clinical disease of other members of the Staphylococcus aureus complex is similar to Staphylococcus aureus. Although higher mortality for Staphylococcus argenteus bacteraemia has been reported, additional studies are required to confirm this. Further studies may aid our understanding of these new species and whether a different treatment approach is required. All clinical isolates were methicillin-susceptible and remained susceptible to the majority of tested antibiotics.

Mediastinitis: an incidence study and case series in an elderly adult centre

Jesica Alonso Torres*,1, Florencia Mesplet1, Natalia Anahi Diaz1, Liucó Zubeldía Brenner1, Glenda Vinicoff1, Maria Fernanda Aguirre1, María Cristina Escurra1, Mariquena Ruiz1, Sandra Arriola1, Maria Alejandra Viteri1, Liliana Cusmano1, Claudia Valdiviezo1, Enrique Schimank1, Ana Laura Terusi1

1Hospital César Milstein, CABA, Argentina

Background: Mediastinitis is a rare complication of cardiovascular surgery. Most studies report an incidence between 0.34 and 8% and a high mortality, ranging from 12 to 47%. Numerous risk factors has been described in the literature such as diabetes mellitus (DM), obesity, duration of the surgical procedure and extracorporeal circulation (ECC), prophylaxis used, packed red blood cell transfusions, hyperglycemia in the short term postoperative period.

Materials/methods: The medical records of all patients undergoing myocardial revascularization surgery (MRS) and/or valve replacement surgery (VRS) were retrospectively analyzed. Demographic information, comorbidities and information related to surgery were collected from December 2017 to September 2019 at César Milstein Hospital in Buenos Aires Argentina.

Results: We included 287 patients undergoing cardiovascular surgery. Fifty three percent of them were males with a mean age of 74.6 (SD 7.3). Thirteen cases of mediastinitis were diagnosed (4.53% CI 2.5 to 7.4). Within this group, six cases were in the context of MRS, two were due to VRS, and three were due to MRS + VRS. Sixty-days mortality was 23.77% (95% CI 6.23 to 50.8) in patients with mediastinitis. Surgical duration was between 90 and 300 minutes, 7 patients required ECC. Only 3 patients required packed red blood cell transfusions.

Ten of 13 patients developed hyperglycemia within 48 hours after surgery (range: 195-455 mg/dL). In patients receiving inadequate surgical antibiotic prophylaxis, mortality was 37% (n=8), while in the group receiving adequate prophylaxis it was 20% (n=5) p 0.98. None required reoperation for bleeding. Sternal dehiscence was found in 5 patients. The most common isolated agent was Staphylococcus coagulase negative (SCN) (39.13%), followed by gram negative bacilli (BGN). Initial antibiotic treatment was inadequate in two cases only, although both had a favorable outcome. The most common comorbidities were DM, obesity and smoking. Three patients developed other concomitant infections.

Conclusions: The incidence and mortality of post-surgical mediastinitis in our study was similar to other reported in other studies. One of the weaknesses of our study is that the incidence reported is inaccurate due to the small sample size.

Gemelli IRCCS, Dipartimento di Scienze di laboratorio e infettivologiche, Rome, Italy

Background: Clinical identification of patients with bloodstream infection (BSI) is challenging. Efficient predictive scores to quickly identify patients at increased risk of BSI are highly desirable. The aim of this study was to use a machine learning algorithm-based approach for identifying the best predictors of BSI and, then, to validate a clinical algorithm based on these predictors in hospitalized patients suspected of having a BSI.

Materials/methods: The study included all the patients from infectious diseases consultancies at 1100-bed University Hospital in Rome (Italy) between 2016 and 2018, for whom blood cultures (BCs) were collected upon the suspect of a BSI. We used data from patients with positive BCs for significant pathogens (i.e. excluding clear contaminants) and from patients with negative BCs concerning the demographic and clinical features that have been described in the published literature as risk factors for BSI. Data were extracted automatically from multiple hospital database sources which are connected through GENERATOR (Gemelli big-data Network for Retrospective Analysis and Test in Oncology and medical Research) infrastructure. Then, the dataset was split into training and validation data (Figure 1). A logistic regression (LOG) algorithm was used to compute the model and the final performance was assessed on the validation data by measuring accuracy, specificity and negative predictive value (NPV).

Results: 6619 consultancies, of which 1231 (19%) were BSI cases and 5388 (81%) non-BSI controls, resulted in 4691 training data and 1928 validation data. Among 41 explored features, the model identified 14 predictors (dialysis, solid tumor, dyspnea, hypoxemia, central venous catheter, previous BSI, renal failure, urea, white blood cells, platelets, hypotension, tachycardia, fever, urinary catheter) with an accuracy, specificity and NPV of 81%, 97% and 82%, respectively.

Conclusions: Despite preliminary, our model performs extremely well in ruling out the BSI while the BSI prediction can be used as an at-risk warning.

Figure 1: Data analysis workflow for selecting the features and developing and validating the predictive model

Abstract 7480

**Genomic analysis of multi-resistant *Mycobacterium tuberculosis* strains in France: evolution from 2006 to 2018**

Florence Morel1,2, Gérald Millot3, Jérémy Jaffre1,2, Alexandre Aubry1,2, Nicolas Veziris1,2,3, Jérôme Robert1,2, Vincent P. Jarlier1,2, Elisa Tagliani4,5, Wladimir Sougakoff1,2

1Sorbonne Universités, Inserm, Centre d’Immunologie et des Maladies Infectieuses (Cimi-Paris), UMR 1135, Paris, France, 2APHP, Pitié-Salpêtrière Hospital, Laboratoire de Bactériologie-Hygiène, Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux [CNR-MyRMA], Paris, France, 3APHP, Hôpitaux Universitaires de l’Est Parisien, Département de Bactériologie, Paris, France, 4Emerging Bacterial Pathogens Unit WHO Collaborating Centre in Tuberculosis Laboratory Strengthening - Supranational Reference Laboratory for TB, San Raffaele Scientific Institute, Div. of Immunology, Transplantation and Infectious Diseases, Milano, Italy, 5EuSeqMyTB consortium, San Raffaele Scientific Institute, Milano, Italy

**Abstract third-party references:** On behalf of the National Reference Center for Mycobacteria (CNR-MyRMA)

**Background:** Multidrug-resistant *M. tuberculosis* (MDR) strains isolated in France are sent to the National Reference Center for Mycobacteria (CNR-MyRMA) for expertise and epidemiological surveillance. We report the evolution at the phylogenomic level of MDR isolates received at the CNR-MyRMA over a 13 years period. A transborder analysis allowed to detect some potential pathways of diffusion in the EU.

**Materials/methods:** Between 2006 and 2018, 921 MDR strains were genotyped by MIRU-VNTR 24 loci and Sanger sequencing. Illumina whole-genome sequencing (WGS) was performed for 273 strains [172 MDRs]. Data assembly and phylogenomic analysis were performed on GALAXY and BIONUMERICS-7.6.°

**Results:** MIRU typing showed that the main phylogenetic lineages among French MDR strains are Beijing-38%, T-20%, LAM-14%, and Haarlem/X-8%. Beijing fluctuated from 21% in 2006-07 to 48% in 2013-14 (wave of former USSR-patients), then 39% in 2017-18. The dominant lineages vary according to the region of birth, e.g. Beijing in Georgia-Armenia (82%); L4 (30%) in Eastern Europe; Haarlem/X (30%) in the Maghreb. The lineages of patients born in France were diverse: L4-23%, LAM-21%, Beijing-21%, Haarlem/X-18%. The MIRU/WGS analysis revealed 81 episodes of genetically linked cases (“clusters”), including 12 XDR. Almost all were family and/or friends close contact cases, excepted one 9-cases outbreak in a workplace and one XDR intra-hospital transmission. The WGS-resistance SNPs of the 132 MDRs and 18 XDR strains showed a perfect correlation with Sanger sequencing. The WGS allowed the differentiation of clusters amongst strains non-distinguishable by MIRU, especially for Beijing [53/273 strains in clusters]. A comparison of our Beijing genomes with a genome database established by the EuSeqMyTB consortium [24 countries] indicated that two Beijing strains isolated in France in 2017-2018 displayed less than 12 SNPs with a single Beijing strain isolated in another European country in 2008.

**Conclusions:** WGS offers ultra-high resolution in the determination of the resistance profiles and the phylogenomic comparison of MDR strains, and is efficient to trace the origin of clusters which are circulating in France but started to spread more than 10 years ago in countries of the EU. Dissemination of MDR strains out of family or close friend’s circles is exceptional in France.

Monitoring and control of the heater-cooler unit colonisation by Mycobacterium chimaera and other NTMs used during open-heart surgery
Beatrice Casini1, Benedetta Tuvo1, Gaetano Privitera1

1University of Pisa Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy

Background: Recent reports have suggested an association between heater-cooler devices and NTM infections among patients undergoing cardiac surgery potentially through the aerosolization of bacteria from contaminated water used in these devices. The Italian Ministry of Health, in the communication n.000067 4/2019 issued recommendations for the control of M. chimaera infections, requesting the microbiological surveillance of all the HCUs.

Materials/methods: In three cardiac surgery centers, water and aerosol samples were collected to determine the microbiological parameters required by the Directive 98/83/CE and to assess the presence of NTMs according to the protocol proposed by the ECDC (ECDC, 2015). Genotyping was performed by sequencing the hsp65 gene, ITS1-rDNA and 16S-rDNA regions. HCUs were decontaminated according to the manufacturer’s guidance, except for the 3T-Heater-Cooler System, LivaNova, where weekly cycles of treatment with 4,5% peracetic acid and maintenance with 22% hydrogen peroxide were performed; moreover the replacement of internal tubing was also carried out to eliminated the presences of biofilm

Results: We sampled 22 HCUs (n.9 3T-Heater-Cooler System, LivaNova, n.3 1T-Heater-Cooler System, LivaNova, n.1 HX2-Heater-Cooler, Terumo and n.9 Heater-Cooler Unit HCU 40, Maquet) for a total of 114 samples (45, 8, 2 and 59 respectively). All the microbiological parameters were compliant, excepted for total microbial load at 36°C that exceed 100 CFU/ml in 50% (57/114) of samples and for the presence of P. aeruginosa in 10.5% (12/114) of them. NTMs were detected in 15.8% (18/114) of HCUs. M. chimaera was identified in 11.4% (13/114) of samples and in 4% (5/114) M. gordonae. All aerosol samples were negative for NTMs, but in the Heater-Cooler Unit HCU 40, Maquet, B. cereus was detected in 7% (4/59), K. oxytoca in 2% (1/59), B. ursincola in 2% (1/59) and S. paucimobilis in 3% (2/59) of the samples. Only S. paucimobilis was isolated also in the same HCU water sample

Conclusions: The implementation of maintenance and disinfection procedures of HCUs devices was able to reduce the risk of contamination and aerosolization by M. chimaera but not of other microorganisms

Abstract third-party references: Supported by Plan Cancer, on Behalf of PREV'HPV Study Group

**Background:** In France, vaccine coverage against HPV is around 20 % in girls. Prev'HPV is a research project to co-construct and evaluate interventions to increase HPV vaccine acceptability. Health students (HS) will be involved in educational interventions. Our aim was to evaluate the knowledge of HS about HPV infections and HPV vaccine.

**Materials/methods:** An anonymous online questionnaire was sent to HS involved in 3 French Universities. We describe the results with the percentages [with 95 % CI] of answers.

**Results:** Five hundred and ninety six HS (mean age 21.4 ± 4.1 years, 30.2 % Nurses, 51.1 % medical students, 15.9 % future pharmacists, 81 % were in 2nd or third year, 74.3 % were female) answered the questionnaire. The role of persisting HPV infection for cervical cancer was known by 81.2 % (78-84.3%) of the HS. For 70.2 % (66.8-74.1) of the HS, HPV infects both males and females. Only 33.7 % (29.9-37.5) agreed that HPV will infect the half of the population during the life. The association between HPV and anal cancer and HPV and genital warts were respectively known by 30.5 % (26.8-34.2) and 40.1 % (36.1-44.1). HPV was wrongly considered as responsible for urinary tract infections by 23.3 % of HS (19.9-26.7). HPV vaccine protects from cervical cancer, other HPV related cancer and genital warts for respectively 83.2 % (80.2-86.2), 41.2 % (37.2-45.1) and 16 % (15.4-21.7) of HS. Condoms were considered as prevention tools for HPV infection by 65.1 % (61.2-68.9). The proportion of HS considering HPV vaccine is safe was 46.1 % (42.1-50.1). The proportion of HS reporting to be vaccinated was 35.9 % (32-39.7). If the HPV vaccine was recommended for them, 70.5 % (66.8-74.1) of the HS would agree to get vaccinated.

**Conclusions:** The role of HPV infection is well known for cervical cancer. However, the role of HPV in other cancers and genital warts is under-recognized by HS. Our results highlight the need for training on HPV infection and their prevention for HS before their involvement in interventions, particularly, whereas the HPV vaccine for boys would be recommended.

Background: A pilot study [PS] was designed to change on of antibiotic treatment in patients with sepsis-code, results of Antimicrobial-Susceptibility-Testing [AST] performed using Accelerate Pheno [Accelerate-Diagnosis] was reporting to smartphone by means of institutional email and Electronic-Clinical-History [EHC].

Materials/methods: 7 clinical services collaborate in these study [intensive care unit, internal-infectious medicine, emergency, digestive, resuscitation, general surgery, microbiology]. SB septic patients with positive blood cultures [BC+] were included, from May-November 2019. In PS 24 patients were included whereas the other 34 were admitted to non-participating services, constituted as Control-Group [CG]. Data of treatment changes were collected in each phases of results reported of BC+: Gram stain, a Maldi-Tof [Bruker-Daltonics] identification, ID/AST by Accelerate-Pheno [ACC-AST] and AST by Microscan-Walkaway [Beckman-Coulter]. Treatment modifications at each stage were collected and evaluated according to next criteria: Escalation, De-escalation, Equivalent.
**Results:** There were 57 modifications on treatment of 39 (67.2%) patients: 16 Escalations, 36, de-escalation and 5 Equivalent, as shown on Table 1.

| Treatment First modification | 1?                | 3(1DE, 1ES, 1ED)                | 4(3DE, 1ES)    | 6(3DE, 2ES, 1ED)      | 10(6DE, 3ES, 1ED)    | 9(6DE, 3ES)      | 39              |
| Treatment Second modification | 1(1DE)            | 5(3DE, 2ES)                     | 2(1DE, 1ES)    | ?                     | 6(4DE, 3ES)          | 4(1DE, 2ES, 1EQ) | 14              |
| Treatment Third modification  |                   |                                  |                |                       |                       |                  | 4               |

Comparing changes in treatment between both, PS and CG groups, when ACC-AST were reported, no significant differences were found (p=0.25). It is possible due to small sample size.

**Conclusions:** Use of fast Identification/AST devices has an important impact in antibiotic management of patients with severe infections or sepsis and use of mobile device to receive and analyze AST results on real time and in point of care is a good strategy for a rational use of antimicrobials.

Pharmacokinetics of radiolabeled anti-mouse PD-L1 in immune-challenged tumour-bearing mice

Gerhard Wemke Sandker1, Peter Wierstra1, Janneke Molkenboer-Kuenen2, Martin Gotthardt1, Gosse Adema2, Johan Bussink2, Sandra Heskamp1, Erik Aarntzen*1

1Radboud University Medical Center, Department of Radiology and Nuclear Medicine, Nijmegen, Netherlands, 2Radboud University Medical Center, Department of Radiation Oncology, Nijmegen, Netherlands

Background: Clinical studies recently demonstrated that nuclear imaging using radiolabeled anti-programmed-death ligand-1 (PD-L1) antibodies can be used to detect and quantify PD-L1 expression on a whole-body scale in vivo. As cancer patients may suffer from secondary infections, it’s important to know whether this affects the biodistribution and tumour uptake of anti-PD-L1 antibodies. Therefore, we investigated the effects of lipopolysaccharide (LPS), Staphylococcus aureus and Candida albicans-mediated immune activation on the in vivo biodistribution of radiolabeled anti-mPD-L1 in a tumour-bearing mouse model.

Materials/methods: Anti-mouse-PD-L1 antibodies were labelled with the radionuclide Indium-111 (111In-anti-mPD-L1). The effect of different infectious stimuli on anti-PD-L1 in vivo biodistribution was evaluated in healthy and Renca tumour-bearing BALB/c mice in 4 conditions; LPS-challenged, heat-inactivated Candida Albicans-challenged, local Staphylococcus aureus infection-bearing and vehicle control mice. Mice were intravenously injected with 30 or 100 µg 111In-anti-mPD-L1. Pharmacokinetics were assessed by taking blood samples and biodistribution was quantified by microSPECT/CT and ex vivo biodistribution studies 24h post injection. PD-L1 expression in relevant organs was evaluated with immunohistochemistry.

Results: There were no statistically significant differences in in vivo biodistribution of 111In-anti-mPD-L1 between tumour-bearing and non-tumour-bearing mice, except for the tumour. In LPS-challenged mice, however, bone marrow, lung and splenic 111In-anti-mPD-L1 uptake significantly increased compared to vehicle control (spleen: 44.6±5.0 vs. 14.8±3.5 %ID/g; p<0.01), thereby accelerating blood clearance and reducing tumour targeting (blood: 2.1±0.7 vs. 8.9±2.6 %ID/g; p<0.05, tumour: 9.2±4.5 vs. 22.2±5.95 %ID/g; p<0.05). Local Staphylococcus aureus infection significantly increased tracer uptake in affected muscles (8.3±0.2 vs. 1.8±0.65 %ID/g; p<0.01) and decreased tumour uptake (13.6±0.03 vs. 22.2±5.95 %ID/g; p<0.15). Candida albicans-challenge only affected blood clearance. Although spleen, bone marrow and lymph node uptake remained higher in LPS-challenged mice, increasing the 111In-anti-mPD-L1 dose to 100 µg resulted in normalized biodistributions, blood clearance and tumour targeting in all conditions.

Conclusions: Our preliminary data show that systemic and local inflammatory responses can significantly alter anti-PD-L1 antibodies’ pharmacokinetics and tumour targeting. Increasing the anti-PD-L1 antibody dose saturates splenic uptake and restores efficient tumour targeting. This information is essential to better understand alterations in in vivo anti-PD-L1 antibody biodistribution and allows exploration of these host responses in infectious conditions.

Evaluation of the MGIT 960/EpiCenter TB eXiST system for drug susceptibility testing for Mycobacterium abscessus group

Natalia Fernandes Garcia Carvalho¹, Sidney Bombarda², Sylvia Leão³, Robert Arbeit⁴, Erica Chimara*¹

¹Adolfo Lutz Institute - Central, Sao Paulo, Brazil, ²CVE - Centro de Vigilância Epidemiológica "Prof. Alexandre Vranjac", Sao Paulo, Brazil, ³Unifesp-SP, Sao Paulo, Brazil, ⁴Tufts Medical Center, Boston, United States

Abstract third-party references: FAPESP #2014/50094-4

Background: Species of the Mycobacterium abscessus group (MAG) are capable of infecting different types of organs and tissues, being the third most isolated non-tuberculous mycobacteria, and are responsible for 80% of pulmonary infections caused by fast-growing mycobacteria (MCR). Their infections are difficult to resolve due to their intrinsic and acquired resistance to most commonly used antibiotic classes, making this group a major public health concern. Drug susceptibility testing (DST) is the minimum inhibitory concentration indicated for therapeutic follow-up, and the only validated methodology is that recommended by the Clinical & Laboratory Standards Institute. This project aimed to evaluate DST by BACTEC MGIT 960/TB eXiST system for MAG isolates.

Materials/methods: M. abscessus ATCC 19977T was used to develop the protocol, and subsequently DST for four antibiotics was performed against 31 clinical isolates using both REMA method and MGIT system.

Results: Comparison between both methods showed that there were no critical errors. Thus, overall, the MGIT system correctly provided the clinically relevant information, with the sole exception being a minor discrepancy. All isolates tested were susceptible to amikacin with the exception of one resistant isolate. For imipenem, all isolates were resistant, while for cefoxitin only two isolates were susceptible. Regarding clarithromycin, 14 isolates were susceptible while the remaining were resistant.

Conclusions: This study describes a protocol for performing DST of rapidly growing mycobacteria using the MGIT 960/TB eXiST system and that applying the method to a set MAG of clinical isolates demonstrated that the MGIT 960 system was reliable and highly reproducible.

Predictors of asymptomatic *Clostridioides difficile* colonisation on admission: prospective cohort study in a French university hospital

Nagham Khanafer1,2, Sabrina Bennia1, Geraldine Martin-Gaujard1, Laurent Juillard1,2, Thomas Rimmelé1,2, Laurent Argaud1,2, Olivier Martin1, Pierre Cassier1, François Vandenesch1,3, Philippe Vanhems1,2

1Hôpital Édouard Herriot-HCL, Lyon, France; 2Université Lyon 1, Lyon, France; 3Hôpital La Croix-Rousse - HCL, Lyon, France

**Background:** *Clostridium difficile* is the most common cause of hospital-acquired infectious diarrhea and can result in asymptomatic carriage. Rates of asymptomatic colonisation on hospital admission range from 1.4%-21%. The objective of this study was to evaluate factors associated with colonization on admission in a French university hospital.

**Materials/methods:** An ongoing prospective cohort study was conducted in the following wards the hospital: intensive care unit (ICU, 3 units), geriatrics (3 units) and nephrology (one unit). Stool or rectal swabs were obtained for microbiological analysis within 48h of admission in participating wards. Multivariate logistic regression was performed to identify factors associated with colonization by *Clostridium difficile* at inclusion in this study.

**Results:** A total 539 patients were included. The mean of age was 71.6 years (min-max: 18-99) and there were 52.9% male and 47.1% female. Most of included patients (92.8%) suffered from at least one underlying disease. The mean length of hospital stay was 23.7 days (min-max: 2-252). The mean incidence density of testing at admission was 61.3/100 admitted patients. *C. difficile* was isolated at inclusion in 20 asymptomatic (no diarrhea) patients (3.7%; 12 had toxigenic *C. difficile*) while 519 included patients had a negative screening. The factors independently associated with colonization by toxigenic strain at inclusion were described in the table below.

Abstract 7501

Surveillance culture-guided empirical therapy for febrile neutropaenia: low prevalence of inappropriately treated Gram-negative bloodstream infections

Jara De La Court*1,2, Jarom Heijmans3, Jeroen Janssen1, Kim Sigaloff2, Rogier Schade1

1Amsterdam University Medical Center (AUMC), Department of Medical Microbiology and Infection Control, Amsterdam, Netherlands, 2Amsterdam University Medical Center (AUMC), Department of Internal Medicine, Amsterdam, Netherlands, 3Amsterdam University Medical Center (AUMC), Department of Hematology, Amsterdam, Netherlands

Background: Prompt initiation of empirical treatment with broad-spectrum antimicrobial therapy reduces the risk of death for patients with febrile neutropenia. Broad-spectrum antimicrobial therapy is however associated with increased antimicrobial resistance. Therefore tailored antimicrobial therapy is needed to reduce inappropriate antimicrobial therapy without endangering high risk febrile neutropenic patient. Two university hospital hematology centers in Amsterdam, historically employed different empirical regimens: carbapenem monotherapy in one center (center A) and ceftazidim monotherapy, with a pre-emptive escalation option for patients colonized with 3GCR-GNB (further referred to as surveillance-culture-guided empirical therapy) in the other center (center B). This provided a unique opportunity to retrospectively compare these different empirical therapy regimens in the same city.

Materials/methods: Retrospective cohort study conducted in both centers. Diagnostic blood cultures drawn from patients > 18 years at risk for protracted febrile neutropenia (ASCO guideline definitions: < 100 neutrophils/μL for > 7 days) in which surveillance cultures were routinely performed, from the first day of chemotherapy until the recovery of neutrophils (> 500 neutrophils/μL) over a time period of 3 years were included. Blood cultures positive for Gram-negative rods (GNB) and candida species were further assessed.

Results: In both centers, 20% of blood cultures were positive. Prevalence of GNB in all blood cultures was 4.2% in center A and 2.4% in center B. In center A 19/38 (50%) of all GNB BSI were resistant to third generation cephalosporin (3GCR), 74% of these were preceded by a culture with a 3GCR-GNB. In center B, 4/22 (18%) 3GCR-GNB BSI were detected of which 3 (75%) were preceded by a 3GCR-GNB in surveillance cultures. Candida prevalence differed between the two centers where 19 candidemias occurred in center A versus 1 candidemia in center B.

Conclusions: In both centers Gram-negative BSI were rare (2.4-4.2%) and therefore 3GCR-GNB which constitute 18-50% of GNB, were even less prevalent. 75% of all 3GCR-GNB BSI were preceded by surveillance cultures and therefore led to escalation of empirical therapy. A surveillance-culture guided empirical therapy approach could reduce the number needed to treat with carbapenems, without compromising appropriate empirical antibiotic treatment for high risk febrile neutropenic patients.

Abstract 7502

Use ESwab in sexually-transmitted disease diagnosis by STD Direct Flow Chip Kit

Tamara Soler Maniega*1, Nelly Daniela Zurita Cruz1, Arturo Manuel Fraile Torres1, Sara Gómez De Frutos1, Alicia García1, Laura Cardeñoso1

1Hospital Universitario de la Princesa, Madrid, Spain

**Background:** The aim of this study was to evaluate the use of soaked swabs (Copan ESwabs (Biomerieux)) for Sexual Transmission Disease (STD) diagnosis using STD Direct Flow Chip-Kit (Master-Diagnóstica).

**Materials/methods:** For STD Direct Flow Chip-Kit, dry swabs (DS) and soaked swabs (SS) can be used. However, only for SS is recommended an additional washing step prior to sample processing.

This study compared 200 samples: 100 DS and 100 SS parallel collected from 39 cervix and 61 urethral exudates coming from 98 patients with STD symptoms, between May-August/2019 at Hospital U. la Princesa.

Diagnosis was made using STD Direct-Flow-Chip-Kit, a molecular diagnosis test based on Multiplex PCR and automatic reverse dot blot on a Microarray Chip under DNA FLOW Technology (hybryspot). DS samples, according to manufacturer guidelines, were suspended in 1mL saline solution, vortex homogenated and concentrated by centrifugation (3’, 12,000rpm). 5µL of suspended pellet was processed. Processing SS was performed as DS removing the above mentioned washing step.

**Results:** STD Positive results: 60/100 (60%) SS and 56/100 (56%) DS. Results were analyzed considering DS as gold standard. No positive result was detected for H.ducreyi, T.pallidum, T.vaginalis and LGV.

A discrepant result in SS for C.trachomatis was confirmed in urine sample with STD Direct Flow Chip-Kit.

None discordant result Ureaplasma/M.hominis had a count >10^4 CFU/mL (Mycoplasma-IST2, Biomerieux) and 8 samples presented count >10^4 CFU/mL, all detected by DS and SS.

**Conclusions:** Please copy and paste the corresponding text here Copan ESwab would be appropriate for STD Direct Flow Chip-Kit diagnosis use, improving laboratory process, optimizing sample processing and contamination possibility. Possible major detection of STD pathogens should be considered. More studies should be performed.

Common and distinctive genomic features of clinical and environmental third-generation cephalosporin-resistant Klebsiella pneumoniae

Jaqueline Rocha*, Catarina Ferreira, Dalila Mil-Homens, Margarida Brito, Catarina Lameiras, Arsénio Fialho, Isabel Henriques, Margarita Gomila, Célia M. Manaia

1Universidade Católica Portuguesa, CBOF - Centro de Biotecnologia e Química Fina – Laboratório Associado, Escola Superior de Biotecnologia, Porto, Portugal, 2iBB-Institute of Bioengineering and Biosciences, Instituto Superior Técnico, Lisbon, Portugal, 3Serviço de Virologia IPOP-FG, Porto, Portugal, 4Serviço de Microbiologia IPOP-FG, Porto, Portugal, 5Department of Life Sciences, Faculty of Science and Technology, University of Coimbra, Coimbra, Portugal, 6CESAM, University of Aveiro, Aveiro, Portugal, 7Microbiologia, Departament de Biologia, Universitat de les Illes Balears, Palma de Mallorca, Spain

Background: Third generation cephalosporin-resistant Klebsiella pneumoniae are clinically relevant pathogens also widespread in the environment. The hypothesis of this study is that the genomes and phenotypes of clinical and environmental isolates evidence some specialization to both types of habitat. To test this hypothesis clinical and environmental cefotaxime-resistant K. pneumoniae isolates were compared based on their genetic and phenotypic traits and capacity to infect the model organism Galleria mellonella.

Materials/methods: A collection of 59 isolates (25 environmental and 34 clinical) of cefotaxime-resistant K. pneumoniae were characterized based on antibiotic resistance phenotype, plasmids content, and conjugative capacity. A subset of these isolates was also tested for infection capacity in Galleria mellonella (23 environmental and 24 clinical). The whole genome sequences of a subset of clinical (n=11) and environmental (n=7) K. pneumoniae isolates together with others available in public databases (66 environmental and 67 clinical) were compared.

Results: Most environmental (80%, 20/25) and clinical isolates (94%, 32/34) were multidrug resistant. Most clinical isolates (76%, 26/34) were able to horizontally transfer part of their antibiotic resistance genes, compared with the environmental isolates (40%, 10/25). The presence of ≥2 plasmids was observed in clinical isolates (59%, 20/34) and in environmental isolates (72%, 18/25). G. mellonella health index was lower after infection with clinical isolates (10/24 scored ≤3) than with environmental isolates (5/23 scored ≤3). A screening of the whole genome sequences searching genes involved in antibiotic and metal resistance, virulence, efflux systems, oxidative stress and quorum sensing, resulted in 1,383 gene variants, 438 of which were common to clinical and environmental isolates. Both types of isolates differed in a large set of genes, with 460 found exclusively in environmental isolates and 485 in clinical isolates. The comparison of the whole genome-deduced amino acid sequences revealed a common putative proteome in environmental and clinical isolates (n=2715). Exclusive amino acid sequences were more frequent in clinical (n=577) than in environmental (n=205) isolates.

Conclusions: These results may reflect the adaptation of K. pneumoniae to environmental or clinical niches, although suggest that putative clinically relevant traits may persist in K. pneumoniae when thriving in the environment.

**Abstract 7506**

**Antimicrobial susceptibility of Neisseria gonorrhoeae in southern Spain and co-infection with other sexually-transmitted pathogens**

Laura Rojas¹, Cristina Gómez-Camarasa¹, Adolfo De Salazar*, Francisco Ferrer¹, Esther Serrano-Conde¹

¹Hospital Universitario San Cecilio, Granada, Spain

**Background:** Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) are the common prevalent sexually transmitted bacteria. Mycoplasma genitalium (MG) is an emerging agent of sexually transmitted infection (STI). Increasing rates of NG antimicrobial resistance is becoming a public health problem. The aim of this study is to present the most recent data on antimicrobial susceptibility of NG in Southern Spain and to describe coinfection with other STI pathogens.

**Materials/methods:** From May 2018 to November 2019, 1589 cervical and 1193 urethral exudates samples received at the Clinical Microbiology Unit of San Cecilio University Hospital (Granada, Spain) for STI diagnosis were analyzed by the FDA approved Aptima Assays (Hologic, San Diego, USA) or the RT-PCR Allplex™ STI Essential Assay (Seegene, Seoul, Korea) to CT, NG, MG and Trichomonas vaginalis (TV). Culture for NG was made in Martin Lewis broth in CO2 conditions. Susceptibility to cefotaxime, azithromycin, ciprofloxacin, tetracycline and penicillin was determined by E-test using EUCAST 2018 and 2019 breakpoints.

**Results:** NG was isolated from 157 patients (5.6%), 89% men; average age 27 years [IQR, 22-34], 136 from urethral exudates and 21 from endo-cervix. 132 cases were NG PCR/positive culture and 25 cases were NG PCR positive/negative culture. In those with positive culture, susceptibility was 64.3% to ciprofloxacin, 96.5% to cefotaxime, and 27% to penicillin and tetracycline.

From may to december 2018, azithromycin susceptibility was 78%, determined using EUCAST breakpoints 2018 (MIC values S<=0.25 mg/L; R>0.5mg/L). From 1st January 2019 following EUCAST recomendations, as the ECOFF is 1 mg/L, no resistance was found to azithromycin.

Coinfection with CT was detected in 26.1% (41/157) of patients and with MG in 4.5% (7/157); no co-detection with TV was found. Three male were CT, NG and MG co-infected.

**Conclusions:** In southern Spain, NG is highly susceptible to cefotaxime. As in another countries, susceptibility to penicillin is low. Given the low susceptibility to tetracycline and ciprofloxacin, their use should be avoided, due to the high risk of therapeutic failure. Molecular methods and monitoring of NG antimicrobial susceptibility are needed.

Abstract 7507

**Fungal prosthetic vascular graft infections: beware of aorto-enteric fistulas!**

Mathilde Puges*1, Xavier Bérard1, Thomas Caulier1, Laurent Stecken4, Olivier Leroy1, Eric Senneville1, Isabelle Accoceberry6, Frédéric Gabriel6, Olivier Robineau3, Charles Cazanave1

1Bordeaux University Hospital, Infectious Diseases Department, Bordeaux, France, 2Bordeaux University Hospital, Vascular Surgery Department, Bordeaux, France, 3Lille-Tourcoing University Hospital, Infectious Diseases Department, Tourcoing, France, 4Bordeaux University Hospital, Anesthesiology Department, Bordeaux, France, 5Lille-Tourcoing University Hospital, Medical Intensive Care Unit, Tourcoing, France, 6Bordeaux University Hospital, Mycology Laboratory, Bordeaux, France

**Background:** Prosthetic vascular graft infections (PVGIs) are often polymicrobial, especially when complicated by aorto-enteric fistulas (AEFs). Fungal PVGIs are rarely described in literature but quite frequent in our practice.

**Materials/methods:** We reviewed retrospectively all cases of fungal PVGIs in our retrospective cohorts (Bordeaux and Lille-Tourcoing University Hospitals) of vascular infections between January 1st, 2006 and October 31, 2019.

**Results:** Of 384 patients, 41 had a fungal infection. One patient with an abdominal aortic aneurysm complicated by AEF was excluded. Of the 40 patients (10.4%) with a fungal PVGI, 92% were men, median age was 64 years, all had an aortic PVGI and the great majority were late infections (87.5%). Mortality rate was high (55%), especially before the 28th day (25%), as early and late relapse rates, 22.5% and 20%, respectively. Only two patients were intravenous drug users, one had parenteral nutrition, six were immunosuppressed, two were splenectomised, three suffered from malnutrition including one with cirrhosis, and the last one had lung cancer. Most patients had an AEF (80%), mainly duodenal (26 patients), but also jejunal (5), and caecal (1). Two grafts were close to digestive structures (jejunum, pancreatic abscess). Bacterial coinfection was diagnosed in 90% of the cases, including 28 polymicrobial infections. Only 24 graft samples were sent to both mycology and bacteriology laboratories, fungal direct examination was positive in 13 cases. In six cases, *Candida* were exclusively isolated on mycological media (Sabouraud or/and Candida Chromogenic agar). Six patients had two and one patient had four different species of *Candida*. *Candida albicans* was clearly predominant (28 isolated strains), followed by *Candida glabrata* (8), *Candida tropicalis* (6), *Candida kefyr* (4), *Candida krusei* (2), one *Candida inconspicua*, and one "non-Candida albicans yeast". Most of patients underwent surgery (95%), only 47.5% received an empiric antifungal therapy peroperatively, mainly caspofungin. Six patients had no antifungal therapy at all, one had an early and a late relapse, one had a late relapse and two others died very early after surgery.

**Conclusions:** In PVGIs, coinfections with *Candida* sp. are frequently associated with AEF, and an empiric antifungal treatment should be introduced peroperatively in these particular cases.

Abstract 7509

Local and national diagnostic and typing capacity for *Clostridioides difficile* infection, Europe, 2018

Samantha Rada1, Elisabeth Kanitz*1, Daniela Schmid1, Ed J. Kuijper2, Carl Suetens3, Pete Kinross3

1The Austrian Agency for Health and Food Safety, Vienna, Austria, 2Leiden University Medical Center, Leiden, Netherlands, 3European Centre for Disease Prevention and Control, Stockholm, Sweden

Background: Suboptimal diagnostic testing for *Clostridioides difficile* infection (CDI) affects patient management, surveillance and prevention. In 2011 and 2014, ECDC ECDIS-Net surveys in 33 European countries recorded optimal diagnostic practices in 19% and 46% of the participating laboratories, respectively. In 2014, 16/32 (50.0%) countries had capillary-based (CE) PCR ribotyping capacity.

In 2017, ECDIS-Net-2 organised a ‘train-the-trainer’ workshop for European national reference laboratories promoting use of 2016 ESCMID diagnostic guidance and algorithms. This survey sought to describe European CDI diagnostic and typing capacity in 2018.

Materials/methods: In December 2018, ECDIS-Net-2 sent a web-based questionnaire on national CDI diagnostic practices, to national-level experts, designated by ECDC’s National Focal Points for Healthcare-Associated Infections, in all 34 European countries. These experts forwarded another web-based questionnaire on local CDI diagnostic practices to local laboratories in their country. In countries with >20 responding laboratories, we randomly selected 20 responses.

Results: By March 2019, 31/34 (91.2%) countries and 364 local laboratories had responded.

15/31 (48.4%) countries reported changes in national CDI diagnostic guidelines since 2014. 22/31 (71.0%) countries had diagnostic algorithm(s) in national guidelines, adopting ESCMID algorithms fully (11/22) or partially (7/22).

22/31 (71.0%) countries with national guidelines and two countries with guidelines in progress had stool selection criteria. 15/20 (75.0%) countries tested on a physician’s request, including 11/15 (73.3%) only testing diarrhoeal samples and 4/15 (26.7%) testing all stool samples. In 5/20 (25.0%) countries, local laboratories defined test criteria.

197/364 (54.1%) local laboratories in 24/29 (82.8%) countries had adopted ESCMID algorithms. In the nine countries that fully adopted ESCMID algorithms and had local laboratory responses, 93/132 (70.5%) laboratories had adopted ESCMID algorithms, while 15/132 (11.4%) had adapted them.

13/31 (41.9%) countries indicated a need for additional training in routine laboratory CDI testing.

25/31 (80.6%) countries had routine *C. difficile* typing capacity, including 21 (84%) with CE PCR ribotyping and eight (32.0%) with next-generation sequencing.

Conclusions: Europe has further improved its capacity to diagnose CDI, measure prevalence and identify subtypes, thus permitting better targeting of local and national public health actions. Countries should consider promoting and providing training on ESCMID-aligned diagnostic and typing practices.

Abstract 7511

Impact of the anti-coagulant therapy before hospitalisation on cerebrovascular complications and mortality in infectious endocarditis

Javier Tomás Solera Rallo*, Francisco Galván Román¹, Laura Domínguez Pérez¹, Santiago De Cossio Tejido¹, Francisco Lopez-Medrano¹

¹University Hospital 12 de Octubre, Madrid, Spain

Background: Infective endocarditis (IE) is still a highly mortal disease. The high rate of cerebrovascular complications (CVC) is one of the main reasons for this. The evidence does not support the initiation of anticoagulant therapy in IE, but many patients have an indication for it before. Intracranial hemorrhage and, therefore, mortality rate, may be increased in these patients. The aim of this study is to compare the risk of death and CVCs in patients with IE under anticoagulant therapy.

Materials/methods: Retrospective study conducted in one referral center, selecting all adult patients that had a definite IE according to modified Duke criteria from January 2013 to December 2018.

Results: One hundred thirty-two patients were recruited, 58 of them were under anticoagulant therapy before the hospitalization. Most of them (81%) were in treatment with acenocoumarol.

CVCs occurred in 55 patients (41.7%) during the active phase of IE, with the same rate in those with and without anticoagulant therapy (p=0.86). There was a non-statistical association between the previous anticoagulant therapy and the increase in the major bleeding events (p=0.23), with a bigger rate of intracerebral hemorrhage (8 vs 12%) and subarachnoid hemorrhage (7 vs 16%).

The mortality rate was 31%. There was a statistical association between the presence of previous anticoagulant therapy and the increase in the mortality rate: 20 vs 45% (p=0.004). We did not find association between the presence of CVCs and death. The group of patients that met surgery criteria but could not be operated had the highest mortality (49%, p<0.001), sixty-five percent of those had previous anticoagulant therapy. When using propensity score matching adjustment we cannot demonstrate the independent association between previous anticoagulant therapy and mortality rate: Odds ratio (OR) 1.95 (CI95%: 0.77, 4.91).

Conclusions: In our study, the presence of previous anticoagulation therapy selects a group of patients with a much higher mortality rate (45% vs 20%). This group presents a non-statistical higher rate of major bleeding events. Most of them could not be operated despite meeting surgery criteria, which is the variable that is most related to a higher mortality rate.

Chikungunya virus: neuromotor evaluation of infants born to infected mothers
Renata Freire¹, Clara Gaspari*¹², Liana Albuquerque¹

¹Instituto Estadual do Cérebro Paulo Niemeyer, Rio de Janeiro, Brazil, ²Instituto Estadual do Cérebro Paulo Niemeyer, Rio de Janeiro, Brazil

Background: Chikungunya virus (CHIKV) is an arbovirus transmitted by the Aedes mosquitoes. The disease in humans is characterized by a disabling skeletal muscle inflammatory syndrome with fever, polyarthralgia, myalgia, rash and/or headache. Due to the recent awareness of the Zika Virus epidemic, studies have also found CHIKV poses a risk to newborns if the mother has acute viremia close to or during labor due to vertical transmission.

The Epidemiological Bulletin of Health reports that in the first half of 2019 60,987 probable cases of CHIKV were reported in Rio de Janeiro, corresponding to an incidence of 355.40 cases per 100,000 inhabitants.

In July 2019, the Health Department issued a technical note reporting the risk of CHIKV vertical transmission and included information regarding the clinical management of the newborn. Symptomatic or asymptomatic newborns to mothers with positive CHIKV test near delivery date were scheduled for an interdisciplinary evaluation at our institution.

The purpose of our report is to describe the neuromotor development of children born to mothers infected with the CHIKV during the end of their gestation.

Materials/methods: This is a prospective cohort study evaluating the neuromotor development of CHIKV-exposed children during pregnancy from July to November 2019.

Results: Fifteen infants were evaluated. Eleven were female (73%), the average age at the evaluation was 3 months. Fourteen infants (93%) were born at full-term and one was considered small for gestational age.

One child (7%) was hospitalized due to seizure following birth.

All mothers reported symptoms of CHIKV in the 3rd trimester of pregnancy. The average age of mothers was 26 years, only 4 (27%) had vaginal delivery. More than half of the mothers (60%) still complained of CHIKV symptoms at the time of the evaluation.

None of the infants presented neuromotor developmental delays or changes in reflexes or postural reactions. Muscle tone was normal in 14 infants (93%) and one was hypotonic requiring physical therapy follow-up.

Conclusions: The evaluations did not show alterations in the neuromotor development of these infants. Longitudinal follow-up is necessary to continue observing the development and delays which may become more evident at a later age.

Abstract 7514

Comparative effectiveness of combined favipiravir and oseltamivir therapy versus oseltamivir monotherapy in critically-ill patients with influenza virus infection

Yeming Wang*1

1Department of Pulmonary and Critical Care Medicine, Center of Respiratory Medicine, National Clinical Research Center for Respiratory Diseases, China-Japan Friendship Hospital, Beijing, China, Beijing, China

Abstract third-party references: National Key Research and Development Program of China [2018YFC1200102]

Background: A synergistic effect of combination therapy with favipiravir and oseltamivir has been reported in pre-clinical models of influenza. However, no data are available on the clinical effectiveness of combination therapy in severe influenza.

Materials/methods: Data from two separate prospective studies of influenza adults were used to compare outcomes between combination and oseltamivir monotherapy. Outcomes includes rate of clinical improvement, defined as a decrease of 2 categories on a 7-category ordinal scale, and viral RNA detectability over time. Sub-hazard ratio (sHR) was estimated by Fine and Gray model for competing risks.

Results: In total, 40 patients were treated with combination therapy and 128 with oseltamivir alone. Clinical improvement on Day 14 occurred in the combination group was higher than in monotherapy group (62.5% vs 42.2%, p=0.0247). The adjusted sHR for combination therapy was 2.06 (95%CI: 1.3-3.26). The proportion of undetectable viral RNA at day 10 was higher in the combination group than oseltamivir group (67.5% vs 21.9%, p<0.01). No significant differences were observed in mortality or other outcomes.

Conclusions: Favipiravir and oseltamivir combination therapy may accelerate clinical recovery compared to oseltamivir monotherapy in severe influenza, and this strategy should be formally evaluated in a randomized controlled trial.

Abstract 7521

**Prospective nested case-control study on colistin-resistant Enterobacterales in the Netherlands**

Karuna Vendrik*1,2, Angela De Haan1, Daan Notermans1,3, Paul Bijkerk1, Annelot Schoffelen1, Sabine C. De Greeff1, Cornelia C.H. Wielders1, Marcel Mennen1, Antoni P.A. Hendrickx1, Ed J. Kuijper1,2, Leo Schouls1

1National Institute for Public Health and Environment, Bilthoven, Netherlands, 2Leiden University Medical Center (LUMC), Leiden, Netherlands, 3Academic Medical Centre, Amsterdam, Netherlands

Abstract third-party references: On behalf of the CCRE survey study group in the Netherlands.

**Background:** There is a rapid emergence of multidrug-resistant Gram-negative bacteria worldwide. Importantly, polymyxins, such as colistin, are last-resort treatment options. Aim of this study was to obtain insight into the prevalence and epidemiology of colistin-resistance in the Netherlands.

**Materials/methods:** As part of a pan-European ECDC multicenter study, a 6-month surveillance project was performed with a prospective nested case-control design on occurrence, geographic distribution, population dynamics and risk factors of colistin-resistant Enterobacterales. Twenty-two Dutch participating laboratories with 36 associated hospitals were requested to send colistin-resistant *Escherichia coli* or *Klebsiella pneumoniae* (ColRE) from a maximum of five patients with a colistin MIC>2 mg/L (confirmed via broth microdilution) and/or a mcr-gene (1-8); and no carbapenem-resistance. For each ColRE isolate, a colistin-susceptible isolate (ColSE) was sent, matched on species, location of collection (hospital/community) and material of origin. Microbiological and epidemiological data were added.

**Results:** In total, 74 ColRE and 67 ColSE isolates from 16 laboratories were collected. Of the ColRE, 72% were *E. coli* and 28% *K. pneumoniae*. The majority was derived from urine samples (70%). Of all ColRE isolates, 60% were collected in a hospital, 32% at a general practice and 8% in other healthcare facilities. Only four ColRE isolates contained a mcr-1 gene (5%). When comparing ColRE-ColSE pairs (*n*=67), the median age was 70 years old in both groups and the proportion of females was similar (ColRE: 75%; ColSE: 70%). Of the ColRE isolates, 68% was reported as infection, similar to 64% in the ColSE group. Of patients with ColRE isolates, 30% had used colistin and 82% other antibiotics in the previous 6 months, which was more than the 7% colistin and 50% other antibiotics observed in the ColSE group (*p*=0.026 and 0.013, respectively). Twenty-three percent of ColRE and 7% of ColSE isolates were from patients that resided in long-term care facilities (*p*=0.044).

**Conclusions:** Seventy-four ColRE isolates were sent by 16 of 22 participating laboratories. The majority of ColRE isolates were *E. coli* and did not contain known mcr-genes. Patients with ColRE had used more colistin and other AB and/or resided more frequently in long-term care facilities compared with patients with ColSE.

**Evaluation of the efficacy of rezafungin in the treatment of Candida albicans endophthalmitis using a rabbit model**

Lisa Long1, Janet Herrada1, Daniel Caley1, Gustavo Munguba1, Rania Sherif1, Ken Bartiza1, Mahmoud A. Ghannoum*1,3

1Case Western Reserve University, University Hospitals Cleveland Medical, Cleveland, United States, 2Cidara Therapeutics Inc., San Diego, United States, 3NTS Ventures, Cleveland, United States

**Abstract third-party references:** Cidara Therapeutics Inc.

**Background:** Candida endophthalmitis is a devastating disease. Echinocandins are first-line therapy for candidemia and invasive candidiasis, however, due to poor penetration of currently approved echinocandins into the eye, once Candida eye involvement is demonstrated, current guidelines recommend a switch to azole therapy. The aim of this study was to evaluate the efficacy of rezafungin, a novel echinocandin with unique PK properties, in the treatment of endophthalmitis in a rabbit candidiasis model.

**Materials/methods:** New Zealand White rabbits with indwelling catheters were inoculated intravenously with $5 \times 10^6$ colony-forming units (CFU) of *Candida albicans* SC5314 and divided into groups: rezafungin 10mg/kg (n=6), micafungin 6.2mg/kg (n=5), voriconazole 10mg/kg (n=4) and vehicle control (n=5). Treatments were administered IV at 0 and 80h post-inoculation. Day 8, the rabbits were anesthetized and indirect ophthalmoscopy performed. Tissues were collected for assessment of fungal burden. Eye scores were given based on the number and size of lesions and total ocular damage caused by infection. The severity of each lesion was scored on a 1-4 scale: 1+, lesion barely visible; 2+, lesion small but easily visible; 3+, lesion large but less than one disk diameter in size; and 4+, lesion larger than one disk diameter.

**Results:** In the kidneys, the voriconazole and vehicle groups had the highest CFU counts, while the rezafungin group showed the lowest [Fig. 1A]. The rezafungin- and micafungin–treated groups showed significantly lower bioburden when compared to the voriconazole and vehicle groups ($P<0.001$). In the retina, humor body, and vitreous humor, the greatest bioburden was observed in vehicle control-treated animals as expected. Animals treated with rezafungin demonstrated no detectable CFU. The rezafungin–treated group compared with the micafungin, voriconazole and vehicle groups showed significantly fewer CFU in the retina ($P<0.05$), humor body ($P<0.001$), and vitreous humor ($P<0.05$). Eye Score—The rezafungin-treated group demonstrated no eye lesions [Fig.1B], while the micafungin, voriconazole and vehicle [Fig.1C] groups showed average eye scores of 1.9, 2.5, and 3.2, respectively.

**Conclusions:** Our findings show that rezafungin is effective in the treatment of endophthalmitis caused by *C. albicans*.

**Figure 1.** Average log CFU/g ± SD fungal burden in tissue (A). Evaluation of lesions in the rezafungin-treated group (B) and those treated with micafungin, voriconazole, or vehicle (C).

Abstract third-party references: CytoVale, Inc.

Background: Globally, Choosing Wisely® campaigns warn against the overtreatment of asymptomatic bacteriuria. Regardless, clinicians often prescribe antibiotics to patients with evidence of bacteriuria or localized inflammation on urinalysis independent of localizing symptoms. This study examines leukocyte deformability, a measure of host immune activation, for predicting outcomes of patients presenting to the Emergency Department (ED) due to a genitourinary process.

Materials/methods: We enrolled 120 adult patients presenting to the ED with signs or suspicion of genitourinary infection. Demographic, clinical, and outcome data were abstracted from the medical record. EDTA-anticoagulated blood was analyzed using deformability cytometry [1]. Treating clinicians did not have access to assay results. Patients were stratified into three categories of immune activation: low, intermediate, and high. Chi-square and Mann Whitney U tests were used.

Results: Of the 120 patients, 40 (33.3%) were classified as low, 47 (39.2%) as intermediate, and 33 (27.5%) as high states of immune activation. Patients in the high immune activation group were older than patients in lower immune activation groups. There were no significant differences in positive urine cultures, hematuria, or pyuria across the three groups. Patients in the high immune activation group had significantly higher admission rates, lengths of stay, positive blood cultures, severity of illness scores (APACHE, SOFA and PIRO), as well as hospital mortality (Figure 1). Patients in the high immune activation group (87.9%) were more likely to receive antibiotics. However, 55% of patients in the low immune activation group and 66% of patients in the intermediate immune activation group also received antibiotics.

Conclusions: Leukocyte deformability can risk stratify patients with genitourinary processes by important clinical outcomes, independent of pathogen detection and urinalysis. Examining host immune activation could result in reduced antibiotic exposure and improved hospital resource utilization.

Figure 1. Outcome data for the Low, Intermediate, and High Immune Activation (IA) Groups. Note: *p<0.05, **p<0.01, ***p<0.001

Abstract 7532

Rectal isolates display high-negative predictive value for bloodstream infections with (ESBL+) Gram-negative bacteria in neonates with suspected sepsis in a low-resource setting neonatal care unit

Annick Lenglet*1,2; Jorien Schuurmans1; Kessiance Charles1; Emily Borgundvaag1; Colette Badjo3; Kate Clezy1; Michiel Lekkerkerker1; Cono Ariti4; Melissa Mcrae1; Heiman Wertheim2; Joost Hopman1;2

1Médecins Sans Frontières, Amsterdam, Netherlands, 2Radboud UMC, Medical Microbiology Department, Nijmegen, Netherlands, 3Médecins Sans Frontières, Port au Prince, Haiti, 4Cardiff University School of Medicine, Centre for Trials Research, Cardiff, United Kingdom

Background: There is scarce evidence around the potential value of understanding bacterial colonization in neonates in guiding empiric treatment for neonatal sepsis. We aimed to analyze the concordance of rectal swab isolates and blood culture isolates with gram negative bacteria (GNB) in neonates with suspicion of neonatal sepsis in Port au Prince, Haiti.

Materials/methods: Due to repeated outbreaks of sepsis in a neonatal care unit in an obstetric emergency hospital between 2014 and 2018, we enhanced microbiological and epidemiological surveillance for all neonates with suspected sepsis after admission. We analyzed data from rectal and blood samples that were taken simultaneously, on the date of onset of suspected sepsis and before the administration of antibiotics. Samples were cultured and tested for antibiotic susceptibility. We calculated the concordance for GNB genus and species of rectal and blood pair isolates. We also calculated the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for GNB and Extended Spectrum Beta-Lactamase (ESBL) producing (ESBL+) GNB for all rectal and blood pair isolates.

Results: We included 238 rectal-blood pairs with 238 and 309 microbiological results from blood and rectal samples respectively; 171 pairs (72%) had a single isolate or no isolate identified in either sample. Klebsiella sp. isolates were the most commonly isolated bacteria from all samples (160/313 isolates). Concordance between blood and rectal isolates was 21% (95%CI:16-26) and 22% (95%CI: 17-28) for species and genus respectively. For GNB and ESBL+GNB isolates we estimated: sensitivity (84%, CI95%:70-93 and 71%, CI95%:59-85), specificity (16%, CI95%:11-22 and 61%, CI95%:54-68), PPV (19%, CI95%:13-25 and 23%, CI95%:16-33) and NPV (82%, CI95%:66-92 and 93%, CI95%:87-96).

Conclusions: Our analysis shows that rectal swab cultures can have added value in choosing and adjusting antibiotic therapy due to the high NPV for mainly ESBL+ GNB. Therefore, the use of rectal swab microbiological surveillance in neonates can improve prudent antibiotic use and stewardship neonatal care units in low resource settings. We recommend that these findings are validated in other contexts in neonatal care settings.

Abstract 7538

Susceptibility profile of Pseudomonas species in a tertiary care hospital over a 9-year period and impact of antimicrobial stewardship

Sanaa Saliba1,2, Omar Zmerli1,2, Amanda Chamieh1,3, Ziad Daoud1,2, Eid Azar1,2, Claude Afifi1,2

1Saint George Hospital University Medical Center, Division of Infectious Diseases, Beirut, Lebanon, 2University of Balamand, Faculty of Medicine and Medical Sciences, Beirut, Lebanon, 3Aix-Marseille University, Marseille, France

Background: Novel therapeutic options can be helpful, but many older molecules are still effective depending on the susceptibility profile. Resistance pattern of Pseudomonas spp. (Ps) is very variable making aggregate data analysis complicated.

Materials/methods: We retrieved from the antimicrobial stewardship (ASP) database at Saint George Hospital (SGH), a 333-bed tertiary care center in Lebanon from January 2010 till December 2018:

- the susceptibility profiles of all recovered Ps isolates
- the antibiotic consumption expressed in daily defined dose [DDD]/1000 PD.

Isolation density is the number of isolates/1000 patient days [PD]. All identified isolates were then categorized according to the Centers for Disease Control and Prevention definitions: multidrug-resistant (MDR), extensively drug-resistant (XDR) and pandrug-resistant (PDR). We compared the rates of resistance on antimicrobial consumption for period 1 (2010-2014) vs. period 2 (2015-2018).

Results: The isolation density of Ps significantly decreased from an average of 5.57/1000PD for the years 2010-2014 of whom 0.19 were PDR to 3.34/1000PD for the years 2015-2018 of whom 0.07 were PDR (p-value= 0.006, CI 95% [0.872, 3.583]). The rest were roughly equally divided between MDR and XDR. The yearly detailed resistance profile is illustrated in figure 1. Carbapenems consumption significantly dropped in period 1 from 176 to 126 DDD/1000PD in period 2 (p-value=0.031, CI 95% [0.026, 0.035]). 51% of the isolates carbapenems were resistant in period 1 vs 47% in period 2. Piperacillin/tazobactam consumption was stable 30 vs 31.4 DDD/1000PD in period 1 and 2 with 32% of the isolates TZP resistant in period 1 vs 21% in period 2. Cefepime consumption dropped from 31.4 to 21.2 DDD/1000PD with 24% cefepime resistant in period 1 vs 16% in period 2.

Conclusions: There have been many reports describing an alarming rise in pseudomonas resistance. In our institution, there has been a significant drop in pseudomonal burden of disease with relatively very few isolates with limited therapeutic options and even more interesting a significant improvement in the overall resistance pattern over the last 4 years maybe due to an improvement in antimicrobial consumption.

Abstract 7542

Posaconazole therapeutic drug monitoring in high-risk haematology patients receiving antifungal prophylaxis (SAPHIR-study)

Christophe Padoin*1, Jean-Pierre Gangneux2, Mauricette Michallet2, Emeline Saillio4, Alexandra Kumichel5, Peffault De La Tour Regis6, Patrice Ceballos7, Thomas Gastinne8, Arnaud Pigneux9

1CHU de Martinique, Fort de France, Martinique, 2CHU de Rennes, Université de Rennes, Rennes, France, 3Clinical Haematology Department, Haematological department, Centre Léon Bérard, Lyon, France, 4MSD France, MSD France, Courbevoie, FR, Courbevoie, France, 5ClinSearch, ClinSearch, Malakoff, France, 6Haematology - Bone Marrow Transplant Department, Saint-Louis Hospital, APHP, Paris, France, 7Clinical Haematology Department, CHRU Lapeyronie, Montpellier, France, 8Clinical Haematology Department, CHU Nantes, Nantes, France, 9Blood Diseases Department, Hospital group Haut Leveque, Pessac, France

Background: The SAPHIR study described the diagnostic and therapeutic management of haematology patients at high risk of Invasive Fungal Disease (IFD) under antifungal prophylaxis (AFP) in France. We evaluated therapeutic drug monitoring (TDM) adopted in French haematology services during this study.

Materials/methods: SAPHIR was an observational, prospective, multicentre, non-comparative study. The included patients were ≥18 years, in a context of myelosuppressive chemotherapy for acute myeloid leukaemia and initiated an AFP treatment.

Results: 404 patients were included (mean age: 56.4±14.0 years). The intensive chemotherapy started 1.06±4.49 days before inclusion and was either induction 79.0%, consolidation 12.6% or treatment of relapse 8.4%. 91.6% patients had experienced a profound and durable neutropenia period with 1.08±0.51 periods during 23.3±16.6 days. For 373 patients (92.3%), the primary AFP prescribed was posaconazole using either tablets (366 patients, 98.1%), or suspension (7 patients, 1.9%). The mean AFP period was 24.2±32.1 days. Twelve of 23 participating services performed TDM during the patients’ AFP period. Therapeutic target was defined as plasma trough levels (PTL)>0.7 mg/L for prophylaxis. A total of 278 posaconazole PTLs were measured in 139 patients (1 to 10 PTLs per patient). Median posaconazole PTL achieved during AFP was 0.94 mg/L (IQR: 0.6-1.5). PTLs were not different in patients with concomitant mucositis or diarrhoea. 29% of the patients whose PTLs were measured after AFP initiation (median=6 days) had concentrations <0.7 mg/L. After AFP period, 267 patients (66.8%) stopped AF treatment because they were at the end of the high-risk period and 126 (31.2%) switched to a non-prophylactic AF treatment (2/3 empirical, 1/3 pre-emptive/curative), mainly because of fever (67.1%). Among these 126 patients, posaconazole PTLs were measured in 57 patients before AFP stopping (median=3 days), 16 patients (28%) presented a PTL<0.7 mg/L.

Conclusions: This real-life study of AFP in France shows that half of services use posaconazole TDM. Almost 30% of patients undergoing TDM have concentration below the target. The prevalence of patients with posaconazole concentration <0.7 mg/L reported in our study with posaconazole tablets is higher than early observational studies. Parameters associated with this lower probability have to be explored.

Evaluating the extraction and molecular detection of *Candida auris* strains using commercial kits

Julie Green*1

1Bruker Microbiology and Diagnostics, Glasgow, United Kingdom

**Background:** *Candida auris* is a multidrug resistant, emerging agent of invasive fungal infection in the intensive care setting, and has been responsible for recent outbreaks in healthcare institutions. Real-time PCR methods for the detection of *C. auris* could provide quick results for both colonisation and infection, help to control spread in the clinical setting and, with accurate identification, could lead to more appropriate patient management.

**Materials/methods:** A diverse sampling of *Candida auris* strains collected worldwide were grown from glycerol stocks in 5 mL of Sabouraud broth and streaked on Sabouraud agar. Strains were grown for 24 hours at 37°C. Following incubation, serial dilutions of 1/10, 1/100 and 1/1000 of each *C. auris* strain were prepared and extracted using three different extraction methods; (i) Qiagen's manual DNeasy PowerLyzer Microbial Kit, (ii) Hain Lifescience's manual FluoroLyse Kit, and (iii) Qiagen's automated EZ1 extraction platform with a DSP Virus Kit. PCR was carried out using Bruker’s Fungiplex Candida Auris RUO Real-Time PCR Kit.

**Results:** No target was detected after extraction using the Qiagen DNeasy PowerLyzer Microbial extraction kit and in all of these samples the internal control failed, highlighting inhibition within the PCR reaction.

*Candida auris* was detected in all samples extracted using both the Hain Lifescience FluoroLyse Kit and the Qiagen DSP Virus Kit for the EZ1. As expected, Ct values increased with increasing dilution factor. When comparing the results from each of the successful extraction methods, Ct values were higher in gDNA samples extracted using the EZ1 system with differences ranging from 2 to 5 Cts higher than the manual extraction values, suggesting that the manual system is more efficient at extracting gDNA compared to the automated platform.

**Conclusions:** This study has shown that the extraction method used in the molecular detection of *Candida auris* is critical. It is clear from comparison of Ct values between a manual and an automated system that the Hain Lifescience manual extraction FluoroLyse kit is more efficient in extracting gDNA compared to the EZ1 system. When extraction was successful, a sensitivity of 100 % was achieved with the Fungiplex Candida Auris Kit.

Abstract 7551

Emergence of “high risk clone” Klebsiella pneumoniae ST307 producing KPC-3 and NDM-1 in Argentina

Daniela Céjas1,2, Micaela Magalí Ferrara1, Francisco Magariños3, Claudia Alfonso1, Alan Elena1,2, Gabriel Gutkind*1,2, Marcela Radice1,2

1Universidad de Buenos Aires, Buenos Aires, Argentina, 2CONICET, Buenos Aires, Argentina, 3Hospital Santojanni, Buenos Aires, Argentina

Background: KPC carbapenemase production constitutes the main resistance mechanism in K. pneumoniae. KPC-K. pneumoniae global expansion has been associated with the clonal dissemination of ST258, however the emergence of new lineages was observed in Argentina. Less frequently KPC has been reported in other Enterobacterales. Also, an increased detection of NDM metallo-enzymes is been observed in our region. Objective: to characterize carbapenem resistant Enterobacterales isolates recovered from inpatients at a hospital in Buenos Aires city, during Nov 2018 - March 2019.

Materials/methods: Antimicrobial susceptibility to clinically relevant antibiotics was assessed by automated system (Phoenix, BD). Coding genes for VIM, IMP, SPM, NDM, KPC, OXA-48 were screened according to Poirel et al, 2011. Further identification of carbapenemase coding genes was performed by complete gene amplification, using plasmid DNA as template, and sequencing. KPC-K. pneumoniae typing was conducted by XbaI-PFGE and MLST. Plasmids were characterized by conjugation assays using E. coli J53 as receptor strain and replicon typing according to Carattoli et al, 2005. Genetic contexts of carbapenemase coding genes were studied by PCR mapping and sequencing.

Results: Eight carbapenem resistant isolates were included (7 K. pneumoniae and 1 Providencia stuartii). They were resistant to ciprofloxacin, levofloxacin and gentamicin and 5/8 were resistant to amikacin. Minimal inhibitory concentration for colistin was >4µg/ml. Six out of 8 isolates harbored carbapenemase coding genes. Among carbapenemase producing K. pneumoniae isolates 2 pulsetypes were observed, belonging to ST258 (n:1) and ST307 (n:4). Three out of 4 K. pneumoniae-ST307 harbored blaKPC-3 and blaNDM-1 and the remaining harbored blaKPC-3. K. pneumoniae-ST258 was positive for both blaKPC-2 y blaNDM-1. In P. stuartii only blaNDM-1 was detected. All blaNDM-1 plasmids were transferred by conjugation and corresponded to IncA/C group. ISKpn14 was detected upstream blaNDM-1 and bleMBL and trpF were detected downstream. Genetic context for both blaKPC-2 and blaKPC-3 corresponded to Tn4401.

Conclusions: The presence of the "high risk clone" K. pneumoniae-ST307 producing both KPC-3 and NDM-1 constitutes a worrisome scenario, as this clone combines hypervirulent and resistance features making it difficult to eradicate. The presence of blaNDM-1 plasmid in different species and lineages indicates the epidemic feature of this mobile element.

Abstract 7553

Preclinical evaluation of liposomes carrying bioactive lipids as an immune therapeutic tool against in vitro and in vivo infection with Mycobacterium abscessus

Camilla Riva1, Noemi Poerio2, Marco Rossi1, Federica De Santis2, Enrico Tortoli1, Maurizio Fraziano2, Daniela M. Cirillo1

1San Raffaele Scientific Institute, Milano, Italy, 2University of Rome "Tor Vergata", Rome, Italy

Background: MA abscessus (MA) in an emerging pathogen that affect individuals with lung pathologies such as chronic obstructive pulmonary disease (COPD), bronchiectasis and, especially, cystic fibrosis (CF). Apoptotic-body like liposomes (ABLs) carrying bioactive lipids have been demonstrated to significantly enhance bactericidal response in macrophages from CF patients and in bronchoalveolar lavage (BAL) cells from non-CF patients with pneumonia caused by different bacterial pathogens, irrespective of bacterial species and multidrug resistance. Our murine model of MA respiratory chronic infection was useful to assess the therapeutic effect of different ABLs against this pathogen. Furthermore the MA infection in vitro allowed us to study the mechanism of action of ABLs on macrophages phagocytosis mechanism.

Materials/methods: We established a chronic pulmonary infection in immunocompetent C57Bl/6N mice up to 36 days with MA ATCC 19977 and at different time point mice were treated with 3 different ABLs [PA, PI3P and PI5P]. Mice lungs were processed for microbiological and inflammatory analysis to establish the therapeutic effect of ABLs. We set up in vitro MA infection on human macrophages to investigate the effect of ABLs on phagocytes mechanism. We set up infection.

Results: In vitro results showed that ABL/PA, PI3P and PI5P were able to statistically increase the phagocytic and the intracellular microbicidal activity of human macrophages infected with MA. The in vivo experiments revealed that after 30 days of treatment all the 3 ABLs induced a statistical reduction of bacterial count in the total lung when compared to the control mice. The results also revealed that these 3 immunomodulatory compounds induced a statistical reduction of the recruitment of total leukocytes, in particular of neutrophils and macrophages, into the bronchoalveolar lung spaces compared to the control mice. Despite the absence of effect in granuloma reduction at parenchymal level, analyzed by histological lung sections, ABLs were also able to statistically decrease the IFNy production during the course of treatment.

Conclusions: ABLs treatment statistically reduced both lung’s bacterial burden and inflammatory response during chronic MA infection. ABLs, combined with an antibiotic therapy, could represent a novel immunotherapeutic strategy to treat pulmonary infection induced by drug-resistant MA.

Monitoring of interactions with clarithromycin: evaluation of routinely performed drug interaction checks
Alexandra Weber*1, Jette Jung2, Rika Draenert3

1University Hospital, LMU Munich, Munich, Germany, 2LMU, Max v. Pettenkofer-Institut für Hygiene und medizinische Mikrobiologie, Munich, Germany

Background: Clarithromycin is a potent inhibitor of cytochrome P450 (CYP) 3A4, which is involved in the metabolism of commonly used drugs. Therefore, clarithromycin may increase the steady state concentrations of drugs that depend primarily on CYP3A4 metabolism.

Materials/methods: Every order of clarithromycin tablets or infusion in the pharmacy department of the Munich university hospital triggers a check for interactions of clarithromycin with the co-prescribed medication. Information on the medication are obtained by contacting the ward over the phone or - if available – retrieved from the electronic medication record. Whenever a relevant drug interaction was identified, a pharmacist contacted the prescriber to discuss the interaction and its management (e.g. discontinuation of a drug, monitoring of serum levels or side effects). Each check was documented in the drug information database and a written information was provided to the prescriber if requested. The clinically relevant interactions were classified according to Lexicomp® Drug Interactions Database into three categories (X = contraindicated; D = avoid combination; C = monitor therapy).

Results: From August 2014 to July 2017, 1160 checks were performed, 829 (71.5%) contained at least one interaction with clarithromycin. Each patient took on average 9.2 drugs (1 – 31) and had 1.4 interactions with clarithromycin. 330 (28.4%) drug regimens contained at least one X-rated drug. Of the 1891 identified interactions 397 (21.0%) were rated as X, 960 (50.8%) as D and 395 (20.9%) as C. 139 interactions (7.3%) were not rated as the drug was not included in the database but were regarded as relevant. The most commonly prescribed X-rated interactants were simvastatin (150, 12.9%), apixaban (44), and (es-) citalopram (40). Other highly relevant interactants included azole antifungals (87), tacrolimus (47), phenprocoumon (28), and colchicine (4). A preliminary evaluation of the effect of the counselling showed an inconsistent implementation of the recommendations.

Conclusions: Though the risk for relevant drug interactions is established, it is not always accounted for when prescribing clarithromycin. There is a need for active interaction testing in clinical practice. Measures need to be taken to raise awareness of the importance of the problem and ensure appropriate implementation of recommendations made.

Abstract 7555

**Improved prediction of mortality in sepsis using peripheral capillary oxygen saturation to estimate the respiratory dysfunction score: a cohort study**

John Karlsson Valik*1,2, Logan Ward3, Aron Henriksson4, Hercules Dalianis4, Kristoffer Stralin1,5, Pontus Naucler1,2

1Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden, 2Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden, 3Treat Systems, Aalborg, Denmark, 4Stockholm University, DSV, Department of Computer and Systems Sciences, Stockholm, Sweden, 5Karolinska Institute, Department of Medicine Huddinge, Stockholm, Sweden

**Background:** The Sepsis-3 criteria are based on sequential organ failure assessment (SOFA) score, which was developed for intensive care units (ICU). Yet, more than half of sepsis patients are admitted to other hospital wards where possibilities to assess full SOFA-score is limited. The respiratory component of SOFA is based on PaO2/FiO2 ratio, which requires arterial blood gas analysis. Peripheral capillary oxygen saturation (SpO2) is a more accessible measure, but this has not been validated in the Sepsis-3 criteria. Current methods to translate SpO2 to PaO2 results in cut-offs at SpO2 96 or 95% without oxygen treatment to get 1 SOFA point. The aim was to assess the association between SpO2 and in-hospital mortality in a population with suspected infection outside ICU.

**Materials/methods:** Subjects were identified in electronic health records from Karolinska University Hospital between July 2012 and December 2013. All adult patients admitted for >24-hours with a suspected infection, defined as any culture taken and administration of at least 2 doses antimicrobials, were included. Time during ICU was censored. Patients were followed until discharge or death. Logistic regression was used to assess the association between worst SpO2 and in-hospital mortality, adjusted for age, gender, comorbidity and other SOFA-score components.

**Results:** In total, 19396 admissions in 14871 patients were included, and 17805 had at least one SpO2 measurement coinciding with the time of suspected infection. The in-hospital mortality was 5.4%. Compared to SpO2 100-97% (reference), SpO2 96 or 95% were not significantly associated with increased mortality. At SpO2 94%, the odds ratio for mortality was 1.62 [95% CI 1.13-2.31] and increased gradually below this level (Figure). The findings were robust to sensitivity analyses and preliminary results shows adding information on oxygen delivery (SpO2/FiO2-ratio) didn’t improve predictability.

**Conclusions:** Current cut-offs for respiratory dysfunction in Sepsis-3 using SpO2 does not seem to be associated with increased mortality in the non-ICU setting. Our results support a gradually increased mortality starting from SpO2 94% and less, which could have implications for SOFA-scoring to define sepsis in the non-ICU setting. These findings are planned to be validated in a prospective cohort with suspected sepsis in Sweden.

Abstract 7556

**Bridging the gap between human and animal antimicrobial resistance and consumption surveillance data, antibiotic policy and stewardship: the EPI-Net and ARCH projects**

Maria Diletta Pezzani*1, Fabiana Arieti1, Elena Carrara1, Roberto Cauda2, Monica Compri1, Siri Goepel3, Fulvia Mazzaferrri1, Elena Mazzolini4, Marc Mendelson5, Nico T. Mutters6, Nithya Babu Rajendran7, Remco Schrijver8, Marcella Sibani1, Andreas Voss9, Evelina Tacconelli1

1University of Verona, Verona, Italy, 2Catholic University of the Sacred Heart, Milan, Italy, 3Tübingen University Hospital, Tübingen, Germany, 4Istituto Zooprofilattico Sperimentale delle Venezie - Sezione di Udine, Basaldella, Italy, 5Groote Schuur Hospital, Cape Town, South Africa, 6University Hospital Freiburg, Freiburg, Germany, 7Eberhard Karls University of Tübingen, Tübingen, Germany, 8VetEffecT Veterinary & Public Health, Bilthoven, Netherlands, 9Radboud University Medical Center, Nijmegen, Netherlands

**Abstract third-party references:** This work has received support from the Innovative Medicines Initiative 1 Joint Undertaking (JU) under grant agreement No 115737; the JU receives support from the European Union’s FP7 research and innovation programme and EFPIA. The project has also received fundings from the Joint Programme Initiative on Antimicrobial Resistance (JPIAMR) under the 2018 call

**Background:** Guidance on how surveillance data on antimicrobial resistance (AMR) and consumption (AMU) should be provided to stewardship teams to drive empiric therapy, policy recommendations and whether a One-Health approach could be practically implemented is unclear.

**Materials/methods:** The COMBACTE-Magnet EPI-Net and JPIAMR projects joined their networks to connect multisector specialists in human and animal settings aiming to bridge the gap between human and animal surveillance data, antibiotic policy and stewardship (ARCH) by studying surveillance of AMU, AMR and frontline AS providers. We carried out a scoping review of the literature (January 2009-June 2019) to draw up a list of actions addressing 3 topics: AS team, AMU and AMR surveillance data throughout both animal and human settings (i.e. hospital, outpatients, long term care facilities-LTCF, and veterinary clinics). Evidence were provided to experts from 34 international networks from high and low medium income countries in a two round RAND-modified Delphi. The panel evaluated the sets of actions based on criteria of relevance, feasibility, and adaptability. Agreement was expressed on a 9-point Likert scale. Then, a 2-day face-to-face consensus meeting was held to discuss results, finalise the recommendations and expand the list of research priorities.

**Results:** A total of 189 papers were reviewed. 32 statements were developed for the hospital, 18 for the outpatient, 19 for the LTCF, and 65 for the animal settings. Recommendations were classified as essential [37] or desirable [32] according to clinical relevance, feasibility and applicability to settings and resources. Agreement was reached for 116 statements; 18 concerning modalities of AMR monitoring were qualified for discussion [median score ≥8 but <70% of all scores in the highest tertile]. 19 statements were deleted after first review and recommendations on topics for future research agenda were developed and agreed.

**Conclusions:** The EPI-Net/ARCH set of actions represents a new, practical and flexible tool to guide the development of calibrated AS intervention in human and animal settings based on surveillance systems collecting AMR and AMU data. The advantage of the tool relies in the One-Health approach used in a practical way to synergize and connect adequate decisions on AS in different compartments.

**Presenter email address:** mariadiletta.pezzani@univr.it
Co-existence of blaNDM- and mcr-1-producing Escherichia coli isolated from human, poultry and environment water from Pakistan: a One Health problem

Muhammad Usman Qamar*, Muhammad Rizwan1, Iqra Bashir1, Muhammad Hidayat Rasool1, Sam Kariuki2, Guy Palmer3

1Government College University Faisalabad, Microbiology, Faisalabad, Pakistan, 2Kenya Medical Research Institute (KEMRI) Headquarters, Microbiology, Nairobi, Kenya, 3Washington State University, Microbiology, Pullman, United States

Background: Emergence and spread of New Delhi metallo-β-lactamase (NDM) and mcr-1 producing Escherichia coli is a serious “ONE HEALTH” threat around the globe particularly in developing countries like Pakistan. NDM producing bacteria showed resistance against multiple antibiotics. mcr-1 is a novel plasmid-mediated gene conferring resistance to colistin which is considering a last resort to treat clinical infection caused by carbapenem resistant pathogens. The aim of the study was to determine the prevalence of both blaNDM and mcr-1 producing E. coli in different settings.

Materials/methods: A 100 each poultry cloacal swabs, environmental water and human samples (blood, urine, pus) were collected from Faisalabad metropolitan. Samples were screened for NDM and mcr-1 producing E. coli using colistin and meropenem (4μg/mL) containing MacConkey agar. Further, isolates were confirmed using UTI ChromoSelect agar and API 20E. Antibiogram and phenotypic confirmation of carbapenemase and metallo-β-lactamase was carried out as per CLSI 2018 guidelines. Molecular identification of mcr-1 and NDM gene was performed by PCR.

Results: Of 100 poultry samples; 22 E. coli were positive for mcr-1. Of 100 water samples, 17 E. coli were NDM producers and 4 were positive for mcr-1. Of human samples, 15 E. coli were NDM producer and none for positive for mcr-1. E. coli from poultry displayed 100% resistance to colistin, tetracycline and doxycycline and 31% to cefepime while 83% sensitive to meropenem. E. coli from water samples also displayed 100% resistance to β-lactam, β-lactam inhibitors followed by 88% to meropenem and 73% to ciprofloxacin while 90% to colistin. Moreover, NDM producing E. coli from human samples also displayed 100% resistance against β-lactam and inhibitors and 80% to levofloxacin moxifloxacin and all were sensitive to colistin.

Conclusions: Dissemination of blaNDM and mcr-1 producing E. coli from clinical, poultry and environmental water is a matter of great concern for both livestock and public health. A “One Health” approach is necessary to further explicate the variability of these high-risk genes.

SAVE: Stewardship Antibiotica VErona: a new model of stewardship to reduce antimicrobial overuse in a setting with high levels of antimicrobial resistance rates

Elena Carrara¹, Marcella Sibani*², Lorenzo Barbato³, Fulvia Mazzaferrì³, Nicola Duccio Salerno¹, Fabio Soldani³, Giuliana Lo Cascio³, Pietro Minuz², Oliviero Olivieri³, Vincenzo Di Francescò³, Luisa Bissoli⁷, Chiara Bovo³, Evelina Tacconelli²

¹University of Verona, Department of Diagnostic and Public Health, Infectious Disease Section, Verona, Italy, ²Verona University Hospital, Pharmacy Department, Verona, Italy, ³Verona University Hospital, Infectious Diseases Department, Verona, Italy, ⁴Verona University Hospital, Microbiology Department, Verona, Italy, ⁵University of Verona, Department of Medicine, Section of Internal Medicine C, Verona, Italy, ⁶University of Verona, Department of Medicine, Section of Internal Medicine B, Verona, Italy, ⁷Verona University Hospital, Verona, Italy

**Abstract 7559**

**Background:** According to the ECDC estimates, Italy is the country with the highest burden of disease due to antimicrobial resistance (AMR) in Europe. Aim of this study is to measure efficacy and safety of a new model of antimicrobial stewardship (AS) intervention in reducing inappropriate use of antibiotics in a 1350-beds University hospital with high AMR rates.

**Materials/methods:** The SAVE program is a 12-months, multifaceted, educational AS intervention with a stepped-wedge implementation started in June 2018. The core elements of the intervention are: 1. provision of a full time ID specialist to the intervention ward for 6 weeks; 2. mandatory CME-accredited training for at least 2 physicians per intervention ward; and 3. development of customized guidance on empirical antibiotic therapy followed by periodic audits and feedbacks. Primary outcome of the study is the overall consumption of systemic antibacterials (ATC-J01) per 1000 patient-days (PDs) measured as Days of Therapy (DOTs) and Daily Defined Doses (DDDs) with an interrupted time series (ITS) analysis over a 24-months period. Secondary outcomes are rate of inappropriate therapy (compliance with local guidance documents); single classes’ DOTs and DDDs. As clinical indicators we measured *Clostridium difficile* infections and crude in-hospital mortality.

**Results:** Four medical wards with a total of 150-bed completed the intervention, 8 non-ID physicians were trained in antibiotic prescribing, 1113 prescriptions were revised, and inappropriateness decreased by 13.8%. A significant change in level of overall antibiotic consumption was measured both in terms of DOTs/1000 PDs (-160.5; p<0.05) and DDDs/1000 PDs (-181.4; p<0.05). Comparison between pre- and post-intervention slope showed a reduction in DDDs/1000 PDs per month (-16.2; p<0.05) and in DOTs/1000 PDs per month (-1.5; p 0.08). Level of fluoroquinolones consumption decreased significantly by 24.2 DOTs/1000 PDs (p<0.05) with a significant drop in slope (-4.4 DOTs/1000 PDs per month; p<0.05). Rates of mortality and *C. difficile* infections remained stable throughout the post-intervention period.

**Conclusions:** The SAVE intervention demonstrated to be effective and safe in reducing antimicrobial consumption and increasing appropriateness of prescription in internal medicine units. Although promising, generalizability of the model and cost effectiveness must be further explored in different clinical and cultural settings.

**Gut colonisation with carbapenemase-producing Enterobacterales: predicting factors for prolonged colonisation among adults**

Laurent Dortet¹, Lelia Escaut¹, Gaëlle Cuzon¹, Irina Bukreyeva¹, Nicolas Fortineau¹, Thierry Naas*¹,²

¹Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, ²Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France

**Background:** The spread of CPEs represents a major public health issue. As 10% of CPE carriers will develop a CPE infection it is important to understand the risk factors for colonisation and for prolonged colonisation. The aim of this work was to follow a cohort of colonised patients over one-year period to identify predicting factors for prolonged colonisation.

**Materials/methods:** This is a two years mono-centric prospective observational study. Patients newly colonised starting 2017 were included. Rectal swabs were taken during their hospitalisation, once a week, and at every novel hospitalisation or consultation. The following definitions were used: Non-Excretors (NE) are patients with 3 negative rectal swabs in three consecutive weeks and Excretors (E) are patients with positive CPEs culture from their rectal swabs. Comorbidities, reasons for hospitalisation, antibiotic treatment and length of hospitalisation were recorded.

**Results:** 109 patients colonised CPE (44F/65M) were included in the study. 124 bacteria were isolated: E. coli (60), K. pneumoniae (47), E. cloacae (7), C. freundii (10). The detected carbapenemases corresponded well to the French epidemiology of CPEs: OXA-48-like (95), NDM-like (20), and KPC-like (9). 35 patients were lost during follow up. The number of NE was 21/74 (28%), 27/74 (36%), 36/74 (49%) and 40/74 (54%) at 1, 3, 6 and 12 months, respectively. The NEs were initially colonised with NDM 4/20 (20%), OXA-48like 29/60 (48%), KPC 7/9 (77%). 34 patients remained Es after 12 months (46%). Characteristics of Es and NEs at 12 months are displayed below.

**Conclusions:** In our cohort, 1/3 of the patients spontaneously became NEs after one month, and nearly ½ after 12 months. Statistically significant predicting factor for prolonged colonisation was orthopaedic surgery. Thus, our data suggest that prolonged carriage depends on factors inherent to the patients [length of hospitalisation and underlying pathology] but also on the bacteria. Indeed, it seems that OXA 48-like or NDM producers are linked to a prolonged carriage. Our results need to be confirmed in larger studies.

Abstract 7561

**What are the reasons behind high handrub consumption? A national in-depth qualitative assessment**

Delphine Berthod*1,2, Anne Perozziello1, Dara Alvarez1, Jean-Christophe Lucet1,3

1University of Paris, INSERM IAME, U1137, Team DesCID, Paris, France, 2Infectious Diseases Department, Central Institute of Valais Hospitals, Sion, Switzerland, 3AP-HP, Infection Control Unit, Bichat-Claude Bernard University Hospital, Paris Cedex, France

**Background:** Hand hygiene (HH) is the most important prevention measure of healthcare-associated infections (HAI) and transmission of multidrug-resistant (MDR) bacteria. Significant correlation between alcohol-based handrub consumption (AHRC) and observed HH compliance rates - and between AHRC and MDR bacteria reduction - has been established. In France, publicly-reported AHRC displayed a large heterogeneity across healthcare facilities (HCFs). The present study aimed to assess factors and mechanisms leading to a high AHRC score in a panel of French HCFs and to describe programs in the top and medium scorers.

**Materials/methods:** Qualitative comparative case study based on semi-structured, in-depth interviews of the Infection Prevention and Control Team (IPCT) members (n=67), quality managers/CEOs (n=20) and frontline workers (n=5) of the 16 highest scoring HCFs (4 university hospitals (UH), 4 large non-university hospitals, 3 cancer centers and 5 rehabilitation hospitals), and 7 medium scoring UH, using an iterative thematic approach.

**Results:** 84 interviews were performed. There was a large heterogeneity in IPCTs’ structures and objectives with specific patterns associated with high AHRC. Four meta-themes emerged: strong IPCT internal organization; external organization with integration into the hospital; active support from the institution; and leadership and role models. The following factors were associated with top scorers: a good intrinsic IPCT organization with joint activity of IPC physicians and nurses; a proactive attitude in defining priorities and anticipation; a continuous IPCT presence in clinical wards with adaptation to local context, time or staff constraints; involvement of link nurses; active participation in an IPC hospital network; institutional support and the role of “champions” (with the highest impact in small HCFs). Agreement with the national AHRC indicator was variable among IPCT members, with top scorers using the score as a tool for change and medium scorers frequently doubting its value.

**Conclusions:** This qualitative study highlights that IPCT structure and activity is heterogeneous, with mainly behavioral characteristics associated with high AHRC score. Our work enhances the importance of strong IPCT structure and behavioral approaches in implementing key IPC programs. It offers material to rethink IPCT’s functioning with several strategies for improvement.

Abstract 7562

Study on the diagnostic value of serum amyloid A (SAA) in pathogen classification and clinical stage identification of hand, foot and mouth disease

Wu Yidong1*, Wei Yi2

1Hangzhou Children’s Hospital, Hangzhou, China

Background: To explore the titer distribution characteristics of SAA in the main enteroviral types of hand, foot and mouth disease and its relationship with severe cases, so as to provide a new reference for the diagnostic value of SAA in hand, foot and mouth disease.

Materials/methods: A total of 815 laboratory confirmed cases of HFMD in our hospital during the epidemic period of 2017-2018 were randomly selected as the study objects. SAA level was detected by turbidimetry, and EV71, CA16, CA6, CA10 and other enteroviruses of HFMD were detected by fluorescence quantitative RT-PCR. SAA was statistically analyzed with enterovirus typing, clinical staging and other relevant indicators.

Results: The SAA values of EV71 (n=108), CA16 (n=39), CA6 (n=472), CA10 (n=63) and the unclassified enteroviruses (n=133) were 13.85 (8.2, 37.05) mg/L, 73.10 (25.7, 158.3) mg/L, 156 (122.1, 176.6) mg/L, 148 (131.172.9) mg/L and 146.9 (121.9, 171.5) mg/L respectively. The titer difference of SAA among common enterovirus types was statistically significant (kruskal-wallis value: 204.94, p=0.000). The AUC of SAA for the diagnosis of EV71 HFMD was established as 0.907 (95%CI:0.884-0.926). SAA= 92.1 ml/L was taken as the threshold, with a sensitivity of 93.52% and specificity of 81.05%. The SAA values were 17.00 (5.80, 24.30) mg/L in critical cases (n=11), 18.00 (9.30, 49.90) mg/L in severe cases (n=82), 148.90 (112.20, 174.60) mg/L in mild cases (n=722) respectively, and the difference among them was statistically significant (kruskal-wallis value: 119.882, p=0.000). With the clinical stage of severe and above as the dependent variables and SAA, enterovirus typing, gender and age as the independent variables, the binary Logistic regression analysis showed that EV71 was highly correlated with severe HFMD (p < 0.05), while SAA value was not correlated with severe HFMD (Wald value 0.3275, p=0.5671).

Conclusions: The distribution of SAA value among common enteroviral types of HFMD was statistically different, and the SAA value ≤ 92.1 ml/L was highly sensitive and specific for the differential diagnosis of EV71 HFMD. Multivariate regression analysis showed no relationship between SAA and severe hand, foot and mouth disease.

Host- and pathogen-related factors for acute cardiac events in pneumococcal pneumonia

Alexander Rombauts1,2; Gabriela Abelenda Alonso1,2; Jordi Càmara3,4; Aida González Díaz2,3,4; Enric Sastre-Escolà5; Laia Lorenzo-Esteller6; Carlota Gudiol1,7,8; Carmen Ardanuy Tisaire3,4; Jordi Carratalà1,7,8

1Bellvitge University Hospital, Department of Infectious Disease, L’Hospitalet de Llobregat, Spain, 2Institut d’Investigació Biomèdica de Bellvitge (IDIBELL), L’Hospitalet de Llobregat, Spain, 3Bellvitge University Hospital, Department of Microbiology, L’Hospitalet de Llobregat, Spain, 4CIBERES, Madrid, Spain, 5Bellvitge University Hospital, Department of Internal Medicine, L’Hospitalet de Llobregat, Spain, 6University of Barcelona, Medical Student, Barcelona, Spain, 7REIPI (Spanish Network for Research in Infectious Disease), Instituto de Salud Carlos III, Madrid, Spain, 8Universitat de Barcelona, Barcelona, Spain

Background: Acute cardiac events are increasingly recognized as a major complication in pneumococcal community-acquired pneumonia (CAP). Host- and pathogen-related factors for these serious complications, including sero- and genotypes of pneumococcal strains, have not been identified.

Materials/methods: Observational study of a prospective cohort of hospitalized patients for CAP in a university hospital from January 1996 to December 2016. Pneumococcal strains were serotyped and molecular typed (PFGE and/or MLST). A logistic regression and funnel plot analysis to determine host- and pathogen-related factors for the development of acute cardiac events was performed.

Results: A total of 1553 patients with pneumococcal CAP were included. One or more acute cardiac events occurred in 265 (17.1%) subjects being the most frequent arrhythmia (n=182), heart failure (n=116) and acute coronary syndrome (n=23). The majority of cardiac events (74.4%) occurred within 48 hours of hospitalisation. Older age, pre-existing heart conditions, pneumococcal bacteraemia, septic shock at admission and high-risk pneumonia (PSI>90) were independently associated with the development of acute cardiac events; whereas pre-hospitalization antibiotic treatment for the acute episode of pneumonia tended to have a protective effect. A propensity score matching of the treatment with antiplatelet drugs, oral anticoagulation, statins, ß-blockers, ACE inhibitors or angiotensin II receptor blockers and diuretics showed no protective effect. Out of 916 pneumococcal isolates, 797 (87%) were serotyped and 694 (75.8%) molecular typed. The funnel plot analysis did not show any significant association between any particular serotype or clonal complex and acute cardiac events; although there was a trend towards a higher risk of developing these complications in cases caused by strains harbouring clonal complex CC230. Patients with acute cardiac events had a higher 30-day case fatality rate than those without (14.3% vs. 5%, p<0.01).

Conclusions: Host factors appear to be more important than pathogen-related factors for developing acute cardiac events in pneumococcal pneumonia. The host factors delineated in this study may help identify those patients who should undergo a strict follow-up and monitoring, particularly during the first 48 hours of hospitalization, for early detection and treatment of acute cardiac events. These high-risk patients should be a target for future preventive intervention strategies.

Abstract 7566

Microbiome ecology drives the epidemiology of antibiotic resistance and the efficacy of antibiotic stewardship interventions: a mathematical modelling study

David Smith1,2,3, Laura Temime1, Lulla Opatowski1,2,3

1Institut Pasteur, Paris, France, 2UVSQ - UFR Simone Veil - Santé, Montigny-le-Bretonneux, France, 3Inserm, Paris, France

Background: Commensal bacteria of the host microbiome (‘flora’) can both support and suppress colonization by bacterial pathogens, through cross-feeding, niche competition, horizontal gene transfer (HGT) and other inter-species interactions. At the within-host level, antibiotics disrupt flora and select for the proliferation of antibiotic resistance-encoding genes, while at the between-host level, recent antibiotic therapy is a colonization risk factor for many pathogens. Here we explore how narrow- and broad-spectrum antibiotics affect flora ecology and its mediating influence on pathogen transmission dynamics, including consequences for antibiotic stewardship.

Materials/methods: We developed a mathematical Susceptible-Colonized transmission model including ecological interactions between flora and pathogens. Numerical simulations were conducted to explore transmission dynamics in the hospital setting. The model was parameterized to several high-risk nosocomial multidrug-resistant pathogens, including MRSA, Clostridiodes difficile and ESBL-Enterobacteria. Across these pathogens, relative reductions in bacterial colonization were compared for two antibiotic stewardship interventions: (i) reduced overall prescribing and (ii) restriction of broad-spectrum antibiotics.

Results: Within-host flora-pathogen interactions shape acquisition dynamics of multidrug-resistant nosocomial bacteria (Figure). For a generic pathogen, in the absence of interactions and across all possible combinations of antibiotics, cross-transmission explains much more pathogen acquisition (55.3–65.4%) than either HGT (21.7–30.6%) or endogenous acquisition (12.7–15.5%). Conversely, when within-host interactions with flora are strong, cross-transmission explains less acquisition (29.5–43.6%) than the endogenous route (37.0%–43.1%), with a similar quantity due to HGT (19.1%–27.3%). These findings are consistent with simulations showing dominance of endogenous acquisition over cross-transmission in species with complex within-host interactions, for instance in ESBL-E. coli.

Differences in pathogen acquisition routes are consistent with simulations showing species-specific differences in how colonization responds to antibiotic stewardship interventions. Interestingly, given identical baselines, a 30% reduction in broad-spectrum prescribing resulted in a 20.2% reduction in hospital prevalence in C. difficile, 10.8% in K. pneumoniae and 6.9% in E. coli, but an increase of 7.6% in MRSA.

Conclusions: This work illustrates the importance of within-host ecology in driving the colonization behavior of pathogens and responses to different antibiotic regimens, and how modelling can help to design and inform effective control strategies in the absence of data.

Evaluation of a multiplex real-time PCR for the diagnosis of intestinal protozoa

Ester Oliva1, Annibale Raglio*1,2, Stefania Varani2,3, Nicola Menegotto4, Raffaele Gargiulo1,2, Antonella Bruno4, Serena Cavallari2,3, Maria Grazia Coppola2,8, Claudio Farina1

1UOC Microbiology and Virology, ASST Papa Giovanni XXIII, Bergamo, Italy, 2AMCLI-CoSP, Milano, Italy, 3UOC Microbiology and Virology, University Hospital St. Orsola-Malpighi, Bologna, Italy, 4UOC Microbiology and Virology, ULSS2 Marco Trevisiana, Treviso, Italy, 5UOC Microbiology and Virology, ASST Ovest Milanese, Legnano, Italy, 6UOC Microbiology and Virology, IRCCS Policlinico S. Matteo, Pavia, Italy, 7UOC Microbiology, ASST Ovest Milanese, Legnano, Italy, 8UOC Parasitology, AORN dei Colli, Cotugno Hospital, Napoli, Italy

Background: The diagnosis of intestinal parasitosis is a very important challenge for many laboratories, in fact it requires a high degree of specific competences from the microbiologist. A lot of studies report that molecular biology, compared to microscopy, has numerous advantages such as greater sensitivity and specificity. The aim of this study is to evaluate an RT-PCR for the detection of intestinal protozoa from faecal samples.

Materials/methods: 164 samples were collected in seven Italian hospitals (Bergamo, Napoli, Pavia, Legnano, Modena, Bologna and Treviso) stored at -20 or -80 °C. The samples were examined using traditional techniques: macro- and microscopic examination after concentration, Giemsa or TrichRome stain, Giardia lamblia, Entamoeba histolytica/dispar or Cryptosporidium parvum antigens and amoebae culture. DNA was extracted with Microlab [NIMBUS]. All samples were examined with RT-PCR multiplex (Biorad, CFX96, Real Time system) using the Allplex GI-Parassite Assay, Seegene kit.

Results: On the 164 samples the traditional investigations allowed to identify the following protozoa: 41 non-pathogenic, 107 pathogens (34 G. lamblia, 65 D. fragilis, 4 C. parvum, 4 E. histolytica), 5 antigen positive only (2 G. lamblia, 2 E. histolytica, 1 C. parvum), 2 RT-PCR positive only, 1 negative from a patient with positivity for antibodies anti-E. histolytica. RT PCR confirmed 126/164 concordant positive and 31/164 concordant negative. RT-PCR detected D. fragilis in 9 samples positive for another parasite with the traditional technique: 6 confirmed with slide revision. RT-PCR detected E. histolytica in a patient with positive serology, but antigen and microscopy negative. C. parvum was also detected, in a reported positive sample only for B. hominis.

Conclusions: RT-PCR detected 6 D. fragilis, 1 C. parvum and 2 E. histolytica undiagnosed by traditional techniques [one of which was positive with the E. dispar/histolytica binary antigen]. Furthermore, RT-PCR confirmed 13 false positives for D. fragilis due to incorrect microscopic interpretation, justifying B. hominis in the Allplex panel. The impossibility of rereading 3 slides did not allow a better evaluation of sensitivity. The detection of E. histolytica in patients with positive serology alone, is important. The RT-PCR technology could therefore improve the limits of diagnosis of intestinal protozoan infections with time resolution.

**Background:** Due to limited therapeutic options, the colistin and polymyxin B are often considered antibiotics of last resort. However, the optimal dosage regimen is not universally agreed upon. We aimed to assess the *in vitro* effect of different combinations of colistin and meropenem against CRGN clinical isolates collected from patients enrolled in the AIDA trial in 2013-2017.

**Materials/methods:** The sample consisted of 354 CRGN isolates (A. baumannii n=276, Enterobacterales n=68, P. aeruginosa n=10). Broth microdilution was used to determine MICs of colistin and meropenem alone. The checkerboard method was used to evaluate colistin-meropenem interactions. A total of 32 combinations of drug concentrations were tested on each isolate (0.12 to 1µg/ml for colistin; 0.5 to 64µg/ml for meropenem). The fractional inhibitory concentration (FIC) index for each combination and the cumulative FIC (ΣFIC) index were calculated for each isolate. Synergy was defined as ΣFIC ≤0.5, additivity as ΣFIC >0.5 to ≤4, and antagonism as ΣFIC >4. In the subsample of meropenem-resistant, colistin-susceptible isolates (n=280), we determined the optimal colistin concentration (1/2, 1/4, or 1/8 MIC) needed to reach bactericidal activity when meropenem concentration is ≤8µg/ml.

**Results:** Synergy was observed in 56.7% of A. baumannii (156/276), 10.0% of P. aeruginosa (1/10), and 7.4% of Enterobacterales (5/68) strains synergism (ΣFIC: 0.1-0.5). Antagonism was detected for 1.5% of the A. baumannii (4/276), 42.6% (29/68) Enterobacterales and 40.0% P. aeruginosa (4/10) isolates [ΣFIC: 4.1-4.5]. One P. aeruginosa isolate exhibited both synergism [FIC₅₀: 0.5] and antagonism [FIC₅₀: 4.1]. Additivity was found in 42.0% of the A. baumannii (116/276), 50.0% of the Enterobacterales [34/68] and P. aeruginosa (5/10) isolates. In the subsample colistin-susceptible isolates, the highest percentage of isolates (48.9%) reached bactericidal activity [at meropenem concentration ≤8µg/ml] when combined with 1/4 MIC colistin concentration. At both 1/2 and 1/8 MIC colistin concentration, only 7.4% of isolates reached bactericidal activity.

**Conclusions:** Although meropenem-colistin combination therapy for CRGN infections has been advocated based on the assumption of synergy, we found in vitro synergy in less than half of isolates. In order to achieve the optimal bactericidal effect of meropenem, the initial MIC of the isolate to colistin must be considered.

**In vitro evaluation of barrier function against foodborne bacteria and oral streptococci on polytetrafluoroethylene membranes**

Gabrijela Begić¹, Olga Cvijanović Pezoa², Sabina Mahmutovic Vranic*³, Marko Blaskovic⁴, Zeljka Peric Kacarevic⁵, Ivana Gobin⁴

¹Faculty of Medicine, Department of Microbiology and Parasitology, Rijeka, Croatia, ²Faculty of Medicine, Department of Anatomy, Rijeka, Croatia, ³University of Sarajevo, Department of Microbiology, Sarajevo, Bosnia and Herzegovina, ⁴Faculty of Dental Medicine, Department of Oral implantology, Rijeka, Croatia, ⁵Faculty of Dental Medicine and Health, Department of Anatomy, Histology and Embryology, Osijek, Croatia

**Background:** In the guided bone regeneration (GBR) process, it is important to choose the optimal biomaterial, which will not degrade rapidly, and which, upon completion of GBR, will maximally contribute to osteogenesis in order to completely close the bone defect. It is equally important to ensure that the processes of bone healing take place without microbial contamination from the oral cavity. New generation of nonresorbable, membranes include dense polytetrafluoroethylene (D-PTFE) tetra fluoroethylene membranes. As they are not degradable, d-PTFE membranes are removed 4 weeks after tooth extraction, creating pre-conditions for possible infection. Commonly used d-PTFE membranes are Permamem (Botiss biomaterials, Zossen, Germany) and Cytoplast (Osteogenics Biomedical, Texas, USA) membranes. The aim of this study was to evaluate adhesion properties, biofilm formation and consequently barrier function of foodborne bacteria *Staphylococcus aureus*, *Enterococcus faecalis*, *Escherichia coli*, and oral streptococci (*Streptococcus mutans*, *S. mitis* and *S. salivarius*) on Permamem and Cytoplast membranes.

**Materials/methods:** Bacterial adhesion and colonization on a two d-PTFE membranes of varying openness [Cytoplast and Permamem] and polystyrene were evaluated. The surfaces of tested membrane and polystyrene were challenged with tested bacteria and incubated statically for 2-48 h. At the end of the incubation, plate were three times washed with PBS and sonificated in a water bath at 40 kHz for 1 min. Bacteria were enumerated by culturing on MH agar or Salivarius Mitis agar up to 2 days until colonies were observed. At the same time, the characteristics of bacteria in the biofilm using fluorescence microscopy and SEM were examined.

**Results:** Numbers of all tested bacteria increased over time on all surfaces. Oral Streptococci showed better adhesive properties than foodborne bacteria. Comparing different materials, all bacteria showed significantly lower biofilm formation [reduced by app. 4 log] on d-PTFE membranes compared to polystyrene. Oral streptococci and foodborne bacteria adhered better on Cytoplast than Permamem membrane [app. to 2 log].

**Conclusions:** Tested PTFE membranes showed to be effective barriers against bacterial colonisation in vitro. Permamem membrane showed the lowest bacterial adhesion and biofilm formation, compared to Cytoplast and polystyrene, suggesting their better resistance towards foodborne bacteria and streptococci.

Abstract 7574

**Clinical effectiveness of temocillin in a French university hospital**
Elise D’huart1, Florence Meyer1, Béatrice Demoré1, Alexandre Charmillon*1

1University Hospital, Nancy, France

**Background:** Temocillin is a narrow spectrum antibiotic that is indicated to treat infections due to *Enterobacteriaceae* producing extended spectrum beta-lactamase (ESBL). The purpose of this study is to evaluate the clinical effectiveness of temocillin in a French University Hospital.

**Materials/methods:** From July 2018 and September 2019 all patients who received more than 1 day of treatment by temocillin were prospectively included in the study. Characteristics of patients, microbiology and treatment data and outcome were retrospectively analysed for each prescription. The effectiveness of temocillin was defined by the clinical improvement and the absence of recurrent infection.

**Results:** Twenty-two patients received temocillin: 19 adults [mean age: 70.3 [36; 95]], 3 children [12 men, 10 women]. Nine patients were immunocompromised, including 5 renal transplant and 1 hepatic transplant patients. One patient was treated twice with temocillin during the study period.

The indications were urinary tract infections (82.6%; 19/23), bacteriemia from unknown source (13.0%; 3/23) and respiratory tract infection (4.4%; 1/23). Temocillin was used after a documented, monomicrobial infection. Bacteria identified were *Escherichia Coli* (54.2%; 13/24), *Enterobacter cloacae* (25.0%; 6/24), *Klebsiella pneumoniae* (12.5%; 3/24), *Serratia marcescens* (4.2%; 1/24), *Morganella morganii* (4.2%; 1/24). In one case, two bacteria were identified. In all cases, MIC was ≤ 8 mg/mL.

The mean duration of antibiotherapy was 12 days ([5; 21]). Temocillin was either administered as a continuous infusion (52.2%; 12/23) or over 30 minutes (47.8%; 11/23). Dosages were adapted to renal impairment. Before temocillin, all patients were initially treated by a broad-spectrum antibiotic: a third-generation cephalosporin (52.2%; 12/23), piperacillin/tazobactam (26.1%; 6/23) or a carbapenem (21.7%; 5/23).

The clinical evolution was favorable in 87.0% (20/23) of cases. A recurrence was observed in 34.8% (8/23) of cases, including all transplant patients. Patients infected with *Escherichia Coli* or *Enterobacter cloacae* recurred in 61.5% (8/13) and in 16.7% (1/6) of cases respectively.

**Conclusions:** Temocillin seems be an effective alternative to broad-spectrum antibiotics to treat documented urinary tract infections in immunocompetent patients. However, this study highlights an important recurrence rate especially in immunocompromised patients despite a favorable initial evolution.

Abstract 7575

Comparison of rifampin synergy in high versus low biofilm-forming Staphylococcus epidermidis

Emily Piehl*1,2, Emily O’neill1,2, Kathryn Daffinee1, Kerry Laplante1,2,3,4

1Providence Veterans Affairs Medical Center, Rhode Island Infectious Diseases Research Program, Providence, United States, 2University of Rhode Island, College of Pharmacy, Kingston, United States, 3Providence Veterans Affairs Medical Center, Center of Innovation in Long-Term Support Services, Providence, United States, 4Warren Alpert Medical School of Brown University, Division of Infectious Diseases, Providence, United States

Background: The role of rifampin in the treatment of biofilm-associated Staphylococcal infections remains controversial. Staphylococcus epidermidis is frequently implicated in medical device infections due to its propensity to form biofilm on foreign materials. We sought to describe synergistic combinations of antibiotics with rifampin and determine if its activity differed when used in high biofilm-forming vs low biofilm-forming S. epidermidis.

Materials/methods: A methicillin-resistant high biofilm-forming S. epidermidis strain RP62a (Hi-BF) and its accumulation-negative mutant M7 (Lo-BF) were utilized in a 24-hour high-inoculum time kill assay to detect synergy with rifampin. An inoculum of 10^7 CFU/mL was used for this assay to simulate high-inoculum biofilm infections. The antibiotics that were tested were levofloxacin, vancomycin, daptomycin, ceftaroline, and minocycline at 0.25x, 0.5x, 1x, and 2x the minimum inhibitory concentration with and without the addition of rifampin. As previously described, synergy was defined at 24 hours as a ≥2-log10 decrease in colony-forming units CFU/mL from the most single active agent, antagonism was defined as an increase of a ≥2-log10 CFU/mL, and indifference was defined as any CFU/mL that was in between this range.

Results: In the Hi-BF isolate, rifampin synergy was observed with daptomycin, vancomycin, and levofloxacin (Table 1). However, rifampin was not synergistic with daptomycin, vancomycin, ceftaroline, levofloxacin, or minocycline in the Lo-BF isolate. Of interest, antagonism was noted with minocycline and rifampin in the Lo-BF isolate.

Conclusions: This study demonstrated that rifampin improved the bactericidal activity of some antibiotics against a Hi-BF S. epidermidis isolate, but not with a Lo-BF isolate. The difference in kill is likely dependent on biofilm formation capability of the isolate. This may explain why the literature is inconsistent in regards to the role of rifampin in therapy. The antagonistic activity of minocycline in combination with rifampin in low biofilm-forming S. epidermidis is of concern and warrants further investigation. Identification of the mechanism behind increased kill with rifampin in biofilm is critical to determining its role in combination therapy for infections.

Performance of the rapid molecular assay BioFire FilmArray Meningitis/Encephalitis for the diagnosis of CNS infections: a one-year evaluation in a tertiary care hospital

Onya Opota*1, Zahera Naseri1, René Brouillet1, Laurence Senn1, Guy Prod’hom1, Gilbert Greub1, Katia Jaton1
1University of Lausanne and University Hospital of Lausanne, Institute of Microbiology, Lausanne, Switzerland, 2University of Lausanne and University Hospital of Lausanne, Service of hospital preventive medicine, Lausanne, Switzerland

Background: The BioFire FilmArray Meningitis/Encephalitis System, BF-ME (bioMérieux) is a rapid (1 h) molecular assay for the diagnosis of meningitis and encephalitis. The test provides a qualitative result for 14 pathogens. We aimed to evaluate the reliability and the added-value of this assay one year after its introduction in our hospital.

Materials/methods: In November 2018, the BF-ME was made available for physicians 7/7 days/8am-10pm. Pathogens for which in-house PCRs were available, were retested within 24h; this included Haemophilus influenzae, Listeria monocytogenes, Neisseria meningitidis, Streptococcus agalactiae, Streptococcus pneumoniae, Cytomegalovirus, Enterovirus, Herpes simplex virus 1 and 2, Human herpes virus 6 and broad range 16S rRNA gene PCR. Clinico-laboratory assessment was achieved to investigate discrepant results.

Results: We analysed results (n=144), obtained during a one year period after the introduction of the ME panel (Nov. 2018 to Nov. 2019) with the following results: sensitivity 90.9% (30/33), specificity 98.6% (139/141), positive predictive value 93.7% (30/32) and negative predictive value 97.9% (139/142). Two adult patients that tested positive for E. coli K1 with the BF-ME panel were negative with in-house PCR, among whom only one of them could eventually correspond to a true positive by clinico-laboratory assessment. Two patients with a clinico-laboratory assessment compatible with a viral encephalitis tested negative for HSV-1 with the BF-ME panel but positive with in-house real-time PCR with very low DNA copy number. One patient with a Listeria monocytogenes rhombencephalitis and bacteraemia tested negative with the BF-ME panel but positive with in-house real-time PCR.

Conclusions: The overall performance of the test appeared intermediate. However, important unexpected discrepant results - false positive and false negative - occurred. This may be problematic for a first line assay expected to support decision making in the setting of a life-threatening disease. In conclusion, the BF-ME provided rapid results with a better sensitivity than Gram staining. However, our study similarly to previous studies re-inforces that: i) a carefully clinico-laboratory assessment is mandatory for the interpretation of any BF-ME results (both negative and positive results) and ii) confirmation with in-house molecular test, ideally quantitative tests, appears to be necessary.

Sulbactam and colistin susceptibility pattern among multidrug-resistant Acinetobacter isolates from respiratory samples

Mallika Sengupta1, Sayantan Banerjee2, Nazia Nagi*3

1ESI-PGIMS, ESIC Medical College and Hospital, Joka, Kolkata, ESI PGIMS and ESIC Medical College, Kolkata, India, 2Indian Council of Medical Research, New Delhi, India, 3Delhi University, Maulana Azad Medical College, New Delhi, India

Background: Healthcare-associated lower respiratory tract infection (LRTI) is one of the major causes of morbidity, prolonged average length of stay, exorbitant healthcare expenses and mortality related to antimicrobial resistance. The most common bacterial agents of LRTI in the Intensive Care Unit (ICU) are Pseudomonas spp., Acinetobacter spp., Klebsiella pneumoniae, Citrobacter spp., and Escherichia coli. Acinetobacter baumannii has emerged as a major cause of nosocomial outbreaks. A unique feature of A. baumannii in particular, is their intrinsic resistance to multiple antibiotics.

Sulbactam being a beta-lactamase inhibitor has been traditionally combined with beta-lactams to treat ESBL producing Acinetobacter. Studies have also described a unique intrinsic bactericidal effect of Sulbactam against Acinetobacter baumannii.

Materials/methods: A prospective study was conducted for six months in the medical ICU of a 500 bedded tertiary care hospital and medical teaching institution in India. Identification of organisms causing LRTI obtained from sputum or invasively collected samples were done by conventional phenotypic and/or VITEK 2 Compact System™. Antimicrobial susceptibility was tested by Kirby-Bauer disc diffusion method according to standard guidelines. Minimum inhibitory concentrations were measured for Acinetobacter spp. to colistin and sulbactam by E-strips and micro broth dilution technique.

Results: A total of 542 respiratory samples were received, 109 of which showed growth of significant colony count of one or two organisms, yielding a sum of 115 isolates. Among these isolates, 51 were (44.35%) Klebsiella pneumoniae, 32 (27.83%) Pseudomonas spp., 30 (26.09%) Acinetobacter spp. and 2 (1.74%) Stenotrophomonas maltophilia. All the Acinetobacter isolates were resistant to ceftazidime, cefepime, piperacillin-tazobactam, cefoperazone-sulbactam, ciprofloxacin, amikacin, gentamicin, tobramycin, meropenem and imipenem. No significant independent intrinsic bactericidal effect of sulbactam was observed against the Acinetobacter isolates.

Conclusions: The common Gram-negative pathogens causing healthcare-associated LRTI were highly resistant to most drugs except polymyxins. Acinetobacter baumannii isolates were not susceptible to either free sulbactam or in combination with cefoperazone. The alarming situation of antimicrobial resistance in these isolates remarkably demonstrates the need for immediate investment in newer and alternative therapeutics.

Abstract 7580

Epidemiology of non-tuberculous mycobacteria in bronchiectasis and non-bronchiectasis patients in a university teaching hospital in Madrid

Sara Gómez De Frutos*1, Leticia Fontan1, Eva Navarro Lara1, Nelly Daniela Zurita Cruz1, Laura Cardeñoso1, Javier García Pérez1, Diego Domingo1
1Hospital de La Princesa, Madrid, Spain

Background: Non-Tuberculous Mycobacteria (NTM) includes species other than M. tuberculosis and M. leprae. These microorganisms are opportunistic pathogens recognized as a cause of pulmonary infection. Patients with pre-existing lung disease, such as bronchiectasis, are predisposed to developing a NTM infection. The aim is to describe the NTM prevalence and etiology of patients suffering bronchiectasis (excluding cystic fibrosis) in relation to non-bronchiectasis patients.

Materials/methods: Retrospective study from 2009 to 2019 in a university hospital in the community of Madrid, Spain. All respiratory samples for mycobacteria diagnosis were included. Microbiological diagnosis was carried out by an automated culture (MGIT™ 960 system, Becton Dickinson). Bacterial identification was obtained by mass spectrometry (MALDI-TOF) or DNA studies.

Results: 2 124 samples from 762 bronchiectasis-patients were processed. NTM were isolated from 811 (38.18%) samples from 228 (29.92%) of these patients. Comparing to general population (1 7163 patients; 606, 3.53% NTM isolates), the presence of NTM was more common in patients suffering bronchiectasis (11.67 OR, 95% CI 9.79-13.90). The most prevalent NTM was M. avium (490 isolates, 54.08%) following by M. abscessus and M. lentiflavum (80 isolates, 9.85% each one) and M. fortuitum (65 isolates, 8.00%). There were not important differences among species found from bronchiectasis and non-bronchiectasis cultures (Table 1). An increase number of NTM isolates is observed: from 15 in 2009 to 84 in 2019.

Conclusions: the NTM isolation from bronchiectasis-patients are common and becoming more frequent. The risk of NTM infection in this patients comparing to general population are much higher although the species found are similar. Therefore, it is necessary to take into account NTM to get a correct diagnosis of infection and optimal management of patients suffering from this disease.

Faecal microbiota in Romanian ankylosing spondylitis patients
Mihaela Oprea1, Daniela Cristea1, Denisa Predateanu2, Violeta Claudia Bojinca1, Marius Trandafir2, Sorin Dinu1, Simona Ciontea1, Codruta-Romanita Usein1

Cantacuzino NIMMRD, Bucharest, Romania, 2Sf.Maria Clinical Hospital, Bucharest, Romania

Background: Ankylosing spondylitis (AS) is a chronic inflammatory autoimmune disease characterized by new bone formation causing syndesmophytes and enthesitis, and represents the prototype of spondyloarthritis inflammatory disorders (SpA). A strong correlation between SpA and gut dysbiosis has been made since up to 50-70% of SpA patients display subclinical gut inflammation and 5-10% of them evolve toward inflammatory bowel disease (IBD).

Materials/methods: Diversity of the gut bacterial microbiome was studied in 25 Romanian patients diagnosed with AS (sex ratio 4:1, 22-68 years) and 16 clinically healthy control individuals with no history of rheumatic disease and IBD. Fecal DNA was used for PCR amplification of hypervariable regions of 16S rRNA gene using Ion 16S™ Metagenomics Kit. High-throughput sequencing was performed on an Ion PGM™. Taxa identification was performed with QIIME within Ion Reporter™ (Thermo Fisher Scientific). Alpha diversity was assessed by richness (Chao1) and diversity (Shannon, Simpson). Beta diversity was evaluated by principal-coordinate analysis plot (PCoA) with Bray-Curtis dissimilarity. LefSe analysis was employed to reveal the significant differences in abundance between the patients and controls.

Results: The rarefaction curves showed a clear tendency toward a saturation plateau, suggesting that most of the diversity was captured. Bacteroidetes, Firmicutes, Proteobacteria, and Actinobacteria were found as dominant taxa in both groups. The number of detected families was significant lower in patients than in control group (p< 0.01). At the genus level, Eubacterium and Roseburia were significantly greater in AS than in controls whereas Herbaspirillum, Lactococcus, Oxalobacter and Paraprevotella were significantly lower in AS than in controls. Examination at species level showed that Blautia producta and Blautia luti are significantly represented in AS patients, and some species such as Alistipes shahii, Alistipes putredinis, Lactococcus lactis, Ruminococcus flavefaciens and Sutterella sp., are underrepresented comparing with controls.

Conclusions: The gut microbiome of AS patients was clearly different from that of controls. There was a loss of richness of the gut microbiome in AS patients. As other previous reports, we conclude that some biomarkers might be involved in the pathogenesis or development process of AS.

Development of in vitro and ex vivo wound biofilm models for the assessment of wound dressings
Kairi Tiirik*, Liis Preem1, Kadi Sagor2, Marta Putrins2, Tanel Tenson2, Karin Kogermann1

1University of Tartu, Institute of Pharmacy, Tartu, Estonia, 2University of Tartu, Institute of Technology, Tartu, Estonia

Abstract 7585

Background: Increasing evidence suggests that the chronicity of wounds is linked to infection and presence of biofilm, thus, novel biofilm targeting wound care products are being developed. It is crucial to have appropriate analytical methods to quantitatively assess these anti-biofilm properties. The aim of present study was to develop in vitro and ex vivo wound biofilm models for assessing the antibiofilm properties of wound dressings.

Materials/methods: For the in vitro model thermally crosslinked electrospun gelatine (GEL) matrix as an artificial skin was used. Ex vivo model was developed using pig ear skin. For wound biofilm model development different pathogenic bacteria (S. aureus, E. coli, S. epidermidis) and media as wound exudate were tested. Biofilm formation was studied according to the schematics. Filter papers immersed into the artificial wound exudate were placed at the bottom of the 24-wellplates, then either GEL matrix or pig skin was positioned on top. Bacterial dispersion was added after which chloramphenicol (CAM)-loaded electrospun wound dressings were applied. These systems were incubated for 24, 48 and 72h, subsequently planktonic bacteria were removed, biofilm disrupted and quantified. Confocal microscopy and scanning electron microscopy were used for the characterisation of the biofilms and wound dressings.

Results: GEL matrix is suitable for being used as an artificial skin in in vitro biofilm model as bacteria adhered to its surface and formed a biofilm (up to 10^8 CFU/cm^2). Compared to GEL matrix, the ex vivo model on pig skin appeared to be a better surface for biofilm formation resulting in 2-10 times higher CFU/cm^2. Application of CAM-loaded dressings effectively reduced the biofilm formation in both models compared to the blank dressings without CAM.

Conclusions: Designed in vitro and ex vivo models allow comparing and evaluating the antibiofilm properties of wound dressings. Both models exhibit their specific advantages, GEL matrix has a defined chemical composition and structure and pig skin has its durability allowing longer experiments over several days. Next studies investigate the efficacy of the dressings for the treatment of already formed biofilm.

Abstract 7586

Efficient inactivation of clinically relevant antimicrobial drug concentrations by two resin-containing media in simulated paediatric blood cultures

Flora Marzia Liotti1, Giulia Menchinelli1, Liliana Giordano1, Giulia De Angelis1, Teresa Spanu1, Maurizio Sanguinetti1, Brunella Posteraro1,2

1Institute of Microbiology, Università Cattolica del Sacro Cuore, Rome, Italy, 2Dipartimento di Scienze di Laboratorio e Infettivologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, 3Institute of Medical Pathology and Semeiotics, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy, 4Dipartimento di Scienze Gastroenterologiche, Endocrino-Metaboliche e Nefro-Urologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: Diagnosis of bloodstream infection in paediatric patients is a major challenge for clinical microbiologists. Improvements in blood culture (BC) media and the availability of automated growth detectors enhance the recovery of bloodstream pathogens and decrease the time to detection (TTD) of microbial growth. However, antimicrobial treatment administered before drawing BCs can reduce or delay pathogen recovery, especially in paediatric patient settings where low-level bacteraemias and small blood sample volumes often complicate the situation. The aim of this study was to evaluate the BacT/Alert PF Plus (bioMérieux) or BACTEC Peds Plus (Becton Dickinson) resin-containing media for their capability of inactivating clinically relevant antimicrobial drug concentrations in simulated paediatric BCs.

Materials/methods: We tested eight antimicrobial-organism combinations in BacT/Alert PF Plus or BACTEC Peds Plus bottles, which were inoculated with 2 or 10 mL of banked whole blood, 0.5 mL of antimicrobial drugs at peak or trough serum concentrations, and 0.5 mL of bacterial suspensions containing 5 or 30 CFU of per bottle. This resulted in eight conditions (each was tested in triplicate) for each combination. Positive and negative controls were included. All bottles were incubated in both BacT/Alert Virtuo and BACTEC FX systems. Results were reported as organism’s recovery rates and mean TTDs, and differences were assessed using the McNemar’s test or the paired t test, as appropriate.

Results: The overall recovery rate of organisms with the BacT/Alert PF Plus medium was 39.1% (75/192 bottles), whereas the rate with the BACTEC Peds Plus medium was 25.0% (48/192 bottles) for all the antimicrobial-organism combinations tested. We found that this difference was statistically significant (P < 0.001). The mean TTDs were 14.26 h and 16.37 h for the BacT/Alert PF Plus medium or the BACTEC Peds Plus medium, respectively (P < 0.05). There was no recovery at any condition with ceftriaxone tested against Streptococcus pneumoniae for both the media and with vancomycin tested against S. pneumoniae only for the BACTEC Peds Plus medium.

Conclusions: Despite preliminary, our findings show that the BacT/Alert PF Plus medium is more efficient than the BACTEC Peds Plus medium in a simulated paediatric BC setting.

Abstract 7587

Five different Borrelia species identified in synovial fluids from patients in Sweden
Katharina Ornstein†1, Ann-Cathrine Petersson2

1Lund University Healthcare, Ystad Hospital, Ystad, Sweden, 2Region Skåne, Lund, Sweden

Background: Sweden is an endemic area for Lyme borreliosis. Serology is the routine diagnostic method while detection of Borrelia specific DNA is considered a complementary diagnostic tool. At the clinical microbiological laboratory in Lund, Sweden, a 16S real-time PCR has been in use since 2007. A cohort of patient samples originating from joints is presented with demographic data together with species and subspecies characterization.

Materials/methods: Patient samples originating from joints referred over the years 2007 to 2018 to the laboratory for Borrelia DNA detection was studied. Two 16S rDNA PCR tests are run in parallel, one targeting the Borrelia genus and the other one targeting Lyme Borrelia species (Borrelia burgdorferi sensu lato). For species and subspecies characterization a nested ospA based PCR followed by sequencing is performed.

Results: During 12 years 1414 of 2495 (56.6 %) samples referred to the laboratory for a Borrelia PCR test were material from joints. Joint samples originated from synovial fluids and occasional synovial membranes from patients living in Sweden and a few cases from Denmark, Norway and Finland. Borrelia DNA was detected in the 16S rDNA PCR in 155 of 1414 (11.0 %) joint samples. Species identification was successful in 116 unique patients by the ospA PCR and sequence analysis. Borrelia afzelii was the most common species identified in 58 samples (50.0 %), followed by Borrelia burgdorferi, Borrelia garinii, Borrelia bavarensis, Borrelia spielmanii identified in 35 (30.2 %), 11 (9.5 %), 9 (7.8 %), 3 (2.6 %) samples, respectively. Female to male ratio was 28.2 % to 71.8 %. Mean age was 31.8 (range 4 to 78 years).

Conclusions: Synovial fluids was the most common material sent for a Borrelia PCR test and there was a year around request. Borrelia DNA is predominantly detected in males. Of the five species found Borrelia burgdorferi sensu stricto was the second most prevalent species in synovial fluids a species much more seldom found in ticks. Molecular based tests in routine diagnostics can provide new important epidemiological data into Lyme borreliosis.

Abstract 7590

qPCR to detect mecA in faecal samples: a tool for assessing resistance burden amongst pets and their owners in the microbiological ‘fast age’?

Siân-Marie Frosini1, Georgina Gallow1, Juliana Menezes2, Adriana Belas2, Cátia Filipa Saraiva Marques2, Catarina Aboim2, Maria Constança Pomba2, Anette Loeffler1

1Clinical Science and Services, Royal Veterinary College, Brookmans Park, United Kingdom, 2Faculty of Veterinary Medicine, University of Lisbon, Lisboa, Portugal

Abstract third-party references: This work was supported by a JPI-EC-AMR grant funded by the Medical Research Council [Grant MR/R000042/1], This work is a part of the PETRisk Consortium.

Background: Current sampling and detection methods for carriers of pathogenic methicillin-resistant staphylococci (MRS) such as MR-Staphylococcus pseudintermedius and MR-S. aureus can be challenging in animals and time-consuming. Developing a faster method to identify mecA in a convenient-to-collect sample, such as faeces, would benefit surveillance efforts and may aid in management of MRS-carrier animals which could be a zoonotic risk to owners. This study aimed to identify whether a quantitative polymerase chain reaction (qPCR) method could be optimised to detect mecA in faecal samples and distinguish MRS-carriers from non-carriers.

Materials/methods: Faecal samples (0.5g) were collected from ten MRS-carriers (n=6 dogs, n=4 humans) and 51 non-carriers (n=21 dogs, n=30 humans); carriage was determined using nasal swabs processed with enrichment salt broth. Bacterial DNA was extracted from faeces using a commercial kit and verified by 16S PCR. A qPCR method previously used for pure bacterial culture was optimised to ensure accuracy and detection of low copy numbers of mecA. A robust method with a single melt curve peak was achieved, and the product confirmed as mecA by Sanger sequencing. Faecal mecA abundance was compared between MRS-carriers and non-carriers (Kruskal-Wallis test).

Results: The limit of detection (LOD) of mecA was approximately 70 copy numbers in 6µL DNA, with a melt curve temperature of 75°C and extraction efficiency of 97.1±3.2% across all plates used for analysis. In 8 individuals (n=2 human carriers, n=4 canine non-carriers, n=2 human non-carriers) mecA was detected [74-36756 copy numbers]; in all others mecA was below LOD. Faecal mecA abundance did not correlate with nasal MRS-carriage (P=0.83).

Conclusions: Using the optimised qPCR method, we could identify mecA directly from faeces of MRS-carrier humans, and in individuals who were not MRS-carriers based on nasal swabbing. Further development and validation of this method may be warranted to enable future large, easy-sampling population screening for resistance gene abundance. We could not discriminate between MRS-carriers and non-carriers in this population. This is possibly due to the small sample size but more likely due to the presence of mecA-positive coagulase-negative staphylococci, or possibly other bacterial species carrying mecA homologues, in the gut microbiota of both groups.

Abstract 7593

Typing of Clostridioides difficile isolates by MALDI-TOF MS

Adriana Calderaro1, Mirko Buttrini*1, Sara Montecchini2, Silvia Covan3, Alberto Ruggeri1, Monica Martinelli1, Sandra Larini3, Maria Cristina Arcangeletti1, Carlo Chezzi1, Flora De Conto1

1University of Parma, Department of medicine and surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Virology, Parma, Italy, 3University Hospital of Parma, Unit of Clinical Microbiology, Parma, Italy

Background: Clostridium difficile infection (CDI) associated with emerging ribotypes is increased both in Europe and worldwide; more than 800 different ribotypes and 34 different toxinotypes of C. difficile are known and the ribotype 027 strain is currently considered the most virulent. In Europe, nosocomial CDI are typically associated with ribotype 027 and 078 strains, while in Italy, the predominant ribotypes are associated to 356/607 (27%) and 018 (12%) strains. Unlike other European countries, the hypervirulent ribotypes 027 and 078 emerged in Italy only recently and accounted for 8% and 4% respectively. In this study MALDI-TOF mass spectrometry was used as a potential innovative method for C. difficile strains typing, compared with the widely known PCR-Ribotyping method.

Materials/methods: Fifty strains of C. difficile isolated in our hospital were typed both by PCR-Ribotyping, according to Bidet et al., and by MALDI-TOF MS. The spectra obtained in the range 2-20 kDa, with the instrument Autoflex speed (Bruker Daltonics, Germany), were analyzed and subsequently imported into the ClinProTools software version 2.2 (Bruker Daltonics) to carry out a statistical analysis in order to verify the presence of specific peaks for each ribotype.

Results: The two typing methods used showed a concordance of 76%. Using PCR-Ribotyping, 5 different ribotypes (named PR1-PR5) were observed, 2 of these, PR1 and PR3, associated to ribotypes 018 and 0126, respectively. MALDI-TOF MS, based on the presence/absence of 13 different peaks, differentiates the 5 ribotypes identified by PCR-Ribotyping. For eight strains (16%) the spectra obtained were classified by the MALDI-TOF MS statistical software as one of such 5 ribotypes but differently to the classification of PCR-Ribotyping. For 4 strains (8%) a protein profile different from each other and from those characterizing the 5 ribotypes observed was obtained, making them unique and belonging to different classes (PR6-PR9).

Conclusions: MALDI-TOF MS typing compared to other molecular typing methods was faster and cheaper. However, the typing of strains, although possible as demonstrated in this study and presenting significant advantages, is currently applicable to the most frequently circulating ribotypes, as a first-level epidemiological investigation in the nosocomial setting.

Background: Diabetic foot ulcers (DFUs) are common and lead to infections with high morbidity-mortality. Diagnosis of DFU infection by clinical signs and conventional-qualitative cultures is sometimes difficult. We aimed to evaluate the role of quantitative cultures from DFUs in predicting the outcome of ulcers.

Materials/methods: Prospective multicenter study (3 Spanish referral centers) including patients with DFUs. At baseline visit, we performed a biopsy from ulcers clinically infected (signs of inflammation, purulent secretion) or not, and quantitative bacterial counts were obtained. Patients were followed-up at 1, 3 and 6 months to evaluate DFU cure; we compared characteristics and outcome of cases with high (≥10E6 UFC/ml) or low microbial load (<10E6 UFC/ml).

Results: 65 DFU cases (28% toes, 72% midfoot-backfoot) were studied; 80% were men (median age 65 years, IQR 59-71) with a chronic diabetes (17 years, IQR 8.5-25). At baseline, 24 (37%) DFU cases were considered clinically infected but only 33% (8/24) presented a high microbial load, whereas 27% of not-infected DFUs (11/41) had high bacterial counts. DFUs had mainly polymicrobial population (74%), S. aureus and Gram-negative bacilli (GNB) being present in 48% and 46%, respectively.

The group with high load in comparison with that with lower bacterial load had more frequently a young ulcer (<4 weeks, 37% vs 13%, p=0.03), a higher percentage of GNB (68% vs 37%, p=0.02) and S. aureus (63% vs 41%, p=0.1). No differences between groups were observed in the value of glycosylated hemoglobin, degree of vasculopathy and the consumption of antibiotics one month before obtaining the biopsy (58% vs 48%, p=0.3). Cases with high bacterial counts required more antibiotic therapy during the first month after biopsy (76% vs 45%, p=0.03), and at 6-month visit they presented more amputations (38% vs 22%, p=0.2) and lower cure rate (44% vs 73%, p=0.04).

Conclusions: Relationship between clinical diagnosis of infection and high bacterial load from DFUs was poor. However, cases with higher bacterial counts presented more frequently GNB strains and a worse prognosis. Our results suggest a potential role of quantitative cultures in predicting the outcome of DFUs that should be further evaluated.

Continuous infusion of cefoxitin is associated with higher probability of target attainment in patients infected with ESBL-producing Enterobacteriaceae

Pilmis Benoit*, Assaf Mizrahi, Alban Le Monnier, Najoua El Helali
1Hospital Group Paris Saint Joseph, Paris, France

Background: Cefoxitin (FOX) is a cephamycin still active against most extended spectrum beta-lactamase (ESBL) producing Enterobacteriaceae. The currently recommended dosages are 3 to 6 gr. Per day. However, few data of therapeutic drug monitoring are available on the use of cefoxitine for ESBL producing Enterobacteriaceae related infections.

Materials/methods: The objective was to compare the use of prolonged or continuous infusion versus intermittent administration of FOX for the treatment of infections caused by ESBL-producing Enterobacteriaceae. We performed a multicentric retrospective cohort study to evaluate continuous, prolonged or intermittent infusion of FOX. Firstly, we analyzed patients’ plasmatic concentrations according to the infusion duration and secondly, we performed a simulation of the percentage of patients who would reach the PK / PD targets set at 100% \( T > \text{MIC} \) or 100% \( T > 4 \times \text{MIC} \).

Results: Seventy-eight patients were enrolled with a median [IQR] age was 68 [56 – 77] years. Seventy-four patients were treated for Escherichia coli related infections and four for Klebsiella pneumoniae related infections. The major source of infections was urinary tract (91%). All patients were treated with 6 gr./day or renally adjusted equivalent.

In all patients infected with strains with MICs ≤ 6 mg/L, PK/PD objectives (100% \( T > \text{MIC} \)) was achieved with prolonged or continuous infusion. In contrast, when MICs was 8 mg/L only continuous infusion was sufficient to achieve the PK/PD objectives (100% \( T > \text{MIC} \)). In contrast, PK/PD objectives (100% \( T > 4 \times \text{MIC} \)) were achieved by prolonged or continuous infusion only when FOX MICs ≤ 2 mg/L.

Conclusions: Only prolonged or continuous infusion of FOX provided sufficient coverage to achieve sufficient probability of target attainment for ESBL PE with MICs ≤ 6mg/L. For more severe patients or in case of MICs to FOX at 8mg/L, only continuous infection of FOX seems sufficient to achieve probability of target attainment.

Abstract 7600

**Screening for carbapenemase-producing Enterobacteriaceae**

Arni Sarian*1,2, Nabeela Mughal1,2, Luke Moore1,2

1Imperial College London, London, United Kingdom, 2Chelsea and Westminster Hospital, London, United Kingdom

**Abstract third-party references:** Imperial College London, Chelsea and Westminster Hospital Foundation Trust

**Background:** Screening for Carbapenemase-producing Enterobacteriacea (CPE) enables early isolation and prevention of transmission in inpatient healthcare settings. The UK Department of Health detailed a national approach to screening in 2013. Implementation of this policy has been variable and challenging given the increasing prevalence of patients who meet these criteria and the limited number of isolation facilities.

**Materials/methods:** We undertook a point prevalence study in a central London teaching hospital in 2019, to ascertain patient risk factors for CPE and the frequency of per-policy screening. We then modelled variations in screening approaches to optimise risk assessments in the context of isolation room availability.

**Results:** We assessed screening compliance on the tertiary Burns Unit, Paediatric High Dependency Unit (PHDU), Acute Admissions Unit (AAU) and general surgery. 141 patient notes were assessed against the three screening criteria: 47/141 met the screening requirements due to previous admission to high risk UK healthcare institutes, 3/141 because of healthcare admission abroad, and 0/141 previously identified CPE carriers. Screening as per national guidelines was performed in only 30% (15/50) of patients that met the eligibility criteria. The highest rate of screening was noted in Burns unit (5/5). The factor most likely to result in screening, was previous admission to a hospital abroad (3/3).

The national toolkit advises that patients who meet eligibility criteria should be isolated immediately. Our data shows that the number of patients that should have been isolated surpasses the capacity of available side rooms in the hospital by 135%.

**Conclusions:** Screening for CPEs is complex and 6 years after role out of a national toolkit there is still variation in adherence to screening policy. In light of a revised national toolkit, due to be published in 2019, reworking of the risk stratification is needed. We suggest that education on risks of carrying CPEs as well as electronic healthcare records may enable better screening adherence.

Abstract 7604

Incidence and utility of follow-up blood cultures in haematology/oncology patients with Gram-negative bacteraemia

Amber Clemmons*1, Daniel Chastain2, Henry Young3, Miki Hayashi1, Eileen Kennedy4, Christopher Bland5

1University of Georgia College of Pharmacy, Augusta, United States, 2University of Georgia College of Pharmacy, Albany, United States, 3University of Georgia College of Pharmacy, Athens, United States, 4St. Joseph's/Candler Health System, Savannah, United States, 5University of Georgia College of Pharmacy, Savannah, United States

Background: Follow-up blood cultures (FUBC) in gram-negative bacteremia are commonly performed; however, recent data demonstrated no benefit in non-cancer patients. This study sought to determine the incidence of FUBC within hematology/oncology patients with gram-negative bacteremia and evaluate potential impact of FUBC on clinical outcomes.

Materials/methods: A multicenter retrospective chart review across 3 centers was performed in adult cancer patients (age ≥ 18 years) admitted to an oncology unit who had microbiologically defined gram-negative bacteremia between January 2018-December 2018. Data collected included: demographics, cancer diagnosis, type of treatment if applicable, microbiologic and clinical data. Primary outcome was incidence of FUBC in the hematology/oncology population with gram-negative bacteremia. Secondary outcomes included central venous catheter removal, presence of infectious diseases (ID) consultation, hospital length of stay, and in-hospital mortality in patients with FUBC versus those without FUBC. Descriptive statistics were calculated to characterize all study variables. Chi-square analyses (or Fisher’s Exact tests), t-tests (or Wilcoxon rank-sum tests), and bivariate regression (logistic and Poisson) analyses were conducted to examine the associations between FUBC and outcomes.

Results: Gram-negative bacteremia was identified in 55 patients. The vast majority of patients received FUBC (50/55; 90.9%). Patient characteristics, such as cancer diagnosis or receipt of cytotoxic chemotherapy, did not differ between those with versus without FUBC. Of 50 patients with FUBC, the average patient received 3.6 FUBC (SD 4.2; range 1-29) with a total of 179 FUBC performed. No growth was demonstrated in 163/179 (91.1%) of FUBC with only 11/179 (6.1%) growing the same initial pathogen and 5/179 (2.8%) growing different pathogen. Patients with FUBC were no more likely to have catheters removed or receive ID consultation than those without FUBC (p=0.6 and p=0.67, respectively). Patients receiving FUBC had greater lengths of stay (coefficient=0.47, CI 0.21-0.73) with median of 13 vs 9 days, respectively, while in hospital mortality was not different between groups (p=0.39).

Conclusions: FUBC are frequent in hematology/oncology patients with gram-negative bacteremia despite lack of supporting evidence. Our data demonstrated increased length of stay for patients receiving FUBC. Future studies should prospectively evaluate effect of FUBC on clinical outcomes to further clarify these findings.

Abstract 7605

**Group B Streptococcus vaginal colonisation from antenatal screening to 2 months after delivery: results from a prospective cohort study in France**

Céline Plainvert*1, Olivia Anselem1, Caroline Joubrel1, Valérie Marcou1, Emile Falloukh1, Amandine Frigo1, Fatma El Alaoui2, Pierre-Yves Ancel1, Pierre-Henri Jarreau1, Laurent Mandelbrot2, François Goffinet1, Claire Poyart1, Asmaa Tazi1

1Hospital Cochin, Paris, France, 2Louis-Mourier Hospital (AP-HP), Colombes, France

**Background:** Maternal vaginal colonization with Group B Streptococcus (GBS) is the major risk factor for neonatal early onset disease. GBS vaginal colonization fluctuates during pregnancy but host factors and bacterial characteristics that may impact GBS colonization and persistence remain poorly investigated. The objective of the study was to identify maternal demographic factors and features of GBS isolates associated with persistent GBS colonization.

**Materials/methods:** GBS vaginal colonization was prospectively recorded during a screening program of pregnant women in France from 2012 to 2016. Clinical data including place of birth were recorded. Vaginal swabs were collected at antenatal screening, at delivery, 21 +/- 7 days (D21) and 60 +/- 7 days (D60) after delivery. Colonization was defined as persistent when all samples from antenatal screening to D60 were positive for GBS. Capsular serotype genotyping and detection of the hyper-virulent CC-17 GBS were performed.

**Results:** A total of 906 women were included. In women screened GBS positive antenatally, GBS colonization was persistent in 63% of the cases, and GBS eradication either at D21 or at D60 was observed in 8% of the cases. Women screened negative remained uncolonized until D60 in 85% of the cases. Loss of colonization at D21 and D60 was more frequent in women born in France whereas persistent colonization was more frequent in those born in Sub-Saharan Africa. The dynamics of GBS vaginal colonization was not associated with any capsular serotype. The hypervirulent CC-17 GBS was over-represented in women born in Sub-Saharan Africa compared to women born in Europe and North Africa.

**Conclusions:** The place of birth which likely reflects the ethnicity impacts the dynamics of GBS colonization. Besides, women born in Sub-Saharan Africa are more frequently colonized with the hypervirulent CC-17 clone. These observations might be related to variations of the vaginal microbiota depending on the geographical origin and the vaginal community state types.

Impact of selective decolonisation of critically ill extreme elderly patients using invasive devices with chlorhexidine 2% daily bath on healthcare-associated infection rates

Julio Cesar Delgado Correal*1, Rogerio Rufino1,2, Marcos Fornasari1, Cassia Alburquerque1, Maria De Lourdes Martins1, Debora Santos1, Paulo Damasco1,2

1Hospital Rio Laranjeiras, Rio de Janeiro, Brazil, 2Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil

Background: Healthcare-associated infections (HAIs) in critically ill elderly patients are frequent and have a major impact on mortality and healthcare costs. These populations are more vulnerable to infections acquired in intensive care units (ICUs) due to frailty related to aging. Additionally most HAIs in Brazil are caused by multidrug-resistant gram-negative bacteria (MDR-GNB). Previous work developed on these populations by our group showed a significant reduction (26%) in colonization by carbapenem-resistant MDR-GNB using universal decolonization with chlorhexidine 2% daily bath.

Materials/methods: A prospective cohort study was conducted at an ICU of a private hospital in Rio de Janeiro with the care of extreme elderly (+80 years-old) populations from January 2016 (beginning the decolonization strategy with daily bath with chlorhexidine 2% in January 2017) through October 2019. A comparative analysis before-after of the adjusted rates of the HAIs (ventilator-associated pneumonia [VAP], catheter-associated urinary tract infection [CAUTI] and central line-associated bloodstream infection [CLABSI]) were done in three periods: Baseline period (January to December 2016); period 1 with universal decolonization in all patients admitted at the ICU (January 2017 to October 2018) and period 2 with selective decolonization only for patients with invasive devices (April 2019 to October 2019).

Results: In total, HAI rates were analyzed following 1,955 extreme elderly critically ill patients (summarizing 24,646 patient-days; baseline period-2016: 6,157 patient-days; period 1:14,608 patient-days; and period 2:23,891 patient-days) [Graph 1]. Following the introduction of the universal decolonization strategy with chlorhexidine 2% daily bath, we observed a significant reduction in all HAIs rates (VAP: 27 to 7.3 episodes/1000 patient-days; CAUTI: 56.8 to 1.9 episodes/1000 patient-days; and CLABSI:63.8 to zero episodes/1000 patient-days). After targeting the strategy to patients with invasive devices only, we observed similar HAI rates in the ICU (VAP: 7.3 to 4.6 episodes/1000 patient-days; CAUTI: 1.9 to 1.8 episodes/1000 patient-days; and CLABSI: zero to 1.1 episodes/1000 patient-days).

Conclusions: The selective decolonization strategy with chlorhexidine 2% daily bath, in addition to decreasing the colonization rate by MDR-GNB, protects the populations of extreme elderly critically ill from healthcare-associated infections. This strategy to reduce use chlorhexidine 2% daily bath is necessary.
Graph 1. Impact of stopping universal decolonization with chlorhexidine 2% daily bath on healthcare-associated infections rates of critically ill extreme elderly patients

Abstract 7612

Screening for latent tuberculosis infection among asylum seekers in Brescia, Italy: results from the E-DETECT Project

Valentina Marchese*1, Paola Zanotti2, Beatrice Formenti1, Benedetta Rossi1, Ester Lovato2, Enrico Girardi3, Lucia Barcellini4, Giovanna Stancanelli1, Daniela M. Cirillo4, Issa El Hamad2, Alberto Matteelli1

1University of Brescia, Institute of Infectious and Tropical Diseases, WHO Collaborating Centre for TB/HIV coinfection and TB elimination, Brescia, Italy, 2University of Brescia/ASST Spedali Civili general Hospital, Department of Infectious and Tropical Diseases, Brescia, Italy, 3National Institute for Infectious Diseases, L. Spallanzani, Clinical Epidemiology Unit, Rome, Italy, 4IRRCS San Raffaele Scientific Institute, Emerging Bacterial Pathogens Unit, Division of Immunology and Infectious Diseases, Milan, Italy

Background: Screening and treatment for latent tuberculosis infection (LTBI) among asylum seekers (AS) is a key element of tuberculosis (TB) elimination in low incidence countries. Screening strategies are heterogenous among countries and completion rates are known to be low. The E-DETECT project aimed at identifying enablers of the cascade of TB prevention in this population.

Materials/methods: The intervention consisted in a modified centralized, system for LTBI screening in AS in the Province of Brescia, Northern Italy. During the intervention phase, all the steps of the LTBI screening cascade were performed at a single site. The cascade consisted of an initial tuberculin skin test (TST) followed, if reactive ≥10 mm, by a confirmatory IGRA. Subjects with double positive tests performed a chest X-ray and those without any abnormality started an LTBI regimen of rifampicin/isoniazid for three months. Results were compared with historical data in the same setting, with similar procedures, but with a fragmented site (consultations at at least three health sites with independent management).

Results: In 2017-2018, 1,356 AS arrived in Brescia. They were mainly male (1178, 86.8%) from sub-Saharan Africa (1034, 76.2%) with mean age of 23.1 (SD 10) years. The standard LTBI screening organization was offered to 1,206 (88.9%) AS at arrival, while 145 (10.7%) received the intervention approach. LTBI diagnosis was more frequent in delayed screening (28.9% vs 17.7%, OR 1.89 p<0.01) without difference in the number of AS coming from high incidence TB countries (cut-off 150/100,000). Screening completion rate was significantly higher during the intervention (98.6% 143/145 vs. 55.1% 665/1206 OR 63.64, p<0.01). Treatment initiation rate also increased in the intervention phase (100%, 42/42 vs 83.6%, 87/104), as well as treatment completion (88.1%, 37/42 vs 71.3%, 62/87, p<0.05).

Conclusions: The LTBI cascade among AS can be significantly improved by a centralized approach to treatment and screening practices. Higher prevalence of LTBI in delayed screening could reflect recent (either during travel or in Italy) acquisition of the infection.

Abstract 7613

**Delafloxacin activity against moxifloxacin-resistant *Clostridiodes difficile* clinical isolates**

Salud Rodríguez-Pallarés¹, Fatima Galan-Sanchez¹, Jorge Arca Suárez¹, Fátima Cano¹, Manuel Rodriguez-Iglesias¹

¹Hospital Universitario Puerta del Mar, Cádiz, Spain

**Background:** *Clostridioides difficile* infection (CDI) is the leading cause of antibiotic associated diarrhea in hospitalized patients worldwide. Fluoroquinolone resistance in *C. difficile* has been blamed to play a key role not only in the occurrence or recurrence of the disease, but also to contribute to the selection of epidemic strains in the hospital environment. Recently the anionic fluoroquinolone delafloxacin has been approved by the FDA. Its combined structural features directly impact on the activity of delafloxacin, with very low minimal inhibitory concentrations against a large array of grampositive and gramnegative organisms and may explain its enhanced potency at acid pH. The aim of this study is to evaluate the activity of delafloxacin against a collection of *C. difficile* with moxifloxacin-resistant phenotype.

**Materials/methods:** Fifteen isolates of *C.difficile*, recovered from non-formed stool specimens from patients with suspected CDI at the Hospital Universitario Puerta del Mar, Cádiz, Spain, with moxifloxacin MICs≥32 ug/ml were included in the study. Susceptibility to moxifloxacin and delafloxacin were determined by the E-test method. Total bacterial DNA extraction was carried out using the EZ1 Advanced XL (Qiagen). The clonal relatedness of the 15 clinical isolates was assesed by PCR-ribotyping. The *C. difficile* PCR ribotypes001, 014, 078, and the epidemic NAP1/027 were used as references. The presence of mutations in the QRDR was assessed by partial sequencing of the *gyrA* and *gyrB* genes.

**Results:** Delafloxacin was more active than moxifloxacin (range 0.01-2 μg/ml; MIC₅₀ and MIC₉₀, 0.38 and 0.75 μg/ml, respectively). Four isolates belonged to ribotype 078, which was the most prevalent (26.6%), followed by ribotype 014 (13.3%). None of the isolates belonged to ribotype 027. The aminoacid substitution Thr82Ile in the *Gyr* A was found in the majority of the isolates (14/15). Six different mutations outside the QRDR of *Gyr*A were also found. Evaluation of the *Gyr*B sequences revealed the presence of mutations in eight isolates, located outside the QRDR.

**Conclusions:** Delafloxacin was active against non-027 moxifloxacin-resistant *C. difficile*, with 100% of isolates being inhibited by delafloxacin at ≤1 μg/ml. Classical Thr82 to Ile substitution, the main genetic event leading to high-level resistance to quinolones, seems not to affect delafloxacin.

**Background:** We aimed to predict which microorganisms would be isolated in our hematological patients' cultures at febrile neutropaenia (FN) onset in order to personalize empirical antibiotic treatments.

**Materials/methods:** A total of 1.11 billion pieces of high-quality data retrieved from electronic health records concerning consecutive episodes of FN at a tertiary hospital in Barcelona were used to feed-forward 4 neuronal networks (NNs). Patients were classified per their predicted risks of infections caused by: 1) *Pseudomonas aeruginosa* (PA) 2) PA multidrug-resistant (MDR) 3) ESBL-Enterobacteriaceae or 4) none of the prior. In the first retrospective phase, algorithms were trained with 70% of the data and tested with the other 30% (2008-2017). In the second phase (2018), the algorithms worked within a prospective setting.

**Results:** A total of 2263 FN episodes were documented [2067 retrospective/196 prospective]. Bacterial infections were documented in 497 patients, with the majority (355, 71.4%) being positive blood cultures. Overall, 104 patients had PA infection, 54 PA-MDR, 49 ESBL-Enterobacteriaceae, and 2111 none of the prior infections. Table 1 summarizes the sensitivity, specificity, positive prediction value, and negative predictive value of NN predictions provided in both the retrospective and prospective phases of the study.

**Conclusions:** NNs analyzing a large amount of high-quality data obtained from EHRs are helpful in predicting which microorganisms will be reported in our patients' cultures. This tool serves as a revolutionary approach, maximizing the power of an artificial intelligence decision support system to personalize empirical antibiotic treatments.

Prevalence of ST131 in community-acquired Escherichia coli urinary tract infections in Gauteng, South Africa

Keegan John Hoog1, Johann Pitout2, Ebrahim Hoosien3, Marthie M. Ehlers1, Marleen Kock*1

1University of Pretoria, Pretoria, South Africa, 2University of Calgary, Calgary, Canada, 3Ampath, Centurion, South Africa

Background: The spread of the pandemic clone, ST131 extra-intestinal pathogenic Escherichia coli (ExPEC) harboring resistance to cephalosporins and fluoroquinolones poses a great risk to patient health. The dissemination of the ST131 E. coli clone and the diversity of its drug resistant associated clades has not been widely documented in South Africa. A study was designed to characterize community acquired E. coli urinary tract infections (UTIs) acquired from a private diagnostic laboratory in South Africa during a three-day period in October 2019.

Materials/methods: A multiplex PCR screened isolates for the E. coli specific gene uidA and ST131-specific single-nucleotide polymorphisms in genes mdh and gyrB. Isolates that screened positive for ST131 were subjected to a published ST131 clade PCR assay for the identification of ST131 clades A, B and C (including subclades C1, C2 and C1-M27).

Results: From the 232 isolates recovered from the diagnostic laboratory, the overall prevalence of pure ST131 E. coli isolates was 17% (n=37). The clade diversity of the ST131 isolates included subclades C1 (n=23), C2 (n=8), clade A (n=3) and subclade C1-M27 (n=3). No isolates screened positive for clades B or C0.

Conclusions: The rapid method for detection of ST131 and its subclades allows for easy surveillance of the dissemination of highly-epidemic pathogen strains as well as their associated antibiotic genes. Clade C of ST131 is of high concern due to the presence of fluoroquinolone resistance in the clade as well as the beta-lactamase cefotaximase-Munich-15 in subclade C2 and presence of the IncF1: A2: B20 plasmids in subclade C1. The presence of the global C1 subclade C1-M27, which is associated with blaCTX-M-27, further poses risk of increased antibiotic resistance. Our results highlight, for the first time, the diversity of the high-risk ST131 ExPEC clone, with associated antibiotic resistance, circulating amongst communities in South Africa. Proper infection control strategies and future vaccination against certain strains would limit the spread of these high-risk clones.

Abstract 7618

18 years of surveillance of nasopharyngeal pneumococcal carriage before, during, and after PCV7 then PCV13 implementation in children with acute otitis media

Robert Cohen*, Corinne Levy*, Naim Ouldali, Stéphane Béchet, Joel Gaudelus, Isabelle Hau, François Angoulvant, Bidet Philippe, Stéphane Bonacorsi, Emmanuelle Varon

1Hospital Center Intercommunal De Créteil, Créteil, France, 2IMRB Paris Est University, Créteil, France, 3Robert Debré Hospital, Paris, France, 4Bondy hospital, Bondy, France, 5Necker Hospital, Paris, France

**Background:** To determine whether the use of 7-valent pneumococcal conjugate vaccine (PCV7) then 13 valent (PCV13) caused a shift in *Streptococcus pneumoniae* serotypes distribution and influenced the antibiotic susceptibility.

**Materials/methods:** Between 2001 and 2019, 121 pediatricians obtained nasopharyngeal swabs from children with acute otitis media aged 6 to 24 months. The swabs were analyzed by the French National Reference Centre for Pneumococci. Demographics, medical history and physical examination findings were recorded.

**Results:** From the 10,740 nasopharyngeal swabs, we observed a slight reduction in the overall pneumococcal carriage, a marked decrease of vaccine serotypes (VT), and an increase in non-vaccine serotypes (NVT). Among the VT, the only serotype still carried at a low level (<3%) were 19F, 19A, and 3. The most frequently (5 to 10%) carried NVT were 15B/C, 23B,11A,15A,10A, and 35B. A significant reduction (40%) in the rate of penicillin-non susceptible (PNSP) strains has been observed. PNSP were mostly represented by NVT 35B, 11A and 15A. No penicillin resistant strain has been found since 2016.

**Conclusions:** Since the PCV13 implementation, in carriage, replacement appears almost complete, the serotype distribution tending to a new equilibrium without emergence of highly resistant pneumococci to date.

**High-resolution mass spectrometry database (Acrion) improves identification of clinical yeasts**

Joanna Freeke1,2, Azadeh Jamalian1,2, Ivan Moser2, Alejandra Giraldo Lopez2, Juha Knuuttila3, Otso Niiranen3, Benjamin Stielow1,2, Sybren De Hoog2,4

1Thermo Fisher Scientific, Microbiology Mass Spectrometry, Landsmeer, Netherlands, 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands, 3Thermo Fisher Scientific, Microbiology Mass Spectrometry, Helsinki, Finland, 4Radboud University Medical Center, Nijmegen, Netherlands

**Background:** Yeast species are frequently identified by MALDI-ToF in the clinical laboratory. Due to their cell wall structure, they give higher quality identifications when they are prepared with manual lysis steps either offline or on the MALDI-ToF plate. While highly effective, it adds both sample preparation time and variability between laboratories, such that protein databases are sometimes less effective elsewhere. A second variability comes from the accuracy of the protein masses, dependent on the mass spectrometer used. By decreasing the mass resolution, the universality of the database improves, but the likelihood of false matches rises, yielding reduced species identification accuracy. We explore the performance a novel integrated high resolution mass spectrometer (HRMS) with automation and a spectral database to investigate whether the Acrion™ system can overcome these two sources of variability and improve yeast identification accuracy.

**Materials/methods:** 37+ clinical yeast species, multiple strains each, were cultured on saboraud dextrose agar and measured with a HRMS to create a comprehensive database of protein masses against which unknown strains could be identified. These measurements were collected with a resolution of <10 ppm, and protein masses in the range of 5-30 kDa were detected for each strain. A classifier was created to identify species. A test set of strains [not used in classifier development] were measured on the Acrion™ system and classified to species level.

**Results:** A comprehensive HRMS database covering clinical yeast species causing >95% of yeast infections was developed. In the highly-automated workflow for this system, hands on time for the sample preparation is limited to sample picking (<30 seconds per sample) and user handling variability is thereby reduced. The HRMS analysis yielded good performance and discrimination even between challenging taxa; for example, we challenged the database with strains from each of the C. auris global lineages and all strains identified correctly.

**Conclusions:** By reducing the user and system variability through automated sample processing we were able to realise the improvement that high resolution mass spectrometry can yield in yeast species identification. Key to this was a comprehensive database enabling discrimination between challenging taxa that are frequently mis-identified in the clinical laboratory.

Limited multidrug-resistant efflux pump overexpression among multidrug-resistant Escherichia coli of ST131
Johannes Camp*1, Sabine Schuster1, Martina Vavra1, Tobias Schweigger1, John Rossen2, Winfried Kern1

1Freiburg University Medical Center, Division of Infectious Diseases, Department of Medicine II, Faculty of Medicine, Freiburg im Breisgau, Germany, 2University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: The development of multidrug resistance (MDR) phenotypes among bacteria presents a threat for patients and an ever-growing challenge for physicians. Gram-negative bacteria rely partly on efflux pumps to facilitate growth under stressful conditions and to increase resistance to a wide variety of commonly used drugs. Over the past years E. coli ST131 has emerged as a major cause of extraintestinal infection frequently exhibiting an MDR phenotype. The contribution of efflux to MDR in emerging E. coli MDR clones however, is not well studied.

Materials/methods: We investigated 34 strains from an international collection of clinical MDR-E. coli isolates within the framework of the Innovative Medicines Initiative (IMI) project “translocation”. Phenotypic analyses included MIC testing with and without addition of the AcrAB-TolC efflux inhibitor 1-(1-naphthylmethyl)-piperazine (NMP). MIC data for in total 17 agents and their reversion by NMP were analysed by Principal Component Analysis (PCA) in order to identify an efflux phenotype. Whole genome sequencing (WGS), multilocus sequence typing (MLST) and qRT-PCR of multiple efflux-related genes were performed.

Results: PCA revealed a group of 18/34 MDR-E. coli exhibiting increased susceptibility to treatment with NMP suggesting enhanced contribution of efflux pumps to antimicrobial resistance in these strains. This phenotype was termed “efflux phenotype”. Conversely, MICs in 16/34 strains remained relatively unchanged after treatment with NMP. In the latter group 11/16 strains belonged to the ST131, whereas in the former only 2/18 did. WGS revealed marked differences in efflux-related genes, with the majority of notable amino-acid substitutions occurring in AcrR, MarR and SoxR. Analysis of qRT-PCR data showed that strains exhibiting the “efflux phenotype” showed a significant overexpression of the AcrAB-TolC system, whereas in the remaining strains we found a trend towards enhanced expression of alternative efflux proteins (Figure 1).

Conclusions: We conclude that a proportion of MDR-E. coli exhibit an “efflux phenotype” which is linked to an overexpression of the AcrAB-ToIC-efflux-pump. Associated with this phenotype we find distinct genomic variations that could together be viewed as constituting an “efflux genotype”. Members of the ST131 are less likely to exhibit the “efflux-phenotype” which bears potential implications for the management of the ST131 pandemic.

A combined strategy of antimicrobial stewardship and hospital-acquired infection control reduced the incidence of bacterial infection in a kidney transplantation programme (Hippomenes-PACTA-PROA study)

Juan Montoro\(^1\), Francisco Lopez-Medrano*\(^1\), María Asunción Pérez-Jacoiste Asín\(^1\), Mario Fernandez Ruiz\(^2\), Jose Tiago Sequeira\(^3\), Rafael San Juan Garrido\(^1\), Esther Gonzalez\(^1\), Amado Andres\(^1\), Jose M. Aguado Garcia\(^1\)

\(^1\)University Hospital 12 de Octubre, Madrid, Spain, \(^2\)Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain

**Abstract**

Infection is a major complication in kidney transplant recipients (KTR), compromising graft and patient survival. Both antimicrobial stewardship programs (ASP) and hospital-acquired infection control (HAIC) initiatives have demonstrated their utility in reducing the incidence of infection in the overall hospital population. We performed a quasi-experimental study to evaluate this combined approach in the setting of KTR.

**Background:** Infection is a major complication in kidney transplant recipients (KTR), compromising graft and patient survival. Both antimicrobial stewardship programs (ASP) and hospital-acquired infection control (HAIC) initiatives have demonstrated their utility in reducing the incidence of infection in the overall hospital population. We performed a quasi-experimental study to evaluate this combined approach in the setting of KTR.

**Materials/methods:** During the intervention period (June 2015-March 2016) an ASP was developed by a dedicated Infectious Diseases specialist who reviewed all antimicrobial treatments among consecutive KTR admitted to the hospital and made recommendations to optimize therapy. An intensive HAIC program was concurrently implemented to reinforce actions among healthcare workers oriented to decrease in-hospital spread of multidrug resistant microorganisms (MDR). The main study outcomes were days of treatment (DOT) for some relevant antimicrobials and incidence rates of overall and MDR infection per 1,000 transplant-days. Results in the intervention cohort were compared with a historical pre-intervention cohort of KTR during the immediately preceding period (June 2014-March 2015). Both cohorts were followed-up for 6 months after transplantation.

**Results:** We included 100 KTR (mean age: 53 years; 70% males) in the intervention cohort and 100 KTR in the pre-intervention cohort. During the intervention period there was a reduction in the consumption of meropenem (incidence rate ratio [IRR]: 0.61; 95% confidence interval [CI]: 0.51-0.72; \(p<0.001\)), vancomycin (IRR: 0.62; 95% CI: 0.5-0.77; \(p<0.001\)) and ciprofloxacin (IRR: 0.64; 95% CI: 0.52-0.78; \(p<0.001\)), and an increase of ceftriaxone (IRR 2.44; 95% CI: 2.0-3.0; \(p<0.001\)) and fosfomycin (IRR: 2.0; 95% CI: 1.3-3.2; \(p=0.001\)). There was a reduction in the incidence of global bacterial infection (IRR: 0.53; 95% CI: 0.35-0.82; \(p=0.002\)) and, specifically, upper urinary tract infection (IRR: 0.51; 95% CI: 0.28-0.90; \(p=0.01\)) and cystitis (IRR: 0.37; 95% CI: 0.15-0.83; \(p=0.01\)). A non-significant trend for a lower incidence of infection due to extended-spectrum beta-lactamase-producing Enterobacteriaceae was observed (IRR: 0.53; CI 95% 0.20-1.34; \(p=0.15\)). No differences were found for incidence rates of bloodstream or *Clostridioides difficile* infection.

**Conclusions:** A multifaceted approach based on ASP and HAIC was effective to optimize the use of antimicrobials and to reduce the incidence of bacterial infection among KTR.

Abstract 7623

**The role of mobile genetic elements and virulence factors in the typing of vancomycin-resistant Enterococcus faecium outbreak isolates of a successful MLST ST117 cluster type 24**

Paola Lisotto*1, Natacha Couto1, Sigrid Rosema1, Mariëtte Lokate1, Xuwei Zhou1, Erik Bathoorn1, Hermie J.M. Harmsen1, Alexander W. Friedrich1, John Rossen1, Monika Chlebowicz1

1University Medical Center Groningen, Groningen, Netherlands, 2University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

**Background:** The vancomycin-resistant E. faecium (VREfm) is a successful nosocomial pathogen able to survive in hostile environments, ultimately causing hospital outbreaks. The rapid emergence of certain VREfm lineages makes it difficult to distinguish isolates based on the core genome. Here we explored if characterization of mobile genetic elements and virulence factors of VREfm isolates from two different outbreaks belonging to the same cgMLST CT24 could be useful for typing.

**Materials/methods:** Twenty-eight E. faecium isolates from patient and environmental samples from two different outbreaks in 2014 and 2017 were sequenced with Miseq of which two isolates were also sequenced using MinION. De novo assemblies were performed in CLC Genomics Workbench and the hybrid assemblies were obtained through Unicycler. The genomes were analyzed by molecular typing (using SeqSphere) and investigated for known E. faecium virulence factors (VirulenceFinder), antimicrobial resistance genes (ResFinder), bacteriocins (BAGEL4), and prophages (PHASTER).

**Results:** All isolates belonged to the MLST ST117, CT24. They were resistant to vancomycin, trimethoprim, macrolides (except for one isolate in which the ermB gene was absent) and aminoglycosides. cgMLST analysis showed that the isolates belonged to two distinct genetic clusters with a minimal allelic difference of 10 between the closest related isolates of each cluster. The vanB carrying transposon Tn1549 was present in all isolates, however its genomic position was different between isolates 2014 and 2017. The gene conferring resistance to Chloramphenicol (cat) was exclusively present in isolates from the 2014 outbreak. All isolates contained the adhesion factors acm, efaAfAm and Esp. In all genomes, Enterocin A and Enterolysin A were identified, but isolates from 2017 additionally contained bacteriocins: Enterocin P, Bac43, Bacteriocin78 and HiracinJM3. In the majority of investigated isolates, three main plasmid families (Inc18, RepA_N and Rep3) were identified. Finally, all isolates carried three prophages: Entero_phiFL1A, Entero_EFAP-1 and Lister_238. In the majority of investigated isolates, three main plasmid families (Inc18, RepA_N and Rep3) were identified. Finally, all isolates carried three prophages: Entero_phiFL1A, Entero_EFAP-1 and Lister_238. Interestingly, isolates of 2014 additionally carried two phages: Entero_vbIME-197 and EnteroIMEEFm-5 while isolates of 2017 contained Lactoc_TP901-1.

**Conclusions:** Closely related isolates from separate VRE outbreaks could be distinguished by phage typing and different genomic location of the Tn1549 carrying vancomycin resistance. Also, the arsenal of bacteriocins was unique for the isolates of each outbreak cluster.

Incidence of hospital-acquired bloodstream infections caused by *Klebsiella pneumoniae* and impact of different preventive strategies: need to going back to basics?

Federico Tassinari¹, Matteo Astengo¹, Alberto Battaglini¹, Francesca Butera¹, Giovanni Noberasco¹, Irene Schenone*¹; Daniela De Florentis², Angela Battistini¹, Laura Sticchi¹, Giancarlo Icardi¹, Andrea Orsi¹

¹Department of Health Sciences, University of Genoa, Genoa, Italy, ²Hygiene Unit, San Martino Policlinic Teaching Hospital, Genoa, Italy

**Background:** *Klebsiella pneumoniae* (Kp) is a frequent cause of hospital acquired bloodstream infections (HA-BSI), as well as a challenging pathogen due to its intrinsic or acquired antimicrobial resistance. Surveillance of Kp epidemiology still provides valuable information for its prevention and control.

**Materials/methods:** We conducted a retrospective observational study at the 1200 acute-care beds “San Martino” Policlinic Hospital, located in Genoa, Liguria, North-West Italy. We analyzed all patients with an HA-BSI caused by Kp from January 2008 to December 2018. Incidence was reported as number of events per 10,000 patient-days.

**Results:** We observed 994 Kp-related HA-BSIs during the study period, 610 caused by carbapenem resistant Kp (CRKp) and 384 by non-carbapenem resistant Kp (nCRKp).

Patients’ median age was 69 years (IQR 58-77), without differences between the two groups. Median onset time and median length of hospital stay were, respectively, 23 and 50 days for CRKp and 18 and 39 days for nCRKp group. Survival was significantly lower in CRKp group ($\chi^2$ p < 0.05 for 7th days all-cause mortality and p < 0.001 for 30th days all-cause mortality). Trends of CRKp and nCRKp incidence rates were different: while CRKp HA-BSIs increased from zero in 2008 to 2.12 in 2015 and then decreased to 0.81 in 2018, nCRKp HA-BSIs trend show a slow grow from 0.62 in 2008 to 1.21 in 2018. Stratifying this data for ward specialty we observed that intensive care units showed the highest incidence for CRKp HA-BSI, with a nadir observed in 2010 (25.47) followed with a marked decrease in the last years (6.94 in 2018).

In Figure 1 we reported the annual incidence of CRKp and nCRKp HA-BSIs observed at “San Martino” Policlinic Hospital and the chronological sequence of the main preventive intervention implemented in the period.

**Conclusions:** Although incidence of CRKp HA-BSI considerably decreased during the last years, the slow and steady increase of nCRKp in our hospital highlights the need to reconsider all the intensified strategies implemented to prevent and control Kp HA-BSI, focusing our attention on a stricter adherence to standard precautions and going back to the basics of prevention.

Seasonal patterns in the burden of common bacterial pathogens in south-east Michigan post-acute care facilities

Marco Cassone1, Julia Mantey1, Kyle Gontjes2, Bonnie Lansing1, Kristen Gibson1, Lona Mody3

1Department of Internal Medicine, University of Michigan, Ann Arbor, United States, 2School of Public Health, University of Michigan, Ann Arbor, United States, 3Department of Internal Medicine, University of Michigan, Geriatric Research and Education Clinical Center, Ann Arbor VA, United States

Background: Knowledge of specific pathogens’ seasonal incidence patterns can improve epidemic surveillance and guide timing and efficacy of infection prevention initiatives. Influence of seasonal patterns on colonization with key pathogens among high-risk older adults in institutional settings is unknown. Through longitudinal screening of older post-acute care (PAC) patients and their immediate environment for two consecutive years, we investigated seasonal variation in patient and environmental burden of common bacterial pathogens in 6 SE Michigan PAC facilities.

Materials/methods: 1370 patients were screened between December 2013 and December 2015. Consenting patients’ hands, nares, groin, oral cavity, perianal area, and room objects (side table, bed control, call button, curtain, TV remote control, railing, toilet seat, wheelchair, door knob) were sampled for vancomycin-resistant enterococci (VRE), methicillin-resistant Staphylococcus aureus (MRSA), Klebsiella pneumoniae, ciprofloxacin sensitive and resistant E. coli. Three-month averaged incidence rates were plotted alongside average maximum temperature for the region.

Results: 418 unique MRSA, 679 VRE, 294 K. pneumoniae, and 443 E. coli were isolated from 640 patients and their rooms. A significant seasonal variation, correlated with regional monthly temperatures with a 1-month lag was observed for K. pneumoniae in patient and room isolates (0.17 and 0.19 unique isolates, respectively, per newly admitted patient and room in March, doubling to 0.34 and 0.38 in July).

Interestingly, there were marked seasonal differences between ciprofloxacin-susceptible and ciprofloxacin—resistant E. coli isolates, and only for the latter the trend was correlated to average regional temperatures (0.08 for patients and 0.02 for rooms in January, more than doubling to 0.19 and 0.09 respectively in June-July). The ratio between incidence of resistant and susceptible E. coli reached a trough of 0.26 in January, and doubled in May-July [up to 0.54]. No clear seasonal variation was observed for MRSA and VRE.

Conclusions: We report seasonal variability in two common gram-negative pathogens in high-risk post-acute care patients, and observe that antimicrobial-resistance may affect such patterns. Unlike some previous reports in hospitals, we did not observe seasonality patterns in MRSA and VRE among our post-acute care patients. Further investigation is warranted on the causes and geographical extension of such patterns in PAC.

Abstract 7631

**Participatient: Patient Engagement Counter Catheter-associated urinary tract infections with an App (PECCA)**

Robbert Bentvelsen\*1,2, Bart Laan3, Suzanne E. Geerlings3, Niels H. Chavannes4, Karin Ellen Veldkamp1

1Leiden University Medical Center (LUMC), Clinical Microbiology, Leiden, Netherlands, 2Amphia Hospital, Clinical Microbiology, Breda, Netherlands, 3Amsterdam UMC, Internal Medicine, Infectious Diseases, Amsterdam, Netherlands, 4Leiden University Medical Center (LUMC), Public Health and Primary Care, Leiden, Netherlands

Abstract third-party references: The Netherlands Organisation for Health Research and Development; project 522004007

**Background:** Catheter-associated urinary tract infections (CAUTI) are the main cause of healthcare associated infections (HAI), leading to additional morbidity, increased antibiotic use and prolonged hospital stay. Inappropriate indication of a urinary catheter and avoidable prolongation of use causes for an increased and preventable risk of infection. This project aims to reduce unnecessary use of urinary catheters.

**Materials/methods:** In a multicentre, interrupted time series study, the smartphone application for patients called ‘Participatient’ (ECCMID2018:P0243) is introduced on thirteen wards in four hospitals in the Netherlands. The fraction of inappropriate use of urinary catheters is the primary endpoint. Secondary endpoints are catheter use and (CA)UTI reduction; increase in patient satisfaction-, involvement-, and trust in health care; measure and improve patient satisfaction with the Participatient app; and obtain analytical data on app use to optimize usefulness and ease of use. Data was collected every other week. This resulted in 12 data points during both the baseline and the post-intervention phase, of both 6 months. Preliminary analyses compared incidence rates before and after the intervention.

**Results:** Data were obtained from 6556 observed patients. App use was 9% of admitted patients, with a range of 6-12% between hospitals. The rate of inappropriate indication for use of urinary catheters dropped from 21.9% (n=175; 95%CI: 19.2-24.9%) to 7.0% (55; 5.4-9.0%) (P<0.0001; OR 0.27; 95%CI: 0.19-0.37). The overall urinary catheter prevalence was stable around 24% (798/3285 to 786/3271). The UTI rate decreased from 8.1% (267) to 4.9% (161), with CAUTI cases nearly halved from 141 to 78. Subsequent analyses will take into account the trends in the time series design, subgroup analyses, and eHealth outcomes.

**Conclusions:** The Participatient bundled eHealth intervention reduces unnecessary use of urinary catheters, with a substantial reduction in catheter-associated UTI. Patient involvement in infection prevention via eHealth is an effective way to improve the quality of care.

Does selective mandatory vaccination affect vaccine coverage of recommended vaccinations?
Giovanni Rezza*, Paolo D’ancona1, Stefania Iannazzo1

1Department of Infectious Diseases, Istituto Superiore di Sanità, Roma, Italy, 2Prevention Directorate, Ministry of Health, Roma, Italy

Abstract 7632

Background: Maintaining high vaccination coverage is important in order to protect the individual and the community. Mandatory vaccination is an option in case of declining coverage. Widely used in the USA, it is considered a rather controversial issue in Europe. In Italy, after a decrease of vaccination coverage for the hexavalent [tetanus, diphtheria, pertussis, polio, hemophilus influenzae, and HBV] and the MPR vaccine under the optimal threshold, a new law which extended the number of mandatory vaccines from 4 to 10 and reinforced coercive measures, was introduced on July 2017.

Materials/methods: Vaccine specific data were collected at the Regional level and reported to the Ministry of Health. The information is analyzed in collaboration with the Istituto Superiore di Sanità in Rome. To the purpose of this analysis, data collected before and after the introduction of the law were compared (2016 and 2018, respectively).

Results: After two years, vaccination coverage increased for all mandatory vaccines. Interestingly, vaccination coverage increased also for other two recommended vaccines [from 89% to 92% for anti-pneumococcal and from 81% to 85% for anti-meningococcal C vaccination in 2016 and 2018, respectively]. Vaccination coverage for HPV, which is included among the recommended vaccines for the adolescents in the National Plan but is not listed among recommended vaccines in the law, remained at relatively low vaccination coverage levels.

Conclusions: Although it is not possible to disentangle the role of other factors contributing to the positive outcome, consistently with the results of studies conducted in the USA, vaccine mandates appeared to be successful in increasing vaccination coverage in Italy for both mandatory and recommended vaccinations. The long-term sustainability of the effect of mandatory vaccination and the potential negative drawbacks of the coercive measures need to be evaluated to generate scientific evidence in public health.

Abstract 7637

**Ranking antibiotic classes by their potential impact on in-hospital selection of resistance: an ecological approach**

Julie Teresa Shapiro*1, Leboucher Gilles1, Anne-Florence Myard-Dury1, Pascale Girardo1, Anatole Luzzati2, Mélissa Mary1, Jean Francois Sauzon1, Bénédicte Lafay3, Olivier Bauwalder4, Frédéric Laurent1,4, Gerard Lina1,4, Christian Chidiac6, Sandrine Couray-Targe1, François Vandenesch1,4, Flandrois Jean Pierre5, Jean-Philippe Rasigade1,4

1University of Lyon, CIRI INSERM U1111 - CNRS UMR5308 - ENS Lyon, Lyon, France, 2Hôpitaux Civils de Lyon, Département de Pharmacie, Lyon, France, 3Hôpitaux Civils de Lyon, Pôle de Santé Publique, Département d’Information Médicale, Lyon, France, 4Hôpitaux Civils de Lyon, Institut des Agents Infectieux, Lyon, France, 5University of Lyon, Laboratoire de Biométrie et Biologie Évolutive, Villeurbanne, France, 6Hôpitaux Civils de Lyon, Service des Maladies Infectieuses et Tropicales, Lyon, France

**Background:** Antibiotic stewardship is a cornerstone strategy to combat antimicrobial resistance (AMR). However, evidence is scarce concerning which antibiotics have the strongest global impact on AMR and should be restricted first. Here, we leverage ecological modeling of hospital-based data to estimate the potential effect of 9 classes of antibiotics on the cumulative incidence of bacterial infections with resistance to either third-generation cephalosporins (3GCs) or carbapenems.

**Materials/methods:** Data were collected in 2016-17 from 357 wards in 4 hospital groups in Lyon, France. Using the ward as the statistical unit, we calculated the cumulative incidences of infection with ESKAPE pathogens and *Escherichia coli* with intrinsic or acquired resistance to 3GCs and carbapenems (3GCR and CR infections, respectively; total = 4,089). Ward-specific antibiotic pressure was estimated from consumption data for 9 antibiotic classes including cephalosporins, carbapenems or fluoroquinolones. We used Poisson regression in a metapopulation ecology framework to model the relationship between antibiotic consumption and the incidence of 3GCR and CR infection. Models were adjusted for sampling bias and the estimated frequency of introduction of 3GCR and CR pathogens from other wards.

**Results:** Consumption volumes of 3 out of 9 antibiotic classes had a positive and significant association with the incidence of 3GCR or CR infections: non-antipseudomonal 3GCs (CTX/CRO), carbapenems and piperacillin-tazobactam (TZP). 3GCR incidence was predicted by CTX/CRO and TZP use, but not carbapenems. CR incidence was predicted by carbapenems and TZP use, but not CTX/CRO. Strikingly, TZP coefficients outweighed other coefficients by a large margin in terms of amplitude and significance in both models.

**Conclusions:** Our approach illustrates how ecological modeling can be used to analyze hospital-wide data on infection incidence and antibiotic consumption while controlling for major sources of bias, including pathogen introduction from other wards. The controlled models identified a strong association between TZP use and the incidence of both 3GCR and CR infections in our setting. This is intriguing because TZP has been repeatedly considered as an alternative drug of choice in carbapenem-sparing strategies. If confirmed in other settings, our findings might call for a reevaluation of the rationale of recommending TZP over other drugs for ecological reasons.

Estimation of cystic echinococcosis prevalence in an endemic region in Uzbekistan

Agnese Colpani1*, Olesya Achilova2, Gian Luca D’alessandro1, Christine Budke3, Mara Mariconti4, Ambra Vola4, Arzu Mamedov2, Maria Teresa Giordani5, Enrico Brunetti1*, Uktamjon Suvonkulov2, Tommaso Manciulli1

1University of Pavia, Department of Clinical, Diagnostic and Pediatric Sciences, Pavia, Italy, 2L.M. Isaev Research Institute of Medical Parasitology, Samarkand, Uzbekistan, 3Texas A&M University, College Station, United States, 4IRCCS San Matteo Hospital Foundation, Unit of Infectious Diseases, Pavia, Italy, 5San Bortolo Hospital Of Vicenza, Department of Infectious Diseases, Vicenza, Italy

Background: Cystic echinococcosis (CE) is a cosmopolitan zoonosis caused by the tapeworm Echinococcus granulosus. While Uzbekistan and other countries in Central Asia are considered endemic, estimates of disease burden are lacking. We present findings from a cross-sectional, ultrasound-based survey evaluating the prevalence of CE in the Samarkand region of Uzbekistan.

Materials/methods: Study villages were selected based on the presence of human cases recorded by the national CE surveillance system. The survey was conducted in September 2019 in the Payaroq district of Samarkand in six rural communities. Residents aged 5 to 90 years underwent a free ultrasound examination of the abdomen. The World Health Organization-Informal Working Group on Echinococcosis (WHO-IWGE) classification was used to stage cysts. During the survey, information was also collected on individuals who had been previously diagnosed with CE and surgically treated.

Results: Over a total population of 34,968 inhabitants, 2,057 individuals (5.88%) agreed to undergo an abdominal ultrasound. Of these, 498 were males (24.2% males). Thirteen patients had abdominal CE (0.63%). Four of the 13 had previously been surgically treated for CE, while one was currently undergoing treatment with albendazole while awaiting surgery for an inactive cyst. In total, there were 5 active and transitional cysts (1 CE1, 1 CE2, 3 CE3b) and 10 inactive cysts (8 CE4, 2 CE5). Four patients had CL lesions and are currently receiving a one month course of albendazole as part of their diagnostic algorithm. Twenty-seven additional individuals reported previously undergoing surgery for CE. Surgeries had been conducted to remove CE cysts from the liver (67.7%), lungs (14.8%), spleen (3.7%), and liver and lungs (14.8%).

Conclusions: Our findings confirm the presence of CE in the Samarkand region of Uzbekistan. Surgical overtreatment of CE patients appears to be common and no conservatively managed patients were found even though most cysts were inactive. Further studies on the epidemiology of CE in Uzbekistan are needed. The local medical community must also be informed about current standards for the clinical management of this neglected disease.

Abstract 7639

**Antimicrobial stewardship in oral and maxillofacial surgery: melting the iceberg**

Insa Joost*1, Melanie Kempe2, Lara Schorn3, Colin R. Mackenzie4

1Düsseldorf, Institute of Medical Microbiology and Hygiene, Heinrich Heine University Düsseldorf, Düsseldorf, Germany, 2Düsseldorf, Pharmacy Department, University Clinic Düsseldorf, Düsseldorf, Germany, 3Düsseldorf, Department of Oral and Maxillofacial Surgery, University Clinic Düsseldorf, Düsseldorf, Germany

**Background:** Irrational antibiotic consumption leads to increasing antimicrobial resistance, significant side effects for patients and rising costs. The key aim of modern antimicrobial stewardship (AMS) is the rational antibiotic use by implementing restrictive as well as supporting measures. In oral and maxillofacial surgery, national or international guidelines regarding antibiotic prophylaxis and therapy are lacking for many clinical entities and antibiotic consumption is traditionally high.

**Materials/methods:** We determined the antibiotic consumption in the Oral and Maxillofacial Surgery clinic of a large German university hospital by using defined daily dose (DDD) per 100 patient days. We then implemented weekly ward rounds by a member of the AMS team, recording data from all patients [name, date of admission, diagnosis, indication, substance, route of application, duration of antibiotic therapy]. Recommendations regarding antibiotic therapy and/or further diagnostics were given. A mandatory consensus guideline covering antibiotic prophylaxis and therapy was developed and implemented. We determined the point prevalence of antibiotics prescribed for therapy and prophylaxis.

**Results:** Before the intervention, prevalence was high with up to 90% of patients receiving antibiotics, mainly amoxicillin/clavulanic acid or clindamycin. Median duration of antibiotic therapy and prophylaxis was 12 and 9 days, respectively. Antibiotic consumption was 97.9 DDD/100 patient days. This value was significantly higher than the national estimates [median 78.55 DDD/100 patient days]. During one year of intervention, antibiotic prevalence dropped to below 50% and the duration of antibiotic therapy and prophylaxis was reduced to 7 and 4 days, respectively. Accordingly, antibiotic consumption decreased and is now below the national estimates [Figure 1]. Interestingly, the ratio of patients receiving antibiotic prophylaxis or therapy did not change considerably.

**Conclusions:** Antibiotic consumption is high in oral and maxillofacial surgery. We show that regular ward rounds by the AMS team as well as the development of consensus guidelines can reduce antibiotic consumption substantially. Consensus guidelines furthermore help define quality indicators that can be used to evaluate long term effects of the AMS measures. However, such interventions are time-consuming and require appropriate personal and financial support of the antimicrobial stewardship team.

Implementation of a homegrown electronic antimicrobial prescribing authorisation process at King Abdulaziz Medical City (KAMC) in Saudi Arabia

Nour Shamas*1, Maher Al Ahmadi1, Asim Alsaeedi1,2, Doaa Naeem1, Doaa Aljeefri1, Mohamad Aseeri1,2, Majid Mousa Alshamrani1

1King Abdulaziz Medical City, Jeddah, Saudi Arabia, 2King Saud bin Abdulaziz University For Health Sciences, Jeddah, Saudi Arabia, 3National guard hospital, Riyadh, Saudi Arabia

Abstract third-party references: King Abdulaziz Medical City

Background: The misuse of antimicrobials is multifactorial and is related to knowledge deficits, resource limitations, and socio-behavioral prescribing trends. The Antimicrobial Stewardship Program at KAMC - Jeddah has been working on several interventions to improve antimicrobial prescribing including education, prospective audit and feedback, surgical prophylaxis improvement, and an electronic antimicrobial prescribing authorization (EAPA) process. This study describes the experience of implementing EAPA and its effect on days of therapy (DOT).

Materials/methods: The EAPA process implementation took 4 years in total from theory to implementation. This process involved proposing a workflow, creating electronic authorization request and reply forms embedded into the available prescribing process, an intensive face-to-face education on the workflow to all pharmacists, nurses, and prescribers, and establishing a dedicated team to handle all requests with an initial 24 hour oncall service for the first two weeks of implementation. The detailed reply form ensured complete recommendation documentation and facilitates electronic extraction of appropriateness evaluation and recommendations. The approving team also communicated recommended changes and inquiries to the prescriber. EAPA was piloted on 4 medications during phase 1 and 4 antimicrobials were later added.

Results: From March 2019 till October 2019, an average of 16 consults were automatically generated per working day [Total = 2701 consults]. Days of Therapy (DOT) of all antimicrobials was 927.6/1000 patient days in October 2018 and 779.2/1000 patient days in October 2019. DOT for the restricted antimicrobials was 239/1000 patient days for October 2018, and 123.3/1000 patient days for October 2019. There was a sharp drop in carbapenem utilization, 85.8/1000 patient days to 32.8/1000 patient days. There were no serious safety drug reports relating to the new process.

Conclusions: The EAPA workflow by the ASP at KAMC - Jeddah is effective at reducing inappropriate antimicrobial use. Further evaluation is required to evaluate the reasons for inappropriate prescribing and the long term effect on resistance patterns.

Abstract 7642

**Amikacin nomogram for treatment of adult cystic fibrosis exacerbations based on an external evaluation of a population pharmacokinetics model**

Valérian Pasche¹², Daniel J.G. Thirion¹³, Elias Matouk⁴⁵⁶, Amélie Marsot¹²

¹Faculté de Pharmacie, Université de Montréal, Montréal, Canada, ²Laboratoire de suivi thérapeutique pharmacologique et pharmacocinétique, Faculté de Pharmacie, Université de Montréal, Montréal, Canada, ³Pharmacy Department, McGill University Health Center, Montréal, Canada, ⁴Adult Cystic Fibrosis Clinic, Montreal Chest Institute, McGill University, Montréal, Canada, ⁵McGill University Health Center Research Institute, Montréal, Canada, ⁶Department of Medicine, McGill University, Montréal, Canada

**Background:** Acute pulmonary exacerbations (APE) expose cystic fibrosis (CF) patients to life-threatening complications and contribute to the progression of the disease. The current guidelines recommend treating an APE with a combination of two antipseudomonal agents (beta-lactams and aminoglycosides). Amikacin is gradually used as a therapeutic alternative to tobramycin in patients harboring tobramycin-resistant pathogens. However, no optimal dosing has been described for amikacin despite important pharmacokinetic (PK) changes in adult CF patients. Current amikacin dosing is quite variable across CF accredited care centers. The main objectives of this study were to perform the external evaluation of the single population PK model available and revise amikacin dosing recommendations in adult CF patients if needed.

**Materials/methods:** Demographic, biological and clinical data of adult CF patients treated with amikacin at the McGill University Health Center (Montreal, Canada) were collected retrospectively. The predictive performance of the previously published two-compartment model was evaluated by determining both bias and inaccuracy. The model included creatinine clearance and weight as covariates on clearance and central volume of distribution, respectively. Monte Carlo simulations (n=1000) were performed with different doses [15-45 mg/kg] to determine the optimal regimen in order to reach the target ratio of the maximum serum concentration (Cmax) to the minimum inhibitory concentration (MIC) ≥8 mg/L.

**Results:** The model predicted the central tendency of amikacin concentrations measured in our patient population, that included 19 patients (age: 18-68 y.o.; weight: 28.1 -92.5 kg) treated for 30 APE episodes in total. The values for bias and inaccuracy were sound for clinical application with values of 7.2% (CI 95%: -0.65 - 15.0%) and 18.2% (CI 95%: 12.0 - 24.4%), respectively. The simulations showed that amikacin doses ranging from 20 to 45mg/kg/day should be adjusted according to the patient’s weight and creatinine clearance (Figure1).

**Conclusions:** This model can be generalized to adult CF patients and is suitable for predictive dosing. Initial doses should be adapted according to the patient’s weight and creatinine clearance. We developed a nomogram to optimize amikacin dosing regimens, which should be validated in a prospective study.

![Amikacin nomogram](image)

Abstract third-party references: The authors gratefully acknowledge the financial support of “Fundação para a Ciência e Tecnologia” [FCT – Portugal], through the reference SFRH/B0/133266/2017 [Medicina Clínica e Ciências da Saúde]. This work was financed by “Dirección General de Protección de Lucha Contra el Cambio Climático y Medio Ambiente del Gobierno de Canarias” and also from “Fondo Europeo de Desarrollo Regional [FEDER]”.

Background: Although wild animals are not directly exposed to clinically relevant antibiotics, the antimicrobial resistance in these animals has been increasingly reported worldwide, in parallel to the situation in human and veterinary medicine. The high prevalence of infections with organisms producing extended spectrum β-lactamases (ESBL, particularly those of the CTX-M type) is threatening the future of the β-lactam drugs. This study was carried out to investigate the molecular epidemiology and genetic characteristics of ESBL-producing *E. coli* isolates originating from wild vultures (*Neophron percnopterus var. majorensis*) from Fuerteventura and Lanzarote (Canary Islands), in Spain.

Materials/methods: Fecal samples of 23 apparently healthy vultures were collected during July 2019. Samples were seeded in MacConkey agar supplemented with cefotaxime (2µg/ml), and *E. coli* identification was performed by Maldi-TOF-MS. Antimicrobial susceptibility was done by disk-diffusion (CLSI, 2018), and phenotypic detection of ESBL or carbapenemases were done by double-disk tests. The presence of *blaCTX-M* [different groups], *blaSHV*, *blaTEM*, and *blaOXA-48* genes, as well as *mcr-1* [colistin resistance], *tetA/tetB* [tetracycline resistance] and *int1* gene [integrase of class 1 integrons], was tested by PCR/sequencing. Furthermore, phylogenetic groups and MLST were tested by PCR/sequencing.

Results: ESBL producing-*E. coli* were detected in 6 of the 23 vultures samples (26%). All of them carried *blaCTX-M* genes, specifically: *blaCTX-M-15* (4 isolates) and *blaCTX-M-55* (2 isolates). ESBL-positive isolates were ascribed to phylogenetic group D (2 isolates), B1 (2 isolates) and A (2 isolates), and 4 sequence types were detected [ST/phylogenetic-group/ESBL]: ST1290/A/CTX-M-15, ST38/D/CTX-M-15, ST457/D/CTX-M-55 and ST6448/B1/CTX-M-55; this suggest a genetic diversity among these isolates. Three CTX-M-15 producing isolates contained the *blaTEM* gene and two carried the *tetA* gene. Four strains contained the *int1* gene.

Conclusions: Vultures frequently are fecal carriers of *E. coli* producer of ESBLs of epidemic CTX-M-15 and CTX-M-55 subtypes. ESBL-positive *E. coli* belonged to different clones [some of them very unusual], what suggest the implication of mobile genetic elements in the dissemination of this relevant mechanism of resistance. This underlies the complexity of bacterial resistance in wild animals and the possible interspecies transmission between humans, domestic animals, wildlife, interspecies and in the environment.

An extreme chain reaction-based multiplex assay for detection of group A/C/G streptococci directly from throat swab specimens

Lijie Gong¹, Brad Keusch¹, Mark Olson¹, Maureen Carey¹, Aaron Ripley¹, Bryson Green², Daniel Kolk², Michelle Mastronardi², Betty Wu¹, Sundu Brahmasandra¹

¹NeuMoDx Molecular, Ann Arbor, United States, ²XCR Diagnostics, Salt Lake City, United States

Background: Group A beta-hemolytic streptococci (GAS) are the most frequently isolated pathogens in acute bacterial pharyngitis. In addition, group C and G streptococci (GCS or GGS) have been increasingly recognized as causes of non-group A streptococcal pharyngitis in children. Diagnosis has traditionally been performed through rapid antigen detection test or culture. Both approaches suffer from significant drawbacks. The NeuMoDx Strep A/C/G Vantage Assay is a multiplex, “sample to result” nucleic acid test implemented using XCR technology to provide ultra-fast results on the NeuMoDx molecular systems. The assay detects and differentiates DNA of GAS and GCS/GGS simultaneously. All reagents and consumables used are stable at ambient conditions and come in ready-to-use configurations requiring no user mediated steps.

Materials/methods: Assay performance was characterized using throat swabs in liquid Amies transport medium. Multiple studies were performed to characterize the assay’s ability to detect GAS (both the M1 and M3 strains), GCS, and GGS. Studies included determination of the analytical sensitivity for all types, analytical specificity across non-target organisms, clinical sensitivity and specificity, and robustness in the presence of interfering substances.

Results: The Limit of Detection of the NeuMoDx Strep A/C/G Vantage Assay for the GAS M1 and M3 strains was established to be 70 and 170 CFU/mL respectively, 2.0E3 CFU/mL for GCS, and 1.0E4 CFU/mL for GGS. No interference was demonstrated in the presence of 20 endogenous and exogenous substances and 44 pathogens. No cross-reactivity was observed against the 44 relevant pathogens tested (meaning the assay displayed 100% analytical specificity). Turnaround time for the complete test was <50 minutes. Finally, excellent sensitivity (GAS: 100%; GCS/GGS: 95.9%) and specificity (100% for GAS and GCS/GGS) against FDA-cleared reference tests was demonstrated in a pilot method comparison study analyzing 230 clinical residual specimens.

Conclusions: The NeuMoDx Strep Vantage Assay is the only test developed for detection of Group A and Group C/G Streptococcus directly from throat swab specimens providing ultra-fast turnaround time and high throughput while requiring minimal (<5 min) user mediated steps to perform the testing.

Abstract 7645

**Performance of the Allplex Assay in comparison to microscopy and in-house real-time PCR for the detection of helminths in Tanzanian stool samples**

Rahel Wampfler1;2, Beatrice Barda1;2, Marie-Therese Ruf1*;2, Jennifer Keiser1;2

1Swiss Tropical and Public Health Institute, Basel, Switzerland, 2University of Basel, Basel, Switzerland

Abstract 7645

Although detection of helminths in stool samples is still mainly done by microscopy, real-time PCR and latest commercial multiplex PCR panels become more and more available. The primary objective of this study was to assess the performance of the Seegene Allplex™ GI-Helminthiasis Assay (Seegene) in comparison to Kato Katz (KK) and standard in-house real-time PCR (PCR).

A total of 310 stool samples, collected at the baseline in the framework of a randomized clinical trial for *Trichuris trichiura* in 2017 in Tanzania were analysed. All participants were *Trichuris* positive in at least one of two stool samples evaluated by Kato Katz for inclusion to the study. The three diagnostic methods studied detected the following helminths: (i) KK detecting *Trichuris*, *Ascaris* and hookworm (species differentiation not possible), not suitable for *Strongyloides*; (ii) PCR detecting *Ascaris*, *Trichuris*, *Ancylostoma*, *Necator* and *Strongyloides*; and (iii) Seegene detecting *Ascaris*, *Trichuris*, *Ancylostoma*, *Necator*, *Strongyloides*, Enterobius, *Taenia*, *Hymenolepis*, *Microsporidia*.

Three helminths (*Trichuris*, *Necator* and *Ascaris*) were detected in all three assays. *Strongyloides* was detected by PCR and Seegene only. Positivity for KK, PCR and Seegene for *Trichuris* was 100% (inclusion criteria), 92% and 85%, for *Ascaris*: 60%, 59% and 54%, for *Necator*: 44%, 49% and 48%, respectively. In comparison to KK, sensitivity of PCR and Seegene was for *Trichuris*: 92% and 85%; for *Ascaris*: 87% and 81%; for *Necator*: 81% and 91%, respectively. Overall rates of agreement of PCR and Seegene compared to KK were for *Trichuris*: 92% and 85%; for *Ascaris*: 86% and 84%; for *Necator*: 76% and 75%, respectively. Only four samples were positive for *Strongyloides* by PCR and three by Seegene. Seegene compared to PCR showed overall rates of agreement >90% for all detected species.

Overall, Seegene Assay and in-house PCR showed comparable results, however both molecular methods missed positive participants detected by microscopy due to uneven and irregular shedding of eggs. The Seegene Assay can be recommended as screening tool for its ease to use in molecular settings; however microscopy remains the most cost-effective method in developing countries and allows the detection of helminth eggs not covered by the used molecular assays.

A new menace emerges in South America: yellow fever outbreak looms in Venezuela

Adriana Tami1*, Alberto Paniz-Mondolfi2, María E. Grillet3, Maria F. Vincenti-Gonzalez2, Erley Lizarazo1, David A. Forero-Peña1, Julio Castro5, José Oletta6

1University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 2Instituto de Investigaciones Biomedicas IDB/Incubadora Venezolana de la Ciencia, Cabudare, Venezuela, 3Central University of Venezuela, Laboratorio de Biología de Vectores y Parásitos, Instituto de Zoología y Ecología Tropical, Facultad de Ciencias, Caracas, Venezuela, 4Hospital Clínico Universitario, Universidad Central de Venezuela, Caracas, Venezuela, 5Tropical Medicine Institute, Universidad Central de Venezuela, Caracas, Venezuela, 6Sociedad Venezolana de Salud Publica, Caracas, Venezuela

Abstract third-party references: The working group on emerging and re-emerging diseases in Venezuela

Background: In South America, yellow fever virus (YFV), an arbovirus, maintains enzootic transmission in sylvatic areas. YFV emerges in cyclic epizootic outbreaks among nonhuman primates associated or not with human cases, every 7-10 years. Venezuela is endemic for YF with urban transmission eradicated ~100 years ago. The last outbreak of sylvatic YF (epizootic wave) was recorded in 2005 comprising several regions of the country and a mortality in humans close to 50%. At the time of writing, a potential new YF epizootic outbreak is evolving and affecting vulnerable indigenous populations and rural areas of southeastern Venezuela. Around 3.5 million people live in high-risk areas for YFV transmission.

Materials/methods: Information published by the Venezuelan Public Health Society and Let’s Defend The National Epidemiology Network, by WHO Disease outbreak news, and unofficial information obtained locally was used. Further information will be gathered and presented at the time of the Congress.

Results: In September 2019, PCR-confirmed YFV infection was reported in a 46-year old male Pemón Amerindian resident of Bolivar State (southeast Venezuela). This is the first confirmed autochthonous case diagnosed since 2005. The patient became severely ill developing renal failure and was hospitalized. There are unconfirmed reports of more (severe) cases from Bolivar and from individuals living in rural areas from another region of the country. The worry that a large epizootic epidemic and eventual expansion to urban transmission occur is due to the low vaccine coverage and to the ubiquitousness and high prevalence of the urban vector Aedes aegypti that currently infests >20% of houses, well over the WHO transmission threshold. Moreover, illegal gold mining activities in Bolivar are fueling transmission, as people live in precarious conditions, there is no surveillance, low vaccination and high human mobility between these areas and the rest of the country increasing the risk of spillover into urban areas.

Conclusions: The potential for a similar or bigger epidemic as the one that took place in Brazil during 2016/18 is a threat that is augmented by the economic and humanitarian crisis affecting Venezuela with the collapse of the vector surveillance and control system and low vaccine coverage.

Abstract 7647

Whole genome sequencing (WGS) and antifungal susceptibility testing of Candida glabrata (C. glabrata) reveals new associations of antifungal resistance (AFR) with gene variants

Irene Stefanini1, Emily Stoakes1, Houdini Wu2, LI Mccrae2, Abid Hussain*, John Moat Moat1, Christopher Dowson1, Miruna David1, Chry-stala Constantinidou1

1University of Warwick, Coventry, United Kingdom, 2Public Health England, Public Health Birmingham laboratory, Birmingham, United Kingdom, 3University Hospitals Birmingham, Birmingham, United Kingdom

Background: The incidence and severity of C. glabrata infections have increased at an alarming rate over the last few years. Studies have attempted to evaluate the epidemiology and investigate the genetic contribution towards AFR. WGS is a powerful tool for establishing the relationship between genetics and AFR.

Materials/methods: Thirty C. glabrata isolates were cultured from the blood of hospitalized patients. The susceptibility to fluconazole, voriconazole, caspofungin, and flucytosine were carried out using the broth dilution according to the EUCAST’s guidelines. WGS was deployed to obtain MLST profiles, and WGS sequence data was also compared with genes associated with AFR: (FKS1, FKS2, FKS3 with echinocandins; FCY1, FCY2, FUR1, FPS1, FPS2 with flucytosine and ERG9, ERG11, CDR1, PDR1, FLR1, SNQ2 with azoles).

Results: Sixteen MLST sequencing types (STs) were identified with ST3 and ST7 were predominantly present in 8 and 3 isolates, respectively. There were also 6 potential new ST profiles. The majority of isolates were resistant to fluconazole (29/30, 97%), while 19, 13 and 1 isolates were resistant to flucytosine, voriconazole and caspofungin, respectively (63%, 43% and 3%). Interestingly, the response to the two tested azoles was not consistent, with 12 isolates being resistant to fluconazole and susceptible to voriconazole or vice-versa. None of the isolates were either susceptible or resistant to every antifungal. The non-synonymous variants found in genes involved in AFR did not characterise resistant isolates, however, significant associations were found between almost every genetic variant and the degree of susceptibility. Eleven genes (FKS1, FKS2, FKS3, FCY2, FUR1, FPS1, ERG9, ERG11, CDR1, PDR1, FLR1, SNQ2) had at least 1 SNP associated with the resistance to a class of antifungals that has not been reported previously. Similarly, associations were also observed between the responses to the antifungals and the copy numbers of AFR genes (FCY2, FKS1, FKS2, FLR1 with fluconazole and FCY2, FKS1, FKS2, FLR1 with caspofungin).

Conclusions: Our study demonstrates increased AFR in bloodstream infections and suggests that C. glabrata clinical isolates may be acquiring AFR through new mechanisms.

Abstract 7648

**Melioidosis in patients suspected with recurrent tuberculosis: a disease in disguise**

Rahul Garg*, Tushar Shaw1, Chiranjay Mukhopadhyay1

1Kasturba Medical College, Manipal, Manipal Academy Of Higher Education, Manipal, India

**Abstract third-party references:** Manipal Academy Of Education

**Background:** Melioidosis is a known endemic infectious disease in many Asian countries with India predicted to have the highest burden for the disease. However, it remained too long neglected in the country and now is gaining the status of an emerging infectious disease. The disease is well known as a great mimicker and the presentation can be very similar to that of tuberculosis thus making difficult for physicians to come up with a clinical diagnosis.

**Materials/methods:** A prospective observational study was conducted from January 2016 to December 2018, to determine the proportion of melioidosis diagnosed among patients suspected with recurrent Tuberculosis infection in the endemic coastal region of the country. All cases suspected of recurrent TB were simultaneously tested for the presence of *B. pseudomallei* in the sample based on enrichment culture and TTSS1 PCR. Basic demographics and clinical details were analyzed to identify predictors of melioidosis infection.

**Results:** A total of 11,138 patients were admitted to the hospital with suspected tuberculosis infection in the last 2 years. 586 (5.2%) patients were diagnosed with primary tuberculosis. Among the confirmed cases, recurrent infection with microbiologically confirmed tuberculosis was documented in 1.8% cases whereas 1.2% of patients showed growth of *B. pseudomallei* in culture. Bone and joint infection, hepatomegaly with deranged liver function, and uncontrolled diabetes were predictors of melioidosis infection. Among the seven patients diagnosed with melioidosis, two died (29%). Five patients had a history of soil exposure.

**Conclusions:** This is the first study estimating the occurrence of melioidosis among patients presenting with recurrent tuberculosis from India. The study foreshadows the need for prompt microbiological diagnosis along with a high index of suspicion from the clinicians in endemic countries thus leading to prevent the abuse of Anti-TB treatment or prophylaxis.

**Presenter email address:** rgdrock89@gmail.com
Evaluation of the BACT/ALERT VIRTUO in terms of time to detection, performance, workflow efficiency and impact on patient management, compared to the BACTEC FX automated blood culture system

Ana Verónica Halperin*, Jose Luis Cortes Cuevas¹, Miriam Cuesta¹, Sergio Talens¹, Robert Birch², Ana Maria Sanchez Diaz¹, Rafael Canton Moreno¹

¹Hospital Ramón y Cajal, Microbiology Department, Madrid, Spain; ²Biomérieux, Data Analytics, Hazelwood MO, United States

**Background:** Bloodstream infections are associated with high rates of morbidity and mortality, therefore prompt identification and antimicrobial susceptibility testing of the causative organism(s) are critical. We compared the microbiological/clinical performance of BacT/ALERT®-VIRTUO™-(BioMerieux) to that of the BACTEC™-FX-(BD) instrument, with time-to-detection (TTD, from loading into system until positivity) as the primary outcome. Secondary microbiological outcomes were positivity and contamination rates, hands-on-time, turn-around-time (TAT) and time-to-identification.

**Materials/methods:** We performed a prospective cross-over study using blood cultures from patients (>18 years) suspected of bacteremia/fungemia, localized in different wards into two strata (Stratum-1: Emergency Department-ED-; Stratum-2: in-hospital patients). Testing was performed in BACTEC™-PlusAerobic/F and BACTEC-Lytic/10-Anaerobic/F bottles and incubated in BACTEC™-FX, or BacT/ALERT®FA-Plus and FN-Plus bottles and incubated in VIRTUO™. Initially, each strata was randomly assigned to one of the incubators and then alternated every 2-weeks for 6 months (October-16th-2018 to April-16th-2019). All samples were processed in parallel with the same work-flow from the moment they were flagged positive. Maximum incubation time was 5 days.

**Results:** We included a total of 3898 extractions (776 1 bottles) in VIRTUO and 4179 (8306 bottles) in BACTEC. The median age was 69 years for both groups and the samples were equally distributed for each ward (ED: VIRTUO 80.9%, BD 75.1%). The number of blood cultures with at least one positive extraction was 278(7.1%) for VIRTUO and 193(4.6%) for BACTEC (p<0.0001). TTD and proportion of aerobic/anaerobic bottles is shown in Table. Hands-on-time was reduced by 15 minutes/day when using VIRTUO.

**Conclusions:** We have compared in a large scale and in a "real world" setting the performance of two automatic blood culture incubators. TTD differed in both systems depending on the type of bottle {aerobic vs. anaerobic}. The number of positive extractions was significantly higher for the VIRTUO incubated samples, which might impact antimicrobial prescription and clinical outcomes.

Enteroaggregative Escherichia coli in mid-Norway

Ingvild Haugan*1, Marit Gudrun Husby1, Dorothea Aamnes Mostue1, Andreas Brun1, Heidi Lange2, Richard White2,3, Line Vold2, Jan Egil Afset1,4

1St. Olav’s Hospital, Department of Medical Microbiology, Trondheim, Norway, 2Norwegian Institute of Public Health, Department of Zoonotic, Food- and Waterborne Infections, Oslo, Norway, 3Norwegian Institute of Public Health, Department of Infectious Disease Epidemiology and Modelling, Oslo, Norway, 4Norwegian University of Science and Technology, Department for Clinical and Molecular Medicine, Faculty of Medicine and Health Sciences, Trondheim, Norway

Background: Enteroaggregative E. coli (EAEC) has been associated with acute diarrhoea in children, travellers’ diarrhoea and persistent diarrhoea in people residing in low-income regions. Other studies have not found any association between EAEC and diarrhoeal illness. The aim of this study was to examine the EAEC prevalence among people in mid-Norway and investigate the association between EAEC and diarrhoea.

Materials/methods: This study included faecal samples from 9511 diarrhoeal episodes and 381 randomly invited healthy controls from March 1st 2017 to February 28th 2019 with multiplex PCR for 19 pathogens. Request forms (diarrhoeal episodes) and questionnaires (healthy controls) provided clinical information. We investigated the relationship between EAEC and diarrhoea with unadjusted analyses on gender, age and concomitant pathogens, and performed multivariate logistic regression analysis on the significant variables.

Results: We detected EAEC in 440 (4.6%) of the diarrhoeal episodes, and eight (2.1%) of the healthy controls. Among diarrhoeal episodes, the prevalence was 4.8% in females, 4.7% in males, 18.8% in those with travel history, and 2.2% in those without. The age group 20-29 had the highest prevalence (9.2%). We detected other pathogens in 65.5% of all diarrhoeal episodes with EAEC, most commonly enteropathogenic E. coli (29.1%), enterotoxigenic E. coli (25.1%), norovirus (10.9%) and Campylobacter spp (9.8%). 80.5% of EAEC positive samples from persons with travel history had concomitant pathogens. Among healthy controls, we detected EAEC in 2.3% of females, 1.9% of males, and 0% of travellers. The prevalence was highest in the age group 60-69 (4.9%). No EAEC positive healthy controls had concomitant pathogens. EAEC was significantly associated with diarrhoea (OR=2.26, 95%CI=1.12-4.59), also when adjusting for age and gender (OR=2.11, 95%CI=1.04-4.29). No significant association was found when adjusting for concomitant pathogens (OR=1.54, 95%CI=0.73-3.17).

Conclusions: EAEC was a common finding in faecal samples in mid-Norway, and it was significantly associated with diarrhoea. The prevalence of concomitant pathogens was high, and the analysis was no longer significant when corrected for these. Further studies on bacterial virulence-related genes to distinguish pathogenic from non-pathogenic strains, as well as on the relevance of pathogens’ coexistence in the gut, are warranted.

Abstract 7655

Aging influences effector functions of neutrophil granulocytes in *Pseudomonas aeruginosa* lung infection

Sommer Charline¹, Nina Cramer², Laura Müller¹, Olga Danov*¹, Burkhard Tümmler², Armin Braun¹, Katherina Sewald¹, Christina Brandenberger¹, Susann Dehmel¹, Sabine Wronski²

¹Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany, ²Hanover Medical School, Clinic for Pediatric Pneumology, Allergology and Neonatology, Hannover, Germany, ³Hanover Medical School, Institute for Functional and Applied Anatomy, Hannover, Germany

**Background:** With the increasingly aging population, the incidence and mortality of *P. aeruginosa* induced lung infections simultaneously rise. This might in part be due to the age-dependent dysregulation of the immune system, including the function of neutrophilic granulocytes. Therefore, the aim of this study was to investigate the impact of the host’s age on the immune response towards *P. aeruginosa* induced pneumonias using precision-cut lung slices (PCLS) and isolated neutrophils.

**Materials/methods:** PCLS prepared from young adult (11-15 weeks) as well as old (18-22 months) C57BL/6NCrl-mice were infected with the *P. aeruginosa* standard lab strain PAO1 or a late clinical *P. aeruginosa* isolate [D61], derived from a chronically infected cystic fibrosis patient. The resulting infection and induced host response were analysed by assessing bacterial load and cytokine production by means of counting colony-forming units and performing ELISA. Furthermore, neutrophils and bacteria were co-cultivated and neutrophil extracellular trap (NET)-formation was quantified and imaged using SYTOX green and antibody staining. Additionally, colony-forming units were quantified to evaluate bacterial clearance by neutrophils.

**Results:** Bacterial load in lung tissue was comparable in PCLS of young and old mice, but was lower when using the clinical isolate D61 as compared to PAO1. Interestingly, an age-dependent increase of pro-inflammatory cytokines such as TNF-α, IL-1β, MIP-3α, KC and IL-17A was observed in PCLS of old mice compared to young animals, with significant differences particularly for D61. Regarding neutrophil effector functions, NET-formation and bacterial clearance were lower when using D61 compared to PAO1. Additionally, NET-release was increased in an age-dependent manner when using neutrophils of old mice in response to PAO1.

**Conclusions:** In line with the increased pro-inflammatory status reported in the elderly population, ex vivo lung tissue of old mice displayed an increased cytokine response towards *P. aeruginosa* infection predominantly for the clinical isolate D61, despite the lower bacterial load compared to PAO1. Furthermore, neutrophil effector functions were impaired for D61 compared to PAO1 in an age-dependent manner. Conclusively, aging seems to be a relevant factor in terms of host immune response and resolution of infection, suggesting that elderly individuals could benefit from therapies restoring effective immune responses.

Multiple mutational possibilities allow ceftazidime-avibactam resistance in KPC-type carbapenemase

Hobson Claire Amaris1, Stephane Bonacorsi2, Herve Jacquier3, Magnan Melanie4, Alaksh Choudhury5, Beatrice Bercot6, Olivier Tenaillon5, Andre Birgy*7

1Université de Paris, IAME, INSERM, Paris, France, 2Université de Paris, IAME, INSERM, Microbiologie, Hôpital Robert Debré, APHP, Paris, France, 3Université de Paris, IAME, INSERM, Service de Microbiologie, Hôpital Saint-Louis/Lariboisière, Paris, France, 4Université de Paris, IAME, INSERM, Service de Microbiologie, Hôpital Saint-Louis/Lariboisière, Paris, France, 5Université de Paris, IAME, INSERM, Microbiologie, Hôpital Robert Debré, APHP, Paris, France

Background: KPC carbapenemases have a broad substrate profile, including penicillins, cephalosporins, carbapenems and most beta-lactamase inhibitors. The association ceftazidime-avibactam can inactivate KPC-type carbapenemases offering a significant advance over some antimicrobials agents, and it keeps an in vitro activity against carbapenem-resistant Enterobacteriaceae (CRE). Mutations in genes such as blaKPC or in genes encoding porins can lead to resistance to ceftazidime-avibactam, limiting the benefit of this last resort strategy. We recently described the impact of anticancer drugs on the bacterial mutation rate, but also on the widening of the beta-lactamase spectrum of the KPC-type carbapenemase towards ceftazidime-avibactam. The aim of this study was to evaluate the KPC mutational possibilities conferring ceftazidime-avibactam resistance.

Materials/methods: We studied a hundred mutants from an in vitro selection of clinical isolates of Enterobacteriaceae. The strains carried either blaKPC-2 or blaKPC-3, and they became resistant to ceftazidime-avibactam after a culture with anticancer drug chemotherapy. To confirm their phenotype, we cloned the KPC genes of a subset of resistant mutants in the plasmid pBR322 and we determined their susceptibility to various beta-lactams +/- inhibitors.

Results: We identified several point mutations in the KPC gene and particularly in the omega loop. The positions 164 and 179 were the most mutated sites. Although several mutations have been previously described in clinical isolates, other mutants, not yet described, showed insertions or deletions within the beta-lactamase, either in the omega loop or close to the position 274. The increase in the MIC to ceftazidime-avibactam is associated with a decrease of MIC to several other beta-lactams +/- inhibitors.

Conclusions: KPCs evolve rapidly and mutations are increasingly described in clinical isolates. We show that many ways lead these enzymes to become resistant to ceftazidime-avibactam, an antibiotic of the latest therapeutic line. These possibilities include insertions or deletions at certain key positions suggesting a common pattern across different class A beta-lactamases responsible for the extension of the substrate spectrum. The MIC results indicate that the acquired mutations in KPC expand its substrate profile by increasing catalytic efficiency for ceftazidime hydrolysis at the cost of carbapenemase activity.

The flow cytometry-assisted susceptibility test (FAST) accurately predicts colistin MICs for Gram-negative bacilli directly from positive blood culture in less than four hours

Teagan Paton*1, Kieran Mulroney1, Malgorzata Kopczyk1, Christine Carson1,2, Timothy Inglis1,2
1PathWest Laboratory Medicine WA, Perth, Australia, 2The University of Western Australia, Perth, Australia

Background: Bloodstream infections require rapid, effective treatment to safeguard patient lives: every hour without appropriate antimicrobial therapy increases cumulative risk of death. Current best practice recommends the use of an automated blood culture incubation system, with subsequent antimicrobial susceptibility testing. Against a background of rising resistance to carbapenems, rapid colistin susceptibility results for Gram negative organisms from positive blood culture are becoming increasingly important. We present the use of the Flow Cytometry-Assisted Susceptibility Test (FAST) to rapidly assess colistin susceptibility of Gram negative bacilli direct from blood culture.

Materials/methods: Using expended and simulated clinical specimens, we tested n=106 positive blood cultures confirmed by Gram stain to contain Gram negative bacilli. Simulated specimens were created by inoculating 3 colonies from an overnight blood agar plate into BD BACTEC™ Plus Aerobic bottles already containing donor blood drawn after informed consent by a phlebotomy service. Bottles were incubated in a BD BACTEC™ blood culture analyser until positive. An aliquot of blood culture mixture was briefly centrifuged, and the supernatant inoculated directly into a Sensititre™ GNX3F plate using a Sensititre™ auto-inoculator module. Plates were incubated at 35°C for 2 or 3 hours, diluted 1:4 with a staining buffer containing 5 µM SYTO® 9, and read using an Attune™ NxT flow cytometer with an autosampler. Data were analysed using bespoke software to predict colistin MIC and susceptibility in ≤ 4 hours. Identification of unknown organisms in specimens was performed by Bruker MALDI-Biotyper® analysis and available within the assay window.

Results: We determined colistin MICs for organisms from the following categories: Enterobacterales (n=71, 3 resistant), pseudomonads (n=23, 4 resistant), A. baumannii (n=12, 1 resistant). The distribution of flow cytometry data proved to be complex when compared with other classes of antimicrobial agents. Essential agreement and categoric agreement compared to BMD were 100% across all 106 isolates tested.

Conclusions: The rapid mutation and dissemination of MCR variants underscores the need for phenotypic tests to capture all colistin resistance phenotypes. We present FAST as a new rapid method to correctly assay colistin susceptibility from positive blood culture, with results in ≤ 4 hours from blood culture positivity.

Abstract 7660

**Pilot study of reimbursement model to ensure access to new critical antibiotics in Sweden**

Jenny Hellman*1, Charlotta Edlund1, Tobias Jamtehov1, Fredrik Robertsson1, Anders Ternhag1

1The Public Health Agency, Solna, Sweden, 2The Public Health Agency, Östersund, Sweden

**Abstract third-party references:** Public Health Agency of Sweden

**Background:** Sweden has low levels of resistance, a restrictive antibiotic use and is a small market. Consequently, some antibiotic products face such low demand that there is a risk that pharmaceutical companies do not choose to have them available on the Swedish market. The Public Health Agency of Sweden (PHAS) was in 2018 commissioned by the Government to pilot a new reimbursement model for new antibiotics of special medical value. The aim of this pilot study is to ensure availability of new antibiotics for critical pathogens. The pilot study will run until 2022.

**Materials/methods:** PHAS has developed an algorithm to identify products for the reimbursement model. To define the need and specific medical value, the algorithm include evaluation of sales, number of Market Authorization Holders, evaluation of products activity, ecological profile and role in the Swedish treatment guidelines.

The reimbursement model implies that a minimum annual revenue to the pharmaceutical companies is guaranteed at national level. In return, the companies warrant high availability for all Swedish hospitals and a security stock. The health-care providers will continue to pay for their use. Annual reconciliation will be done. If the revenue of companies is lower than the guaranteed level, the difference will be paid from national level. If the revenue of companies is higher than the guaranteed level, the companies will be paid 10 percent of the value of the security stock (Figure). The guaranteed annual revenue is based on clinical need.

**Results:** The contracting process is set as a public procurement process. The call will be opened for antibiotic products identified by the algorithm and with effect against multi-resistant Enterobacteriaceae, carbapeneme-resistant *Pseudomonas aeruginosa* and/or carbapeneme-resistant *Acinetobacter baumannii*.

**Conclusions:** Existing financing models fail to secure a steady supply of new drugs in small markets like Sweden. This novel reimbursement model is predictable for pharmaceutical companies and the total revenue over the contract years will be higher. The model may possibly be adapted and scaled up to similar countries.

Abstract 7661

**Prospective evaluation of bacteraemia rates and infectious complications among patients undergoing endoscopic retrograde cholangiopancreatography**

Şerife Altun Demircan¹, Necla Tulek*², S. Kinikli¹, Esra Yuşekkaya¹, Fatma Şebnem Erdinç¹, Çiğdem Ataman Hatipoğlu³, Murat Kekilli⁴

¹Ankara Training and Research Hospital, Ankara, Turkey, ²Atilim University, Faculty of Medicine, Ankara, Turkey, ³Health Sciences University, Ankara, Turkey, ⁴Gazi University, Ankara, Turkey

**Background:** Endoscopic retrograde cholangiopancreatography (ERCP) is becoming a common procedure for diagnosis or treatment of biliary and pancreatic illness worldwide. Although improvements in the technical and hygienic standards led to reduce the complications, infections still remain one of the most serious complications of ERCP. In this study, infectious complications of ERCP and patient characteristics were evaluated prospectively in a tertiary-care hospital.

**Materials/methods:** Patients undergoing ERCP were evaluated prospectively in a 15 months period. Patients' demographic features, underlying diseases, reasons for ERCP, antimicrobial prophylaxis, type of infections, causative agents, antimicrobial susceptibility of microorganisms, duration of hospital stay, and prognosis of all were recorded.

**Results:** Totally 788 patients underwent to ERCP in study period. Infectious complications were developed in 13 (1.66%) patients (eleven males and two females). Mean age of the patients were 38 years (range 34-87 yrs.). All the patients were admitted to the tertiary referral centre were retrospectively included. Therapeutic intervention was the primarily indications in 11 (84.4%) patients due to choledocholithiasis and stenosis in biliary tract system. Diabetes mellitus (in 2 patients) and malignancy (in 2 patients) were the underlying diseases. All the patients were received ciprofloxacin + metronidazole (8 patients; 61.5%) either ceftriaxone + metronidazole (5 patients; 38.5%) prophylaxis. Bacteraemia occurred in 11 (84.4%) patients, liver abscess detected in 2 patients (one was with bacteraemia). The most prevalent isolates detected during bacteraemia were *Klebsiella pneumoniae* (6/13), *Escherichia coli* (4/13). Five of *Klebsiella pneumoniae* and 3 of *Escherichia coli* isolates were ESBL+. One of the patients had to be admitted to the intensive care unit. Carbapenems were the most frequently used agents (8/13). Mean duration of antibiotic use was 16 day (5-30 days) and mean hospital stay was 21 day (5-90 day).

**Conclusions:** ERCP-related infectious complications are decreasing but infections with resistant microorganisms are becoming a serious problem. All centres need to evaluate their own cases and to develop strategies to prevent the infectious complications.

**Presenter email address:** ntulek@gmail.com
Analysis of chloramphenicol susceptibility in metallo-beta lactamase producing Enterobacterales

Alma Tuohy¹, Nial Delappe¹, Elaine McGrath¹, Wendy Brennan¹, Mark Maguire¹, Martin Cormican*¹,²

¹University Hospital Galway, Galway, Ireland, ²National University of Ireland Galway, Galway, Ireland

Background: Systemic use of chloramphenicol has been limited by rare adverse effects including aplastic anemia. However with increasing antimicrobial resistance it is sometimes necessary to consider all therapeutic options for multidrug-resistant Enterobacterales including Carbapenemase Producing Enterobacterales (CPE) and for Acinetobacter species.

Materials/methods: Ninety-two class B Metallo-Beta Lactamase (MBLs) isolates of CPE and Acinetobacter spp. from throughout Ireland submitted to the national reference laboratory service during the period February to August 2019 were included. Duplicate isolates were excluded. Isolates from CPE screening samples and general diagnostic samples were included. Isolates were identified by Maldi-TOF. CPE production was confirmed by immunochromatographic detection enzyme and by whole genome sequencing performed using Nextera XT (Illumina) library preperation and MiSeq (Illumina). Species included were Escherichia coli, Enterobacter cloacae complex, Citrobacter species, Klebsiella pneumoniae, Klebsiella species, Klebsiella oxytoca, Proteus mirabilis, Serratia species and Acinetobacter baumannii complex. Chloramphenicol susceptibility testing was performed by broth microdilution.

Results: MIC values were as follows ≤8 (n=58), 16 (n=8), 32 (n=3), 64 (n=22), 128 (n=6) and >128 (n=15) mg/L. Among the 58 isolates with MIC values of ≤8 mg/L 36 had no genes encoding resistance to chloramphenicol, 18 encoded catB3 and 4 contained a combination of catB3 and catA2. All but one isolate with chloramphenicol MICs of >64 mg/L contained catA1 or floR while no isolates containing these genes had MICs ≤32 mg/L. There was poor correlation between chloramphenicol MICs and the presence of catB3, catA2 and cml. EUCAST (≤8 mg/L = susceptible, >8 mg/L = resistant) and CLSI (≤8 mg/L = susceptible, 16 mg/L = intermediate and ≥32 mg/L resistant) have different interpretative criteria. Among the 34 isolates classified as resistant by EUCAST CLSI would categorise 8 as intermediate and 26 as resistant.

Conclusions: Chloramphenicol may be an option for treatment of metallo-β-lactamase producing CPE and Acinetobacter species when other options are very limited. Detection of catA1 and floR genes predict high level resistance to chloramphenicol (MIC≥64 mg/L) but this is not the case for catB3, catA2 and cml. Many isolates that were called resistant by EUCAST criteria had no chloramphenicol resistant genes detected. This was less of an issue when using CLSI criteria as many of these would be classified as intermediate.

**Real-world multi-centre experience with eravacycline at academic hospital systems**

Sara Alosaimy\(^1\), Kyle Molina\(^2\), Kimberly Claeys\(^1\), Justin Andrade\(^4\), James Truong\(^4\), Madeline King\(^4\), Benjamin Pullinger\(^5\), Glen Huang\(^6\), Taylor Morrisette\(^*1\), Abdalhamid Lagnf\(^1\), Michael J. Rybak\(^1\)

\(^1\)Anti-Infective Research Laboratory, Department of Pharmacy Practice, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University, Detroit, United States, \(^2\)University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, United States, \(^3\)University of Maryland School of Pharmacy, Baltimore, United States, \(^4\)The Brooklyn Hospital Center, Brooklyn, United States, \(^5\)Philadelphia College of Pharmacy, University of the Sciences, Philadelphia, United States, \(^6\)University of California Los Angeles, Los Angeles, United States

**Background:** Eravacycline (ERV) received Food and Drug Administration (FDA) approval for the treatment of adults with complicated intra-abdominal infections (cIAIs) in 2018. ERV is a novel fluorocycline with broad-spectrum activity against Gram-positive, Gram-negative and anaerobic bacteria including those with tetracycline-acquired resistance mechanisms. Real-world data regarding ERV use in FDA and non-FDA approved indications is limited. We evaluated the clinical and safety outcomes of patients treated with ERV for various infections.

**Materials/methods:** Multi-center, retrospective, observational study from September 2018 to November 2019. Adult patients treated with ERV for ≥72 hours were included. Primary outcome was 30-day survival. Secondary outcomes were 30-day lack of infection-recurrence and resolution of signs/symptoms of infection.

**Results:** Overall, 31 patients were included from 5 geographically distinct medical centers across the United States. Median age was 56 years (45-67); 58.1% were male and 54.8% were Caucasian. Median APACHE II and Charlson Comorbidity scores were 16 (11-20) and 3 (2-7), respectively. Common sources of infection were intra-abdominal (35.5%), respiratory (29.0%), and bone/joint (12.9%). The most common pathogens were *Klebsiella pneumoniae* (22.6%), and *Enterococcus faecium* (22.6%), followed by *Escherichia coli* (19.4%). Infectious diseases consultation was obtained in 96.8%, and surgical interventions in 64.5%.

Most patients received active therapy prior to ERV initiation (61.3%). Median ERV therapy duration was 9.1 (4.5-19.4) days. Among cases with documented cultures, ERV was initiated within a median of 6.9 (4.1-14.8) days. Combination therapy ≥48 hours was given in 48.4%. Among clinically evaluable population (n=26), 73.1% (19/26) achieved the primary endpoint. Of patients who died, majority had positive blood cultures (4/7), intra-abdominal as a source (4/7), were critically ill (4/7), and on monotherapy (4/7). For secondary outcomes; 88.5% (23/26) lacked 30-day infection-recurrence and 53.8% (14/26) resolved signs/symptoms of infection. Overall, only 7/31 switched to an alternative agent. Four patients experienced a probable ERV-related adverse event [n=4, 3: gastrointestinal, 1: rash], but only one led to drug discontinuation.

**Conclusions:** 30-day survival was achieved in majority of patients treated with ERV for various infections. Studies with longer follow-up and more patients are required to assess the effectiveness and safety of ERV, particularly compared to standard of care.

Does the new recommendations of treatment for non-severe Clostridiodes difficile-associated diarrhoea ensure a better outcome?

Mihaela Lupse1*, Iulia Darau2, Crina Diaconu2, Kinga-Maria Komlodi2, Khaulah Momani2, Mirela Flonta2, Nicolae Todor3

1University of Medicine and Pharmacy, Cluj-Napoca, Romania, 2University Hospital of Infectious Diseases, Cluj-Napoca, Romania, 3Institute of Oncology, Cluj-Napoca, Romania

Background: In February 2018 IDSA and SHEA published updated guidelines for Clostridium difficile associated diarrhea (CDAD). We followed this recommendation for patients admitted with the first episod of CDAD during this year. The purpose of our study was to evaluate the outcome of CDAD by monitoring patients for recurrences or death for 2 month after the first episod.

Materials/methods: A comparative study, including all adult patients who were admitted for or who developed the first episod of CDAD in our hospital (GDH and toxin A/B positive) regarding outcome: cure, recurrences and death. Patients were monitored for 2 months after CDAD. Cases were considered: non-severe, medium and severe according with ATLAS score published by Mark A Miller and colleagues in 2013. The outcome of non-severe CDAD [ATLAS score < 4] was compared for patients admitted during 2012-2016 treated according with the previous CDAD IDSA guidelines and patients admitted during summer 2019 (June-Sept) treated with vancomycin. We compared the outcome for all non-severe cases and also for non-severe cases without co-administered antibiotics during CDAD, considering that as a risk for recurrences.

Results: 61 patients were admitted between 1st of June-30th of Sept 2019, 37 women (61%), average age 64 years (min22, max92, median 66 years). 42 (69%) patients had an ATLAS score less than 4, were treated with oral vancomycin and 7 patients (17%) died or had recurrences. From 39 patients with non-severe CDAD without concomitant antimicrobials during CDAD treatment, 7 (18%) had unfavorable outcome. During 2012-2016, 768 patients were admitted with the first episod of CDAD, 412 female (54%), average age 65.6 years (min 18, max 97, median 69). 539 (70%) were non-severe and were treated with: metronidazole 258, vancomycin 63 and vancomycin plus metronidazole 199 patients. 128 (31%) patients died or had recurrences. From 202 patients with non-severe CDAD without concomitant antibiotics, 63 patients died (31%).

Conclusions: New IDSA/SHEA guidelines recommendation for CDAD decreased the risk of death/recurrence for patients with non-severe disease, possible due to a real resistance of C. difficile to metronidazole in our country and to a better effect of vancomycin.

First insight into the genome sequence of *Clostridioides difficile* strains isolated from Romanian patients

Ilda Czobor*1,2;1, Violeta-Corina Cristea2;1, Irina Gheorghe1;2, Carmen Chifiriuc1;5, Yu Feng2, Xiaohui Wang2, Laura Ioana Popa1;2, Marcela Popa1;3, Luminita Marutescu1;3, Veronica Lazăr1;5, Magdalena Popa1, Zhijong Zong1;4

1University of Bucharest, Research Institute of University of Bucharest, Bucharest, Romania, 2Synevo Central Laboratory Medicens, Bucharest, Bucharest, Romania, 3University of Bucharest, Faculty of Biology, Department of Microbiology and Immunology, Bucharest, Romania, 4University of Bucharest, Faculty of Biology, Department of Microbiology and Immunology, Research Institute of Bucharest, Bucharest, Romania, 5Centre of Infectious Diseases, West China Hospital (Huaxi), Chengdu, Sichuan, China, Chengdu, China, 6University of Bucharest, Faculty of Biology, Department of Microbiology and Immunology, Bucharest, Romania

**Background:** Recurrent *Clostridioides difficile* infections (rCDI) are difficult to treat, due to various factors, including antibiotic resistance profiles. Here we investigated the background of antibiotic resistance and virulence in *C. difficile* strains isolated from Romanian patients.

**Materials/methods:** The analyzed *C. difficile* strains were isolated from stool samples of male patients with recurrent *C. difficile* infection, aged 67 - A, 78 - B and 84 - C. The stool samples were screened using CoproStrip *C. difficile* GDH+ToxA+ToxB (Savyon Diagnostics). The strains were cultured on Columbia Agar with 5% sheep blood and identified by MALDI-TOF MS. The strains were subjected to whole genome sequencing using Illumina HiSeq System. The ribotype was determined *in silico* based on genomic sequences. The antibiotic resistance genes (ARGs), virulence factors and multilocus sequence typing profiles were analyzed.

**Results:** The phenotypic analyses revealed the presence of ToxA and ToxB in A and B strains, while for strain C both toxins were absent. *In silico* ribotyping revealed that all three strains belong to 027 ribotype (RT), previously described in our country and to the ST1 sequence type. The bioinformatic analysis of sequencing data revealed similar patterns of ARGs in strains A and B (respectively vanG-like operon, nimB <nitroimidazole resistance>, cdeA <multi antimicrobial extrusion protein>, dfr-like genes), present also in strain C which also harboured aminoglycoside modifying enzymes (namely ant(6)-Ib and aph(2")-Ia). Genome sequences revealed also the presence of toxA and toxB genes in all strains, despite the absence of toxA and toxB production by strain C.

**Conclusions:** The WGS analysis of clinical *C. difficile* isolates demonstrated that the strains belong to the epidemic ribotype 027, but harbor a considerable genetic diversity, suggesting diverse reservoirs for CDI. The presence of multiple resistance determinants to glycopeptides, imidazoles, trimethoprim sulfamethoxazole and aminoglycosides could explain the recurrency of underlying infections.

Abstract 7673

**Dalbavancin as a sequential treatment for Gram-positive infective endocarditis: 2-year experience at the University Hospital 12 de Octubre (Madrid)**

Javier Tomás Solera Rallo*, Miguel Calderón Flores1, Ignacio Fernández Herrero1, Christian Vigil Martín1, Eduardo Aparicio Minguijón1, María Arrieta Loitegui1, José Manuel Caro Teller1, Santiago De Cossio Tejido1, Laura Domínguez Pérez1, Francisco Lopez-Medrano1

1University Hospital 12 de Octubre, Madrid, Spain

**Background:** Dalbavancin is a second-generation lipoglycopeptide antibiotic with a broad spectrum of activity against virtually all important gram-positive pathogens, being a potent bactericidal drug against methicillin-resistant Staphylococcus aureus (MRSA). It demonstrated an excellent safety profile in different studies. Its main advantage is its long half-life, having an attractive role in outpatient (OPAT) intravenous therapy. It is only approved for skin and skin structures infections. This study aims to expand the evidence of the effectiveness and safety of prolonged treatment with dalbavancin in Gram-positive infective endocarditis (IE) after the clearance of the bacteremia.

**Materials/methods:** Prospective observational study conducted in one referral center, including all consecutive possible or definite IE according to modified Duke criteria treated with dalbavancin from January 2018 to November 2019.

**Results:** During the study 22 patients were enrolled, with a median age of 84.4 years. Sixteen were males (73%), with a mean of 7.5 points in the Charlson Comorbidity Index (CCI). Sixty-eight percent presented some type of valvulopathy. Fifty-five percent had prosthetic intracardiac material. The most common microorganism was methicillin-sensitive Staphylococcus aureus (MSSA) (32%), followed by Enterococcus faecalis (21%), coagulase-negative staphylococcaceae (16%) and viridans streptococci (11%). Only one MRSA was isolated. All the enterococci were ampicillin-susceptible. There was a high rate of complications (68%), being valve regurgitation (45%) and central nervous system emboli (32%) the most frequent. Fifty-five percent of the patients met surgery criteria, but only half of them could be operated. All the patients had been previously treated with another active antibiotic, for a mean of 27.4 days (SD: 11.8). Dalbavancin was used as OPAT extended therapy for a median of 14 days (IQR: 14-31.5). This led to a reduction of approximately 283 days of hospitalization (14.2 per patient). Two patients presented adverse events not attributable to dalbavancin: mild diarrhea and neutropenia. Two patients died of unrelated causes during follow-up.

**Conclusions:** This study shows the effectiveness and safety of prolonged treatment with dalbavancin in IE, even in the elderly population with a high comorbidity score. Furthermore, its potential cost-saving associated with hospitalization-shortening and avoidance of long-dwell intravenous lines should be taken into consideration.

Abstract 7675

**Recurrent bacteraemia with Enterococcus faecalis is predominantly caused by the same clone**

Chaitanya Tellapragada*1, Helena Östlund2, Pontus Naucler3, Magnus Rasmussen4, Christian Giske5, Andreas Berge6

1Department of Laboratory Medicine, Division of Clinical Microbiology, Karolinska Institute, Stockholm, Sweden, 2Unit of Infectious Disease, Department of Medicine, Karolinska Institute, Stockholm, Sweden, 3Department of Infectious Diseases, Karolinska University Hospital, Unit of Infectious Diseases, Department of Medicine, Karolinska Institute, Stockholm, Sweden, 4Department of Clinical Sciences, Division of Infection Medicine, Lund University, Division for Infectious Diseases, Skåne University Hospital, Lund, Lund, Sweden, 5Department of Laboratory Medicine, Division of Clinical Microbiology, Karolinska Institute, Department of Clinical Microbiology, Karolinska University Hospital, Stockholm, Stockholm, Sweden, 6Department of Infectious Diseases, Karolinska University Hospital, Unit of Infectious Disease, Department of Medicine, Karolinska Institute, Stockholm, Sweden

**Background:** Enterococcus faecalis is a member of the normal gut microbiome and causes several clinical infections such as the urinary tract infection (UTI) and bloodstream infection. *E. faecalis* is a common cause of infective endocarditis (IE) associated with high mortality and morbidity. Isolation of the causative pathogen from blood culture is a major criterion for establishing the diagnosis. We report the clinical and microbial characteristics from a Swedish cohort of patients diagnosed with recurrent monomicrobial *E. faecalis* bacteremia (MEFsB).

**Materials/methods:** From 2012 to 2016, medical record data from patients with more than one episode of MEFsB were retrospectively analyzed, together with the bacterial blood culture isolates from the corresponding episode. *E. faecalis* isolates obtained from both the first and subsequent episodes of bacteremia were subjected to whole genome sequencing (WGS). From the WGS data, multilocus sequence typing (ST) was performed using the microSAL T pipeline [https://github.com/Clinical-Genomics/microSALT].

**Results:** Clinical data and bacterial isolates from 27 patients were available for inclusion in the study. 24/27 (88%) of the patients had two episodes and 3 patients had three episodes of MEFsB. The median time to a recurrence was 57 days (IQR: 30-97 days). During the first episode, the source of infection was identified in 9/27 (33%) of the cases but in only 3/27 (11%) in the last episode (p=0.10); with UTI (8 and 3 cases, respectively) dominating. IE was diagnosed in 1/27 (4%) and 11/27 (41%) of the cases during the first and second episodes (p<0.001), respectively. Isolates from both episodes in a patient were of the same sequence type (ST) in 26/27 (96%) of the patients. The ST distribution among the study isolates was diverse. Half of the patients diagnosed with IE were infected with ST6 and ST179 (3 cases each).

**Conclusions:** Multiple episodes with blood culture positive for *E. faecalis* was significantly correlated to IE. In recurrent infections, the vast majority of the coupled episodes in a patient are due to strains with the same ST, suggesting it is likely the same strain.

Epidemiology and genetic diversity of *Plasmodium falciparum* in Kobeni, south-eastern Mauritania

Sileye Diallo*1, Leonardo Basco2

1Université de Nouakchott Al Aasıriya, Institut de Recherche pour le Développement, Nouakchott, Mauritania; 2Aix-Marseille Université, Faculté de Médecine - secteur Nord Marseille, Institut de Recherche pour le Développement, Marseille, France

**Abstract third-party references:** Aix Marseille Université, University of Nouakchott Al Aasıriya, Institut Hospitalo-Universitaire Méditerranée-Infection, Marseille

**Background:** *Plasmodium falciparum* malaria is endemic in the Sahelian zone of Mauritania where intense internal and trans-border human movement occurs. The risk of spread of drug-resistant parasites needs to be regularly assessed in this region. Our objective was to assess the malaria epidemiological situation in Kobeni, a potential ‘hotspot,’ using parasitological and molecular tools.

**Materials/methods:** Patients with fever or history of fever, presenting at the health centre of Kobeni, were screened for malaria using a rapid diagnostic test (RDT) and microscopic examination of blood smears in 2015–2017. The diagnosis was confirmed by PCR. *P. falciparum* microsatellites and *Pfcr*t, *Pfmdr1*, and *Pfk13* markers were genotyped to assess genetic diversity and resistance to artemisinin-based combination therapies (ACT), respectively.

**Results:** A total of 2,326 febrile patients (mean age, 20.2 yrs) were screened. The presence of malaria parasites was detected by RDT and microscopy in 53.0% and 49.3% of patients, respectively, and was confirmed by PCR in 59.7%. Of 1,361 PCR-positive samples, 1,205 (88.5%) were *P. falciparum*, 47 (3.5%) *Plasmodium vivax*, and 100 (7.3%) *P. falciparum-P. vivax* mixed infection. Malaria transmission occurred mostly during and shortly after the rainy season. *Plasmodium falciparum* populations in Kobeni exhibit high genetic diversity (He >0.7) consistent with a high level of malaria transmission. Molecular analysis suggested an absence of resistance to ACT.

**Conclusions:** *P. falciparum* is the predominant species in the Sahelian zone, and malaria transmission is seasonal. *P. falciparum* parasites in Kobeni were heterogeneous and characterized by a high genetic diversity.

Abstract 7682

Screening, diagnosis and treatment of latent tuberculous infection in rheumatic patients candidate to biological therapy: experience of a tertiary tuberculous control unit

Xavier Martinez Lacasa*, Silvia Martinez, Georgina Salvador, Manel Pujol, Roser Font I Canals, Gemma Grau, Emma Padilla, Eva Maria Cuchi Burgos, Teodora Pribic

1 Mútua Terrassa University Hospital, Terrassa, Spain, 2 CatLab (Parc Logístic de Salut), Viladecavalls, Spain

Background: Patients who receive biological treatment have a significant risk of infections, including tuberculosis. Previously these patients have LTI that is reactivated under the influence of biological treatments. The programs of detection and treatment of LTI have been carried out in these patients for many years, especially in rheumatologic patients and here we present our data.

Materials/methods: During 2014-2019 all patients with rheumatic diseases who were candidates for biological treatment were tested with both the Mantoux test and the IGRA test, Quantiferon tb plus (QF TB plus). Any of the tests that were positive (except in patients vaccinated with BCG who had to have the PPD and the QF TB plus positive) were considered positive. In all positive cases, a chest Rx was performed to rule out active disease and in all of them the treatment of LTI was considered. Here we exposed our data in screening of LTI and treatment in those patients.

Results: During these years a total of 440 rheumatologic patients were analyzed and a total of 84/410 (21%) patients were registered with a positive test according to the before mentioned criteria. In no case was an active disease detected. The agreement between the different techniques analyzed was high, 86%, while QF TB plus was more sensitive than the Mantoux. All patients received treatment: 85% with isoniazid, 10% with rifampicin and 5% with the combination of rifampicin + isoniazid. Hepatic toxicity was recorded in 10/84 (12%) patients, although only two patients had to stop treatment. No cases of active tuberculosis were detected during follow-up. The average follow-up is 3.4±1.2 years. The average time from the beginning of LTI diagnosis to the start of the biological treatment was 48±12 days.

Conclusions: The combination of Mantoux test and IGRA test proved to be a good tool to detect cases of LTI. The agreement between them was good, although QF TB plus were more sensitive. The patients were very adherent to the treatment. There were no cases of active disease in the follow up. The toxicity was low and all the patients finished therapy.

Fever of unknown origin: a prospective observational study from a tertiary university hospital

Stefanos Vlachos1, Dimitrios Bassoulis*1, Michail Samarkos1, Georgios Patavoukas1, Christos Siafarikas2, Fotinie Ntziora2, Eirini Apostolidi2, Nikolaos Sypsas1, George L. Daikos1, M. Psichogiou1

11st Internal Medicine Department, Laiko General Hospital, National and Kapodistrian University of Athens, Athina, Greece, 21st Propaedeutic Internal Medicine Department, Laiko General Hospital, National and Kapodistrian University of Athens, Athina, Greece, 3Department of Pathophysiology, Laiko General Hospital, National and Kapodistrian University of Athens, Athina, Greece

Abstract 7686

Background: According to the latest definition, classic fever of unknown origin (FUO) is characterized as a condition of temperature exceeding 38.3 °C on at least three measurements over a period of at least three weeks, with no diagnosis made despite 1 week of in-patient investigation or 3 outpatient visits or 1 week of “intelligent and invasive” ambulatory investigation. The aim of the study was to update the data relating FUO, as the last available published series, in Greece, was 9 years ago.

Materials/methods: Clinical data were prospectively collected from patients meeting the criteria of classic FUO hospitalized in the 3 departments of internal medicine of “Laiko” General Hospital in Athens, Greece, a tertiary university hospital, from November 2017 to November 2019.

Results: During the study period, 87 cases fulfilled the criteria of classic FUO, yielding an incidence of 4,98 cases per 1000 patient-days. The patient sample consisted of 44 men (50.6%) and 43 women (49.4%), 76 natives (87.4%) and 11 foreigners (12.6%). The median patient age was 59 years (IQR: 43.5 – 77.5). The median time interval from onset of fever until study enrollment was 30 days (IQR: 21 – 54). 31 patients (35.6%) were included in the study on the 21st day of fever. The median hospital stay was 11 days (IQR: 7 – 22). The etiology of FUO was determined in 57 cases (65.5%), whereas 30 cases (34.5%) remained undiagnosed. The most common group of diagnosed cases was that of non-infectious inflammatory diseases (23 cases – 26.4%), followed by infections (17 cases – 19.5%), neoplasms (15 cases – 17.2%) and miscellaneous conditions (2 cases - 2.3%).

Conclusions: There is a rise in the frequency of non-infectious inflammatory diseases at the expense of infections as classic FUO diagnoses, compared to older data. There also seems to be a rise in the proportion of the undiagnosed cases of FUO. This can be explained by the advances in diagnostics which allow a quicker diagnostic approach to cases presenting with prolonged fever, which are no more considered as classic FUO cases.

The burden of enteric fever from three urban centres: a multi-centre, multi-component prospective epidemiological study with 626,219 person years of observation

Abstract 7689

James Meiring*1, Mila Shakya2, Farhana Khanam2, Merryn Voysey1, Maile Phillips1, Susan Tonks1, Thomas Darton4, Stephen Baker1, Christiane Dolecek6, Sarah Dunstan7, Gordon Dougan5, Kathryn Holt8, Rob Heyderman9, Firdausi Qadri2, Virginia Pitzer3, Buddha Basnyat10, Melita Gordon11, John Clemens2, Andrew Pollard1

1Oxford University, Oxford Vaccine Group, Oxford, United Kingdom, 2icddr,b, Dhaka, Bangladesh, 3Yale University, New Haven, United States, 4Sheffield University, Sheffield, United Kingdom, 5Cambridge University, Cambridge, United Kingdom, 6University of Oxford, Oxford, United Kingdom, 7University of Melbourne, Parkville, Australia, 8Monash University, Clayton, Australia, 9University College London, London, United Kingdom, 10Oxford University Clinical Research Unit, Kathmandu, Nepal, 11Malawi-Liverpool-Wellcome Trust Clinical Research, Blantyre, Malawi

Background: Enteric fever is a serious public health concern in many low- and middle-income countries. Numerous data gaps exist concerning the epidemiology of Salmonella Typhi and Paratyphi, the causative agents of enteric fever, in different global contexts. A comprehensive epidemiological study was conducted to quantify the burden of disease and to generate the evidence for typhoid Vi-conjugate vaccine implementation.

Materials/methods: In this multicentre, multicomponent prospective study, a demographic census was used to enumerate an open cohort of approximately 100,000 individuals in each of three urban sites in Africa (Malawi) and Asia (Nepal and Bangladesh). Facility-based passive surveillance was conducted for two years with blood-culture collection for febrile illness. Healthcare utilisation surveys performed in a sample of households enabled adjustment of incidence estimates for healthcare-seeking behaviour. Community-based serological surveillance was performed on an age-stratified cohort of over 24,000 randomly selected individuals, with blood samples collected at baseline and three months to provide an estimate of seroincidence.

Results: Between November 2016 and December 2018, 626,165 participants were enrolled in the demographic census across the three sites. From this population, 625 S. Typhi and 107 S. Paratyphi A isolates were cultured from the blood of 11,529 febrile patients. Multi-drug resistance was observed in 44% and fluoroquinolone resistance in 61% of S. Typhi isolates. The overall crude incidence rates of blood-culture confirmed S. Typhi per 100,000 person-years of observation were 58 (95% confidence interval [CI]: 48-70) in Malawi, 74 (95% CI: 62-87) in Nepal and 161 (95% CI: 145-179) in Bangladesh. Adjusted incidence rates were highest in the 5-9-year age group in all three sites, with overall adjusted rates per 100,000 person-years of 477 (95% CI: 372-770) in Malawi, 1,256 (95% CI: 827-2,074) in Nepal and 1,312 (95% CI: 1,037-1,701) in Bangladesh. Through serological surveillance, seroconversion rates suggest higher rates of exposure and infection than captured through passive surveillance.

Conclusions: S. Typhi is a major cause of febrile illness in young children in the populations studied. Combined with high rates of anti-microbial resistance, the introduction of typhoid conjugate vaccines and improvements in water and sanitation infrastructure are a necessity to control this pathogen.

Abstract 7691

Ceftriaxone and cefotaxime have similar impact in emergence of resistance in gut microbiota from hospitalised patients

Pilmis Benoit*, Olivier Jiang1, Assaf Mizrahi1, Jean-Ralph Zahar2, Alban Le Monnier1

1Hospital Group Paris Saint Joseph, Paris, France, 2Avicenne Hospital [AP-HP], Bobigny, France

Background: Resistance to third generation cephalosporins (3GC) in Enterobacteriaceae is a major concern. Most risk factors associated with colonization and infection with 3GC-resistant Enterobacteriaceae included healthcare exposure, travel in high endemic region and recent antibiotic therapy [especially 3GC]. ceftriaxone and cefotaxime, two intravenous administered 3GC, have different pharmacokinetics characteristics, mostly regarding elimination half-life and route. In previous studies, ceftriaxone could be responsible for the selection of 3GC-resistant Enterobacteriaceae. However, these datas are still controversial today.

Thus, the objective of this study was to compare the impact of ceftriaxone versus cefotaxime on emergence of resistance in gut microbiota from hospitalized patients.

Materials/methods: We conducted a prospective study in patients hospitalized in internal medicine and treated with ceftriaxone or cefotaxime. Patients were included during two periods according to the 3GC received: ceftriaxone during the first period (ceftriaxone group) and cefotaxime during the second period (cefotaxime group).

A dynamic collection with 3 fecal samples was collected from each patient [at days 0, 3, 7 or at the cessation of antibiotic therapy] in order to determine intestinal colonization with 3GC resistant Enterobacteriaceae (ESBL-PE and AmpC-hyperproducing Enterobacteriaceae) and their relative faecal abundance, and emergence of toxigenic Clostridium difficile, yeasts and vancomycin resistant Enterococci. Total cultivable aerobic bacteria and total Gram-negative Enterobacteriaceae were also counted.

Results: During the study period, 28 patients were included in the ceftriaxone group and 17 in the cefotaxime group. No differences in the counts of 3GC resistant Enterobacteriaceae was observed in both groups over time. Carriage of toxigenic Clostridium difficile was observed in 3 patients [2 in the ceftriaxone-group and one in the cefotaxime group] but was associated with clinical infection in only one case in cefotaxime group.

Conclusions: In our prospective study, Ceftriaxone and cefotaxime seems to have the same impact on the emergence of 3GC resistant Enterobacteriaceae or toxigenic C. difficile in gut microbiota of hospitalized patients. These results need to be confirmed on a larger cohort in order to use safely ceftriaxone.

Abstract 7692

Development of an extraction control in Fungiplex Candida IVD real-time PCR Kit

Julie Green*1, Colette Dalton1

1Bruker Microbiology and Diagnostics, Glasgow, United Kingdom

Background: This study is designed to test contrived samples spiked into serum, plasma and whole blood material to assess the impact of a new extraction control on the limit of detection of the Fungiplex Candida IVD Real-Time PCR Kits and to ensure sensitivity was unaffected by this change.

Materials/methods: Simulated samples have been prepared and analysed for this study as well as synthetic DNA. Samples prepared in serum, plasma and whole blood were spiked with specific concentrations of Candida DNA prior to extraction. Samples were prepared and tested using the control material both as an extraction control and as a PCR inhibition control. This study has included limit of detection analysis, dynamic range determination, interference testing, extraction efficiency calculation. Extraction was performed using the BioRobot® EZ1™ by Qiagen. The PCR was prepared using the Fungiplex Candida IVD Real-Time PCR Kit and tested across 5 common laboratory thermal cycler platforms.

Results: When tested with the Fungiplex Candida IVD Real-Time PCR Kit, the limit of reproducibility for various Candida species samples was 1 – 5 CFU. No difference in sensitivity was observed between the different sample types. With plasmid DNA samples the LOD remained at 20 input copies as defined by previous studies and Candida DNA was detected between 20 and $2 \times 10^6$ input copies. Detection was not affected by the presence of inhibitors or interfering substances. The extraction control was detected in every sample analysed with no significant differences observed in Ct value reported. Depending on the extraction method/protocol used, the amount of DNA in the resultant extract varied and in some instances a 50% loss was observed. The extraction control has been developed to endure differences in extraction efficiency.

Conclusions: 100% sensitivity was reported for the Fungiplex Candida Kit when analysing Candida samples at the predefined limits of detection of 20 input copies or 1 – 5 CFU. The sensitivity is not dependent on sample type and the new extraction control implemented in this product did not affect the performance of the Kit.

Evaluation of MediScout for the planning, operationalisation and monitoring of community-based tuberculosis active-case finding interventions: a prospective study in the Democratic Republic of Congo

Mauro Faccin1, Olivier Rusumba2, Fairouz Boutachkourt1, Dussema Smaoui3, Julie Vanvolsem1, Freddy Birembano4, Jean-Pierre Kabuayi5, Michel Kaswa4, Emmanuel Andre*6,7

1UCLouvain, Ottignies-Louvain-la-Neuve, Belgium, 2Ambassadeurs de Lutte Contre la Tuberculose, Bukavu, Democratic Republic of Congo, 3Savics, Brussels, Belgium, 4PNLT (Programme National de Lutte Contre La Tuberculose), Kinshasa, Democratic Republic of Congo, 5International Union Against Tuberculosis and Lung Disease (The Union), Kinshasa, Democratic Republic of Congo, 6Katholieke Universiteit Leuven, Leuven, Belgium, 7UZ Leuven, Leuven, Belgium

Abstract third-party references: Innoviris, Brussels, Belgium

Background: To find the 3 million missing tuberculosis (TB) cases worldwide — 50% of TB cases in Africa—, the WHO recommends to perform community-based screening in populations where the incidence of the disease is above 1% per year. In practice, no country presents such a high incidence at national level, and TB programs limit active case finding to the households of TB cases, people living with HIV and people living in prisons or mines. Additional tools are required to identify pockets of high TB incidence at the sub-national level.

Materials/methods: The MediScout© (Savics, Belgium) approach is a two-step triage process aiming to identify communities and individuals at high risk for TB. The first step consists in using artificial intelligence and open data (population, satellite images, TB reports) to build a map which gives a risk score for TB to each area of a country or a province. The second step consists in performing door-to-door verbal screening using a scoring system based on questions related to symptoms and exposure to TB. We performed a prospective community-based study in the South-Kivu province of the Democratic Republic of Congo to evaluate the performance of this approach.

Results: Between March and October 2019, 7,714 interviews were performed by community health workers using the MediScout mobile application in 8 different locations (Figure 1A), among which 3,849 (50%) in 3 zones predicted to show an incidence rate above 1%. Individuals categorized at high risk for TB were referred for Ziehl-Neelsen microscopy test. Overall, positivity rate was 3.5 times higher in the 3 zones predicted to be at high risk (42 people tested positive) compared to the 4 zones predicted to be at lower risk (12 people tested positive).

Conclusions: Community-based screening should be performed in communities where the incidence of TB is expected to be above 1% per year. MediScout© is the first commercial solution which allows to efficiently target these communities at sub-national level and to operationalize the required targeted community-based interventions. In this study, combining artificial intelligence technologies with smart application resulted in high yield of detection of previously unrecognized active TB infections.

(A) Predicted TB intensity based on artificial intelligence analysis for Africa, with a zoom on the South-Kivu province of the Democratic Republic of Congo.
(B) Correlation between the predicted incidence rate for TB and the actual yield of community-based TB screenings. The WHO recommends to perform active case finding when the expected incidence is higher than 1%.

Clinical and laboratory study on invasive infections due to Fusarium species in critically ill adult and paediatric patients in Serbia: ten years' experience of National Laboratory for Medical Mycology

Valentina Arsic Arsenijevic*1, Suzana Otasevic2, Anna Maria Tortorano3, Dragana Ivanovic4, Jovanka Kolarovic5, Lejla Paripovic6

1University of Belgrade - Faculty of Medicine, Institute of Microbiology and Immunology, Београд, Serbia, 2University of Niš, Niš, Serbia, 3University of Milan, Milano, Italy, 4Institute of Public Health of Serbia, Serbia, 5University of Novi Sad, Novi Sad, Serbia, 6Institute for Oncology and Radiology of Serbia, Beograd, Serbia

Abstract third-party references: Ministry of Education, Science and Technology Development Grant OI 174034

Background: Invasive mold infections (IMIs) are being increasingly recognized as a major threat in critically ill adult and paediatric patients. Data from Serbia reported Fusarium as the second most common IMIs pathogen, especially in paediatric critically ill patients [Tortorano AM et al, 2014, Arsic Arsenijevic V and Denning D, 2018]. This study aims to investigate the epidemiology of fusariosis in Serbia, during ten years. The clinical and laboratory data were launched.

Materials/methods: Fusarium cases analyses performed from January 2009 to January 2018. Onychomycosis due to Fusarium were excluded. A total of 16 proven cases collected, and Fusarium identified by sequencing the translation elongation factor 1α gene. Antifungal susceptibility was done by broth microdilution method.

Results: In adult patients sporadic ocular infections were seen (n=7), while in paediatric patients (n=9) deep site infections occur. Ocular Fusarium infections were proven by microscopy and culturing, and deep site infection by blood culture (n=8) or tissue sample culture. Risks for adults were the increased use of corticosteroids and trauma, and for pediatrics nosocomial route of infection. As the result of fungal dissemination the skin involvement was common in children. Gibberella fujikuroi species complex (SC), including Fusarium verticillioides and F. proliferatum, and F. solani SC were identified. Amphotericin B was the most potent, and itraconazole the least effective. The azoles exhibited lower minimum inhibitory concentrations against F. verticillioides strains, with posaconazole having a slightly better performance. F. solani SC isolates were resistant to all azoles.

Conclusions: Beside relatively low number of proven IMIs due to Fusarium two different spectrum of infections seem to be age dependent in critically ill patients in Serbia, ocular form found in adults and disseminated form in pediatric patients. Fusariosis is a rare but difficult to treat IMIs, and this is important because Serbia is agriculture reach country and further surveillance of these predominant plant pathogens causing severe human infections is urgent need. New proven cases and epidemiology data are important for development of effective prevention strategy for fusariosis among high-risk patients.

Optimisation of bacterial whole genome sequencing workflow for implementation in routine clinical and epidemiological applications

Celine Helsmoortel\textsuperscript{1,2}, Lies Laenen\textsuperscript{1,2}, Erika Souche\textsuperscript{1,2}, Luc Dehaspe\textsuperscript{1,2}, Nina Dedoncker\textsuperscript{1,2}, Wouter Bossuyt\textsuperscript{1,2}, Stefanie Desmet\textsuperscript{1,2}, Emmanuel Andre\textsuperscript{1,2}

\textsuperscript{1}UZ Leuven, Leuven, Belgium, \textsuperscript{2}Katholieke Universiteit Leuven, Leuven, Belgium

Background: Whole genome sequencing (WGS) of bacterial pathogens has several advantages over current diagnostic methods. WGS can provide clinically and epidemiologically useful information related to pathogen identification, antimicrobial resistance and typing. Further, the exhaustiveness and the digitalization of the results are major advantages compared to conventional analysis which have to be repeated when new parameters need to be assessed. Large scale adoption WGS in the clinical environment is lagging however due to cost and complexity of data analysis which are mainly driven by the cost of reagents, multiple manual steps and finally the time required by bio-informaticians to process the data. Here we present a novel integrated, high-throughput and highly automated workflow that significantly decreases, cost, turn-around-time and data analysis complexity of bacterial WGS.

Materials/methods: We optimized several aspects of the workflow. First, we validated the Nextera XT (Illumina) library preparation on the Echo (Labcyte) acoustic liquid handling system. This system allows to work with minimal amounts of reagents, as small as nanoliters, and to work on large series of samples with minimal hands-on time. Second, we allowed automated transfer of sequencing data to a cloud-based repository. Third, we developed and automated two pathogen-specific cloud-based pipelines. To improve functionality and compatibility, we integrated these modules as Docker images to make the entire system modular and easy to share. Such system could easily be transferred to partner laboratories willing to perform bacterial WGS without investing in laborious bioinformatical development, validation and maintenance.

Results: In this proof-of-principle study, we successfully performed 454 WGS analysis. The optimized workflow compared to the conventional workflow resulted in significant decrease in reagents cost (40%) and hands-on time in the lab (90%). Automated data processing after demultiplexing was typically finalized after 49 minutes (Streptococcus pneumoniae) and 55 minutes (Mycobacterium tuberculosis).

Conclusions: Considering the higher automation and the better traceability of this new approach together the decreased cost and time-to-result, this optimized bacterial WGS workflow meets our quality standards and cost constraints. This evaluation allows to reconsider the place of bacterial WGS for clinical diagnostic and surveillance purposes in our University Hospital.

Abstract 7700

Evaluation of a multiplex real-time PCR assay for detection of the aetiologic agents of vaginitis
Paula Salmerón*, Patricia García, Miguel Fernández-Huerta, Candela Fernández Naval, Tomás Pumarola-Suñé, Yannick Hugos-Mallecot, Judit Serra Pladevall

1Vall d’Hebron University Hospital, Barcelona, Spain

Background: Vaginitis is one of the most common reasons women seek professional assistance. Vulvovaginal candidiasis, trichomoniasis and bacterial vaginosis (BV) are the main infectious syndromes that cause abnormal vaginal discharge. Diagnosis of these disorders presents several barriers such as low tests sensitivity and the need of experienced microscopists. The aim of this study is to evaluate the Allplex™ Vaginitis Screening Assay for the detection of etiologic agents of vaginal pathology from clinical samples

Materials/methods: Between July and September 2019, a total of 100 vaginal swabs (11 Candida albicans positive, 5 Candida spp. positive, 4 Trichomonas vaginalis (TV) positive, 39 BV, 5 C. albicans and BV coinfection and 36 samples with healthy vaginal microbiota) were collected from women with symptoms of vaginitis. Test was performed using the multiplex RT-PCR Allplex™ Vaginitis Screening Assay (Seegene, Korea), DNA extraction was performed in the Starlet platform (Seegene, Korea) and Real-time PCR was performed in a CFX-96-real-time thermocycler (Bio-Rad, USA), according to the manufacturer’s instructions. Results were compared with reference methods: yeast culture (BBL™ CHROMagar Medium) and Gram staining for C. albicans and Candida spp. and Gram staining (Nugent score) for BV. We compared TV-PCR results with culture (Roiron Medio, DIFCO).

Results: Results are displayed in table 1. Sensitivity of Allplex™ assay was 93.8% [n=16; 95% CI: 69.7–99.8%] for C. albicans, 100% [n=5; 95% CI: 48.0–100%] for Candida spp., 100% [n=4; 95% CI: 39.7–100%] for TV and 84.1% [n=44; 95% CI: 69.9–93.4%] for BV. Specificity was 88.1% [n=84; 95% CI: 79.2–94.1%] and 89.3% [n=56; 95% CI: 78.1–96.0%] for C. albicans and BV, respectively. This lack of specificity is due to the fact that 10 C. albicans and 6 BV were detected by Allplex™ assay but not by the reference method. Moreover, two TV-culture negative were detected by Allplex™ assay.

Conclusions: Allplex™ Vaginitis Assay demonstrated good concordance with conventional methods what supports the feasibility of this assay as an alternative test for screening of women with abnormal vaginal discharge. However, due to the high sensitivity of RT-PCR, Allplex™ assay detected several cases that had not been detected by reference method, probably due to low microorganism load, and this fact could be a disadvantage since it could lead to over-diagnose.

Abstract 7701

**Digital antimicrobial dashboard facilitates antimicrobial stewardship in a large London teaching hospital**

Laura Whitney¹, Mark Gilchrist*¹, Aneeka Chavda¹, Anne Kinderlerer¹, Siddharth Mookerjee¹, Alison H. Holmes¹,²

¹Imperial College Healthcare NHS Trust, London, United Kingdom, ²Imperial College London, London, United Kingdom

**Background:** Our antimicrobial stewardship (AMS) programme routine consumption reporting revealed a 20% increase in carbapenem usage between 2016/17 and 2017/18 (154-186 DDDs/1000 admissions), placing our usage 40% above the London mean and 1.3% above the Shelford hospital group mean. This rise was compounded by fragile drug supply lines and local resistance patterns.

A patient-level audit of 62 patients showed 7% of 688 meropenem days of therapy were potentially inappropriate; primarily due to delays between treatment initiation and infection specialist advice. This identified the need for a robust real-time method to identify patients on antimicrobials within our newly adopted electronic prescribing system (Cerner powerchart) and facilitate stewardship interventions.

**Materials/methods:** An AMS dashboard (figure 1) was developed within Cerner which identifies all in-patients currently prescribed antimicrobials. It shows patient details, antimicrobial information (drug, route, dose, duration, missed doses), and recent laboratory results (cultures and susceptibilities and inflammatory markers). This links directly to patient records and can be filtered (by location/drug/treatment duration), annotated to flag patients requiring review, and record stewardship interventions. The dashboard was piloted between August and October 2019 with refinements on-going and improvements to stewardship practices measured.

**Results:** The pilot confirmed the dashboard accurately identifies patients on antimicrobials, albeit with some missing data (allergies and route of anti-infective administration). It was used to facilitate the Trust antimicrobial point prevalence survey (August 2019), reducing the time burden of data collection, and to facilitate AMS rounds in high carbapenem consumption areas. Reductions in average time taken to identify patients requiring intervention were seen (from 24 to 10mins per ward round). It also facilitated intervention (in 53% of patients), particularly stopping unnecessary antimicrobials (30% of patients reviewed). Carbapenem consumption fell by 12% to 163 DDDs/1000 admissions in 2018-19.

**Conclusions:** Implementation of a digital AMS dashboard facilitated both audit and timely patient level review of antimicrobials. Work is ongoing to optimise both data display and utilisation of this novel stewardship strategy within the larger AMS and infection prevention and control programme. Expansion to the out-patient setting and linking to clinical decision support systems are also longer term ambitions.

Abstract 7703

The case for pharmacokinetic/pharmacodynamic studies during epidemics of high consequence pathogens: Tekmira for Ebola virus disease in Sierra Leone

Janet Scott1, Raman Sharma2, Luke Meredith3,4, Jake Dunning5,6, Catrin Moore6, Foday Sahr7,8, Steve Ward2, Ian Goodfellow3,4, Peter Horby6

1Glasgow, MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom, 2Liverpool School of Tropical Medicine, Liverpool, Liverpool, United Kingdom, 3University of Cambridge, Dept Pathol, Div Virol, Cambridge, United Kingdom, 4University of Makeni, Department of Public Health, Makeni, Sierra Leone, 5National Infection Service, Public Health England, London, United Kingdom, 6University of Oxford, Centre for Tropical Medicine and Global Health, Oxford, United Kingdom, 7Republic Sierra Leone Armed Forces, Military Hosp 34, Freetown, Sierra Leone, 8Republic Sierra Leone Armed Forces, Military Hosp 34, Freetown, Sierra Leone

Background: Pharmacokinetic/Pharmacodynamic (PK/PD) studies during epidemics pose substantial logistical and safety challenges. However, data generated can be used in dose optimisation, and delineating toxicology thresholds [TT]. It is possible to draw conclusions from relatively small numbers of subjects. PK can alter in the disease state, making measurements from patients invaluable, particularly in the haemodynamic destruction caused by Ebola virus. For example: isolated PK measurements were used to evaluate Favipiravir concentrations in EVD patients [1] and a PKPD study of Tekmira (TKM-130803) in EVD patients yielded sufficient information to develop an in silico model presented below.

Materials/methods: TKM-130803 is a specific anti-EBOV therapeutic comprised of two small interfering RNAs (siRNA) siLpol-2 and siVP35-2. During the clinical trial [Sierra Leone, 2015], patients were infused with 0.3 mg/kg of TKM-130803 over 2 hours daily for up to 7 days [2]. The trial was discontinued having reached a predefined statistical endpoint which indicated a low probability of demonstrating overall therapeutic benefit compared to historic controls [2]. Plasma concentration of siRNA was compared to survival at 14 days. PK data were fitted to two-compartment models then Monte Carlo simulated PK profiles were compared to Efficacy Thresholds (Cmax 0.04-0.57 ng/mL and mean concentration 1.43 ng/mL), and TT (3000 ng/mL).

Results: SiRNA was in quantitative excess of virus genomes throughout treatment, a level considered needed for efficacy, but the 95% percentile exceeded TT. The maximum AUC for which the 95% percentile remained under TT was a continuous infusion of 0.15mg/kg/day. Plasma concentration of both siRNAs were higher in subjects who died compared to subjects who survived (p<0.025 both siRNAs).

Conclusions: Subjects who died exhibited impaired drug clearance, justifying caution in dosing strategies for such patients. This analysis is the first PK model derived from EVD subject and indicates that such studies are possible, if challenging. It has given a useful insight into the pharmacokinetics of the siRNA in the disease state and illustrates the value of designing PKPD studies into future clinical trials in epidemic situations.

Abstract

Background: Terbinafine resistance is increasingly reported in Trichophyton rubrum and Trichophyton interdigitale rendering susceptibility testing important particularly in non-responding cases. We performed a multicentre evaluation of a recently proposed EUCAST method implementing medium supplemented with chloramphenicol and cycloheximide (CC) to avoid contamination.

Materials/methods: A blinded panel of wild-type and squalene epoxidase [SOLE] target gene mutant T. rubrum and T. interdigitale strains were distributed to 10 laboratories. Susceptibility to terbinafine, itraconazole, voriconazole and amorolfine were performed according to the EDef 9.3.1 method with and without addition of chloramphenicol and cycloheximide [final concentrations 50 mg/L and 300 mg/L]. Plates were incubated at 25°C [one laboratory used 28°C] for 5-7 days until sufficient growth. MICs were determined visually [ignoring trailing growth for itraconazole] and spectrophotometrically with 90% and 50% endpoints [total 7,829 MICs]. A. flavus ATCC204304 and A. flavus CMM-C1813 were included as controls. Very major errors VME [mutant MICs\(\geq 6\)-WT-UL] and major errors ME [wild-type MICs WT-UL] were determined.

Results: 100%/96% [itraconazole] and 84%/84% [itraconazole] MIC determinations fell within the QC ranges for the two QC methods, respectively, and 99%/96% terbinafine MICs fell in a 0.25-1 \(\mu\)g/mL range suggesting a high interlaboratory reproducibility. Across the six methods, the number of terbinafine MEs varied from 2-5 [2.6%-6.6%] for T. rubrum and between 0-2 [0%-2.0%] for T. interdigitale [lowest for the CC-method [2.6%-4.4%/0-1% for T. rubrum/T. interdigitale]]. The difference between the modes for the wild-type and mutant population were \(\geq 7\) two-fold-dilutions in all cases [Table]. If excluding a F397L/V237I T. rubrum mutant, and two mixed T. interdigitale strains, the number of VMEs were CC visual: T. rubrum: 1/77 [1.3%], CC spec-90%: 3/68 [4.4%] and CC spec-50%: 1/76 [1.3%], and none for T. interdigitale. The activity of voriconazole, itraconazole and amorolfine were quite uniform against T. rubrum and T. interdigitale, but unacceptably wide MIC ranges were found for the visual and spec-90% inhibition methods for itraconazole.

Conclusions: Although none of the laboratories perform dermatophyte testing at a regular basis an acceptable interlaboratory agreement and good separation between SOLE wt and mutants were found with very low error rates, suggesting a robust performance of the proposed method.

Table. Comparison of terbinafine MICs determined using the EUCAST CC-method for 20 wild-type and 18 SOLE mutant T. rubrum and T. interdigitale isolates. MICs were read visually (with a no growth endpoint) and by spectrophotometer using a 90% and 50% inhibition endpoints.

**Abstract 7707**

**Distribution during 10 years of the genotypes A and B of *Giardia intestinalis* among the infected subjects attending to an Italian tertiary care hospital**

Adriana Calderaro1, Sara Montecchini*2, Mirko Buttrini1, Sabina Rossi3, Federica Motta1, Giovanna Piccolo1, Marco Maria Antonaci3, Maria Loretana Dell’anna1, Maria Cristina Arcangeletti1, Carlo Chezzi1, Flora De Conto1

1University of Parma, Department of medicine and surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Virology, Parma, Italy, 3University Hospital of Parma, Unit of Clinical Microbiology, Parma, Italy

**Background:** *Giardia intestinalis* is considered one of the principal causative agents of diarrhea and an important waterborne disease pathogen that infects animals and humans worldwide. Investigations such as host specificity and transmission patterns require the direct genetic characterization of parasites from fecal samples. *G. intestinalis* is distributed into eight distinct genetic assemblages (A-H), however only assemblages A and B are known to infect humans. The present study aims to investigate the distribution, among the infected subjects, of the genotypes A and B of *G. intestinalis* in the last 10 years (2009-2018) in a tertiary care hospital.

**Materials/methods:** A total of 162 DNAs extracted from human stools positive for *G. intestinalis* was analyzed for the Assemblages identification. The DNA extracted was used to amplify, by a real-time PCR assay based on melting curve analysis, the translation initiation factor, and the cathepsin L precursor genes for assemblage A and B, respectively. Chi-square test was used for the comparison of the frequency of Assemblage A and B between Italians and foreigners, between adults and children and between male and female. Statistical significance was set at p< 0.01.

**Results:** Out of 162 samples analyzed, 72 samples were assigned to Assemblage A, 37 to Assemblage B, 7 were mixed and 15 were not amplified. The frequency of Assemblage A in association with origin was 70.8% in Italians and 47.7% in foreigners, while the frequency of Assemblage B was 25% in Italians and 43.2% in Foreigners: this different Assemblages distribution resulted significant (p=0.0229). On the contrary, no significant difference was observed in the frequency of Assemblage A and B in association with age (p=0.119) and sex (p=0.3948). The 15 not amplified samples are at present under investigation to assess if they could be included in a non-A non-B Assemblage.

**Conclusions:** The performed real-Time PCR was able to amplify *G. intestinalis* DNA in 90.7% of the tested samples. The result show that Assemblage A, related to a major risk of zoonotic transmission, is prevalent, as already described in Italy. Assembly B is less common in our area, with a frequency attributable mainly to immigrants from developing countries.

Clinical characteristics and mortality-related factors of bloodstream infections in patients with acute leukaemia: a single-centre experience with 152 patients

Gustavo Mendez1,2, Carla Niveyro*1,2, Pedro Villalba1, Karina Alejandra Salvatierra1,2, Claudia Villalba1,2, Haydee Bernard1,2

1Catholic University Missions, Posadas, Argentina, 2Hospital Dr. Ramón Madariaga, Posadas, Argentina

Background: Bloodstream infection (BSI) is an important cause of morbidity and mortality in patients with acute leukemia (AL) undergoing chemotherapy or stem cell transplantation. BSI was documented in 11-30% of the febrile neutropenia (FN) episodes. The epidemiology of BSI in FN constitutes the basis for selection of empiric antibiotic therapy for febrile neutropenia.

Objectives: To establish the incidence, microbial etiology, risk factors and prognosis of BSI in patients with AL.

Materials/methods: Retrospective observational study. All patients with AL and FN (absolute neutrophil count of <500/mm³) consecutively hospitalized between June 2011 and December 2018 were included. The package Infostat 2014 program was used for statistical analysis.

Results: 365 episodes of FN (in 152 patients) were evaluated, 126 BSI were documented (34.5%), including 13 (10.3%) episodes polymicrobial bacteremia. The mean age of the patients was 34.11 ± 7.2 years and 58% were male. Low-risk group (according MASCC Risk Index) 294 episodes (80.5%). Twenty-five (6.8%) patients died. Gram-negative bacteria (GNB) were found in 62.5%, Gram-positive bacteria (GPB) 36.6% and one patient had fungemia (C. parapsilosis) of the isolates. Clinically documented infections could be observed in 162 of 365 febrile episodes (44.3%). The majority of them localized in the abdomen 44 cases (12%), catheter-associated infections 39 cases (10.6%) and lung infections 36 cases (9.8%). Risk factors associated with BSI were relapse of hematological disease (p = 0.009), hospitalization in the last 30 days (p = 0.003), antibiotics in the last 30 days (p = 0.03). In the group of BSI patients mortality was higher than in non-bacteremic patients (p = 0.0003).

Conclusions: Bacterial epidemiology and antimicrobial resistance in these patients should be regularly monitored, which will provide guidance for local policies for the use of antimicrobial agents for empirical antibiotic therapy in FN. Mortality in BSI and FN is worse than in non-bacteremic patients. Reducing the fatality rate of bacteremia remains a major challenge.

Abstract 7712

**Microbial predictive virulence factors for pyelonephritis caused by extended-spectrum beta-lactamase-producing Escherichia coli in children harbouring such strains in their gut microbiota**

Bidet Philippe*1,2, André Birgy1,2, Corinne Levy1, Fouad Madhi3, Elsa Sobral3, Robert Cohen3, Stéphane Bonacorsi1,2

1Université de Paris, IAME, INSERM, Paris, France, 2Hopital Robert Debré APHP, Service de Microbiologie, Centre National de Référence Escherichia coli, Paris, France, 3Association Clinique Thérapeutique Infantile du Val de Marne (ACTIV), Saint-Mour-des-Fossés, France

**Background:** Emergence of extended spectrum beta-lactamase (ESBL) Escherichia coli strains causing pyelonephritis in children is increasing worldwide and questions empirical antimicrobial therapy. However, implementing carbapenems as first line antibiotics would probably lead to an increase of carbapenem-resistant strains. Fecal carriage monitoring of resistant strains can be used to adapt the choice in patients hospitalized during long periods of time. However these patients are more frequently carriers of multidrug resistant bacteria and thus more frequently treated with carbapenems.

In this study we have analyzed the virulence factors of ESBL-producing E. coli strains causing pyelonephritis in children in comparison with those encountered in fecal carriage by asymptomatic children in order to identify a pyelonephritis-associated virulence profile

**Materials/methods:** From March 2014 to March 2017, 218 ESBL-producing E. coli isolates were recovered from French pediatric pyelonephritis cases. From October 2010 to July 2017, 154 ESBL-producing E. coli were isolated from fecal carriage among French children aged 6 to 24 months in the community.

Strains were sequenced with the Nextera kit (Illumina, San Diego, CA, USA). We used the Centre for Genomic Epidemiology (CGE) website to characterize the strains and 180 virulence factor genes were searched using the NCBI BLAST tool.

**Results:** The most frequent phylogroup was B2 both in pyelonephritis (64%) and carriage isolates (60%). The most frequent ST was ST-131 (44%) in both collections. We found no significant difference between pyelonephritis and carriage isolates in terms of phylogroup, ST or serotype. Among the 180 virulence genes searched 27 were present in > 20% of pyelonephritis isolates. After Bonferroni correction, five (papC, papGII, hlyC, hek and traJ) remained significantly associated with pyelonephritis. The strongest association with pyelonephritis was found for individual genes with adhesin papGII (54% vs 16%) and for gene combinations with papGII and/or traJ (63% vs 24%).

**Conclusions:** ESBL-producing E. coli strains found in fecal carriage genetically resemble those causing pyelonephritis in children with the exception of few genes. Combining the detection of two genes (papGII and/or traJ) would permit to attribute a risk-associated genetic profile to 63% of pyelonephritis isolates versus only 24% of healthy carriage isolates

**Presenter email address:** philippe.bidet@aphp.fr
Central nervous system infections caused by herpes simplex virus and varicella zoster virus in France, 2014-2018: a nationwide retrospective study

David Boutolleau*1, Sonia Burrel1

1Pitié-Salpêtrière University Hospital, National Reference Center for Herpesviruses, Paris, France

Background: Herpes simplex virus 1 and 2 (HSV-1 and HSV-2) and varicella-zoster virus (VZV) remain major causes of sporadic meningoencephalitis worldwide. The French National Reference Centre for Herpesviruses-Associated Laboratory Pitié-Salpêtrière [Paris] performed a nationwide retrospective observational study to examine epidemiological and clinical characteristics of alphaherpesvirus central nervous system (CNS) infections during the period 2014-2018.

Materials/methods: Forty-eight public or private microbiology laboratories throughout France participated in this study. Participants indicated the total number of cerebrospinal fluids (CSFs) tested for HSV-1, HSV-2 and VZV and the diagnosis procedures used. For each positive result, data related to patient demography, clinical presentation, biological features, and antiviral treatment were collected.

Results: A total of 189,010 CSFs from 181,559 distinct patients were analysed by the 48 laboratories, and 3,860 patients had a positive result: 1,247 (32.3%) for HSV-1, 822 (21.3%) for HSV-2, 1,791 (46.4%) for VZV. The overall prevalence of alphaherpesvirus CNS infections was 2.13%: 0.69% for HSV-1, 0.45% for HSV-2, 1.12% for VZV. Molecular diagnosis on CSF was performed by real-time PCR in all laboratories. The most common platforms used were easyMAG/EMAG (BIOMERIEUX) for nucleic acid extraction (50%) and LightCycler (Roche Diagnostics) for gene amplification (35%). R-GENE® kits (ARGENE, BIOMERIEUX) were used by 59% of participants. Only 13 (28%) laboratories used a sample-to-answer instrument (LIAISON MDX, DiaSorin or FilmArray, BIOMERIEUX). Data for patients with a positive CSF result have been analysed so far for 36 (75%) laboratories. CSF positivity for any alphaherpesvirus did not differ according to gender (men, 49.5%; female, 50.5%) and was not associated with immunosuppression. The median age of patients with a positive CSF result was 61 years for HSV-1, 39 years for HSV-2, 58 years for VZV. HSV-1 prevalence was similar among men and female, whereas HSV-2 prevalence was almost twice higher among female than men. Among patients with a positive CSF, 19.3% had a normal white blood cell count <5/mm3, and 25.2% had a normal protein level ≤5g/L. Analyses are still in progress for remaining laboratories and items.

Conclusions: This national study will permit to improve our knowledge regarding HSV and VZV CNS infections in France.

Abstract 7715

**Pan-bacterial cumulative antibiograms**

Anatole Luzzati, Mélissa Mary, Julie Teresa Shapiro, Gerard Lina, Frédéric Laurent, François Vandenesch, Olivier Bauwalder, Jean-Philippe Rasigade

1Hospices Civils de Lyon, Institut des Agents Infectieux, Lyon, France, 2University of Lyon, CIRI INSERM U1111 - CNRS UMR5308 - ENS Lyon, Lyon, France

**Background:** Cumulative antibiograms are increasingly used to inform antimicrobial stewardship and to monitor antimicrobial resistance (AMR). Cumulative antibiograms are typically defined on a species-specific basis and, thus, focus on acquired resistance. However, the overall AMR burden also depends on the distribution and selection of bacteria with intrinsic resistance to key antibiotics. We propose that pan-bacterial cumulative antibiograms, that aggregate all species to consider both acquired and intrinsic resistance, can complement species-specific antibiograms by providing a less detailed but more complete picture of AMR. Here, we examine and overcome the challenges of computing such antibiograms and we illustrate their relevance to linking ward-level antibiotic use and resistance.

**Materials/methods:** Routine susceptibility testing involves different antibiotics depending on the isolate's species and other factors. To obtain comparable resistance profiles across multiple species, we implemented a 3-step data enrichment pipeline comprised of: (1) inclusion of EUCAST intrinsic resistances; (2) application of EUCAST deduction rules; and (3) random-forest-based imputation of remaining missing data. The pipeline was used to calculate cumulative antibiograms for 14 drugs from 73,962 non-duplicate, non-screening clinical isolates collected in 2015-2017 from 381 wards in 4 hospitals in Lyon, France. We examined the correlation of ward-level consumption (in DDD/bed/y) of cefotaxime and ciprofloxacin with their respective resistance rates using either *E. coli*-specific or pan-bacterial cumulative antibiograms.

**Results:** The input dataset contained 615,430 tested drug-isolate pairs out of 10.3x10^6 possible pairs (59.4% completeness). Data enrichment increased completeness to 82.5% (+23.1%) with a major contribution from intrinsic resistance inclusion (+18.3%). Using linear regression, cefotaxime consumption explained only 2.6% of the variance of *E. coli*-specific resistance across wards (P=0.01) but 10.3% of pan-bacterial resistance variance (P<1x10^{-6}). Likewise, ciprofloxacin consumption explained a higher proportion of the variance of resistance rates in pan-bacterial antibiograms (12.9%) than in *E. coli*-specific antibiograms (8.5%).

**Conclusions:** Automated data enrichment enables the computation of pan-bacterial cumulative antibiograms reflecting both intrinsic and acquired AMR. Compared to *E. coli*-specific resistance to cefotaxime and ciprofloxacin, pan-bacterial resistance was more strongly associated with cefotaxime and ciprofloxacin consumption, possibly reflecting the local antibiotic pressure. Pan-bacterial cumulative antibiograms could facilitate the comparison of global AMR rates across hospital wards.

Abstract 7719

A real-time PCR for the detection of Mucormycetes: Fungiplex Mucorales

Julie Green*, Kate Dempsey

1Bruker Microbiology and Diagnostics, Glasgow, United Kingdom

**Background:** Mucorales have been increasingly reported as causes of invasive fungal infections in immunocompromised subjects, particularly in patients with haematological malignancies, uncontrolled diabetes mellitus or those undergoing dialysis. Mucorales are now also being reported in Aspergillus-positive patients who are not responding to first line treatments.

Histology and culture are still the most important diagnostic approaches for mucormycosis because of the lack of molecular diagnostic methods available, and β-d-Glucan detection is not useful due to the extremely low content of the biomarker in the Mucorales order. Timely diagnosis of invasive mucormycosis is essential due to the rapid progression of the disease, and because signs and symptoms of the infection are consistent with other invasive fungal infections. PCR would improve detection of Mucorales and complement the current Bruker offering within the area of invasive fungal disease.

**Materials/methods:** The Bruker real-time PCR assays are designed in an easy to use format with minimum hands on time and results generated 1 hour after extraction. Universal primer and probe sequences have been designed to target the internal transcribed spacer (ITS) region of the rRNA gene for the genera detailed in Table 1. The probes associated with each pathogen have been labelled with different fluorescent dyes enabling some differentiation within the multiplex reaction. A specific control material has been developed to give the users an option of running it as an extraction control or a PCR inhibition control.

**Table 1: Genera detected by the Fungiplex Mucorales Real-Time PCR Kit**

|------------------|---------------|------------|

**Results:** The coverage specified in Table 1 has been confirmed using a range of simulated samples prepared from plasmid and genomic DNA. The limit of detection for species representing the highest prevalence of IFD for each genus has been assessed over six thermocycler platforms to ensure accuracy across a variety of systems.

**Conclusions:** Bruker have developed a Mucorales assay which identifies a wide range of clinically relevant genera. The assay has been developed into a kit to provide rapid detection of the main causative agents in invasive mucormycosis.

**Presenter email address:** julie.green@bruker.com
Non-B subtypes are a major driver of clustered HIV-1 transmission in north Italy in recent years

Luna Colagrossi1, Maria Cristina Moioli2, Alice Nava3, Stefani Carta4, Stefania Chiappetta4, Valentino Costabile6, Davide Motta2, Leonardo Gerolamo Chianura2, Roberto Rossotti2, Diana Fanti3, Perno Carlo Federico3, Massimo Puoti2, Claudia Alteri3;5

1University of Milan, Residency in Microbiology and Virology, Milan, Italy
2ASST Grande Ospedale Metropolitano Niguarda, Infectious Diseases, Milan, Italy
3ASST Grande Ospedale Metropolitano Niguarda, Chemical-clinical and Microbiological Analysis, Milan, Italy
4University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy
5University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

Background: To evaluate the dynamics and phylogenetic relationships of HIV-1 strains circulating in North Italy in the last years.

Materials/methods: HIV-1 pol sequences were obtained from 272 drug-naïve individuals diagnosed for HIV-1 infection at ASST GOM Niguarda Hospital (Milan, Italy) between 2012 and 2018. Phylogenetic trees were built using GTR model and 1000 bootstrap with maximum-likelihood method using PhyML. Transmission clusters (TCs) included large TCs (≥3 sequences, LTCS) and pairs [2 sequences]. Factors associated with TCs were evaluated by uni-multivariable logistic regression analysis.

Results: Most patients were men (82.4%) and caucasian (65.4%), with a median age of 39 (IQR:30-48) years. Heterosexual intercourse were the main route of transmission (46.7%), followed by men who have sex with men contact (MSM; 36.0%). Patients were infected mostly by B (64.3%), BF recombinant forms (11.0%) or CRF02_AG (8.1%) clades. Non-B subtypes, and particularly recombinant forms, were increasingly represented across years (from 26.9 to 44.1% and from 13.9 to 30.1%, respectively, p=0.01 2 and 0.006).

Overall, 67 (24.6%) individuals took part in TCs, including 39 (58.2%) in small TCs and 28 (41.8%) patients in LTCS. Non-B subtypes were increasingly represented across LTCS (60.7% of non-B subtypes vs. 39.3% of B subtypes were involved in LTCS, p=0.004). Respect to other patients, LTCS-individuals were more frequently MSM (p=0.003), and infected by CFR02_AG and CRF42 BF (p=0.016 and 0.010, respectively). None of the identified LTCS carried transmitted drug resistance. By multivariate logistic regression, the HIV-1 infection by non-B subtypes was the only factor significantly associated with higher probability to be in LTCS (odds ratio: 3.29 [1.37-7.93]). No other factors, including risk factors, were significantly associated with LTCS.

Conclusions: Remarkable changes in HIV-1 infection occurred in Italy over the last years, with active spreading among large TCs, and contributing to the epidemiological shift from B to non-B subtypes in North Italy. Our results highlight the role of molecular epidemiology in HIV-1 non-B diagnoses, suggesting the need to promptly identify local outbreaks, particularly those characterized by large clusters of transmission. This can help in decreasing the rate of transmission, and in improving the efficacy of HIV-1 therapy.

Pharmacokinetic/pharmacodynamic informed assessment of pyrazinamide phenotypic resistance testing and pncA sequencing in multidrug-resistant tuberculosis

James Millard*1,2,3, Camus Nimmo1, Ntombifuthi Mthabela2, Kandaseelan Chetty1, Kayleen Brien1, Taryn Naidoo1, Sashen Moodley2, Farina Karim2, Alex Pym2, Gerry Davies1

1University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom, 2Africa Health Research Institute, Durban, South Africa, 3Wellcome Trust Liverpool Glasgow Centre for Global Health Research, Liverpool, United Kingdom, 4University College London, London, United Kingdom

Background: Pyrazinamide (PZA) is a key drug in therapy of multidrug-resistant tuberculosis (MDR TB). Despite one-third to two-thirds of MDR-TB isolates being phenotypically resistant, PZA is often administered to all patients with MDR-TB because of difficulties in phenotypic testing. Most PZA-resistant isolates demonstrate mutations in the pncA gene and sequencing technologies may offer an alternative. However, neither phenotypic nor genotypic PZA resistance testing has been fully informed by a pharmacokinetic / pharmacodynamic (PK/PD) analysis.

Materials/methods: Patients with at least rifampicin resistant TB were recruited in KwaZulu-Natal, South Africa. Baseline positive sputum samples were evaluated with phenotypic drug susceptibility testing, PZA minimum inhibitory concentrations (MICs) in the BACTEC MGIT 960 system and whole-genome sequencing. Pharmacokinetic sampling was performed at 0,1,2,4,6 and 8 hours post-dose at steady-state, PZA concentrations quantified using high performance liquid chromatography-mass spectrometry and population pharmacokinetic analysis performed using NONMEM® (from which area under the PZA time-concentration curve (AUC_{0-24}) values were derived). Attainment of a PZA PK/PD efficacy target (AUC_{0-24}:MIC >11.3 mg/L/h) was assessed after stratifying by phenotypic or genotypic PZA resistance testing results using Monte-Carlo simulations.

Results: Ninety-two PZA MICs and fifty PZA AUC_{0-24} values were available for simulation. Using the MIC distribution for all isolates from this population, 39.1% achieved the efficacy target. Target attainment was 0% and 63.9% when using the MIC distribution from isolates with and without a pncA mutation respectively. Whereas target attainment was 0 and 82.7% when using an MIC distribution from isolates with an MIC ≤100µg/ml (the current critical concentration) or >100µg/ml respectively. Only by using an MIC distribution from isolates with an MIC of ≤40µg/ml did ≥95% achieve the target.

Conclusions: Amongst patients with MDR TB, the presence of pncA mutations identify those where PZA is unlikely to be of use. In contrast, the absence of pncA mutations does not reliably distinguish those in whom PZA is likely to be of benefit versus those in whom it is unlikely to be beneficial. These results question the rationale for MDR TB regimen design based on pncA sequencing. Phenotypic testing provides better discrimination, but the current critical concentration may be too high.

Giaccone, Palermo, Italy

Background: Dalbavancin is approved for the treatment of Acute Bacterial Skin and Skin-Structure Infections (ABSSSI); the efficacy in the treatment of osteomyelitis and endocarditis is still under investigation. Few data are available about Dalbavancin use in real-life settings. We aimed to evaluate the efficacy and safety of Dalbavancin in Italy.

Materials/methods: Retrospective multicenter study involving 11 Italian hospitals. Patients that received \( \geq 1 \) dose of Dalbavancin (May 2016–June 2019) were enrolled. The primary outcome was clinical cure at the end of treatment (improvement of lesions and resolution of infection as defined by clinicians); secondary outcomes were safety and tolerability. ABSSI and other infections will be compared. Chi-square and Mann-Whitney test were used for statistics.

Results: 206 patients were enrolled (males 50%, median age 62 years, Charlson index 3). 60.2% were ABSSI; non-ABSSI (39.8%) included: osteomyelitis, prosthetic joint infections, septic arthritis, catheter-related bloodstream infections, and sepsis. 151/194 (77.8%) of patients received previous and concomitant antibiotic treatments for the same infection, respectively. A microbiological isolation was available in 38% of patients (12% MRSA). Clinical cure was obtained in 82.5% of patients. 62.1% had no relapse at the follow-up visit (1-6 months). 11/167 (5.4%) patients had adverse events, mostly non-severe. No difference in efficacy and safety was found according to ABSSI and non-ABSSI diseases (Table 1).

Conclusions: Dalbavancin demonstrated an overall success rate of more than 80% in a multicenter Italian cohort. The efficacy and safety were similar in both ABSSI and infections with off-label indication. In this real-life setting Dalbavancin is often used as maintenance therapy and in a combination regimen. Further data are needed about the use of this long-acting lipoglycopeptide in non-ABSSI in order to optimize therapeutic strategies.

Abstract 7730

In-hospital and midterm out-hospital complications of hospitalised respiratory syncytial virus-positive adults in France

Alexandre Descamps*1, Paul Loubet1,2, Nezha Lenzi2, Florence Galtier2,3, Laine Fabrice2,4, Zineb Lesieur2, Philippe Vanhems2,5, Xavier Duval2,6, Fabrice Carrat7, Odile Launay1,2

1Université de Paris, Faculté de médecine Paris Descartes; Inserm, CIC 1417, Assistance Publique Hôpitaux de Paris, Hôpital Cochin, Paris, France; Inserm, F-CRIN, Réseau Innovative Clinical Research in Vaccinology (I-REIVAC), Paris, France, 2CIC 1411, CHU Montpellier, Hôpital Saint Eloi, Montpellier, France; 3Inserm, CIC 1414, Hôpital Pontchaillou, Rennes, France; 4Epidemiology and Infection Control Unit, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France; 5CIC 1125, Assistance Publique Hôpitaux de Paris, Hôpital Bichat Claude Bernard, Paris, France; 6CIC 1125, Assistance Publique Hôpitaux de Paris, Hôpital Saint Antoine, Paris, France

Background: Although respiratory syncytial virus (RSV) is recognized as an important cause of respiratory infections among older adults with comorbidities, associated hospital burden and long term complications are still underestimated. We aimed to compare baseline characteristics, comorbidities, in and out-hospital outcomes of RSV versus influenza infected adult patients.

Materials/methods: Adults hospitalized with acute respiratory infection (ARI) were included in a prospective, multicenter study conducted in five French university hospitals during two consecutive winter seasons (2017/2018 and 2018/2019). RSV and influenza virus were detected by multiplex RT-PCR in nasopharyngeal swabs. Poisson regression models with a robust error variance approach were used to estimate the prevalence ratio (PR) associated with in/out-hospital outcomes between RSV positive patients and influenza positive patients after adjustment for potential confounders.

Results: Overall, 1,428 hospitalized adults with ARI were included, median age was 72 years (IQR 60-82), 55% were male (790/1,428) and 87% had underlying chronic conditions (1,250/1,428). RSV was detected in 8% (114/1,428) and influenza virus in 31% (437/1,428). After excluding RSV-influenza co-infections (n=6), there was a higher proportion of patients aged ≥60 years or more in adults hospitalized with RSV compared to those with influenza (86% vs 76%; p=.02). Patients with RSV were more likely to have chronic respiratory diseases (52% [56/108] vs 39% [166/431], p=.012) and chronic cardiac diseases (52% [56/108] vs 41% [176/431], p=.039) than those with influenza. Median hospital length of stay was higher for RSV than influenza positive [8 (IQR, 5-13) vs 6 days (IQR, 4-11), p<.001]. In-hospital complications prevalence ratios were significantly higher among RSV patients: respiratory failure (aPR=1.7; 95%CI 1.2-2.4), acute respiratory distress syndrome (aPR=1.9; 95%CI 1.2-3.0), ICU admission (aPR=2.1; 95%CI 1.5-3.1) and invasive mechanical ventilation (aPR=1.8; 95%CI 1.2-2.7). No differences were observed in out-hospital outcomes defined as new hospital admission and mortality within 1 or 3 months after hospital discharge.

Conclusions: In our setting, RSV positive patients had more severe in-hospital outcomes than influenza positive patients. Improvement in the early diagnosis and management of RSV infections in hospitalized adults are needed with specific new therapeutics to protect older adults and those with high risk conditions.

Abstract 7734

Development of a dried blood spot assay to quantify levofloxacin drug concentrations for personalised dose adjustment in multidrug-resistant tuberculosis in endemic settings

Sagal Mohamed1*, Suzanne Stroup1, Margaretha Sariko2, Erwin Jongedijk3, Daan Touw3, Peter Mbelele4, Stellah Mpagama4, Jan-Willem Alffenaar3, Scott Heysell1

1University of Virginia, Charlottesville, United States, 2Kilimanjaro Clinical Research Institute, Moshi, Tanzania, 3University of Groningen, Groningen, Netherlands, 4Kibong’oto National TB Hospital, Sanya juu, Tanzania

Abstract third-party references: Acknowledgement: This project was financially support by the Bill & Melinda Gates Foundation, Grant Challenges program (grant number OPP1191221). Sagal Mohamed’s work was supported by the NIH T-32 AI007046 grant.

Background: Levofloxacin is one of the two fluoroquinolones recommended as a group A drug to treat multidrug-resistant tuberculosis (MDR-TB), but is subject to considerable individual pharmacokinetic variability where low circulating levofloxacin exposures drive poor treatment outcomes. Measurement of serum drug concentrations for personalized dose adjustment has been limited in TB endemic settings due to inability to preserve the cold chain for serum analyses and lack of access to specialized equipment for quantification.

Materials/methods: A dried blood spot (DBS) based assay was developed to bypass the need for serum which could be transported at room temperature by conventional mail services. Our previous method to detect levofloxacin concentrations from serum for analysis by high performance liquid chromatography (HPLC) was adapted for the DBS platform on Whatman™ FTA™ DMPK-C paper filter cards. Spiked filter paper punches were extracted and precipitated by perchloric acid in acetonitrile. A levofloxacin standard curve, concentrations (μg/mL): 50, 40, 30, 25, 20, 12, 8, 4, 2, 0.5, was tested as well as the controls of serum only and 20 μg/mL of levofloxacin only without blood, and using difloxacin as an internal control. Linearity, intra-day and inter-day variability were compared over different environmental conditions and durations from time of blood spotting.

Results: No degradation of levofloxacin or the internal control was observed. The assay was linear over the testing concentration range with R2 of >99%, with a lower limit of quantification of 0.5 μg/mL, which extended above and below the commonly observed peak concentration range (8-12 μg/mL). Intra-day and inter-day variability demonstrated acceptable precision up to 42 days from spotting with relative standard deviation (RSD) < 15%. The assay was replicated onsite with transport condition and local laboratory equipment at Kibongo to Infectious Diseases Hospital and Kilimanjaro Clinical Research Institute.

Conclusions: A DBS based assay for levofloxacin quantification was successfully developed and adapted for a TB endemic setting in Tanzania. Ongoing studies include comparison of the DBS assay to a novel saliva-based methodology for implementation strategies in Tanzania.

Abstract 7740

Arakki: a workflow-based system for virus identification in the clinic
Mohamed Abouelhoda*1, Manojkumar Selvaraju2, Moustafa Shokrof2, Zeeshan Shah1, Yasser Alnakhli2, Thamer Alamoudi2, Hussain Aljafar2

1King Faisal Specialist Hospital and Research Center (KFSHRC), Genetics Dept., Riyadh, Saudi Arabia, 2King Abdulaziz City for Science and Technology, Riyadh, Saudi Arabia, 3UC Davis, Davis, United States

Background: The recent advances in next generation sequencing (NGS) provided a fast and cost effective means to characterize viral infections in clinical samples. Many NGS data analysis tools have been developed to identify the virus genomes in samples. However, the clinical use of NGS technology requires extra analysis options not existing in these tools, such as identification of multiple types/sub-types in the population, the discovery of mutations in the viral genomes, and annotating the mutations with relevant information. Moreover, the tool should be fast, flexible to configure, and easy to use.

Materials/methods: We introduce the Arakki system, which provides functionalities to support analysis of viral samples in the clinic. The Arakki workflow is composed of four phases: First, viral identification, including taxonomy classification. This is achieved by mapping the NGS reads to all available viral genomes in the public databases. Second, viral de novo assembly, to check for novel sequences. Third, variant identification and annotation. The annotation is based on a user defined database of clinically relevant positions [for example, substitutions in the core positions 70 and 91 of HCV virus]. Fourth, report generation and visualization. Each of these steps provides a list of candidate hits, to detect multiple types/sub-types in the population. Arakki is developed using the Tavaxy workflow engine and it is so flexible that the users can re-configure the workflow using graphical user interface [Figure below]. Users can add/remove steps, select NGS platform, or even select among programs for mapping and assembly.

Results: Arakki is available for free (www.arakki.org), for local installation or in the cloud. Arakki achieved using many clinical samples infected with HCV, HBV. Some samples were sequenced using Illumina and the others using Ion Torrent. The analysis time takes few minutes per sample.

Conclusions: Arakki is an efficient system for analysis of viral samples in the clinic. It is efficient in terms of time and resources. A recent study using Arakki could prove that the sample has HPgV co-infection and not only HCV infection, as primarily thought according to PCR analysis.

Abstract third-party references: ZonMW [The Netherlands Organisation for Health Research and Development], Fonds NutsOhra

Background: In haematology patients with high risk neutropenia due to intensive chemotherapy the optimal antibiotic treatment duration for fever of unknown origin [FUO] is unknown. Early antibiotic discontinuation has been advocated to reduce unnecessary exposure to broad-spectrum antibiotics, but there is limited evidence for the safety of this strategy. We aimed to assess if short treatment with carbapenems is non-inferior to extended treatment for neutropenic patients with FUO.

Materials/methods: Multicentre, open-label, randomised clinical trial in 6 centres in the Netherlands. Haematology patients with FUO during high risk neutropenia [≥7 days] were eligible for participation. Eligible patients were randomly assigned (1:1) to either the short treatment arm, where the carbapenem was discontinued after 72 hours, irrespective of presence of fever, or the extended treatment arm, where the carbapenem was continued for ≥9 days until afebrile for 5 days or end of neutropenia [EON], whichever came first. The primary endpoint was treatment failure defined as a composite of recurrent fever or a carbapenem-sensitive infection between day 4 and day 8 and septic shock or death from day 4 until EON. Secondary endpoints included all-cause and infection-related mortality until 30 days post-EON. We used 10 percentage points as non-inferiority margin.

Results: Between December 2014 and August 2019 268 patients were included. Risk of treatment failure in the modified intention-to-treat analysis [mITT] was 23.7% (32/135) in the short treatment versus 18% (24/133) in the extended treatment arm [adjusted risk difference (ARD) 4.0% [90% CI: -2.3% to 10.3%]] and in the per-protocol analysis 28.2% (29/103) versus 18% (22/122) [ARD 9.3% [90% CI 0.8% to 17.7%]]. In both analyses the confidence intervals included the non-inferiority margin of 10%. All-cause mortality until 30 days post-EON was significantly higher in the short treatment group: 3.7% (5/135) versus 0.8% (1/133) [ARD 2.9%, 95% CI 1.3 to 4.4%], but infection-related mortality until 30 days post-EON was not statistically different between the treatment arms: 2.2% (3/135) in the short and 0.8% (1/133) in the extended treatment arm [ARD 1.6%, 95% CI 0.6 to 3.7%].

Conclusions: Early discontinuation of carbapenem treatment in neutropenic patients with fever was not non-inferior to extended treatment.

Prevalence of non-tuberculous mycobacteria in patients with cystic fibrosis in a tertiary hospital

Diego Ortega Larrea*1, Eric López1, Miguel Moreno Hijazo1, Saray Mormeneo Bayo1, Sandra Nabal Díaz1, Emilio David Valverde1, María Antonina Arias1, Blanca Fortuño1, Margarita Elu1, Jesús Viñuelas1

1Miguel Servet University Hospital, Zaragoza, Spain

Background: Nontuberculous mycobacteria (NTM) are increasingly insulated and with higher frequency in adults and children with Cystic Fibrosis (CF). Data from the US CF Patient Care Registry reveal that 19% of patients who were cultivated over a 4-year period (2011-2015) had one or more species of isolated MNT.

Materials/methods: Review of the last 8 years of the MNT isolations from respiratory samples of patients with CF diagnosis from the Pneumology Clinic of the Miguel Servet University Hospital in Zaragoza.

Results: The identification of MNT was performed from culture by mass spectrometry (MALDI Biotyper System, Bruker) and molecular methods (GenoType Mycobacterium CM and AS, Hain). During the last 8 years 1147 samples were received from 297 patients with CF, 73 MNT isolates were found in 16 patients, 15 adults with an average age of 32 years and 1 pediatric patient. There was no difference respect the sex, 8 women and 8 men. In most of these patients the same MNT isolation was repeated (3, 5 and up to 10 times). Single isolates were considered contaminations. Two different species of MNT were isolated in two patients. The most isolated MNT was *M. lentiflavum* (29), followed by *M. intracellulare* (19), *M. abscessus* (12), *M. chimaera* (6), *M. gordonae* (4), *M. mucogenicum* (1), *M. xenopi* (1) and *Mycobacterium sp.* (1), which could not be identified and was considered a contaminant.

Conclusions: The increase in MNT isolates in recent years is related to the search and the value of these mycobacteria as pathogens and the new liquid culture media and the new species identification techniques, which help to detect them. The prevalence of MNT in CF patients has increased in recent years. Its role is difficult to determine and should always be individualized according to the clinical and radiological characteristics of the patient and once other more frequent pathogens in these patients have been ruled out.

Abstract 7746

**Human papilloma virus 16 viral load quantification using droplet digital PCR and correlation with cervical lesion**

Marianna Martinelli*, Chiara Giubbi, Rosario Musumeci, Federica Perdoni, Federica Paola Sina, Robert Fruscio, Fabio Landoni, Clementina Cocuzza

1University of Milano-Bicocca, Department of Medicine and Surgery, Monza, Italy, 2San Gerardo Hospital, ASST Monza, Monza, Italy

**Background:** Human Papillomavirus (HPV) infection is known to be associated to cervical cancer development. Presently, many countries are changing their screening policy switching to HPV testing as primary screening as suggested by European guidelines. Even if cytology is the preferred triage method, HPV viral load measurement has been suggested to be a predictor of cervical lesion progression. The aim of this study was to evaluate the correlation between HPV16 viral load and cervical lesion grade using droplet digital PCR (ddPCR) among women referred to colposcopy.

**Materials/methods:** Cervical samples were collected from women attending the Colposcopy Clinic, San Gerardo Hospital (Monza, Italy) for abnormal cervical cytology. All samples were extracted using NucliSENS easyMAG and HPV detection was carried out using AnyplexII HPV28. All HPV16 positive samples were tested using ddPCR and read in a QX Droplet reader (Bio-Rad). PCR was set up in duplex, combining HPV16 with the CCR5 gene to obtain cell quantification. Viral copy number/cells were calculated as: HPV16 copies/(CCR5 copies/2).

**Results:** Currently, 47 HPV16 positive samples collected from women with different grade of lesion have been tested. A higher mean viral load/cells value was observed among women with a high-grade lesion (HSIL) compared to women with lower grade lesion (36.3 vs 21.9 copies/cells). The same result was obtained comparing viral load quantification with biopsy (22.1 vs 6.0 copies/cells, CIN2+ vs <CIN2). Moreover, 4 women showing HPV16 persistent cervical infection were followed-up at different time points to evaluate viral load changes with cervical cytology. Preliminary results show a possible correlation between HPV16 viral load and progression/regression of the cervical lesion [Figure1].

**Conclusions:** Preliminary data suggest that ddPCR method represents a promising tool for HPV viral load estimation. Viral load measurement could represent a useful biomarker in the follow up of HPV-positive women although larger longitudinal clinical studies are required to assess its clinical value.

Fayssoil Fouad1, Magali Lemaitre1, Antoine Bessou1, Fabrice Carrat2, Pascal Crépey3, Jacques Gaillat4, Gaetan Gavazzi5, Odile Launay6, Anne Mosnier7, Marie-Cécile Levant8, Mathieu Uhart9

1iqvia, Courbevoie, France, 2Sorbonne Université, Paris, France, 3ehesp, Rennes, France, 4Centre Hospitalier Annecy Genevois, Épagny Metz-Tessy, France, 5chu Grenoble, Grenoble, France, 6cochin, Paris, France, 7open Rome, Paris, France, 8sanofi, Lyon, France, 9sanofi, Lyon, France

Background: Seasonal epidemics caused by influenza viruses lead to 2 to 6 million influenza cases each season in France. Severe influenza disease can result in hospitalisations due to the virus itself or due to a secondary infection, making it difficult to estimate the overall burden. The objective of the study was to estimate the burden attributable to influenza in terms of hospitalisations between 2010 and 2018 in France.

Materials/methods: The number and the characteristics of patients hospitalised due to influenza for the period 2010 to 2018 were obtained from the French national hospital administrative database (PMSI). This analysis was supplemented by an ecological approach for estimating excess hospitalisations, costs and mortality (CepiDc) attributable to influenza. Cyclic regression models were developed integrating different parameters [trend, season, and incidence of influenza syndromes (sentinel network)].

Results: The mean number of influenza hospitalisations was 19,280 [min: 8,627; max: 44,024] per season with an average stay of 8 days. Patients aged 65 years old and over experienced the longest stays [11 days] and accounted for the largest share of hospitalisations, with a mean of 57% of hospital-days [ranging from 17% of the 2009/10 pandemic season to 80% for the 2016/17 season]. Among patients aged 65 and over, 29% were re-hospitalized within 90 days post-discharge. A mean average of 32,424 respiratory hospitalizations were attributable to influenza [min: 13,075, max: 48,672] per season, with 68% of excess respiratory hospitalisations accounted for by patients aged 65 years and over. The number of deaths attributable to influenza was estimated at 9,656 on average per season between 2010/11 and 2014/15, 90% of which were among patients aged 65 years old and over.

Conclusions: The combination of two complementary approaches allowed the estimation of the hospital burden attributable to influenza in France. These results highlight the major public health burden represented by influenza and its complications among hospitalised cases, which is particularly evident in individuals aged 65 years and over.

Prospective evaluation of three rapid multiplex PCR assays for the detection of gastrointestinal pathogens from stool samples

Khanh Villageois-Tran1, Nicolas Argy2, Lucie Noel1, Cécile Pauc3, Théo Montagne1, Philippe Lehours1, Lucie Benejat1, Astrid Ducournau3, Sandrine Houze2, Benoît Visseaux1, Laurence Armand-Lefevre2

1Hospital Beaujon AP-HP, Clichy, France, 2Bichat-Claude Bernard Hospital, Paris, France, 3Chu Pellegrin Bordeaux, Bordeaux, France, *Institut Pasteur, Paris, France

Background: The detection of gastrointestinal (GI) pathogens (bacteria, parasites and/or viruses) by conventional methods is time-consuming, requires strong technical experience, and lacks sensitivity. Several rapid multiplex PCRs (mPCR) have recently been developed to improve the identification of such pathogens and their relative performance should be evaluated. The aim of the present study is to assess the performance of 3 rapid mPCR GI assays (FilmArray® gastrointestinal panel [bioMérieux], QIAstat-Dx® gastrointestinal [Qiagen] and Novodiag® gastrointestinal panel [Mobidiag] - bacteria search only).

Materials/methods: Enteric pathogens were detected in stool samples using the 3 mPCR kits as well as conventional methods (standard stool culture, GenXpert PCR [Cepheid] for Clostridioides difficile, parasitological stool examination and/or in-house PCR). The patients enrolled were adults consulting for digestive disorders in the emergency department or the infectious diseases department of Bichat Hospital (Paris). We used a composite gold standard considering the conventional method, the positivity of 2 out of 3 mPCRs or the results of the national reference center (NRC).

Results: 85 stool samples were studied, including 77 collected prospectively from April to September 2019 and 8 stored at -80 °C. Prevalence of bacterial pathogens was 45.9% (n=39) including Clostridioides difficile at 9.4% (n=8). Prevalence of parasites and viruses was 12.9% (n=11) and 2.4% (n=2), respectively. For bacteria detection, 95.7% (732/765) of the overall results and 70.6% (36/51) of positive results were concordant between the 3 mPCRs. We observe a concordance between FilmArray® and QIAstat-Dx® for parasites and viruses, at 99.4% (338/340) and 99.8% (424/425) of overall results and 90.9% (10/11) and 100.0% (2/2) of positive results, respectively. Performances of the 3 kits are detailed in the table below. The discrepancies in Yersinia sp. detection were explained because Novodiag® only detects toxigenic Yersinia sp. whose absence was confirmed by the NRC. Discrepancies in the detection of Campylobacter sp. were also investigated by the corresponding NRC.

(Se = Sensitivity, Sp = Specificity, NA = Not applicable, NR = Not realized)
* Prevalence of Campylobacter sp. includes results given by the NRC
** No toxigenic Yersinia sp. was detected by the NRC which is consistent with the results found with Novodiag® (n=0; Sp=100 %)

Conclusions: All tested rapid molecular methods have identified more enteric pathogens than conventional methods. Although some discrepancies were identified, the 3 mPCR assays showed good agreements.

What clinicians and researchers should know about machine learning for infection management: review of methods, targeted outcomes and reporting of future technologies

Christian Luz*1, Marcus Vollmer1, Johan Decruyenaer3, Maarten Nijsten4, Corinna Glasner1, Bhanu Sinha1

1University of Groningen, University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 2 University Medicine Greifswald, Institute of Bioinformatics, Greifswald, Germany, 3Ghent University, Ghent University Hospital, Department of Intensive Care, Ghent, Belgium, 4University of Groningen, University Medical Center Groningen, Department of Critical Care, Groningen, Netherlands

Background: Machine learning (ML) is already used in many healthcare areas. Recent reviews have identified an increasing albeit still experimental use of ML for diagnosis and management of infections. These reviews focused on introducing ML to practitioners in the field and investigated the underlying data source. We aimed at extending this introduction by assessing methods, targeted outcome, and reporting quality of ML research in infection management.

Materials/methods: A Medline search was performed to identify ML research for infections between 2014-01-01 to 2019-08-20. Studies were included if routinely available electronic hospital record data from an inpatient setting with a focus on bacterial and fungal infections were used. Articles were assessed on their research focus and definitions of the targeted/labelled outcome (e.g. sepsis onset). ML techniques and performance metrics were extracted. A special focus lied on reporting of (missing) data handling, availability of software code, and information on external model validation.

Results: Most studies the 52 included studies focused on the detection/prediction of sepsis (n = 19). Target outcome definitions in this group were heterogeneous and comprised bacteraemia, sepsis by ICD code, clinical sepsis definitions, and sepsis-associated mortality. Similar heterogeneity was found for studies on hospital-acquired infections (HAI; n = 11), surgical site and other postoperative infections (n = 11), microbiological test results (n = 4), infections in general (n = 2), musculoskeletal infections (n = 2), and other topics (n = 3). Of 35 ML techniques, neural networks showed best performance by AUROC for sepsis and HAI outcomes. Overall, detailed information on data handling and software code was often lacking. Validation on new datasets and/or in other institutions was rarely done. Despite existing reporting guidelines, documentation of ML approaches was often poor.

Conclusions: Not all clinicians and researchers need to be experts in ML, but it is crucial to get acquainted with ML concepts and their application. Promising approaches of ML use in infection management were identified (e.g. early identification of septic patients). However, building trust in these new technologies will require improved reporting. Explainability and interpretability of the used models was rarely addressed and should be further explored.

Abstract 7760

**MALDI-TOF MS as new tool for the identification of serological biomarkers for diagnosis of hepatitis B and C viruses infections**

Adriana Calderaro1, Mirko Buttrini*, Sara Montecchini1, Francesca Ferraglia1, Federica Pinardi2, Maria Cristina Arcangeletti1, Flora De Conto1, Carlo Chezzi1

1University of Parma, Department of medicine and surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Virology, Parma, Italy

**Background:** Hepatitis B virus (HBV) and Hepatitis C virus (HCV) represents two of the major health problem worldwide. Only few studies investigate by MALDI-TOF MS the presence of specific peptides/proteins that can be considered predictive indicators for HBV infection. In this study, we used MALDI-TOF MS to examine serum samples aiming at searching peptides/proteins that can be used as serological biomarkers to detect HBV and HCV.

**Materials/methods:** Fifty-six serum samples, received for diagnostic purposes with suspected HBV and/or HCV infection, previously analyzed with the diagnostic assays currently used in our laboratory and resulted positive or negative for HBsAg or HCVcoreAg, were examined by MALDI-TOF MS.

**Results:** In the first step, 3 different protein extraction approaches were evaluated to obtain valid, reliable and reproducible results. The protocol adopted involved ultracentrifugation of serum samples with water. The analysis performed at low molecular weight showed the presence of unique peaks for each class of sera (HBV-positive, HCV-positive or both negative), while the analysis carried out at high molecular weight showed the absence of significantly discriminating peaks. In particular, the detection of HBV-positive sera is associated with 8 discriminating peaks; similarly, detection of HCV-positive sera is associated with 8 discriminating peaks. Noteworthy the trend of the intensity of 3 peaks (3224, 6632, 7478 Da) showed a significant increase or decrease depending on the virus responsible for the infection. However, it was not possible to identify the protein/peptide matching to the markers found. The second step involved the creation of statistical models able to differentiate the three different categories of serum analyzed on the basis of these peaks. In particular, using this model it was correctly classified all 56 sera.

**Conclusions:** Our results demonstrated, on a limited number of sera with high concentration of specific antigen, the presence of peaks differentiating classes of positive sera, for both HCV, for the first time to our knowledge, and HBV, as already reported by other Authors. This could be a starting point to add MALDI-TOF MS as a tool for the diagnosis of such infections, being independent of antigen mutations that could affect the conventional assays.

Abstract 7764

**Metanet: synchronisation and quality assessment of methods for rapid metagenomics-based pathogen detection**

Robert Schlaberg1,2, Leonard Schüle1, Philipp Oberhettinger4, Stefan Bletz2, Dag Harmsen6, John W. A. Rossen*3, Alexander Mellmann5, Karola Prior6, Martin Schou Pedersen7, Henrik Westh6, Natacha Couto3, Silke Peter4, Alexander W. Friedrich3

1University of Utah School of Medicine, Department of Pathology, Salt Lake City, United States, 2IDbyDNA, San Francisco, United States, 3University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 4University of Tübingen / EKU Tübingen, Institute of Medical Microbiology and Hygiene, Tübingen, Germany, 5Universitätsklinikum Münster, Institut für Hygiene, Münster, Germany, 6Universitätsklinikum Münster, Zentrum für Zahn-, Mund- und Kieferheilkunde Poliklinik für Parodontologie, Münster, Germany, 7Hvidovre Hospital, Department of Clinical Microbiology, Hvidovre, Denmark

**Background:** Adoption of rapid metagenomics-based pathogen detection by clinical microbiology laboratories is accelerating. However, integration into routine diagnostic practice requires standardization, quality control, and objective result interpretation. The “Metanet” network includes 6 laboratories across Europe and North America and was established to optimize standardization of wet-lab and bioinformatic methods for this disruptive technology.

**Materials/methods:** In phase 1, DNA and RNA extracted from 8 spiked samples were distributed to Metanet sites. DNA and cDNA libraries were prepared by each laboratory and sequenced (NextSeq, Illumina) using a common standard operation procedure (SOP). In phase 2, DNA and RNA extracted from 18 pooled bronchoalveolar lavage samples were distributed to participating sites and processed with the same SOP. In phase 3, residual DNA and RNA from phase 2 was tested by 2 sites with optimized methods, additional training, and after standardization of processing steps that were found to affect reproducibility. Sequence data were analyzed using the Explify Platform (IDbyDNA).

**Results:** In phase 1, all sites reported identical results, except for one sample spiked with *Klebsiella pneumoniae* at a low concentration [detected by 3 of 5 laboratories]. Phase 2 demonstrated QC below expected ranges for 50% of runs and 27.8% of samples, as well as higher inter-laboratory and inter-run variation. Comparing sequence data from across the 6 sites highlighted variable quality of sequencing libraries as a source of error. Laboratory protocols were optimized and residual DNA and RNA retested. In phase 3, sequencing data was consistent, high quality with all runs and 31 of 32 samples (96.9%) passing sequencing QC. In addition, reproducibility of pathogen detection was also significantly improved. Respiratory viruses were detected in 42 of the expected 45 times (93.3%, compared to 79.7% in phase 2). Two of the 3 missed detections were in samples that did not meet internal control requirements, which would have flagged results as invalid.

**Conclusions:** As clinical microbiology laboratories adopt rapid metagenomics, standardized methods and comprehensive QC are critical. Easy-to-use software supporting QC and objective result interpretation are essential for clinical laboratories. Multi-center networks like Metanet help refine QC, optimize workflows, standardize methods, and inform future guidance documents.

Plasmodium ovale curtisi and wallikeri infections in imported malaria: a 2013-2018 retrospective study from the French National Malaria Reference Centre

Valentin Joste*, Justine Bailly1, Veronique Hubert1, Eric Kendjo2, Nicolas Argy1,3, Sandrine Houze1,3

1Bichat-Claude Bernard Hospital, Centre national de référence du paludisme, Paris, France, 2University Hospitals Pitié Salpêtrière - Charles Foix, Centre national de référence du paludisme, Paris, France, 3UMR261-MERIT, Institut de recherche pour le développement, Paris, France

Background: Plasmodium ovale curtisi (Poc) and Plasmodium ovale wallikeri (Pow) are two sympatric human malaria species despite their identical morphology[1] and the resulting burden of disease is not known. Dimorphism in defined genes has led to P. ovale parasites being divided into classic and variant types. We hypothesized that these dimorphs represent distinct parasite species.

METHODS: Multilocus sequence analysis of 6 genetic characters was carried out among 55 isolates from 12 African and 3 Asia-Pacific countries.

RESULTS: Each genetic character displayed complete dimorphism and segregated perfectly between the 2 types. Both types were identified in samples from Ghana, Nigeria, São Tomé, Sierra Leone, and Uganda and have been described previously in Myanmar. Splitting of the 2 lineages is estimated to have occurred between 1.0 and 3.5 million years ago in hominin hosts.

CONCLUSIONS: We propose that P. ovale comprises 2 nonrecombining species that are sympatric in Africa and Asia. We speculate on possible scenarios that could have led to this speciation. Furthermore, the relatively high frequency of imported cases of symptomatic P. ovale infection in the United Kingdom suggests that the morbidity caused by ovale malaria has been underestimated.

In France, Plasmodium ovale (Po) was responsible of 6% of imported malaria cases in 2018[2].

Materials/methods: We used data from the French National Malaria Reference Center (FNMRC) over 6 years (2013-2018) to analyze epidemiological, clinical and biological data, and malaria diagnosis corresponding to Poc or Pow mono-infection, confirmed using HRM-qPCR[3].

Results: We included 311 Poc and 372 Pow cases, imported from 27 countries, mainly in Africa with no difference between Poc and Pow (p=0.49). There was no difference in parasitic density median with 1882 p/µL for Poc and 1658 p/µL for Pow (p=0.088), in white blood cells count [5.6 G/L for Poc versus 5.2 G/L for Pow; p=0.054] and hemoglobin [127 g/L for Poc versus 126 g/L for Pow; p=0.94] but Pow infected patients presented deeper thrombopenia than Poc infected patients [94.5 G/L versus 111 G/L; p=0.0001]. Rapid Diagnostic Test (RDT) using aldolase detected respectively 45 and 55% of Poc and Pow infections whereas pan-LDH RDT detected respectively 4 and 16% of Poc and Pow infections.

Poc and Pow infected patients were comparable in age, sex ratio and ethnic origin. No difference in symptoms, clinical presentation (97% of uncomplicated malaria for both species), and taking-care of patients (hospitalization in respectively 56 and 61% of Poc and Pow cases; p=0.45) was observed. But, delay between last exposure to Po and symptoms was longer for Poc than Pow infections [34 days for Pow, 72 days for Poc; p=0.0001]. Relapses were observed in 16 Pow and 8 Poc infected patients, with no difference in delay [89 days for Poc, 78 days for Pow, p=0.92]

Conclusions: Pow caused more severe thrombopenia and had shorter appearance of symptom after leaving endemic area than Poc. There is no clear evidence of difference in clinical presentation. Thus, Po spp diagnosis without Poc/Pow differentiation is sufficient in patient’s management.

Aldolase RDTs were more efficient in Poc and Pow diagnosis than p-LDH RDTs. Furthermore, p-LDH RDTs were more efficient to detect Pow, as previously described[4].

Abstract 7767

Letermovir reduces rehospitalisations among cytomegalovirus-seropositive allogeneic haematogenous stem-cell transplant recipients

Yoav Golan*1, Yuexin Tang2, Shahrul Mt-Isa2, Hong Wan2, Valerie Teal2, Cyrus Badshah2, Sanjeet Dadwal3

1Tufts Medical Center, Boston, United States, 2Merck, Kenilworth, United States, 3City of Hope Comprehensive Cancer Center, Duarte, United States

Background: CMV infection post A-HSCT is associated with substantial morbidity, mortality, and resource utilization. Letermovir was shown to prevent clinically significant CMV infection (CS-CMVi) in CMV-seropositive A-HSCT recipients and lower mortality at week 24. We evaluated letermovir’s impact on rehospitalization post-transplant.

Materials/methods: We used data from a phase-3 multicenter RCT to assess CMV-associated and all-cause rehospitalizations at weeks 14, 24, and 48 post-transplant among recipients of letermovir versus placebo (study drug started between day 0 and 28 post-transplant and given up to 14 weeks). We reported unstandardized rehospitalization rates, estimate standardized rates accounting for censoring due to death or early study discontinuation, and average rehospitalization days. We calculated 95%CI using Clopper–Pearson’s exact method.

Results: Of 495 patients in the primary efficacy study population, 325 received letermovir and 170 received placebo. Unstandardized rates of CMV-associated rehospitalization in letermovir vs. placebo recipients at weeks 14, 24, and 48 were 0.6% vs. 7.1% (95%CI 0.1%-2.2% vs. 3.7%-12.0%), 2.8% vs. 7.6% (95%CI 1.3%-5.2% vs. 4.1%-12.7%), and 3.1% vs. 8.8% (95%CI 1.5%-5.6% vs. 5.0%-14.1%), respectively. Unstandardized rates of all-cause rehospitalization in letermovir vs. placebo recipients at weeks 14, 24, and 48 were 36.6% vs. 47.6% (95%CI 31.4%-42.1% vs. 39.9%-55.4%), 49.2% vs. 55.9% (95%CI 43.7%-54.8% vs. 48.1%-63.5%), and 55.7% vs. 60.6% (95%CI 50.1%-61.2% vs. 52.8%-68.0%), respectively. Standardized rehospitalization rates per 100 patient-months in letermovir vs. placebo recipients at weeks 14, 24, and 48 were 12.8 vs 19.6, 9.5 vs. 11.1, and 6.3 vs. 7.2, respectively. In addition, the mean duration (days) of rehospitalization was shorter among letermovir vs. placebo recipients at weeks 14, 24, and 48: 14.4 vs. 17.9, 15.9 vs. 17.9, and 16.5 vs. 19.2, respectively. Standardized total length of rehospitalization per 100 patient-months in letermovir vs. placebo recipients at weeks 14, 24, and 48 were 264.4 vs 462.6, 267.3 vs. 308.0, and 202.5 vs. 245.2.

Conclusions: Letermovir, apart from preventing CS-CMVi in A-HSCT recipients and reducing all-cause mortality, is consistently associated with lower rates of CMV-associated and all-cause rehospitalizations with a shorter length of stay (especially within first 14 weeks post-transplant). Letermovir prophylaxis can significantly reduce healthcare utilization among CMV-seropositive A-HSCT recipients.

Abstract 7768

**Epidemiology of carbapenemases isolated from Enterobacteriaceae other than Klebsiella pneumoniae and Escherichia coli in Belgium (2015-2018)**

Olivier Denis*1, Pierre Bogaerts1, Catherine Berhin1, Warda Bouchahrouf1, Martin Hoebeke1, Youri Glupczynski1, Te-Din Huang1

1National Reference Center of Antibiotic-resistant Gram-negative bacilli, CHU UCL Namur - Site Godinne, Yvoir, Belgium

**Background:** The epidemiology of carbapenemase-producing Enterobacteriaceae (CPE) among species other than Klebsiella pneumonia (KP) and Escherichia coli (EC) is less explored. We retrospectively analyzed a large collection of isolates to determine the distribution and the epidemiology of non-KP non-EC CPE isolates (NKPECCPE) in Belgium.

**Materials/methods:** 119 Belgian hospital-based (n=95) and community-serving (n=24) laboratories referred 1237 non-duplicate EOTKpEc collected from various clinical specimens between 2015 and 2018 to the National Reference Center (NRC) for suspicion of CPE. The species identification was confirmed by MALDI-TOF and the antimicrobial susceptibility profile was determined by disk diffusion. Carbapenemase production was tested by Beta-Carba test (BioRad). Carbapenemases were identified by immunochromatographic lateral flow assay (LFA) RESIST-4 OKVN (Coris) or by multiplex PCR.

**Results:** Of the 1237 referred isolates, 531 (43%) EOTKpEc isolates including Enterobacter cloacae (n=249), Citrobacter freundii (n=119), Klebsiella oxytoca (n=67) and 13 other Enterobacteriaceae species (n=96) collected from 87 laboratories were confirmed as CPE. Carbapenemase types were mostly OXA-48-like (n=282; 53%), VIM (n=167, 31%), NDM (n=59; 11%), and six other types (n=25; 5%). Eight isolates coproduced two different types mostly OXA-48-like combined to another one (n=7). OXA-48 and VIM producing EOTKpEc were widely reported by 69 (79%) and 39 (45%) laboratories, respectively whereas 18 (21%) found NDM producing EOTKpEc. NDM and OXA-48 isolates were widely distributed in the three regions of the country, whereas VIM producers were reported more frequently in Wallonia including 8 hospitals with clusters (>1 cases with the same carbapenemase).

**Conclusions:** Our data shows a high diversity of carbapenemase producing EOTKpEc with E. cloaceae, C. freundii and K. oxytoca representing the three main species. Despite the predominance of OXA-48 type carbapenemase, VIM carbapenemase was found much more frequently in NKPECCPE than in E. coli and K. pneumoniae (less than 5% of VIM producers according to the NRC data during the same period). These data highlight the importance to conduct active survey that includes or targets other species of CPE to have a comprehensive epidemiology with representative distribution of different major carbapenemase types.

**Presenter email address:** odenis@ulb.ac.be
Bacterial and fungal infections associated with influenza virus in hospitalised patients

Francisco Arnáiz De Las Revillas1, Luis Gibert Hernandez2, Jose David García Palacios2, Pablo Gonzalez García2, Nuria Puente Ruiz3, Mónica Gozalo Margüello2, Carlos Armirñanzas Castillo1, Manuel Gutierrez-Cuadra1, Mª Carmen Fariñas4

1Marqués de Valdecilla University Hospital, Infectious Diseases Department, Santander, Spain, 2Hospital Universitario Marqués de Valdecilla, Internal Medicine Department, Santander, Spain, 3Marqués de Valdecilla University Hospital, Microbiology Department, Santander, Spain, 4Marqués de Valdecilla University Hospital, Infectious Diseases Department. Cantabria University, Santander, Spain

Background: The aim of this study was to describe the clinical characteristics, antiviral treatment and outcome of patients with influenza virus infection and bacterial and fungal co-infection.

Materials/methods: Prospective observational study conducted in a third level hospital between December 2016 and March 2019. Patients > 18 years of age, admitted to the hospital who met the criteria for severe influenza disease (pneumonia, respiratory distress, multiorgan failure, septic shock, admission to ICU) were included.

Results: We included 351 patients with influenza virus infection: 60% (209/351) had influenza B infection. Fifty one percent were women; mean age was 72.4 ± 17.74 years. One hundred and twenty-six patients were vaccinated, of these 86 (68%) developed influenza B and 40 (31%) influenza A (p < 0.001). Sixty-four patients were admitted to the ICU: 46 (71%) with influenza A and 18 (28%) with influenza B (p = 0.02). Seventy-nine patients had coinfections: 27 (34%) were admitted to the ICU and 52 (66%) in conventional ward (p < 0.001). Bacterial or fungal coinfection occurred in 22.5% (79/351) of patients. The most common bacteria were S. pneumoniae (35 patients-10%), S. aureus (6 patients-2%) and H. influenzae and P. aeruginosa in 5 patients (1.4%) each. Four patients had fungal infection: 1 P. jirovecii and 3 A. fumigatus (IFI). All 3 patients with IFI (2 influenza A and 1 B infection) were immunosuppressed (1 Lymphoma, 1 lung adenocarcinoma and 1 infliximab treatment); no immunocompetent patients (0/278) had IFI (p = 0.008). Oseltamivir treatment was prescribed in 87% (69/79) of patients with coinfections and in 77% (209/271) without coinfections (p = 0.04). Death within 30 days after the diagnosis of influenza was similar in patients with (7/77) or without (25/274) coinfections (p > 0.05); and no statistically significant differences were observed in mortality between patients with influenza type A or B (p > 0.05) or those vaccinated or not vaccinated (p > 0.05).

Conclusions: Patients with influenza A virus infection required admission to the ICU more frequently. S. pneumoniae was the most frequent bacteria isolated. Only immunosuppressed patients had fungal coinfection. Patients with coinfections received more Oseltamivir treatment. Thirty-days mortality was similar in patients with or without bacterial coinfections and in those vaccinated or not vaccinated.

Presenter email address: francisco.arnaizlasrevillas@scsalud.es
Public health impact of similar ESBLs/pAmpC-producing Escherichia coli causing urinary tract infections in non-related companion animals and humans

Adriana Belas*1, Juliana Menezes1, Luis Teo Da Gama1, João Carriço2, Maria Constança Pomba1

1University of Lisbon, Faculty of Veterinary Medicine, Lisbon, Portugal, 2University of Lisbon, Faculty of Medicine, Lisbon, Portugal

Background: This study aimed to characterize ESBL/AmpC β-lactamases producing E. coli strains causing urinary tract infections (UTI) in companion animals (CAs) and non-related humans from the community (H).

Materials/methods: 3GC-resistant E. coli (companion animals n=35; humans n=85) isolated from patients with UTI were tested against 14 antimicrobials. PCR was used to detect E. coli phylogenetic groups, Pathogenicity associated-islands (PAIs), urovirulence genes, ESBLs/pAmpC resistance genes. ESBL/pAmpC-producing E. coli isolates were typed by MLST. Subclades C2 (H30-Rx) and C1 (H30-R1) by PCR. Genetic relationships among E. coli isolates were visualized by the goeBURST algorithm based on the PHYLViZ software (v.2). Molecular epidemiology was investigated using rep-PCR typing method.

Results: The frequency of resistance against fluoroquinolones (CAs=74.3%, H=88.2%), trimethoprim/sulphamethoxazole (CAs=71.4%, H=74.1%) and gentamicin (CA=40%, H=37.6%) was higher in 3CG-resistant E. coli from both groups. All isolates were susceptible to carbapenems. Considering phylogenetic group 3GC-resistant E. coli strains from CAs and humans mainly belonged to group-D and B2 (48.6%, 67.1%, respectively). The most frequent PAIs and virulence genes among isolates from CAs and H were: PAI IV536 (CAs=72%, H=91.8%, p=0.017) and PAI ICFT073 (CAs=54.3%, H=78.8%, p=0.013); ecpA (CAs=100%, H=100%) and iucD (CAs=48.6%, H=83.5%, p=0.0002). MLST typing of the ESBL/pAmpC producing E. coli strains revealed a heterogeneous population of E. coli clonal groups in CAs and in non-related humans with UTI. CAs and humans E. coli strains shared two MDR high-risk clonal lineages: ST131, and ST648, an emergent virulent lineage. The blaCMY-2 and blaCTX-M-15 were the most frequently ESBL/pAmpC detected genes in CAs and human strains. ST131 strains from CAs and humans mostly belonged to subclade C2 (H30-Rx). Rep-PCR confirmed that similar high-risk clonal lineages occur between non-related CAs and humans.

Conclusions: Considering that CAs with UTI are generally treated at home by the owners, measures should be implemented to avoid the spread of multidrug-resistant high-risk clones to the environment.

Universidad Central del Ecuador, Quito, Ecuador, ²Universidad, Facultad de Medicina. Universidad de las Américas, Quito, Ecuador, ³Hospital, Hospital Gineco Obstétrico Nueva Aurora Luz Elena Arismendi, Quito, Ecuador, ⁴Hospital, Hospital IESS Quito Sur, Quito, Ecuador, ⁵Hospital, Hospital Vozandes. Servicio de Microbiología, Quito, Ecuador, ⁶Universidad, Facultad de Medicina. Pontificia Universidad Católica del Ecuador, Quito, Ecuador

Background: Critical antibiotics in human medicine are being used in industrial poultry production in Ecuador (e.g. colistin). This practice has led the emergence and dissemination of resistance mechanisms of last resort antibiotic compounds. The aim of this study was to identify and characterize CTX-M-type extended spectrum β-lactamases (ESBL) and evaluate the prevalence of mcr (1 to 5) genes; in cefotaxime resistant Escherichia coli which were isolated from broiler carcasses, farms and extraintestinal human infections in Ecuador.

Materials/methods: Sampling was carried out in Quito (2018-2019), 126 samples from poultry batches, 319 carcasses from markets and 624 third generation cephalosporins resistant E. coli (3GC E. coli) isolates from human extraintestinal infections were considered. Samples were screened for the presence of 3GC E. coli inoculating a representative amount of sample in TBX + cefotaxime (3 mg/l). Antibiotic susceptibility profiles were established by Vitek® 2 system with AST-N27 cards. MIC for colistin were tested by microdilution. The mcr and bla\textsubscript{CTX-M} genes were identified by PCR and further characterized by sequencing.

Results: 92.9% (117/126) of caecum samples and 78.4% (250/319) of carcasses were positive for 3GC E. coli. None of the isolates were resistant to carbapenems and amikacin. Low resistance was registered for gentamycin. A half of the isolates were resistant to quinolones and fosfomycin and high percentage of the isolates were resistant to trimethoprim/sulfamethoxazole. Colistin resistant isolates showed MICs from 2 to 16 µg/ml. The most prevalent bla\textsubscript{CTX-M} allele was bla\textsubscript{CTX-M-55} (53%), followed by 28.4%. Other genes were found in less than 10% of the samples (bla\textsubscript{CTX-M-1},  bla\textsubscript{CTX-M-2},  bla\textsubscript{CTX-M-3},  bla\textsubscript{CTX-M-17},  and  bla\textsubscript{CTX-M-23}). The mcr-1 was found in 18.8% and 10.6% of farms and carcasses respectively. One isolate positive to mcr-1 and one isolate positive to mcr-4 were identified from human samples.

Conclusions: Poultry production in Ecuador is an important reservoir of ESBL and mcr positive E. coli. The prevalence of mcr-1 and mcr-4 in ESBL-E. coli from extraintestinal infections remains low. Further research is needed to find the most possible sources of these bacterium.

Model-informed exposure response analyses for ceftazidime and levofloxacin against *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* in murine thigh infection models

Yuanyuan Jiao1, Kun-Yuan Lin2,3, Dhruvitkumar Sutaria1, Ju-Hsin Chia2,3, Deborah Nicole Griffith2,3, Chin-Wei Chiang2,3, Yu-Chuan Yeh2,3, Jui-Che Chien2,3, Jung-Hsin Lo2,3, Nirav Shah1, Xun Tao1, Lynn Miesel2,3, Jürgen Bulitta*1

1University of Florida, Department of Pharmacotherapy & Translational Research, College of Pharmacy, Orlando, United States, 2Pharmacology Discovery Services, Ltd, New Taipei, Taiwan, 3Eurofins Panlabs, Inc, St. Charles, United States

**Background:** Exposure response (E-R) analyses based on robust pharmacokinetic (PK) and pharmacodynamic (PD) data play a critical role in antimicrobial development. However, model-informed approaches are less common in preclinical settings. This study aimed to characterize E-R relationships for ceftazidime and levofloxacin in murine thigh infection models with *K. pneumoniae* and *P. aeruginosa* using an integrated experimental and optimal design strategy informed by population modeling.

**Materials/methods:** Strains *K. pneumoniae* ATCC 43816 (MIC <sub>CAZ</sub>: 0.25 mg/L, MIC <sub>LVX</sub>: 0.0625 mg/L) and *P. aeruginosa* ATCC 27853 (MIC <sub>CAZ</sub>: 2 mg/L, MIC <sub>LVX</sub>: 0.50 mg/L) were employed in neutropenic murine thigh infection models. Ceftazidime and levofloxacin were subcutaneously administered as single or multiple doses in dose range and dose fractionation studies. Doses for PK/PD studies and PK sampling times were based on D-optimal designs. Drug concentrations and protein binding in plasma were analysed by LC-MS/MS and modelled via population methods. E-R relationships were determined using viable count data at 24 h and PK/PD targets calculated.

**Results:** Apparent clearances differed slightly with the infecting pathogen for ceftazidime, but not levofloxacin [Table]. The fAUC/MIC was most predictive for levofloxacin and fT>MIC for ceftazidime. However, the PK/PD targets for stasis and 2-log<sub>10</sub> killing differed between strains [Table, n=1,397].

**Conclusions:** This study presents an integrated experimental, optimal design and modeling strategy that efficiently identified the most predictive PK/PD indices and targets for ceftazidime (fT>MIC) and levofloxacin (fAUC/MIC) against two common pathogens. This serves as a case study for how to implement this translational approach in future pre-clinical drug development programs. This model-informed approach was valuable to efficiently generate robust and informative E-R relationships.

Emergence of penicillin non-susceptible Group B streptococci within the hypervirulent CC17 clone colonising pregnant women in Portugal: a genomic analysis

Rafael Mamede¹, José Melo-Cristino¹, Mario N. Ramirez*, Elisabete Raquel Ferreira Martins¹

¹Instituto de Medicina Molecular (IMM), Instituto de Microbiologia, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal, ²Faculty of Medicine, University of Lisbon, Instituto de Microbiologia, Instituto de Medicina Molecular, Lisboa, Portugal

Background: Group B streptococci (GBS) have been considered uniformly susceptible to penicillin. However, increasing reports from Asia and North America are finding penicillin-non-susceptible GBS (PRGBS) with mutations in the pbp genes. We used a high throughput sequencing approach to characterize three PRGBS isolates colonizing pregnant women in Portugal.

Materials/methods: Three out of 252 GBS isolates (G0305, G0503 and G0516) recovered from vaginorectal swabs of pregnant women showed decreased penicillin susceptibility [MIC>0.12µg/ml]. The isolates were sequenced (Illumina, San Diego, USA) and analyzed by both mapping and de novo assembly approaches. Capsular serotype, multilocus sequence type (MLST), surface-associated structures and pbp genes were extracted from the genomes.

Results: Genomic analysis revealed that all isolates contained the type III capsular polysaccharide locus, carried the rib surface protein gene, pilus islands 1 and 2b, and were represented by sequence type (ST)109, a single-locus variant of ST17, founder of the hypervirulent CC17 clone. Comparison of the PBPs with those of the susceptible strain 2603V/R revealed, in all isolates, the presence of 4, 3, 1 and 2 amino acid substitutions in PBP1A, PBP2A, PBP2B and PBP2X, respectively. All these changes are commonly found among other susceptible isolates. Additionally, the isolates carried a G398A substitution in PBP2A, previously found among PRGBS isolates in Japan. The core-genome MLST comparison of the 3 isolates with a reference genome (COH1, ST17) and a penicillin susceptible representative of ST17 in the collection (G0235) revealed that the ST109 isolates are more similar to each other (between 46 and 86 allelic differences) than to the ST17 isolate, which is closer (94 allelic differences) to the COH1 reference (Figure).

Conclusions: Recent reports of PRGBS in America and Europe suggest a widespread distribution of PRGBS outside Asia where they were first described. Our results show the emergence of PRGBS within the hypervirulent CC17 clone. Although PRGBS are reported at an increasing rate, the clinical significance of in vitro penicillin non-susceptibility is still not fully understood. The possible emergence of penicillin resistance in GBS, particularly among the most prevalent and invasive clones, may have significant implications for the prevention and management of GBS disease.

Abstract 7778

**Bacteroides as a next-generation of probiotics in neonatology**

Lyudmila Lyubasovskaya¹, Priputnevich Tatiana¹, Vera Muravieva¹, Elena Isaeva¹, Daria Serdyukova¹, Alexey Gordeev¹, Natalia Shabanova*¹, Gennadiy Sukhikh¹

¹National Medical Research Center for Obstetrics, Gynecology and Perinatology named after Academician V.I. Kulakov of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

**Background:** Most healthy adult microbiota are dominated by *Bacteroides* which used to be the "pioneers" in colonization of newborns gastrointestinal tract after vaginal delivery. It plays the key role anti-inflammatory effects inducing the maturation of enterocytes in newborns. We are trying to define the differences in the process of colonization involving *Bacteroides* in two groups of infants after vaginal (group I) and caesarean section (group II) delivery.

**Materials/methods:** We examined the feces of 66 term healthy infants both from group I (n=33) and group II (n=33) on the 1st, 7th and 30th day of life using cultural methods. As a tool for identification of bacterial species, MALDI-TOF mass-spectrometry was used. In case if the ID score was less than 2.0 the 16S rRNA gene-sequencing has been chosen as an alternative to complete the identification.

**Results:** Among all the participants on the 1st day after birth, only 13 infants had any bacteria in meconium samples. We found the abundance of *Propionibacterium* in the samples whereas *Bacteroides* has been cultivated just once and only in the group I. Further, we also determined *Bacteroides* only in the group I. In comparison with the 1st day the 7th day of life was characterized with the higher rate of colonization of *Bacteroides* in the group I (3% and 36% of infants respectively), while *Bifidobacterium* and *Propionibacterium* dominated. Out of all *Bacteroides* species present in feces, we identified *Bacteroides uniformis, Bacteroides fragilis, Bacteroides ovatus, Bacteroides vulgatus*. On the contrary, the group II lacked *Bacteroides* whereas *Bifidobacterium, Lactobacillus, Clostridium* and *Veillonella* were most commonly identified. The 30th day results in both groups demonstrated the comparable microbial taxa (*Bifidobacterium, Lactobacillus* and *Veillonella*) with the 7th day results of the group II. It is important that the 30th day also demonstrated the abundance of *Bacteroides* and the lack of *Clostridium* in group I (37.5 %) with the absence of the first one in the group II, except one patient. While the group II results exhibited reciprocal prevalence of *Clostridium*.

**Conclusions:** We think *Bacteroides* helps to prevent colonization of GI-tract by *Clostridium* and might be used as a probiotic candidate.

Abstract third-party references: Collaboration des 17 CPias

**Background:** In France, the HAI notification was written in the law, since 1998 and implemented in 2001 by decree. The system aimed to early detection of unusual events at local, regional and national level for their prompt investigation and control. An HAI has to be notify to health care authorities if: (i) it is unusual, unexpected according to identification, pathogenicity or antimicrobial resistance of the causative micro-organism or according to its localisation or mechanism; (ii) it occurs in a cluster of cases; (iii) death of the patient is related to HAI, (iv) it is included in the list of mandatory notifiable disease. The first step of notification is the regional level (Health authorities (ARS) and Regional centre for HAI prevention (CPIAS). Secondarily, the national level Sante publique France is informed. In 2012, a secure web system was implemented called “e-Sin”.

**Materials/methods:** In 2017, according to the evolution of antimicrobial resistance epidemiology and the spread of Carbapenem-resistant Enterobacteriaceae (CRE) and Glycopeptide Resistant Enterococci (GRE), a new specific module was added. It can be used to report infections and colonisations. Further information as implemented control measures are included, to assess their compliance with national recommendations.

**Results:** Since 2012, near 20 000 notifications including around 5000 CRE and GRE have been reported. In 2018, Sante publique France received more than 3000 notifications, 62 % of them were CRE or GRE, mostly colonisations and 3% of bacteremia. Despite the spread of these MultiDrug Resistant Bacteria, the French level of CRE (E. coli and K. pneumoniae) and GRE in European Antimicrobial Resistance Surveillance Network remains very low (<1%). Moreover, this notification system allows us to identify and control other emerging micro-organisms as *Candida auris* in immunocompromised patients, non-tuberculosis Mycobacteria in cardiac surgery, *Bacillus cereus* spreads in neonates.

**Conclusions:** The system has some limits rely on professional adhesion and data quality. However, it has an added value to HAI and AMR surveillance for immediate implementation of investigations and control measures, information and potential support of Regional and national level to Health care facilities.

Fluoroquinolone and Macrolide resistance-associated mutations in *Mycoplasma genitalium*

Massimo Oggioni*, Sara Colonia Uceda Rentería, Livia Tartaglione, Carmine Melchionna, Maria Gabriella Maddeo, Anna Orlandi, Marco Cusini, Giovanna Lunghi

1Virology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, 2Unit of Dermatology, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

**Background:** We analyzed the macrolide and fluoroquinolone resistance in *M. genitalium* positive samples collected from symptomatic patients, attending an STI center in Milan (Italy) between March 2017 and October 2019.

**Materials/methods:** A total of 99 *M. genitalium* positive samples (73% males and 26% females), including 71 urethral swabs, 25 vaginal swabs and 3 anal swabs, were analyzed at the Virology Laboratory of the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy. The samples were tested using two commercially-available multiplex qPCR assay [ResistancePlus™ MG, Speedx and Allplex™ MG & AziR assay, Seegene] for simultaneous detection of *M. genitalium* and mutations responsible for resistance to macrolides in region V of the 23S rRNA. Moreover, 99 samples were analyzed with Allplex™ MG & MoxiR assay, Seegene to evaluate clinical performance of new assay. The resistant specimens were subsequently sequenced with the Sanger method.

**Results:** From 99 *M. genitalium* positive specimens 52 (52.5%) and 51 (51.5%) resulted resistant to macrolide with the ResistancePlus™ MG kit and MG & AziR assay, Seegene respectively. The presence of a single point mutation was confirmed in 51 of 52 samples with the Sanger Sequencing, while 1 sample resulted wild type (WT). The most common mutations were A2059G (35/51, 68.6%) and A2058G (10/51, 19.6%), while the least frequent were A2058T (7/51, 13.7%).

Moreover, 14/99 (14.1%) *M. genitalium* positive specimens resulted positive for moxifloxacin resistance with a frequency of mutations of G259A (4/14, 28.6%), G248T (4/14, 28.6%), G259T (3/14, 21.4%), G248A (2/14, 14.3%), A247C (1/14, 7.1%).

Interestingly, 11/99 (11.1%) positive specimen presented both macrolide and fluoroquinolones resistance.

**Conclusions:** *M. genitalium* was found to represent an important microbial pathogen in patients presenting with genital symptoms in Milan, Italy. In Italy azithromycin is still widely used for the treatment of *Chlamydia trachomatis* infections, therefore a rise of the percentage presented in this analysis is expected in the next few years. Our findings support the need for ongoing antibiotic resistance surveillance and the importance of using molecular assays to tailor treatment.

**Abstract 7787**

**Invasive *Acinetobacter baumannii* infections in paediatric infectious disease intensive care unit**

Lorna Stemberger Maric*, Nina Krajcar¹, Neven Papic¹, Iva Butic¹, Goran Tesovic¹

¹University Hospital for Infectious Diseases “Dr. Fran Mihaljevic”, Zagreb, Croatia

**Background:** *Acinetobacter baumannii* has become an important cause of nosocomial infections and has displayed increasing antimicrobial resistance over the last decade. The goal of this study was to examine the occurrence, clinical presentation, risk factors, antimicrobial susceptibility and mortality of invasive *A. baumannii* infections in pediatric infectious diseases intensive care unit (PICU).

**Materials/methods:** We conducted a retrospective cohort study that included patients treated for invasive *A. baumannii* infection in PICU at the University Hospital for Infectious Diseases in Zagreb, Croatia, in a 9-year period (2010 – 2019).

**Results:** Seven children [eight infection episodes]; 4 girls and 3 boys with median age 14 months [range 4 months – 13 years] were treated during the studied period. They all had hospital-acquired *A. baumanii* infection (6 in other hospitals and 2 in our PICU). All patients had some predisposing factors for invasive infection [ventriculo-peritoneal drainage in 4/7 (57.1%), combined heart defect in 1/7 (14.3%), tracheostomy in 1/7 (14.3%) and systemic erythematous lupus in 1/7 (14.3%)]. *Acinetobacter* was isolated mainly from cerebrospinal fluid (5/8, 62.5%) and blood cultures (3/8, 37.5%), while 3 patients (37.5%) had concomitant isolate from tracheal aspirates.

5 infection episodes (62.5%) were postoperative shunt-meningitis with bacteria isolated from cerebrospinal fluid. The average CSF cell count was 7168 [range 240-17920] cells in 3mm3. One patient had concomitant pneumonia. Patients were treated with meropenem (4 patients) and colistin (1 patient); two patients received intrathecal amikacin. 3 patients had sepsis (37.5% infection episodes), treated with ampicillin-sulbactam (2 patients) and meropenem (1 patient). Two of them had external source [central venous catheter] and one had origin in pneumonia/tracheal colonization [due to chronic tracheostoma]. Four isolates (50%) had good antimicrobial susceptibility, 3 (37.5%) were susceptible only to ampicillin-sulbactam and colistin while one (14.3%) was susceptible solely to colistin. Mortality rate was 50% (2 patients with sepsis and 2 with shunt-meningitis died).

**Conclusions:** *Acinetobacter baumannii* predominantly causes severe invasive infections in conditioned pediatric patients with exposure to hospital enviroment. Although *Acinetobacter* infections are not common in our PICU, the isolation of this nosocomial pathogen should be of particular concern due to high antimicrobial resistance rate and significant mortality.

**Presenter email address:** lorna_stemberger@yahoo.com
Background: In Tunisia, coastal regions are ecosystems of economic importance; however, they are highly subjected to potential anthropogenic impacts. Over the past decade, Enterobacterales producing extended-spectrum β-lactamases (ESBLs) and carbapenemases have emerged among animals and animal products. Those multidrug resistant bacteria have been recognized from non-human sources and were found in rivers and hospital wastewater, suggesting that aquatic organisms are a reservoir of such enzymes. Here, we investigated the presence of ESBLs and carbapenemases in Enterobacterales isolated from Mediterranean clams (Ruditapes decussatus).

Materials/methods: Between March and April 2016, 1075 clams originating from the Bizerte region and bought at retail were distributed in 215 pools of 5 clams each. Resistant Enterobacterales were selected on MacConkey agar plates either supplemented with imipenem or cefotaxime (final concentration of 2µg/ml). Antimicrobial susceptibility was performed by disk diffusion and ESBL and carbapenemase genes were detected by PCR and sequencing. Plasmids were characterized by rep-typing (Diatheva) and southern blot on S1-PFGE gels. Clonality was assessed by PFGE and MLST.

Results: Among the 215 analyzed pools, 21 gave a positive result on the cefotaxime-enriched medium, including 16 ESBL-producing Escherichia coli and 5 ESBL-producing Klebsiella pneumoniae isolates. In E. coli isolates, CTX-M-1, CTX-M-14, CTX-M-15 and CTX-M-27 were produced by 8, 5, 2 and one isolate(s), respectively. PFGE demonstrated 13 different profiles and genetic backgrounds [10 different STs]. Two E. coli ST131 were identified, suggesting a human contamination. ST147, already identified in Tunisian mussels, was also found in two samples. Plasmid characterization is ongoing. For K. pneumoniae, all isolates (n=5) produced CTX-M-15. Three of them, all belonging to ST147, co-produced the OXA-48 carbapenemase.

Conclusions: This is the first report of OXA-48 producing Enterobacterales isolate from mollusks in Tunisia. Next to the recent finding of KPC-3 in Mytilus galloprovincialis at retail, we confirm that other filter feeder mollusk species are at risk to concentrate carbapenem-resistant Enterobacterales from the human reservoir.

**Evaluation of Novodiag C. difficile and GenePOC CDiff test for quick and accurate detection of Clostridioides difficile infection**

Ann-Cathrine Petersson*, Lealdina Rebihic†, Sara Karlsson Sobirk‡

†Clinical microbiology, Region Skåne, Lund, Sweden

**Background:** *Clostridioides difficile* is the most important cause of hospital-acquired diarrhoea and antibiotic-associated pseudomembranous colitis. Rapid identification of strains producing toxin B is necessary for appropriate treatment of the patients and for infection control. Over the last decade diagnostic tests have switched from culture and cytotoxicity assays or enzyme immunoassays (EIAs) to more rapid techniques such as PCR. The aim of the present study was to compare the performance and workflow of molecular methods suitable for decentralized rapid detection of toxigenic *C. difficile* in stool samples, to the routine method used at the central laboratory in Region Skåne.

**Materials/methods:** Two new fully automatic PCR systems, Novodiag® *C. difficile* (MobiDiag, Espoo, Finland) and GenePOC™ CDiff test (GenePOC Diagnostics, Quebec, Canada), were evaluated for the detection of the *C. difficile* toxin B gene (*tcdB*) direct from stool samples. Included were fresh samples with stool type 5-7 according to Bristol Stool Scale, from patients >2 years of age, which could be analyzed consecutively within 48 h from time of sampling. Culture on CHROM-agar *C.difficile* (CHROMagar, Paris, France) followed by test for toxin A and B of cultured strains, using Vidas (bioMérieux, Marcy l’Etoile, France), was used as reference method. In total 212 samples were analyzed in parallel with all three methods. PCR’s were performed according to instructions by the manufacturers.

**Results:** Both systems showed high concordance (both 99.1 %) with the results obtained with the reference method where 77 samples were positive for toxin producing *C. difficile*, 4 had indeterminate, and 131 had negative results. Diagnostic sensitivity and specificity, compared to the reference method, were identical for both systems: 100 % and 98.5 %, respectively.

Evaluation of the workflow showed few differences between Novodiag and GenePOC. Differences were random access versus batches of 1-8 samples, possibility to analyse samples in eSwab versus only fresh stool samples, and calibration of instrument versus evaluation of amplification curves.

**Conclusions:** Both Novodiag *C. difficile* and GenePOC CDiff provide quick and accurate results, are easy to handle, and are suitable for decentralized diagnostics of *C. difficile* infection.

**Presenter email address:** ann-cathrine.petersson@skane.se
Abstract 7794

Evaluation of association between immune modulation and incidence of cytomegalovirus reactivation in sepsis-induced immunosuppression

Gaurav Lambe⁎1, Farhad Kapadia1, Camilla Rodrigues1, Anjali Shetty1, Shanaz Khodaiji1, Dia Mansukhani1

1P. D. Hinduja National Hospital & Medical Research Centre, Mumbai, India

Abstract third-party references: National Health and Education Society, P. D. Hinduja Hospital and Medical Research Center

Background: Sepsis is a global health priority, often accompanied by transient immune paralysis due to progressive immunosuppression and increased susceptibility to secondary infections. Reactivation of Cytomegalovirus (CMV) has been associated with adverse outcomes and mortality in immunocompetent patients, including sepsis. We aimed to evaluate the relationship between incidence of CMV reactivation and immune alteration in sepsis-induced immunosuppression in patients with prolonged sepsis.

Materials/methods: Prospective observational study, including consecutive patients admitted to hospital ICU, with severe sepsis and length of stay >48 hrs. Patients with immune-suppression due to other disorders/steroids/anti-CMV treatment were excluded. Blood sampling was done on enrolment and further weekly until 21 days or death/discharge. Quantification of CMV viremia was done using RT-PCR (qPCR). Determination of immune cell subsets (CD3+, CD19+, CD16+CD56-, CD4+, CD8+ and CD25+CD127- regulatory T cells) and surface receptor expression of HLA-DR on monocytes, PD-1 on T lymphocytes were analyzed by flow cytometry. Measurement of Th1/Th2/Th17 cytokines was done using CBA assay by flow cytometry.

Results: Among 25 CMV seropositive analyzed patients, CMV reactivation occurred in 80% (n=20) of the population. CMV viremia >1000cp/ml were detected in 60% (n=12) patients while, <1000cp/ml were detected in 40% (n=8) patients at any time point. Median time for reactivation was 7 days. Patients with CMV reactivation had T lymphopenia. Elevation in inhibitory expression of PD-1 on both CD4+, CD8+ T cells was observed in CMV reactivated group, which found decreased in non-reactive group over time (515.9±526.8 vs 580.12±246 vs 174.2±47.8, p <0.01). Levels of IL-10 were significantly higher in CMV reactivated group which continued to elevate, compared to non-reactive group (18.7±30.8 vs 5.0±2.95, p <0.01). HLA-DR expression on monocytes was significantly low in all patients however, did not show major difference in CMV reactive vs non-reactive patients.

Conclusions: Our study suggests impairment in immune defense is a major cause of sepsis-induced immune tolerance and risk factor for viral reactivation. Incidence of CMV reactivation was associated with PD-1-related T lymphocyte dysfunction and IL-10 suppressive activity. Targeted and individualized immune therapy with PD-1 blockade and immune stimulation can effectively help prevent CMV reactivation and improve clinical management of patients with severe sepsis.

Abstract 7795

**Identification of DNA virus in conventional culture by MALDI-TOF MS**

Gabriel Martin*1, Susana Rojo1, Rainer Campo Ramos1, Isabel Costales1, Zulema Pérez1, Xana García1, Marta E Alavarez-Argüelles2, Santiago Melón-García1

1Hospital Universitario Central de Asturias, Oviedo, Spain

**Background:** Traditionally, gold standard method for viral diagnosis has been cell lines culture. Nowadays qPCR and other genomic techniques are extended. Proteomic techniques implanted for bacterial and fungal identification, like MALDI-TOF/MS, are quick and cheaper, but are not available for viral identification. Thus the aim of this study was MALDI-TOF/MS apply for viral identification.

**Materials/methods:** An in house library was created following manufacturer instructions (Bruker Daltonics, Germany). It contains 104 spectrums of viruses (54 HSV, 4 VZV, 13 CMV and 16 ADV) and cell lines (8 MRC5, 7 VERO and 2 MDCK), used to define background spectrums. Strains used to do this library were also checked by immunofluorescence and qPCR.

Pellet and supernatant of cell cultures from: 50 positive samples for HSV1 [27] and HSV2 [23], 50 positive for ADV grown in conventional cultures [MRC5 and VERO], and 50 non infected cell cultures [25 MRC5 and 25 VERO] were assayed. Each strain was identified by IF and qPCR.

**Results:** In pellet, 45 (90%) of HSV strains were identified, while 27 (54%) were detected in supernatant. For HSV1, 25 (92.59%) strains were detected in pellet and 17 (62.96%) were detected in supernatant. For HSV2 strains, 20 (86.95%) were detected in pellet while 10 (43.47%) were detected in supernatant. About ADV strains, 32 (64%) were detected in pellet, while 46 (92%) were identified in supernatant. All strains were positive by IF and/or qPCR. In any not-infected cell line assayed any virus was detected. This table shows the identified virus and the score of MALDI-TOF/MS.

Infectious complications in patients with multiple sclerosis treated with monoclonal antibodies (anti-CD20 and anti-CD52) and autologous stem cell transplantation

Riccardo Ungaro*1,2, Alessio Signori1, Matilde Inglese1,5, Alice Laroni1, Giovanni Novi1, Giacomo Boffa1, Caterina Lapucci1, Margherita Ghigliotti2, Giovanni Luigi Mancardi4,5, Antonio Uccelli4,5, Matteo Bassetti2,6, Malgorzata Karolina Mikulska2,6

1Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Infectious Diseases Unit, Department of Internal Medicine, Milano, Italy, 2University of Genoa, Department of Health Sciences (DISSAL), Genoa, Italy, 3University of Genoa, Department of Health Sciences (DISSAL), Section of Biostatistic, Genoa, Italy, 4University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINGMI), Genoa, Italy, 5Ospedale Policlinico San Martino IRCCS, Department of Neuroradiology, Genoa, Italy, 6Ospedale Policlinico San Martino IRCCS, Infectious Diseases Clinic, Genoa, Italy

Background: Novel therapies for multiple sclerosis (MS) include autologous stem cell transplantation (ASCT) and monoclonal antibodies targeting CD20/CD52 antigens. Although similar treatments have been used for non-neurological conditions, risk of infections may vary in MS population. The aim of our work was to compare the incidence and severity of infections in patients receiving anti-CD20 (ocrelizumab [OCR] and rituximab [RTX]), anti-CD52 (alemtuzumab [ALM]) antibodies and ASCT for MS treatment.

Materials/methods: Three-year follow-up records of MS patients treated with monoclonal antibodies or ASCT at the Neurology Unit of San Martino Hospital (Genoa, Italy) were retrospectively reviewed. Demographic, clinical and laboratory data were collected. Severe infections were defined as grade ≥3 [Common Terminology Criteria for Adverse Events v5.0-2017]. Rate of infections requiring systemic antibiotic use per 1000/patients-year was compared between treatment groups using RTX as reference. Univariate and multivariate Cox regression analyses were performed to evaluate risk factors using rate of infections requiring systemic antibiotic use as dependent variable.

Results: We collected data of 254 patients (64.6% female, median age 44 years, 48% with relapsing-remitting form), 33 treated with ALM, 84 with OCR, 84 with RTX and 54 with ASCT. Overall infection rate during the three-years follow-up was 63.6%, 52.4%, 69% and 89% for, respectively, ALM, OCR, RTX and ASCT, and severe infections were observed in 3%, 3.6%, 1.2% and 83.3% respectively. Rate of infections requiring systemic antibiotic use per 1000/patients-year was significantly higher in the groups treated with ASCT (IRR 4.75 [2.27 -9.94], p<0.001), ALM (IRR 3.35 [1.54-7.30], p=0.002) and OCR (IRR 2.15 [1.09-4.24], p=0.028) compared to RTX. In multivariate analysis, higher number of previous therapeutic lines (IRR 1.76 [1.09-2.85]; p=0.02) was associated with increased risk of moderate to-severe infections in ALM group, while more recent treatment start with an increased risk in ASCT group (IRR 1.15 [1.09-1.20], p<0.001), and RTX group (IRR 1.76 [1.20-2.59], p=0.004). Rate of infections decreased substantially after the engraftment in the ASCT group, conversely remained stable during treatment with monoclonal antibodies [Fig.1].

Conclusions: Risk of severe infections was low during monoclonal antibodies treatment, and the rate of infections requiring systemic antibiotics was the lowest in RTX group.

Figure 1. Overall incidence of infections

**Prevalence, antimicrobial susceptibility and molecular typing of **Legionella pneumophila** **in hot water systems in Morocco**

Abdelwahid Assaidi*, Mostafa Ellouali1, Hassan Latrache1, Hafida Zahir1, Christophe Ginevra2, Sophie Jarraud2, Mostafa Mliji3

*1Sultan Moulay Slimane University, Faculty of Sciences and Techniques, Beni Mellal, Morocco, 2Hospices Civils de Lyon, Groupement Hospitalier Nord, Institut des Agents Infectieux, Centre National de Référence des Légionelles, Lyon, France, 3Institut Pasteur du Maroc, Casablanca, Morocco

**Background:** The aims of this study were to determine the prevalence of **Legionella pneumophila** in hot water systems in Morocco, assess the antimicrobial susceptibility and investigate the molecular distribution of **Legionella pneumophila** serogroup 1.

**Materials/methods:** A total of 149 water samples from 111 different hotels were analyzed. The minimum inhibitory concentrations (MICs) of sixty environmental **Legionella spp.** strains were tested for twelve antimicrobial agents, including Macrolides, fluoroquinolones, ketolide and rifampicin. Moreover, a selection of 20 **L. pneumophila** sg1 strains were typed by monoclonal antibodies, pulsed field gel electrophoresis and new generation sequencing.

**Results:** Out of the 149 samples, 77 (51.7%) were positive for **L. pneumophila**. Serological typing of the isolates revealed that 54 (70.1%) are **L. pneumophila** serogroup2-15 and 23 (29.9%) are **L. pneumophila** serogroup1. Counts were over 1000 cfu/l in 44% of all building. Contamination was strongly correlated with temperature in the circulation, the age of the premise plumbing and the size of the building. All tested strains of **L. pneumophila** were inhibited by low concentrations of fluoroquinolones and macrolides. Rifampicin was the most effective antibiotic against the isolates in vitro. All isolates were inhibited by the following antibiotics (MICs): doxycycline < cefotaxime < tigecycline. MAb typing results showed a prevalence of MAb 3/1 negative isolates (n = 100%) with 6 subgroups of Camperdown (30%), 7 Oxford (35%) and 7 OLDA (35%). The pfge analysis showed five different profiles, some of which are present at several buildings in different cities of Morocco. After sequencing, SBT analysis revealed 3 sequence type (STs) with a high prevalence of ST1 found in 13 strains (65%), followed by ST560 in 4 (20%) and a new ST was found in 3 (15%). 46% of ST1 are Oxford, 23% of Camperdown and 31% of OLDA.

**Conclusions:** The results show a relevant exposure to **L. pneumophila** in the community and the identified risk factors can serve as indicators for risk assessment and relevant actions. This study revealed the genetic diversity of environmental **L. pneumophila** sg1 isolates in Morocco, providing also a useful data for future epidemiological investigations, especially of travel associated Legionnaires’ diseases.

**Impact of unique blood culture sampling in the emergency departments of Strasbourg University Hospital, France**

Pierre Boyer1, Angéline Chabaud1, Pascal Bilbault1, David Menahem2, Eugénie Fonti2, Vincent De Peyrecave2, Thierry Lavigne1, Benoit Jaulhac1

1Strasbourg University Hospital, Strasbourg, France, 2BD Diagnostic Systems, Le Pont-de-Claix, France

**Background:** Bacteremia are responsible for a high morbi-mortality worldwide. Detection of bacteremia is directly related to the quality of blood culture (BC) sampling.

The purpose of this study is to evaluate the impact of a resensibilisation action to good practices of BC sampling. During this action, unique sampling (US) of 3 pairs of HC was also promoted.

**Materials/methods:** A retrospective before/after observational study was conducted. Two groups were compared: one ‘before’ (October-December 2017) and the other ‘after’ intervention (October-December 2018). Patient inclusion criteria was the sampling of at least one BC in the emergency department during these periods.

The following indicators were used to compare the 2 groups:
- The rate of patients who had a US
- The positivity rate (excluding contamination)
- The isolation rate of commensal skin microorganisms, which could be linked to contamination
- BC sampled by venipuncture
- The average volume of blood per blood culture bottle

**Results:** In 2017 1450 patients and 1462 patients in 2018 were included, which represented 1804 pairs of BC in 2017 and 3579 pairs of BC in 2018.

Table 1 summarizes the values of the indicators and the statistical significance of the difference before/after.

*Percentage calculated on sites with prescription information.

The average filling volume of the vials did not increase and remains low at 3 mL per vial.

**Conclusions:** The adhesion of US of three pairs of BC was good. This led to a significant increase of the BC positivity rate. However, this increase is not as high as it can be found in the literature, the low filling volume per bottle is undoubtedly the cause of it.

Raising awareness of good sampling practices has reduced the rate of contamination and direct punctures were preferred.

The adoption of US increases the number of BC sampled, this increase may also lead to the need to clarify the indications of this laboratory testing.

Abstract 7803

**HEV infection as an emergent public health issue: is it a concern for Italian blood donors?**

Luna Colagrossi¹*, Marcella Mercuri², Alice Nava¹, Elisa Matarazzo⁴, Daniela Adele Pia Campisi¹, Perno Carlo Federico²,³, Diana Fanti²

¹University of Milan, Residency in Microbiology and Virology, Milan, Italy, ²ASST Grande Ospedale Metropolitano Niguarda, Chemical-clinical and Microbiological Analysis, Milan, Italy, ³University of Milan, Department of oncology and Hemato-oncology, Milan, Italy

**Background:** In high-income countries, HEV infection is usually associated with an asymptomatic, self-limiting, acute or mild hepatitis. However, the risk of HEV transmission through blood or blood products raises concerns, especially in the setting of immunosuppressed patients. The aim of the present study was to determine the presence of HEV infection in blood donors at ASST GOM Niguarda Hospital using a combined approach (HEV-RNA/seroprevalence).

**Materials/methods:** From January to July 2019, 9,081 sera and plasma samples from blood donors were retrospectively analysed. Pools of 6 plasma donations were assessed to detect HEV-RNA using the commercial Cobas® HEV Test (Roche Molecular Diagnostics, LLOD 18.6 IU/mL). Among them, 7,771 serum samples were tested for anti-HEV total IgM/IgG with ELISA test (DIA.PRO Diagnostic Bioprobes srl).

**Results:** Overall, the blood donors were predominantly men (73.6%; 5,720/7,771) with a median age of 42 (IQR: 31-50). HEV-IgM/IgG positivity was found in 4.3% (334/7,771) of blood donations, however none of them carried detectable HEV-RNA.

The rate of HEV-infection in this healthy population was compared with that of symptomatic patients [with altered transaminases]. HEV-IgM/IgG positivity was found in 4.3% (14/324) and 10.6% (50/472) of patients, respectively. Among them, 1.6% (3/184) of patients had detectable HEV-RNA: two of them were mother and son from Egypt with acute HEV-infection and the third was an Italian man with chronic HEV-infection.

**Conclusions:** The circulation of HEV-RNA in blood donations at Niguarda Hospital results to be absent, with an HEV-IgM/IgG prevalence of 4.3%, one of the lowest reported among blood donors in Italy [8.7%; Spada et al., Blood Transfusion 2018]. At the same time, HEV active infection has been detected in few patients whose HEV-RNA was assessed for hepatic symptoms [elevated ALT]. From these data, the screening for HEV-RNA appears not to be crucial in our population of blood donors, while further studies are warranted to define its relevance in case of liver pathologies.

Abstract 7811

**LUISA: Low Cost Unit for Sequencing Applications**

Louise Cerdeira*1,2, Ryan Wick2, Louise Judd2, Margaret Lam2, Kelly Wyres2, Kathryn E. Holt2,3

1Universidade de São Paulo, São Paulo, Brazil, São Paulo, Brazil, 2Monash University, Melbourne, Australia, 3The London School of Hygiene & Tropical Medicine, London, United Kingdom

**Background:** Over the last years, next generation sequencing had a revolutionary advance for molecular biology, made microbial genome sequencing cheap and accessible with high accuracy and throughput. However, short-reads length limits its ability to resolve repetitive and/or high %GC content regions, hindering the mobile genetic elements spread tracking creating implications for Global Health since these elements have the ability to transport antibiotic resistance genes and virulence factors. In this regard, this is one of the reasons that led to the development of long-read sequencing, such as generated by Oxford Nanopore Technologies (ONT) platforms, that has a portable real time sequencer (MinION), with potential to render other sequencing technologies obsolete. Although, high error rates pose a challenge for generating accurate genome assemblies, emerging a demand of paramount importance focused on developing new tools able to deal efficiently with the high error rate. Generating a subsequent avalanche of development of new tools and computational algorithms, as well as the application of machine learning (ML) in order to reduce error rate. But most of tools require a high computational cost causing a performance bottleneck which involves high financials costs. In this regard, we develop LUISA.

**Materials/methods:** In this regard, we develop LUISA (Low Cost Unit for Sequencing Applications) embedded with custom carrier board, Ubuntu OS, Bioinformatics tools and two options versions that can be powered by solar energy: GPU-based, option 1: Jetson TX2 NVIDIA board, 8GB RAM, SSD M.2 1Tb, wifi 802.11 b/g/n 5GHz) and option2: Mini ITX board, Intel i7-4300Y, 16GB RAM, SSD M.2 1Tb, wifi 802.11 b/g/n 2.4GHz.

**Results:** Benchmarking of LUISA provided results that consensus calling, de novo assembly and machine learning training model in GPU-based version can be five times faster than LUISA CPU-based version. Additionally, it offers a cost-effective solution compared to other available options.

**Conclusions:** LUISA will lead benefits to genomic surveillance and epidemiological studies of the endemic diseases for low income countries. In this context, LUISA is currently the most cost-effective option available for nanopore data analysis. Providing the analysis of sequencing feasible, open solution, low cost and also an alternative powered by renewable energy.

Evaluation of different methods for the detection and differentiation of mechanisms of resistance in carbapenemase-producing Enterobacterales at a large district hospital, UK

Sonal Parikh¹, Hala Kandil*²

¹West Hertfordshire Hospitals NHS Trust, Watford General Hospital, Watford, United Kingdom, ²West Hertfordshire Hospitals NHS trust, Watford General Hospital, Watford, United Kingdom

Background: Carbapenemase-producing Enterobacterales [CPE] have been increasing rapidly globally and are considered to be significant health threat. The accurate, simple, cost effective and rapid detection of carbapenemases in laboratories is an important step to control the spread of CPE. However, no consensus has yet been reached with regards to the single most optimal method and hence the detection of CPE represents a substantial challenge for many laboratories. The aim of this study is to evaluate the performance of four different carbapenemase detection tests to develop guidance in Microbiology laboratory.

Materials/methods: A total of 69 samples were included in this study. MASTDISCS combi Carba plus disc D73C, Coris RESIST-4, BD MAX™ and Gene Xpert Carba-R were challenged, according to the manufacture’s instruction, with Enterobacterales isolates molecularly characterised by the reference laboratory (PHE, Colindale) including NDM, OXA-48, VIM and NDM and negative CPE. Additional 14 of the isolates were not characterised by the reference laboratory were excluded but tested by the other detection methods. We considered equivocal results by D73C as negative. IMI, OXA-23 and OXA-51 were only included when tested by D73C.

Results: The overall sensitivity for the carbapenemase detection tests were 100% for each of BD MAX™, Gene Xpert Carba-R and D73C. While, the sensitivity of RESIST-4 was 97%. The specificity was 100% with Gene Xpert Carba-R and Coris RESIST-4 while dropped to 68.8% and 36.8% with BD MAX™ and D73C respectively. Interestingly, additional detection of NDM gene was reported on five isolates by BD MAX™ where only OXA-48 was detected by the reference laboratory. The other methods were in concordance with the reference laboratory report for these five isolates. BD MAX™ was unable to differentiate between VIM and IMP. The turnaround time was fastest with Coris RESIST-4 (15mins), followed by Gene Xpert Carba-R (53mins), BD MAX™ (2.5hrs). D73C takes longest time as overnight incubation is required.

Conclusions: In this study, except for MASTDISCS combi Carba plus disc D73C, all other methods showed high sensitivity. Lower specificity was detected by BD MAX™. The very low specificity of D73C made it necessary to have additional confirmatory test.

Abstract 7819

ESBL- and/or carbapenemase-producing *Klebsiella pneumoniae* with multidrug-resistant phenotypes as a main cause of non-*Escherichia coli* Enterobacterales healthcare-associated bacteraemia of urinary origin episodes in Spain

Federico Becerra*, Desirée Gijón, Irene Merino Velasco, Silvia Gómez-Zorrilla, Ana Silverio, Dámasir Berbel Palau, Carlos Sanchez Carrillo, Emilia Cercenado, Alba Rivera, Ana De Malet, Mariona Xercavins, Enrique Ruiz, Luis Canoura-Fernández, José Antonio Martínez Martínez, Soledad Salvo, Jose Luis Del Pozo, Miriam Cuesta, Diego Lopez, Jazmin Díaz-Regañón, Rafael Canton Moreno, Antonio Oliver, Juan P. Horcajada, Patricia Ruiz-Garbajosa

1Hospital Universitario Ramón y Cajal, Madrid, Spain, 2Hospital Universitario Río Hortega, Valladolid, Spain, 3Hospital del Mar, Barcelona, Spain, 4Hospital de Bellvitge, Barcelona, Spain, 5Hospital Gregorio Marañón, Madrid, Spain, 6Hospital Santa Creu i Sant Pau, Barcelona, Spain, 7Hospital Marqués de Valdecilla, Santander, Spain, 8Hospital Universitario Mutua Terrassa, Barcelona, Spain, 9Hospital San Espases, Mallorca, Spain, 10Complejo Hospitalario de Pontevedra, Pontevedra, Spain, 11Hospital Clinic, Barcelona, Spain, 12Hospital Clínico Lozano Blesa, Zaragoza, Spain, 13Clínica Universidad de Navarra, Pamplona, Spain, 14Departamento Médico MSD España, Madrid, Spain

Abstract third-party references: Merck Sharp & Dohme (MSD)

**Background:** *Escherichia coli* (*Ec*) is the main pathogen causing healthcare-associated bacteraemia of urinary origin (HCA-BUO), but other Enterobacterales are also involved. We assessed the prevalence and microbiological characteristics of ESBL and/or carbapenemase producing non-*Ec* Enterobacterales causing HCA-BUO in Spain (ITUBRAS-2 project) and compared with those previously obtained in 2011 (ITUBRAS project).

**Materials/methods:** Patients with HCA-BUO [Sep-2017 to Apr-2019] from 12 tertiary hospitals were prospectively included and blood isolates were stored. Bacterial identification (MALDI-TOF) and antimicrobial susceptibility (microdilution, EUCAST-2019) were performed. Isolates were classified as multi-drug (MDR), extensively-drug (XDR) and pan-drug-resistant (PDR) (Maggiorakos, 2012). ESBL and carbapenemase production were screened by double-disk synergy and colorimetric (CarbaNP, BioMerieux) tests, respectively. Genes encoding ESBLs (*bla*<sub>SHV</sub>, *bla*<sub>TEM</sub>, *bla*<sub>CTX-M</sub>) and carbapenemases (*bla*<sub>OXA-48</sub>, *bla*<sub>VIM</sub>, *bla*<sub>KPC</sub>) were characterized (PCR, sequencing).

**Results:** 372 episodes with 389 Enterobacterales isolates were collected; 42.9% (167/389) corresponding to non-*Ec* species. Among them, *Klebsiella pneumoniae* (*Kpn*) (57.5%) was the most prevalent, followed by *Proteus mirabilis* (*Prm*) (11.4%) and *Enterobacter cloacae* (*Eclo*) (8.4%). Overall, 45.5% [76/167] of non-*Ec*-Enterobacterales were MDR, 3.6% [6/167] XDR and 0.6% [1/167] PDR. Resistance to ceftolozane/tazobactam (CMI>2 mg/L) was detected in 10.7% of isolates [18/167; 5 *Eclo*, 4 *Klebsiella aerogenes* and 9 *Kpn*; all of them producing carbapenemases, AmpC or ESBL enzymes]. Prevalence of ESBL-producers increased from 9% (15/167) in 2011 to 26.3% [44/167] in 2019 (p<0.01). The majority of ESBL-producers were *Kpn* [39/44] with MDR phenotype [36/39]. CTX-M-15 [70.4%] was the dominant enzyme. ESBL-producers showed higher resistance rates than non-producers to tobramycin [95.5% vs 9.7%], trimethoprim/sulfamethoxazole [93.2% vs 19.5%], ciprofloxacin [93.2% vs 22%], gentamicin [72.7% vs 8.1%], and amikacin [13.6 vs 2.4%] (p<0.01 for all comparisons). Carbenpenemase production was detected in 10 isolates [6%] [6 *Kpn*, 2 *Eclo*, 1 *Klebsiella oxytoca* and 1 *Morganella morganii*], while carbapenemase-producers were not identified in 2011. OXA-48 was the most frequent enzyme [n=7]. Other types were VIM-1, OXA-244 and KPC-19. ESBL co-production was presented in six isolates which were classified as MDR [1 *Kpn*], XDR [3 *Kpn* and 1 *Eclo*] and PDR [1 *Kpn*].

**Conclusions:** We describe a significant increase of ESBL/carbapenemase-producing *Kpn* with MDR/XDR/PDR phenotypes causing HCA-BUO in Spain among non-*Ec*-Enterobacterales episodes.

Risk factors for daptomycin-induced eosinophilic pneumonia: a matched case-control study in a population with osteoarticular infections

Laura Soldevila-Boixader*1, Ariadna Padullés Zamora2, Eva Benavent Palomares1, Joan Gomez Junyent1, Dolors Garcia-Somoza3, Xavier Cabo4, Javier Ariza1, Oscar Murillo1

1Bellvitge University Hospital, Infectious Diseases Department, L’Hospitalet de Llobregat, Spain, 2Bellvitge University Hospital, Pharmacy service, L’Hospitalet de Llobregat, Spain, 3Bellvitge University Hospital, Microbiology service, L’Hospitalet de Llobregat, Spain, 4Bellvitge University Hospital, Orthopedic and Traumatology service, L’Hospitalet de Llobregat, Spain

Background: The use of daptomycin in osteoarticular infections is widespread and usually prolonged for long periods because of its remarkable anti-biofilm activity. Daptomycin-induced eosinophilic pneumonia (DEP) is an unusual but severe adverse effect. As issues for developing DEP are still not well known, we aimed to determine the risk factors through a case-control study.

Materials/methods: Retrospective, matched case-control study performed in our Bone-Joint Infection Unit (BJIU, January 2014-December 2018). Patients with osteoarticular infections treated with daptomycin were included as cases if they developed DEP [fever, dyspnea with increased oxygen requirement, pulmonary infiltrates and improvement following daptomycin withdrawal]. Controls (2:1) were matched by the total cumulative dose of daptomycin (TCDD, daily dose-mg · X days of treatment), sex and the closest date of drug administration. Data of daptomycin consumption for all patients attended in BJIU during the same period of study was collected.

Results: We identified 11 cases of DEP; 1 patient died (respiratory insufficiency), and 10 cured with daptomycin withdrawal and corticosteroids (6/10, 60%). Percentage of DEP cases increased progressively with days of daptomycin therapy [1% (<7 days), 3.3% (7-14d), 13.3% (≥15d); P<0.001], and with TCDD [1.9% (TCDD<10g), 9.8% (10-15g), and 16.7% (>15g); P<0.001].

In case-control study we found DEP cases were older than controls [median age, 77years –IQR 71-82 vs 62.5 –IQR 50-71; p=0.006, respectively], but they did not differ in the presence of previous pulmonary or cardiac disease nor in renal function. While median values of daily dose of daptomycin and days of treatment were similar between case and controls [700mg/d IQR 700-750 and 19days IQR 12-25 vs 700mg/d IQR 700-850 and 19days IQR 12-23, respectively], the number of eosinophils was higher in DEP cases either with half treatment administered [490x10⁶/mL –IQR 250-850 vs 160x10⁶/mL –IQR 100-310 after median 9.5days; P=0.006] or at the end of treatment [1010x10⁶/mL –IQR 570-1420 vs 210x10⁶/mL –IQR 110-340; p=0.0008].

Conclusions: Older patients with high TCDD (>15g) and prolonged daptomycin therapy (>15 days) are at high risk for developing DEP. Monitoring the increase in the eosinophil counts after 1 week of treatment may be helpful to identify patients at risk for DEP.

Does tigecycline have a place in therapy for rickettsial infections of the central nervous system?

Antonio Mastroianni*, Giuliana Guadagnino1, Sonia Greco1, Valeria Vangeli1, Salvatore De Santis1, Giovanni Apuzzo1

1“Annunziata” Hospital, Azienda Ospedaliera di Cosenza, Infectious Diseases Unit, Cosenza, Italy

Background: Rickettsial infection may present as meningitis. The treatment of these infections can be challenging, as the antimicrobial options are restricted.

Materials/methods: The aim of this retrospective study was to describe the efficacy and safety of tigecycline in a case series of patients with rickettsial infections of the CNS. The conditions of all patients responded well to tigecycline therapy. Although tigecycline is not approved for CNS infections, it was the best available option for the treatment of these five cases.

Results: Herein, we report a case series of five patients with rickettsial infections of the CNS. The diagnosis was based on clinical and CSF findings. Focal neurologic signs were rare, and cerebrospinal fluid profiles were similar to those of viral and tuberculous meningitis. Other major organ involvement (renal, liver, or lungs) occurred in all five patients. Three patients were immediately intubated and placed on mechanical ventilation; initial laboratory investigations showed severe acidosis with elevated lactic acid in these patients. Chest radiography, head CT, and MRI were normal. The finding of abnormalities on electroencephalogram (EEG) during the course of aseptic meningitis was considered to be indicative of parenchymal brain involvement. Cerebral spinal fluid and blood cultures were negative. Investigation for herpesvirus, enterovirus, arbovirus, Borrelia, and Mycobacterium tuberculosis was negative. Serological blood studies were all negative. The diagnosis was confirmed by serology (immunofluorescence assay) that showed a seroconversion, with an eightfold increase of IgG antibodies for Rickettsia rickettsii in 2 weeks (with titres of 128 and 1024). Intravenous tigecycline was administered for 7-10 days with progressive improvement. All patients evolved favourably with remission of symptoms and had no sequelae. Treatment was changed to oral doxycycline as patients were able to take the tablets correctly. Our patients completed 5-10 days of doxycycline.

Conclusions: To the best of our knowledge, this is the first report of tigecycline therapy for CNS infections caused by Rickettsia rickettsii. Tigecycline will be most useful as therapy for rickettsial meningitis and encephalitis, especially in cases in which parenteral therapy is needed. Further research is necessary to determine the role of tigecycline in the treatment of rickettsial infections of CNS.

Fighting a rare cystic fibrosis pathogen: characterisation of Burkholderia cenocepacia cell division machinery

Viola Camilla Scoffone*1, Gabriele Trespidi1, Laurent R. Chiarelli1, Giulia Manina2, Vadim Makarov3, Giovanna Riccardi1, Silvia Buroni1

1University of Pavia, Pavia, Italy, 2Institut Pasteur, Paris, France, 3Federal Research Centre “Fundamentals of Biotechnology” of the Russian Academy of Sciences, Moscow, Russian Federation

Background: Burkholderia cenocepacia is multidrug-resistance dangerous cystic fibrosis (CF) pathogen associated with heightened mortality.

The benzodiotiazol derivative C109 showed efficacy against B. cenocepacia and other CF pathogens inhibiting the GTPase and polymerization activity of FtsZ.

In order to expand our knowledge on the cell division machinery of this rare pathogen, we identified and characterized the components involved in this essential mechanism.

Materials/methods: Using molecular biology techniques, the structure and regulation of the dcw operon has been studied.

Then, taking advantage of a bacterial two hybrid system, we clarified the interaction among FtsZ and the other divisome components like FtsA, ZipA, SulA and other later proteins in vivo and in vitro through co-sedimentation, co-polymerization, biochemical assays and electron microscopy studies. Finally, using microfluidics and time-lapse microscopy, we characterized the behaviour of B. cenocepacia cells treated with C109.

Results: First, we identified the binding site of MraZ regulator upstream the dcw operon, the transcription start site and its minimal promoter of this operon in B. cenocepacia. We confirmed the interaction among FtsZ and the other components of the cell division machinery of B. cenocepacia, in vivo and in vitro.

Moreover, our results on time-lapse microscopy of B. cenocepacia cells with C109, showed how the treatment induces an elongated phenotype in a sub-population of B. cenocepacia cells that could be considered “persisters”.

On the other hand, we screened C109 derivatives against B. cenocepacia cells and FtsZ to identify more powerful molecules.

Conclusions: Our final goal is to explore the B. cenocepacia divisome machinery to identify new druggable targets suitable for antibacterial therapies effective against B. cenocepacia.

Evaluation of FT-IR spectroscopy in vancomycin-resistant enterococcal nosocomial outbreak investigation

Sarah Vandamme*1, Jasmine Coppens1, Stefanie Van Koeveringe1, Katherine Loens2, Herman Goossens3, Veerle Matheeussen1, Hilde Jansens1

1University Hospital Antwerp, Department of Microbiology, Edegem, Belgium, 2University Hospital Antwerp, National Reference Centre for Enterococci, Edegem, Belgium

Abstract 7825

Background: Early detection of nosocomial outbreaks due to multidrug-resistant pathogens is very important to reduce their spread. Limitations of existing typing methods necessitate more rapid, economical and easy-to-apply techniques, such as Fourier Transform Infrared (FT-IR) spectroscopy. We retrospectively compared the IR-Biotype® (Bruker Daltonik GmbH) to MLST and WGS for detection of vancomycin-resistant E. faecium (VREfm) nosocomial outbreaks.

Materials/methods: VREfm strains (n=106) were provided by the National Reference Centre for Enterococci, collected from 12 Belgian hospitals during 7 different outbreaks over a three-year period (2016-2019). All strains were analysed by FT-IR and MLST. For FT-IR, isolates were clustered using the average linkage algorithm and displayed as dendrograms using the IR-Biotype® software. Seventy-seven strains were sequenced using Nextera XT (2×250bp), Miseq (Illumina), followed by core genome SNP based phylogeny using ParSNP. We applied the adjusted Wallace coefficient (AW) to compare partitions and Simpson’s diversity index (SDI) to compare the discriminatory power of the different techniques.

Results: FT-IR accurately clustered 77% (82/106) and 74% (57/77) of strains within outbreaks according to MLST and WGS respectively. For each outbreak FT-IR suggested the presence of a predominant clone in agreement with epidemiological findings. Overall, 16 partitions obtained by FT-IR were compared with the corresponding 8 MLST- and 16 ParSNP-types. AW showed that FT-IR is predictive of MLST-types, but less predictive of clonality (see table). This finding might be due to genetic variation in closely related strains. The discriminatory power of FT-IR was slightly higher than that of MLST.

Conclusions: FT-IR seems a sensitive rather than a specific typing method in detecting nosocomial outbreaks, making it suitable for screening. Yet, confirmation of clonality is warranted by alternative techniques. Further research is needed to explore the role of FT-IR in optimising outbreak investigation and ensuing impact on infection control.

Abstract 7832

Complex sharing of *Klebsiella pneumoniae* carbapenemase (KPC) plasmids in patients harbouring multiple KPC-positive organisms

Amy Mathers1, Hardik Parikh1, David Eyre2, Katie Barry3, Nicole Stoesser4, Anna Sheppard4, Derrick Crook2, A. Sarah Walker2

1University of Virginia, Charlottesville, United States, 2University of Oxford, Oxford, United Kingdom

**Background:** Our understanding of inter-species dissemination of carbapenemase-encoding gene *bla*KPC, which is typically plasmid-associated, has been limited due to genomic sequencing efforts using short-read technology alone. Herein, we describe sharing of similar incompatibility-group KPC-carrying plasmids between multiple bacterial species in patients using long read sequencing.

**Materials/methods:** We evaluated all patients colonized with multiple KPC-producing organisms (KPCOs) from a single University Hospital between August 2007 and March 2017. Short-read and long-read sequencing was performed on all available isolates from patients with distinct species having *bla*KPC. Species identification and genomic relatedness were determined from short-read data alone. Bacterial genomes were assembled using Unicycler’s hybrid assembly-approach, followed by incompatibility-group assignment of circularized plasmid structures using in-silico replicon typing schema. Inter-species plasmid similarity and sharing was assessed by pairwise comparisons of their incompatibility-groups and MASH k-mer distribution distances.

**Results:** 158 longitudinal isolates from 37/507 (7%) patients colonized with two or more distinct KPCOs were sequenced and analyzed as described above. Species identification and chromosomal relatedness from genomic data showed the isolates belonged to 67 distinct bacterial clades, spread across 22 species. Of the 37 patients, two patients were colonized five distinct species, one with four, and three or two. A total of 578 circularized plasmid structures were obtained from the assemblies. As shown in the figure, five incompatibility-group plasmids – IncN, IncL/M, IncA/C2, IncX5 and a novel non-typable repA plasmid (pKPC_UVA01), were the most prevalent KPC-plasmid types across multiple species harboring the *bla*KPC gene with all other incompatibility-groups aggregated into Other group. Pairwise comparisons of longitudinal isolates showed sharing of at least one KPC-carrying plasmids between 39 distinct species pairs in 24/37 patients.

**Conclusions:** Longitudinal sampling paired with long read sequencing of from patients colonized with more than one species of KPCOs demonstrate a complex pattern of plasmid transmission and horizontal gene transfer of *bla*KPC within patients. There was little narrow host range plasmid sharing and a single non-typeable novel plasmid (pKPC_UVA01) demonstrated frequent movement and an apparent broad host range.

**Figure:** Prevalence of KPC-carrying plasmids in patients. Heatmap showing presence [red] and absence [white] of *bla*KPC harboring plasmids in patients isolates.

Abstract 7833

**Heterogeneity of antimicrobial prescribing in large paediatric tertiary centres: implications for future interventions and benchmarking of antimicrobial stewardship activities**

Mark Gilchrist*, Aneeka Chavda1, Faye Chappell1, Caroline Dalton1, Alicia Demirjian2, James Hatcher1, Hermione Lyall1, Orlagh Mcgarrity1, Joanna Peters1, Claire Watterson2, Elizabeth Whittaker1, Laura Whitney1

1Imperial College Healthcare NHS Trust, London, United Kingdom, 2Evelina London Children’s Hospital, London, United Kingdom, 3Great Ormond Street Hospital, London, United Kingdom

**Background:** Dedicated paediatric antimicrobial stewardship programmes (pAMS) within the UK are emerging and there is currently debate ongoing about which metrics should be included in pAMS. Three centres decided to compare simple AMS metrics to allow for benchmarking. Centre 1 (C1) and 2 (C2) are acute admitting tertiary centres whilst centre 3 (C3) is a non-acute quaternary specialist centre. All three centres are geographically close and have had increasing support for pAMS programmes over the last four years.

**Materials/methods:** 2019 Antimicrobial Point Prevalence Survey (PPS) results were reviewed. Prescribing quality indicators (number of patients on antibiotics including intravenous, percentage of documented indications and those prescriptions with a 48-72 hour review) together with examining the top indications and antimicrobials used in a variety of patient groups

**Results:** C1 and C2 had approximately 30% of patients on antimicrobials (C1:39/1 34, C2:67/198) compared to 56% (153/272) in C3. In C1, 89 antimicrobials were prescribed of which 66% were intravenous compared to 76% in C2 (n=99) and 65% in C3 (n=396). 100% of antimicrobials in C1 had a documented indication and 48-72 hour review. Indication documentation was lower in C2 (96%) and in C3 (85%) as was 48-72 hour review with C2 84% and C3 70%. C1 and C2 amongst neonates, sepsis was the most common indication with benzylpenicillin & gentamicin predominating. In C3 the antimicrobial spectrum was broader including amikacin, piperacillin-tazobactam and meropenem covering indications such as NEC, sepsis and central nervous system infections. Within paediatric intensive care, C1 respiratory infections predominated with piperacillin-tazobactam driving prescribing compared to co-amoxiclav in C2. C3 prescribing saw slightly more WHO reserve category antimicrobials due to the complexity of infections. Both C1 and C2 aminoglycoside of choice was gentamicin compared with amikacin in C3. Medical prophylaxis and febrile neutropenia treatment predominated within immunocompromised patients at both C1 and C3.

**Conclusions:** These relatively simple PPS results between three geographically close centres highlights the heterogenous nature of prescribing in paediatric populations of differing acuity and complexity. Local and national interventions to optimise and benchmark AMS activities need to be carefully implemented to ensure stewardship efforts are both effective and sustainable.

Abstract 7836

Evaluation of the MDR/MTB ELITe MGB assay for the detection of Mycobacterium tuberculosis complex and resistance to rifampicin and isoniazid

Vichita Ok¹, Lucas Gandy², Sabrina Goumghar², Gérald Millot², Alexandra Aubry¹,², Jérôme Robert¹,², Wladimir Sougakoff¹,²

¹Sorbonne Universités, Inserm, Centre d’Immunologie et des Maladies Infectieuses (Cimi-Paris), UMR 1135, Paris, France, ²APHP, Pitié-Salpêtrière Hospital, Laboratoire de Bactériologie-Hygiené, Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux [CNR-MyRMA], Paris, France

Abstract third-party references: On behalf of the National Reference Center for Mycobacteria [CNR-MyRMA]

Background: Antibiotic resistance being the main threat to tuberculosis control, early and accurate detection of Mycobacterium tuberculosis complex (MTB) and resistance to first-line antibiotics rifampicin and isoniazid are needed for efficient patients care. MDR/MTB ELITe MGB® Kit is a novel fully automated real-time PCR assay designed for the simultaneous detection of the DNA of MTB and of resistance to rifampicin and isoniazid. Here, we report the first evaluation of the MDR/MTB ELITe MGB® in comparison with the phenotypic and molecular tests routinely performed in our laboratory.

Materials/methods: Forty-seven clinical samples including sputa, tracheal aspirate, bronchoalveolar lavage, gastric aspiration, vertebra, lymph node, and 6 strains of MTB formerly isolated were analyzed. Detection of MTB in clinical samples was compared to microscopic observation and identification by MTB-specific PCR. Resistance typing results, which were obtained from DNA extracted from both smear positive samples and strains, were analyzed using the Genotype MTBDRplus (Hain) assay as gold standard.

Results: MTB detection from smear-positive clinical samples was observed in 34/36 tests (94%), the 2 discordant results awaiting for culture results to be interpreted. The smear negative samples (n=11) were all tested negative. Overall, MDR/MTB ELITe displayed a positive predictive value of 100% and a negative predictive value of 85%. Among the 6 strains tested, 5 grew on solid and liquid medium and 1 in liquid medium only. The 6 (100%) were detected by the new assay. Regarding resistance typing, 25/26 (96%) of the rpoB mutations, 7/7 (100%) of the inhA mutations and 22/22 (100%) of the katG mutations were detected. The only discordant result observed for rpoB was caused by a L533P mutation not detected by the MDR/MTB ELITe assay and conferring a low-level of resistance to rifampicin. There was no false-positive result.

Conclusions: With a sensitivity of 94% and a specificity of 100 % for MTB detection, and a single discordant result for resistance typing, this first assessment from clinical samples of the fully automated MDR/MTB ELITe MGB® assay looks very promising, even if further investigation with a larger set of samples is required.

Abstract 7838

**Multi locus sequence typing of Treponema pallidum subspecies pallidum in Barcelona**

Candela Fernández Naval1,2, Maider Arando1,2, Mateu Espasa1, Andres Anton1,2, Miguel Fernández-Huerta1,2, Juan Jose González-López1,2, Judit Serra Pladevall1,2, Tomás Pumarola-Suñé1,2, Martí Valls1,2, Juliana Esperalba1,2

1 Vall d’Hebron University Hospital, Barcelona, Spain, 2 Universitat Autònoma de Barcelona, Bellaterra, Spain, 3 Parc Taulí University Hospital, Sabadell, Spain

**Background:** Enhanced CDC Typing (ECDCT) has been widely used as the reference methodology for molecular characterisation of Treponema pallidum subspecies pallidum. The new Multi Locus Sequence Typing (MLST) system consists in the sequence analyses of the TP0136, TP0548 and TP0705 loci. The objective was to determine the MLST profiles of clinical samples and to compare them with the ECDCT types.

**Materials/methods:** A total of 213 samples were collected from subjects diagnosed with syphilis at the STI Unit Vall d’Hebron-Drassanes during 2015. MLST was performed by Sanger-sequencing on samples with positive PCR result. The ECDCT types (arp, tpr and TP0548 genes) and the genetic azithromycin and doxycycline resistance (mutations within 23S rRNA and 16S rRNA genes respectively) were previously determined.

**Results:** Until now, a total of 29 samples could be characterised following the MLST typing system (analyses in process). Six different sequence-types were identified, two of them have not been described (table 1). The most frequent MLST profile was 1.3.1 (72%) and all of them were genetically resistant to azithromycin but sensitive to doxycycline. A higher number of types were identified following the ECDCT typing system: 1.3.1 samples were previously classified into 6 different ECDCT types and 1.1.1 were previously classified into 2 different ECDCT types.

**Table 1. MLST profiles and ECDCT types**

*Macrolide resistance: S=sensitive, R8=A2058G mutation*

**Conclusions:** Preliminary results showed that 1.3.1 and 1.1.1 profiles are the most frequent MLST types according to literature. Moreover, the discrimination power of the ECDCT seems to be higher than of the MLST. However, the techniques used for arp and tpr determination (molecular weight and restriction fragment length polymorphism) are more subjective than Sanger-sequencing, used for TP0136, TP0548 and TP0705 characterisation.

Abstract 7840

**The association of antibiotics and *Clostridioides difficile* infections in allogeneic stem cell recipients**

Carolin Jakob*1, Maria J.G.T. Vehreschild1,2,3, Udo Holtick1, Christof Scheid1, A. Sarah Walker1,4, Nathalie Jazmati1,4, Oliver A. Cornely1,3,5, J. Janne Vehreschild1,3,6

1Department I for Internal Medicine, University Hospital of Cologne, University of Cologne, Cologne, Germany, 2Department of Internal Medicine, Infectious Diseases, Goethe University Frankfurt, Cologne, Germany, 3German Center for Infection Research (DZIF), partner site Bonn-Cologne, Cologne, Germany, 4Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Cologne, Germany, 5Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Medical Faculty, University of Cologne, Cologne, Germany, 6Department of Internal Medicine, Hematology and Oncology, Goethe University Frankfurt, Frankfurt am Main, Germany

**Background:** Oncological patients receiving allogeneic stem cell transplantation (aSCT) are at risk of contracting hospital-acquired *Clostridium difficile* infection (CDI) followed by severe diarrhea.

**Materials/methods:** We conducted a cohort analysis based on aSCT recipients treated at the Department I of Internal Medicine at the University Hospital of Cologne between 01/2016 and 12/2018. We extracted demographic, clinical, and microbiological data, as well as the antibiotic therapeutic and prophylactic medication from the Cologne Cohort of Neutropenic Patients. The 100-day CDI incidence rates from onset of conditioning chemotherapy were computed. Antibiotic usage and further covariates from onset of conditioning chemotherapy were assessed in an adjusted multivariable backward-stepwise logistic regression. Patients with signs of CDI infection before aSCT were excluded.

**Results:** We included 253 patients, of whom 23 were positive for CDI. Among these patients, the incidence rates for the 100-day CDI was 9.1 with a rate of 19.2 per 10,000 patient days. The median time from conditioning chemotherapy to CDI was 34 days (interquartile range: 15-41 days). In 15 patients, an acute graft-versus-host disease was present at onset of CDI. In 12 patients, CDI occurred during neutropenia (neutrophils <500/μL [×10^9/L]). The two most frequently administered therapeutic antibiotics were piperacillin and tazobactam (group without CDI: 147/230 [63.9%], group with CDI: 13/23 [56.5%]) and meropenem (group without CDI: 128/230 [55.7%], group with CDI: 10/23 [43.5%]). Antibiotic prophylaxis was administered in 44/230 (19.1%) and 2/23 (8.7%) of patients for the group without and with CDI, respectively. The adjusted logistic regression analysis revealed no significant association of antibiotics and CDI.

**Conclusions:** In contrast to other studies, in our analysis, we could not find an association of antibiotics and CDI. For further conclusions, a time-dependent and time-varying consideration of further covariates and risk factors in a larger and multi-centric cohort is needed.

Abstract 7844

**ComParison of patients' brain microdialysate and cerebrospinal fluid concentrations versus time profiles of cefotaxime and metronidazole as representative antibiotic substrates or not of efflux transport systems**

Alexia Chauzy*, Salim Bouchene², Nicolas Gregoire¹, William Couet¹, Olivier Mimoz¹, Sandrine Marchand¹, Claire Dahyot-Fizelier³

¹University of Poitiers, Inserm U1070, Poitiers, France, ²Certara, Paris, France, ³University hospital of Poitiers, Inserm U1070, Poitiers, France

**Background:** Cefotaxime (CTX) is used as an empirical therapy for bacterial meningitis, ventriculitis, and cerebral abscesses associated with metronidazole (MTZ) [1-2]. The aim of this study was to develop a population pharmacokinetic (PK) model to characterize and compare their PK in central nervous system (CNS), from extracellular fluid (ECF) or cerebrospinal fluid (CSF) concentrations in ICU patients.

**Materials/methods:** The trial received ethical approval. Patients received 500 mg of MTZ (n=8) or 2 g of CTX (n=10), every 8 h through a 30-min IV-infusion. Half of the patients (n=4 in the MTZ group and n=5 in the CTX group) were equipped with an external ventricular drainage system into their lateral brain ventricles, and half with microdialysis probes placed in brain tissue. Unbound antibiotic concentrations were measured in CSF or dialysates samples, as well as in concomitant plasma ultrafiltrates, by LC-MS/MS. Measured dialysate concentrations were corrected for probes recoveries. A population PK model was developed, with bidirectional transfer across the blood brain barrier (BBB) and blood cerebrospinal fluid barrier (BCSFB) characterized by clearance in (CLin) and out (CLout). Parameters values were estimated using NONMEM 7.4.

**Results:** CSF concentration-time profiles were flat compared with brain ECF concentration-time profiles, for both MTZ and CTX. The model successfully described the unbound PK profiles of both drugs in plasma, ECF and CSF. MTZ distribution was faster in ECF (CLin=303 mL/h) than in CSF (CLin=70 mL/h) but CLin equals CLout in both fluids, consistent with passive bidirectional diffusion across the BBB and the BCSFB. By comparison, CTX distribution was slower both in ECF (CLin=21 mL/h) and in CSF (CLin=1.4 mL/h). Furthermore CLout values (88 and 11 mL/h) were several fold higher (4 and 8) than corresponding CLin, consistent with efflux transport systems, and leading to limited CNS exposure (AUC_{ECF}/AUC_{Plasma} = 24% and AUC_{CSF}/AUC_{Plasma} = 13%).

**Conclusions:** Brain microdialysis and CSF sampling can be used for the assessment of antibiotics CNS distribution, but may not exhibit similar results, especially for efflux transport system substrates.

Abstract 7848

An unusual cluster of community-acquired skin infections by a multidrug-resistant MRSA harbouring genes that encode for exfoliative toxins

Daan Notermans*, Els Denie1, Welmoed Silvis2, Bent Postma3, Sabine Bantjes1; Annelot Schoffelen1, Marieke Dimmendaal4, Helma Ruijs1, Fleur Koene-Bennett5, Mariska Petrignani6, Karuna Vendrik1, Leo Schouls1, Ed J. Kuijper*1

1National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 2Slingeland Hospital and Streekzienhuis Koningin Beatrix, Winterwijk/Doetinchem, Netherlands, 3Laboratory for Medical Microbiology and Public Health (LabMicTA), Hengelo, Netherlands, 4Public Health Service of Noord- en Oost-Gelderland, Warmsveld, Netherlands, 5Public Health Service of Amsterdam & Amsterdam UMC, Amsterdam, Netherlands, 6Public Health Service of Amsterdam, Amsterdam, Netherlands

Background: The Netherlands has a low prevalence of MRSA and an active surveillance. Cultured strains from all colonised and infected patients are collected nationally and typed using multiple locus variable number of tandem repeat analysis (MLVA). Next-generation sequencing (NGS) based whole genome MLST (wgMLST) is applied on a selection of isolates.

Materials/methods: Between June and October 2019, an outbreak of skin infections with MRSA occurred. The first case discovered was a child admitted to hospital with impetigo bullosa. Contact tracing led to identification of several positive family members, some living in elsewhere in The Netherlands. In that area, an increase was observed of patients with impetigo not responding to treatment with fusidic acid. Therefore, general practitioners in the area were encouraged to submit samples for culture and to use mupirocin in case of MRSA.

Results: In total, 54 cases were identified, including 45 children. The cases focussed around two villages in the east of the country. All but one were community acquired. Resistance was found for beta-lactams, fusidic acid, erythromycin, clindamycin and co-trimoxazole, and sensitivity for mupirocin, vancomycin, rifampicin, linezolid, doxycycline and ciprofloxacin. Typing showed the isolates had MLVA-type MT4627 and were negative for PVL. This MLVA-type was found only three times before in our country. NGS of 23 isolates revealed the isolates had classical MLST-type ST121 and clustered closely together in wgMLST, including one isolate from 2018 from the same region. Two isolates from children living in another part of the country differed slightly more. These children had recently visited family in Morocco.

The strains harboured exfoliative toxin genes eta, etb and edinC. This combination was not present in any other of the 3,800 sequenced isolates in our collection. ComParison to 460 publicly available genomes showed a clear distinction of the Dutch isolates with 482 genes difference to the nearest isolate in wgMLST. After putting in place active case finding and appropriate treatment, as of October 11, 2019, no new cases occurred.

Conclusions: An outbreak with community acquired fusidic acid resistant MRSA occurred with a rare strain, harbouring exfoliative toxin genes. Most cases were children with impetigo-like skin lesions.

**Genomic epidemiology and antimicrobial resistance surveillance of gonococci in Spain**

Carlos Francés-Cuesta\(^1\)^*^2^, Judit Serra\(^3\), Alex Fabregat-Bolufer\(^4\), Beatriz Romero\(^5\), Tomás Pumarola-Suñé\(^1\), Javier Cololina Rodriguez\(^6\), Juan Carlos Galán\(^5\), Fernando Gonzalez-Candelas\(^1\)^*^2^.

\(^1\)University of Valencia, Institute for Integrative Systems Biology, I2SysBio, Paterna, Spain, \(^2\)FISABIO, Valencia, Spain, \(^3\)Vall d’Hebron University Hospital, Barcelona, Spain, \(^4\)University Public Hospital of La Ribera, Alcira, Spain, \(^5\)Hospital Ramón y Cajal, Madrid, Spain, \(^6\)University Hospital, Valencia, Spain.

**Background:** Gonorrhea is the second most common sexually-transmitted bacterial infection at global scale. Its increasing incidence along with the growing number of antimicrobial resistant (AMR) strains, has made Neisseria gonorrhoeae (NG) a major threat to Public Health. Our aim was to analyse the population structure of NG circulating in Spain and to identify the AMR determinants present in this population.

**Materials/methods:** DNAs from 342 NG isolates from three main urban areas of Spain were collected, and their whole-genome sequences were obtained with Illumina NextSeq platform. Sequence Types (STs) were inferred using SRST2. AMR determinants were detected using ARIBA. Reads were mapped against FA1090 strain and a maximum-likelihood phylogenetic tree was constructed using IQTREE. Additionally, reads were assembled de novo to verify SRST2 and ARIBA results by using the contigs and BLAST, and to find other elements such as plasmids and gonococcal genomic islands.

**Results:** 45 different STs were found, with ST 7363 and 1901 being the majority. For cephalosporins, 53.6% of isolates were phenotypically susceptible. Mutations in penA were found in resistant isolates, most of them being mosaic forms XXXIV and X. 63.1% of isolates were resistant or had reduced susceptibility to penicillin, carrying mutations in porB1b and/or ponA, or having bla TEM plasmid. Regarding azithromycin, 20.1% had some resistance, all of them with C2597T mutation in 23S rDNA. 24.9% were resistant to doxycycline, mostly by tetM plasmid than by mutations in rpsJ. 21.1% had resistance to fluoroquinolones, with mutations in both parC and gyrA.

**Conclusions:** The use of whole-genome sequences (WGS) has led to more a accurate depiction of NG population structure in Spain than MLST schemes, e.g. ST 7363 is polyphyletic in this population, this could be detected by using WGS and can be explained by recombination. NG shows a great diversity in the regions studied. The detection of AMR determinants is comparable to phenotypic analyses, improving the AMR surveillance. Spanish NG show high number of resistant isolates for penicillin, doxycycline, and fluoroquinolones. Most cases in which an AMR determinant was not detected but phenotype was resistant might be explained by inactivation of the MtrCDE efflux pump repressor.

Impact of total laboratory automation systems on efficiency, cost and clinical outcomes: a systematic review

Megan Wimmer¹, Dilip Makhija¹, Kaiwen Guo*, Devin Gary¹

¹Becton Dickinson, Sparks, United States

Abstract third-party references: BD, the BD Logo and BD Kiestra are trademarks of Becton, Dickinson and Company or its affiliates. All other trademarks are the property of their respective owners. © 2019 BD. All rights reserved.

Background: Total laboratory automation (TLA) is usually defined as the automation of the diagnostic workflow including all steps from inoculation to final result. A systematic review of the literature was conducted to evaluate the impact of TLA on clinical microbiology laboratory efficiency/productivity, quality, and to ask the question whether faster, more accurate lab results are linked to improved clinical and economic outcomes.

Materials/methods: A search string was conducted in Embase and PubMed from 1999 to present. Various study designs including randomized controlled trials, cohort studies/longitudinal studies, case-control studies, cross-sectional studies, reviews, and prospective-retrospective (pre-post) were included. Human and English publications were included, and no exclusions were made based on age, gender, race or other demographics. After data extraction, a meta-analysis was ruled out due to high data heterogeneity.

Results: After double-blind review, 31 publications were selected for inclusion into this clinical microbiology TLA-system systematic review. The relevant publications addressed at least one of the following commercial TLA platforms: BD Kiestra™, Copan WASP®. The included publications addressed multiple laboratory endpoints that included accuracy and quality, efficiency and workflow, cost savings and cost-effectiveness, or clinical outcomes. Eight publications demonstrated improvements in lab accuracy and quality. Seventeen publications discussed efficiency and workflow, fourteen of which, demonstrated improvement due to TLA. Two publications demonstrated significant cost savings due to reduced labor costs, with additional gains in quality, efficacy, reduced ergonomic injuries, and improved laboratory safety due to TLA implementation. Only one study demonstrated a statistically significant reduction in the duration of empirical therapy and 30-day crude mortality rate for patients with mono-microbial bloodstream infections; this was attributed to shorter time-to-result following processing of samples by BD Kiestra™ TLA.

Conclusions: TLA consistently created positive impact for a variety of laboratory endpoints and measurements; demonstrating the potential of TLA for improving clinical laboratory efficiency in the future. This review identifies the need for further research on TLA and effects on clinical outcomes and overall hospital costs.

Abstract 7855

The role of complement and diabetes in invasive candidiasis
Verena Harpf1, Reinhard Würzner*2

1Med. University Innsbruck, Innsbruck, Austria, 2Med. Univ. Innsbruck, Innsbruck, Austria

Background: Complement is an important link between the innate and the adaptive immunity and has several crucial functions in first line defense against non-self structures. To avoid detrimental effects, complement activity is tightly controlled by several regulators, one of which is factor H (fH). *Candida albicans* (CA) has developed mechanisms to escape complement. One of these is to bind fH on its surface via the “high affinity glucose transporter 1” (Hgt1p), whose expression is glucose-dependent. Hence, we aimed to study the effect of glucose and complement on CA pathogenesis.

Materials/methods: Immunocompetent (wt), diabetic and C3-deficient (DC3) mice were intravenously infected with CA wild-type (wt) or a mutant lacking Hgt1p (Dhgt1). Survival and clinical status were monitored over 14 days. Immunological and inflammation parameters and fungal load were analyzed at defined time points.

Results: The murine model revealed that the CA wt strain is less virulent in immunocompetent mice than the Dhgt1 strain, with a lower risk of lethal outcome and a slower pathogenesis. No significant difference in virulence was detected between diabetic and wt mice infected with Dhgt1 or between diabetic mice infected with the different *Candida* strains. In contrast, CA wt showed a significant higher virulence in diabetic and, in particular, DC3 mice, compared to wt mice. This proves that diabetes is a relevant risk factor for a worsened outcome of candidiasis and the causal association to complement. The higher fungal load in the urine as a parameter of a pronounced kidney infection and consecutive inflammation confirmed the survival data. Furthermore, the higher granulocyte numbers correlated with the virulence of the different *Candida* strains.

Conclusions: The complement system is linked to the virulence of CA in diabetic animals. This might be due to lower C3b deposition on the surface of CA. Despite this, the depletion of Hgt1p cannot be attributed to be beneficial for the survival in the murine model. An explanation might be that this depletion could lead to either an up-regulation of other fH-binding molecules or other virulence factors.

Changes in the laboratory diagnosis of CDI in Wales after the introduction of *C. difficile* toxin gene detection

Michael Perry*, Trefor Morris¹, Selina Scotford¹, Bethan Anderson¹, Sophie Jones¹, Sarah Copsey¹, Carol Davis¹, Harriet Hughes¹

¹Public Health Wales Microbiology Cardiff, United Kingdom

**Background:** UK and European guidelines recommend a 2-step algorithm for the laboratory diagnosis of *C. difficile* infection (CDI). Detection of glutamate-dehydrogenase (GDH) or toxin gene[s] are acceptable as the first screening method. During 2018 toxin gene (*toxB*) detection was introduced to all Public Health Wales laboratories whilst others continued to use GDH assays. Changes in laboratory detection rates and PCR ribotyping results between October 2014 and September 2019 are presented.

**Materials/methods:** More than 290,000 results for GDH, *toxB* PCR, toxin EIA, *C. difficile* culture and PCR ribotyping were extracted for comparison. GDH and toxin EIA testing was performed using a variety of commercial methods. Toxin B gene detection was accomplished using the Serosep EntericBio *C. difficile* PCR assay.

From December 2017, all first screen positive samples referred to the UK Anaerobe Reference Unit (UKARU) were cultured for *C. difficile* with ribotyping performed for all toxin positive samples. From January 2019, all culture positive-GDH/PCR positive samples referred to the UKARU, regardless of toxin result, were ribotyped.

**Results:** Between October 2014 and September 2019 first screen positivity declined annually using both test modalities (10%-7.9% for GDH; 5.7-5.3% for PCR) with test numbers increasing in every year except 2016-17 (43770 in 2014-15 to 50091 in 2018-19). Toxin EIA positivity showed an overall decline (30% in 2014-15 & 25%-GDH/27%-PCR in 2018-19).

Between December 2017 and September 2019 *C. difficile* culture positivity for toxin positive samples was >99% for samples tested by both GDH and PCR. For toxin EIA negative samples, it was 78% and 89% respectively. In 2019 culture positivity for toxin EIA positive samples remained >99% but decreased to 76% for GDH, and increased to 91% for PCR, from toxin EIA negative samples.

RT027 is no longer common within our CDI patients. Toxin negative/variable strains were isolated more commonly from GDH positive compared with PCR positive samples.

**Conclusions:** *C. difficile* toxin gene detection, within a 2-step algorithm, has not lead to an increase in laboratory CDI diagnosis in Wales. In fact, the added specificity of PCR as a frontline screen may be beneficial in excluding patients that harbor toxin negative/variable strains.

Phenotypic and genotypic examination of Dientamoeba fragilis and Blastocystis isolates in patients with ulcerative colitis and irritable bowel syndrome

Tugce Unalan-Altintop1, Cavansir Vahabov2, Koray Ergunay1, Ozgur Kurt3, Taylan Kav1, Yakut Akyon1, Sibel Erguven1

1Hacettepe University Faculty of Medicine Department of Medical Microbiology, Ankara, Turkey, 2Hacettepe University Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey, 3Acibadem University Faculty of Medicine, Department of Medical Microbiology, Istanbul, Turkey

Background: The aim of this study is to compare the efficacies of different diagnostic methods in the recovery of D. fragilis and Blastocystis in stool samples of patients with active and remittent ulcerative colitis (UC), and irritable bowel syndrome (IBS) and identification of their subtypes.

Materials/methods: A total of 100 patients (35 IBS, 35 active UC and 30 remittent UC) were enrolled in the study between April 2018 and March 2019. Initial diagnoses of all UC patients and IBS patients were based on Mayo Score and Rome IV Criteria, respectively. Stool samples were investigated by iodine, trichrome staining, Kinyoun acid-fast staining, bacteriological cultures and by conventional-PCR, nested-PCR with amplification of cysteine peptidase, serine peptidase and metallopeptidase genes and q-PCR. All amplicons were sequenced and interpreted according to data on GenBank.

Results: Four patients were diagnosed with D. fragilis by iodine and trichrome staining; 4 by conventional PCR; 6 with the amplification of cysteine peptidase by nested-PCR; 6 with serine peptidase; 6 with metallopeptidase; and 8 by q-PCR. Five patients were diagnosed with Blastocystis spp by iodine; 6 by trichrome staining; 9 by conventional PCR. 5 active UC, 1 remittent UC, 3 IBS patients were diagnosed with Blastocystis, 2 active UC, 2 remittent UC, 4 IBS patients were with D. fragilis. D. fragilis was most common in IBS patient group whereas Blastocystis in active UC. Most D. fragilis isolates were identified by q-PCR. All D. fragilis isolates were evaluated as Genotype 1 by sequencing; whereas all Blastocystis as Subtype 3. Examination of Kinyoun stained smears revealed no Coccidians (Cryptosporidium, Cyclospora and Cystoisospora), while the bacterial cultures were negative.

Conclusions: Our findings demonstrated that nested PCR is relatively more sensitive than conventional-PCR, compared to q-PCR which is the golden standard for D. fragilis. All D. fragilis isolates were found as Genotype 1, which is the predominant genotype worldwide. To our knowledge, this is the first study investigating D. fragilis genotypes in Turkey. Further assessments involving the assessment of gut microbiota together with these results may help unveil the interactions between the microorganisms in gut and their outcomes on human health.

Performances evaluation of the first sample-to-result system for detection and quantification of *Pneumocystis jirovecii* in respiratory tract samples

Salvatore Patanè*, Giulia Bovolenta1, Alessandro Camporese2, Rosamaria Tedeschi2, Paola Stano2, Silvia Costa1, Cinzia Bittoto1, Gulielmo Stefanuto1

1Turin, ELITechGroup SPA, Torino, Italy, 2Pordenone, Presidio Ospedaliero S. Maria degli Angeli, Pordenone, Italy

Abstract third-party references: ELITechGroup SPA

**Background:** The most common pathogenic fungi are *Candida, Aspergillus, Cryptococcus,* and *Pneumocystis spp.* — causing more than 90% of reported deaths due to fungal disease. The top ten fungal infections are responsible for at least as many deaths as tuberculosis or malaria. Traditionally considered a protozoan, *Pneumocystis* has been shown to belong to the family of fungi. It is estimated that approximately 400,000 individuals are affected by *Pneumocystis jirovecii* pneumonia (PCP) every year. In the Western world, PCP used to be the most common opportunistic infection in HIV-positive individuals. Today, the principal risk group comprises patients who are iatrogenically immunocompromised because of either malignancy, transplantation or rheumatological disease. This study describes the performance of the first quantitative Real-Time PCR assay “Pneumocystis ELITe MGB® Kit” (ELITechGroup Spa, Turin, Italy) in association with ELITe InGenius® instrument (ELITechGroup Spa, Turin, Italy), for highly sensitive *Pneumocystis jirovecii* detection and quantification, in Bronchoalveolar lavage (BAL) and Sputum.

**Materials/methods:** The clinical performance evaluation study of Pneumocystis ELITe MGB Kit on ELITe InGenius instrument was carried out by “Azienda per l’Assistenza Sanitaria n. 5 Friuli Occidentale” (Pordenone, Italy) on 102 BAL and 73 sputum retrospectively collected samples.

**Results:** Pneumocystis ELITe MGB Kit LoD, calculated on BAL samples and confirmed in BAL and Sputum samples, is equal to 97 copies/mL. Inclusivity was verified on different clinical samples and by analysis of a QCMD proficiency panel. Cross-reactivity was tested against 18 respiratory tract pathogens. The diagnostic specificity for BAL was equal to 96.6% and for sputum to 97.1%. The diagnostic sensitivity for BAL was equal to 100% and for Sputum to 84.2%. The turnaround-time was about 100 minutes.

**Conclusions:** Pneumocystis ELITe MGB Kit in association with ELITe InGenius instrument constitutes a highly sensitive and timely system for detection and quantification of *Pneumocystis jirovecii* in BAL and sputum samples. This innovative and fast solution simplifies the laboratory workflow, dramatically cut the report time and provide a valuable add on tool to clinician for correct patient management.

Abstract 7860

Fighting antimicrobial resistance with breath analysis
Emily Adams*, Emma Brodrick1, James Covington1, Nicholas Feasey1, Joe Skinner3, Matteo Radice4, Daniel Sanders5

1LSTM, LSTM, Liverpool, United Kingdom, 2Imspex, Abercynon, United Kingdom, 3University of Warwick, Coventry, United Kingdom, 4Cardiff, RedKnight Consultancy, Cardiff, United Kingdom, 5Dortmund, Gesellschaft für analytische Sensorsysteme, Dortmund, Germany

Background: Identification of bacterial respiratory tract infection (RTI) is key to alleviating antimicrobial resistance via improved antibiotic stewardship. The aim of this observational study is to discriminate adult participants with suspected upper or lower RTI with bacterial infection from those without, using breath analysis. Breath samples were tested using a gas chromatography – ion mobility spectrometry (GC-IMS) to measure volatile organic compounds (VOCs) components. Confounding factors, such as age, smoking habits and gender will be investigated to demonstrate the efficacy of results.

Materials/methods: 1229 subjects were recruited, all suspected of a RTI from 8 NHS sites across the UK. Patients were recruited from both primary (397 subjects) and secondary care (832 subjects) settings. Breath samples were analysed using a commercial GC-IMS (G.A.S. BreathSpec®, Dortmund, Germany).

Results: Initial data analysis indicates that the G.A.S. BreathSpec® GC-IMS was able to separate between diagnostic groups well. Ongoing VOC analysis indicates that certain compounds play a crucial role in distinguishing between diagnostic groups. Analysis of possible confounding factors indicate that gender, age and smoking habits have insignificant influence on breath content.

Conclusions: This observational study confirms the utility of exhaled breath analysis to distinguish between bacterial RTI and those without. This potential diagnostic power would reduce antibiotic prescribing by over 30% in a primary care setting alone. Therefore, the G.A.S. BreathSpec® GC-IMS instrument offers great potential as a non-invasive, high-throughput, diagnostic tool for RTI in a clinical setting while reducing antimicrobial resistance through improved antibiotic stewardship.

Abstract 7863

The management of Enterococcus bloodstream infections in cancer patients: impact of central venous catheters

Hesham Awadh1, Melissa Khalil1, Anne-Marie Chaftari*, Johny Fares1,2, Ying Jiang1, Rita Wilson Dib3, Shahnoor Ali1, Ray Hachem1, Issam Raad1

1 UT MD Anderson Cancer Center, Houston, United States, 2 Lankenau, Wynnewood, United States, 3 Augusta University, Augusta, United States

Background: There has been a rise in Enterococcus species Central Line-Associated Bloodstream Infections (CLABSIs) ranking as the third overall causative organism according to the Centers for Disease Control and Prevention (CDC) report issued in 2014. Central Venous Catheter (CVC) management including the need and timing of removal is not well defined for enterococcus bacteremia (EB) in the 2009 Infectious Diseases Society of America (IDSA) management guidelines given the paucity of studies addressing CVC management.

Materials/methods: We conducted a retrospective chart review on 542 patients diagnosed with EB between 2010 and 2018. We excluded patients without an indwelling CVC. We further subgrouped the remaining 397 patients into the following three groups based on the IDSA definition for catheter-related bloodstream infection (CRBSI) and the CDC definitions for CLABSI (with and without MBI) and non-CLABSI: CRBSI and CLABSI without MBI, CLABSI with MBI, and non-CLABSI. Impact of catheter removal was evaluated at different intervals; less than 3 days (early) and at 3–7 days (late). The composite primary outcome included: absence of microbiologic recurrence, 90-day infection related mortality, and 90-day infection related complications. Failure to meet any of those parameters was designated as failure.

Results: Early catheter removal within 3 days was associated with higher success rate compared to removal in 3-7 days (88 and 63 percent respectively, P = 0.08). We also noted that bacteremia with a vancomycin resistant isolate was associated with higher all-cause mortality (53 percent, P = 0.018), however multivariate analysis identified isolation of Enterococcus faecium to be associated with higher all-cause mortality (OR 2.38, 95% CI 1.54, 3.68). The use of combined antimicrobials that are potentially effective and previously studied was not associated with differences in outcome.

Conclusions: Early CVC removal within 3 days is recommended as it is associated with a better outcome compared to later CVC removal in 3-7 days. Further prospective data is needed to decide optimum CVC management. Enterococcus faecium (vancomycin resistant) is associated with a worse outcome in cancer patients.

Abstract 7865

Understanding the Corynebacterium diphtheriae population through whole genome sequencing
Natalie Groves1, Meera Chand1,2, David Litt1, Samuel Rose1, Charlotte Gower1, Alice Enefer1, Gayatri Amirthalingam1, Norman Fry2

1Public Health England, London, United Kingdom, 2Guys & St Thomas NHS Foundation Trust, London, United Kingdom

Background: The UK has high diphtheria immunisation coverage, the majority of cases being sporadic and imported. However, a small number of cryptogenic cases and clusters are raising concerns about transmission within communities with low immunisation coverage. Increasing numbers of isolates with detectable diphtheria toxin genes but which do not express the toxin have also been seen, and are of uncertain significance. We used whole genome sequencing (WGS) to investigate the Corynebacterium diphtheriae population in the UK to improve the evidence base for public health measures.

Materials/methods: Public Health England receives all UK C. diphtheriae isolates for toxigenicity testing. All toxigenic and non-toxigenic tox-gene bearing (NTTB) C. diphtheriae strains referred since 2003, and where possible a geographically and temporally similar non-toxigenic strain, were sequenced using HiSeq-2500 (150 isolates). MASH distances were calculated to construct a dendrogram of isolate assemblies (Unicycler) and complete Corynebacterium genomes (RefSeq). The tox gene and promoter were extracted and aligned to identify genetic changes likely to lead to a loss of toxin production.

Results: The dendrogram showed several clusters of highly related isolates. For two clusters, WGS demonstrated relatedness where epidemiological links had been suspected, but not previously identified. High genomic similarity suggests cases were closely linked to known transmission events, rather than reflecting more widespread undetected disease in the community. Two NTTB clones were identified and showed different loss-of-function mutations; one, the loss of the promoter region, and the other, both a single base deletion and a large deletion of the second half of the tox gene. Penicillin non-susceptibility was distributed throughout the dendrogram and, with the exception of isolates with known links, did not suggest a single resistant clone within the population.

Conclusions: WGS of C. diphtheriae can define isolate characteristics and contribute to outbreak detection and management. However, without developing a more robust phylogeny of the current global population, it is difficult to contextualise these relationships and set specific thresholds for similarity. Substantial gene disruption in NTTB clones suggests reversion to toxigenicity is highly unlikely in the UK and public health measures should be reviewed; however, genomic surveillance of NTTBs would be beneficial.

Abstract 7866

**Piperacillin-tazobactam resistance developed during febrile neutropenia**

Carolina Gomes*1, Evelyn Patricia Sanchez Espinoza1, Marina Farrel Côrtes1, Ana Paula Marchi1, Thais Guimaraes1, Flávia Rossi1, Lauro Perdigao Neto1, Vanderson Rocha1, Silvia Figueiredo Costa1

1Clinical Hospital, University of Sao Paulo, Sao Paulo, Brazil

**Background:** Emerging resistance solely to piperacillin/tazobactam (pip-taz) due to its use has surfaced with few cases documented worldwide. The main mechanism of resistance are beta-lactamases, out-membrane protein mutation and efflux pumps.

**Materials/methods:** Three patients [P1, P2 and P3] from the BMT unit developed [pip-taz] resistant *K. pneumoniae* bloodstream infections, one of them after stem cell infusion. All of the samples were submitted to routinely VITEK® antibiogram, susceptibility testing by disk diffusion (DD), broth microdilution (BMIC) with and without Carbonyl Cyanide 3-Chlorophenylhydrazone (CCCP) assay, clonality was assessed by pulsed field gel electrophoresis (PFGE). Whole genome sequence (WGS) was also performed.

**Results:** The VITEK® antibiogram showed that P1 and P3 isolates were only resistant to pip-taz and ampicillin, while P2 showed resistance to quinolones, cephalosporins, aminoglycosides and ampicillin. All isolates were resistance to pip-taz by DD whereas P2 isolate was intermediate by BMIC. None of the microdilution tiles were affected by CCCP.

PFGE analysis showed that P1 an P3 were closely related and shared 94% of similarity while P2 isolate seemed to belong to a different clone with 69% of similarity. These patients were not hospitalized at the same time, but P1 and P3 did use the same hospital room with a twenty day gap period.

WGS analysis demonstrated different resistance genes to b-lactams [Table1], only P2 showed blaTEM-1b a gene already portrayed as pip-taz resistant. Unknow mutations were found in porin genes (*ompk36* and *ompk37*) and in the efflux pump regulators genes (*acrR* and *ramR*) except for P2 that lacked *ramR* mutations. The 3D protein structure prediction showed that mutated *ramR* gene presented differences in morphology that may lead to functional alterations. No modification in penicillin binding proteins was identified.

**Conclusions:** These data indicate pip-taz resistance as an emerging problem that should be carefully investigated and surveilled. More data is needed to better understand this important new mechanism of resistance.

**Table 1. Description of the bone marrow transplant patients (P1,P2,P3) and the K. pneumoniae Phenotypic and Genotypic profile when Piperacillin-Tazobactam Resistance was evaluated.**

Abstract 7868

**Adjuvants that contain saponin may be an important component of influenza peptide vaccines to induce broadly reactive functional antibodies**

Clara J. Sei*1, Nimisha Rikhi1, Richard F. Schuman2, Kevin Muema1, Luke T. Daum3, Gerald W. Fischer1

1Longhorn Vaccines and Diagnostics, LLC, Gaithersburg, Maryland, United States, 2Antibody and Immunoassay Consultants, Rockville, Maryland, United States, 3Longhorn Vaccines and Diagnostics, LLC, San Antonio, Texas, United States

**Background:** Broadly reactive peptide vaccines that contain conserved epitopes to Hemagglutinin (HA), Neuraminidase (NA) and Matrix Ectodomain (M2e) antigens that promote functional activity against contemporary Group 1 and 2 influenza strains may provide new and useful strategies for influenza epidemic and pandemic control. The ability of different adjuvants to promote robust immune responses against influenza antigens should be assessed to improve vaccine efficacy. Here, we evaluate the interaction of three adjuvants: Saponin-derived, Squalene-based sorbitan-trioleate, and Squalene-based block copolymer, with HA, NA and M2e peptides, and report a comparative analysis of their binding profiles to influenza antigen epitopes and functional activities across Group 1 and 2 influenza viruses.

**Materials/methods:** A composite peptide (HA, NA and M2e, in combination) vaccine conjugated to CRM was administered subcutaneously to mice using Saponin-derived Quil-A®, Squalene-based AddaVax™ or Squalene-based TiterMax® Gold adjuvant. Serum antibody titers were analyzed using an anti-influenza ELISA on peptides and live influenza contemporary viruses (H3N2 and H1N1) with isotype-specific detection. Functional activity was evaluated in vitro using a micro-neutralization assay.

**Results:** The composite peptide vaccine given to mice in the Saponin-derived adjuvant group produced higher serum anti-influenza titers across HA, NA and M2e, and induced broad isotypes (IgG1, IgG2a, IgG2b) to all the peptides. However, the Squalene-based block copolymer adjuvant preferentially promoted antibody responses mainly to M2e. Binding activity of serum antibodies to live contemporary viruses (H3N2 and H1N1) was superior for the Saponin-derived group compared to the Squalene-based groups. Neutralization activity against influenza A (H3N2 and H1N1) contemporary strains was demonstrated in all groups; however, it was markedly enhanced in the Saponin-derived group.

**Conclusions:** The Saponin-derived adjuvant with composite peptide CRM-conjugate vaccine induced broadly reactive serum antibodies across surface peptides, matrix and live influenza viruses, and demonstrated a more robust humoral response across isotypes. Functional activity against contemporary influenza strains was greater for the Saponin-derived group, compared to Squalene-based groups. Antibody-Dependent Cellular Cytotoxicity (ADCC) assays are currently in progress and in vivo protection studies are being designed. Saponin-derived adjuvants may play an important role in the induction of key immune responses that are critical for immunity to influenza.

**Presenter email address:** cs@lhnvd.com
**Abstract 7872**

**Genetic context of the poxtA gene that confers resistance to linezolid in enterococci**  
Loren Dejoies*1,2, Sacha Schutz1, Asma Zouari1, Sophie Potrel1, Anais Collet1, Gabriel Auger1, Mohamed Sassi2, Vincent Cattoir1,2  

1CHU de Rennes, Rennes, France, 2Université de Rennes 1, Rennes, France

**Background:** Acquired resistance to linezolid (LZD) is rising worldwide among enterococci, especially due to the spread of resistance genes carried by mobile genetic elements (cfr, optrA and poxtA). Whereas the genetic context of cfr and optrA genes has been well studied, little is known about the most-recently reported gene poxtA. The aim of this study was then to characterize the genetic support and environment of poxtA in enterococcal clinical isolates from France.

**Materials/methods:** All enterococcal isolates suspected to be LZD-resistant enterococci (LRE) received at the National Reference Center for Enterococci from 2016 to 2018 were included. These strains were screened for the presence of cfr-like, optrA and poxtA genes by PCR and phenotypically characterized. The genome of poxtA-positive strains was sequenced using the Illumina technology (MiSeq) while a long-read sequencing approach (MinION, Oxford Nanopore Technologies) was also used for one strain (18-276). Bioinformatic analysis was performed with the CLC Genomic Workbench software (Qiagen) and a homemade pipeline.

**Results:** A total of 12 non-clonally related strains were positive for poxtA [11 Enterococcus faecium, 1 Enterococcus faecalis], including 2 strains that co-carried optrA. Note that only 3 strains were resistant to vancomycin [2 vanA and 1 vanB]. In all strains, poxtA was identified in 3-kb contig and flanked by IS1216 elements. The hybrid assembly for the genome of 18-276 (ST80) showed that poxtA was part of a 35-kb plasmid (named p18-276) that co-carried 3 other resistance genes [tet(M), tet(L), fexB]. Note that the vanA operon in 18-276 was not co-located on p18-276. The association of poxtA-tet(M)-tet(L)-fexB was also detected in 4 other strains [16-021 (ST323), 16-164 (ST650), 17-318 (ST324) and 18-204 (ST18)], suggesting the potential presence of p18-276.

**Conclusions:** The poxtA gene is emerging among LRE clinical isolates collected in France. Concerning its genetic environment, poxtA is linked to IS1216 elements that could drive its mobilization. For one strain, it is part of a plasmid that co-carries genes responsible for resistance to tetracyclines and phenicols, which is likely involved in horizontal genetic transfer of resistance gene[s]. Additional hybrid genome analyses are in progress to confirm the plasmidic support of poxtA.

Abstract 7875

Community faecal carriage of extended-spectrum beta-lactamase-producing Escherichia coli in Niger

Herve Jacquier*1,2, Anne-Laure Page1, Matthew Coldiron3, Bachir Assao4, Antoine Bridier-Nahmias1, Françoise Chau1, Bénédicte Condamine1, Erick Denamur1, Ousmane Guindo4, Magnan Mélanie1, Celine Langendorf3, Victoire De Lastours1,5

1IAME UMR 1137, INSERM and Université de Paris, Paris, France, 2Department of infectious agents, University Hospital Saint-Louis – Lariboisière – Fernand Widal, APHP, Paris, France, 3Epicentre, Paris, France, 4Epicentre, Maradi, Niger, 5Department of Internal Medicine, University Hospital Beaujon, AP-HP, Clichy, France

Background: Little is known about the epidemiology of extended-spectrum beta-lactamase-producing E. coli (ESBL-E. coli) in Sub-Saharan Africa. Here, we studied the molecular epidemiology of ESBL-E. coli in the faecal carriage of a community population in Niger.

Materials/methods: Between April 22, 2017, and May 18, 2017, 383 stools of healthy people were collected from 20 villages in the district of Madarounfa, in rural southern Niger. Stools were plated on MacConkey agar media containing 1 mg/l cefotaxime. Of 383 people, 354 (92.4%) were carriers of cefotaxime-resistant Enterobacteriales (CTX-R-E). 90 stools with CTX-R-E were randomly selected for further analysis. Colonies of different morphologies obtained on cefotaxime containing agar plates were identified by mass spectrometry (MALDI-TOF-MS). Antimicrobial susceptibility was tested by the disk diffusion method according to the EUCAST, and ESBL detection was performed using the synergy test. Genomes of ESBL-E. coli isolates were sequenced on HiSeq (2×100 bp) (Illumina, San Diego, CA) and assembled with SPAdes (v3.12.0). Resistance and virulence genes were searched using abricate (v0.7), resfinder and VFDB. Phyllogroup were determined by ClermonTyping method. PlaScope was used to discriminate the plasmidome from the genome. Genome distances were estimated using Mash.

Results: A total of 109 ESBL-E. coli were recovered from 90 stools: 72, 17 and 1 people carried a single, two or three different ESBL-E. coli, respectively. Most ESBL-E. coli isolates (91/109, 83%) belonged to phylogroup A. 41 different sequence types (ST) were identified; ST10 was most frequent (10/109, 9%). ESBL-phenotype was mostly associated with blaCTX-M-15 (107/109, 98%). blaCTX-M-15 gene was integrated into the chromosome for about one-third of isolates (32/109), in various integration sites. Phylogenetic analysis displays a high diversity of circulating clones within and between different villages.

Conclusions: CTX-M-15 producing E. coli are highly prevalent in the community in Niger and are mainly phylogroup A isolates, associated with commensalism, and have different genetic backgrounds, suggesting co-circulation of many distinct clones. Given these surprising results, enhanced monitoring in this region will be essential.

Abstract 7876

**Performance assessment of MDR/MTB ELiTé MGB Kit for tuberculosis diagnosis**

Elisabeth Hodille*1, Yvonne Benito1, Thomas Delqué1, Charlotte Genestet1, Isabelle Fredenucci1, Jean-Philippe Rasigade1, Frédéric Laurent1, Gerard Lina1, Oana Dumitrescu1

1Hospices civils de Lyon, Lyon, France

**Background:** Tuberculosis (TB) is a worldwide public health concern. Mycobacterium tuberculosis complex (MTB) culture still is the reference method for TB diagnosis, but it is time-consuming. To accelerate the TB diagnostic, guidelines from the Centers for Disease Control and Prevention recommend performing a TB NAAT (nucleic acid amplification tests) directly on specimens from patients. Here, we evaluated the performance of MDR/MTB ELiTé MGB® kit.

**Materials/methods:** Forty-nine specimens were selected retrospectively, among the left-overs of the Mycobacteria Laboratory of the University Hospital, Lyon, France. All samples were collected before anti-mycobacterial treatment and included forty-two specimens with MTB positive culture (6 pulmonary smear-positive with isoniazid (INH) and/or rifampicin (RIF) resistant MTB, 27 pulmonary smear-negative, 7 extra-pulmonary smear-negative) and 7 pulmonary samples with a non-tuberculous mycobacteria culture. Specimens were stored at -20°C before testing by MDR/MTB ELiTé MGB® kit in association with ELiTé Ingenius system and SP200 or SP1000 extraction kit.

**Results:** Interpretable results were obtained for forty-seven samples, excluding 1 MTB pulmonary smear-negative sample and 1 MTB extra-pulmonary smear-negative sample. Overall performance of MDR/MTB ELiTé MGB® kit for TB detection and for each samples category was collected in table below:

95% confident interval [-]

For TB-resistance detection performance, MDR/MTB ELiTé MGB® kit was performed on the 6 MTB pulmonary smear-positive samples including 1 strain multi-resistant-TB, 1 strain RIF-R and 4 strains INH-R. Overall sensitivity for resistance detection was 100.0%.

**Conclusions:** MDR/MTB ELiTé MGB kit display good performance for detection of TB infection and TB resistance, notably for pulmonary specimens with a very good sensitivity on pauci-bacillary smear-negative respiratory samples (80.7%), equivalent to the sensitivity of GeneXpert MTB/RIF Ultra on the kind of specimens.

Evaluation of carbapenem resistance in Enterobacteriaceae isolated from intensive care unit using phenotypic and genotypic methods

Nasheed Shaikh*1, Lizanne Drego1, Anjali Shetty1, Camilla Rodrigues1

1P. D. Hinduja National Hospital & Medical Research Centre, Mumbai, India

Abstract third-party references: National Health and Education Society, PD Hinduja Hospital & Medical Research Centre

Background: Carbapenemase-producing Enterobacteriaceae (CPE) are a global emerging threat with high transmissibility, multidrug-resistance and limited treatment options. Reliable detection is important for prevention, containment of these pathogens as well as for antimicrobial stewardship.

The aim of this study was to investigate the phenotypic and genotypic features of carbapenem-resistant Enterobacteriaceae (CRE) strains isolated from Intensive Care Unit (ICU).

Materials/methods: A total of 107 rectal swabs were collected and cultured in MacConkey broth with meropenem (1µg/ml). Identification and susceptibility testing by disk diffusion method. Carbapenem resistant was confirmed by meropenem and imipenem E-Test. Carbapenemase enzyme production was confirmed by Modified Hodge Test (MHT), Carba-NP, modified carbapenem inactivation method (mCIM) according to the Clinical and Standard Institute (CLSI) guidelines (M100-S27). In-house Real-time PCR was performed to confirm carbapenemase genes (KPC, NDM, VIM, IMP, OXA-48).

Results: Based on phenotypic results, our study depicted that out of the 107 patients screened, 71 patients were found positive for harbouring CRE mainly E.coli (n=30), K.pneumoniae (n=24), Enterobacter spps (n=13), and K.oxytoca (n=4) strains. All isolates were resistant by E-test. Carba-NP test was positive in 62 isolates whereas it was negative in 9 isolates.

Of the 71 isolates analyzed by real-time PCR, 36 isolates expressed blaNDM and 3 isolates expressed blaOXA. Twenty-nine isolates showed co-expression of blaNDM and blaOXA. One showed co-expression of blaNDM and blaVIM. One K.pneumoniae and one K.oxytoca showed co-expression of blaNDM and blaVIM.

The sensitivity of mCIM, CARBA NP and MHT were 100%, 84.5% and 74.6% respectively. mCIM showed higher sensitivity than CARBA NP & MHT. The mCIM assay perfectly correlated with the genotypic findings of the 71 isolates with 100% sensitivity and specificity for CPE detection.

Conclusions: The results of our study show high prevalence of colonization of CPE isolates. The predominant genes harboured by CPE strains were blaNDM and blaOXA. Therefore, CRE should be rapidly determined in high risk patients and strict infection control precautions should be immediately taken to prevent spread of these pathogens.

Also our results showed mCIM is a suitable and reliable method for detecting CPE than CARBA NP and MHT and is an economical alternative to molecular method.

Diagnostic challenges in Whipple’s disease: an update
Judith Kikhney1, Alexandra Wiesner1, Verena Moos2, Manuel Wolters3, Holger Rohde3, Annette Moter*1

1 Charité University Medicine Berlin Campus Benjamin Franklin, Biofilmcenter, Department for Microbiology, Infectious Diseases and Immunology, Berlin, Germany, 2 Charité University Medicine Berlin Campus Benjamin Franklin, Berlin, Germany, 3 Universitätsklinikum Eppendorf, Hamburg, Germany

Background: Whipple’s disease (WD) is a rare infection with Tropheryma whipplei that is fatal if untreated. Diagnosis is challenging, and it is based mainly on invasive sampling. We previously reported on a kidney biopsy, where we observed morphologically intact bacteria within the glomerular capsular space and tubular lumen. This lead to evaluation of polymerase chain reaction (PCR) testing of urine as a diagnostic test for WD. Here we give insights into WD using fluorescence in situ hybridization (FISH) and update on the performance of urine testing for the diagnosis of WD.

Materials/methods: In selected cases, we used FISH to localize T. whipplei directly within the patients’ tissue (duodenal biopsies, lymph node, skin, and heart valves). We prospectively investigated urine samples of 25 newly diagnosed and treated WD patients by PCR. As controls, we investigated samples from 110 healthy volunteers and patients with excluded WD or acute gastroenteritis.

Results: Out of 25 urine samples from independent, therapy-naive WD patients, 19 were positive for T. whipplei PCR. In three patients, FISH visualized T. whipplei in urine. All control samples were negative, including those of 11 healthy carriers with T. whipplei-positive stool samples. In our study, the detection of T. whipplei in the urine of untreated patients correlated in all cases with WD. In other specimens, FISH visualized T. whipplei in the intercellular spaces and showed impressive biofilms on heart valves. One case of relapse in T. whipplei endocarditis yielded a mixed infection of the heart valve prosthesis with T. whipplei and Cardiobacterium hominis pointing to insufficient therapy.

Conclusions: We showed that T. whipplei is detectable by PCR in the urine of the majority of therapy-naive WD patients. With a low prevalence but far-reaching consequences upon diagnosis, invasive sampling for WD remains mandatory, but must rely on a strong suspicion. Recent results from the Consilary Laboratory strengthen the approach of urine testing as a novel, easy-to-obtain specimen for guiding the initial diagnosis of WD, in particular in patients with extra-intestinal WD. FISH sheds light on the invasiveness and biofilm potency of T. whipplei.

Impact of early infectious diseases intervention and microbiologically led antimicrobial therapy in patients with idiopathic granulomatous mastitis

Rebecca Ryan1, Robert Lever*12, Stephen Morris-Jones13, Joanna Franks3, Victoria Rathbone4, Ula Mahadeva4, Michael Brown1

1Hospital For Tropical Diseases, London, United Kingdom, 2University College London, London, United Kingdom, 3University College Hospital, London, United Kingdom, 4Guys & St Thomas NHS Foundation Trust, London, United Kingdom

Background: Idiopathic Granulomatous Mastitis (IGM) is a poorly understood entity defined by the presence of granulomata on histology in the context of mastitis with a reported association with the presence of lipophilic Corynebacterium spp. IGM has a variable response to classical mastitis treatment and optimal management is controversial. We conducted a retrospective review of early specialist infection intervention in a group of IGM patients at our centre.

Materials/methods: We reviewed referrals to our infection service who had a presumptive diagnosis of IGM over a 3 year period. We defined IGM as the presence of at least one of: Gram positive rods on histology, granulomata identified on histology or bacteriological evidence of Corynebacterium spp. Data regarding clinical features, interventions and outcome were collected through case note review.

Results: 13 of the patients referred to our service met our inclusion criteria. The median age of patients at referral to our service was 42.02 years, all patients were female and 1 was HIV positive. The median time between review in breast clinic and review in our Infectious Diseases Service was 47.5 days.

9 patients (69.2%) underwent biopsy of which 7 (77.8%) were granulomatous on histology. 1 patient showed evidence of Gram positive bacilli on histology. Corynebacterium spp. was isolated on culture in 7 cases (53.8%), with 2 further cases identified on 16S rRNA PCR.

Operative drainage of abscess was performed in 7 patients (53.8%), with over half of these (4/7 57.1%) receiving more than one procedure [range 1-7 procedures].

Interventions by the infectious diseases team included extended and sensitivity targeted antimicrobial therapy [12/13 patients, 92.3%], and corticosteroid therapy [7/13 patients, 53.8%]. We will present details of culture results, antimicrobial strategies and steroid management.

At 6 months 11/13 (76.9%) had symptomatically resolved. We will present extended follow up data and treatment response chronologies.

Conclusions: IGM remains a challenging clinical entity to treat and we will present data which inform the management of this condition and demonstrate the impact of early specialist assessment. This will lay the foundation for the development of a multidisciplinary integrated care pathway for this condition.

Antibiotic Initiated on Infectious Disease Review

Clinical metagenomics next-generation sequencing for diagnosis of suspected clinical infections, a prospective multi-centre cohort study

Jingwen Ai*1, Haocheng Zhang2, Yi Zhang2, Jinmin Ma3, Wenhong Zhang1

1Department of Infectious Diseases, Huashan Hospital affiliated to Fudan University, Shanghai, China, 2Huashan Hospital affiliated to Fudan University, Shanghai, China, 3BGI genomics, BGI-Shenzhen, Shenzhen, China

Background: Timely and precise pathogen identification is crucial for clinical approaches to infectious diseases. Metagenomics next-generation sequencing (mNGS) is a powerful culture-independent tool for direct microbes detection, and we conducted a multi-center prospective study to set up a standard filter mNGS pipeline and evaluated its clinical diagnostic value in suspected infections.

Materials/methods: 205 clinical samples including bone marrow, plasma, BALF, sputum, CSF, and hydrothorax were used to build the standard pipeline to identify positive mNGS threshold for different pathogens. Then, we prospectively collected 2247 samples and medical data from patients with suspected respiratory, CNS, focal and bloodstream infections between August 2017 to August 2018, from 6 hospitals. Each sample was sent for culture and mNGS synchronously. After nucleic acid extraction and library construction, single-end sequencing was performed on BGISEQ platform and bioinformatics and statistical analysis were conducted.

Results: We generalized standardized mNGS-positive identification cutoff, which achieved 83.4%, 80.0%, 86.8%, 0.945 in accuracy, sensitivity, specificity, and AUC. During clinical evaluation, mNGS detected an overall 1501 pathogenic organisms [54% bacteria, 23% virus, 13% fungi, 7% mycobacteria and 3% parasites]. Top 3 identified bacterias were Klebsiella, Streptococcus, and Acinetobacter, while top 3 identified viruses were Epstein-Barr virus, Cytomegalovirus and Herpes simplex virus 1. Compared to culture, mNGS reported 79.21% in sensitivity and 94.53% of specificity. Compared to clinical diagnosis, extra detection rate of mNGS in culture-negative specimens was 94.25%, 37.60%, 28.10%, and 26.97% in respiratory, focal, CNS and bloodstream infections respectively. mNGS had a higher sensitivity in bacteria than fungi and mycobacteria (80.28% vs 61.54% and 75.00%, P<0.0001). The sensitivity of mNGS in CNS infection was statistically higher than focal and respiratory infection (89.66% vs 81.03% and 68.46%, p<0.05). The average time for mNGS to identify culturable pathogens was within 48 hours, significantly lower than 5.28 days of traditional culture, P<0.0001. Bacteria (excluding Mtb.) and fungi culture took an average of 3.56 and 4.32 days, while culture of Mtb. took 23.24 days, significantly longer than mNGS.

Conclusions: This study demonstrated that mNGS, combined with traditional laboratory methods, may provide a potentially powerful tool in the rapid diagnosis of suspected clinical infections.
Figure 1 A-C. Standardized mNGS-positive identification cutoff set up. A. The rank of mNGS pathogen sample percentage of positive validation for different types of pathogen (Bacteria, Virus, Fungi, Mycobacterium). B. The receiver operating characteristic (ROC) curve (blue line) of mNGS pathogen identified for all validated positive and negative samples. C. Pathogen identification efficiency evaluation for different type of samples. AUC: Area Under Curve. D. The diagnostic ability of mNGS and culture for different pathogens. E. The diagnostic sensitivity of mNGS in different types of pathogens among different types of samples and infections. F. Time to diagnosis by traditional culture and mNGS infections.

Why don’t hospital prescribers stop antibiotics when it would be safe to do so? Results of a discrete choice experiment

Laurence Stanley James Roope1,2,3, James Buchanan1,2,3, Elizabeth Morrell1, Koen Pouwels1,3, Katy Sivyer4, Fiona Mowbray4, Lucy Abel5, Elizabeth L.A. Cross6, Lucy Yardley4,7, Tim Peto2,8,9, A. Sarah Walker2,3,8, Martin Llewelyn*6,10, Sarah Wordsworth1,2

1 Health Economics Research Centre, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, 2NIHR Oxford Biomedical Research Centre, John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom, 3NIHR Health Protection Research Unit (HPRU) in Healthcare Associated Infections and Antimicrobial Resistance at the University of Oxford in partnership with Public Health England (PHE), Oxford, United Kingdom, 4Centre for Clinical and Community Applications of Health Psychology, University of Southampton, Southampton, United Kingdom, 5Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, United Kingdom, 6Department of Microbiology and Infection, Brighton & Sussex University Hospitals NHS Trust, Eastern Road, Brighton, United Kingdom, 7School of Psychological Science, University of Bristol, Clifton, United Kingdom, 8Nuffield Department of Medicine, University of Oxford, John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom, 9Oxford University Hospitals NHS Trust, Oxford, United Kingdom, 10Brighton and Sussex Medical School, Brighton, United Kingdom

Abstract third-party references: The study is funded by the National Institute for Health Research (NIHR) Programme Grants for Applied Research (Grant Reference Number RP-PG-0514-20015).

Background: Early antibiotic prescription review is a cornerstone of hospital antimicrobial-stewardship practice worldwide. The ability to decide whether to continue or rationalize antibiotics at the time of review is a key competency for hospital prescribers. In England this approach is set out in government guidance (“Start Smart then Focus”) but in reality <10% of hospital empiric antibiotic prescriptions are discontinued at review, despite evidence that 20-30% could be discontinued safely. We have quantified the factors that influence prescriber decision-making in this situation.

Materials/methods: We conducted an online choice experiment, a survey method for eliciting preferences for alternative healthcare options. Prescribers working in acute/general hospital medicine in England were asked whether they would continue or discontinue antibiotic-treatment in 15 hypothetical scenarios. Scenarios were described in terms of six attributes, including patient presenting symptoms and whether antibiotic discontinuation would conflict with local guidelines. Respondents’ choices were analysed using conditional fixed-effects logistic regression.

Results: 100 respondents completed the survey. Respondents were more likely to continue antibiotics when discontinuation would ‘strongly-conflict’ with local guidelines [average marginal effect (AME) on probability of continuing 0.194 (p<0.001) relative to ‘no-conflict’]; when presenting symptoms more clearly indicated antibiotics [AME of typical symptoms of urinary tract infection 0.173 (p<0.001) relative to unclear symptoms]; and when patients had severe frailty and comorbidities [AME=0.101 (p<0.001) relative to patients previously fit and well]. Respondents were less likely to continue antibiotics when there was no external pressure to continue [AME=-0.101 (p<0.001) relative to heavy pressure]. Decisions were also influenced by the competing risks of continuing treatment (e.g. antibiotic resistance) [AME of 1% higher risk -0.013 (p<0.001)] versus discontinuing (e.g. treatment failure) [AME of 1% higher risk 0.026 (p<0.001)]. Respondent feedback also highlighted that perception of treatment response influences decision making at antibiotic review.

Conclusions: Antibiotic guidelines that conflict with empiric antibiotics being discontinued at review (e.g. by pre-specifying durations) may be a major barrier to prescribers stopping antibiotics at review. Making guidelines less prescriptive about duration, but conditional on patient factors and treatment response, could help prescribers discontinue antibiotics in hospitalised patients as diagnostic information suggesting they are no longer indicated becomes available.

**Abstract 7889**

**Outbreak of cryptosporidiosis among responders to a rollover of a truck carrying calves: Normandy, France, October 2019**

Gilles Gargala*, Denis Dulieu2, Hery Tina Romy Razakandrainibe3, Denis Lemèteil4, Venceslas Villier5, Damien Costa2, Loïc Favennec4

1Rouen University Hospital, Centre National de Référence-Laboratoire Expert Cryptosporidioses, Rouen, France, 2SDIS76, Fire and rescue Center of Neufchatel en Bray, Neufchatel en Bray, France, 3Rouen University Hospital, Centre national de Référence-Laboratoire Expert Cryptosporidioses, Rouen, France, 4Rouen Universiy Hospital, Centre National de Référence-Laboratoire Expert Cryptosporidioses, Rouen, France, 5University of Rouen, Centre national de Référence-Laboratoire Expert Cryptosporidioses, Rouen, France

**Background:** In October 2019, the Fire and Rescue Center medical Officer of Neufchatel (Normandy, France) notified the French CNR-Laboratoire Expert Cryptosporidioses of one case of cryptosporidiosis among emergency responders to a tractor-trailer rollover. On 1st of October, the truck was carrying approximately 140 two week old calves that were not reportedly suffered from diarrheal disease.

**Materials/methods:** An outbreak investigation was led. A case was defined as a person with diarrhea, or at least two of the following symptoms: vomiting, nausea, abdominal pain, fever, or identification of Cryptosporidium in a stool sample; and onset of symptoms up to two weeks after the intervention. DNA was extracted from stools and PCR was performed to identify Cryptosporidium sp., C. hominis and C. parvum.

**Results:** Nine cases of cryptosporidiosis were identified among the 11 individuals who entered the trailer to evacuate calves. The median incubation period was 7 days [3-15]. Nine (100%) individuals reported diarrhea and abdominal pain, 3 (33%) reported vomiting. Four had to stop or significantly reduce work for at least one day. The median duration of illness was 2 weeks [1-3]. PCR analysis revealed presence of Cryptosporidium DNA in 8 out of 9 stools tested and sequencing of the hypervariable gp60 gene of isolates revealed the parasite responsible as C. parvum, strain Ilia15G2R1. One proved and two probable secondary cases were identified.

**Conclusions:** Disease was associated with carrying calves and contact with fecal matter. Because of the age of the calves and the conditions at the rollover scene, a high potential existed transmission of Cryptosporidium. The same C. parvum Ilia15G2R1 subtype, the most commonly genotype detected in calves in Normandy, was found in stool samples which supports a transmission of Cryptosporidium attributed solely to direct contact with animals and their feces. This is the first report in France of emergency responders contracting cryptosporidiosis. Cryptosporidiosis resulting from contact with animals during an emergency response might be minimized if 1) people are aware of potential zoonotic transmission, 2) education is provided on proper animal handling with appropriate protective equipment, and 3) thorough hand hygiene and clothing decontamination following contact with feces are practiced.

Abstract 7891

**Early cytomegalovirus reactivation and bacterial infections affect the mortality of patients after kidney transplant**

Ilaria Spalliera1, Marco Iannetta1, Novella Cesta1, Margherita De Masi1, Vincenzo Malagnino1, Carlotta Cerva1, Ludovica Ferrari1, Luca Toti2, Giuseppe Tisone1, Massimo Andreoni1, Loredana Sarmati1

1Università degli Studi di Roma Tor Vergata, Facoltà di Medicina e Chirurgia, Infectious Disease Unit, Department of System Medicine, Roma, Italy, 2Università degli Studi di Roma Tor Vergata, Facoltà di Medicina e Chirurgia, Liver Unit, Department of Experimental Surgery, Roma, Italy

**Background:** Kidney transplant (KT) recipients are prone to develop bacterial infections (BIs) and Cytomegalovirus reactivation (CMVr). Here we report a single-centre real-life experience of a cohort of KT recipients followed up after renal transplant.

**Materials/methods:** A single-centre retrospective study including patients undergoing KT between 2012 and 2016 was performed. Infectious complications [BIs and CMVr], were recorded during an observation period of 6 months after kidney replacement. Statistical analysis was performed using GraphPad Prism ver. 6.0.

**Results:** 191 (124 males, 66%) CMV seropositive KT recipients were enrolled, with a median age of 54 years (range 19-75). CMVr and BIs occurred in 92 (48.2%) and 41 (21.5%) patients, respectively, during the six-month observation period after KT. BI episodes were associated to CMVr, considering that 31/92 patients in the CMVr group compared to 10/99 in the non-CMVr group had BI (Chi-Squared test p <0.001). Considering all the BI episodes, Gram negative isolates were more frequent than Gram positive, without any statistically significant difference between CMVr and non-CMVr groups (25 vs 6, and 9 vs 1, respectively).

Overall mortality was assessed and associated to CMVr and BIs. Globally, patients with BIs showed an increased mortality compared to patients who did not experience BIs (7/41 vs 6/150, respectively; Chi-Squared test p= 0.003). After stratifying patients in CMVr and non-CMVr, BIs were associated to increased mortality in the CMVr group only (6/31 vs 3/61, respectively; Chi2 test p= 0.028), while no differences in mortality were found in the non-CMVr group after comparing patients with and without BIs.

**Conclusions:** In our cohort of KT recipients CMVr was associated to bacterial infections. The occurrence of both infectious complications in the six months after kidney replacement seems to increase the overall mortality. Larger studies addressing the interactions between bacterial infections and CMVr should be performed in KT recipients, in order to understand the causal and temporal relationship of these two infectious complications.

Abstract 7893

**Studying the association of the human vaginal microbiome with HPV infection using enriched metagenomic sequencing**

Ardashel Latsuzbaia*, Anke Wienecke-Baldacchino¹, Malte Herold¹, Irma Karabegovic¹, Jessica Tapp¹, Marc Fischer¹, Friedrich Mühlschlegel¹, Joël Mossong¹

¹National health Laboratory, Dudelange, Luxembourg

**Background:** We investigated the association of the vaginal microbiome with human papillomavirus (HPV) infection in young women participating in a HPV vaccine monitoring study using metagenomic sequencing enriched for HPV.

**Materials/methods:** Cervical samples were analysed from seven hundred twenty-nine women (mean age 22.4 y) participating in a HPV vaccine monitoring program who also filled in a questionnaire. DNA extracts from ThinPrep underwent rolling circle amplification (RCA) to amplify circular DNA aiming for HPV and sequenced on Illumina MiniSeq. Quality checked reads were filtered by mapping to the human reference genome. Samples were considered positive for an HPV genotype if concordantly mapping paired reads covered at least 100bp of a HPV reference genome. Taxonomic assignment was performed by mapping remaining reads via Bowtie2 against an in-house compilation of bacterial NCBI reference of complete genome sequences. For each sample, bacterial genera were reported if at least 10 reads were assigned to the respective reference genomes. Samples with >1000 bacterial reads were considered for further analysis (N=591). Alpha diversity was calculated using the Shannon diversity index. Beta diversity was calculated by computing pairwise Bray-Curtis distances between samples. Inter-sample distances in beta diversity were linked to metadata-derived groups using PERMANOVA.

**Results:** Overall, 72.1% reads mapped to human, 3.8% to bacteria, 1.1% to HPV and 0.005% to fungi. A substantial proportion 332/729 (45.5%) were HPV positive. Cluster analysis identified two main bacterial community clusters, Lactobacillus and Gardnerella genera dominant in 67% and 30% of the samples, respectively (Fig 1). Difference in beta diversity is associated with nationality (Luxembourgish, Portuguese and other migrants), but not by HPV status, abnormal cytology, condom use, smoking status, age and sexual behaviour. The alpha diversity was significantly higher for participants of non-Luxembourgish nationality and smokers.

**Conclusions:** Our results suggest that RCA enriched metagenomic sequencing has the potential to characterize both the bacterial cervical microbiome and HPV, but not fungi. As the RCA enrichment may introduce some bias, further investigation is required to compare this approach with both targeted 16S sequencing and direct shotgun sequencing.

Nasal microbiota: is it the war between staphylococci and corynebacteria?

Josselin Rigaill¹, Anaïs Barray²*, Marie Gavid¹, Yann Lelonge¹, Frédéric Laurent², Philippe Berthelot¹, Jean-Philippe Rasigade², Paul Verhoeven¹

¹Saint-Étienne, France, ²Lyon, France

Abstract third-party references: This research was promoted and has been funded by the University Hospital of St-Etienne.

Background: *Staphylococcus aureus* (SA) nasal carriage is a well-recognized risk factor of infection with this bacterium. Nasal decolonization procedures help in reducing this risk, with the risk of emergence of antibiotic resistant strains. We aimed to characterize the microbial communities associated with SA carriage at 3 nasal sites, in order to uncover antagonistic interactions between SA and other bacteria of the nasal flora that might be used to prevent or eliminate SA colonization.

Materials/methods: 15 SA carriers and 15 matched non-carriers, were sampled at 3 nasal sites (vestibule, spheno-ethmoidal recess, nasopharynx) by an otolaryngologist specialist. 16S rDNA V3 PCR and Ion Torrent PGM sequencing were performed. Reads were filtered with BBduk and VSEARCH, then BLASTn aligned to the NCBI 16S database with 16S-copy number normalization. Species-level resolution of taxonomies was refined using an in-house algorithm. Alpha- and beta-diversities were compared across sites and depending on the presence of SA. Indicator species were characterized using Linear discriminant analysis Effect Size (LEfSe).

Results:

Comparison between sites: Alpha- and beta-diversity indices were similar across the 3 nasal sampled sites, with the exception of a higher Shannon index-based diversity in vestibule samples\((p<0.05,\) Mann-Whitney test). LEfSe analysis showed an increase of *Propionibacteriaceae* in the vestibule and the recess, while *Streptococcaceae* and *Prevotellaceae* were mostly found in the nasopharynx.

Comparison depending on SA carriage: Shannon and Simpson alpha-diversity measurements showed a significant increase in diversity in SA carriers compared to non-carriers after exclusion of SA reads, but not by keeping SA reads. These results suggest that SA is a major factor in the stability of the community. Beta-diversity PCoA profiling suggests that both carrier groups differ significantly with and without SA. Based on LEFSE analyses, several *Corynebacterium* species were discriminant in non-carriers while non-*aureus* staphylococci were associated to SA carriage.

Conclusions: This study brings new insights into the microbial communities colonizing various nasal sites. Results point towards a war between staphylococci and corynebacteria when SA is involved, suggesting antagonistic relationships. The role of corynebacteria as SA competitors should be further examined to determine if corynebacteria nasal inoculation can prevent or displace SA colonization.

Abstract 7897

The growth dynamics of *Pseudomonas aeruginosa* isolated from peritoneal fluid, blood and homogenates of the organs of septic mice

Mariya Cherkasova*1, Vladimir Zhukhovitsky1, Tat`yana Borovaya1

1N. F. Gamaleya National Research Center of Epidemiology and Microbiology, Ministry of Health of the Russian Federation, Laboratory of Indication and Ultrastructural Analysis of Microorganisms, Moscow, Russian Federation

Abstract third-party references: N. F. Gamaleya National Research Center of Epidemiology and Microbiology, Ministry of Health of the Russian Federation, Moscow, Russia.

Background: To detail the patterns of development of sepsis, taking into account the increased etiopathogenetic role of *P. aeruginosa*, it is important to study the dynamics of the spread of the pathogen in the body.

Materials/methods: For sepsis modeling, we used strain *P. aeruginosa* 1623 isolated from bronchial flushing of a patient under cystic fibrosis and cultivated on Columbia agar. 42 male C57Bl/6 mice were administered intraperitoneally at a dose of $7 \times 10^6$; 3 control animals were injected with saline. Infected animals were opened 15, 30, 60, 120, 180, 240, and 480 min after infection. Samples weighted, homogenates in porcelain mortars, cultured on Columbia agar, calculated of CFU and logarithmized. Throughout the experiments, the animals were processed according to the ethical guidelines for the care of laboratory animals.

Results: 15 minutes after infection, seeding of *P. aeruginosa* 1623 from peritoneal fluid was $1.34 \times 10^5$ CFU / ml (lg5.13); while CFU from the blood increased from 0 to $2.01 \times 10^4$ CFU (lg4.3). By 15-30 min, the level of seeding of the pathogen from the peritoneal fluid was maintained and a slight increase in seeding from the blood was recorded. Seeding from liver homogenates sharply increased - $2.85 \times 10^6$ CFU (lg6.45); from kidneys - $2.04 \times 10^6$ CFU (lg6.31); from lungs - $4.24 \times 10^5$ CFU (lg5.63); from spleen - $8.3 \times 10^5$ CFU (lg5.92). From 60 to 120 minutes, pathogen seeding rates from organs decreased slightly, although it remained at a sufficient level. By 240 min, the number of CFU from liver, spleen and kidney decreased, and remained almost unchanged in the lungs. A new rise in the CFU of the pathogen from the blood and a small increase in CFU from the peritoneal fluid were recorded.

Conclusions: Analysis of the growth of *P. aeruginosa* 1623 during the first 480 minutes of the development of sepsis was revealed a chronological vector of the spread of the pathogen in the body and of its potential reproduction in the studied organs.

Activity of imipenem-relebactam against Enterobacterales and Pseudomonas aeruginosa isolates collected in Latin America and Brazil from 2017-2018: results from the Study for Monitoring Antimicrobial Resistance Trends [SMART]

Elisa Maria Beirao*1, Felipe Tuon2, Suellen Rodrigues1, Tarik Klain De Andrade1, Fernando Serra1, Marina Della Negra De Paula1, Thales Jose Bueno Polis1, Ana Gales4

1Hospital Mandaqui, Sao Paulo, Brazil, 2PUC, Curitiba, Brazil, 3MSD - Merck Sharp & Dohme Pharmaceuticals, Sao Paulo, Brazil, 4Unifesp-SP, Sao Paulo, Brazil

Background: In Latin America, especially Brazil, Gram-negative bacterial (GNB) infections are increasingly difficult to treat due to antimicrobial resistance. imipenem-relebactam (IMI/REL) is a β-lactam/β-lactamase inhibitor combination with activity against carbapenem-resistant Enterobacterales. The Study for Monitoring Antimicrobial Resistance Trends [SMART] evaluates the in vitro activity of various Gram-negative antimicrobial agents since 2002 and includes IMI/REL since 2015. We compared the activity of IMI/REL against clinical isolates, focusing on Enterobacterales and Pseudomonas aeruginosa, collected in LATAM from 2017-2018.

Materials/methods: 13,843 Gram-negative bacterial isolates including Acinetobacter baumannii, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa and other Enterobacterales from 36 sites in LATAM (08 Brazilian) were collected in the period. Samples were consecutive and non-duplicated; each site collected up to the indicated number of isolates in 2017/2018 from lower respiratory tract infections (RTI), complicated urinary infections (cUTI), complicated intra-abdominal infections (cIAI) and blood. Minimum inhibitory concentrations were determined by broth microdilution for several antibiotics including ceftolozane-tazobactam, colistin, imipenem-relebactam and meropenem. Antimicrobial susceptibility results were interpreted by CLSI criteria and molecular resistance mechanisms were also evaluated.

Results: 46% of isolates came from RTI and blood. Among Brazilian centers, E. coli (N=537), K. pneumoniae (N=423), P. aeruginosa (N=353), P. mirabilis (N=110), S. marscenses (N=107) and A. baumannii (N=101) were the 6 most prevalent pathogens isolated. Susceptibility to imipenem-relebactam ranged from 41.8% to 100%. Susceptibility of K. pneumoniae to imipenem-relebactam was 96.9% (MIC50/90 0.25/1 µg/mL). For E. coli, imipenem-relebactam inhibited 100% (MIC50/90 0.12/0.25 µg/mL) of the microorganisms. The susceptibility to IMI-REL of P. aeruginosa, P. mirabilis, S. marscenses and A. baumannii was 87.3% (MIC50/90 0.5/4 µg/mL); 41.8% (MIC50/90 2/4 µg/mL); 72.8% (MIC50/90 1/2 µg/mL); and 14.9% (MIC50/90 >32/>32 µg/mL), respectively. An analysis was performed to describe the profile of resistant mechanisms in 432 isolates. From which KPC-producing K. pneumoniae were 67% from 209 analyzed isolates. The majority of IMI/REL-non susceptible isolates were ENT class B (metallo beta-lactamase) and class D (OXA-48 like) producers.

Conclusions: Imipenem-relebactam has shown relevant activity against a variety of the analyzed microorganisms, especially KPC-producing K. pneumoniae, collected from multiple LATAM centers, showing it is an option for addressing infections caused by MDR strains.

Genetic relatedness, antimicrobial resistance, virulence and biofilm-forming abilities of Klebsiella pneumoniae from healthy broilers and turkeys

Fiona Franklin*1, Marit Andrea Klokkhammer Hetland2, Ragna-Johanne Bakksjø2, Live Nesse1, Iren Høyland Löhr2, Amar Telke1, Marianne Sunde1

1Norwegian Veterinary Institute, Oslo, Norway, 2Stavanger University Hospital, Stavanger, Norway

Background: Klebsiella pneumoniae (Kp) belongs to the ESKAPE pathogens, which are important causes of nosocomial infections. Kp is a well-studied human pathogen and antimicrobial resistant high-risk clones and hypervirulent clones have emerged globally. Kp is also present in a variety of environmental niches, but currently there is a lack of knowledge on the occurrence and characteristics of Kp from non-human sources. Certain environments may be associated with high Kp abundance and Kp in these niches may constitute a reservoir for further transmission of strains and genetic elements. The aim of this study was to explore and characterize Kp from healthy broilers and turkeys.

Materials/methods: A total of 565 faecal samples [broiler n=404, turkey n= 161], included in the Norwegian monitoring program on antimicrobial resistance in the veterinary sector [NORM-VET] in 2018, were screened for Kp by culturing on SCAI agar. Susceptibility testing was performed using disc diffusion (EUCAST) and the isolates ability to produce biofilm was investigated in a crystal violet microtiter plate assay. All Kp isolates (n=203) were whole genome sequenced and genomes were analysed using bioinformatic tools.

Results: A total of 203 (36%) samples were Kp positive; 70% of the samples from turkey and 24% of the samples from broiler. The overall antimicrobial resistance occurrence was low, with 23 (11%) isolates [17 turkey, 6 broiler] showing resistance, mainly against tetracycline and sulfamethoxazole. The 203 isolates grouped into 64 different sequence types (STs), with ST35 identified in 14% and ST290-LV in 7% [figure]. Forty-three different capsule types were identified. Plasmid (IncFII) mediated virulence genes iuc5 and iro5 encoding siderophores were identified in 15 clonal ST290-LV from turkey. Chromosomally encoded yersiniabactin (ybt) was found in 13 of the ST290-LV isolates. Isolates from both poultry species displayed good biofilm forming abilities with an average of OD595 0.69 and 0.64.

Conclusions: Detection of Kp was significantly higher in samples from turkey, than broilers. The overall antimicrobial resistance occurrence among Kp from Norwegian poultry was low. Plasmid-located and chromosomal virulence genes encoding siderophores were detected in some isolates. High genetic diversity was found with some STs overlapping with STs commonly described from humans.

Abstract 7900

**blaCTX-M-55/mcr-1/IncHI2 plasmids in Escherichia coli from foodstuffs in Tunisia**

Raoudha Grami1, Wejdene Mansour2, Chatre Pierre3, Melody Dazas4, Amel Bouazizi4, Olfa Bouallègue1, Ridha Mzoughi4,5, Marisa Haenni*3, Jean-Yves Madec3

1University Hospital Sahoul Sousse, UR12SP37 Department of Microbiology, Sousse, Tunisia, 2University of Sousse, Laboratory of Metabolic Biophysics and Applied Pharmacology (LR12ES02), Department of Biophysics, Faculty of Medicine Ibn El Jazzar Sousse, Sousse, Tunisia, 3University of Lyon Claude Bernard, Anses, Lyon, France, 4Regional Public Health Laboratory of Sousse, Sousse, Tunisia, 5University of Monastir, Laboratory for analysis, treatment and recovery of environmental pollutants and products LR01ES16 Faculty of Pharmacy, Monastir, Tunisia

**Background:** Antimicrobial resistance (AMR) in bacteria represents one of the most important challenges for public health worldwide. As such, plasmid spread of resistances to broad-spectrum cephalosporins and colistin in foodborne zoonotic Gram-negative bacteria of animal origin is of concern. The objective of this study was to characterize mcr-1/ESBL plasmids in Enterobacterales recovered from foodstuffs in Tunisia.

**Materials/methods:** From March to June 2017, 148 cefotaxime-resistant Gram-negative bacteria were isolated on selective medium from 100 food samples (raw milk, chicken meat, beef minced meat and merguez). Antimicrobial susceptibility was performed by disc diffusion and the mcr-1 gene was specifically searched by PCR and sequencing within this collection. Plasmids were characterized by rep-typing (Diatheva) and Southern blot on S1-PFGE gels. Clonality was assessed by XbaI-PFGE and phylogrouping.

**Results:** The collection comprised 80 Escherichia coli, 20 Klebsiella pneumoniae and 16 Enterobacter cloacae cefotaxime-resistant isolates. The mcr-1 gene were detected in 9 E. coli isolates (11.3%) from chicken meat, merguez or minced meat, together with blaCTX-M-1 (5 isolates) and blaCTX-M-55 (4 isolates) and among diverse E. coli genetic backgrounds. Notably, mcr-1 was co-harbored with blaCTX-M-55 on IncHI2 plasmids. All mcr-1-positive E. coli isolates were multdrug resistant, exhibiting resistances to common antimicrobials such as tetracyclines, florfenicol, sulfonamides or fluoroquinolones.

**Conclusions:** It is the first report of mcr-1-positive E. coli in meat at retail in Tunisia. More importantly, the co-occurrence of mcr-1 and blaCTX-M-55 on IncHI2 plasmids in meat is reminiscent of previous data obtained in our country where mcr-1/bluCTX-M genes were also identified on IncHI2 plasmids in livestock. Work is in progress to further characterize those plasmids using advanced NGS technologies. Those data highlight the wide spread of mcr-1 in the food chain in Tunisia, most likely through dominant ESBL plasmids, which is of major importance for public health.

Abstract 7902

**Exploring posaconazole pharmacodynamics against Candida krusei isolates: determination of EUCAST PK/PD susceptibility breakpoints**

Maria-Ioanna Beredaki*1, Maiken C. Arendrup2,3,4, Spyros Pournaras1, Joseph Meletiadis1,5

1Clinical Microbiology Laboratory, Attikon University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 2Statens Serum Institut, Unit of Mycology, Statens Serum Institut, Copenhagen, Denmark, 3Department of Clinical Microbiology, Rigshospitalet, Copenhagen, Denmark, 4Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, 5Dept Medical Microbiology and Infectious Diseases, Erasmus MC, Rotterdam, Netherlands

**Background:** Posaconazole has some activity against the intrinsically fluconazole resistant species C. krusei, however, paucity of clinical data prohibit establishment of clinical breakpoints. We assessed the pharmacodynamics of posaconazole in an in vitro pharmacokinetic/pharmacodynamic (PK/PD) dilution model and determined EUCAST PK/PD susceptibility breakpoints for the available posaconazole formulations.

**Materials/methods:** Three clinical C. krusei isolates (EUCAST posaconazole MICs 0.03, 0.06 and 0.25 mg/L) were tested in a one compartment in vitro PK/PD dilution model using a 10⁴ CFU/mL initial inoculum. Steady state posaconazole serum concentration-time profile of 400 mg b.i.d. was simulated for 48h with fCmax 0.15, 0.85, 2.25 and 5 mg/L and with t1/2=36 h. The 48h log₁₀ CFU/mL - fAUC₀-2⁴/MIC relationship was analyzed with the Emax model and the exposure associated with 50% of maximal activity (EI₅₀) was determined. The probability of attaining the EI₅₀ was calculated with Monte Carlo analysis for isolates with EUCAST MICs 0.015-4 mg/L in patients treated with 400 mg oral posaconazole b.i.d. (Ullmann et al, AAC 2006) or 300 mg tablet/i.v. posaconazole o.d. (Duarte et al, AAC 2014, Maertens et al, AAC 2014) attaining tAUC₀-2⁴ of 17.15±14.71 and 34.17±14.68 mg.h/mL, respectively, adjusted for fAUC based on the 99% protein binding

**Results:** Posaconazole reduced >1 log₁₀ the fungal burden of isolates with MIC 0.03 and 0.06 mg/L at fCmaxs ≥0.85 mg/L whereas the same effect was observed for the isolate with MIC 0.25 mg/L only at fCmax 5 mg/L. The in vitro PK/PD relationship followed a sigmoid curve (R²=0.96) with a mean (95% CI) EI₅₀ of 31 (18-52) fAUC/MIC. Monte Carlo showed that the PTA for C. krusei isolates with MICs ≤0.125, 0.25, 0.5, 1 and ≥2 mg/L were 96%, 76%, 46%, 13% and <2% for the oral formulation and 100%, 100%, 96%, 51%, and <4% for the tablet/i.v formulation, respectively.

**Conclusions:** The PK/PD susceptibility breakpoints 0.125 and 0.5 mg/L was determined for the oral and tablet/i.v. formulations of posaconazole, respectively. Given the corresponding EUCAST epidemiological cutoff value [ECOFF 0.5 mg/L], posaconazole tablet/i.v. may be used for the treatment of C. krusei infections provided that adequate exposure is attained.

Abstract 7904

**Mycoplasma genitalium: evaluation of macrolide resistance in a very large setting of sexually-transmitted infections**

Alice Nava¹, Elisa Matarazzo², Luna Colagrossi*, Perno Carlo Federico¹,², Diana Fanti¹

¹S.C Analisi Chimico Cliniche e Microbiologia, ASST GOM Niguarda, Milan, Italy, ²Università degli Studi di Milano, Università degli Studi di Milano, Milan, Italy

**Background:** *Mycoplasma genitalium* (MG) is a slowly growing microorganism causing inflammation of the urogenital tract. Azithromycin is the most used antibiotic, nevertheless a recently increased number of treatment failure was observed. Macrolide resistance is associated to single nucleotide mutation on gene 23S rRNA. The aim of this project was a retrospective evaluation of macrolide resistance on positive samples for *M. genitalium* on our population.

**Materials/methods:** From 15th March 2018 to 15th November 2019, samples positive for MG were assessed with Anyplex II STI™ (Seegene). Results were confirmed with STI PLUS ELItE MGB® kit and with Macrolide-R/MG ELItE MGB® kit (detection of A2058C, A2058G, A2058T, A2059G, A2059C mutations) on ELItE InGenius platform (ELITechGroup S.p.A.).

**Results:** 4100 samples were analysed for sexual transmitted infections: 2940 were negative, whereas 1160 were positive for at least one pathogen. The most commonly isolated microorganisms was *U. parvum* in 17.1% (701) samples, followed by *U. urealyticum* 7.98% (327), *M. hominis* 4.9% (201), *C. trachomatis* 1.9% (78), *N. gonorrhoeae* 1.05% (43), *M. genitalium* 0.95% (39), and *T. vaginalis* 0.93% (38). The 39 positive samples for MG were urine 56.4% (22), anal swab 20.5% (8), uretral swab 7.7% (3), cervical swab 10.3% (4), vaginal swab 2.6% (1) and one fetal placenta 2.6%, belonging to 34 patients: 70.6% (24) were males, 23.5% (8) were females and 5.9% (2) were transgender. Among them, 55.9% (19) declared at risk sexual intercourses; 35.3% (12) were symptomatic, 5.9% (2) were controlled for sterility problems and 2.9% (1) had a corioamnionitis. Regarding the sensitivity to macrolide, 52.9% of strains (18) were sensitive, while 47.1% (16) were resistant. Among the latter, 43.7% (7) belonged to symptomatic patients; 56.3% (9) had at risk sexual intercourses.

**Conclusions:** *M. genitalium* shows a low prevalence (0.95%), among patients tested for sexually transmitted infections, but remarkably high level of macrolide resistance (47.1%). Since azithromycin is the first choice of empirical treatment in Italy also for *C. trachomatis*, the spreading of MG strains resistant to macrolides may further increase in the following years. Hence, multicenter studies aimed at the national evaluation of resistance of MG to macrolides is warranted.

**Presenter email address:** luna.colagrossi@unimi.it
Changes in epidemiology, treatment and outcomes of candidaemia at a tertiary care children’s hospital

Antonio Arrieta*1, Negar Ashouri1, Delma Nieves1, Stephanie Osborne2

1CHOC Children’s Hospital, University of California, Irvine School of Medicine, Orange, United States, 2CHOC Children’s Hospital, Research Institute, Orange, United States

Background: Candidemia, a serious infection in hospitalized children, is associated with significant morbidity and mortality. Highest incidence is reported in premature neonates (premie). *C. albicans*, consistently sensitive to fluconazole, has been the most common species. Infection prevention measures to reduce central line infections (CLABSI) were implemented widely. Resulting epidemiologic changes may impact prevention and treatment.

Results: 195 (133 and 62) subjects had 233 (154 and 79) candidaemia episodes (periods 1 and 2 respectively); overall rate per 1000 discharges decreased between periods (-52.5%; 1.98 to 0.94); rate decrease was larger in premie (-61.5%) than oncology (-37.5%). Comparing period 1 with period 2 respectively; intestinal failure (IF) occurred in 28.6% and 69.4% of subjects; *C. albicans* (37.7% to 28.1%) and *C. parapsilosis* (33.1% to 28.1%) decreased while *C. glabrata* (11.7% to 12.2%) and *C. krusei* (3.3% to 6.1%) increased; fluconazole MIC (mcg/ml) 50 and 90 (1 and 16 in each period) remained constant while % sensitive (MIC < 4) decreased (84% to 76.8%) and mortality increased (19.5% to 25.8%). End organ involvement was identified in 32 (19.2%) of 167 events with metastatic evaluation. Micafungin (98), fluconazole (62) or the combination (41) were most common antifungal agents used for initial treatment. Temporary renal and liver toxicity was common. (table)

</table>

Median [1 – 3 quartile]. Comparison sum rank by Mann-Whitney
* Not enough had final creatinine measured.

Conclusions: CLABSI reducing measures substantially decreased candidemia incidence, particularly in premie, yet candidemia associated mortality increased. IF emerged as a common comorbidity in these patients. Non-albicans Candida species increased, particularly fluconazole resistant ones; > 25% have elevated MIC or are fully fluconazole resistant impacting future treatment options. Fluconazole and micafungin are well tolerated. Evaluation for end organ involvement is important.

Development of bovine herpesvirus 4-based vaccines as an antibiotic-free strategy to control bacterial infection in livestock

Hester Nichols*1, Michael Jarvis2, Aisling Murphy2, Thekla Mauch2, Summer Henderson1, Yvonne Wezel1

1University of Plymouth, The Vaccine Group, Plymouth, United Kingdom, 2University of Plymouth, Plymouth, United Kingdom

Abstract third-party references: Dr Michael Jarvis, The Vaccine Group, Plymouth

Background: Bovine herpesvirus 4 (BoHV-4) is a benign gamma-herpesvirus common across multiple ruminant species that is being developed as a vaccine vector platform. BoHV-4 has been shown to induce high levels of durable antibody and T cell immunity against encoded heterologous pathogen target antigens, in many cases, following only a single dose. Unlike many other vaccine platforms, DNA encoding multiple target antigens can also be inserted into a single BoHV-4 vector and prior immunity does not prevent reuse. Deletion of ORF73, a gene required for persistence of BoHV-4 in the host, provides an additional level of safety without impacting immunogenicity. Herpesvirus-based vaccines are also inexpensive to produce, with a related commercial vaccine (Bovilis IBR) being marketed at £3/dose wholesale. For many bacterial diseases in livestock there are either no vaccines available or they induce suboptimal protection and require multiple rounds of vaccination.

Materials/methods: Our strategy is to use the BoHV-4 vaccine vector platform to reduce the occurrence of antimicrobial resistance (AMR) by stimulating the host immune system against these difficult to control bacterial infections, thereby decreasing the need for antibiotics. Target pathogens include Streptococcus suis, bovine tuberculosis (bTB) and mastitis caused by E. coli, all of which are high priority vaccine targets. It will also be possible to develop vectors targeting currently unknown bacterial diseases through this pipeline as they emerge.

Results: BoHV-4 prototype vectors expressing target antigens from these three bacterial pathogens were constructed. Following complete in vitro characterization, these vectors were tested in a rabbit model, and shown to induce antibody responses against the targeted pathogen. In future work, we will determine the impact of this immunity on replication and viability of the bacteria in vivo.

Conclusions: We propose that BoHV-4 based vaccines targeting these key livestock bacterial pathogens will provide an additional means by which antibiotic usage can be reduced in these agricultural animals to decrease the incidence of antimicrobial resistance and prevent spread of antibiotic resistant strains into the human population.

Background: Meningitis and related invasive bacterial diseases (IBD) are life-threatening infections with severe morbidity and mortality. Recently, several outbreaks of meningococcal meningitis were reported from different countries and Italy too. Procalcitonin (PCT) is a marker of systemic bacterial infection. Thomas-Ruddel et al (Critical Care, 20018) described the possibility that PCT levels could be associated to specific pathogens and foci of infection. The aim of the present study is to evaluate this possible association in patients with meningitis and IBD.

Materials/methods: All patients with meningitis or IBD due to S. pneumoniae (SP), N. meningitidis (NM) and L. monocytogens (LM) previously enrolled in the MeningItaly study were considered. The MeningItaly study is a prospective observational multicentric study on epidemiology, clinical, laboratory and microbiologic characteristics and therapeutical approaches in patients with meningitis and/or IBD; it involved 11 centres in Italy.

Results: We enrolled 151 patients; 128 patients had an infection due to SP, NM or LM. Table 1 report on the main characteristic of the study population. In particular, NM is associated with higher PCT levels (mean 35 for NM, vs 9.25 for SP and 4.25 for LM), less comorbidity – described as Charlson comorbidity index – and younger patients.

Conclusions: PCT serum concentration is significantly higher in patients with NM meningitis invasive infections than in patients with SP or LM infections. This finding could be useful to quickly hypothesize NM etiology and, as a consequence, to start appropriate therapies and public hygiene measures.

Usefulness of flow cytometry as a screening technique in the detection of bacterial vaginosis and vaginitis

Juan Manuel Peñate*, Inmaculada Guerrero Lozano1, Salud Rodríguez-Pallarés1, Fatima Galán-Sanchez1, Manuel Rodríguez-Iglesias1

1Puerta del Mar Univ Hosp, Cadiz, Spain

Background: Vaginal symptoms are typical and common in the general population and about 30% of women with complaint of vaginal discharge or irritation remain undiagnosed despite extensive testing. The most common causes of vaginitis/vaginosis are bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis. BV is the most common cause of vaginal discharge in reproductive-aged women. VVC is the second most common cause of vaginitis in reproductive-aged women. Gram stain and culture are conventional methods for diagnosis BV/VVC but they are time-consuming methods. Automated molecular methods have been introduced to increase sensitivity and facilitate workflow. Flow cytometry is frequently used in the screening of urine samples and other biological samples. Our objective has been to implement flow cytometry in BV/VVC screening.

Materials/methods: Five-hundred-fifty-four vaginal samples from patients with symptoms of BV/VVC were collected in liquid transport medium (ESwab, Copan). The samples were processed by microscopy, culture, and realtime PCR (BDMax Vaginal Panel, Becton Dickinson). Previously, all the samples were analysed by cytometry (UF4000, Sysmex) for the detection of bacteria, yeast, epithelial and inflammatory cells per microliter.

Results: Realtime PCR were positive in 158 samples for BV (28.5%), 183 for VVC (33.0%), and 14 (2.5%) for trichomoniasis. Sixteen samples were positive for bacterial vaginosis and vaginal candidiasis. The samples positive for BVs were a median of 39029.9 bacteria/μl with an AUC of 0.727. The cutoff value was 8965.5 bacteria/μl for 85% and 42.7% of sensitivity and specificity respectively. In samples positive for VVC we found a median of 435.3 yeast/μl with an AUC of 0.717. The cutoff value was 117.4 yeasts/μl for 85% and 37.9% of sensitivity and specificity respectively.

Conclusions: The results show that the BV samples have a higher bacterial count than the samples in which VVC is detected and the negative samples. On the other hand, in VVC samples, cytometry detects, in addition to a greater number of yeasts, as the inflammatory status is reflected by the presence of a greater number of leukocytes and squamous cells. These preliminary data show that flow cytometry could be a quick and inexpensive screening technique to detect situations of vaginosis and vulvovaginitis.

Evaluation of the FluoroType mycobacteria assay for the detection and differentiation of clinically relevant mycobacteria
Claudia Niccolai1, Anna Maria Bartolesi2, Fiorella Marcelli2, Angela Andreini2, Roberta Mannino2, Alberto Antonelli1, Enrico Tortoli3, Gian M. Rossolini1,2

1University of Florence, Department of experimental and clinical medicine, Florence, Italy, 2Careggi Florence University Hospital, Clinical Microbiology and Virology unit, Florence, Italy, 3IRCCS San Raffaele Hospital, Emerging Bacterial Pathogens Unit, Milan, Italy

Background: The genus Mycobacterium includes many species that can be divided into three large groups: i) Mycobacterium tuberculosis complex (MTBC) causing tuberculosis which is one of the major health problems worldwide, ii) Mycobacterium leprae; iii) non tubercular mycobacteria (NTM), environmental opportunistic pathogens frequently associated with human diseases.

In the last few years, infections caused by NTM have been steadily increasing in western countries, while tuberculosis is more prevalent in low-income countries.

In order to limit the diffusion of mycobacterial infections, specific and rapid diagnostic methods for detection of MTBC and NTM are urgently needed.

The aim of this study was to evaluate the novel FluoroType Mycobacteria assay (FTMA) (Hain, Germany), a rapid molecular method based on the innovative LiquidArray technology, which allows detection of MTBC and differentiation of most relevant clinical NTM in only one tube.

Materials/methods: FluoroLyse DNA extracts of 43 positive liquid cultures, inactivated at 95°C for 30 min, were tested with the FTMA on the FluoroCycler XT. The results, obtained within 2.5 hours (handling and analysis time included), were compared with routine diagnostic methods - GenoType Mycobacteria CM/AS, GenoType NTM-DR, and/or genetic sequencing.

Results: The FTMA identification of 39 NTM (4 Mycobacterium abscessus abscessus, 4 Mycobacterium abscessus bolletii, 4 Mycobacterium abscessus massilense, 5 Mycobacterium avium, 2 Mycobacterium chelanae, 2 Mycobacterium chimaera, 2 Mycobacterium fortuitum, 5 Mycobacterium xenopi, 4 Mycobacterium intracellulare, 3 Mycobacterium gordonae, 1 Mycobacterium kansasii, 2 Mycobacterium malmoense) resulted identical with reference diagnostic methods, while Mycobacterium flavescens and Mycobacterium arupense were not identified at the species level (but only as Mycobacterium spp.), due to database limitations. Moreover, the new method detected the presence of two MTBC in accordance with reference methods.

Conclusions: The FTMA showed to be a powerful tool for automated detection of mycobacteria, correctly identifying 39 clinically relevant NTM and 2 MTBC from liquid culture in 2.5 hours. Testing of additional samples is in progress, with simplified extraction protocol in order to confirm the performance of this novel technology.

Abstract 7919

**Extended-spectrum β-lactamase in Escherichia coli and Klebsiella pneumoniae of chicken meat in butchers in Algeria, with detection of ESBL-CTX-M-55 and E. coli-B2/ST131**

Chenouf Nadia Safia1,2,3, Isabel Carvalho2,4,5,6, Chafik Redha Messai7, Yacine Titouche1, Abdelghani Zitouni3, AHCène Hakem1, Carmen Torres*2

1University of Djelfa, Laboratoire d’Exploration et de Valorisation des Ecosystèmes Steppiques, Djelfa, Algeria, 2University of La Rioja, Área Bioquímica y Biología Molecular, Logroño, Spain, 3École Normale Supérieure de Kouba (ENS), Laboratoire de Biologie des Systèmes Microbiens (LBSM), Kouba, Algeria, 4University of Trás-os-Montes and Alto Douro, Microbiology and Antibiotic Resistance Team (MicroART), Department of Veterinary Sciences, Vila Real, Portugal, 5University of Trás-os-Montes and Alto Douro, Department of Genetics and Biotechnology, Vila Real, Portugal, 6Universidade NOVA de Lisboa, Laboratory Associated for Green Chemistry [LAOV-REQUIMTE], Lisboa, Portugal, 7École Supérieure Nationale Vétérinaire, Algiers, Algeria

**Background:** ESBL constitute a mechanism of resistance of great clinical relevance that is spreading not only in the human niche but also among food-producing animals and derived-food. This study was designed to determine the prevalence and the genetic content of ESBL-producing *Enterobacteriaceae* recovered from food sold in butchers of Djelfa area (Algeria).

**Materials/methods:** 136 broiler livers randomly purchased in chicken butchers were collected. Analysis was performed by enrichment in BHI broth and isolation on Hektoen agar. Bacterial identification was performed using API 20E system and Mal-di-TOF MS. Susceptibility against 13 antimicrobials was evaluated by disc diffusion method. PCR/sequencing were adopted for the detection of ESBL and other resistance genes, phylogenetic grouping and molecular typing. Ultimately, transferability of associated ESBL-genes was checked-up through conjugation experiments.

**Results:** 78 *Enterobacteriaceae* isolates were recovered (one/sample: 73 *Escherichia coli* and 5 *Klebsiella pneumoniae*). In *E. coli* strains, the highest resistance levels were expressed to tetracycline (98.6%), nalidixic acid (86.3%) and trimethoprim/sulfamethoxazole (72.6%). ESBL activity was detected in 8 *E. coli* and the 5 *K. pneumoniae* isolates (rates of 5.9% and 3.7% in analyzed samples, respectively). The following ESBLs were detected (number of isolates): *blaCTX-M-15*(8), *blaCTX-M-1*(3), *blaCTX-M-55*(1) and *blaSHV-12*(1); all ESBL-*K. pneumoniae* isolates carried the *blaCTX-M-15* gene. ESBL producing *E. coli* isolates were assigned to lineages: A/ST48, B1/6448, B1/ST5087, B1/ST23, and B2/ST131 [two *blaCTX-M-15* *E. coli* isolates]. *K. pneumoniae* isolates were ascribed to sequence types ST2010 and ST3483. The four ESBL subtypes were successfully transferred by conjugation. Transconjugants carrying the *blaCTX-M* genes acquired either the IncK or the IncI1 plasmids, while the transfer of the *blaSHV-12* was associated with the acquisition of IncFIB or IncI1 plasmids. In non-ESBL *E. coli* isolates, the most commonly observed resistance genes were: *aac-(3)-ii* (100%), *tetA* (75%), *cmlA* (70%), *blaTEM* (57.1%) and *sul2* (43.5%) genes.

**Conclusions:** Relevant ESBL genes (*blaCTX-M-15* and *blaCTX-M-55* in *E. coli* or *K. pneumoniae*), as well as epidemic clones (B2/ST131) are detected among ESBL-producing *E. coli* from Algerian chicken markets. These findings reveal a serious public health concern, given that, such isolates could be transmitted to human consumers via the food chain.

**Presenter email address:** carmen.torres@unirioja.es
Background: Even with newer molecular diagnostic instruments offering an "open channel" for LDT automation, these implementations can be constrained by slow operation, forced batching, and significant hands-on time. The NeuMoDx 96 and NeuMoDx 288 Molecular Systems allow for complete standardization of LDTs with solutions to overcome the above-mentioned drawbacks of LDT automation, while offering significant advantages of room temperature stable reagents with long in-use life as well as extremely fast turnaround times and integration with laboratory information systems. Ability to implement these LDTs from CSF, transport medium, and whole blood specimen types is presented here.

Materials/methods: Whole blood, swabs in transport media, and CSF specimens spiked with following model DNA/RNA targets: Chlamydia trachomatis (CT) in 400µL vaginal swabs in UVT, Cytomegalovirus (CMV) in 200µL CSF and 250µL whole blood, and Enterovirus (EV) in 200µL CSF and 400µL nasal swabs in UVT was used to demonstrate efficacy of LDT implementation. Once extraction and PCR parameters were optimized, LDTs were processed automatically using the NeuMoDx Master Mix Test Strips (for PCR or RT-PCR) coupled with analyte specific reagents (ASRs). Studies to determine limit of detection, linearity, effectiveness of the sample process control, and the effect interfering substances testing were performed for each matrix and target set to determine effectiveness.

Results: Excellent sensitivities were obtained for all five specimen and target combinations tested: 10 EB/mL for CT in vaginal swabs in UVT, 0.0032 TCID₅₀/mL for EV in nasal swabs in UVT, 20 IU/mL for CMV in CSF, 0.0032 TCID₅₀/mL for EV in CSF, and 200 IU/mL for CMV in whole blood. All LDTs demonstrated excellent linearity (slopes of -3.1 to -3.4, efficiencies of 96-108%) across the range tested. The incorporated sample process control was determined to be an effective indicator of the extraction process for all tested targets and specimen types. No interference was observed at clinically relevant levels of endogenous/exogenous substances tested in any of the matrices.

Conclusions: This study demonstrated the extreme ease and excellent performance of LDT implementation using CSF, Transport Medium and Whole Blood specimens on the NeuMoDx Molecular System.

Cationic antimicrobial polymers as new anti-biofilm agents
Ramon Garcia Maset*1, Freya Harrison1, Sebastien Perrier2

1University of Warwick, Coventry, United Kingdom, 2University of Warwick, Coventry, United Kingdom

Background: The rational design of new antibiotic agents is of imminent global necessity; more than 10 million deaths and an immense cost in health systems are predicted by 2050 due to multidrug bacterial infections. Inspired by natural antimicrobial peptides, cationic polymers can be developed as a new category of antibiotics to treat bacterial and biofilm infections.

Materials/methods: Cationic polymers mimicking antimicrobial peptides were synthesized by reversible addition-fragmentation chain transfer (RAFT) polymerization with various organizations of cationic regions. The positively charged moieties (guanidinium and ammonium) mimicking arginine and lysine amino-acids respectively. Standard antimicrobial susceptibility tests were performed using Staphylococcus aureus, following the Clinical Laboratory Standards Institute (CLSI) guidelines. Mammalian cell proliferation was tested following the XTT assay. Potential haemolytic activity of the compounds was tested in sheep red blood cells (RBC). The antibiofilm activity was evaluated using a synthetic collagen wound biofilm model.

Results: The synthesized cationic polymers showed good antimicrobial activity against S. aureus strains in Muller-Hilton broth (MHB) and in synthetic wound media (SWM) which is more representative for a clinical wound infection environment. The compounds were non-hemolytic, which is promising for future application as intravenous treatment for systemic infections. However, the polymers (especially guanidinium compounds), showed some toxicity against fibroblast cells (3T3).

The activity against S. aureus biofilms was tested in a collagen wound model. The artificial collagen wound was loaded with a polymeric solution and then a bacterial inoculum was added. Total biofilm inhibition was observed. In order to test biofilm disruption, a mature biofilm was formed in the collagen-wound model and afterwards treated with a polymeric solution. A significant decrease in colony forming units (CFU) in the treated wound can be observed.

Conclusions: Antimicrobial cationic polymers possess promising antibacterial and anti-biofilm activities as a new class of antibiotics. However, the toxicities against mammal’s cells need to be further studies in more complex models for further application in vivo.

Nosocomial respiratory syncytial virus infections: a two-season European multi-centre cohort study

Torcato Moreira Marques1, André Almeida2, Matteo Boattini3, Eirini Christaki4,5, Rita Corte Real6, Maria Inês Moreira7, Valentina Tosatto1, Diogo Antao1, Lourenco Cruz1, Gabriele Bianco3, Cristina Costa1, Rossana Cavallo1, Marco Iannaccone1, Georgios Tsiolakkis2, Diamanto Kasapi4, Elina Khattab4

1Central Lisbon Hospital Centre, Internal Medicine Department, Lisbon, Portugal, 2NOVA Medical School, Lisbon, Portugal, 3University Hospital Città della Salute e della Scienze di Torino, Microbiology and Virology Unit, Turin, Italy, 4Medical School, University of Cyprus, Nicosia, Cyprus, 5Nicosia General Hospital, Department of Medicine, Nicosia, Cyprus, 6Central Lisbon Hospital Centre, Clinical Pathology Department, Lisbon, Portugal, 7Central Lisbon Hospital Centre, Pneumology Department, Lisbon, Portugal

Background: Respiratory syncytial virus (RSV) is a well-known cause of respiratory infection in infants, but the data about adult infection is scarce, especially regarding nosocomial infections. Despite the usual mild disease that it causes in healthy adults, those with cardiopulmonary diseases can be severely affected.

Materials/methods: We collected data from all patients with a positive PCR result for Influenza or RSV virus on oropharyngeal swabs who were admitted to the three centers represented in the study – Lisbon, Turin and Nicosia, during the 2017-2018 and 2018-2019 season. Patients included were older ≥ 18 years old, admitted for admission to a hospital ward and/or intensive care unit and had both positive PCR and clinical manifestations only take place at least 48h after admission. Univariate analysis was conducted using chi-square tests. Multivariate analysis used logistic regression including variables which showed associations with p values <0.25 on univariate analysis.

Results: Of the 1151 patients with positive PCR swabs, 246 met the inclusion criteria. Median age was 73 years and 59% (101) were female. Regarding comorbidities, 36% (88) had COPD/asthma, 26% (65) DM, 19% (47) CKD, 15% (37) interstitial disease, 13% (33) were smokers and 8% (19) had a solid neoplasm. 5% were co-infected with Influenza A (mostly H3N2) and only 1.6% co-infected with Influenza B. There were 32 deaths (13%) registered during the course of admission, 53% (17) during the four first weeks of the year (2018 or 2019). Median length of stay was 15 days. 16% (40) needed ventilatory support with non-invasive ventilation (NIV) and 6% (15) were submitted to invasive mechanical ventilation (IMV). Patients with solid neoplasms were more prone to die (p= 0.02, OR 3.5, CI95% [0,1 -0,8]). There was a trend relating co-infection of RSV and Influenza B with NIV but with no statistical significance (p= 0.3) was reached.

Conclusions: January was the deadliest month, in every year, for patients with nosocomial infections with RSV. Co-infection with Influenza B seems to be related with higher need for NIV. Oncologic patients are more prone to die due to nosocomial VSR infections.

Presenter email address: torcato.marques@chlc.min-saude.pt
Severe viral respiratory infections in paediatric intensive care unit: a 4-year experience in an Italian paediatric hospital

Maia De Luca1, Carmen D’amore1, Livia Gargiullo1, Vitangelo Clemente1, Costanza Tripiciano1, Stefania Mercadante1, Daniela Perrotta1, Joseph Nunziata1, Roberto Bianchi1, Emanuele Rossetti1, Carlo Concato1, Anna Chiara Vittucci2, Paola Zangari1, Lorenza Romani*1, Francesca Calò Carducci1, Marta Luisa Ciofi Degli Atti1, Patrizia D’argenio1

1Bambino Gesù Children’s Hospital, Roma, Italy

Background: Viral respiratory infections (VRIs) are one of the main causes of hospitalization in children; 2-3% of cases need Intensive Care Unit (ICU) admission. Herein we describe a series of pediatric patients affected by severe VRIs requiring ICU admission in an Italian tertiary care pediatric hospital to explore the determinants for mechanical ventilation requirement and prolonged ICU hospitalization.

Materials/methods: We described demographical and clinical characteristics of all children aged between 0 and 18 months admitted to the Bambino Gesù Children’s Hospital in Rome over a four-year period (2015-2018) because of a VRI requiring ICU admission. Categorical data were compared through Chi square test; continuous data were expressed as median and interquartile range (IQR) and compared through the Wilkoxon test.

Results: 132 patients were included in the study; the median age was 3 months (IQR 2-9) and the median weight was 5 kg (IQR 4-8). Comorbidities affected 37% of patients. The main viruses isolated in the respiratory tract were VRS-A (31.1%) and Rhinovirus (22.7%). 41% and 57% of children required mechanical ventilation and prolonged ICU admission, respectively. The median stay in ICU was 8 days (IQR 6-16). Patients younger than 7 months and with a weight below 6 kg had more frequently an ICU hospitalization longer than 8 days (p<0.001). Comorbidities, previous admissions for a respiratory infection, the type of virus and viral co-infections did not result to be risk factors for mechanical ventilation and prolonged ICU hospitalization. Otherwise, bacterial co-infections, mainly caused by Haemophilus influenzae, led commonly patients to endotracheal intubation and longer ICU stays (p<0.001).

Conclusions: VRIs can be an important cause of morbidity, especially in young children and children with comorbidities. Many patients with VRIs require endotracheal intubation and need a prolonged ICU hospitalization that can expose them to further complications, such as hospital-acquired infections and tracheostomy. Studies are necessary to identify tools such as specific antiviral therapies to reduce the severity of these infections and to improve the outcomes.

Abstract 7933

Next generation sequencing of influenza A virus from environmental samples at the human-animal interface
Natalie Bell*, Brian Kwok¹, Lily Yip¹, Christian Bekking¹, Yohannes Berhane³, Karren Prost¹, Mohammad Oadir², Samira Mubareka¹
¹Toronto, Sunnybrook Research Institute, Toronto, Canada, ²Fusion Genomics Corp., Burnaby, Canada, ³National Centre for Foreign Animal Disease, Winnipeg, Canada

Background: The 2009 pandemic influenza A virus [H1N1] highlighted gaps in surveillance of influenza viruses of swine origin, specifically at the human-animal interface. Current influenza surveillance systems are costly and labour-intensive, often under-prioritizing zoonotic sources of emergent strains with pandemic potential. The genetic diversity and reassortment of influenza A virus in swine underscores the need for a non-invasive, population based surveillance technique to improve pandemic preparedness. Aggregate, environmental samples from agricultural settings can be analyzed using a next-generation sequencing (NGS) techniques, providing an alternative approach to classic surveillance methods for influenza viruses of public health importance.

Materials/methods: Environmental samples consisting of 88 pooled oral fluids from swine, 183 room-level and personal breathing zone bioaerosols and 45 surface swabs were collected from a swine barn in Southern Ontario, Canada. Room-level air samples were obtained using two low and two high volume bioaerosol samplers. All samples were analyzed by RT-PCR for detection of the matrix gene. Suspect positive and positive samples were subject to target enrichment using captured probes against influenza genomic segments, designed by Fusion Genomics Corporation. Enriched libraries were sequenced using an Illumina NextSeq sequencing instrument at a read depth of 2-5 million reads per sample.

Results: Among 76 rooms deemed positive by oral fluids, 23.8%, 33.3%, 11.5%, and 45.2% were positive by PTFE, NIOSH, Coriolis, and swabs, respectively. Suspect positive samples were detected in 23.8%, 50%, 38.4%, and 23.8% by PTFE, NIOSH, Coriolis, and swabs, respectively. NGS recovered 35%, 18%, 6% of the viral genome by oral fluids, swabs, and bioaerosol samples, respectively. Hemagglutinin and neuraminidase segments showed the highest percent coverage in all sample types. Non-structural and polymerase segments (excluding polymerase basic protein 2) were unable to be sequenced.

Conclusions: Environmental sampling of swine barns could provide a non-invasive option for the detection of influenza A virus, however complete characterization of influenza A virus requires whole genome sequencing of all segments. Further optimization of environmental sampling is needed to enhance sequencing yield, prior to consideration as a stand-alone method for surveillance.

Impact of a multiplex PCR in the management of viral meningitis

Gauthier Pean De Ponfilly*, Anthony Chauvin, Hanaa Benmansour, Emmanuel Lecorche, Faïza Mougari, Anne-Lise Munier, Sabrina Temim, JeRome Le Goff, Emmanuelle Cambau, Herve Jacquier

1Hospital Lariboisière Ap-Hp, Laboratory of Microbiology, Department of Infectious Agents, Paris, France, 2Hospital Lariboisière Ap-Hp, Department of Emergency, Paris, France, 3Hospital Lariboisière Ap-Hp, Department of Infectious Diseases, Paris, France, 4Hospital Saint Louis Ap-Hp, Laboratory of Virology, Department of Infectious Agents, Paris, France

Background: Infectious meningitis and meningo-encephalitis are life-threatening conditions associated with high morbidity and mortality. In emergency departments, their diagnoses are still a challenge for the clinician since pleiocytosis is not specific of infectious meningitis. Recently, multiplex PCRs have been developed to improve this diagnosis and optimize patient management and treatment. The objective of this study was to measure the impact of multiplex PCR in the management of viral meningitis.

Materials/methods: We conducted a retrospective monocentric study in the Emergency department of our University hospital including all patients who underwent lumbar puncture with pleocytosis (> 5 leukocytes / mm3). The study was divided into two periods: Period 1 from April 2014 to March 2017 before the implementation of the FilmArray® ME test (bioMérieux) and Period 2 from April 2017 to March 2019 after implementation. Microbiological and clinical data were collected from hospital informative systems.

Results: Out of 7,674 CSF (7,341 patients) analyzed, 1,121 (1104 patients) showed pleocytosis (587 in Period 1 and 534 in Period 2). Meningitis or meningo-encephalitis were diagnosed in more cases in Period 2 than in Period 1 [325 [60.9%] vs. 312 [53.2%], respectively (p=0.009)]. The proportion of pathogens identified among those covered by the FilmArray® ME test was not different between period 1 and period 2 (127/312, 40.7% vs. 153/325, 47.1%, p=0.1). For the subgroup of Enteroviral (EV) meningitis, patients were less often hospitalized in Period 2 than in Period 1 (38/58, 65.5% vs 32/88, 36.4%, p<0.001). The duration of hospitalization for patients with EV or HSV-2 meningitis was significantly shorter (mean duration of 1.63 days vs 2.54 for EV and 3.6 days vs 6.6 for HSV-2, p<0.001 and p=0.01 respectively). Empirical prescription of acyclovir was reduced during Period 2 for patients with EV (10/58 vs 6/88, p=0.05) or VZV meningitis (20/25 vs 7/18, p=0.01). The prescription of antibiotics was also reduced in Period 2 for patients with HSV-2 meningitis (4/9 vs 0/25, p=0.002).

Conclusions: The implementation of a rapid multiplex PCR in the diagnosis of community meningitis in emergencies appears to have an impact on the management of viral meningitis and may reduce inadequate antimicrobial treatments.

Presenter email address: gauthier.pean-de-ponfilly@aphp.fr
Abstract 7940

Evaluation of the performances of BD MAX enteric bacterial panel and extended enteric bacterial panel for detection of gastrointestinal pathogens in clinical stool specimens using FecalSwab

Sentis Celia1, Olivier Dauwalder1, Anne Tristan1, Buis Coralie1, Kevin Santos1, Farrah Sonia1, Pascaline Duraffourg1, François Vandenesch1, Frédéric Laurent1, Anne-Gaëlle Ranc*1

1CHU Lyon, Lyon, France

Background: The goal of this study was to evaluate the analytical performance of BD MAX enteric bacterial panel (EBP) and extended EBP (xEBP) for identification of bacterial pathogens.

Materials/methods: 982 prospective stool specimens collected on FecalSwab® (Cary-Blair) were screened by molecular biology using BD Max EBP and xEBP assays (MB). Results were compared to i) standard culture routinely used in the laboratory (Hektoen before and after selenite enrichment, Karmali and CIN agar), ii) new specific cultures (chromogenic or selective agar) inoculated on the MB results.

Results: Utilization of MB elevated the overall detection rate from 5.6% (55/982) to 7.9% (78/982) for the detection of Campylobacter spp, Salmonella spp, Shigella spp, Yersinia spp and Plesiomonas spp. It also allowed the detection of 3.6% (35/982) positive specimens for pathogens not usually identified by standard culture such as ETEC, EHEC (shigatoxins+) and Vibrio spp. Five samples were positive by MB for 2 or more pathogens (2 pathogens, n=4; 5 pathogens, n=1). All discrepancies corresponded to MB+/culture-, except one case for which culture was positive for Salmonella and MB- but MB+ when retested. The rough overall agreement between MB and culture (including both standard culture and specific culture) were as follows: 17/18 Salmonella spp, 37/47 Campylobacter spp, 1/2 Y. enterocolitica, 0/2 Vibrio spp and 1/1 P. shigelloides. For the detection of shigatoxins, 14/21 specimens were confirmed with home-made PCR. 11 samples were positive for Shigella spp/EIEC by MB among which 6 Shigella were detected in culture. Complementary investigations (Biofire assays and specific tests in French National Reference Centers) are underway to investigate further some specimens with MB+/culture- and for the detection of EIEC for Shigella spp/EIEC positive samples by MB. The selected use of specific media for specimen with MB+ allowed the additional culture of 6 Campylobacter and 2 Salmonella compared to standard culture.

Conclusions: BD Max EBP and xEBP showed higher number of positive samples compared to culture and very good performances for the detection of enteric bacterial pathogens. The use of specific media based on MB results allowed the increase of isolation of pathogens implicated in diarrhea, in particular Campylobacter and Salmonella.

**Abstract 7942**

**Drug repurposing as an effective strategy to treat multidrug-resistant infections: teaching old drugs new tricks**

Daniela Alves Ferreira¹, Catarina Roma-Rodrigues¹, Pedro Baptista², Alexandra Fernandes², Marta Sofia Martins¹

¹Trinity College Dublin, School of Genetics and Microbiology, Dublin, Ireland, ²Faculdade de Ciências e Tecnologia da Universidade Nova de Lisboa, Departamento Ciências da Vida, Caparica, Portugal

**Background:** Antibiotic resistance has become one of the main health crises of the 21st century. Due to the lack of new molecules, the repurpose of "old" drugs used to treat different conditions is becoming attractive. The antipsychotic Thioridazine (TZ) has been reported as an efflux pump inhibitor with demonstrated activity against *Mycobacterium tuberculosis*, *Acinetobacter baumannii*, etc. but its mechanism of action has never been fully described. The main aims of this study were to uncover the mechanism of action of TZ in *Salmonella Typhimurium* (model bacterium) and assess its use as an adjuvant to treat infected macrophages.

**Materials/methods:** The in vitro antibacterial activity of TZ was determined based on its minimum inhibitory concentration (MIC). Membrane permeability assays were performed with sub-MIC concentrations of TZ and fluorescence measured using the Ethidium-Bromide accumulation assay. *Salmonella* was exposed to sub-MIC of TZ and its effects on membrane potential and cell wall assessed by flow cytometry and Transmission Electron Microscopy, respectively. Effects on the bacterial proteome were assessed through 2D gel electrophoresis. Cytotoxicity was determined in THP-1 cells. Infection assays were performed in THP-1 and RAW 264.7 cells treated and non-treated with TZ.

**Results:** The MIC of TZ against *Salmonella* was 200mg/L. Our in vitro data demonstrates that TZ mechanism[s] of action involves primarily *Salmonella*’s membrane by affecting its permeability and potential after 15 minutes of exposure to TZ. At half of the MIC, and only after 15 minutes, TZ disrupts the bacterial membrane leading to leakage of the cellular contents and lysis of *Salmonella*. Proteomic profiling revealed 75 upregulated and 62 downregulated proteins, among which were TolC and AtpD, involved in cell energetics. TZ demonstrated no cytotoxicity on human cells at clinically relevant concentrations. Infected macrophages treated with sub-MIC of TZ, showed a reduction on intracellular CFU/mL compared with the control. This may be indicative of TZ’s ability to enhance the killing activity of infected macrophages.

**Conclusions:** TZ seems to act in vitro by targeting the bacterial cell-envelope. Due to its effect on infected macrophages, TZ can be considered a adjuvant to current therapeutic regimens to treat multidrug resistant infections.

Identification and quantification of microdialysis variability using an integrated in vitro, ex vivo and in silico approach

Luis Ilia*, David Busse1, Lisa Ehmann1, Philipp Simon2,3, Robin Michelet1, Charlotte Kloft1

1Freie Universitaet Berlin, Institute of Pharmacy, Dept. of Clinical Pharmacy & Biochemistry, Berlin, Germany, 2University of Leipzig Medical Center, Department of Anaesthesiology and Intensive Care, Leipzig, Germany, 3University of Leipzig, Integrated Research and Treatment Center (IFB) Adiposity Diseases, Leipzig, Germany

Background: For the antibiotic linezolid (LIN), a catheter-based microdialysis (µD) study [1] investigated its pharmacokinetics in obese and non-obese patients at target site [1]. However, the observed µD technique variability prompted investigations to identify and quantify its sources to optimise study designs of future clinical trials. Hence, LIN inter- and intracatheter variability assessed by relative recovery (RR) was compared in an in vitro dynamic µD system (dIVMS) in different matrices and an ex vivo approach in human subcutaneous interstitial space fluid (ISF) with different locations of µD catheter to quantify their influence on the observed in vivo variability of the µD technique.

Materials/methods: The typical in vivo LIN concentration-time profile in ISF [2] was mimicked in the dIVMS using Ringer’s solution (RS) and mimicked artificial ISF (pooled plasma + saline 0.9%, 1+1) as in vitro matrices, respectively. Retrodialysis was performed as a calibration method in vitro and ex vivo with sampling from three µD catheters (CMA 60, cut-off 20kDa) simultaneously.

Statistical analysis of catheter variability was performed in R (3.6.0) using one-way ANOVA and linear mixed-effects modelling with the R-package lmer (v1.1-21).

Results: RR between catheters was significantly different in the ex vivo setting (p<0.001), but not in the in vitro approaches in the dIVMS in RS and artificial ISF (p=0.741 and p=0.890).

RR variability was split in intercatheter and residual variability (including intracatheter variability) being slightly smaller ex vivo (RSO=21.4%CV and 10.4%CV) compared to in vivo (RSO=16.0%CV and 18.1%CV).

Conclusions: The integrated in vitro, ex vivo and model-based analysis approach provided quantitative and qualitative insights into the µD technique variability of the clinical µD study. Changing of matrices from RS to artificial ISF seem to have no significant influence on the µD technique variability, whereas different localisations of the inserted µD catheters in the ex vivo setting can partially explain the observed in vivo variability. Further investigations are warranted to unveil sources of the remaining unexplained variability such as handling of µD equipment or the staff experiences.

Abstract 7945

Development and preliminary evaluation of Multidrug Resistance Direct Flow Chip kit, a molecular method for a rapid detection of multiple antibiotic resistance markers

Juana Carrero*, Antonio Gallana, David Gomez, Asunción Olmo, Montserrat Ruiz, Nieves Gonzalo-Jiménez

1 Master Diagnóstica, Granada, Spain, 2 Hospital General Universitaria de Elche, FISABIO, Elche, Spain, 3 Hospital General Universitaria de Elche, Elche, Spain

Background: The preliminary evaluation of the new commercial assay Multidrug Resistance (MDR) Direct Flow Chip (Master Diagnóstica, Spain) for the simultaneous detection of multiple resistance markers in multidrug resistant bacterial causing several infections is described.

Materials/methods: MDR is a multiplex PCR followed by automatic flow-through hybridization, colorimetric detection and image analysis, which detects 5 pathogens and 47 resistance markers in 4 hours. Both steps were simultaneously performed in the fully automated HS12 PCR auto platform. DNA from multidrug resistant (MDR) clinical isolates was purified with the automatic extraction by the system NucliSens EasyMag using a generic protocol. Direct PCR was also tested starting from blood cultures, rectal or nasal swabs.

Results: A total of 70 clinical isolates and 24 clinical samples were tested with MDR assay. Figure 1 shows the antibiotics resistance genes detected and correlation with the antimicrobial susceptibility tests (AST).

Conclusions: The resistance markers detected by MDR Direct Flow Chip could explain the antibiotic resistance profile in approximately 90% of the isolates. Furthermore, preliminary results showed a correct performing of the test in direct PCR from clinical samples such as blood cultures, rectal and/or nasal swabs, thus this test could be a useful tool for a rapid detection of multiple resistances in a single assay avoiding the spreading of resistances and overuse of broad-spectrum antibiotics. An ongoing study is being carried out with a larger number of samples in order to provide unbiased sensitivity and specificity values of MDR kit.

Abstract 7946

Histoplasmosis epidemiology in Costa Rica
Juan Villalobos1, José Castro1, Carlos Ramírez*1, Laura Villalobos González2
1Costa Rica, Hospital México, San José, Costa Rica, 2Costa Rica, San José, Costa Rica

Background: Histoplasmosis has a worldwide distribution, with major areas of high endemicity in USA and in some Latin America countries. To our knowledge, no epidemiological studies have been published from Central America. This paper describes the epidemiological behavior of histoplasmosis in Costa Rica from 2001 to 2015.

Materials/methods: This is a retrospective, descriptive study based on the national discharge registry of Costa Rica’s public health care system. The cumulative incidence of histoplasmosis per 100,000 persons per year, gender, distribution by age, co-morbidities, clinical form and in-hospital mortality rate were determined. In this analysis the period was divided into 5-year intervals.

Results: During this period, 424 Histoplasma capsulatum infections were recorded for a cumulative incidence of 0.64 cases per 100,000 persons-years. A significant increase in the incidence between the first (0.51 cases/100,000 per persons) and second quinquennium (0.71 cases/100,000 per persons) was observed (RR = 1.28; 95% CI 1.01-1.64), to subsequently a mild decrease. Men were affected more than women (RR = 2.68; 95% CI 2.14-3.29). Median age was 31 years (interquartile range of 18 to 43 years), 26% of cases occurred in children under 19 years and 59% between 20 and 49 years. More frequent associated co-morbidities were: HIV-infection (49%), cancer (5%), chronic liver disease (2%) and kidney transplant (3%), just 5% of the individuals did not possess any underlying illness. The proportion of histoplasmosis in non-HIV infected patient gradually increases among the periods, from 44% to 54% but it was not statistically significant. The clinical form of histoplasmosis was classified as pulmonary (48%) and disseminated disease (52%). The in-hospital mortality by quinquennium was 12, 15% and 17% respectively due to a significant rise in HIV-infected group mortality.

Conclusions: The incidence of histoplasmosis in Costa Rica had a significant growth. A clear predominance of the disease was observed in young men HIV-infected. In-hospital mortality rate in HIV patients experienced a significant increase during this period.

Abstract 7947

**Acquisition of antimicrobial resistance organisms by US international travellers**

Guillaume Mellon*, Sarah Turbett, Collin Worby, Elizabeth Oliver, Paul Kelly, Daniel Leung, Mark Knousse, Stefan Hagmann, Ashlee Earl, Edward Ryan, Regina Larocque

1Massachusetts General Hospital: Infectious Diseases Division, Boston, United States, 2Broad Institute, Cambridge, United States, 3BronxCare Health System, Bronx, United States, 4University of Utah Hospital, Salt Lake City, United States, 5Lehigh Valley Hospital - 17th Street, Allentown, United States, 6Cohen Children’s Medical Center, Queens, United States

**Background:** Antibiotic-resistant bacteria are an increasing health threat in the U.S., with an estimated 2.8 million cases and 35,000 deaths annually. Carbapenem and polymyxin antibiotics, including colistin, are the “last resort” treatment for highly antibiotic-resistant Gram-negative organisms. Increasing evidence shows that international travelers asymptotically acquire antibiotic-resistant bacteria in the gut while abroad and may contribute to the global spread of these medically important organisms.

**Materials/methods:** We recruited subjects seen for pre-travel health evaluation in select Global TravEpiNet network (GTEN) sites. GTEN is a consortium of 25 travel clinics across the U.S. that provide pre-travel health consultations to U.S. international travelers. Data were collected from December 2017 to August 2019. Participants self-collected stool samples before and after international travel and sent them for processing through the U.S. postal service. Using selective media, we screened the stool for extended spectrum beta-lactamase producing *Enterobacteriaceae* (ESBL). All identified isolates subsequently underwent whole-genome sequencing using Illumina technology.

**Results:** We collected a total of 570 stool samples. 44 U.S. study subjects had ESBL prior to departure. We identified 219 U.S. international travelers who had positive post-travel samples for ESBL. The most common destinations associated with travel-associated acquisition of ESBL were India, Ghana, and Peru. Most ESBL were *E. coli* (90% pre-travel and 97% post-travel). Eighty-five of the ESBL colonized travelers (39%) experienced diarrhea on their trip, and 29 (34%) took antibiotics. Whole-genome sequencing of the bacterial isolates revealed the vast majority of ESBLs were of the CTX-M type. CTX-M group 55 predominated in South East Asia and South America.

**Conclusions:** This study highlights the acquisition risk of antimicrobial resistance organisms, including ESBL, in association with international travel. These acquisition rates are similar to smaller European studies. Prevention measures and screening policies, including genomic surveillance, for U.S. international travelers may be needed to help contain the global spread of drug resistance elements.

Cytomegalovirus reactivation as a diagnostic and prognostic indicator of increased risk of cardiovascular diseases

Valeria Cento1, Luna Colagrossi*,1 Alice Nava1, Elisa Matarazzo1, Marcella Mercuri2, Francesco Pansera3,4, Enrico Piccinelli3,4, Irene Bossi3, Daniele Armenia2, Pierpaolo Paba2, Fabbio Marcuccilli5, Daniela Adele Pia Campisi2, Diana Fantl2, Fabrizio Oliva1, Francesca Ceccherini Silberstein1, Cristina Giannattasio3,4, Perno Carlo Federico2,8

1University of Milan, Residency in Microbiology and Virology, Milan, Italy, 2ASST Grande Ospedale Metropolitano Niguarda, Chemical-clinical and Microbiological Analysis, Milan, Italy, 3ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy, 4Cardiology 4, De Gasperis Cardio Center, Milan, Italy, 5Saint Camillus International University of Health Sciences, UniCamillus, Rome, Italy, 6Policlinico Fondazione Tor Vergata, UOC Virologia Molecolare, Rome, Italy, 7University of Rome “Tor Vergata”, Department of Experimental Medicine and Surgery, Rome, Italy, 8University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

Background: The pro-inflammatory status related to chronic infection by human cytomegalovirus (HCMV) has been associated with an increased cardiovascular risk and formation of atherosclerotic plaques, that could lead to acute clinical manifestations. We aimed to investigate the potential correlation among the occurrence of an acute coronary syndrome with a cardiac and/or systemic HCMV-reactivation.

Materials/methods: Between January and November 2019, 200 patients were enrolled in the study; 11 have been excluded (lack of adequate sampling, informed consent missing, etc). Therefore 189 subjects were evaluable, and divided as follows: 123 with acute coronary disease, 49 with chronic coronary disease (classified as acute or chronic “cases”, respectively) and 17 healthy patients (classified as “controls”). All cases underwent to a coronary angiography and to HCMV-DNA quantification from culprit coronary withdrawal. HCMV-DNA in peripheral blood and HCMV total IgM/IgG were quantified in all patients through real-time PCR assay (ELITech group) and ELISA test (Diasorin Molecular), respectively. HCMV-DNA was tested in triplicate in 22 patients, according to samples’ availability.

Results: Most patients were men (74.1%; 140/189), caucasians (67.2%; 127/189), with a median age of 66 (IQR: 55-73) years. HCMV seroprevalence was higher in acute/chronic cases (91.5/100%, respectively) than in controls (9/17, 52.9%), the latter in line with the seroprevalence in general population (50-70%, Lachmann et al., Plos One 2018) (p<0.001). IgG-positive acute/chronic cases also had detectable (but not quantifiable) HCMV-DNA in peripheral blood more frequently than IgG-positive controls (22/132, 20.0% vs. 1/9, 11.1%, p=n.s.). At coronary level there was a trend of higher prevalence of HCMV-DNA positivity in patients with acute disease, compared to chronic controls (15.3% vs 8.2%). Of note, 43.5% of acute patients showed a HCMV-DNA positivity only in coronary plasma sample, while in chronic patients the HCMV-DNA was detected only in peripheral plasma samples or in both specimens (p=0.018).

Conclusions: Our results show a higher CMV seroprevalence (90-100%) relative to the Italian population. Furthermore, the increased presence of CMV-DNA in coronary samples is somewhat associated with acute cardiovascular disease. This finding should be confirmed by a uni-multivariable logistic regression analysis for the epidemiological confounding factors, currently ongoing.

Penicillin-binding protein 2 (PBP2), PBP2a and PBP4 clone-specific polymorphisms are not associated to ceftaroline (CPT) susceptibility in Chilean clinical isolates of methicillin-resistant Staphylococcus aureus (MRSA)

Maria De Los Angeles Spencer1, Rodrigo Martinez1, Lina María Rivas1, Marcelo Rojas1, Rafael Rios1, An Dinh4, Lorena Diaz1, Jinnethe Reyes1, Blake Hanson4;4, Patricia Garcia5, Cesar Arias4, Jose Munita2

1Universidad del Desarrollo - UDD, Genomics and Resistant Microbes (GeRM), Las Condes, Chile, 2Universidad del Desarrollo - UDD, Centro de Genética y Genómica, Las Condes, Chile, 3Universidad Del Bosque, Molecular Genetics and Antimicrobial Resistance Unit, Bogotá, Colombia, 4UTHealth, Center for Antimicrobial Resistance and Microbial Genomics and Division of Infectious Diseases, Houston, United States, 5Universidad Catolica de Chile, Departamento de Laboratorios Clínicos, Santiago, Chile

Background: CPT is a last-generation cephalosporin active against MRSA due to its affinity for PBP2a. CPT-resistance (CPT-R) is well-described, with mutations in the active transpeptidase domain of PBP2a associated to high-level resistance. The accumulation of changes in the non-penicillin-binding domain of PBP2a has been linked to elevations of the minimal inhibitory concentration (MIC) to CPT to levels around 2-4ug/mL (susceptible dose-dependent [SDD]). PBP4 and PBP2 have also been implicated as potentially relevant mecA-independent mechanisms of CPT-R. We recently reported high rates of CPT-non-susceptibility in clinical MRSA strains from Chile. However, the mutational landscape of PBPs in clinical MRSA isolates from Chile and its relation to CPT susceptibility has not been assessed.

Aim: To assess the mutational profile of PBP2, PBP2a and PBP4 in clinical MRSA isolates from Chile and compare it to CPT-susceptibility obtained by broth microdilution (BMD).

Materials/methods: We analyzed 180 MRSA isolates collected from 2000-2018 in Santiago, Chile. Identification was confirmed by MALDI-TOF and methicillin resistance with cefoxitin disk-diffusion. CPT susceptibility was performed by BMD following CLSI-2019 guidance. Whole-genome sequencing was performed for all isolates, the mutational profile of PBPs was determined using reference sequences for PBP2 (AGY89563.1), PBP2a (NG_047938.1) and PBP4 (X91786.1).

Results: All isolates were phenotypically-confirmed MRSA and harbored mecA. The MIC50/MIC90 by BMD was 2/2μg/dL; only 71 (39%) isolates were CPT-susceptible (MIC <1µg/mL). Most isolates belonged to ST5/SCCmecI (70%,126/180), ST105/SCCmecII (10%,18/180) and ST8/SCCmecIV (5%, 9/180). All ST5/SCCmecI isolates carried the mutations in PBP2 (Y156D), PBP2a (M122I and E150K), and PBP4 (T189S, L234H, and T409A); CPT-susceptibility among ST5/SCCmecI was only 22%. On the other hand, all ST105/SCCmecII isolates had mutations in PBP2 (S707L) and PBP4 (T189S, L234H, and T409A) and exhibited a higher CPT-susceptibility rate (67%). All 9 isolates belonging to the ST8/SCCmecIV lineage harbored a non-coding mutation in PBP2a (g-6t) and the previously observed L234H change in PBP4. Importantly, no association between specific polymorphisms and MIC to CPT was found.

Conclusions: Changes in the studied PBPs were frequent among MRSA circulating in Chile and were conserved among different genetic backgrounds. However, these changes were not associated with the level of CPT MIC among these isolates.

Abstract 7955

**Varicella zoster: a complicated primoinfection in an elderly patient**

Sara Brandão Lopes*1, Gonçalo Cruz1, Flávia Santos2, Conceição Ventura1, Eduardo Rabadão1, José Cunha1

1Hospitalar and University Centre of Coimbra, Infectious Diseases Department, Coimbra, Portugal, 2Hospitalar Centre of Leiria, Internal Medicine Department, Leiria, Portugal

**Background:** Chickenpox is a primary infection caused by Varicella-Zoster virus (VZV), highly contagious and characterized by a pruriginous vesicular exanthema, preceded by systemic symptoms. It is common in children and generally has a benign course, however in adults and immunocompromised patients might have a more severe presentation and serious complications. Viral pneumonia is one of the most common complications with an incidence 25 times higher in adults compared with children. Treatment with acyclovir is recommended in adults, immunocompromised and patients with severe presentations, because it reduces the viral replication and frequency of complications.

**Materials/methods:** case report: Man, 91 year-old, totally dependent and institutionalized, examined at the emergency room with fever, pruriginous vesicular exanthema with two day onset associated with cough, respiratory distress and low peripheral oxygen saturation.

He presented with exuberant, disseminated cutaneous lesions, in different development stages, some of them infected, sparing the palmar, plantar and anterior region of the lower limbs. Pulmonary auscultation with wheezing in both lungs. Analytically without leucocytosis, PCR 6 mg/dl (<0.50 mg/dl), hepatic alterations with cytolysis pattern and hypoxemia. It was performed a swab of the lesions that revealed VZV positivity (PCR). IgM and IgG VZV antibodies were negative. Chest radiography showed interstitial infiltration and the abdominal ultrasound was unremarkable. The patient was admitted with chickenpox, superinfected lesions and viral pneumonia and started treatment with acyclovir and amoxicillin/clavulanate. VZV serology was repeated and IgM and IgG antibodies turned positive which was compatible with recent infection.

**Conclusions:** The authors intend to show a clinical case of chickenpox primoinfection due to its rarity in elderly patients and exuberant presentation. This infection is associated with severe complications in adults, therefore it is necessary to promptly recognise and initiate antiviral therapy.

Abstract 7958

**Tuberculosis in elderly patients**

Pauline Caraux Paz*, Anna Belkacem, Medina Fernanda, Alice Raffetin, Kevin Diallo, Danielle Jaafar, Jacques Naturel, Olivier Patey

1Centre Hospitalier Intercommunal de Villeneuve Saint Georges, Department of infectious diseases, Villeneuve Saint Georges, France
2Centre Hospitalier Intercommunal de Villeneuve Saint Georges, Geriatric department, Villeneuve Saint Georges, France

**Background:** The geriatric population among all ethnic groups represents the largest reservoir of tuberculosis (TB) infection, particularly in developed nations. The rate of progression from infection to disease is substantially modified by age and multiple other immunosuppression factors. Clinical features of tuberculosis in older adults may be atypical, non specific and confused with concomitant age related disease. Mortality even with treatment is increased with age. The aim of this study was to describe the characteristics of elderly patients with TB.

**Materials/methods:** We conducted a retrospective study analyzing the characteristics of patients over 65 years of age who were treated for a TB disease in a French hospital between 2009 and 2019.

**Results:** We included 40 patients aged 65 years or older with TB disease. Mean age was 78 [65-92] and sex ratio was 0,9. Pulmonary TB was found in 29 patients (72,5%). Other types of extra pulmonary TB were lymph node (5), gastrointestinal (4), bone (3), neurological (2), cardiac (2), and ophthalmologic TB (1). Among the patients 35% were born in France and 35 % had African origin, 10% Asian, 5% other European countries, 7,5% Caribbean and 7,5% with unknown origins. The Charlson comorbidity index scores was high (>4) for 29 (72,5%) patients. TB was bacteriologically proven in 72,5% (1 resistance to isoniazid was found), histologically in 12,5% and clinical/radiologically in 15% of cases. Thirty seven patients received an antituberculosis quadritherapy including isoniazid, rifampin, pyrazinamide (PZA) and ethambutol at diagnosis. 3 patients received triple therapy; 2 without PZA, 1 without ethambutol (renal failure). Adverse effects of treatment were recorded in 17 cases (42,5%), particularly hepatic dysfunction (41,1%), occurred more commonly. In 8 cases, the anti-tuberculosis treatment initiated had to be suspended and reintroduced after normalization of the liver function, in 3 cases without pyrazinamide. Nine patients were lost to follow-up before the end of treatment.

**Conclusions:** More drug-induced adverse reactions are experienced by this population during TB therapy according to the literature. Optimal treatment of associated chronic diseases, minimization of invasive procedures, limitation of polymedication and adequate nutritional support are essential for this vulnerable population.

**Presenter email address:** paulinecaraux@hotmail.com
The microbial aetiology of the acute appendicitis: the possible role of microbiota in the disease

Eveliina Munukka*1,2, Sanja Vanhatalo2,3, Suvi Sippola4, Marianne Gunell5, Juha Oskari Grönroos4, Pentti Huovinen3, Antti J. Hakanen2, Paulina Salminen6

1University of Turku, Biomedicine, Turku, Finland, 2Turku University Hospital, Dept. of Clinical Microbiology, Turku, Finland, 3University of Turku, Biomedicine, Turku, Finland, 4Turku University Hospital, Dept. of Digestive Surgery, Turku, Finland, 5Turku University Hospital, Dept. of Clinical Microbiology, Turku, Finland, 6Turku University Hospital, Dept. of Digestive Surgery, Turku, Finland

Background: Acute appendicitis (AA) is the most common cause of abdominal pain in emergency. It appears that complicated (perforated) and uncomplicated (non-perforated) AAs are two distinct disease forms most likely having different pathophysiology. However, the cause and etiology of these two forms remains poorly understood. The differentiation between disease forms is essential prior the determination of the optimal treatment since over two thirds of cases are of uncomplicated nature. Thus, appendectomy is not necessity in every case. Further, promising results have been reported in treating uncomplicated AA by antibiotics. Our MAPPAC (Microbiology Appendicitis Acuta) trial aims to determine the microbiological etiology and possible microbiological and immunological differences between the two AA forms. Further, the possible mediating role of both appendiceal and gut microbiota in the disease is investigated.

Materials/methods: Disease form has been confirmed by computed tomography (CT). Two appendiceal lumen swabs, one for culture and one for microbial DNA extraction (Puritan DNA/RNA Shield Tube), were collected right after the removal of appendix. In addition, two rectal swabs have been collected from the same patient during the stay in an emergency. Appendiceal content were cultured on six different plates both aerobically and anaerobically. Morphologically distinct colonies were selected from primary cultures and identified with MALDI-TOF Mass SpectRometry. DNA was extracted as previously described. Microbiological profiles were assessed by 16S rRNA sequencing (V3+V4 area, Illumina MiSeq).

Results: Majority of the appendix samples exhibited polymicrobial growth. In both disease forms common aerobic species were Esherichia coli, Pseudomonas aeruginosa, Streptococcus anginosus and S. constellatus. In complicated AA, P. aeruginosa was frequent. Commonly found anaerobes were Bacteroides fragilis, B. ovatus, B. thetaiotaomicron, B. vulgatus and Clostridium innocuum in both disease.

Conclusions:

Based on culture complicated and uncomplicated AA may differ microbiologically. Ongoing NGS analysis will provide crucial addition to the abovementioned results.

Presenter email address: laevmu@utu.fi
Delayed diagnosis of neuroschistosomiasis in a non-endemic country: a tertiary referral centre experience

Angus De Wilton*, Dinesh Aggarwal1, Peter Chiodini1,2

1Hospital For Tropical Diseases, London, United Kingdom, 2London School of Hygiene & Tropical Medicine, London, United Kingdom

Background: Neuroschistosomiasis is a severe complication of schistosomiasis, triggered by the local immune reaction to egg deposition, with spinal cord involvement the most well recognised form. Early treatment with praziquantel and high dose steroids leads to a reduction of neurological sequelae. The rarity of this condition in returning travellers to high income countries can result in delayed diagnosis and treatment. We aimed to evaluate the diagnosis and management of neuroschistosomiasis in a UK national referral centre.

Materials/methods: A retrospective review of confirmed clinical cases of neuroschistosomiasis referred to the Hospital for Tropical Diseases, UK, between 2016 and 2019 was undertaken. Electronic referral records were interrogated and patient demographic, clinical, laboratory, and radiological data collected.

Results: Four cases of neuroschistosomiasis were identified. The median age at diagnosis was 28 (range 21 to 50) with three male patients. All patients had epidemiological risk factors for schistosomiasis based on travel history and freshwater exposure; two in Uganda (River Nile), one in Malawi and one in Nigeria. All patients presented with features of transverse myelitis including back pain, leg weakness, paraesthesia and urinary dysfunction. Mean time from presentation to health services to definitive treatment was 40.5 days (range 16-74 days). Diagnosis was confirmed with CSF serology for schistosomiasis in all cases. Radiological features on MRI spine included enhancement focused predominantly in the lower thoracic spinal cord in three cases and the conus in one patient. All patients received a minimum of three days of oral praziquantel and high dose steroids. At three month follow-up, two patients had complete resolution of symptoms and two had residual deficit; one patient was left with urinary and faecal incontinence whilst another had ongoing leg weakness.

Conclusions: We observed a marked delay in diagnosis of neuroschistosomiasis in a non-endemic country. We advocate undertaking a thorough travel history, and early use of imaging and CSF schistosomal serology to ensure early diagnosis of neuroschistosomiasis in patients presenting with consistent symptoms. If Schistosomal diagnostics are not immediately available, presumptive treatment under the guidance of a tropical medicine specialist should be considered, to minimize the risk of residual disability.

Abstract 7965

Identification of central nervous system infection in children without cerebrospinal fluid pleocytosis using a syndromic meningitis/encephalitis panel

Lamprini Posnakoglou*, Tania Siahanidou¹, Vassiliki Syriopoulou¹, Athanasios Michos¹

¹First Department of Pediatrics, Division of Infectious Diseases, National and Kapodistrian University of Athens, “Aghia Sophia” Children’s Hospital, Athens, Greece

Background: The syndromic approach for the diagnosis of Central Nervous System (CNS) infections enables the rapid detection of multiple pathogens in cerebrospinal fluid (CSF) specimens. The aim of the study was to evaluate the use of CSF pleocytosis as an indicator for the optimal utilization of BIOFIRE® FILMARRAY® Meningitis/Encephalitis (FA) panel.

Materials/methods: In the first period of the study (06.2018-05.2019), FA was performed only in children with suspected CNS infection and CSF pleocytosis >15 cells/mm³. In the second period (06.2019-11.2019) there was no cut-off and all CSF samples were tested with FA. Pathogen detection rate (%) was compared between children with CSF ≤15 or >15 cells/mm³, within two age groups (>3 or ≤ 3 months of age).

Results: A total of 170 children were included in the study with median age 2.5 months (IQR: 0.7-27). Pathogen detection rate (%) with FA in the first and second study period was 46.3% (37/80) and 21.1% (19/90), respectively (P-value: 0.001). In CSF samples without pleocytosis which were tested with FA, the pathogen detection rate was 15.3% (9/59). Enterovirus was detected in 5 CSF samples (6.7%), HHV-6 in 3 (5.1%) and parechovirus in 1 (1.7%). The median age of children without pleocytosis, but with a pathogen detected was 0.66 months (IQR:0.41-4.75). In children >3 months (n=68) with CSF ≤15 or >15 cells/mm³, a pathogen was detected in 2/15 (13.3%) and 26/53 (49.1%), respectively (P-value: 0.013). In children ≤3 months (n=102) with ≤15 or >15 cells/mm³, a pathogen was detected in 7/44 (15.9%) and 21/58 (36.2%) samples, respectively (P-value: 0.023). No difference in detection rate was found in newborns ≤1 month (n= 65) between CSF ≤15 or >15 cells/mm³, 6/29 (20.7%) and 9/36 (25%), respectively, (P-value: 0.682).

Conclusions: Absence of CSF pleocytosis does not exclude CNS infection, especially in infants less than 3 months of age and newborns.

Presenter email address: lina.posnakoglou@hotmail.com
Intravenous amoxicillin in patients with various degrees of renal function: are we dosing adequately?

Femke De Velde¹, Alan Abdulla¹, Anouk Edwina Muller¹, Teun Van Gelder¹, Birgit Koch*¹

¹Erasmus University Medical Center, Rotterdam, Netherlands, ²Erasmus.nl, Rotterdam, Netherlands

Background: Amoxicillin dosing is often adjusted in patients with renal impairment (RI). The dosing recommendations for these patients differ remarkably in the literature. Our objectives were to determine if the pharmacodynamic target of 40% fT>MIC (time that the free concentration exceeds the MIC) was achieved with the local dosing guidelines in patients with and without RI and to compare amoxicillin concentrations and half-lives in both groups.

Materials/methods: Seven internal medicine ward patients treated empirically with intravenous amoxicillin/clavulanic acid were included. Median estimated Glomerular Filtration Rate (eGFR, measured by CKD-EPI) was 27 ml/min/m² (range, 21-33) in RI patients (n=4) and 99 ml/min/m² (range, 78-121) in non-RI patients (n=3). Amoxicillin dose was 1000mg four times daily for all patients. Five blood levels per patient were drawn after two or three days of therapy. Total amoxicillin concentrations were determined by liquid chromatography with mass spectrometry. Unbound concentrations were calculated using a protein binding of 20%. Non-compartmental pharmacokinetic analysis was performed using PKsolver. The %fT>MIC was calculated for a MIC of 8 mg/L (EUCAST breakpoint for Enterobacterales).

Results: One patient without micturition had an unreliable eGFR of 99, indicated by high amoxicillin levels and a prolonged half-life, and was transferred to the RI group (now n=5). Amoxicillin half-life was higher in the RI group: median 3.6h (range, 2.2-4.4) compared to 0.8h and 1.3h in the 2 non-RI patients. In all patients fT>MIC was at least 40%, although the fT>MIC was higher for the RI patients (median 100%, range 94-100%) than the non-RI patients (48 and 51%). The concentrations 3h after start of infusion were higher in the RI group (median 22.9 mg/L, range 15.3-48.9) than in the non-RI patients (7.8 and 11.5 mg/L).

Conclusions: All subjects attained the 40% fT>MIC target, concluding that the current amoxicillin dose of 1000mg four times daily is sufficient for patients with and without RI. Concentrations in RI subjects are much higher than in non-RI patients, which raises the question if their dosing is not unnecessary high. However, as the supratherapeutic concentration limit is unknown, more research is necessary to suggest a new dosing regimen in RI.

Efficacy of an engineered protegrin-1 analogue in a murine model of Pseudomonas aeruginosa sepsis

Mansour Dughbaj*, Rajasekaran Ganesan1, Steven Beringer1, Julio Camarero1, Paul Beringer1

1University of Southern California, University of Southern California School of Pharmacy, Los Angeles, United States

Abstract: Sepsis is a leading cause of death among hospitalized patients where the increasing prevalence of multidrug-resistant organisms complicates treatment. Protegrin-1 (PG-1) is a cationic peptide that exhibits broad-spectrum antimicrobial activity; however, proteolysis limits its use. Our group has developed a novel approach of engraving PG-1 into a cyclotide that increases its protease stability. The purpose of this study is to evaluate in vitro antipseudomonal activity, in vivo safety and efficacy of our engineered cyclotide MCo-PG1.

Materials/methods: PG-1, MCoTI-1 (cyclotide scaffold), and MCo-PG1 were prepared using Fmoc synthesis. In vitro stability was assessed using mass spectrometry on active human serum. In vitro antimicrobial activity was determined using microbroth dilution susceptibility testing and time-kill kinetics with laboratory and clinical isolates of P. aeruginosa. The maximum tolerated dose (MTD) of MCo-PG1, PG-1, and colistin was determined following single ascending intraperitoneal doses in 8-10-week-old Balb/c mice. Sepsis was established by an intraperitoneal injection of 1.5×10⁷ CFU/mouse of P. aeruginosa (ATCC 27853). Treatment was administered immediately by intraperitoneal injection with saline, 15 mg/kg colistin, 5 mg/kg PG-1, 10 mg/kg MCo-PG1 or 25 mg/kg MCo-PG1. Animals were monitored for seven days and/or euthanized if moribund appearances were observed.

Results: MCo-PG1 in vitro stability improved in comparison to PG-1 (81 and 53 hours, respectively). MCo-PG1 retained antimicrobial activity with MICs against laboratory and clinical isolates of P. aeruginosa (MCo-PG1: MIC₅₀ and MIC₉₀ of 1.5 and 3 μM, respectively, PG1: MIC₅₀ and MIC₉₀ of 0.2 and 0.78 μM, respectively). Time-kill experiments demonstrate rapid, concentration-dependent antimicrobial activity with ≥10³ CFU/mL reduction at concentrations ≥4× MIC. Considering molarity, MCo-PG1 had an increased tolerability in mice in comparison to PG-1 (25 mg/kg and 5 mg/kg, respectively) while the MTD for colistin was 5 mg/kg. Single-dose administrations of 10 mg/kg and 25 mg/kg MCo-PG1 were associated with a high survival rate of septic mice (Hazard ratio (HR): 11.4 and 20.8 respectively, p <0.001) comparable to 5 mg/kg PG-1 considering molarity and 15 mg/kg colistin administration (HR: 24.8, p <0.001).

Conclusions: MCo-PG1 exhibited potent antipseudomonal activity in vitro, improved tolerance and demonstrated reduced mortality in a murine model of P. aeruginosa sepsis.

Abstract 7969

**Impact of different components of a national intervention on CLABSI rates**

Debby Ben-David*1, Azza Vaturi1, Ester Solter1, Elizabeth Temkin1, Yehuda Carmeli1,2, Mitchell Schwaber1,2

1National Center for Infection Control, Israel Ministry of Health, Tel-Aviv, Israel, 2Tel Aviv University Sackler Faculty of Medicine, Tel-Aviv, Israel

**Background:** Central line-associated bloodstream infection (CLABSI) is one of the most common preventable infectious complications among intensive care unit (ICU) patients. In 2012, the Israeli National Center for Infection Control (NCIC) initiated a country-wide intervention to reduce the incidence of CLABSI. The objective of this study is to evaluate the impact of different components of the intervention on CLABSI rates.

**Materials/methods:** All medical-surgical ICUs in Israel were included in the national intervention. CLABSI prevention guidelines were distributed in 2011. National surveillance of hospital-acquired BSI and CLABSI rates was initiated in January 2012 with bi-annual feedback to hospital management and local infection control teams. A national workshop on effective prevention measures was conducted in June 2013. Public reporting of CLABSI rates was announced in 2015. In 2017, additional steps were implemented: setting national targets, providing quarterly feedback to hospitals, assessing local infection control measures using an online survey and conducting site visits by a physician and infection control nurse from the NCIC. We calculated incidence rate difference between each year and the year prior. The number of cases prevented was calculated by comparing the expected number of CLABSI based on the 2012 rate to the observed number.

**Results:** A total of 121 ICUs in 30 hospitals were included in the national intervention. The pooled average rate in 2012 was 7.2/1000 line-days [Figure]. Following the introduction of surveillance and feedback in 2012, a significant decrease in CLABSI rates was observed during 2013. (IRD: -2.8, 95% CI: -3.7 - -1.8, P<0.001). Between 2013 and 2017, no significant change was observed (IRD range -0.7 - 0.1). In 2018, a significant decrease was observed: (IRD -1.4 95% CI: -2.0 - -0.8, P<0.001). The decrease in CLABSI incidence since 2012 translates into approximately 1500 CLABSI cases prevented between 2013-2019.

**Conclusions:** National surveillance and data feedback resulted in an initial reduction in CLABSI rates but the effect was limited. In the wake of additional interventions, including more frequent and detailed feedback, goal setting and site visits, a further sustained reduction was observed.

**Figure:** CLABSI rates in Israeli medical-surgical ICUs, by year

Virulence profile and comparative genomics analysis of the emerging Klebsiella pneumoniae genotypes ST45, ST101 and ST629

Eliana Pia Esposito*, Matteo Cervoni, Chandler Roe, Luisa Maria Vieira Peixe, Spyros Pournaras, Sylvain Brisse, Jason W. Sahl, Francesco Imperi, Raffaele Zarrilli

1Department of Public Health, University of Naples "Federico II", Naples, Italy, 2Department of Science, University Roma Tre, Rome, Italy, 3Pathogen and Microbiome Institute, Northern Arizona University, Arizona, United States, 4Departamento de Ciências Biológicas, Universidade do Porto, Porto, Portugal, 5Department of Microbiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 6Institut Pasteur, Biodiversity and Epidemiology of Bacterial Pathogens, Paris, France

**Background:** Klebsiella pneumoniae isolates associated with hospital-acquired infections have primarily been assigned to CC258 and to the additional emerging genotypes ST45, ST101, ST629 in Europe and worldwide. The aim of this study was to analyze the virulence profile and to perform comparative genomic analysis of a collection of K. pneumoniae isolates, from different sources and human or non-human hosts, assigned to the ST45, ST101 and ST629 genotypes.

**Materials/methods:** The virulence profiles of K. pneumoniae strains was assessed using the Galleria mellonella infection assay. Genome sequencing of K. pneumoniae isolates was performed using Illumina MiSeq. Genes associated with virulence, heavy metal resistance, and drug resistance were identified using the Large-Scale Blast Score Ratio pipeline.

**Results:** ST45, ST101 and ST629 K. pneumoniae strains were isolated from either human or non-human hosts and from different body sites. Among them, human clinical K. pneumoniae isolates showed multidrug-resistant profiles. High variability in the infectivity of G. mellonella larvae was observed among K. pneumoniae isolates assigned to different genotypes, with lethal dose 90% (LD$_{90}$) values ranging from dozens of cells [isolates M1A and SB5970 assigned to ST45] to more than ten million of cells [isolate Kp-Mo-5 assigned to ST629]. Kaplan-Meier survival curves confirmed the different pathogenicity of the strains in this infection model. Overall, K. pneumoniae isolates assigned to ST45 showed higher virulence than those assigned to ST101 or ST629, with LD$_{90}$ values $10^2$ to $10^3$-fold lower than those of ST101 or ST629 isolates. Notably, a hyper-virulent phenotype was found in some ST45 K. pneumoniae isolates irrespective of their source of isolation. The distribution of virulence and/or resistance genes among ST45, ST101 and ST629 K. pneumoniae isolates is currently under investigation.

**Conclusions:** Our data highlight a trend toward increased virulence in K. pneumoniae strains assigned to the ST45 genotype. Comparative genomics is ongoing to verify whether an association exists between this phenotype and the acquisition of specific virulence determinants.

**Patients related barriers for delay in seeking confirmatory test and treatment of hepatitis C in treatment naïve patients visiting a tertiary care hospital in Karachi, Pakistan**

Hiba Ashraf1, Nuha Mahmood2, Ujala Shujat2, Naila Baig-Ansari1, Sundus Iftikhar1, Rukhsana Ansari2

1The Indus Hospital, Karachi, Pakistan, 2Jinnah Sindh Medical University, Karachi, Pakistan

**Background:** Hepatitis C virus (HCV) is a leading cause of chronic liver disease worldwide, resulting in significant morbidity and mortality. Though it is a preventable disease but has turned into an epidemic in South-Asia, with the disease burden in Pakistan being one of the highest in the world. Researches from various countries have identified factors for the poor uptake for the diagnosis and treatment at three different levels: patient level, physician level and organizational level. This study aims to determine the reasons for patient level delay in seeking confirmatory diagnosis and treatment of hepatitis C as it is important to ascertain these factors to reduce unnecessary complications and mortality from a curable disease.

**Materials/methods:** A cross-sectional survey conducted between 2014 to 2016 in HCV treatment naïve patients visiting out-patient family medicine clinics at a free tertiary care hospital. Patients were interviewed using a pre-coded questionnaire. Delay was defined as taking greater than 3 months at any stage as follows: Delay 1: not going to a doctor for advice after initial diagnosis; Delay 2: not getting a confirmatory PCR test after being advised; Delay 3: delay in initiating treatment.

**Results:** A total of 368 participants with positive HCV antibody status constituted the study population. The mean age of the participants was 33.2 years (SD ± 8.3), with the majority two-thirds being women (n=242; 66%). Types of delay with their frequencies can be consulted in Figure 1. Most common reasons for type 1 delay was financial constraints (47.9%), followed by assuming it was curable through alternative treatment (33.6%), and lack of time due to household responsibilities (24.3%). Delay 2 and Delay 3 also showed inability to afford the test (80.2%) and treatment (66.2%) as being the leading cause.

**Conclusions:** Barriers to Hepatitis C testing and treatment vary at different care stages and are not entirely patient-related. However, understanding the patient related barriers for the delay will not only help in the successful delivery of Hepatitis C care in a resource poor country, but also decrease the morbidity and mortality associated with this chronic disease.

Impact of interferon gamma on Staphylococcus aureus internalisation within human osteoblasts

Chauvelot Pierre1, Aubin Souche1, Lelia Abad1, Paul Verhoeven1,2, Jerôme Josse1, Tristan Ferry1, Frédéric Laurent1, Florent Valour*1, Alan Diot1

1Lyon, France, 2Saint-Etienne, France

Background: Staphylococcus aureus is responsible for difficult-to-treat bone and joint infection, partly due to its ability to constitute an intraosteoblastic bacterial reservoir associated with chronic and relapsing infections. We evaluate here the impact of the interferon gamma (IFNg)-mediated host cellular response against this intracellular infection.

Materials/methods: The ability of the S. aureus wild-type strain SA113 (ATCC35556) to adhere and to invade bone cells were evaluated in an ex vivo model of MG63 human osteoblast infection (gentamicin protection assay) pre-treated or not by recombinant human IFNg at 1, 10 or 100 ng/mL. Our results led us to further investigate: i) the impact of the supernatant of MG63 cells pre-treated or not by IFNg on bacterial adhesion and internalization (gentamicin protection assay); and ii) the effect of IFNg on the cellular expression of the β1 intergrin (RT-q-PCR) which represent the osteoblastic receptor of S. aureus during the internalization process.

Results: Pre-exposition of MG63 cells to IFNg resulted in a significant and dose-dependent reduction of SA113 internalization rate, from 4.0% (95% confidence interval [CI], 3.1 -4.8) for untreated cells to 1.2% (95%CI, 0.8- 1.6) for osteoblasts treated by 100 ng/mL of IFNg (p<0.001) (figure, panel A), due to a significant reduction of SA113 adhesion to bone cells (figure, panel B). This observation was not due to a cell-released soluble factor, as preincubation of SA113 with the supernatant of osteoblasts pre-treated by IFNg did not influence bacterial survival or adhesion to MG63 cells. Surprisingly, the observed reduction of adhesion and internalization was not related to a decrease in cellular expression of the β1 intergrin.

Conclusions: During the acute inflammatory phase of bone and joint infection, IFNg secretion might prevent the constitution of an intraosteoelastic reservoir of S. aureus, limiting bacterial adhesion to bone cells. The involved mechanism is not related to a decreased expression of the cellular β1 intergrin, and remains to be clarified.

Figure. Internalization [A] and adhesion [B] rates of S. aureus SA113 in a ex vivo model of infection of MG63 osteoblastic cells pre-treated or not by increasing concentrations of interferon gamma [IFNg].

Abstract 7975

**Early (within 7h) phenotypic detection of fluconazole-resistant Candida glabrata isolates**

Panagiota-Christina Georgiou*, Maiken C. Arendrup2,3,4, Spyros Pournaras1, Joseph Meletiadis5

1Clinical Microbiology Laboratory, Attikon University Hospital, Athens, Greece; 2Unit of Mycology, Statens Serum Institut, Copenhagen, Denmark, 3Department of Clinical Microbiology, Rigshospitalet, Copenhagen, Denmark, 4Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, 5Department of Medical Microbiology and Infectious Diseases, Erasmus MC, Rotterdam, Netherlands

**Background:** The wild-type *Candida glabrata* population is susceptible to increased exposure of fluconazole (800 mg/12 mg/kg daily). However, acquired resistance is common. Rapid detection of fluconazole resistance is important for early effective antifungal therapy. We therefore developed a phenotypic test based on EUCAST E.Def 7.3 protocol for the detection of fluconazole resistant isolates utilizing the colorimetric dye XTT.

**Materials/methods:** Twenty-five clinical *C. glabrata* isolates were included: 14 fluconazole resistant (MICs >16 mg/L) and 11 Susceptible Increased exposure (MICs ≤2-16 mg/L). For the XTT assay, 0.5-2.5×10^5 CFU/mL of each isolate was added to RPMI1640+2% glucose medium containing different concentrations of XTT/MEN in 96-flat bottom microtitration plates (200 μL/well). In order to find the optimal concentration 100-400 mg/L of XTT with 0.39-25 μM of menadione were tested. Fluconazole at a concentration of 32 mg/L corresponding 1 two-fold to EUCAST R breakpoint (16 mg/L) was added and together with drug-free wells, plates were incubated at 37°C. The metabolic activity in each well was kinetically assessed by measuring absorbance at 450nm every 15min for 18h in a microplate reader (Tecan Infinite F200). The differences in XTT absorbance between the drug-free and the drug-treated wells for resistant and susceptible to increased exposure isolates were assessed with student t test at different time points.

**Results:** The optimal conditions discriminating between resistant and susceptible to increased exposure isolates were: 100mg/LXTT/0.39μM MEN after 7h incubation. The mean±SD XTT-absorbance in drug-free and wells containing 32 mg/L were 0.32±0.11 and 0.25±0.10 for the resistant isolates and 0.32±0.06 and 0.15±0.03 for susceptible to increased exposure isolates, respectively. The XTT-absorbance differences of the 32 mg/L containing well from the drug-free well were 0.07±0.06 for the resistant isolates significantly lower than the 0.17±0.05 (p=0.0005) for the susceptible to increased exposure isolates.

**Conclusions:** A simple, cheap and fast phenotypic test was developed using the XTT dye with high specificity in detecting fluconazole-resistant *C. glabrata* isolates within 7h.

Risk factors [derived from host, pathogen and disease] did not affect the efficacy of delafloxacin monotherapy in acute bacterial skin and skin structure infections trials

Bartomeu Pizà Vallespir\textsuperscript{1}, Sara Biliotti\textsuperscript{2}, Andrea Nizzardo\textsuperscript{2}, Alessandra Nuti\textsuperscript{2}, Sue Cammarata\textsuperscript{3}, Daniela Zinzi*\textsuperscript{2}

\textsuperscript{1}Clinical Research, Laboratorios Menarini S.A., Badalona, Spain, \textsuperscript{2}Clinical Sciences, Menarini Ricerche S.p.A., Florence, Italy, \textsuperscript{3}Melinta Therapeutics, Melinta, Lincolnshire, United States

Background: DLX is a new anionic fluoroquinolone available as IV and oral formulations that has been recently approved in Europe for the treatment of ABSSSI. It is characterised by a broad-spectrum of activity, including MRSA strains and a favourable safety profile in terms of cardiac effects and phototoxicity.

Specific factors such as age, diabetic status or type of infection represent risk factors that are recognised to impact the response to treatment. This analysis assesses the impact of these factors on the efficacy using data from pooled phase 3 ABSSSI trials.

Materials/methods: Risk factors relative to the host, the pathogen or the disease were examined in the pooled population of two pivotal trials performed in ABSSSI patients \(n=1510\) comparing DLX single agent IV/OS \(n=754\) vs the combination of Vancomycin/Aztreonam IV \(\text{VAN/ATZ}; n=756\) given for 5 to max 14 days in order to explore their potential impact on the success [cure + improvement] rate at end of treatment [EOT] and at follow-up [FU, i.e. 14 days after EOT].

The following risk factors at baseline were considered: age \(>65\) years; BMI \(\geq 30\) kg/m\(^2\); diabetes; prior antibiotic treatment; MRSA; bacteraemia; polymicrobial infection; >3 signs of systemic infection; type of infection: wound infection; and erythema area: \(\geq 4\)th quartile.

Results: The ABSSSI population was split into 2 categories based on the median number of baseline risk factors: lower risk \(<3\) risk factors \(n=881\), and higher risk \(\geq 3\) risk factors \(n=629\).

In patients treated with DLX, comparable success rate has been achieved in higher vs lower risk patients at the EOT [90.3% vs 90.8%] as well as at the FU [82.9% vs 86.0%]; no significant difference was observed when the two categories of patients are compared between treatment groups.

Conclusions: The number of risk factors did not affect the efficacy of DLX for the treatment of ABSSSI, with a high success rate being confirmed also in difficult to treat patients.

Examining the urinary tract infection patient journey to identify opportunities to enhance the role of community pharmacists

Nathan Peiffer-Smadja*1,3, Rosie Allison4, Leah Jones4, Donna Lecky4, Cliodna Mcnulty4, Raheelah Ahmad2

1Bichat-Claude Bernard Hospital, Department of Infectious Diseases, Paris, France, 2Imperial College London, Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, London, United Kingdom, 3Inserm, Infection Antimicrobials Modelling Evolution, Paris, France, 4Public Health England, Primary Care Unit, Gloucester, United Kingdom

Background: Community pharmacists are involved in antimicrobial stewardship by providing patients with self-care advice and recommending over-the-counter treatments for common infections. The aim of this study is to identify opportunities to enhance the role of community pharmacists specifically in the management of urinary tract infections (UTI) by exploring the journey of service users with urinary symptoms.

Materials/methods: We collected data about the management of suspected or confirmed UTI through different sources: interviews and electronic questionnaires with community pharmacists and electronic and paper surveys with service users. Interviews were recorded, transcribed and coded using NVivo 12. Data were analysed using the classic grounded theory approach.

Results: We conducted 31 interviews and collected 38 questionnaires from 22 pharmacists working in 20 pharmacies. Eight pharmacists (36%) were women with a median of 15 years (IQR, 5-30) since qualification. Fifty service users completed the survey, 92% women, median age 50 years (IRQ, 27 -60), 41% suffering from recurrent UTIs. Triangulating responses from pharmacists and service users, 70% of the service users with urinary symptoms come to the pharmacy following a GP visit after an antibiotic prescription and 30% seek help first from a pharmacy. Pharmacists identified a number of barriers and facilitators of giving advice in the pharmacy [Table]. Sixty-four percent of the service users were comfortable discussing their urinary symptoms with pharmacists and even reported an enhanced role when compared with GPs; but stressed the importance of privacy. We collected the most important self-care advice given by pharmacists and their reasons for referral to the GP. Pharmacists declared that they could be the first contact for patients with urinary symptoms but pointed out the lack of a specific pathway to refer patients, the need for additional funding and staff to do so and the importance of increasing the possibilities to prescribe antibiotics for pharmacists.

Conclusions: We collected qualitative data among community pharmacists and service users about the journey of patients with suspected or confirmed UTI. This work could be useful to inform future strategies in England and other settings to enhance the role of community pharmacists in the management of patients with urinary symptoms.

Abstract 7983

**Outcome and characteristics of invasive fungal infections in critically ill burn patients: a multi-centre retrospective study**

Veronique Maurel¹, Matthieu Camby¹, Alexandre Alanio², Marie Lagrange³, Christian De Tymowski¹, Matthieu Legrand², Blandine Denis*¹

¹Université de Paris/ Hôpital St Louis, APHP, Paris, France, ²Université de Paris/ Hôpital Saint Louis, APHP, Paris, France, ³CHU Félix Guyon, Saint Denis, La Réunion, France

**Background:** Characteristics and outcome of Invasive fungal infection (IFI) in critically ill burn patients have been poorly explored. We report the epidemiology and factors associated with 90-day mortality in a multicenter retrospective European study.

**Materials/methods:** All burn patients with confirmed IFI admitted between January 2010 to December 2015 in 10 centers in France and Belgium were included. Data were collected from mycology laboratories and from medical records of burn centers patients and reviewed by an expert committee including an infectious disease specialist and two burn care specialists.

**Results:** During the study period, 8503 burn patients were admitted to burn centers of whom 94 (1%) presented an IFI with a total of 110 IFI collected. Patients with IFI were mostly male (62%), with a median age of 50 [42-68] years, with high severity scores (median SAPS II score of 40 [28-49]), and with a median Total Burn Surface Area (TBSA) of 43 % [25-60]. Among the 110 IFIs collected, 77 were proven and 33 probable, 79 [72%] were yeast infections (Candida albicans (57% of yeasts), C. parapsilosis [20%] and C. glabrata [10%]), and 31 [28%] were filamentous infections (Mucorales infections [52 % of filamentous infections], Aspergillus sp. [26%] and Fusarium sp. [19%]). The 90-day mortality was 37% for all IFIs combined, 52% for filamentous infection and 32% for yeast infection (p: 0.08). Patients with more than one IFI had a higher 90-day mortality than patients with only one episode (62% vs 34 % (P = .006)). In multivariate analysis, higher SAPS II (OR= 1.05 (95%CI: 1.02-1.09) P = .002), bacterial co-infection (OR= 5.6 (95% CI: 1.6-19.6), P = .007) and use of allograft at the time of IFI diagnosis (OR= 5.3 (95% CI: 1.6-17.1), P = .005) were associated with 90-day mortality.

**Conclusions:** Although rare, invasive fungal infections remain associated with poor outcome in burn patients. The mortality appears however lower compared to control historical cohorts, suggesting improved survival over time. Bacterial co-infection and presence of allograft at time of IFI were factors independent associated with mortality and potential modifiable factors.

**Presenter email address:** blandine.denis@aphp.fr
Pharmacodynamic properties of amoxicillin-clavulanic acid in a neutropenic mouse thigh infection model

Anouk Edwina Muller1,2*, Wendy Kloezen2, Brenda De Winter2, Aart Van Der Meijden2, Heleen Van Der Spek2, Marian Ten Kate2, Sanne Van Der Berg2, Joseph Meletiadis2,3

1HaaglandenMC, The Hague, Netherlands, 2Erasmus University Medical Center, Rotterdam, Netherlands, 3Attikon University Hospital, Athens, Greece

Background: Amoxicillin (AMOX)-clavulanic acid (CLAV) has been used for decades. Various formulations with different AMOX:CLAV-ratios are available, but the rationale between these differences is unknown. The minimum CLAV concentration (Ct) required for efficacy has not been determined. We evaluated the pharmacodynamic properties of AMOX:CLAV combination against 3 bacterial species in a murine thigh infection model.

Materials/methods: 10^6-10^7 CFU of 1 Escherichia coli (No 39), 1 Klebsiella pneumoniae (No 17) and 2 Staphylococcus aureus isolates (ATCC 29213 and MUP2273) with AMOX/AMOX+CLAV MICs of >2048/16, >2048/32, 1/0.5 and 0.5-1/0.25-0.5 mg/L were used in a thigh infection model in neutropenic mice. Two hours after infection mice were treated with 256, 128 and 64 mg/kg q2h of AMOX alone. For combination studies, AMOX 64mg/kg q2h (S. aureus) and 128mg/kg q2h (E. coli, K. pneumoniae) was combined with 0.5-16 mg/kg q2h and 2-128mg/kg q8h CLAV, respectively. After 24h the mice were euthanized and the number of CFU in thigh homogenates were counted with serial quantitative cultures. For AMOX %fT>MIC and for CLAV %fT>Ct were calculated using the pharmacokinetic analysis (NONMEM) using different target Ct’s for each species.

Results: AMOX monotherapy up to total daily doses (TDD) of 2048 mg/kg had no effect against E. coli and K. pneumoniae. High TDD of 1072-3297mg/kg for stasis and 2423-3201 mg/kg for 1log kill were needed for S.aureus, resulting in %fT>MIC of 95.1-100%. When AMOX was combined with CLAV, q2h regimens were more efficacious than the q8h regimens for all 3 species. TDDs to obtain stasis/1logkill were 100/486, 64.1/328, and 1.0-1.1/1.2-1.6 mg/kg for E. coli, K. pneumoniae and S. aureus, respectively. For AMOX:CLAV combination with AMOX TDD of 1536 mg/kg (E. coli, K. pneumoniae) and 768 mg/kg (S. aureus), target Ct’s of CLAV for E. coli, K. pneumoniae, and S. aureus were 0.5, 1, and 0.031 mg/L, respectively, resulting in %fT>Ct of 29.1%, 10.4%, and 3.7% (SD 1.2) for stasis, respectively.

Conclusions: The addition of CLAV to AMOX increased the efficacy. Target concentrations for CLAV needed for efficacy are lower for S.aureus as compared to E.coli and K. pneumoniae. The effect of CLAV is time-dependent. These results can be used to optimise human dosing regimens.

Epidemiology of Neisseria meningitidis infections over a 17-year period in a tertiary hospital in Madrid, Spain

Daniel Marcos Mencia1, Andrea García Caballero1, Rosa Escudero Sánchez1, Patricia Ruiz-GBarbajosa1, Maria Isabel Moya1, Rafael Canton Moreno1, Ana Maria Sanchez Diaz1

1Hospital Ramón y Cajal, Madrid, Spain

Background: Non-B non-C meningococcal infections are rising in European countries. The knowledge of the epidemiology of these infections is crucial to establish preventive actions in risk population. The aim of this work was to study the epidemiology of Neisseria meningitidis (Nm) infection diagnosed in a 17-years period in a tertiary hospital in Madrid, Spain.

Materials/methods: All patients with Nm isolation in blood cultures and/or cerebral spinal fluid (CSF) from 2003 to 2019 were included. Microorganism identification was performed by biochemical tests (API-NH biochemical gallery, Biomérieux) and/or mass spectrometry (MALDI-TOF MS, Bruker Daltonics). Serogroup identification was assigned by agglutination (BD). Antibiotic susceptibility testing was performed by disk diffusion and/or Etest (Biomérieux) and results interpreted according to CLSI/EUCAST criteria. Epidemiological and clinical data were collected from patients’ clinical records.

Results: Forty-two patients (50% men, median age 33 years; IQR: 9.25-72.25) with meningococcemia (n=24, 57.1%), meningitis (n=7, 16.7%) or both (n=11, 26.2%) were included. Patients were mainly hospitalized at Infectious Diseases (20, 47.6%), Pediatric (13; 30.9%) or Internal Medicine (5; 11.9%) Departments. Almost half of them (19; 45.2%) needed intensive care admission and mortality rate was 7.1% (3 patients died). Most of the cases occurred in 2004, 2005, 2006 (5 each year; 35.7%) and 2019 (6; 14.2%). Serotyping was only feasible in half of the isolates (n=21) that belonged to serogroups: C (10; 47.62%), B (5; 23.81%), W135 (3; 14.29%), A (2; 9.52%); and Y (1; 4.76%). Nm serogroup W135 was only isolated during 2019 and these cases presented with meningococcemia and respiratory symptoms but did not associated meningitis. All isolates were susceptible to third generation cephalosporins, rifampicin, quinolones and only two isolates were resistant or had intermediate susceptibility to penicillin.

Conclusions: Nm infection has remained low in our setting over a 17 years period. An increase in the number of cases has been observed in the last years along with a switch in serotypes circulation. Monitoring this epidemiological change should be a priority in surveillance programs.

Abstract 7991

**Performances of BD MAX Cdiff assay for detection of toxigenic *Clostridioides difficile* in 1321 clinical stool specimens using FecalSwab**

Anne-Gaëlle Ranc*1, Olivier Dauwalder1, Sentis Celia1, Anne Tristan1, Buis Coralie1, Kevin Santos1, Farrah Sonia1, Pascarine Duraffourg1, François Vandenesch1, Frédéric Laurent1

1CHU Lyon, Lyon, France

**Background:** The goal of this study was to evaluate the analytical performance of BD MAX Cdiff assay for detection of toxigenic *C. difficile*.

**Materials/methods:** 1321 prospective stool specimens collected on FecalSwab (Cary-Blair) were screened with BD Max Cdiff assay (BD) from October to November 2019. Results were compared to routine algorithm including immunochromatographic testing for glutamate dehydrogenase (GDH) and toxinA/B by *C. diff* QuickChek Complete (Abbott) (QC) completed by Xpert *C. difficile* assay (Cepheid) (GX) when GDH+/Tox-. In case of discrepant results (BD-/GDH+/Tox+ or BD+/GDH-Tox-), GX was performed.

**Results:** The overall agreement between BD and routine algorithm was 97.4%. The prevalence of toxigenic *C. difficile* was 7.6% (n=99) using BD versus 5.4% (n=71) using the routine QC/GX algorithm (see table 1). Among the 99 BD+ specimens:

- 29% (n=29) were confirmed GDH+/Tox+ using QC.
- 42% (n=42) were GDH+/Tox- using QC and were therefore tested using GX. Among these 42 samples, 41 were GX+ confirming BD results.
- 28% (n=28) were GDH-/Tox- using QC. 16 were confirmed GX+ while 12 remained negative. Interestingly, three out of these 12 specimens showed a late positive Ct (>37 cycles) interpreted as negative by GenXpert platform.

Of note, one specimen was found QC+ but both BD- and GX-. Complementary analyses are underway for the fourteen specimens in bold characters in table 1.

**Conclusions:** BD Max Cdiff assay shows good performances for the detection of toxigenic *C. difficile* and has a good agreement with the routine algorithm used in the laboratory. However, it shows an increased sensitivity for ICD. Nevertheless, the potential lost of specificity due to asymptomatic carriage of toxigenic strains must be taken into account to avoid overestimation of ICD. Complementary analyses, that are underway, will allow to compare accurate sensitivity and specificity of BD and routine algorithm.

Abstract 7992

**Bacteriophage therapy in the treatment of burn wounds**

Mitichkin Alexander¹, Iren Grigoryan*², Alina Melkumyan¹, Olga Safronova¹, Yryi Turnikov¹

¹F.I. Inozemtsev City Clinical Hospital, Moscow, Russian Federation, ²Moscow State University of Medicine and Dentistry after A. I. Evdokimov, Moscow, Russian Federation

**Background:** Purulent-septic infections are a major problem in combustiology. The search for alternative methods of treatment of wound infections is relevant at the time of the rise of antibiotic resistance. Phage therapy is one of the most promising directions in this field of medicine. The unique features of bacteriophages attract physicians since the 20-ies of XX century. Researchers around the world are exploring alternative ways of combating infections, in particular, the treatment of bacteriophages.

To define the algorithm of complex therapy with antibiotics and bacteriophages of burn wounds caused *Staphylococcus aureus* and *Pseudomonas aeruginosa*.

**Materials/methods:** The results of research of 187 separated wounds samples of 100 patients with burns less than 30% of body surface have been analyzed. All the patients were treated at the burn center F.I. Inozemtsev City Clinical Hospital. Identification of the bacteria and determination of the sensitivity was performed on the analyzer AutoScan 4 (Siemens, USA). Strains of *S. aureus* and *P. aeruginosa* were tested for sensitivity to the drug of domestic production "Bacteriophage staphylococcal liquid" and "Bacteriophage pseudomonas aeruginosa" [FSUE NPO "Microgen", Russia].

**Results:** In the study 272 strains of microorganisms have been isolated. *S. aureus* – 44.2%, *Acinetobacter baumannii* – 37.7%, *P. aeruginosa* – 27.3%, *Klebsiella pneumoniae* – 11.7%, other -26.0%. In the study of antibiotic susceptibility strains *S. aureus* (n=120) received 20.8% (n=25) methicillin-resistant (MRSA) and 79.2% (n=95) – methicillin-sensitive strains of *S. aureus* (MSSA) were obtained. Among MSSA sensitivity to bacteriophage made 90.5% and among MRSA strains it was 92.0%. Among the *P. aeruginosa* strains (n = 74) were sensitive to Meropenem – 54.0%, Imipenem – 59.5%, Ceftazidime – 67.6%, Cefepime – 68.9%, Amikacin – 64.9% and Ciprofloxacin – 60.8%, panresistance – 21.6% strains *P. aeruginosa*. Among the *P. aeruginosa* strains (n = 74) were sensitive to bacteriophage – 85.7%.

**Conclusions:** The results of the study show the high sensitivity of strains of *Staphylococcus aureus* and *Pseudomonas aeruginosa* in relation to drugs with bacteriophages domestic production [FSUE NPO "Microgen", Russia] and the feasibility of their use in the treatment of burn wounds. The special relevance gains bacteriophages in the treatment of burn infections caused by antibiotic-resistant bacteria.

Amphotericin B as rescue therapy for alveolar echinococcosis in patients with benzimidazole treatment failure or toxicity

Johannes Bloehdorn¹, Sanne Burkert*, Lynn Peters¹, Julian Schmidberger¹, Andreas Hillenbrand¹, Tilmann Gräter¹, Martina Furitsch¹, Thomas Barth¹, Doris Henne-Bruns¹, Wolfgang Kratzer¹, Nina Eberhardt¹, Ambros Beer¹, Beate Grüner¹

¹University Hospital Ulm, Ulm, Germany

Background: Curative resection is the treatment of choice for alveolar echinococcosis (AE) with circumscribed manifestation. However, in most cases complete resection is impracticable due to extended involvement of critical anatomic structures. Benzimidazole treatment (BMZT) is the only available medical treatment approved in such cases, but may be limited due to inefficacy or intolerance. Thus, new drugs are urgently needed. Amphotericin B treatment (AMBT) has been used with success in desperate situations.

Materials/methods: We report long-term follow-up data from 5 patients with AMBT at our centre who were diagnosed with unresectable AE and BMZT intolerance or treatment failure. Initial AMBT loading phase of 2 weeks was followed by 1-3 applications per week, depending on response. Close monitoring was conducted for the first month and afterwards every 3 months. Responses were confirmed by PET-CT scan, showing stable or regressive metabolic activity or lesion size. Furthermore, clinical evidence of response was documented with healing AE associated cutaneous fistulae and regression of abdominal discomfort.

Results: All patients had complex disease manifestation requiring repeated surgical interventions due to complications. Three patients exhibited disseminated disease with pulmonary, cardial, vertebral and cerebral manifestations. Patients showed intolerance (n=2) and progression (n=3) under BMZT. Age at diagnosis ranged from 29-58 years and AMBT was initiated 10-25 years after diagnosis and a median of 3 previous lines of systemic therapy. With AMBT, 4 patients achieved stable disease (SD), of which 2 are still on therapy after 2 months and 13 years, respectively. The other two patients died after having achieved SD for 4 months and 3 years, respectively, but AMBT had to be discontinued due to an ileus or renal toxicity. One patient had shown only a partial remission for 17 months and achieved SD with alternative treatment. Side effects under AMBT were mostly manageable, however deteriorating renal function after 3 years prompted the halt of AMBT in one patient.

Conclusions: Salvage AMBT might be a valuable treatment option in cases of BMZT failure and can induce persistent disease control, although with potentially significant side effects, high treatment costs and the need for repeated intravenous therapy.

Abstract 7994

**Potential role of procalcitonin in antimicrobial stewardship programme in febrile neutropenic cancer patients**

Patrick Chaftari1, Anne-Marie Chaftari1, Ray Hachem1, Sai-Ching Yeung1, Ying Jiang1, Alexandre E. Malek1, Victor Mulanovich1, Issam Raad1

1UT MD Anderson Cancer Center, Houston, United States

**Background:** The assessment of cancer patients with chemotherapy-induced neutropenic fever in the emergency center could be challenging. Clinical decision should be made regarding initiation of antimicrobial agents and need for hospitalization. Cancer patients are often subjected to overuse of antimicrobial therapy which contributes to the emergence of multidrug-resistant pathogens. Procalcitonin (PCT)-based algorithm has been proposed as part of antimicrobial stewardship programs to guide and reduce antibiotic use in patients with sepsis and respiratory tract infections. Initiation of intravenous antibiotics in patients with baseline PCT levels <0.25 μg/L has been strongly discouraged whereas levels ≥0.25 dictate hospitalization and antibiotic use. We evaluated the role of PCT in febrile neutropenic cancer patients.

**Materials/methods:** We conducted a retrospective study of all febrile neutropenic cancer patients who presented to our emergency center and had a serum PCT level collected from April 1, 2018 to April 30, 2019. Fever was defined either as a documented temperature of ≥100.4 °F or a chief complaint of fever reported at home. Neutropenia was defined as an absolute neutrophil count ≤500 cells/mL.

**Results:** We identified 550 neutropenic febrile cancer patients of whom 440 (80%) were hospitalized for a median duration of 5 days. Among all patients, 70% had hematological malignancies. Bloodstream infections (BSI) were diagnosed in 24% of patients with gram negative organism in 56%, gram positive in 41%, and both in 3%. A PCT level ≥0.25 was significantly associated with BSI and overall mortality (P<0.0001). Among the 110 patients who were treated as outpatient, 37% had a PCT ≥0.25 and 15% had a BSI of whom 71% had a PCT ≥0.25. Among the 440 patients who were admitted to the hospital, 48% had a PCT level <0.25.

**Conclusions:** A PCT level ≥0.25 in febrile neutropenic cancer patients is significantly associated with BSI and mortality and may prompt initiation of intravenous antibiotics and hospital admission. PCT < 0.25 is associated with a low mortality and may suggest treatment of the patient in the ambulatory setting. PCT may reduce inappropriate use of antibiotics in an oncologic emergency center and may contribute to an antibiotic stewardship program.

Evaluation of the CAMPYLOBACTER QUIK CHECK to detect Campylobacter in stool samples

Justine Franco1,2, Lucie Benejat1, Astrid Ducournau2, Francis Megraud2, Philippe Lehours2, Emilie Bessède2

University Hospital of Bordeaux, Bordeaux, France, 2University Hospital of Bordeaux, Centre National de Référence des Campylobacters et Helicobacters, Bordeaux, France

Background: Campylobacters are the main cause of bacterial diarrhea in the world. Antibiotic therapy in Campylobacter diarrhea is of interest in the first 3 days in order to shorten carriage and duration of the disease. For a long time, stool culture was the reference test to detect Campylobacters but the result was obtained in a minimum of 48 hours. Now, several different rapid tests are available. One of them is a rapid membrane enzyme-linked immunosorbent assay, the CAMPYLOBACTER QUIK CHEK™, commercialized by Abbott and providing a result in less than 30 minutes. The aim of this study was to evaluate its performance.

Materials/methods: This retrospective study was conducted in the Bacteriological Laboratory of Bordeaux University Hospital, France. One hundred and eight samples were analyzed: 88 were issued from patients hospitalized at the Bordeaux University Hospital and 22 were kindly provided by a private laboratory (Exalab, Le Haillan, France), and transported at +4°C in an e-swab medium. Culture was systematically performed, then specimens were frozen at -80°C until use. After thawing, specimens were tested by the rapid CAMPYLOBACTER QUIK CHEK™ following the manufacturers’ instructions, and by a molecular method (in house RT-PCR and/or BOMAX (Beckton Dickinson) and/or Rigadene (r-Biopharm)). The reference test was a composite reference standard: a positive case corresponded to a positive culture and, in case of a negative culture result, by the association of a positive molecular test and the ELISA (Ridascreen, r-Biopharm).

Results: Following the composite reference test, 53 stools were positive and 55 were negative. The Abbott test detected 1 additional positive sample and missed 2 cases, corresponding to e-swab stools, whereas culture did not detect 5 positive samples. Sensitivity of the CAMPYLOBACTER QUIK CHEK™ was 97% and specificity was 98%. In contrast, culture sensitivity was 90% and its specificity was 100%.

Conclusions: The CAMPYLOBACTER QUIK CHEK™ showed an excellent performance. It is a very easy test to use and does not require any specific automation. Its main advantage is the rapidity in obtaining a result, enabling an adapted medical care if needed. The place of this test in daily clinical practice needs to be evaluated.

Abstract 7997

Serum galactomannan antigenaemia of HIV-positive patients in an endemic area for Talaromyces marneffei

Yu-Tsung Huang*¹, Chun Hsing Liao¹, Chia-Jui Yang¹
¹Far Eastern Memorial Hospital, New Taipei, Taiwan

Background: Cross-reactivity of serum galactomannan (GM) test (Platelia, Bio-rad) has been demonstrated in patients with cryptococcosis, talaromycosis marneffei, and paecilomycosis. In our previous study, we have demonstrated significant elevation of serum GM in HIV-positive patients with symptomatic talaromycosis. We prospectively evaluated prevalence of serum GM antigenemia in HIV/AIDS patients in an endemic area of talaromycosis.

Materials/methods: From January-2009 to August-2019, we prospectively tested serum GM of all patients within one week after their confirmation of HIV-infection. A GM optic density index (O.D.) more than 0.5 was considered to be positive. CD4 T cell count, HIV viral load and serology testing for syphilis, cryptococcosis and toxoplasmosis were also determined during the initial assessment of these patients. Diagnosis of talaromycosis was defined as having positive culture of T. marneffei from blood, sputum, sterile site fluid or any biopsied tissue. Medical records regarding further management were obtained.

Results: A total of 1143 adult HIV/AIDS patients were enrolled and followed at our institute during study period (man: woman= 1100:33). Thirty-six patients (3.1%, all male) were positive for serum GM test at their initial evaluation (O.D. index; range: 0.508-4.763, mean±S.D.: 1.2 15± 1.019) with a median CD4 count of 299 cell/μl (range, mean±S.D.: 7 - 1 305, 404.2±317.6). None of these patients was considered to have aspergillosis or talaromycosis judged by their physician according to clinical presentations therefore no anti-mold agents were ever prescribed. Other co-infections included 8 syphilis, one cryptococcosis, one toxoplasmosis and one amebiasis.

Conclusions: GM antigenemia of HIV/AIDS patients were not rare in endemic area for T. marneffei. A close follow up of their symptoms rather than initiate antifungal treatment may be more suitable for these patients.

*In vitro comparative activity of cefepime/taniborbactam against metallo-beta-lactamase-producing Pseudomonas aeruginosa and Klebsiella pneumoniae isolates*

Pasxalis Paranos1, Panagioti-Christina Georgiou*1, Stavroula Antonopoulou1, Aikaterini Michelaki2, Eleni Vagiakou2, Sophia Vourli1, Spyros Pournaras1, Joseph Meletiadis1,3

1"Attikon" University General Hospital, Clinical Microbiology Laboratory, Athens, Greece, 2General Hospital "G. Gennimatas", Department of Microbiology, Athens, Greece, 3Erasmus Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands

**Background:** Multidrug resistant bacteria are a major problem for public health. Treatment with last-line antibiotics becomes less and less effective. Taniborbactam (VNRX-5133) is a newly developed β-lactamase inhibitor (BLI) which directly inhibits all four classes of β–lactamases (Class A, C, D Serine- and VIM/NDM class B metallo-β-lactamases). To evaluate the efficacy of BLI taniborbactam combination with cefepime we used MIC determinations and compare them with a panel of antimicrobial agents that are used in clinical practice, against metallo beta-lactamase (MBL) producing Pseudomonas aeruginosa and Klebsiella pneumoniae isolates.

**Materials/methods:** Fifty phenotypically characterized MBL producing (VIM and NDM) P. aeruginosa (N=25) and K. pneumoniae (N=25) clinical strains isolated in the last two years in two major hospitals in Athens were tested against amikacin (0.06-128 mg/l), aztreonam (0.03-64 mg/l), cefepime (0.03-64 mg/l), cefepime/tazobactam (0.03-64/8 mg/l), cefepime/taniborbactam (0.03-64/4 mg/l), levofloxacin (0.016-32 mg/l), gentamicin (0.016-32 mg/l), ciprofloxacin (0.008-16 mg/l), levofloxacin (0.016-32 mg/l), imipenem (0.016-32 mg/l), meropenem (0.016-32 mg/l), meropenem/vaborbactam (0.03-64/8 mg/l), piperacillin/tazobactam (0.06-128/4 mg/l), tigecycline (0.016-32 mg/l) and MICs were determined using the broth microdilution ISO standard. Classification of isolates to susceptible (S), intermediate (I) and resistant (R) was performed according to EUCAST breakpoints (for cefepime/tazobactam the breakpoints of cefepime were used whereas for cefepime/taniborbactam the S/R ≤8/>16 breakpoints were used). The quality control (QC) strains Escherichia coli ATCC25922, Pseudomonas aeruginosa ATCC27853 and Klebsiella pneumoniae ATCC700603 were used.

**Results:** High levels of resistance (>84%) were found for K. pneumoniae MBL isolates to most antimicrobial agents tested except cefepime/taniborbactam for which only 16% were resistant (Table). High levels of resistance (>82%) were also found for P aeruginosa MBL isolates to all drugs except amikacin, aztreonam and cefepime/taniborbactam for which 67%, 29%, and 54% were resistant, respectively (Table). Taniborbactam reverse resistance to cefepime in 84% of K. pneumoniae isolates and in 46% P aeruginosa MBL isolates.

Efficacy and safety of intravenous fosfomycin in patients with periprosthetic joint infection: preliminary results from the PROOF study: a prospective multi-centre study

Svetlana Karbysheva*, Paula Morovic1, Donara Margaryan1, Lilith Johannsen1, Andrej Trampuz1

1Charité – Universitätsmedizin Berlin, Berlin, Germany

Background: Fosfomycin exhibits bactericidal activity against a broad-spectrum of bacteria and has good tissue and bone penetration. We evaluated the efficacy and safety of treatment regimens based on combinations with 15g/d intravenous fosfomycin followed by oral antibiotics for totally 12 weeks for the treatment of periprosthetic joint infection (PJI).

Materials/methods: Consecutive patients with PJI caused by at least one of the following isolates were prospectively included: staphylococci (MIC ≤32 mg/l), streptococci (MIC ≤128 mg/l), enterococci (MIC ≤128 mg/l), Enterobacteriaceae (MIC ≤32 mg/l) and Pseudomonas spp. (MIC ≤128 mg/l). Follow up with clinical (joint function and quality of life scores), laboratory and radiological evaluation at 3, 12 and 24 months after last surgery is performed. The probability of infection-free survival was estimated using the Kaplan-Meier survival method.

Results: 50 patients were screened for eligibility, of which 2 were excluded due to intolerance or allergy to fosfomycin, 1 due to isolation of fosfomycin resistant pathogen and 2 patients died due to unrelated cause to infection. The remaining 45 patients were included. The infection occurred postoperatively in 31 patients (69%) and hematogenously in 14 (31%). Two-stage exchange was performed in 27 (60%), debridement with retention in 13 (29%) and one-stage exchange in 5 patients (11%). Due to persistence of infection, 3 patients underwent prosthesis explantation after initial debridement and retention, 1 patient underwent debridement of Girdlestone-situation; all 4 infections were caused by S. aureus. 41 patients were infection-free (91%) after a median follow-up of 6 month (range, 1 - 14 months). Nausea (n=14) and hypokalemia (n=13) were the most frequent adverse events and resolved after fosfomycin discontinuation. Isolated pathogens were staphylococci (n=30), streptococci (n=3), enterococci (n=5) and gram-negative rods (n=2). Cultures were negative in 9 patients and polymicrobial in 2 patients.

Conclusions: The applied PJI treatment algorithm including intravenous fosfomycin in the initial postoperative period was associated with infection-free outcome of 91% after a median follow-up of 6 month. The Kaplan-Meier survival method showed the probability of infection-free survival of 88.5% after 1 year. Adverse events occurred in 21 patients (46%) mostly nausea and hypokalemia. Adverse events were mild and resolved completely.

Haematology/oncology patients might have different risks for MDR according to different types of chemotherapy

Julia Barbosa*1, Karim Yaqub Ibrahim2, Patricia Bonazzi3, Driele Peixoto3, Raquel Ita3, Edson Abdala4, Maristela P. Freire4

1Clinical Hospital, University of Sao Paulo, Sao Paulo, Brazil, 2Clinical Hospital, University of Sao Paulo, Sao Paulo, Brazil, 3ICESP - Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil, 4Clinical Hospital, University of Sao Paulo, Sao Paulo, Brazil

Background: Few studies analyzed chemotherapy schemes regarding the risk of infections by multidrug resistant bacterial (MDR) infections. The goal of this study was to analyze risk factors for laboratory confirmed bloodstream infection (LCBI) by MDR among hematological cancer patients submitted to chemotherapy.

Materials/methods: We performed retrospective cohort study that included all patients with hematologic malignances submitted to chemotherapy between January-2017 and June-2018 with LCBI within 30 days of the end of chemotherapy. The outcomes evaluated were LCBI by MDR bacteria and LCBI by carbapenem resistant Gram-negative bacteria (CRGNB). The independent variables analyzed were gender, age, hematological diagnosis, type of chemotherapy, chemotherapy drug, outpatient or inpatient chemotherapy, number of chemotherapy cycles, neutropenia on LCBI diagnosis, lymphopenia on LCBI diagnosis, invasive devices use, ICU stay at LCBI diagnosis, site of infection, ECOG, Karnofsky performance score. The analysis was performed by LCBI episode. Statistical analysis was performed by chi-square, Fisher and Mann-Whitney test when appropriated and logistic regression for multivariate analysis.

Results: During study period 1467 patients were submitted to chemotherapy. It was identified 167 LCBI in 135 (9.2%) patients. The most common hematological diagnosis was acute myeloid leukemia, 41 (24.6%). 118 (70.7%) episodes occurred during neutropenia period. The most common site of infection was intrabdominal infection, 59 (35.3%). MDR bacteria were identified in 60 (35.9%) episodes, and LCBI by CRGNB occurred in 35 (21.0%) cases. 12 (7.2%) LCBI by MDR were identified in patients under ambulatory chemotherapy. Variables identified in final model of risk factors for LCBI by MDR were: chemotherapy during hospital stay (p<0.02, OR 2.60 CI95% 1.20-5.67), mechanical ventilation in previous 7 days of LCBI (p<0.001, OR 3.45, CI95% 1.46-7.17), and chemotherapy with cytarabine (p<0.06, OR 1.91 CI95% 0.95-3.85). Risk factors for LCBI by CRGNB in final model were chemotherapy during hospital stay (p<0.02, OR 3.66, CI95% 1.27-10.56), mechanical ventilation in previous 7 days of LCBI (p<0.001, OR 4.08, CI95% 1.79-9.32), chemotherapy with vincristine (p<0.10, OR 1.98 CI95% 0.86-4.55).

Conclusions: Hospital assistance is the most important determinant of MDR infections among hematological patients. Different types of chemotherapy drugs maybe associated to different risks for MDR infections.

Distribution of minimum inhibitory concentration of ceftriaxone to gonococcal strains in a reference sexually-transmitted disease clinic in Madrid, Spain

Clara Lejarraga*1, Blanca Menendez1, Estela Tello1, Flor Geriz1, Oskar Ayerdi1, Teresa Puerta1, Mar Vera Garcia1, Juan Ballesteros1, Petunia Clavo1, Giovanna Delia1, Carmen Rodriguez1, Jorge Del Romero1

1Centro Sanitario Sandoval, Hospital Clinico San Carlos, IdISSC, Madrid, Spain

Background: Sexually transmitted infections (STI) are increasing all around the world. Considering that N.gonorhoeae is a common STIs worldwide, with an estimated 87 million new cases in 2016, lack of effective treatment would result in a major public health problem. Some isolated ceftriaxone-resistant strains of N. gonorhoeae have recently been reported. Overall, stronger surveillance is needed to better characterize the extent of antimicrobial resistance among gonococcal strains. The aim of this study was to know the minimum inhibitory concentration (MIC) for ceftriaxone to gonococcal strains in a reference STI/HIV clinic in Madrid.

Materials/methods: A total of 240 N. gonorrhoeae isolates were collected, from June until October 2019 in Centro Sanitario Sandoval. Urethral, pharyngeal, rectal and endocervical swabs were cultured on Chocolate agar PolyViteX VCAT3 [BioMérieux]. Neisseria gonorrhoeae was identified using API®NH [Biomerieux]. Moreover, all samples were identified using RT-PCR [Abbott RealTime CT/NG]. Consequently, we determined the MIC for ceftriaxone by using the E-test strip [Liofilchen srl], after 24 hours of culture. MIC (mg/l) values were interpreted according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST).

Results: 240 gonococcal isolates were tested for ceftriaxone susceptibility. Seventy-nine strains were urethral infection, 126 were rectal infection, 31 were pharyngeal infections and 4 were endocervical infections. Distribution by ages and gender shows that 91.7% of the samples were collected from men with ages between 16 and 58 years old, and 73.3% of them were men who have sex with men (MSM). Ceftriaxone MICs ranged from less than 0.002 to 0.016 mg/L. The MICs distribution for ceftriaxone are shown in Table 1.

Conclusions: Not only none of the strains have a decrease in the sensitivity but also the 50% of the isolates have a MIC below 0.003, therefore, we should consider ceftriaxone as monotherapy.

Background: Mucormycosis is a rare and life-threatening invasive fungal infection occurring mostly in immunocompromised patients. The most common presentations of mucormycosis are pulmonary, rhinocerebral and cutaneous. New therapeutic and diagnostic tools have become available. We aimed to describe current pulmonary mucormycosis presentation, diagnosis, therapeutic management and outcome.

Materials/methods: A multicenter retrospective survey was conducted in six French tertiary hospitals. Patients diagnosed with pulmonary mucormycosis, localized or disseminated, according to modified EORTC/MSG criteria were enrolled. Patients with positive results of quantitative PCR (qPCR) in serum without other mycological criteria were classified as putative mucormycosis.

Results: From January 2008 to January 2019, 112 patients were recruited including 49 proven, 43 probable and 20 putative cases. Mucormycosis was disseminated in 40% patients. Eighteen percent of patients were diagnosed post-mortem. Main risk factors for mucormycosis were hematological malignancy (48%), allogeneic hematologic stem cell transplantation (21%), and solid organ transplantation (17%). Fourteen percent of patients developed mucormycosis while on posaconazole prophylaxis. Median time to diagnosis was 13 [7-23] days after first symptom, which was isolated fever in 67% cases.

CT-scan showed vascular involvement in 19% cases. Ground-glass opacity was more frequent in neutropenic patients than in non-neutropenic patients (64% vs 32%, p<0.01). A bronchoalveolar lavage contributed to diagnosis in 54/94 cases (57%). A qPCR was positive in serum in 32/40 patients (80%). The most frequent Mucorales genus were Rhizopus (31%), Rhizomucor (30%) and Lichtheimia (26%). Histological analysis revealed more frequently angio-invasion in patients with disseminated mucormycosis than with localized mucormycosis (58% vs 10%, p<0.01). Antifungal therapy was initiated in 86% patients and based on liposomal amphotericin B in 91/96 cases. Surgical excision was performed in 14% patients. Post-operative complications occurred in 5/16 patients, contributing to death in 3 patients. Fifty-three percent patients were admitted in ICU. Mortality rate was 33% at day 14 and 59% at day 90.

Conclusions: There are several different clinical pictures of pulmonary mucormycosis. A high mortality rate is observed despite the use of early liposomal amphotericin B treatment. Non-invasive diagnostic techniques such as qPCR assays should be used as a screening tool in febrile patients at risk for mucormycosis.

**Abstract 8010**

**A retrospective study of rhinoviruses molecular diversity in three Paris hospitals: differential behaviours of HRV groups?**

Oshra Haddad¹, Mélanie Bertine¹, Nadhira Fidouh¹, Donia Bouzid¹, Xavier Duval¹, Vincent Bunel², Raphael Borie³, Jean-Christophe Lucet⁴, Diane Descamps¹, Benoit Visseaux*¹⁶

**Background:** Rhinoviruses are commonly thought as only the “common cold” agent. Recent diagnosis improvements revealed their high frequency among lower respiratory tract infection. The role, molecular epidemiology and patients’ characteristics associated to these viruses are still unclear today.

**Materials/methods:** We retrospectively included all nasopharyngeal or bronchoalveolar-lavages positive for rhinovirus using multiplex PCR assay in three Paris hospitals, France, from January to September 2018. The VP2/VP4 region was sequenced for subtyping. Associated clinical data were retrieved.

**Results:** Rhinoviruses were identified among 178 patients during the study period, mostly male (56%), with a median age of 62.2 [IQR:46.8-71.4] and frequently presenting chronic respiratory diseases (56%) and/or immunosuppression (46%). 63% of patients presented respiratory distress. Pneumonia diagnostic was retained for 25% of all patients. 95 (53%), 27 (15%) and 56 (32%) were HRV group A, B and C positive, respectively. HRV-B, compared to HRV-A and -C, appeared associated with immunosuppressor (56 vs 31 and 34% of patients, respectively, p=0.058), higher ICU admission rates (30 vs 17 and 9%, p=0.055) higher coinfections rates (52 vs 35 and 23%, p=0.04), and longer hospitalisation duration. Inversely, HRV-A was more frequently associated to a final diagnostic of pneumonia (54 vs 31 and 11% for HRV-B and -C, p=0.01). 137 HRV positive samples were identified <48h of hospitalisation and 41 >96h of hospitalisation. The latter were associated to higher ICU admission rates (29 vs 12%, p=0.01) and longer hospitalisation duration (22 vs 4 days, p<0.0001).

**Conclusions:** In this retrospective study, we highlight the high proportion of rhinovirus positive patients with chronic respiratory diseases or immunosuppression (69%) and observed some differences between rhinoviruses group regarding patients’ population or retained pneumonia diagnosis.

In vitro antibacterial activities of cefiderocol (S-649266) against multidrug-resistant Acinetobacter baumannii

Jacinda Abdul-Mutakabbir*1, Logan Nguyen1, Philip Maassen2, Kyle Stamper2, Katherine Lev2, Razieh Kebriaei3, Keith S. Kaye4, Michael J. Rybak5

1Wayne State University, Detroit, United States, 2Wayne State University, Detroit, United States, 3Wayne State University, Detroit, United States, 4University of Michigan, Ann Arbor, United States, 5Wayne State University, Detroit, United States

Background: The propensity for Acinetobacter baumannii to develop mechanisms of resistance against antimicrobials has rendered most therapeutic options ineffective. Nevertheless Cefiderocol (FDC), a siderophore-antibiotic conjugate, has shown success in overcoming the dependence on the outer membrane porins for bacterial entry. In A. baumannii, FDC has demonstrated potent activity against MDR isolates. However, the activity of FDC in combination with additional antimicrobials has yet to be evaluated. The objective of this study was to determine the activity of FDC alone and in combination with other antimicrobials through minimum inhibitory concentration (MIC) testing and time-kill experiments (TKE).

Materials/methods: One hundred and fifty carbapenem-resistant isolates, including 32 COL-resistant (COL-R) strains, were evaluated using MIC testing and TKE. MIC testing via broth micro-dilution was performed for FDC, colistin (COL), meropenem (MEM), amikacin (AMK), tigecycline (TGC), minocycline (MIN), ampicillin (AMP), sulbactam (SUL), and ceftazidime (CAZ). Four representative strains, displaying the highest MICs to FDC (16-32 mg/l), were selected for synergy testing via 24-h TKE. A bacterial reduction of $\geq 3 \log_{10}$ CFU/ml from the starting inoculum was considered bactericidal activity, while a $>2 \log_{10}$ CFU/ml reduction from the most active single agent was considered synergistic activity.

Results: The MIC testing revealed a lower range of MIC values for FDC in comparison to the other agents evaluated, with both the FDC MIC50 and MIC90 demonstrating 1 mg/l for the COL-S strains. While in the 32 COL-R strains, the MIC50 and MIC90 was 1 mg/l and 4 mg/l, respectively. In the TKEs, we observed synergistic activity with FDC and all other Gram-negative agents tested. Most notably, each of the TKEs demonstrated both synergistic and bactericidal activity, indicated by an average 4 $\log_{10}$ CFU/ml reduction in bacterial counts, with the FDC +AMK and FDC+MEM combinations. The enhanced activity occurred despite the increased MICs of 256 mg/l and 64 mg/l for AMK and MEM, respectively.

Conclusions: Susceptibility testing demonstrated that FDC is highly active against carbapenem-resistant A. baumannii including COL-R isolates. The combination of FDC with other agents showed promise in eradicating MDR A. baumannii. Further research is warranted to solidify the role of FDC-based combination treatment in current therapy.

Abstract 8012

Prevalence of *Mycoplasma pneumoniae* infections during six years (2014-2019) in two hospitals of Saint Petersburg

Olga Kameneva¹, Svetlana Morozova², Natalia Kameneva², Valentina Zhukova⁴, Karina Kosyakova*³

¹Municipal Children’s Hospital №22, Saint Petersburg, Russian Federation, ²Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation, ³North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation

**Background:** Epidemics of *Mycoplasma pneumoniae* (Mp) infections typically occur in 3–7 year intervals, with seasonal peaks in autumn and winter. The diagnostics of mycoplasmosis is carried out by detection of DNA or antigens of pathogen in sample and specific antibodies in serum because of the lack of pathognomonic signs. The purpose is to assess an incidence of MP among children and adults from Saint Petersburg, that have a community-acquired pneumonia or other respiratory infections.

**Materials/methods:** During six years between 2014 and 2017, 1471 patients of Kolpino district of Saint-Petersburg [945 children and 526 adults] were screened for Mp. Specimens were mostly nasopharyngeal (NPS) or oropharyngeal (OPS) swab (n=1302), sputum (n=167), pleural fluid (n=2). Specimens were extracted using AmpliSens®RIBO-prep [InterLabService Ltd.] and detection was performed on CFX96 [Bio-Rad] with AmpliSens® Mp/Cp [InterLabService Ltd.]. Specific antibodies were detected with Mp-IgG-EIA-BEST and Mp-IgM-EIA-BEST [Vector-Best].

**Results:** Mp was detected among 222 of 1471 specimens, moreover the percentage of patients with DNA of pathogen was higher among children than adults [16.3 children:11.8% adults]. A frequency of detection of Mp during 2014-2016 years was 3.1-3.6%, during 2017-2019 years the frequency had increased to annual average 11.1-23.0% (children) and 9.4-16.9% (adults). The maximum level of Mp detection was registered from September of 2018 till January of 2019: 18.2-38.8% (children) and 11.1-31.6% (adults).

IgG, IgM antibodies to Mp were detected in 28 children with positive and in 6 children with negative results of PCR of specimens from the upper respiratory tract. 23 (82.1%) patients with Mp had antibodies [IgG, IgM], 1 patient with Mp had IgG, that verified the diagnosis of mycoplasma pneumonia; 4 patients with Mp hadn’t IgG, IgM. Among 6 children with PCR negative results, only 1 patient had IgM, the antibodies in serum of other 5 patients weren’t detected.

**Conclusions:** At 2017-2019 years there was an increase Mp detection till 38.8% [children] and till 31.6% [adults] at the hospitals of Saint-Petersburg, mainly in autumn and winter. For accurate diagnosis of a community-acquired pneumonia the molecular biology test should be supply the serological diagnostic methods.

**Evaluation of the efficacy of combination of antifungals against invasive aspergillosis in an invertebrate animal model**

Sana Jemel*1,2, Vincent Jullien1, Eliane Billaud3, Jacques Guillot3, Françoise Botterel1,4, Eric Dannaoui1,5

1EA DYNAMYC UPEC, EnVa, USC Anses, Faculté de Médecine de Créteil, Créteil, France, 2Service de mycologie et de parasitologie CHU La Rabta, Tunis, Tunisia, 3Université Paris-Descartes, Faculté de Médecine, APHP, Hôpital Européen Georges Pompidou, Service de Pharmacologie, Paris, France, 4Unité de Parasitologie - Mycologie, Département de Bactériologie Virologie Hygiène, Mycologie Parasitologie, DHU VIC, CHU Henri Mondor, Créteil, France, 5Université Paris-Descartes, Faculté de Médecine, APHP, Hôpital Européen Georges Pompidou, Unité de Parasitologie-Mycologie, Service de Microbiologie, Paris, France

**Background:** Evaluation of new therapeutic strategies for the treatment of aspergillosis is needed due to emergence of azole-resistance in Aspergillus fumigatus (Af). Galleria mellonella is a promising invertebrate model to estimate antifungal efficacy in vivo. The aim of the study was to evaluate the efficacy of antifungal combination against azole-resistant Af in G. mellonella model.

**Materials/methods:** Two Af clinical strains have been used: HEGP064, a susceptible strain without any Cyp 51A mutation, and HEGP2666, an azole-resistant strain with TR34/L98H mutation. Groups of 10 G. mellonella larvae were infected with the LD90 (inoculum concentration that gave 90% mortality at 7 days post-infection) and treated by voriconazole (VRZ, [Vfend®]) at 0.5, 1, 2, 4, and 8 µg/larva. Subsequently, HEGP064 or HEGP2666-infected larvae were treated by VRZ at 4 µg/mL alone and in combination with caspofungine (CSP) at 4, 2 or 1 µg/larvae. The mortality was estimated daily for 7 days. The pharmacokinetics of VRZ in the hemolymph was established in uninfected larvae and in HEGP064-infected larvae by recovering the hemolymph after injection of VRZ at 1, 4, 8 and 16 µg/larva. Dosage was performed by mass spectrometry coupled with high performance liquid chromatography.

**Results:** The LD90 values for the HEGP064 and HEGP2666 strains were 4.38x10^7 and 1x10^8 CFU/mL, respectively. In untreated groups, mortality was at least 90% on day 7 post-infection. VRZ at 4 µg/larva increased significantly the mortality of HEGP064-infected larvae (p=0.0007) but not HEGP2666-infected ones (p=0.25). Bitherapy (VRZ 4 µg/larva and CSP 4 µg/larva) lead to a more significant decrease in mortality compared to monotherapy (VRZ 4 µg/larva) and control group infected by HEGP064 (p=0.002) or HEGP2666 (p=0.0018) strain. Combination of CSP (1 and 2 µg/larva) decreased significantly mortality of HEGP2666-infected larvae compared to untreated larvae (p=0.037 and 0.024, respectively). Residual doses of VRZ in hemolymph were higher in infected versus non-infected larvae.

**Conclusions:** The combination VRZ-CSP showed its effectiveness in G. mellonella model especially when larvae were infected with an azole-resistant strain. This model could be used for screening and evaluation of different therapeutic strategies for the treatment of aspergillosis.

**Predict to prevent: system dynamic modeling for healthcare-associated influenza**

Martina Sansone*, Lars-Magnus Andersson, Johan Westin, Rickard Norden

*Sahlgrenska University Hospital, Institute of Biomedicine, Gothenburg, Sweden*

**Background:** System dynamic modelling is a way to illustrate complex problems including non-linear relationships and multiple interactions. Our aim was to develop a model to estimate healthcare-associated influenza (HCAI).

**Materials/methods:** By using ithink® computer simulation software1, we constructed a model for predicting the accumulated number of healthcare associated influenza cases per season. The model was constructed based on hospital data obtained from previous seasons regarding patient flow and management as well as national surveillance data and relevant published data. Multiple step-wise simulations were performed to identify potential strategies in order to reduce nosocomial influenza transmission.

**Results:** Seasonal scenarios regarding the number of patients exposed for influenza by shared ward room, diagnostic accuracy at the emergency ward, the extent of antiviral treatment as well as post-exposure prophylaxis were investigated. In total, 240 simulations were performed. The single most effective preventive measure was post-exposure prophylaxis followed by reduced number of exposed patients per ward room (Table 1). Antiviral treatment of symptomatic cases may have individual benefits but seem to have limited impact on in-hospital transmission in the current model.

**Conclusions:** System dynamics is a valuable tool which may help hospitals to improve infection control policies. Preventive measures rely on early identification of influenza cases, and antiviral prophylaxis seem to be the most effective way to reduce in-hospital transmission.

Table 1. Accumulated seasonal estimates of HCAI-cases according to share of exposed patients treated with antiviral prophylaxis and mean number of exposed patients per room.

Abstract 8017

Urine alkaline pH effect on ciprofloxacin and fosfomycin efficacy in a murine urinary tract infection model by Escherichia coli

Marta Claudia Carretero Ledesma*1, Tania Cebrero Cangueiro1, Gema Labrador Herrera1, Younes Smani1, Jose Miguel Cisneros Herreros1, Jeronimo Pachon-Diaz1, Jesus Blazquez2, Elisa Cordero Matias1, Maria Eugenia Pachon-Ibáñez2

1University Hospital Virgen del Rocío/CSIC /University of Seville, Sevilla, Spain; 2National Centre for Biotechnology, CSIC, Madrid, Spain

Abstract third-party references: University Hospital Virgen del Rocío/CSIC, Institute of Biomedicine of Seville (IBiS), University of Seville

Background: The high incidence of urinary tract infections (UTI) by Escherichia coli in renal transplant recipients, in the era of antimicrobial resistance, prompts to optimize treatments. This work evaluates the effect of urinary alkaline pH on the efficacy of ciprofloxacin (CIP) and fosfomycin (FOS) in a UTI model and the development of resistance.

Materials/methods: An UTI murine model by E. coli using a wild-type [NU14], 2 low-level quinolone resistant [LLQR, NU14-D87G and NU14-S83A] and 3 low-level fosfomycin resistant [LLFR, NU14-glpT, NU14-uhPT and NU14-cyaA] strains. Seventy-two hours before infection, 5% glucose or 5% glucose plus 0.5% sodium bicarbonate was added to the drinking water. C57BL/6J female mice were transurethral inoculated with 50 x 10^5 cfu/ml. Forty-eight hours post-infection, therapy was initiated. Groups: i) control, infected not treated, ii) CIP [20mg/kg/ip/12h/24h], and iii) FOS [500mg/kg/ip/8h/24h]. After 24h, bacterial concentrations in aseptically collected urine and bladder were analysed (U Mann-Whitney test) and MIC of CIP and FOS were determined.

Results: CIP and FOS were similarly effective, independently of the urine pH (table). The treatment with CIP increased its MIC against the LLQR strains from 0.125/0.25 to 64/1.28 mg/l. Treatment with FOS did not increase its MIC for LLFR.

Conclusions: CIP and FOS are effective in UTI model, at both urinary pH. CIP resistance appeared after 24 hours of treatment.

Abstract 8018

**Catheter-associated urinary tract infections in patients hospitalised in intensive care unit**

Moufida Hamidi*, Hanifa Belekhal, Samia Yahi, Dalila Bougdal, Souhila Sadat, Kamel Mustapha Guenane, Mohamed Fatih Denia

1University of Algiers 1/Salim Zemirli Emergency Hospital, Algiers, Algeria, 2Salim Zemirli Emergency Hospital, Algiers, Algeria

**Background:** The occurrence of urinary tract infections in patients referred for intensive care is almost inevitable; it is proportionally related to the duration of bladder catheterization.

We aimed to determine the causative agents of Catheter-associated urinary tract infections in patients hospitalised in intensive care unit and antimicrobial susceptibilities of the pathogens.

**Materials/methods:** This is a retrospective study from January 2012 to July 2019, where the positive results of urines performed in patients surveyed with at least one clinical sign (fever, hypothermia, sepsis) hospitalised in intensive care are selected for study. A threshold of $10^5$ CFU/ml is used for the diagnosis of urinary tract infection. The antimicrobial sensitivity test of isolated strains is performed according to CLSI recommendations. The Whonet 5.6 software is used to analyze the antibiotic sensitivity of the main bacterial species found.

**Results:** CA-UTI rate was 17.24% (95% CI: 15.01-19.72%). A total of 214 patients (mean age 40.2 years, sex ratio m/f: 1.27) had positive urinary tract infections with 245 strains distributed as follows:

- 58% of gram-negative bacilli, with *Escherichia coli* (48, 34%), *Klebsiella pneumoniae* (31, 22%), *Acinetobacter baumannii* (30, 21%)
- Gram-positive cocci account for 23% (57 strains) dominated by *Enterococcus* sp and *Staphylococcus* non-aureus with 51% and 23% respectively and 19% (46) yeasts, mainly *Candida albicans*.

The resistance of *Escherichia coli* to ampicillin, cotrimoxazole, ciprofloxacin and gentamicin is of the order of 80%, 45%, 25% and 20% respectively.

More than half (53%) of *Klebsiella pneumoniae* produce extended spectrum beta-lactamase (ESBL), 80% of *Acinetobacter baumannii* are resistant to imipenem. The same germ was isolated at least twice in 116 patients after the catheter was changed.

Bacteremia were recorded in 42 patients with mainly *Klebsiella pneumoniae* and *Acinetobacter baumannii*, 4 cases of candidemia due to *Candida albicans* were reported.

**Conclusions:** Gram-negative rods (58%) represent the main isolated germs of urinary tract infections with high rates of antimicrobial resistance which forms an important reservoir of multidrug-resistant bacteria.

The proportion of *Candida* spp is not negligible (19%) probably due to the use of broad-spectrum antibiotics in intensive care unit.

Abstract 8019

Genome sequencing of Leishmania infantum causing cutaneous leishmaniosis from a Turkish isolate: meta-analitic study for evaluation of proteins with polymorphism

Dilek Guldemir*1, Serpil Nalbantoglu2

1Public Health General Directorate, Ankara, Turkey, 2Ankara University, Faculty of Veterinary Medicine, Ankara, Turkey

Background: It has been nearly 13-14 years since the completion of the first whole-genome sequence (WGS) of a Leishmania parasite. However, much information about these parasites remains to be elucidated, such as the causes of differences in tissue tropism. The aim of this study is to evaluate of proteins with polymorphism on the WGS of L.infantum causing cutaneous leishmaniosis from a Turkish isolate.

Materials/methods: Genomic sequencing was performed on the Illumina HiSeq 2500 platform. The TruSeq Nano DNA Low Throughput Library Prep Kit, compatible with the Illumina HiSeq 2500 platform, was used to generate the library. Synthesis sequencing (SBS) was performed with a HiSeq Rapid SBS Kit v2 to generate single-fragment reads (2 x 150 bp; PE) with two fragment end-to-end assemblies. Bioinformatics analyses were performed on the Geneious 11.0.5. (www.genius.com) platform. L.infantum JPCM5 strain was used as the reference genome for genome mapping. Polymorphic regions were determined by using the Find Variations/SNPs program on the Geneious platform. The literature review was searched by using PubMed database for this proteins with polymorphism.

Results: In our study, a high-quality WGS of L.infantum was successfully generated, and a total of 32,009,138 bp of genomic DNA from 36 chromosomes were obtained. The genomic DNA sequence was submitted to the NCBI GenBank (www.ncbi.nlm.nih.gov) database and registered under the name Leishmania infantum_TR01. The accession numbers of the 36 chromosome of the L.infantum genome available from the NCBI [BioProject PRJNA433593]. As a result of the annotation of the genome, 3153 polymorphisms, 8324 genes, 8199 CDSs, 8109 mRNAs, 6 T tRNAs, 11 rRNAs and 58 ncRNA were identified.

Conclusions: The protein-coding-polymorphisms were found 166 among the 3153 polymorphisms, affecting 63 different proteins. In literature, it was determined that 14 studies of these 63 proteins have been done before. Of the 14 proteins mentioned herein, 5 are related to virulence, 2 to vaccine candidate, 4 to diagnosis / typing, 2 to drug resistance, 3 to drug target and 1 to vital function. The data obtained in our study contributes to sciences, provides a basis for Leishmania genome studies in Turkey and will contribute to studies a global level.

Abstract 8020

A review of the resistance to integrase inhibitors in HIV-1 patients in a third level hospital: a four-year experience
Laura Vanessa Haces Pinto1, David Ampuero1,2, Ana Candela*, Paula García Morales1, María Angeles Jodar Checa1, Roberto Alonso1,3, Patricia Muñoz1,3,4

1 Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases Department, Madrid, Spain, 1 ISGlobal, Barcelona Institute for Global Health, Barcelona, Spain, 3 Universidad Complutense de Madrid, Department of Medicine, School of Medicine, Madrid, Spain, 4 Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Hospital Gregorio Marañón, Madrid, Spain

Background: The Integrase inhibitors [INIs] have been the last drug family to join the antiretroviral therapy for human immunodeficiency virus type 1 (HIV-1) infection. Currently the resistance prevalence to these drugs remains unknown, perhaps due to the lack of commercialized and standardized detection methods, for that reason our laboratory has implemented a “home-made” INIs resistance detection technique. The objectives of our study are to determine the prevalence of INIs resistance in our Hospital and to share the diagnostic approach used in our laboratory.

Materials/methods: A retrospective and descriptive study was carried out. All the requested samples to determine Raltegravir (RAL), Elvitegravir (EVG), Dolutegravir (DTG) and Bictegravir (BIC) resistance, between September 2015 and October 2019, were analysed, excluding those with viral load < 700 copies/mL or non-interpretable sequences. The genetic material extraction was made using the EZ1 system (QIAGEN) and the sequencing reactions were performed according to the Sanger method using primers RT-INTF , RT-INTR, INT-SF and INT-SR. Raw data was edited with Bioedit software and analysed with Geno2Pheno (Max Planck Institute) and HIV Drug Resistance Database (Stanford University).

Results: Out of the 188 samples submitted, 131 could be included and 17 (13%) showed resistance mutations. Major resistance mutations were observed in 10 (58.8%) of the samples, being the N155H the most frequent mutation with resistance to RAL and ELV. In the remaining 7 (42%) samples, accessory mutations were observed, all of them related to the presence of potential low-level resistance to any of the four drugs.

Conclusions: Prevalence of INIs resistance in our centre was observed at considerable proportion. Samples carrying the N155H mutation were mainly associated to RAL and ELV resistance, supporting the known high genetic barrier of DTG and BIC. The relevance of the strains with accessory resistance mutation is still unknown, therefore, more studies, greater number of cases and a standardized PCR technique may be useful to assess what could be a future concern.

Abstract 8027

Rapid identification of methicillin-resistant Staphylococcus aureus (MRSA) in clinical microbiology labs by infrared spectral fingerprinting following growth on agar supplemented with cefoxitin

Tamao Tsutsumi*1, Charles Frenette2, Nancy Doherty2, Jacqueline Sedman1, Ashraf Ismail1

1McGill University - Macdonald Campus, Sainte-Anne-de-Bellevue, Canada; 2McGill University Health Centre, Montréal, Canada

Background: Staphylococcus aureus is a leading cause of bacterial infections in humans, ranging from skin, wound, and surgical-site infections to potentially life-threatening invasive endocarditis and bloodstream infections. It is critical to rapidly identify the causative agent as methicillin-susceptible (MSSA) or methicillin-resistant S. aureus (MRSA) for appropriate treatment of invasive infections. In previous work, we employed Fourier transform infrared (FTIR) spectroscopy as a rapid and cost-effective technique for discrimination between S. aureus and coagulase-negative staphylococci (CoNS) by developing a spectral database. In this study, we use this database in conjunction with a modified growth protocol, employing cefoxitin to inhibit growth of MSSA, for FTIR-based MRSA identification with high sensitivity and selectivity.

Materials/methods: Blood agar plates (BAP) were made using Columbia agar (5% sheep blood) supplemented with colistin (10 mg/L) and nalidixic acid (15 mg/L) (CNA) to inhibit Gram-negative bacteria and with cefoxitin at levels of 4 mg/L (4FOX) and 8 mg/L (8FOX). 234 staphylococcal isolates (previously identified by MALDI-TOF MS) were cultured on BAP, 4FOX-CNA-BAP, 8FOX-CNA-BAP and MRSA selective chromogenic agar. Isolated colonies were deposited onto IR-reflective slides for FTIR spectral acquisition and identified as S. aureus or CoNS by matching their spectra against the FTIR spectral database. Isolates were identified as MRSA if colonies growing on cefoxitin-containing agar were spectrally identified as S. aureus.

Results: All S. aureus (n = 86) and CoNS (n = 144) isolates were correctly identified by matching their FTIR spectra against the spectral database, irrespective of whether they had been cultured with or without antibiotics. Based on comparison with VITEK 2 AST results, MRSA was identified with 100% sensitivity and 100% specificity at 24 hours incubation when isolates were grown on 8FOX-CNA-BAP, whereas growth on 4FOX-CNA-BAP yielded 100% sensitivity and 97% specificity. These results were comparable to those obtained with MRSA selective chromogenic agar (97.8% sensitivity and 100% specificity).

Conclusions: This new FTIR-based methodology achieved high sensitivity and specificity for MRSA identification through accurate identification of S. aureus isolated on cefoxitin-containing agar. As an MRSA screening tool, this methodology may provide an alternative to the use of costly chromogenic media at substantially lower cost.

The role of procalcitonin as a predictor of severity, prognosis and appropriate empirical antibiotic therapy in community-acquired pneumonia of bacterial aetiology

Alessandro Milia*, Lorenzo Roberto Suardi, Carlo Nozzoli, Filippo Pieralli

Università di Firenze, Dipartimento di Medicina Sperimentale e Clinica, Firenze, Italy, Careggi University Hospital, Firenze, Italy, Azienda Ospedaliero Universitaria Careggi, SOD Medicina Interna ad Alta Intensità, Firenze, Italy

Background: The role of procalcitonin (PCT) in patients hospitalized for community acquired pneumonia (CAP) outside the ICU is still undefined, as well its role as predictor of appropriateness of antibiotic therapy. In this study we aimed to define the prognostic role of PCT and its association with appropriateness of antimicrobial treatment in patients with bacterial CAP (BCAP) admitted to Internal Medicine wards.

Materials/methods: We retrospectively analyzed consecutive patients with BCAP (defined by bacterial isolation from sputum, bronchoalveolar lavage, blood cultures or recovery of urinary antigens). We evaluated the association of PCT at admission (APCT), subsequent 1 (∆-24h-PCT), 4-5 days (∆4-5d-PCT) variations with in-hospital mortality and need of intensive respiratory and vasopressor support (IVRS). We also explored the relationship between appropriateness of initial empirical antimicrobial therapy (IET) and APCT, ∆-24h-PCT, ∆4-5d-PCT and clinical evolution identified by MEWS score variations 0-72 hours.

Results: 356 patients with CAP were screened; 56 (15.7%) had BCAP. The median values of APCT were higher in BCAP with positive cultural analysis of sputum or bronchoalveolar lavage versus patients with no isolation at the same diagnostic exams (2.87 vs 0.33; p=0.006). We found neither association between APCT, nor its variations, and in-hospital mortality. In patients with BCAP, APCT was an independent predictor of IVRS at multivariate analysis, and the most accurate cut-off was 3.4 ng/ml (OR 16.67; 95%CI 2.9-95; p<0.001. PPV 81% NPV 68%). ∆-24h-PCT and ∆4-5d-PCT values were not associated with an increased risk of IVRS. PCT values and variations were not predictive of inappropriate IET, which was an independent predictor itself of in-hospital mortality (OR 68.2; 95%CI 1.7-271.87; p= 0.025). Only worsening of MEWS was related to inappropriate IET (OR 4; 95%CI 1.18-13.49; p=0.022).

Conclusions: APCT revealed to be a useful predictor of bacterial etiology of CAP. Moreover, APCT was an independent predictor of IVRS but not of in-hospital mortality. PCT values and variations were not predictive of appropriateness of IET. PCT it doesn’t appear useful for identifying the appropriateness of antimicrobial therapy, suggesting that upgrading empirical antibiotic therapy based on PCT variation is not an appropriate strategy subsequently leading to antibiotics overuse.

Abstract 8037

Potential use of data from a national HIV testing surveillance system to improve community-based testing strategies, Ireland

Melissa Brady*, Kate O’donnell¹, Adam Shanley², Erin Nugent¹, Caroline Hurley¹, Maitiú O’tuathail³, Margaret Fitzgerald⁴, Cillian Flynn⁵, Richard Carson⁷, Derval Igoe¹

¹HSE Health Protection Surveillance Centre (HPSC), Dublin, Ireland, ²HIV Ireland, Dublin, Ireland, ³HSE Sexual Health and Crisis Pregnancy Programme, Dublin, Ireland, ⁴Safetynet Primary Care, Dublin, Ireland, ⁵HSE Social inclusion and Vulnerable groups, Dublin, Ireland, ⁶Gender, Orientation, Sexual Health and HIV (GOSHH), Limerick, Ireland, ⁷AIDS Care Education & Training, Dublin, Ireland

Background: An estimated 10% of people living with HIV in Ireland do not know their HIV status. Data from surveillance of national voluntary community-based HIV testing (VCBT) can be used to improve targeting of hard-to-reach groups and reduce the proportion of undiagnosed individuals.

Materials/methods: National monitoring of VCBT commenced in Ireland in 2018; data are provided by statutory and non-statutory organisations to the Health Protection Surveillance Centre. This study includes available case based data on individuals who underwent VCBT (using rapid point-of-care-test methods) during the period 01st January 2018 to 31st December 2018. Analysis was conducted of reactivity rates by country of birth, and whether clients were first-time or repeat testers.

Results: In all, data on 2,643 results were reviewed.

Twenty-one (0.8%) people had a reactive HIV test result, 20 of whom were male and one was female. Age was available for 76% of cases, median age was 29 years (range: 19 - 60 years).

Of 21 individuals with a reactive test result, 19 were men who have sex with men. By country of birth, the highest proportion of people who had a reactive test were born in Latin America (n=10; 48%), six were born in Ireland, two in sub-Saharan Africa, and three in other countries.

Information on whether or not the client had previously tested for HIV was available for 2,443 tests. Of those, 776 (32%) were first time testers and 1667 (68%) were repeat testers.

HIV test reactivity rate was similar among first-time testers (0.8%) and repeat testers (0.9%) overall. We found a higher reactivity rate in first time testers born in Latin America (6.3%) and in sub-Saharan Africa (3.7%).

Conclusions: Data from surveillance of VCBT can be used to improve targeting and increase uptake of community HIV testing among people at risk of HIV. Design of future VCBT strategies, including information and promotion campaigns, should take into account differences in HIV test reactivity among demographic subgroups, and by history of having tested previously. Separate messaging campaigns designed to reach first-time testers and repeat testers may help to increase/retain uptake in both groups.

Abstract 8038

In vivo virulence of different growth states of Pseudomonas aeruginosa

Fien De Winter*1, Rohit Ruhal2, Bart S. Jongers1, Basil Britto Xavier1, Christine Lammens2, Herman Goossens2, Surbhi Malhotra-Kumar2, Samir Kumar-Singh1

1University of Antwerp, Laboratory of Cell Biology and Histology, Molecular Pathology Group, Antwerpen, Belgium, 2University of Antwerp, Laboratory of Medical Microbiology, Antwerpen, Belgium

Background: Pseudomonas aeruginosa biofilms are often involved in chronic or recurrent infections and associated with high mortality. Inducing dispersal of cells in the biofilm is a strategy that is being explored to regain effectiveness of antibiotics in biofilm related infections. However, prior in vitro data suggest that these induced dispersed cells express more virulence factors. Here, we employ a pneumonia model to study in vivo virulence and immune responses against different P. aeruginosa biofilm and dispersed phenotypes.

Materials/methods: 1E6 CFU of biofilm, planktonic form (bacteria collected from broth cultures), and uninduced (naturally dispersed from biofilm) and induced dispersed cells by either nitric oxide treatment or depletion of c-di-GMP were intratracheally inoculated in mice. As control, sham animals were utilized where mice were inoculated with saline. Animals were monitored for 24 hours before euthanization after which bacterial counts were estimated in bronchoalveolar lavage fluid, lungs, liver and spleen. Cytokines were studied from serum by a meso-scale discovery panel containing IFN-γ, IL-10, IL12p70, IL-1β, IL-2, IL-4, IL-5, IL-6, KC/GRO and TNF-α.

Results: Animals treated with induced dispersal methods (nitric oxide treated or c-di-GMP depleted) showed a significant drop in survival within 24 hours compared to animals treated with other P. aeruginosa cell phenotypes. Dissemination in hematopoietic organs was significantly higher in induced dispersed cells and planktonic cells compared to biofilm and untreated biofilm cells. In serum, the similarities observed in CFU counts were also reflected in the cytokine measurements with planktonic cells showing significant upregulation for KC/GRO and IL-6 compared to other groups.

Conclusions: Here we show that induced dispersed cells lead to higher mortality and dissemination in hematopoietic organs when compared to biofilm cells or uninduced dispersed cells. These data suggest that although induced dispersal might decrease biofilm mass, an increased in vivo virulence observed in this study warrants a more careful re-evaluation of the clinical use of the dispersal agents.

Letermovir pre-existent mutations in human cytomegalovirus UL56 terminase in solid organ and haematopoietic stem cell transplant recipients

Marta Santos Bravo1, Sonsoles Sanchez-Palomino2, Nicolas Plault2, María Del Mar Mosquera Gutiérrez2, Veronica Gonzalo3, Francesc Fernández4, María Suárez-Lledó5, Montserrat Rovira4, Federic Cofan4, Maria Moreno Camacho4, Laura Linares4, Marta Bodro Marimont4, Sophie Alain3, Maria Angeles Marcos1

1Hospital Clínic de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, 2Hospital Clínic de Barcelona, Fundación Clínica, Barcelona, Spain, 3University Hospital Limoges Dupuytren Hospital, UMR Inserm 1092, Limoges, France, 4Hospital Clínic de Barcelona, Barcelona, Spain

Abstract third-party references: Group for the Study of Infection in Transplantation (GESITRA) & Spanish Network for Research in Infectious Diseases (REIPI)

Background: Letermovir (LMV) is a HCMV terminase inhibitor recently approved for hematopoietic stem cell transplant (HSCT) prophylaxis. LMV presented better safety and tolerance profiles, however, LMV-resistance mutations selected in vitro emerged much earlier than for current anti-CMV DNA polymerase inhibitors, suggesting a lower LMV-resistance genetic barrier. Many LMV resistance mutations have been described from clinical samples in the pUL56 terminase subunit, but studies of UL56 polymorphisms before treatment are scarce. We aimed to study preexistent mutations in UL56 prior LMV treatment in solid organ transplant (SOT) and HSCT recipients.

Materials/methods: UL56 sequences from HCMV clinical strains of 50 SOT and HSCT patients comprised into the Spanish Network for Research in Infectious Diseases (REIPI) and the Group for the Study of Infection in Transplantation (GESITRA) were analyzed by Sanger sequencing. Phenotypic assay by recombinant bacmid technology, LMV antiviral susceptibility test and growth assays were performed for previously undescribed mutations found by genotypic assay in collaboration with the French Reference Center. All patients accomplished the suspected resistance criteria for current anti-CMV drugs. None of them received LMV previous the study.

Results: Missense mutation R246C was detected in the UL56 gene of 2 patients (4%) located within the LMV resistance mediating region [codons 230-370] and adjacent to the leucine zipper [249-271]. Recombinant bacmid assay showed no LMV-resistance association. However, its replicative capacity was much higher than the HCMV backbone strain AD169 (figure 1). No other gene variations were found in the remaining patients.

Conclusions: New LMV sensitive polymorphism R246C was found in two transplant patients. This mutant was positively selected in both cases due to its increased replicative capacity, which confirms it does not alter the HCMV fitness although it is located next to the catalytic site of the pUL56. Its position also confirms the phenomenon of vicinity of resistance and natural polymorphism in UL56, previously described for UL97 phosphotransferase, corroborating that mutations phenotypes cannot be predicted by their gene position.

Figure1. Growth assay performed on MRC5 cell line of the mutant recombinant strain R246C compared to the reference strain AD169 after 7 days post-infection.

Abstract 8043

Host transcriptome analysis accurately diagnoses and prognoses acute infections and sepsis in emergency department patients

Wolfgang Bauer1, Kai Kappert1, Dana Lehmann1, Noa Galtung*, Oliver Liesenfeld1, James Wacker1, Rudolf Tauber2, Rajan Somasundaram1

1Charite Universitaetsmedizin Berlin, Emergency and Acute Medicine, Berlin, Germany, 2Charite Universitaetsmedizin Berlin, Institute of Laboratory Medicine, Clinical Chemistry and Pathobiochemistry, Berlin, Germany, 3Inflamatix Inc, Clinical Affairs, Burlingame, United States

Background: Rapid diagnostic tests for the detection of acute bacterial and/or viral infection and sepsis are needed in the emergency department (ED). Current diagnostic and prognostic tests are impeded, e.g. by slow turnaround time for blood cultures. Differentiating between bacterial and viral infections as well as managing the appropriate level of care are critical deliverables. Thus, over-treatment leading to antimicrobial resistance, as well as Clostridium difficile infection or late diagnosis and treatment of sepsis may result.

Materials/methods: In a prospective single-site study at the ED of the Charité University Hospital (Campus Benjamin Franklin) we investigated the efficacy of a novel host response test from blood which uses 29 host response mRNA targets and a machine learning algorithm (HostDx Sepsis) to quickly and accurately differentiate between viral and bacterial infections including co-infections and non-infected patients and predict the probable clinical course. Patients who presented with signs of acute infection were enrolled. All patients were adjudicated using chart review by two expert physicians using clinical data, radiological and laboratory tests (incl. C-reactive protein [CRP] and procalcitonin [PCT]) but blinded to the HostDx Sepsis results.

Results: We here present an interim analysis of 125 patients enrolled and adjudicated since January 2019. The accuracy of HostDx Sepsis predictions was compared to standards of rapid bacterial infection detection, such as CRP and PCT. The Area Under the Receiver Operating Characteristics (AUROC) for HostDx Sepsis at predicting bacterial and co-infections vs. non-infected and virally infected patients was 0.89 compared to 0.87 for PCT and 0.83 for CRP. HostDx Sepsis also predicted viral and co-infections vs. non-infection and bacterial infection with an AUROC of 0.85. When combined with quick Sequential Organ Failure Assessment (qSOFA)-scores the test predicted multiorgan failure with an AUROC of 0.85, compared to 0.80 for qSOFA-scores alone.

Conclusions: Our results suggest that the use of a host-response test to determine the infection status and severity allows for more informed rapid decisions on antibiotic treatment and further level of care in the ED.

**Influenza immunoglobulin in hospitalised patients with serious influenza A**

Amy Dahl*1, Michael G. Ison2, Tim Babinchak1, Christine Hall1, Debbie Anderson1

1Emergent BioSolutions, Winnipeg, Canada, 2Northwestern University Feinberg School of Medicine, Northwestern University Feinberg School of Medicine, Chicago, United States

**Background:** Seasonal influenza remains a significant burden in the US and worldwide, and there are no approved treatment for hospitalized patients with severe influenza. FLU-IGIV is a human immunoglobulin produced from healthy donor plasma; final product contains high titers of antibodies against seasonal influenza A strains.

**Materials/methods:** Adults with NEW score ≥3 hospitalized in the US and Europe over two flu seasons (2017-2019) with laboratory-confirmed influenza A infection were randomized 1:1:1 in a double-blind Phase 2 study. Subjects received either a fixed volume low dose (approx.16 g) or high dose (approx. 32 g) of FLU-IGIV or placebo, in addition to standard of care (oseltamivir; 75 mg BID/5 days). The primary study objective was to evaluate safety of FLU-IGIV and determine an optimal dose. Analysis of PK parameters and clinical benefit (6-category ordinal scale) is ongoing.

**Results:** The study randomized 65 subjects, with 60 dosed (safety population, 50% female and 50% male). Five subjects (8%) discontinued prior to dosing. Subjects 18 to 87 years old (median 54.5), within the weight range of 46 to 184 kg (median 87.9 kg), were randomized to receive FLU-IGIV high dose (19, 32%), low dose (19, 32%), or placebo (22, 37%). Oseltamivir ≥80% compliance was 93% in the safety population. There were 6 adverse events (AEs) considered related to FLU-IGIV; nausea, peripheral edema, infusion site warmth, and headache (2). There were 19 serious AEs (15 treated vs 4 placebo) reported in 8 subjects (7 FLU-IGIV-treated vs 1 placebo) and none were considered related to study medication. No deaths were reported. Constipation was the most common AE (1 [5.3%] high dose vs 3 [13.6%]) placebo group. Duration of hospitalization was 2 to 40 days (median 4) vs. 2 to 16 days (median 5) in the treatment vs placebo group. Subjects that completed Day 8 (36 treated vs 21 placebo) will have their ordinal outcome assessed.

**Conclusions:** Administration of FLU-IGIV was well tolerated at both dose levels compared to placebo in hospitalized patients with serious influenza A infection.

Abstract 8046

**SOS response to a novel inhibitor of DNA replication**

Stéphane Renard*1, Valérie Bazin1, Floriane Davy1

1Evotec ID Lyon, Lyon, France

**Background:** SOS response is a protective mechanism against antibacterial molecules that affect DNA replication. In this study, we used analysis of DNA content by flow cytometry to measure the impact of SOS response after antibiotic treatment and differentiate the mechanism of action of several antibiotics, including a novel scaffold ATB-93.

**Materials/methods:** Bacterial DNA content was labeled by picogreen after cell fixation.

**Results:** This study compares ATB-93, with Ciprofloxacin and Mitomycin C. Strains with deletion of several SOS response effectors were treated with those compounds and their DNA content was compared to determine which components of SOS response are involved in the bacterial response to treatment. This study demonstrates that RecB is necessary to observe replication following ATB-93 treatment. It also shows that SulA deletion does not prevent filamentation after ATB-93 treatment contrary to Mitomycin treatment.

**Conclusions:** Analysis of DNA content by flow cytometry is a potent tool to compare inhibitors of DNA replication.

**Presenter email address:** stephane.renard@evotec.com
**Abstract 8048**

**Candidaemia: a decade-long experience from India**

Ranjeeta Adhikary*1, Bhavana Mv2, Sangeeta Joshi3, Beena Hb2, Anjana A4

1Manipal Hospital, Bangalore, India, 2Manipal Hospital, Bangalore, India, 3Ex Manipal Hospital, Bangalore, India, 4Manipal hospital, Bangalore, India

**Background:** Candidemia is one of the leading causes of mortality in healthcare associated infections. There is an increase in the incidence because of various invasive procedures and complexities of patients. This study was conducted to analyze the prevalence, risk factors, antifungal susceptibility and outcome of candidemia in a tertiary care unit.

**Materials/methods:** This study was performed in a 600 bedded tertiary care centre in South India. A retrospective analysis of all patients between January 2010 and October 2019 was done from the laboratory and hospital information system.

**Results:** In this ten-year study, a total of 11269 blood cultures were positive. Out of which 508 patients (4.5%) grew Candida species. Only the first isolate of the patient was considered for further analysis. The median age of the patients was 52 years (range, 7 days to 90 years), and 315 of the patients (62%) were male. Among the top five isolates, Candida tropicalis was the most common fungal species (141/508, 27.8%), followed by Candida haemulonii (95/508, 18.7%), Candida albicans (76/508, 15%) and Candida parapsilosis (62/508, 12.2%). Candidemia was diagnosed while admitted in the wards in 55.9% of patients, 35.2% in intensive care units and 8.9% in outpatients. Analysis of the risk factors has shown that 17.5% of these patients had uncontrolled diabetes, 16.1% had malignancies, 11.3% had lung infections, 9.9% developed candidemia in post-surgical turn of events and others. The most frequently isolated Candida species, i.e., C. tropicalis was sensitive to fluconazole in 95.7%, voriconazole 98.6%, flucytocine 96.7% and 100% susceptible to amphotericin B, caspofungin and micafungin. 54% of these patients recovered, 40% expired and 6% were discharged against medical advice.

**Conclusions:** C. tropicalis was the most frequently isolated species. This report shows that invasive candidiasis is a significant source of morbidity in Indian healthcare settings, causing substantial burden of disease in immunosuppressed and uncontrolled diabetic patients. An important and high alert issue is that mortality remains unacceptably high. This type of data analysis is needed to track trends of serious infection and to develop guidelines for infection control strategies and antimicrobial stewardship program.

Abstract 8050

Diversity of capsular switch among carbapenemase-producing Klebsiella pneumoniae
Adriana Chiarelli*, Nicolas Cabanel1, Remy Bonnin1,2, Philippe Glaser1
1Institut Pasteur, Paris, France, 2Bicêtre Hospital, EA7361, French National Reference Center for antibiotic resistance, Le Kremlin Bicêtre, France

Abstract third-party references: Institut Pasteur

Background: Klebsiella pneumoniae (Kp) is a leading cause of intractable multidrug-resistant (MDR) infections in hospitals. Most of the Kp clinical isolates produce capsule (CPS) as a major virulence factor. Extensive recombination events at the cps locus are frequent and responsible for capsule diversity in Klebsiella spp. Capsular diversity may also occur within the same bacterial population, generating differences in colony aspect, i.e. mucoid and non-mucoid. Our objectives were to characterize colony variants appearing among eight clinical carbapenemase-producing Kp isolates: capsulated, mucoid (M) and non-capsulated, non-mucoid (NM) phenotype.

Materials/methods: The M and NM colony variants were distinguished by appearance on solid medium. Whole genome sequencing of 74 NM variants was used to infer mutations causing phenotypic differences. CPS was quantified by uronic acid assay and visualized by India Ink staining. The frequency of CPS switching on Tryptic-Soy agar (TSA) was determined. Antimicrobial susceptibility testing (AST), biofilm and autoaggregation assays were performed to unveil putative differences in resistance.

Results: Spontaneous loss or reduction of CPS results from point mutations and IS elements hopping into essential genes for capsule synthesis. Frequency of mutations was strain-dependent but overall higher at later growth stages on solid medium. Little or no capsule was produced by the NM variant. Strikingly, differences in carbapenem susceptibility, in vitro biofilm formation and autoaggregative properties were observed between the two variants.

Conclusions: Reduced or loss of capsular production led to various phenotypic changes that might lead to different in vivo adaptation according to the Kp strain. However, as the colony opacity differences in stored isolates may go undetected, researchers might unconsciously work with mixed populations. This could be problematic for many studies, especially those involving virulence and resistance.

Abstract 8052

**Active surveillance mitigates the risk of donor-derived infections in solid organ transplant recipients: the role of infection control**

Maria Campanella*1, Alice Medaglia1, Elena Conoscenti1, Sabina Caruso1, Giovanna Panarello1, Vincenzo Lamonaca1, Floriana Barbera1, Francesco Monaco1, Anna Pasquariello1, Francesca Cardinale1, Daniele Di Carlo1, Pier Giulio Conaldi1, Paolo Antonio Grossi1, Alessandra Mularoni1

1ISMETT IRCCS, Transplant Center, Palermo, Italy

**Background:** Unexpected donor-derived infections (DDIs) are a major concern in SOT. Our SOT center is located in Sicily, an endemic area for Multidrug-resistant (MDR) gram-negative bacilli (GNB), especially Carbapenem-Resistant Enterobacteriaceae (CRE) infections. To prevent and manage MDR DDIs, an active surveillance system was implemented.

**Aim of this study is to evaluate the effectiveness of an active surveillance system for DDI prevention in SOT recipients.**

**Materials/methods:** Since December 2015, together with the organ, our surgical team collects donor blood culture and transport liquid for all organs, urine for kidney and broncho-aspirate for lung donors. These specimens are cultured at our microbiology lab. The Infection Control Nurses (ICN) check results of donor cultures every day and maintain a prospective database. In case of significant positive result, ID physician starts immediately targeted treatment following internal guidelines. ICN inform Regional Transplant Center in case of significant positivity to protect other recipients. ICN perform surveillance of potential DDI in the 30 days after transplant for every HR recipients. In case of suspected DDI, NGS will be performed on donor and recipient strains.

Recipients were considered at High Risk (HR) of DDI when the donor had positive blood culture or infection at transplanted organ.

**Results:** During study period (Dec 2015-Jun 2019) 489 SOT were performed, 124 (25%) were at HR of DDIs. In particular 26 (5.3%) of recipients were at HR for MDR-GNB DDI (11 carbapenem-resistant *Acinetobacter baumannii*, 13 Carbapenem-Resistant Enterobacteriaceae, 2 ESBL).

Active surveillance system allowed prevention of 93% of DDI infections in HR recipients (115), 7% of recipients (9) developed a DDI but they were promptly diagnosed and effectively treated, see Table 1.

**Conclusions:** Active surveillance system managed by ICN is effective for prevention or prompt management of unexpected DDI. Given the shortage of organs for transplantation, this innovative approach, together with reinforcement of infection control practices in the donor intensive care units, should be consistently applied to improve the quantity, quality, and allocation of organs for transplantation, and survival of patients and grafts after transplantation.

Abstract 8053

**Comparison between Bedside Blind Bone Biopsy (B4) and Basic Bone Biopsy (B3) in the management of diabetic foot osteomyelitis**

Gauthier Pean De Ponfilly*, Florine Feron, Louis Potier, Diane-Cécile Gauthier, Anne-Lise Munier, Herve Jacquier, Emmanuel Lecorche, Nathalie Grall, Marie Laloï-Michelin, Michel Marre, Jean-Pierre Riveline, Emmanuelle Cambau, Jean-François Gautier, Ronan Roussel, Jean-Philippe Kevorkian

1Hospital Lariboisière Ap-Hp, Laboratory of Microbiology, Department of Infectious Agents, Paris, France, 2Hospital Lariboisière Ap-Hp, Department of Diabetology, Paris, France, 3Hospital Bichat, Ap-Hp, Department of Diabetology, Paris, France, 4Hospital Lariboisière Ap-Hp, Department of Infectious Diseases, Paris, France, 5Hospital Bichat, Ap-Hp, Laboratory of Bacteriology, Paris, France

**Background:** Bedside Blind Bone Biopsy (B4) performed by a diabetologist has been recently shown as a reliable tool to manage antimicrobial therapy in case of Diabetic Foot Ulcer (DFU) with suspected osteomyelitis. Here, we evaluated the performance of B4 compared to the conventional procedure (Basic Bone Biopsy, B3) performed either by surgery or interventional radiology.

**Materials/methods:** A bi-centric, observational, retrospective study was conducted in two different diabetes departments. B4 was performed by a diabetologist from December 2015 to September 2018 (33 months) in Center A. B3 was performed by a surgeon or an interventional radiologist from September 2013 to September 2018 (62 months) in Center B. The primary endpoint was complete healing with Exclusive Medical Treatment (EMT) and no recurrence (EMT=offloading, wound care ± antimicrobial therapy) at 6 months. The secondary endpoints were the rates of contaminations and sterile Bone Biopsies (BB).

**Results:** Among 1112 patients with Diabetes Mellitus (DM) admitted with foot ulcer, 127 consecutive patients (11.4%) had clinically and/or radiological suspicion of osteomyelitis, eligible for EMT and consequently with an indication of BB. 81/415 (19.5%) patient in center A underwent a B4 and 46/697 in center B underwent a B3 (6.6%, surgery n=31/46 [67.4%], radiology n=15/46 [32.6%]). Patients characteristics were similar between the 2 groups: males (76.4%), mean age (69 ± 12 years), mean duration of DM (19 ± 10 years), mean glycated hemoglobin (8 ± 2%). Bacterial strains were comparable between the two groups with a similar proportion of *Staphylococcus aureus* (B4 18.2% vs B3 23.3%, p=0.58). The rate of patients with complete healing with EMT and no recurrence at 6 months was similar between the two groups (B4=59% B3=58.7%, p=1.00). The mean duration of follow up was 604+/−446 days. No statistical difference was observed for the rate of contaminations (B4=13.7% [31/236 bone samples], B3=11.1% [7/63 bone samples], p=0.55). The rate of patient with sterile bone biopsies was significantly higher in B4 group (43/83, 51.8%) than in B3 group (11/46, 23.9%), p=0.002.

**Conclusions:** B4 is a simple and valid diagnostic procedure to manage DFU with suspected osteomyelitis. It results in similar healing rate to more sophisticated and expensive procedures.

Next-generation sequencing for kinetics of the respiratory microbiota of intensive care unit intubated patients

Sylvain Meyer*1, Thomas Daix2, Bruno François2, Delphine Chainier1, Alexandra Gay2, Marie-Cécile Ploy1, Philippe Vignon2, Olivier Barraud1

1Centre Hospitalier Universitaire de Limoges, UMR INSERM 1092, Limoges, France, 2Centre Hospitalier Universitaire de Limoges, Centre d’Investigation Clinique 1435, Limoges, France

Abstract: Ventilator associated pneumonia (VAP) remains a public health concern in the intensive care units (ICU) due to its related increase in hospital stay, mortality and over costs. Nowadays, the pathophysiology from colonization to infection is still not fully understood. A better understanding of the respiratory microbiota changes during mechanical ventilation (MV) could help to better target patients with increased risks of VAP. The objective of the study was to describe, thanks to next-generation sequencing (NGS), the kinetics of the respiratory tract microbiota during MV in ICU patients.

Methods: This is a pilot monocentric prospective observational study enrolling 10 adult ICU patients under MV for at least 48h for neurological issue with no past medical history of respiratory diseases and without antibiotic use since one month. Endotracheal aspirates (ETA) were collected daily from intubation until extubation (7 patients, 51 ETA samples) or until prescription of antibiotics for suspected VAP (3 patients, 13 ETA samples). After human cells depletion and DNA extraction of all ETA samples, 16S rRNA-encoding gene amplification was performed with the Ion 16S Metagenomics Kit. After libraries preparation, the Ion GeneStudio S5 platform was used. Twenty ETA samples were sequenced per chip to assure a high sequencing depth. Bioinformatic analysis was performed with the IonReporter® and the Shaman software. Semi-quantitative conventional culture was performed in parallel following ESCMID recommendations. Results were compared to culture.

Results: NGS results were in agreement with culture, all pathogens being detected. Respiratory microbiota and kinetics were very different from one patient to another. For each patient, changes in the respiratory microbiota were highly variable from one day to the other. Anaerobes were systematically detected, sometimes at very high proportions even when pathogens were present at high concentrations. Interestingly, Bacteroidetes phylum was more represented in patients finally receiving antibiotics whereas uneventfully extubated patients had a higher proportion of the Actinobacteria phylum.

Conclusions: Following the kinetics of the respiratory microbiota of MV ICU patients shows interesting results with distinct profiles. NGS monitoring promises accurate results that could help on giving new perspectives to the understanding of pathophysiology of VAP in the ICU setting.

Abstract 8056

Low incidence of Gram-negative infections in people who inject drugs in Tennessee

Michael Veve1*, Grace Cooksey2, Brandon Nabors1, Zachary Smith1, Mahmoud Shorman2

1University of Tennessee, Knoxville, United States, 2University of Tennessee Medical Center, Knoxville, United States

Background: People who inject drugs (PWID) are thought to be at risk of Gram-negative (GN) infections given non-sterile injection techniques or contaminated injection material. Despite limited knowledge about the incidence of GN infections in PWID, broad-spectrum antibiotics with are routinely prescribed. The objective of this study was to describe the infection microbiology in PWID, and to describe patient characteristics associated with GN infections in this population.

Materials/methods: Cross-sectional study with nested cohort performed at an academic medical center included patients with injection-drug related infections seen in an emergency department or admitted from 6/2017-6/2018. Urinary and respiratory tract infections were excluded. Injection drug use was defined as patient admittance or self-identification as a PWID within the past 30-days, admittance to a history of substance use with a positive urine drug screen for illicit substances on admission, and/or an infection determined to be related to injection drug use by an infectious diseases physician. Patient characteristics were described and compared.

Results: 250 patients were included: 25 (10%) had a GN infection. 140 (56%) were women, and the median [IQR] age was 36 [29-44] years. 96 (38%) patients had no insurance at time of care. 236 (94%) patients were admitted to the hospital; the median [IQR] length of stay was 6 [3-14] days. The predominant illicit drugs used were opioids (95%) and amphetamines (42%). Common infection types were: 40% skin/skin structure, 25% infective endocarditis, 14% unknown source, 12% osteomyelitis, 9% multiple infections. 195 organisms were identified from 166 (66%) patients; the most commonly identified organisms were: 41% methicillin-resistant Staphylococcus aureus, 18% methicillin-sensitive S. aureus, 17% streptococci, 5% enterococci, 2% P. aeruginosa, 1% Candida spp., 9% other Gram-positive organisms, 7% other GN organisms. 233 (93%) patients received empiric GN therapy; 215/233 (92%) had anti-pseudomonal coverage. In multivariable logistic regression, variables independently associated with GN infection was a history of mental health disorder [Table 1].

Conclusions: The incidence of GN infections, particularly P. aeruginosa, in PWID are low, but empiric anti-GN antibiotics are prescribed in the majority of patients. Antimicrobial stewardship actions targeted towards improved antibiotic use in this population are warranted.

Mutations in *Aspergillus fumigatus* hmg1 confer increased expression of ergosterol biosynthesis and efflux pump encoding genes

Jeffrey M. Rybak*1, Wenbo Ge1, Nathan Wiederhold2, Vincent M. Bruno3, P. David Rogers1, Jarrod R. Fortwendel1

1University of Tennessee Health Science Center, Department of Clinical Pharmacy and Translational Science, College of Pharmacy, Memphis, United States, 2University of Texas Health Science Center at San Antonio, Fungus Testing Laboratory, San Antonio, TX, United States, 3University of Maryland School of Medicine, Institute for Genome Sciences, Baltimore, MD, United States

**Background:** Triazole antifungals are relied upon as primary therapy for the treatment of infections caused by *Aspergillus fumigatus*. Recently, we have demonstrated that mutations in the *A. fumigatus* HMG-CoA reductase encoding gene, hmg1, represent a novel genetic determinant of clinical triazole resistance, conferring reduced susceptibility to all clinically available triazoles used for the treatment of invasive aspergillosis. In this work, we employ RNAseq-derived transcriptional profiling to determine the effects of hmg1 mutations on gene expression with or without voriconazole exposure.

**Materials/methods:** Three previously characterized hmg1 mutant strains with reduced voriconazole susceptibility (MIC 1 to 2mg/L), constructed in the *akuBΔKU80* background, as well as a hmg1WT control strain (MIC 0.25mg/L), were included in this study. All strains were subjected to RNAseq-derived transcriptional profiling in biological triplicate following growth in RPMI media without voriconazole, with 7 hours of voriconazole exposure, or with 48 hours of voriconazole exposure. Voriconazole was supplemented at half the minimum inhibitory concentration of each strain.

**Results:** Following growth in RPMI without voriconazole, transcriptional profiling revealed that expression of multiple ergosterol biosynthesis related genes including erg1, erg3B, erg24, erg24B, erg25, and srb8, as well as the efflux pump-encoding genes abcA and mdrA were increased 2 to 5-fold in all hmg1 mutant strains relative to the hmg1WT control strain. After growth in RPMI with 7 hours of voriconazole exposure, similar increases in the expression of ergosterol biosynthesis genes was observed among all hmg1 mutant strains, while the expression of the efflux pump-encoding genes abcA and mdrA further increased to 4 to 9-fold that of the hmg1WT control strain. Following growth in RPMI with 48 hours of voriconazole exposure, the expression of the efflux pump-encoding genes abcA, abcC, abcD, atrI, mdr1, and mdrA was observed to be increased 2 to 4-fold relative to the hmg1WT control strain.

**Conclusions:** These data demonstrate that mutations in *hmg1* are associated with increased constitutive and voriconazole inducible expression of multi-drug efflux pump encoding genes and ergosterol biosynthesis genes. Further research is needed to delineate the direct contributions of these changes in gene expression to clinical triazole resistance conferred by *hmg1* mutations.

Identification of the extended-spectrum β-lactamase L2 in an extensively drug-resistant Pseudomonas aeruginosa isolate, United States

Richard Stanton*1, Gillian McAllister1, Wenming Zhu1, Davina Campbell1, Julian Grass1, Marion Kainer2, Maroya Walters1,3, Alison Laufer-Halpin1,3

1Centers for Disease Control and Prevention, Division of Healthcare Quality Promotion, Atlanta, United States, 2Tennessee Department of Health, Nashville, United States, 3Commissioned Corps, U.S. Public Health Service, Rockville, United States

Background: Pseudomonas aeruginosa, an opportunistic pathogen that causes >32,000 healthcare-associated infections each year in the United States, is known to harbor a variety of acquired β-lactamase genes. Here we report the first identification of the Stenotrophomonas maltophilia L2 extended-spectrum β-lactamase (ESBL) in a P. aeruginosa isolate.

Materials/methods: The isolate was submitted to CDC as part of the Emerging Infections Program, which conducted laboratory- and population-based surveillance for carbapenem-resistant P. aeruginosa from 2016-2018. We screened the isolate for carbapenemase activity using the modified carbapenem inactivation method (mCIM). Antimicrobial susceptibility testing (AST) was performed using reference broth microdilution according to Clinical and Laboratory Standards Institute guidelines. The isolate underwent whole genome sequencing (WGS) using both Illumina and PacBio platforms. We analyzed the WGS data with our custom QuAISAR-H pipeline and identified antimicrobial resistance (AMR) genes using publicly available databases (ResFinder, ARG-ANNOT, and NCBI AMRFinder).

Results: The isolate was mCIM-positive and extensively drug-resistant (XDR; non-susceptible to at least one agent in all but two or fewer antimicrobial categories), though it was susceptible to colistin and amikacin. Using WGS data, the isolate was identified as multilocus sequence type 3054 and the bla_{L2} gene was the only acquired β-lactamase detected. This gene was located on a 20.6kb plasmid along with tetracycline and aminoglycoside resistance genes, Figure 1).

Conclusions: S. maltophilia and P. aeruginosa are associated with water sources in healthcare environments, thus gene transfer events between the two gram-negative species may occur. While nominally an ESBL, the AST and WGS results suggested that the strain may produce a carbapenemase-like phenotype in a P. aeruginosa background. This work demonstrates the utility of WGS to rapidly identify potentially novel or unexpected pathogen-carbapenemase combinations, a crucial component for early containment of emerging antimicrobial resistance among healthcare-associated pathogens.

Figure 1. Annotation of the 20.6kb plasmid with bla_{L2} found in the XDR P. aeruginosa.

Abstract 8065

Evolutionary dynamics of carbapenem resistance genes among different international clones of Acinetobacter baumannii: resistance and dissemination implications

Saranya Vijayakumar1, Jobin John Jacob2, Karthick Vasudevan2, Veeraraghavan Balaji1

1Christian Medical College, Vellore, India

Background: Carbapenem resistant Acinetobacter baumannii has been emerged as a global threat. A. baumannii genome has remarkable plasticity and undergo large scale homologous recombination events resulting in diverse lineages. In this study, we investigated the evolutionary dynamics of class D OXAs, NDM and its association with mobile genetic elements (MGEs) among different International clones (ICs) of A. baumannii.

Materials/methods: A total of 112 genomes of A. baumannii were analyzed which includes 31 Indian genomes from this study and 81 global genomes from Genbank. The phylodynamics of Indian genomes against global genomes with regards to carbapenem resistance and genomic diversification was studied using BEAST analysis. For a subset of 12 genomes from this study, complete genome was obtained using hybrid assembly of IonTorrent and MinION reads. Resistance profile and sequence types were identified using ResFinder and MLSTFinder respectively. Genetic arrangement of MGEs associated with bla\textit{OXA-23}, bla\textit{OXA-58}, bla\textit{NDM-1} and bla\textit{OXA-51} was determined. The diversity of A. baumannii Resistance (AbaR) islands was examined by manual cura-
tion.

Results: Phylodynamic analysis classified A. baumannii genomes into four globally disseminated ICs, IC1, IC2, IC7/CC25 and IC3 along with a few unknown clades. Transmission events predicted the evolution of A. baumannii in the late 18th century and the acquisition of carbapenem resistance genes by different clones at respective intervals thereafter. bla\textit{OXA-23} was the most widespread carbapenemase while bla\textit{OXA-24}, bla\textit{OXA-51} and bla\textit{NDM-1} was less prevalent. The 31 Indian isolates were distributed in all identified ICs with predominant group belongs to IC2. Variant of bla\textit{OXA-51} specific to ICs were observed. Analysis of the genetic environment of 12 complete genomes revealed novel findings like insertion of IS\textit{Aba1} upstream OXA-51 variant, bla\textit{NDM-1} and Tn125-like harboring bla\textit{NDM-1} with insertion sequence, IS\textit{Aba14}. Four diverse AbaR Island was identified, of which two were novel with Tn6166 like backbone.

Conclusions: The current study unveils the evolutionary dynamics of carbapenem resistance genes among different lineages. Emergence of less dominant clone, CC25/IC7 and predominance of AbaR4 like Resistance Island with its diverse variants were observed in this study. Transposons carrying bla\textit{OXA-23} and bla\textit{NDM-1} unleash the transposition events resulting in wide spread of carbapenem resistance among A. baumannii.

Abstract 8069

Travel health advice: do travellers follow the recommendations?

Marta Díaz-Menéndez1, Víctor Quesada Cubo2, Marta Arsuaga Vicente3, Fernando De La Calle Prieto*, Mº Concepción Ladrón De Guevara1, Mar Lago1, Pablo Barreiro1, Elena Trigo Esteban1

1Hospital La Paz- Carlos III, Madrid, Spain, 2Gregorio Marañón Hospital, Madrid, Spain

Background: In the last decade, there has been a rapid growth in the number of international travels. Tropical destinations suppose increased risk of travel-related diseases. Many of them are preventable through vaccination, chemoprophylaxis or anti-vectorial personal protective measures (PPM). However, although PPM are easy to comply with, many travellers do not seek or adhere to these recommendations. We describe compliance with preventive measures in a cohort of Spanish travellers.

Materials/methods: Travellers attended at Travel Medicine Unit from the National Reference Centre Hospital La Paz- Carlos III, Madrid (Spain) between June 2017 and June 2019 were asked to complete an online questionnaire close after the travel. Demographics, travel characteristics (length of stay, reasons for travel, destination) and questions related to PPM were recorded.

Results: The survey was completed by 2338 travellers, of a total of 6354 requests (36.8%). Median age of respondents was 38 years (range 18-81); 59.5% (n=1391) were women. Most frequent destinations were Sub-Saharan Africa (31.2%) and South-east of Asia (24.4%). The median duration of the trip was 15 days (range 4-456), and the most frequent reason for travel was tourism (81.6%).

PPM were followed by most travellers (89.1%), although more than half [65.1%] applied them less than 2 times a day. Visiting Friends and Relatives [VFR] travellers were more likely to underuse skin repellents [P>0.001]. Up to half of travellers [50.9%] drunk uncontrolled beverages, and 57.6% ate fresh/undercooked food. No differences were found through different reasons for travel. Those travelling for business were more likely to avoid walking on barefoot [p>0.001], but nearly 55% of all travellers admitted to having done so. Finally, up to 34.6% of travellers bathed in fresh water. Table 1 summarize compliance with preventive measures according to reason for travel.

Conclusions: Most travellers followed PPM but they didn’t applied the recommended protective dose of repellent as well as most of them didn’t follow recommendations regarding safe food or drinks or avoid walking on barefoot. New approaches to motivate travellers’ compliance are required to increase the awareness of risk in travellers and to improve knowledge about the risks they are exposed to during international travels.

Abstract 8070

The rapid clinical diagnosis of lower respiratory infection by an unbiased real-time metagenomics methods in validated intensive care unit patients

Haocheng Zhang*1, Jingwen Ai1, Qiran Zhang1, Wenhong Zhang1

1Huashan Hospital Affiliated to Fudan University, Shanghai, China

Background: Efficient and rapid detection of pathogens is an urgent need in lower respiratory infections (LRIs), especially for those validated ICU patients with life-threatening infections. Nanopore (ONT) has been reported as a promising diagnostic tool in infectious diseases.

Materials/methods: The single-center prospective study was conducted in Huashan Hospital affiliated to Fudan University, Shanghai, China from May 2019 to October 2019. Validated patients in ICU, aged over 16, were consecutively enrolled. All of the collected sputum samples were sent for Nanopore, culture and smear. Complete clinical microbiological data was available for all samples. Pneumonia severity index (PSI) was used to evaluate the clinical condition of the validated patients.

Results: A total of 23 patients with tracheal incubation were enrolled, and serial sputum of one patient with severe pneumonia was collected. Culture detected one or more pathogens in 20 specimens, while ONT detected all the culture-detected pathogens in 95.0% (19/20) specimens. ONT detected pathogens in 3 culture-negative specimens, which were confirmed by PCR later, representing an increase in sensitivity from 87.0% (20/23) to 95.7% (22/23) compared with culture. Average time of sample preparing and ONT process took 13-17 h per sample and showed an advantage over smear (critical value) and traditional culture in identification of the particular microorganisms (P < 0.05). Klebsiella pneumoniae can be detected precisely one hour after sequencing in a specific sample. For the above-mentioned sample there was 49.26% coverage within 2 h with 28257 specific reads. The condition and PSI of patients with severe pneumonia continuously deteriorated after treatment, a marked increase in Klebsiella pneumoniae sequencing reads was observed. Genome coverage increased to 99.64% after 48 h. Among the 10 resistance genes, 7 matched the phenotype seen.

Conclusions: Nanopore showed promising potential in pathogenic diagnosis and surveillance during validated patients in ICU with lower respiratory infection and might enable clinicians to make more timely and targeted therapeutic decisions. However, new bioinformatics analysis method for resistance gene detection deserves to be explored.

**Abstract 8072**

**Daptomycin or vancomycin for methicillin-resistant Staphylococcus aureus infective endocarditis complicated by septic pulmonary emboli**

Lisa Vuong¹, Trang Trinh*²

¹University of California, San Francisco School of Pharmacy, San Francisco, United States; ²University of California, San Francisco School of Pharmacy, San Francisco, United States

**Background:** Methicillin-resistant Staphylococcus aureus (MRSA) causes serious infections including infective endocarditis (IE) and bacteremia. Septic pulmonary emboli (SPE) are complications more commonly observed in intravenous drug users (IDU). Daptomycin is an approved alternative to vancomycin for MRSA bacteremia and right-sided endocarditis treatment but it is inactivated by pulmonary surfactants. However, in vivo studies suggest that mechanisms necessary to inactivate daptomycin are not present during SPE. Its use in the presence of SPE has remained controversial with small studies describing mixed results of clinical success and failure. It is crucial to explore daptomycin effectiveness for MRSA bacteremia complicated by SPE as an alternative to vancomycin especially given concerns for reported vancomycin failures in MRSA bacteremia.

**Materials/methods:** This is a single-center retrospective cohort study of adult patients ≥18 years old with MRSA-positive blood cultures complicated by SPE between 2014 and 2019. Inclusion criteria were daptomycin or vancomycin for ≥72 hours initiated ≤48 hours of SPE suspicion or diagnosis. Exclusion criteria were concurrent pneumonia, polymicrobial bacteremia, and treatment with other anti-MRSA antibiotics during the initial 48 hours. The primary outcome was composite failure defined as 30-day mortality or worsening respiratory signs and symptoms. Descriptive statistics were used for baseline demographics. Bivariate analyses were used to compare differences between treatment groups.

**Results:** A total of 23 adults were included. Six (26%) received daptomycin and 17 (74%) received vancomycin. The median (IQR) age was 52 (36 – 59) years, 57% were male, and 57% were IDU. Almost half (43%, n = 10) had definitive infective endocarditis and source control (valvular repair) was pursued in one person. Two people experienced 30-day mortality, one in each treatment group. No one experienced worsening respiratory signs and symptoms.

**Conclusions:** This study represents real-world evidence describing daptomycin use in a vulnerable IDU population. No obvious signal of daptomycin failure was observed. However, the small number of people precludes statistical inferences and additional multicenter studies are needed to elucidate the role of daptomycin in MRSA bacteremia complicated by SPE. This research is important in the context of the opioid and IDU epidemic in the United States.

Abstract 8074

**Dose optimization of carbapenems in critically ill patients for highly resistant *Klebsiella pneumoniae* environment: population pharmacokinetics and simulations**

Anh Q. Truong¹, Dao Xuan Co², Dinh Hoa Vu⁴*, Hoang Nguyen¹, Do Thi Hong Gam³, Nhat Minh Tran¹, Dinh Chi Le⁴, Ngan Binh Vu⁴, Hong Huyen Pham⁵, Cuong Bui², The Anh Trinh¹, Quoc Tuan Dang⁶, Gia Binh Nguyen², Jeffrey Lipman⁶, Jason Roberts⁶

¹Hanoi University of Pharmacy, National Drug Information and Adverse Drug Reaction Monitoring Center, Hanoi, Vietnam, ²Bach Mai Hospital, Intensive Care Unit, Hanoi, Vietnam, ³Bach Mai Hospital, Department of Pharmacy, Hanoi, Vietnam, ⁴Hanoi University of Pharmacy, Department of Analytical Chemistry and Toxicology, Hanoi, Vietnam, ⁵Bach Mai Hospital, Department of Microbiology, Hanoi, Vietnam, ⁶The University of Queensland, Royal Brisbane & Women’s Hospital, UQ Centre for Clinical Research, Brisbane, Australia

**Background:** Critically ill patients showed alteration in pharmacokinetics (PK) of carbapenems, backbone antibiotics for multiple drugs resistance (MDR) *K. pneumoniae*. This study aimed to optimize the doses of meropenem (MEM) and imipenem (IMI) for critically ill patients admitted to an intensive care unit (ICU) with highly resistant *K. pneumoniae*.

**Materials/methods:** Plasma samples were collected from 70 ICU patients at 0.5 and 3 h after prolonged infusion of MEM (27 patients) and IMI (43 patients). Population PK modelling was performed using nonparametric method with the help of Pmetrics on R v.3.5.3. Susceptibility data of *K. pneumoniae* were obtained from microbiology department. Monte Carlo simulations was performed for dose optimization with threshold to achieve 90 % probability of target attainment (PTA) for 100% $T>MIC$ and cumulative fraction of response (CFR) against *K. pneumoniae*.

**Results:** A one-compartment model best fit the PK data ($V$ and total clearance (CL): 16.5 L and 8.4 L/h for MEM and 22.4 L and 12.7 L/h for IMI, respectively). Eight-hour urine creatinine clearance was significant covariate of CL of both antibiotics while body weight and the indwelling drainage were predictors for $V_e$ of IMI and MEM, respectively. Prolonged infusion of MEM and IMI could cover sensitive pathogens only. Higher PTA and CFR were attained with continuous infusion, which can cover pathogens with MIC up to 8 mg/L. Target on pathogens of MIC $\geq$ 32 mg/L could not be achieved with regular dose (see Table)

**SNP-based phylogeny revealing establishment of ciprofloxacin-resistant Shigella sonnei lineage in India**

Dhiviya Prabaa M.S.*,1, Agila Kumari Pragasam1, Karthick Vasudevan1, Dhivya Murugan1, Shalini Anandan1, Veeraraghavan Balaji1

1Christian Medical College, Vellore, India

**Background:** S. sonnei is replacing S. flexneri as the most common cause of shigellosis worldwide, particularly in countries undergoing economic development. Previous studies reported that South Asia as a hub for recent international spread of fluoroquinolone resistant S. sonnei. S. sonnei lineage III is widespread globally among the five reported lineages. This study investigated the local establishment of ciprofloxacin resistant S. sonnei in India through whole genome sequence analysis.

**Materials/methods:** A total of 444 S. sonnei genomes were studied. This includes 106 Indian isolates and 338 global isolates. Sequences were mapped to the S. sonnei Ss046 reference sequence (Accession number: NC_007384) using SMALT and SNPs were called against the reference and filtered using SAMtools. RAxML tree resulted was displayed and labelled using iTOL. Further establishment of ciprofloxacin resistance in India was investigated by temporal phylogenetic reconstruction of 76 Indian S. sonnei from 1990 to 2017 using BEAST analysis.

**Results:** Phylogenetic analysis in global context showed, all Indian isolates clusters within lineage III (Central Asia clade). Notably, 68% of the isolates within Central Asia III had triple (gyrA – S83L, D87G/N, parC – S80I) mutations for fluoroquinolone resistance. No PMQR genes were identified except in one isolate. Central Asia III lineage isolates had more number of AMR genes and different plasmid profile compared to isolates in other lineages. A time-scaled phylogenetic tree demonstrated the sequential accumulation of mutations and showed that all ciprofloxacin resistant S. sonnei comprised a distinct clade. The most recent common ancestor (MRCA) of the ciprofloxacin resistant clade in India was estimated to be at late 2005.

**Conclusions:** This is the first study to investigate the temporal structure of S. sonnei Central Asia III lineage in India. The successful global expansion of this lineage could be due to acquisition of double or triple mutations and mobile elements. This study indicates the continued surveillance of this lineage and recommends for an urgent re-evaluation of the empirical use of ciprofloxacin for a range of gastrointestinal infections.

Abstract 8077

**Hospitalised patients with a label of penicillin allergy: which antibiotic therapy do they receive?**
Margot Lehericey *, Cecile Morice¹, Helene Roger², Renaud Verdon¹

¹Hospital Center University Of Caen Normandie, Department of infectious diseases, Caen, France, ²Hospital Center University Of Caen Normandie, Department of dermatology, Caen, France, ³Chpc - Hospital Center Public Du Cotentin : Hospital Louis Pasteur, Department of infectious diseases, Cherbourg-en-Cotentin, France

**Background:** About 10% of patients report being allergic to penicillin, while only 10% of them are skin-test positive. Reporting a notion of penicillin allergy (PA) (NPA) can lead to negative consequences for patients. The alternative antibiotic therapy can be: less efficient, more expensive or with a higher impact on the intestinal microbiota. Our study aimed to describe the consequences of a NPA on the antibiotic strategy in two tertiary care referent centers in France.

**Materials/methods:** We performed a multicenter, prospective study in hospitalized patients in 2 tertiary care hospitals between 01/02/19 and 31/08/19. Inclusion criteria were: requiring curative antibiotic therapy and a NPA reported by the patient (whatever the results of prior or subsequent skin-tests). Information were collected through a questionnaire developed for the purpose of assessing their allergy and the adopted antibiotic strategy. Information was checked in their medical records and through interviews of their general practitioner, and local pharmacist.

**Results:** 53 patients were included. 57% did not notified the type of allergy with an increased risk of serious side effects. Nine patients (17%) received a penicillin despite the NPA, of whom one presented a maculopapular exanthema during hospitalization. The most prescribed antibiotics in case of PA were cephalosporin’s (23% of prescriptions), fluoroquinolones (18%), glycopeptides (15%), and macrolides (11%). On the basis of the interview of the pharmacist and the general practitioner 8 (15%) patients had no penicillin allergy. A correct evaluation would have avoided the prescription of critical and expensive antibiotics in 5 (9.5%) cases. Regarding cephalosporin’s prescription, 26% of patients should not have received it according to the French guidelines in case of penicillin allergy but no side effects were reported.

**Conclusions:** Antimicrobial stewardship programs should include PA evaluation and proposition of alternative therapy algorithms to help practitioners on the management of possible PA.

Next-generation sequencing for the research and development of novel antibiotics

Chantal Monlong1, Aurelia Delherme1, Mickael Deuez1, Carine Taillier1, Thierry Vermat1, Michael Mourez1, Sébastien Coyne1, Emilie Lessoud*1

1EVOTEC ID Lyon, Marcy l’etoile, France

Background: Understanding the mechanism of action (MoA) and predicting resistance issues are key points in the development of novel antibacterials.

To document these properties and decipher structure activity relationship studies (SAR) during chemical optimization, we use transposon sequencing (TnSeq). TnSeq uncovers the genes that upon inactivation influence the efficacy of a drug candidate. The generation of a database with compounds of known classes allows comparisons and clustering analyses.

Here we present examples of the application of TnSeq to help the research and development of novel antibiotics.

Materials/methods: A saturated Tn5 transposon library was generated in Escherichia coli ATCC35218. Challenges were performed with reference or novel compounds. Next generation sequencing determined the fitness of each mutant.

First analysis probed efflux and influx properties, and predicted mechanisms of resistance. Differential analysis and clustering methods were applied to compare the profiles and predict potential target pathways of the novel compounds. The same approach was also used to guide chemical SAR optimization.

Results: Characterization of the Tn5 library confirmed a highly saturated collection with a 15bp-frequency of insertion.

Profiling existing compounds using TnSeq confirmed previously published data associated to influx and efflux liabilities. TnSeq also documents resistance and target pathways. Comparing profiles allowed to determine signatures. For instance, mutants implicated in DNA repair ([recN, dinG, xseA and hupAB] have a decreased fitness in presence of quinolones. Some have clear efflux liabilities like levofloxacin, minocyclin or tetracyclin, when others are clearly more active with short-LPS in waaP or waaG mutants.

The same approach applied to new compounds enables to rapidly predict their target pathways and resistance issues. For instance, we showed that a new compound targets DNA replication and has a dedicated influx pathway. In addition, we used TnSeq to compare three compounds of a novel series and document possible target deviation.

Conclusions: We have validated TnSeq as a powerful tool for the MoA identification, and guiding SAR making use of a robust collection of known molecules profiles.

Abstract 8079

**Evaluation of clinical safety and efficacy of letermovir for cytomegalovirus infection prevention in allogenic haematopoietic cell transplant recipients**

Marie Korostelev*, David Michonneau¹, Isabelle Madelaine¹, Touratier Sophie¹

¹Hospital Saint-Louis, Paris, France

**Background:** Cytomegalovirus (CMV) infection remains a common opportunistic infection after allogenic haematopoietic stem cell transplantation (HSCT). Letermovir is a new antiviral drug indicated in CMV infection prophylaxis post allogenic HSCT. By interfering with CMV terminase complex, letermovir has a different mechanism of action from ganciclovir with the benefit of non-inducing nephrotoxicity or myelotoxicity. The aim of this study is to assess clinical safety and efficacy of letermovir in a French reference centre of HSCT.

**Materials/methods:** This is a monocentric observational prospective study conducted during 23 months (01/2018-11/2019). All patients treated by letermovir during this period were included. Patients with high risk of CMV reactivation are defined by criteria: haplo-identic or non-related donor, SCT collected from umbilical cord, Graft-versus-Host Disease (GvHD) grade 2 or more, requiring systemic use of corticosteroids.

**Results:** During the study, 23 patients received letermovir. The average age of patients was 52 +/- 14 years old [19;69] and the sex ratio was 1:1. The allogenic HSCT was indicated for aplastic anemia [n=2]; acute myeloid leukemia [n=7]; chronic myeloid leukemia [n=2]; Griscelli disease [n=1]; lymphoma [n=2] and myelodysplastic syndRome [n=9]. CMV serological statuses were: R+/D- [n=7], R+/D+ [n=14], R-/D+ [n=1], R-/D- [n=1]. Twelve patients received 240 mg per day of letermovir in association with ciclosporin whereas 11 patients were treated by 480 mg of letermovir per day without ciclosporin. In median, letermovir was started 88 days [2;299] after transplantation and lasted 140 days [20;326]. Nine patients (39%) had a GvHD when they began letermovir. Reasons to stop letermovir were: the planned end of treatment without CMV infection (n=17; 74%); hematological disease relapse (n=3); CMV infection because of unfulfilled treatment (n=1) or explained by a resistance mutation (n=1), and patient death (n=1).

**Conclusions:** Our experience demonstrates the efficacy of letermovir in a real-world setting for CMV prevention with an effective prevention for 74% of patients. The long duration of treatment by letermovir (> 100 days) in this study is explained by the profile of patients with high risk of CMV reactivation. A long term evaluation would be necessary to evaluate the proportion of CMV infection after the end of letermovir treatment.

Evaluation of the PROMPT inoculation system with the MicroScan antibiotic susceptibility testing microplate designed for low-resource settings

Jean-Baptiste Ronat*1, Saoussen Oueslati2, Alessandra Natale3, Olivier Vandenberg4, Jan Jacobs5, Thierry Naas2

1Doctors Without Borders, Paris, France, 2Bicetre Hospital AP-HP EA 7361 (UPSud) - Structure, dynamique, fonction et expression de bêta-lactamases à large spectre, Le Kremlin-Bicêtre, France, 3Doctors Without Borders, Mini-Lab project, Paris, France, 4CHU Saint-Pierre, LHUB-ILB, Bruxelles, Belgium, 5Institute of Tropical Medicine Antwerp, Antwerpen, Belgium

Abstract third-party references: Médecins Sans Frontières

Background: The Mini-lab is a Médecins Sans Frontières (MSF) project for the development of an all-in-one clinical bacteriology laboratory deployable in low-resource settings (LRS). Three microplates were designed for AST, covering most clinically-relevant bacteria found in bloodstream infections using MicroScan lyophilized broth micro dilution plates (Beckman Coulter, Sacramento, USA). PROMPT™ inoculation system (Beckman Coulter, Sacramento, USA) was chosen as an easy method to obtain a standardized inoculum by none-expert microbiology technicians.

Materials/methods: The PROMPT inoculation system was evaluated against standard turbidity method using frozen isolates from routine clinical laboratory and challenging isolates from LRS following ISO20776-2:2007 guidance's with the MSF MicroScan Gram Pos panels [C32698] for Staphylococcus spp and Enterococcus spp species and MSF MicroScan Gram Neg panels [C32699] for Gram-negative bacterial isolates. EUCAST V9 recommended Disc diffusion, gradient diffusion method (E-test) or standard Micro broth dilutions using turbidity method, were used as comparators. In total, 123 Gram-positive and 157 Gram-negative isolates were tested. All panels were read visually using manufacturer instructions.

Results: With the MSF MicroScan Gram Neg panels no difference in performances was evidenced, the percentage of category agreement (CA) were all above 90% and major (MAJ) and very major error (VMJ) were below the 3% ISO threshold when using the PROMPT or standard inoculum. With the MSF MicroScan Gram Pos panels, for Staphylococcus spp, category agreement was much lower using the PROMPT versus standard inoculum for amikacin (78% - 93%), erythromycin (88% - 96%) and trimethoprim-sulfamethoxazole (81% - 93%) with no difference in VMJ. However, MAJ error rate was higher with the PROMPT for ciprofloxacin (8% - 2%), amikacin (7% - 1%), gentamicin (9% - 3%), vancomycin (4% - 0%), erythromycin (9% - 1%), trimethoprim-sulfadiazine (14% - 1%) and linezolid (5% - 1%).

Conclusions: PROMPT inoculation system results in increased MICs, which results in increase of Major Errors for ciprofloxacin and erythromycin for Staphylococcus spp. In addition, we found that the use of the PROMPT increased as well MICs and MAJ rates for gentamicin, amikacin, vancomycin, trimethoprim-sulfamethoxazole, and linezolid. Our results confirm the manufacturer recommendation not to use the PROMPT for Staphylococcus spp, standard inoculum should be used instead.

Abstract 8084

**Impact of saponin-based host DNA depletion on respiratory resistome measures**

Emily Reesey¹, Erik Clarke¹, Ebbing Lautenbach¹, Magda Wernovsky¹, Pam Tolomeo¹, Brendan Kelly*¹

¹University of Pennsylvania, Philadelphia, United States

Abstract third-party references: National Institute for Allergy and Infectious Diseases, Centers for Disease Control and Prevention (CDC)

**Background:** The low ratio of microbial to host cell biomass poses a challenge to metagenomic studies of the respiratory tract microbiome. Saponin-based host DNA depletion improves the efficiency of metagenomic respiratory microbiome analysis using long-read sequencing. We sought to (1) define the impact of saponin-based host DNA depletion on short-read metagenomic analysis of the respiratory tract microbiome and (2) evaluate the potential for saponin-based host DNA depletion to improve detection of respiratory tract antimicrobial resistance (AMR) determinants.

**Materials/methods:** We enrolled a cohort of subjects on admission to an academic long-term acute care hospital (LTACH) for ventilator weaning and performed longitudinal sampling of endotracheal aspirates. From 37 subjects, we selected 100 respiratory specimens which were split for DNA extraction with and without saponin-based host DNA depletion prior to metagenomic sequencing (Illumina HiSeq). Taxonomic assignment was performed with Kraken; resistome analysis with CARD-RGI. Statistical analysis was performed with R and Stan; mixed effects models were fit to define microbiome and resistome differences.

**Results:** Saponin-based host DNA depletion produced more metagenomic reads per respiratory specimen after human read filtering (Kruskal-Wallis p < 0.002). At the family level, saponin-treated specimens demonstrated higher read counts of Enterobacteriaceae and Halomonadaceae. However, saponin-based host DNA depletion did not significantly increase the detection of AMR determinants, at either the drug-class or gene category level.

**Conclusions:** Saponin-based host DNA depletion improves yield of microbial reads from respiratory tract specimens to which short-read shotgun metagenomic sequencing is applied, but this does not significantly improve detection of AMR determinants in the respiratory microbiome.

Epidemiology of candidaemia in Swiss tertiary care hospitals: a 15-Year Study 2004 to 2018
Kai-Manuel Adam*1, Michael Osthoff1, Anna Conen2, Veronique Erard3, Katia Boggian4, Peter W. Schreiber1, Frederic Lamoth6, Stefan Zimmerli2, Pierre-Yves Bochud6, Dionysios Neofytos8, Hans Fankhauser2, Reno Frei1, Konrad Mühlethaler9, Jacques Schrenzel8, Reinhard Zbinden5, Nathalie Vernaz8, Oscar Marchetti6, Nina Khanna1

1University Hospital of Basel, Basel, Switzerland, 2Cantonal Hospital of Aarau, Aarau, Switzerland, 3HFR Fribourg – Hôpital cantonal fî HFR Frébourg – Kantonsspital, Villars-sur-Glâne, Switzerland, 4Cantonal Hospital St. Gallen, St. Gallen, Switzerland, 5University Hospital of Zürich, Zürich, Switzerland, 6Lausanne University Hospital, Lausanne, Switzerland, 7Inselspital, Bern, Switzerland, 8University Hospital and University of Geneva, Geneva, Switzerland, 9Institut für Infektionskrankheiten, Bern, Switzerland

Background: Candidemia is the most frequent fungal bloodstream infection. Its epidemiology has evolved over the last two decades. New antifungal agents and new management strategies such as antifungal prophylaxis and preemptive therapy have been recommended over the last decade. These changes may have resulted in a change of *Candida* species causing invasive infections. However, recent comprehensive longitudinal data from Europe are limited.

Materials/methods: We conducted a 15-year nationwide survey of candidemia in all five university and two university-affiliated tertiary care hospitals from 2004-2018. Incidences of candidemia per 1000 admissions and antifungal consumption in defined daily doses (DDD) per 100 patient days were calculated. Preliminary descriptive data are presented.

Results: The annual number of hospital admissions and solid organ/hematopoietic cell transplantations increased from 152,036 to 378,865/year and 830 to 1,410/year over 15 years, respectively. A total of 2,233 episodes of candidemia were observed. *Candida* species ranked 9-10 among etiologic agents (2-3% of all bloodstream isolates). The incidence of candidemia decreased from 0.86 to 0.44/1000 admissions over the 15-year period [Figure 1]. *Candida albicans* episodes decreased significantly over 2004-2018 [0.55 to 0.22/1000 admissions] by remaining the predominant cause of candidemia [63% to 50%]. *C. glabrata* ranked second, and while the number of episodes decreased [0.20 to 0.12/1000 admissions], the proportion increased from 19% to 27%. *C. krusei* remained a rare isolate [3%), other non-albicans *Candida* episodes remained stable (around 0.10/1000 admissions). No *C. auris* blood isolate was recovered until 2018. Notably, species distribution varied significantly by age. *Candida albicans* was more common in children and in adults >40 years, than in adults 18-40 years. Fluconazole and voriconazole consumption remained stable since 2007, whereas posaconazole, liposomal amphotericin B and echinocandin consumption increased significantly.

Conclusions: Despite increasing high-risk activities, the incidence of candidemia decreased over 15 years, with a predominant decrease of *Candida albicans* episodes and a relative shift to resistant species. These epidemiological trends are possibly due to the increased use of prophylactic and preemptive antifungal management strategies. Additional analyses will be performed to investigate the causes of the noted epidemiological trends.

Ceftazidime-avibactam monotherapy for 7 days as treatment of KPC carbapenemase-producing Enterobacteriaceae bacteraemia in severely immunosuppressed patients

Fabian Herrera1, Elena Temporiti1, María Laura Jorge1, Andrés Nicolas Rearte1, Federico Nicola1, Sofía Zerboni1, Florencia Bues1, Rocío Rojas1, Pablo Bonvehi1

1CEMIC, Buenos Aires, Argentina

**Background:** Bacteraemias caused by KPC carbapenemase-producing Enterobacteriaceae (KPC-CPE) in immunosuppressed patients have more than 50% mortality rate. Treatment usually includes a combination of 2 or more active antibiotics for ≥10 days. Ceftazidime-avibactam (CA) has an important microbiological activity against these microorganisms, being able to be used as monotherapy, even in severe infections. However, to our knowledge, there are not enough data regarding short treatment for bacteraemia in severely immunosuppressed patients.

**Materials/methods:** Immunosuppressed patients with KPC-CPE bacteraemia who received treatment with ceftazidime-avibactam for 7 days were prospectively included, between August 2018 to June 2019. Clinical success was assessed at the end of treatment and 30-day follow-up was performed to evaluate mortality and recurrence of bacteraemia.

**Results:** Seven patients were included. Median age (IQR 25-75): 47 (38-59), APACHE II score (IQR 25-75): 23 (19-25). Other baseline, clinical and microbiological features as well as outcome are described in table 1.

**Conclusions:** Immunosuppressed patients with KPC-CPE bacteraemia who have clinical resolution during treatment with ceftazidime-avibactam, could be treated with this drug as monotherapy for a short period of time.

Intra- and inter-facilities spread of multidrug-resistant Enterobacteriaceae across a large nursing homes network

Clément Legeay1, Basile Fuchs2, Thomas Haudebourg3, Céline Poulain1, Françoise Raymond3, Stéphane Corvec2, Gabriel Birgand*3

1CHU Angers, Angers, France, 2CHU Nantes, Nantes, France, 3CPIAS Pays de la Loire, Nantes, France

Background: Nursing homes (NH) may play a major role in the spread of multi-drug resistant Enterobacteriaceae (MRE) over the healthcare network. We assessed the prevalence of, and factors associated with, ESBL or carbapenemase producing Enterobacteriaceae (ESBLPE or CPE) carriage across a large network of NHs in western France.

Materials/methods: Fifty NH from the Pays de la Loire region were randomly selected according to the geographical situation and density of NHs. One resident every three rooms was included in the prevalence survey. Stool samples were collected with swab and cultured on selective chromogenic media (ESBL-chromID® and chromID CARBA-SMART ID®). Mass spectrometry (Vitek MS) was used to identify Enterobacteriaceae species. ESBL, AmpC or carbapenemase production was respectively confirmed with MAST® and CORIS® test. Antibiotic susceptibilities were assessed using Vitek 2. Demographic and clinical data were collected prospectively on the day of the survey. Clonal relatedness was investigated by pulsed-field gel electrophoresis (PFGE).

Results: 734 residents from 30 different NHs were included. 83 (11.3%) were found colonized with ESBLPE (59 [71%] Escherichia coli – E. coli, 12 [14%] Klebsiella pneumoniae - Kp). The prevalence varied from 0% to 45% according to NHs. 44 (6%) carried an AmpCPE (18 [41%] Citrobacter spp, 14 [31%] Enterobacter spp.). None CPE was identified. Demographic and clinical data were available for 698 residents. 75% were female with a mean age of 88 years old. 37% were dement, 4% travelled abroad in the prior 12 months, 4% had a urinary tract catheter, 0.7% had a peripheral venous catheter and respectively 58% and 67% had fecal or urinary incontinence. History of travel abroad was associated with the ESBLPE carriage (n=9 [31%] ESBLPE+ vs 67 [10%]; OR = 3.9; IC95 = 1.7 – 8.9; p < 0.01).

A total of 10 clusters of ESBL E.coli and 1 of Kp were identified within 9 NH. 7 similar E.coli strains were identified across 8 different NH and 1 Kp across 2 NHs.

Conclusions: This study suggests that NH play a role in the intra and inter spread of MRE. The ongoing whole genome sequencing of strains and analysis of residents’ movements will help understanding these findings.

Abstract 8095

Effectiveness and safety of isavuconazole treatment for invasive fungal infections in solid organ transplant recipients

Arnau Monforte1, Ibai Los-Arcos1, Maite Martin1, David Campany1, Victor Monforte1, Cristina Berastegui1, Judith Sacanell1, Lluís Castells1, Isabel Campos-Varela1, Ricardo Ferrer1, Carles Bravo1, Joan Gavaldà1, Oscar Len1

1Hospital Universitari Vall d’Hebron, Barcelona, Spain

Abstract third-party references: Supported by a grant from Pfizer

Background: IFI is a significant complication following solid organ transplantation. Voriconazole is the treatment of choice for invasive aspergillosis. However, it is associated with many serious adverse events and has an important interaction with anticalcineurin and mTOR inhibitors. Isavuconazole is an alternative for voriconazole in hematological patients affected with IFI. Evidence regarding its use in SOTR is lacking. Our aim was to study the safety and tolerability of isavuconazole in SOTR.

Materials/methods: We prospectively included all SOTR from January 2018 to November 2019 who received isavuconazole for treatment of an IFI. The study was performed in Vall d’Hebron University Hospital, Barcelona, Spain. The duration of treatment depended on the type of infection and the treating physician. All patients were followed at least for 3 months after treatment. IFI was defined by ISHLT criteria for lung transplant recipients (LTR) or revised EORTC/MSG criteria in non-LTR.

Results: We included 28 SOTR treated with isavuconazole. Most of them (26/28, 92.9%) were LTR. The most frequent IFI treated was tracheobronchitis (12/28, 42.9%). SOTR were infected with Aspergillus spp. (87.5%): A. terreus (7/28, 25%) and A. fumigatus (7/28, 25%); all of them with ISA MIC≤0.5 μg/mL. Other treated infections included Scedosporium prolificans, Alternaria alternata and Trichosporon ashii, one case each. ISA was the initial treatment in 15/28 (53.6%) SOTR and following voriconazole due to adverse events in 4/28 (14.3%). The median duration of treatment was 98 days (IQR 19-193). Hepatotoxicity (mild elevation of cholestatic enzymes) was the commonest adverse event (39.3%). Myopathy was reported in 5/28 (17.9%) SOTR related to combination with corticosteroids. None of the patients developed breakthrough IFI. ISA was prematurely discontinued in only one patient (3.7%) due to significant elevation of transaminases. Dose of anticalcineurin inhibitors was initially adjusted in 33% SOTR, and up to 66.7% on the first days of treatment with a median of 33% decrease (1.2 mg). Four patients received concomitantly mTOR inhibitors with overall good tolerance. Eight (28.5%) SOTR died while on isavuconazole treatment. Another patient died during follow-up.

Conclusions: We consider that ISA was well tolerated and proved to be an effective treatment for IFI in SOTR.

*Staphylococcus aureus* dampen autophagy flux to survive inside a model of keratinocytes mimicking *S. aureus* nasal colonisation

Estelle Audoux1, Robin Caire1, Jérome Josse2, Celine Dupieux-Chabert2, Philippe Berthelot1, Frédéric Laurent2, Paul Verhoeven1

1Saint-Étienne, France, 2Lyon, France

**Abstract third-party references:** This research was funded by a grant from the University of St-Etienne

**Background:** *SA* uses the eukaryotic cell as a Trojan horse to escape both the immune system and antibiotics unable to diffuse into the cell. *SA* can invade non-professional phagocytic cells and induce autophagy by damaging endosomes. A recent study has shown that *SA* is able to induce selective autophagy and to dampen the autophagy flux through MAPK14/p38α phosphorylation. Our study aimed to characterize a model of HaCaT cells mimicking *SA* nasal colonization in order to identify *SA* virulence factors involved in the slowdown of autophagosome maturation.

**Materials/methods:** HaCaT cells were inoculated with *SA* HG001 strain. *SA* intracellular survival was quantified by lysostaphin protection assay. Autophagy response was followed by western blot and immunofluorescence microscopy using either chemical inducers or inhibitors of autophagy.

**Results:** *SA* HG001 was found to invade and to multiply inside HaCaT cells without inducing cell death up to 5-hour post-infection (hpi).

*SA* was able to induce both p38α phosphorylation at 1 hpi (p-p38/p38 = 0.5) and a significant accumulation of LC3-II and SQSTM1 at 5 hpi. Interestingly, neither p-p38 nor LC3-II and SQSTM1 accumulation was observed when HaCaT cells internalize heat-killed *SA* cells.

*SA* intracellular survival at 2 and 3 hpi was significantly increased in cells treated with rapamycin compared to untreated cells. Rapamycin treated cells inoculated with *SA* showed a 3.5 fold-change increase of p-p38 at 2 hpi and a 4 and 6 fold-change increase of SQSTM1 and LC3-II respectively at 5 hpi compared to untreated cells inoculated with *SA*.

Using bafilomycin A1 (BafA1), the intracellular *SA* load doubled at 5 hpi compared to untreated cells. As expected, BafA1 was found to increase LC3-II while SQSTM1/actin and p-p38/p38 ratios were similar to those observed in untreated cells suggesting that *SA* has no need to further slowdown the autophagy flux in BafA1 treated cells.

**Conclusions:** Here, we showed that HaCaT cells are a useful in vitro model to decipher how *SA* is able to take advantage of autophagy by dampening autophagosome maturation and fostering its survival inside keratinocytes. Using targeted CRISPR/Cas9 technology, further experiments are underway to identify *SA* virulence factors involved in autophagy subversion in keratinocytes.

The N-terminus of APOBEC3C regulates the antiviral activity against HIV-1
Kannan Balakrishnan*1,2, Ananda Ayyappan Jaguva Vasudevan1, Anucha Sangwiman1, Sharmistha Banerjee2, Carsten Münk1
1Clinic for Gastroenterology, Hepatology, and Infectiology, Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany, 2Department of Biochemistry, School of Life Sciences, University of Hyderabad, Gachibowli, Hyderabad, India

Background: The APOBEC3 (A3) family of single stranded DNA deaminases defends hosts from retroviruses, including human immunodeficiency virus (HIV)-1 lacking viral infectivity factor (vif) [HIV-1 Δvif]. Within primates, A3s have evolved diversely via gene duplications and fusions. A3 enzymes catalyze the dC to dU deamination in the viral genome, causing hypermutation that abrogates the virus. Human APOBEC3C (hA3C) is a strong restriction factor of Vif-deficient simian immunodeficiency virus (SIV Δvif), but exhibit a weak inhibition against HIV-1 Δvif for reasons unknown. Here, we set out to address the mechanistic understanding of A3C’s antiviral function and identify the determinant(s) of functionality of A3C.

Materials/methods: HIV-1 reporter viruses containing A3s were generated by transfection in HEK293T cells. Luciferase-based infectivity assay was used for checking HIV-1 infectivity. Differential-DNA-denaturation (3D) PCR and in vitro DNA cytidine deamination assays were used to study G-to-A mutations on the plus-strand of viral DNA. Molecular docking and simulation were performed between the A3C and ssDNA structure. EMSA was performed to check the protein-DNA interaction. Relative L1 retrotransposition activity was determined by applying a rapid dual-luciferase reporter based assay.

Results: Here we demonstrate that modifying the WE residues in hA3C loop 1 to RK leads to stronger interactions with ssDNA substrate, facilitating catalytic function, which resulted in a drastic increase in both deamination activity and the ability to restrict HIV-1 and LINE-1 replication. Conversely, the modification hA3F WE resulted only in a marginal decrease in HIV-1 Δvif inhibition. The two series of ancestral gene duplications that generated A3C, A3D-CTD and A3F-CTD allowed neo/subfunctionalization: A3F-CTD maintained the ancestral RK residues in loop 1, while strong evolutionary pressure selected for the RK: WE modification in catarrhines A3C, possibly allowing for novel substrate specificity and function.

Conclusions: In conclusion, we have identified the loop 1 region of A3C might have a conserved role in anchoring ssDNA substrate for efficient catalysis and that hA3C’s weak deamination and anti-HIV-1 activity might have been the result of losing DNA interactions in loop 1 during its evolution.

Abstract 8102

**Analysis of patients with severe complicated influenza in a hospital, 2015-2019**

Yi-Ching Huang*1

1Jen-Ai Hospital – Dali, Taichung, Taiwan

**Background:** Influenza, a viral respiratory infection, can cause mild to severe illness. Influenza A and B viruses are responsible for seasonal influenza epidemics every year. Elderly, young children and people with chronic diseases are high-risk groups for severe influenza with complications. In Taiwan, 7 % of patients having influenza with serious complications need intensive care, and about 20 % of whom died.

**Materials/methods:** The data was from the records of medical charts and microbiology laboratory at Jen-Ai Hospital - Dali, a 602-bed regional teaching hospital in central Taiwan. This study enrolled patients with severe complicated influenza from 1 January 2015 to 31 October 2019. Severe complicated influenza was defined as influenza followed by a complication (such as pneumonia, encephalopathy, invasive bacterial infection, or myocarditis) requiring hospital admission in the intensive care unit or leading to death within two weeks. The following information was collected: age, gender, chronic diseases, body mass index, vaccination, type of influenza viruses, concomitant bacterial infection, antimicrobial treatment, length of hospital stay, use of central venous catheter (CVC) or extracorporeal membrane oxygenation (ECMO), and outcomes.

**Results:** Totally 30 patients (15 men and 15 women) were enrolled. The average age was 65 years old (60 % were under 65 years old). The virus types included A/swH1 (60 %), AH3 (23 %), and B (17 %). Nearly half of patients had diabetes mellitus (47 %). Twenty percent of patients had hemodialysis. Forty percent of patients were overweighted (one fourth were obese) and ten percent of patients were underweighted. Only 4 patients received flu vaccine. *Klebsiella pneumoniae* was the most common bacteria isolated from sputum (23 %). Thirty percent of patients had CVC placement. Four patients received ECMO. The average length of hospital stay was 12 days. The mortality rate was 23 %.

**Conclusions:** In this study, patients with severe complicated influenza were mostly middle-aged, A/swH1 type, diabetes mellitus, overweighted, and had less flu vaccination. The patients with A/swH1 type had higher mortality rate and longer hospital stay.

Assessment of the performances of the novel BioNumerics-7.6 MTBC plugin for phylogenomic analysis and drug resistance prediction from Mycobacterium tuberculosis whole genomes

Wladimir Sougakoff*1;2, Florence Morel1;2, Gérald Millot1, Alexandra Aubry1;2, Jerome Robert1;2

1Hôpital Pitié-Salpêtrière, Sorbonne Université, APHP, Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux (CNR-MyRMA), Paris, France, 2Sorbonne Université, site Pitié-Salpêtrière, Centre d’Immunologie et des Maladies Infectieuses, Paris, France

Background: There are 3 major challenges regarding tuberculosis which still kills 1.4 million people/year: 1) the delay of diagnosis, 2) the identification of multidrug resistance, and 3) the development of new diagnostic tools. BioNumerics-7.6 is a programs suite that offers modules allowing the analysis of whole genomes sequences. Recently, a new MTBC genotyping plugin has been implemented with 3 functionalities: species and lineage typing, spoligotyping and resistance prediction. Here, we report the first evaluation of this plugin from a large set of clinical isolates.

Materials/methods: 406 whole genomes were obtained by Illumina sequencing from clinical isolates collected between 2006-2019, then assembled by using a Galaxy pipeline and BioNumerics-7.6. The lineages were determined by 24-loci MIRU-VNTR typing. The most common resistance mutations were detected by the MTBDR(+) assay (Hain) and by Sanger sequencing of PCR amplicons. The phenotyping of the clinical isolates was done on solid medium.

Results: We analyzed 344 isolates for which the MIRU-VNTR results were available. Amongst the 17 different lineages identified by MIRU-VNTR, the BioNumerics typing was concordant with MIRU-VNTR for 100% of EAI [N=12], 97% of Beijing [N=109/112], 95% of Delhi/CAS [N=19/20], 84% of Haarlem [N=67/80], 94% of LAM [N=34/36], 62% of Cameroon [N=8/13], 85% of H37Rv [N=11/13], and 57% of S [N=4/7]. Concordance was 100% for TUR [N=6], URAL [N=12], Ghana [N=19], Ugandan [N=5], Ugandan II [N=2], M.bovis BCG [N=2], and West African 1 [N=1]. The single M.canetti was not identified. The curated database of BioNumerics contains mutations related to resistance to 12 antituberculosis drugs. The MTBC plugin correctly predicted the sensibility/resistance profiles in 99% [379/384] of the strains for rifampicin, 98% [378/384] for isoniazid, 90% [283/314] for pyrazinamide, 94% [306/327] for ethambutol, 99% [381/384] for fluoroquinolones, 97% [216/222] for injectable aminoglycosides, 100% [207/207] for linezolid, and 100% [158/158] for bedaquiline.

Conclusions: We report the first evaluation of the use of the BioNumerics MTBC module for genotyping and prediction of drug resistance of Mtb. The MTBC plugin of BioNumerics is very promising for routine analysis of whole genomes of M.tuberculosis, specially to characterize and better control the spreading of multidrug- and extensively-drug resistant tuberculosis.

Abstract 8109

**Study of microbial adhesion to nanostructured and nanocoated orthoprosthetic material through dynamic models**

Simone Leonetti*1, Benedetta Tuvo1, Beatrice Campanella2, Massimo Onor2, Stefano Legnaioli2, Emilia Bramanti2, Angelo Baggiani1, Michele Totaro1, Paolo Domenico Parchi1, Beatrice Casini1

1University of Pisa, Dept. of Translational Research, N.T.M.S, Pisa, Italy, 2C.N.R. Istituto di Chimica dei Composti Organometallici, Consiglio Nazionale delle Ricerche, Pisa, Italy

**Background:** Bacteria can form submerged biofilms and are one of the most important causes in most states of chronic infectious diseases. Biofilms can also develop on abiotic surfaces, including medical devices such as orthopedic prostheses, artificial heart valves, coronary stents, intravascular and urinary catheters, breast implants, prosthetics eye devices.

**Materials/methods:** Two different types of nanostructured and nanocoated orthoprosthetic materials, crafted experimentally, were used to create coupons to be used inside the Drip Flow Reactor (DFR) bioreactor, TiAl6V4 titanium with and without coating in silver nanoparticles (TiAl6V4-AgNPs) and cobalt - chromium with and without coating (CoCr-AgNPs). The composition of coupons was verified by two different methods: X-ray fluorescence spectroscopy (XRF) and Laser-induced breakdown spectroscopy (LIBS). Biofilm formation on materials was evaluated according to the American Standards or Testing and Materials ASTM-E2647-13 on the Pseudomonas aeruginosa ATCC 700888 strain. Silver release during continuous flow was evaluated by ICP-MS spectrophotometric analysis. The expression level of the genes of the Las and Rhl system of Quorum Sensing was evaluated using the ΔΔCt method.

**Results:** The results showed an improved ability of cobalt-chromium to reduce microbial adhesion and biofilm formation, independently of the presence of silver nanoparticles [TiAl6V4-AgNPs] and cobalt - chromium with and without coating [CoCr-AgNPs]. The composition of coupons was verified by two different methods: X-ray fluorescence spectroscopy (XRF) and Laser-induced breakdown spectroscopy (LIBS). Biofilm formation on materials was evaluated according to the American Standards or Testing and Materials ASTM-E2647-13 on the Pseudomonas aeruginosa ATCC 700888 strain. Silver release during continuous flow was evaluated by ICP-MS spectrophotometric analysis. The expression level of the genes of the Las and Rhl system of Quorum Sensing was evaluated using the ΔΔCt method.

**Conclusions:** Nano-structuring and nano-coating of orthoprosthetic materials can be a valid strategy in the prevention of device-related infections, however their effectiveness should be evaluated with dynamic models that simulate the real dynamics of biofilm formation. The release of silver from the analyzed material resulted below the minimum inhibitory concentration, but this quantity found to promote the up-regulation of Rhl system. Furthermore investigation should be conducted to optimize the effectiveness of the coating.

Abstract 8110

**Characterisation of multidrug resistant *Shigella sonnei* isolated from men who have sex with men in Zagreb, Croatia**

Jasmina Vranes*, Nada Prazic, Branka Bedenic, Biserka Matica, Gernot Zarfel, Ivana Mareković

1Teaching Institute of Public Health “Dr. Andrija Stampar” and Zagreb University School of Medicine, Zagreb, Croatia, 2Teaching Institute of Public Health “Dr Andrija Stampar”, Zagreb, Croatia, 3University Hospital Zagreb and Zagreb University School of Medicine, Zagreb, Croatia, 4Institute for Hygiene, Microbiology and Environmental Medicine, University of Graz, Graz, Austria

**Background:** During 2018 epidemic spread of ciprofloxacin-resistant *Shigella sonnei* strains among men who have sex with men (MSM) in Zagreb was noticed. In MSM population *S. sonnei* infection is in most cases sexually transmitted and clusters are regularly reported. We investigated an outbreak of ciprofloxacin-resistant *S. sonnei* among MSM and studied its resistance profile.

**Materials/methods:** Eight isolates of *S. sonnei* from outbreak among MSM in 2018 in Zagreb were compared by antibiotic susceptibility testing and molecular typing by use of pulsed-field gel electrophoresis (PFGE). Isolates were tested for susceptibility to ampicillin, co-amoxiclav, cefazolin, cefuroxime, ceftriaxone, ceftazidime, amikacin, gentamicin, tetracycline, co-trimethoprim, pefloxacin, ciprofloxacin, and azithromycin. Disk diffusion and e-test were used for phenotypic characterisation of antibiotic resistance and PCR was used to detect genes encoding β-lactamases.

**Results:** The isolates were uniformly resistant to ampicillin, tetracycline, co-trimethoprim, pefloxacin, ciprofloxacin, and azithromycin (MIC>256). Ampicillin resistance was attributed to the production of TEM1 β-lactamase. PCR for SHV and OXA1 was negative. All isolates were resistant to co-amoxiclav according to disk-diffusion test with inhibition zone of 17-18mm, but susceptible according to e-test (MIC 2-6). Isolates collected during the outbreak from eight men with diarrhoea showed identical PFGE and resistance patterns and can therefore be regarded as clonally identical.

**Conclusions:** Asymptomatic and prolonged shedding in the reconvalescent phase may contribute to the transmission risk of shigella infection during oral-anal sexual practices. The risk of transmission of multidrug resistant *S. sonnei* in MSM population in Zagreb is further complicated by the resistance of shigella to usually used therapeutic options. Enhanced surveillance and risk-reduction interventions against the spread of shigellosis among MSM is needed.

Biomarker profiles in streptococcal skin and soft-tissue infections with or without necrosis or shock: a prospective multi-centre study

Eivind Rath*, Steinar Skrede, Laura M. Palma Medina, Knut Anders Mosevoll, Edoardo Saccenti, Sanjeevan Jahagirdar, Anna Norrby-Teglund, Trond Bruun

1Haukeland University Hospital / Health Bergen, Bergen, Norway, 2University of Bergen, Bergen, Norway, 3Karolinska Universitetssjukhuset Huddinge, Stockholm, Sweden, 4Wageningen University & Research, Wageningen, Netherlands

Background: β-haemolytic streptococcal (BHS) skin and soft tissue infections (SSTIs) range from mild superficial impetigo to necrotising soft tissue infections (NSTIs). Streptococcal NSTIs are associated with high rates of septic shock, organ failure and death. In the initial phase, symptoms can be vague and development can be rapid. Discriminating streptococcal NSTIs from less severe SSTIs can be difficult. The diagnosis of NSTIs is still, mainly based on clinical suspicion leading to surgical exploration, confirming the diagnosis. We aim to explore plasma biomarker profiles in severe and non-severe cases of streptococcal SSTIs, in an effort to detect biomarkers that could serve as novel diagnostic and prognostic tools.

Materials/methods: Cases were derived from the INFECT study, a prospective Scandinavian multicentre cohort study. Patients with monomicrobial NSTI or cellulitis caused by Streptococcus pyogenes or Streptococcus dysgalactiae were selected and plasma were analysed using a customised multiplex assay of 37 biomarkers (cytokines, chemokines, adhesion molecules and tissue remodeling factors). To identify immunological profiles associated with specific clinical endotypes, biomarker levels were evaluated in relation to type of infection, streptococcal species, presence of septic shock, and amputation or death using the Mann-Whitney U test, random forest plots and hierarchical cluster analysis.

Results: Altogether 125 monomicrobial streptococcal SSTIs (NSTI=102, cellulitis=23) were included. Significant differences in biomarker levels between streptococcal NSTI and streptococcal cellulitis were observed and several biomarkers showed area under receiver operating characteristic curve (AUROC) above 0.90. Within the NSTI cohort we identified several distinctions in biomarkers in those with or without septic shock, and some differences between deceased or amputated cases compared to those whom did not have these outcomes. Random forest plots predicted similar results. Hierarchical cluster analysis demonstrated distinct grouping of biomarker levels corresponding well to the different infections, clinical findings and outcome (Figure 1), substantiating the conventional analysis.

Conclusions: In a homogenous patient cohort of solely monomicrobial BHS SSTIs the measurement of a wide range of plasma inflammatory biomarkers allowed the characterisation of profiles from which candidate biomarkers for diagnostic or prognostic use can be further explored.
Application of direct MALDI-TOF MS analysis in routine study of gut microbiota of newborns

Priputnevich Tatiana*1, Alexey Gordeev1, Vera Muravieva1, Elena Isaeva1, Lyudmila Lyubasovskaya1, Alina Melkumyan1, Alexey Skorobogatiy1, Sergey Trubinov1, Gennadiy Sukhikh1

1National Medical Research Center for Obstetrics, Gynecology and Perinatology named after Academician V.I.Kulakov of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

Background: One of the main goals in studying microbiota of different biotopes is correct and relatively fast species identification of a large number of isolates of microorganisms, which became possible with the implementation of high-tech methods, including MALDI-TOF MS and sequencing of species-specific DNA loci. The aim of the study was to evaluate the possibility of using the direct MALDI-TOF MS analysis for reliable identification during the study of gut microbiota of newborns.

Materials/methods: Fecal samples of 50 healthy full-term newborns and 51 babies with gestational age 34-37 weeks were investigated by culturomics and mass-spectrometry. To isolate aerobic, facultative and obligate anaerobic microorganisms, method by "culturomics" with an extended set of nutrient media consisting of 17 selective and non-selective nutrient media was used. Microorganisms were identified by direct (non-extraction) MALDI-TOF MS analysis on the Autoflex LT mass spectrometer (Bruker Daltonics, Germany). Upon receipt of the SCORE value ≥2.1 a culture was considered identified to species with high probability. At values SCORE <2.0 isolates considered "hardly identified": species identification was considered controversial at SCORE from 1.6 to 2.0, not correct at SCORE<1.6. For all "hardly identified" isolates, verification control of identification was checked by sequencing the 16S rRNA gene on the 3130 Genetic Analyzer with BigDye™ Terminator v3.1 Cycle Sequencing Kit.

Results: At cultural study 1832 isolates of microorganisms were isolated: 1226 isolates of facultative anaerobes and 606 isolates of strict anaerobes. When evaluating the obtained SCORE values, it was found that in 1.5% of isolates SCORE value was <1.6; in 71.8% - was in the range of 1.6-2.0 and in 26.7% it exceeded 2.1. Eighty four "hardly identified" isolates were selected for sequencing. The correspondence of species identification obtained by both methods was 71%, with a SCORE above 1.8 all isolates were identified correctly.

Conclusions: The use of MALDI-TOF MS by direct application of the colony without extraction with a SCORE above 1.8 can be considered appropriate in routine microbiota research.

Abstract 8114

Antimicrobial susceptibility of Neisseria gonorrhoeae in Málaga, Spain

Fernández Ana María1, Miriam Valverde Troya1, Inmaculada De Toro Peinado1, Maria Dolores Rojo Martin1, Begoña Palop*1, Maria Concepcion Mediavilla Gradolph1

1Hospital Regional Universitario de Málaga, Servicio de Microbiología, Málaga, Spain

Background: Gonococcal infection is a public health problem as it is the second most common bacterial sexually transmitted infection. The analysis of antibiotic susceptibility data over a period of time allows knowing variations on it and helps in the selection of empirical treatment. Our objective was to analyze the evolution of Neisseria gonorrhoeae (NG) susceptibility to different antimicrobials over the last years in our hospital.

Materials/methods: We studied a total of 393 NG strains, isolated from genital samples processed in our laboratory from January-2012 to October-2019. We considered one strain per patient and year. Each antibiogram was performed by E-test or disk diffusion test, following EUCAST criteria. The tested antibiotics were penicillin, cefotaxime, cefixime, azithromycin, spectinomycin, ciprofloxacin and tetracycline.

Results: 83.7% of the strains were isolated from urethral exudate samples. The average age of our patients was 30 years and 88% were male. Antibiotic susceptibility is shown in the following table:

Penicillin: we found a decrease in susceptibility in the studied period, which remains relatively low.

The susceptibility of cefotaxime and cefixime showed a minimal decrease, remaining above 90%.

Azithromycin: a decrease in susceptibility is observed in recent years, worrying in 2019, which should be carefully monitored.

Ciprofloxacin: presents a discreet increase in susceptibility since 2015, which should continue to be evaluated.

Tetracycline: an increase in susceptibility is observed in 2015-2016, but it decreases again in subsequent years.

Conclusions: We can recommend cephalosporins as an empirical treatment and use azithromycin cautiously, evaluating the trend over the next few years.

Abstract 8115

**Supervised machine learning algorithms to predict the patient outcome during febrile neutropenia**  
Carolin Jakob*1, Maximilian Schons1, Melanie Stecher1,2, Frieder Fuchs3, A. Sarah Walker2,3, Oliver A. Cornely1,2,4, J. Janne Vehreschild1,2,5

1University of Cologne, Faculty of Medicine and University Hospital Cologne, Department I for Internal Medicine, Cologne, Germany, 2German Center for Infection Research (DZIF), partner site Bonn Cologne, Cologne, Germany, 3University of Cologne, Faculty of Medicine and University Hospital Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 4Cologne Excellence Cluster on Cellular Stress Responses in Aging Associated Diseases (CECAD), University Hospital of Cologne, Cologne, Germany, 5Department of Internal Medicine, Hematology and Oncology, Goethe University Frankfurt, Cologne, Germany

**Background:** Prolonged febrile neutropenia despite broad-spectrum empirical antibacterial treatment remains a clinical challenge, as standard empirical treatment has failed and a broad spectrum of differential diagnoses has to be considered. A reliable prediction of patient outcome could indicate that experts need to be consulted and could provide information on the effectiveness of treatment.

**Materials/methods:** We analyzed retrospective data of the Cologne Cohort of Neutropenic Patients (CoCoNut) including highly granular clinical data of cancer patients treated at the university hospital of Cologne between 2008 and 2014. We predicted the patient outcome (28-day survival or death/admission to intensive care unit) after four successive days of febrile neutropenia (neutrophils < 0.5 × 10^9/L and body temperature ≥ 38°C). We implemented four supervised machine learning approaches in order to (i) identify the best prediction algorithm and (ii) better explain the interaction and importance of features.

**Results:** We included 927 episodes of prolonged febrile neutropenia in the analysis of which 61% (562/927) were male with median age of 52 years (interquartile range 42-62). 42% (390/927) had acute myeloid leukemia (AML) and 32% (297/927) lymphoma. 23% (211/927) adverse outcomes were identified. We computed 240 features describing changes and interactions of clinical parameters. After feature selection and model tuning using repeated cross-validation we obtained in the validation dataset (neutropenic episodes in 2014) following area under the operating characteristic curve (AUC), sensitivity/specificity, and number of selected features: random forest; 0.70; 0.41/0.99; 135, Adaptive Boosting; 0.63; 0.27/0.99; 239, neural networks; 0.65; 0.32/0.99; 241, naive Bayes; 0.67; 0.36/0.99; 180. The performance of random forest for specific underlying diseases and age groups was: AML; 0.78; 0.55/1.00, lymphoma; 0.68; 0.36/1.00, age <52; 0.67; 0.33/1.00, age ≥52; 0.72; 0.46/0.98.

**Conclusions:** Our findings in a retrospective setting indicate that supervised machine learning algorithms can be used to fuse medical events for a prediction of the patient outcome. The high specificity shows the potential to use the algorithm in the clinic. Classification performance could vary for specific patient groups.

Abstract 8122

**Phylogenetic and taxogenomic approaches to elucidate the *Citrobacter* genus**

Teresa Gonçalves Ribeiro¹, Carla Rodrigues², Luisa Maria Vieira Peixe³

¹UCIBIO-REQUIMTE. Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, ²Biodiversity and Epidemiology of Bacterial Pathogens, Institut Pasteur, Paris, France

**Background:** *Citrobacter* genus comprises members inhabiting different habitats, including human and animal gut, with some species being involved in human infections and presenting multidrug resistance. Recent phylogenetic analysis based on recN or multilocus sequence analysis (MLSA), and comparative genomics (ANI; Genome-to-Genome Distance Calculator-GGDC) unveiled novel species within this genus (*Citrobacter pasteurii*, *Citrobacter europaeus*, and *Citrobacter portucalensis*). Nevertheless, the polyphyletic structure of *Citrobacter* sp. observed in 16S rRNA gene-based phylogeny motivated a reassessment of *Citrobacter* spp. taxonomic position among other genera of *Enterobacteriaceae* family.

**Materials/methods:** MLSA, recN-based phylogenetic analysis, ANI and GGDC were conducted with type strains of *Citrobacter* spp. and closely related genera (*Salmonella*, *Escherichia*, *Kluyvera* and *Klebsiella*). Furthermore, a core-genome phylogeny from all publicly available genomes of *Citrobacter* spp. and type strains from closely related genera (n=243) was produced using Roary (BLASTP identity cut-off of 50% and presence in more than 90% of the isolates) and a maximum-likelihood tree inferred using FastTree.

**Results:** MLSA- and recN-phylogenetic tree clearly demonstrated that *Citrobacter* genus is not monophyletic, with *Citrobacter* species being grouped into two distinct clusters and one branch. The 2,211 core-genes-based phylogeny was highly consistent with MLSA- and recN-based phylogeny, and revealed that the type strain of *Citrobacter* genus (*Citrobacter freundii*) grouped with eight other species in cluster I, while *Citrobacter amalonaticus*, *Citrobacter farmeri*, *Citrobacter rodentium* and *Citrobacter sedlakii* were within cluster II, and *Citrobacter koseri* formed a distinct branch (Figure 1). Moreover, it is noteworthy that cluster II was more closely related to *Salmonella* spp. than to *Citrobacter* cluster I. ANI values between *Citrobacter* clusters (80.36-81.96%) and between each cluster and *Salmonella enterica* LT2 (80.38-81.30% and 80.67-81.12%, respectively) were similar. GGDC values between *Citrobacter* clusters (23.90-25.50%) and between each cluster and *C. koseri* (26.00-26.90%) were clearly below the criterion for bacterial species (70%) delineation.

**Conclusions:** These data strongly support that species included in cluster I should be assigned to *Citrobacter sensu stricto*, while species from cluster II and *C. koseri* should be reclassified into novel genera.

**Figure 1.** Maximum likelihood phylogenetic tree inferred based on the concatenated nucleotide sequence alignments of 2,211 core genes.

Prevalence and clonal distribution of azole-resistant Candida parapsilosis isolates causing human bloodstream infections in a tertiary Italian hospital

Cecilia Martini*1, Margherita Cacaci1, Riccardo Torelli1, Elena De Carolis1, Theun De Groot3, Francesca Bugli1, Maurizio Sanguinetti1, Brunella Posteraro1, Jacques F. Meis3

1Dipartimento di Scienze di Laboratorio eInfettivologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, 2Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze di Laboratorio eInfettivologiche, Rome, Italy, 3Canisius Wilhelmina Hospital, Department of Medical Microbiology and Infectious Diseases, Nijmegen, Netherlands, 4Dipartimento di Scienze Gastroenterologiche, Endocrino-Metaboliche eNefro-Urologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: Candida parapsilosis species complex is a common human opportunistic pathogen that causes invasive fungal infections, particularly bloodstream infections (BSIs) in hospitalized patients. Among three closely related species, C. parapsilosis sensu stricto is responsible for most of infections associated with this species complex. The spread of the fungus from the healthcare environment to susceptible patients and the increasing emergence of fluconazole-resistant isolates in hospital settings complicate the situation. Here we report on the molecular characterization of azole-resistant C. parapsilosis sensu stricto (hereafter designated as C. parapsilosis) isolates recovered from BSIs in order to define their clonal prevalence and distribution over a 5-year period in a large Italian university hospital.

Materials/methods: C. parapsilosis isolates were identified at the species level using MALDI-TOF MS analysis, and were tested for antifungal susceptibility against fluconazole and voriconazole using the broth-microdilution based CLSI reference method. The azole target ERG11 gene from each isolate was sequenced by PCR, whereas multilocus microsatellite typing was performed using a previously described panel of six short tandem repeat (STR) markers.

Results: During the study period (May 2014–September 2019), we isolated C. parapsilosis from 249 cases of BSIs, including 80 central venous catheter-associated BSIs. Forty-nine (19.6%) of 249 C. parapsilosis isolates were resistant to fluconazole (MIC, ≥4 mg/L; range, 16–128 mg/L) and non-susceptible to voriconazole (MIC, ≥0.25 mg/L; range, 0.25–2 mg/L) according to CLSI clinical breakpoints. Of these isolates, 40 harboured the Y132F substitution and nine of them the Y132F substitution in combination with the R398I substitution. STR typing of 49 azole non-susceptible and 10 susceptible isolates showed the presence of two major genotypes, which only included the 49 fluconazole-resistant isolates. This was consistent with the idea that Y132F mutation may relate to the persistence of isolates in the hospital, whereas R398I mutation may arise to compensate for azole resistance-associated mutations.

Conclusions: Fluconazole-resistant clonal isolates harbouring the Y132F mutation were circulating in our hospital. The presence of two clusters of isolates with identical genotypes that infected different patients seems indicate a patient-to-patient transmission or a direct infection of patients possibly via a common source.

Abstract 8135

**Proinflammatory biomarkers are not useful as sepsis outcome predictors in patients older than 75**

Sonja Mitic*, Sonja Adamovic, Anita Vukelic, Dunja Becejac, Dajana Lendak

1Clinical Center of Vojvodina, Novi Sad, Serbia, 2Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

**Background:** Individual therapeutic approach to sepsis patients has been proposed recently based on the results of most studies. In the past, different biomarkers and their prognostic values for the outcome of sepsis have been studied, mostly on the population as a whole. A very few researches focus on immune response to sepsis taking into the consideration the patients age. Since the immune response is highly dependent on age, we have hypothesized that predictive value of different biomarkers could differ between age groups, and decided to examine predictive value of baseline measured C reactive protein, fibrinogen, procalcitonin serum levels as well as SOFA score on the outcome of septic patients, depending on their age.

**Materials/methods:** 514 consecutive septic patients were included. Patients were divided into two groups: younger and older than 75. Inflammatory biomarkers [C reactive protein, fibrinogen, procalcitonin] and SOFA score were compared within each group with the outcome through multivariate binary regression analysis.

**Results:** In the first group [18-75 years old], multivariate binary regression analysis revealed higher values of CRP serum levels, SOFA score, and lower PCT and fibrinogen serum levels as an independent predictor of lethal outcome (Table 1). In the second group [older than 75] binary logistic regression revealed only SOFA score as independent predictor of sepsis outcome \(p=0.025, \text{OR} 1.233 \ (95\%CI 1.027-1.481)\), while none of the proinflammatory biomarkers were noted as predictors of outcome.

**Conclusions:** The difference in the reactivity of immune system among different age groups enables the use of inflammatory biomarkers as predictors with regard to sepsis outcome in patients younger than 75 years of age.

Colistin heteroresistance in carbapenemase-producing *Acinetobacter baumannii*

Diana Machado*1, Sarah Gothe1, Marta Sofia Martins2, Teresa Pacheco1, Judite Batista1, Cristina Toscano1, Miguel Viveiros1

1Global Health and Tropical Medicine, GHTM, Instituto de Higiene e Medicina Tropical, IHMT, Universidade NOVA de Lisboa, UNL, Lisboa, Portugal, 2Department of Microbiology, Moyne Institute of Preventive Medicine, School of Genetics and Microbiology, Trinity College Dublin, Department of Microbiology, Moyne Institute of Preventive Medicine, School of Genetics and Microbiology, Trinity College Dublin, Dublin, Ireland, 3Serviço de Patologia Clínica, Laboratórios de Microbiologia Clínica e Biologia Molecular - Hospital de Evas Moniz - Centro Hospitalar de Lisboa Ocidental, Serviço de Patologia Clínica, Laboratórios de Microbiologia Clínica e Biologia Molecular - Hospital de Evas Moniz - Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

**Background:** Colistin is often the last therapeutic option against carbapenemase-producing *Acinetobacter baumannii*. We investigated the mechanisms of resistance in eight-colistin heteroresistant carbapenemase-producing *A. baumannii* strains isolated in 2010 from fatal bloodstream infections in elderly patients acquired during therapy.

**Materials/methods:** Heteroresistance to colistin was studied using E-test, broth microdilution and Levine-agar assay; ER-IC-PCR and MLST for genotyping; and whole genome sequencing. Biofilm formation and viability was determined by CFU’s determination and FilmTracer Live/Dead Biofilm Viability assay, respectively. Efflux activity was studied by MIC determination and time-kill assays for colistin in the presence of efflux inhibitors, real-time ethidium bromide efflux activity evaluation and analysis of mRNA transcriptional levels of selected efflux pump genes in response to colistin.

**Results:** All strains displayed heteroresistance to colistin demonstrated by E-test. Growth on Levine-agar supplemented with colistin revealed strain-variants exhibiting different colony morphologies, growth rates and susceptibilities to colistin. The colistin sub-population showed increased capacity to form biofilms. ERIC patterns showed the presence of three clusters comprising strains belonging to ST218 and ST350. All strains harbored mutations in the genes associated with colistin resistance: *lpxA*, *lpxC*, *lpxD*, *pmrA* or *pmrB*. Checkerboard assays showed MIC reductions ranging from 256- to 8-fold of colistin in the presence of the efflux inhibitor, thioridazine [TZ]. Real-time efflux assays demonstrated increased efflux activity in these strains, which could be inhibited by TZ. The efflux pump genes *adeB*, *adeJ*, *adeG*, *craA*, *amvA*, *abeS* and *abeM* were found overexpressed in these strains in response to colistin exposure.

**Conclusions:** This study provides a clear evidence of the impact of colistin-heteroresistant strains on patient outcome demonstrating the high versatility by which this bacterium manages to survive treatment. Under selective pressure, persistent colistin-resistant variants rapidly overtake the susceptible population and give rise to variants with high-level resistance. The use of efflux inhibitors as adjuvants of therapy may prevent the emergence of colistin resistant subpopulations during therapy. Understanding the mechanisms behind the development of colistin resistance will enable us to develop more effective therapies and give additional information on how to implement appropriate approaches for its detection.

Abstract 8138

Real-world experience with prolonged courses of tedizolid at a large academic medical centre
William Alegria*1, David Ha1, Marisa Holubar2, Lina Meng1, Emily Mui1, Stan Deresinski2
1Stanford Hospital at 300 Pasteur Drive, Stanford, United States, 2Stanford University, Stanford, United States

Background: Linezolid and tedizolid are important antibiotics in the management of infections due to resistant gram-positive organisms, including vancomycin-resistant Enterococcus (VRE). Tedizolid use has been purported to have a lower incidence of drug-induced thrombocytopenia compared to linezolid, although clinical experience, especially with administration for >6 days, is lacking. The primary objective of this study was to describe the real-world use of tedizolid, including tolerability and associated outcomes.

Materials/methods: We conducted a retrospective, observational study of patients receiving tedizolid for ≥ 10 days between September 2014 and October 2019. In patients without baseline thrombocytopenia, changes in platelets were evaluated. In patients with an intolerance to linezolid, subsequent tedizolid tolerability was evaluated. Clinical failure, microbiological failure, and 30-day all-cause mortality was also assessed.

Results: A total of 43 patients were included. The median duration of therapy was 20 days (IQR 15-37). 53% [23/43] had received linezolid; 13/23 had therapy discontinued due to an adverse drug event (ADE). The most common reason for linezolid discontinuation was thrombocytopenia [9/13]. Of these 9 patients, all but one went on to tolerate tedizolid for a median duration of 20 days [IQR 18-46]. In the overall cohort, only 3 [70%] patients had therapy interrupted for an ADE attributed to tedizolid. In the 17 patients without pre-existing thrombocytopenia, the average change in platelets was -4%, -11%, -4%, and -4% at days 10, 14, 21, and 30, respectively. Clinical failure was reported in 26% of patients [11/43] and 30-day all-cause mortality was 30% [13/43]. In patients with clinical failure,10/11 had documented VRE bacteremia with 6/10 experiencing microbiological failure (defined as a positive blood culture at ≥ 5 days from the index culture while receiving tedizolid).

Conclusions: Tedizolid administration for ≥ 10 days was well tolerated in this cohort of patients, including those with linezolid-induced thrombocytopenia. The high rate of clinical and microbiological failure in patients with documented VRE bacteremia warrants further investigation.

**Construction and investigation of lncRNA-associated ceRNA network in chronic hepatitis B infection**

Shengjie Wang*, Yinhao Wei, Jie Chen

1West China Hospital of Sichuan University, Chengdu, China
2West China Hospital of Sichuan University, Chengdu, China

**Background:** Researches on the functional role and underlying mechanism of long non coding RNA(lncRNA)-associated competing endogenous RNA (ceRNA) network in hepatitis B virus (HBV) persistence are facing challenges and it is worthwhile devoting much effort to them. This study aims to explore novel RNA biomarkers or therapeutic targets, and the molecular mechanism in HBV persistence as well as searching via analyzing ceRNA network in chronic hepatitis B (CHB).

**Materials/methods:** This study recruited three patients with CHB and three patients with spontaneous clearance of HBV (group 1), and twenty spontaneous clearance of HBV and nineteen CHB (group 2) in West China Hospital. Gene expression profiles of patients in group 1 were analyzed using microarray analysis to identify differently expressed (DE) lncRNAs, mRNAs and miRNAs. miRNA-target interactions and lncRNA–mRNA co-expression pairs were predicted via bioinformatics analysis. A lncRNA-associated ceRNA network of HBV persistence was constructed based on systematical investigation through miRNA-target predictions and co-expression relationships. Finally, Reverse Transcription-Polymerase Chain Reaction (rt-PCR) was performed to validate the expression levels of key RNAs (n332762, AIFM2, EPSTI, and LY6E) in group 2.

**Results:** A total of 368 lncRNAs, 256 mRNAs and 48 miRNAs were detected to be differentially expressed in patients with CHB compared with patients with spontaneous clearance of HBV (fold change > 1.2 and P < 0.05). After bioinformatics analyses and systematical investigation, a ceRNA network in CHB constructed based on co-expressed relationships above, which included 12 lncRNAs, 7 miRNAs, and 7 mRNAs (Figure 1). Expression levels of n332762 and AIFM2 were significantly downregulated in CHB compared with spontaneous clearance of HBV group while LY6E showed the higher expression level in CHB than the latter. The expression level of EPSTI have no significant difference between them.

**Conclusions:** These results suggested that the ceRNA network in CHB included 12 lncRNAs, 7 miRNAs, and 7 mRNAs might involve in HBV persistence. The downregulation of AIFM2 is associated with malignant prognosis of HBV infection while upregulation of LY6E enhance the HBV infectivity. These findings might provide new insights into the pathogenesis of CHB and lay a foundation for further functional research.

Abstract 8142

Comparative in vitro activity of ceftolozane/tazobactam, ceftazidime/avibactam, meropenem/vaborbactam, and imipenem/relebactam against susceptible and resistant Pseudomonas aeruginosa

Jason Pogue*, Keith S. Kaye1, Vincent Marshall1, Aaron Smith1, Carol Young1, Paul Lephart1, John P. Mills1, Owen Albin1, Twisha S. Patel1

1University Of Michigan Health System, Ann Arbor, United States

Background: β-lactam resistance in P. aeruginosa (PSA) is common and previous analyses have demonstrated high rates of cross-resistance between traditional anti-pseudomonal β-lactams, stressing the need for novel therapies. Four β-lactam/β-lactamase inhibitor combinations have recently been approved, but comparative in vitro susceptibility data against resistant PSA are lacking. The purpose of this analysis was to compare the in vitro activity of ceftolozane/tazobactam, ceftazidime/avibactam, meropenem/vaborbactam, and imipenem/relebactam against PSA at an institution that routinely tests all isolates to each agent.

Materials/methods: All non-duplicate PSA identified from patient samples at Michigan Medicine from 6/1/19 through 10/30/19 were included. Minimum inhibitory concentrations for antimicrobials were determined using TREK broth microdilution panels. CLSI breakpoints were used to determine susceptibility rates for all agents, except meropenem/vaborbactam where USCAST breakpoints were applied (≤8/8 mg/L).

Results: The table shows comparative susceptibility rates. All four novel therapies were more active than traditional β-lactams and retained high degrees of activity against resistant isolates. Importantly, even in the setting of resistance to one of the novel agents, the other agents often retained in vitro activity.

Conclusions: All four novel agents have improved in vitro activity compared to traditional β-lactams against resistant PSA at Michigan Medicine. Ceftolozane/tazobactam performed worse and meropenem/vaborbactam performed better in our isolates compared to published data. These results highlight the importance of understanding local susceptibility data and routinely testing all agents to inform both empiric and definitive therapy decisions.

Abstract 8143

Role of glucose transporters in the intracellular proliferation of Toxoplasma gondii
Thelma Belem Fernández Rebolledo*, Wendy Díaz Beltrán1, Manuel González-Del Carmen1

1Universidad Veracruzana: Facultad de Medicina campus Cd. Mendoza, Ciudad Mendoza, Mexico

Background: The protozoan Toxoplasma gondii is an obligate intracellular parasite which produces the human disease toxoplasmosis, which can progress to death, mainly in immunocompromised patients. This parasite has the ability to infect animals and humans, through the invasion of all nucleated cells of the organism by tachyzoites, the rapid stage of infection. The presence and uptake of glucose could be essential for its optimal growth, survival and dissemination. The uptake is done by activation of GLUT 4 glucose transporters, which migrate from the nucleus to the host cell membrane.

Materials/methods: HFF cell culture were infected with T. gondii tachyzoites extracted from peritoneal lavage of a mousse BALB/c model. Some conditions included the preincubation with WZB 117, a GLUT4 blocker, which was added in different concentrations, 5mM and 10mM. T. gondii tachyzoites and GLUT4 were stained by indirect immunofluorescence. Subsequently, the staining was observed under phase contrast microscope, quantifying the number of parasites per parasitic vacuole. The amount of glucose, in and out of the cell was determined using an enzymatic kit.

Results: The proliferation of Toxoplasma gondii tachyzoites decreases by inhibiting GLUT4 glucose transporters by WZB 117. Apparently, the decrease in intracellular glucose is associated with the inhibition of parasitic division.

Conclusions: The presence of glucose at the intracellular level regulates the cell division of Toxoplasma gondii, which is mediated by GLUT 4 transporters.

Abstract 8144

**Invasive aspergillosis caused by Aspergillus non-fumigatus in children and adults after haematopoietic stem cell transplantation (HSCT) & chemotherapy**

Marina Popova1, Yuliya Rogacheva*, Alisa Volkova1, Inna Markova1, Alexander Shvetcov1, Ilia Nikolaev1, Olga Pinegina1, Svetlana Ignatyeva2, Tatjana Bogomolova1, Aleksandr Siniaev1, Asmik Gevorgian2, Olesya Paina1, Tatjana Bykova1, Elena Darskaya1, Oleg Goloshapov1, Maria Vladovskaya1, Sergey Bondarenko1, Ivan Moiseev1, Ludmila Zubarovskaya1, Nikolai Klimko1,2, Boris Afanasyev1

1Raisa Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation, 2I.I. Mechnikov North-Western State Medical University, Ministry of Health of Russia, Saint Petersburg, Russian Federation

**Background:** Invasive aspergillosis (IA) is a major cause of morbidity in hematological patients. Aspergillus caused by non-fumigatus species is poorly studied.

**Materials/methods:** We design the retrospective study in order to investigate the epidemiology of IA caused by *Aspergillus* non-fumigatus as a single agent in large cohort of patients after HSCT and chemotherapy from 2013 to 2018 in CIC725. According to EORTC/MSG 2008 criteria 1 proven and 29 probable cases were diagnosed in patients with hematological malignances and non-malignant hematological diseases. The median age was 26 (3-60) y.o., males – 53%. The median follow up time was 10 months; for survivors – 17,5 months.

**Results:** The most common underlying diseases in patients with *A. non-fumigatus* IA were acute lymphoblastic leukemia (37%) and acute myeloid leukemia (30%). *A. non-fumigatus* IA was more often diagnosed in allo-HSCT recipients (90%) then after chemotherapy (10%). Most of the patients at the moment of IA diagnosed received antifungal prophylaxis with fluconazole (83%) or echinocandins (6,7%). Breakthrough IA (prophylaxis with voriconazole – 2, posaconazole – 1) was diagnosed in 10% of patients. Etiology agents were *A. niger* – 60%, *A. flavus* – 34%, *A. glaucus* – 3%, and *A. terreus* – 3%. The main sites of infection were lungs (80%), paranasal sinuses (10%), or combination lungs and paranasal sinuses (10%). *A. non-fumigatus* IA developed in combination with other infections in 20% (n=6): *Klebsiella pneumonia* – 33,3%, *Pseudomonas aeruginosa* – 33,3%, *Kocuria kristinae* – 16,7%, *Trichoderma viride* – 16,7%. The median time of onset of *A. non-fumigatus* IA after allo-HSCT was 155 (19-922) days. Antifungal therapy was used in all patients: voriconazole – 73,3%, lipid amphotericin B – 6,7%, posaconazole – 6,7%, combination therapy – 13,3%. *A. non-fumigatus* IA developed on the background of acute graft-versus-host diseases (GVHD) grade 2-3 + glucocorticoids therapy (25%) and CMV reactivation (19%). Overall survival (OS) at 12 weeks from the IA diagnosis was 83,3%. Death could be attributed to IA was registered in one case.

**Conclusions:** *Aspergillus* non-fumigatus invasive aspergillosis affected patients predominantly with acute leukemia (67%) and allo-HSCT recipients (90%). *Aspergillus niger* was the main etiology agent. *Aspergillus* non-fumigatus IA developed on the background of CMV reactivation and acute GVHD. OS at 12 weeks from the IA diagnosis was 83,3%.

Evaluation of efflux pump inhibitor combination with fluoroquinolones and aminoglycosides in resistant clinical isolates of Mycobacterium tuberculosis

Fernando Pavan*1, Camila Maringolo1, Júlia Grecco1, Debora Bellato1

1Sao Paulo State University (Unesp), Araraquara, Brazil

Abstract third-party references: This study was supported by the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) 2018/00163-0, Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPQ grant 162676/2013-1)

Background: Since antibiotic resistance is a factor that negatively influences the effective treatment of tuberculosis, treatment alternatives have been sought to overcome the mechanisms of bacterial resistance. Efflux pumps (EP) are membrane proteins capable of expelling substrates and antibiotics (ATB) from the bacterial interior. Increased activity or expression of these EP may result in resistance, which may be the main mechanism or a parallel mechanism to the presence of genetic mutations. For this study were selected from a library of Brazilian clinical isolates, those resistant to fluoroquinolones or aminoglycosides and that did not show mutations in rrs and gyrA genes to evaluate how much EP may be responsible for such resistance, combining ATB with efflux pump inhibitors (EPI) potentials: verapamil, reserpine and carbonyl cyanide m-chlorophenyl hydrazine (CCCP).

Materials/methods: Two phenotypic methods were used, the first one combining EPI in non-toxic concentrations with ATB ofloxacin, streptomycin and amikacin in an adaptation of Resazurin drugs combination microtiter assay (REDCA) or Checkerboard method and the second method was the evaluation of Bromide accumulation. Ethidium (EtBr) and the clinical isolate was previously exposed to subinhibitory ATB concentrations for 24 or 48h and also removing this exposure for the same period.

Results: As a result, it was observed that the presence of EPI in some cases reversed ATB susceptibility in the REDCA assay. Regarding the EtBr accumulation assay, it was observed that in the presence of EPI, the accumulation of EtBr within M. tuberculosis was differently changed in the presence of pretreatment and for each EPI present, showing that there is no unique profile of EPI. Verapamil stands out as a potential inhibitor in the ABC family responsible for mainly aminoglycoside efflux and CCCP for the MSF family most related to fluoroquinolone efflux.

Conclusions: So, it can be concluded that the combination of EPI with ATB is a therapeutic possibility and perhaps does not exert as much selective pressure as the use of other antibiotic combinations.

Contrast-enhanced ultrasound for the detection of abdominal complications in infective endocarditis

Gregor Paul*, Vanessa Priesner¹, Guido Michels², Christopher Hohmann¹, Roman Pfister¹, Navid Mader³, Lara Blanke¹, Myriam Ohler¹, Ellen Piepenbrock¹, Jan Rybniker¹, Clara Lehrmann², Gerd Fätkenheuer¹, Natalie Jaspers⁵, Norma Jung¹

¹University of Cologne, Department I of Internal Medicine, Division of Infectious Diseases, Cologne, Germany, ²University of Cologne, Department III of Internal Medicine, Cologne, Germany, ³University of Cologne, Department of Cardiothoracic Surgery, Cologne, Germany, ⁴University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, ⁵University of Cologne, Department of Gastroenterology and Hepatology, Cologne, Germany

Background: Embolic events are associated with increased morbidity and mortality in patients with infective endocarditis (IE). Contrast enhanced ultrasound (CEUS) is a highly sensitive imaging modality, which is safe, fast, cheap and omits the need for ionizing radiation or nephrotoxic contrast agents. The goal of this study was to assess the diagnostic potential of CEUS to detect abdominal complications of IE.

Materials/methods: This is a single-center cohort study. Abdominal CEUS was performed in 40 patients out of 235 prospectively registered patients with definite or possible IE between July 2013 and December 2016. Conventional B-mode ultrasound preceded CEUS in every patient. The definition of IE related lesions on CEUS included embolic infarction, metastatic abscesses and vascular aneurysms.

Results: CEUS was able to detect abdominal embolic events or metastatic infection in 12 patients (30%). Most commonly seen were splenic infarction (n=10), followed by renal infarction (n=2), liver abscess (n=1) and mycotic aneurysm (n=1). Six out of 14 lesions were only detected by CEUS and not by conventional ultrasound. Abdominal complications revealed by CEUS were associated with a detectable valve vegetation (P=0.04) and larger vegetation size (P=0.01). In three patients a non-IE related abdominal lesion (2 hepatocellular carcinomas, 1 psoas hematoma) was detected.

Conclusions: CEUS is a feasible diagnostic method in detection of abdominal complications of IE and enhances the detection rate of conventional ultrasound. Further prospective studies are needed to evaluate its diagnostic value in patients with IE, especially in comparison to other imaging modalities.

Background: HIV-1 diversity is increasing in European countries due to immigration flows as well as travels and human mobility leading to the circulation of both new viral subtypes and new recombinant forms with important implications for public health.

Materials/methods: We analyzed 710 HIV-1 sequences comprising protease and reverse transcriptase (PR/RT) coding regions, sampled from 2011 to 2017 from naïve patients in Spedali Civili’s Hospital, Brescia, Italy. Subtyping was performed using a combination of different tools; the phylogenetic analysis with a structured coalescence model and Makarov Chain Monte Carlo was used on the datasets to determine clusters and evolution.

Results: We detected 304 (43%) patients infected with HIV-1 non-B variants, of which only 293 sequences were available, with 4 pure subtypes and 5 recombinant forms; subtype F1 (17%) and CRF02_AG (51.1%) were most common. Twenty-five transmission clusters were identified, three of which included >10 patients; belonging to subtype CRF02_AG and subtype F. Most cases of alleged transmission were between heterosexual couples. Probably due to strong migratory flows, we have identified individual subtypes with particular patterns of recombination or, as in the case of the subtype G (18/293, 6.1%), to a complete lack of relationship between the sequenced strains revealing that they are all singletons.

Conclusions: The methods of phylogenetic analysis are advancing rapidly and the timing of the nodes as well as directionality of transmission being ever more accurate, provide consistent data in phylogenetic inference. This knowledge is important to monitor the efficacy of public health interventions aimed at controlling the HIV epidemic.

Abstract 8154

**Retrospective analysis of spinal infections over a 10-year period (2008-2018) in tertiary care hospital**

Alan Kan¹, Evangelos Vryonis*¹, Vjeran Cajic¹

¹University Hospital Coventry & Warwickshire, Coventry, United Kingdom

**Background:** Pyogenic spinal infections (PSI) are an all-encompassing spectrum of conditions with debilitating morbidity and mortality risk. Prognosis depends on early multidisciplinary approach to diagnosis and initiation of appropriate anti-microbial therapy.

**Materials/methods:** This a retrospective descriptive study aiming to review management of patients admitted in our hospital with PSI over the last 10-year period. Demographic characteristics, clinical, microbiological, and radiological data and outcomes were collected from patients’ hospital electronic records between 01/07/2008 to 30/06/2018.

**Results:** 183 patients were included in our study, median age 64 [59.6% males]. Most frequent site of PSI was lumbar spine (40%), followed by thoracic (20%), whilst 34% presented with disease in multiple spinal levels. 44% had discitis, 4% osteomyelitis, 17% epidural abscesses, and 34% combination of all three. PSI due to Gram-positive bacteria was found in 53% of cases and *Staphylococcus aureus* (SA) was the most frequent pathogen isolated in all age groups (44%). Gram-negative pathogens were isolated in 9% of PSI, with *E. Coli* accounting for 5%. SA was isolated in 21% of blood cultures and a significant correlation between SA presence in blood culture and spinal tissue was identified (OR16.06, CI: 3.2 to 78.92, p<0.05).

70% of our patients had antibiotic treatment alone (ATG) and 30% received concomitant surgical treatment (STG). SA was associated with severe disease and need for STG (p<0.05). STG was more associated with neurological deficits than ATG [OR 4.04, CI 1.936 to 8.091, p<0.05]. There was no significant difference in median antibiotic treatment duration between ATG (56 days) vs STG (70 days). In-patient mortality was 6% and there was no difference in mortality between ATG vs STG group. 90-day readmission rate was 12% and was higher in ATG (15.5%) vs STG (4%) [OR 4.77, CI 1.151-21.19, p<0.05].

**Conclusions:** There was no significance in admission length, duration of antibiotic therapy and mortality rates between surgically- and medically-managed patients with PSI. SA was the most prevalent pathogen isolated (44%) and SA isolation from blood cultures was predictive for SA-related spinal infection. SA was associated with more severe disease, abscess formation and need for surgical management.

The impact of candidaemia management on mortality: a 4-year retrospective study from a tertiary care hospital

António Martins*1, Cláudio Silva¹, João Paulo Caldas¹, Elsa Alves Branco¹, Sara Almeida Lacerda Pereira¹, Beatriz Prista Leão¹, Rita Filipe¹, Sara Magalhães¹, Maria Dolores Pinheiro¹, André Silva-Pinto¹, António Sarmento¹, Lurdes Santos¹

1Saint John Hospital, Porto, Portugal

Background: EQUAL Candida Score is a tool that aggregates factors regarding diagnosis, treatment and follow-up of candidaemia that measures adherence to the strongest recommendations of ESCMID and IDSA guidelines. Association between this score and outcome is still unclear. We aimed to review its impact on patients’ mortality.

Materials/methods: Retrospective study of candidaemia during a 4-year period in a tertiary hospital. Candidaemia was defined by at least one blood culture (BC) positive for Candida species. Data were collected from individual medical records. Two groups (fatality and non-fatality) were compared regarding patients’ characteristics and infection-related variables present within 60 days of first positive BC. The parameters daily follow-up BC collection until negative, echocardiography, ophthalmoscopy, antifungal treatment, initial treatment with echinocandin, step-down to fluconazole and 14 days treatment after first negative follow-up BC were individually included in a multiple logistic regression analysis adjusted for the variables differently distributed between groups.

Results: Two hundred and four episodes of candidaemia were reported (mean age 65 ± 23 years, mortality rate 46.6%). Variables associated with increased mortality were older age (p-value 0.004), hospitalization in intermediate or intensive care unit at the time of BC collection (p-value < 0.001), previous total parenteral nutrition (p-value 0.028), mechanical (invasive and non-invasive) ventilation (p-value < 0.001), sepsis due to Candida spp. (p-value < 0.001) and gastrointestinal perforation (p-value 0.036). Mean EQUAL Candida Score was 9 ± 3 points in both fatality and non-fatality groups (p-value 0.484). After adjusting for the possible confounding effect of the aforementioned 6 factors, using multiple logistic regression analysis, only treatment for 1-4 days after first negative follow-up BC had predictive value for mortality decrease (OR 0.331, CI 0.127-0.862).

Conclusions: The only confounder-adjusted parameter with positive impact on mortality was antifungal treatment for 14 days after negative follow-up BC. However, EQUAL Candida Score was low in both groups. Optimization of adherence to international guidelines is mandatory in order to re-assess the impact of quality candidaemia management practices on patients’ survival.

Use of whole genome sequencing for rapid detection of a national nosocomial outbreak of Listeria monocytogenes associated with contaminated prepacked sandwiches in England, 2019

Gauri Godbole*, Saheer Gharbia, Tim Dallman, Lisa Byrne, Ameze Simbo, Jim McIachlin, Sandra Lai, Nick Phin

Public Health England, London, United Kingdom

Abstract third-party references: Public Health England

Background: Prepacked sandwiches are commonly catered in hospitals in England. However, sandwiches are complex food items with multiple ingredients and serve as a potential vehicle for L. monocytogenes, a pathogen that can multiply and persist, particularly under suboptimal storage conditions. In April 2019, a national outbreak of listeriosis associated with the consumption of prepacked sandwiches served in hospitals was identified in England.

Materials/methods: The Public Health England (PHE) undertakes national surveillance of listeria, clinical data are collected from patients using a standard questionnaire, and food exposure data (30 days prior to onset of symptoms) are collected by direct interview. Isolates from cases and foods are voluntarily referred to the PHE Reference Laboratory for molecular typing. The isolates undergo whole genome sequencing (WGS) using Illumina, FASTQ files generated, the identification is confirmed using Kmer, MLST and clonal complex (CC) is derived (Pasteur) and SNP clustering tool is used to define the phylogeny and relatedness of strains.

Results: Between April- June 2019, nine confirmed cases of listeriosis associated with the outbreak were identified in England using WGS. The median age of cases was 75 years, six were female and all had received care at hospitals supplied by sandwich Supplier X prior to onset. All cases had underlying risk factors for listeriosis, seven have since died. The outbreak strain was L. monocytogenes serotype 1/2a, CC8, isolates from all cases and cooked meat sampled from Supplier X and Producer Y were phylogenetically linked and fell within a 5 SNP cluster (Figure 1). It was a unique strain and there are no isolates matching at a threshold of less than 25 SNPs in the PHE database.

Conclusions: This was one of the largest nosocomial outbreaks of listeriosis in the UK. WGS provided the highest level of strain discrimination, supported early detection and linked food isolates. This is especially important for listeria, which has a long incubation period and withdrawal of implicated food is an important control measure. The outbreak highlighted the risk of prepacked sandwich supply to vulnerable patients in healthcare settings.

Figure 1: Phylogenetic tree including confirmed cases and non-clinical isolates of L. monocytogenes outbreak strain
Impact of porin deficiency and expression levels of environmental CRH-1 and CRP-1 class A β-lactamases on carbapenem and ceftazidime resistance

Florencia Brunetti1,2, Barbara Ghiglione1,2, Dereje Dadi Gudeta3, Roque Figueroa1, Gabriel Gutkind*1,2, Luca Guardabassi3, Pablo Power1,2

1Universidad de Buenos Aires, Instituto de Investigaciones en Microbiologia y Virologia Molecular (IBaViM), Ciudad de Buenos Aires, Argentina, 2CONICET, Consejo Nacional de Investigaciones Científicas y Tecnicas, Buenos Aires, Argentina, 3University of Copenhagen - ITX, Department of Veterinary and Animal Sciences, Faculty of Health and Medical Sciences, Frederiksberg, Denmark

Background: CRP-1 and CRH-1 are class A β-lactamases (BLA) isolated from two environmental species, Chromobacterium piscinae and Chromobacterium haemolyticum, respectively. These enzymes have a high amino acid identity with KPC-2 (76% for CRP-1 and 69% for CRH-1) and were found to confer low-level resistance to carbapenems and oxyimino-cephalosporins in recombinant Escherichia coli clones. Here we assessed the impact of BLA expression on carbapenem and ceftazidime resistance levels in porin-deficient strains.

Materials/methods: CRH-1- and CRP-1-encoding genes were cloned in pMBLe vector, and transformed in E. coli TOP10, E. coli K12, and isogenic Omp-deficient strains. Since the pMBLe vector allows regulating the levels of protein expression by IPTG, MICs of carbapenems and ceftazidime were determined in recombinant E. coli TOP10 clones with increasing concentrations of this inductor. BLA expression was qualitatively measured by MALDI-TOF. For analyzing the porin-deficient clones, MICs were obtained with 50 µM IPTG, according to CLSI’s guidelines.

Results: MIC values of all β-lactams tested were higher in recombinant clones expressing CRP-1 that in those expressing CRH-1. E. coli TOP10 clones harboring CRP-1 and CRH-1 showed resistance towards imipenem and meropenem at all IPTG concentrations tested (50, 100 and 250 µM). MALDI-TOF assays showed that BLA expression in E. coli TOP10 clones was higher for CRP-1, compared to CRH-1. It also exhibited differences in CRP-1 and CRH-1 expression according to IPTG concentration, but such differences did not correlate with the MICs values. Absence of OmpF expression in CRP-1-producing clones yielded an increase in the MICs of meropenem (4 to 32 µg/ml) and ceftazidime (2 to 16 µg/ml). No changes were observed in the resistance phenotype of porin-deficient strains harboring CRH-1, probably due to lower protein expression.

Conclusions: Porin deficiency results in high-level carbapenem resistance in E. coli strains expressing CRP-1, indicating that some class A β-lactamases isolated from environmental bacteria can be expressed in E. coli and confer carbapenem resistance in combination with other resistance mechanisms like porin deficiency. This result supports the hypothesis that KPC-2 and other carbapenemases occurring in clinical pathogens could have evolved from environmental bacteria.

Abstract 8160

The rise and fall of a resistome: travel returners shed light on the dynamics of ESBL-producing Escherichia coli
Alfredo Mari*1,2, Ferdinando Bonfiglio3, Esther Kuenzli1, Daniela Lang2, Danica Nogarth2, Helena Seth-Smith2, Adrian Egli1,2

1University of Basel, Basel, Switzerland, 2University Hospital of Basel, Basel, Switzerland, 3Swiss Tropical And Public Health Institute, Basel, Switzerland

Abstract third-party references: Personalised Health Basel (PHB) Infectious Diseases Cluster

Background: Although ESBL E. coli are among the most studied microorganisms, a thorough understanding of their colonization and transmission dynamics in colonized people remains elusive. Travel returners from high-endemic countries pose a potential source for multi-drug resistance, but may help to understand ESBL-gene and -plasmid dynamics within colonized persons. We aimed to explore the AMR gene population (resistome) and plasmid population (plasmidome) of healthy travel returners being colonized with ESBL-E. coli strains over 5 years.

Materials/methods: We performed rectal swabs of 45 travel returners from South-East Asia and India prior to (H), directly after the travel (R0), and 3, 6, 12, 24 months after return, and for few participants, a follow-up 5 years (R5) later. A total of 82 ESBL E. coli strains were isolated on ChromID ESBL plates (Biomerieux). Whole genome sequencing (WGS) was performed via short-read sequencing (NextSeq500, Illumina), and R0 genomes additionally with long-read sequencing (Nanopore). Genome assemblies were screened for antimicrobial resistance (AMR) genes and plasmidic sequences with abricate, annotation was assigned using respectively the NCBI and PlasmidFinder database.

Results: Preliminary results indicate an immediate increase of AMR gene diversity after travel, and its progressive decrease over following months, correlating with loss of plasmid marker diversity. The resistome shows prominent patient specificity, which explained more than 50% of the resistome variance according to PERMANOVA (p-value=0.045, 1000 permutations). Large part of this patient specificity is linked to blaTEM genes fluctuations according to likelihood ratio test on fitted generalized linear models (p-value<0.05, 500 permutations). Interestingly, pairwise Wilcoxon-Mann-Whitney test showed a significant decreased detection of blaTEM.40 genes after 12 months, mirrored by the increased detection of blaCTX-M, seemingly in gene variant 27 and 55 (p-value<0.05).

Conclusions: Our results reveal a particular aspect of ESBL E. coli resistome dynamics in ESBL colonized otherwise healthy travel returners. Though the shift in resistome diversity may be somewhat expected, our results underpin the hypothesis of a pivotal role of blaTEM genes, which dynamically switches to blaCTX-M genes over time. This suggests a displacement of genetic elements or a succession of strains over time. Additional studies are needed to assess further the possible dynamics of the displacement itself.

Abstract 8162

Persistence of antimicrobial resistance genes in treated sewage water intended for reuse

Milena Dropa*1, Jessica Santiago Bispo Da Silva1, Terezinha Knöbl1, Marcos Paulo Vieira Cunha1, Ronalda Silva Araujo1, Carlos Jesus Brandão1, Maria Tereza Pepe Razzolini1, Maria Inês Zanoli Sato1,2

1University of São Paulo, School of Public Health, Sao Paulo, Brazil, 2University of São Paulo, Veterinary School, Sao Paulo, Brazil, 3CETESB - State of São Paulo Environmental Company, Sao Paulo, Brazil

Abstract third-party references: Supported by Fundação de Amparo à Pesquisa do Estado de São Paulo, Process n. 2016/06469-9.

Background: Water scarcity is a worldwide concern, and several countries use treated wastewater for varied purposes. Considering current Brazilian regulations do not define limits for antimicrobial resistance (AMR) determinants in reuse water, this study evaluated the persistence of AMR genes in raw and treated wastewater from sewage treatment plants in São Paulo, Brazil, during a one-year period using culture-independent methods.

Materials/methods: Samples of raw sewage (500mL), secondary effluent (activated sludge stage) (500mL) and reuse water (disinfection stage) (1L) were filtered through 0.45µm membranes and DNA was extracted directly from the membranes. Samples were also cultured to check bacteria viability. PCR was performed for the search of integrons and genes encoding resistance for β-lactams, Fluoroquinolones, Polymyxins, Aminoglycosides and Fosfomycins. Real time absolute quantification was carried out to enumerate total bacterial load (16S rRNA gene), Escherichia coli load (uid gene), and the genes encoding CTX-M and qnrB resistance proteins.

Results: Bacterial growth was observed in raw sewage and secondary effluent, but not on reuse water. PCR revealed that 88% (n=22) of the resistance genes were present in raw sewage, 72% (n=18) in secondary effluent and 40% (n=10) in reuse water. Mean total bacterial count was 9.7 log_{10}/L in raw sewage, 8.8 log_{10}/L in secondary effluent and 6.6 log_{10}/L in reuse water. Relative abundance (RA) of E. coli was 0.32% in raw sewage, 0.04% in treated wastewater and 0.05% in reuse water. For CTX-M, RA was 0.03% in raw sewage, 0.003% in treated wastewater and 0.004% in reuse water. Finally, qnrB concentration was 0.59% in raw sewage, 0.05% in secondary effluent and 0.06% in reuse water.

Conclusions: Results indicate that disinfection methods, although effective in attenuating culturable bacteria, do not remove all bacterial DNA. Resistance genes, which are easily spread due to their frequent location within bacterial mobile genetic elements, persisted throughout the treatment processes and got more concentrated from activated sludge to the disinfection stage. This is a concern due to the potential human exposure to AMR, even because treated wastewater is generally discharged into natural aquatic sources that can eventually contaminate water supplies, contributing to the resistance spread dynamics.

Abstract 8170

Neglected tropical diseases contribute to the number of years with civil war
Katharina Last*, Cihan Papan1, Sören Leif Becker1, Nico T. Mutters2

1Saarland University Hospital, Centre for Infectious Diseases, Institute of Medical Microbiology and Hygiene, Hamburg, Germany, 2Medical Centre, Faculty of Medicine, University of Freiburg, Institute for Infection Prevention and Hospital Epidemiology, Freiburg, Germany

Background: Both neglected tropical diseases (NTDs) and civil wars are strongly influenced by poverty conditions. However, while civil wars regularly lead to rising infectious diseases rates, the impact of NTDs on civil wars is less clear. On a micro level, high NTD prevalence is theorized in this study to influence civil wars via reinforced poverty conditions. On a macro level, high NTD prevalence is assumed to lead to a reduced tax income for the state and thus reduced state capacity.

Materials/methods: The prevalence rates of seven selected NTDs (leishmaniasis, schistosomiasis, trypanosomiasis, malaria, typhoid fever, filariasis and dengue fever) in 109 countries were analysed based on available epidemiological data. To circumvent causal inference problems, historic prevalence rates from the years 1944 and/or 1952-61 were used. The number of years with civil war was calculated for the period 1990-2011 to exclude Cold War dynamics. Proxies for poverty (bottom decile income/capita) and state capacity (road/telephone density and urban population) were included as mediator variables, while population size, percentage of mountainous terrain, previous civil war and a measure of regime authority were included as control variables. Zero-inflated negative binomial regressions were calculated to estimate effects.

Results: In our model, a one unit increase in a country’s NTD prevalence rate increased the number of years with civil war by a factor of 1.75 while holding all other variables in the model constant (0.56, CI 0.23-0.89, P = 0.001). Other significant variables included the percentage of mountainous terrain (0.21, CI 0.05-0.38, P = 0.01) and population size (0.26, CI 0.09-0.42, P = 0.002), which is consistent with civil war literature. Previous civil war events (-1.92, CI -3.23- -0.62, P = 0.004) and limited state capacity (6.53, CI 1.12-11.93, P = 0.018) were significantly associated with increased odds for a country to experience civil war.

Conclusions: We found an association between a high NTD prevalence rate and a country’s increased likelihood to experience civil war in the analyzed time period. Policies directed at affected populations in terms of prevention, diagnostics and treatment of NTDs may contribute to reduce the civil war risk profile of these countries.

Abstract 8174

Slovenian national outbreak of *Salmonella* Paratyphi B variant Java between 2014 and 2016

Spela Klemen1, Marija Trkov2, Alenka Storman3, Ziva Petrovic4, Anamarija Juricevic Dodic5, Ingrid Berce6, Mateja Ravnik4, Mateja Pirs7

1National Laboratory of Health, Environment and Food, Maribor, Slovenia, 2National Laboratory of Health, Environment and Food, Ljubljana, Slovenia, 3National Laboratory of Health, Environment and Food, Celje, Slovenia, 4National Laboratory of Health, Environment and Food, Koper, Slovenia, 5National Laboratory of Health, Environment and Food, Nova Gorica, Slovenia, 6National Laboratory of Health, Environment and Food, Kranj, Slovenia, 7University of Ljubljana | Faculty of Medicine, Institut Of Microbiology And Immunology, Ljubljana, Slovenia

Abstract third-party references: Slovenian Society for Clinical Microbiology and Hospital Infections of the Slovenian Medical Association

**Background:** *Salmonella* Paratyphi B d-tartrate positive (*S. Paratyphi B var. Java, S. Java*) is a less virulent variant of serotype 1,4,12:b:1,2 which has been increasingly reported serovar in recent years with a number of recognized national or multinational outbreaks. In Slovenia the incidence of S. Java rose from 0.53/100,000 inhabitants in 2011 to 1.12/100,000 in 2014, peaking in 2015 with 2.28/100,000; in 2017 the incidence was 0.73/100,000. S. Java became the second most frequently reported serovar in 2015 and the third in 2016. Between 2011 and 2017 147 S. Java isolates were reported in Slovenia, 59.9% (88/147) from Central Slovenian region (CSR), majority of those were detected since 2014, transient increase was present in one additional region. At the time the cases appeared sporadic and no detailed epidemiological investigation was launched. The aim of the study was to analyse whether the S. Java isolates were related and to establish whether an epidemiologically unrecognized outbreak occurred.

**Materials/methods:** One S. Java isolate per month per region isolated between 2013 and 2017 was selected for genotyping. In total 64 S. Java isolates were included in the study (27 isolates from CSR, 37 isolates from 5 other regions including one environmental isolate). Pulsed-field gel electrophoresis (PFGE) was used to determine relatedness among selected isolates according to the Pulse-Net protocol. Whole-cell DNA was digested using XbaI restriction endonuclease. PFGE profiles were analysed using BioNumerics software, dendrogram was constructed using the Dice coefficient with 1.5 optimization and tolerance and unweighted-pair group method using average linkages (UPGMA) clustering.

**Results:** PFGE analysis demonstrated that 90.6% [58/64, 57 patients, 1 environmental isolate] of S. Java belonged to the same pulsotype which was present in 6 Slovenian regions spanning all investigated years. Remaining 6 isolates belonged to 5 different pulsotypes.

**Conclusions:** Our study has demonstrated that the majority of the S. Java isolates belonged to the same pulsotype and even though the cases between 2014 and 2016 clinically appeared to be sporadic, our findings indicate that there may have been a common source. Further investigation into epidemiological connections is needed as well as more detailed genotyping using whole genome sequencing.

Abstract 8178

**Application of WISCA (Weighted Incidence Syndromic Combination Antibiogram) to guide empiric therapy in oncological paediatric patients with febrile neutropenia**

Elisa Barbieri*1, Daniele Bottigliengo2, Paola Costenaro2, Antonio Marzollo1, Maria Grazia Petris1, Marta Pierobon1, Giada Biddeci1, Carlo Giaquinto1, Alessandra Biffi3, Daniele Donà1

1University of Padova, Division of Paediatric Infectious Diseases- Department for Woman and Child Health, Padova, Italy, Padova, Italy, 2University of Padova, Unit of Biostatistics- Epidemiology and Public Health- Department of Cardiac- Thoracic and Vascular Sciences and Public Health, Padova, Italy, Padova, Italy, 3University of Padova, Pediatric Hematology-Oncology Unit - Department for Woman and Child Health, Padua, Italy, Padova, Italy

**Background:** Febrile neutropenia (FN) is an acute potentially life-threatening oncological complication which should be treated promptly with antibiotics. With the spread of antibiotic resistance, the choice of an empiric therapy is driven by local epidemiology usually described by cumulative pathogens susceptibilities antibiograms. The WISCA attempts to address the unmet need for syndrome-specific local susceptibility data to guide empirical prescribing, providing estimates for different treatment regimens as a weighted average of pathogens susceptibilities. Our aim was to create a WISCA model to inform empirical antibiotic regimens selection for FN in children.

**Materials/methods:** We included all non-duplicate blood cultures from patients aged 0-17 years with FN admitted to the paediatric oncology/hematology wards in Padua from January 2016 to August 2019. WISCA was developed by estimating the sensitivity of 29 antibiotic regimens with a Bayesian probabilities distribution. Moreover, we created a second model with 57 blood cultures excluding potentially contaminant bacteria.

**Results:** We collected 69 blood cultures, 41 Gram- and 28 Gram+ bacteria. Considering most used combinations such as piperacillin-tazobactam + amikacin the median sensibility was 58% (BUI 33-84%) that increased to 70% (BUI 42-85%) in the second model. When adding a glycopeptide to this combination the median sensibility increased dramatically (Figure 1). The highest median sensibility for a beta-lactam + aminoglycoside combination was 66% (BUI 37-86%; meropenem + amikacin) in the first model and 75% (BUI 46-85%) in the second model; the lowest was 42% (BUI 26-75%; ceftriaxone + amikacin) and 50% (BUI 32-76%) respectively. Overall mono-treatments had median sensibility lower than 50%, except meropenem (65%; BUI 35-85) and gentamycin (60%; BUI 33-84%), but in the second model most median sensibilities increased above 50%. WISCA model with median sensibilities and uncertainty intervals is shown in Figure 1.

**Conclusions:** WISCAs represent a valid tool to maximize the clinical utility of microbiological surveillance data supporting appropriate empirical antibiotic treatment selection, while contributing to conservation of broad-spectrum antibiotics.

Abstract 8179

Diagnostic approach for Aspergillus infection: performance evaluation of a new molecular assay for detection and quantification of Aspergillus spp. in clinical samples

Rosamaria Tedeschi⁎1, Paola Stano1, Lucia Pagani1, Giada Lorenzi1, Graziella Ciganotto1, Paola Zigante1, Alessandro Camporese1

1Microbiology and Virology Unit, AAS5 S. Maria degli Angeli Hospital, Pordenone, Italy

Background: The conventional diagnosis of Aspergillus infection is based on the presence of risk factors, radiological features, and microbiological results, i.e., histopathology and/or culture of Aspergillus spp. Important advances to the diagnostic field were brought by the introduction of non cultural tests in respiratory samples and blood, including PCR assay. Our study describes the performance of the new quantitative Real-Time PCR assay Aspergillus spp. ELItel MGB® Kit in association with ELItel InGenius instrument for Aspergillus spp detection in bronchoalveolar lavage (BAL) and plasma samples.

Materials/methods: Totally, 88 BAL and 82 plasma, collected in the period may-november 2019, were evaluated. The BAL were collected from patients undergoing bronchoscopy for monitoring or diagnosis of pulmonary infiltrates and blood samples were collected from immunocompromised and/or oncological patients in clinical follow-up. Clinical information was picked up during the routine diagnostic process; patients were classified as having IPA (proven/probable/possible) or no-IPA according to the EORTC/MSG diagnostic criteria. The Aspergillus spp. ELItel MGB® Kit in association with the ELItel InGenius® instrument (Elitech, Torino) is a quantitative real-time PCR with a target within the 28S rDNA. The volume of clinical sample required was 1ml. BAL fungal culture were also performed.

Results: The diagnostic specificity was 100% for BAL and 98% for plasma. The diagnostic sensitivity was 88.6% for BAL and 100% for plasma. The turnaround-time was about 150 minutes. PCR was positive in BAL from 24 patients: 6/24 (8.1%) had pulmonary chronic aspergillosis, 7/24 (9.4%) had invasive pulmonary aspergillosis and 11/24 (14.8%) had colonization.

Conclusions: Aspergillus spp. ELItel MGB® Kit in association with ELItel InGenius instrument is a highly sensitive method for detection and quantification of Aspergillus spp in BAL and plasma samples. This molecular system represents an innovative and fast solution with a simply laboratory workflow and a short report time. It is conceivable that the introduction of this assay in routine diagnosis and its incorporation into the patient care pathways could be a promising tool, in combination with other clinical information and biomarkers, for an improvement in detection and management of Aspergillus infection, and subsequently in the patient outcome.

Background: Although bone marrow (BM) samples are recommended for the diagnosis of certain infections in the living patient, little is known about the performance of BM in diagnostic autopsies. We aimed to investigate the performance of molecular testing in BM samples for the diagnosis of fatal disseminated infections.

Materials/methods: This study is part of the CaDMIA project; an observational study that included complete diagnostic autopsies (CDAs) for cause of death (CoD) ascertainment. Body fluids and tissue samples were collected for microbiological and histopathological analyses. For the present study, 61 cases from the Fundação de Medicina Tropical Doutor Heitor Vieira Dourado in Manaus, Brazil were included. The median age of the patients was 39 years-old [range 18-81] and 67% were male. Nucleic acid extractions of BM samples were performed using a semi-automated system and were tested for pathogens causing fatal disseminated infections using specific real time PCR assays.

Results: Twenty-seven disseminated infections were detected in the CDA, from which 21 (78%) were HIV infected. The aetiology of the fatal disseminated infections and the results obtained with the analysis of BM samples are shown in Table 1. Molecular testing of BM samples detected 23/27 (85.2%) disseminated infections causing death. Mycobacterium tuberculosis was the pathogen most frequently causing death and was detected in 6 out 7 deaths in BM samples. The pathogens could be also detected in cases dying of fatal localized infections and in cases dying of other etiologies.

Conclusions: Molecular investigation of BM samples detected most pathogens causing fatal disseminated infections. Some microorganisms such as cytomegalovirus can be frequently detected in postmortem BM samples.

Abstract 8183

Pragmatic ranking of antibiotics based on spectrum and ecologic impact for educational purposes: results from a Delphi survey for Dawaa

Liem Binh Luong Nguyen1,2, Charles Cazanave3, Vincent Dubee4, Camille D'humieres2,5, Stéphane Jauréguiberry6, Solen Kerneis7, Agnes Lefort2,8, Raphael Lepeule9, Benoit Pilmis10, Salam Abbara11

1Unité des Maladies Emergentes, Institut Pasteur, Paris, France, 2University of Paris, IAME, UMR 1137, INSERM, Paris, France, 3Hospital Center University De Bordeaux, Department of Infectious and Tropical Diseases, Bordeaux, France, 4centre hospitalier universitaire d’Angers, Department of Infectious and Tropical Diseases, Angers, France, 5Bichat-Claude Bernard Hospital, AP-HP, Department of Microbiology, Paris, France, 6Bicêtre Hospital, AP-HP, Department of Infectious and Tropical Diseases, Le Kremlin-Bicêtre, France, 7Hospital Cochin, AP-HP, Antimicrobial Stewardship Team, Paris, France, 8Hospital Beaujon, AP-HP, Department of Internal Medicine, Clichy, France, 9Hôpital Henri-Mondor AP-HP, Antimicrobial Stewardship Team, Créteil, France, 10Hôpital Necker, APHP, Department of Infectious and Tropical Diseases, Paris, France, 11Institut Pasteur, UMR 1181 INSERM, Paris, France

Background: “Dawaa” is an educational board game aiming at raising awareness on antimicrobial resistance and teaching antibiotic use to medical students. It ranks antibiotic, based on spectrum and potential for selection of resistant strains. This ranking is difficult to achieve, because there is no clear hierarchy nor strong evidences, especially other than beta-lactam antibiotics. The aim of this work was to reach a consensus.

Materials/methods: We formed a scientific board which included six infectious disease specialists, one internal medicine physician and one microbiologist, among which six were academics. Twenty-three antibiotics were selected for ranking. Each expert was asked to attribute penalty points from 1 to 5 to each antibiotic. A Delphi process with successive rounds was conducted to reach an agreement. More than 70% of similar answers were necessary to reach a consensus.

Results: The study was carried out between February and July 2019. A consensus for all antibiotics except carbapenems was reached after three rounds. No experts attributed a penalty of 1. A penalty of 2 was attributed to penicillin M, penicillin A, piperacillin, 1st- and 2nd-generation cephalosporins, pristinamycin, rifampicin, vancomycin, aminoglycosides, macrolides, metronidazole, fosfomycin, cyclins, and aztreonam. A penalty of 3 was attributed to amoxicillin-clavulanate, 3rd- and 4th-generation cephalosporins, and clindamycin. A penalty of 4 was attributed to piperacillin-tazobactam, ticarcillin-clavulanate, and fluoroquinolones. A panel discussion was conducted at the beginning, and in the end of the survey. It appeared that antibiotics were first ranked by the broadness of their spectrum, and a penalty of 4 was attributed to antibiotics known for selecting resistant strains. Experts finally attributed a penalty of 5 to carbapenems to teach students to consider these molecules, with extremely broad spectrum, as last resort treatment.

Conclusions: Through a Delphi process with experts, we were able to attribute antibiotic penalties to most clinically-used antibiotics, including other than beta-lactam antibiotics, for “Dawaa”. These penalties first accounted for the broadness of the antibiotics’ spectrum, and then supposed ecologic impact, and carbapenems to be kept as last resort treatment.

Abstract third-party references: MeMed diagnostics LTD.

**Background:** Distinguishing bacterial from viral etiology in febrile patients with lower respiratory tract infection (LRTI) is a frequent challenge faced by physicians at the emergency department (ED). Based on meta-analyses of published data, procalcitonin (PCT), a bacterial induced biomarker, was recently cleared to guide antibiotic treatment in adult patients with LRTI. However, prospective data on PCT accuracy in differentiating bacterial from viral infection is lacking. Here we evaluated its diagnostic performance for differentiating bacterial from viral infection in adult and pediatric patients presenting to the ED with LRTI.

**Materials/methods:** This is a sub-analysis of two European commission funded, prospective studies, conducted at European and Israeli EDs that recruited patients with suspicion of LRTI (OBSERVER; NCT03011515; grant #684599; adults>18 years old) or respiratory tract infection and fever without source (AutoPilot-Dx; NCT03052088, grant # 701088; 3 months<children<18 years). For every participant, we collected medical history, physical examination, routine lab, imaging and respiratory multiplex PCR data. The cohorts included patients with LRTI discharge diagnosis and PCT test results, who were assigned reference standard bacterial or viral by majority adjudication of an expert panel; children (n=293) and adults (n=139).

**Results:** 63 pediatric patients were assigned reference standard bacterial and 230 reference standard viral. LRTI included pneumonia (46%), bronchiolitis (6%), acute bronchitis (18%), influenza (21%) and unspecified LRTI (9%). 67 adult patients were assigned reference standard bacterial and 72 reference standard viral. LRTI included pneumonia (53%), acute bronchitis (36%), asthma or COPD exacerbation (8%) and unspecified LRTI (3%). PCT at cutoff of 0.25 μg/l displayed significantly decreased sensitivity and increased specificity in adults as compared to children (p<0.05; Table 1). Adherence to PCT guided antibiotic prescription for adults would have resulted in ~36% underuse rate (24 patients with PCT≤0.25 μg/l out of 67 reference standard bacterial) and ~10% overuse rate (7 patients with PCT>0.25 μg/l out of 72 reference standard viral).

**Conclusions:** PCT did not meet in adults or children the target product performance for differentiating bacterial from viral infection as defined by Foundation for Innovative New Diagnostics (FIND), indicating an unmet need for host-response biomarkers with higher performance to support improved antimicrobial treatment decisions.

Impact of a French regional centre infectiology hotline on antibiotic prescriptions in general medical practice

Margaux Bachelet¹, Pascal Thibon², Anaïs Lesourd³, Sylvie Dargère⁴, François Caron⁵, Renaud Verdon⁶, Elise Fiaux⁷

¹University Hospital Charles Nicolle, Emergency Unit, Rouen, France, ²University Hospital Caen, Epidemiology, Caen, France, ³University Hospital Charles Nicolle, Infectious diseases Unit, Rouen, France, ⁴Rouen University Hospital, Rouen, France, ⁵University Hospital, Infectious diseases unit, Caen, France

Background: Since 2016 a regional hotline dedicated to antibiotic (AB) stewardship is available for physicians and especially used by general practitioners (GP). We aimed to measure the impact on GP’s AB prescriptions and to study the population of GP using this device.

Materials/methods: We conducted a prospective observational regional study from April to July 2019. All the AB queries from GP were identified. The AB suggested by the GP was compared to the AB prescribed by the infectious diseases (ID) specialist. D7 a survey was sent to all the GP in order to collect characteristics of the GP population and evaluated the reduction of AB consumption.

Results: Overall 783 calls were received, 176 came from a GP of which 122 were reviewed. Mean age of patients was 51.4 yr (+/-23.3), sex ratio 1.2. Urinary tract infections represented 40.2% (49/122) of inquiries, cutaneous infections 23.0% (28/122) and genital infections 9.0% (11/122). Before ID advice, GP would have prescribed an AB for 71.6% of patients (73/122). After ID advice, AB was stopped/delayed/not started in 18 cases (17.6%) and an AB with a narrower spectrum was chosen in 16 cases (15.7%). Altogether, the reduction in AB pressure was estimated of -30.4% (IC 95% -40.4 ; -20.3, p<10⁻³). ID advice led to an improvement in the AB use in 64.8% of cases (IC 95% : 55.6% ; 73.2%) concerning: indication (48.1%), molecule (41.8%), dose and duration (both 5.1%). The D7 survey was completed by 56.6% (69/122). Advices given by ID specialists were judged relevant by 94% of GP and were followed in 100% of the cases. The GP investigated, comparatively to the regional population of GP, seemed to be younger (55% under 35), more feminine (sex ratio 0.54) and 70% were regular users of the hotline.

Conclusions: Our study revealed a significant reduction of AB pressure thanks to an AB stewardship hotline. An improvement in the good use of AB and a reduction of AB consumption were major results, warranting the quality of the advice given by the ID specialists as well as the existence of the structure itself.

Abstract 8194

Sulbactam-durlobactam (ETX2514) activity against carbapenemase-producing Acinetobacter baumannii in the presence or absence of imipenem or meropenem using an in vitro hollow-fibre infection model

Yuanyuan Jiao1, Angela Tanudra2, Jürgen Bulitta3, John O'Donnell*2

1University of Florida, Orlando, United States, 2Entasis Therapeutics, Waltham, United States, 3University of Florida, Orlando, United States

Background: Increased incidence of infections attributed to multidrug-resistant (MDR) Acinetobacter baumannii (Ab) has elevated the threat level to urgent as highlighted by the CDC Antibiotic Resistance Threats Report 2019. Infections caused by carbapenem-resistant Ab (CRAB) pose a particular threat due to a paucity of effective therapeutic options. Sulbactam-Durlobactam (SUL-DUR), a novel β-lactam/β-lactamase inhibitor combination, is currently evaluated in a Phase 3 clinical trial with carbapenem background therapy. This study sought to evaluate clinically relevant SUL-DUR dosage regimens with or without imipenem (IPM) or meropenem (MEM) using the dynamic in vitro hollow fiber infection model (HFIM) and translational, mechanism-based modeling (MBM).

Materials/methods: Concentration time profiles of SUL (1g Q6h), DUR, IPM (0.5g Q6h), and MEM (0.5g Q6h) at clinically relevant dosage regimens were simulated in the HFIM over 24-h and quantified via LC-MS/MS using three DUR exposures (i.e. average concentrations at steady state [Css,avg] of 0.44, 2.6 and 6.1 mg/L). We tested CRAB strain ARC5082 that produces the ADC, OXA-66, and OXA-23 β-lactamases [MIC: 128 mg/L for MEM and IPM; 4 mg/L for SUL-DUR]. All drug concentration and viable count profiles were simultaneously analyzed via population pharmacokinetic/pharmacodynamic modeling.

Results: SUL-DUR achieved 1.9 log10 bacterial killing at 8 h at a DURCss,avg of 2.6 mg/L. Three-drug combination regimens (with DURCss,avg of 2.6 and 6.1 mg/L) yielded at least 2.8 log10 killing at 8 h followed by regrowth. SUL-DUR plus imipenem yielded >5 log10 killing without regrowth by 24 h. In the MBM, one bacterial population was susceptible and the second less susceptible to SUL-DUR. The susceptible population was rapidly killed when DUR concentrations exceeded approximately 1 mg/L in presence of SUL (at Css,avg of 6 mg/L). β-Lactamase-related inactivation of carbapenems was inhibited at DUR exposures of 2.6 and 6.1 mg/L (Css,avg). Population fits were unbiased and reasonably precise.

Conclusions: SUL-DUR with or without a carbapenem achieved robust bacterial killing of CRAB at clinically relevant doses. Killing by SUL-DUR was enhanced by IPM (and MEM). As shown by MBM, these 2- and 3-drug combinations hold great promise to combat CRAB infections.

Abstract 8198

Cost-effectiveness analysis for human papilloma virus mitigation strategies implemented since 2019 in the Republic of Moldova based on infectious disease modelling

Andrzej Jarynowski*

1Moldova State University, Kishinev, Moldova

Background: Human papillomavirus (HPV), is a sexually transmittable virus infection, which is necessary risk factor for developing cervical cancer, first killer in working age women in Moldova (one of the poorest countries in Europe). Since 2018 Moldova has modified screening program and vaccination program [mainly externally funded]. The optimal preventive guidelines for cervical cancer are known: cervical screening practice, widespread vaccination and sexual education. However, interventions with the highest impact and lowest price should be prioritized in low resource setup.

Materials/methods: To assess the performance of the mitigation policy we propose cost-effectiveness analysis with mathematical model according to 2 already implemented strategies. (1) Vaccination of a single age-cohort, although vaccinating a single cohort may not have a substantial effect in other countries with distinct socio-economic situation. (2) Transition to more technologically advance screening ecosystem (changing from Romanowski to Pap smear), which might not necessary be cost-efficient in low resource settings [if GDP per capita will not growth substantially at the same time].

Results: (1) We verified that single cohort vaccination is both cost-beneficial [total costs reduction will balance intervention costs around the year 2040] and cost-efficient [with incremental impact in 20 years perspective on the level of 2300 EUR/QAL Y]. (2) Transition between Romanowski -> Pap smear cytology in screening benefits unquestionably in epidemiology e.g. due to higher specificity. However, further maintenance and higher procedure costs could exceed treatment costs, hence intervention costs would gather unacceptable share in whole national limited resources dedicated to public health.

Conclusions: (1) We recommend continuation of vaccination which is both financial [with GAVI substitute] and economic cost-effective. (2) In terms of screening technology transition: there is no way to go back, however screening costs have to be periodically monitored and national guidelines could be revisited [if necessary] according to economic situation in Moldova.

Fig. Simplified Moldovan history of pathogenic HPV strains costs. Intervention (int) costs [sexual education, vaccination, screening] and Total (tot) costs [intervention costs with mainly cervical cancer treatment as well as other treatment costs of pre-cancer abnormalities, anus cancer, genital warts] with tunable variables [vaccination coverage type and smear cost]

Abstracts 2020

Abstract 8199

Comparison of the preclinical renal effects of piperacillin/tazobactam and imipenem-cilastatin/relebactam in combination with vancomycin

Manjunath Pai*, Miao He1, Alexsas Matvekas1, Ernane Souza1

1University of Michigan College of Pharmacy, Ann Arbor, United States

Background: Vancomycin (V) is a commonly used antimicrobial against gram-positive bacteria that is associated with acute kidney injury (AKI) in a dose-dependent manner. Combination of V with select beta-lactams such as piperacillin/tazobactam (PT) has been associated with an increased risk for AKI. Imipenem-cilastatin/relebactam (ICR) is a recently approved agent that contains a novel beta-lactamase inhibitor R to restore I activity against I non-susceptible gram-negative bacteria, and C to inhibit I metabolism. Preclinical models have shown that C decreases the risk of drug-induced AKI. The objectives of this study were to compare the AKI potential of V in combination with PT and ICR, respectively.

Materials/methods: Ten to twelve week old male C57BL/6J mice (Charles River Laboratory) were used in these studies. Three mice per group were dosed with saline (control), 300 mg/kg of VAN by intraperitoneal injection once daily over 4-days period. V was also combined with PT at 2500 mg/kg/day and ICR at 320 mg/kg/day. These V combinations included fractionated doses of ICR and PT every 6 [V+ICR6 or V+PT6], 12 [V+ICR12 or V+PT12], and 24 [V+ICR24 or V+PT24] hours, respectively. Mice were sacrificed 24 hours after the 4th dose, blood collected for serum creatinine (SCr) and blood urea nitrogen (BUN) assays. The right kidney from each animal was graded for acute tubular damage (ATD) by histopathology (blinded to treatment group). Experimental procedures were repeated for V combinations with IMP-C/REL and P/T every 6 hours based on the results.

Results: Mice treated with V alone had a near doubling of their baseline SCr and BUN compared to control, and ICR or PT alone (Figure 1). Combinations of V and ICR and PT had numerically lower SCr and BUN values though this was statistically significant (p<0.05) for the V+ICR24 or V+PT24 groups for BUN and V+ICR24 for SCr compared to V alone. Renal tubular degeneration grade was higher in the V+PT6 group than V alone.

Conclusions: ICR and PT attenuate V induced AKI at single daily doses. ICR maintains a nephroprotective effect while PT does not with fractionated doses.

Presenter email address: amitpai@med.umich.edu

Figure 1. Box and whisker plot of renal biomarkers against PT and ICR alone, control, and V alone along with fractionated combinations. The * symbol denotes statistical significance (p<0.05) relative to V alone.
Rapid detection and characterisation of the Ambler class of carbapenem-resistant Enterobacteriaceae with the mCIMplus assay

Morgane Petit1, François Caméléna*1, Martine Rouveau1, Matthieu Lafaurie1, Stephane Bonacorsi2, André Birgy2, Beatrice Bercot1

1Hôpital Saint-Louis, Paris, France, 2Hôpital Robert Debré, Paris, France

Background: The spread of carbapenemase-producing Enterobacteriaceae (CPE) is a major public health problem. Recently, the mCIM (Modified Carbapenem Inactivation Method) assay was developed for carbapenemase detection, which reported a sensitivity and specificity of 99% and 100%, respectively. This test has been approved by the Clinical and Laboratory Standards Institute (CLSI). In this study, we evaluated the performance of a faster version, the mCIMplus, which allows the detection of carbapenemase in 8 hours (vs 20h for mCIM) and its characterization according to the Ambler classification in 20 hours.

Materials/methods: The performance of the mCIMplus assay was evaluated on a panel of 159 isolates, including 137 CPE isolates (17 KPC, 1 GES, 33 NDM, 7 VIM, 1 IMP; 59 OXA-48, 13 OXA-48-like and 6 NDM plus OXA-48) and 22 carbapenem-resistant isolates that do not produce carbapenemases. Briefly, 3 bacterial suspensions of the tested isolate each containing a meropenem disc were prepared, with respectively tryppticase soy broth (TSB) (Bio-rad), EDTA solution (0.05M) and phenylboronic acid solution (20 mg/mL) in TSB, respectively. At the same time, an Escherichia coli strain (ATCC 25922) was inoculated onto MH agar from a 0.5 McF suspension. After 4 hours of incubation at 37 °C, the meropenem discs were removed from the bacterial suspensions and placed on the seeded agar and incubated again at 37 °C. The inhibition diameters were read at 4h (detection only) and 16h (detection and characterization).

Results: For the detection of carbapenemase, the mCIMplus assay showed a sensitivity of 99.3% and 98.5% at 8 hours and 20 hours respectively, with a specificity of 100% regardless of the reading time. For enzyme characterization, the mCIMplus assay successfully identified the Ambler class in 98.5% of the CPE isolates tested. The characterization was correct for 100%, 95%, and 100% of Ambler class A, B, and D isolates.

Conclusions: The mCIMplus test shows excellent performance for detection and characterization of CPE. This test is easy to perform, inexpensive, effective and can be performed without specific equipment.

Abstract 8201

Cell immunity in maxillofacial actinomycosis diseases
Nigar Agayeva¹, Vidadi Narimanov², Emma Agayeva¹, Hayat Aliyeva¹, Ramila Bayramova²

¹Azerbaijan Tibb Universiteti, Department of Microbiology and immunology, Baku, Azerbaijan, ²Azerbaijan Tibb Universiteti, Baku, Azerbaijan

Background: Actinomycosis is present in all parts of the world and makes up to 3-20% of chronic pus processes. Some types of actinomycosis (i.e. Actinomycesisraeli, Actinomycesodontolyticus) create actinomycosis in different parts of human organism and structures. They cause diseases when the relevant conditions occur. In addition, they have some obligate pathogen members as well. Medically and socially it is very important to research the spreading of such forms in various substrates. For better understanding of pathogenesis and prognosis of actinomycosis it is necessary to evaluate host’s immune status. Therefore, main aim of our research was to study host immune status in patients with maxillofacial actinomycosis.

Materials/methods: 14 patients in the age range of 25 to 60 with maxillofacial actinomycosis were involved in the study. The control group consisted of 40 healthy persons. In both groups subpopulation of T-lymphocytes (CD3, CD4, CD8) and also CD22 were detected by commercial test "Kolonospekt", which based on immune peroxidase staining of the cells. Conventional microbiology methods were used for identification of etiology agent and to detect association of actinomycetes with different bacteria.

Results: Actinomycetes were isolated in experimental group. Most prevalent microorganisms associated with actinomycetes were beta-hemolytic streptococcus, Helicobacter pylori, Staphylococcus aureus, Porphyromonas spp., Pseudomonas spp. and Candida spp. The rate of CD3 was 37%, CD4 -27%, CD8-12,7, CD22-3% in experimental group. The following rates were detected in control group: CD3 - 65,5%, CD4-38,5%, CD8-29,5%, CD22-12,8%.

Conclusions: Quantitative detection of T-lymphocytes (CD3, CD4, CD8) showed attenuation of cell mediated immunity in patients with maxillofacial actinomycosis. In addition, immunodeficiency was also detected in humoral immunity with decreased levels of CD22.

Abstract 8203

The role of co-morbidities in the prescription of carbapenemes
Anna Makina*1, Garyfallia Poulakou2, Efstatia Liakopoulou3, Andriana Makina1, Antonios Papadopoulos3, Liana Sybardi3

1Thriasio General Hospital of Elefsina, Thriasio General Hospital of Elefsina, Attica, Greece, Elefsina,Athens, Greece, 2National and Kapodistrian University of Athens,Medical School, Sotiria General Hospital of Athens, Athens, Greece, 3National and Kapodistrian University of Athens, Medical School, Attikon University General Hospital of Athens,Greece, Athens, Greece

Background: Extended carbapenem use has been associated with the emergence of Carbapenem-resistant, difficult to treat Gram-negative nosocomial pathogens. Adequate empirical treatment is crucial for patient’s outcome and is based on estimation of risk factors for multi-drug-resistant (MDR) infection. We sought to investigate the presence of comorbidities in a cohort of severely ill patients being considered as high risk for MDR infections, for whom treating physicians prescribed a carbapenem.

Materials/methods: A retrospective analysis of data collected prospectively during an observational study, conducted at a 450-bed tertiary hospital of Athens from September 2013 to December 2015. In the context of an antimicrobial stewardship program (ASP) targeting carbapenem restriction, the Antimicrobial Stewardship Program team (ASPT) provided unsolicited face-to-face consultation for every patient with prescription of meropenem or imipenem. Treating physicians were advised to switch to carbapenem-sparing options for empiric or definite treatment based on risk estimation or microbiological data respectively. Comorbidities as predisposing factors for MDR infections were studied.

Results: The study included 304 patients classified into two groups based on the strategy of treatment; group A consisted of patients who were treated with alternative to carbapenem regimens following ASPT consultation, (N= 168) whereas group B (N= 136) consisted of those who were maintained on carbapenem following treating physician’s decision. The most common comorbidities observed in the study population were in decreasing frequency diabetes mellitus type 2 (T2DM) 74(26.3%), malignancy6 (2.1%), chronic obstructive pulmonary disease (COPD) 53 (18.8%) and immunosuppression51 (18%). Between two groups of study statistical results showed p-value =0.001 in COPD and 0.015 in T2DM. All cause of mortality of the cohort was 30 % (26,2% vs 35,3% in group A and B respectively). The survival analysis with Cox regression model for comorbidities showed p=0,96(OR=0,96, 95%CI for OR=0,06-7,21).

Conclusions: T2DM and in COPD were significantly more frequent in the group of patients who were maintained on a carbapenem regimen, despite ASPT consultation. Local antibiotic policies should further explore epidemiology of infections in these subgroups of patients and tailor relevant recommendations

Abstract 8204

**Screening of colonisation for carbapenemase-producing Enterobacterales: impact in the empiric antibiotic choice of carbapenemase-producing Klebsiella pneumoniae infection in a Portuguese hospital**

Ana Cipriano*1, Margarida Pereira2, Antonia Read2, Filipa Carneiro2, Margarida Monteiro2, Maria Soares2, Valquiria Alves2

1Centro Hospital Universitário do Porto, porto, Portugal, 2Unidade Local de Saúde de Matosinhos, matosinhos, Portugal

**Background:** Carbapenemase-producing *Klebsiella pneumoniae* (CPKP) infection is a major concern. Carbapenemase-producing Enterobacterales (CPE) colonization is associated with an increased risk of infection. Knowledge of CPE colonization can be relevant not only to infection control but also to antimicrobial stewardship. The purpose of this study was to evaluate infection caused by CPKP and understand the role of screening of CPE in empirical therapy management.

**Materials/methods:** Since January 2016 was implemented an active screening in selected patients admitted in our hospital with an increased risk of colonization for CPE. Rectal swab samples were screened by real time PCR (Xpert Carba-R® test and later BD MAX™ Check-Points-CPO). From 2016 to August of 2019 we evaluated retrospectively all clinical isolates with CPKP concerning the age, genre, source of infection, antibiotherapy and screening results.

**Results:** During the analysed period, 7233 patients were screened at admission, of which 327 (4.5%) were positive. We identified 110 CPKP in clinical isolates that corresponding to 91 infections, and 19 colonization. Only 42 (46%) were screened at admission, of which 28 (67%) had positive CPE screening. The mean age was 77.9 years (min 18; max 95) and 46 (53.5%) were females. The main source of infection was urinary (n=43; 47%), followed by respiratory infection and surgical site infection. Only nine had bacteremia. Piperacillin/Tazobactam was the most widely used empirical therapy (30%; n=27). The mortality of infected patients was 26.4% (24).

**Conclusions:** Our study demonstrates low adherence to assessment of risk factors to CPE colonization and active screening. Our results showed no difference in empirical therapeutic strategy in patients with positive CPE screening in Infections caused by CPKP.

Molecular investigation of a 4-year outbreak of human adenovirus A31 (HAdV-A31) infection on a paediatric haematopoietic stem cell transplantation ward

Ramzi Fattouh1, Patrick Stapleton2, Alireza Eshaghi3, Angela Thomas4, Michelle Science4, Tal Schechter-Finkelstein4, Laurie Streitenberger1, Jonathan Gubbay1, Adriana Kajon5, Brian Fisher6, Jonathan Dean7, Petr Hubacek8, Martha Brown9, Aaron Campigotto4, Samir N. Patel3, Morag Graham10, Susan Richardson*4

1St. Michael’s Hospital, Toronto, Canada, 2University Hospital Limerick, Limerick, Ireland, 3Public Health Ontario Laboratory, Toronto, Canada, 4The Hospital for Sick Children, Toronto, Canada, 5Lovelace Respiratory Research Institute, Albuquerque, United States, 6Children’s Hospital of Philadelphia, Philadelphia, United States, 7University College Dublin, Dublin, Ireland, 8Motol University Hospital, Prague, Czech Republic, 9University of Toronto - St. George Campus, Toronto, Canada, 10National Microbiology Laboratory, Winnipeg, Canada

Background: Weekly adenovirus PCR blood screening revealed an increased incidence of adenovirus infections on the SickKids HSCT ward in early 2015. Institution of routine typing of all new cases identified a total of 20 cases of HAd-A31 infection occurring between October, 2014 and September, 2018. Sanger sequencing of the E3 and hexon genes was inconclusive regarding strain relatedness, so whole genome sequencing (WGS) was performed.

Materials/methods: Routine weekly HAdV blood monitoring was performed (day 0 to 100 post-HSCT), using the RealStar quantitative Adenovirus PCR assay (Altona Diagnostics, Hamburg, Germany). Urine, stool and nasopharyngeal samples were also tested after a first positive blood. Where possible, samples were genotyped using an in-house assay, followed by viral culture. Culture isolates were subjected to WGS. Additional isolates, specimens, DNA or sequences from pediatric HAd-A31 HSCT infections were obtained from 4 international pediatric HSCT centers for WGS. Disseminated infection was defined as ≥ 2 sites positive, e.g. plasma, stool, urine, respiratory, other.

Results: 20 HSCT patients were found to have disseminated infection with HAd-A31. During the same time period, there were 43 other cases of adenovirus infection (6 genotypes, 10 untypeable). 25/33 (76%) non-HAd-A31 patients (excluding non-typed) had disseminated infection. Urine and stool adenoviral loads were often very high (10⁷–10¹⁰ copies/ml) even in the absence of GI symptoms. WGS was successful in 19/20 HAd-A31 patients. 16/19 HAd-A31 sequences formed a distinct clade, with ≤ 8 SNP difference among them. 3/19 HAd-A31 sequences were unique, differing by at least 20 SNPs from any of the outbreak strains. Two of these strains had significant sequence similarity to strains from 3 of the 4 collaborating international centers. Intensive environmental cleaning, educational efforts directed at staff and family, and restriction of access to contaminated areas resulted in a one-year period since the last outbreak strain-associated infection.

Conclusions: Our findings strongly implicate nosocomial spread of HAd-A31 on an HSCT unit and demonstrate the value of molecular techniques in defining and mapping the anatomy of an outbreak. An as yet unexplained close sequence similarity to HAd-A31 strains from other international pediatric HSCT centers was observed.

Abstract 8220

**Hunt for Leishmania RNA Virus (LRV) in transcriptome database of Leishmania species: which is best for bioinformatic analysis?**

Deniz Ece Kaya, Orhan Ozcan, Ozgur Kurt, Ugur Sezerman

1Acibadem University, istanbul, Turkey

**Background:** Leishmaniasis is a vector-borne protozoal disease caused by *Leishmania* species and transmitted to humans by sandflies (Phlebotomus sp., Lutzomyia sp.). *Leishmania* RNA Virus (LRV; LRV-1 in the New World, LRV-2 in the Old World), present in some *Leishmania* isolates may worsen clinical manifestations through interactions with host’s immune system. Therefore, investigation of LRV is suggested in resistant cases. Described correlation between *Leishmania* species and LRV subtypes label them as epidemiological markers and may help researchers track infection's origin to reveal its causes and contributing factors. Since unveiling of LRV's interactions with disease pathology is relatively new, assessment of the older transcriptome data is essential to identify LRV (+) isolates. NCBI has recently introduced a next generation sequence data archive (SRA: Sequence Read Archive), which supplies faster sequencing with lower costs. The aim of this study is to test the efficacy of SRA in seeking LRV in Leishmania transcriptome database.

**Materials/methods:** The consensus sequence of LRV was sought in NCBI’s Sequence Read Archive (SRA) Blast for all recorded *Leishmania* transcriptomes before 20th of November 2019. All *Leishmania* transcriptome reads bearing positive signals were downloaded and their validity was tested by guided assemblies, using SPAdes® (Center for Algorithmic Biotechnology, St. Petersburg State University) and BBTools® (Joint Genome Institute). Geneious Prime® (Biomatters) was used to visualise the outcomes (Figure 1).

**Results:** LRV-1 and LRV-2 were present in 53 (11.1%) and 6 (1.3%) of 477 transcriptional data. Five of these LRV-positive transcriptomes were assembled (4 LRV1 and 1 LRV2) and 1 was found positive for LRV1.

**Conclusions:** Consequent guided assembly applied to five SRA-positive *Leishmania* transcriptomes confirmed that only one of them actually had LRV. Despite being fast and inexpensive for bioinformatic analysis, we suggest combined use of SRA followed by guided assembly to avoid false positives in searching LRV in Leishmania transcriptomes. This preliminary study also indicated that LRV can be an epidemiological marker of leishmaniasis.

Figure 1: LRV consensus sequences created from Leishmania Transcriptome.

Abstract 8221

Controlled human infection with Neisseria lactamica induces B cell responses that are cross-reactive with Neisseria meningitidis

Adam Dale*1, Anastasia Theodosiou1, Jay Laver1, Eleanor Roche1, Alison Hill1, Andrew Gorringe1, Marta Polak1, Andrew Vaughan1, Robert C. Read2

1University of Southampton, Southampton, United Kingdom, 2Public Health England, Porton Down, Salisbury, United Kingdom

Background: Neisseria lactamica (Nlac) is a commensal of the human oropharynx. Colonisation with Nlac significantly reduces colonisation by N. meningitidis (Nmen). We hypothesised that cross-reactive adaptive cellular immune responses were responsible for this effect.

Materials/methods: 31 volunteers were inoculated intra-nasally with 105 colony-forming units of viable Nlac or vehicle control. Nlac/Nmen colonisation status was assessed at baseline and at 7-, 14- and 28-days post-inoculation. ELISpot assays were utilised to detect Nlac- and Nmen-specific plasma cells (PCs) and memory B-cells in peripheral blood mononuclear cells (PBMCs) across study time points having coated ELISpot well membranes with Nlac/Nmen-derived outer-membrane vesicles.

Results: Nlac-specific PC frequencies increased significantly amongst Nlac-colonised volunteers (n=17). Median baseline vs. post-colonisation peak Nlac-specific PC frequencies/2x105 PBMCs were 0 (range 0-0.5) vs. 2 (0-31) for IgM (p<0.0001), 0 (0-1) vs. 5 (0-20.5) for IgA (p<0.0001), and 0 (0-1) vs. 3 (0-27) for IgG (p<0.0001). Nlac-specific IgG memory B-cell frequencies (as a proportion of total IgG memory B-cells) increased significantly amongst Nlac-colonised volunteers from 0.000% (range 0.000-0.0027%) at baseline to 0.04% (0.000-0.119%) at day 28 (p<0.0001). As expected, there was no induction of Nlac-specific PCs or memory B-cells in volunteers who received the vehicle control (n=10). Interestingly, there was also a significant increase in IgM, IgA and IgG Nmen-specific PCs amongst Nlac-colonised volunteers. Median baseline vs. post-colonisation peak Nmen-specific PC frequencies/2x105 PBMCs were 0 (range 0-0) vs. 0 (0-30) for IgM (p=0.008), 0 (0-1) vs. 0.5 (0-8.5) for IgA (p=0.01), and 0 (0-0.5) vs. 0.5 (0-10) for IgG (p=0.006).

Conclusions: The increase in Nmen-specific PCs in volunteers colonised with Nlac demonstrates the presence of cross-reactive B-cell epitopes between Nlac and Nmen. Cross-reactivity towards Nmen suggests that the previously observed protective effect of Nlac on Nmen colonisation may have an immunological basis. A plethora of animal models have demonstrated that Th1-polarised effector mechanisms are essential in mediating clearance of bacteria from mucosal epithelia, including Streptococcus pneumoniae and Staphylococcus aureus. Therefore, we plan to assess the frequency and effector phenotype of Nlac-specific CD4+ memory T-cells in response to Nlac colonisation. We hypothesise that cross-reactive CD4+ memory T-cells directed towards Nmen will be Th1.

Colistin MIC determination by a rapid flow cytometry assay

1 Clinical Microbiology Department, Hospital and University Center of Porto, Porto, Portugal, Porto, Portugal, 2 FASTinov, SA, Porto, Portugal, 3 CINTEIS-Center for Health Technology and Services Research, Faculty of Medicine of the University of Porto, Porto, Portugal, 4 Servicio de Microbiología, Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación Sanitaria (IRYCS), Madrid, Spain, 5 Division of Microbiology, Department of Pathology, Faculty of Medicine, University of Porto, Porto, Portugal

Abstract third-party references: This work received funding from the H2020 F7Pilot 2016 project nº 730713 'FAST-bact—A novel fast and automated test for antibiotic susceptibility testing for Gram positive and negative bacteria'.

Background: The increasing prevalence of multidrug-resistant Gram-negative bacteria worldwide leads to a re-evaluation of previously discarded antibiotics, such as colistin (CS), belonging to the class of polymyxins. Its use is being increasingly as a ‘last-line’ resort therapy. The emergence of clinical isolates with reduced susceptibility to this antibiotic has been reported. As susceptibility results obtained with automated systems are not valid due to technical issues, different minimum inhibitory concentration (MIC) assays appear in the market. Nevertheless, they are laborious and time-consuming (minimum of 24h). In present study we evaluate a rapid flow cytometry method that can easily and quickly determine CS MIC values in 2 hours versus 24h from pure colonies with standard broth microdilution.

Materials/methods: A total of 84 Enterobacterales isolates, including 12 QC control strains, with well characterized mechanisms were tested for MIC determination by flow cytometry and compared with broth microdilution (EN ISO 20776-1, 2016) interpreted according to CLSI and EUCAST criteria protocols. For flow cytometry assay (FC), bacteria were inoculated in a microplate containing colistin in variable concentrations (from 0-25 to 32 µg/L) together with a fluorescent dye that detect cell membrane lesion; after incubation (1h), the susceptibility of colistin was analyzed by CytoFLEX Flow Cytometer. FASTinov results were provided by a dedicated software. Categorical agreement (CA) and Essential agreement (EA) were calculated.

Results: The distribution of the strains by CS MIC are represented in Table 1. The CA was 100% and the EA 90.5% with 6 strains showing by FC MIC values 2 dilutions below the reference method and 2 strains 2 dilutions above.

Table 1. Distribution of strains by colistin MIC

<table>
<thead>
<tr>
<th>MIC values (µg/ml)</th>

Population pharmacokinetics and pharmacodynamics of colistin A and B in the murine thigh infection model with *Pseudomonas aeruginosa*: an integrated experimental and modelling approach

Yuanyuan Jiao, Ju-Hsin Chia, Kun-Yuan Lin, Deborah Nicole Griffith, Dhruvitkumar Sutaria, Chin-Wei Chiang, Yu-Chuan Yeh, Jui-Che Chien, Jung-Hsin Lo, Nirav Shah, Xun Tao, Lynn Miesel, Jürgen Bulitta

1University of Florida, Department of Pharmacotherapy & Translational Research, College of Pharmacy, Orlando, United States, 2Pharmacology Discovery Services, Ltd, New Taipei, Taiwan, 3Eurofins Panlabs, Inc., St. Charles, United States

**Background:** The pharmacokinetics (PK) and pharmacodynamics (PD) of colistin in murine infection models has been studied for colistin (i.e. the sum of colistin A and colistin B) via non-compartmental methods. No PK data exists on each component. This study aimed to characterize the PK of colistin A and colistin B individually and their PK/PD targets in the neutropenic murine thigh infection model with *P. aeruginosa*. An integrated experimental, optimal design, and population PK modeling strategy was leveraged. Secondly, we sought to determine the strain-to-strain variability in PD endpoints for twelve multidrug-resistant *P. aeruginosa* (MDR-PA) strains.

**Materials/methods:** Optimal designs were employed in the exposure response studies with *P. aeruginosa* strain ATCC 27853 (MIC<sub>90</sub>: 1.0 mg/L). The PK of colistin A and B was determined in murine thigh infection models at single subcutaneous doses of 3.5, 7, 10, 20 and 40 mg/kg and analysed by population PK. Robust and informative dose fractionation studies were designed at daily doses from 10 to 160 mg/kg given as Q3h, Q6h, Q12h or Q24h. The strain-to-strain variability in the dose required for PD targets was assessed in twelve MDR-PA strains (MIC<sub>90</sub>: 1-2 mg/L).

**Results:** Clearance and volume of distribution were comparable between colistin A and B (Table). The fAUC/MIC best predicted bacterial killing at 24 h. Strain-to-strain variability in the daily doses required for stasis and 1-log<sub>10</sub> bacterial killing was moderate (Table, n=1,157).

<table>
<thead>
<tr>
<th>PK parameters</th>

</tr>
<tr>
<td>Apparent volume of distribution at steady state (Vss/F, mean±SD, mL)</td>
<td>20 (6.7%)</td>
<td>20 (6.7%)</td>
</tr>
</tbody>
</table>

**Coefficient of determination (r²) for**

- Free Cmax-over-MIC (fCmax/MIC): 0.57
- Free AUC-over-MIC (fAUC/MIC): 0.83
- Free time-above-MIC (fT>MIC): 0.22

<table>
<thead>
<tr>
<th>Dose targets of colistin A&amp;B required in the twelve MDR-PA strains for</th>
<th>Colistin A</th>
<th>Colistin B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stasis (mg/kg/day, mean±SD)</td>
<td>27 ± 10</td>
<td>33 ± 16</td>
</tr>
<tr>
<td>1-log killing for the twelve MDR-PA strains (mg/kg/day, mean±SD)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Conclusions:** While the PK of both components was comparable, apparent total clearance of colistin B was slightly larger than that of colistin A. The fAUC/MIC best predicted bacterial killing. Moderate strain-to-strain variability was observed in the daily colistin dose required for PD endpoints.

**Risk factors for mortality, intensive care unit admission, and bacteraemia of patients admitted with suspected infection in the emergency department**

Valentino D’Onofrio1,2,3, Agnes Meersman4, Sara Vijgen5, Peter Messiaen4, Reindou Cartuyvels3, Inge C. Gyssens1,3

1Hasselt University, Faculty of Medicine and Life Sciences, Hasselt, Belgium; 2Jessa Hospital, Department of Infectious Diseases and Immunity, Hasselt, Belgium; 3Radboud University Medical Center, Department of Internal Medicine, Nijmegen, Netherlands; 4Jessa Hospital, Emergency Department, Hasselt, Belgium; 5Jessa Hospital, Department of Clinical Biology, Hasselt, Belgium

**Background:** In the latest sepsis guidelines, SOFA score was introduced as a risk-assessment tool for patient outcomes, including mortality, and has been evaluated in ICUs, clinical wards, and emergency departments (EDs). The objective was to identify other potential risk factors associated with all-cause mortality, ICU admission, and bacteraemia in the ED.

**Materials/methods:** A prospective observational cohort study was conducted in a 981-bed teaching hospital between February and August 2019. All adult patients admitted to the ED and suspected of infection for whom blood cultures were ordered were eligible. Clinical and laboratory data were collected from electronic medical files. For each outcome 2 multiple logistic regression models were calculated using SPSS Statistics (version 25; IBM). Model 1 included total SOFA score ≥2, model 2 included individual SOFA score variables.

**Results:** In total, 929 admissions of 868 unique patients were included. There were 131 (14%) admissions with true bacteraemia and 394 (4%) with contaminated blood cultures. Diagnoses were 162 (17.4%) pneumonia, 48 (5.2%) lower RTI, 48 (5.2%) urosepsis, 40 (4.3%) upper UTI, 76 (8.2%) intraabdominal infections, 72 (7.8%) ABSSSI, 38 (4.1%) primary bacteraemia, 45 (4.8%) influenza, and 131 (14.1%) other, mostly minor infections. In 269 (28.9%) admissions there was no diagnosis of infection. Of admissions with bacteraemia (n=131), 11 (8.4%) had pneumonia, 1 (0.8%) lower RTI, 48 (36.6%) urosepsis, 20 (15.3%) intraabdominal infection, 8 (6.1%) ABSSSI, and 5 (3.8%) other infections. Model 1 showed only age, serum lactate ≥2mmol/L, and abnormal WBC count, as independent risk factors for mortality (Table). For ICU admission, SOFA score ≥2 and serum lactate ≥2mmol/L were significant. For bacteraemia, serum lactate ≥2mmol/L, abnormal WBC count, and elevated bilirubin levels were significant. Last, for bacteraemia, serum lactate ≥2mmol/L, abnormal WBC count, and elevated bilirubin levels were significant.

**Conclusions:** Besides SOFA score ≥2, other independent risk factors for mortality, ICU admission, and bacteraemia were identified in this population. These factors can help to identify patients most at risk for severe infections, and guide management and empirical antibiotic therapy in the ED.

**Table.** Multiple logistic regression: factors measured on admission influencing 30-day mortality, ICU admission, and bacteraemia

Abstract 8230

Development and validation of a questionnaire to explore tuberculosis knowledge, attitudes and practices in foreign-born subjects from high tuberculosis-incidence countries

Mariachiara Di Nuzzo1, Giorgia Valpiani2, Chiara Morotti2, Enrico Biagi1, Lorenzo Massoli1, Martina Maritati1, Anastasio Grilli1, Altea Gallerani1, Nicole Barp1, Carlo Contini*1

1University Hospital of Ferrara, Infectious Diseases Department, Cona, Italy, 2University Hospital of Ferrara, Research and innovation department, Cona, Italy

Background: Italy is a low tuberculosis (TB) incidence country, and TB cases cluster especially among foreign-born subjects from high TB incidence countries. Several determinants of health contribute to active TB development in this population and TB control strategies should address all. TB knowledge represents only one of these determinants, and all alone does not increase person’s empowerment. However, TB knowledge could represent a contribution to TB control, when integrated into a framework of actions. To our knowledge, there are no validated questionnaires to explore TB knowledge, attitudes and practices in foreign-born subjects from high TB incidence countries who are living in a low TB incidence country.

Materials/methods: The questionnaire’s item pool was compiled from literature reviews. The questionnaire collected demographic data, social determinants’ data, TB knowledge, attitudes and practices information. Questionnaire had to be performed face-to-face and answers were open-ended or multiple choice. Content validity was assessed by content validity index (CVI) and Delphi technique. Linguistic and cultural barriers were assessed performing a focus group and two pilot tests. Reliability was assessed calculating Cronbach’s alpha coefficient. We enrolled and interviewed 86 adult foreign-born subjects from high TB incidence countries in November 2019 in four different facilities (a school, a refugee centre, an infectious diseases unit and an immigrant-health ambulatory) in Ferrara, Italy.

Results: Seven TB experts evaluated the questionnaire with two Delphi technique rounds. Nineteen (50%) out of 38 items presented CVI <80% and were deleted. The focus group was conducted with four foreign-born subjects and two items were deleted. 11 subjects underwent the first pilot test and 40 subjects the second one: no items were deleted. Cronbach’s alpha coefficient was 0.65 for knowledge items (four items).

Conclusions: We developed and validated a questionnaire as a reliable and valid tool for measuring TB knowledge among foreign-born subjects from high incidence TB countries, who are living in a low TB incidence country. We hope this questionnaire could contribute to TB control.

Abstract 8235

Characterisation of a Portuguese population with candidaemia in a tertiary care hospital

Cláudio Silva*1; João Paulo Caldas1; António Martins1; Sara Almeida Lacerda Pereira1; Elsa Alves Branco1; Rita Filipe1; Beatriz Prista Leão1; Sara Magalhães1; Maria Dolores Pinheiro1; André Silva-Pinto1; António Sarmento1; Lurdes Santos1

1Saint John Hospital, Porto, Portugal

Background: Candidemia is an infection with increasing relevance due to its rising incidence and resistance to antifungal treatment. It is associated with substantial morbidity and mortality. The aim of our study was to describe the general characteristics of a population of patients with fungemia by Candida spp.

Materials/methods: We performed a retrospective cohort study of all patients admitted in our hospital during a 4-year period with isolation of Candida spp. in at least one blood culture. Candida species were identified using MALDI-TOF technology, VITEK1 MS, bioMérieux. Information regarding patients’ demographics, comorbidities, relevant clinical and microbiological parameters were collected from individual medical records.

Results: There were 204 episodes of candidemia, 47.1% of cases were male patients and the median age was 65 years. About a quarter of cases (23.8%) were previously colonized with Candida spp., most of them in urine. Patients had high comorbidity burden, with a significant number of them with previous surgery (56.9%), corticosteroid therapy (31.8%) and solid cancer (26.6%). Eighty-four percent of patients had more than one comorbidity. Eighty-two (43.4%) patients were in an Intermediate or Intensive Care Unit (ICU) at the time of diagnosis and 13.7% were admitted in ICU after the diagnosis. The most frequent isolated species was C. albicans (52.5%), followed by C. glabrata (20.6%), C. parapsilosis (17.2%) and C. tropicalis (3.9%). Nearly 1/3 of the patients did not receive any antifungal treatment and around 1/3 received empirical treatment with azoles. Daily follow-up blood cultures were performed in 5.6% of patients. Less than half of the cases had an evaluation by Ophthalmology (31.2%), echocardiography (40%) or by an Infectious Diseases physician (20.7%). The mortality rate was 47.3%.

Conclusions: Our series demonstrates a high prevalence of candidemia, most of the cases due to C. albicans. Most of the patients have important comorbidities and prolonged and frequently complicated admissions. Regarding management and follow-up, a low adherence to international candidemia guidelines was observed. It is thus important to raise awareness to this frequently ignored infection, to recognize potential cases, anticipate diagnosis and improve care measures, in order to ameliorate such reserved prognosis.

Hospital admission for sepsis and mortality in Brazil from 2009 to 2018: analyzing 10 years of government database (Datasus) information

Rogerio Fleury¹, Wania Freitas*¹

¹Hospital Universitário Clementino Fraga Filho, Unidade Cardio-intensiva - UFRJ, Rio de Janeiro, Brazil

Background: Sepsis is a common cause of death among patients in intensive care units (ICU) in Brazil and worldwide. We analyzed hospitalizations for septicemia and deaths in Brazil from 2009 to 2018, through data from Datasus.

Materials/methods: Data from Datasus (www.datasus.gov.br), government database for health information, about hospitalizations for septicemia and mortality from 2009 to 2018 in patients over 15 years old in Brazil. We analyzed length of hospital stay and mortality by gender and age group.

Results: From 2009 to 2018, 788,333 patients with diagnosis of septicemia were hospitalized, 408,865 males (51.9%) and 379,468 females (48.1%). Annual mortality rate was average 51.6%, with rates less than 50% in those below 60 years old and greater than 50% in those over 60 years old, reaching 67.2% in those over 80 years old. Mortality had little risen over the period, with 50.7% in 2009, 51.7% in 2013, a peak of 52.2% in 2016 returning to 50.8% in 2018. Analyzing age group, 298,138 patients (73.4%) were over 60 years old. The age group with highest number of deaths was over 80 years old with 118,454 cases (29.1%). Mean length of stay was 11.8 days, with minimum of 11.4 in 2018 and maximum of 12.2 days in 2013.

Conclusions: Mortality of septicemia at admission is high all over the world. In Brazil we observed rates averaging 50%. Advanced age is at highest risk. Length of hospital stay is average 12 days. Cases of septicemia not diagnosed during hospitalization, alternative diagnoses, or progression to septicemia only during hospitalization may disrupt the correct measurement.

Abstract 8241

**Antibacterial and anti-biofilm activity of colistin-loaded nanoparticles against Acinetobacter baumannii**

Rana Awad*1,2, Frederic Tewes1,2, Sandrine Marchand1,2,3, William Couet1,2,3, Mohamad Nasser4

1INSERM U1070, Poitiers, France, 2Faculté de Médecine et de Pharmacie, Poitiers, France, 3Poitiers University Hospital, Poitiers, France, 4Lebanese University, Hadat Campus, Beirut, Lebanon

**Background:** Colistin (COL) is an antibiotic used in last resort against multidrug-resistant gram-negative bacteria such as Acinetobacter baumannii (AB). AB forms adherent biofilms on endotracheal tubes of ventilated patients. These biofilms limit access of COL to AB and require higher doses of COL than for the treatment of infections caused by planktonic bacteria. The aim of the study was to develop COL-loaded lipid-nanoparticles [NANO-COL] to improve COL antimicrobial and anti-biofilm activities in order to avoid the appearance of resistance to this antibiotic.

**Materials/methods:** NANO-COL were formulated using the method initially described by Heurtault et al. (Pharmaceutical research 2002). Various adjuvants (fatty acid, farnesol) were added to improve COL encapsulation efficiency and increase its efficacy against biofilm compared to free COL. Size and zeta potential of the NANO-COL were evaluated. The efficacy of NANO-COLs against an AB COL-resistant AbS2 (C1–D7-12, MIC = 32 mg/L) planktonically grown was tested by MIC measurements. Anti-biofilm activity was evaluated on 48-hours biofilms grown into 96-well microplates by evaluating their total biomass by crystal violet (CV) staining.

**Results:** Stable monodisperse NANO-COL with an average diameter around 120 nm were formulated. In the presence of fatty acid, the negative zeta potential was maintained around -9 mV, suggesting that the positively charged amphipathic COL was encapsulated in the NANO-COLs and not on their surface. Compared to free COL, NANO-COL reduced by 32 times the MIC of COL against planktonic AbS2. When present as NANO-COL, no CV staining was observed from a COL concentration greater than 4 mg/ml, whereas a staining was still observed at 256 mg/L of free COL.

**Conclusions:** The COL was successfully encapsulated in lipid nanoparticles, which allowed restoring the sensitivity to COL of a resistant Acinetobacter baumannii and improved the effectiveness of COL against an abiotic adherent biofilm of Acinetobacter baumannii.

**Within-host genetic diversity of *Staphylococcus epidermidis* in prosthetic joint infections: consequences for microbiological diagnosis**

Micael Widerstrom¹,²; Marc Stegger³; Anders Johansson¹; Anders Rhod Larsen²; Tor Monsen¹

¹Umeå University, Clinical Microbiology, Umeå, Sweden, ²Statens Serum Institut, Dept. of Bacteria, Parasites and Fungi, København, Denmark

**Background:** Prosthetic joint infection (PJI) is a devastating complication after arthroplasty with high hospital costs, increased in-hospital mortality, and both diagnosis and treatment are challenging. *Staphylococcus epidermidis* is a major pathogen in PJIs. The current guidelines of a definite PJI diagnosis is partly based on the finding of two or more periprosthetic cultures that yield the same organism (indistinguishable based on common laboratory tests including genus and species identification or common antibiogram). Since phenotypic morphological variation, including small colony variants and different antibiograms (clonal variability), as well as polyclonal infections has been reported in *S. epidermidis* infection, the definition of "phenotypically identical organisms" is ambiguous. The aim of the present study was therefore to evaluate the phenotypic and genotypic diversity among multiple *S. epidermidis* isolates identified in individual PJI patients.

**Materials/methods:** A retrospective cohort study of 62 consecutive patients with PJI due to coagulase-negative staphylococci in two hospitals in Northern Sweden from 2008 to 2011. Multiple *S. epidermidis* isolates (n=71) from multiple tissue samples (range 2-9 isolates/patient) were available from 16 PJI patients. WGS was performed using Illumina MiSeq. The sequence data was assembled using SPAdes v.3.9.0. Raw reads were aligned against the *S. epidermidis* ATCC 12228 reference chromosome for SNP detection using NASP.

**Results:** In 10 of 16 PJI, only a single ST (or a single locus variant) was identified (max. intrahost pairwise SNP difference = 64). In six (38%) of the cases, 2 - 5 different ST types were detected within each case showing a intrahost SNP difference of 3156 to 39 618. Colony polymorphism was detected in all cases. Importantly, we identified variations in phenotypic and genotypic antibiograms in 13/16 (81%) of cases and in 11 (68%) also variations between isolates of the same ST (Figure 1).

**Conclusions:** Morphologic, phenotypic and genotypic polymorphism is common in PJIs due to *S. epidermidis*. The present study underscore the complexity in assessing whether phenotypically different *S. epidermidis* isolates from multiple cultures meets the current criteria for microbiological diagnosis of PJI.

Abstract 8243

Implementation of an antimalarial stewardship programme in a tertiary care hospital in South India

Sureshkumar Dorairajan*1, Soujanya Saravanakumar2, Akshya S3, Priya Biji4

1Apollo Hospital Chennai, Best of IDs, Chennai, India, 2Kasturba Hospital, Manipal, Mangalore, India, 3Vanagaram, Pharmacy, Chennai, India, 4Apollo Speciality Hospitals, Vanagaram, Chennai, India

Background: Increasing incidence of non-malarial acute febrile illness and the declining cost of anti-malarial drugs has resulted in inappropriate use of antimalarial drugs in the developing world. Implementation of antibiotic stewardship programs (ASP) reduced unnecessary antibiotics use in the hospitals. However, very limited data is available regarding the impact of Anti-malarial stewardship program (AMSP) in reducing anti-malarial drug usage in the hospitals. Here we assessed the impact on AMSP on anti-malarial drug usage pattern in a tertiary care hospital.

Materials/methods: This before and after intervention study was conducted in a 200 bed tertiary care referral hospital in South India. In before intervention phase (January 2017 to December 2018) malarial prescription audits was conducted in the post discharge period in the medical records room by physician assistant (PA) and results were discussed latter in the clinical meetings. During intervention phase (January 2019- October 2019) AMSP team consisting an infectious disease (ID) physician, clinical Pharmacist (CP) & PA was established, prescription audits and feedback regarding anti-malarial use indication, choice, dose and duration were immediately provided to the prescriber on the receipt of malarial by AMSP team. The number of malarial prescriptions were compared before and after intervention and analyzed.

Results: 27,020 patients were admitted during the study time. The important difference between pre & post intervention period were shown in the table 1 below

Table-1 Differences between before and after implementation of anti-malarial stewardship program

<table>
<thead>
<tr>

Performance of a computerised decision support system for the semi-automated detection of healthcare associated infections: an explorative pilot study

Alice Ranzani*1,2, Gaud Catho1, Aliki Metsini3, Walter Zingg3, Benedikt Huttner1

1Division of infectious diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, 2Infectious Diseases Unit, ASST Fatebenefratelli-Sacco, L. Sacco Hospital, University of Milan, Milano, Italy, 3Infection Control Programme and WHO Collaborating Centre on Patient Safety, University of Geneva Hospitals, Geneva, Switzerland

Abstract third-party references: Supported by Fonds National Suisse

Background: Current methods for surveillance of health care associated infections (HAI), such as Point Prevalence Surveys (PPS), may be time and resource intensive. With the development of healthcare information technologies, semi-automated real-time surveillance of HAI becomes a real option. Geneva University Hospitals (HUG) are currently involved in the COMPASS trial (NCT03120975), during which a computerised decision support system (CDSS) for antimicrobial prescription has been implemented. The CDSS is integrated into the electronic health record and each antimicrobial prescribed is linked to an indication. We aimed to assess the performance of the COMPASS tool to detect HAI by comparison with data collected in the yearly PPS.

Materials/methods: The annual PPS at HUG conducted in May 2019 was based on the ECDC protocol (version 5.3 for the ECDC-PPS II). In order to assess HAIs detected by the CDSS, we selected all the patients hospitalized in the 8 COMPASS intervention wards who received antimicrobials on the day of the PPS. We then selected patients with (1) indications containing a term referring to a HAI with no restriction for antimicrobial starting date (e.g. hospital acquired pneumonia (HAP)), (2) indications containing a term referring to a possible HAI (e.g. “pneumonia”) linked to antimicrobials prescribed at least 48 hours after hospital admission. HAIs considered were HAP, urinary tract infection (UTI), bloodstream infections (BSI), central-line associated BSI, and C. difficile infections. We compared HAIs detected by the CDSS and by the PPS. A manual chart review was performed for discordant cases and reasons underlying discrepancies were analyzed.

Results: Eight HAIs were correctly identified by both systems (4 HAP, 3 UTI). Five HAIs were only detected by the PPS (1 HAP, 4 UTI). Among them, 3 UTI were excluded by manual revision. Four HAIs were only detected by COMPASS but further excluded by manual review (3 HAP, 1 UTI). The main reasons for discordance were the use of a wrong indication in COMPASS and erroneous reporting during the PPS.

Conclusions: COMPASS is a promising semi-automated surveillance tool. We plan to assess its performance further in a prospective study, exploring different algorithms including other electronic data (e.g. microbiology data).

*: liver-kidney [3], kidney-pancreas [1], liver-bowel [1]  # AF: antifungal (most in prophylaxis)

$ COPD: chronic obstructive pulmonary disease

Antifungal therapy administered was voriconazole [61%], lipid amphotericin [34%], candins [26%], nebulized amphotericin [19%], isavuconazole [6%] and posaconazole [7%]. Combination treatment was administered in 47% of patients. Length of therapy in those who survived >3 months was 24 weeks [lung. tx 30w, kidney: 13w, liver tx: 14w, heart tx: 28w].

**Conclusions:** IA in SOT presents a high mortality, slightly lower in lung transplant (specially in tracheobronchial forms). It is frequently associated with dialysis, rejection and COPD. Voriconazole is the most commonly used treatment but AmphotericinB is used in a third of cases. Near half of them receive a combination regimen. The length of therapy is prolonged, especially in lung transplant recipients.

Abstracts 2020

Abstract 8261

**Comparison of the molecular-based test system hyborg Dx and culture for the diagnosis of prosthetic joint infections**

Andreas Boesl*, Harald Dirschmid, Claudia Ohmayer, Agnes Neugebauer, Andreas Brachner, Bernhard Ronacher, Felix öffner

1Academic Teaching Hospital Feldkirch, Institute of Pathology, Feldkirch, Austria, 2Cube Dx GmbH, St. Valentin, Austria

**Background:** Prosthetic joint infection (PJI) remains one of the most serious complications of joint replacement. Due to the formation of biofilms the diagnosis of PJI may be difficult particularly in infections caused by low virulent microorganisms. The treatment decisions and the ultimate necessity of explantation of implants depend on a timely and precise diagnosis.

**Materials/methods:** 111 orthopedic samples (e.g. prosthesis, implants) suspicious for bone and joint infections were sonicated using the Bactosonic® (Bandelin, Germany) for biofilm removal, followed by culture within the scope of microbiological analysis. 100% (111/111) of the samples were used for the evaluation of the hyborg Dx using Real-Time PCR followed by compact sequencing technology (Cube Dx, Austria). After Real-Time PCR-based amplification of the bacterial 16S-rDNA followed by high resolution melting curve analysis, positive samples (Ct value <26) were analyzed by compact sequencing.

**Results:** 68.5% (76/111) showed microbial or mycotic growth of different pathogens. 42.1% (32/76) show more than 100 colony forming units (CFU) per milliliter (ml), 9.2% (7/76) between 10-99 CFU/ml and 50% (38/76) <10 CFU/ml (positive only after enrichment). For the molecular approach nucleic acid extraction was performed with the GINA 500 extraction kit (Cube DX, Austria). 41.4% (46/111) were tested positive with the hyborg Dx. 14.3% (5/35) were negative in culture but positive with the hyborg 93.75% (30/32) of the positive samples >100 CFU/ml were correctly identified with the hyborg DX resulting in a concordance of 94%. 71.4% (5/7) of the samples between 10-99 CFU/ml were correctly identified with the hyborg resulting in a concordance of 91.4% and 16% (6/38) of the samples below 10 CFU/ml, respectively.

**Conclusions:** The use of molecular biology based broad-range RT-PCR followed by comparative sequencing provides an assay complementary to culture to identify microorganisms from PJI and has a theoretical advantage of a rapid turnaround time and higher sensitivity than conventional microbiological methods, particularly for patients who received antimicrobials. It is also critical to evaluate the results of molecular testing as a stand-alone test, because of risk of contamination at any point of during procedure. However, the hyborg seem to be a useful tool to support microbiological analysis.

**Novel mutations found in UL56 terminase subunit and UL54 DNA polymerase after human cytomegalovirus infection treatment with letermovir**

Marta Santos Bravo*, Sonsoles Sanchez-Palomino*, María Del Mar Mosquera Gutiérrez†, Cecilia Martin Gandul‡, María Jesús Rodríguez Hernandez*, Nicolas Plault§, Veronica Gonzalo*, Elisa Cordero Matias*, Sophie Alain‡, Maria Angeles Marcos*

1Hospital Clinic de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, 2Hospital Clinic de Barcelona, Fundació Clinic, Barcelona, Spain, 3Hospital Clinic de Barcelona, Barcelona, Spain, 4Virgen del Rocio Hospital, Institute of Biomedicine of Seville (IBiS), Sevilla, Spain, 5University Hospital Limoges Dupuytren Hospital, UMR Inserm 1092, Limoges, France

Abstract third-party references: Group for the Study of Infection in Transplantation (GESITRA), Spanish Network for Research in Infectious Diseases (REIPI)

**Background:** Letermovir (LMV) is a HCMV terminase inhibitor recently approved for hematopoietic stem cell transplant (HSCT) prophylaxis. LMV presents better safety and tolerance profiles than current anti-CMV DNA polymerase inhibitors. However, its efficacy against HCMV infection during replication is currently being studied.

**Materials/methods:** A transplant recipient with persistent HCMV infection was treated with LMV as compassionate treatment after therapeutic failure with valganciclovir, ganciclovir, leflunomida or immunoglobulins. Immunosuppressive and antiviral treatments were adjusted to clinical response during the five HCMV reinfections until LMV was dispensed. Kidney function advised against the use of foscarnet.

Plasma CMV DNAemia was monitored with real-time polymerase chain reaction. Anti-CMV drugs target genes [UL56, UL54, UL97] of clinical samples before and after LMV treatment were analyzed by Sanger sequencing. Phenotypic assay by bacmid recombinant technology was performed for undescribed mutations found by sequencing at the French Reference Center. Anti-viral susceptibility test and growth assay are in progress at the moment and will be finished before February 2020.

**Results:** Two previously undescribed mutations were found after 20 days of LMV treatment which were not present prior LMV dispensation. F345L missense mutation was found within the LMV-resistance region (codon 230-370) of HCMV UL56. This mutation is located adjacent to previously described LMV-high-resistance-associated mutations (Y321C, C325Y, M329T, R369M/G/S).

Second S462P unknown mutation was detected in the HCMV UL54, located between the conserved functional domains IV and delta-C. S462P mutant emerged after 20 days valganciclovir withdrawal and LMV treatment. No resistance-associated mutation was detected until this point.

**Conclusions:** F345L and S462P are novel mutations found in HCMV UL56 and UL54 genes, respectively, at very early stage after LMV treatment. Based on evidence supporting a low LMV-resistance genetic barrier, emergence of the F345L mutant only under LMV selective pressure suggest its association to LMV resistance. The role of DNA polymerase S462P mutant is questioning. The potential replicative advantage conferred by this mutation has to be evaluated alone and in association with UL56 F345L.

Characterization of target genes variations from clinical specimens under different antiviral therapies is crucial for an early diagnosis of resistance and treatment adaption.

Prevented ciprofloxacin resistance development in *Pseudomonas aeruginosa* by immunomodulatory S100A8/A9 in a murine biofilm wound model

Anne Sofie Laulund*, Franziska Angelika Schwartz¹, Lars Jackie Christophersen¹, Kim Thomsen¹, Oana Clofu², Hannah Trestrup Pedersen¹, Niels Helby², Claus Moser¹

¹Rigshospitalet, København, Denmark, ²University of Copenhagen, København, Denmark

**Background:** *Pseudomonas aeruginosa* is known to contribute to pathogenesis of chronic wounds by establishing biofilm. Increased tolerance to host response and antibiotics, with development of antibiotic resistance *per se*, are consequences of biofilm formation in chronic wounds. The neutrophil factor S100A8/A9 has a promising adjuvant effect when combined with ciprofloxacin, measured by bacteriology, and increased anti- and lowered pro-inflammatory proteins. This raised the question "Can S100A8/A9 prevent ciprofloxacin resistance development in chronic wounds with *P. aeruginosa* biofilm?".

**Materials/methods:** Full-thickness necrosis (2.9 cm²) was inflicted on 33 mice. On day 4, 100µL of 10⁷ CFU/mL *P. aeruginosa* embedded in seaweed alginate was injected sub-eschar to mimic a biofilm infection.

Mice were randomized into groups: I) ciprofloxacin (500µL s.c. (2mg/mL)) and S100A8/A9 (200µL sub-eschar (5µg/mL)). Group II) Ciprofloxacin monotherapy and saline. Group III) Saline controls.

Half of the mice were terminated day 10 and the remaining on day 14. All mice were treated until sacrifice. The study was evaluated by means of quantitative bacteriology, appearance of ciprofloxacin resistant *P. aeruginosa* detected with E-tests, genetic characterization of resistance mechanism and cytokine production.

**Results:** Bacterial wound densities were significantly different between all groups (p=0.018). The osteopontin level, a chemokine that recruits inflammatory cells, was higher in the ciprofloxacin monotherapy group compared to the double treated group on both termination-days (p=0.0012, p=0.018). In contrast, IL-2 was highest in the double treated group and different from the ciprofloxacin group on both days (p=0.007, p=0.037).

Three mice receiving ciprofloxacin monotherapy had developed resistance after 10 days of ciprofloxacin therapy. These mice also had the highest osteopontin levels. None of the mice receiving combination therapy changed resistance pattern. Whole genome sequencing of these mice identified two high-resistant strains mutated in the DNA gyrase *gyrA* C248T. No mutation was found in the sample with low ciprofloxacin resistance (MIC 1.5 mg/L).

**Conclusions:** The present study indicates a protective effect of adjuvant S100A8/A9 in terms of hindered ciprofloxacin resistance development in biofilm infected chronic wounds. In addition, the adjuvant S100A8/A9 therapy resulted in reduced wound inflammation.

Abstract 8271

**Epidemiology, management, and costs of syphilis in Germany: a public health analysis**

Renata Smit*1,2, Benedikt Lohr1, Klaus-Peter Hunfeld1,2

1Institute for Laboratory Medicine, Microbiology & Infection Control, Northwest Medical Centre, Academic Teaching Hospital, Medical Faculty, Goethe-University, Frankfurt am Main, Germany, 2INSTAND e.V., Düsseldorf, Germany

**Background:** Syphilis is becoming a re-emerging public health concern in Europe. Because relatively little is known about the epidemiology and economic impact of syphilis in Germany, we analyze currently available statutory health insurance data to get deeper insights into the epidemiology and costs of syphilis in Germany from a public health perspective.

**Materials/methods:** The standardized incidence rate of syphilis is calculated, using the 2010 to 2012 claim data provided by one of the biggest German statutory health insurances “DAK-Gesundheit” and compared with the incidence of notified cases provided by the Robert Koch Institute (RKI) as well as the standardized seroprevalence for blood donors. In addition, we investigated the total number of treatments delivered and the number of diagnostic syphilis tests using claim data and proficiency testing reports as provided by INSTAND e.V, Düsseldorf to approximate costs and quality of diagnostics for syphilis in Germany.

**Results:** During the studied period, the average annual standardized incidence is 8/100,000, while the annual incidence for notified cases is 5/100,000 and the average annual standardized seroprevalence is 80/100,000. In average, 375 incident cases treated for syphilis are diagnosed annually in the cohort of 5.8 million insured DAK members. Extrapolation on the country level leads to 6,414 expected cases annually for Germany as a whole. Correspondingly, 72,234 screening tests (TPPA/TPHA) with a calculated sensitivity of 96.5% and specificity of 98.1% are performed annually in the outpatient sector alone, leading to approx. 1,006,727 annual syphilis tests for Germany as a whole with an annual cost of 4,491,607 €. For the blood donor cohort, 2,472,587 tests are estimated annually for donor screening in Germany with calculated positive predictive values of 2% and negative predictive values of 100%. For donor screening, the annual test cost amounts to 12,257,422 €. In addition, the total extrapolated average annual expenses calculated from claim cases leads to 13,904,813 € of syphilis in Germany.

**Conclusions:** Syphilis has an unexpectedly high economic impact on the German public health care system, therefore raising awareness of the disease and strengthening prevention is recommended for a reduction of the incidence and consequently economic burden of syphilis in Germany.

Investigation of hypervirulent Group B Streptococcus ST17 clone by MALDI-TOF MS

Elif Aktas1, Eyyüb Karacan*1, Nur Kina1, M. Emin Bulut1, Gulsah Malkoçoğlu2

1Health Sciences University, Şişli Hamidiye Etfal Research and Training Hospital, Department of Medical Microbiology, Istanbul, Turkey, İstanbul, Turkey, 2Kocaeli Public Health Laboratory, Kocaeli, Turkey

Background: Group B streptococci (GBS) is one of the leading causes of invasive infections in newborns and pregnant women and GBS Sequence-Type 17 (ST17) is defined as a hypervirulent clone by multilocus sequence typing (MLST). There have been reports that GBS ST17 clone can be detected during the identification of bacteria by evaluating the peaks in the spectra obtained using MALDI-TOF MS. In a previous study by our team, as a first report of circulation of the hypervirulent clone in our region, six out of 101 isolates were found as ST17 clone by MALDI-TOF MS and confirmed by MLST. The aim of this study is to determine the ratio of ST17 clone in a larger population of various clinical GBS isolates by MALDI-TOF MS.

Materials/methods: A total of 318 GBS isolates obtained from various clinical specimens between January 2015-July 2019 at the Clinical Microbiology Laboratory of a research hospital were included in the study. Identification was done by MALDI-TOF MS (Bruker, Daltonics). Detection of GBS ST17 was done by MALDI-TOF MS as described by Lartigue et al. A peak shift from 7650 Da to 7625 Da was used to distinguish ST17 clone

Results: Of the 318 GBS isolates from 212 urine, 75 cervicovaginal, 12 blood 10 abscess and 9 other samples, 19 (%6) were identified as ST17 clone. Samples yielding ST17 isolates were from obstetrics&gynecology [7 from nonpregnant patients], urology [4], nephrology [4] and pediatrics [4]. Of the 19 ST17 isolates, 15 were from urine and 4 were from cervico-vaginal samples.

Conclusions: Here we demonstrate hypervirulent GBS ST17 clone circulating in our population with a rate of 6% of all GBS isolates. Rapid detection of this hypervirulent clone by MALDI-TOF MS without the need for additional cost during bacterial identification may help develop strategies for the early treatment. Further investigation of this high-risk clone is essential for developing strategies for the control and prevention of invasive infections.

Abstract 8278

Xpert MTB/RIF assay useful for paediatric patient tuberculosis disease diagnosis

Virginia Lora*1

1Hospital del Niño Poblano, Hospital para el Niño Poblano, Puebla, Mexico

Background: Diagnosis tuberculosis in children is difficult because the incidence for extra-pulmonary sites such as lymphatic and meningeal tuberculosis, are more common in young children. Samples such as sputum (gastric lavage fluid), cerebrospinal fluid and lymphatic ganglion, may have very few tuberculosis bacteria in it (paucibacillary smear-negative disease). The Xpert MTB/RIF assay is a nucleic acid amplification (NAA) test that uses a disposable cartridge with the GeneXpert Instrument System. The test simultaneously detects *Mycobacterium tuberculosis* complex (MTBC) and resistance to rifampin (RIF).

Materials/methods: The investigational assay was used to test gastric lavage fluid, sputum, bronchial lavage, cerebrospinal fluid and lymphatic ganglion samples from 231 pediatric patients with tuberculosis disease presumptive diagnosis. All the collected samples were available for smear with microscopy for acid-fast bacilli, culture for mycobacteria, and for the Xpert MTB/RIF assay.

Results: This clinical study included 231 pediatric patients; female 53.2%, male 46.8%. Age groups affected 0-5 years: 56.75%, 6-15 years: 40.75% and > 15 years: 2.6%. 17 patients had tuberculosis disease (7.35%), 8 patients had pulmonary tuberculosis, 4 lymphatic tuberculosis, 3 disseminated tuberculosis and 2 meningeal tuberculosis. The Xpert MTB/RIF assay detected 16 of 17 cases for MTBC and one of these for resistance to rifampin, failure MTBC detected once for a ganglion sample. Culture for mycobacteria was positive in 16 of 17 cases, failure once for a gastric lavage fluid sample. Smear with microscopy for acid-fast bacilli was effective in 10 of 17 cases for tuberculosis. All the collected samples were paucibacillary.

Conclusions: The standard cultures can take 2 to 6 weeks for MTBC to grow and conventional drug resistance test can add 3 more weeks, but the Xpert MTB/RIF assay results are available less than 3 hours, and this information provided by the Xpert MTB/RIF assay aids in selecting treatment regimens very quickly. However, the Xpert MTB/RIF assay does not replace the need for smear with microscopy for acid-fast bacilli and the culture for mycobacteria.

Decline of the Brazilian endemic clone and dominance of internationally disseminated lineages among MRSA from bacteraemic patients in Porto Alegre, Brazil

Cezar Vinícius Würdig Riche1,2, Rafael Mamede3, Rebeca Inhoque Pereira1, João Carriço1, Cícero Dias1, Mario N. Ramirez3

1Federal University of Health Sciences of Porto Alegre, Porto Alegre, Brazil, 2Ernesto Dornelles Hospital, Porto Alegre, Brazil, 3Instituto de Medicina Molecular (IMM), Lisboa, Portugal

Background: Methicillin-resistant Staphylococcus aureus (MRSA) is one of the most frequent causes of healthcare-associated (HA) and community-associated (CA) infections, with bacteraemic patients representing a particularly serious challenge. We aimed to investigate the clinical and molecular epidemiology of MRSA invasive infections.

Materials/methods: This cohort study was performed in four tertiary care public hospitals located in Porto Alegre, Brazil. Only MRSA bloodstream isolates were included and were prospectively collected - isolates from the same episode of bacteraemia were counted only once. The study period was from April 2014 until June 2018. The isolates were subjected to high throughput sequencing using Illumina technology. Clinical data was obtained from electronic records.

Results: A total of 91 MRSA isolates were included; 64 (70%) were from HA and 27 (30%) from CA infections. The patients were predominantly male (55%), median age was 58y. (IQR 39-68y.) and Charlson score median was 3 (IQR 1-6). The sequence types (ST) and clonal complexes (CC) identified were: ST5, ST105, ST1176 and ST552 (CC5, 36%); ST30 and ST5522 (CC30, 31%); ST8 and ST239 (CC8, 29%); ST669 (2%) and ST398 (2%). The Brazilian endemic clone (BEC–ST239–III–PVL), a previously prevalent lineage, was now represented by 3 isolates (3%). Both ST30 and its CC were associated with CA infections (p=0.005 and p=0.006 respectively; Fisher exact test). In contrast, CC5 was associated with HA infections (p=0.008). ST669 was present only in paediatric patients (p=0.006). Forty-nine isolates (54%) had the PVL encoding locus and were associated with CA infections (p=0.005). The ST8 and ST30/CC30 were associated with PVL presence (p=0.0001 for both) and the CC5 with PVL absence (p=0.0001) with all CC5 isolates being PVL negative. The major SCCmec type found was IV (67%), with subtypes IVa (31%), IVc (27%) and IVg (9%).

Conclusions: The major clones in our collection represent widely disseminated lineages, which, in our cohort, were associated with specific presentations and age groups. The low incidence of BEC in our study supports the replacement of this lineage by international clones in recent years in Latin America, as reported also in other centers in Brazil. A more detailed genomic analysis will reveal if there are specific sub-lineages of these international clones circulating in our region.

Abstract 8282

**Intra-osteoblastic activity of dalbavancin during treatment of Staphylococcus aureus bone and joint infection**

Chauvelot Pierre¹, Lelia Abad¹, Aubin Souche¹, Céline Dupieux¹, Jérôme Josse¹, Tristan Ferry¹, Frédéric Laurent¹, Florent Valour*¹

¹Lyon, France

**Background:** Long-acting lipoglycopeptides such as dalbavancin are promising therapeutic options in the treatment of *Staphylococcus aureus* bone and joint infection (BJI). However, the ability of dalbavacin to eradicate the intraosteoblastic reservoir of *Staphylococcus aureus*, associated with BJI chronicity and relapse, has never been evaluated.

**Materials/methods:** In an *ex vivo* model of bone cell infection, osteoblastic MG63 cells were infected with a standardized inoculum of the *S. aureus* reference strain HG001 (multiplicity of infection, 100:1), and incubated for 24h with dalbavancin, vancomycin or rifampin using the minimal inhibitory concentration (MIC), 10MIC, 100MIC, and the intraosseous concentrations reached using standard therapeutic doses in humans [i.e., vancomycin, 10mg/L; rifampin, 2mg/L; and dalbavancin, 6mg/L]. The remaining intracellular bacteria were quantified by plating cell lysates. Four independent experiments in technical triplicates were performed. Results are expressed as means and 95% confidence intervals (95%CI).

**Results:** HG001 was fully susceptible to the three tested molecules, with MICs of 0.125, 1 and 0.004 mg/L for dalbavancin, vancomycin and rifampin, respectively. Dalbavacin was able to significantly reduce the intracellular inoculum of *S. aureus* starting at a concentration equal to the MIC, with a significant dose effect ranging from a reduction of 31.4% (95%CI, 19.3-43.5) at MIC to 51.6% (95%CI, 41.3-61.9) at 100MIC compared to untreated cells. At intraosseous concentrations [figure], dalbavancin reduced the intracellular inoculum by 49.6% (95%CI, 46.4-54.6) compared to untreated cells (p<0.001), with no difference compared to vancomycin [38.1%; 95%CI, 21.5-54.7; p=0.646], and was less efficient than rifampin [69.0%; 95%CI, 63.9-74.1; p<0.001].

**Conclusions:** Dalbavancin was able to decrease by 50% the intraosteoblastic *S. aureus* inoculum at intraosseous concentrations reached during standard human therapeutic dosing, with no difference compared to vancomycin, but remained less efficient than rifampin. Future studies should investigate its activity against internalized methicillin-resistant staphylococci, including vancomycin-intermediate isolates.

Figure: Ability of dalbavancin to eradicate the intraosteoblastic inoculum of *S. aureus* at intraosseous concentrations reached with standard human therapeutic dosing, in comparison with vancomycin and rifampin

Abstract 8284

Effect of nikkomycin Z and caspofungin upon in vitro induction of echinocandin resistance by Candida tropicalis

Ana Teresa Silva1,2, Joana Branco*1, Isabel Miranda1, Acácio Gonçalves Rodrigues1,2,4, Sofia Costa-De-Oliveira1,2

1Faculdade de Medicina da Universidade do Porto - FMUP Division of Microbiology, Department of Pathology, Faculty of Medicine, Porto, Portugal, 2Faculdade de Medicina da Universidade do Porto - FMUP, Center for Research in Health Technologies and Information Systems (CINTESIS), Porto, Portugal, 3Faculdade de Medicina da Universidade do Porto - FMUP, Department of Surgery and Physiology and Cardiovascular R&D Unit, Porto, Portugal, 4Saint John Hospital, Burn Unit, Porto, Portugal

Abstract third-party references: This work was supported by Astellas and Grupo de Infeção e Sepsis (GIS) from Centro Hospitalar São João [Clinical Mycology Research grant].

Background: Echinocandins represent the first-line therapy for the treatment of invasive candidosis. They inhibit the \( \beta(1,3) \)-glucan synthase which is responsible for producing a key component of the fungal cell wall and is encoded by \( \text{FKS} \) genes. The increase in chitin content plays a role in maintaining fungal cell integrity following exposure to echinocandins. Nikkomycin Z (NZ), a peptidyl nucleoside that functions as a substrate analogue and inhibits chitin synthase at its catalytic site, may be a promising therapeutic drug. The aim of this study was to evaluate the effect of the chitin synthesis inhibitor, nikkomycin z, in the evolution of caspofungin resistance by \( \text{Candida tropicalis} \).

Materials/methods: One \( \text{C. tropicalis} \) clinical isolate susceptible to echinocandins (CTs strain) was incubated overnight at 35°C with sub-Minimal Inhibitory Concentration (sub-MIC) concentration (0.03 \( \mu \)g/mL) of caspofungin (CSF). The drug concentration was increased to double whenever yeast growth was prominent, reaching the final concentration of 8 \( \mu \)g/mL. In parallel, CTs strain was incubated overnight with 0.03 \( \mu \)g/mL of CSF plus 25 \( \mu \)g/ml (sub-MIC concentration) of nikkomycin Z (NZ) (CT_CS-F+NZ). \text{In vitro} induction experiment took 30 days. Every 5 days, MIC values of echinocandins were determined according to the broth dilution antifungal susceptibility testing from CLSI.

Following DNA extraction, random amplification of polymorphic DNA was performed using the primers OPE-18 and OPA-18. The HS1 and HS2 of the \( \text{FKS1} \) and \( \text{FKS2} \) genes were amplified and sequenced in an ABI PRISM 3130 Genetic Analyzer.

Results: After 30 days of exposure to CSF, a cross resistant echinocandin strain was obtained (CT_CSFr); with the exposure of CTs to CSF + NZ the phenotype remained susceptible to all echinocandins. CT_CSFr was sub-cultured for an additional 30 days in the absence of CSF and MIC values re-determined and the resistant pattern remained stable. All isolates were confirmed to be isogenic. A point mutation was found in CT_CSF, corresponding to an amino acid replacement of aspartate to valine at position 702 of Fks1p HS1.

Conclusions: Our results demonstrate that the presence of nikkomycin Z prevented the evolution of echinocandin resistance, suggesting therapeutic potential of nikkomycin Z-echinocandin combinations in managing echinocandin resistance.

Abstract 8285

Extended-spectrum ß-lactamase-producing/carbapenemase-producing Enterobacterales prosthetic joint infection in patients with positive rectal screening

Marie-Charlotte De Carne*1, Amandine Henry1, Emma Pinet1, Stéphanie Balavoine1, Nicaise Nebot1, Philippe Boisrenoult1, Caroline Neulier1, Marlene Amara1, Audrey Therby2

1Hopital André Mignot, Le Chesnay, France, 1Hopital André Mignot, Le Chesnay, France

Background: Gram-negative Bacilli represent approximately 10% of PJI (TANDE, CMR 2014). Since 2002, the incidence of ESBL Enterobacterales is growing (RAISIN network, 2016). In France, CPE infections remain rare but increasing (Santé Publique France, 2018). The rectal carriage of resistant Enterobacterales could play a role in the PJI due to these strains.

The aim of this study is to clarify if the results of rectal screening swabs should be taken in account for the adaptation of probabilistic antibiotic therapy for PJI.

Materials/methods: We performed a monocentric retrospective observational study, between January 2015 and June 2019, at the Reference Center for Osteo Articular Infections in Versailles.

All the patients with ESBL and CPE PJIs during the study period were included.

Phenotypes of Enterobacterales CPE and ESBL strains isolated from rectal swabs and strains isolated from PJIs were compared.

Results: 26 1 P JIs were treated in 227 patients during the study period. 85/227 (37%) patients had a ESBL/CPE positive rectal screening. Among them 15/227 (7%) had a ESBL or EPC PJI (16/26 1).

Sex ratio was 1.1 4 and average age was 7 4 years.

7/15 (47%) patients were immunocompromised. Patients underwent a median number of 3 surgeries.

9/15 (60%) patients [i.e. 10/16 PJI because 1 patient was infected twice] had positive rectal screening; 8 ESBL PJIs and 2 CPE.

5/8 (63%) ESBL infected patients [4 hip / 1 knee prosthesis] and 2/2 (100%) CPE infected patients [2 knee prosthesis] were infected with their carrying strain.

3 patients were infected with a different strain.

6/14 (43%) of ESBL-infected patients had negative rectal screening.

Conclusions: In our study, 5/14 (35,7%) and 2/2 (100%) of patients infected with ESBL or CPE were infected with the same profile of rectal carrying strain. Risk factors of infections to multiresistant Gram negative strains seem to be age, number of surgeries but have to be clearly identified. Today, it is not recommended to adapt the probabilistic antibiotic therapy of PJIs to the germs found in rectal screening. In patients with high risk of ESBL/CPE PJIs, enlargement of probabilistic therapy might be considered. Multicentric studies could be useful since more data are needed.

**Mycobacterium tuberculosis** serostatus in patients with multiple sclerosis treated with anti-CD20/52: effects of treatment and lymphocytic asset on Quantiferon assay results

Emanuela Zappulo1*, Antonio Riccardo Buonomo1, Roberta Collicchio1, Giulia Scalía1, Cinzia Valeria Russo1, Martina Petruzzo1, Marcello De Angelis1, Biagio Pinchera1, Riccardo Scotta1, Vincenzo Bresciamorra1, Paola Salvatore1, Ivan Gentile2

1University of Naples “Federico II”, Naples, Italy, Department of Clinical Medicine and Surgery Section of Infectious Diseases, Naples, Italy, 2University of Naples “Federico II”, Naples, Italy, Department of Molecular Medicine and Medical Biotechnologies, Naples, Italy, 3CEINGE-Biotechnologie Avanzate, Naples, Italy, Clinical and Experimental Cytometry Unit, Naples, Italy, 4University of Naples “Federico II”, Department of Neurological Sciences, Reproductive and Odontostomatological Sciences, Naples, Italy

**Background:** Tuberculosis screening is routinely carried out in patients with multiple sclerosis (MS) receiving anti-CD20/52 agents in order to minimize the risk of reactivation. Our study was aimed to investigate the prevalence of the different serostatus and the effect of such regimens and lymphocytic counts on Quantiferon TB-Gold In-Tube (QTF) results.

**Materials/methods:** QFT assay were performed before and after treatment with anti-CD20 (ocrelizumab/rituximab) and anti-CD52 (alemtuzumab) agents and results were compared according to time of testing. The effects of lymphopenia and treatment history on indeterminate QTF results were evaluated by logistic regression. Pre/post-treatment QTF results were compared in a subset of patients.

**Results:** Two-hundred forty-three patients were enrolled, 47% on ocrelizumab, 26% rituximab, and 27% alemtuzumab. Considering the time of testing, QTF assay was negative in 143/168 (85%) vs 95/108 (88%), indeterminate in 4/168 (2%) vs 6/108 (6%) and positive in 21/168 (13%) vs 7/108 (7%) of patients screened before and after treatment, respectively. Pre-treatment QTF results did not differ according to prior/ongoing treatments or immune status at sampling (Fig. 1). Post-treatment QTF results were significantly different based on prior fingolimod (p=0.047), lymphocytopenia (p=0.034), CD4+ counts<200 cells/μl (p=0.011), and median CD8+ counts (p=0.027) (Fig. 1). Indeterminate QTF results were recorded in 9 patients and main risk factors were evaluated. At multivariate analysis, no prior MS treatment was significantly associated with indeterminate results (OR: 2.4, p=0.039). Twenty-six patients were tested before and after treatment: changes in QTF assay results were recorded in 6 (23%) patients (median time-to-re-test: 320 days). In particular, in two patients QTF switched from negative to indeterminate (both on alemtuzumab, severe lymphopenia <100 cells/μl at re-testing); in two from positive to negative (both on rituximab and isoniazid prophylaxis, after 3 months); in one from indeterminate to negative (on alemtuzumab, with prior fingolimod and baseline lymphopenia); in one from negative to positive (after 15 months and 3 cycles of rituximab with no known risk factor, clinically negative).

**Conclusions:** Post-treatment QTF results in patients receiving anti-CD20/52 agents can significantly be affected by prior fingolimod exposure and lymphocytopenia. QTF changes and conversions were observed in a remarkable proportion of patients screened before and after monoclonal antibody treatment. No significant effect of lymphocytic levels and ongoing treatment was observed in patients with indeterminate QTF.

**Table 1:** Comparison of QTF assay results in patients receiving anti-CD20/52 agents screened before or after treatment.

Identification of gene expression profiles of *Leishmania major* by integrated bioinformatics analyses

Ozlem Ulusan¹, Aygul Sadıqova², Ufuk Mert³, Sercan Öztürk³, Ayse Caner*¹,⁴,⁵

¹Departments of Parasitology, Ege University Medical Faculty Hospital, Izmir, Turkey, ²Infectious Disease Division, The University of Texas Medical Branch at Galveston, Houston, United States, ³Departments of Computer Science, Dokuz Eylul University, Izmir, Turkey, ⁴Departments of Bioinformatics, Ege University, Institute of Health Sciences, Izmir, Turkey, ⁵Departments of Experimental Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, United States

**Background:** *Leishmania major* infection causes a localized cutaneous lesion in patients and has been widely used to study the development of vaccines against leishmanial infections in mice. *L. major* infected C57BL/6 mice are susceptible to infection and fail to control parasite replication due to the development of Th2 responses. In this study, our aim is to identify the changes in gene expression between mice with infected *L. major* and healthy mice and show molecular pathways and biological functions relate to the pathogenesis of *L. major*.

**Materials/methods:** We used GSE56029 data set from the GEO database for our study. In the whole-genome transcriptional analysis, the skin samples were obtained from healthy mice and mice infected intradermally with *L. major* for 4 weeks. Normalization of the raw data was performed with the Robust Multi-array Analysis. We performed paired t-test and fold change analysis to see for statistically significant changes in expression profiles between mice infected with *L. major* and control group. To define the molecular pathways of all the genes mapped within amplicons in *L. major*, Ingenuity pathway analysis was carried out with each set of significantly differentially expressed genes using IPA8.0 software. Then, we conducted macrophage cell culture infected with *L. major* strain to validate the expression level of some genes, which showed significantly increased/decreased gene expression.

**Results:** We showed the top 20 genes that have significantly increased and decreased expression in *L. major* infection. The top 5 significant genes, Arg1, FCGR4, CXCL9 and CXCL2, had more significant fold change and FDR values than the others and important positions in leishmaniasis. The expression levels of these genes in cell culture were compatible with bioinformatics analysis. The pathway analysis existed that the TREM 1 signaling was the most activated pathway in *L. major*. We showed the upregulated and downregulated genes in TREM signaling pathways in detailed and validated the gene expression levels in cell culture.

**Conclusions:** The results revealed that the activated TREM-1 signaling pathway is associated with *L. major* infection and has a pathogenic impact during parasitic infection in mice. Besides, *L. major* may modulate some genes relate to TREM-1 in macrophages.

**Omics approaches for detection of unique features of *Mycobacterium tuberculosis* Beijing B0/W148 cluster**

Julia Bespyatykh*, Egor Shitikov, Dmitry Bespiatykh, Ksenia Klimina, Marine Dogonadze, Viatcheslav Zhuravlev, Elena Ilina

1Federal Research and Clinical Centre of Physical-Chemical Medicine, Moscow, Russian Federation, 2Research Institute of Pulmonology, St. Petersburg, Russian Federation

**Background:** *Mycobacterium tuberculosis* Beijing B0/W148 is one of the most widely distributed clusters in the Russian Federation and in some countries of the former Soviet Union. Recent studies have improved our understanding of the reasons for the "success" of the cluster but this area remains incompletely studied. The aim of the present study was to investigate the features of these endemic strains on different -omics levels.

**Materials/methods:** We used 20 Beijing B0/W148 strains and H37Rv strain from our collection. WGS and transcriptome analysis were conducted on Illumina HiSeq 2500. Additionally, WGS data for 10000 *M. tuberculosis* isolates were obtained from NCBI. Proteome analysis was performed on a Q Exactive HF mass spectrometer.

**Results:** Overall, we identified 397 Beijing B0/W148 strains, which showed a restricted genetic diversity (a pairwise distance of 28 SNPs, ±SD 19 SNPs). Additionally, we described 59 cluster-specific SNPs, which can partly explain the "success" of the cluster. During the study whole (circular) genome of RUS B0 strain was obtained (CP030093.1). In turn, proteome and transcriptome studies allowed to confirm the genomic data and to identify a several features that have not previously been described. Our results demonstrated that expression of the *whiB6* which contains cluster-specific polymorphism (a151c) increased almost 40 times in RUS B0. Additionally, the level of *ethA* transcripts in Beijing B0/W148 was increased by more than 7 times compared to the H37Rv. A comparative quantitative proteomic analysis showed a statistically significant difference between cluster strains and H37Rv in the representation of 192 proteins. Functional analysis revealed differences in the representation of lipid metabolism proteins and proteins involved in the response to hypoxia, which was confirmed by the results of transcriptome analysis. Start sites for 10 genes were corrected based on the combination of proteomic and transcriptomic data. Additionally, based on the omics approach, we identified 5 new genes.

**Conclusions:** We presented the most complete description of the cluster Beijing B0/W148 cluster members. In summary, our results suggest that the specific features of Beijing B0/W148 strains are likely to contribute to their increased virulence and successful geographical distribution.

Supported by the RSF (№ 19-75-10109) and RFBR (№ 18-34-00168).

**Introduction of automated blood culture in a resource-limited setting in West Africa**

Anja Von Laer*1,2,3; Micheline N’guessan4; Fidèle Sounan Touré5; Tim Eckmanns3; Kathrin Nowak1; Karin Groeschner3; Chantal Akoua-Koffi4

1Postgraduate Training for Applied Epidemiology, Robert Koch-Institute, Berlin, Germany; 2European Programme for Intervention Epidemiology Training, European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden; 3Department of Infectious Disease Epidemiology, Robert Koch-Institute, Berlin, Germany; 4Centre Hospitalier et Universitaire de Bouaké, Laboratoire Central, Bouaké, Côte d’Ivoire; 5Robert Koch-Institut, Department for nosocomial infections and surveillance of antimicrobial resistance and antimicrobial consumption, Berlin, Germany

**Background:** Blood cultures (BC) have a high clinical relevance and are a priority specimen for surveillance of antimicrobial resistance. Manual BC (M-BC) is still most frequently used in resource-limited settings. Data on automated BC (A-BC) performance in Africa is scarce. We implemented A-BC within the African Network for improved Diagnostics, Epidemiology and Management of Common Infectious Agents (ANDEMIA) in the Ivory Coast. We compared the performance of A-BC and M-BC.

**Materials/methods:** Between June 2017 and January 2018, bottle pairs of BacT/ALERT® FA Plus (A-BC) and M-BC with self-made brain-heart infusion were compared at a university hospital in the Ivory Coast. BC bottles were inoculated each with a target blood volume of 10ml from the same venipuncture. A-BC’s were incubated for up to 5 days in the BacT/Alert 3D system, M-BC’s for up to 10 days at 37°C. Terminal subcultures were performed for M-BC’s only. Contamination was defined by the clinical microbiologist. The two systems were compared regarding yield, contamination and processing time. During the study period, clinicians were trained in best practice of BC sampling.

**Results:** A total of 337 matched pairs of BC specimens were included. Overall, 37% (95%CI: 31.3-41.9) of A-BC and 24% (95%CI: 19.6-29.0) of M-BC had a positive result with a contamination proportion of 48% (95%CI: 38.8-57.2) and 44% (32.7-55.3), respectively. Processing times were shorter with A-BC than with M-BC (see table). Most contaminants were members of the skin flora. Most common detected pathogens were *Klebsiella* spp. (32%) and *Staphylococcus aureus* (19%).

**Conclusions:** Implementing A-BC in a resource-limited setting is possible. A-BC increased yield and shortened turnaround times, but increased contamination. Training of clinicians has to be intensified to increase the number and the quality of BC sampling. Pre-analytical training to improve diagnostic stewardship is essential when implementing a new microbiological method.

Abstract 8294

**Ceftaroline+rifampin versus vancomycin+rifampin in the treatment of methicillin-resistant Staphylococcus aureus meningitis in an experimental rabbit model**

Damla Akdağ1, Tuncer Turhan1, Elif Bolat1, Gamze Şanlıdağ1, Furkan İşbilen1, Şöhret Aydemir1, Tansu Yamazhan1, Husnu Pullukcu1, Bilgin Arda*1, Meltem Isiköz Tasbakan1, Berke Gökkilic1, Ekin Kartal1, Hilal Tipirdamaz Sipahi1, Sercan Ulusoy1, Oguz Resat Sipahi1

1Ege University, Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, İzmir, Turkey, 2Ege University, Faculty of Medicine, Department of Neurosurgery, İzmir, Turkey, 3Ege University, Faculty of Dentistry, Department of Endodontics, İzmir, Turkey, 4Ege University, Faculty of Medicine, Department of Medical Microbiology, İzmir, Turkey, 5Ege University, Faculty of Medicine, İzmir, Turkey, 6Bornova Public Health Directorate, İzmir, Turkey

**Background:** In this study it was aimed to compare the antibacterial activity of ceftaroline+rifampin with vancomycin+rifampin in the treatment of methicillin-resistant Staphylococcus aureus (MRSA) meningitis in experimental rabbit meningitis model.

**Materials/methods:** Meningitis was induced by direct inoculation of ATCC 43300 MRSA strain into cisterna magna of New Zealand rabbits. After 28 hours of incubation, rabbits were divided into three groups as ceftaroline+rifampin (S+R), vancomycin+rifampin (V+R), and control (C) groups. The S+R group received 58 mg/kg ceftaroline (Pfizer, Istanbul, Turkey) twice a day, the V+R group received 20 mg/kg vancomycin (Koçak Farma, Istanbul, Turkey) two dosages (at T0 and 5 h later). Rifampin (Koçak Farma, Istanbul, Turkey) was given 15 mg/kg at T0 and 5 h later. The C group did not receive any treatment but 0.9 NaCl. Quantitative bacterial cultures were performed in cerebrospinal fluid (CSF) samples, which were obtained at the beginning and 24th hours of the treatment.

**Results:** After 28 hours of incubation, 25 of 46 rabbits (8 C, 9 S+R, 8 V+R) met the criteria of meningitis. There was no difference in the number of bacteria [calculated as log10] between the three groups at the beginning of the treatment [C: 4.498±0.566 cfu/mL, S+R: 4.646±0.890 cfu/mL, V+R: 4.269±0.524 cfu/mL, p:0.506]. There was no statistically significant difference between the groups in terms of surviving rabbits at the end of treatment [C: 5/6, S+R: 8/9, V+R: 7/8, p:0.096]. At the end 24th hour of treatment, bacterial count decreased significantly in both treatment groups compared to the control group [C: +3.054±3.817 cfu/mL, S+R: -4.411±0.832 cfu/mL, V+R: -3.185±3.126 cfu/mL, p: 0.034]. However, there was no statistically significant difference between the S and the V groups (p:0.541).

**Conclusions:** Our results suggest that the antibacterial activity of both ceftaroline+rifampin and vancomycin+rifampin are similar in the treatment of MRSA meningitis in experimental rabbit model.

A majority of adult hospitalised patients with community-acquired lower respiratory tract infections had viral infections

Nicklas Sundell1, Lars Gustavsson1, Magnus Lindh1, Lars-Magnus Andersson1, Johan Westin*

1Dept of Infectious Diseases, University of Gothenburg, Gothenburg, Sweden

Background: Community-acquired lower respiratory tract infections (LRTI) is a frequent reason for in-patient hospital care. Bacterial etiology is commonly suspected and antibiotic therapy initiated in these cases. We aimed to investigate the relative proportion of viral infections in this patient group and describe the clinical characteristics and outcome of such infections.

Materials/methods: We collected nasopharyngeal (NP) samples prospectively from adult hospitalized patients at the infectious disease unit of a 2000 bed teaching hospital in Western Sweden, during three consecutive winter seasons 2016-2019. Syndromic testing was performed using a multiplex PCR panel including 16 viruses and 4 bacteria. Medical records were reviewed for information regarding symptoms at presentation, antimicrobial therapy, microbiological and radiological findings, length of hospital stay, ICU admission, need for oxygen therapy, readmission rate as well as 30-day mortality.

Results: In total, 220 patients were included in the study of which 71 (33%) had viral infections, 51 (23%) had viral/bacterial coinfections, 66 (30%) had bacterial infections while the etiology remained unknown in 31 (14%) cases. The predominant viral agent was influenza (A or B) virus. Sporadic cases of respiratory syncytial virus, metapneumovirus and parainfluenza virus was detected. Rhinovirus was uncommon among viral infections but frequently detected as a potential bystander in viral/bacterial coinfections. Streptococcus pneumoniae was the predominant bacterial pathogen in bacterial and viral/bacterial coinfections. Absence of chest x-ray findings and low CRP level but not low CRB-65 or NEWS scores were associated with viral infections. Patients with viral infections had a shorter length of hospital stay (median 4 vs. 5 days) and received less antibiotics (median 4 vs. 10 days) than patients with bacterial or unknown etiology.

Conclusions: Syndromic testing by a multiplex PCR panel identified either viral infection or viral/bacterial coinfections in a majority of hospitalized adult patients with community-acquired LRTI. Identification of viral etiology based on clinical presentation and routine laboratory tests is challenging and clinical scoring systems like CRB-65 and NEWS add limited value, while chest x-ray and CRP remain relevant. Systematic use of syndromic testing for virus and bacteria may reduce overuse of antibiotics in adult hospitalized patients with LRTI.

Abstract 8298

Relevance of EBV load monitoring in renal transplant recipients: a retrospective cohort study

Lilli Gard*1, Claudy Oliveira Dos Santos2, Willem Van Doesum2, Hubert G.M. Niesters2, Willem Van Son1, Arjan Diepstra1, Coen Stegeman1, Henk Groen1, Jan-Stephan Sanders1, Annelies Riezebos-Brilman3

1University Medical Center Groningen, Groningen, Netherlands, 2Certe, Groningen, Netherlands, 3UMC Utrecht, Utrecht, Netherlands

Background: EBV load monitoring after solid organ transplantation is used to predict post-transplant lymphoproliferative disorder (PTLD) development in high risk populations. We studied in a retrospective single center cohort, the additive value of EBV monitoring in renal transplant recipients (RTR).

Materials/methods: 373 RTR were included who received a kidney transplant between 2010 and 2012. The incidence of EBV-viremia in whole blood, graft and patient survival, PTLD and biopsy proven acute rejection (BPAR) was studied.

Results: 121 recipients were EBV-DNA negative in whole blood (32.4%), whereas EBV-DNA was detectable at least once in 252 recipients (67.5%). One patient developed histological proven PTLD (0.4%). Incidence of graft failure was not significantly different between the EBV-viremia group (n=25/247, 10.1%) and the EBV-viremia negative group (n=7/121, 5.8%) (RR=1.75, 95% CI 0.8-3.9, p=0.17). In recipients with EBV viral load > log 4 cp/ml graft loss occurred significantly more often (p=0.004). BPAR and mortality rate did not differ significantly between the groups with or without EBV-viremia.

Conclusions: EBV-viremia is common in RTR. With EBV viremia > log 4 cp/ml more graft loss was observed. However, no association with patient survival, PTLD and BPAR was found.

Molecular epidemiology of Neisseria gonorrhoeae clinical isolates in Reunion and Mayotte: lessons from the study of island populations

Herve Jacquier*, Guillaume Miltgen#, Damien Hoarau, Olivier Rollot, Sandrine Bruniquet, Ndeindo Ndeikoundam, Sylvain Kumanski, Ghislaine Ly Pat Yuen, Olivier Belmonte Garcia, Beatrice Bercot, Bénédicte Roquebert

1 APHP, Saint-Louis – Lariboisière - Fernand-Widal Hospital, Department of Infectious Agents, French National Reference Center for Bacterial STI, Associated laboratory for gonococci, Paris, France, 2 Université de Paris, IAME, UMR 1137, INSERM, Paris, France, 3 Université de La Réunion, CNRS 9192, INSERM U1187, IRD 249, Unité Mixte Processus Infectieux en Milieu Insulaire Tropical [PeMIT], Plateforme Technologique CYROI, Sainte Clotilde, Reunion, 4 Microbiology Laboratory, Felix Guyon Hospital, CHU La Réunion, Saint Denis, Reunion, 5 INSERM CIC 1410, CHU La Réunion, Saint Pierre, Reunion, 6 Santé Publique France, French National Public Health Agency, Saint Maurice, France

Background: Little is known about the epidemiology of Neisseria gonorrhoeae (NG) in the Indian Ocean. We characterized the main circulating genotypes of NG and their resistance profiles on two French islands in the Indian Ocean (Reunion and Mayotte).

Materials/methods: A retrospective study was performed between October 2016 and April 2017, within a network of laboratories on French overseas islands at which NG isolates are cultured. For 88 NG isolates, Minimum inhibitory concentrations (MICs) were determined for 6 antibiotics and genotyping was performed using the NG-MAST technique.

Results: NG isolates were recovered from symptomatic patients, 38 women (43.2%) and 50 men (56.8%), with a median age of 25 years. Genotypic diversity was low and the main genotypes belonged to ST5441 (19/88, 21.6%), followed by ST2318 (16/88, 18.2%) and ST2 (9/88, 10.2%). The ST5441 and ST2 isolates were fully susceptible to ceftriaxone and ciprofloxacin. All ST2318 isolates were resistant to ciprofloxacin, and 9/16 displayed a MIC of ceftriaxone above the ECOFF.

Conclusions: Our results show the circulation of three major clusters. ST5441 and ST2 belong to the most frequent genotypes in mainland France. All isolates with increased MICs for ceftriaxone belong to ST2318. This clonal complex is poorly represented in France but predominates in China, particularly in NG isolates with high MICs for ceftriaxone. Here, we highlight the link between the epidemiological features of NG and population flow in an island study model.

Background: An increase of Staphylococcus aureus with penicillin susceptibility (SA-PENS) has been reported in several countries, which might be of therapeutic relevance. This work aimed to study the current situation in Spain, by determining the prevalence of SA-PENS isolates among patients with bacteraemia SA from Spanish Hospitals, and their molecular characteristics.

Materials/methods: A total of 852 SA isolates (MSSA, n=632) was recovered from blood cultures during 2018-2019 in 17 Spanish hospitals. Antimicrobial susceptibility profile was determined for all isolates [Vitek® (BioMérieux) and/or Microscan® (Beckman)] but only methicillin-susceptible SA (MSSA)-PENS isolates were included in this study. For all MSSA-PENS isolates, it was studied: 1) the presence of blaZ gene and of other non-beta-lactam antimicrobial resistance genes, according to the antimicrobial resistance profile, by PCR; 2) the spa-type by PCR/sequencing; 3) the presence of the genes coding for Panton-Valentine leucocidin (PVL, lukF/lukS-PV), exfoliative toxin A and B [eta, etb] and toxic shock syndrome toxin [tst], by PCR.

Results: Of 632 MSSA isolates, 132 were PENS [MIC: ≤0.12; 20.8%], all but five being blaZ-negative. MSSA-PENS-blaZ-negative represented 20.1% of MSSA and 14.9% of SA. Among MSSA-PENS-blaZ-negative isolates, 77 spa-types were detected with predominance of 1002/CC5 (11.02%) and 1571/CC398 (10.2%). 74.8% of MSSA-PENS-blaZ-negative isolates were pan-susceptible, while the remaining isolates were mostly resistant to macrolides (19%) and lincosamides (15%), harbouring one or a combination of these resistance genes: erm(A), erm(B), erm(C), erm(T), msr(A), lnu(A) and vga(A). Virulence genes were also detected among MSSA-PENS-blaZ-negative isolates (eta [n=8], etb [n=1] and tst [n=4]), however none of them carried the lukF/lukS-PV genes.

Conclusions: A high prevalence of MSSA/SA and MSSA-Pen-blaZ-negative/MSSA was detected among blood cultures SA isolates. Most of MSSA-PENS-blaZ-negative isolates were susceptible to non-beta-lactam antimicrobials. With 20% of invasive infections caused by MSSA-PENS, we can hypothesize that penicillin could be back as an antimicrobial option for MSSA. This situation raises therapeutic options which should be re-evaluated with wider studies and clinical assays.

Abstract 8303

Genomic features of Argentinean KPC-2 producing *Klebsiella pneumoniae* ST25 and comparative genomics with carbapenem susceptible ST25 isolates

Daniela Cejas1,2, Vincenzo Di Pilato3, Lucia Henrici De Angelis4, Sabrina Di Gregorio1, Lucia Pallecchi4, Fabio Arena4, Gian Maria Rossolini3, Gabriel Gutkind*1,2, Marcela Radice1,2

1Universidad de Buenos Aires, Buenos Aires, Argentina, 2CONICET, Buenos Aires, Argentina, 3Università di Firenze, Firenze, Italy, 4Università di Siena, Siena, Italy

**Background:** The hypervirulent-*K. pneumoniae* (hvKp) strains display higher virulence potential, such as, an increased capsular production, giving a hypermucoviscous phenotype. Carbapenem resistance in hvKP has rarely been reported, and KPC-2 positive isolates are concentrated in four clonal lineages, ST11, 15, 101, 258/512. However, we have described the emergence KPC-2-hvKp strains, belonging to ST25, in Argentina. Objective: to explore the genomic features of these isolates and to establish the phylogenetic relationship with other worldwide ST25 strains, which did not displayed carbapenem resistance.

**Materials/methods:** KPC-2 producing isolates, hvKp2015 and hvKp2017, recovered in different hospitals in Buenos Aires, in 2015 and 2017, were included. These isolates displayed resistance to all beta-lactams, gentamycin and trimethoprim-sulphamethoxazole, susceptibility to amikacin and colistin, and intermediate to fluoroquinolones. WGS was performed on total DNA using Illumina MiSeq and reads were assembled using SPAdes. BLASTn, Plasmid Finder, Rest Finder, Kleborate, PROKKA, Roary, SnIPPy and GUBBINS, were used for sequence analysis. Phylogenetic studies were performed using IQ-Tree and RaxML.

Nineteen samples were analyzed, including hvKp2015 and hvKp2017, and all publicly available genomes of ST25 isolates from Australia(1), Belgium(1), Croatia(2), Denmark(1), Germany(2), Italy(2), Poland(1), Romania(2), Turkey(1), UK(3) and USA(1). All these genomes corresponded to clinical human samples.

**Results:** Genomes presented an approximate size of 5.0 Mb [6391 and 6088 CDS for Kp2015 and Kp2017]. *bla*KPC-2 plasmids belonged to IncL/M in both isolates. A capsular locus KL2-wzi72 resembling KN2 capsular type was detected, however the loci were not identical and genetic rearrangements were identified. Among resistance genes *bla*KPC-2, *bla*OXA-1, *aac(6')-Ib-cr, *aac(3)'-IIa, *aph(3'')-Ib, *aph(6)-Id, *dfrA14, *qnrB1, *oqxA* in both isolates and *bla*CTX-M-15 hvKp2015.

Whole and core genome phylogenetic analysis showed strong relationship and two main clusters could be recognized. Argentinean samples grouped together with Italy, Belgium and USA isolates. The same group setting was observed when a closely related ST (ST65) was used to route the phylogenetic tree.

**Conclusions:** Phylogenetic analysis of ST25 isolates including KPC-2-producing isolates is not available in indexed literature. Carbapenem-resistant *K. pneumoniae*-ST25 appear to have evolved from susceptible strains, indicating a confluence of virulence and carbapenem resistance, which might poses major problems in the management of *K. pneumoniae* infections.

**Abstract 8304**

**Retrospective and prospective evaluation of the rapid carbapenem inactivation method test for AmpC-producers**

Alexandru Muntean*1,2, Mădălina-Maria Muntean1,2, Saoussen Oueslati3, Agnes Jousset1, Delphine Girlich1, Sandrine Bernabeu1, François Guérin4, Vincent Cattoir4, Cerasella Dragomirescu1,2, Mircea-Ioan Popa1,2, Thierry Naas3

1Carol Davila University of Medicine and Pharmacy, București, Romania, 2Cantacuzino National Institute, București, Romania, 3Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, 4Centre Hospitalier Universitaire de Caen, Caen, France

**Background:** Simple, cost-effective and rapid differentiation methods between Enterobacterales that produce a carbapenemase and those that are carbapenem-resistant through non-enzymatic mechanisms are mandatory. Herein, we optimised the protocol of the rCIM for efficient use with AmpC hyper-producers.

**Materials/methods:** The classic rCIM was performed as previously reported. Experimentally, cloxacillin was added in the first step of the test. The test was initially validated on 48 well-characterized strains belonging of the various *Enterobacter* species. These consisted of 47 non-carbapenemase producing strains and one strain which harboured OXA-204. After validation, the test performance was evaluated on 6 clinically-relevant AmpC hyper-producing strains.

**Results:** Within the 48 validation strains, CarbaNP had a specificity of 95.74%, but did not detect an OXA-204 producing isolate. Using the standard rCIM protocol, the specificity was 91.49%, being falsely positive for 4 isolates. With the addition of cloxacillin, the rCIM’s specificity was 100% (95% CI: 92.45 - 100%). Both rCIM protocols correctly identified the OXA-204 producer. To evaluate test characteristics, 61 chromosomal and plasmid harbouring AmpC isolates have been evaluated. Using the standard rCIM protocol, the sensitivity and specificity of rCIM was 95.74% and 50%, respectively, being falsely positive for 7 isolates and negative for 2 isolates (one IMI-1, and one LMB-1-producers). Using the modified rCIM protocol, with the addition of cloxacillin, the sensitivity and specificity was 93.62% (95% CI: 82.46 - 98.66%) and 100% (95% CI: 76.84 - 100%), respectively. Three isolates were falsely negative: the LMB-1-, an NDM-1- and an IMI-3-producers. When colonies were tested off Uri4 and carbapenem-infused media all but the LMB-1-producing isolate gave a positive test, suggesting very low carbapenemase production in the absence of an inducer.

**Conclusions:** The addition of cloxacillin in the rCIM protocol can be used to improve the test’s performances for AmpC-producers as it can differentiate between a carbapenemase and AmpC-hyperproduction. The rCIM can therefore be successfully used as a rapid, cost-effective phenotypic test for carbapenemase detection in AmpC-producers in low resource laboratories.

**Dengue awareness in patients with acute febrile illness in Sindh province of Pakistan**

Joveria Farooqi*1, Maureen Long2, Kelli Barr3, Khekashan Imtiaz4, Erum Khan4

1Aga Khan University, Karachi, Karachi, Pakistan, 2University of Florida, Gainesville, United States, 3Baylor University, Waco, United States, 4Aga Khan University Hospital, Pakistan, Karachi, Pakistan

**Abstract third-party references:** Defense Threat Reduction Agency, Basic Research Award # HDTRA1-14-1-0022, to the University of Florida

**Background:** Dengue has been endemic in Pakistan since 2001 but large epidemics continue to occur every few years. It is important to know how the knowledge of dengue has affected arboviral disease occurrence over different socioeconomic backgrounds. We describe here the rate of awareness of dengue in febrile patients evaluated for arboviral infections in Sindh province of Pakistan, stratified over socioeconomic groups.

**Materials/methods:** Patients presenting with acute febrile illness at medical centers in five cities of Sindh, Pakistan, from April 2015 to July 2017 were enrolled in a study screening for arboviral infections: Dengue (DEN), West Nile (WN), Chikungunya (CHIK) and Japanese Encephalitis (JE). Dengue was confirmed with NS1 antigen, IgM ELISA positivity; CHIK diagnosed using IgM ELISA and PCR; WN and JE by IgM ELISA, further confirmed on Plaque Reduction Neutralisation Test (PRNT). Study participants were stratified by socioeconomic status into lower (LSE) quartile, middle half (MSE) and upper (USE) quartile. Dengue awareness was determined using a questionnaire pertaining to knowledge on dengue transmission, prevention, treatment, source of information, and preventive practices.

**Results:** A total of 989 patients between 6-86y were enrolled with five major febrile syndromes: arthralgia/myalgia (64.7%), headache (33.3%), neurologic (20.5%), petechial or macular rash (8.8%) and bleeding diathesis (6.2%). Of these, 40.6% tested positive for arboviruses: DEN (51.2%), CHIK (24.6%), WN (20.4%) and JE (3.7%). Only 54.9% LSE had knowledge of dengue compared with 72% MSE and 79.7% USE. Similar proportion of LSE, MSE and USE correctly identified how dengue was transmitted (54.6%, 70.5%, 79.7%), prevented (47.4%, 66.7%, 71.7%), and treated (50.5%, 69%, 78%), and had received public awareness messages (50.9%, 65.4%, 72%). All three groups similarly agreed on dengue and malaria being a major problem in Pakistan (84%, 82.7%, 86.7% respectively). 24.2% of LSE versus 49.4% MSE and 66.7% USE had covered drains in their homes, 62.8% LSE, 80.2% MSE and 84.7% USE covered their water storage containers, and 74% LSE, 84% MSE and 87.3% USE used indoor insecticide sprays.

**Conclusions:** Dengue awareness and preventive activities differ by socioeconomic status in febrile patients evaluated for arboviral infections.

Diagnostic value of IgG avidity and/or Western blot test for the diagnosis of Rubella virus infection during pregnancy

Gargouri Olfa1, Amel Chtourou1, Saba Gargouri1, Hatem Triki1, Ben Amor Feiza1, Lamia Feki-Berrajah1, Adnene Hammami*1, Hela Karray-Hakim2

1Habib Bourguiba, Sfax, Tunisia, 2Habib Bourguiba, Sfax, Tunisia

Background: Rubella infection during early pregnancy often results in congenital Rubella syndrome. Specific Immunoglobulin (Ig)M research is recommended for Rubella infection screening. However, the diagnosis of Rubella infection during pregnancy requires mostly the use of additional tests such as Rubella virus (RV) IgG avidity and/or IgG Western-blot test (WB). We aim to evaluate the interest of these two tests to distinguish old and recent Rubella infection in woman pregnancy.

Materials/methods: A retrospective study was conducted from January 2007 to November 2019 including 107 pregnant women with detectable anti-Rubella IgM, with or without clinical symptoms.

Anti-Rubella IgM and IgG were determined respectively using ELISA technique (PLATELIA RUBELLA IgM-Bio-Rad, France) and automated ELFA (VIDAS RUB IgG II, Biomerieux, France). RV IgG avidity and IgG WB were performed using commercial kits (Euroimmun, Lübeck, Germany). Old Rubella infection has been considered face to WB anti-E2 IgG detection.

Results: Among 107 women with suspected Rubella primary infection based on positive IgM, recent infection was concluded in only 21 cases (19.6%) by low IgG avidity and in 29 cases (27%) by negative WB anti-E2 IgG. Among 21 women having low IgG avidity, 14 have recent rubella western blot pattern. Only 38 from 50 women, with high IgG avidity, have a WB pattern concordant with an old infection. Therefore, concordance rate between the two techniques is around 73.2%.

The WB test allows us to exclude recent Rubella infection in patients with low (n=21) or intermediate IgG avidity (n=36) in 42% (n=24). However, high IgG avidity excludes recent Rubella infection in patients with non conclusive WB (n=16) or with negative WB anti-E2 IgG (n=29) in 26.66% (n=12).

Conclusions: Although a medium concordance rate between RV IgG Avidity and WB test, combination between the two techniques is highly required for a better Rubella infection diagnosis.

Abstract 8310

**Evaluation of FAST-Prep Liquid Colony for early antimicrobial sensitivity testing of positive blood culture by disk diffusion method**

Aye Aye Khine*, Namida Fernandez, Laxman Pandey, Abdossamad Talebpour, Susan Novak, Tino Alavie

1Qvella, Richmond Hill, Canada, 2Qvella, Carlsbad, United States

**Background:** Conventional antimicrobial susceptibility testing (AST) of microorganisms from positive blood cultures (PBC) can take ≥ 2 days. In order to improve the turnaround time for AST on a PBC, CLSI and EUCAST have made efforts to standardize procedures for disk diffusion (DD) direct from a PBC. Qvella (Richmond Hill, ON, CA) has recently developed FAST-Prep, an automated centrifugal sample preparation system that rapidly delivers a Liquid Colony consisting of a purified, concentrated, viable cell suspension directly from a PBC. This study was performed to investigate the feasibility of DD AST off of a PBC using a FAST-Prep Liquid Colony.

**Materials/methods:** Contrived PBC samples were prepared by spiking 6 species of Gram-positive and 4 species of Gram-negative bacteria (3-5 strains per species) into FA® Plus bottles and incubating in the BACT/ALERT® VIRTUO® System (bioMerieux, Durham, NC). After positivity, 3 mL of PBC was added to the FAST-Prep cartridge. After 20 minutes of processing in the FAST-Prep instrument, the Liquid Colony was removed from the cartridge and a 0.5 McFarland sample was prepared for DD AST. In parallel, the DD AST from a PBC was performed using 4 drops of PBC (CLSI direct method). Both methods were compared to conventional colony-based DD AST. After 16-18 hours of incubation zone diameters and S/I/R interpretations were determined. Categorical agreement (CA) and errors for both DD AST methods were calculated. In addition, colony plate counting was performed on 0.5 McFarland suspensions of Liquid Colony and the plate colony to determine biomass recovery and sample purity.

**Results:** CA for a FAST-Prep DD AST for Gram-positive and Gram-negative bacteria was 95.6% and 98.6%, respectively, compared to CA for CLSI DD AST of 77.2% and 81.9%, respectively. Biomass in the Liquid Colony was 7.2x10^8 and 1.2x10^9 CFU for Gram-positive and Gram-negative bacteria, respectively. Cell concentration in the 0.5 McFarland suspension of the Liquid Colony was 3.7x10^7 and 5.9x10^7 CFU/mL for Gram-positive and Gram-negative bacteria, respectively, which was similar to the concentration for the reference colony suspension.

**Conclusions:** The results support the potential role of FAST-Prep in providing a Liquid Colony for use in rapid AST.

Abstract 8317

Detection of \textit{blaKPC-2} in a conjugative IncP-6 plasmid in \textit{Escherichia coli} isolated from wastewater in Romania

Laura Ioana Popa\textsuperscript{1}, Alina Cristina Negu\textsuperscript{2}, Ilda Czobor*\textsuperscript{1}, Irina Gheorghe\textsuperscript{1}, Sajjad Mohsin\textsuperscript{1}, Mihaela Magdalena Mitache\textsuperscript{3}, Marcela Popa\textsuperscript{1}, Luminita Marutescu\textsuperscript{1}, Mariana Carmen Chifiriuc\textsuperscript{1}

\textsuperscript{1}University of Bucharest, Faculty of Biology, Microbiology Department, Research Institute of the University of Bucharest, Bucharest, Romania, \textsuperscript{2}National Institute for Infectious Diseases 'Matei Bals', Bucharest, Romania, \textsuperscript{3}Faculty of Medicine, University Titu Maiorescu of Bucharest, Public Health Direction Bucharest, Faculty of Dental Medicine, University Titu Maiorescu of Bucharest, Bucharest, Romania

\textbf{Background:} \textit{Escherichia coli} is one of the leading causes of nosocomial and community-acquired infections worldwide which makes the emergence and dissemination of carbapenem-resistant strains a main risk for global public health. This is the first study reporting the molecular characterization of a carbapenem-resistant \textit{E. coli} strain isolated from a wastewater treatment plant in Romania.

\textbf{Materials/methods:} \textit{E. coli CE1} strain was isolated from a wastewater treatment facility in 2018, on CHROMID\textsuperscript{\textregistered} CARBA selective medium. The presence of carbapenemases was confirmed by the Blue-Carba phenotypic test and by PCR and sequencing. Transferability of carbapenem resistance was investigated by conjugation (liquid matting) followed by PCR confirmation, using the \textit{E. coli} J53 strain as a recipient. The \textit{E. coli} CE1 strain was subjected to paired-end whole genome sequencing using a MiSeq System Sequencer (Illumina). De novo assembling of the reads into contigs was performed with Spades software and annotation with CARD, BLAST, ResFinder, PlasmidFinder, VirulenceFinder. ISSs were annotated using ISFinder and INTEGRALL.

\textbf{Results:} The \textit{E. coli} CE1 strain (the nearest MLST result: ST3486) exhibited high resistance to \textit{β}-lactams correlated with the presence of \textit{blaNDM-1}, \textit{blaKPC-2}, \textit{blaTEM-1B}, \textit{blaOXA-1} genes, out of which only \textit{blaKPC-2} proved to be transferred by conjugation. Sequencing revealed plasmids harboring resistance genes belonging to 5 other classes of antibiotics apart from \textit{β}-lactams, namely aminoglycosides: (aac(3)-la, aac(6')-lb-cr, aph(3')-Ia, aadA1, aac(3)-Ila, rmtC); fluoroquinolones: qnrB19, aac(6')-lb-cr; phenicols: catA1, catB4; sulphonamides: sul1, sul2 tetracyclines: tet(D), and macrolide: md diluted (A). Some of these genes grouped on the same genetic platforms, such as [catB2, bla\textsubscript{GIM4}, aac(6')-lb-cr] or [bla\textsubscript{NDM1}, rmtC]. The genetic context of \textit{blaNDM1} gene exhibits same conserved region as other plasmids previously reported in Romania, comprising ISCR14-rmtC-ISAbac125-bla\textsubscript{NDM1}-ble\textsubscript{MBL}. The \textit{blaKPC-2} gene is integrated in a Tn3-like transposon [ISApu1 – ISApu2 – tnpA – tnpR – ISKpn27 – ΔblaTEM – blaKPC-2 – ΔISKpn6] within an IncP6 plasmid previously encountered in wastewaters in other countries.

\textbf{Conclusions:} The transferability of \textit{blaKPC-2} gene raises concern, as commensal bacterial strains may acquire and disseminate this gene. Therefore, the characterization of resistome from wastewater in our country is mandatory.

Abstract 8318

Real-life experience with ceftazidime-avibactam in South Spain

Maria Nunez1, Ana M. Perez-Bailón1, Marta Trigo-Rodriguez1, Celia Castaño-Amores1, Natalia Chueca Porcuna2, Andres Ruiz-Sancho1, David Vinuesa Garcia1, Jose Cabeza1, Jose Hernández-Quero1, M Eugenia Yuste1

1San Cecilio University Hospital, Granada, Spain, 2San Cecilio University Hospital, Granada, Spain

Background: Real-life studies in the treatment of carbapenem-producing Enterobacteriaceae and carbapenem-resistant P. aeruginosa are limited and new antibiotics have recently been launched. We aim to describe our clinical experience using Ceftazidime-avibactam for different severe infections.

Materials/methods: Retrospective study of episodes of infection treated with ceftazidimeavibactam. Efficacy and safety were evaluated as 14 and 30 day mortality and occurrence of adverse events.

Results: Twenty-one patients were included. The median age was 69 years (IQR: 22–72), 10 (47.6%) were male and the median Charlson index was 5 (IQR: 2-8). McCabe score was ultimately fatal in 6 (28.6%). The most frequent sources of infection were respiratory (23%) followed by intra-abdominal (24%) and urinary (29%). 14 (66.7%) were admitted in ICU. Median length of stay in hospital and ICU were 65 (IQR: 41-89) and 33 (2-65) respectively. Eighteen (86%) patients had a severe infection (defined as presence of sepsis or septic shock) and the median Increment score was 8 (IQR: 6-13). Median Giannella score 14 (IQR: 10-16). The 30-day and 90-day mortality rates were both 38.1%. Clinical cure was achieved in 14 (66.7%) of episodes. Only one (4.8%) patient presented adverse event (seizures) in the context of impaired renal function. Among patients with Increment score ≥7 (15, 71.4%), eight died by 30-day and only 7/15 received combine therapy. The most frequent associations with ceftazidime-avibactam were amikacin (4/8) and metronidazole (3/8).

Beside colonization, isolated pathogens in clinical samples were: OXA-48-like carbapenem producing Klebsiella pneumoniae (N=12), IMP (N=1), VIM (N=1) and OXA48 (N=2) producing Enterobacter cloacae and 2 (9.5%) carbapenem-resistant Pseudomonas aeruginosa. In one Klebsiella pneumoniae isolate the carbapenemases were confirmed to be IMP and OXA-48 types.

Conclusions: From our limited experience, ceftazidime-avibactam seems to be an effective drug with a convenient safety profile for the treatment of patients with severe infections due to carbapenem resistant pathogens and limited therapeutic options.

Abstract 8319

**Beta-D-glucan to aid the diagnosis of Pneumocystis pneumonia in HIV-positive patients**

Thomas Juniper*, Christopher Eades, Eliza Gil, Emmanuel Wey, Stephen Morris-Jones, Killian Quinn, Frank Post, Robert F. Miller

1King’s College Hospital, London, United Kingdom, 2Royal Free Hospital, London, United Kingdom, 3University College Hospital, London, United Kingdom

**Background**: Confirmation of a PCP diagnosis often requires invasive procedures. Serum concentrations of beta-d-glucan (BDG) are elevated in HIV positive patients with *P. jirovecii* pneumonia (PCP) and more readily available to aid the diagnosis of PCP. We summarized the experience with BDG in HIV positive patients presenting to three hospitals in London, UK.

**Materials/methods**: We retrospectively identified HIV positive patients with a BDG result and bilateral infiltrates on chest x-ray from January 2018 to May 2019. A confirmed PCP diagnosis required demonstration of *P. jirovecii* on direct stain or by PCR in bronchoalveolar lavage, sputum or on lung biopsy specimens. A BDG concentration >80pg/mL measured using the Fungitell assay was considered a positive BDG result.

**Results**: Thirty-four patients (Median age 44; CD4 count 44; HIV Viral load 446684) including 21 (61.7%) with confirmed PCP, were studied. All patients with confirmed PCP, compared to 8 of 13 (61.5%) without confirmed PCP, had a positive BDG (p<0.01, NPV 100%, PPV 72.41%). Patients with confirmed PCP (both median and lower quartile >500pg/mL) compared to those deemed not to have PCP clinically (Median 47, IQR 10-95pg/mL) had significantly higher serum BDG levels (t 9.17, p<0.001). The distribution of BDG concentrations is shown in table 1.

**Conclusions**: We confirmed a high negative predictive value of serum BDG levels for confirmed PCP. This suggests that in HIV positive patients, BDG levels in combination with chest x-ray findings and clinical parameters may be useful to rule out PCP.

Detection of Aspergillus spp. in bronchoalveolar lavage fluid of haematological and non-haematological patients with invasive aspergillosis by real-time PCR

Svetlana Ignatyeva*, Tatyana Bogomolova1, Vera Spiridonova1, Olga Shadrivova2, Natalya Vasilyeva1, Ekaterina Desyatik1, Yuliya Borzova1, Nikolai Klimko2

1North-Western State Medical University n.a. I.I. Mechnikov, Kashkin Research Institute of Medical Mycology, Saint Petersburg, Russian Federation, 2North-Western State Medical University n.a. I.I. Mechnikov, Department of Clinical Mycology, Allergy and Immunology, Saint Petersburg, Russian Federation

Background: To evaluate the sensitivity of real time PCR with High Resolution Melt analysis (mHRM-RT-PCR) test for detection of Aspergillus spp. in bronchoalveolar lavage fluid (BAL) of hematological and non-hematological patients with invasive aspergillosis (IA).

Materials/methods: The investigation included 60 BAL samples collected during 2014-2019 from 30 hematological and 30 non-hematological patients with diagnosis of IA confirmed by mycological methods according to ESCMID-ECMM-ERS, 2017. As controls, 50 BAL were collected from patients without mycoses. Clinical samples were examined by fluorescent microscopy and culture. Fungal DNA was extracted from BAL by a chloroform-isoamyl extraction method. DNA amplification was performed using aspergillus-specific primers and EvaGreen based mHRM-RT-PCR on Rotor-Gene 6000 cycler. Detection of galactomannan (GM) in BAL was performed using “Platelia Aspergillus Ag” (Bio-Rad). Sensitivity and specificity for the PCR assay and GM were calculated.

Results: Microscopy of 30 BAL from hematological patients with IA was positive in 50% cases. Aspergillus spp. were isolated in 83%: A. fumigatus [63%], A. niger [19%], A. flavus [6%], A. versicolor [2%]. From 3 patients (10%) two different species were isolated: A. fumigatus + A. niger [6%] and A. fumigatus + A. flavus [3%]. In 30 non-hematological patients with IA microscopy of BAL was positive in 60% of cases. Aspergillus spp. were isolated in 57%: A. fumigatus [31%], A. niger [31%], A. flavus [11%], A. ochraceus [1%]. From 8 patients (26%) two or more different species were isolated including A. ustus [6%] and A. versicolor [3%]. At similar specificity (83% vs. 86%) PCR assay performed in BAL yielded 89% sensitivity in hematological and 83% in non-hematological patients. GM test was positive in 77% BAL samples from hematological and 60% from non-hematological patients. The positive results of PCR assay correlated with positive results of microscopy and culture in 75% and 78% for hematological patients and in 72% and 80% for non-hematological patients with IA.

Conclusions: This study indicated that the mHRM-RT-PCR may be a very useful tool for detection of Aspergillus spp. in BAL of hematological and non-hematological patients with IA. Sensitivity of PCR assay in BAL was higher than sensitivity of GM test and basic mycological methods.

Abstract third-party references: International Health Management Associates [IHMA]

Background: Bacterial resistance to carbapenems including occurrence of carbapenemase producers is an important growing threat to public health. We present the data of the antimicrobial susceptibility of Gram-negative bacilli to carbapenems as a part of the Study for Monitoring Antimicrobial Resistance Trends [SMART] in the Clinical Center Niš, South Serbia.

Materials/methods: The study included 1146 Gram-negative bacilli from the fam. Enterobacterales and 221 isolates of Pseudomonas aeruginosa collected from patients with intra-abdominal infections (IAI), urinary tract infections (UTI) and lower respiratory tract infections (LRTI), during 2012-2018. The isolates were processed at the IHMA laboratory. Minimal inhibitory concentrations [MICs] were determined by broth microdilution and susceptibility interpreted according to European Committee on Antimicrobial Susceptibility Testing guidelines. Multiplex PCR was used to detect carbapenemase genes.

Results: All enterobacterial isolates were tested for susceptibility to ertapenem and imipenem, and 535 of them tested to meropenem. Susceptibilities of all isolates to these carbapenems were 84.12%, 89.2% and 92.1%, respectively. Susceptibilities of isolates from different sources shown in the table. During the studied period, decrease in susceptibilities to ertapenem, imipenem and meropenem was noted for Klebsiella spp. resulting in 67.5%, 87.5% and 87.5%, respectively. For Escherichia coli, susceptibilities retained for all tested carbapenemes. Susceptibilities of 221 isolates of Pseudomonas aeruginosa to imipenem and meropenem were 56.1% and 51.8%, respectively. There was a trend of a decrease in susceptibility to imipenem, from 71.4% in 2012 to 34.4% in 2018. Susceptibility to imipenem and meropenem was the lowest for LRTI isolates [41.9% and 43.9%, respectively]; susceptibility for UTI that were 57.69% and 63.64%, respectively, and the highest susceptibility were for IAI (78.9 and 79.2%). Screening by multiplex PCR to detect β-lactamase genes among non-Proteae Enterobacteriaceae [NPE] showed that in Serbia 16.3% of all isolates were carbapenemase producers, with presence of NDM, OXA-48-like and KPC enzymes. In Pseudomonas aeruginosa isolates, this percent was 16.9%, with NDM and GES enzymes.

Conclusions: Increasing resistance to carbapenems and the onset of carbapenemase producers require continuous monitoring of resistance, and introduction of measures for its prevention.

Abstract 8325

**An automated data extraction from primary-care paediatricians' computers: a French paediatric ambulatory research in infectious diseases**

Stéphane Béchet¹, Andreas Werner², François Vie Le Sage², Georges Thiebault³, Nathalie Gelbert², Fabienne Cahn-Sellem², Fabienne Kochert², Corinne Levy³, Robert Cohen*¹

¹ACTIV, Créteil, France, ²AFPA, Saint-Germain-en-Laye, France

**Background:** Infectious diseases account for 50-70% of ambulatory pediatric daily practice. In order to improve the diagnostic performance of primary-care pediatricians by providing real time data on epidemiology of several infectious diseases, we have set up a national surveillance network, PARI (Pediatric and Ambulatory Research in Infectious diseases) using an automated data extraction from the primary-care-pediatricians' computer. The participating pediatricians were specifically trained in diagnostic and treatment of infectious diseases and the use of rapid diagnostic tests.

**Materials/methods:** We daily prospectively collect anonymized data (age, sex, height, weight, daycare attendance, vaccines, diagnosis and prescriptions) of children with infectious diseases in 100 primary-care-pediatricians all over France using the same software (Axi5-Infansoft®, CompuGroup Medical).

**Results:** Between September 2017 and November 2019, data on 47,446 patients, 65,752 consultations, 92,204 diagnoses, 328,851 vaccines and 278,521 drug-prescriptions were collected. Mean age at diagnosis was 3.0 ± 2.7 years and boys accounted for 58.4%. Frequencies of the different infectious diseases were weekly and automatically provided on a dedicated website as graphs for all pediatricians, to allow them to monitor the epidemiology of the diseases, locally as well as at national level. If the epidemiology over the two years and half was identical for otitis, bronchiolitis, group A *Streptococcus* pharyngitis, gastro-enteritis and enterovirus infections, the peak for influenza had already been reached by the end of December in 2017, whereas it had just begun in December 2018.

**Conclusions:** For the first two years and half of this study, the seasonal distribution of the pediatric infectious diseases is perfectly stackable, except for influenza diseases. These robust results validate the PARI network as an efficient and reliable tool for monitoring infectious diseases and enforce the impact of this automated surveillance on the pediatricians’ practice and public health.

Abstract 8334

Acquired resistance to colistin in Enterobacteriaceae isolated at university hospital of Algiers
Bachtarzi Mohamed Azzedine¹, Djennane-Hadibi Fazia¹, Lallaoui Farah¹, Mohamed Tazir¹, Wahiba Amhis¹

¹Mustapha University Hospital Center, Sidi M’Hamed, Algeria

**Background:** The emergence of plasmid resistance to colistin currently fears evolution towards panresistance particularly in carbapenemase-producing Enterobacteria. Such strains begin to be described in our hospital. The aim of this work is to discriminate between colistin-resistant Enterobacteria, those involving the MCR-1 mechanism and those with a chromosomal mechanism.

**Materials/methods:** This is a five-year study (2015-2019) in which any Enterobacterial strain with reduced sensitivity to colistin [MIC ≥ 2 μg/ml] was studied. This MIC was determined by microdilution on Mueller-Hinton II broth (cation adjusted) as currently recommended by CLSI. For each of these strains, a PCR search of the mcr-1 and mcr-2 genes was performed. A rapid immunochromatographic detection test of MCR-1 (NG biotech® NG-Test MCR-1) was performed for strains with a PCR positive PCR result.

**Results:** Fifteen colistin-resistant Enterobacteriaceae strains were isolated in our hospital during this period. Nine strains isolated from infections [Four from blood culture, three from urine and two from pus] and six strains from rectal carriage. Among the isolated species we report:

- Six strains of *Escherichia coli*: four of them showed a colistin MIC of 4 μg/ml and were carbapenem sensitive. These strains showed mcr-1 positive PCR and a positive MCR-1 test. Two other strains of *Escherichia coli* having a colistin MIC of 16 μg/ml and 32 μg/ml gave a PCR mcr-1 and mcr-2 negative result and were carbapenem resistant strains.

- Nine strains of *Klebsiella pneumoniae*: all were carbapenem resistant strains and showed a colistin MIC greater than 32 μg/ml. The nine strains showed PCR mcr-1 and mcr-2 negative results.

**Conclusions:** This preliminary study demonstrates the existence of a plasmid support for colistin resistance in our hospital and emphasizes the risk of dissemination of this mechanism to other species that could become pan-resistant.

Abstract 8335

**Inoculum effect of OXA-48-like-producing Enterobacteriaceae against ceftazidime-avibactam**

Laureen Chat1, Jean-Claude Nguyen Van1, Benoît Pilmis2,3, François Caméléna4,5, Alban Le Monnier1,3, Beatrice Bercot4,5, Hervé Jacquier4,5, Assaf Mizrahi*1,3

**Background:** The spread of OXA-48 producing Enterobacteriaceae is a major issue in the diffusion of multidrug-resistance. Several studies have evaluated the clinical relevance of ceftazidime/avibactam (CAZAVI) in OXA-48-producing Enterobacteriaceae infections without exploring the impact of high inocula.

The aim of this study was to investigate in vitro the impact of high inocula of OXA-48-producing Enterobacteriaceae on minimum inhibitory concentrations [MIC] of CAZAVI and meropenem (MER).

**Materials/methods:** Enterobacteriaceae isolates were collected from January 2013 to June 2018. A total of 56 isolates were tested, including 37 *E. coli* (66%), 14 *K. pneumoniae* (25%), 4 *C. freundii* (7.2%), 1 *E. cloacae* (1.8%). For each isolate, 3 inocula: 0.5; 1 and 5 Mac Farland (MF) were prepared. Bacterial suspension was plated on Mueller-Hinton agar to determine by E-test (bioMérieux) for MER and CAZAVI according to EUCAST guidelines. After 24h, the MIC were compared to the averages MIC of MER and CAZAVI for each inoculum. Bacterial genomes of the isolates were sequenced with a NextSeq (2×151 bp; Nextera XT library, Illumina) and assembled with SPAdes (v3.1 2.0). Resistance genes were checked using abricate (v0.7) and resfinder. Averages MIC were compared according to the presence/absence of genes encoding for CTX-M enzymes.

**Results:** Among the 56 strains, 49 (87.5 %) were OXA-48 and 7 (13.5 %) were OXA-181 carbapenemase. Twenty isolates (36%) isolates carried genes encoding for CTX-M: CTX-M-15 (15; 27%) CTX-M-14, (4; 7%) and CTX-M-1 (1; 2%).

For all strains, we found that averages MIC for all tested inocula were not significantly different with the CAZAVI (p>0.5). In comparison we observed that averages MIC of MER for all inocula were significantly different (p<0.01). (Figure 1)

The presence of a CTX-M enzyme did not change the MIC results for both antibiotics.

**Conclusions:** In this study, we observed in vitro an inoculum effect of meropenem for Enterobacteriaceae-producing OXA-48 or OXA-181, which was not observed with the ceftazidime/avibactam combination. This result must be confirmed on a larger number of strains and suggests that ceftazidime/avibactam may be a better option than meropenem in high inoculum infections.

ComParison of different inocula of OXA-48-like producing Enterobacteriaceae on ceftazidime/avibactam and meropenem MIC

**Presenter email address:** amizrahi@hpsj.fr
ComParison of four ESBL detection tests directly from blood cultures and urine samples

François Camélêna*, Hervé Kafando1, Annie Ly1, Pauline Thiebot1, Martine Rouveau1, Touratier Sophie1, Matthieu Lafaurie2, Beatrice Bercot1

1Saint-Louis, APHP, Paris, France

Background: The 3rd generation cephalosporins (3GC)-resistance in Enterobacteriales, mainly due to Extended-Spectrum Beta-Lactamase (ESBL) production, is increasing worldwide. Bacteremia, as urinary tract infections, due to ESBL-producing Enterobacteriales increase delays to initiate effective antibiotic therapies. In this context, we evaluated 4 ESBL detection tests directly from blood cultures (BC) and urine samples based on 4 different principles: colorimetry (β-Lacta Test (BLT), Bio-Rad), molecular biology (BCID-GN cartridge including the CTX-M target, ePlex apparatus [GenMark]), electrochemistry (BL-RED, Coris) and immunochromatography (NG-CTX, NG-Biotech).

Materials/methods: Between May and September 2018, 46 BC and 52 urine samples with Gram-negative bacilli (GNB) at the microscopy examination were tested. The ePlex and the BLT were prospectively tested and the BL-RED and NG-CTX were performed from samples conserved at -80°C. The results were compared to antimicrobial susceptibility testing interpreted according to EUCAST 2018 recommendations.

Results: Among the 46 GNB-positive BC, 32 Enterobacteriales including 9 ESBL-producers (CTX-M type), and 14 other GNB were identified. The 9 ESBL enzymes were detected by BLT, BL-RED and NG-CTX while ePlex detected 8/9. For the 37 remaining BC, no enzyme was detected by each test, except for the BL-RED which was positive for 1 S. maltophilia and 1 VIM-producing P. stutzeri-positive BC. Among the 52 GNB-positive urines, 52 were positives with Enterobacteriales, including 11 ESBL producers (10 CTX-M). BLT, ePlex, NG-CTX and BL-RED detected 9, 9, 10 and 11 of ESBL-producing Enterobacteriales respectively. No false positives were found except for the BL-RED which was positive for 5 urine samples with 3GC-susceptible Enterobacteriales.

The Sensibility/Specificity/Positive Predictive Value/Negative Predictive Value on BC and urine samples were 100%/100%/100%/100% and 91%/100%/100%/98% for the NG-CTX, 100%/100%/100%/100% and 82%/100%/100%/95% for the BLT, 89%/100%/100%/97% and 92%/100%/100%/95% for the ePlex, and 100%/95%/82%/100% and 100%/95%/65%/100% for the BL/RED, respectively.

Conclusions: Finally, ESBL detection tests may constitute valuable tools for ESBL-detection directly from blood cultures and urine samples, notably the BL-RED which has 100% of sensibility on both specimens. A combination of these tests could be a best way to improve probabilistic antibiotic therapy and save on broad spectrum antibiotics.

Abstract 8337

Vancomycin plus piperacillin-tazobactam and the risk for acute kidney injury: what is the effect size?
Sean Avedissian*, Jiajun Liu, Gwendolyn Pais, Marc Scheetz, Nathaniel J. Rhodes

1University of Nebraska Medical Center, UNMC College of Pharmacy, Omaha, United States, 2Midwestern University, Downers Grove, United States, 3Midwestern University, Downers Grove, United States, 4Midwestern University, Pharmacometrics Center of Excellence, Downers Grove, United States

Background: Accumulating evidence suggests that vancomycin (V) combined with piperacillin-tazobactam (PT) is associated with increased risk of acute kidney injury (AKI) defined using serum creatinine. Meta-analyses suggest a greater risk of AKI with V+PT compared to PT, V, or other beta-lactams (BL) alone. However, the impact of heterogeneity between studies and potential publication bias on the minimum detectable effect-size has not been robustly evaluated.

Materials/methods: We performed a systematic literature to find systematic reviews comparing V+PT to comparators using PubMed. Meta-analyses were sought and study-level data were extracted to generate effect-size, heterogeneity, and random-effects estimates. Inverse-variance weighted random-effects meta-analyses were performed using the meta package in R. Trim-and-fill was used to adjust for publication bias. Effect-size estimates of increased risk of AKI with V+PT tested were: 10, 12, 14, 16, 18, or 20% vs. comparators. We used Monte Carlo simulation to generate 1000 trials for each of these mean effect-sizes in Microsoft Excel. The variance estimator tau was used as the standard deviation of the effect-sizes for all simulations. Simulated trial effect-sizes were compared against the lower bound of the 95% confidence interval (CI) the trim-and-fill random-effects model. If a given mean effect-size exceeded the lower bound of the 95% CI in 90% or more of simulated trials then it was considered as a detectable difference.

Results: The results of the MCS are shown in Table 1 below. Compared to V alone, V+PT was only considered a detectable difference if the risk increase was 18% or greater. Compared to BL or PT alone, V+PT was only considered a detectable difference if the risk increase was 16% or greater.

</table>

Conclusions: Our simulation study suggests that small effect-sizes (i.e., less than 16% increased risk of AKI) cannot reliably be distinguished from a null effect, given the heterogeneity in the observed literature. Our findings have implications for sample size estimation for any future prospective comparative trials.

Exploiting CRISPR-Cas9 to eradicate ESBL genes and tracing conjugative plasmids within complex microbial communities at single-cell resolution

Reetta Penttinen*1,2, Lara Ambrosio Leal Dutra2, Pilvi Ruotsalainen2, Ole Franz2, Cindy Given2, Kimi Nurminen2, Pauliina Salmi2, Marja Tiirola2, Matti Jalasvuori2

1University of Turku, Department of Biology, Turku, Finland, 2University of Jyväskylä, Department of Biological and Environmental Science, Jyväskylä, Finland

Background: Bacteria acquire resistance towards antimicrobial compounds via resistance genes. These genes are often localized in mobile plasmids, which disperse between bacteria via conjugation and even across species boundaries. Besides the fact that the exposure to antibiotics selects for conjugative plasmids, they can also serve as life-buoys in cases where originally susceptible bacteria receive resistance from the resistant bacteria. This so-called evolutionary rescue can occur even after the exposure to lethal antibiotic concentration and efficiently rescue susceptible bacteria from extinction. Resistance genes could be eradicated from bacterial reservoirs by utilizing CRISPR-Cas9 system. It acts in a sequence-specific manner and is programmable to target any desired DNA sequence, such as antibiotic resistance genes. Yet, the challenge in recording the movements of conjugative plasmids has been the lack of efficient tools for analyzing complex bacterial populations at single-cell resolution.

Materials/methods: With genetic engineering, we generated a conjugative CRISPR plasmid system that targets ESBL-genes. Further, we developed a single-cell method on droplet digital PCR (ddPCR) platform in order to identify the bacteria that harbor the target plasmid. Briefly, individual bacterial cells are enclosed into droplets in a ddPCR reaction. During PCR, a fusion amplicon consisting of 16S rRNA and the desired target gene is produced. By amplicon sequencing, the subpopulation harboring the target gene can be identified.

Results: We show that the conjugative CRISPR-Cas9 system efficiently decreases the frequency of drug-resistant phenotypes within bacterial communities. Additionally, we demonstrate that the single-cell ddPCR technique allows the detection of plasmids together with their hosting bacteria within a heterogeneous bacterial population. We also discuss the potential challenges and limitations of using CRISPR-based molecular tools for eradicating antibiotic resistance as well as in bacterial sample preparation for single-cell analysis.

Conclusions: Our results suggest that CRISPR-based antimicrobials can be a promising weapon against antibiotic resistance. Furthermore, the single-cell ddPCR method is suitable for localizing the desired plasmid within bacterial populations and it may be applied to resolve various research questions where there is a need to identify which bacteria harbor the specific gene of interest.

Prevalence of blaZ gene types and the inoculum effect with cefazolin among bloodstream isolates of methicillin-susceptible Staphylococcus aureus

Inmaculada Guerrero Lozano1, Fatima Galan-Sanchez*, Juan Manuel Peñate1, Violeta Andrada-Brazo1, M. Francisca De La Rubia1, Manuel Rodriguez-Iglesias1

1Puerta del Mar Univ Hosp, Cadiz, Spain

**Background:** Cefazolin, the first generation cephalosporin used as the second line of treatment in bacteriemia caused by methicillin susceptible Staphylococcus aureus (MSSA), offers certain advantages over drugs used in the first instance as cloxacillin. However there have been concerns about cefazolin treatment failure associated with b-lactamase production and inoculum effect. The aim of this study was to determine the prevalence of both blaZ gene and the inoculum effect.

**Materials/methods:** A total of 54 MSSA bloodstream isolates were included in the study. All isolates were identified using standard methods. The blaZ gene was detected using PCR. The MICs of cefazolin, were determined by the broth microdilution method using standard and high inoculum. A pronounced inoculum effect was defined as a ≥4-fold increase in the MIC between the standard and high inoculum.

**Results:** BlaZ gene was detected in 47/54 isolates (87%). Using standard inoculum, values for CMI50 and CMI90 were 0.5 and 4µg/ml, respectively. Using high inoculum, values for CMI50 and CMI90 were 0.5 and 16µg/ml, respectively. A pronounced cefazolin inoculum effect was observed in 4 isolates (7.4%) all of them harboured blaZ gene.

**Conclusions:** The phenotypic and genotypic detection coincided in the results in all the strains studied. The inoculum effect to cefazolin obtained has been low and this was detected in a low number of strains of all those that were positive for Gen BlaZ. The minimum inhibitory concentrations of both standard inoculum and high inoculum obtained were similar to the published studies. Further complementary studies of beta-lactamases subtyping are necessary to search for an association between beta-lactamases types and inoculum effect.

**Presenter email address:** fatima.galan@uca.es
Abstract 8344

The role of a monthly active surveillance programme for multidrug-resistant Gram-negative bacteria in a neonatal intensive care unit: impact evaluation of preventive measures

Laura Saporito1, Giorgio Graziano*1, Federica Mescolo1, Vincenzo Inselinga2, Grazia Rinaudo1, Aurora Aleo1, Celestino Bonura2, Marcello Vitaliti2, Carmelo Massimo Maida1, Mario Giuffè1

1University of Palermo, Palermo, Italy, 2Civico-Di Cristina-Benfratelli Hospital, Palermo, Italy

Background: Antimicrobial resistance is a public health threat. Neonatal Intensive Care Unit (NICU) patients are particularly at risk, due to the large use of invasive devices and antimicrobial treatment.

Since 2014 an active surveillance program of multidrug-resistant organisms is in place in the five NICUs of Palermo, Italy. High prevalence of multidrug-resistant Gram-negative bacteria (MDR-GNB) carriage observed in one NICU suggested the need of a long-lasting approach to achieve effective control of MDR-GNB circulation.

Materials/methods: Rectal swabs were obtained every month from each hospitalized new-born. Samples were enriched in liquid cultures, plated in McConkey Agar with three antimicrobial discs (amoxicillin-clavulanate, meropenem, ceftazidime). Resistant colonies were isolated, identified and submitted for antimicrobial susceptibility testing and ESBL detection. Molecular characterization of MDR-GNB was performed using pulsed-field gel electrophoresis (PFGE).

From November 2017 multiple intervention measures were done:
- Strengthening of sample collection for two months;
- Stakeholders meetings;
- Standardized protocols for antimicrobial therapy and common procedures.

Prevalence of MDR-GNB carriage between the pre-intervention (November 2016-October 2017) and the post-intervention period (November 2017-October 2018) was compared by chi-square test. Clinical features were analysed in a subgroup of patients to identify possible risk factors. All associated variables with p-values <0.25 were included in a multivariate logistic regression model. P<0.05 was considered significant.

Results: 39 patients were included in the 2 months of strengthened microbiological surveillance. MDR-GNB and ESBL-Klebsiella pneumoniae (KP) were detected in rectal swabs (34.8%; 23.2%), nasal swabs (24.6%; 14.5%), oral swabs (14.5%; 5.4%), milk samples (32.1%; 17.9%) soother swabs (30.8%; 17.9%). ESBL-KP was also detected from a sub-intensive room surface. Thirteen ESBL-KP strains isolated from clinical and environmental samples showed identical or closely related PFGE patterns suggesting a common origin for all tested strains. Prevalence of MDR-GNB and ESBL-KP carriage after intervention significantly decreased compared to the year before (61.1% vs 20.6%; p<0.001 and 94.5% vs 53.8%; p<0.001). Admission in post-intervention period significantly reduced the risk of MDR-GNB carriage (OR=0.15, p=0.01).

Conclusions: MDR-GNB broadly circulate in NICU setting, can colonize different body sites and spread by various vehicles. Cooperation between epidemiologist and clinicians can effectively reduce diffusion of antimicrobial-resistant bacteria.

Ceftazidime-avibactam/aztreonam synergism assay against carbapenem-resistant Enterobacteriales and Pseudomonas aeruginosa carrying metallo-beta-lactamases

Julia Barbosa¹, Kamilla Moraes²*, Evelyn Patricia Sanchez Espinoza¹, Lauro Perdigao Neto¹, Sânia Santos¹, Ana Paula Marchi², Roberta Cristina Ruedas Martins¹, Thais Guimaraes¹, Flávia Rossi¹, Silvia Figueiredo Costa¹

¹Clinical Hospital, University of Sao Paulo, Sao Paulo, Brazil, ²Instituto de Infectologia Emilio Ribas, Sao Paulo, Brazil, ³Hospital Paulistano, Sao Paulo, Brazil

Background: The emergency of carbapenem-resistant Enterobacteriales (CRE) has promoted the develop of new antimicrobials to target this bacteria, nevertheless none of the new antimicrobials covers one of the most difficult threats these days: metallo-beta-lactamases (MBL). The aim of this study is to analyze synergism between ceftazidime-avibactam and aztreonam in isolates with *blaNDM* and *blaSPM* obtained from three different hospitals in Sao Paulo-Brazil.

Materials/methods: Nine *Klebsiellas pneumoniae*, fourteen *Pseudomonas aeruginosa* and two *Serratia marcescens* carbapenem-resistant clinical isolates analyzed by Whole Genome Sequence (WGS) using MiSeq illumina and Ion Torrent as NDM and SPM respectively where included. All isolates were submitted to disk diffusion (DD) prior to the synergism assay and evaluated using the Clinical and Laboratory Standards Institute breakpoints. The synergism assay was performed using ceftazidime-avibactam and aztreonam disks, in duplicate by two different persons, the results were evaluated in duplicate as well.

Results: The DD assay showed all of the *K. pneumoniae* resistant to aztreonam and susceptible to ceftazidime-avibactam, the synergism assay was positive in all of these isolates (n=9) that were assigned 5 isolates to three ST (ST340, ST258, ST11). For the *S. marcescens* the DD showed one of them was resistant to both ceftazidime-avibactam and aztreonam while the other was susceptible to ceftazidime-avibactam, both isolates were positive in the synergism assay (n=2). Finally, among the fourteen *P. aeruginosa* analyzed half were portrayed as intermediate to aztreonam and the other half was susceptible, all of them were resistant to ceftazidime-avibactam in the DD assay. Only one isolate displayed synergism, moreover, the other thirteen isolates had undetermined results (Table 1). Eleven isolates were assigned to two ST (ST277, ST308).

Conclusions: The synergism between ceftazidime-avibactam and aztreonam seen in *Klebsiella pneumoniae* carrying NDM is promising and will probably need an animal model to corroborate the in-vitro results, for *Pseudomonas aeruginosa* other types of synergism for MBL should be tested.

Table 1: Evaluation of *Klebsiella pneumoniae*, *Serratia marcescens* and *Pseudomonas aeruginosa* by Disk Diffusion (DD), Whole Genome Sequence (WGS) and Ceftazidime-Avibactam-Aztreonam (Caz-Avi-Azt) Synergism

Non-tuberculous lymphadenitis in children: epidemiology and management strategy in France during the last decade

Cécile Le Brun*, Hélène Guet-Revillet, Olivia Peuchant, Alice Gaudart, Christelle Koebel, Caroline Piau, Julien Bador, Frédérique Canis, Anne Vachée, Camille Brehin, Lucas Ricco, Pascale Bemer, Philippe Lanotte, Claudia Carvalho Schneider, Zoha Maakaroun Vermesse, Aurélie Guillouzouic

1CHRU de Tours, Tours, France, 2CHU de Toulouse, Toulouse, France, 3CHU de Bordeaux, Bordeaux, France, 4CHU de Nice, Nice, France, 5CHU de Strasbourg, Strasbourg, France, 6CHU de Rennes, Rennes, France, 7CHU de Dijon, Dijon, France, 8CH de Valenciennes, Valenciennes, France, 9CH de Roubaix, Roubaix, France, 10CH de Nantes, Nantes, France, 11CHU de Tours, Tours, France

Abstract third-party references: On behalf of the MYCOMED group

Background: Nontuberculous mycobacterial (NTM) lymphadenitis is a rare disease. Its treatment is not standardized; even a "wait-and-see" approach is shown to be effective in the literature. The aims of this study were to describe characteristics, diagnostic approach, management and outcome of such infections in France.

Materials/methods: We performed a retrospective study of all children under 18 years-old with culture-confirmed NTM lymphadenitis documented in 10 French hospitals within the MYCOMED network from 2010 to 2018. The MYCOMED network was created on a voluntary basis and collects data on all culture-positive mycobacterial infections diagnosed in the participating hospitals. Demographic data, diagnostic tests, histological examination, treatment and follow up information were recovered.

Results: 211 cases were registered, with a mean age of presentation of 36 months (range 10 months – 14 years). The mean time between the symptoms onset and first consultation was 63 days (range 5 – 519 days). The most frequent location was cervical in 92/211 cases (43.6%), followed by sub-maxillar and parotid in 84 (39.8%) and 20 (9.5%) cases respectively. Fistulae were observed in 45 cases. Microbiological cultures were positive for Mycobacterium avium in 144 (68%), Mycobacterium intracellulare 30 (14%), and Mycobacterium lentiflavum 19 (11.1%) cases. There is no significant change in the number of cases or species distribution over the years. Histological examination was performed for 123 patients and granulomatous necrotizing lymphadenitis was retrieved in 94 (76%). Antibiotic susceptibility testing was performed for 98 strains. All were susceptible to clarithromycin. Surgical treatment alone was given in 57/192 cases (30%), medical treatment only in 55 (28%), and combined treatment of antibiotics and surgery in 49 (26%). 31 patients (16%) had no treatment. Surgical drainage was chosen for 45/114 patients (39%) and 57 (50%) underwent chirurgical excision. Antibiotic treatment was mostly clarithromycin (n = 100, 96%) alone or with rifampicin (n = 30, 29%). Median antibiotics duration was 92 days (range 3-671 days). Ten patients required a new surgery and 112/159 (70%) had a favorable evolution.

Conclusions: Epidemiology and numbers of NTM lymphadenitis appears stable in France since 2010. Surgical excision, antibiotic treatment or combination do not show difference in the evolution.

Abstract 8350

*My*oc*ab*terium *tuberculosis* genotypes’ landscape in HIV-negative and HIV-positive tuberculosis patients in Russia

Anna Panova*, Grigory Kaminski1, Anatoli Vinokurov1, Anastasia Shemetova1, Marina Shulgina1, Irina Vasilyeva

1Federal State Budgetary Institution “National Medical Research Center of Tuberculosis and Infectious Diseases” of the Ministry of Health of the Russian Federation, Federal State Budgetary Institution “National Medical Research Center of Tuberculosis and Infectious Diseases” of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

**Background:** Genotyping of *M. tuberculosis* (MBT) isolates is widely used during the last decades for studies in genetic diversity of MBT molecular epidemiology, evolutionary and population genetics. Results of MBT genotypes’ assays are considered to be also useful for clinical management. We had analyzed MBT isolates from HIV- and HIV+ TB patients from different regions of the Russian Federation.

**Materials/methods:** TB patients’ MBT isolates from six regions of Russia (400 from HIV- and 117 HIV+ patients) were tested for 1st (rifampicin, isoniazid, streptomycin, ethambutol, pyrazinamide) and 2d line (amikacin, capreomycin, levofloxacin, moxifloxacin, prothionamide) drugs’ susceptibility (Bactec MGIT 960, BD), for mutations conferring drugs’ resistance by microbiochip technology (TB-TEST, Biochip IMB, Moscow, Russia). Spoligotyping analysis of 43 spacers’ nucleotide sequences was done by microbiochip technology (SPOLIGO-BIOCHIP, Biochip IMB, Moscow, Russia). Statistical evaluation was done with Statistica 11.

**Results:** MBT strains belonging to Beijing family constituted 64.5% and 72.6% in isolates both from HIV- and HIV+ TB patients (including 18.5 and 20.5% representatives of B0/W148 Beijing, correspondingly), p>0.05. Statistically significant difference were revealed in proportions LAM family of isolates (17.5% in HIV- and 6.8% in HIV+ patients, p<0.001), Ural family (7.5% in HIV- and 15.4% in HIV+ patients, p=0.018) and a group of minor genotypes’ families (10.5% in HIV- and 5.1% in HIV+ patients, p=0.035). Proportions of Beijing family strains were higher in MDR and XDR strains both in isolates from HIV- and HIV+ TB patients (86.4% and 81.1%, correspondingly) compared to isolates susceptible to anti-TB drugs and lacking mutations conferring drug resistance (41.8%), p<0.001 for all. Proportions of LAM and Ural families’ representatives was higher in susceptible strains (19.9% and 14.8% correspondingly) than in MDR strains (10.7%, p=0.013 and 2.8%, p<0.001, correspondingly).

**Conclusions:** Beijing family strains with high proportion of B0/W148 Beijing dominated in MBT isolates from HIV- and HIV+ TB patients. The proportion of Beijing strain was higher in drug resistant strains compared to susceptible ones. Diversity of minor genotype groups was higher in MTB isolates from HIV- TB patients compared with isolates from HIV+ TB patients.

Abstract 8352

**Immunodominance Hierarchy after seasonal Influenza vaccination**

Laura Sanchez De Prada*, Iván Sanz1, Raúl Ortiz De Lejarazu2, Jose María Eiros3, Adolfo Garcia-Sastre4,5,6, Teresa Aydillo4,5

1University Clinical Hospital of Valladolid, Valladolid, Spain, 2National Influenza Centre of Valladolid, Valladolid, Spain, 3Hospital Universitario Rio Hortega, Valladolid, Spain, 4Icahn School of Medicine at Mount Sinai, Department of Microbiology, New York, United States, 5Icahn School of Medicine at Mount Sinai, Global Health and Emerging Pathogens Institute, New York, United States, 6Icahn School of Medicine at Mount Sinai, Division of Infectious Diseases, Department of Medicine, New York, United States

**Background:** Hemagglutination inhibiting (HI) antibodies against the head of the haemagglutinin (HA) have been used as a correlate of protection for inactivated influenza vaccines (IIVs). Although, HA molecule comprises two major structural regions, head and stalk, the head remains the primary target for licensed IIVs. Five highly variable antigenic sites (Sb, Sa, Cb, Ca1, Ca2) have been described as immunodominant compared with other antigenic regions in the HA head. We aimed to characterize the antibody responses against these variable epitopes after influenza vaccination with an adjuvanted-trivalent-(ATIV) or quadrivalent-(QIV) IIV.

**Materials/methods:** Prospective human cohort study of 166 volunteers vaccinated with either ATIV (118, 71.1%, age ≥65 years) or QIV (48, 28.9%, age <65 years) during 2018/2019 influenza season. Sera was obtained pre- and 28 days post-vaccine. Antibody titers were measured by HI assay against recombinant PR8 (H1N1) virus expressing a pandemic-like A/Michigan/45/2015 (Wt) H1 HA protein and the counterpart modified viruses in which classically defined antigenic sites were partially substituted with heterologous antigenic sites from exotic H5 or H1 3 HAs: H1 - Sb, H1 - Sa, H1 - Cb, H1 - Ca1 and H1 - Ca2. Seroprotection was defined as an HI titer ≥40. Seroconversion was considered when a 4-fold induction occurred after influenza vaccination.

**Results:** Baseline seroprotection against the H1-Wt pandemic-like virus was 67.5% (112). Of these, only 14.3% (16) showed seroprotection against H1-ΔSbvirus, meanwhile 90.4% (90), 89.3% (100), 90.2% (101), 63.4% (71) were also seroprotected against H1-ΔSa, H1-ΔCb, H1-ΔCa1 and H1-ΔCa2, respectively. The seroconversion rate after influenza vaccination was 39.8% for both cohorts. No differences on baseline seroprotection or seroconversion were found between ATIV and QIV for the H1-Wt or any of the viruses containing the modified antigenic sites. A positive correlation was found (p<0.001) between de novo antibodies produced after ATIV and QIV vaccination between the H1-Wt and H1-ΔSa (r=0.74), H1-ΔCb (r=0.82), H1-ΔCa1 (r=0.82) and H1-ΔCa2 (0.67). No correlation was found with H1-ΔSb (0.13, p=0.09).

**Conclusions:** A significant reduction in baseline seroprotection was found for the viruses lacking single antigenic sites, especially for H1-ΔSb. No differences in seroconversion rates were found between ATIV or QIV for H1-Wt or the viruses containing the modified antigenic sites. Our results suggest that the HI responses mostly depend on the antigenic sites surrounding the sialic acid receptor binding domain such as Sb and Ca2.

Abstract 8353

Identification of risk factors for extrapulmonary tuberculosis
Gule Aydin*1, Irem Akdemir1, Alpay Azap1, Kemal Osman Memikoglu1
1Ankara University Medical School Ibni Sina Hospital, Ankara, Turkey

Background: Studies from developed countries have reported on host-related risk factors for extra-pulmonary tuberculosis (EPTB). However, similar studies from high-burden countries like Turkey are few. Therefore, we carried out this study to compare demographic, life-style and clinical characteristics between EPTB and PTB patients.

Materials/methods: A retrospective analysis was carried out on 589 tuberculosis (TB) patients diagnosed in a tertiary care hospital infectious diseases clinic between 2008-2018. We aimed to determine associations between the demographic, clinical, and life style characteristics of patients with tuberculosis (obtained from medical case records) and the risk factors for occurrence of extrapulmonary tuberculosis, by using logistic regression analysis.

Results: The study included 335 patients with EPTB (female:male ratio of 2.2) and 254 with PTB (male:female ratio of 1.17). The most commonly seen two types of EPTB were urogenital TB (26.2%) and lymph node TB (18.4%). Bone/joints, skin, peritoneal cavity/intestines, central nerve system (CNS), adrenal gland, eye and ear involvement occurred at a frequency ranging from 0.29% to 11.2%. Meningeal and bone/joint TB were more commonly observed among the male patients, while lymphatic, urogenital, peritoneal and skin TB cases were more frequently seen among females. Risk factors of PTB were smoking [Odds Ratio [OR] 3.98; 95% confidence interval [CI] 1.66–9.56], contact with patients with TB [OR: 2.51; 95% CI 1.06-5.95], diabetes mellitus [OR 1.69, 95% CI 1.12–2.56] and use of immunosuppressive drugs/steroids [OR: 2.82, 95% CI 1.59–5.00]. Treatment success rate for EPTB was 70.1% compared to 84.2% for PTB (p<0.001). In logistic regression, younger age [≤40 years] [OR 3.19; 95% CI 2.69–3.79], female gender [OR 1.59; 95% CI 1.35–1.88] were found to be significantly associated with EPTB compared with PTB. Being immunocompromised [OR 1.35; 95% CI 1.10–2.25] and having CNS TB [OR 3.88; 95% CI 1.14–13.23] were associated with mortality among EPTB patients.

Conclusions: Results suggest that younger age and female gender may be independent risk factors for EPTB. TB control programmes may target young and female populations for EPTB case-finding.

Abstract 8354

**Development of an in-house cell-SELEX methodology for Acinetobacter baumannii aptamers selection**

Marina Farrel Côrtes*, Taniela Marli Bes⁷, Beatriz Déo¹, Ester Cerdeira Sabino¹, Silvia Figueiredo Costa¹, Carlos Santos²

¹Faculty of Medicine - USP, Sao Paulo, Brazil, ²CliniMol DM, Sao Paulo, Brazil

Abstract third-party references: Fundação de Amparo a Pesquisa do Estado de Sao Paulo

**Background:** Infections caused by multi-drug resistant agents are a worldwide health problem and are a leading cause of human disease with high mortality rates. Rapid identification of these infections is critical as they can be highly contagious, difficult to treat and have high hospitalization costs. In this context, the development of fast and economically viable detection methodologies, as well as development of new therapeutic alternatives are challenging. One of the promising solutions may be the development of nucleic acid aptamers capable of interacting with bacteria. These aptamers can be used for specific recognition of infectious agents as well as blocking their functions. Cell-SELEX technology currently allows the selection and identification of aptamers and is flexible enough to target any protein of interest or any target present in an entire bacterial cell without their prior knowledge. However, aptamer technologies still face many challenges including the difficulty of the screening process. The Main objective of this work was to standardize an inhouse methodology of aptamer selection and identification.

**Materials/methods:** A new inhouse methodology, based in whole cell-SELEX, for aptamer identification with rapid execution and low cost was described based on previously publications. The selected aptamer was identified by cloning in pGEM vector and sequenced by Sanger. The binding specificity was tested in *Acinetobacter baumannii, Klebsiella pneumoniae, Staphylococcus aureus* and *Candida albicans*. The ability to interfere in the bacterial growth was measured by time kill assays.

**Results:** This protocol is 10 times less expensive than other ones previously described and allowed the identification of the aptamer A01 with the whole *Acinetobacter baumannii* cell as target. Although its ability to bind to the bacteria cell, the aptamer did not affect the bacterial growth in the analyzed conditions. A01 also showed the ability to bind to other bacterial and fungal cells.

**Conclusions:** While studies in developing aptamers for clinical applications are still incipient, aptamers are promising molecules that may be widely used in bacterial detection and therapy with the improvement of selection methodologies. These data indicate that soon aptamer-based technology may become a tangible alternative to traditional approaches to infectious disease diagnosis and therapy.

Abstract 8356

**Comparison of clinical characteristics and mortality between patients with pulmonary nocardiosis and patients with pneumonia**

Ili Margalit*, Elad Goldberg1, Khitam Muhsen2

1Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel, 2Tel Aviv University, Tel Aviv, Israel

**Background:** Despite appropriate antibiotic therapy, mortality rate among pulmonary nocardiosis patients remains high. The current study compared clinical characteristics and mortality between patients with pulmonary nocardiosis and patients with pneumonia caused by other pathogens.

**Materials/methods:** A historical cohort study of adults hospitalized in a tertiary hospital during 2007-2018 was undertaken. Patients with nocardiosis (n=48) were matched by year of hospitalization to 96 patients with pneumonia caused by other pathogens. Data on both groups were retrieved from the medical charts and mortality was determined using the national death registry. Conditional logistic regression models were used to assess differences in clinical characteristics between the groups and the Cox proportional hazards model was implemented for survival analysis.

**Results:** In comparison to patients with pneumonia, pulmonary nocardiosis patients were younger by 15 years (P<0.001), were more likely to be solid-organ transplant recipients (OR 30.5 95% CI 4.0-230.7, P=0.001), and had a higher rate of corticosteroid therapy during the 90 days prior to diagnosis (OR 55.7 95% CI 7.6-408.0, P<0.001). One-month all-cause mortality rates were 8% and 20% among the pulmonary nocardiosis patients and in those with pneumonia, respectively (P=0.072); the respective one-year all-cause mortality rates were 38% and 37% (P=0.901). Patient’s age was the only variable significantly associated with mortality (HR 1.3 per decade, 95% CI 1.1-1.6, P=0.005). Exclusion of patients with central nervous system involvement did not change the results. Among pulmonary nocardiosis patients, the presence of malignancy significantly increased the risk for one-year all-cause mortality (OR 14.5, 95% CI 1.6-133.7, P=0.018), while corticosteroid therapy, a history of solid-organ transplantation and central nervous system involvement were not significantly associated with mortality.

**Conclusions:** A non-significant trend of higher one-month mortality was noted among patients with pneumonia than those with pulmonary nocardiosis. However, despite pulmonary nocardiosis patients had a substantially younger age, no significant differences were found in one-year mortality rates between the groups. This might be due to severe comorbidity among pulmonary nocardiosis patients, possibly malignant diseases.

Abstract 8358

The case for infectious disease-centered antimicrobial stewardship: a 10-year experience at Saint George Hospital

Sanaa Saliba*1,2, Omar Zmerli1,2, Amanda Chamieh1,3, Claude Afif1,2, Eid Azar1,2

1Saint George Hospital University Medical Center, Division of Infectious Diseases, Beirut, Lebanon, 2University of Balamand, Faculty of Medicine and Medical Sciences, Beirut, Lebanon, 3Aix-Marseille University, Marseille, France

Background: In order to optimize antimicrobial prescription, Saint George hospital (SGH) implemented different educational modalities. Starting February 2012, an instant email forwarded to the infectious diseases (ID) consultant and the fellow on service upon prescribing a broad-spectrum antimicrobial, mandates a consult. The case is then reviewed for approval. Narrower spectrum antibiotics can be freely prescribed. Our antimicrobial stewardship program (ASP) also provides internal guidelines for best practices; for example, the carbapenems sparing strategy was implemented in July 2016.

Materials/methods: At SGH in Lebanon, a 333-bed hospital, the restricted antibiotics (RA) list consists of: carbapenems, amikacin, vancomycin, teicoplanin, ceftaroline, ceftolozane/tazobactam, piperacillin/tazobactam, cefepime, ceftazidime, tigecycline and colistin. Unrestricted antimicrobials are amoxicillin/clavulinate, first, second and third generations cephalosporins, ciprofloxacin and levofloxacin. We extracted from our ASP database consumption of each antibiotic reported as the daily defined dose (DDD) per 1000 patient days (PD) from January 2010 till June 2019. We also retrieved the number of ID consultations per 1000PD from 2012 till 2018.

Results: The unrestricted antimicrobial consumption was stable ranging from 295-345 DDD/1000 PD with a mean of 319. (Figure 1)

Shortly after adapting of our email notification system in February 2012, an absolute drop of 50 DDD/1000PD representing 15.6% of the total consumption of RA was noted. In 2013, this early success was difficult to maintain mainly due to an increase consumption of carbapenems that peaked in 2015.

However, after the implementation of strict carbapenems sparing strategy in 2016, consumption dropped from a peak of 208 DDD/1000PD to 33 DDD/1000PD in 2019. The total consumption of RA dropped from an average of 303 DDD/1000PD from 2010-2016 to 177 DDD/1000PD from 2017-2019.

The number of ID consultations was flat between 20-21 consults per 1000PD from 2012-2018.

Conclusions: Our 10 year experience in ASP favors that education, unlike restriction, did not result in any concrete change of consumption rates. Creating a system whereby an ID clinician enforces the best practices of the institution seems to yield interesting results without additive resources.

Abstract 8369

**Serum Galectin-3 status in hospitalised patients with catheter-associated asymptomatic bacteriuria**
Simona Iftimie¹, Anna Hernández-Aguilera², Lopez Azcona Ana Felisa³, Isabel Pujol¹, Frederic Ballester¹, Antoni Castro¹, Jordi Camps*¹

¹Hospital Universitari Sant Joan de Reus, Reus, Spain, ²Universitat Rovira i Virgili (FMCS), Reus, Spain

**Background:** Urinary tract infections (UTI) are common in hospitalized patients with bladder catheters. Identifying new biochemical markers of urinary tract infection is an active line of research, since the management of UTI requires many resources. Galectin-3, which belongs to the lectin family able to bind to β-galactosides, plays an important role in the pathogenesis of numerous diseases such as cancer and inflammatory and metabolic disorders. It is known than its expression is increased by inflammatory stimuli such as microbial and non-microbial. Our study sought to evaluate alterations in inflammation-related Galectin-3 in patients with an indwelling catheter to assess their potential usefulness as biomarkers of infection.

**Materials/methods:** Patients (n=165) who had had the urinary catheter removed and healthy volunteers (n=72) were recruited and their medical records were also examined. Pertinent demographic data, comorbidities, bacteriologic and therapeutic data were recorded and were reviewed based on whether or not they have asymptomatic bacteriuria related to the catheter (CAAB). In all participants we measured plasma galectin-3, procalcitonin (PCT) and C-reactive protein (CRP).

**Results:** Patients with and without CAAB were significantly different in terms of percentages of sex, ischemic heart disease, chronic renal failure, history of malignancies and reception of antimicrobial treatment 24 hours before sample collection. Patients showed a higher inflammatory status than healthy individuals, with higher Galectin-3 concentration (17.15 ng/ml vs 6.15 ng/ml, p<0.01), CRP (24.60 mg/l vs 1.17 mg/l, p<0.001) and PCT levels (41.41 mcg/l vs <10 mcg/l, p<0.001). In patients, we observed that the galectin-3 concentration significantly correlated with age and with the number of days the urinary catheter was indwelling (Figure 1). The discriminatory capacity of the circulating concentration of these parameters was analyzed by means of the receiver operating characteristics (ROC) curves for patients with or without acute concomitant infection and CAAB, being galectin-3 the marker with the best area under the curve in both cases (Figure 1).

**Conclusions:** Our results suggest that the measurement of these biochemical variables may be useful in investigating complications of long-term use of these devices and can help to optimize antimicrobial treatment and shorten hospital stays.

Detection and identification of intact carbapenemases using liquid chromatography and tandem mass spectrometry from microbial lysates in a rapid carba method using the Acrion system

William Mcgee*, Arvind Verma*, Marjaana Viirtola*, Scott Kronewitter†, Jason Neil†, Jaakko Haakana†, Jim Stephenson†

†Thermo Fisher Scientific, Cambridge, United States; †Thermo Fisher Scientific, Vantaa, Finland

**Background:** Carbapenemase-producing organisms (CPOs) pose a rapidly-growing global health threat, not only for the ability to metabolize the potent antibiotic family of carbapenems, but also for the frequent association of high morbidity and mortality rates from these infections. Effective treatment of these infections can be maximized by rapidly detecting the specific mechanisms of resistance. Mass spectrometry (MS) has been used to individually characterize the “big five” carbapenemases: KPC, VIM, IMP NDM and OXA-48-like. We have developed a single method that, following automated sample preparation from bacterial cultures, uses a combination of liquid chromatography and tandem mass spectrometry (LC-MS/MS) for direct detection of intact carbapenemases.

**Materials/methods:** Carbapenemase-producing and carbapenemase-non-producing isolates were used, including several species from Acinetobacter, Pseudomonas and Enterobacteriales. Bacterial colonies from either agar or blood culture were harvested and mechanically lysed, with the lysate being transferred directly to disposable columns for liquid chromatography (LC) for rapid separation and elution, followed by electrospray ionization (ESI) and MS analysis. Tandem mass spectrometry (MS/MS) is used to determine the presence of carbapenemases by dissociating the intact protein(s) in a data-independent manner. Diagnostic fragments produced directly from unique carbapenemase, each possessing specific characteristics as mass-to-charge (m/z) and charge state, are used to determine the presence of specific carbapenemases.

**Results:** To date, our methods have been used to determine the presence or absence of KPC, VIM, IMP NDM and OXA-48-like in Enterobacteriales; KPC, VIM and IMP in Pseudomonas, and VIM in Acinetobacter, based on isolate availability. Multiple variants from each of the big five are detected, with the exception of IMP, in which we focus specifically on IMP-1. Several isolates harboring multiple carbapenemases, most frequently of OXA-48-like and NDM, have been evaluated. Carbapenemase-non-producing isolates have shown negative carbapenemase results. Following carbapenemase detection, results of all claimed carbapenemases present are reported.

**Conclusions:** This research allows detection of the big five carbapenemases in an automated fashion, with the duration of the assay lasting under 5 minutes. The method presented takes advantage both of the ability of liquid chromatography to simplify complex protein mixtures and the high-resolution, targeted capabilities of mass spectrometry for confident detection of carbapenemases.

**Goal achieved! Elimination of hepatitis C in three penitentiary centres**

Sofía García Martín*1, Carolina Freyre1, Francisco Téllez Pérez1, Ianire Virto1, María Carmen Martínez Rubio1

1Universitary Hospital Puerto Real, Puerto Real, Spain

**Background:** The WHO has purposed to eliminate the hepatitis C (HCV) in 2030. In order to achieve this objective it is essential to eliminate it in vulnerable and high prevalence population such as de Penitentiary Center (PC) which also present multiple difficulties for their approach. Therefore, an HCV elimination program was designed with the development of innovative strategies.

**Materials/methods:** In June 2016 a multidisciplinary team composed of doctors, nurses, pharmacist and officials was created in the PCs Puerto I, II and III. All the inmates, 2068, were included. A training program, diagnostic and follow-up protocols were developed and the prevalence of active infection was determined by viral load and core antigen positive serology inmates. Hepatic fibrosis was analyzed by Fibroscan and HCV was genotyped. The infectologist monthly attended consultations in the PC. The prescribed treatment was administered directly observed. Sustained virologic response (SVR) was used to measure effectiveness of HCV treatment.

**Results:** HCV active infection was positive in 214 of the 2068 inmates. The prevalence was 10.35%. In the table 1, co-infected with HIV, monoinfected and total patients results are shown.

Risk factors for mortality in diabetic foot infections

Pınar Sen1, Tuna Demirdal*2

1Izmir Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey, 2Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Infectious Diseases and Clinical Microbiology, Izmir, Turkey

Background: Foot ulceration and infection represent an important source of morbidity and mortality in people with diabetes mellitus. We aimed to determine the risk factors for mortality in diabetic foot infection (DFI).

Materials/methods: Data of patients who were hospitalized for DFI between 2010 and 2019 were recorded retrospectively from the hospital records. The data of the patients who died and survived were evaluated statistically for predicting mortality.

Results: Data were collected for 401 patients including 280 (69.8%) men. The mean age was 59.6±11.1 (29-81) years. Thirteen (3.2%) of the patients were type 1 diabetes and mean duration of diabetes was 14.1±9.2 years. The causes of the DFI were as follows; ischemic ulcer (33.7%), trauma (13.5%), neuropathic ulcer (11.5%), venous ulcer (10.5%) burn injury (2.7%) and idiopathic (25.4%). Of these patients, 47.4% had right foot wound, 43.6% had left foot wound and 9% had bilateral foot wounds. Treatment modalities included medical treatment (146, 36.4%), debridement/drainage (88, 21.9%), minor amputation (71, 17.7%) and major amputation (96, 23.9%). Mean duration of follow-up was 23.7±22.9 months; 146 (46.8%) patients completely recovered, 63 (20.2) patients developed a chronic foot ulcer and 103 (33%) patients required re-operation. The overall mortality rate was found 3% (12/401).

Ischemic wound (p = 0.025), hindfoot wounds (p = 0.043), whole foot wound (p = 0.035), peripheral arterial disease (p = 0.005), high leukocyte levels (p < 0.001), high thrombocyte levels (p < 0.001) and high C-reactive protein levels (p = 0.018) were found to be significant factors in terms of mortality. Among these factors, peripheral arterial disease (OR:13.430, 95% CI: 1.129-59.692; p=0.040), high thrombocyte levels (>378000 K/ul) (OR:1.000, 95% CI:1.000-1.000; p=0.022) and isolation of multiple bacterial species from the tissue culture (OR:7.790, 95% CI: 1.592-38.118; p=0.011) were independent risk factors for mortality in DFI (Figure).

Conclusions: Early recognition of risk factors for mortality is crucial in terms of decreasing mortality rates. We conclude that these clinical parameters are simple, broadly available and cost-effective promising parameters for predicting mortality in DFI.

Genomic characterisation of MBL-producing non-aeruginosa Pseudomonas spp. in Saint-Louis University hospital in Paris, France

François Caméléna*, Manel Merimèche¹, Martine Rouveau¹, Sarah Delliere¹, Mourad Benyamina¹, Touratier Sophie¹, Matthieu Lafaurie¹, Beatrice Bercot¹

¹Saint-Louis, APHP, Paris, France

Background: Acquisition of antimicrobial resistance determinants, including metallo β-lactamase (MBL) carbapenemases have been reported in non-aeruginosa Pseudomonas spp. The aim of this study was to identify and characterize MBL-producing non-aeruginosa Pseudomonas spp. (MPP) isolated at Saint-Louis hospital in France.

Materials/methods: MPP isolates were collected retrospectively from patients hospitalized in several Units of the St Louis hospital from January 2011 to June 2019. Antimicrobial susceptibility was tested toward 19 antibiotics including last cephalosporin and β-lactamase inhibitor combinations [broth microdilution Sensititre™ (Thermofisher Scientific) and diffusion gradient E-test® (Biomérieux)]. Genomic characterization was performed by whole genome sequencing (NextSeq™ or MiSeq™, Illumina®). Sequences were analyzed for genes encoding acquired antibiotic resistance (ResFinder) and Core genome single nucleotide polymorphisms (SNP) from reference-based read alignment were used to infer phylogenetic relationships.

Results: Among the 19 carbapenems resistant non-aeruginosa Pseudomonas spp., 13 were MPP. Four were isolated from screening rectal swabs, 4 from blood cultures, 3 from stool samples, 1 from urine sample and 1 from skin sample. The bacterial species observed were P. putida (n=8), P. stutzeri (n=4) and P. mosselii (n=1). All isolates were resistant to all β-lactam antibiotics except 5 isolates which were susceptible to aztreonam. All were susceptible to colistin. MPP isolates produced VIM-type carbapenemase with VIM-2 (n=9), VIM-4 (n=3) and VIM-1 (n=1) enzymes.

The core-genome analysis identified several clusters with one cluster corresponding to 3 P. stutzeri. which suggest a potential transmission of MPP isolates in our hospital. Characterization of the genetic support and the environments surrounding carbapenemase genes are ongoing.

Conclusions: Non-aeruginosa Pseudomonas spp. with MBLs are emerging and may represent difficult-to-treat infections. Identification of MBLs in these species is essential for limiting the spread of carbapenemase-producing isolates in hospital which could occur via plasmid circulating in the Pseudomonas genus. Whole Genome Sequencing represents a powerful tool for investigation and traceability of strains circulating in the hospital.

**Background:** *Actinotignum schaalii* is an emerging uropathogen which can be frequently overlooked in routine culture due to its special growth conditions. It has also been described as a rare cause of septicemia.

**Materials/methods:** *A. schaalii* isolates in blood cultures were identified retrospectively in the clinical laboratory database, comprising results from January 2009 to July 2019. Once cases were identified, the medical history of each patient was searched to extract variables such as age, sex, comorbidities, urogenital risk factors, the presence of septic shock (defined by use of vasopressors), clinical diagnosis of UTI (described by the treating physician) with or without positive urine cultures. All isolates were identified by MALDI-TOF, and antimicrobial susceptibility was determined via Sensititre®.

**Results:** A total of 10 isolates from blood cultures of 10 patients were identified, with 5 female and 5 male patients. The median age was 74.5 years. Only one case was associated with septic shock. 6 patients had predisposing urinary tract conditions upon admission, with an additional 3 requiring indwelling urinary catheters during hospitalization. All patients had significant comorbidities, including oncologic and neurologic diseases. 6 cases were clinically diagnosed as bacteremia secondary to UTI, despite there only being 2 urine cultures positive for *A. schaalii*. The susceptibility of only the 4 latest isolates could be obtained, with all 4 sensitive to penicillin, tetracycline, moxifloxacin and vancomycin, 2 out of 4 resistant to clindamycin, and all 4 resistant to metronidazole.

**Conclusions:** *A. schaalii* is a rarely reported cause of urinary sepsis, most commonly found in elderly patients with urinary tract disease and other comorbidities. In this study there is a clear disparity between positive blood cultures and urine cultures, indicating a need for protocols directed towards the isolation of emerging uropathogens in select populations.

In vitro model of Pseudomonas aeruginosa pulmonary biofilm to evaluate the efficacy of cationic antibiotics

Rana Awad1,2*, Frederic Tewes1,2, Sandrine Marchand1,2,3, William Couet1,2,3, Mohamad Nasser4

1INSERM U1070, Poitiers, France, 2Faculté de Médecine et de Pharmacie, Poitiers, France, 3Poitiers University Hospital, Poitiers, France, 4Lebanese University, Hadat Campus, Beirut, Lebanon

Background: Pseudomonas aeruginosa (PA) forms pulmonary biofilms in cystic fibrosis patients. These biofilms are aggregates of PA (50-100 μm) entrapped in a self-produced matrix of anionic polymers (alginate, eDNA), often surrounded by patient mucus. These conditions limit the efficacy of cationic antibiotics (ATB) used by inhalation, such as tobramycin (TOB) and colistin (COL). The aim of this study is to develop an in-vitro model composed of these anionic polymers (alginate, mucins, DNA) to mimic PA biofilms and evaluate the efficacy of these ATB.

Materials/methods: A constitutively bioluminescent PA01 strain was incorporated into calcium alginate beads dispersed in various growth media. The effects of the beads size (60 and 1200 μm) and the medium in which they were dispersed (Muller-Hinton (MH) or artificial pulmonary mucus (ASM)) were tested on TOB and COL efficacy by performing bioluminescence kinetics produced by PA for 40 h, followed by a measurement of bacterial concentrations (log10 CFU / ml). Then, the appearance of resistance to the ATB used in the surviving PAs was evaluated by measures of MIC.

Results: Below 10 MIC, TOB did not slow the growth of PAs under all conditions tested. Above 10 MIC, adding ASM or increasing the beads size further decreased TOB efficacy. TOB concentrations higher than 200 MIC allowed eradicating PA in beads dispersed in MH, but remained insufficient to eradicate those in beads dispersed in ASM. Compared to TOB, COL at this concentration allowed the total eradication of PA from large beads dispersed in ASM. For PAs loaded in large beads dispersed in MH, the apparition of small colony variants was observed from TOB concentrations ≥ 25 MIC. The percentage of this phenotype in the total bacterial population increased with the TOB concentration. This phenotype, which was not observed in the presence of COL, has been described in CF patients with chronic pulmonary infections.

Conclusions: PA incorporated into large alginate beads dispersed in ASM seems to be an in vitro model reproducing PA lung biofilms. In this model, COL was more effective than TOB, suggesting a better clinical efficacy of COL than TOB against pulmonary PA biofilms.

Abstract 8393

Impact of the use of C-reactive protein in micro-methods on the prescription of antibiotics in case of suspected respiratory infection in children and adults in ambulatory care in France

Robert Touitou1, Corinne Levy1, Stéphane Béchet1, Emmanuel Pinto1, Alice Laplante1, Juliette Lion-Altmayer1, Blandine Trincard1, Camille Jung3, Robert Cohen2

1EFGH Croix Saint Simon, Paris, France, 2ACTIV, Créteil, France, 3CHI Créteil, Créteil, France

Background: Respiratory tract infections and particularly the “febrile cough” are the leading cause of unnecessary antibiotic prescriptions while a minority of them are linked to bacterial infections requiring antibiotics. These massive prescriptions contribute to increase bacterial resistance not only for respiratory pathogens but also for bacterial species of digestive microbiota. Point of care tests such as C-reactive protein micro-method (POCT-CRP) have been developed to help differentiate between viral and bacterial infections and thus contribute to the proper use of antibiotics. The decrease in antibiotics prescriptions due to POCT-CRP is likely to have a greater positive impact in countries such as France, where antibiotic consumption is high.

Materials/methods: 24 investigators were randomized in 4 clusters to conduct a stepped wedge randomized multicentric study. All clusters began the study at the same time, but they were randomized to start using POCT-CRP at different times: 3, 6, 9 and 12 months after the beginning of the study. Because of a too large number of subjects to enroll in a stepped wedge design, the study was early stopped after 8 months, and it was decided to conduct a second study. Nevertheless, the rate of antibiotic prescriptions during the first study were compared according to the use of the POCT-CRP. Results were also analyzed according to age group (3-17, 18-64, >64 years).

Results: Between June 2018 and February 2019, 404 patients were included in the first study. Mean age was 41.2 ± 24.5 years, with a minimum of 3 years and a maximum of 92 years and male accounted for 58.4% of patients. Seventy five (18.6%) POCT-CRP were used, for patients with mean age of 21.9 ± 32.8 years. Antibiotics were prescribed for 163 patients (40.5%): 147 (45.2%) when a POCT-CRP was not used and 14 (18.2%) when a POCT-CRP was used (p<0.001).

Conclusions: The use of POCT-CRP allowed to reduce the prescription of antibiotics in adults and children on an outpatient basis for suspected respiratory infection. We are confident that those results will be confirmed by the second study.

Abstract 8395

**Antimicrobial stewardship starts at home: in-house developed digital tool for real-time resistance surveillance**

Marta Gonzalez Sanz*, Natalie Marshall¹, Alleyna Claxton¹, Kate Woods¹

¹Homerton University Hospital NHS Foundation Trust, London, United Kingdom

**Background:** Accurate bacterial susceptibility surveillance data is a cornerstone of the fight against Antimicrobial Resistance (AMR). Hospital antibiotic guidelines are often based on regional and national data which might not be directly applicable to the local population served. Smaller hospitals may lack the necessary infrastructure for regular analysis of local susceptibility patterns. Our team designed a tool to semi-automate analysis of local susceptibility patterns in order to ensure our antibiotic guidelines are appropriate for current AMR patterns in the local population.

**Materials/methods:** We created a programme on SPSS® [software platform for statistical data analysis], to analyse data extracted directly from Winpath, our Laboratory Information Management System (LIMS). The syntax can be configured for any sample type, demographics or location; and output data can be compared with local antibiotic guidelines and national AMR data.

Urine samples which were culture positive between April 2016 and March 2019 were retrospectively extracted from Winpath, and analysed using the SPSS® tool. The target study group were Enterobacterales culture positive samples from patients older than 16 years.

**Results:** 26,192 Enterobacterales culture positive urine samples were identified. 19,767 (75.5%) from community/outpatient settings; 3,588 (13.7%) and 2,837 (10.8%) from acute/inpatient settings respectively. The most common organisms isolated were: *Escherichia coli* (75.7%), *Klebsiella pneumoniae* (9.1%), *Proteus mirabilis* (5.4%), *Citrobacter koseri* (2.6%), *Enterobacter cloacae* (1.3%). Among these organisms (N=24,657) the proportion of non-susceptible isolates to first-line antibiotics was: amoxicillin (78%), cefalexin (10.2%), nitrofurantoin (6.1%), trimethoprim (30.8%), fosfomycin (4.6%), pivmecillinam (4.1%) and ciprofloxacin (11.5%). Second-line susceptibilities were performed in 2,228/24,657 (9%) of samples: 1,183/2,228 (53.1%) were ESBL producers, 1,115/1,379 (8.2%) and 31/2,223 (1.4%) were gentamicin and amikacin resistant respectively; no carbapenemase producing organisms were identified. Resistance patterns have remained stable over time, however gentamicin resistance sharply increased to 26.9% from April 2018 to March 2019.

**Conclusions:** Homerton’s AMR tool is simple to use and enables rapid, detailed analysis of local antibiotic susceptibility data. It can be implemented with limited resources and by small Antimicrobial Stewardship teams. The data generated is essential to ensuring antibiotic policies are appropriate for local populations. The development of this tool and sharing the process with the international community could improve local AMR surveillance capabilities.

Prevalence of Hepatitis E Virus in allogeneic-haematopoietic stem cell transplant recipients from Portugal

Sara Cruz*1, Nânci Santos-Ferreira2, Maria São José Nascimento1, Carlos Pinho Vaz1, Fernando Campilho1, Luís Leite1, Rosa Branca1, Antonio Campos Jr1, Rui Medeiros1, Hugo Sousa1,3

1IPO Porto, Porto, Portugal, 2Faculty of Pharmacy, University of Porto, Porto, Portugal, 3ICVS - Life and Health Sciences Research Institute, Braga, Portugal

Background: Hepatitis E virus (HEV) is an emerging cause of acute hepatitis in healthy individuals. In developed countries, locally acquired HEV infections can lead to chronic infection in immunosuppressed patients. Little is known of HEV infection in hematopoietic stem cell transplant (HSCT) recipients, and their prolonged immunosuppression state makes them an important risk group. We developed an epidemiology study to characterize HEV prevalence in a retrospective cohort of allogeneic-hematopoietic Stem Cell Transplant (allo-HSCT) recipients.

Materials/methods: A retrospective study was performed in a cohort of 196 patients submitted to allo-HSCT in a single center between 2016-2018. Allo-HSCT recipients were screened prior transplantation for HEV RNA by real-time RT-PCR and for anti-HEV IgM and IgG using an enzyme immunoassay.

Results: All 196 samples were tested for the presence of anti-HEV IgG, and 39 were positive, giving an anti-HEV IgG prevalence of 19.9%. Furthermore, we found a prevalence of recent/active HEV infection of 4.1% with 8 positive cases for HEV infection, of which 6 were positive for HEV RNA, and 2 were positive for both anti-HEV IgM and IgG.

Conclusions: Over the last years, some attention has been given to this group of immunocompromised patients, but there is still a small number of studies. This study shows that recipients of allo-HSCT are at risk for HEV infection. Therefore, allo-HSCT recipients should be screened prior transplantation, and during episodes of liver enzyme abnormalities post-transplantation, with HEV RNA testing as the preferred diagnostic method in these immunocompromised patients. Nevertheless, more studies are needed to increase our understanding of the epidemiology of HEV in HSCT recipients, as it may be an important factor in the outcome of patients.

Dynamic study of microbial interactions in the skin microbiota of patients with epidermal necrolysis (DynaMiCut)

Justine Lavaud1,2, Christophe Rodriguez3, Saskia Oro1, Nicolas De Prost4, Guillaume Gricourt1, Floriane Kouby1,2, Vanessa Desmontant1, Camille Hua1, Françoise Battereli1, Bruno Costes1, Elise Melloul1, Lolita Roisin2, Pierre Wolkenstein1, Jean-Winoc Becquesp1, Olivier Chesidow1, Charlotte Bernigaud1,2,3, Olivier Chosidow1, Charlotte Bernigaud1,2,7,8, Paul-Louis Woerther2,6,8

1Hôpital Henri-Mondor Ap-Hp, Service de dermatologie, centre de référence des toxidermies bulleuses, Créteil, France, 2Université Paris Est Créteil, EA 7380, DYNAMYC, Université Paris-Est Créteil, EnVA, Créteil, France, 3Hôpital Henri-Mondor Ap-Hp, Plateforme de génomique, Créteil, France, 4Hôpital Henri-Mondor Ap-Hp, Service de réanimation, Créteil, France, 5INSERM, Equipe 05 [IMRB]-U955 INSERM, Créteil, France, 6Hôpital Henri-Mondor Ap-Hp, Service de bactériologie, Microbiologie, DHU VIC, Créteil, France, 7QIMR Berghofer Medical Research Institute, Infectious Diseases Program, Brisbane City, Australia, 8Equal Contribution, Créteil, France

Background: Toxic epidermal necrolysis (TEN) is a potential life-threatening dermatologic disorder characterized by necrosis and bullous detachment of the epidermis and mucous membranes most often secondary to drug intake. Mortality is related to skin barrier disruption, colonization and infection with opportunistic bacteria [OP]: notably Staphylococcus aureus (SA) and Pseudomonas aeruginosa (PA). The study objective was to describe the evolution of the skin microbiota from the phase of skin detachment to the epidermization of patients with TEN.

Materials/methods: Patients hospitalized in the dermatology or ICU reference center department with a skin detachment > 10% were included. Swabs (Eswab*) were taken from healthy and detached skin three times a week until epidermization. At each time-point, seborrheic areas (thorax), moist areas (crook of the elbow, inguinal fold and umbilicus/abdomen) and dry areas (anterior forearm and anterior thigh) were sampled. For all samples, targeted sequencing of the 16S ribosomal RNA gene [V3-V4] on Miseq Illumina® was performed after automated extraction (QIAsymphony®).

Results: 153 samples from 5 patients included between 06/2018 and 03/2019 were analyzed. 11,023,208 sequences were used for the targeted metagenomic analysis. The OTUs (Operational Taxonomic Unit) allowed identification in 99.97% [99.82%-100%] of cases up to the genus. The alpha diversity (Shannon) between skin detachment and healthy or epidermised skin was significantly different (p = 0.0094) and between seborrheic and non-seborrheic areas (dry and wet) (p = 0.028). Beta-diversity was also significantly different in skin detachment in quantitative analysis (p = 0.007) and at the limit of significance in qualitative analysis (p = 0.082). The results of the targeted metagenomic analysis showed the predominance of four bacterial genera: Pseudomonas, Staphylococcus, Corynebacterium and Enterobacter.

Conclusions: We did not observe a specific microbiota associated with TEN [low number of patients included]. During the detachment phase, there was a homogeneous loss of the healthy microbiota in favor of OP. Diversity analyzes showed a significant difference between skin detachment and healthy skin. There was a predominance of Staphylococcus followed by Pseudomonas and finally the microbiota recovered during the epidermization phase with a reappearance of commensal bacteria [Corynebacterium] (fig1). Similar observations have been described in burn patients.

Presenter email address: paul-louis.woerther@aphp.fr
Local prevalence of molecular resistance mechanisms in carbapenem-resistant Enterobacteriaceae at a tertiary healthcare centre in Lebanon

Omar Zmerli*1,2, Sanaa Saliba1,2, Amanda Chamieh1,3, Claude Afif1,2, Eid Azar1,2

1Saint George Hospital University Medical Center, Division of Infectious Diseases, Beirut, Lebanon, 2University of Balamand, Faculty of Medicine and Medical Sciences, Beirut, Lebanon, 3Aix-Marseille University, Marseille, France

Background: Clinical syndromes caused by carbapenem-resistant Enterobacteriaceae (CRE) vary in severity owing to the myriad of mechanisms of resistance harbored by these organisms. This often results in limited therapeutic options. These mechanisms have a well-documented geographic variation, with a predominance of OXA-48 and metallo-β-lactamases reported in the Mediterranean region. In practice, novel antimicrobial molecules marketed for treating CRE infections exhibit different levels of therapeutic success.

Materials/methods: We retrieved from the records of the antimicrobial stewardship program at Saint George Hospital, a 333-bed tertiary care center in Lebanon, the CRE isolation density defined as the number of isolates/1000 patient-days (PD) from January 2010-December 2018.

Results of real-time PCR identification of carbapenemase genes (Cepheid Xpert® Carba-R) performed from January 2015-November 2019 were retrieved from the laboratory electronic database. Descriptive analysis was done using SPSS© Version 25.

Results: Over eight years, the isolation density of CRE increased 25-fold from 0.05/1000PD in 2010 to 1.28/1000PD in 2018. A total of 113 CRE isolates from 106 patients were tested from January 2015-November 2019. Only two isolates were tested in 2015, 20 in 2016 and 2017, and 51 in 2018. Overall, 84 isolates were found to possess ≥ 1 gene. The most commonly detected molecular mechanism of carbapenem-resistance was OXA-48 (38/84 tested; 45%) followed by NDM (33/84; 39%). Fifteen isolates (18%) co-expressed NDM and OXA-48. One isolate expressing KPC was detected from the wound of a patient who had undergone CNS surgery in Latin America. The most frequent organisms tested were Klebsiella pneumoniae (42/84; 50%), followed by Escherichia coli (33/84; 39%) and Enterobacter sp. (9/84; 11%). The most tested isolates were wound and fluid samples (42/113; 37%).

Conclusions: Although our sample may not fully represent the CRE burden of disease, it is highly suggestive of the rise in CRE with an OXA-48 and NDM predominance in our area. This is very challenging as it points towards a lower than expected benefit from the novel antimicrobial agents currently on the market. Epidemiologic surveillance, diagnostics and antimicrobial stewardship are necessary to understand CRE dynamics.

Burden of tuberculosis in Nepal: where do we stand?
Prabin Shrestha*1

1Young Professional Development Society Nepal (YPDSN), Kathmandu, Nepal

Background: Tuberculosis is a communicable disease causing ill health and one of the top ten causes of death worldwide. In Nepal, tuberculosis is a major public health problem and seventh leading cause of death.

Materials/methods: Desk review was conducted. Various literatures, reports, policy documents and guidelines related to tuberculosis in Nepal were reviewed using policy review framework. Descriptive analysis was conducted to present the findings.

Results: The World Health Organization estimates 44,000 new tuberculosis cases every year in Nepal, however in 2017/18, only 32,474 cases were notified, depicting missing cases needed to be notified and brought into treatment. It is estimated around 13,000 incident tuberculosis cases are missed to be diagnosed or notified annually and everyday there are 123 new tuberculosis cases, 18 deaths because of tuberculosis and 34 cases are missed to be diagnosed. The case notification rate stands at 112/100,000 and this has remained almost constant. Among the notified cases, 97.7% were incident (New and Relapse) cases and 71% were pulmonary cases of which 80% were bacteriologically confirmed. Around 24% of the cases were reported from Province 3 of which Kathmandu district alone holds around 41% (3,183 cases) which accounts for 10% of national cases. In terms of eco-terrain, Terai region reported more than half of cases (18,590, 57%). Most cases were reported in the middle age group with the highest of 50% in 15-44 year of age. Men were nearly 1.73 times more than women and childhood tuberculosis was around 5.5%. Among the notified cases, 67% were tested for Human Immunodeficiency Virus and 0.90% (196) were found positive and 94% (185) were enrolled for antiretroviral therapy. In Nepal, tuberculosis prevalence survey is undergoing that will provide the latest estimates of the disease and the results are expected by the end of 2019.

Conclusions: Significant efforts are required to identify the missing cases. There is a need for more accountable, equitable and quality service delivery approach making services universally accessible and patient centered. Awareness, accessible services, private sectors involvement and screening programs for high risk groups definitely can help increase the case notification.

Abstract 8404

The real-life impact of the Xpert MTB/RIF Ultra assay on the diagnosis of tuberculosis in a hospital in central Israel

Orna Schwartz¹, Orit Yosseppowitch², Yasmin Maor*³

¹Wolfson Medical Center, Microbiology laboratory, Wolfson Medical Center, Holon, Israel, ²Wolfson Medical Center, Infectious Disease Unit, Wolfson Medical Center, Holon, Israel, ³Wolfson Medical Center and Tel Aviv University, Infectious Disease Unit, Wolfson Medical Center, Holon, Israel

Background: The Xpert MTB/RIF Ultra assay (Cepheid, USA) has high sensitivity for Mycobacterium tuberculosis (TB) detection. Our aim was to assess the real-life impact of this assay.

Materials/methods: To assess the impact of the Ultra assay at the Wolfson Medical Center, a secondary hospital in Israel, we compared two periods: Period I (1.11.2015-31.10.2017) when diagnosis was based on the Xpert MTB/RIF assay to Period II (1.11.2017-31.10.2019) when diagnosis was based on the Ultra assay. The Xpert MTB/RIF reports semiquantitative results (very low, low, medium, and high). In addition to improved sensitivity the Ultra assay also identifies trace amounts of TB DNA. The significance of this is not clear and is left to clinical judgement.
