After a debridement without any exchange of the mobile components for an acute *S. aureus* PJI, total antibiotic regimen duration was six weeks (26%), three months (68%), or suspensive (4%). After arthroscopic lavage for *S. aureus* native joint septic arthritis, total antibiotic regimen duration was three weeks (6%), four weeks (35%), six weeks (53%), eight weeks (1%), or 12 weeks (3%).

**Conclusions:** Despite PJI is a common infection, its medical management is still heterogenous, reflecting the lack of evidence and the numerous different possible combinations depending on the clinical presentation and the pathogen involved.

Abstract 5452

Regional lymphadenopathy caused by Bartonella henselae among children: a single-centre study

Ivana Valenčak-Ignjatić1, Diana Didovic*1, Ante Šokota1, Laura Prtoric1, Vedran Stevanovic1, Oktavija Dakovic Rode1,2, Marija Gužvinec1, Branko Miše1,3

1University Hospital for Infectious Diseases Dr. Fran Mihaljevic, Zagreb, Croatia, 2School of Dental Medicine, Zagreb, Croatia, 3School of Medicine, University of Zagreb, Zagreb, Croatia

Background: The aim of this study was to analyze lymphadenopathy caused by B. henselae among children treated at the University Hospital for Infectious Diseases, Zagreb, from January 2014 until June 2019.

Materials/methods: We retrospectively analyzed epidemiology, clinical and laboratory characteristics along with ultrasound features of lymphadenopathy among children with positive indirect immunofluorescence assay for B. henselae IgM and IgG or positive B. henselae polymerase chain reaction (PCR) from lymph node aspirate.

Results: A total of 95 patients were enrolled in this study, 52 (54.7%) males and 43 (45.3%) females. A history of cat contact was present in 92 (96.8%) children. Acute infection was serologically confirmed in 78 (82.1%), in 5 (5.3%) with PCR while both methods were positive in 12 (12.6%) patients. Lymphadenopathy without fever was present in 51 (53.6%) patients. Axillary lymph nodes were most often affected (42 patients, i.e. 44.2%), followed by cervical in 37 (38.9%), inguinal in 15 (15.1%) and supraclavicular in 1 (1.0%) patient. Average lymph node size according to ultrasound was 2.8 cm (range, 1.8 to 5.5 cm).

Fine-needle aspiration of the affected lymph nodes was performed in 47 (49.5%) patients. The lymph node aspirate was assessed histopathologically and microbiologically, as well as by molecular methods. Histopathologically, 20 (42.5%) were cases of lymph node hyperplasia, 11 (23.4%) lymph node hyperplasia with granulomatous inflammation, 12 (25.5%) supplicative inflammation and 4 (8.5%) were cases of suppurative necrosis. Cultured lymph nodes aspirate were positive for Staphylococcus aureus in 3 and coagulase-negative staphylococci (CoNS) in 2 patients. Along with lymphadenopathy, hepatosplenomegaly was found in 5 (5.3%) and Parinaud's syndrome in 1 (1.05%) patient. The average white blood cell count was 9.9 x 10⁹/L, while the average value of C-reactive protein was 23.02 mg/L. Azithromycin was the most commonly prescribed antibiotic (76.8%, n=73). Surgical drainage of the lymph node was performed in 10 (10.5%) patients. Full recovery was the most frequent outcome (98.9%, n=94).

Conclusions: B. henselae infection among children is usually a mild disease often presenting as regional lymphadenopathy. Serology and PCR are useful tests for diagnosis. Treatment duration and choice of therapy depends on clinical manifestations and developed complications.

Impact of the FILMARRAY gastrointestinal polymerase chain reaction panel on the clinical management of children with suspected acute bacterial diarrhoea

Jeanne Truong*1, Enora Leroux1, Morgane Michel1, Julien Boize1, Patricia Mariani1, Aurélie Cointe1, Marie Desmarest1, Luigi Titomanlio1, Albert Faye1, Stephane Bonacorsi1

1Robert-Debré Universitary Hospital, Paris, France, 2Hôtel dieu Hospital, Paris, France

Background: The FilmArray Gastrointestinal polymerase chain reaction panel (GI-PCR) is a multiplex molecular assay allowing simultaneous detection of 22 pathogens in 1 hour (13 bacteria, 5 virus and 4 parasites). The objective was to assess the impact of the results of the GI-PCR on the clinical management of children with acute diarrhea consulting in a pediatric emergency department of a tertiary care center.

Materials/methods: All children admitted in the pediatric emergency department of Robert-Debré, universitary hospital, Paris, France, from May to October 2019, for an acute diarrhea with medical indication for stool culture were included in this prospective monocentric study. Indications for stool culture followed European guidelines. A GI-PCR was performed on each stool sample. Data on children initial care and on changes in their medical management following GI-PCR results were collected.

Results: 176 children were included. The median age was 1 year and 10 months old, IQR (6 months; 6 years old). The main indications for stool culture were bloody diarrhea and/or traveller’s diarrhea (74% of cases). The GI-PCR was positive in 70% of cases. Enteroaggregative Escherichia coli (22%), enteropathogenic E. coli (20%), Shigella/ enteroinvasive E. coli (15%) and Campylobacter (12%) were the most commonly detected pathogens. PCR-GI compared to stool culture detected respectively 21 versus 19 Campylobacter, 12 versus 10 Salmonella and 27 versus 13 Shigella/ enteroinvasive E. coli.

Results of the GI-PCR resulted in a change of medical care for 60 patients (34%) before stool culture results (28 initiations, 4 changes and 1 discontinuation of antibiotic therapy; 2 hospitalizations; 4 specific Clostridium difficile isolations; 36 decisions to call parents by phone; 7 additional test prescriptions and 3 test cancellations). The most prescribed antibiotic following the GI-PCR results was azithromycin (22 cases) for Shigella/ enteroinvasive E. coli (n=11), Campylobacter (n=6) and Shigatoxin-producing E. coli (n=5) infections. A cost analysis was carried out.

Conclusions: The GI-PCR has a significant impact on the prescription of antibiotics before the results of stool culture in children with bacterial suspected acute diarrhea. Further studies are needed to better assess the cost-effectiveness of this assay.

Impact of early carbapenemase notification on infection control management and antimicrobial stewardship

Leandro Perez1*, Cibele Magagnin2, Cícero Dias1, Gabriel Narvaez3

1Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil, 2Laboratório Weinmann, Porto Alegre, Brazil, 3Mãe de Deus Hospital, Porto Alegre, Brazil

Background: The worldwide spreading of carbapenemase-producing Enterobacterales (CPE) is a matter of concern due to the limited therapeutic options available. In severe infections, an early carbapenemase detection and notification is crucially important.

Materials/methods: During a one-year follow-up survey (August 2017 to August 2018), an observational study was performed in patients at a tertiary hospital from Porto Alegre, Brazil. Enterobacterales isolates recovered from any clinical specimen were submitted to blue-carba test (BCT) for phenotypic carbapenemase detection. Isolates were identified using Vitek 2 and antimicrobial susceptibility testing determined by disc-diffusion or broth microdilution. Carbapenemase characterization was carried out by phenotypic tests using specific inhibitors. The main objective was to determine the time from culturing sample until CPE notification in comparison with the time to report a final microbiology result (bacterial identification plus antimicrobial susceptibility testing), also, we aimed to evaluate the burden of this notification for the infection control measures and antimicrobial resistance predictability.

Results: A total of 300 CPE notifications were made, including 155 distinct patients. Average time was 1.19 days for CPE notification vs. 2.38 days for final report (Figure). KPC-producing Klebsiella pneumoniae was the most prevalent agent (97%; 291/300) and no other carbapenemase than KPC was detected in this period. Apart from that, antimicrobial resistance was observed as follow: meropenem 97.7%, gentamicin 77.6%, fosfomycin 31.6%, polymyxin 29%, amikacin 7.3% and tigecycline 5%. For the infection control point of view, 16% and 78% patients were previously clustered in standard and contact precaution, respectively, based on a BCT notification.

Conclusions: CPE notifications allow an earlier intervention (at least 24h). Additionally, the knowledge of the susceptibility profiles [and carbapenemase type] promoted an empirical adjustment with greater likelihood of adequacy, particularly by use of a combined therapy in cases of a BCT positive. An active communication between laboratory and clinical services is necessary to better explore this notification, significantly reducing the time for a first intervention.

Average time: 2.38

Average time: 1.19

Evaluation of the efficacy of vaccination programmes in HIV-positive patients against vaccine-preventable diseases

Ayse Uyan¹, Meltem Isikgöz Tasbakan², Tansu Yamazhan², Deniz Gökengin², Aysin Zeytinoglu³, Husnu Pullukcu²

¹Kastamonu State Hospital, Kastamonu, Turkey, ²Ege University, Faculty of Medicine; Department of Infectious Diseases and Clinical Microbiology, İzmir, Turkey, ³Ege University, Faculty of Medicine; Department of Microbiology, İzmir, Turkey

Background: Retrospective evaluation of before and after immune responses among the HIV positive patients by the vaccination against vaccine-preventable diseases was the main objective of our study.

Materials/methods: HIV positive patients who were admitted to outpatient or vaccination clinic between the dates of January 1st 2016 – October 8th 2018, were screened retrospectively in a tertiary-care educational hospital. HIV positive patients whose serological results were available before and after the vaccination against Pneumococcus, Hepatitis B and Hepatitis A, were recorded in the terms of demographic features, immune deficiency status and immune responses to vaccinations together with affecting factors. Statistical analysis was performed via Chi square test, p value less than 0,05 was considered significant.

Results: Total number of 128 patients were included in this study. Pre-vaccination and post vaccination immune status was evaluated in 36, 69 and 48 patients for pneumococcal vaccine, hepatitis A and B vaccine, respectively. There was statistically significant increase in pneumococcal antibody titers after the vaccination in HIV positive patients (p=0,000) (Graphic). There was no correlation between the CD4 titer with basal pneumococcal antibody titer and pneumococcal antibody titer after the vaccination. Antibody response rate via vaccination was 81.8% for the patients with CD4 < 350 cell/mm³ whereas 84% for the patients with CD4 ≥ 350 cell/mm³ (p=0,609). On the other hand, Hepatitis B antibody response rate via vaccination was 56,3% for the patients with CD4 < 350 cell/mm³ whereas 88,7% for the patients with CD4 ≥ 350 cell/mm³ which was found as statistically significant (p=0,008). There was no correlation between the HIV RNA levels and Hepatitis B vaccine response rate (p=0,350).

46 out of 48 (95%) Hepatitis A vaccinated HIV positive patients had the immunity after the vaccination.

Conclusions: Pneumococcal vaccination should be done for HIV positive patients according to our study results which shows the enough efficacy of vaccination in HIV positive patients. Although there was no relationship between the CD4 level and pneumococcal vaccine response in HIV positive patients, CD4 level was shown to affect the Hepatitis B vaccine response rate. Finally, vaccination should be performed according to guidelines for the immunocompromised patients.

Abstract 5458

Rapid diagnosis of seasonal influenza virus and cohorting of hospitalized patients on a ‘flu ward': a prospective analysis of outcomes

Brendan O’Kelly1, Adam Kelly2, Aileen Conway3, Sam Mcconkey2,3, Cora McNally3, Eoghan De Barra2,3

1The Mater Misericordiae University Hospital, Dublin, Ireland, 2RCSI, Dublin, Ireland, 3Beaumont Hospital, Dublin, Ireland

Background: The influenza season of 2017/2018 was burdensome which was in part due to high incidence of Influenza B compared to previous years. In-patient management of seasonal influenza patients is poorly described.

Materials/methods: A prospective cohort study with enrolment from Jan 1st to Feb 1st 2018. Laboratory Influenza PCR testing was performed on patients seen in the Emergency Department (ED) with possible influenza, with a turn-around time of 1 hour. Patients diagnosed with influenza in the ED were cohortated under an infectious disease (ID) firm or a general internal medicine (GIM) firm on a 35 bed influenza ward. At times of maximum capacity some patients were managed on other wards in single isolation rooms by other firms ‘non flu ward’.

Results: 91 patients were admitted to the influenza ward from ED (64 ID, 27 GIM), 38 of whom had influenza A. 64 (70.3%) received antibiotics, initial route was intravenous in 45 (49.5%). Patients managed by ID were more likely to be switched to oral antibiotics sooner median 3 vs 5 days p=0.049. Antibiotic duration was shorter for patients managed by the ID firm median 7 vs 9 days p=.016. LOS was shorter for patients managed by the ID firm on the flu ward vs ‘non flu ward’, median 5 vs 9 days p=.007. No significant difference was seen between ID and GIM LOS on the flu ward median 5 vs 7 days p=0.30.

Conclusions: Influenza patients managed by an infectious disease service on an influenza ward had a reduced length of intravenous (IV) and total antimicrobial use compared to a GIM service and had reduced LOS compared to the standard of care, ‘non flu ward’ influenza patients. HAI incidence was lowest on record for the hospital.

**Abstract 5459**

**Candidemia management: can we do better?**

Jorge Calderón*, Jesús Herraiz Jiménez1, Antonio Ramos Martínez1, Elena Muñez Rubio1, Alejandro Callejas1, A. Díaz De Santiago1, Isabel Sanchez Romero1, Marcos Lopez Dosíl1,2, Ana Fernandez-Cruz1

1Puerta de Hierro, Infectious Diseases Unit, Madrid, Spain, 2Puerta de Hierro, Microbiology, Madrid, Spain

**Background:** Recently, several scores to quantify candidemia management according to guidelines (EQUAL, GEMICOMED, Valerio) have been developed. We aim to evaluate impact of outcome of candidemia guidelines adherence using these scores and identify improvement opportunities.

**Materials/methods:** Our institution is a 613-bed tertiary teaching hospital in Madrid. We recorded retrospectively epidemiological, clinical and microbiological data from candidemia episodes (January 2017-December 2018). We analyzed candidemia management according to EQUAL, GEMICOMED and Valerio scores, and correlated those to outcome.

**Results:** Fifty-four first episodes of candidemia were retrieved during the study period. Five patients who died < 48h after bloodcultures were not included. Evaluable patients 30-d mortality was 18.4%.

Median adherence to guidelines according to EQUAL score [maximal score 22 if catheter, 19 if no catheter] was 17 (IQR 15-19), and median adherence to GEMICOMED was 86% (IQR 72.5-100%). Least followed recommendations were: daily bloodculture (12.2%), initial echinocandin (57.1%), adjustment to MIC (75.5%), catheter withdrawal <24h (82.1%) [EQUAL]; initial echinocandin in septic or neutropenic patients (71.4% and 37.5%, respectively), change of antifungal class (47%) [GEMICOMED]. Adequacy of antifungal prescription was 8.5/10 (SD 1.9); areas of improvement were: antifungal selection (30.6%), adjustment to antifungigram (26.5%), change to oral route (26.2%) and duration (15.9%) [Valerio].

Patients who died had lower EQUAL score and adherence to GEMICOMED (15 vs 17.1, p=0.041, and 67.7% vs 86.2%, p=0.002, respectively). A cut-off of >=17 for EQUAL, or compliance of <70% of GEMICOMED were associated with inferior 30-d mortality (71% vs 33.3%, p=0.028, and 7.9% vs 54.5%, p=0.002, respectively).

Infectious Diseases Unit [IDU] evaluated 65.3% of patients in 3d (IQR 1-8). IDU-evaluated cases obtained a better EQUAL score (>17) [82.1% vs 42.9%, p=0.006] and had less 30-d mortality (9.4% vs 35.3%, p=0.049)

**Conclusions:** Adherence to guidelines for candidemia management evaluated according to EQUAL and GEMICOMED was associated with a decreased 30-d mortality. There is room for improvement in initial antifungal therapy with echinocandins in septic patients, early catheter withdrawal and antifungal adjustment according to MIC. Adequacy of antifungal prescription can be improved regarding antifungal selection, adjustment to MIC, duration and switch to oral. IDU evaluation improves guideline adherence and mortality.

Abstract 5461

**Epidemiology and outcomes of *Clostridioides difficile* infections among allogeneic haematopoietic cell transplant recipients in Switzerland: 2009-2019**

Silvio Ragozzino¹, Sarah Tschudin-Sutter², Jakob Passweg³, Nicolas Mueller¹, Antonia Müller¹, Dionysios Neofytos³, Christian Van Delden², Stavroula Masouridi Levrat⁴, Yves Chalandon⁵, Nina Khanna*¹

¹Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, Basel, Switzerland, ²Division of Hematology, University Hospital Basel, Basel, Switzerland, ³Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland, ⁴Department of Medical Oncology and Hematology, University Hospital Zurich, Zurich, Switzerland, ⁵Transplant Infectious Diseases Unit, University Hospitals Geneva, Geneva, Switzerland, ⁶Division of Hematology, University Hospitals Geneva, Geneva, Switzerland

**Background:** *Clostridioides difficile* infection (CDI) represents the leading cause of healthcare-associated diarrhea. Patients undergoing allogeneic hematopoietic cell transplantation (allo-HCT) are a highly susceptible population. In contrast to international treatment recommendations, metronidazole is considered as first line treatment for CDI in Switzerland. We therefore assessed outcomes of CDI among allo-HCT recipients in Switzerland.

**Materials/methods:** Multicenter retrospective cohort study of adult patients with allo-HCT included in the Swiss Transplant Cohort Study (STCS) from 2009-2018. The STCS includes all Swiss centers (University Hospitals of Basel, Zürich, and Geneva) performing allo-HCT. Clinical and laboratory data of all transplant recipients, including CDI episodes and follow-up information in the post-transplant period, are prospectively collected. CDI severity was classified using the Zar score. Preliminary results are presented using descriptive statistics.

**Results:** Overall, 155 episodes of CDI occurred in 134 patients. CDI incidence was 10% (range 5-16% according to center). Median age was 54 years (interquartile range 43-63) and 60% were male. The most frequent underlying hematological diseases were acute myeloid leukemia (44%), acute lymphoid leukemia (17%), and myelodysplastic syndrome (12%). CDI was healthcare-associated in 66% of the cases and was classified as severe in 24 patients (15%). Severe complications occurred in 6 patients (4%): ileus 3, hypotension/shock 2, toxic megacolon 1. Seventy-nine percent of all patients were exposed to antibiotics in the 3 months before CDI diagnosis; 80% were under therapy with proton-pump inhibitors. Thirty-nine patients (25%) were neutropenic at the time of CDI diagnosis. Other predisposing factors were the receipt of immunosuppressant therapy (73%) and/or chemotherapy (37%). Thirty-six patients (23%) suffered concomitantly from gastrointestinal GVHD. Ninety-eight patients (63%) were treated with oral metronidazole, 38 (25%) were managed with a regimen that included oral vancomycin. At least one recurrence occurred in 27 (17%) patients. Overall 30-day mortality was 5% and 1-year mortality 29%.

**Conclusions:** The vast majority of CDI episodes were classified as mild and the most frequently administered therapy was metronidazole. The recurrence rate was 17%, similar to that reported in other populations. These data support further analyses aiming to identify patients likely to benefit most from novel treatment options targeting recurrent CDI.

Abstract 5464

**Impact of artificial intelligence on time to result in culture-based MRSA screening**

Angela Nowag\(^1\), Nathalie Jazmati\(^1\), Steven Giglio\(^3\), Sarah Wirth\(^1\), Barbara Pohl\(^1\), Xenia Quante\(^3\), Hilmar Wisplinghoff\(^*^1,2,5\)

\(^1\)Wisplinghoff Laboratories, Cologne, Germany, \(^2\)University Hospital of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, \(^3\)Clever Culture Systems, Bach, Switzerland, \(^4\)LBT Innovations, Adelaide, Australia, \(^5\)University Witten/Herdecke, Institute for Virology and Medical Microbiology, Witten, Germany

**Background:** Introduction of artificial intelligence (AI) has shown to be a way to increase reliability and throughput in culture based MRSA-screening. However, time to result remains a problem in culture-based methods due to the time the organisms need to grow. This study was conducted to evaluate the possibilities of decreasing time to result using AI-based classification of solid culture media.

**Materials/methods:** The APAS\(^\text{®}\) Independence in combination with MRSA Analysis Module was evaluated reading time-series (2-24 hours) of dedicated samples (n= 50). MRSA Screening was performed using the chromID\(^\text{®}\) MRSA (bioMerieux). Samples were processed using the AutoPlak\(^\text{®}\) (Beckman Coulter) and evaluated every 1-2 hours up to 24 hours of incubation. Results of AI-based classification were compared to conventional plate reading by experienced medical technicians and microbiologists.

**Results:** There was high agreement between AI-based and conventional reading. Sensitivity and negative predictive (NPV) value estimates at 24 hours were both 1.0, increasing from 0.65 (NPV, 0.45) at 2 hours to 0.90 (NPV, 0.75) at 7 hours. Specificity varied between reads, increasing from 0.75 at 2 hours to 0.87 at 7 hours. Performance did not vary between individual runs.

**Conclusions:** In this study, sensitivity of the AI-based APAS\(^\text{®}\) Independence system at 2-7 hours was comparable to conventional reading at 18-24 hours suggesting that the time to result can be considerably shortened when AI-based systems are used.

Faecal calprotectin could help distinguish Clostridioides difficile infection from C. difficile colonisation.

Cecilia Suárez Carantoña*1, Luis Adrián Viteri Noel1, Jorge Fernández Sedeño1, Argeme Rodriguez Torres1, Daniel Mora Pimentel1, Fuensisla Martin Jusdado1, Sergio García-Fernández1, Rosa Escudero Sánchez1, Javier Cobo Reinoso1

1Hospital Ramón y Cajal, Madrid, Spain

Abstract 5469

Background: Distinguishing among colonized and infected patients with Clostridioides difficile (CD) is not always an easy task. The availability of NAAT has increased the overdiagnosis and overtreatment. Patients with CD infection (CDI) show higher faecal calprotectin (fCP) concentrations than patients without CDI. Also, patients with severe CDI show higher fCP than patients with mild CDI. Nevertheless, the role of fCP in distinguishing CDI from CD colonization has not been addressed.

Materials/methods: Prospective cohort study. Patients with IBD were excluded. An infectious diseases specialist (IDS), blind to fCP, evaluated and gave recommendations to all cases with toxigenic CD detection from January to June 2019. Patients were classified in group I (presumed CDI) when anti-CD treatment was prescribed without doubts; group II (doubtful CDI) when either the IDP had doubts but gave anti-CD antibiotics or recommended not to treat, but the responsible physician decided to treat; and group III (CD colonization) when the IDP recommended not to treat and the patient did not receive anti-CD treatment during the next month. Original faecal samples were frozen for ulterior Calprotectin ELISA Assay. fCP were compared among group I and III by Mann-Whitney test. Sensitivity, specificity, likelihood ratios and ROC curve were calculated.

Results: 114 patients were diagnosed having toxigenic CD during the study period. Sixty-nine (52.3% women; mean age 68.8 years) were evaluated. Thirty-seven (53.3%) presented positive direct toxin test and 32 (46.7%) presented toxin test negative but NAAT positive for toxigenic CD. Median fCP concentrations was 382.7 μg/g, IQR (126.6-833.9) in group I (44 cases), 126.5 μg/g, IQR (57.4-273.9) in group II (14 cases) and 34.3 μg/g, IQR (20.0-115.4) in group III (11 cases); (p<0.001 for comparison among group I and III). ROC curve value was 0.855. With a cut off of 100 μg/g, sensitivity was 81.8%, specificity 72.7% and positive and negative likelihood ratios were 3 and 0.25, respectively. Fifteen cases in group I and II had fCP levels below 100 μg/g.

Conclusions: fCP could be useful in distinguishing patients that do not need anti-CD antibiotics. If results are confirmed, interventional studies should be performed to demonstrate the utility of fCP in the clinical decision process.

Abstract 5470

Catheter-related and non-catheter-related bloodstream infections in oncological patients

Mariola Blanco1, Cristina Traseira1, Antonio Ramos Martínez1, Isabel Sánchez-Romero1, Elena Muñez Rubio1, Alejandro Callejas3, Juan Cristóbal Sánchez1, Miriam Méndez1, Lourdes Gutiérrez1, Beatriz Núñez1, Mariano Provencio1, Ana Fernandez-Cruz1

1Hospital Universitario Puerta de Hierro-Majadahonda, Majadahonda (Madrid), Spain

Background: Information regarding catheter-related bacteremia (CRB) in oncological patients is scarce. We studied retrospectively all admitted oncological patients who presented an episode of bloodstream infection (BSI) and compared CRB with non-CRB.

Materials/methods: Our institution is a 613-bed tertiary teaching hospital in Madrid, with a 20-bed Oncology ward. We recorded epidemiological, clinical and microbiological data from all BSI from January 2015 to December 2018. We considered CRB both according to IDSA definition and to CDC definition (CLABSI).

Results: We recorded 124 BSI in 107 patients (33 per 1000 oncological admissions) during the study period.

BSI was healthcare-associated in 42.7% and hospital-acquired in 46.8%. Catheter was the main bacteremia source (29%; 46% among 77 patients with central venous line). Gram negative microorganisms were the most prevalent (34.7%), followed by Staphylococci (29.8%), Enterococci/Streptococci 11.3% and anaerobes (0.8%). Polymicrobial BSI accounted for 21.7% episodes. Among 155 isolated microorganisms, 8.4% were MDR. Complications occurred in 5.6% (arthritis 3, endocarditis 2, thrombophlebitis 1, liver abscess 1). ICU admission was required in 4%. In-hospital mortality was 12%, attributable mortality (according to treating physician) and 10-day mortality were both 4%.

When patients with CRB and non-CRB episodes were compared, the independent differential characteristics were as follows: in CRB patients, the most prevalent microorganisms were gram positive (77.8%, vs 38.6%, OR 5.2, p =0.001), persistence of BSI was more common (33.3% vs 11.4%, OR 3.2, p =0.032) and so was recurrence (13.9% vs 1.1%, 16.4, p=0.022).

There were not differences according to sex, age, place of acquisition, kind of underlying neoplasia or tumor stage, neutropenia at the moment of the infection, admission to ICU, empirical therapy, infectious complications or presence of antimicrobial resistance.

Conclusions: The main source of BSI in admitted oncological patients in our centre is catheter, and the most frequent microorganisms involved are gram positives. Furthermore, patients with CRB present persistent and recurrent bacteremia more often. Bacteremia attributable mortality in our study was 4%. To prevent bacteremia and its complications, catheter management should be optimized.

Abstract 5472

Therapeutic innovation in bone and joint infections: evaluation of the activity of exebacase (CF-301 lysin) on clinical strains belonging to Staphylococcus epidermidis species

Aubin Souche*1,2, Camille Kolenda1,2, Céline Dupieux1,2,3, Raymond Schuch4, Tristan Ferry2,5,6, Frédéric Laurent1,2,3,6, Jérome Josse6

1Institute for Infectious Agents - Croix Rousse Hospital, Hospices Civils de Lyon, Lyon, France, 2International Centre for Infectiology Research - Team Staphylococcal pathogenesis, INSERM U1111 - CNRS UMR5308 - ENS Lyon - University of Lyon, Lyon, France, 3French National Reference Centre for Staphylococci - Croix Rousse hospital, Hospices Civils de Lyon, Lyon, France, 4ContraFect Corporation, Yonkers, United States, 5Infectious Diseases service - Croix Rousse hospital, Hospices Civils de Lyon, Lyon, France, 6Regional Reference Centre for Management of Complex Bone and Joint Infections (CRIOAC Lyon), Hospices Civils de Lyon, Lyon, France

Background: Staphylococcus epidermidis is one of the main pathogens responsible for bone and joint infections (BJI) and is more prevalent in case of prosthetic material infections. Although not highly virulent, Staphylococcus epidermidis can be involved in chronic infections because of its ability to form biofilm, which protects bacteria from antibiotics and host immune cells and plays a key role in therapeutic failures. Moreover, the prevalence of antimicrobial resistance in Staphylococcus epidermidis strains is worrisome. In this context, the development of additional or alternative therapies for antibiotics targeting the biofilm is a priority.

Materials/methods: The objective of this study was to evaluate, in vitro, the activity of phage lysin exebacase on biofilms formed by a panel (n=19) of Staphylococcus epidermidis clinical strains responsible for BJI. We determined the remaining viable inoculum inside biofilm (plating counting) and the biomass (crystal violet staining) after 24h of exposition to different concentrations of exebacase The effect of exebacase was compared to that of antibiotics currently used to treat BJI at different concentrations (rifampin, vancomycin, daptomycin) and we assessed if synergistic effects could be observed when combining exebacase with these antibiotics.

Results: Our results demonstrate that exebacase had a significant anti-biomass effect against Staphylococcus epidermidis biofilms from the concentration of 0.5 mg/L of exebacase, with a decrease in biomass of up to 90% with the concentration of 150 mg/L. A bactericidal effect on biofilm was also highlighted from the concentration of 50 mg/L, however this effect was heterogeneous among the tested strains. Synergistic effects for the association with rifampin and daptomycin were observed using low exebacase concentrations (5mg/L).

Conclusions: Exebacase appears as a promising adjuvant therapy for rifampin and daptomycin in the context of BJI. Further studies are needed to understand the mechanism of action on Staphylococcus epidermidis biofilm and the heterogeneity of strain behavior.

Abstract 5474

Infectious complications during anti-CD19 targeted chimeric antigen T cell receptors (CAR-T) immunotherapy in relapsed/refractory aggressive B cell non-Hodgkin lymphomas (NHL): observational retrospective study in one centre

Roberta Di Blasi*, Sylvie Chevret¹, Jerome Paillassa¹, Blandine Denis¹, Lorea Aguinaga¹, Sophie Bernard¹, Hannah Moatti¹, Matthieu Lafaurie³, Elie Azoulay¹, Michael Darmon⁴, Eugenio Galli¹, Catherine Thieblemont¹

Background: Aim of present study is to describe infectious complications (IC) between day 0-90 in patients receiving CAR-T treatment for NHL.

Materials/methods: We retrospectively collected data about IC in 52 patients undergoing CAR-T in Saint-Louis Hospital from June 18th, 2018 until July 31st, 2019. Patients completed at least day 90 follow up.

Results: Median age was 54 y.o. (22-76). Male patients were 32 (61%). Most patients (42-80%) received CAR-T for DLBCL. The mean number of previous lines of treatment was 4 (range 2-9). 14 patients underwent auto-SCT (27%), and 2 allo-SCT (4%). High-intensity bridging chemo-immunotherapy was administered to most patients (33;63%). 20 patients presented hypogammaglobulinemia at admission (≤ 4g/l, 38%, 1.7-9.3). Tisagenlecleucel was used in 28 patients (54%) while 24 (46%) received Axicabtagene-ciloleucel. At reinjection, median lymphocytes count was 0.36G/L (0-1.3). Anti-Pneumocystis prophylaxis was administered in 50 patients (96%), antiviral in 49 patients (94%). One patient received antibacterial prophylaxis by azithromycin and antifungal prophylaxis was not prescribed. 87% of patients presented fever and mean onset was day 3 (1-13). IC occurred in 17 patients. 92% presented neutropenia, severe (≤0.5G/L) in 90% of cases, with mean duration of 11 days (1-180). 26 IC were microbiologically documented. During d0-30, 17 infections occurred in 14 patients (9 bacterial, 8 viral); during d31-60, 6 infections in 5 patients [2 bacterial, 4 viral]; during d61-90, 4 infections in 2 patients [1 bacterial, 2 viral, 1 fungal]. Most patients received antimicrobial empiric treatment (44/S2,85%). Hospitalization in intensive care unit was necessary for 21/52 patients (40%). Most episodes occurred at d0-30, hence we evaluated outcome of infection at d30 from CAR-T injection. Only 3/14 patients presented poor outcome. In 2 patients death occurred because of haematologic disease progression with infection, 1 patient had positive CMV at D30 while receiving Foscarnet. No mortality was attributable to IC alone. Univariate analyses of infection selected age (p=0.009), PS≥2 (p=0.02), LDH (p=0.035), allo-SCT (p=0.05), use of GCSF (p=0.03) as associated with the outcome.

Conclusions: Febrile neutropenia is frequent during CAR T-cell treatment. IC are usual in the first 30 days and bacterial and viral infections are most frequent. IC appear mild and not fatal.

### In vitro activity of imipenem-relebactam plus aztreonam against metallo-β-lactamase producing Pseudomonas aeruginosa

Nicholas O'Donnell1, Vibert Putra1, Gina Belfiore1, Brittney Maring1, Katherine Young1, Thomas Lodise1

1Albany College of Pharmacy and Health Sciences, Albany, United States, 2Merck Inc., Kenilworth, United States

**Background:** There are limited treatment options for MBL-producing *Pseudomonas aeruginosa* infections. IMI-REL plus ATM may be an option for these organisms.

**Materials/methods:** Ten OprD deficient *P. aeruginosa* isolates (3 parent strains; 7 MBL-producers) were evaluated using checkerboard methodology and Fractional Inhibitory Concentration Index (FICI) (Table 1). Isolates exhibiting synergy in checkerboard studies (FICI ≤0.5) were evaluated using 24-hour static concentration time-kill. Bacteria in late log-phase growth were diluted to 1x10⁶ cfu/mL and incubated at 37°C for 24 hours. Samples were drawn at 0, 2, 4, and 24 hours. Physiologic \( f_{\text{Cmax}} \), \( f_{\text{Cmin}} \) and \( f_{\text{Css}} \) of IMI (26.7, 5.6, 0.5 mg/L), REL (13.1, 4, 0.8 mg/L) and ATM (62, 29, 8 mg/L) were used for time-kill studies. Synergy in time-kill studies was defined as >2 log₁₀ cfu/mL reduction compared to the most active individual agent.

**Results:** Synergy was observed in five isolates in checkerboard studies, including 3/7 MBL-producing isolates. No antagonism was observed. Isolates which were OprD(-) and harbored inducible AmpC did not show synergy as defined by FICI, however individual agent MICs were significantly reduced with the combination. In time-kill studies, synergy was observed at \( f_{\text{Cmax}} \) concentrations for CL5701, MB10480, MB10620. The combination improved bacterial killing at \( f_{\text{Cmin}} \) concentrations for MB10480 and \( f_{\text{Css}} \) concentrations for CL5702 (-1.69 and -1.51 log₁₀ cfu/mL reductions, respectively). No synergy was observed for MB10481; bacterial killing was driven by ATM.

**Conclusions:** IMI-REL plus ATM appears to exhibit synergy for some MBL-producing *P. aeruginosa* at physiologic concentrations. Further study of the effect of dynamic concentrations is needed to fully understand the utility of this combination.

**Table 1. Isolate Characteristics and Susceptibility**

| Isolate | IMI-REL MIC (mg/L) | ATM MIC (mg/L) | AmpC Status | MBL | Combination MIC (IMI-REL|ATM) | FICI |

Genetic characterisation of virulence factors of non-O1 non-O139 Vibrio cholerae strains from clinical and environmental origin isolated in Chile between 1992 and 2018

Cindia Tong1, Camila Sanhueza2, Lorena Porte1, Jeannette Dabanch3, Isabel Briceño5, Mónica Lafourcade6, Francisco Silva4, Loriana Castillo7, Gonzalo Osorio2, Maria Ulloa*8
1Universidad, Universidad de Chile, Santiago, Chile, 2Universidad, Universidad de Chile, Santiago, Chile, 3Hospital/Universidad, Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana, Santiago, Chile, 4Hospital, Hospital Clínico Universidad de Chile. Santiago, Chile, Santiago, Chile, 5Hospital, Hospital Naval Almirante Nef, Valparaiso, Chile, Santiago, Chile, 6Hospital, Clínica Santa María. Santiago, Chile, Santiago, Chile, 7Hospital, Hospital La Florida, La Florida Santiago, Chile, Santiago, Chile, 8Universidad, Universidad de Chile, Santiago, Chile

Background: Non-O1 non-O139 V. cholerae generally lack cholera toxin (Ctx) and toxin-coregulated pilus (Tcp). However, some non-O1 non-O139 strains are capable of causing human infections due to virulence factors such as: thermostable toxins, hemolsins, pore-forming toxin and type III secretion system [found in a genomic island homologous to Vibrio parahaemolyticus VPAI-7]. Our objective was to genetically characterize virulence factors of Chilean clinical and environmental strains of non-O1 non-O139 V. cholerae strains isolated between 1992 and 2018.

Materials/methods: 58 strains were included; 30 from environmental origin (provided by the National Public Health Institute, I.S.P.) and 28 from diarrheal episodes. End-point PCR was used to detect the following virulence genes in all strains: cholera toxin (ctxA); colonization factor (tcpA); hemolysin (hlyA); pore-forming protein (rtxA); regulatory protein (toxR) [a prominent transcriptional regulator of virulence genes]; ocludens zonule toxin (zot); cholix toxin (chxA); accessory choleric enterotoxin (ace); mannose sensitive type IV hemagglutinin (mshA); F protein (vopF) [important in intestinal colonization]; type secretion system proteins III or SST3-2 (vspD, vscN2, vscV2, vscC2) and gene segments homologous to pathogenicity island VPaI-7, previously described in Chilean strains of non-O1 non-O139 V. cholerae.

Results: ctxA, tcpA and ace virulence genes were not detected in our group of strains. In contrast, hlyA and rtxA genes were present in all strains. The mshA and chxA genes were found in different proportions in clinical and environmental strains; mshA: 14.29% vs. 23.33% and chxA: 14.29% vs. 10%, respectively. The zot gene was detected only in environmental strains with a frequency of 10%. The 4 SST3-2 genes were more frequently found in clinical strains (78.57% vs. 36.62%; p = 0.0177), as well as toxR (92.6% vs. 76.6%) and vopF (82.14% vs. 50%; p = 0.0355). Finally, homologous segments of pathogenicity island VPaI-7 [5’, middle segment and 3’] were found in 52.14% of clinical strains and 40% of environmental strains.

Conclusions: Higher prevalence of SST3-2, toxR and vopF in clinical strains, as well as homologous segments [5’, middle segment and 3’] of pathogenicity island VPaI-7, suggests a role of these virulence factors in human pathogenicity.

Neisseria gonorrhoeae transcriptome analysis: profiling molecular determinants of resistance

Hanalydia De Melo Machado¹, Guilherme Toledo-Silva², Jessica Motta Martins³, Marcos Andre Schörner³, Lisléia Golfetto⁴, Ricardo Mazzon¹, Maria Luiza Bazzo*³

¹Federal University of Santa Catarina Florianópolis Campus Trindade, Programa de Pós Graduação em Biotecnologia e Biociências, Florianópolis, Brazil, ²Federal University of Santa Catarina Florianópolis Campus Trindade, Programa de Pós-Graduação em Biologia Celular e Desenvolvimento, Florianópolis, Brazil, ³Federal University of Santa Catarina Florianópolis Campus Trindade, Programa de Pós-Graduação em Farmácia, Florianópolis, Brazil, ⁴Federal University of Santa Catarina Florianópolis Campus Trindade, Federal University Hospital, Florianópolis, Brazil

Abstract third-party references: Department of Diseases of Chronic Conditions and STI/MoH/Brazil

Background: Neisseria gonorrhoeae (NG) is the etiological agent of gonorrhea, a sexually transmitted infection that affects about 78 million people per year. Since the implementation of the treatment, gonococcus rapidly developed resistance mechanisms to the multiple classes of antimicrobials used to treat the infection. Nowadays, ceftriaxone (CRO) is the drug used as a first-line treatment recommended by the World Health Organization (WHO), although resistance to this drug was already described. Owing to the possibility of the gonococcal infection becoming untreatable, there is a need to understand the molecular and phenotypic mechanisms related to antimicrobial resistance mainly to ceftriaxone. In this study, we sequenced some genes and performed RNA sequencing to evaluate resistance mechanisms.

Materials/methods: To perform the transcriptome analysis, the NG isolate [MIC CRO 0.125mg/mL] was cultured in both GC medium plates and GC medium plates with CRO subinhibitory concentration [0.06mg/mL]. Illumina RNA sequencing was performed (Novaseq 100bp paired-end) in biological triplicates. RNAseq data analysis was performed in Rockhopper system. The mutations analysis corresponded to the sequencing of the isolate’s mtrR, porB, penA and ponA genes and analysis of mutation patterns were performed on the NGSTAR platform.

Results: The patterns for each gene for the isolate were: mtrR: -35A del, ponA: L42P, penA: mosaic, porB: G120K/A121D. The SNPs of the respective genes revealed an identical pattern of mutation in the clinical isolate [CRO MIC 0.125 mg/mL] with resistant strains [MIC CRO ≥0.250 mg/mL], leading to the absence of genotypic differentiation between strains with unequal susceptibility to CRO. Analysis of RNAseq data presented 115 differentially expressed genes showing fold-change (FC) > 1.68 and q-value <0.05, of these 53 upregulated and 62 downregulated in the condition of presence of CRO. Of those genes, only 14 have a defined molecular function, 46 are predicted RNAs [no coding RNAs], 28 are hypothetical and 26 had their function automatically annotated.

Conclusions: These results show a major lack of knowing about NG phenotypic status and how NG cell deal with CRO, calling for deep analysis of NG transcriptome. The great proportion of predicted RNAs suggests that no coding RNAs may regulate CRO resistance mechanisms.

**Molecular characterisation of Fusarium oxysporum species complex isolates from the United States and susceptibility profile of the investigational antifungal olorofim**

Hamid Badali*1, Connie Gibas1, Hoja Park Patterson1, Carmita Sanders1, James Mele1, Hongxin Fan1, Nathan Wiederhold1

1University Texas Health Science Center, San Antonio, United States

**Background:** Fusariosis is one of the most serious non-Aspergillus mold infections among immunocompromised patients, and members of the *Fusarium oxysporum* species complex (FOSC) are major etiologic agents of this opportunistic infection. Recently, members of the FOSC have been distinguished into more than 20 phylogenetic species. Our objective was to evaluate the species distribution and antifungal susceptibility profiles of FOSC isolates in the U.S, including the investigational agent olorofim.

**Materials/methods:** 49 clinical FOSC isolates received by the Fungus Testing Laboratory at the UT Health Science Center San Antonio for identification and antifungal susceptibility testing were included. Identification was performed by DNA sequencing and phylogenetic analysis of translation elongation factor 1-alpha (TEF1α) and RNA polymerase II second largest subunit (RPB2). Antifungal susceptibility testing was performed by CLSI M38 broth microdilution. MICs for olorofim were determined after 48 hours of incubation at the 50% and 100% inhibition endpoints, while those of amphotericin B, posaconazole, voriconazole, itraconazole, and isavuconazole were determined at 100% inhibition.

**Results:** Of the 49 isolates, 40 were identified to the species level, including 20 *F. veterinarium*, 12 *F. nirenbergiae*, 5 *F. fabacearum*, 2 *F. triseptatum*, and 1 *F. cugenangense*. Nine isolates were unnamed species. Olorofim demonstrated good in vitro activity against FOSC isolates (MIC range 0.03 - 0.5 and 0.06 - >4 mg/L at 50% and 100% inhibition, respectively). Of the antifungals, olorofim also had the lowest GM MIC values (0.107 and 0.559 mg/L at 50% and 100% inhibition) followed by amphotericin B (1.59 mg/L), posaconazole (6.11 mg/L), voriconazole (6.94 mg/L), and itraconazole and isavuconazole (>16 mg/L for each). Interestingly, olorofim GM MICs were higher against *F. nirenbergiae* (0.177 and 1.19 mg/L at 50% and 100% inhibition) compared to *F. veterinarium* (0.081 and 0.391 mg/L; p < 0.01).

**Conclusions:** Olorofim demonstrated potent in vitro activity against FOSC isolates, and this activity was maintained regardless of the specific species. Interestingly, differences in olorofim activity was observed between the two most prevalent species, *F. veterinarium* and *F. nirenbergiae*. Further studies are needed to determine how these findings may translate into in vivo efficacy.

Abstract 5484

Real-world multi-centre experience of meropenem-vaborbactam in patients treated for serious Gram-negative bacterial infections

Sara Alosaimy, Abdalhamid Lagnf, Sarah Jorgensen, Taylor Morrisette*, Travis Carslon, Jinhee Jo, Kevin Garey, David Allen, Veena Venugopalan, Susan Davis, Michael Veve, Kimberly Claeyss, Vasilios Athans, Stephan Saw, Jessica Ortwine, Christine Yost, Ryan Mynatt, Jason Pogue, Michael J. Rybak

1Anti-Infective Research Laboratory, Department of Pharmacy Practice, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University, Detroit, United States, 2Fred Wilson School of Pharmacy, One University Parkway, Highpoint, United States, 3College of Pharmacy, University of Houston, Houston, United States, 4University of Houston College of Pharmacy, Houston, United States, 5Inova Fairfax Hospital, Falls Church, United States, 6College of Pharmacy, University of Florida, Gainesville, United States, 7Department of Pharmacy, Henry Ford Hospital, Detroit, United States, 8College of Pharmacy, University of Tennessee, Knoxville, United States, 9School of Pharmacy, University of Maryland, Baltimore, United States, 10Hospital of the University of Pennsylvania, Philadelphia, United States, 11Parkland Health and Hospital System, Dallas, United States, 12Beaumont Hospital, Royal Oak, United States, 13University of Kentucky Healthcare, Lexington, United States, 14University of Michigan, Ann Arbor, United States

Background: Gram-negative bacteria (GNB) resistance, particularly carbapenem-resistant Enterobacteriaceae (CRE), is a critical challenge in infectious diseases. The combination of meropenem with vaborbactam (MVB) received Food and Drug Administration (FDA) approval for the treatment of complicated urinary tract infections (cUTI) and acute pyelonephritis (AP) caused by susceptible organisms in August 2017. MVB combines a carbapenem with a novel beta-lactamase inhibitor and has potent in vitro activity against CRE. Unfortunately, evidence regarding MVB use in non-FDA approved indications is limited. We aim to evaluate the efficacy and safety of MVB when used to treat patients with serious GNB infections.

Materials/methods: Multi-center, retrospective cohort study from October 2017 to October 2019. We included adult patients treated with MVB for ≥ 72 hours. CRE was defined according to the Centers for Disease Control and Prevention. Clinical success was defined as survival, absence of recurrence at 30 days following the onset of infection and resolution of signs and symptoms of infection. Susceptibility was defined per Clinical and Laboratory Standards Institute minimum inhibitory concentrations (MIC) interpretive criteria.

Results: A total of 75 patients were included from over 10 institutions across the United States: median age 55 (IQR:37-66) years, 65% were male, 45% were Caucasian. Median APACHE II and Charlson Comorbidity index scores were 16 (IQR:10-24) and 4 (IQR:2-6), respectively. Common sources of infection were respiratory (33%), intra-abdominal (20%), urinary (16%), skin and soft tissue (11%) and primary bacteremia (8%). CRE were the most common pathogens isolated (81%). Specifically, Klebsiella pneumoniae (56%) followed by Enterobacter cloacae (20%). MVB MICs of 0.06 (range;0.02-4.00) mcg/mL and 0.38 (range;0.05-6.00) mcg/mL, respectively. MVB was started within 90 (IQR:25-142) hours and median therapy duration was 12 (IQR:6-15) days. 31% had combination therapy ≥ 48 hours, primarily minocycline and amikacin. Clinical success was achieved in 72%; with 30-day survival of 88%. Three patients experienced a probable MVB-adverse event; 2 nephrotoxicity and 1 skin reaction.

Conclusions: MVB demonstrated a high clinical success rate and appears to be well-tolerated in patients with GNB infections. Studies with longer follow-up and larger sample sizes are required to assess the role of MVB compared to other anti-GNB agents.

Abstract 5486

End-to-end Workflow for HIV-1 drug resistance genotyping of protease and reverse transcriptase in major group-M subtypes

Karen Clyde1, Charmaine Hinahon2, Xingwang Fang2, Emily Zeringer1, Luming Ou He2, Angie Cheng2, Jorge Fonseca1, Joshua Trotta1, Edgar Schreiber*1

1Thermo Fisher Scientific, South San Francisco, United States, 2Thermo Fisher Scientific, Austin TX, United States

Background: To meet the UNAIDS 90-90-90 goal, low-cost, robust drug resistance (DR) genotyping solutions for HIV are urgently needed. Moreover, the ability to extract viral RNA from Dried Blood Spots (DBS) as well as plasma provides greater flexibility for sample collection in low and middle-income countries (LMICs). Most on-market DR genotyping solutions demonstrate variable performance on non-B subtypes, and existing workflows for DBS are expensive and/or insensitive. We have created an end-to-end DR genotyping workflow that includes RNA extraction from either plasma or DBS using a modified version of the MagMAX Viral/Pathogen Nucleic Acid Isolation Kit followed by sequencing using the HIV-1 Genotyping Kit and data processing using secondary analysis software.

Materials/methods: DBS research samples containing various subtypes at varying viral loads (VLs) were extracted using the new MagMAX workflow or the bioMérieux EasyMAG system, and the samples were subjected to amplification using the HIV-1 Genotyping Kit.

Results: Both the MagMAX and EasyMAG systems successfully extracted amplifiable viral RNA across all VLs tested to <2,000 copies/mL. The HIV-1 Genotyping Kit, originally developed by the U.S. Centers for Disease Control and Prevention, achieved a Limit of Detection of 1,000 copies/mL from plasma samples and 2,000 copies/mL from DBS on subtypes A, B, C and D and CRF01 AE and CRF02 AG. DR mutation detection sensitivity was 98.1% for plasma and 98.4% for DBS, and specificity was 99.6% for both sample types at a VL of 10,000 copies/mL.

Conclusions: Overall, the DBS sample prep protocol, genotyping kit and analysis software provide lower-cost but robust alternatives to existing on-market solutions for HIV-1 drug resistance research and are specifically designed for the needs of LMICs.

The role of genomics in typhoid control: sentinel traveller surveillance, in-host evolution and transmission dynamics

Zoe Anne Dyson*, Veeraraghavan Balaji, Firdausi Qadri, Tim Dallman, Andrew Pollard, Gordon Dougan, Kathryn E. Holt

1Monash University, Melbourne, Australia, 2University of Cambridge, Cambridge, United Kingdom, 3Christian Medical College, Vellore, India, 4International Centre for Diarrhoeal Disease and Research, Dhaka, Bangladesh, 5Public Health England, London, United Kingdom, 6University of Oxford, Oxford, United Kingdom, 7London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Salmonella Typhi is the causative agent of typhoid fever, a systemic human infection with a burden exceeding 10 million cases annually, occurring disproportionately among children in LMIC. Pathogen whole genome sequencing (WGS) is increasingly used for genomic surveillance and transmission modelling, however, most routine WGS of S. Typhi is conducted in non-endemic countries, and it is unclear whether the evolutionary rate of typhoid pathogens is sufficient to resolve transmission chains in outbreak scenarios. We investigated whether S. Typhi from travellers returning from endemic areas are representative of pathogen populations at the destination of travel, and measured the evolutionary rate in vivo during human challenge.

Materials/methods: WGS was used to identify SNPs, type S. Typhi into genotypes, infer phylogenies, and detect molecular determinants of antimicrobial resistance (AMR). AMR and genotype profiles of travel-associated isolates collected by public health laboratories in the United Kingdom and Australia were compared with those collected locally in India, Bangladesh, Samoa, and Papua New Guinea. Genomes from isolates obtained from human challenge study participants were compared with the complete genome of the inoculating strain to identify mutations arising in vivo.

Results: For all endemic countries examined, travel-associated isolates were intermingled in the phylogeny with those collected locally across similar sampling periods, and were significantly positively correlated in terms of both the genotypes present (Pearson correlation, 0.94, p=1.1x10^-15) and AMR determinants (Pearson correlation 0.96, p=2.22x10^-07). Of 200 post-challenge isolates, n=11 (~1 in 18) harboured de novo DNA base substitution mutations compared with the inoculating strain, yielding an estimate of in-host evolution of 5.70x10^-7 [95% CI, 3.18x10^-7 – 1.02x10^-6] substitutions/site/genome/year, in line with substitution rates estimated from Bayesian phylogenomic analyses of WGS data on natural infections.

Conclusions: Genomic surveillance is highly informative for typhoid control strategies, revealing transmission dynamics, AMR mechanisms, regional strain circulation patterns, and resolving point source outbreaks, although the substitution rate of S. Typhi is too low to resolve individual transmission events during outbreaks. Similarity between travel-associated and locally isolated S. Typhi demonstrates the utility of the former as a source of routine sentinel surveillance for regions where local genomic surveillance is not yet available.

Abstract 5491

**Cardiac 18F-fluorodeoxyglucose Positron Emission Tomography (18F-FDG-PET/CT) use in infective endocarditis: a 10-year multi-centre cohort study**

Marta Hernández-Meneses 1, Sonia Calzado 2, Jaume Llopis 3, Ana Paula Carecía-Aróztegui 4, Andres Perissinotti 5, Lucía Boix-Palop 6, Javier Diez De Los Rios 7, Jordi Cuquet Pedragosa 8, Marta Andrés-Santamaria 9, Carmen Agustí 10, Maria Ortiz 11, Josep M. Tricás 12, Juan Ambrosioni 1, David Fuster 5, María Moreno Camacho 6, Oriol Gasch Blasi 2, José Miro 1

1 Hospital Clinic de Barcelona, Infectious diseases Service, Barcelona, Spain, 2 Hospital Parc Taulí de Sabadell, Infectious diseases Service, Sabadell, Spain, 3 University of Barcelona, Genetic, Microbiology and Statistics Department, Barcelona, Spain, 4 Hospital Parc Taulí de Sabadell, Nuclear Medicine Department, Sabadell, Spain, 5 Hospital Clinic de Barcelona, Nuclear Medicine Department, Barcelona, Spain, 6 Hospital Mutua De Terrassa, Infectious diseases Service, Terrassa, Spain, 7 Hospital General de Vic, Infectious diseases Service, Vic, Spain, 8 Hospital General de Granollers, Infectious diseases Service, Granollers, Spain, 9 Hospital de Terrassa, Infectious diseases Service, Terrassa, Spain, 10 Hospital de Sant Celoni, Infectious diseases Service, Sant Celoni, Spain, 11 Hospital Plató, Infectious diseases Service, Barcelona, Spain, 12 Hospital Mollet, Infectious diseases Service, Mollet del Vallès, Spain

**Background:** Cardiac 18F-fluorodeoxyglucose Positron Emission Tomography Computed Tomography (18F-FDG-PET/CT) has recently been included as a major diagnostic criterion of prosthetic valve endocarditis (PVE) in the 2015 European Society of Cardiology (ESC) infective endocarditis (IE) guidelines. The aim of this study was to know the influence of those guidelines on the implementation of 18F-FDG-PET/C and the variables associated with 18F-FDG-PET/CT performance in a ten-year multicenter cohort study.

**Materials/methods:** All IE consecutive episodes in one reference cardiac center and nine non-cardiac central-Catalonian community hospitals were retrospectively collected for 2009 to 2018. Two centers performed 18F-FDG-PET/CT using the same protocol. We analyzed the performance of cardiac 18F-FDG-PET/CT according to the calendar year and compared the characteristics of patients with and without a cardiac 18F-FDG-PET/CT.

**Results:** From 872 consecutive episodes of IE, 165 (19%) had a cardiac 18F-FDG-PET/CT performed. The rates of cardiac 18F-FDG-PET/CT done in 2009-11, 2012-14 and 2015-19 were 5%, 15% and 31%, respectively (see Figure) and this trend was statistically significant (p<0.001). Comparing both cohorts, PVE was more frequent in patients with cardiac 18F-FDG-PET/CT performed (46% vs. 22% p<0.001) and less frequent in patients with *Viridans group streptococci* (19% vs. 13% p<0.02); mitral valve involvement (33% vs 44.5% p<0.004) and patients with severe valve regurgitation (23% vs. 39% p<0.001). There were no differences between other causative microorganisms nor within surgery indication and surgery actually performed. In-hospital mortality and one-year-mortality rates were lower in patients with cardiac 18F-FDG-PET/CT. The variables associated with cardiac 18F-FDG-PET/CT performance in the multivariate analysis were being transferred from a community hospital to the reference cardiac center (OR 1.93 [1.27 , 2.92]), suspicion of PVE (OR 2.22 [1.27 , 3.89]) and the most recent calendar year (2014-2018 period, OR 4.26 [2.79, 6.50]). In the multivariate analysis of predictors of in-hospital and one-year mortality, after adjusting for classical variables, performing cardiac 18F-FDG-PET/CT was independently associated with survival (OR, 95%CI, 0.20 [0.17-0.49] and 0.29 [0.15-0.54], respectively).

**Conclusions:** The use of cardiac 18F-FDG-PET/CT for diagnosis of IE has increased since the 2015 ESC IE guidelines, especially in patients with PVE, and identifies a subset of patients with better prognosis.

Abstract 5493

**Interest of immunoblotting with Aspergillus fumigatus western blot IgE assay for the differential diagnosis of IgE sensitisation and allergic broncho pulmonary aspergillosis**

Raphaël Piarroux*, Stéphane Ranque†, Joana Vitte‡

1Lyon, LDBIO Diagnostics, Lyon, France, ‡Aix-Marseille University, IRD, APHM, IHU-Méditerranée Infection, VITROME, Marseille, France

**Abstract**

**Background:** Allergic Broncho-Pulmonary Aspergillosis (ABPA) diagnostic is complex and based on a multi-criteria definition. One of the major criteria is the presence of specific immunoglobulin E (sIgE) to *Aspergillus fumigatus* (*Af*), but sIgE also reflects sensitization to *Af*. Discrimination between *Af* sensitization and ABPA is complex, and no diagnostic test allows a clear distinction between these two entities to date. We recently reported that a Western Blot detecting IgE antibodies specific for *Af* could separate those two entities. This work aimed to evaluate the LDBIO *A. fumigatus* WB IgE assay for differentiating ABPA from *Af*-sensitization.

**Materials/methods:** 229 sera (2014-2018 period, Marseille, France) with known sIgE reactivity (23 ABPA, 206 *Af*-sensitized) were assayed with the LDBIO *A. fumigatus* WB IgE. All had been previously assayed with ImmunoCap® for sIgE. We evaluated the ability of WB to detect *Af* sensitization and to discriminate between ABPA and *Af*-sensitized patients, relying on ImmunoCap® and clinical chart conclusions as a reference.

**Results:** Samples displayed 0 to 10 bands in the 10-37 kDa range. The 4 most frequent bands were considered as major bands (16, 18-20, 22 and 30 kDa) and the others as minor bands (10, 17, 33, 34, 36 and 37 kDa). *A. fumigatus* WB IgE positivity was defined by the presence of 2 major bands. This WB was thus positive in 23/23 ABPA and 124/206 *Af*-sensitizations sera (64% sensitivity). WB positivity was strongly correlated to sIgE level; it was positive in 95% (98/103) of the sera with sIgE >1.5 kUa/l.

The ABPA WB IgE profile was defined by the presence of at least 2 major bands and 2 minor bands with 96% sensitivity (22/23) and 93% specificity (192/206) for ABPA diagnostic.

**Conclusions:** This study highlights the interest of the WB *A. fumigatus* IgE assay in the work-up of IgE responses to *Af* in asthmatics and cystic fibrosis patients: WB could discriminate ABPA from *Af*-sensitized patients with a sensitivity of 96% and a specificity of 93%. These encouraging results must now be reproduced in a multicentric evaluation.

¹University of Geneva Hospitals, Geneva, Switzerland, ²University of Lausanne, Lausanne, Switzerland, ³SIB Swiss Institute of Bioinformatics, Lausanne, Switzerland, ⁴University Hospital of Bern, Bern, Switzerland, ⁵University of Geneva, Geneva, Switzerland, ⁶SIB Swiss Institute of Bioinformatics, Geneva, Switzerland, ⁷Ifakara Health Institute, Dar es Salaam, Tanzania, ⁸Ifakara Health Institute, Dar es Salaam, Tanzania, ⁹University of Geneva Medical School, Geneva, Switzerland, ¹⁰Swiss Federal Institute of Technology (ETH Lausanne), Lausanne, Switzerland

Background: The full characterization of the human blood virome in different continents and/or populations could contribute to identify new infectious agents and possibly predict virus emergence. We performed metagenomics next-generation sequencing (mNGS) on blood samples from a paediatric cohort with fever to identify clinically pertinent viruses not routinely screened in low-resource setting, variants not detected by available diagnostic assays, or viruses unknown to infect humans.

Materials/methods: mNGS was performed on 816 serum collected between 2014 and 2016 from a large paediatric cohort (2-59 months of age) presenting with fever at nine outpatient clinics in Dar es Salaam, Tanzania. Raw data were analysed in all cases using in parallel a bioinformatics pipeline and a new database specifically developed in the context of this study to report any known vertebrate viruses and by de novo.

Results: The mNGS analysis reported the detection of a large diversity of RNA and DNA virus sequences. Of the 816 children, 394 (48.3%) were found positive for at least one virus recognized as causing infection or diseases in humans. Among the 35 viral species detected and considered of clinical significance, we observed a predominance of human enteroviruses (113/816, 13.8%), rotaviruses (98/816, 12%), human herpesvirus type 6 (90/816, 11%) and 7 (36/816, 4.4%). Anelloviridae were detected in all except one samples and up to 92.2% of samples were co-infected by three anellovirus genus. In addition, a large number of sequences related to 33 arthropod, vertebrate or mammalian virus species and so far unknown to cause human infections were detected; the most frequent being dicistroviruses, porcine parvoviruses 4-6 and ambidensoviruses.

Conclusions: We have extensively characterized the human virome of children living in Tanzania and presenting a febrile illness. Beyond the usual viral agents, we reveal the presence of a large number of human enterovirus and rotavirus infections. The prevalence and diversity of Anelloviridae observed is far higher than expected. In addition, we observed a large number of viruses of unknown clinical significance for humans. The later ones deserve specific attention and further studies in the febrile paediatric population in Africa.

Abstract 5495

**Enterovirus-C99 associated with cases of acute flaccid paralysis in the south-eastern region of Brazil**

Rita De Cássia C. Carmona*1, Braulio Caetano Machado1, Juliana Dias1, Audrey Cilli Chirelli2, Ligia Louzado2, Adriana Luchs2, Cleusa Aparecida Sousa1, Maria Do Carmo S. Timenetsky4, Maria B. P. Eduardo3

1Adolfo Lutz Institute, Enteric Diseases Laboratory, Virology Center, São Paulo, Brazil, 1Adolfo Lutz Institute, Enteric Diseases Laboratory, Virology Center, São Paulo, Brazil, 3São Paulo State Epidemiological Surveillance Center, São Paulo, Brazil, 4Adolfo Lutz Institute, Virology Center, São Paulo, Brazil

**Background:** Enteroviruses (EV) are members of the genus *Enterovirus* within the order *Picornavirales*, family *Picornaviridae*, and have been assigned to four species: *Enterovirus* A, B, C, and D. Acute flaccid paralysis (AFP) is the most common clinical presentation of acute poliovirus infection. Although polio eradication to be a public health emergency of global interest, non-polio enteroviruses (NPEV) detection amid polio surveillance to be considered. NPEV requires attention as potential causative agents of many AFP cases. The aim of this study was to provide further insights into the circulation of NPEV in children with AFP, in São Paulo State, southeastern region of Brazil.

**Materials/methods:** During nineteen years of poliovirus surveillance, January 2001 to October 2019, sixty-nine samples were analysed from AFP cases that had previously been confirmed as NPEV by the WHO-recommended RD-L20B cell culture-based algorithm. Total RNA was extracted on the RD cell culture supernatant from each sample by QIAamp Viral RNA Mini Kit (QIAGEN, Hilden, Germany) and reverse transcription polymerase chain reaction RT-PCR was applied to amplify a partial region of viral protein 1 (VP1) followed by sequencing for identifying, using the enterovirus genotyping tool and phylogenetic analysis.

**Results:** Among 69 samples NPEV positive, *Enterovirus B* was the most frequently detected species, followed by *Enterovirus A* and *Enterovirus C*, 62.3%, 27.6% and 10.1%, respectively. No *Enterovirus D* was detected. In total, we found 27 different genotypes. Within EV-B, the most frequently detected genotypes were Echovirus 11 (7/43, 16.3%) and Echovirus 6 (6/43, 14.0%). EV-A71 (5/19, 26.3%) was the genotypes most frequently detected within EV-A. In EV-C, EV-C99 (4/7, 57.1%) was the most frequently detected genotypes.

**Conclusions:** This is the first report of EV-C99 in AFP case in South America. Continuous surveillance of EV is important to afford further information on the circulation NPEV in the Brazil. This study shows the importance of increasing NPEV monitoring in order to understand the etiological role of EV-C99, as well as other EV associated with AFP. Financial Support: FAPESP (#2017/05350-0).

**Presenter email address:** rita.carmona@ial.sp.gov.br
Background: Catheter-associated urinary tract infection (CA-UTI) is one of the leading healthcare-associated infections (HAIs) in Latvia. CA-UTI threatens patient safety, imposes an additional burden on health care costs and contributes to the spread of antimicrobial resistance. It is acknowledged that CA-UTI may be potentially avoided by limiting unnecessary and prolonged urinary catheterization by implementing a number of preventive strategies. The aim of the conducted study is to estimate and decrease unjustified urinary catheter (UC) use during two-year period in university hospital in Riga, Latvia.

Materials/methods: Prospective interventional study was performed in university hospital in December 2017 through October 2019. To assess the frequency and appropriateness of UC use in the hospital, the first Point Prevalence Survey (PPS) was carried out in December 2017, after which three departments with a high UC use were selected for multifaceted interventions using a breakthrough series model. Main activities involved staff engagement, education and documenting the number of catheterized patients and all new catheterization cases on a daily basis. A PPS protocol was developed based on the local hospital’s guidelines, ECDC PPS protocol and in close collaboration with partners from EU-JAMRAI [European Union Joint action on antimicrobial resistance and HAI]. Specific departments were repeatedly surveyed to evaluate the impact of interventions. The primary outcome indicators were catheter-days per patient-days and number of new catheterizations per 1000 patient-days.

Results: The study sample of the first PPS consisted of 609 patients, of whom 107 (17.6%) had an UC. Urology, neurology and neurosurgery departments were identified as high-risk and were selected for further interventions and repeated PPS. Significant improvement was observed only in neurology department where the recorded prevalence of catheterized patients was 64.5% in 2017, 14.8% in 2018 and 25.4% in 2019; catheter-days per patient-days were reduced from 0.27 to 0.19 and new cases of catheterizations per 1000 patient-days gradually decreased from 28.0 to 19.9 during the study period.

Conclusions: An interventional approach managed to achieve a significant reduction of unjustifiable catheter use and prolonged catheterization although long term effect remains to be assessed. The best model of collaboration with clinical departments still has to be established.

**Abstract 5500**

**Acute rheumatic fever in children in Morocco: a prospective study**
Sara Himri*, Bouchra Oumokhtar¹, Samira El Fakir², Samir Atmani²

¹Faculty of medicine and pharmacy, Fez, Morocco, ²HASSAN II University Hospital, Fez, Morocco

**Background:** Acute rheumatic fever (ARF) is a major problem of public health in developing countries like Morocco, because of the high prevalence of its principal complication "carditis". The objective of this study is to find out the clinical manifestations and laboratory features of patients with ARF in Fez city in Morocco.

**Materials/methods:** A prospective study was conducted from January 2016 to July 2019 in the pediatric ward of the university hospital Hassan II of Fez. We included patients with age less than 18 years. A total of 152 children diagnosed ARF, based on modified Jones criteria, was studied.

**Results:** The mean age of ARF cases were 12 years and 10 months. The sex ratio male/female was 0.7. The most represented age class was the class between 5 and 15 years (76.16%). Urban residence was found in 78.8% of cases and the majority of patients with and without carditis were admitted in winter and autumn respectively. Cases of ARF with carditis was documented in 78.3% and without carditis in 21.7%. In the groups with/without carditis, arthritis was the major criterion most represented (24.4% and 12.1% respectively) and arthralgia was the minor criterion most represented (67.2% and 78.8% respectively). In the two groups, History of sore throat presented the same percentage. Penicillin A was the most antibiotic prescribed in the two groups. Commonest valvular lesions among ARF with carditis cases was mitral regurgitation (69%). A high ESR level is found in 29.4% and the ASO was positive in 37.2% of cases. Corticosteroids were prescribed in 42.8% of cases with carditis and in 30.3% of cases without carditis.

**Conclusions:** ARF continues to occur in Morocco, despite the progress made in the socioeconomic development of the country, often associated with severe cardiac involvement.

Abstract 5504

Analysis of causes of death and mortality risk factors in extreme elderly patients with sepsis

Julio Cesar Delgado Correal1, Rogerio Rufino1, Marcos Fornasari1, Cassia Alburquerque1, Maria De Lourdes Martins1, Paulo Damasco1,2,3

1Hospital Rio Laranjeiras, Rio de Janeiro, Brazil; 2Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil; 3Universidade Federal do Estado do Rio de Janeiro - UNIRIO, Rio de Janeiro, Brazil

Background: Extreme elderly patients (+80 years-old) are admitted to hospitals with sepsis / septic shock, and the mortality rate for such cases is high.

Materials/methods: The subjects were patients admitted to our hospital with sepsis / septic shock from October 2017 to October 2019. In addition to analyzing their causes of death, the following factors were compared with cases that showed improvement: comorbidities, physical examination, laboratory parameters, gravity scores at hospital admission, infection source, compliance with sepsis protocols [3 hours and 6 hours goals], length of hospital stay and outcomes. An multivariate analysis by logistic regression was utilized for identification of mortality risk factors.

Results: A total of 346 cases (mean age; 80.9 years) were targeted for analysis (table 1). Most prevalent comorbidities of the patients were hypertension [65%], diabetes [27.5%], chronic pulmonary obstructive disease [11.3%], and hypothyroidism [13.1%]. Most patients were previously hospitalized [3 month] [24.6%]. The main sources of infection were lung [47.4%] and urinary tract [32.8%]. Many patients were admitted in septic shock [19.9%]. The mean sequential organ failure assessment score [SOFA] and quick-SOFA were 4.7 and 2.01 respectively. Compliance with institutional sepsis protocols were 83.3% and 73.1% in the 3 hours and 6 hours bundles, respectively. All-causes mortality were high [39.0%], being at < 48 hours in low proportion [7.8%]. In the multivariate analysis were independent associated with mortality the necessity for hemodialysis [Risk ratio [RR]: 2.0; 95% Conf. Interval [CI]: 1.4-2.7; p=0.05]; Pneumonia like source of sepsis [RR: 1.44; 95% CI: 1.14-1.87; p=0.005], and the presence of septic shock at admission [RR: 2.07;95% CI 1.64-2.61; p<0.05]. Otherwise, survival were associate with adequate initial volemic resuscitation with 30 ml/kg [RR:0.55;85% CI:0.4-0.71;p<0.05].

Conclusions: In extreme elderly patients with sepsis/septic shock, the presence of septic shock at hospital admission, acute kidney insufficiency requiring hemodialysis, pneumonia like source of sepsis, and lack of adequate volemic resuscitation were risk factor strongly associated to in-hospital mortality, knowing these characteristics would be useful when making decisions regarding the intensity of treatment.

Abstract 5505

**High-throughput culture-based vancomycin-resistant enterococci screening using artificial intelligence**

Angela Nowag1,2, Hilmar Wisplinghoff*1,2,3, Xenia Quante1, Steven Giglio4,5, Sarah Wirth1, Barbara Poh1, Nathalie Jazmati1,2

1Wisplinghoff Laboratories, Cologne, Germany, 2University Hospital of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 3University Witten/Herdecke, Institute for Virology and Medical Microbiology, Witten, Germany, 4Clever Culture Systems, Bach, Switzerland, 5LBT Innovations, Adelaide, Australia

**Background:** Reading of culture media is one of the most demanding and time consuming parts of conventional microbiology. Even with the use of chromogenic media there is still considerable subjectivity. Introduction of artificial intelligence (AI) has shown to be a way to increase reliability and throughput in culture based MRSA-screening. This study was conducted to evaluate the accuracy of AI-based classification of solid culture media designed for VRE-detection.

**Materials/methods:** The APAS® Independence in combination with VRE Analysis Module was trained using 1500 routine specimens over a 3 month period. VRE Screening was performed using the Brilliance VRE® (ThermoFisher). Routine samples were processed using the AutoPlak® (Beckman Coulter) and evaluated after 24 and 48 hours of incubation. Results of AI-based classification were compared to conventional plate reading by experienced medical technicians and microbiologists.

**Results:** There was high agreement between AI-based and conventional reading. After adoption to the specific chromogenic media, sensitivity of the VRE-detection algorithms was consistently high (>95%) while specificity varied between 70% and >85% in stool and swab specimens, respectively. However, these numbers are expected to increase due to continuous training during further clinical evaluation was observed. Performance did not vary between individual runs. Using plates from routine samples the throughput averaged approximately 200 plates per hour.

**Conclusions:** In this study, accuracy of the AI-based APAS® Independence system was comparable to conventional reading, while the system was able to maintain an average throughput of 200 plates per hour. AI-based systems may provide a great addition to current practices in cultural microbiology.

Abstract 5508

Outcome of community-onset extended-spectrum β-lactamase-producing Escherichia coli bacteraemia and urinary tract infection: a historical population-based cohort study

Rasmus Kapalu Broge Richelsen*1,2, Pavithra Mariadas3, Jesper Smit2, Henrik Carl Schønheyder1,4, Jesús Rodríguez-Baño5,6,7, Henrik Nielsen1,2

1University of Aalborg, Department of Clinical Medicine, Aalborg, Denmark, 2Aalborg University Hospital, Department of Infectious Diseases, Aalborg, Denmark, 3Odense University Hospital, Center for Clinical Epidemiology, Odense, Denmark, 4Aalborg University Hospital, Department of Clinical Microbiology, Aalborg, Denmark, 5Universidad de Sevilla, Department of Medicine, Sevilla, Spain, 6Hospital Universitario Virgen Macarena, Infectious Diseases, Clinical Microbiology and Preventive Medicine Unit, Sevilla, Spain, 7Biomedicine Institute of Seville (IBiS), Seville, Spain

Background: Extended-spectrum β-lactamase-producing Escherichia coli (ESBL-EC) infection is increasingly acquired in the community, leaving the patients at an increased risk of receiving inappropriate empirical antibiotics. Yet, the prognostic impact of infections with ESBL-EC in our low prevalence region remain sparse. Therefore, we investigated mortality and length of hospital stay (LOS) in patients with community-onset ESBL-EC and non-ESBL-EC infections.

Materials/methods: We conducted a population-based cohort study of all adult patients hospitalised with a first-time community-onset E. coli bacteraemia or urinary tract infection (without concurrent bacteraemia) in the North Denmark Region between 2007 and 2017. We computed hazard ratios as a measure of mortality rate ratios (MRR) using cox proportional hazards regression and compared short-term (30-day) and long-term (one-year) mortality between patients with ESBL-EC and non-ESBL-EC infections. We adjusted for age, gender and co-morbidity. LOS was investigated separately for survivors and non-survivors and overall with a cumulative incidence function considering death a competing risk.

Results: A total of 21,667 patients were hospitalised with a first-time community-onset E. coli infection during the study period of which 4,085 (18.9%) had bacteraemia. ESBL-EC accounted for 810 (3.7%) of the infections. The 30-day cumulative mortality in patients with bacteraemia was 16.1% in patients with ESBL-EC and 14.0% in non-ESBL-EC, for an adjusted MRR of 1.09 (95% confidence interval [CI], 0.76-1.57). The one-year cumulative mortality was 37.1% and 31.9% respectively, adjusted MRR 1.11 (95% CI, 0.88-1.42). The 30-day cumulative mortality for patients with urinary tract infection was 9.8% in ESBL-EC and 8.9% in non-ESBL-EC. The median LOS among survivors of bacteraemia was 9 days (interquartile range [IQR], 6-13) for patients with ESBL-EC compared to 7 days (IQR, 5-11) for patients with non-ESBL-EC, which was significantly longer for an overall adjusted hazard ratio of being discharged of 0.79 (0.68-0.93). The corresponding LOS for patients with urinary tract infection was 5 days (IQR, 3-10) compared to 5 days (IQR, 2-9).

Conclusions: Patients hospitalised with community-onset infections with ESBL-EC did not experience a higher short- or long-term mortality compared to patients with non-ESBL-EC, but a longer LOS among patients with bacteraemia.

Comparison in vitro activity of ceragenins for treatment of Burkholderia cepacia complex infections
Elif Sena Demir*1, Özlem Oyardı1, Ozlem Altay1, Paul B. Savage3, Cagla Bozkurt Guzel1

1University, Istanbul University Faculty of Pharmacy Department of Pharmaceutical Microbiology, Istanbul, Turkey, 2University, Science for Life Laboratories, KTH Royal Institute of Technology, Stockholm, Sweden, 3University, Brigham Young University Department of Chemistry and Biochemistry, Utah, United States

Background: Burkholderia cepacia complex (Bcc) is a Gram negative pathogen bacteria which cause severe infections in immunocompromised patients and fatal chronic respiratory tract infections in cystic fibrosis patients. Burkholderia species are intrinsically resistant to antibiotics such as penicillin, cephalosporin, aminoglycosides and polymyxin. Ceragenins [Cationic Steroid Antibiotic-CSA] designed to mimic the activities of antimicrobial peptides, are a new class of antimicrobial agent. In this study, we examined in vitro activities of ceragenins CSA-13, CSA-131 and CSA-131 poloxamer (P) form against Bcc isolates.

Materials/methods: Bcc clinical isolates (n=36) were collected from Hacettepe University Faculty of Medicine, between 2007-2017. CSA-13 and CSA-131 were synthesized from cholic acid Scaffold technique. Pluronic F-127 was purchased to obtain CSA-131 in poloxamer micelles in order to decrease the cytotoxicity of CSA-131. Minimum inhibitory concentrations (MICs) were determined for levofloxacin, meropenem, trimethoprim-sulfamethoxazole, ceftazidime by using broth microdilution technique according to CLSI guidelines. CSA-13 (prototype ceragenin) and CSA-131 with or without 5% pluronic F-127 were determined, as well. Five different isolates that have lowest MIC results were selected and time kill curve experiments were performed with 1x, 2x and 4x MICs of ceragenins.

Results: The MIC (µg/ml) results of CSA-13, CSA-131 and CSA-131P were between 2-128, 4-128, 2-128. The MIC50 values were determined 16 µg/ml for all ceragenins tested. The results of time-kill curve analysis indicated that CSA-131P showed bactericidal effect in two hours against all isolates, whereas CSA-131 has bactericidal effect for only two isolates at 2x and 4x concentrations. For two isolates, after rapid initial killing, regrowth was observed for CSA-131P.

Conclusions: Although CSA-13, CSA-131 and CSA-131P had similar MIC results, CSA-131P showed bactericidal activity against more isolates. The results demonstrated that CSA-131 in poloxamer micelles formed with pluronic F-127 can make it better candidate than CSA-131 and CSA-13 against Bcc infections.

Mechanisms of resistance in *Pseudomonas aeruginosa* against ceftazidime-avibactam and ceftolozane-tazobactam from Qatar

Mazen Sid Ahmed1,2, Faisal Ahmad Khan2, Hamad Abdel Hadi2, Ali A Sultan4, Muna Al-Maslamani3, Abdullah Al-Khal2, Bo Söderquist5, Emad Ibrahim1, Ali Omrani3, Jana Jass2

1Hamad Medical Corporation, Department of Laboratory Medicine and Pathology, Microbiology division, Doha, Qatar; 2Orebro University, The Life Science Centre - Biology, School of Science and Technology, Orebro, Sweden; 3Hamad Medical Corporation, Communicable Diseases Center, Doha, Qatar; 4Weill Cornell Medical in Qatar, Department of Microbiology and Immunology, Doha, Qatar; 5Orebro University, School of Medical Sciences, Faculty of Medicine and Health, Orebro, Sweden

**Background:** Infections with multidrug-resistant organisms and its corresponding increase in morbidity and mortality is a global healthcare challenge. Ceftolozane/tazobactam (C/T) and ceftazidime/avibactam (CZA) have been approved for the treatment of serious infections caused by Gram-negative bacteria including multidrug-resistant *Pseudomonas aeruginosa* (MDR-PA). Resistance to both CZA and C/T has been increasingly reported but the mechanisms have not been fully explored. This study aims to investigate the associated genetic diversity and molecular mechanisms of resistance to CZA and C/T in clinical MDR-PA isolates from Qatar.

**Materials/methods:** A total of 525 MDR-PA isolates were collected from various clinical specimens between 2014 and 2017. Microbiological identification and antimicrobial susceptibility testing were performed by both automated BD Phoenix™ system and manual Liofilchem MIC Test Strips. A total of 75 isolates were resistant to CZA and/or C/T and subsequently processed for genomic analysis using Next-generation sequencing. To identify the potential antibiotic resistance genes (ARGs) responsible for the resistance to CZA and/or C/T, Pearson's correlation between ARGs.

**Results:** The 75 isolates belonged to 29 different sequence types; the resistant ST-235 was predominant at 13% (10/75), followed by ST-357 at 10.7% (8/75), ST-389 at 8% (6/75), ST-1284 at 8% (6/75), and others; 60% (45/75). The isolates carried multiple β-lactamase genes from all Ambler classes: class A β-lactamases including *bla*<sub>TEM-1</sub>, *bla*<sub>TEM-87</sub>, *bla*<sub>TEM-96</sub>, *bla*<sub>TEM-15</sub>, *bla*<sub>TEM-25</sub>, *bla*<sub>TEM-51</sub> and *bla*<sub>TEM-57</sub>; class B including *bla*<sub>IMP-1</sub>, *bla*<sub>VIM-2</sub>, *bla*<sub>VIM-5</sub> and *bla*<sub>PDC-2</sub>, class C including *bla*<sub>PDC-1</sub>, *bla*<sub>PDC-3</sub>, *bla*<sub>PDC-7</sub> and *bla*<sub>PDC-10</sub>, and class D including *bla*<sub>OXA-1</sub>, *bla*<sub>OXA-50</sub>, *bla*<sub>OXA-114</sub>, and *bla*<sub>OXA-129</sub>. Among the β-lactamase genes, the predominant was OXA-50 at 97% (73/75), followed by *bla*<sub>PDC-2a</sub>, *bla*<sub>VIM-2</sub>, *bla*<sub>VEB-9</sub>, *bla*<sub>PDC-3a</sub>, and *bla*<sub>VIM-2</sub>. Pearson’s correlation showed that resistance to both CZA and C/T was associated with the presence of *bla*<sub>PDC-2a</sub>, *bla*<sub>VIM-2</sub>, *bla*<sub>VEB-9</sub>, *bla*<sub>PDC-2</sub>, and *bla*<sub>PDC-7</sub>; while *bla*<sub>KPC-3</sub> presence was associated with resistance to C/T.

**Conclusions:** In MDR-PA, the mechanisms of resistance to CZA and CT is highly correlated to the presence of multiple β-lactamase genes, ie *bla*<sub>PDC-2</sub>, *bla*<sub>VIM-2</sub>, and *bla*<sub>VEB-9</sub>. The analysis was based on genomics and statistical correlation, however the relative contribution of the individual β-lactamase genes is yet unclear.

Pentameric IgM does not improve clinical outcome in adults with sepsis after major abdominal surgery

Alessandro Perrella*1, Luca Rinaldi2, Maurizio Castriconi3, Maria Mazzone4, Pia Clara Pafundi5, Maria Montanaro3, Paola Saturnino6

1Azienda Ospedaliera dei Colli Monaldi, Napoli, Italy, 2università vanvitelli, Naples, Italy, 3Hospital Antonio Cardarelli, Naples, Italy

Background: Sepsis still represents a major public health issue worldwide, and the immune system plays a main role during infections and therefore its activity is mandatory to resolve this clinical condition. In this report we aimed to retrospectively verify in real life setting the possible usefulness of Pentameric IgM plus antibiotic in recovering patients with sepsis after major abdominal surgery.

Materials/methods: We reviewed, from January 2013 until December 2018, all adult patients admitted in ICU for Sepsis or Septic shock (2) after major abdominal surgery. Among these patients, were identified those that according to legal indication and licence in Italy, were treated with Pentameric IgM plus antibiotic (Group A) or with antibiotic alone (Group B). We analysed the following parameters were evaluated: Blood gas analysis, Lactate, CRP, Procalcitonin, Endotoxin activity, Liver and Renal Function, Coagulation, Blood Cell count at different time points (Every 48 hrs for at least 7 days). Differences between groups have been analysed by Fisher’s exact test or Chi square test for categorical variables. Mann–Whitney U test or Kruskal–Wallis test have instead been performed to compare continuous variables. Univariate and Multivariate analysis were also performed.

Results: Over a period of 30 months 24 patients were enrolled in Group A and 20 patients in Group B. In those subjects no statistical differences have been found in terms of bacterial or fungal infection isolates, when detected in a blood culture test, or in inflammatory index, SOFA score, lactate levels and mortality rate. A 48hrs response was statistically more frequent in Group B than in Group A, while no differences were found in the other clinical and laboratory evaluation.

Conclusions: Based on our results, the use of pentameric IgM do not seem to give any clinical advantage in sepsis after to major abdominal surgery.

Abstract 5516

Comparison of different platforms and analysis tools in microbiome analysis

Claus Jürgen Scholz¹, Anne Kretzschmar¹, Angela Nowag¹,², Fabiola Sack¹, Melanie Polke¹, Stephanie Stepanow¹, Nathalie Jazmati¹,², Hilmar Wisplinghoff*¹,²,³

¹Wisplinghoff Laboratories, Cologne, Germany, ²University Hospital of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, ³University Witten/Herdecke, Institute for Virology and Medical Microbiology, Witten, Germany

**Background:** Recent findings from microbiome analyses underscore the importance of bacterial community composition at various body sites for human well-being. Next-generation sequencing (NGS) is now routinely used for community assessment, however, the lack of widely accepted standards in wet-lab protocols, sequencing and data analysis is a considerable source of variation in microbiome profiles.

**Materials/methods:** We assessed microbiota from stool (n=12), oral (n=12) vaginal swabs (n=16) and stool-like samples of known bacterial composition (n=2) with commercial 16S rDNA amplicon sequencing methods (Illumina and Ion Torrent) and analysis tools (Qiime2 and Ion Reporter). Multiparametric maximization of the sensitivity vs. precision trade-off was used to find an optimal cross-platform post-processing method for platform output. Microbiome profiles from sampling materials were characterized by alpha and beta diversities and compared between platforms using an empirical Bayesian approach; results were subjected to multi-level visualization.

**Results:** Removal of taxa with unresolved genus level or detection frequencies below 0.05% greatly improved precision of microbiome profiles while maintaining sensitivity. Independent of assessment platform, alpha diversities from oral samples were around 2.9, from stool around 3.0 and from vaginal swabs around 0.03. Between-sample heterogeneity was lowest in vaginal, and highest in stool microbiomes. In the latter we detected a total of 77 genera; thereof, only 36 were quantified equally well by all platforms, while 41 displayed platform-specific preferential detection. This effect was attributable to data generation for 23 genera and to analysis methods for 14 genera. Similar observations were made with other sampling materials, thus, the choice of wet-lab processes and sequencing method had greater impact on profiling than selection of the data analysis pipeline.

**Conclusions:** Diagnostic application of NGS-based microbiome profiling requires post-processing of output from assessment platforms and consideration of their sampling material-specific detection biases.

Abstract 5518

Daptomycin and pulmonary eosinophilia: An unrecognised opportunity
Katelyn West*1, Ahmed Sheeti1, Graeme Forrest1

1VA Portland Health Care System, Portland, United States

Background: Daptomycin pulmonary eosinophilia (DPE) has been described as a rare event. The diagnosis is uncommon since peripheral eosinophilia (EOS) may be absent and bronchoalveolar lavage (BAL) is rarely performed for suspected pneumonia. As Daptomycin (DAP) is not used for pneumonia treatment, stopping DAP often resolves the symptoms. We evaluated 331 patients who received DAP from 1/1/10-9/30/18 for DPE using the US Food and Drug Administration (FDA) criteria for proven and probable cases.

Materials/methods: Retrospective chart review of 331 patients who received DAP (inpatient and outpatient). Data collected was age, gender, weight, dosing/duration of DAP, EOS, and infection diagnosis. Pneumonia was recorded per FDA criteria with EOS and DPE. Chi-square analysis compared patients with and without EOS and DPE. Univariate analysis assessed duration and re-exposure of DAP with EOS and DPE.

Results: Overall there were 110 patients [33%] with EOS and 98 [30%] cases of DPE based on inclusion criteria. There was no difference in DPE with EOS or non-EOS groups. It was statistically significant for presence of EOS with longer durations of DAP P<0.001 [OR 4.2 CI 3.6-16.6]. Re-exposure of DAP with prior EOS was associated with severe early onset DPE P<0.05 [OR 1.5, CI 0.7-1.3]. This onset with re-exposure to DAP occurred with a median duration of 14 days compared to the initial DAP median of 25.5 days. There was no association with weight, age, or dose of DAP.

Conclusions: EOS is common with DAP usage especially with longer durations but absence of EOS does not preclude DPE. Previous EOS and re-exposure to DAP was significantly associated with early onset DPE. We recommend monitoring EOS with DAP usage as a predictor for future DPE on re-exposure.

Abstract 5520

Prevalence of azole resistance in clinical Aspergillus fumigatus isolates in Greece

Maria Siopi*, Olga Rivero-Menendez2, Athanasios Chatzimoschou3, Aristea Velegraki1,5, Ana Alastruey-Izquierdo2, Emmanuel Rolides3, Georgia Vrioni4, Spyros Pournaras1, Joseph Meletiadis1,6

1Clinical Microbiology Laboratory, “Attikon” University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 2National Centre for Microbiology, Instituto de Salud Carlos III, Mycology Reference Laboratory, Majadahonda, Madrid, Spain, 3Infectious Diseases Laboratory, 3rd Department of Pediatrics, Hippokration General Hospital, Faculty of Medicine, Aristotle University School of Health Sciences, Thessaloniki, Greece, 4Microbiology Department, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 5University of Athens/Hellenic Collection for Pathogenic Fungi (UOA/HCPF), Medical School, National and Kapodistrian University of Athens, Athens, Greece, 6Department of Medical Microbiology and Infectious Diseases, Erasmus University Medical Center, Rotterdam, Netherlands

Background: We have recently shown that azole-resistant Aspergillus fumigatus (AR-Af) with an environmental signature is present in Greece (Siopi ECCMID2019). Nevertheless, the prevalence of azole resistance in Greek clinical isolates remains uncertain. We therefore investigated the prevalence of clinical AR-Af in Greece.

Materials/methods: A total of 140 A. fumigatus species complex (SC) strains recovered from respiratory specimens of 133 patients (64 hematological, 16 hospitalized in ICU, 53 other) were collected from 5 centers (4 Athens, 1 Thessaloniki) and were retrospectively tested. Isolates were macro-/microscopically identified and were subcultured on Sabouraud+chloramphenicol plates at 48°C to differentiate A. fumigatus sensu stricto (SS). In vitro susceptibility testing of A. fumigatus SC strains to amphotericin B (AMB), itraconazole (ITC), voriconazole (VRC), posaconazole (POS), isavuconazole (ISA), anidulafungin (AFG), caspofungin (CAS) and micafungin (MFG) was performed according to EUCAST E.DEF9.3.1. Isolates exhibiting reduced susceptibility to azoles were subjected to confirmatory molecular identification (White 1990, Balajee 2005) and were further studied for the detection of specific mutations in the cyp51A gene, including its promoter region associated with azole resistance (Mellado 2007).

Results: All isolates grew at 48°C indicating that they belonged to A. fumigatus SS. Antifungal susceptibility patterns among all strains are summarized in Table. In total, all isolates were AMB-susceptible and exhibited echinocandin wild-type phenotypes. POS was the most potent azole in vitro (geometric mean MIC 0.11 mg/L), followed by ITC, VRC and ISA (geometric mean MIC 0.46, 0.59 and 0.70 mg/L, respectively). Overall, 1/133 (0.8%) AR-Af SS from 1/133 (0.8%) patient was detected. Particularly, the isolate was recovered from a pleural fluid culture of an ICU patient, did not have mutations in cyp51A, showed resistance to ITC and POS (MIC >8 and 0.5 mg/L, respectively) and was susceptible to VRC and ISA (MIC 1 mg/L for both drugs).

Conclusions: All clinical A. fumigatus isolates were sensu stricto. We report the detection of an azole-resistant clinical A. fumigatus without cyp51A mutations. The rate of AR-Af in Greece seems to be low (0.7%).

A multi-centre evaluation of the US prevalence and regional variation in macrolide-resistant Streptococcus pneumoniae from blood or respiratory cultures among adult patients

Vikas Gupta1, Kalvin Yu1, Jennifer Schranz1, Hanna Jokinen-Gordon1, Steven P. Gelone2

1Becton, Dickinson and Company, Franklin Lakes, United States, 2Nabriva Therapeutics US, Inc., King of Prussia, United States

Abstract third-party references: Nabriva Therapeutics US, Inc.

Background: S. pneumoniae continues to be designated by the 2019 CDC Antibiotic Resistance Threats Report as a "Serious Threat", underscoring need for rapid detection and prevention strategies. Additionally, the 2019 IDSA/ATS community acquired pneumonia (CAP) guidelines revised recommendations for macrolide use only in those areas where outpatient macrolide resistance is < 25%. This study sought to quantify the prevalence and rates of macrolide resistant S. pneumoniae from blood or respiratory cultures in adult ambulatory and hospitalized patients.

Materials/methods: All adults with a positive S. pneumoniae blood or respiratory culture (first isolate of a species per 30 day period) in the ambulatory and inpatient setting from 329 US hospitals from Q4 2018-Q3 2019 were evaluated [BD Insights Research Database, Becton, Dickinson & Company]. Macrolide resistance was defined as resistant to S. pneumoniae per commercial panels. Macrolide resistance was calculated overall, by source (blood vs. respiratory), by setting (ambulatory vs. inpatient), and by U.S. Census geographic region. The Chi square test was used to test for significance.

Results: There were 3,626 non-duplicate S. pneumoniae isolates across 3,510 patients; 43.8% were from the blood and 56.2% were from respiratory source. The majority of isolates were collected in the inpatient setting (n=2,798) as compared to the ambulatory setting (n=828). Overall, macrolide resistance was 39.5% and was significantly higher in respiratory versus a blood source (47.3% vs. 29.6%, respectively, p < 0.0001). Macrolide resistance was also higher in ambulatory isolates as compared to inpatient isolates (45.3% vs. 37.8%, respectively, p < 0.001). Regional differences in macrolide resistance are summarized below (p < 0.0001).

</tbody>
</table>

Conclusions: This large, contemporary database study helps quantify the national burden of S. pneumoniae resistance in respiratory and blood isolates. About 5 in every 10 respiratory and 3 out of every 10 blood cultures are macrolide resistant. Regional variances occur per source, and highlight the need for continued susceptibility testing to help inform empiric CAP therapy. Evaluating risk factors for resistance such as geographic region and source of pathogen identification is a key critical first step to evaluating empiric macrolide therapy in patients with CAP.

Do we really have to worry about acyclovir-induced nephrotoxicity?

Imran Hasanoğlu*, Ayse Kaya Kalem, Bircan Kayaaslan, Zeynep Atalay Altinkaynak, Rahmet Guner

Yıldırım Beyazıt University Ankara City Hospital, Ankara, Turkey

Background: Acyclovir remains the only treatment option for herpes encephalitis but can potentially cause nephrotoxicity. Aim of this retrospective cohort study was to evaluate acyclovir-induced nephrotoxicity.

Materials/methods: The study population consisted of adult patients who received ≥ 48 hours acyclovir for treatment of viral encephalitis between 2010 and 2018. Acute kidney injury (AKI) was defined according to RIFLE criteria.

Results: Among 260 patients, AKI was observed in 27 (16.8%) of the patients. There were 9 (5.6%), 11 (6.9%), and 7 (4.4%) patients in Risk, Injury, and Failure categories respectively. No loss of function and end-stage renal disease were observed. Mean time to AKI was 5.2 days. We found no correlation between treatment time and AKI development. Rates of concomitant nephrotoxic agent use were similar between AKI and non-AKI group. In AKI group, 92% of the patients’ creatinine decreased after dose reduction. Two (1%) patients received hemodialysis. Characteristics of the patients are given in Table. Hypertension and diabetes are found to be significant risk factors for AKI. We found no statistically significant difference between two groups in terms of age, sex, clinical improvement, and mortality rates.

Conclusions: Nephrotoxicity is an important but manageable side effect of acyclovir. But still clinicians should be more careful in patients with hypertension and diabetes.

Epidemiology of sexually-transmitted infections in women with suspected pelvic inflammatory disease admitted to gynaecology emergency unit of an Italian hospital

Simona Fiorentini*, Annalisa Pirozzi1, Alberto Matteelli2, Valentina Marchese1, Roberto Stellini2, Marilena Traversi2, Francesca Caccuri3, Sabrina Rubessa2, Maurizio Gulletta2

1Dept. of Molecular and Translational Medicine, University of Brescia Medical School, Brescia, Italy, 2Clinic of Infectious and Tropical Diseases, University of Brescia and Brescia Spedali Civili General Hospital, Brescia, Italy, 3Division of Obstetrician and Gynecology department, Spedali Civili Hospital, Brescia, Italy

Background: Pelvic inflammatory disease (PID) is an acute inflammation of female upper genital tract, often resulting in long-term sequelae. The majority of PID cases (85%) are caused by sexually transmitted pathogens or bacterial vaginosis-associated pathogens, so there is no single diagnostic test as gold standard and clinical diagnosis remains the primary practical approach. Our objective was to evaluate the epidemiology of PID in a population of symptomatic patients admitted to the Gynecology Emergency Unit using a new sampling approach (Self Vaginal FLOQSwab™, COPAN Italia) combined with molecular diagnostic methods to detect Chlamydia trachomatis (CT), Neisseria gonorrhoeae (NG) and Mycoplasma genitalium (MG).

Materials/methods: From December 2017 to August 2019 a total of 14,623 women were admitted at the Gynecology Emergency Unit with clinical signs of PID. PID was confirmed only in 101 patients (age 18 to 74 years old). Depending on symptoms severity, women were hospitalized or discharged with indications for empirical treatment at home. Clinicians performed a double sample collection: cervical sampling with regular FLOQSwab™ and vaginal collection using a new Self-Vaginal swab (COPAN Italia). Both samples were then processed by molecular assays for detection of CT, NG (Xpert CT-GC, Cepheid) and MG (Elitech assay).

Results: 18 on 101 patients were positive respectively for Mycoplasma genitalium (n=4), Chlamydia trachomatis (n=7) and Neisseria gonorrhoeae (n=7). Two patients had a co-infection, one was CT/MG and one was CT/NG. In negative STIs patients others bacteria have been identified: Bacterial Vaginosis (10.3%), E.coli (20.6%) and H.influenzae (4.4%). Vaginal samples demonstrated 100% of overall agreement with the cervical collection. Post-therapy self-made sampling resulted negative and concordant with control routinary tests.

Conclusions: NG, CT and MG are the primary cause of symptomatic PID but STIs proportion among PID women was lower than expected. This is in agreement with the observation that milder symptoms occur more frequently in patients with STIs. In acute PID, the presence of other microbes should always be considered. Self-collected swabs would be a good alternative in populations that may not go for testing at all, do not have the option of clinical testing, or refuse a clinical examination.

**Abstract 5530**

**Cycle of quantification (Cq) does not differentiate colonisation from *Pneumocystis jirovecii* pneumonia, using real-time PCR**

Peter Paul Basazemajja1, Theo A. Schuurs2, Age Jan Stellingwerff2, Aziz Al Moujahid*

1Martini Hospital, Groningen, Netherlands, 2Izore, center for infectious diseases friesland, Leeuwarden, Netherlands

**Background:** Real-time PCR shows high sensitivities (97–99%) and specificities (90–94%) in the detection of *Pneumocystis jirovecii* in clinical samples. Due to the biological nature of the pathogen and PCR targets used in differing laboratories, different quantification cycle (Cq) cut-off values have been proposed to distinguish colonization from infection. This study aimed to determine a cut-off Cq-value to distinguish colonization from *P. jirovecii* pneumonia (PJP) in the province of Friesland (the Netherlands).

**Materials/methods:** A retrospective study was conducted on respiratory samples that were sent to Izore because of clinical suspicion of PJP (study group: n=150).

Diagnostic consisted of real-time PCR. Patient’s clinical symptoms were gathered from the hospital information systems and/or the Izore application form, after informed consent. Symptoms of fever, cough, dyspnoea and clinical findings of low oxygen saturation, arterial hypoxia, chest X-ray or computed tomography abnormalities were used as symptoms associated with the clinical diagnosis of PJP in the study group.

The reference group (n=92) consisted of immunocompetent patients with lung conditions, without clinical suspicion of PJP, for which further diagnosis using deep respiratory material was required.

**Results:**
- In the study group (n=150), 54 samples (36%) were PJP positive with a mean Cq-value of 27.9 (SD ± 3.40).
- To assess correlation between the number of PJP-related symptoms and Cq-value, the 54 PJP PCR-positive samples were divided into two groups. Group A consisted out of samples with 3 or less symptoms and group B consisted out of 4-7 symptoms (strongly indicative for PJP). There was no significant difference in Cq-value between group A and B (P=0.59).
- In the reference group, 3 samples (3%) were positive with a mean Cq-value of 30.4 (SD ± 4.07). These were termed as colonization. There was no significant difference between the mean Cq-values of the immunocompetent reference group and the immune-incompetent PJP-positive group (P=0.48).

**Conclusions:**
- No Cq-value was found to differentiate colonization from PJP using real-time PCR. There was no correlation between number of symptoms and Cq-value.
- There is a low prevalence of colonization (3%) in the immunocompetent yet chronically sick population

Abstract 5531

The recombinant NP-HA2 fusion protein as a candidate for designing of universal influenza vaccines

Maryam Zeinolabedin1, Masoud Moghadaszadeh2*, Payam Zeinolabedini3

1Tabriz University of Medical Sciences, Department of Basic Sciences, School of Allied Medical Sciences, Tabriz, Iran, 2Tabriz University of Medical Sciences, Biotechnology Research Center, Tabriz, Iran, 3University of Tabriz, Department of Food Science and Technology, Tabriz, Iran

Background: Influenza is as an extremely contagious respiratory tract disease. Influenza A virus is a member of the Orthomyxoviridae family that has segmented genome and great antigenic diversity. Influenza viruses possess multiple conserved epitopes that are designed for universal vaccines. These epitopes are the nucleoprotein (NP) and HA2.

Materials/methods: In this survey, we have constructed new plasmids to express above-mentioned epitopes as a single recombinant product. To this aim, two peptide genes of N-terminal NP and HA2 were linked together with a (Gly4Ser)4 peptide linker, synthesized, and cloned into pET26b vector. Then, the construct was transferred into E. coli BL21 (DE3) cells and induced using isopropyl β-D-1 thiogalactoside (IPTG). Immunization of mice with above peptides significantly induced humoral immune responses. Three weeks after the last booster, mice were inoculated intranasally with 1×106 EID50 of H9N2 virus.

Results: The recombinant NP-HA2 fusion protein gene was cloned into pET26b vector. The results of sequencing displayed that gene was properly cloned in vector. Also, SDS-PAGE showed a strong single band. Moreover, Western blot analysis indicated a single band in correct position. Real-time RT-PCR studies exhibited reduction of virus in BALB/c mice lung tissues. Our study revealed that this protein could protect mice against H9N2 virus.

Conclusions: The recombinant NP-HA2 fusion protein characterizes a potential candidate for influenza vaccine studies in animal model. According to the findings, the NP-HA2 fusion protein induced humoral immunity responses. The findings of this study suggest that the recombinant fusion peptide which is economical to yield can be used for induction specific antibodies responses. The results of the current study showed that above protein can protect mice by decreasing virus shedding.

Abstract 5534

**Accurate discrimination of *Shewanella algae* from *Shewanella putrefaciens* with Acrion system: an under-reported marine pathogen**

Jake D’Addiego1, Jarkko Räbinä2, Soniya Gurung1, Juha Knuuttila2, Jason Chew1, Mark Hutchins1, Attaybenes Socas1, Pirjo Wacklin2, Naomi Chant1

1Thermo Fisher Scientific, Basingstoke, United Kingdom, 2Thermo Fisher Scientific, Vantaa, Finland

**Background:** *Shewanella* species are a group of Gram-negative bacteria associated with marine environments. The only two reported species of clinical relevance are *Shewanella algae* (which causes around 80% of all *Shewanella* infections in humans) and *Shewanella putrefaciens*. The most common clinical manifestations are skin and soft tissue infections associated with ulcers or trauma, ear infections present as acute infections or acute exacerbations in chronic otitis media and bacteraemia. The accurate identification of *Shewanello* species by MALDI-TOF technologies has been challenging in the past due to the lack of representation of *S. algae* in their database, resulting in misidentifications. The inclusion of *S. algae* into the database of Acrion™, a novel automated diagnostic platform based on high-resolution mass spectrometry, will likely reduce the misidentifications of these marine pathogens.

**Materials/methods:** Five (5) strains each of *Shewanella algae* and *Shewanella putrefaciens* were obtained from culture collections and clinical laboratories and cultivated on two media types in appropriate conditions. Each strain was prepared for Acrion™ analysis using high resolution mass spectrometry from each cultivation condition. Analysis of all strains was carried out using intact protein analysis (MS1) to discriminate strains to species level, and the results were further confirmed through 16S rRNA sequencing.

**Results:** Using the high-resolution mass spectrometry technology employed by Acrion™, all strains of *S. algae* and *S. putrefaciens* were accurately discriminated which was in accordance with 16S rRNA sequencing results.

**Conclusions:** This study shows Acrion™ allows accurate and reliable discrimination of *S. algae* and *S. putrefaciens* through high-resolution mass spectrometry technology. The addition of these taxa in Acrion™ database will allow the identification of these emerging marine pathogens.

Analysis of *Escherichia coli* phylotypes and known sepsis-causing sequence types in UK sewage reveals a direct link between sepsis rates and carriage of pathogenic sequence types in the community

Mark Alexander Toleman*, Jordan Mathias1, Abdulrahman Almusallam1, Dmitriy Babenko2

1Cardiff University, Cardiff, United Kingdom, 2Karaganda Medical University, Karaganda, Kazakhstan

**Background:** UK *Escherichia coli* sepsis rates have been rising for the last 20 years. However, the reason behind this consistent year on year increase is an enigma. The sepsis rate also varies greatly between NHS geographic regions and considerably between London (64/100K) and South Wales (85/100K). We hypothesized that the different rates could be due to differing prevalence of pathogenic *E. coli* types in the different UK NHS regions.

**Materials/methods:** Sewage was collected from Longreach, Marlow, Reading, Bristol, Ponthir and Cardiff sewage works from 19/9/2019-26/9/2019. We diluted and streaked these samples on chromogenic UTI agar (no antibiotics) and randomly chose c. 100 *E. coli* isolates from each location. Species was confirmed by Maldi-TOF-MS and susceptibility determined by disc diffusion (EUCAST methodology). The phylotype was determined by multiplex PCR (Clermont method). Each pathogenic B2 isolate was further tested for known common sepsis sequence types (ST): ST131, ST73, ST95 and ST69 by multiplex PCR (Doumith method).

**Results:** The prevalence of pathogenic B2 phylotype *E. coli* was considerably higher in South Wales than in England, 31.5% verses 1.2%, reflecting the higher sepsis rates in Wales as compared to England. B2 phylogenetic prevalence at each location was: Ponthir (33%), Cardiff (31%), Bristol (24%), Reading (6%), Marlow (4%), Longreach (14%) with prevalence lowest in the London region (8% overall). The multiplex PCR for detecting known sepsis causing pathogenic *E. coli* ST95, ST131, ST73 and ST69 detected one or more of these ST at all locations (Table 1). The prevalence of these specific ST was also considerably higher in S. Wales than in England, 10.5% verses 6.25%. The highest rate of specific sepsis *E. coli* ST was found in Bristol mostly due to a very high prevalence of ST95 (9%) in the Bristol community.

**Conclusions:** Our results show that regions of the UK with high *E. coli* sepsis rates correlate with high levels of group B2 *E. coli* carriage in the community and vice versa. It is reasonable therefore to suggest that the UK sepsis is due to increasing carriage rates of sepsis causing strains in the community.

**Abstract 5546**

**A novel variant of CTX-M β-lactamase in a clinical strain of Serratia marcescens**

Piotr Celejewski-Marciniak¹, Renata Wolinowska², Marta Wroblewska*¹,³

¹Department of Dental Microbiology, Medical University of Warsaw, Warsaw, Poland, ²Department of Pharmaceutical Microbiology, Medical University of Warsaw, Warsaw, Poland, ³Central Clinical Hospital, University Clinical Centre, Medical University of Warsaw, Warsaw, Poland

**Background:** Gram-negative rods classified in the genus *Serratia* are widely distributed in the external environment – in soil and water. Simultaneously, these bacteria may cause opportunistic healthcare-associated infections, particularly in immunocompromised patients. In humans, the most common etiological agent of infections is *Serratia marcescens*. Strains within this species are characterised by resistance to many antibiotics and other antimicrobial agents, which may be determined by both the genes localised on the bacterial chromosome, as well as by mobile genetic elements (plasmids and integrons). The aim of the study was to characterise mobile genetic elements present in clinical strains of Gram-negative rods classified in the genus *Serratia*, and to determine their role in the transfer of the genes determining resistance to antibacterial agents.

**Materials/methods:** Analysis comprised 120 clinical strains of Gram-negative rods *Serratia* spp., obtained from 7 clinical microbiological laboratories located in Warsaw and Otwock (Poland). Identification of the isolates was done with three techniques – MALDI-TOF MS, Vitek 2 Compact and API 20E. Sequencing was performed of the amplification products of the genes coding for type CTX-M β-lactamases.

**Results:** Identification of 112 strains was confirmed as *Serratia* spp., including 103 isolates of *S. marcescens*, 7 – *S. liquefaciens*, 1 – *S. fonticola* and 1 – *S. ureilytica*. Nucleotide sequences encoding type CTX-M-15 β-lactamase were present in over 75% of the analysed strains which were ESBL-positive. An isolate of *S. marcescens* no. 120 was characterised by the presence of a plasmid pPM120-1, classified in the incompatibility group IncL/M (IncM), which was encoding a CTX-M β-lactamase of the structure not described so far. It was determined that this novel variant of CTX-M β-lactamase was a hybrid of CTX-M-19 and CTX-M-3 β-lactamases.

**Conclusions:** 1. Over 75% of ESBL-positive strains of *Serratia* spp. contained nucleotide sequences coding for β-lactamase type CTX-M-15. 2. For the first time in the world, a novel variant of CTX-M β-lactamase was detected, which constitutes a hybrid of CTX-M-19 and CTX-M-3 β-lactamases. A unique nucleotide sequence *bla*\textsubscript{CTX-M-22} was deposited in the GenBank NCBI with the number MH538139.1.

**Abstract 5551**

**Rapid diagnostic test: Identification of Candida spp. directly from the blood culture bottle using short-term subculture incubation and MALDI-TOF MS in a routine microbiology laboratory**

Andréa Celestino De Souza¹, Patricia Orlandi Barth*¹, Paulo André De Souza Sampaio¹, Larissa Lutz¹, Valério Aquino¹, Eliane Wurdig Roesch¹, Dariane Castro Pereira¹

¹Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

**Abstract third-party references:** Hospital de Clínicas de Porto Alegre

**Background:** The development of rapid diagnostic assays for the identification of candida causing bloodstream infections is of utmost importance to reduce morbidity and mortality. Rapid diagnostic tests of pathogens is critical to guarantee adequate therapy for infections. In this study, we evaluated a rapid modified Candida spp. identification from positive blood cultures based on a short-time culture incubation to reduce the turnaround time in bloodstream infection diagnostics in a routine microbiology laboratory.

**Materials/methods:** All hemocultures flagged as positive by bacT/ALERT®, Gram staining positive to yeast of patients admitted at a tertiary hospital in southern of Brazil were included [March to November 2019]. Rapid identification was performed as follow: five drops of blood culture were transferred to the center of a Sabouraud agar and then incubated (35 °C for ut to 4-5h). Growth on the plate was placed onto a spot according to the manufacturer’s instructions for analyses using VITEK MS® system database v3.0 [bioMérieux, France]. Results were compared with standard identification from the subculture in solid medium after 24 hours. A minimum confidence level of 80% has been set for identification criteria.

**Results:** A total of 112 samples were tested: 40 (35.7%) Candida albicans, 2 (1.8%) Candida dubliniensis, 3 (2.7%) Candida krusei, 44 (39.3%) Candida parapsilosis Complex and 23 (20.5%) Candida tropicalis. The percentages of total correct identification of the isolates tested at species level using the rapid protocol were 94.64% [106] samples. Only 6 samples were not identified by this methodology, 1 C. albicans and 5 C. parapsilosis complex. The Vitek MS system was not able to identify closely related species belonging to C. parapsilosis Complex.

**Conclusions:** Current technologies employed in routine diagnostics are based culture growth, which constitutes the actual gold standard. Although those methods are precise and sensitive, they are rather slow. Rapid identification directly from the blood culture bottle using rapid culture is feasible and easy to perform within the laboratory routine. Identification by the rapid method showed a high degree of accuracy. The marked reduction in time to results may have significant implications for patient care.

Abstract 5552

Missed opportunities for an early HIV diagnosis

Dimitrios Bassoulis*, Evangelia-Georgia Kostaki1, Chrysoula Gialouri1, Eirini Iliadi1, Dimitrios Paraskevis2, M. Psichogiou1

11st Internal Medicine Department, Laiko General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 2Division of Hygiene - Epidemiology, National and Kapodistrian University of Athens, Athens, Greece

Background: The World Health Organisation has set out the goal of 90-90-90 in order to control the HIV pandemic. Individuals with indicator conditions (IC) are not always offered testing, suggesting a missed opportunity for an early diagnosis.

Materials/methods: HIV infection dates were inferred by molecular clock analysis using a Bayesian method. Patients’ files were reviewed in order to identify healthcare contacts, where there would be an IC for HIV testing prior to HIV diagnosis.

Results: Among the study population, 82.7% (206/235) were male, 46.8% (110/235) were reported MSM, 41.3% (97/235) PWID, and 10.2% (24/235) heterosexuals. Regarding their diagnosis status, 54% (127/235) were late presenters, and 29.4% (69/235) had advanced disease.

A total of 178 healthcare contacts were recorded in 124 patients (52.7%) between their infection date and the HIV diagnosis date. The most frequent, included mononucleosis-like syndrome (35/178, 19.7%), unexplained weight loss (17/178, 9.6%), sexually transmitted infections (17/178, 9.6%) and a diagnosis of hepatitis B and/or C (13/178, 7.3%). AIDS defining conditions were 24/178 (13.5%). Only 60.4% of people with indication for testing were diagnosed within 1 month of their first healthcare contact.

Our population was divided in 3 groups, i) those diagnosed with preemptive testing (PT) (N=111), ii) individuals with medical indication and proper testing (MIPT) (N=75) and iii) people with indication but no testing (MINT) (N=49).

The median time interval from infection to diagnosis was much shorter for the PT group (230 days, IQR:77-542) than the MIPT group (487 days, IQR:215-827) and the MINT group (680 days, IQR:361-1527) [p<0.001].The median CD4 at diagnosis was 409cells/µl (IQR:226-610), 310cells/µl (IQR:126-480) and 283cells/µl (IQR:135-485) [p=0.039], for the 3 groups respectively.

People in the PT group were less likely to present with advanced disease [24/111, 21.6% vs 27/75, 36% vs 18/49, 36.7%, p=0.046].

Conclusions: Our study shows that preemptive and IC-guided HIV testing can facilitate early diagnosis of HIV. This is one of the few studies that used a combination of clinical and molecular methods to provide evidence about the benefits of different testing strategies to combat late diagnosis.

Effectiveness of bacteriophage-antibiotic combinations for daptomycin-resistant Enterococcus faecium harbouring LiaS and LiaR substitutions

Taylor Morrisette1, Katherine Lev1, Razieh Kebriaei1, Jacinda Abdul-Mutakabbir1, Philip Maassen1, Sandra Morales2, Cesar Arias3, Michael J. Rybak1

1Wayne State University, Anti-Infective Research Laboratory, Detroit, United States, 2Bacteriophage Researcher, Sydney, Australia, 3University of Texas McGovern Medical School, Houston, United States

Background: Enterococcus faecium (E.fcm) infections are difficult to eradicate and there is a growing concern regarding the increased prevalence of daptomycin (DAP)-nonsusceptible (DNS) strains. It has been shown that alterations in liaFSR (three-component regulatory system) are crucial mediators of DNS in enterococci. Given the rising occurrence of DNS E.fcm, there is an urgent necessity of novel therapies. Obligately lytic bacteriophages [phages] are viruses that infect bacteria, replicate within the cell, then lyse the cell to release their progeny to reinitiate the infection cycle. Positive interactions have been described with phage-antibiotic combinations; however, no study has evaluated phage-antibiotic combinations against DNS E.fcm strains, and limited studies have analyzed membrane vesicle (MV) formation [virulence mechanism] with phage-antibiotic combinations. The objective of this study was to determine the ability of combinations of phage plus DAP alone and in combination with DAP plus beta-lactams to improve bacterial killing and/or alter resistance development in DNS E.fcm.

Materials/methods: Clinical strain E.fcm R497 (with substitutions in liaFSR) was evaluated. Due to DAP’s calcium-dependency, Mueller-Hinton broth II (Difco, Detroit, MI) supplemented with 50 mg/L calcium was utilized for susceptibility testing and time-kill analyses (TKA). Minimum inhibitory concentration [MIC] testing was performed and 24h TKAs were evaluated at 0.5x MIC or biologic free peak concentration [whichever was lower]. Phage ATCC 19950-B1 was utilized at ~105 PFU/mL. Synergy (≥ 2-log10 CFU/mL kill compared to the most effective agent alone at 24 hours) and bactericidal activity (≥ 3-log10 CFU/mL reduction at 24 hours compared to the starting inoculum) were evaluated in TKAs. MV experiments and evaluation of antibiotic resistance development were performed as previously described.

Results: R497 exhibited elevated MICs to all antimicrobials evaluated [DAP=16 mg/L, ampicillin [AMP]=128 mg/L, ertapenem [ERT]=>64 mg/L]. The combinations of DAP-AMP and DAP-ERT failed to demonstrate bactericidal or synergistic effects [exception: synergy observed with DAP-AMP]. In contrast, the addition of phage to DAP-AMP and DAP-ERT exhibited bactericidal and synergistic effects (figure 1). There were no significant differences in MV formation and no emergence of antibiotic resistance was observed.

Conclusions: Based on these encouraging results, further research is needed to evaluate phage-antibiotic combinations in DNS E.fcm strains.

Atelerix algirus as host of Salmonella species in Tenerife, Spain
Elena Mercedes Izquierdo Rodríguez¹, Natalia Martín Carrillo*, Edgar Baz-González¹, Pilar Foronda Rodríguez¹

¹University of La Laguna, Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias, San Cristóbal de La Laguna, Spain

Abstract third-party references: by ProID2017010092, Gobierno de Canarias, FEDER

Background: The Algerian hedgehog, Atelerix algirus, is an invasive species in the Canary Island, Spain. Nowadays, it seems to have colonized the islands of Fuerteventura, Lanzarote, Gran Canaria, Tenerife, and La Palma. There is not much information available about A. algirus biodiversity impact on the Canary Islands, and only few studies had been carried out studying the zoonotic pathogens that it could be hosting around the world. Besides, wild hedgehogs are often kept as pets in Canaries, especially by children. Because of the lack of knowledge about the possible pathogens that A. algirus could be hosting, the aim of this study was to analyse the presence of species of Salmonella in faeces of A. algirus.

Materials/methods: Two different types of samples were collected: fresh faeces from living specimens (36) and faeces from the intestine of dead animals (2). All samples and their provenance were provided by La Tahonilla, a wildlife recovery center of Excmo. Cabildo Insular Tenerife. Samples were analysed by FilmArray gastrointestinal panel (Biomerieux).

Results: Salmonella sp. were found in 26 of the 38 samples analysed (68.42%), in nearly every area in which this study was performed, not finding any difference in the prevalence between warm and cold areas.

Conclusions: The high prevalence of Salmonella sp. present in wild hedgehogs in Canaries, could implies a high risk of transmission, not only to other wildlife animals, but to humans, as these animals are often kept as pets by children, the most severe affected by gastrointestinal diseases. Another factor to take into consideration is that hedgehogs present a behavior named anting or anointing, which consist in moistening their spines with saliva. The fact that hedgehogs showed high prevalence of Salmonella sp. could imply a risk for humans to get this bacterium only by touching these animals. The present results could be of help to competent entities to take control measurements in order to prevent the transmission of this causative agent of diarrhea. [Funded by ProID2017010092, Gobierno de Canarias, FEDER].

Abstract 5556

**Appropriateness of antibiotic recommendations within infectious diseases guidelines for patients with a penicillin allergy: a systematic review**

Monica Bianchini1,2,3, Evan Atchley1, Jenna Markus1, Meghan Jeffres*1

1University of Colorado Anschutz Medical Campus (CU Anschutz), Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, United States

**Background:** Clinical practice guidelines are used by clinicians to assist in the management of patients with infectious diseases (ID) and include antibiotic recommendations for patients allergic to penicillin. Modern investigations have established that cross-reactivity between penicillin, cephalosporins, and carbapenems is primarily based on side-chains, not the shared beta-lactam ring. These data indicate that cephalosporins with dissimilar side chains and carbapenems can safely be used in patients with penicillin allergies. The objective of this systematic review is to describe penicillin allergy recommendations and assess the appropriateness based risk of cross-reactivity.

**Materials/methods:** Current guidelines written and/or endorsed by American Academy of Pediatrics, Centers for Disease Control and Prevention, Infectious Diseases Society of America, and Pediatric Infectious Diseases Society that included antibacterial recommendations were included in the analysis. The primary outcomes were the frequency in which ID guidelines recommend non-beta-lactams for patients allergic to penicillin and the risk of cross-reactivity between penicillin and first-line beta-lactams.

**Results:** Twenty-eight guidelines were included, resulting in 560 antibacterial recommendations. Beta-lactams were identified as first-line treatment for 413 (74%) recommendations. Penicillins were included in first-line options in 174 (31%) recommendations, cephalosporins in 184 (33%), and carbapenems in 61 (11%) recommendations. Of the 413 beta-lactam recommendations, there were 261 (63%) alternative antibiotic recommendations: 188 (72%) of those recommendations were specific for patients with penicillin allergies and 73 (28%) included alternative antibiotic recommendations not specific for patients with penicillin allergies. Non-beta-lactams were recommended in 202/261 (77%) treatment recommendations. The risk of cross-reactivity between penicillin and first-line beta-lactams was less low (less than 2%) for 235/413 (57%) recommendations, medium (2 – 20%) for 14/413 (3%) recommendations, and high (greater than 20%) for 164/413 (40%) recommendations.

**Conclusions:** ID guidelines recommend non-beta-lactams for patients with penicillin allergies in 77% of the recommendations. This results in the increase use of less effective and/or more toxic antibiotics than beta-lactams. These ID guidelines should be updated and include recommendations for cephalosporins with dissimilar side chains or carbapenems for patients allergic to penicillin.

**Presenter email address:** meghan.jeffres@cuanschutz.edu
Antifungal susceptibility patterns among clinical isolates of *Aspergillus fumigatus* from paediatric cystic fibrosis patients in Greece: a laboratory-based study with focus on azole resistance

Maria Siopi*, Angeliki Stathi1, Helen Kirikou2, Levantia Zachariadou2, Spyros Pournaras1, Joseph Meletiadis1,3

1Clinical Microbiology Laboratory, “Attikon” University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; 2Microbiology Department, “Aghia Sophia” Children’s Hospital, Athens, Greece; 3Department of Medical Microbiology and Infectious Diseases, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** Allergic bronchopulmonary aspergillosis is estimated to occur in ~18% of cystic fibrosis (CF) patients in Greece [Armstead 2014]. *Aspergillus fumigatus* species complex (SC) is the predominant mould recovered from respiratory secretions of these patients. The prevalence of azole-resistant *A. fumigatus* (AR-Af) in CF patients varies greatly between centres and may reach 9% [Seufert 2018]. Data on Greek clinical isolates are lacking. We therefore investigated the occurrence of AR-Af in Greek paediatric CF patients.

**Materials/methods:** A total of 55 *A. fumigatus* SC strains recovered from sputum samples of 37 paediatric CF patients (14 male-23 female) during 2008-2009 (32 isolates-21 patients) and 2017-2019 (23 isolates-16 patients) were retrospectively tested. Isolates were macro-/microscopically identified to SC level. *A. fumigatus sensu stricto* (SS) were presumptively identified based on growth at 48°C. *In vitro* susceptibility testing of *A. fumigatus* SC strains to amphotericin B (AMB), itraconazole (ITC), voriconazole (VRC), posaconazole (POS), isavuconazole (ISA), anidulafungin (AFG), caspofungin (CAS) and micafungin (MFG) was performed according to EUCAST E.DEF9.3.1. Azole resistance was also tested with the agar dilution method (EUCAST E.Def10.1) and gradient concentration strips (MTS).

**Results:** All isolates grew at 48°C indicating that they belonged to *A. fumigatus* SS. Antifungal susceptibility patterns among all strains are summarized in Table. In total, all isolates were AMB-susceptible and exhibited echinocandin wild-type phenotypes. POS was the most potent azole in *in vitro*, followed by ITC, ISA and VRC. Overall, 2/55 (3.6%) pan-AR-Af SS (ITC, VRC, ISA, POS MIC >8, 4, 8, 1 mg/L, respectively) were detected. The pan-AR-Af phenotype was also found with the agar dilution method (visible growth on azole-containing plates) and MTS (ITC, VRC, ISA, POS MIC >32, 2, 4, 0.75-1 mg/L, respectively). Particularly, these isolates were recovered from subsequent specimens (August/December 2018) of 1/37 (2.7%) 16-year-old male patient without prior azole exposure. Confirmatory molecular identification of the pan-AR-Af isolates and detection of specific mutations in the cyp51A associated with azole resistance are under investigation.

**Conclusions:** This is the first study to document the presence of AR-Af SS in Greek CF patients emphasizing the importance of antifungal susceptibility testing of *A. fumigatus*. Further surveillance multicentre studies are required to estimate the exact prevalence of AR-Af.

Abstract 5559

**Increasing frequency of OXA-48-producing Enterobacterales worldwide and activity of ceftazidime-avibactam, meropenem-vaborbactam and comparators against these isolates**

Mariana Castanheira*, Timothy Doyle¹, Paul R. Rhomberg¹, Helio S. Sader¹, Rodrigo E. Mendes¹

¹JMI Laboratories, North Liberty, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services related to preparing this abstract.

**Background:** OXA-48 are oxacillinases with weak carbapenemase activity that poorly hydrolyze cephalosporins. Isolates producing these enzymes usually harbour other resistance mechanisms that may increase the MICs for $\beta$-lactam agents. We describe the occurrence, additional $\beta$-lactam resistance mechanisms and activity of ceftazidime-avibactam, meropenem-vaborbactam and other antimicrobials against 319 OXA-48-like-producing isolates collected in a 3-year surveillance period.

**Materials/methods:** Among 55,162 Enterobacterales isolates collected during 2016 to 2018, 319 carbapenem-resistant isolates carried genes encoding OXA-48-like enzymes. All isolates were susceptibility tested for ceftazidime-avibactam and comparator agents using reference broth microdilution methods. Meropenem-vaborbactam was tested using lyophilized broth microdilution panels (ThermoFisher). Analysis of $\beta$-lactam resistance mechanisms and MLST was performed in silico using whole genome sequencing data.

**Results:** OXA-48-like-producing isolates increased from 0.5% (80/18,656) in 2016 to 0.8% (150/18,808) in 2018. Isolates were mainly recovered in Europe and adjacent countries (Russia, Turkey and Belarus) and 286 were *K. pneumoniae* (plus 6 species). *K. pneumoniae* isolates belonged to 47 sequence types (STs) with ST395, ST23 and ST11 being the most common (93, 31 and 27 isolates, respectively. All these common STs were detected in Russia. A total of 266 isolates carried *bla*_{OXA-48} and 5 variants of this gene were detected (*bla*_{OXA-163}, *bla*_{OXA-181}, *bla*_{OXA-232}, *bla*_{OXA-244}, *bla*_{OXA-370}). All but 3 isolates carried additional $\beta$-lactamases and 248 isolates carried CTX-M enzymes (229 CTX-M-15) alone or with acquired cephalosporinases, OXA-1 or other $\beta$-lactamase genes. OmpC/OmpK36 was disrupted in 264 isolates and 206 had disrupted OmpF/OmpK35 and these 2 porins were interrupted in 181 isolates. All isolates tested were susceptible to ceftazidime-avibactam and 36.7%/45.5% were susceptible to meropenem-vaborbactam applying CLSI/EUCAST breakpoints. Other $\beta$-lactams were active against 7.5%-21.6% of these isolates and aminoglycosides were active against 14.7% to 51.4%. Tigecycline and colistin were the most active comparators against these isolates inhibiting 95.6%/81.7% at US FDA/EUCAST susceptible breakpoints.

**Conclusions:** The rates of OXA-48-like-producing isolates almost doubled in the 3-years of this investigation, with most isolates being detected in Russia and Turkey. These isolates have multiple $\beta$-lactam resistance mechanisms. OXA-48-like-producing isolates were resistant to most agents tested, but among $\beta$-lactams, ceftazidime-avibactam was active against all isolates tested.

Abstract 5563

**Intestinal colonisation with extended-spectrum beta-lactamase-producing Escherichia coli after international trips in travellers attending a travel clinic in Rio de Janeiro**

Samantha Tufic; Luiz Guilherme De Araújo Longo; Gabriela Caramano De Oliveira; Lucas Cecílio Vilar; Valeria Brígido De Carvalho; Beatriz Meurer Moreira; Karis Maria Rodrigues

1Instituto de Microbiologia Paulo de Góes, Laboratório de Investigações em Microbiologia Médica [LIMM], Rio de Janeiro, Brazil, 2Universidade Federal do Rio de Janeiro, Cives - Centro de Informação em Saúde para Viajantes, Rio de Janeiro, Brazil, 3Universidade Estácio de Sá, Faculdade de Medicina, Rio de Janeiro, Brazil

**Background:** Travel is an important factor for acquisition of colonization by extended-spectrum beta-lactamase (ESBL) producing microorganisms. Risk factors for acquisition of these bacteria include destination region, usage of antimicrobial agents, and occurrence of diarrhea during travel. The aim of this study was to determine the frequency of acquisition of ESBL-producing *Escherichia coli* colonization by travelers attended at the travel medicine center of Universidade Federal do Rio de Janeiro.

**Materials/methods:** Travelers over 18 years of age attended between 2015 and 2018 were invited to participate in the study. Subjects answered a questionnaire and were oriented to collect an anal stool specimen with a cotton swab before travel and upon one week after return. Stool samples were stored into skim-milk, tryptone, glucose and glycerin media. Cultures in Mac-Conkey agar containing 2 microg/mL ceftriaxone were used for ESBL-producing testing. Identification of isolates as *E. coli* was performed by MALDI-TOF. ESBL enzymes were identified by PCR and sequencing. Antimicrobial susceptibility tests (CLSI, 2018), phylogenetic grouping and random amplification of polymorphic DNA (RAPD) were performed for one isolate pre and other isolate post-travel per participant.

**Results:** 153 travelers were interviewed; 65% were female and 143 provided the swab on return. Prior to the trip, ESBL production was observed in 7% (10/153) of the isolates. Among the 143 participants, 29 (20%) returned from the trip with ESBL-producing *E. coli*. All ESBL types isolated were CTX-M: *blaCTX-M15* (18), *blaCTX-M14* (4), *blaCTX-M55* (3), *blaCTX-M2* (2), *blaCTX-M8* (1) e *blaCTX-M27* (1). The highest frequency of acquisition was in the Southeast Asia (50%) (p=0.003). Tourism travel was related to a higher rate of colonization of ESBL producing *E. coli* (p=0.020). Most isolates belonged to phylogroups A or C, followed by B1 and B2. RAPD typing of multidrug resistant isolates revealed that isolates from each subject belonged to a different RAPD type. Isolates showed high resistance frequencies to gentamicin (9%), ampicillin (44%) and trimethoprim-sulfamethoxazole (38%) after return.

**Conclusions:** These data show that travelers departing to international trips from Brazil acquire resistant bacteria in high frequencies, similar to what is observed in travelers from developed countries.

Abstract 5565

Antimicrobial activity of cefepime in combination with taniborbactam (formerly VNRX-5133) against clinical isolates of Enterobacterales from Europe collected from 2018-2019 surveillance

Meredith Hackel*, Dan Sahm1, Mark Wise1

1IHMA, Schaumburg, United States

Background: Taniborbactam is a novel cyclic boronate-based broad-spectrum β-lactamase inhibitor with potent and selective direct inhibitory activity against both serine- and metallo-β-lactamases (Ambler Classes A, B, C and D). Taniborbactam greatly enhances the activity of cefepime against many difficult to treat organisms, including cephalosporin- and carbapenem-resistant Enterobacterales and Pseudomonas aeruginosa. The activity of the investigational combination cefepime-taniborbactam (FTB) and comparator agents was evaluated against clinical isolates of Enterobacterales from Europe during a 2018-2019 surveillance study.

Materials/methods: MICs of cefepime with taniborbactam fixed at 4 mg/L and comparators were determined following CLSI M07-A11 guidelines against 2,977 Enterobacterales. Isolates were from community and hospital infections collected from 113 sites in 24 European countries in 2018-2019. Resistant phenotypes were based on 2019 EUCAST breakpoints v9.0. A provisional susceptible breakpoint of ≤8 mg/L for FTB was considered for comparative purposes. A set of 198 Enterobacterales with meropenem MIC ≥4 mg/L (n=95) or with cefepime/ceftazidime MIC ≥2 mg/L (n=103) was evaluated for the presence of MBL, KPC, ESBL, and OXA-48 group genes via PCR and sequencing. Three isolates with FTB MIC values of 16 mg/L were interrogated by WGS.

Results: FTB showed potent in vitro activity against all Enterobacterales, with MIC90 values of 0.06/0.25 mg/L and >99% inhibited at the provisional susceptible breakpoint of ≤8 mg/L. FTB maintained activity against MBL-, KPC-, OXA-48 group, and ESBL-positive isolates (MIC90 range, 1 to 8 mg/L; 93.3% to 100% of MIC values of ≤8 mg/L).

Conclusions: Taniborbactam significantly restored the in vitro activity of cefepime against Enterobacterales, including isolates nonsusceptible to recently-approved BL/BLI combinations and expressing serine and metallo-β-lactamases. These findings support the continued development of FTB as a potential new treatment option for challenging infections due to resistant Gram negative pathogens.

**Serum concentrations of intravenously administered posaconazole in critically ill patients**

Werner Heinz*1, Dominic Wichmann2, Hartwig Klinker3, Stefan Kluge2

1Klinikum Weiden, Med. Clinic, Weiden, Germany, 2University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 3University of Wuerzburg Medical Center, Med. Clinic II, Division of Infectious diseases, Wuerzburg, Germany

**Background:** Posaconazole is mainly used for prophylaxis and salvage therapy of mold infections in hematological patients and stem cell transplant recipients. To improve bioavailability compared to oral solution in 2016 an intravenous formulation was introduced. Up to now very limited data on the serum concentration of posaconazole in critically ill patients on intensive care units (ICU) are available.

**Materials/methods:** An opportunity to determine posaconazole concentrations (PC) in serum from ICU patients after intravenous application of the azole has been provided to German clinical centers. PC have been determined by HPLC assay. As part of the therapeutic drug monitoring (TDM) information of dosage, time point of first and most recent application, organ impairments, and laboratory values have been requested. All PC of patients receiving a dose of 300 mg daily have been analyzed retrospectively in a pseudonymized databank.

**Results:** 59 PC have been determined from 32 patients (19 female, median age 52 years, range 17-72 years, median body weight 75 kg, median BMI 25.1, range 16.0 – 36.7). Median PC from all 59 samples was 816 ng/mL, mean 1005 ng/mL, range 45 to 4468 ng/mL (figure). 15 PC were below 500 ng/mL and one above 3750 ng/mL. Taking into account only the first sample of each patient median PC was 1129 ng/mL, mean 857.5 ng/mL, range 82 to 4468. Using the average PC per patient the results respectively were 846.0 ng/mL, 1128.9 ng/mL and 82 to 4468 ng/mL. No association of PC with age, BMI or bodyweight have been detected.

**Conclusions:** The majority of patients had sufficient PC. As the PC in this study were lower than those published previously in non-ICU patients, it seems reasonable to use posaconazole TDM in ICU patients. Further investigations are needed to analyze factors having influence on PC in critically ill patients.

![Figure: Posaconazole serum concentrations in 59 samples from ICU patients.](image)

Abstract 5567

**Outcome of Clostridioides difficile infection in patients that are PCR positive: comparison of toxin positive with toxin negative cases**

Claire Johnston*1, Bethan Carter1, Sharon Weinberg1, Abigail Holborow2, Alice Bone1, Ian Blyth2, Joanne Walters1, Michael Perry1, Trefor Morris3, Harriet Hughes1, Joanna Hargreaves2, Charlotte Richards1, Julie Harris1, Brendan Healy2

1Swansea Bay University Health Board, Morriston Hospital, Swansea, United Kingdom, 2Public Health Wales NHS Trust, Singleton Hospital, Swansea, United Kingdom, 3Public Health Wales Microbiology Dept, UHW, Cardiff, United Kingdom

**Background:** Optimal algorithms for the laboratory diagnosis of Clostridioides difficile infection (CDI) remain somewhat controversial. Molecular detection of the toxin gene[s] is sensitive but lacks clinical specificity. Conversely, assays that detect free toxin are specific but lack sensitivity. The most appropriate management at population level for patients with diarrhoea who test positive for the toxin gene only remains unclear. Management of 100 patients with toxin gene positive stool samples was assessed.

**Materials/methods:** In our hospital stool samples are tested on all adult patients with diarrhoea (type 5 stool or above). Specimens are processed using the Serosep EntericBio realtime® C. difficile assay for the detection of the C. difficile toxin B gene. Positive samples are subsequently tested for the presence of toxin using an EIA toxin detection test (Abbott tox A/B Quik Chek®). Clinicians are informed of the EntericBio result only. Management is determined at ward level by clinical parameters. Detailed analysis of the presentation and management of 100 randomly selected patients from a 12 month period was performed.

**Results:** 77 patients were toxin negative, 23 toxin positive. Mean CT values were 31.17 (24.81-35.98), Median 31.59. Of the PCR positive, toxin negative cases 31 had subsequent positive tests [range 1-8, 11 > one subsequent positive] and 27 had subsequent negative tests [range 1-8, 12 > one subsequent negative, 14 had subsequent positive tests]. Ribotype data below (excluding 13 not isolated, 15 not available). Data on treatment, stool frequency, stool consistency, response and severity assessment is also presented.

**Conclusions:** The optimal management of diarrhoea in patients who are C. difficile toxin gene positive, but free toxin negative is not well defined. We present data on the clinical parameters and management of a subset of these patients based on clinical assessment and without access to the free toxin result to further inform this debate.

Abstract 5568

**Spread of metallo-β-lactamases among distinct species of Pseudomonas putida group in Brazil**

Felipe Lei, Carolina Silva Nodari, Ana Streling, Francisco Ozorio, Juliana Paulino, Rodrigo Cayó Da Silva, Ana Gales

1Universidade Federal de São Paulo, Laboratório Alerta, Division of Infectious Diseases, Department of Internal Medicine, São Paulo, Brazil

**Background:** PpG species are usually ubiquitous and rarely involved in human infections. However, these strains might act as a reservoir of antibiotic resistance determinants, which may be transferred to clinical isolates and vice-versa. Herein, we report the emergence of carbapenem-resistant PpG carrying distinct MβL encoding genes causing human infections in Brazil.

**Materials/methods:** A total of 12 non-duplicated carbapenem-resistant Pseudomonas spp. isolates initially identified as *P. putida* by Phoenix BD® automated system were recovered from different clinical specimens in two Brazilian hospitals located in the city of São Paulo, Brazil, between May/2010 and October/2019. The identification at species level was confirmed using MALDI-TOF MS. Minimal inhibitory concentrations (MICs) of nine antimicrobials were determined by EUCAST broth microdilution. The detection of carbapenemase encoding genes was performed by PCR followed by sequencing. Genetic relationship within species was determined by ERIC-PCR.

**Results:** Most isolates were identified as *P. monteilii* (n=7), followed by *P. putida* (n=3), *P. graminis* (n=1), and *P. plecoglossicida* (n=1). They were recovered from blood (n=6), sputum (n=1), peritoneal fluid (n=2), and urine (n=3). All isolates were resistant to meropenem (MICs varying from 32 to >128 mg/L), ceftazidime (MICs varying from 16 to >128 mg/L), and aztreonam (MICs varying from 16 to >128 mg/L). In addition, most PpG isolates (n=10) were resistant to imipenem (MICs varying from 4 to >128 mg/L), piperacillin/tazobactam (n=9, MICs varying from 2 to >128 mg/L), and ciprofloxacin (n=8, MICs varying from 1 to >128 mg/L). In opposite, all isolates were susceptible to amikacin and polymyxin B (MIC90, 8 and 0.5 mg/L, respectively). MβL encoding genes were found in all PpG isolates, as follows: *bla*<sub>VIM-2</sub>-like (n=4), *bla*<sub>IMP-16</sub>-like (n=3), *bla*<sub>IMP-34</sub>-like (n=2), and *bla*<sub>IMP</sub>-like (n=1). Preliminary sequencing results showed that one *P. monteilii* carried a novel putative carbapenemase. Additionally, one *P. putida* isolate harbored both *bla*<sub>MP13</sub>-like and *bla*<sub>VIM-2</sub>-like genes. Interestingly, no predominant clone among the MβL-producing PpG isolates was detected.

**Conclusions:** This is the first report of MβL encoding genes among distinct PpG species causing infections in Brazil. We demonstrated that these environmental species can also be pathogenic and act as reservoirs for further spread of antimicrobial resistance determinants.

Abstract 5571

The variability of the lymphocyte populations in the cerebrospinal fluid of patients with tick-borne encephalitis
Sambor S. Grygorczuk*, Joanna Osada1, Anna Moniuszko1, Justyna Dunaj1, Slawomir Pancewicz1

1Uniwersytet Medyczny w Białymstoku, Department of the Infectious Diseases and Neuroinfections, Białystok, Poland, 2Uniwersytet Medyczny w Białymstoku, Department of the Hematologic Diagnostics, Białystok, Poland

Abstract third-party references: Medical University in Białystok, Poland, National Science Centre, Poland, grant UMO-2018/31/B/NZ6/02744

Background: The clinical presentation and outcome of tick-borne encephalitis (TBE) is highly variable, with no validated prognostic markers. Lymphocytes infiltrating central nervous system (CNS) are probably crucially involved both in the control of TBE virus infection and in the immune-mediated tissue pathology. However, the pathogenetic role and a potential prognostic significance of particular lymphocyte subsets remains unclear. To constrain it better, we have analyzed abundances of blood and CSF lymphoid cell populations in TBE patients stratified according to a clinical presentation and severity.

Materials/methods: We have studied paired blood and CSF samples from 50 patients in the early neurologic phase of TBE (30 with uncomplicated meningitis, 18 with mild to moderately severe meningoencephalitis and 2 with myelitis), 20 meningitis controls with non-TBE aseptic meningitis and 11 healthy controls (blood only). TCD3+, TCD3+CD4+, TCD3+CD8+, double-positive TCD3+CD4+CD8+, CD19+ B lymphocytes and CD16/56+ NK cells were labeled with fluorochrome-stained monoclonal antibodies and counted cytometrically. The data were analyzed with non-parametric tests, p<0.05 considered significant.

Results: Blood: Compared to controls, TBE patients had decreased total lymphocyte, TCD3+, TCD3+CD4+ and TCD3+CD8+, marginally decreased NK and not altered B lymphocyte counts. Cell counts did not associate with the TBE clinical presentation. CSF: Compared to aseptic meningitis, TBE patients had lower counts of all the studied populations except B cells. Lymphocytes B were more abundant in meningoencephalitis/myelitis than in meningitis. The higher TCD3+, TCD4+ and TCD8+ counts associated with the altered consciousness, but not with the other symptoms of encephalitis (focal neurologic deficits, cerebellar syndrome). However, two myelitis patients had exceptionally high proportion of both TCD8+ and B lymphocytes. The minor double-positive TCD4+CD8+ population associated negatively with clinical severity and was relatively more abundant in meningitis than in meningoencephalitis/myelitis.

Conclusions: The distinct CSF lymphoid cell populations associate differently with the clinical presentation of TBE, suggesting their distinct pathogenetic roles and offering a potential of distinguishing TBE phenotypes based on the intrathecal immune response and associated clinical features. Higher counts of B, TCD4+ and TCD8+ lymphocytes may associate with overlapping but distinct spectra of CNS manifestations, while a higher fraction of double-positive T cells associates with uncomplicated meningitis.

Effectiveness of ceftazidime-avibactam in a tertiary hospital of Spain

Malen Aguirregabiria¹, Nerea Antona Urieta¹, Leyre Lopez Soria¹, Josune Goikoetxea¹, Mikel Castaño Lopez¹, José Luis Barrios Andrés*¹

¹Hospital Universitario Cruces, Barakaldo, Spain

Background: Ceftazidime-avibactam (CAZAVI) is a broad spectrum antimicrobial for the treatment of gram-negative multi-drug-resistant bacilli infections. Its activity against OXA-type and KPC carbapenemases is particularly relevant. The aim of our study was to evaluate the effectiveness of the treatment in the infections caused by this type of microorganisms.

Materials/methods: Between June 2018 and October 2019 patients treated with CAZAVI in the Cruces University Hospital (Basque Country, Spain) were analysed. This is a 900 bed tertiary hospital, covering a health area of 300,000 inhabitants. Demographic, clinical and microbiological data were analyzed for each patient.

Results: During the study period, 14 patients received treatment with CAZAVI, 11 males and 3 females with a median age of 63.5 years. There were four cases of septicaemia, 3 urinary tract infections, 3 abdominal syndromes, 3 respiratory infections and CAZAVI was only used empirically in other case of non-specific febrile syndrome but after previous positive colonization cultures. Treatment was directed against OXA-48 producing K. pneumoniae in 9 patients, KPC producing enterobacteria and other multi-resistant microorganisms in 2 each one and ceftazidime susceptible P. aeruginosa in other one. One patient suffered 2 episodes and was treated in both with CAZAVI. The median number of days of treatment was 5. The evolution was favourable in 11 patients while 3 died. In 6 patients microbiological eradication was achieved in subsequent cultures, while in 6 not and in 2 was unknown due to lack of subsequent cultures. In one deceased patient, treatment was directed towards a multidrug resistant A. baumannii. Of the other 2 deceased patients, one suffered a cholecystitis by K. pneumoniae producing OXA-48 that was microbiologically eradicated and the other one, a septicaemia by E. coli KPC + CIT-type plasmidic AmpC with unknown eradication. Both were terminally ill and died for underlying diseases.

Conclusions: The evolution of the patients treated with CAZAVI was favourable in 78% of the cases. The deceased patients were patients with multiple comorbidities and their death was due to other causes than infectious. Ceftazidime-avibactam was shown to be an effective treatment for infections produced by microorganisms harbouring carbapenemases type OXA-48 and KPC.

Abstract 5573

**ESBL- and pAmpC-producing *Escherichia coli* in imported broiler breeding birds for the Swedish broiler production**

Stefan Börjesson*1,2, Oskar Nilsson1, Annica Landén1, Christina Greko1, Björn Bengtsson3

1National veterinary institute (SVA), Uppsala, Sweden, 2Linköping University, Linköping, Sweden

**Background:** Extended-spectrum beta-lactamases (ESBL) and plasmid mediated AmpC (pAmpC) producing *E. coli* is commonly described in the European broiler production, including in countries i.e. Sweden that are regarded as favorable countries regarding the antibiotic resistance situation. In Sweden use of antibiotics in broilers production is very limited, and extended spectrum cephalosporins are not used at all. Thus, selection due to usage was unlikely. Instead it was hypothesized that the bacteria could have been introduced from imported breeding birds and spread through the production pyramid. This theory was proven correct in a study following imports and their prodigy in 2010 to 2011. As a results SVA has since 2010 monitored all imports of breeding birds for the occurrence of ESBL- and pAmpC-producing *E. coli*.

**Materials/methods:** Samples of paper linings from shipments of breeding animals was first pre-enriched in either MacConkey broth supplemented with 1 mg/L cefotaxime or buffered peptone water. From the enrichment 10 µl was plated on MacConkey Agar with 1µg/mL cefotaxime, suspected isolates were than confirmed with PCR.

**Results:** Of 107 shipments in the period 2010 to 2018, 40% of the shipments were shown to be positive for either ESBL- or pAmpC-producing *E. coli*. In addition, the proportion of positive shipment decreased over the years and in 2018 all shipments were negative [Figure 1.]. The ESBL genes detected were blaCMY-2-gene group, blaCTX-M-1 -gene group and sporadically the blaSHV-group.

**Conclusions:** Due to the potential risk of transfer of ESBL- and pAmpC-producing *E. coli* from broilers directly or via food to humans, it is important to monitor and understand the occurrence of these bacteria in broilers. We could show that these bacteria were present in imported breading birds for the Swedish broiler production on arrival to Sweden and that the proportion of positive shipments decreased over the years.

![Figure 1. Percent of shipments of imported breeding animals positive for ESBL/pAmpC-producing E. coli from August 2010 to 2018.](image)

Abstract 5575

A multi-omics approach to understanding the aetiology of Q fever fatigue syndrome
Ruud Raijmakers1, Megan Roerink1, Anne F.M. Jansen1, Stephan Patrick Keijmel1, Ranko Gacesa2, Yang Li1,3, Leo A.B. Joosten1, Jos W.M. Van Der Meer1, Mihai Gheorghe Netea1, Chantal Bleeker-Rovers1, Chengjian Xu1,3
1Radboud University Medical Center, Nijmegen, Netherlands, 2University Medical Center Groningen, Groningen, Netherlands, 3Centre for Individualised Infection Medicine, Hannover, Germany

Background: Q fever fatigue syndrome (QFS) is characterised by a state of prolonged fatigue following 20% of acute Q fever infections that has major health-related consequences. However, the aetiology of QFS remains unclear. In order to understand this, we compared the gut microbiome, blood metabolome, and inflammatory proteome of QFS with those of chronic fatigue syndrome (CFS) patients and healthy controls.

Materials/methods: The study population consisted of 31 QFS patients, 50 CFS patients, and 50 healthy controls. All subjects were matched for age (± 10 years), gender, and general geographical region. The gut microbiome composition was assessed by Metagenomic sequencing using the Illumina HiSeq platform. For inflammatory proteome and metabolome, a total of 92 circulating inflammatory markers and 1607 metabolites were measured using Proximity Extension Essay and a high-throughput non-targeted metabolomics approach.

Results: Significant differences are documented in microbiome taxonomy when comparing QFS and CFS patients to healthy controls, reflected by upregulation of pathways like urate biosynthesis/inosine 5'-phosphate degradation (P = 1.32x10^-30 and 8.94x10^-57) and CMP-3-deoxy-D-manno-octulosonate biosynthesis I (P = 3.37x10^-23 and 5.27x10^-34). When comparing QFS patients to CFS patients, differences are less significant, reflected by upregulation of pathways like L-lysine biosynthesis III and VI (P = 8.93x10^-5 and 2.12x10^-4). Blood metabolite profiles show significant differences when comparing QFS and CFS patients to healthy controls, reflected by upregulation of pathways like sphingolipid (P = 0.008 and 6.25x10^-4) and glycerophospholipid (P = 0.036 and 0.028) metabolism. No significant differences were found when comparing QFS to CFS patients. Inflammatory markers 4E-BP1 (P = 9.60x10^-16 and 1.41x10^-7) and MMP-1 (P = 7.09x10^-9 and 3.51x10^-9) are significantly more expressed in both QFS and CFS patients compared to healthy controls.

Conclusions: We show that; QFS and CFS patients have similar profiles in gut microbiome taxonomy and blood metabolite composition, QFS patients have more of an inflammatory profile compared to both CFS patients and healthy controls, and 4E-BP1 and MMP-1 have potential to differentiate QFS and CFS patients from healthy controls.

Antimicrobial activity of cefepime in combination with taniborbactam (formerly VNRX-5133) against a European 2018-2019 surveillance collection of Pseudomonas aeruginosa

Meredith Hackel*, Dan Sahm1, Mark Wise1

1IHMA, Schaumburg, United States

Background: Taniborbactam is a novel cyclic boronate-based broad-spectrum β-lactamase inhibitor with potent and selective direct inhibitory activity against both serine- and metallo-β-lactamases (Ambler Classes A, B, C, and D). Taniborbactam greatly enhances the activity of cefepime against many difficult to treat organisms, including cephalosporin- and carbapenem-resistant Enterobacteriales and Pseudomonas aeruginosa. In this study, we evaluated the in vitro activity of the investigational combination cefepime-taniborbactam and comparator agents against clinical isolates of P. aeruginosa collected in Europe during 2018-2019 surveillance.

Materials/methods: MICs of cefepime with taniborbactam fixed at 4 mg/L (FTB) and comparators were determined following CLSI M07-A11 guidelines against 676 P. aeruginosa from community and hospital infections collected from 86 sites in 23 countries in Europe in 2018-2019. Resistant phenotypes were based on 2019 EUCAST breakpoints v9.0. As FTB breakpoints have not yet been established, a provisional susceptible breakpoint of ≤8 mg/L was considered for comparative purposes. The presence of metallo-β-lactamase genes was assessed via PCR and Sanger sequencing for 95 randomly selected isolates with meropenem MIC ≥28 mg/L and 45 isolates with cefepime or ceftazidime MIC ≥16 mg/L, and via WGS for 18 isolates exhibiting FTB MIC values ≥16 mg/L.

Results: FTB demonstrated potent in vitro activity (MIC50/90, 2/8 mg/L; 96.9% inhibited at ≤8 mg/L) against P. aeruginosa isolates from Europe. Provisional susceptibility rates to FTB ranged from 75.0% vs ceftolozane-tazobactam nonsusceptible (NS) isolates to 90.1% vs meropenem NS isolates compared to 0 to 72.8% susceptible for comparators against the NS subsets (Table). Against the 22 strains with acquired β-lactamases identified, FTB MICs were ≤8 mg/L (n=13), 16 mg/L (n=7) and >32 mg/L (n=2; both IMP producers).

Conclusions: Cefepime in combination with taniborbactam demonstrated potent in vitro activity against P. aeruginosa from Europe with different phenotypic resistance profiles, including nonsusceptibility to cefepime, meropenem, and piperacillin/tazobactam, and to the recently introduced protected β-lactam/β-lactamase inhibitors ceftazidime-avibactam, cefotazidime-tazobactam, and meropenem-vaborbactam. These findings support the continued development of FTB as a potential new treatment option for challenging infections due to resistant Gram negative pathogens.

Abstract 5578

Comparison of bacterial recovery of stored sonication fluid cultures using liquid broth and solid media obtained from orthopaedic implant-associated infections

Mariana Kurihara1, Ingrid Nagara Marcelino Santos1, Beatriz Castro1, Antônio Pignatari1, Mauro Jose Costa Salles*2

1Unifesp-SP, São Paulo, Brazil, 2UNIFESP, São Paulo, Brazil

Background: Sonication of explanted hardware during surgery has shown superior results as microbiological diagnostic tool in orthopedic implant-associated infections (OIAI) when compared to periprosthetic tissue cultures. In addition, sessile microorganisms seem to grow easily and faster on liquid media compared to solid agar plates. Notwithstanding, contamination on liquid media may be a source of false-positive results. We aimed at investigating the usefulness of the thioglycollate (TG) and brain heart infusion (BHI) broth compared to solid media (5% sheep blood agar and MacConkey agar) for the microbial recovery of stored sonication fluid samples of implant-associated infections.

Materials/methods: This study analyzed sonication fluid samples stored at -80°C, which were obtained from retrieved prosthesis, plates and screws of 426 patients with OIAI, between 2014 and 2018. Diagnosis of OIAI was based upon standard criteria as previously published. Briefly, implants were packed into sterilized solid polyethylene containers and covered with Ringer’s solution, sonicated for 5 minutes at a frequency of 40±2 kHz and power density 0.22±0.04 W/cm², followed by 30 seconds of vortexing. Stored sonication fluid was defrosted at room temperature and 15-20 µL plated onto aerobic plates, TG and BHI, and incubated aerobically at 35°C in 5% CO2 for 4 days. The microorganisms isolated were identified according to standard method. Statistical analysis was performed using McNemar’s test for related proportions.

Results: Sonication fluid cultures yielded 63.4% (n= 270/426) of pathogen detection. Subsequently, 162 positive sonication samples were plated on agar and 146 on broth (TG and BHI). Identification of pathogens using agar plaques and broth (TG and BHI) resulted in 41.3% (n= 67/162) and 66.4% (n= 97/146) of positivity, respectively (p<0.0001). Identification of pathogens using TG or BHI broth resulted in no statistical significance, in which microorganisms were recovered by BHI and TG in 60.8% (n=59/97) and 39.1% (n= 38/97), respectively (p=0.11).

Conclusions: We highlight that the recovery of subcultured samples in liquid broth contributed to the identification of the microorganism. Lastly, it is important to emphasize that TG broth is an enriched medium, given that, contaminants can grow as well occurring false-positive diagnostic.

In vitro susceptibility of carbapenem-resistant Enterobacteriaceae from the Arabian Peninsula to ceftazidime-avibactam, aztreonam-avibactam and other rescue antibiotics

Tibor Pal*¹, Agnes M. Sonnevend², Akela Ahmed Ghazawi¹, Dania Darwish¹, Greeshma Bharathan¹, Rayhan Hashmey³, Tanveer Ashraf⁴

¹United Arab Emirates University, Al Ain, United Arab Emirates, ²University of Pécs Faculty of Medicine, Pécs, Hungary, ³Tawam Hospital, Al Ain, United Arab Emirates, ⁴Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates

Background: The aim of the study was to assess susceptibility of carbapenem resistant Enterobacterales (CRE) from the Arabian Peninsula to potential rescue drugs, and to relate the data to various mechanisms of carbapenem resistance.

Materials/methods: Altogether 1192 non-repeat CRE isolated in 2009-2017 from 33 hospitals in 5 countries of the Arabian Peninsula were tested. Minimum inhibitory concentration (MIC) of 14 antibiotics including ceftazidime-avibactam and aztreonam-avibactam was determined by broth microdilution, and of fosfomycin and tigecycline by agar dilution. Common carbapenemase and 16S methylase genes were detected by PCR. Clonality of the strains was assessed by PFGE.

Results: The highest rate of susceptibility was detected to aztreonam-avibactam (95.5%) followed by colistin (79.8%), fosfomycin (71.8%) and tigecycline (59.9%). Aminoglycoside susceptibility was affected by the frequent production of a 16S methylase (44.2% of isolates), most commonly armA and rmtF. Susceptibility to ceftazidime-avibactam was impacted by the high rate of MBL producers (46.3% of all isolates). Ceftazidime-avibactam susceptibility rate of the non-MBL producers was 98.9%. While the majority (93.4%) of carbapenemase non-producing strains exhibited a meropenem MIC value <16 mg/L, this was comparatively rare (27.8%) among carbapenemase producers. With considerable variations between countries, 12.4% of the strains expressed both NDM and OXA-48-like carbapenemases, and these exhibited the lowest rate of susceptibilities. The aztreonam-avibactam resistance was not related to any carbapenem resistance mechanism, and although the majority of the 54 isolates were E. coli (n=41), they did not exhibit clustering by PFGE.

Conclusions: Based on the in vitro susceptibility rates, of the currently available options to treat CRE infection in the Arabian Peninsula, colistin, tigecycline and co-administration of ceftazidime-avibactam with aztreonam appear to be the most effective. In the light of the relatively high rate of fosfomycin susceptibility, it is desirable to have parenteral fosfomycin licensed in the region. A notable concern is the presence of non-clonal CRE isolates, in which avibactam does not lower the aztreonam MIC below the clinical breakpoint, potentially hindering the efficacy of co-administered ceftazidime-avibactam and aztreonam as a rescue therapy.

Abstract 5580

Increased burden of invasive pneumococcal disease caused by non-vaccine serotypes in individuals with underlying diseases: a population-based case-control study

Pontus Naucler*1,2, Evangelos Alexandros Petropoulos1, Ilias Galanis3, Eva Morfeldt1, Ake Örtqvist1, Birgitta Henriques-Normark1

1Karolinska Institutet, Stockholm, Sweden, 2Karolinska University Hospital, Stockholm, Sweden, 3Public Health Agency of Sweden, Solna, Sweden

Background: The impact of introducing pneumococcal conjugate vaccines (PCV) in the childhood vaccination program on invasive pneumococcal disease (IPD) in individuals with co-morbidities is insufficiently understood. In this nation-wide study we investigated the risk of serotype-specific IPD in individuals with co-morbidities, and the effect of co-morbidities on the IPD incidence after PCV introduction in Sweden in 2009.

Materials/methods: A case-control study was performed during 2006-15, including all IPD cases in Sweden, and randomly selected controls from the general population, matched on age, sex and region. It is mandatory to report IPD to the Public Health Agency of Sweden where serotyping of isolates is performed. Data on co-morbidities was obtained from the Patient and Pharmaceutical Registers that contain information on all hospital visits and prescriptions. Co-morbidities were defined as immunocompetent chronic medical conditions (CMC), and immunocompromising conditions (IC). Incidences and risks were analyzed for certain serotypes, and according to serotypes included in the vaccines: PCV13, non-PCV13, PPV23-non-PCV13, and non-vaccine serotypes (NVTs).

Results: Totally 14096 IPD cases and 137289 controls were included. Preliminary analyses show an increase of co-morbidities both among cases and controls when 2006-7 (pre-vaccine) was compared to 2014-15 (post-vaccine). The absolute increase of the IPD incidence caused by non-PCV13, PPV23-non-PCV13 and NVTs, was higher in individuals with IC and CMC, than in those without co-morbidities. The odds ratios (OR) for IPD caused by non-PCV13, and particularly NVTs, compared to PCV13 serotypes, were higher for individuals with CMC and IC. Five serotypes [16F, 15C, 19F, 35F and 23A], of which four are not included in PCV13 or PPV23, conferred the highest risks with ORs between 4 and 5 in individuals with CMC and >10 for those with IC. The mortality due to non-PCV13 serotypes increased from the pre- to the post-vaccine period in individuals with IC and CMC, while it remained stable for those without co-morbidities.

Conclusions: We observed an association between PCV childhood immunization and an expansion of NVTs that preferentially cause IPD in individuals with underlying disease, in particular those with IC. These results have implications for development of new vaccines and immunization strategies.

The trouble with gentamicin: a realist evaluation exploring two distinct protocols for prescribing gentamicin in hospital settings

Nadine Dyar*, Karen Mattick1, Rob Bethune2

1University of Exeter- Saint Luke's Campus, Exeter, United Kingdom, 2Royal Devon & Exeter Hospital, Exeter, United Kingdom

Background: Gentamicin is one of the most frequently prescribed aminoglycosides in UK hospitals, but it is challenging to prescribe and the evidence basis for prescribing it is limited. Consequently, each hospital in the UK has developed their own prescribing protocol.

We used a realist evaluation approach to explore two distinct protocols for prescribing gentamicin in hospital settings, to understand the mechanisms they trigger and the clinical outcomes they achieve.

Materials/methods: The project was conducted in three phases: initial programme theory (IPT) generation; testing; and refinement of the IPT.

We collected empirical data using a mixed-methods approach. The qualitative component involved semi-structured interviews of healthcare professionals' experiences of prescribing gentamicin according to the existing protocols in their institution [Site 1, a more traditional, complex protocol; Site 2 a newer, simplified protocol]. The quantitative component included prospectively auditing the accuracy of 100 gentamicin prescribing episodes.

We developed the IPT from analysis of the gentamicin prescribing protocols. We detailed the 'intended' process of prescribing, identifying possible key contexts, mechanisms and outcomes in this process. We then tested and refined these theories during the interviews. Qualitative and quantitative data were analysed together to support developing theories.

Results: The mean accuracy of gentamicin prescribing at Site 1 was 65.67% and 78.79% at Site 2 (p<0.01). Eight patients developed an acute kidney injury. Of these, seven had received an accurate dose of gentamicin.

Thirty participants were interviewed. From respondents we identified key contexts [prescriptiveness of protocol; clinician experience; availability of patient information] that influenced their ability to prescribe, and triggered hidden mechanisms [uncertainty; fear; confidence; frustration] which can lead to both the intended outcome (adherence to the prescribing protocol), and unintended outcomes [intentional deviation from protocol; unintentional non-adherence; unnecessary gentamicin levels]. The audit data supported our suggested mechanisms, contexts and outcomes. For example, participants frequently reported concerns about nephrotoxicity and were aware that this could lead to cautious prescribing. According to audit data, under-dosing occurred at 24% at Site 1, 12% at Site 2.

Conclusions: A simplified prescribing protocol for gentamicin is better accepted by prescribers, leads to better adherence to protocol and more accurate prescribing.

Evaluation of a quantitative multiplex PCR panel for the diagnosis of pneumonia: how do we optimise utilisation?

Susan Whittier*, Mabel Lopez1, Yunhua Chen1

1Columbia University Medical Center, New York, United States

Background: Guidelines for the management of adults with hospital-acquired pneumonia (HAP) and ventilator-associated pneumonia (VAP) were recently published by IDSA and ATS. For patients with suspected infections, the recommendations include empiric therapy against Staphylococcus aureus (SA) and Pseudomonas aeruginosa (PA). While antimicrobial de-escalation can occur when susceptibility results are available 48 hours after specimen collection, this is often a missed opportunity.

Materials/methods: We chose to evaluate a recently FDA-approved quantitative multiplex PCR panel designed to aid in the diagnosis of pneumonia in an effort to determine the potential impact on the recommendations of this guideline. A total of 126 BALs and mini-BALs submitted for routine bacteriologic culture were tested using the FilmArray Pneumonia Panel (BioFire, Salt Lake City, UT), a multiplex PCR panel that includes 18 bacteria (15 of which are quantitated as copies/ml), 7 antimicrobial resistance markers and 8 viruses. Pneumonia Panel (PP) results were compared to quantitative and semi-quantitative cultures. Out-patient (N = 29) and in-patient (N = 97) results were analyzed separately.

Results: Of the 97 in-patient specimens, 34 (35%) were categorized as positive (>10^4 CFU/ml) for at least one bacterial pathogen by either PP or culture. For 23 of these 34 (67%), PP and culture were concordant. For discordants, 8/11 cultures grew organisms that are not on the PP panel and 3/11 PP were positive for PA and cultures were negative. PA and/or SA were detected in 15 of 34 (44%) positive samples. Sixty-three specimens were PP negative and were ultimately finalized as "No growth" or "Mixed Commensal Microbiota".

Conclusions: Based on this analysis, we determined that utilization of the PP could have a positive impact on antimicrobial management of patients suspected to have HAP or VAP. Targeted therapy for patients with PA and/or SA could have been initiated for 44% and antimicrobial avoidance could have been considered for 65% of patients being evaluated. In conclusion, we believe the PP is an excellent adjunct to other aspects of clinical care and diagnostic testing.

Abstract 5584

Routine use of MALDI-TOF MS for identification of non-tuberculous mycobacteria species in the clinical laboratory
David Rodriguez-Temporal*1,2, Neus Vila1, Erika I. Garcia1, Mireia Mas1, Fernando Alcaide1,2

1Servei de Microbiologia, Hospital Universitari de Bellvitge-IDIBELL, Hospitalet de Llobregat, Spain, 2Department of Pathology and Experimental Therapy, Universitat de Barcelona, Hospitalet de Llobregat, Spain

Background: Currently, there are 199 different mycobacterial species described and the isolation of nontuberculous mycobacteria (NTM) is increasing in clinical laboratories. It is important for patient management to reach species level identification, but the commercial molecular methods used to identify them are limited to a certain number of species. The MALDI-TOF mass spectrometry system has proved to be faster and cheaper, and it could be an alternative for mycobacteria identification. The aim of this study was to evaluate the routine use of MALDI-TOF for identification of NTM isolates from clinical samples.

Materials/methods: A prospective study of all NTM isolated in our geographical area (Costa de Ponent, Barcelona) was carried out during two years (2018-2019). The identification to species level was performed as follows: a) MALDI-TOF Biotyper system (Bruker Daltonics); b) PCR-reverse hybridization (GenoType CM/AS, Hain Lifescience); c) Sequencing of partial 16S rRNA gene in case of discrepancy among the previous methods. The protein extraction procedure for MALDI-TOF was carried out by heat inactivation, acetonitrile, formic acid and sonication. A score cut-off ≥1.7 was used as correct species identification.

Results: A total of 274 isolates of NTM were identified during the period of the study. The MALDI-TOF identified 250 (91.2%) isolates with a score ≥1.7 (26 different species). The PCR-reverse hybridization identified 262 (95.6%) isolates (16 different species). Among the isolates that did not reach score ≥1.7: a) 2 1/24 were slow-growing mycobacteria, and b) 1 7/24 were processed from liquid media. Three (1.1%) isolates that were not recognized neither by MALDI-TOF nor PCR-reverse hybridization were identified by gene sequencing. The results provided by MALDI-TOF were obtained between 0-4 days after culture positivity. The PCR-reverse hybridization required to batch the samples, so it was performed once a week.

Conclusions: All the NTM species with a score ≥1.7 by MALDI-TOF were accurately identified. Although the number of isolates identified by mass spectrometry was slightly lower than PCR-reverse hybridization, it reached a higher important number of different NTM species. Thus, the first method of choice for rapid, accurate and diverse NTM identification could be MALDI-TOF, followed by other molecular methods.

Neuro-inflammation in patients with chronic and Q fever fatigue syndrome

Ruud Raijmakers*1, Megan Roerink1, Stephan Patrick Keijmel1, Leo A.B. Joosten1, Mihai Gheorghe Netea1, Jos W.M. Van Der Meer1, Iris Sommer1, Hans Klein2, Chantal Bleeker-Rovers1, Janine Doorduin2

1Radboud University Medical Center, Nijmegen, Netherlands, 2University Medical Center Groningen, Groningen, Netherlands

Background: The pathophysiology of chronic fatigue syndrome (CFS) and Q fever fatigue syndrome (QFS) remains elusive. Increasing evidence suggests that neuroinflammation plays a role. Neuroinflammation is characterised by microglia and astrocyte activation, which in turn is associated with increased expression of translocator protein (TSPO). This study investigated the presence of neuroinflammation in CFS patients and QFS patients compared with healthy controls, using Positron Emission Tomography (PET) with the TSPO ligand [11C]-PK11195.

Materials/methods: The study population consisted of CFS patients (n = 9), QFS patients (n = 10), and healthy controls (n = 9). All subjects were matched for age (± 5 years), gender and geographical region (south-eastern part of the Netherlands). All subjects were between 18 and 59 years of age and did not use any medication (including doxycycline), other than paracetamol or oral contraceptives, and were not vaccinated in the last six months. None of the subjects reported substance abuse in the past 3 months or showed signs of underlying psychiatric disease, i.e., depression, bipolar disorders, anxiety, schizophrenia, psychosis, or eating disorders, on Mini-International Neuropsychiatric Interview (MINI). All subjects underwent a [11C]-PK11195 PET scan and the [11C]-PK11195 distribution volume ratio (DVR) was calculated using the cerebellum as a reference region.

Results: The DVR was found to be highest in the brainstem for all groups (1.15 ± 0.05). For all other examined brain regions the DVR ranged between 0.83 and 1.2. No statistically significant differences were found for CFS patients when compared to healthy controls, although for the right temporal cortex, right parietal cortex, and left and right occipital cortex a 1.9 to 2.8% increase in DVR was found. A statistically significant higher DVR (P < 0.05) was found in the right parietal cortex (0.98 ± 0.04) of QFS patients when compared to healthy controls (0.93 ± 0.03).

Conclusions: This study revealed a statistically significant increase in [11C]-PK11195 DVR in the right parietal cortex of QFS patients, indicating the presence of neuroinflammation. Patients with CFS tended to show a higher [11C]-PK11195 DVR in cortical regions, but these differences were not statistically significant.

Innovative procedures for micro-elimination of hepatitis C virus infection in a high-risk population of undocumented migrants and low-income refugees

Lorenzo Onorato*, Loredana Alessio2, Stefania De Pascalis1, Vincenzo Messina2, Caterina Sagnelli3, Evangelista Sagnelli3, Giovanni Di Caprio2, Margherita Macera1, Mariantonieta Pisaturo3, Nicola Coppola3

1University of Campania “Luigi Vanvitelli”, Napoli, Italy, 2AORN Sant’Anna e San Sebastiano, Caserta, Italy, 3University of Campania “Luigi Vanvitelli”, Napoli, Italy

Background: Because of the intermediate HCV endemicity in immigrant populations and the high efficacy of DAA therapy, programs should be undertaken to eradicate the infection in this difficult-to-manage setting. The aim of this study was to evaluate an innovative model to eliminate HCV infection in this population.

Materials/methods: A prospective, multicenter, collaborative study, based on the long-term cooperation between five first-level clinical points and two corresponding third-level units of Infectious Diseases (ID) was performed in Campania, Southern Italy. A screening to identify the subjects with HCV infection, free of charge and without bureaucratic procedures, was proposed to all undocumented migrants and low-income refugees prospectively observed by a physician and a cultural mediator at one of the first-level clinical centers from June 2018 to March 2019. All migrants received correct information and illustrated brochures on transmission and prevention of HCV infection, related diseases and available treatments. All anti-HCV positive subjects were addressed at one of the two ID units for further clinical investigation including HCV-RNA determination and, if positive, HCV-genotyping (GT). HCV-RNA positive patients were treated with sofosbuvir plus velpatasvir+ribavirin for 12 weeks and followed up for 12 weeks after treatment withdrawal.

Results: Of the 3,401 migrants observed, 3,286 [96.6%] accepted to be screened. They were young [median age 27 years], predominantly male [83.3%] and came mainly from Northern Africa [4%], Sub-Saharan Africa [67.1%], Eastern Europe [9.3%], and Indo-Pakistan region [16.4%]. Of the 3,286 enrolled subjects, 180 [5.4%] resulted anti-HCV positive. The Figure shows the HCV-cure cascade. All the 180 anti-HCV-positive subjects were linked to care at 3rd level center and tested for HCV-RNA, and 48 [26.6%] resulted HCV-RNA positive. Of these, 40 [83.3%] started DAA regimen [14 with GT 1b, 21 with 1a, 18 with 3, 4 with 4 and 2 with 2]: 38 completed the follow-up with a SVR rate of 100% and 2 are still pending. No subject had adverse neither was drop-out.

Conclusions: This innovative procedures for micro-elimination of HCV infection seems to be effective in undocumented migrants and low-income refugees with rates of diagnosis, linkage to care and cure in line with the WHO goals.

Presenter email address: lorenzoonorato@libero.it
Abstract 5601

Change of antimicrobial susceptibility testing guidelines from CLSI to BRCAST: impact of breakpoint change on the susceptibility of clinical isolates in a tertiary care hospital in Brazil

Andrea Celestino De Souza1, Patricia Orlandi Barth1*, Larissa Lutz1, Matheus Brasil Da Silva1, Valério Aquino1, Eliane Wurdig Roesch1, Bariane Castro Pereira2

1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Abstract third-party references: Hospital de Clínicas de Porto Alegre

Background: The Brazilian Ministry of Health appointed the use of Brazilian Committee for Antimicrobial Susceptibility Testing (BRCAST) standards as mandatory in all clinical laboratories in Brazil from 2020. However, the actual effect of the guideline changes on cumulative hospital antibiograms is unknown, even though local cumulative antibiograms are important for guiding empirical antibiotic therapy. We set out to compare antibiotic susceptibility interpreted by the two guidelines to determine whether adoption of BRCAST guidelines would affect our institution’s susceptibility patterns.

Materials/methods: Antibiotic susceptibilities of non-duplicate isolates collected within a 2 month period (October to November 2019). The Kirby-bauer method was used for TSA determination. We reviewed inhibition zone diameters of various antibiotics routinely reported for Enterobacteriaceae, Staphylococcus aureus, Coagulase-Negative Staphylococcus (CoNS) and Pseudomonas aeruginosa at the Microbiology Laboratory - Hospital de Clínicas de Porto Alegre. The inhibition zone diameters were then interpreted using both CLSI 2019 and BRCAST 9.0 2019 breakpoints and classified as resistant, intermediate or susceptible. We compared the susceptibility rate between the CLSI and BRCAST categorizations.

Results: A total of 226 susceptibility data from 153 Enterobacteriaceae (105 E. coli, 35. K. pneumoniae and 13 Enterobacter spp.), 27 S. aureus, 23 CoNS and 23 P. aeruginosa clinical isolates were included. The majority of species/drug combinations showed no differences in susceptibility rates comparing CLSI 2019 and BRCAST 9.0 2019, 72% vs 71.8%, respectively. However, in some gram-negative bacilli, decreased susceptibility rates were observed when comparing CLSI 2019 with BRCAST 9.0 2019 within E.coli / cefepime, 92% [CLSI] vs. 87% [BRCAST]; K.pneumoniae / cefepime, 51% [CLSI] vs. 49% [BRCAST]; P.aeruginosa / cefepime 86% [CLSI] vs. 79% [BRCAST].

Conclusions: The results show comparable antibiotic susceptibility patterns between CLSI and BRCAST breakpoints. The change of AST guidelines led to a decrease of susceptibility rates in clinical isolates for defined species/drug combinations. Given that BRCAST guidelines are freely available, it makes it easier for laboratories in resource poor settings to have an updated and readily available reference for interpreting antibiotic susceptibilities.

A leak in compliance with ventilation system maintenance instructions resulted in an aspergillosis outbreak

Gulcin Dizman¹, Gokhan Metan*¹, Dolunay Gülmez¹, Zeynep Bastug¹, Ömer Dizdar¹, Sevtap Arikan-Akdagli¹, Serhat Unal¹

¹Hacettepe Üniversitesi Tip Fakültesi, Ankara, Turkey

Abstract 5603

**Background:** Invasive aspergillosis (IA) is an important cause of morbidity and mortality in patients with hematologic malignancies. Here, we shared our experience for an aspergillosis outbreak in an oncology hospital in November 2017.

**Materials/methods:** Detection of four consecutive patients with IA who were hospitalized in the same ward triggered an outbreak investigation. A case was defined as any patient with clinical symptoms that could be related to IA after at least 1 week of hospitalization and *Aspergillus* spp isolation from culture. Possible causes of the outbreak were questioned. Samples for fungal culture were taken from the ventilation system outlets in the patient rooms.

**Results:** Although there were no cases that matched with the case definition in October, four cases were detected in November. All patients with IA had neutrophil count < 500 mm³, *Aspergillus fumigatus* or *Aspergillus flavus* were isolated from respiratory samples of three patients and sinus biopsy culture of one patient. Three patients were diagnosed as probable pulmonary IA and one patient was diagnosed as *Aspergillus* sinusitis according to EORTC/MSG definitions for invasive mold diseases.

The investigation revealed that the filters of the ventilation system were changed in all patient rooms without compliance with the institutional instructions for maintenance and repair for air conditioning and ventilation system. Patients were kept in their rooms without any air protection during the filter change and all further steps such as, use of hepafiltered cleaner, cleaning and disinfection of the room and change of curtains and sheets were missed. *Aspergillus* spp (*Aspergillus fumigatus, Aspergillus niger, Aspergillus spp*), *Paecilomyces* spp, *Chrysonilia* spp and unspecified mold growth were detected in environment cultures. N95 masks were recommended for all the neutropenic patients in the ward and they were quickly transferred to other wards. New patient admissions were stopped. After then, the air conditioning filters were changed according to the instructions, ventilation system and the rooms were cleaned and disinfected. After the intervention, no fungal infection (pneumonia or sinusitis) was detected in the first quarter of 2018 (Figure 1).

**Conclusions:** Any leak for infection control precautions can lead to severe consequences. Continuous education and surveillance are crucial.

Abstract 5611

Role of multidrug-resistant bacteria on nosocomial pneumonia mortality
Ana Rocio Romero Paternina1, Monica Martinez-Abarca Marquez*, Ivanna González Carrasco1, Irene Burruezo López1, Maria Pilar Paz Arias1, Andrea Valcarcel1, Marcos Fragiel Saavedra1, Cristina Outón1, Ester Emilia Dubon Peralta1, Noemí Cabello-Elotet1, María José Nuñez1, Vicente Estrada2

1Hospital Clinico Universitario San Carlos, Madrid, Spain

Background: Nosocomial pneumonia is a leading cause of infections in the hospital setting. In recent years, an increased incidence of multidrug-resistant bacteria (MDR) has been described as causative pathogens of different respiratory tract infections. The presence of MDR is associated with poor clinical outcomes, including increased mortality.

Materials/methods: Descriptive and retrospective study of 738 patients diagnosed with nosocomial pneumonia between Jan 2012 and December 2017 at a single center. Diagnosis was based on the identification of a pneumonia 48 hours or more after admission and not present at admission. In-hospital mortality was established as the outcome variable. Both univariable and multivariable analysis was performed using logistic regression to assess the differences between survivors and non-survivor groups, adjusting for demographic and clinical variables. MDR was defined as non-susceptibility to at least one agent in three or more antimicrobial categories.

Results: 738 patients were selected, of which 565 cases (76.6%) were associated with ward hospitalization and 173 (23.3%) with mechanical ventilation; 59.2% male, mean age 71 years (SD ±17); median hospitalization days prior to diagnosis 10 days (IQR 25-75); Median Charlson comorbidity index 6 points (IQR 4-8); 32% previous stay at ICU. In 303 patients there was microbiological identification of a pathogen: 69 blood cultures (9.3%), 161 sputum cultures (21.8%) and 111 (15%) bronchoaspirate samples; 71.6% were monomicrobial and 28.4% polymicrobial; in 173 cases (57.1%) gram-negative bacteria were isolated. In 91 cases (30%), MDR were identified, the most frequent were Pseudomonas (12%), Klebsiella (13%) and Acinetobacter (9%). 216 patients (29.3%) died during admission, of whom 38 (17.6%) presented MDR isolations. In multivariate analysis, identification of MDR (OR 1.75 [95%CI, 1.05-2.79], p=0.031), Charlson comorbidity score (OR 1.24 [95%CI, 1.17-1.32], p<0.01), the use of vasoactive drugs (OR 3.48 [95%CI, 2.11-5.72], p<0.01); and the use of antifungals on empirical treatment (OR 2.40 [95%CI 1.09-5.72], p=0.29) were independently associated with mortality.

Conclusions: The identification of MDR in patients with nosocomial pneumonia is associated with higher mortality. Empirical therapy for nosocomial pneumonia must include adequate antibiotic coverage for MDR, based on local susceptibility patterns.

Increasing importance of *Enterococcus faecium* as an aetiological agent of healthcare-associated bloodstream infections

Halina Marchel¹,², Marta Wroblewska*¹,²

¹Department of Dental Microbiology, Medical University of Warsaw, Warsaw, Poland; ²Central Clinical Hospital, University Clinical Centre, Medical University of Warsaw, Warsaw, Poland

**Background:** *Enterococcus faecium* is an important etiological agent of healthcare-associated infections (HAI). It causes both localised and systemic infections. Enterococci are characterised by natural resistance to cephalosporins, isoxazolyl penicillins and linkosamides, as well as low concentrations of aminoglycosides. Of particular clinical importance is an acquired resistance of enterococci to glycopeptides and oxazolidinones. The aim of the study was to assess the trend in the change of epidemiology of bloodstream infections (BSI) caused by *E. faecium* in 2015–2018 in a university-affiliated hospital (1050 beds).

**Materials/methods:** Analysis comprised the results of blood culture (n=68709). Only non-repetitive, clinically significant isolates of bacteria cultured from samples of peripheral blood were included in the study (n=10723). Blood samples were monitored in the Bactec FX system (Becton Dickinson). Bacterial isolates were identified using MALDI-TOF MS analyser (Bruker). Antimicrobial susceptibility was evaluated by disk-diffusion technique, according to the EUCAST recommendations, as well as with the use of antibiotic gradient strips (E-test, bio-Merieux).

**Results:** In the analysed period, the percentage of BSI episodes caused by *E. faecium* was 5.56%, 8.30%, 11.39%, and 7.18%, respectively [an increasing trend]. Simultaneously, a decrease in the rate of infections caused by *Staphylococcus aureus* was recorded (15.08%, 11.30%, 9.61% and 11.26%, respectively). No significant changes were noted in the frequency of BSI episodes caused by predominant Gram-negative rods – *E. coli* (14.29%, 16.25%, 16.90% and 15.01%, respectively) and *K. pneumoniae* (13.29%, 9.57%, 13.35% and 10.77%, respectively). In the analysed period, a steady increase was observed in the percentage of VRE strains causing BSI – from 42.86% in 2015 to 59.46% in 2018. Since 2016, *E. faecium* strains resistant to linezolid have emerged.

**Conclusions:** 1. *E. faecium* infections should be monitored closely due to an increase in the frequency of HAI BSI of this etiology. 2. An increase in the rate of *E. faecium* HAI BSI may be linked to a high percentage of glycopeptide-resistant strains and an emergence of linezolid-resistant isolates. 3. An emergence of linezolid-resistant strains of *E. faecium* denotes depletion of therapeutic possibilities in treatment of BSI caused by *E. faecium* VRE strains.

European and national *Clostridioides difficile* infection surveillance

Karuna Vendrik*, Tjallie I.I. Van Der Kooi¹, Virginie Viprey², Kerrie Davies², Ed J. Kuijper¹

¹Leiden University Medical Center (LUMC), Leiden, Netherlands, ²University of Leeds, Leeds, United Kingdom

Abstract third-party references: On behalf of the COMBACTE-CDI consortium

Background: In 2018, the "Combatting Bacterial Resistance in Europe – *Clostridioides difficile* Infections (COMBACTE-CDI) project" was initiated that aims to assess the epidemiology and clinical impact of CDI across Europe. A specific work package was developed to analyse and compare CDI surveillance practices per country.

Materials/methods: In each of the 12 participating countries, several laboratories/hospitals, that perform diagnostic testing of faecal samples from both in-patients and community patients, were recruited and requested to send all diarrheal samples from two selected days in 2018. Each centre and their associated community practices, that had sent samples, were requested to complete a web-based questionnaire on surveillance practices.

Results: Here we present data from 105 hospital/hospital-based laboratories facilities that responded. Of these, 13 (12.4%) mentioned participation in international surveillance. Five sites in five countries participated in the CDI surveillance of the European Centre for Disease Prevention and Control, and others referred to temporary studies. Participation in national surveillance was reported from 11 countries by at least one hospital/laboratory (figure). On local site level, 44.8% participated in national surveillance. Inclusion criteria and content however, varied between and within countries. National CDI surveillance programmes of five countries focussed only on hospital-diagnosed or -acquired cases. In three countries both hospital- and community-acquired cases were recorded and the remaining countries provided varying answers. Cases were included in national surveillance either when there was a combination of a positive test and clinical characteristics (44.7%) or when there was a positive test, irrespective of clinical characteristics (55.3%). A combination of a positive test and symptoms was required for inclusion in at least one hospital/laboratory in the majority of countries (8/12). Furthermore, surveillance programmes differed in inclusion requirements regarding recurrences and age. Case-based data, other than gender and age, and hospital-based data were only reported in some programmes.

Figure: Participation in national CDI surveillance.

Conclusions: National CDI surveillance has been established in at least one hospital/laboratory in 11/12 participating countries. The overall focus in national surveillance schemes is on hospital-diagnosed CDI, but there is considerable variation in inclusion criteria, required positive tests and reported case- and hospital-based data between and within countries.

Mycoplasma genitalium infections can comprise mixtures of both quinolone-susceptible and quinolone-resistant strains

Emma Sweeney*, Kym Lowry1, Cheryl Bletchly2, Graeme Robert Nimmo1,3, David Whiley1,2

1Centre for Clinical Research, The University of Queensland, Herston, Australia, 2Pathology Queensland Central Laboratory, Herston, Australia, 3Griffith University, School of Medicine, Brisbane, Australia

Background: Mycoplasma genitalium is an important sexually-transmitted infection that has recently been added to the CDC antimicrobial resistant threats “watch list” as it has rapidly become resistant to mainstay treatments, including macrolides and quinolones, over the past decade. In Australia, despite changes to treatment guidelines for M. genitalium, treatment failure remains common and may occur even where patient samples are shown via Sanger sequencing to harbor only wild-type (susceptible) strains.

Materials/methods: Suspecting that some patients may potentially harbor mixtures of both susceptible and resistant strains, which may be missed by Sanger sequencing, we developed and applied a suite of molecular assays to detect both wild-type sequences and resistance mutations. Here, we focused on quinolone resistance mutations that occur at amino acid positions 83 and 87 of the parC gene in M. genitalium and have been previously associated with quinolone resistance/susceptibility. We specifically included technologies that can readily identify mixtures of susceptible/resistant nucleotides sequences, including both allele-specific PCR and amplicon deep sequencing. These results were compared to Sanger sequencing.

Results: A total of 433 M. genitalium-positive samples were screened. For the majority of samples (n = 412), only a single allele, either wild-type (n = 354) or mutant (n = 58), was identified using all methods. However, 21 (4.8%) samples were shown via allele-specific PCR and/or deep sequencing to harbor mixtures, with the most common mixtures being wildtype S83 and mutant S83I. Notably, only 4 of these mixtures were identified by Sanger sequencing, even where the chromatographs were further scrutinized for additional peaks.

Conclusions: Our data show that M. genitalium infections can often comprise a mixture of both quinolone-susceptible and quinolone-resistant strains, and that such mixtures will typically be missed using “gold standard” Sanger sequencing. These findings highlight the complex nature of antibiotic resistance in M. genitalium, and have obvious implications for the selection of appropriate antimicrobial treatments to improve patient-directed therapy and minimize treatment failure for M. genitalium infections.

Abstract 5619

**Research priorities to increase vaccination coverage (EU Joint Action on Vaccination)**
Florence Francis-Oliviero¹, Sandor Bozoki², Marie-Paule Kieny³, Geneviève Chêne¹, Jean Daniel Lelievre⁴

¹Inserm, Bordeaux, France, ²Sztaki, Budapest, Hungary, ³Inserm, Paris, France, ⁴Inserm, Créteil, France

**Background:** The EU Joint Action on Vaccination was launched with the aim to increase vaccine coverage in Europe. Filling evidence gaps to allow the design of effective strategies and approaches towards this goal is of key importance. We therefore propose a prioritization process to identify research priorities towards generating and synthesizing needed evidence to increase vaccine coverage.

**Materials/methods:** We used a multi-criteria decision analysis (MCDA) method inspired by the Child Health and Nutrition Research Initiative developed by Rudan et al. This quantitative methodology follows a series of steps including different groups of experts and relevant stakeholders. The first step consists in identifying key research questions through a broad consultation. In parallel, a first group of experts is tasked to select criteria for prioritization research questions, taking into consideration the ultimate goal of the exercise. Another group of experts is then requested to assess a weight to each of the criteria, using pair-wise comparisons. The final step consists to gather experts who will assess each research question against the weighted criteria. This evaluation leads to assigning a score to each individual research question, which can then be ranked in order of priority.

**Results:** We focused our work on four pre-selected pilot vaccines (pertussis, measles containing combination vaccines, influenza and HPV). The consultation generated 110 questions, which were secondarily sorted and re-worded to obtain 30 questions to be ranked. Criteria for setting priorities are the following: accessibility, answerability, deliverability, disease prevalence/incidence, effectiveness, equity, generalization, and territory. The final list of ranked research topics will be defined – using weighted criteria - during a face-to-face meeting in Paris in early 2020.

**Conclusions:** With the great diversity of possible topics, in a context of limited resources, prioritizing research questions becomes crucial. We have developed a transparent, evidence-based rigorous process applied to defined key research questions to generate evidence towards the design of strategies to increase vaccine coverage. Results will be disseminated broadly and submitted to the EC for funding in the context of The Horizon Europe Program. Following thorough evaluation of the methodology, it will be adapted as needed and generalized all types of vaccines.

Whole genome sequence-based country-wide study reveals a high ongoing transmission of multidrug-resistant Mycobacterium tuberculosis in southern Brazil

Richard Salvato*1, Ana Júlia Reis2, Sun Hee Schiefelbein1, Stephanie Salvato1, Regina Barcellos1, Elis Regina Dalla Costa6, Pedro Almeida Da Silva2, Joao Perdigao2, Afrânio Kritski6, Maria Lucia Rosa Rossetti1,3

1Universidade Federal do Rio Grande do Sul, Programa de Pós-graduação em Biologia Celular e Molecular, Porto Alegre, Brazil, 2Universidade Federal de Rio Grande, Rio Grande, Brazil, 3Universidade Luterana do Brasil, Canoas, Brazil, 4Methodist University - IPA, Porto Alegre, Brazil, 5Centro de Desenvolvimento Científico e Tecnológico, CEVS, SES/RS, Porto Alegre, Brazil, 6Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, 7Universidade de Lisboa, Lisboa, Portugal

Abstract third-party references: Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, Brazil

Background: The Mycobacterium tuberculosis (M.tb) is the pathogen responsible for tuberculosis (TB) that remains as the major death cause from a single infectious agent worldwide. The knowledge about molecular characteristics of different M.tb strains enables more effective surveillance and control measures. In this way, whole genome sequencing (WGS) provides high-throughput and resolutive data. We are carrying on a WGS-based evaluation of the M.tb strain diversity, drug-resistance and ongoing transmission across Brazil. M.tb strains from different Brazilian States were already sequenced and here we show the preliminary results.

Materials/methods: Here we are carry on a WGS-based evaluation of the M.tb strain diversity, drug-resistance and ongoing transmission in different Brazilian States. We used a 5 SNPs cut-off to delineate genomic clusters and in addition searched for possible epidemiological-links (epi-links) for recent TB transmission substantiation.

Results: The main results regarding the population-based study conducted in Rio Grande do Sul State including 325 drug-resistant M.tb isolates, indicated a high rate of multidrug-resistant (MDR) M.tb recent transmission. Of the 325 clinical isolates, 189 were grouped in 32 genomic clusters. In total, 27 epi-links were identified involving 91 patients, where 62 were patients in community epi-links, 29 in prison establishments and two household contacts. Among the isolates from the 183 MDR-TB patients 131 (71.58%) were grouped into genomic clusters, this number has decreased for the patients with INH-monoresistant TB (39.83%) and with poly-resistant TB (47.36%).

Conclusions: Our preliminary results put in evidence a scenario involving a high transmission of multiple phylogenetically distinctive clades of MDR M.tb strains in Southern Brazil, stressing the need for measures in order to quickly TB diagnosis and contacts tracing.

Abstract 5626

The effect of intestinal alkaline phosphatase and physical activity on the course of experimental colitis in obese mice

Dagmara Wójcik*, Marcin Surmiak, Magdalena Hubalewska-Mazgaj, Zbigniew Śliwowski, Sławomir Kwiecień, Tomasz Brzozowski

1Jagiellonian University Medical College, Department Of Physiology, Kraków, Poland

Background: Inflammatory bowel diseases (IBDs) are chronic inflammatory disorders of the colon and small intestine, commonly described as Crohn disease and ulcerative colitis. Even though most of IBD's patients are underweight, the ratio of intraabdominal fat is greater than in healthy individuals. Visceral fat constitutes the major source of pro-inflammatory cytokines. Intestinal alkaline phosphatase (IAP) is an important apical brush border enzyme acting through dephosphorylating of bacterial lipopolysaccharide released from cells walls during stressful events. However, whether IAP administration combined with exercise known to exerts the intestinal anti-inflammatory effect, can improve the healing of experimental colitis and the alterations in microbiota during the course of healing of colitis remains unknown.

Materials/methods: We determined the effect of IAP and physical activity on the course of experimental colitis in obese mice. Animals fed high-fat-diet (HFD) were randomly assigned to exercise group maintained on in-cage running wheels for 8-weeks. Then mice were administered i.g. with IAP for 2-weeks followed by intrarectal administration of 2,4,6-trinitrobenzenesulfonic acid (TNBS). Disease activity index (DAI) and the colonic blood flow (CBF) were determined. The composition of intestinal microbiota was examined by Next-Generation Sequencing (NGS). The effect of physical activity was assessed by Grip-strength test. The intensity of oxidative stress was examined by determination of factors involved in radical genesis.

Results: HFD delayed healing of colitis as manifested by increase of DAI and fall in CBF. In contrast, IAP administration and physical exercise reduced DAI, oxidative stress (MDA, SOD, GSH) and increased GBF in mice with colitis. In HFD mice, the combination of IAP with exercise favored intestinal colonization of Faecalibacterium, Helicobacter, Alistipes and reduced Clostridium, Bacteroides, Desulfovibrio, Parasutterella.

Conclusions: Combination of IAP and exercise accelerates healing of colonic mucosal damage in mice model of colitis via mechanism involving the attenuation of oxidative stress markers and enhancement of CBF. The alteration of bacterial composition was observed in obese mice and the high load of bacteria with the loss of their diversity were reversed when IAP was combined with physical exercise. These experimental results may be recommended as complementary non-pharmacological treatment of intestinal disorders when confirmed in human IBD.

Abstract 5627

Stephane Emery¹, Mathilde Vannini², Veronique Mondain³, Nicolas Retur¹, Remy Collomp¹, Lilia Hasseine¹, Florence Lieutier-Colas*¹

¹UH of Nice, Pharmacy, Nice, France, ²UH of Nice, Laboratory of Mycology, Nice, France, ³UH of Nice, Infectious Diseases Department, Nice, France

Background: The prevalence of Invasive Candida Infections (ICI) has significantly increased in recent years, and candidemia has still a mortality rate up to 40%. Our objective was to evaluate the appropriateness of antifungals (AF) first-line treatment, adaptation after documentation, and time to adaptation.

Materials/methods: Patients with at least one blood culture positive for yeasts and a systemic AF treatment between January 2014 and December 2018 were included. Epidemiology, susceptibility, patients’ data and treatments were collected from computerized medical records and Mycology Laboratories. Deaths were attributed to ICI when there was no other cause and no negative blood culture control.

Results: 151 patients were included, 70 females and 81 males. Candida albicans was isolated in 47% of patients. No resistance for the 4 tested AF (amphotericin B, caspofungin, voriconazole and fluconazole) was observed for C. albicans and C. parapsilosis. Patients were hospitalized in ICU (33%), gastroenterology (17%), surgery (12%), infectious diseases department (8%), but also in geriatric units (12%) and other departments not used to treat those severe patients. Thirty-two percent of patients died within 3 months after candidemia. The delay between blood culture and first-line treatment was 2.3 days. Delays were shorter among the deceased patients (1.7 days vs 2.5 days among alive patients). First-line treatment was caspofungin (67%), fluconazole (28%), voriconazole (n = 3), micafungin (n = 2) or amphotericin B (n = 1). Time between documentation and treatment adaptation was 3.2 days, and time between susceptibility results and treatment streamlining was 1.8 days. Seventy-nine percent of AF treatments was appropriate, inappropriate in 17 patients (16% inappropriate in deceased patients vs 9% among alive patients), and 14 patients were lost. The probability of survival was worse at 90 days if treatment was inappropriate (p = 0.56).

Conclusions: This work underlined the importance to treat invasive Candida infections quickly, but with an appropriate drug. A systematic monitoring of candidemia by an antifungal stewardship team could improve management and clinical outcome of these severe patients, with invasive Candida infections, hospitalized in many departments apart from ICU.

Abstract 5628

Preliminary results for the evaluation of the impact of syndromic lower respiratory tract panel on antimicrobial management and infection control

Rabia Can Sarınoğlu*, Elif Tukenmez-Tigen², Huseyin Bilgin², Burak Aksu¹, Volkan Korten², Guner Soyletir¹

¹Medical Microbiology Dept., Marmara University Hospital, Istanbul, Turkey, ²Infectious Diseases Dept., Marmara University Hospital, Istanbul, Turkey

Background: Diagnosis of lower respiratory tract infections, hospital-acquired pneumonia (HAP) or community-associated pneumonia (CAP) in patients remains an important and challenging problem associated with significant morbidity, mortality, and cost. Syndromic lower respiratory tract infection panel (Biofire LRTI Panel) may shorten the time to apply the targeted antimicrobial treatment in patients with pneumonia and provide rapid application of isolation measures.

The aim of this study was to investigate the impact of Biofire LRTI Panel on targeted antimicrobial therapy and management of infection control in patients diagnosed with community-acquired pneumonia (CAP) or early hospital-acquired pneumonia (HAP) whom are planned to be hospitalized and treated in intensive care unit (ICU).

Materials/methods: Between October 2018 and September 2019, >18 years old patients admitted to Marmara University Pendik Training and Research Hospital, and planned to be hospitalized with the diagnosis of CAP or early HAP were chosen. Patients excreted sputa with <10 squamous epithelial cells, > 25 PNL in each high-power field at microscopic examination were included. Bacterial culture and syndromic lower respiratory tract infection panel (Film Array LRTI Panel, RUO version, BioFire Diagnostics, USA) performed simultaneously on sputum samples. Results were blind evaluated by two infectious diseases specialists for the decision of treatment change and application of infection control measures. Decision of antibiotic change, time to optimal antimicrobial change, bacterial culture result, Biofire LRTI panel result and applied infection control measures were recorded for each patient.

Results: Forty patients were met the inclusion criteria and evaluated. Biofire LRTI Panel detected at least one pathogen in 31 patients (77.5%), among these, 29 had bacterial, 15 had bacterial and viral, and 2 had viral pathogens. No pathogen could be detected in 9 patients (22.5%). Sputum cultures were positive only in 14/40 (35%) patients. Antibiotic change was decided in 20 patients and infection control measures were applied in 21 patients (Table 1 & 2).

Conclusions: Biofire LRTI Panel provides faster access to optimal antimicrobial treatment and high rate of antibiotic de-escalation in patients diagnosed with CAP and early HAP, and also contributes to the rapid implementation of infection control measures.

Abstract 5629

Quality of life and its determinants among pulmonary tuberculosis patients taking direct observation therapy in Kabul, Afghanistan

Atefa Azizi*, Khatera Hashemi

1Kabul University, Kabul, Afghanistan

Background: Afghanistan faces a high burden of tuberculosis (TB) among the global, according to the World Health Organization (WHO). An estimated 60,000 new cases arise yearly, and the treatment success rate is only 49 percent on average in the country. Literature extensively supports that TB significantly destroys the quality of life (QoL) of the patients. Direct Observation Therapy (DOT) was introduced by WHO to enhance the effectiveness of treatment. This program uses sputum negativity and weight gain as prognostic indicators but does not consider health related QoL. The purpose of this study was to assess the QoL among Pulmonary Tuberculosis (PTB) patients of > 18 years of age, taking the DOT therapy.

Materials/methods: An analytical cross-sectional study was conducted to answer the study questions. Through convenient sampling, 302 PTB patients (age >18 years) were selected from National Tuberculosis Center Sanatorium, Kabul Afghanistan for interviewing, based on the WHOQoL-BREF tool.

Results: This study estimated the mean score of QoL as 25.61 among the participants. The participants showed that environmental (23+15.03) and physical (24.4 + 13.3) domains were most affected after PTB. The study presented 36.8% associated factors that affect the QoL of PTB patients independently in the multivariate regression. Among the participants, the ones who were satisfied with the DOT therapy (p=0.003) and had good knowledge about the disease (p=0.01) possessed good QoL. Whereas, participants who were on the intensive phase of Category-2 (p=<0.001), had kidney disorders (p=0.03), intensive cough which hindered prayers (p=<0.001), nausea initiating pain (β=9.0, p= 0.02), lost their significant other in the last one year (p=0.002), and facing financial difficulties (p=0.01) had poor QoL. Moreover, stigmatization stood out as the biggest problem for the PTB patients in the society, especially when it affected the relationship with siblings (p=0.001), and other kept a distance (p=0.001).

Conclusions: This study showed a very poor QoL among adult PTB patients in Kabul Afghanistan. Cough, pain stigmatization, knowledge related to disease, financial difficulties, parent’s support, and loss of significant other were significantly associated with QoL among PTB patients. Broad interventions are needed to address the problems of the PTB sufferers.

Abstract 5630

**Surveillance of circulating carbapenemase genes with automated molecular system (BD Max) at a healthcare centre in Buenos Aires, Argentina**

Mariela Soledad Zárate*, Gabriela Weltman¹, Gisela Serruto¹, Paula Mainetti¹, Barbara Wisner¹, Juan Zaracho¹

¹Sanatorio Guemes, Buenos Aires, Argentina

**Background:** Carbapenemase-producing Enterobacteriaceae (CPE) represent an increasing public health problem. Early detection of patient colonization at healthcare facilities can help the implementation of appropriate infection control measures. Predominant documented carbapenemase enzymes are KPC, OXA, NDM, VIM and IMP type. Our objectives were: 1- To evaluate the prevalence of CPE in rectal swabs from patients in critical areas of our institution; 2- Evaluate the prevalence of carbapenemase gene types. 3- Evaluate the turnaround time to results report with implementation of a molecular methodology (in comparison to manual methods).

**Materials/methods:** Prospective descriptive study, period 01/2018-05/2019. Rectal swabs samples were obtained from patients with any of the following criteria: 1) patients referred from another healthcare institution with ≥6 days of hospitalization; 2) hospital admission in the previous 30 days; 3) history of CPE colonization or infection in the last 30 to 90 days. Samples were processed with BD MAX™ System and Check-Direct CPE Screen for BD MAX™ molecular methodology (MM) according to the manufacturer’s recommendations.

**Results:** From a total of 2461 samples, 768 (31%) were. The frequency of carbapenemase gene detection in our center was: 330 for blaKPC (13.4%), 194 for blaOXA-48 (7.9%), 160 for blaVIM (6.5%) and 84 for blaNDM (3.4%). The turn-around time for results reporting was reduced from 48 to 3 hours.

**Conclusions:** The use of MM for detection of CPE colonization, provides a considerable shorter turn-around time, enabling same day screening and reporting of newly admitted patients. CPE screening results delivered in just a few hours, could improve the clinical management of colonized/infected patients reducing the possibility of resistance spreading.

Background: Nocardiosis is a rare but life-threatening opportunistic infection. Despite the fact that solid organ transplant (SOT) recipients with nocardiosis have a one-year mortality rate around 10-20%, their therapeutic management is still a matter of debate. Our aim was to report our real-life experience with cotrimoxazole (trimethoprim-sulfamethoxazole, SXT) monotherapy in SOT recipients with nocardiosis.

Materials/methods: We analysed data from a previously published retrospective multicentre European study. In the current study, we included all patients who received SXT and less than 5 days of combination with another antibiotic in the first 15 days post-diagnosis (cohort A). To assess effectiveness, we focused on the subset of patients who received at least 30 days of SXT monotherapy (cohort B). A standardized clinical form was sent to each investigator to collect additional data. Acute kidney injury (AKI) was defined according to the KDIGO classification: increase in serum creatinine by ≥ 0.3 mg/dl (≥ 26mmol/l) within 48 h; or increase in serum creatinine to ≥ 1.5 times baseline.

Results: Thirty-one patients were included. Transplanted organs were mostly kidney (20/31, 65%) and heart (5/31, 16%). Among them, 11/31 (36%) had a disseminated infection and 4/31 (13%) had a brain abscess; most had lung or pleural involvement (26/31, 84%). SXT was discontinued in one-third of the cases due to toxicity (10/31, 32%). Treatment was interrupted because of isolated hematological toxicity (n=3), isolated AKI (n=3), combination of AKI/hepatitis, AKI/hyperkalemia, AKI/leucopenia, diarrhea/hepatitis (n=1 for each). Regarding effectiveness, we focused on the 24/31 (77%) patients who received at least 30 days of single-drug regimen with SXT (cohort B). Among these 24 patients, four had late (> 30 days) drug discontinuation, one experienced treatment failure (likely due to a lack of adherence) and 19/24 (79%) completed treatment with SXT monotherapy. Clinical outcome was favourable in all these 19 patients, despite the facts that 8/19 (42%) had a disseminated infection and 2/19 (11%) had a brain abscess.

Conclusions: SXT monotherapy was an effective option in SOT recipients with Nocardia infection but treatment was interrupted in around 1/3 of the cases, mostly because of AKI or hematological toxicity.

Abstract 5636

Evaluation of Bacillus anthracis agar-based susceptibility testing by Etest for ciprofloxacin, levofloxacin, doxycycline and tetracycline

Blake Cherney*, Pierre Michel1, Julia Bugrysheva1, Amy Gargis1, Thiphasone Kongphet-Tran1, Christine Lascols1, Heather Mclaughlin1, David Sue1

1Centers for Disease Control and Prevention, Atlanta, United States

Background: Following exposure to Bacillus anthracis, the causative agent of anthrax, antimicrobial susceptibility testing (AST) results are crucial to guide antibiotic treatment. Broth microdilution (BMD) is the reference method for AST with B. anthracis, but requires specialized expertise for MIC endpoint determination and can be resource-intensive. The Etest method is a simple and cost-effective AST alternative. Here, the utility of the Etest method was evaluated for B. anthracis using strains from the CDC collection; Etest MICs for ciprofloxacin (CIP), levofloxacin (LVX), doxycycline (DOX), and tetracycline (TET) were compared to MICs generated by BMD.

Materials/methods: Twenty-five genetically and geographically diverse B. anthracis strains including four naturally occurring penicillin-resistant strains were included in this study. Additionally, four avirulent (ΔpXO2) strains were included as fluoroquinolone and tetracycline non-susceptible controls. All B. anthracis strains were tested in triplicate. For BMD, in-house prepared, 96-well panels containing Mueller-Hinton broth with increasing concentrations of CIP, LVX, DOX and TET, were inoculated following CLSI guidelines. The Etest method was performed concurrently. All MIC endpoints were visually interpreted by three readers.

Results:

The 25 wild-type B. anthracis study strains were susceptible to CIP, LVX, DOX and TET by Etest and BMD. Essential agreement (EA) was >99% for all strains tested, and categorical agreement was 100%. MIC50 and MIC90 values of both the wild-type and control strains were similar for both methods.

Conclusions: Etest showed a high-level of agreement compared to the conventional BMD reference method for all drugs tested. Etest is a suitable AST method for determining B. anthracis susceptibility to CIP, LVX, DOX and TET.

Risk factors for carbapenem-resistant Enterobacteriaceae acquisition among kidney transplant recipients
Maristela P. Freire*1, Laina Carvalho2, Fernanda Spadao2, Flavio Jota De Paula3, William C. Nahas3, Elias David Neto3, Ligia Pierrotti2

1Clinical Hospital, Infection Control Service, São Paulo, Brazil, 2Clinical Hospital, Infectious Diseases Department, São Paulo, Brazil, 3Clinical Hospital, Kidney Transplant Service, São Paulo, Brazil

Background: Carbapenem-resistant Enterobacteriaceae (CRE) infections have a high mortality rate among solid organ transplant patients. However, there are few studies about risks for CRE-acquisition among kidney transplant recipients (KTR).

The goal of this study was to identify risk factors for CRE-acquisition among KTR and risk factors for CRE-infection among CRE-colonized KTR.

Materials/methods: We performed a case-control study. Case was defined as any KTR that had CRE-acquisition identified from January 2010 to January 2019. We chose two controls per case, selected among KTR hospitalized in the same period of the case. We also analyzed the risk factors for CRE-infection within 90-days of first positive CRE-culture, among CRE-colonized KTR. In this retrospective cohort, we analyzed only the first infection episode per patient. Infections criteria used were those outlined by NHSN. All patients were followed until death, graft lost or end of follow-up. We included variables related to recipient, KT-procedure and post-KT intercurrences. Variables were recorded until first CRE-culture for cases and until discharge for controls. Statistical analysis was performed by chi-square, Fisher Test and Mann-Whitney test when appropriate and binary logistic regression for multivariate analysis.

Results: During study period we identified 332 CRE-colonized patients, in 271 (81.6%) the first culture was a surveillance culture. The most common CRE was K. pneumoniae (91.9%). The median time from KT to CRE identification was 41.5 days, 11 (3.1%) KTR was submitted to KT colonized by CRE. Risk factors for CRE acquisition were: diabetic nephropathy (p<0.03), delay of graft function (p<0.001), acute cellular rejection in previous 6 mouths (p<0.001), ureteral stent (P 0.001), increased age at CRE identification (p<0.01), and previous carbapenem use (p<0.08). 108 (32.5%) KTR developed CRE-infection and 53 (16.0%) had bacteremic infection. The most common site of infection was urinary tract infection, 59 (54.6%). Risk factors for infection among CRE-colonized patients were: previous carbapenem use (0.02), platelets count under 105/µL at CRE-acquisition (p<0.01), lymphocytes count under 1500/mm3 at CRE acquisition (p<0.01), and polymyxin-resistant strain (P0.003).

Conclusions: In conclusion, the proportion of CRE-colonized KTR that develop infection is high. KTR have risk factors for CRE acquisition and infection that are unique for this population.

Abstract 5640

Comparison of three rapid diagnostic blood culture identification panels for Gram-negative bloodstream infections
Richard Smith¹, Stephanie Hitchcock¹, J. Kristie Johnson*¹, Kimberly Claeys²

¹University of Maryland School of Medicine, Baltimore, United States, ²University of Maryland School of Pharmacy, Baltimore, United States

Background: To best manage bloodstream infections, rapid diagnostic testing (RDT) has become critical in improving patient outcomes. The primary objective of this study was to assess and compare three gram-negative rapid diagnostic blood culture panels.

Materials/methods: Retrospective study from 8/2018 to 11/2019 at the University of Maryland Medical Center. Positive blood cultures from each patient were tested for gram-negatives using Verigene® Blood Culture, BioFire® Blood Culture Identification panel (BCID), and the new BioFire® Blood Culture Identification Panel 2 (BCID2; Research-Use-Only) panels were compared to each other against standard culture identification with VITEK®MS and antibiotic susceptibility testing using VITEK®2.

Results: 103 positive gram-negative blood cultures were used in this study. P. multocida (2), Burkholderia spp (1), P. laetus (1), P. intermedia (1), Achromobacter (2), P. pseudoalcaligenes (1) and Psychrobacter (1) were not on any of the panels so they were excluded. The Verigene® panel does not include B. fragilis (1), and S. marcescens (10) so they were excluded (82/103 included). Among included organisms, Verigene® failed to identify 1 K. pneumoniae for an overall positive agreement of 99% (81/82). BCID panel also does not include S. maltophilia (1), B. fragilis (1), Citrobacter (1) and A. junii (1) so those were excluded (90/103 included). BCID misidentified 3 E. coli, 2 E. cloacae complex, 1 Acinetobacter spp., 2 Proteus spp., 1 K. oxytoca, 2 S. marcescens, and 1 K. pneumoniae for 87% (78/90) overall positive agreement. BCID2 (RUO) had a positive agreement of 96% (89/93) misidentification of 2 E. coli, 1 S. maltophilia, and 1 E. cloacae complex. Citrobacter (1) samples were not included in BCID2 analysis as it is not on the panel (93/103 included). Verigene® and BCID2 identified the 6 CTX-M. CTX-M was not on the BCID panel and, therefore was not detected.

Conclusions: Verigene® and BCID2 have high percent positive agreements. BCID2 is an improvement on BCID as it has increased positive agreement and the panel includes more organisms. BCID2 has the most extensive gram-negative panel of the three. Local epidemiology of bloodstream infections should be considered when laboratories are determining optimal use of rapid detection testing.

Seroprevalence of hepatitis E virus among blood donors in the Qassim Region, Saudi Arabia

Bader Alhatlani*, Waleed Aljabr, Mohammad Almarzuqi, Sami Alhatlani, Abdulrahman Almusallam

1Al Qassim, Qassim University, Unayzah, Saudi Arabia, 2Riyadh, King Fahad Medical City, Riyadh, Saudi Arabia, 3Unayzah, King Saud Hospital, Unayzah, Saudi Arabia

Background: Hepatitis E virus (HEV), belonging to the Orthohepevirus genus in the family Hepeviridae, causes liver diseases in humans. HEV is now recognized as a major public health issue, causing over 20 million infections every year worldwide and accounting for approximately 70,000 deaths. Fecal-oral transmission is considered the main route of HEV transmission, but other transmission routes have been suggested. In particular, blood transfusion transmission has become one of the main routes, especially in some low-income countries in Asia. In this study, we estimated the HEV seroprevalence among blood donors in Qassim Region, Saudi Arabia. This is to evaluate whether the HEV routine screening would be considered as a routine screening of blood donations in Saudi Arabia in the future.

Materials/methods: Serum samples (n = 1,078) were collected from volunteer blood donors from January to April 2019 and tested for the presence of anti-HEV IgG and IgM by indirect enzyme-linked immunosorbent assays. Samples were tested in duplicate and samples yielding borderline results were retested in duplicate to confirm the initial results. Only IgG-positive samples were tested for the presence of anti-HEV IgM.

Results: The study was composed of 1,002 men (93%) and 76 women (7%). The number of Saudi donors was 924 (85.7%) and non-Saudi donors were 154 (14.7%). Overall, the seroprevalences of anti-HEV IgG and IgM among blood donors were 5.7% and 1.3%, respectively. Additionally, the seropositive rates of anti-HEV IgG and IgM were significantly higher in non-Saudi donors (22.1% and 7.8%) than in Saudi donors (3% and 0.2%). The seroprevalence of anti-HEV IgG increased with age; however, there was no correlation between gender and anti-HEV IgG and/or IgM.

Conclusions: The seroprevalence of HEV among blood donors in the Qassim Region was lower than previous estimates for other regions of the country. This low HEV seroprevalence might be related to the sensitivity and/or specificity of the commercial ELISA; therefore, further investigation is needed. These results extend our understanding of the distribution of HEV in Saudi Arabia, providing a basis for the development of screening strategies.

Audit on HIV quality of care to new patients in a level 4 teaching Hospital

Nadra Nurdin*, Colm Kerr, Colm Bergin

1St James Hospital, Dublin 8, Ireland, 2St James Hospital, Dublin 8, Ireland, 3Royal College of Physicians of Ireland, Dublin, Ireland

Background: HIV has become a complex, chronic condition requiring a comprehensive, multifaceted care approach. Recognising this, the HIV Medical Association has developed criteria to benchmark the quality of care provided to HIV patients.1 St. James’s Hospital has the largest HIV positive patient cohort in Ireland, with 2,535 patients attending the clinic at the of the Department of GU Medicine and Infectious Diseases (GUIDe) in 2018.

Materials/methods: We performed a retrospective analysis of all new patients attending GUIDe in 2018. Data was collected using the Electronic Patient Record System (EPR).

Results: There were 260 new patients attending the clinic in 2018. Data analysis is currently ongoing. 86% were retained in care and 94% had a CD4 count >200. 98% were prescribed ART with 98% achieving virological suppression [VL<40 or not detected]. Where appropriate, 100% of patients were prescribed PCP prophylaxis. Chlamydia and Gonorrhoea screening was performed on initial presentation in 68% of the cohort with 0% testing positive. 61% of patients were screened for injection drug use, while 100% were screened for risky sexual behaviour. 100% of patients were screened for syphilis on first clinic review with 40% testing positive on initial antibody screening. 96% of patients were screened for Hepatitis B using core antibody testing with 2% testing positive. 36% of patients had prior Hepatitis B immunity defined as surface antibody positive > 10 IU/ml. 14% received no hepatitis B Immunisation, 26% completed 3 doses hepatitis B vaccination. Hepatitis C screening was performed in 100% of patients. 95% of patients were given at least 1 dose of the influenza vaccine, with 45% achieving yearly immunization, 95% of these in the influenza window (October – April). Regarding TB screening, 60% of patients had a chest X Ray and 6% were investigated with quantiferon testing.

Conclusions: This audit outlines the strengths of the HIV care provided at the GUIDe clinic, largely complying with the HIVMA standards of care. Additionally, it raises clinically important areas where further educating care providers could improve the uptake of screening and vaccination.

Abstract 5645

Descriptive analysis of carbapenemase genes in Acinetobacter baumannii in the Antibiotic Resistance Laboratory Network: United States, 2017–2019

Jennifer Huang*, Kellan Burrell1, Katie Bantle1, Allison C. Brown1

1Centers for Disease Control, Atlanta, United States

Background: Acinetobacter baumannii is an opportunistic pathogen often associated with multidrug resistance, outbreaks of healthcare-associated infections, and severe outcomes for patients who are infected. Carbapenemases are enzymes that confer resistance to carbapenems and other beta-lactam drugs. Plasmid-mediated carbapenemase determinants, including Ambler Class A (bla\textsubscript{KPC}), Class B (bla\textsubscript{NDM}, bla\textsubscript{VIM}, bla\textsubscript{IMP}) and Class D (bla\textsubscript{OXA23-LIKE}, bla\textsubscript{OXA48-LIKE}, bla\textsubscript{OXA58-LIKE}) are of particular public health concern because they can spread easily. Carbapenem-resistant Acinetobacter baumannii (CRAB) is not a reportable condition to Public Health Departments in most states in the United States; therefore in 2017, the U.S. Centers for Disease Control and Prevention (CDC) initiated sentinel CRAB surveillance. We describe the distribution of carbapenemases among CRAB in the Antibiotic Resistance Laboratory Network from 2017 through 2019.

Materials/methods: Beginning in 2017, sentinel clinical laboratories from 42 of 50 states submitted all CRAB isolates to AR Lab Network regional public health laboratories for organism identification and PCR detection of Class A and B carbapenemase genes (bla\textsubscript{KPC}, bla\textsubscript{NDM}, bla\textsubscript{VIM}, and bla\textsubscript{IMP}). In 2019, the Network laboratories started testing isolates for the presence of Class D oxacillinase genes (bla\textsubscript{OXA23}, bla\textsubscript{OXA48-LIKE}, bla\textsubscript{OXA58-LIKE}). Testing results were submitted to CDC at least monthly.

Results: From January 2017 through October 2019, regional laboratories tested 3,595 sentinel CRAB isolates; Class A or B carbapenemase genes were detected in 21 (0.58%) of these (10 bla\textsubscript{KPC}, 11 bla\textsubscript{NDM}). From January through September 2019, 6 of 7 regional labs also tested 1,116 CRAB isolates for the presence of Class D carbapenemase genes; the percentage of Class D-positive CRAB was much higher (median of 68%) and varied by geographic region.

Conclusions: Class A and Class B carbapenemases among Acinetobacter baumannii appears to be rare whereas Class D carbapenemases appear to be much more common in the United States and vary by geographic region. Healthcare facilities and public health officials should respond aggressively to any carbapenemase-producing Acinetobacter baumannii detected in order to prevent their spread.

Presenter email address: uz00@cdc.gov
Prevalence and molecular characterisation of methicillin-susceptible Staphylococcus aureus carrying Panton-Valentine leucocidin gene isolated from patients with invasive infections and nasal carriers

Danixa Tapia¹, Camila Sanhueza¹, Camilo Campusano¹, Irma Gallardo¹, Lorena Porte²*, Carmen Varela³, Maria Ulloa¹,⁴

¹University, Universidad de Chile, Facultad de Medicina, Santiago, Chile, ²University/Hospital, Clínica Alemana de Santiago. Fac. Medicina -Clínica Alemana, U. del Desarrollo, Santiago, Chile, Santiago, Chile, ³Hospital, Clínica Alemana de Santiago, Santiago, Chile, ⁴Universidad de Chile, Universidad de Chile, Santiago, Chile

Background: Staphylococcus aureus causes a wide range of infections. Panton-Valentine Leucocidin (PVL) is an important virulence factor mainly present in community-acquired methicillin-resistant S. aureus (CA-MRSA). CA-MRSA is commonly associated with rapidly progressive skin and soft tissue infections, especially USA 300 clonal lineage. However, PVL-positive [PVL (+)] methicillin-susceptible S. aureus (MSSA) have also been described both in carriers and in infections, with variable prevalence. Some of these strains have Spa types related to USA 300, such as t008 and t024. Our aim was to describe the prevalence and Spa types of PVL (+) MSSA isolated from invasive infections and nasal carriers in Santiago, Chile.

Materials/methods: 142 isolates of MSSA were included: 95 from invasive infections [tissue, blood, normally sterile sites] treated at Clínica Alemana de Santiago and 47 from nasal carriers [University of Chile healthcare students]. Endpoint PCR was used for detection of PVL and mecA genes in all strains. Spa type of PVL (+) MSSA and a representative sample of PVL-negative strains were determined by sequencing. Sequence analysis and Spa type was performed using DnaGear Software and Ridom database, available at: https://www.SpaServer.ridom.de/. Antimicrobial susceptibility phenotype was determined by disk diffusion (CLSI M100, 2019).

Results: 10.5% [10/95] of MSSA clinical isolates was PVL (+) versus none in carriers. Eight Spa types were found in PVL (+) MSSA strains [2 t318 and 1 of each of the following: t4908, t1164, t088, t2409, t330, t012, t5160]. One strain had a new combination of repetitions, so no known Spa type could be assigned. Seventeen Spa types were found in PVL (-) MSSA strains [19/23]. Spa type t008 and t068 were the most prevalent [2 strains of each]. MSSA clinical strains showed higher antimicrobial resistance than isolates from carriers: ciprofloxacin 3.16% vs. 2.13%; erythromycin 32.63% vs. 25.53%; clindamycin 24.21 vs. 8.51%, respectively. No strain was resistant to trimethoprim-sulfamethoxazole.

Conclusions: the PVL gene is present in MSSA clinical isolates but not in nasal carriers. Spa types related to USA 300 clonal lineage were found in 2 PVL (-) MSSA strains. Macrolide and clindamycin resistance is common in clinical strains.

Direct-acting antiviral based treatment for HCV-infected persons who inject drugs: a multi-centre real-life study

Lorenzo Onorato*1, Giovanni Di Caprio1, Antonio Russo1, Ciro Caruso1, Valerio Rosato2, Ernesto Claar4, Vincenzo Iovinella3, Vincenzo Messina2, Nicola Coppola1

1University of Campania “Luigi Vanvitelli”, Naples, Italy, 2AORN Sant’Anna e San Sebastiano, Caserta, Italy, 3San Paolo Hospital, Naples, Italy, 4“Villa Betania” Evangelical Hospital, Naples, Italy

Background: The treatment of HCV in high-risk population, such as people who inject drugs (PWID), is essential to reduce the spread of infection worldwide. In the present study we aimed to evaluate the factors associated with virological response in a cohort of HCV infected PWID treated with DAAs.

Materials/methods: We conducted a multicentre retrospective cohort study enrolling all HCV infected subjects who reported a former or recent injection of illicit drugs, for which HCV-RNA loads at 12 weeks after end of treatment were available. The primary outcome evaluated was the SVR12 rate; the epidemiological, clinical and virological characteristics associated with the viral response were analysed. A logistic regression analysis was applied to identify independent predictors of virological failure.

Results: During the study period, 551 PWID treated with DAAs were enrolled; the mean age was 47.15 ± 8.5 and 485 (88%) were male; 181 (32.8%) patients presented a genotype 1a, 115 (20.87%) a genotype 1b, and 177 (33.0%) a genotype 3; 113 (20.36%) showed a staging of fibrosis according to Metavir score of 3, while 161 (29.45%) had a cirrhosis; 120 (21.77%) and 388 (70.41%) were treated with a DAA regimen of second and third generation, respectively. Only 13 subjects (2.35%) showed a positive HCV-RNA at 12 weeks after EOT, 6 of which had dropped out before the scheduled duration of therapy. No epidemiological and virological characteristic were associated with treatment failure. Patients F3-F4 showed a lower rate of SVR12 compared to patients with less advanced fibrosis (95.8 vs 99.23%, p=0.03); as expected, subjects treated with first or second generation DAAs presented a higher treatment failure than those treated with a third generation regimen (SVR12: 93.3 vs 98.9%, p=0.002). At the multivariate analysis, the treatment with a first or second generation DAA resulted the only factor independently associated with treatment failure (OR: 10.9, 95%CI 2.39-42.61; p=0.002).

Conclusions: The treatment with DAAs led to a high SVR12 rate (97.65%) among a large cohort of HCV-infected PWID. Systematic screening and treatment with highly effective third generation regimens will make the elimination of HCV in this setting a feasible goal.

Presenter email address: lorenzoonorato@libero.it
Abstract 5656

Analysis of treatment failures of haematogenous prosthetic joint infections: new infections occur more often than infection persists or relapses

Nora Renz1,2*, Anastasia Rakow1, Carsten Perka1, Andrej Trampuz1

1Charité – Universitätsmedizin Berlin, Center for Musculoskeletal Surgery, Berlin, Germany, 2Inselspital, Department of Infectious Diseases, Bern, Switzerland

Background: The optimal management of haematogenous periprosthetic joint infection (hPJI) is controversial. While guidelines recommend debridement and implant retention (DAIR) for acute hPJI, some authors advocate prosthesis removal due to poor outcome with DAIR. We investigated the treatment outcome of hPJI according to surgical procedure and failure type.

Materials/methods: Consecutive patients with hPJI treated at our institution between 2010 and 2017 were included and followed-up for infection occurrence. Infection failure was stratified into persistence/relapse of infection (defined as infection with the same or no pathogen or infection-related death) or new infection (defined as infection caused by a new pathogen). The probability of persistence/relapse-free and infection-free (overall) survival was estimated using the Kaplan-Meier survival method.

Results: Of 106 patients with hPJI, follow-up was available for 94 patients, involving hip (n=50), knee (n=42), shoulder (n=1) and elbow (n=1) prostheses. At the time of diagnosis the following pathogens were isolated: Staphylococcus aureus (n=34), Streptococcus spp. (n=30), Enterococcus faecalis (n=13), Enterobacteriaceae (n=9), coagulase-negative staphylococci (n=6), Clostridium innocuum (n=1) and no pathogen (n=1). DAIR was performed in 38 (40%), prosthesis exchange or permanent removal in 56 (59%) and no surgery in 2 episodes (2%). At 48-month follow-up (Figure), infection relapse occurred in 14 patients (15%) (including 11 with same or no identified pathogen and 3 infection-related deaths) and new infection in 19 patients (20%). Consequently, the persistence/relapse-free survival was 85% and the overall infection-free survival 65%. New infections occurred more often after prosthesis exchange/removal compared to DAIR (13 vs. 6 failures), whereas infection persistence/relapses were similar in both surgical groups (6 vs. 7 failures, one without surgery). Among 33 failures, 17 (52%) were another hPJI, caused by same (n=6) or new pathogen (n=11). The type of surgical treatment, causative pathogen or CRIME80-Score had no impact on the treatment outcome.

Conclusions: The persistence/relapse-free survival after treatment of hPJI was high (85%), irrespective of the surgical treatment. However, new infections occurred in additional 20% of treated patients in the following 4 years, reducing the overall success to 65%. About half infection failures were again hematogenous, mainly caused by a new pathogen, suggesting a general predisposition for hPJI.

Characterisation of carbapenemase-producing Enterobacterales isolates with phenotypic and genotypic methods in southern Hungary

Márió Gajdács*1,2, Marianna Ábrók3, Lazar Andrea3, Laura Járvári3, Akos Toth4, Katalin Burian5, Gabriella Terhes3
1University of Szeged Faculty of Pharmacy, Department of Pharmacodynamics and Biopharmacy, Szeged, Hungary, 2Hungarian Society for Clinical Microbiology and Infectious Diseases, Szeged, Hungary, 3University of Szeged - Faculty of Medicine, Institute of Clinical Microbiology, Szeged, Hungary, 4National Institute of Public Health, Department of Bacteriology, Budapest, Hungary, 5University of Szeged - Faculty of Medicine, Department of Medical Microbiology and Immunobiology, Szeged, Hungary

Background: Infections caused by carbapenem-resistant Enterobacterales (CRE) are serious issues in clinical practice, leaving physicians with few treatment options available. For infection control and public health purposes, the differentiation of carbapenemase-producers (CP-CRE) is essential, because these resistance determinants are readily transferable. The aim of our study was to characterise carbapenemase-producing strains in a low-prevalence setting in Hungary, through the use of various phenotypic and genotypic methods.

Materials/methods: Fifty strains obtained between 2014 and 2017 were included in the study from the culture collection of the Institute of Clinical Microbiology (University of Szeged). Inclusion of these strains was based on the screening criteria recommended by ESCMID (meropenem disk diameter <28 mm). The following phenotypic methods were used: modified cloverleaf (Hodge) test (MHT), modified carbapenem inactivation method (mCIM) and chromID CARBA SMART agar (bioMérieux). The presence of carbapenemase- and extended spectrum beta-lactamase (ESBL) encoding genes were detected using PCR, followed by sequencing. Production of AmpC-β-lactamases was verified using AmpC Detection Disk Set (Mast Diagnostics). Susceptibility of the strains to colistin (broth microdilution, Merlin Diagnostika) and fosfomycin (E-test, Liofilchem) was also determined.

Results: Carbapenemase genes were detected in 18 isolates (2 blaNDM, 6 blaOXA-48-like and 10 blaVIM), nine of these isolates were carbapenemase/ESBL (mainly blaCTX-M) co-producers. 12 isolates were inducible AmpC β-lactamase-producers, while in 5 isolates, none of the above could be verified. Sensitivities/specificities of the modified Hodge-test, CARBA SMART agar and mCIM test were 85.7%/80%, 95%/100% and 100%/100%, respectively. All tested isolates were susceptible to colistin (MIC range: 0.5-1 mg/L), while 37 out of 50 isolates were resistant to fosfomycin.

Conclusions: The diversity of carbapenemase enzymes and their co-occurrence with other resistance mechanisms affecting susceptibility to β-lactam antibiotics (AmpC, ESBLs, porin loss) often makes detection of these resistance-determinants difficult for routine diagnostic laboratories. Based on our results, the use of modified Hodge-test is not recommended due to its poor specificity, while chromogenic media (easy to use) and mCIM (panels can be prepared in-house) offer viable options for the detection and confirmation of carbapenemase-producing Enterobacterales for routine laboratories.

Abstracts 2020

Abstract 5661

Linezolid treatment for methicillin-sensitive Staphylococcus aureus bacteraemia
Ammara Asif1*, Anda Samson1, Omodolapo Ogunfuye2, Laura McLachlan1

1Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom, 2Hull York Medical School, Hull, United Kingdom

Background: Standard care for Methicillin-Sensitive Staphylococcus aureus bacteraemia is currently a minimum of 14 days of intravenous flucloxacillin or an equivalent antibiotic. Pharmacokinetic data show that linezolid is very well absorbed orally, and recent data suggest that linezolid can be an effective oral agent in the treatment of Methillin-Resistant Staphylococcus aureus and Methillin-Sensitive Staphylococcus aureus bacteraemia.

Materials/methods: We conducted a retrospective cohort study of adult patients who were treated with oral Linezolid for Staphylococcus aureus bacteraemia between August and October 2019 in an outpatient setting in a tertiary care hospital. Outcomes were safety data, inflammatory markers, clinical need to switch to other agents and recurrence of bacteraemia.

Results: Fifteen adult patients were included of the 3-month period. The leading sources of bacteraemia were including discitis, osteomyelitis, wound infections and cellulitis. Of the 15 patients, 13 were started on linezolid, and two started with intravenous flucloxacillin but were then switched to oral linezolid. All the patients were followed up weekly in the OPAT clinic and had blood test monitoring on all their follow up visits. There were no drug related events leading to discontinuation of linezolid observed. All the patients responded to the oral linezolid monotherapy as suggested by the clinical and biochemical improvement, and no recurrence of bacteraemia occurred after cessation of therapy. The duration of linezolid ranged from 2-5 weeks depending on the source of infection.

Conclusions: Treatment of Methillin-Sensitive Staphylococcus aureus bacteraemia with oral linezolid was found to be effective and safe in all 15 patients. Additionally, oral linezolid treatment enabled patients to continue treatment for Methillin-Sensitive Staphylococcus aureus bacteraemia without the need to stay in hospital. Oral linezolid therapy could serve as a cost-effective treatment for Methillin-Sensitive Staphylococcus aureus bacteraemia.

Abstract 5662

**Reporting of interferon gamma release assay results close to cut-off value**

Dorte B. Folkvardsen¹, Yen Holicka², Troels Lillebaek¹, Vladyslav Nikolayevskyjj*²

¹Statens Serum Institut, Copenhagen, Denmark, ²Public Health England, London, United Kingdom

Abstract third-party references: Abstract submitted on behalf of European TB Reference Laboratory network (ERLTB-Net-2) funded by ECDC

**Background:** Detection and treatment of latent tuberculosis infection (LTBI) can reduce the risk of developing active tuberculosis (TB) thus contributing to elimination of TB. Interferon gamma release assays (IGRA) are widely used for detection of LTBI. Several reports have shown high rates of conversion and reversion in results close to the clinical decision cut-off value, and determination of uncertainty as well as use of a borderline zone has been suggested to reduce an impact of test variability on diagnostic and clinical management of patients.

**Materials/methods:** To better understand practices in reporting IGRA results and identify potential areas for improvement, we conducted a survey within the ECDC European Reference Laboratory Network for TB (ERLTB-Net-2) using structured questionnaire.

**Results:** Responses were received from 16 National TB reference laboratories (NRLs) offering IGRA testing using QFT-plus (Qiagen) as part of their routine laboratory services, response rate was 100%. Four NRLs reported qualitative IGRA results, 11 qualitative results with numerical values, one quantitative plus qualitative for specific cases.

Six laboratories do not report results close to the cut-off value as equivocal and/or indeterminate within an uncertainty range. Ten NRLs have policies on reporting equivocal and/or indeterminate results based on either pre-defined ranges, or use specific methodologies to determine ranges for reporting results as equivocal.

When asked about special provisions for reporting of results close to the clinical decision cut-off value, seven laboratories responded that they report them as positive or negative following Manufacturer’s instructions. Six laboratories ask customers for another specimen. Two laboratories repeat the test and report the second result. One NRL suggests interpreting the results based on clinical history. In total, seven laboratories do not repeat tests with results close to a cut-off value, nine do.

**Conclusions:** Practices of reporting of IGRA results close to the clinical decision cut-off value differ significantly among NRLs, a finding that calls for further attention. Harmonization of reporting results close to cut-off value could be beneficial for patient management. A phase II study potentially involving collection of data on repeat testing is currently in the pipeline. Consent to participate has been obtained from 14 European NRLs.

An interoperable informatics application for the work-flow improvement of an antimicrobial stewardship programme in a tertiary hospital

Miguel Alaguero1, Mauricio Telenti1,2, Emilio Garcia-Prieto1,2, Enrique Garcia1, Tomas Suarez-Zarracina1, Cristina Calzón1, Lorena Forcelledo Espina1, Lucía López-Amor1, Estefanía Salgado1, Laura Villa1, Lorena Fernandez-Hernandez1, Eugenia Llaneza1, María Luisa Sánchez-Núñez1, Javier Fernández1,2

1Hospital Universitario Central de Asturias, Oviedo, Spain, 2Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain

Background: Hospital antimicrobial stewardship programs are aimed to reduce inappropriate use of these drugs by optimizing treatments (molecule, dose, route of administration and therapy duration) in order to improve patient outcomes and reduce antimicrobial resistances. Informatics technology in these programs are essential since can speed up the prescription revision, the interventions in the clinical records and help to measure the antimicrobial consumption, the number of interventions and their acceptation rate. The aim of this study was to develop an interoperable informatics application for the work-flow improvement of an antimicrobial stewardship program.

Materials/methods: A database interoperable with the patient clinical records was designed and evaluated in a tertiary hospital in northern Spain during a one-year period (November 2018 to November 2019). This application is capable of automatically update treatments, culture results (including antimicrobial susceptibility data) as well as patient information such as location in the hospital, somatometry and analytical results; being all this information filterable, facilitating the antimicrobial prescription revision. Interventions were classified in the application as: multidrug-resistant microorganism control, antimicrobial de-esacalation and escalation, dose adjustment, duration of therapy, sequential therapy, restricted antimicrobials control, antimicrobial prophylaxis duration, adherence to empirical therapy guidelines and therapeutic drug monitoring.

Results: A total of 6452 antimicrobial regimens from patients admitted in the hospital were reviewed by the antimicrobial stewardship team during the study period by using this application. These revisions led to 3325 interventions in the patient clinical records with a grade of acceptation among the patient’s responsible physicians of 75%. A reduction of 3% and 8% of days of therapy (DOTs) in antibiotics and antifungals were achieved, respectively; with an antimicrobial direct costs reduction of 13.7% (306015 euro) with respect to the same previous year-period.

Conclusions: Our application allowed to streamline the prescription revision by the antimicrobial stewardship team, leading to a high number of interventions with a high rate of acceptance, which resulted on an improvement in the global data of antimicrobial consumption. Further analysis of the impact in patient length of stay, infection outcomes and mortality is required, but our application seems to be a promising useful tool for antimicrobial stewardship programs.

Abstract 5664

An OXA-48 variant hydrolysing carbapenems, expanded-spectrum cephalosporins and aztreonam: welcome OXA-793

Marianlaura Dabos*1, Remy Bonnin1, Laurent Dortet1, Thierry Naas1,2

1Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 2Bicetre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: The spread of carbapenemase-producing Enterobacteriaceae (CPE) has become a major public health concern. Among these CPEs, OXA-48-producing Enterobacteriaceae have now widely disseminated throughout European countries. OXA-48 confers high-level resistance to penicillins, including temocillin and hydrolyzes carbapenems at a low level, but spares expanded-spectrum cephalosporins (ESC). Since the first identification of OXA-48, different variants have been reported, differing by few amino acid substitutions or deletions mostly in the region of the β5-β6 loop. Whereas some OXA-48-variants have similar hydrolytic activities to OXA-48, others, such as OXA-405 do not hydrolyze carbapenems but ESCs instead. Here, we have characterized a novel OXA-48 variant, named OXA-793, able to hydrolyze both ESCs and carbapenems.

Materials/methods: Multidrug-resistant K. pneumoniae strain 163G4 was isolated in France in 2018. Whole genome sequencing using an Illumina MiSeq platform was performed. OXA-793 was cloned in pTOPO and expressed in Escherichia coli Top10. Disc diffusion and MIC determinations were used to study antibiotic susceptibility. Plasmid reconstruction, characterization and mating-out assay were performed. Steady state kinetic parameters of the purified enzymes were determined and compared to those of OXA-48

Results: OXA-793 conferred resistance to expanded-spectrum cephalosporins and aztreonam, as well as carbapenems. OXA-793 differed from OXA-48 by a amino acid deletion (Ile215 and Glu216) in the β5-β6 loop. The substrate specificity was confirmed by steady state kinetic parameters of the purified enzyme, which exhibited high catalytic efficiencies for all the β-lactams including cephalosporins (broad and expanded-spectrum) aztreonam and carbapenems but no activity against temocillin. The blaOXA-793 gene was located on a conjugative ca. 60-kb plasmid identical to the prototype IncL blaOXA-48 -carrying plasmid.

Conclusions: OXA-793 is the second description of an OXA-48-like β-lactamase capable of hydrolyzing ESCs and carbapenems at the same time. The presence of blaOXA-793 gene on the highly conjugative IncL plasmid increases the risk of dissemination of this new variant. Finally, as temocillin resistance is currently used for OXA-48 detection, OXA-793 may go undetected and thus spread silently.

Abstract 5665

Take care of the cents and the euros look after themselves? Antimicrobial activity of European money

Johannes K. Knobloch*, Cristina Belmar Campos1, Eva M. Klupp1, Gefion C. Franke1

1University Medical Center Hamburg-Eppendorf, Inst. f. Medical Microbiology, Virology and Hygiene; Department for Infection Prevention and Control, Hamburg, Germany

Background: Money is a frequently touched surface and it is supposed that money might be involved in pathogen transmission. Due to copper fractions of >75% in euro and cent coins loose change is assumed to have antimicrobial activity. Antimicrobial activity of solid surfaces are often investigated by the unrealistic ISO 22 196. In this study we investigated the antimicrobial activity of european coins and banknotes under realistic conditions using a touch transfer assay [Knobloch, PlosOne, 2016] modelling the dry contamination by skin contact.

Materials/methods: For the touch transfer assay primary contaminated surface (PCS) were prepared with Enterococcus faecium ATCC 6057 or Staphylococcus aureus ATCC 6538 dried on the surface of ceramic tiles. Uptake of bacteria from the PCS was performed with moistened sterile cotton gloves. With the contaminated gloves bacteria were transferred to 5 cent, 50 cent and 1 euro coins as well as 5 Euro banknotes by touching the surface. Ceramic tiles were used as control surface in the touch transfer assay. Quantitative culture of the SCS was performed immediately [T0] as well as after 24 h storage.

Results: In independent experiments using E. faecium (n=4) and S. aureus (n=5) variable numbers of transferred bacteria were observed on the different surfaces. Similar transfer rates were observed for the ceramic tile (control) and banknotes. The smaller surface of the 5 cent coin resulted in a lower amount of transferred bacteria compared to 50 cent and 1 euro coins. All copper containing coins displayed a detectable antimicrobial activity. Reduction rates (log10) on 5 cent, 50 cent and 1 euro were calculated with 1.9, 2.1 and 2.3 for S. aureus as well as 1.5, 2.0 and 1.9 for E. faecium, respectively. In contrast, the decrease of bacteria after 24 h on the banknote was similar compared to the control.

Conclusions: In contrast to a 5 euro banknote, copper containing coins display a detectable antimicrobial activity. However, in most experiments bacteria were not completely eliminated from the coins. Therefore, even coins might act as vectors for the transmission of microbes.

Impact of antibiotic stewardship programme on the most utilised antibiotics’ utilisation and financial expenditure in 57,357 Children Cancer Hospital Egypt inpatient setting

Ehsan Khaled Mohamed Abualanain1, Ahmed Elzeiny2, Mohamed Nagy1, Amr Kashef1, Asmaa Badie*2, Amira Sameh1, Lobna Shalaby2

1Children’s Cancer Hospital Foundation, Cairo, Egypt, 2Children’s Cancer Hospital Foundation, Cairo, Egypt

Abstract third-party references: 57357 Children Cancer Hospital Egypt, Dr Lobna Shalaby - Head of the Infectious Disease Unit

Background: Antibiotic Stewardship program (ASP) was designed and implemented to reduce the misuse and abuse of antibiotics, and to reduce the overall bacterial resistance patterns in our hospital, 57357 Children Cancer Hospital Egypt. In order to evaluate the effectiveness of the program, and justify the costs involved in implementing it, a monthly outcome measures were set.

Aim of this study: to measure the effect of ASP on cost, and utilization of the high volume antibiotics in our hospital, CCHE, in 2019 after implementation of ASP against the same drugs at the same period of time in 2018, before implementation of ASP.

Materials/methods: This is a retrospective study, analyzing the cost per patient, defined daily dose (DDD) and days of therapy (DOT) per 1000 patient days; from January till September before and after implementation of the ASP for the most utilized antibiotics in our hospital. Drugs under study are, amikacin, liposomal amphotericin b, vancomycin and voriconazole. The entire population administering these antibiotics in the inpatient setting was included with exclusion of the outpatient, emergency and daycare setting.

Results:

</table>

Conclusions: ASP initiatives were associated with an observed reduction in stewardship-focused antibiotic utilization. Significant decreases in antimicrobial expenditures were also observed. These observed outcomes were related to the implementation of our hospital-designed-ASP; mainly focusing on infectious disease pharmacists and infectious disease physicians’ rounds, and ensuring the implementation of our local fever & neutropenia guidelines.

Molecular characterisation of multiresistant *Mycobacterium tuberculosis* strains circulating in the state of Santa Catarina, Brazil from 2013 to 2017

Luis Felipe Nunes¹, Manoela Valmoribida², Darcita Burger Rovaris³, Luciane Cauduro Lima³, Mara Cristina Scheffer*⁴, Maria Luiza Bazzo¹

¹Federal University of Santa Catarina Florianópolis Campus Trindade, Curso de Graduação em Farmácia, Florianópolis, Brazil, ²Federal University of Santa Catarina Florianópolis Campus Trindade, Laboratório de Biologia Molecular, Microbiologia e Sorologia - LBMMs, Florianópolis, Brazil, ³Laboratório Central de Saúde Pública/Lacen/SC, Setor de Tuberculose, Florianópolis, Brazil, ⁴Federal University of Santa Catarina Florianópolis Campus Trindade, Federal University Hospital, Florianópolis, Brazil, ⁵Federal University of Santa Catarina Florianópolis Campus Trindade, Programa de Pós Graduação em Farmácia, Florianópolis, Brazil

**Background:** Santa Catarina State, a high-income state in southern Brazil, with a TB incidence rate of 22.5 per 100,000 population. However, some regions have higher rates than the national average (>33.5/100,000 population). Previous studies conducted in Santa Catarina State showed predominance of the LAM lineage circulating strains, including the MDR isolates. Molecular epidemiology study is essential to understand the transmission dynamics of multidrug-resistant (MDR) isolates in the state. MDR phenotype is characterized by simultaneous resistance to rifampicin and isoniazid.

**Materials/methods:** The samples were culture in liquid medium (MGIT-BD, USA) and reisolated in Ogaw-Kudoh medium. DNA were extracted by CTAB. DST testes were made by critical concentrations. The study included all MDR isolates from Santa Catarina State during the evaluated period (2013-2017), corresponding to 63 isolates of *Mycobacterium tuberculosis*. Molecular epidemiology was characterized by the combined analysis of spoligotyping and MIRU.

**Results:** The 63 isolates were classified into 14 SITs, 13 sublineages and four lineages, and three isolates had unknown profile and one isolate Orphan profile (sublineage T2). The LAM lineage was the most prevalent (75%), followed by the T superfamily (14%), Harleem (5%) and EAI (2%). With 71% of isolates integrating 4 SITs (2263, 42,106 and 73), all corresponding to the LAM lineage (LAM9, LAM7 and LAM5). The LAM9 sublineage was responsible for 52% of isolates. The dendrogram constructed by the combined analysis of MIRU and spoligotyping identified nine clusters (100% similarity) and 13 Recent Infection Group (GIR) (90-99% similarity). The largest cluster consisted of 18 isolates from SIT2263 (LAM9), the second largest consisting of eight isolates from SIT106 (LAM7). The largest GIRs consisted of nine isolates of the LAM9 sublineage and one with 31 isolates of LAM9 and one T1, corresponding to 52.3% of the total isolates (33/63).

**Conclusions:** The isolates classification maintained similar proportions during the five years studied. The work was fundamental to determine the epidemiological profiles of multidrug-resistant *Mycobacterium tuberculosis* in Santa Catarina State, identifying the LAM lineage as the main family and as sublineages LAM9 (SIT2263 and SIT42) and LAM7 (SIT106).

**Figure1:** Spoligotyping result for the 63 MDR isolates, grouped by families and subfamilies

Abstract 5675

Is Mycobacterium lentiflavum “the new” Mycobacterium avium?

Sara Gómez De Frutos*, Arturo Manuel Fraile Torres, Aylia Yarci Carrión, Tamara Soler Maniega, Laura Cardeñoso, Rosa M. Girón, Diego Domingo

1Hospital de La Princesa, Madrid, Spain

Background: Mycobacterium lentiflavum is a slow-growing nontuberculous mycobacteria (NTM) that has been increasing gradually during the last years. Its pathogenic role is controverted, and as Mycobacterium avium complex (MAC) it has been isolated from respiratory samples and from lymph nodes specially from children.

Materials/methods: retrospective study from 2009 to 2019 in a universitary hospital in the community of Madrid, Spain. All samples for micobacteria diagnosis were included. Microbiological diagnosis was carried out by an automated culture (MGIT™ 960 system, Becton Dickinson). Bacterial identification was obtained by mass spectrometry (MALDI-TOF) or DNA studies.

Results: a total of 3338 samples were positive for micobacteria (2751 NTM): 53.73% MAC and 13.34% M. abscessus were the most prevalent micobacteria. Mycobacterium lentiflavum was isolated from 230 samples (8.36% total NTM isolates) from 173 patients: 40.46% female, median age 63.12 years, 50 (28.90%) suffering bronchiectasis and 11 (6.35%) cystic fibrosis. The respiratory tract was the main origin of M. lentiflavum isolates (198, 86.09%), following by lymph nodes (28, 12.17%). All the positive lymph nodes came from children except one from an adult. 22 patients (12.71%) had two or more M. lentiflavum isolates: the principal origin was respiratory tract (21 patients, 95.45%), M. lentiflavum was the only microorganism isolated from 12 patients (54.54%). During the period, an increase in the number of isolates and the M. lentiflavum-NTM proportion is observed (Graph 1): from 5 isolates (2.67% NTM) in 2009 to 19 (9.6% NTM) in 2019.

Conclusions: the high frequency of isolation, the isolation from more than one sample and the absence of other microorganism in the cultures, support this NTM as causative agent of infection not only in pediatric population, but also in adults. Moreover, during this ten years’ period a continuous rise of isolation is noted, even displacing MAC as the main micobacteria isolated from lymph nodes in paediatric population, therefore new studies that clarify its pathogenic role are necessary to improve the correct management of these patients.

Occurrence and predictors of nephrotoxicity in adult patients treated with intravenous colistin: a cohort study
Luísa Graça¹, João Torres², André Silva-Pinto¹, Francisco Almeida¹, Nuno Rocha Pereira*¹, Paulo Andrade¹, Raquel Duro¹, Carlos Alves¹

¹Saint John Hospital, Porto, Portugal, ²Hospital Egas Moniz, Lisboa, Portugal

Background: Colistin has been increasingly used due to the emergence of multidrug resistant bacteria. Nephrotoxicity is its most important side effect. Our aim was to determine the prevalence and risk factors associated with nephrotoxicity in patients treated with colistin.

Materials/methods: Retrospective cohort study of adult patients treated with at least 48h of intravenous (IV) colistin in a single tertiary care hospital from 2015 to 2018. Nephrotoxicity was defined according to RIFLE criteria. The adequacy of dosage was classified according to the International Consensus Guidelines. The association of independent variables with nephrotoxicity was evaluated using logistic regression.

Results: The prevalence of nephrotoxicity in our cohort was 41.07% (69/168) and it led to treatment interruption in 6 patients (3.57%). Five patients (7.25%) needed dialysis, 52 (75.36%) classified as Failure, 5 (7.25%) as Injury and 7 (10.14%) as Risk. Sixty-two patients (36.9%) received an insufficient dose of colistin. These patients were less likely to develop renal toxicity (OR 0.07; IC95% 0.01 - 0.56; p=0.01). The occurrence of nephrotoxicity was adjusted for dosage of colistin. Older age (OR 1.03; IC95% 1.00 - 1.06; p=0.03), duration of treatment (OR 1.08; IC95% 1.03 - 1.14; p=0.02) and colistin use in the preceding month (OR 10.86; IC95% 1.31 - 90.31; p=0.03) were identified as risk factors for nephrotoxicity. In 36 (23.38%) patients the kidney injury had not reversed on discharge home. The overall 30-day mortality was 41 (24.40%).

Conclusions: The prevalence of nephrotoxicity in our cohort was high and similar to other studies, although more than one third of patients were treated with suboptimal dose. Most kidney injury was severe and long-lasting. There are settings when colistin is the only therapeutic option but its use is greatly limited by toxicity. Better tolerated antibiotics should be used whenever possible, especially in high risk patients.

Abstract 5681

Usefulness of human cytomegalovirus (HCMV)-specific immunological monitoring in the management of HCMV infection in lung transplant recipients

Sara Colonia Uceda Renteria1, Irene Cassaniti2, Letizia C. Morlacchi3, Valeria Rossetti2, Rosaria Carrinola4, Giovanni Giacomel1, Monica Spolti1, Cristina Vigano1, Livia Tartaglione1, Anna Orlandi1, Massimo Oggoni2, Elena Benazzi5, Alessandro Paleschi4, Fausto Baldanti2, Giovanna Lunghi1

1Virology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, 2Molecular Virology Unit, Microbiology and Virology Department, Fondazione IRCCS Policlinico San Matteo, Milan, Italy, 3Respiratory Unit & Cystic Fibrosis Adult Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, 4Thoracic Surgery and Lung Transplant Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, 5Nord Italia Transplant Program, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: We evaluated the usefulness of immunologic monitoring in LTRs for predicting the onset of HCMV DNAemia after stopping antiviral prophylaxis post-transplant and to individuate possible markers predictive of the risk for HCMV infections using both aspecific and HCMV-specific immunological monitoring.

Materials/methods: In this prospective cohort study were enrolled 63 consecutive LTRs between February 2017 and December 2018 and monitored for at least six months post-transplant. Antiviral prophylaxis was based on donor (D) and recipient (R) serology. The virological and immunological monitoring was established at time 0, 1 and each three months after transplant. Immunological monitoring was performed using two commercially-available tests QuantiFERON and ELISpot.

Results: The median age was 35 years [IQR 25-51] at time of transplant, 58.7% were male and 61.9% LTRs came from cystic fibrosis.

At 120 days post-transplant, the CD4+ T-cell count was significantly higher in the group of patients with undetectable HCMV DNAemia in comparison to those with detectable HCMV DNAemia post-transplant (p=0.0124). The cumulative incidence of HCMV DNAemia events was significantly higher in the group of patients with CD4+ T-cell count lower than 650 cells/µl (89.2%) than respect to patients with CD4+ T-cell count higher than 650 cells/µl (28.6%; p<0.0001).

We observed an excellent agreement between ELISpot and serology status at transplant (kappa 0.93) while lower agreement between QuantiFERON and serology status (kappa 0.63). On 696 assays performed during the follow up of LTRs, the agreement between ELISpot and QuantiFERON was moderate (kappa of 0.54). 14/49 patients R+ showed persistent negative QuantiFERON assay despite the presence of detectable immunity measured by ELISpot. 28.6% of R+ LTRs showed persistent negative QuantiFERON in presence of positive ELISpot during all the period of follow-up.

Analyzing IE1-specific T-cell response at pre-transplant, we observed a statistical trend of significance (p=0.0505) for the prediction of HCMV reactivation in HCMV-seropositive patients.

Conclusions: ELISpot resulted most sensible that QuantiFERON to detect the HCMV-specific T-cell response in LTRs. CD4+ T-cell count measured at 120 days post-transplant and IE1-specific T-cell response could represent predictive markers to identifying LTRs at risk of HCMV infection and to adjust the period of prophylaxis.

**Increase of *Escherichia coli* with reduced susceptibility to cefepime and OXA-1 compatible phenotype in urinary tract infections along the years**

Sandra Nabal Díaz1, Jessica Bueno1, Palacián Ruiz Pilar1, Saray Mormeneo Bayo1, Beatriz Sanz1, Carmen Guerrero1, Juan Manuel Garcia-Lechuz Moya1, Antonio Rezusta1, Ana Isabel López-Calleja*1

1Servicio de Microbiología, Hospital Universitario Miguel Servet, IIS Aragón, Zaragoza, Spain

**Background:** *E. coli* isolates with reduced susceptibility or resistance to amoxicillin-clavulanate (AMC), piperacillin-tazobactam (PTZ) and cefepime (CEF) (OXA-1-beta-lactamase compatible phenotype) are emerging in the last years. The aim of this study was to quantify the number of *E. coli* isolates with this OXA-1 compatible phenotype from 2015 to 2019 from clinical samples and to analyze the antibiotic susceptibility patterns and patient’s characteristics.

**Materials/methods:** From January 2015 to October 2019, 31085 non duplicate *E. coli* from various clinical specimens were obtained (first isolate per patient). Antimicrobial susceptibility testing was determined by MicroScan WalkAway (Beckman Coulter) and Eucast criteria were applied. *E. coli* isolates (excluding ESBL and AMPC) in which the MIC of AMC was ≥16 mg/L, PTZ ≥16 mg/L, and CEF ≥2 mg/L were considered compatible with an OXA-1-beta lactamase. Cefuroxime (30 µg) disk diffusion test was performed in a selection of isolates. Microbiological and clinical data were recorded.

**Results:** A total of 224 patients presented an *E. coli* with OXA-1 compatible phenotype (28 in 2015, 29 in 2016, 35 in 2017, 75 in 2018 and 57 until October 2019), mainly isolated from urine samples (85%); 83% were outpatients, 73% women, and 52% ≥65 years. The percentages of susceptibility (S) were: 20.5% cefuroxime, 98% cefixime, 78% cefotaxime, 96% ceftazidime, 98% aztreonam, 100% carbapenems, 53% ciprofloxacin, 72% gentamicin, 65% tobramycin, 90% amikacin, 58.5% trimethoprim-sulfamethoxazole, 97% nitrofurantoin, and 96% fosfomycin. In 34 isolates cefuroxime susceptible by the Microscan WalkAway system a cefuroxime disk diffusion test was performed, that resulted resistant in 32 (94%) of the 34 isolates.

**Conclusions:** The number of *E. coli* isolates with OXA-1 compatible phenotype has gradually increased in recent years (especially from 2018) mainly associated with urinary tract infections (UTI) in outpatient women. Reduced susceptibility has been found for cefuroxime (with false susceptible results from the MicroScan WalkAway system), cefotaxime, gentamicin, tobramycin, ciprofloxacin and trimethoprim-sulfamethoxazole, that added to the resistance profile to amoxicillin-clavulanate, piperacillin-tazobactam and cefepime may result in multidrug-resistant isolates with limited treatment options. Fosfomycin and nitrofurantoin remain a good treatment option for uncomplicated UTI.

1ISMETT-IRCCS, Palermo, Italy, 2Fondazione Ri.MED Palermo, 90133, Italy, *Clinica delle Malattie Infettive e Tropicali, Università degli Studi dell’Insubria, Varese, Italy

Background: HHV8/KSHV causes neoplastic and non-neoplastic diseases in SOT (solid organ transplant). At ISMETT (Mediterranean Institute for Transplantation and Advanced Specialized Therapies) a prospective study on liver donors and recipients published in 2011 showed that 50% of mismatch recipients (D+/R-) developed a primary HHV8 infection, 50% with fatal outcome. In 2016 we described the first case of KICS (KSHV Inflammatory Cytokine Syndrome) in an HIV-negative SOT recipient, successfully treated.

We aimed to describe epidemiology and incidence of infection and disease HHV8-related in different risk-groups of SOT population: mismatch (D+/R-), patients HHV8Ab-positive pre-transplant, seronegative patients.

Materials/methods: Donors and recipients were screened for HHV8-Ab at transplant time. We performed infectious, dermatological and virologic follow-up with different timing according to the risk category, in order to identify infection or treat associated disease.

Results: We found an overall HHV8-seroprevalence of 6.3% in our population of donors and recipients [January 2012-March 2019]. Among 27 mismatch recipients (1 heart, 1 lung, 5 kidney, 20 liver), 12 liver recipients presented HHV8 transmission (44.4%), intended as seroconversion or detectable viremia. (Table 1)

Of note, 6 patients (22%) developed a KICS-like syndrome after SOT: two patients had fatal outcome. Both happened before strict clinical and virologic monitoring took place.

Among 76 positive recipients before SOT, four patients (5.3%) developed HHV8-disease: three cutaneous Kaposi Sarcoma and one visceral Kaposi Sarcoma with fatal outcome. One patient presented a de novo HHV8 infection after transplant with KICS syndrome.

HHV8-related mortality in risk-patients [mismatch and positive recipients, n=103] was 2.9%.

Mismatch liver recipients represent a high-risk group

Conclusions: Considered the possible serious complications, SOT patients must be strictly followed-up for HHV8 infection/ reactivation. Knowledge about HHV8 related disease in SOT need to be improved.

Table 1. HHV8 transmission in mismatch recipients

Abstract 5686

The effectiveness of antibiotic prophylaxis in the prevention of respiratory tract infections in antibody-deficient patients: a single-centre cohort study

Mahableswar Albur*, Alexandros Grammatikos†, Sarah Johnston‡

†North Bristol NHS Trust, Severn Infection Sciences, Bristol, United Kingdom, ‡North Bristol NHS Trust, Severn Pathology, Bristol, United Kingdom

Background: Antibiotic prophylaxis has become an integral part of the management of antibody deficient patients, but very few studies have been attempted to define its role. In an era of therapeutic immunoglobulin shortage and rising antimicrobial resistance (AMR), the need to clarify this role has become even more critical.

Materials/methods: In a tertiary immunology referral centre in England (UK), we retrospectively analysed the hospital Immunology database to identify adult antibody deficient patients who had received antibiotic prophylaxis to prevent lower respiratory tract infection (LRTI) over the past 15 years. Primary outcome was to assess the impact on hospital admissions and sputum culture positivity. Secondary outcome was to assess the emergence of AMR and adverse drug reactions.

Results: One hundred and five patients were identified with a cumulative monitoring period of 870 years (mean 3.9 years). There was a significant reduction in infection-related hospital admissions by almost 50% [53/year vs 27/year] and positive sputum cultures were reduced by a third [1.61/year vs 1.05/year] [Figure 1]. Although 10% of patients reported antibiotic related side effects, diarrhoea (n=4) and genital thrush (n=3) being the most common, none of them developed Clostridium difficile infection. Overall, emergence of secondary AMR to the corresponding antibiotic the patient was receiving at the time occurred in 15 patients (14%). This was mainly against macrolides and there was evidence of cross resistance across different agents in the same class. In terms of risk of colonisation with multi-drug resistant organisms (MDRO), there were 8 patients with extended-spectrum Beta-lactamase (ESBL) producing Enterobacteriaceae, 5 patients with Methicillin-resistant Staphylococcus aureus (MRSA) and a single case of vancomycin resistant Enterococcus (VRE). The annual cost of the top three agents Cotrimoxazole, Azithromycin and Amoxicillin were £56, £120 and £32 respectively. They are significantly lower than the cost of a single day of hospitalisation in a publicly funded National Health Service (NHS) in England.

Conclusions: Overall, antibiotic prophylaxis is effective in antibody deficient patients. Taking into account the cost and scarcity of immunoglobulin and hospital beds in the NHS, our study shows the cost effectiveness of antibiotic prophylaxis in this patient population.

Possibilities of implementation of lactobacilli’s antagonistic properties for Clostridioides difficile growth suppression

Marina Sukhina1,2, Anton Safin*1, Anzhelika Zagaynova2

1 A.N. Ryzhikh State Scientific Center for Coloproctology, Moscow, Russian Federation, 2Center for Strategic Planning and Management of Medical and Biological Health Risks, Moscow, Russian Federation, 3A.N. Ryzhikh State Scientific Center for Coloproctology, Moscow, Russian Federation

Background: Colon-derived Lactobacillus strains could be divided into groups with high, intermediate, low and absent antagonistic activity (AA). Lactobacilli’s antagonistic properties are promising for prevention and treatment of nosocomial multiresistant infection

Materials/methods: We isolated 30 Lactobacillus spp. strains, 3 Yersinia spp. strains and 150 C. difficile strains from the patients’ colon biotope. All C. difficile strains caused clinically relevant antibiotic-associated diarrhea, 28 strains were toxin B positive, 116 strains were toxin (A+B) positive and 6 strains were toxin-negative. We also used Lactobacillus plantarum 38 strain from “Lactobacterin dry” probiotic [Microgen, Russia] and Helicobacter pylori NCTC 11639, Campylobacter jejuni NCTC 11635, Salmonella enterica serovar typhimurium 3542 reference strains. Lactobacilli’s AA was quantified by measurement of growth suppression zone of the culture of interest: > 30 mm – high, 20 – 30 mm – intermediate, 5 – 20 mm – low, ≤ 5 mm – absent.

Results: Lactobacillus spp. content in 30 faeces samples varied from 10³ to 10⁶ CFU / g. 10⁶ - 10⁸ CFU / g Lactobacilli multiplicity was characterized by high [38,9%], intermediate [11,1%] and low [11,1%] AA. AA-absent strains [38,9%] had very heterogeneous multiplicity [10³ - 10⁸ CFU / g]. None of the Lactobacillus strains have shown high level of AA against Salmonella enterica serovar typhimurium 3542. We revealed high AA against Helicobacter pylori NCTC 11639 in 17 [55,6%] Lactobacillus strains and low AA only in 8 [26,3%]; this parameter was coordinated with AA against Campylobacter jejuni NCTC 11635 and Yersinia spp. strains. Lactobacillus plantarum 38 reference strain has shown monotonous high AA against all clinically relevant microorganisms except toxin-producing C. difficile. Luminal-derived Lactobacilli of the patients have shown high and intermediate AA against toxin-negative and toxin B positive C. difficile while having low or absent AA against (A+B) positive C. difficile.

Conclusions: Lactobacilli’s AA evaluation is perspective for fighting nosocomial infection caused by resistant microorganisms; particularly the use of Lactobacillus autostrains could suppress the growth of toxigenic C. difficile strains.

Abstract 5692

Systematic review of Legionella amelioration systems in healthcare facilities
Jennifer Mcdanel¹, Alexandre Marra¹, Daniel J. Diekema¹, Elizabeth Kiscaden², Heather Healy², Loreen Herwaldt*¹

¹University of Iowa Hospitals & Clinics, Iowa City, United States, ²The University of Iowa, Hardin Library for the Health Sciences, Iowa City, United States

Background: Contaminated water systems have been the source of healthcare-associated Legionella infections. We conducted a systematic literature review to assess the effect of mitigation systems on Legionella contamination of healthcare facilities’ water systems.

Materials/methods: We searched reference lists, MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, and clinicaltrials.gov using the key terms legionnaires, legionella, water, hospitals, and healthcare facilities to identify articles published through 7/10/2017 pertaining to Legionella amelioration methods. We included studies that provided information on amelioration methods for Legionella in hospital water systems and cultured water samples for Legionella for > 1 year after implementation of the system. We excluded articles that: were not in English, addressed only Legionella infections, provided inadequate information, or provided aggregate data from > 1 facility.

One investigator screened titles, abstracts, and manuscripts. Two investigators independently abstracted data. They resolved disagreements by reviewing the papers together.

Results: 62 articles published between 1975-2017 met inclusion criteria. 72 hospitals were located in: the United States (34), Europe (28), Canada (5), and Asia (5). 52% of hospitals used > 1 amelioration system during their study periods.

Abstract 5695

Implementing rapid susceptibility testing directly from positive blood cultures in the routine laboratory workflow for sepsis

Paraskevi Mantzana1, Eleni Kandyliotou2, Maria Kyriakopoulou1, Fotini Netsika1, Maria Arhonti1, Areti Tychala*1,2, Georgios Meletis1, Olga Vasilaki1, Georgia Kagkalou1, Efthymia Protonotariou1, Lemonia Skoura1

1AHEPA University Hospital, Department of Microbiology, Thessaloniki, Greece, 2Thessaloniki Psychiatric Hospital, Department of Microbiology, Stavroupoli, Greece

Background: Early diagnosis and treatment of bloodstream infections decreases mortality rate of sepsis. Timely reporting of susceptibility results of bacteria isolated from blood cultures (BC) is crucial for promptly administering an appropriate antimicrobial treatment, improving patients’ outcome and possibly conferring cost savings. The aim of this study was the evaluation of the performance of light scattering technology Alfred60®T (Alifax, Italy) for rapid (in a few hours) susceptibility testing directly from positive BC and its applicability in routine use.

Materials/methods: We evaluated 156 significant episodes of bacteraemias produced by 77 Gram-negative and 77 Gram-positive bacteria. Only monomicrobial according to Gram stain BC were included. The antimicrobials tested were chosen among ciprofloxacin, gentamicin, meropenem, piperacillin-tazobactam and colistin for Gram-negative and cefoxitin, vancomycin, linezolid and daptomycin for Gram-positive bacteria. Alfred60®T provided qualitative results in terms of clinical category (SIR). Concordance assessment was performed in comparison with the routine method Vitek2 (bioMérieux, France) except for colistin which was compared with the automated broth microdilution system MICRONAUT-S (Merlin, Germany). Discrepancies were resolved with MICRONAUT-S or E-test (bioMérieux, France). Interpretation of clinical categories (SIR) was determined according to EUCAST recommendations.

Results: Total turnaround time for a complete Alfred60®T result was 6-6.5h. Out of 587 (320 for Gram-negative and 267 for Gram-positive) susceptibility determinations, 94.73% (95.62% for Gram-negative and 93.64% for Gram positive) showed categorical agreement (CA) with the routine method and this percentage increased to 95.41 (96.56 and 94.02 respectively) after discrepancy analysis. CA for most antimicrobials was above 90% except for daptomycin for Gram-positive (86.4%). There were 0.68% very major errors, 3.23% major errors and 1.36% minor errors. It should be pointed out that very major errors were reported only for cefoxitin in Staphylococci.

Conclusions: The evaluated method Alfred60®T was easy to use, provided rapid and reliable results given in a few hours after BC positivity compared to the 48 h required in the conventional method on isolated colonies. Implementing this technology in routine workflow for critically ill patients allows clinicians to optimize adjusted therapy with potential clinical benefit and impact on the antibiotic stewardship.

Abstract 5697

In vitro activity of imipenem/relebactam among Gram-negative clinical isolates in two Spanish tertiary hospitals
Marina Peñuelas Martínez1, Cristina García Salguero1, Melanie Iñigo2, Francisco Javier Candel*1, Jose Luis Del Pozo2, Esther Culebras1

1Hospital Clínico Universitario San Carlos, Madrid, Spain, 2Clínica Universidad de Navarra, Pamplona, Spain

Background: According to WHO objectives, carbapenem resistant Enterobacteriaceae, carbapenem resistant Pseudomonas aeruginosa and carbapenem resistant Acinetobacter baumanii, are considered "priority pathogens" to promote research and development of new antimicrobials. Imipenem/relebactam is a new combination which attempts to recover imipenem activity between resistant strains. In our study we tested 192 strains to imipenem and imipenem/relebactam and compared the minimum inhibitory concentrations obtained.

Materials/methods: Imipenem/relebactam was tested against 192 strains previously characterized (49 E.coli imipenem susceptible which carry different extend spectrum betalactamases [ESBL] or AmpC betalactamases, 50 carbapenem resistant Enterobacteriacea by different carbapenemases [19 KPC, 19 OXA-48, 11 VIM and 1 NDM], 50 A.baumanii and 43 imipenem resistant P.aeruginosa [23 of them carbapenemases carrier; 19 VIM and 4 KPC]. Minimum inhibitory concentrations [MIC] were obtained by standard broth microdilution method following the CLSI guidance.

Results: All E.coli imipenem susceptible were also susceptible to imipenem/relebactam, and in 28/49 strains MICs were reduced one to two folds, with a MIC90 of 0.125 mg/L. Focusing on the carbapenem resistant Enterobacteriacea group, the greatest MIC reduction was obtained among KPC carriers (≥ 5 fold in most cases). In 10 of the 19 OXA-48 carrying strains, MIC was reduced to 8 mg/L or below, where 9 of these 10 strains were BLEE carriers too. The 12 strains carrying class B carbapenemase obtained MIC equal to or greater than 16 mg/L. There were no changes in MIC50 and MIC90 for A.baumanii strains. For P.aeruginosa strains without carbapenemases, MIC was reduced 1 to 5 folds, it was reduced 4 folds for the 4 KPC carriers and there was no reduction or one fold reduction for the VIM strains.

Conclusions: In our study imipenem/relebactam showed a great activity against KPC carriers. Activity against OXA-48 strains seemed to be related to the activity against ESBL. The small differences found in the MICs obtained against class B carbapenemases carriers do not cause any improvement. There was also no recovery in the activity against A.baumanii. For P.aeruginosa this combination showed a good activity except to class B carbapenemases carriers.

Abstract 5702

An audit of community-acquired pneumonia antimicrobial compliance using a mobile audience response system (ARS) care bundle in an Irish hospital

Brendan O’Kelly1*, Mary Regan1, Ana Rueda Benito2, Katherine Finan2

1The Mater Misericordiae University Hospital, Dublin, Ireland, 2Sligo University Hospital, Sligo, Ireland

Background: Hospitalisations with community acquired pneumonia (CAP) are often not managed in accordance with antimicrobial guidelines. The aim of this study was to assess if guideline driven antimicrobial prescribing for CAP can be improved using an intervention bundle. Secondary measures assessed were duration of iv antibiotics and total antibiotic duration, length of stay, mortality, improving uptake of appropriate investigations and documentation of CURB65.

Materials/methods: A retrospective cohort of hospitalised CAP patients from August -September 2018 was compared with a post intervention prospective cohort from May-June 2019. Intervention bundle included a mobile audience response system (ARS) session, promotion of the antimicrobial app, development of a physical card with local guidelines and incorporating CURB65 into the unscheduled admission hospital proforma. Local guidelines are in keeping with BTS CAP guidelines1.

Results: 69 patients were included in the study (37 retrospective, 32 prospective). Overall compliance with local CAP guidelines improved from 21% to 62.5% (p<.001). No difference in initial intravenous antibiotic duration was seen 4.1 vs 4.2 days (p=0.73), total antibiotic duration was significantly shorter in the post intervention group, 9.4 vs 7.3 days (p=.01). No difference in length of stay or mortality was seen between the groups. Documentation of CURB65 improved from 5.6% to 46.9% (p<.01). Uptake of streptococcal urinary antigen improved from 18.9% to 40.6% (p=.024).

Conclusions: A simple cost-effective quality improvement bundle featuring a mobile ARS can significantly increase appropriate antimicrobial prescribing and shorten total length of antibiotics.

Comparison of two molecular methods for the diagnosis of sexually-transmitted pathogens

Marta Adelantado Lacasa¹, Alberto Gil-Setas¹,², Estibaliz Erviti¹, Xabier Beristain Rementeria¹,², Irati Arregui¹, Carmen Ezpeleta Baquedano*¹,²

¹Department of Clinical Microbiology, Complejo Hospitalario de Navarra, Pamplona, Spain, ²Instituto de Investigación Sanitaria de Navarra (IdisNA), Pamplona, Spain

Background: Rising sexually transmitted infections (STI) is a major concern worldwide. Molecular methods offer rapid and sensitive diagnosis method. The aim of this study is to compare two different PCR assay to detect STI-causing pathogens.

Materials/methods: We performed a prospective observational study between 20/09/2019-15/11/2019 including routine clinical care samples received from patients with suspected STI (urethral, endocervical/vaginal, rectal swabs and urines). Samples were submitted in parallel into two commercially available PCR methods: Allplex™ STI Essential Assay (Seegene) and Alinity m STI Assay (Abbott). Allplex assay requires a previous step of sample pre-treatment and DNA extraction before the amplification step. By contrast, Alinity can analyze directly the samples in the same recipient in which they are collected and includes a combined extraction-amplification method.

Results: Out of 833 samples included, 156 (18.7%) showed positive results, 138 (16.6%) in both assays. Allplex assay detected 139 (16.7%) positive samples and Alinity assay 155 (18.6%) samples, 17 (2.0%) samples were positive only by Alinity assay. By microorganism, Alinity detected 79/79 (100.0%) Chlamydia trachomatis, 29/29 (100.0%) Neisseria gonorrhoeae, 31/31 (100.0%) Mycoplasma genitalium and 16/17 (91.7%) Trichomonas vaginalis and Allplex 74/79 (93.7%), 26/29 (89.7%), 23/31 (74.2%) and 16/17 (91.7%), respectively. Alinity assay detected 5/12 (41.7%) coinfections not detected by Allplex, the cycle threshold (Cts) of the microorganisms detected only by Alinity were all more than 35.0. The average Cts of Alinity assay were 24.4 for C. trachomatis, 24.1 for N. gonorrhoeae, 26.9 for M. genitalium and 17.1 for T. vaginalis, and for Allplex 24.9, 24.8, 30.3 and 22.3, respectively. The differences between average Cts for Alinity and Allplex were significant (p=0.05) for C. trachomatis, M. genitalium and T. vaginalis.

Conclusions:
- Alinity detected 2.0% STI-causing microorganism more than Allplex assay
- Alinity assay detected 100% C. trachomatis and N. gonorrhoeae vs 93.7% and 89.7% for Allplex, differences were remarkable for M. genitalium (100.0% vs 74.2%)
- Alinity had lower average Cts by microorganism than Allplex assay
- Alinity assay is less time-consuming and easier to perform than Allplex

Presenter email address: carmen.ezpeleta.baquedano@navarra.es
Diagnostic test characteristics of radiographic keywords in the diagnosis of bacterial pneumonia
Owen Albin*, Jason Pogue1, Lindsay Petty1, John P. Mills1, Keith S. Kaye1

1University of Michigan, Ann Arbor, United States

Background: Noninfectious syndromes mimicking bacterial pneumonia lead to unnecessary antibiotic use in hospitalized patients. Reliable tools to aid in ruling out bacterial pneumonia could help stewardship programs de-escalate or discontinue antibiotics. The purpose of this study was to assess the diagnostic test characteristics of the presence or absence of pre-specified keywords in radiology reports of chest imaging studies to rule out pneumonia in patients who were treated for pneumonia.

Materials/methods: Retrospective cohort study of adult hospitalized patients between 2008-2017 with presumptive pneumonia (defined as positive respiratory cultures and continuous receipt of ≥ 5 days of new antibiotics) who achieved clinical cure. All clinical data and imaging were independently reviewed by blinded Infectious Diseases physicians to validate the diagnosis of pneumonia, based on formal IDSA/ATS criteria with the additional requirement that a more likely alternative diagnosis was not suspected. Subjects were grouped into those with pre-specified keywords [infection, pneumonia, consolidation, opacity[ies], opacification, infiltrate[s], airspace] in the radiologist interpretation of chest imaging obtained within 48 hours of pneumonia diagnosis and those without pre-specified keywords present. Select clinical criteria measured at the time of presumptive pneumonia diagnosis were abstracted from the medical record.

Results: Of 705 cases reviewed, 242 cases [34.3%] were deemed to not be pneumonia, and 463 [65.7%] cases were consistent with a diagnosis of pneumonia. Pre-specified keywords in chest imaging were present in 640 (90.8%) cases, including 450 patients [97.2%] with a confirmed diagnosis of pneumonia and 190 [78.5%] patients without pneumonia (p<0.01). The absence of keywords had a sensitivity of 97.2% and a negative predictive value (NPV) of 80.0% for the diagnosis of pneumonia. The absence of keywords, when combined with different clinical criteria, augmented the NPV (Figure 1).

Conclusions: Among patients with positive sputum cultures who received antibiotics for treatment of suspected pneumonia, the absence of specific radiographic keywords was associated with a low likelihood of true pneumonia, particularly when combined with certain clinical criteria. The absence of radiographic keywords can be used to target patients for further assessment by stewardship personnel where de-escalation or discontinuation opportunities are likely.

Abstract 5705

Direct-acting antivirals-based treatment for HIV/hepatitis C virus co-infected patients: analysis of factors of virological sustained response in a real-life study

Lorenzo Onorato*, Loredana Alessio1, Vincenzo Sangiovanni1, Francesco Borrelli4, Elio Manzillo2, Vincenzo Esposito2, Filomena Simeone3, Salvatore Martini1, Nicolina Capoluongo2, Sebastiano Leone3, Giovanni Di Filippo1, Maurizio D’abbraccio2, Angelo Salomone Megna4, Eugenio Milano5, Annalisa Saracino6, Nicola Coppola1

1University of Campania “Luigi Vanvitelli”, Naples, Italy, 2AORN Sant’Anna e San Sebastiano, Caserta, Italy, 3AORN dei Colli, Pozzobonone, Naples, Italy, 4AOU Federico II, Naples, Italy, 5A.O S.G. Moscati, Avellino, Italy, 6A.O G. Rummo, Benevento, Italy, 7University of Bari, Bari, Italy

Abstract 5705

Background: Coinfection with HCV is common in HIV seropositive subjects. It is well known that both viruses can alter glucose tolerance, lipids metabolism and renal function. However, data from real-life studies evaluating the virological outcome of regimens based on all-oral direct acting antiviral agents (DAAs). The aim of this study was to identify the factors associated with the viral response of the treatment with DAAs in a cohort of HIV/HCV coinfected patients.

Materials/methods: We conducted a multicenter retrospective cohort study enrolling all HIV/HCV coinfected patients treated with DAAs in one of the nine participating centers [8 in Campania, 1 in Apulia], for which HCV-RNA loads at 12 weeks after EOT were available. The outcome evaluated was the SVR12 rate; the epidemiological, clinical and virological characteristics associated with the viral response were analysed.

Results: During the study period, 243 HCV-RNA-positive PLWHIV treated with DAAs, with a median post-treatment follow-up of 48 weeks [range 12-144] were enrolled. The median age of patients was 52; 77.8% were males; 64.2% were injection drug users. At the enrolment the mean CD4+ cell count was 629.9 (+322.4) and 91.3% of patients had a HCV-RNA load <50 cps/mL; 39.3% were infected with HCV genotype 1a and 32.5% with genotype 3. A cirrhosis was present in 36.6% of subjects; 17 (7.0%), 110 (45%) and 116 (47.7%) were treated with first, second and third generation DAAs, respectively. The SVR12 was registered in 233 (95.9%) patients; no difference in sex and age distribution, risk factors, virological and immunological features, cardiovascular, metabolic, renal or psychiatric comorbidities, stage of liver disease and treatment received was observed between SVR and non-SVR patients.

Conclusions: The treatment with DAAs led to a high SVR12 rate in our cohort of HIV/HCV coinfected subjects, irrespective of epidemiological, clinical or virological characteristics.

All p values >0.05

CD377, a novel antiviral Fc-conjugate, demonstrates a lower resistance potential than baloxavir and oseltamivir against pandemic influenza A(H1N1)
Amanda Almaguer*, Allen Borchardt1, Wanlong Jiang1, Zhi-Yong Chen1, Tom Brady1, Jeffrey Locke1, Leslie W. Tari1

1Cidara Therapeutics, Inc., San Diego, United States

Background: AVCs (antiviral Fc-conjugates) developed by Cidara Therapeutics are novel, long-acting immunotherapeutic conjugates of potent antivirals and the Fc domain of human IgG1. CD377 is an AVC development candidate for the prevention and treatment of seasonal influenza, comprising a neuraminidase-targeting small molecule conjugated to IgG1 Fc. CD377 was designed to provide broad-spectrum coverage of influenza A and B, including drug-resistant strains. Herein, the resistance potential of this agent was assessed by in vitro serial passage in comparison to standard of care agents baloxavir and oseltamivir.

Materials/methods: Serial passage was conducted in Madin-Darby canine kidney (MDCK) cells infected at an MOI of 0.01 with A/California/07/09 H1N1 pdm. Selecting agent concentrations were optimized as required for maximum virus inhibition, while maintaining sufficient virus for subsequent passages [CD377 - 4 nM, baloxavir - 4 nM, oseltamivir - 200 nM]. A PBS no-drug control group was also included. Following the addition of drugs, cells were incubated for 24 hours. Next, viral supernatants were collected and used to quantify viral titer by plaque assay. Finally, freshly seeded cells were re-infected in the presence of compounds. The process was repeated for 10 passages.

Results: Over the course of 10 passages, A/California/07/2009 H1N1 pdm did not show any increase in viral titer in the presence of CD377 [Fig. 1]. In contrast, viral titers in the baloxavir and oseltamivir selection groups increased to levels similar to those observed in the PBS control after passages 6 and 8, respectively, indicating reductions in susceptibility.

Figure 1. Viral titers for A/California/07/2009 passaged in MDCK cells with sub-inhibitory concentrations of CD377, baloxavir, or oseltamivir

Conclusions: CD377 demonstrated a low resistance potential as compared to baloxavir and oseltamivir in serial passage with a pandemic H1N1 influenza strain. Follow-up studies on plaque-purified viruses from each passage group will characterize any changes in genotype, phenotype, or fitness. Future serial passage studies will investigate the resistance profile of CD377 against other clinically relevant influenza strain types, such as H3N2 and B.

Abstract 5709

Analyzing the public health impact of human immunodeficiency virus and tuberculosis co-infections in Brazil

Hari Pai*, Alin Suseanu†, Omar Butt‡

†King’s College London, London, United Kingdom

Background: Tuberculosis (TB) is the biggest cause of death amongst persons living with Human Immunodeficiency Virus (HIV) in the world and the greatest global risk factor for acquiring TB is a prior HIV infection. Brazil is the largest Latin American country and the WHO ranks Brazil amongst the top 30 countries globally with the highest burden from this dual epidemic. The prevalence of TB/HIV is thought to be around 20%. The objective of this review was to show the effects of the HIV/TB co-infection on the public health system of Brazil in terms of both economic and social impact.

Materials/methods: The two main databases used to analyze papers for this review were: Pubmed and Web of Science.

Results: The results of our review showed that patients with a TB/HIV co-infection presented a far greater economic burden to the Brazilian public health system compared to other related conditions. Compared to those with a HIV/AIDS infection, mean total costs were shown to be at least 3 times higher. Reasons for this increased cost included: patients with TB/HIV presenting with more advanced conditions than those with HIV/AIDS and TB/HIV patients being more treated with more expensive medications in general. Various papers also showed that patients with TB tended to have higher have higher rates of lifestyle vulnerability [such as drug and alcohol dependency] compared to sole HIV/AIDS sufferers. Pertinently, patients with well controlled or latent TB/HIV infection had far lower treatment costs compared to other related groups. Frequently mentioned risk factors for developing a HIV/TB included: homelessness, alcohol or drug use, lower socioeconomic or educational status.

Conclusions: The results of this review highlight the great burden the TB/HIV co-infection is placing upon the Brazilian public health system. It shows the need for increased collaborative TB/HIV activities such as more thorough TB and HIV screening programs within Brazil. It also emphasizes the need for prompt TB treatment in HIV/TB sufferers due to associated improved health outcomes for the patient and decreased economic burdens for the public health system in Brazil.

Abstract 5711

Incidence of ventilator-associated pneumonia in children intubated in paediatric intensive care unit
Emilien Maisonneuve¹, Claire Masson²,³, Hugo Terrisse¹, Claire Richarme⁴, Isabelle Wroblewski¹, Guillaume Mortamet¹, Caroline Landelle²,³

¹Centre Hospitalier Universitaire de Grenoble, Service de réanimation pédiatrique, La Tronche, France; ²Centre Hospitalier Universitaire de Grenoble/CNRS, ThEMAS TIM-C UMR 5525, La Tronche, France; ³Centre Hospitalier Universitaire de Grenoble, Service d’hygiène hospitalière, La Tronche, France; ⁴Centre Hospitalier Universitaire de Grenoble, Laboratoire de bactériologie, La Tronche, France

Background: Ventilator-associated pneumonia (VAP) is the second most common nosocomial infection diagnosed in mechanically ventilated patients. A great variability exists regarding the incidence of VAP in the pediatric population and previous studies found incidences ranging from 0.6 to 41 episodes per 1000 ventilation-days. In addition to the estimation of VAP incidence, our study is the first to use a survival analysis to study risk factors. We aimed to study VAP incidence in our French pediatric intensive care unit (PICU) and risk factors.

Materials/methods: We performed a single-center retrospective study in the PICU of Grenoble-Alpes university hospital. All patients <18 years admitted to the PICU supported by invasive mechanical ventilation for more than 48 hours between January 2013 and December 2018, were included. Patients with aplasia or bacterial community-acquired pneumonia were excluded. VAP definition of the Centers for Disease Control and prevention was used. A survival analysis adjusted on duration of mechanical ventilation was used to study risk factors of VAP.

Results: Among 1092 mechanically ventilated patients during the study period, 355 patients were included [median age 18 months, interquartile range [IQR]: [2-84], 62% were boys]. A total of 39 children [11%] developed a VAP and among them, 22 children [56%] had a bacteriological confirmation. Overall, the incidence rate of VAP was 15.5 per 1000 ventilation days. Median delay between admission and VAP was 6 days [3-11]. The most performed microbiological sampling was semi-quantitative culture of tracheal suction [n=36, 92%]. The main organism identified were Haemophilus influenzae [7/26] and Staphylococcus aureus [5/26]. The age group 2-6 years was the most at risk of VAP [Hazard Ratio [HR] 2.66, 95%Confidence Interval [CI] 1.26-5.62]. Patients admitted for non-bacteriological respiratory disease were 76% [HR 0.24, 95%CI 0.05-0.99] less likely to have VAP before 15 days of ventilation. Median duration of mechanical ventilation was significantly longer for VAP patients in comparison to patients without VAP [14 vs 5 days].

Conclusions: VAP are common in PICU. Risk factors identified in our study were considered as inherent to the patient but the establishment of a prevention protocol may reduce this high rate.

Twenty-seven years of chromoblastomycosis in Martinique

Yohann Le Govic1, Nathalie Berrette1, Emilie Baubion1, Emmanuelle Amazan1, Gladys Ferrati-Fidelin1, Charline Miossec1, Sybren De Hoog2, Nicole Desbois-Nogard1

1University Hospital of Martinique, Fort-de-France, Martinique, 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands

Background: Chromoblastomycosis (CBM) is an endemic but neglected fungal infection that prevails in regions with tropical and subtropical climates. It is caused by a variety of dematiaceous fungi, which gain entry into the skin via traumatic implantation. CBM is prevalent throughout the Caribbean region including Martinique island, where its incidence has never been described.

Materials/methods: We performed an observational retrospective study including all the cases of CBM diagnosed at the University Hospital of Martinique between 1993 and 2019, whose infection was proved by the presence of muriform cells in direct examination of skin smears and the etiologic agent identified by culture.

Results: A total of 19 patients (18 males and 1 female) were enrolled in this study. Cases were distributed throughout Martinique regardless of rainfall intensity (Fig.1). None of them had travelled to another CBM endemic area. The mean age at diagnosis was 71 years. The time elapsed between the onset of symptoms and consultation was highly variable, ranging from 3 months to 40 years. Patients had lesions of mild to moderate severity, localized in exposed parts of the body. Miscellaneous clinical presentations were observed, the most frequent being verrucous or nodular. The most common initial topography was the lower limbs (55%). Fonsecaea pedrosoi was involved in 17 of the 19 cases, while Cladophialaphora carrionii and Fonsecaea monophora were responsible for the remaining two cases, respectively. The various treatments used, whether surgical or by antifungal chemotherapy, never lead to complete healing, but significant improvements were noted for some cases.

Conclusions: This study confirms CBM endemicity in Martinique, where F. pedrosoi seems to be the best adapted species. Although relatively rare, several factors such as slow and insidious evolution, variability in clinical presentation, as well as global ignorance suggest that the burden of CBM remains under-estimated. Moreover, failure of antifungal therapy (mainly due to poor medication adherence) and relapse remain a substantial issue. Improved prevention and medical management and follow-up of the infected patients seems mandatory, in order to avoid complications and the appearance of new cases in the next future.

Figure 1. Distribution of chromoblastomycosis cases in Martinique (1993-2019)

Impact of applying mucosal barrier injury laboratory-confirmed bloodstream infection criteria in patients with solid tumours and haematologic malignancies

Ana Puin¹, Michely Fernandes Vieira¹, Maristela P. Freire¹, Patricia Rodrigues Bonazzi¹, Karim Yaqub Ibrahim¹, Maria Del Pilar¹, Juliana Pereira¹, Vanderson Rocha², Edson Abdala*¹

¹Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil, ²Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: The Centers for Disease Control (CDC) has defined criteria for Mucosa Barrier Injury Laboratory-Confirmed Bloodstream (MBI-LCBI), excluding from Central Line-Associated Bloodstream Infections (CLABSI) rates the cases whose source is probably the translocation of the gastrointestinal tract. The aim of this study was to evaluate the impact of using the MBI-LCBI criterion on the CLABSI rate in patients with solid tumors and hematologic malignancies.

Materials/methods: Retrospective cohort study at a university cancer hospital. Revised CLABSI from 2015 to 2017, and reclassified as MBI-LCBI and Catheter-Related Bloodstream Infections (CRBSI) according to the criteria of the CDC and the American Society for Infectious Diseases, respectively. Outcomes Evaluated: CLABSI rate considering or not MBI-LCBI, MBI-LCBI rate and proportion of CRBSI among those classified as MBI-LCBI. Rates were compared between patients with solid tumors or hematologic malignancies.

Results: 339 CLABSI were detected in the period, 51 (15.0%) classified as MBI-LCBI, and among the last, 10 (19.6%) met criteria for CRBSI. In patients with solid tumors, the CLABSI rate dropped from 2.67 to 2.60 after MBI-LCBI withdrawal, and none of them was CRBSI. In the population with hematologic malignancy, the rate of CLABSI dropped from 9.61 to 5.57 after removal of the MBI-LCBI, and among these, 22% were CRBSI. In the ICU, in patients with solid tumors, the CLABSI rate dropped from 2.47 to 2.35 after MBI-LCBI removal, and among them, none was CRBSI; In the population with hematologic malignancy, the rate of CLABSI dropped from 34.21 to 26.37 after removal of the MBI-LCBI, and among these, 27% were CRBSI.

Conclusions: The use of MBI-LCBI criteria significantly decreased the rate of CLABSI in individuals with hematologic neoplasia, but not in those with solid tumors, regardless of the hospitalization unit. However, a significant proportion of cases classified as MBI-LCBI were actually CRBSI. Use of the combined criteria can measure the risks associated with greater accuracy.

**Abstract 5721**

**Molecular epidemiology of methicillin-resistant *Staphylococcus aureus* infections during 7 years in a regional hospital in Israel**

Regev Cohen*1,2, Talya Finn1, Frida Babushkin1, Keren Geller1, Chana Alexander1, Marina Afraimov1, Shoshana Cohen1, Svetlana Paikin1, Einav Anuka1, Moti Baum3, Assaf Rokney3

1Laniado Hospital, Netanya, Israel, 2Technion - Israel Institute of Technology, Haifa, Israel, 3Ministry of Health, Jerusalem, Israel

**Background:** Molecular characterization of Methicillin-resistant *S. aureus* (MRSA) is useful for surveillance studies and infection control decisions. In Israel, several hospital- and community-based studies emphasized the importance of community-associated (CA)-MRSA strains in both settings, although clonal repertoire differs between hospitals and geographic locations. We studied the molecular epidemiology of MRSA infections in a single, regional, medium-sized hospital during 2012-2019.

**Materials/methods:** Healthcare-associated (HcA)-MRSA was defined when isolate was taken >72 hours from admission, or on admission in case the patient had a history of hospitalization or facility residency in the previous year. All other infections were defined as CA. MRSA were determined by the presence of *mecA/C* gene. The presence of LukS/F-PV (PVL toxin) and *SCCmec* type were determined by PCR. *spa* types were assigned by the BioNumerics 7.6.3 software.

**Results:** During 7 years, we analyzed 166 clinical MRSA: 115 (69%) bloodstream, 42 (25%) wounds/abscesses and 9 (5%) anterior nares screening isolates. 145 (87%) isolates were HcA and only 21 (13%) were CA. Common *spa* types (73%) were t002, t032, t008, t001 and t065. 67/145 (46%) were from *spa* types related to *SCCmec*-IV. t032 (EMRSA-15) was CA in only 1 case, while it was the second most common among the HcA isolates. The *lukS/PV* gene was found in 7 isolates, 4 were CA and 4 were bloodstream isolates. Of the HcA isolates, 65 were acquired in our hospital. The dominant hospital *spa* types were t002 (n=23), t032 (n=13) and t001 (n=6). There were no temporal fluctuations of types over the course of time and no association between types and specific wards. 80 isolates were imported from long-term care facilities. There were no differences in the demographics or outcomes of patients with CA- or HcA-MRSA infections. Most isolates (95%) were sensitive to trimethoprim/Sulfamethoxazole, 47% to clindamycin/erythromycin and 60% to mupirocin.

**Conclusions:** The MRSA population in this longitudinal study was stable and consisted mainly of molecular lineages widespread in Europe. The most common MRSA isolates in this cohort, mostly bloodstream infections, were acquired in the healthcare setting. High level mupirocin resistance, within-hospital acquisition, as well as import of new cases are among the challenges and targets for infection control.

Abstract 5724

**Time to positivity for mycobacterial culture as a measurement of bacillary load in clinical practice**

Michaela Jonsson Nordvall*, Anna Bornefall¹, Vita Kholod¹, Blanka Andersson¹, Katarina Niward⁴, Thomas Schön⁵

¹Linköping University Hospital, Department of Clinical Microbiology, Linköping, Sweden, ²Linköping University Hospital, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden; Department for Infectious Diseases, Linköping, Sweden, ³Linköping University, Department of Clinical and Experimental Medicine, Division of Medical Microbiology, Linköping, Sweden, ⁴Linköping University, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden; Department of Infectious Diseases, Linköping, Sweden, ⁵Kalmar County Hospital, Department of Infectious Diseases and Clinical Microbiology, Kalmar, Sweden

**Background:** The bacillary load of Mycobacterium tuberculosis (Mtb) may be estimated in the BACTEC 960 MGIT (MGIT) by the time to positivity (TTP) which is automatically recorded but rarely reported. TTP-analyses are increasingly used in early bactericidal activity (EBA) studies of new drugs. The aim of this study was to evaluate the potential use of including TTP-analysis in clinical practice.

**Materials/methods:** TTP in MGIT was recorded in consecutive clinical isolates from tuberculosis (TB) patients in South-East Sweden during 2016-2018. The shortest TTP registered at diagnosis was compared to smear microscopy and PCR-results as well as to sedimentation rate-levels, chest X-ray and body mass index (BMI). Reproducibility of TTP was analyzed comparing the variability between three individual sputum samples from the same patient. Additionally, a standard curve was developed by comparing TTP to CFU-counts on Middlebrook 7H10 medium. In a subset of patients (n=7), TTP was analyzed repeatedly during the first two months of treatment.

**Results:** Overall, TTP was distributed between 3-31 days (n=51) where 23.5% patients had a TTP within one week, 41% patients between 1-2 weeks, 29.5% between 2-3 weeks and 6% after three weeks. Among high-grade, smear positive patients and those with a strongly positive PCR (Ct<33), 89% and 78% respectively had a TTP of less than one week. Patients with TTP <one week had more extensive lung involvement (>one lung lobe involved) compared to patients with TTP>one week. When three samples were obtained at diagnosis, 82% (29/35) and 60% had TTP levels within ±7 and 2 days respectively. There was a linear correlation between CFU counts and TTP levels where a TTP of one week corresponded to 37250 CFUs. A pilot study showed a steady and significant prolongation of TTP during treatment for patients with drug susceptible TB on first line treatment (median delta TTP: 16 hours/day for week 0-1).

**Conclusions:** In conclusion, we explored the potential use of TTP in routine clinical practice. The data show that TTP is strongly linked to the bacillary load and may be an important surrogate marker for clinical improvement during treatment of use both in routine practice and clinical trials.

Tricyclic boronates inhibit carbapenemases
Anete Parkova\(^1\), Karina Calvopiña\(^2\), Philipp Schneider\(^3\), Christopher Schofield\(^2\)

\(^1\)Lios, Latvia, \(^2\)Oxford, United Kingdom, \(^3\)Freiburg, Germany

**Background:** The rapid increase of the prevalence of \(\beta\)Lactamases (BLAs) and the emergence of new-variants in carbapenem-resistant bacteria (CRE) menace the antimicrobial effectiveness of last resort carbapenems. It is particularly worrying that carbapenemases that only showed weak activity in the past have evolved to improve their catalytic efficiency. To prevent the detrimental action of carbapenemases in public health, the search of pan \(\beta\)Lactamase inhibitors is fundamental. Cyclic boronates appeared to be one the few compounds that could inhibit several serine-\(\beta\)-lactamases (SBLs) but more interestingly metallo-\(\beta\)-lactamases (MBLs). Meropenemvaborbactam was the first combination of a carbapenem and a boronate based \(\beta\)Lactamase inhibitor. Others, such as VNRX-5133 has proved to have good *in vitro* and *in vivo* properties. However, none of the bicyclic boronates demonstrate to be as potent as avibactam against the clinically relevant class D \(\beta\)Lactamases. Therefore, we have aimed to have a mechanistic insight of the structure-function relationship of novel tricyclic boronate derivatives against SBLs and MBLs carbapenemases.

**Materials/methods:**

**Inhibition assays:** tricyclic boronate (TB1, TB2, TB3) were screened against a panel of SBLs and MBLs. FC5 was used as the reporter substrate.

**Minimal Inhibitory Concentration (MIC):** meropenem and cefepime were tested alone and in combination with TB versus NDM-1 and OXA-48 producing strains (NCTC 13443, NCTC 13442). **Crystallography:** NDM-5 and OXA-10 were crystallized by sitting drop vapor diffusion. Crystals were cryoprotected and diffraction data was collected at Diamond Light Source. The structure was solved by molecular replacement and iterative refinement in PHENIX.

**Results:** TB2 derivative showed to have the widest range of activity in the series, being more effective against the clinically relevant \(\beta\)Lactamases NDM-1, VIM-2, and IMP-1 when compared to Lcaptopril. Structural studies confirm the mode of binding of the boron atom of TB2 which is comparable to the mode of binding observed for VNRX-5133 and NDM-1 and OXA-10. The \(\beta\)Lactamase inhibitory activity of APC-434 tested in bacterial cells, restores meropenem activity in the *Klebsiella pneumoniae* OXA-48 carrier and proves to be at least 3-fold better than vaborbactam.

**Conclusions:** Structural studies and biochemical characterization demonstrate the potential of tricyclic boronates to design pan-\(\beta\)-Lactamase inhibitors.

**Investigation of antibiotic susceptibilities, clonal relationships and carbapenems resistance mechanisms of *Serratia marcescens* obtained between 2011 and 2019 in a university hospital**

Gülşen Hazirolan*, Seyma Nigiz1, Aycan Gundogdu1, Gülşen Altınkanat-Gelmez3, M.Ufuk Hasdemir3, Fatma Bayrakdar4, Deniz Gür1

1Faculty of Medicine, Medical microbiology, Ankara, Turkey, 2Faculty of Medicine, Medical microbiology, Kayseri, Turkey, 3Faculty of Medicine, Medical microbiology, İstanbul, Turkey, 4Public Health General Directorate, National Molecular Microbiology Reference Laboratory, Ankara, Turkey

**Background:** *Serratia marcescens* can cause an opportunistic infection in several sites, especially in immunocompromised patients. Additionally, *S. marcescens* species may harbor multidrug resistance mechanisms that can complicate treatment decisions. In this study, antibiotic resistance rates, resistance to carbapenems and clonal relationships of carbapenems resistant isolates of *Serratia marcescens* from various clinical specimens of inpatients were investigated.

**Materials/methods:** We investigated 84 *S. marcescens* isolates from various clinical specimens in clinical bacteriology laboratory between 2011-2019. MALDI-TOF MS was used for bacterial identification. Susceptibilities of ceftriaxone, ceftazidime, meropenem, amikacin, gentamicin, tigecycline and ciprofloxacin were studied by microdilution method and the results were evaluated according to EUCAST standards. ATTC Escherichia coli 25922 was used as control isolate. In meropenem resistant *Serratia marcescens* isolates (*n* = 10), KPC, NDM-1, IMP, VIM, SPM, AIM, OXA-48, GES and SME-1 type carbapenemases were investigated by PCR and clonal relationships were evaluated by PFGE method. To investigate the activity of efflux pumps in meropenem resistant *S. marcescens* isolates, MICs of meropenem in the presence of efflux pump inhibitors Phe-Arg β-naphthylamide dihydrochloride (PAβN) (Sigma) or carbonyl-cyanide-m-chlorophenylhydrazone (CCCP) (Sigma) were determined. At least four fold reduction in the presence of CCCP and PAβN compared to MIC determined by microdilution was considered significant for the presence of active pump.

**Results:** The MICs of the 84 isolates to 7 antimicrobial agents are shown in Table 1. Genotyping of β-lactamases revealed that *bla-OXA-48* was presence in only one isolate. A greater than or equal to fourfold decrease in MIC of meropenem when tested in combination with either efflux pump inhibitors PAβN or CCCP, was shown in one and three of the *S. marcescens* isolates, respectively. Eight pulsotypes were detected by PFGE. The number of clusters was determined as three and the number of strains in each cluster varied between 1-3 (Figure-1).

**Conclusions:** In *S. marcescens* isolates, it was observed that the resistance to carbapenems was due to different mechanisms. Meropenem resistant isolates belong to three different clones. Other mechanisms such as porine loss and overexpression of AmpC may be found in isolates whose resistance mechanism can not be determined.

Abstract 5730

Epidemiological study of main enteropathogens causing infectious gastroenteritis in a Madrid tertiary hospital

Ayla Yarci Carrión1, Leticia Fontan1, Sara Gómez De Frutos1, Eva Navarro Lara1, Alicia García1, Teresa Alarcon Cavero*1

1Hospital de La Princesa, Madrid, Spain

Background: acute infectious gastroenteritis (GE) is one of the most chief complaints in our health system. The aim of this study was to characterise the epidemiological distribution and prevalence of main enteropathogens causing GE in our area and to analyse the possible association between these agents with sex, age and its seasonality in order to gain insight about our risk population and infectious patterns.

Materials/methods: a retrospective cohort study with all positive stool culture analysed between April 2018 and September 2019 in a tertiary hospital was performed. Positive samples were defined as the isolation of species from the genus Aeromonas, Campylobacter, Salmonella, Shigella, Yersinia and Vibrio. Microbiological data was recovered and statistically analysed by means of the Chi Square distribution.

Results: during the study period, enteropathogens were detected in 282 stool cultures (6.35% of positivity). Median age was 46 years and 66% were male. Isolated species were Campylobacter jejuni (108) and coli (22), Salmonella enterica group (68), Aeromonas spp. (40), Yersinia spp. (25), Shigella spp (17) and Vibrio parahaemolyticus (2). There was a statistically significant relationship between age and the isolation of Aeromonas [which was mainly isolated in adults over 50 years old, p<0.001], and Campylobacter, Salmonella, Yersinia and Shigella [which were most isolated in patients under 50 years old, p<0.0001]. Moreover, a statistically significant association was found between sex and the isolation of Campylobacter [which was more prevalent among men, p<0.05] and Shigella [which was more prevalent among women, p<0.05]. No statistically significant differences were found about the rest of enteropathogens with age or sex. Furthermore, seasonal variations in the isolation of three of these enteropathogens were observed: Campylobacter was most prevalent during the summer-spring period, Salmonella during the summer and Shigella during the autumn-winter period (p<0.01).

Conclusions: According to these results, the isolation of the main enteropathogens is strongly associated with sex, age and seasonality, in line with previous reports. The sex distribution of Campylobacter in men and Shigella in women requires further studies.

Abstract 5731

Serodiagnosis of Lyme disease: cheese and chalk or peas in a pod?
Kirsten Macgregor¹, Fergus Hamilton¹, Mahableshwar Albur*²

¹North Bristol NHS Trust, Severn Infection Sciences, Bristol, United Kingdom

Background: Serological testing for Lyme disease (LD) varies across the world. Recently, United States Food and Drug Administration (FDA) cleared several serologic assays with new indications for use, allowing for an EIA rather than western immunoblot assay as the second test in a LD testing algorithm. Current UK NICE guidelines (2018) have raised a question mark over the ELISA based screening tests for LD. In Bristol (South-West England), we have some of the highest rates of Lyme serology positivity in the UK. However, the demographics of LD across the region are not clear, and the sensitivity and specificity of local screening tests are not well established. We aimed to look at the epidemiology of our local Lyme ELISA results as compared to the National reference laboratory.

Materials/methods: We recorded basic demographics of patients tested, then evaluated our local Diasorin Liaison XL® analyser ELISA IgM (OspC and VlsE) and IgG (VlsE only) assay for LD in terms of positivity; compared with the National reference laboratory’s screening C6EIA and confirmatory Immunoblots for the whole of 2017. In general, any positive local result for IgG or IgM was sent to the reference laboratory. Full analysis of the epidemiology of test results was performed.

Results: A total of 3131 tests were performed on 2803 patients by our local EIA. 74% of these were from primary care. Median age was 48.5 years (range 0.6 – 95) and 57% were from females. Our ELISA showed 93.4%, 2.1% and 4.5%; 89.8%, 1.8% and 8.4% respectively for negative, equivocal and positive against IgG and IgM. Comparative results with the reference C6EIA and immunoblots are shown below (Figure 1). Of the 328 repeat tests performed, 22(6.7%) and 37(11.3%) seroconverted for IgG and IgM respectively during 2017.

Conclusions: Local epidemiology of Lyme disease is complex in South-West England. We have a reasonably high positivity rate on screening tests, especially IgM. A significant number of positive IgM and IgG results locally were not ultimately confirmed by the reference lab, leading to some difficulty in patient management. Scientifically robust tests/algorithms are urgently needed for the diagnosis of LD.

Ceftriaxone penetration into epithelial lining fluid: are dosing regimens sufficient for severe community-acquired pneumonia?

Anna Motos1,2,3,4, Rosanel Amaro1,2,3,4, Gianluigi Li Bassi1,2,3,4, Minlan Yang1,2,5, Hua Yang1,2, Joaquim Bobi1,2, Laia Fernandez Barat1,2,3,4, Eli Aguilera Xiol1,2,3, Montserrat Rigol1,2, David Nicolau1,5, Joseph Kuti6, Antoni Torres1,2,3,4

1Hospital Clinic, Barcelona, Spain, 2IDIBAPS, Barcelona, Spain, 3CIBERES, Madrid, Spain, 4University of Barcelona, Barcelona, Spain, 5University of Genoa, Genoa, Italy, 6Hartford Hospital, Hartford, United States

Abstract third-party references: FIS [PI15/00506], ISCIII, Madrid, Spain, SEPAR [064/2015 and 086/2018], Madrid, Spain, BITRECS, IDIBAPS, Barcelona, Spain, La Marató Foundation of TV3, Barcelona, Spain

Background: Ceftriaxone (CRO), a third-generation cephalosporin with a broad-spectrum, is commonly administered for the empirical or pathogen-directed therapy of numerous infections, such as community-acquired pneumonia (CAP). Despite being a frequently used antibiotic, no data are available on CRO epithelial lining fluid (ELF) penetration.

Materials/methods: In six pigs (33.2±2.2 kg) with severe pneumococcal pneumonia, pharmacokinetics of CRO were assessed. Animals were allocated to intravenously received: 50 mg/kg, 100 mg/kg, or 150 mg/kg of CRO as 1-h infusion. Sequentially, plasma and bronchoalveolar lavage (BAL) fluids were collected to quantify CRO concentrations at 1, 2, 4, 6, 8, 12, and 24h after the dose in each pig. Protein binding was assessed in duplicate at 1 and 2h. Urea correction was used to calculate ELF values. CRO plasma and ELF concentrations were fitted to a two-compartment model. A 5,000 subject Monte Carlo simulation was performed for each dose to define the ELF penetration [area under the curve in ELF (AUCELF) / free AUCplasma] and the percentage of free time above the minimum inhibitory concentration (fT>MIC) for MIC of 2 mg/L.

Results: 41 plasma and 31 BAL samples were fitted adequately by the model. The model parameters (mean ± standard deviation) for CRO pharmacokinetics were volume of central compartment, 9.54±4.36 L; clearance, 4.47±1.36 L/h; and volume of peripheral compartment, 34.77±18.16 L. The resulting simulated free AUC0-24h and %fT>MIC of 50 mg/kg dose achieved similar human exposures in plasma (2g q24h)1. The median [interquartile range] ELF AUC0-24h was 36.8 [30.6-45.1], 73.5 [62.2-90.2], 111.3 [91.8-135.3] mg·h/L for 50, 100 and 150 mg/kg doses, respectively. The overall penetration ratio was 8.4 [7.8-9.7] %. For MIC of 2 mg/L, 50, 100 and 150 mg/kg doses achieved 25.8 [21.3-31.7], 37.1 [29.6-46.3], and 43.3 [34.2-54.2] % ELF fT>MIC, respectively.

Conclusions: Our data indicate that CRO penetration into ELF achieved 8.4% in a swine model. At MIC of 2 mg/L, the percentage ELF fT>MIC ranged from 25.8 to 43.3, depending on the dose. Future studies assessing the bactericidal activity of these regimens against common pathogens of severe CAP are needed.

Abstract 5734

The effects of antibiotic cycling and mixing on acquisition of antibiotic-resistant bacteria in the intensive care unit: a post-hoc analysis of a prospective cluster-randomised crossover study

1University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2University Hospital Antwerpen, Department of Critical Care Medicine, Edegem, Belgium, 3Uniklinik Köln Bettenhaus, Klinik für Anästhesiologie und Operative Intensivmedizin, Köln, Germany, 4Universitätsklinikum Schleswig-Holstein, Lübeck, Klinik für Anästhesiologie und Intensivmedizin, Lübeck, Germany, 5Raymond Poincaré University Hospital - (AP-HP), General Intensive Care Unit, Garches, France, 6Raymond Poincaré University Hospital - (AP-HP), Microbiology Unit, Garches, France, 7University Medical Center, Ljubljana, Department of Infectious Diseases, Ljubljana, Slovenia, 8University of Ljubljana, Faculty of Medicine, Institute of Microbiology and Immunology, Ljubljana, Slovenia, 9Hospital Golnik - University Clinic of Pulmonary and Allergic Diseases Golnik, Intensive Care Department, Golnik, Slovenia, 10Hospital Golnik - University Clinic of Pulmonary and Allergic Diseases Golnik, Department of Medical Microbiology, Golnik, Slovenia, 11Centro Hospitalar De Trás-Os-Montes E Alto Douro, E.P.E., Intensive Care Department, Vila Real, Portugal, 12Hôpitaux Universitaires de Genève (HUG), Infection Control Program, Genève, Switzerland, 13University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands

Background: Antibiotics exert selective pressure for antibiotic resistant bacteria (ARB). Cyclic rotation of empiric antibiotic treatment strategies diversifies antibiotic selective pressure, but different strategies [antibiotic cycling and mixing] failed to change unit-wide prevalence of ARB carriage in an international cluster-randomized crossover study (Lancet ID 2018, PMID: 29396000). However, unit-wide and individual risks can differ due to what is called an "ecological fallacy". The aim of this post-hoc analysis was to assess carriage acquisition risks of Gram-negative ARB in individual patients between cycling and mixing treatment strategies.

Materials/methods: This was a nested-cohort in a cluster-randomized crossover study with 8,267 inclusions from 7 ICUs in 5 countries. The study compared two 9-month antibiotic rotation strategies: cycling (changing first-line empiric therapy for Gram-negative bacteria every other 6-weeks), to mixing (change of antibiotic type every other empiric antibiotic course). Rotated antibiotics were 3rd or 4th generation cephalosporins, piperacillin-tazobactam and carbapenems in randomized order.

For this analysis ARB was defined as Enterobacterales species with reduced susceptibility to: 3rd- or 4th generation cephalosporins or piperacillin-tazobactam, and Acinetobacter species and Pseudomonas aeruginosa with reduced susceptibility for piperacillin-tazobactam or carbapenems. Patients were selected with >1 clinical culture, of which the first had to be negative for ARB and without carriage with ARB in the first 2 days of admission. Primary endpoint was acquisition of ARB. Interventions were compared using bivariate testing and mixed effects logistic regression modelling.

Results: For this analysis 3,944 (48%) admissions were eligible with 21,662 clinical cultures. Incidences of acquisition with ARB were 3.8% (n=137) and 3.5% (n=145) during cycling and mixing, respectively (p-value 0.56), yielding an adjusted odds ratios (aOR) 0.98 (95% CI 0.74 till 1.29) for acquisition during mixing.

Conclusions: Individual patients’ risk of acquiring infection or carriage with Gram-negative ARB was comparable during cycling and mixing. Adjusted analysis, showed no difference between interventions. These findings substantiate the lack of effect of cycling and mixing on the epidemiology of Gram-negative ARB in ICU.

Background: *Staphylococcus aureus* (SA) of lineage CC398 is causing human infections in Europe. In Spain, the prevalence of Livestock-Associated (LA) methicillin-resistant SA (MRSA)-CC398 at hospital level was closely related to pig-farming density, tetracycline-resistance (TET\textsuperscript{R}) being a phenotypic marker of this clone. Methicillin-susceptible SA (MSSA)-CC398 was reported as an emerging cause of invasive infections, mainly in France; however, data and epidemiological characteristics are still scarce. Our work aimed to determine the prevalence of MSSA-CC398 and LA-MRSA-CC398 among blood culture SA isolated from patients in Spanish hospitals located in regions with different pig-farming density and to analyse the antimicrobial resistance pheno/genotype, the virulence factors and the molecular characteristics of CC398 isolates.

Materials/methods: A total of 951 SA isolates was recovered from patients’ blood cultures during 2018-2019 in 17 Spanish hospitals located in regions with different pig-farming densities \([\text{in } 10^3 \text{ pigs/km}^2]\) \(\text{[Low Pig Density: 0-10; Medium Pig Density: 11-60; High Pig Density (HPD): } >160]\). The isolates were subjected to antimicrobial susceptibility test: MSSA (\(n=706\)) and MRSA (\(n=245; 18 \text{TET}^{\text{R}}-\text{MRSA}\)). All MSSA and TET\textsuperscript{R}-MRSA isolates were further characterized. CC398 lineage identification, spa\textsuperscript{-}typing, antimicrobial resistance genes and human immune evasion cluster (IEC) genes detection were performed by PCR/sequencing. Moreover, \textit{eta}, \textit{etb} and \textit{lukF/lukS-PV} genes were screened by PCR.

Results: The prevalence of MSSA-CC398 was 5.2% respect to MSSA and 3.9% to SA \((n=37\text{ isolates})\). The prevalence of MRSA-CC398 was 0.4% respect to SA and 22.2% to TET\textsuperscript{R}-MRSA \((n=4\text{ isolates})\). Among MSSA-CC398, six spa-types were recorded (predominant: t571, 43.2% and t1451, 35.1%). All, but three MSSA-CC398 isolates \((t011\text{ and } t1451)\), were IEC-negative. Resistance to erythromycin/clindamycin-inducible, mediated by \textit{erm}(T) gene, was detected in 72.9% of MSSA-CC398. Three isolates harboured the \textit{eta} gene. No correlation of MSSA-CC398 and pig density was evidenced. On the other hand, all 4 MRSA-CC398 isolates were detected in HPD regions, and were \textit{spa-t011} or \textit{t034}, and IEC-negative.

Conclusions: LA-MRSA-CC398, infrequent in blood culture samples, is related to HPD regions. On the other hand, MSSA-CC398 \((\text{mostly } t571\text{ and } t1451)\), is not associated with HPD and seems to be an emerging human-adapted clone \((5.2\%/\text{MSSA})\). The \textit{erm}(T) gene, associated with erythromycin/clindamycin-inducible resistance, could be a MSSA-CC398 marker.

Abstract 5738

Prevalence of antibiotic resistance in skin infections among migrants compared to Danish-born patients

Güldas Köse*1, Louise Sloth1, Rikke Thoft Nielsen1, Christian Østergaard4, Marie L. Nørredam5

1MB, Section of Immigrant Medicine, Department of Infectious Diseases, Hvidovre Hospital, Denmark, Hvidovre, Denmark, 2MD, Section of Immigrant Medicine, Department of Infectious Diseases, Hvidovre Hospital, Denmark, Hvidovre, Denmark, 3PhD, Department of Clinical Microbiology, Hvidovre Hospital, Denmark, Hvidovre, Denmark, 4DMSc, Department of Clinical Microbiology, Hvidovre Hospital, Denmark, Hvidovre, Denmark, 5DMSc, Research Centre for Migration, Ethnicity and Health, Section of Health Services Research, Department of Public Health, University of Copenhagen, Copenhagen, Denmark

Background: Skin infections are one of the most common infections among patients in primary and secondary care. Previous studies have documented a high prevalence of MRSA and multi-resistant gram-negative bacteria infections among refugees and asylum seekers admitted to hospital care. However, little is known about pathogen causes of skin infections and resistance patterns among migrants, in comparisons to Danish-born patients. The aim of the study is to address this gap in the literature.

Materials/methods: The study is a register-based cohort study building on a cohort of more than 80,000 migrants (≥ 18 years) and a Danish comparison group. Migrants, who obtained residence in Denmark from 1.1.1993 – 31.12.2015, were included. The migrant cohort and the comparison group were merged with clinical data extracted through a microbiology database covering the hospitals in the Copenhagen Capital Region. All patients with positive skin cultures from 1.1.2000 – 31.12.2016 were identified. Descriptive analyses and multivariate regression analysis was used when comparing migrants and Danish-born regarding differences in resistance patterns.

Results: Our dataset compromises 39,589 individuals, respectively 34,865 Danish-born and 4,724 migrants, with positive first skin swab samples. Migrants were further categorized as refugees (n=1,712) or family reunified migrants (n=3,012). Staphylococcus aureus was the most prevalent pathogen for skin infections found in both groups; constituting 58.9 % among migrants and 63.7 % among Danish-born individuals. Yet, fewer refugees (OR 0·87, 95% CI: 0·78-0·96) and family-reunified patients (OR 0·80, 95% CI: 0·74-0·86) had infections due to Staphylococcus aureus compared to Danish-born individuals. Significantly more refugees (OR 1·56, 95% CI: 1·34-1·82) and family-reunited migrant patients (OR 1·50, 95% CI: 1·33-1·69) compared to Danish-born patients had gram-negative bacteria infections. Especially Pseudomonas aeruginosa (OR 1·35, 95% CI: 1·16-1·54) were more prevalent among migrants. The regression analysis has been adjusted for age, sex, socioeconomic status and co-morbidities. The analyses for antibiotic susceptibility will follow and is currently preliminary.

Conclusions: In order to prevent the increase of antibiotic resistance among patients with skin infections, it is important to identify persons at increased risk. Our finding can contribute to developing guidelines to improve future treatment and prevention of antibiotic resistance in patients.

Abstract 5740

Measurement of influenza antibodies in a cohort of vaccinated patients admitted to a cardiac intensive care unit: are they clinically relevant?

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases Department, Madrid, Spain, 2Hospital General Universitario Gregorio Marañón, Cardiology Department, Madrid, Spain, 3Complejo Hospitalario Universitario de Santiago, Cardiology Department, Santiago de Compostela, Spain, 4Complejo Hospitalario Universitario de Santiago, Clinical Microbiology Department, Santiago de Compostela, Spain, 5Hospital Universitario Puerta de Hierro, Infectious Diseases Department, Madrid, Spain, 6Hospital Universitario 12 de Octubre, Clinical Microbiology Department, Madrid, Spain, 7Hospital Universitario 12 de October, Internal Medicine Department, Madrid, Spain, 8Hospital Universitario La Paz, Clinical Microbiology Department, Madrid, Spain, 9Hospital Universitario 12 de October, Clinical Microbiology Department, Madrid, Spain, 10Hospital Universitario Puerta de Hierro, Clinical Microbiology Department, Madrid, Spain

Background: As part of a prospective study that we are carrying out to determine the usefulness of systematic influenza screening in patients who require admission to a Cardiac intensive care unit (C-ICU), we decided to assess whether the presence of antibodies against influenza could be related to the risk of having a flu episode during C-ICU admission or to its severity.

Materials/methods: Multicentric (5 centres), prospective cohort, including Flu vaccinated patients admitted to a C-ICU during the last two Flu seasons. Influenza was diagnosed using Xpert® Flu/RSV assay. Serum IgG screening against Flu A and Flu B was performed by a chemiluminescence technique (VIRCLIA/Vircell®). In case of positivity, IgG titres were determined by indirect immunofluorescence (Vircell®). Clinical data were registered.

Results: 526 patients were admitted to the 5 coronary ICUs during the last two influenza seasons. Overall, 235 (44.7%) had been vaccinated, from which 179 agreed to participate in the study. Influenza PCR was positive in 14/179 (7.8%) recruited vaccinated patients (11 Flu A and 3 Flu B). A positive IgG against influenza was only detected on admission in 92 patients (51.4%) (87 for Flu A, 75 for Flu B and 74 for both). The distribution of IgG titres were as follows: ≤128: 16 (17.4%), 256: 41 (44.6%), 512: 35 (38.0%), 1024: 32 (34.8%), ≥2048: 22 (23.9%). The titres were higher for Flu B than for Flu A (IgG ≥2048: 27.8% vs 2.8%). Conditions related to non-production of influenza antibodies despite vaccination were: transplantation (6.9% vs 0%, p=0.01) and immunosuppression (9.2% vs 2.3%, p=0.05). The presence of antibodies did not correlate with whether influenza developed during the stay in the C-ICU (5/92-5.5% in patients with antibodies vs 8/87-9.2% without antibodies), nor with its severity, nor with the rate of associated complications.

Conclusions: Only half of the influenza vaccinated patients admitted to a C-ICU in different hospitals during the last two Flu seasons developed antibodies. No antibodies production was mostly related to transplant and immunosuppressed patients. No correlation was found between a specific titre and the presence of influenza, its severity or related complications.

Abstract 5741

A cross-sectional survey of the perceived workload of UK infection specialists related to Lyme disease

Kirsten Macgregor*1, Matthew Dryden1

1Lyme Disease Diagnostic Service, Rare and Imported Pathogens Laboratory, Public Health England, Porton, United Kingdom

Background: Anecdotally, there is a perception from UK infection specialists that they are predominantly consulted on Lyme disease (LD) in relation to patients with long-standing, non-specific symptoms. However, no formal description of this perception exists. The project’s aim was to describe UK infection specialists’ perceptions in relation to consultations concerning LD.

Materials/methods: An electronic cross-sectional survey was distributed to members of the British Infection Association’s ‘e-list’. This is an open forum for infection clinicians. Respondents answered questions relating to demographics, and LD-related queries received. This included questions on the format their consultations took, patient’s symptoms, number of consultations per year, and confidence in dealing with these consultations.

Results: 82 specialists responded to at least one survey question. The most common grade was consultant (68/79, 86%), with remaining respondents at specialty-trainee level. South-West England (24/80, 30%) and North England (20/80, 25%) regions predominated. The other endemic areas in the UK - South-East England and Scotland - made up 15% and 5% of respondents, respectively. Phone advice (65% 146/226) was the most common interaction, involving discussions around diagnostic testing and management for confirmed LD. In relation to how patients presented, non-specific long-standing symptoms, or asymptomatic tick-bites were most common. In relation to numbers of consultations per year, proportions were relatively evenly split between those for possible early LD, and those relating to long-standing symptoms. Respondents were more confident in dealing with queries relating to possible early LD [highest proportion - 32% (25/79) graded their confidence as 9 out of 10], than those relating to long-standing symptoms [highest proportion – 24% (19/79) graded their confidence as 5 out of 10].

Conclusions: The management of typical confirmed Lyme borreliosis was not perceived as a problem. In contrast to anecdotal perceptions, UK infection specialists’ workload in relation to LD appears to be relatively evenly split between queries relating to early possible LD, and those relating to long-standing symptoms. However, they were more confident in dealing with the former, highlighting an area to target in future UK LD-related training and education. Further guidance and research around long-standing medically-unexplained symptoms and any relationship to borreliosis would be helpful.

Profile of neurological manifestations related to varicella zoster virus reactivation

Pierre Girardie², Jean-Michel Mansuy¹, Caroline Protin¹, Fabrice Boneville¹, Jérémy Pariente¹, Pierre Delobel¹, Guillaume Martin-Blondel*¹

¹Toulouse University Hospital, Toulouse, France, ²CHU Toulouse, Toulouse, France

Background: Varicella-zoster virus (VZV) is neurotropic. In about 20% of patients with an history of VZV primary infection, VZV reactivates later in life producing herpes zoster with potential neurological manifestations. Our aim was to describe neurological complications related to VZV reactivation.

Materials/methods: All patients from the Toulouse University Hospital between 2010 and 2019 with CNS manifestations and a positive PCR for VZV in the CSF were analysed. Patients with primary VZV infection were excluded. Risk factors for severe manifestations and death were investigated by uni- and multivariate analyses.

Results: 55 patients with CNS manifestations related to VZV reactivation were included. Mean age was 50.5 ± 20.5 years, 21/55 (38 %) were immunocompromised, 35/55 (65%) displayed shingles. None were vaccinated against shingles. CSF analysis showed 253 ± 200 leucocytes/mm³, 1.36 ± 0.7 g/L of proteins, and normal glucose level. 28/55 (51%) had meningitis while 29/55 (49%) had meningoencephalitis. Patients with meningoencephalitis were significantly older (62.9 ± 23 years) than those with meningitis (38.5 ± 22 years, p<0.001), and had lower CSF pleiocytosis (167 ± 183 versus 340 ± 339 leucocytes/mm³, p=0.049) while proportion of patients having zoster, trigeminal zoster, being immunocompromised, and biochemical CSF profile, did not differ between the two groups. All received acyclovir at a mean dose of 30 ± 5 mg/kg/day for a mean duration of 21 ± 7 days. Four patients died, all in the meningoencephalitis group, including 2 immunocompromised patients and 2 elderly patients. Of note, 6 patients in the meningoencephalitis group did not display CSF pleiocytosis, including 4 immunocompromised patients and 2 elderly patients, leading to delayed acyclovir initiation that may have participate to death in 1 patient and severe neurological sequelae's in 2. Within 12 months after the VZV reactivation, 1 patient relapsed from VZV infection and 2 developed strokes related to post-VZV cerebral vasculitis requiring steroids.

Conclusions: The burden of neurological complications related to VZV reactivation among elderly and immunocompromised patients is significant. In those populations, the absence of CSF pleiocytosis doesn’t exclude the diagnosis. The recombinant zoster vaccine may help to reduce in the future this burden.

Presenter email address: guillaumembi@gmail.com
Prevalence of infections in the risk for infection in immunosuppression outpatient consultation: a retrospective analysis between 2014-2018

Joana Granado1, Ana Claudia Miranda1, Maria Sanches1, Sara Casanova1, João Domingos1, Joana Vasconcelos1, João Alves1, Teresa Baptista1, Susana Peres1, Kamal Mansinho1

1Hospital Egas Moniz, Lisboa, Portugal

Background: With the growing usage of immunosuppressive therapies, clinicians face the challenge of having to prevent/treat infections in the immunosuppressed population. It is important to study which factors are associated with infections in order to define strategies to minimize their impact. The aim of this study was to identify types and risk factors associated with infections affecting patients referred to the risk for infection in immunosuppressive/immunomodulatory therapies outpatient consultation, which is targeted for patients with autoimmune diseases, cancer or transplanted hosts.

Materials/methods: A retrospective analysis was conducted which included patients followed in our risk for infection in immunosuppression/immunomodulatory outpatient consultation between May 2014 and December 2018. Data was collected regarding epidemiologic, clinical and therapeutic information. Infectious events were only considered in the analysis if they occurred between the diagnosis of the underlying disease and December 2018. Statistical analysis was performed using IBM SPSS.

Results: 758 patients were included, mostly female (51%). 94% were referred to this consultation being diagnosed with an autoimmune/inflammatory disease and 52% had severe immunosuppression at first consultation. 283 infectious events were registered in 182 patients (24%; n=758): 42 (14.8%) were considered opportunistic and 241 (85.2%) were non-opportunistic. 60 (8%) patients had more than one infectious event and 17 (3%) had three or more events. The most prevalent aetiology was bacterial (65,3%). The most common non-opportunistic infections were urinary tract infections (52 episodes, accounting for 21.6%) and upper respiratory infections (31 episodes, accounting for 12.9%). 24% of the opportunistic infections were caused by mycobacterium tuberculosis and 17% were cytomegalovirus reactivations. TNF-alfa inhibitors were associated only with the occurrence of opportunistic infections (p < 0,05). There was no association between corticotherapy and the occurrence of infection (p>0,05). Age (OR 1,153), systemic lupus erythematosus (OR 3,403) and being transplanted (OR 9,184) were independent factors associated with the occurrence of opportunistic infections (p < 0,05).

Conclusions: In our population, age and the underlying disease were considered relevant risk factors for the occurrence of infection, as described in the literature. Despite what would be expected, corticotherapy alone or in association was not associated with the occurrence of an infectious event.

Abstract 5746

Emergence and spread of plasmid carrying blaIMP and mcr-9 in Enterobacteriaceae isolated from hospitalised patients in West London from 2016 to 2019

Adhiratha Boonyasiri1,2, Frances Davies1,3, Frances Bolt1,3, Elita Jauneikaite1,4, Alice Ledda4, Siddharth Mookerjee1, Hala Abbas1, Alireza Abdolrasouli1, Jonathan Otter1,3, Mark Gilchrist3, Tracey Galletly3, Eimear Brannigan1,5, Jane Turton5, Matthew Ellington1,5, Gerald Larrouy-Maumus1,6, Jesus Rodriguez-Manzano1,7, Xavier Didelot8, Alison H. Holmes1,3

1Imperial College London, NIHR Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, Department of Infectious Disease, London, United Kingdom, 2Mahidol University, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, 3Imperial College Healthcare NHS Trust, London, United Kingdom, 4Imperial College London, Department of Infectious Disease Epidemiology, School of Public Health, London, United Kingdom, 5Public Health England, National Infections Service, London, United Kingdom, 6Imperial College London, MRC Centre for Molecular Bacteriology and Infection, Department of Life Sciences, Faculty of Natural Sciences, London, United Kingdom, 7Imperial College London, Centre for Bio-Inspired Technology, Department of Electrical and Electronic Engineering, Faculty of Engineering, London, United Kingdom, 8University of Warwick, School of Life Sciences and Department of Statistics, Coventry, United Kingdom

Background: The emergence of carbapenemase-producing Enterobacteriaceae (CPE) infections drives the use of colistin, with colistin resistance a major concern for public health systems worldwide. The plasmid-located mcr-9 was first reported in May 2019 with subsequent studies confirming the co-harboring of beta-lactamase (bla) genes and mcr-9 from hospitalised patients. Here, we describe the genomic epidemiology of blaIMP and mcr-9 CPE from a diagnostic laboratory.

Materials/methods: Loop-mediated isothermal amplification was used to examine the prevalence of mcr-9 amongst 47 blaIMP CPE isolates circulating between 2016-2019 in a London acute hospital group. Colistin susceptibility testing was performed by broth microdilution (Micronaut) according to EUCAST guidelines and we also adapted the MALDIxin test for phenotypic resistance to colistin. These isolates were then characterized by WGS (Illumina NextSeq 500). An in-house bioinformatic pipeline was developed to improve the resolution in plasmid phylogeny using long-read sequences (MinION) as reference plasmids.

Results: WGS confirmed blaIMP in 47 CPE isolates, Enterobacter cloacae was the most common species (n=18) followed by Klebsiella pneumoniae (n=9). Four isolates were from clinical samples (a skin biopsy, 2 urines and a nasopharyngeal aspirate), the rest screening isolates. 40 out of 47 blaIMP carrying CPE isolates harboured mcr-9 and all of these were co-located on an IncHI2 plasmid. 11 of the blaIMP isolates were non-susceptible to colistin (MIC 2 to >64). WGS analysis revealed that 10 co-harboured blaIMP and mcr-9, and, of these, 4 had novel chromosomal point mutations at pmrA, pmrB, PhoP or PhoQ, which are associated with colistin non-susceptibility. 5 of the isolates without chromosomal point mutations (all with colistin MIC 2) were susceptible on Micronaut re-testing.

Conclusions: 85% of the blaIMP CPE isolates in this study encoded for the recently described mcr-9 gene. Genomic analysis found that the two genes were co-located on IncHI2 plasmid. However, only 15% of mcr-9 carrying isolates were consistently phenotypically resistant to colistin, highlighting phenotypic detection difficulties and questions regarding the gene’s impact on resistance. This work shows that WGS can be used to detect plasmid spread in real-time, to help direct hospital resources and focus interventions to mitigate spread.

Abstract 5751

**Prospective evaluation of septic shock patients in a tertiary care educational university hospital: a series of 739 cases**

Deniz Akyol*1, Cansu Bulut1, Ugur Onal1, Ayse Uyan1, Damla Akdağ1, Merve Mert1, Gamze Şanlıdağ1, Dilsah Başkoc1, Seichan Chousein Memeti1, Günel Guliçeva1, Serhat Uysal1, Melike Demir1, Sinan Mermer1, Hilal Sipahi1, Sercan Ulusoy1, Öğuz Reşat Sipahi1

1Ege University Medical Faculty Hospital, İzmir, Turkey, 2Bornova Public Health Center, İzmir, Turkey

**Background:** Herein, we aimed to evaluate the septic shock (SS) cases in terms of mortality and affecting variables for outcomes in a tertiary-care educational university hospital.

**Materials/methods:** Patients who had SS (sepsis+hypotension+adrenergic agent) and consulted by Infectious Diseases consultants between December 2013 and October 2019 in our center were followed up prospectively. Arterial lactate level of >2 mg/dL criterion was added as an including criteria for SS according to 3rd International Sepsis and Septic Shock Consensus Statement after 23rd Feb 2016. Statistical analysis was performed via Chi square test and a p value <0.05 was considered significant.

**Results:** There were a total of 739 patients (mean age 65.55 ± 15.16 years and 42.89% female). 393 (53.17%) patients in community-acquired (CASS), 346 (46.82%) patients in nosocomial SS (NSS-developed after 48-72 h of hospitalization) group fulfilled the study criteria. Mean CRP, leukocyte count and procalcitonin levels were 17.35 ± 12.23 mg/dl, 16806 ± 22102/mm³ and 24.81 ± 33.74 µg/l, respectively. Arterial lactate level was available in 634 cases (mean:5.44 ± 4.56 mg/dl). The most common infection sites were pneumonia [n:401] followed by intraabdominal infection [n:188] and urinary tract infection [n:174]. Microbiological etiology was elucidated in 338 cases. The most common pathogens were 101 E.coli (76 ESBL+), 66 Klebsiella spp. (42 carbapenem-resistant), 65 yeasts and 38 Acinetobacter spp (35 carbapenem-resistant). In 115 out of 338 cases, >1 pathogen were isolated. Mortality on day 30 was 66,98% (495/739) and significantly higher (144/188-76.5% vs 351/551 - 63.7%, p=0.0016) in the intraabdominal infection SS subgroup vs others. Mortality was lower in SS with elucidated microbiological etiology [176/338-52% vs 319/401-79.5%] (p<0.0001). Among 236 patients qSOFA score was equal to 3 points and mortality rate at day 30 was significantly higher than qSOFA 1 or 2 [p:0.00001] (185/236-78,3 (qsofa3) vs 235/366-64,2% (qsofa2) vs 75/137-54,7% (qsofa1). One month mortality was 65,3% [257/393] in CASS, 68,7% [238/346] NSS (p:0.347).

**Conclusions:** SS patients have different properties in terms of infection source and it seems to be possible that qSOFA score >2 for sepsis screening seems to define the cases associated with poor outcome. Determining the etiology is important in terms of survival.

Abstract 5753

An eight years-long experience of Nocardia spp. infection in Italy: does immunosuppression matter?

Marta Colaneri1, Vincenzina Monzillo2, Bianca Mariani3, Andrea Lombardi3, Enrico Brunetti4, Margherita Sambo3, Elena M. Seminari1

1Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases Unit, Pavia, Italy, 2Fondazione I.R.C.C.S. Policlinico San Matteo, Unit of Clinical Microbiology, Pavia, Italy, 3Fondazione I.R.C.C.S. Policlinico San Matteo, Viale Camillo Golgi, Pavia, Province of Pavia, Italy, 4Unit of Infectious Diseases, Pavia, Italy

Background: Nocardia spp. have always been considered a pathogen of the immunocompromised patient. Recently, evidences have highlighted its role as pathogen also in the immunocompetent subject. We reviewed all the cases of Nocardia spp. infections in our center to assess the role of immunosuppression in the disease.

Materials/methods: We retrospectively collected clinical and microbiological data of all the patients with a diagnosis of nocardiosis hospitalized at the IRCCS San Matteo Hospital Foundation of Pavia, Northern Italy, between 01/01/2012 and 30/09/2019. Patients were divided among three groups: typical immunocompromised, atypical immunocompromised and immunocompetent.

Results: Overall, we identified 53 patients with an infection caused by Nocardia spp. The median age at diagnosis was 66.7 years and men were the majority (28, 52.8%). Thirty-two patients (60.4%) were immunocompromised: 17 (53.2%) typical and 15 (46.8%) atypical immunocompromised. The two most common conditions associated with the infection were chronic lung disease (41.5%) and high dosage of immunosuppressive drugs (33.9%). The lung was the most common site of infection, being involved in 47 patients (88.8%). Among the 5 different Nocardia species identified in 27 patients, Nocardia abscessus (16, 59.2%) was the most frequently isolated, followed by Nocardia farcinica (6, 22.2%).

Conclusions: In our series the most frequent risk factor was chronic lung disease. Less than half of the patients had classic immunosuppressive risk factors. A remarkable prevalence of nocardiosis in immunocompetent and atypical immunosuppressed patients was observed, thereby stressing the importance of always suspecting this infection particularly in the presence of known chronic pulmonary disease.

Abstract 5756

**Independent risk factors associated to inappropriate antibiotic prescription in the emergency department**

Maria Jose Nuñez Orantos¹, Francisco Javier Candel¹, Eva Orviz¹, Juan Gonzalez Del Castillo*¹

¹Hospital Clinico Universitario San Carlos, Madrid, Spain

**Abstract third-party references:** On behalf of the Infectious Disease Group of the Emergency Medicine Spanish Society

**Background:** inappropriate antibiotic treatment is frequent in the Emergency Departments (ED) and it could be associated with an increase in the mortality in shock septic patients, or with an increase of the cost in non-severe patients. The aim of this study was to describe the individual risk factors associated with inappropriate antibiotic treatment in the ED.

**Materials/methods:** national, retrospective cohort study including all patients attended for an infectious disease in 54 Spanish ED during 2017, in whom a microbiological isolation was available from a culture obtained during their attention in the ED. Demographic, clinical, type of bacterial isolation and first treatment prescribed in the ED were collected. A multivariable analysis was done to recognise the independent risk factors associated with inappropriate antibiotic prescription in the ED.

**Results:** during the study period, 5,460 bacteria were isolated from samples obtained in the ED. The mean age of patients was 70.5 years (standard deviation [SD] 18.3), and 2,846 (52.1%) were males. Patients with inappropriate treatment were 1,082 (19.8%). Regarding mortality, 507 (9.3%) patients died, 330 (7.9%) in the group of appropriate treatment and 147 (13.6%) in patients with inappropriate antibiotic treatment (p<0.001). The independent risk factors associated with inappropriate treatment have been described in the Table 1.

**Conclusions:** one in five patients had inappropriate treatment in the ED. Several factors has been identify as independent associated factors.

Abstract 5758

**CREATE: Carbapenem-Resistant Enterobacteriaceae: Animal Testing and Epidemiology. A plan for veterinary medicine**

Stephen Cole¹, Donna Oakley¹, Shelley Rankin*¹

¹University of Pennsylvania School of Veterinary Medicine, Philadelphia, United States

**Background:** The emergence of carbapenem resistant *Enterobacteriaceae* (CRE) in companion animal veterinary medicine was inevitable – and yet we are completely unprepared. In April 2019, passive surveillance identified the blaNDM-5 gene in a carbapenem-resistant *E. coli* isolated from a dog at a veterinary teaching hospital (VTH) in Philadelphia, USA. A retrospective review of hospital records showed, that from July 2018 through June 2019, CR-*E. coli* was isolated from 15 animals (14 dogs, 1 cat). The outbreak response showed that: there were no validated microbiology methods for the detection of colonized or infected animals; no veterinary specific infection prevention recommendations on how to deal with CRE colonized, or infected, animals in veterinary healthcare facilities and there were no antimicrobial stewardship guidelines for the treatment of animals with CRE.

**Materials/methods:** A crisis management team (CMT) was formed. Representatives from the VTH leadership, the Diagnostic Laboratory, the Infectious Disease Committee (IDC) and the Antimicrobial Stewardship Committee (ASC) addressed Infection Prevention (IP), Facilities and stewardship issues. A literature review was performed to determine if a sensitive, screening and/or culture method was available to comply with recommendations to conduct point prevalence testing and colonization screening of animals at the facility.

**Results:** Limited literature existed on the prevalence of CRE in companion animals. Recommendations to deal with CRE infections were targeted to human healthcare settings. A plan was initiated, known as CREATE (Carbapenem-Resistant Enterobacteriaceae: Animal Testing and Epidemiology). The Diagnostic Laboratory developed a testing strategy to rapidly screen animals for CRE colonization: with selective culture confirmation to obtain isolates. Methods were validated and tested with weekly point prevalence surveys, and a period prevalence survey. The IDC revised the Infection Control Manual and the ASC developed guidelines for consultation.

**Conclusions:** Veterinary hospitals must prepare for the emergence of CRE in companion animals, now that spill over from human medicine has occurred. CREATE a Plan defines validated lab methods that can be standardized across the veterinary community to enable rapid colonization screening of animals and determine the molecular mechanism of resistance. IP and stewardship guidelines are defined and there is a strong recommendation to enhance global veterinary surveillance efforts.

Abstract 5760

Mucosal barrier injury laboratory-confirmed bloodstream infection in oncology patients: descriptive analysis of epidemiological and laboratorial data

Ana Puin1, Maristela P. Freire1, Patricia Rodrigues Bonazzi1, Michely Fernandes Vieira1, Karim Yaqub Ibrahim1, Maria Del Pilar1, Juliana Pereira1, Vanderson Rocha1, Edson Abdala*1

1Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: In 2013 the Centers for Disease Control (CDC) defined the criteria for infection of serious diseases associated with Mucosal Barrier Injury Laboratory-Confirmed Bloodstream Infection (MBI-LCBI), cases whose source is probably the translation of the gastrointestinal tract. The aim of this study was to describe the epidemiological and laboratory data of MBI-LCBI in cancer patients.

Materials/methods: Retrospective cohort study conducted in a large cancer hospital. Central Line-Associated Bloodstream Infections (CLABSI) were reviewed from 2015 to 2017, and those that met the CDC criteria were reclassified as MBI-LCBI. Collected epidemiological data - gender, age, underlying disease; and laboratory - microbiological.

Results: 339 CLABSI were detected in the period, 51 (15.0%) classified as MBI-LCBI - 6 (11.8%) in patients with solid tumors, and 45 (88.2%) in patients with hematologic neoplasms. Twenty-six (51.0%) were male, mean age 46.88 years (22-69 years). Thirty-five (68.5%) of the oncologic diagnoses were Leukemia. All patients had neutropenia. Sixty-two microorganisms were isolated in blood cultures (Table).

Abstract 5762

Contribution of high risk clones *Pseudomonas aeruginosa* ST111 and ST235 in the spread of VIM-2 carbapenemase in a Greek Hospital

Aggeliki Verra¹, Vasiliki Galani¹, Ergina Malli¹, Katerina Tsilipounidaki¹, Stylianos Xitsas¹, Costas Papagiannitsis¹, Efthymia Petinaki*¹

¹University Hospital of Larissa, Larissa, Greece

**Background:** Carbapenem-resistant *Pseudomonas aeruginosa* isolates are currently a serious problem in the management of health-care associated infections. The aim of this study was to examine the molecular characteristics of carbapenem-resistant *P. aeruginosa* detected in a Greek hospital, during 2018.

**Materials/methods:** A total of 120 *P. aeruginosa*, isolated in 2018, from patients treated in University Hospital of Larissa (UHL) (Greece) were included in this study. Identification to species level and susceptibility testing against various antimicrobial agents was performed by the automated system Vitek 2. All *P. aeruginosa* isolates were typed by PFGE and MLST. Additionally, all isolates were tested for carbapenemase production by a modified Hodge test with a meropenem disk. Carbapenemases were detected phenotypically and by PCR. The metallo-β-lactamase (MβL)-encoding integrons were amplified and sequenced.

For 4 isolates representing different STs, bacterial genomes were sequenced using the Illumina MiSeq platform. Annotation and analysis were performed using software available on the Internet.

**Results:** A total of 50 (41.6%) out of 120 *P. aeruginosa* isolates were MHT positive. The population structure of the carbapenemase-producing isolates studied by MLST was classified into 7 sequence types (STs). The international clone ST111 was the most prevalent, accounting for 30 isolates. Fourteen of the isolates were distributed in the pandemic ST235. The remaining six isolates belonged to distinct STs. The majority of the carbapenemase-producing *P. aeruginosa* isolates (n=48; 96%) produced the VIM-2 MβL, while two isolates produced VIM-4. No other carbapenemase-encoding genes, *bla*<sub>OXA-48</sub>, *bla*<sub>KPC</sub>, *bla*<sub>NDM</sub> and *bla*<sub>IMP</sub>, were found. Three different class I integrons were identified: two structures coding for VIM-2 (*aacA29a*<sub>1</sub>|*bla*<sub>VIM-2</sub>, and *bla*<sub>oxa-10</sub>|*aacA4</sub>||*bla*<sub>VIM-2</sub>|*sma-2*), and one for VIM-4 (*bla*<sub>VIM-4</sub>|-*fbr*<sub>7</sub>|*arr-7</sub>|-*aacA4</sub>|-*bla*<sub>PSE-1</sub>*). In selected isolates, S1 profiling and Illumina sequencing showed that MβL-encoding integrons were integrated into their chromosomes.

**Conclusions:** VIM producers comprised 642% of the carbapenem-resistant *P. aeruginosa* recovered in UHL during 2018. Most (88%) of the VIM producers belonged to the internationally-distributed clones of ST111 and ST235, which produced VIM-2 or VIM-4 enzymes. Therefore, recognition of carbapenemase-producing *P. aeruginosa* hyper-epidemic clones by molecular tools represents an important step towards tracing transmission routes, developing targeted control and prevention strategies, and monitoring their effectiveness.

Abstract 5763

Optimisation of culture protocol for the recovery of fungal pathogens from expectorated sputum of cystic fibrosis patients

Warda Memon*, Relinda Abellera1, Sean X. Zhang1,2, Remedios Marayan1

1Johns Hopkins Hospital, Baltimore, United States, 2Johns Hopkins University School of Medicine, Baltimore, Maryland, United States

Background: The role that fungi play in patients with Cystic Fibrosis (CF) is not well characterized, largely due to a lack of standardized laboratory guidelines for the optimal recovery of fungi in respiratory tract of CF patients. We previously reported use of selective fungal culture media increased rates of detection of fungi in CF cultures. In this study, we attempted to further determine the impact of incubation temperature of culture media and pre-treatment of expectorated sputum with a mucolytic agent on CF fungal cultures.

Materials/methods: 400 prospective CF expectorated sputa samples were simultaneously tested by two protocols: 1) the current protocol included inoculating sputa on the following media: MacConkey, CNA, blood, chocolate with and without bacitracin, Burkholderia cepacia selective, Mannitol salt & Sabouraud dextrose with Gentamicin (SABG), and incubated at 37°C for 3 days. 2) the study protocol including Phase I [P I] and Phase II [P II]. In P I, 200 sputa were inoculated on SABG, Inhibitory mold with Gentamicin (IMAG) and Brain heart infusion with Gentamicin (BHIG) and incubated at 30°C and 37°C, respectively. In P II, 200 CF sputa were pre-treated with and without a DTT free mucolytic agent, Liquilizer® (Metasystems Group, Inc) followed by repeating the P I protocol (excluding BHIG). All culture plates were observed for seven days.

Results: Total growth rate for the current protocol was 22% (88/400), for P I 38% (76/200), for P II 43% (85/200) using a combination of SABG and IMAG at 30°C and 37°C. The study protocol was statistically better than the current protocol (p<0.05). Pre-treatment of sputa with Liquilizer® did not significantly enhance the yield of fungal organisms. The most common fungal pathogens recovered were Aspergillus (56%), Exophiala (12%), Scedosporium (9%), Trichosporon (6%) and Rasamsonia (5%). The rate of recovery of these fungi was not significantly affected by temperature and media; however, extended incubation time increased the quantity of fungi recovered.

Conclusions: A combination of SABG and IMAG inoculated at both 30°C and 37°C along with a prolonged incubation of 7 days' time produced the maximum isolation of fungal pathogens, 87% (139/159).

**Abstract 5764**

**Clostridioides difficile infection is associated with persistent high level of innate immune response**

Alessandra Oliva*1, Maria Antonella Zingaropoli1, Massimiliano De Angelis1, Fabio Mengoni1, Maria Ciardi1, Vincenzo Vullo1, Claudio M. Mastroianni1

1Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy

**Background:** The expression of CD11b (member of the beta-integrins) and CD64 (Fc receptor for IgG) on neutrophils increases in the presence of bacterial components. While their expression has been studied during neonatal sepsis, little is known during Clostridioides difficile infection (CDI). The aim of the study was to investigate the dynamic changes of CD64 and CD11b expression on neutrophils and monocytes before and after CDI-specific treatment.

**Materials/methods:** Patients with CDI and, as a control group, 7 healthy donors (HD) matched for age and sex were enrolled in the study. For each subject, whole blood samples were collected before (T0) and at the end (T1) of CDI-specific treatment. Identification and expression of CD64 and CD11b on peripheral blood neutrophils and monocytes were evaluated by flow cytometry and expressed as percentage or median fluorescence intensity (MFI), as appropriate.

**Results:** Twelve patients (median age 78 years) with CDI were included in the study, with 4/12 (30%) having a severe CDI. As for the 60-day outcome, 5/12 (41.6%) had a recurrence and 1/12 (8.3%) developed a nosocomial bloodstream infection. At T0, neutrophils and intermediate monocyte percentages were significantly higher than HD (p=0.007; p=0.01, respectively) as well as the CD64 MFI on neutrophils and monocytes (p=0.007 and p=0.04, respectively). Overall, CD64 MFI on neutrophils and monocytes showed a reduction from T0 to T1, especially on intermediate monocytes (p=0.04). Of note, at T1 values of CD11b and CD64 remained significantly higher than that observed in HD. Stratifying patients according to the development of recurrence or not (R+ and R- groups, respectively), a significant reduction of CD64 and CD11b MFI on neutrophils and monocytes from T0 to T1 in R- subjects was observed (p=0.03, p=0.03 for CD64; p=0.01 and p=0.01 for CD11b, respectively) whereas in R+ these biomarkers remained persistently high (Figure 1).

**Conclusions:** CDI is associated with a high level of innate immune response which lowers at the end of CDI-specific therapy, however without reaching values comparable to HD. Persistent high level of CD64 and CD11b expression on neutrophils and monocytes might have a role on the development of CDI recurrence.

Abstract 5770

Prescribing in paediatric inpatients in England, 2016: factors associated with prescribing “watch” and “reserve” antibiotics

Alicia Demirjian*1,2, Rachel Freeman1, Berit Muller-Pebody1, Diane Ashiru-Doredope1, Susan Hopkins1

1Public Health England, London, United Kingdom, 2Evelina London Children’s Hospital, London, United Kingdom

Background: In England, 89% of antibiotics for human use are prescribed in primary care. Of these, approximately a third are for children younger than 15 years. There is little published information on paediatric antimicrobial prescribing in English hospitals; our objective was to describe inpatient paediatric antimicrobial use in order to inform future stewardship interventions.

Materials/methods: Data collected from the 2016 national healthcare-associated infection and antimicrobial usage point prevalence survey, conducted in accordance with the European Centre for Disease Prevention and Control protocol, was analysed. The dataset was restricted to paediatric inpatients, either recorded as admitted to a paediatric specialty or aged less than 16 years old. Healthy neonates were excluded from the analysis. Descriptive statistics were prepared and logistic regression was performed to identify factors associated with prescribing “Watch” and “Reserve” antibiotics as defined in the World Health Organization’s AWaRe categories.

Results: Of 3465 paediatric patients hospitalised in 87 Trusts, 1865 (53.8%) were less than 12 months old and 1649 (47.7%) were female. There were 247 (7.1%) admissions to paediatric intensive care units (PICU) and 455 (13.3%) to neonatal intensive care units (NICU). One thousand four hundred and forty-five (41.7%) patients received at least one antibiotic or antifungal agent. Of 2330 prescriptions, the most common agents were gentamicin (277, 11.9%), benzylpenicillin (255, 10.9%), and amoxicillin-clavulanate (219, 9.4%). The most common indications were community-associated infection (979, 42.0%), healthcare-associated infection (615, 26.4%), and medical prophylaxis (325, 13.9%). Age 12 months or older, admission to PICU, and the presence of a healthcare-associated infection were predictors of “Watch”/“Reserve” antibiotic prescribing (odds ratio OR 1.27, 95% confidence interval CI 1.22-1.33; OR 1.21, CI 1.13-1.30; OR 1.09, CI 1.03-1.15, respectively).

Conclusions: These findings highlight possible areas where national stewardship interventions could focus, such as in paediatric intensive care units. Further work is required to assess the appropriateness of antibiotics prescribed in these areas and target interventions aimed at optimising antibiotic prescribing. In addition, efforts aimed at reducing healthcare-associated infections may help decrease prescribing of “Watch”/“Reserve” antibiotics. The creation of a national paediatric antimicrobial stewardship network may support the implementation of these interventions.

Double carbapenem therapy for isolated pneumonia in carbapenem-resistant *Klebsiella* spp. and *Acinetobacter* spp.

Deniz Akyol*, Seichan Chousein Memetali1, Melike Demir1, Günel Guliyeva1, Uğur Onal1, Hilal Sipahi2, Sercan Ulusoy1, Oğuz Reşat Sipahi1

1Ege University Medical Faculty Hospital, İzmir, Turkey, 2Bornova Public Health Center, İzmir, Turkey

**Background:** Herein, we aimed to describe the outcomes of patients with carbapenem-resistant (*CR*) *Klebsiella* spp and *Acinetobacter* spp pneumonia who received ertapenem containing double carbapenem therapy (*ECDCT*), retrospectively.

**Materials/methods:** (>18 years old) patients with culture-proven *Klebsiella* spp and *Acinetobacter* spp carbapenem-resistant pneumonia (clinical+radiographic findings+lower respiratory tract culture) treated with ECDCT between August 2016-October 2019 were included in the study. Patients with other concomitant CR infections in other foci were excluded. Bacterial identification was performed via MALDI-TOF MS [BioMerieux, France] and antimicrobial susceptibility testing of the isolates was performed via the VITEK 2 system [bioMérieux]. Resistance to imipenem, ertapenem, and meropenem was tested by E-test [bioMérieux]. The results were interpreted according to the EUCAST criteria. Ertapenem dosage was adjusted as creatinine clearance as >30 1 gr/day (12 cases); <30 0.5 gr/day (2 cases) while meropenem dosage was 3x1 gr/day when creatinine clearance >50 (9 cases), 2x1gr/day when 10-50 (5 cases).

**Results:** Fourteen cases (8 female-67.71 +/- 11.30 years- eight *Klebsiella* spp. six *Acinetobacter* spp.) fulfilled study criteria. Ten cases had a history of antibiotic usage in the previous one-month period. Two cases had concomitant fungal urinary tract infection and two cases had concomitant bacteraemia. All isolates were resistant to meropenem and ertapenem with the MIC levels ≥ 16 and ≥8 μg/ml, respectively. Ten isolates were resistant to gentamycin and thirteen isolates were also resistant to ciprofloxacin. Three isolates were found to be sensitive (MIC ≤ 2 μg/ml) and three isolates were intermittently sensitive (MIC=4 μg/ml) to tigecycline. All cases were treated with ECDCT while eleven were combined with colistin and eight were combined with tigecycline. The mean duration of ECDCT was 18.07 +/- 7.11 days. Microbiological eradication was observed in 4 of 8 (50%) *Klebsiella* spp. cases and in 2 of 6 *Acinetobacter* spp cases (33%) [p=0.627 via Fisher Exact test]. Overall one-month survival rates (with one relapse) were 35.7% (5/14), 3/8 in *Klebsiella* spp. and 2/6 in *Acinetobacter* spp. (p=1 via Fisher Exact test).

**Conclusions:** Although the number of cases is low and uncontrolled, ECDCT containing therapy resulted in relatively unsuccessful outcomes in CR *Klebsiella* spp and *Acinetobacter* spp pneumonia.

**Presenter email address:** denizakyol416@gmail.com
Antibiotic consumption in 417 nursing homes: results from a pilot survey

Catherine Dumartin1*, Muriel Péfau2, Amélie Jouzeau1, Lory Dugravot1, Aurelie Chabaud1, Christian Martin4, Elodie Couve-Deacon1, Emmanuelle Reyraud2, Marie-Cécile Ploy1, Julien Claver3, Olivia Ali-Brandmeyer3, Christian Rabaud3, Anne-Marie Rogues1, Loïc Simon3

1Bordeaux University, Inserm CR 1219, Bordeaux, France, 2CPias Nouvelle-Aquitaine, Bordeaux, France, 3CPias Grand-Est, Nancy, France, 4Limoges University Hospital, Limoges, France

Background: Point prevalence surveys (PPS) in French nursing homes (NH) highlighted frequent use of broad-spectrum antibiotics such as ceftriaxone and fluoroquinolones. Easier than PPS, continuous monitoring of antibiotics dispensed by pharmacies, with feedback to prescribers, could help in improving prescribing practices. Antibiotic consumption was described in 417 NH in 2018.

Materials/methods: The standardized methodology and webtool (ConsoRes) provided by the national project for surveillance and prevention of antimicrobial resistance in hospitals (SPARES) were used to collect antibacterials for systemic use (J01class, WHO Anatomical Therapeutic Chemical classification, ATC-DDD system, 2019 version), oral imidazole derivatives and fidaxomicin dispensed in 2018 by the internal pharmacy for residents in voluntarily participating nursing homes. Consumption was expressed in number of defined daily doses (DDD) per 1 000 resident-days (RD).

Results: Among 417 participating nursing homes, 5 were independent, 15 were part of private clinics, 12 part of psychiatric centres, 27 part of long-term care or rehabilitation centres and 358 were part of public hospitals. Antibiotic use ranged from 31 DDD/1000 RD in independent nursing homes to 41 in nursing homes belonging to long-term care or rehabilitation centres. Most used antibiotics were co-amoxiclav (33%); amoxicillin (28%), ceftriaxone (7%). Ofloxacine accounted for 44% of fluoroquinolones. Nitrofurantoin use accounted for 5.3% of antibiotics in NH belonging to psychiatric centres whereas it represented 0.7% to 3% in other types of NH. No relationship between consumption and the size of the NH was observed.

Conclusions: When expressed in number of DDD/1000 RD, the three most used antibiotics were not the same than reported in PPS where number of treatments or resident treated are measured. In the lastest, the most used antibiotic was ceftriaxone (in 13% of residents). As continuous monitoring of antibiotic prescriptions from individual electronic records is not yet available in French nursing homes, retrospective surveillance of dispensed antibiotics expressed in number of DDD/1000 RD through a national network allowing benchmarking could be useful to raise awareness among prescribers. Adjustment for risk factors (patient dependency) could be used to improve reliance of benchmarking.

Presenter email address: catherine.dumartin@chu-bordeaux.fr
Background: For non-tuberculous mycobacteria (NTM), minimum inhibitory concentration (MIC) distributions of wild-type isolates have not been systematically evaluated and epidemiological cut-off values (ECOFF) not determined. Evidence-based clinical breakpoints for NTM do not exist and should be defined from ECOFFs, clinical outcome and pharmacokinetic/pharmacodynamic (PK/PD) data, as for other bacteria. Currently, the Clinical and Laboratory Standards Institute (CLSI) recommend using broth microdilution (BMD) in cation adjusted Mueller Hinton broth (CAMHB) for AST of most NTM. We collected MIC distributions for major clinically relevant NTM using BMD as a first step towards determining EUCAST ECOFFs.

Materials/methods: MIC distributions in CAMHB for the major NTM drugs were gathered from six laboratories for M. abscessus (MAB; M. abscessus subsp. abscessus, massiliense and bolletii) and M. avium complex (MAC; M. avium and M. intracellulare) along with quality control (QC) strains. Species identification was made by line probe assays and/or gene sequence-analysis. ECOFFs were analyzed according to the EUCAST guidelines.

Results: For M. avium, M. intracellulare and MAB, MICs from 1240, 409 and 656 isolates were analyzed. Clarithromycin wild-type MIC ranges were 0.25-16 (mode 2) mg/L and 0.12-8 (mode 2) mg/L for M. avium and M. intracellulare respectively with corresponding ECOFFs at 16 and 8 mg/L. Amikacin MIC wild-type ranges were 2-64 (mode 16) mg/L and ECOFFs 64 mg/L for all three species. Reproducibility for QC strains were within ±one MIC dilution for all drugs and within CLSI targets. MIC-distributions and tentative ECOFFs for subspecies and other drugs such as imipenem and tigecycline (MAB), rifamycins and ethambutol (MAC) as well as moxifloxacin, linezolid and sulfamethoxazole (MAB and MAC) are under analysis.

Conclusions: As a first step towards evidence-based clinical breakpoints for NTM, tentative ECOFFs were defined for MAC and MAB. Based on the results and internal work, a detailed reference protocol for NTM AST is expected from the EUCAST subcommittee for antituberculosis drug susceptibility testing (AMST) during 2020 which will then be used to set clinical breakpoints using the EUCAST procedure.

Antibiotic use indicators: which and how? Pilot study of 3 indicators in French hospitals

Maider Coppry Maries Firpiou1*, Muriel Péfau2, Amélie Jouzeau2, Lory Dugravot3, Aurelie Chabaud4, Elodie Couve-Deacon1*, Christian Martin4, Marie-Cécile Ploy2, Olivia Ali-Brandmeyer3, Julien Claver1, Remy Gauzit4, Christian Rabaud3, Loïc Simon3, Anne-Marie Rogues1, Catherine Dumartin1

1Bordeaux University, Inserm CR 1219, Bordeaux, France, 2CPias Nouvelle-Aquitaine, Bordeaux, France, 3CPias Grand-Est, Nancy, France, 4Limoges University Hospital, Limoges, France, 5Cochin University Hospital, Paris, France

Background: Antibiotic consumption is monitored to assess selection pressure on bacteria. In addition to the overall amount of antibiotics, the nature of the antibiotic plays a role in selection and dissemination of resistant bacteria. This is why indicators based on the proportion of specific antibiotics among the total quantity of antibiotics may be developed, building upon lists of specific antibiotics from national or international organisations. In France, the national medicines agency established a list of 51 critical antibiotics. In the United Kingdom, 23 narrow-spectrum antibiotics were used to define an index adapted from the WHO AWaRe index (AWaRe-UK). An indicator representing the percentage of broad-spectrum antibiotics is used by ECDC for the hospital sector. In this context, we studied the usefulness of these indicators for comparisons of hospitals involved in the surveillance network managed by the national mission for surveillance and prevention of antimicrobial resistance (SPARES).

Materials/methods: The three indicators (one based on the French medicines agency list, ANSM; AWaRe-UK; ECDC) were calculated for 1622 hospitals that provided data on antibiotic use in 2017: 560 public non-teaching hospitals, 452 private clinics, 389 rehabilitation centres, 127 psychiatric centres, 49 university hospitals, 20 long term care hospitals, 20 cancer centres and 5 military hospitals. For each indicator, hospital ranks were compared using Spearman test among hospitals of the same type.

Results: Comparison of ranks differed according to hospital types. The ANSM and AWaRe-UK indicators were significantly linked for all types of hospitals (Rs 0.74 to 0.89) except for cancer centres. ECDC indicator resulted in different ranking or in similar ranking than the two others but with a weaker correlation Rs 0.32 to 0.52 with ANSM; Rs 0.39 to 0.53 with AWaRe-UK – except university hospitals (0.75) and cancer centres (0.71).

Conclusions: As indicators to better express antibiotic use and its relationship with antimicrobial resistance are being developed, this pilot study underlined the utility of complementary indicators that provide different information for hospital benchmarking. In addition to ECDC indicator, an index based on “virtuous antibiotics” for first-line prescription could be used, adapted from the AWaRe-UK to fit to the national hospital context.

Short-term prognosis and factors associated with acute kidney injury in imported severe malaria: results of a multi-centre retrospective study

Conan Pierre-Louis*1, Eliott Gaudray2, Thibaut Martinez3, Mathieu Boutonnet3, Stephane De Rudnicki2, Pierre Pasquier1, Cécile Ficko1, Eric Peytel2, Nicolas Libert1

1Department of infectious and tropical diseases, military teaching hospital Bégin, Saint-Mandé, France, 2Department of Anesthesia and Critical Care, military teaching hospital Laveran, Marseille, France, 3Department of Anesthesia and Critical Care, military teaching hospital Percy, Clamart, France

Background: Acute kidney injury (AKI) is a well recognized complication of severe malaria (SM) in endemic areas and its prevalence can reach 40% of adult patients. Few data are available on AKI in imported SM. This study aimed to determine the prevalence, the prognosis and associated factors of AKI in this setting.

Materials/methods: We conducted a multicentre retrospective study in four intensive care units between January 1, 2000 and December 31, 2016. All consecutive patients with SM were included. AKI was defined using the KDIGO classification: increase in serum creatinine by ≥ 0.3 mg/dl (≥ 26mmol/l) within 48 h, or increase in serum creatinine to ≥ 1.5 times baseline. The reference serum creatinine (SCr) was estimated for each patient according to age and ethnicity. The evolution of renal function was assessed from the last SCr available for each patient. A logistic regression was used to compare the groups with and without AKI.

Results: One hundred and twenty-nine patients were included, Forty-two (32.6%) had AKI at presentation (mean age 46.9 (standard deviation 2.3), 31/42 (74%) males): 17/42 (40%) stage 1, 13/42 (31%) stage 2 and 12/42 (29%) stage 3. None had prior chronic renal failure. A worsening of AKI was seen in 6 patients during their hospital stay: 1 patient with KDIGO1 and 4 patients with KDIGO-2 evolved to KDIGO-3. 1 patient with KDIGO 1 developed KDIGO 2. The average time from ICU admission to the maximum serum creatinine value was 2.9 days (0.9). Among the 42 patients, 22 (52%) needed renal replacement therapy.

Higher age (p<0.01), shock (p=0.02), respiratory distress (p=0.03), higher leukocytes count (p<0.01) and coexisting bacterial infection (p=0.01) were associated with AKI at presentation.

The average follow-up was 45 (12.4) days and data were available for 38 patients. Among them, 30/38 (79%) patients had recovered a SCr at +/- 50% of the reference value and only 23/38 (61%) had a SCr at +/- 5% of the reference value.

Conclusions: SM patients with AKI portend unsatisfactory short-term renal outcomes and deserve a careful and longer follow-up, especially under nephrology care.

Abstract 5785

Phage-antibiogram
Ali Khalid1, Aleksandra Petrovic Fabijan1, Carola Venturini1, Susan Maddocks2, Ruby Cy Lin1, Jonathan Iredell1

1The University of Sydney, The Westmead Institute for Medical Research, Westmead, Australia, 2The University of Sydney / Westmead Hospital WSLHD, Institute for Clinical Pathology and Medical Research [ICPMR], Westmead, Australia

Background: Bacteriophage (phage) therapy is re-emerging a century after it began and is widely considered to be the solution to antibiotic resistance. Phages have been championed as ideal personalised medicines in the critically ill due to their specificity at species and strain level. Thus, measuring the bacteria host range plays an important role in utilizing the phages as antimicrobials. Here we designed a high-throughput, liquid assay to simultaneously and efficiently detect host range and phage-antibiotic synergy. This has the potential to inform adjuvant phage therapy in critically ill patients in a timely manner.

Materials/methods: The 96-wells microtiter plates were prepared on Eppendorf epMotion 5075 liquid handling robot for high throughput testing containing LB broth, target bacterial isolates, gradient dilutions of phage [s] across rows and fixed concentrations of antibiotics [1/2 - 1/4 MIC]. Lytic phages against clinical isolates of Klebsiella pneumoniae and Escherichia coli belonging to virulent ST and capsular types were included in this study. Standard plaque assay for host range was done in parallel for comparison. Representative antibiotics from each drug class were investigated for synergy effect with phages, biological replicates were used. The plates were incubated at 37°C for 18 hours with orbital shaking in SpectraMax iD5 microplate reader with bacterial kinetics monitored every 30 minutes.

Results: The automated plate assay correctly determined the phage virulence in majority of cases in comparison to the plaque assay (>96% agreement). The plaque assay tended to overestimate phage host range. The advantage of using this platform was continuous monitoring of bacterial growth and the rise of bacterial resistance over continued phage exposure. Phage combination with imipenem and ciprofloxacin exhibited synergistic activity among the Klebsiella pneumoniae phages tested and significantly delayed the appearance of resistant mutants (P value=<0.05).

Conclusions: Parallel experiments indicated that this high throughput liquid assay is reproducible and comparable to the standard reference plaque assay to determine phage virulence determination. The results inform synergistic activity between phages and different antimicrobial drugs. Thus, this system can potentially assist with clinical decisions at the bedside, especially where phage therapy is being used with best established antibiotic therapy in refractory infections.

Abstract 5787

Phenotypical and molecular characterisation of non-lactose fermenting Escherichia coli isolated from outpatients with urinary tract infection in a private health centre in Santiago, Chile

Katherine Ocares1, Camila Sanhueza1, Francisca Morales1, Cecilia Tapia1, German Hermosilla1, Maria Ulloa*1

1University, Facultad de Medicina, Universidad de Chile, Santiago, Chile, 2Hospital, Clínica Dávila, Santiago, Chile

Background: Isolation of non-lactose-fermenting E. coli (NLF-E. coli) is increasing, especially sequence type (ST) 1193. It is more resistant to fluoroquinolones, gentamicin and trimethoprim –sulfamethoxazole than lactose-fermenting E. coli. Data about this clonal group is lacking in Chile. The aim of this study was to determine the prevalence, antimicrobial resistance (AM) patterns (phenotype/genotype), virotype, phylotype, sequence and clonal relationship of NLF-E. coli isolated from urine samples of outpatients with urinary tract infection (UTI).

Materials/methods: 96 isolates of E.coli from urine samples of outpatients with UTI, studied in a private health center in Santiago, Chile, between August-December 2017, were included (1 isolate/patient). NLF-E. coli was detected by phenotypic tests. AM susceptibility testing was performed by agar diffusion. ESBL was confirmed by double disk method and blaCTX-M PCR. Virulence genes were detected by multiplex PCR (kpsMTII, feoB, iutA, fimH, hlyA, cfn1 and sat). Quadruplex PCR was used to establish phylotype (chuA, arpA, yjaA, ytsPE4C2). MLST was used for detection of clonality. Sequence type was performed using the MLST. Clonal relationship was investigated by generating a Minimum Spanning Tree (MST), through the Phyloviz 2.0 software. STs of 23 NLF-E. coli and 62 UPEC were analyzed using http://enterobase.warwick.ac.uk/species/ecoli/search_strains.

Results: The prevalence of NLF-E. coli was 26% [25/96]. It showed higher rates of AM resistance than lactose-fermenting E.coli for ciprofloxacin: 68% versus 12% (p = 0.00) and trimethoprim-sulfamethoxazole: 48% vs. 17% [p = 0.0028]. 12% [3/25] produced CTX-M-15 ESBL. Mutations in S83L and D87N were present in the QRDR zone of the gyrA gene in 10 ciprofloxacin-resistant NLF-E. coli studied. Phylotype B2 was the most common (92%). Frequency of virulence factors was: fimH (100%), feoB (92%), sat (80%), kpsMTII and iutA (76% each), cfn (68% and hlyA (16%). ST1193 (54%) was the most prevalent, belonged to phylotype B2, was 100% resistant to ciprofloxacin and showed low ESBL production (7.7%).14 strains belonged to clonal complex (CC) 14.

Conclusions: The prevalence of NLF-E. coli isolated from outpatients with UTI was 26%. ST1193 was the most frequent ST, belonged to phylotype B, was related to CC14 and highly resistant to fluoroquinolones.

Abstract 5788

**Antiviral treatment in severe influenza pneumonitis**

Ya-Tang Pai¹, Yu-Kai Huang*², Chia-Ping Su³,⁴, Kuo-Chien Tsao¹, Chen-Yiu Hung¹, Yu Chia Hsieh¹, Kuo-Chin Kao¹, Chung-Chi Huang¹, Avijit Dutta¹, Ching-Tai Huang¹

¹Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan, ²Chang Gung Memorial Hospital, Linkou, Taoyuan, Taiwan, ³National Taiwan University, Taipei, Taiwan, ⁴National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan

**Background:** Severe influenza is under-recognized and not always timely treated with anti-viral agent, even though the role of antiviral agents is not documented. We want to define whether antiviral treatment may improve the outcome of severe influenza pneumonitis.

**Materials/methods:** We started to enhance our awareness of severe influenza at Linkou Chang Gung Memorial Hospital upon the 2009 novel H1N1 pandemic. Since then, all bronchoscopic bronchoalveolar lavage (BAL) samples in intensive care units (ICUs) were tested for influenza by PCR. There were 82 adult ICU patients with severe pneumonitis and PCR positive BAL samples from 2009 to 2019. Nineteen cases of APACHE 3 predicted extreme high and low mortality were excluded. Demographic and clinical data were collected for the other 63 patients. Outcome measurements were compared between those with and without timely treatment (within 3 days of symptoms onset), those with and without empiric treatment, those with treatment before and after BAL examination, and those of the first and the second halves of the 10 years study period.

**Results:** Co-morbidities and disease severity are matched between the comparison groups. Survival rates were higher for patients treated within 3 days after symptoms onset [89% (16/18) vs 51% (23/45), p=0.005], for patients empirically treated before definitive laboratory diagnosis [79% (22/28) vs 49% (17/35), p=0.015], and for patients treated before BAL exams [75% (30/40) vs 39% (9/23), p=0.005]. The survival rate was also slightly higher for the patients of the second half of the 10 years study period, although not statistically significant [66% (21/32) vs 52% (16/31), p=0.098]. There was no difference in other outcome measurements.

**Conclusions:** Early, timely, even empiric treatment before definitive laboratory diagnosis, especially without delay until invasive bronchoscopy conferred a significant survival benefit. The patients of the second 5 years of the 10 years study period were with higher disease awareness. They came to medical attention earlier and as a result, they get earlier treatment. In conclusion, it is prudent advice to encourage empiric antiviral treatment for patients with possible severe respiratory tract infection with influenza.

Implementation of a smartphone application intervention to increase linkage to and engagement with HIV care among people with tuberculosis and substance use in Irkutsk, Siberia

Jacqueline Hodges*, Ava Lena Waldman1, Olga Koshkina2, Alexey Suzdalnitsky1, Elena Moiseeva3, Mikhail Koshcheev2, Jason Schwendinger1, Serhiy Vitko1, Oleg Ogarkov2, Svetlana Zhdanova3, Rebecca Dillingham1, Scott Heysell1

1University of Virginia Health System , Charlottesville, United States, 2Irkutsk Regional Tuberculosis Referral Hospital, Irkutsk, Russian Federation, 3Scientific Centre for Family Health and Human Reproduction, Irkutsk, Russian Federation

Abstract third-party references: Supported by the National Institutes of Health and the Russian Foundation for Basic Research

Background: Fueled by injected heroin use, Irkutsk, Siberia faces a high prevalence of co-infection with human immunodeficiency virus (HIV) and drug-resistant tuberculosis (TB). Treatment for co-infection in this context tends to consist of cumbersome multi-drug regimens delivered in separate care settings, which along with associated stigma and social isolation poses considerable barriers to engagement in care for people living with HIV (PLWH) and TB.

Materials/methods: The Irkutsk HIV/AIDS Centre and Irkutsk Regional Tuberculosis Referral Hospital partnered to implement a smartphone app-based intervention called MOCT (Russian for 'Bridge') for a co-infected cohort developed for the local language and cultural context. The app includes daily medication and appointment reminders, educational resources, and peer and provider messaging. The cohort was trained on MOCT use and initiated on antiretroviral therapy. Participants were surveyed on medication adherence, visit attendance and perspectives on the app, and usage was compared to other commercial health apps.

Results: This cohort (N=52) had a high proportion of history of intravenous drug use (IVDU) (60%), alcohol use (81%) and hepatitis C infection (42%). Patients using the MOCT app reported a high medication adherence ('I take medications as prescribed most days') at 6 months (27/29 for both HIV and TB meds). Surveys thus far also indicate that patients remained engaged in HIV care at 6 months (27/28 patients attended at least one visit, 25/26 patients refilled meds at least once). Comparing retention in care scale scores [1-10 points] at baseline and 6 months, we observe an increase by 2.07 points [p=0.001] in patients’ self-scoring of their likelihood of contacting the HIV clinic with questions [N=27]. The cohort demonstrated a higher mean response rate to daily queries over 6 months (49.5%) compared to popular commercial mobile apps (4-20%).

Conclusions: A language and cultural context adapted app was associated with excellent engagement in care among a cohort of people using substances and at considerable risk for lack of engagement, as well as improved patient self-efficacy in terms of likelihood of reaching out to providers, with high rates of app usage over time.

Abstract 5793

**Efficacy of CD377, a novel antiviral Fc-conjugate against seasonal influenza in lethal mouse models**

James Levin*1, Karin Amundson1, Kim Shathia1, Allen Borchardt1, Thanh Lam1, Wanlong Jiang1, Zhi-Yong Chen1, Tom Brady1, Simon Döhrmann1, Voon Ong1, Leslie W. Tari1

1Cidara Therapeutics, San Diego, United States

**Background:** Cidara’s AVCs (antiviral Fc-conjugates) are novel, immunotherapeutic conjugates of potent, antiviral agents with the Fc domain of human IgG1. CD377 is an AVC development candidate for prevention and treatment of influenza that has demonstrated broad anti-neuraminidase activity in both enzymatic and cell-based assays, and the ability to engage the immune system through its Fc domain. These attributes, coupled with an exceptional PK profile, underscore the potential of CD377 for the long-term prevention of seasonal influenza.

**Materials/methods:** Efficacy studies were conducted in female BALB/c mice lethally challenged intranasally at 3x the LD95 with influenza A virus [H1N1, H3N2] and influenza B [Victoria, Yamagata lineages]. CD377 was administered as a single dose subcutaneously (SC) at various concentrations 2 hours after viral challenge. Body weights (BW) and health scores were monitored daily, with 20% BW loss recorded as a mortality.

**Results:** In mice challenged with a lethal dose of a pandemic H1N1 strain [A/California/07/09], a single dose of CD377 (0.1 to 3 mg/kg) administered 2 hours post-challenge was fully protective (P=0.0026 relative to vehicle). This result was accompanied by only a transient drop in BW that was greatest on Day 4 before full recovery to starting BW by Day 9. In a similar study against a mouse-adapted H3N2 subtype [A/Hong Kong/1/68], a single dose of CD377 at 0.3 mg/kg was fully protective (P=0.0025).

The activity of CD377 was also evaluated against both lineages of influenza B. Against influenza B/Malaysia/8/34 (Victoria), a single CD377 dose of 0.1 mg/kg was fully protective (P=0.0027) while the Fc-only control dosed at 1 mg/kg was not (P=0.3173), as expected. Against the Yamagata lineage [B/Florida/4/06], CD377 demonstrated even greater potency, achieving full protection from lethal challenge at 0.03 mg/kg (P=0.0023).

**Conclusions:** CD377 was protective against lethal challenge with several seasonal influenza subtypes at single doses of 0.3 mg/kg or less. The exceptional PK profile of CD377 combined with its ability to engage the immune system highlight its potential for use as a long-term preventative against seasonal influenza.

**Presenter email address:** jlevin@cidara.com
Clonal expansion of extended-spectrum β-lactamase-producing Escherichia coli ST131 in bloodstream infections of Ecuadorian patients from 2009 to 2018

Jeannete Zurita1,2; Gabriela Sevillano1,2; Ariane Paz Y. Mino1; Nathali Haro2

1Facultad de Medicina. Universidad Catolica del Ecuador, Quito, Ecuador, 2Unidad de Investigaciones en Biomedicina. Zurita&Zurita Laboratorios, Quito, Ecuador, 3Servicio de Microbiologia y Tuberculosis. Hospital Vozandes, Quito, Ecuador

Background: Escherichia coli-St131 (E. coli-ST131) clone has emerged rapidly worldwide until it became an important extra-intestinal pathogen. The aim of this study was to determine, in a collection of E. coli strains from 2009 to 2018, the sequence type (ST), the phylogenetic groups and the blaCTX-M genes in ESBL-E. coli strains collected from bloodstream infections.

Materials/methods: From the collection of E. coli strains, 147 were E. coli-ESBL. During this period, a total of 509 E. coli (147/509; 28.8%) were isolated from bloodstream infections and processed in the Bactec 9120 system and bacterial identification in Vitek2. Demographic data was obtained from Whonet software. The genes for β-lactamases, and phylogroup analysis were determined by conventional PCR and sequencing. The sequence type was determined by MLST analysis (CH type).

Results: The rates of ESBL-positive strains ranged from 9.4% in 2008, and increased to 27.9% in 2018, with the highest rate of 40% in 2015. The blaCTX-M-15 gene was the most frequent (88/147; 60%) among the strains carrying blaCTX-M during all the analyzed years, followed by blaCTX-M-27 (8/147; 5.44%) and blaCTX-M-55 (7/147; 4.76%). Phylogroup B2 was the most prevalent (102/147; 69.38%), followed by phylogroup A (18/147; 12.24%). E. coli-ST131 first appeared in 2010; this strain did not carry a blaCTX-M15 gene, but a variant of the CTX-M-25 group. Before the appearance of E. coli-ST131 in 2010, the blaCTX-M-15 gene was found in E. coli-ST88 belonging to the phylogroup F (2009).

Conclusions: The presence of clone E. coli ST131 was not evidenced before 2009 in this study. A higher prevalence of the ST131 clone together with blaCTX-M-15 was observed throughout these 10 years, which could indicate that this clone is responsible for the dissemination of blaCTX-M-15. The persistence of this clone in the 10 years period demonstrates its presence in Latin America and Ecuador has not escape to the emergence of ST131 outbreak clone.

Evaluation of large urban-rural outpatient antibiotic stewardship programme

Larissa May*1, Taseem Chechi1, Haylee Ann Bettencourt1, Mengxin Wang1

1University of California Davis Medical Center, Sacramento, United States

Background: Judicious prescribing of antibiotics is necessary in addressing the crisis of emerging antibiotic resistance and reducing adverse events. Nearly half of antibiotic prescriptions in the outpatient setting are inappropriate. Data outlining the misuse of antibiotics in the outpatient setting provide compelling evidence of the need for more rational use of antimicrobial agents beyond hospital settings. To evaluate the effect of a behaviorally enhanced quality improvement (QI) intervention to reduce inappropriate antibiotic prescribing for viral URI in the ambulatory care clinics an Outpatient Antibiotic Stewardship program was implemented.

Materials/methods: The program was implemented in January 2018 at five pilot sites. Interventions included identification of a site champion, educational sessions, sharing of clinic and individual provider data, and patient and provider educational materials. In addition, pre-clinic huddles and resident education sessions for internal medicine resident physicians were conducted with a display of public commitment to prescribe antibiotics appropriately. The primary outcome was defined as the provider-level antibiotic prescribing rate for acute URI, defined as patient visits with antibiotic-nonresponsive diagnoses without concomitant diagnostic codes to support antibiotic prescribing.

Results: 116,122 antibiotic prescriptions were dispensed from April 2017 through December 2018 compared to the period from April to December 2017 where 9,129 fewer prescriptions were ordered. Inappropriate antibiotic prescribing for viral URI for ambulatory clinic encounters (n=>45,000 visits/month) declined from 14.3% to 7.6%. Academic hospital-based sites showed little seasonality trends and no statistically significant decrease in prescription rates (p=0.5176). On the other hand, community-based sites showed strong seasonal fluctuations and a statistically significant decrease in prescription rates after intervention (p=0.000189).

Conclusions: A multifaceted behaviorally enhanced QI intervention to reduce inappropriate prescribing for URI in ambulatory care encounters at a large integrated health system was successful in reducing both inappropriate prescriptions for presumed viral URI as well as total antibiotic use. Findings suggest that implementing leadership roles, education sessions, and low-resource behavioral nudging together can decrease excessive use of antibiotics by physicians. A Hawthorne effect may be an important component of these interventions. Future studies are needed in order to determine the optimal combination of behavioral interventions that are cost-effective in outpatient settings.

Abstract 5800

Clonal diversity of uropathogenic Escherichia coli strains from Zimbabwe

Faustinos T atenda T akawira1,2, Johann Pitout1,3, Tapfumanei Mashe1,2, Andrew Tarupiwa2, Marthie M. Ehlers1,4, Sekesai Zinyowera2, Marleen Kock1,4

1University Of Pretoria, Department of Medical Microbiology, Pretoria, South Africa, 2National Microbiology Reference Laboratory, Harare, Zimbabwe, Harare, Zimbabwe, 3Alberta Public Laboratories, Cummings School of Medicine, University of Calgary, Calgary, Calgary, Canada, 4Tshwane Academic Division, National Health Laboratory Service, Pretoria, South Africa

Background: Extra-intestinal pathogenic Escherichia coli (ExPEC) is a common cause of community and hospital-acquired urinary tract and bloodstream infections (BSIs) globally. Limited information is available on the real burden of the pathogenic ExPEC and the population structure of such isolates in Zimbabwe. A study was designed to characterise E. coli from urinary tract infections (UTIs) that were collected and stored at the National Microbiology Reference Laboratory (NMRL) in Zimbabwe from 10 One Health participating centres during 2017 to 2019.

Materials/methods: A total of 823 non-repetitive UTI E. coli isolates were referred to NMRL, 110 isolates were randomly selected for this study. The Kirby Bauer method was used for antimicrobial susceptibility testing and interpretation as per CLSI guidelines. Extended spectrum beta-lactamase (ESBL) production was tested in all ceftazidime/cefepime resistant isolates, while the presence of carbapenemases was determined using the modified carbapenem inactivation method (mCIM) in meropenem resistant isolates as per CLSI guidelines. Sequence types (STs) and fimH types were determined using a published 7-single nucleotide polymorphism quantitative PCR.

Results: The overall non-susceptibility rates were as follows: ampicillin (102/110; 92.7%), trimethoprim-sulfamethoxazole (95/110;86.4%), ceftriaxone (95/110;77.2%), ciprofloxacin (100/110;90.9%), tetracycline (99/110;89.9%), nalidixic (102/110; 92.8%), ceftazidime (77/110;70%), cefepime (46/110;41.9%), meropenem (10/110; 9%). Extended spectrum beta-lactamase production was confirmed in 84 isolates, while 14 isolates harbored a carbapenemase. Five dominant sequence types (STs) were identified and included ST10 (38), ST131 (12); with different fimH types, ST58 (6), ST73 (4) and ST95 (3). Other STs that were detected included ST88 (2), ST69 (1), ST14 (1), while seaptypes 770 (31), 61 (7), 701 (4) and 660 (1) could not be converted to STs and require sequencing. Most isolates belonging to ST58, ST95 and ST73 had susceptible profiles. The ST131 and ST10 isolates displayed ESBL positive and carbapenem resistant phenotypes.

Conclusions: The population structure of ExPEC causing UTIs in Zimbabwe is dominated by clone(s) ST10 displaying ESBL and carbapenem resistance. Two-thirds of the isolates were multidrug resistant (MDR) and belonged to several STs/septatypes. Our results indicate that targeting specific STs [e.g. ST10, ST131 and ST58] through control programmes will substantially decrease antimicrobial resistance of cephalosporins and fluoroquinolones among ExPEC.

Disease prevention not decolonisation: a cohort study for faecal microbiota transplantation for patients colonised with multidrug-resistant organisms

Rohma Ghanis**, Benjamin H. Mullish**, Julie Mcdonald1, Anan Ghazy1, Horace Williams1, Giovanni Satta1, Eimear Brannigan2, Mark Gilchrist1, Neil Duncan2, Richard Corbett1, Jiri Pavlu1, Andrew Innes2, Mark Thursz1, Julian Marchesi1, Frances Davies1

1 Imperial College London, London, United Kingdom, 2 Imperial College Healthcare NHS Trust, London, United Kingdom

Abstract third-party references: BRC NIHR Gut Health Theme

Background: Faecal Microbiota Transplantation (FMT) is widely utilised for the treatment of recurrent Clostridioides difficile infection. Use for eradication of multidrug-resistant organisms (MDROs) in the intestine has been described, with intestinal decolonisation rates from 37.5% to 87.5%, in heterogeneous studies with few looking at prevention of infection. We perform FMT via naso-gastric tube using donor stool prepared anaerobically, using prevention of MDRO invasive disease as an endpoint.

Materials/methods: MDRO colonisation was defined as carbapenemase-producing Enterobacteriaceae (CPE), vancomycin resistant Enterococci (VRE) or extended-spectrum beta lactamase Enterobacteriaceae (ESBL) isolated on rectal screening. Patients considered were colonised with at least one MDRO (Group 1) and who were at risk of invasive MDRO disease or patients who had recurrent MDRO-mediated invasive disease (Group 2). Clinical outcomes were analysed for six months pre and post-FMT by Wilcoxon ranked pairs, for non-parametric data.

Results: FMT was performed on 20 patients. Figure 1 describes the outcomes. In Group 1, all 11 patients had an underlying haematological disorder. Six had a MDRO bloodstream infection (BSI) pre-FMT. Eight underwent a stem cell transplant post-FMT. All patients had shorter inpatient stays (P=0.002) and fewer days on carbapenems compared to the preceding six months (P=0.00167). In Group 2, all nine patients had recurrent ESBL UTIs. Four patients were co-infected with C. difficile and five patients had a previous renal transplant. There was a reduction in frequency of MDRO UTIs post-FMT (P=0.0078). Across both groups there was a reduction in invasive BSIs for both MDRO BSIs (P=0.0469) and all BSIs (P=0.0283). Forty one percent of patients lost detection of colonising MDRO on stool culture post-FMT within 6 months.

Conclusions: Despite lack of complete decolonisation, concordant with published literature, patient outcomes post FMT were significantly improved in this study. The mechanism of FMT has not fully been established; therefore, improvement of colonisation resistance to invasive disease by manipulating microbiota composition, lowering the carriage of the pathogen (disinfection <10^5 CFU) or improvement of gut barrier functionality in at risk groups appears to be a more important factor independent of full intestinal eradication of MDRO in terms of patient outcome.

Abstract 5806

**Gastrointestinal colonisation by vancomycin-resistant enterococci and carbapenem-resistant Gram-negative bacteria in an endemic setting: prevalence, risk factors, and outcomes**

Alexandra Vasilakopoulou1, Polyxeni Karakosta1, Sophia Vourli1,2, Aikaterini Tarpatzi1,2, Arhodoula Papadomanolaki1, Paraskevi Varda1, Maria Kostoula2, Anastasia Antoniadou2,3, Spyros Pournaras*1,2

1Athens Medical School/Attikon University Hospital, Clinical Microbiology Laboratory, Athens, Greece, 2Attikon University Hospital, Infection Control Committee, Athens, Greece, 3Athens Medical School/Attikon University Hospital, 4th Department of Internal Medicine, Athens, Greece

**Background:** Acquisition and gastrointestinal colonization by vancomycin-resistant enterococci (VRE) and carbapenem-resistant Gram-negative bacteria (CRGN) constitutes a major public health concern as it may be followed by clinical infection development or lead to intra-hospital dissemination. Detection of carriers and implementation of infection control measures are essential in every hospital. In this study we determined the point prevalence of VRE and CRGN in the fecal flora of the inpatients of a tertiary university hospital in Greece, we identified risk factors for colonization and examined the impact of colonization on hospital outcomes.

**Materials/methods:** A point prevalence study of VRE/CRGN rectal colonization of inpatients was conducted on March 2018. Specimens were selectively cultured for VRE/CRGN, microorganisms were biochemically identified, submitted to antibiotic susceptibility testing and tested for carbapenemase production. Data on potential risk factors and hospital outcomes were collected at the time of culture and until hospital discharge. Multivariable logistic and linear regression models were used adjusting for confounders.

**Results:** 491 patients were enrolled in the study. Of them, 64 (13.0%) carried VRE, 40 (8.2%) CRGN and 10 patients (2.1%) were carrying both VRE and CRGN. VRE colonization was independently associated with age over 65 years (adjusted OR: 2.4 [95%CI: 1.3, 4.5]) and length of stay (LOS) before rectal sampling (OR: 1.1 [95%CI: 1.0, 1.1]). Carrying a CRGN was associated with 11 days increase of LOS after rectal sampling (β-coef: 11.4 [95%CI: 1.6, 21.2]), with 3.5-fold increased risk of acquiring a resistant pathogen after rectal swabbing (RR: 3.5 [95%CI 1.2, 9.9]) and with 8-fold increased risk of mortality (RR: 6.1 [95%CI: 2.1, 17.9]), after adjusting for sex, age and comorbidity index.

**Conclusions:** High prevalence rates were found for VRE and CRGN colonization among the inpatients of our hospital. Prolonged hospitalization and age were independent risk factors for VRE colonization, while CRGN carriage was associated with increased risk of acquiring a resistant pathogen, prolonged hospital stay and increased mortality.

Simulated exposures of oritavancin in vitro PK/PD models select for MRSA with reduced susceptibility to oritavancin but minimal cross-resistance or seesaw effect with other antimicrobials

Brian Werth* 1, Nathaniel Ashford 1, Ismael Barreras Beltran 1, Kelsi Penewit 2, Elizabeth Holmes 2, Adam Waalkes 2, Stephen Salipante 2

1University of Washington School of Pharmacy, Seattle, United States, 2University of Washington School of Medicine, Seattle, United States

Background: Oritavancin is a long-acting lipoglycopeptide with activity against Gram positive bacteria including MRSA. The long elimination half-life (~10 days) allows for once weekly or single dose treatments but could prolong the mutant selection window, increasing the risk of resistance. The objective of this study was to evaluate the capacity of average post-distributional pharmacokinetic exposures of oritavancin to select for cross-resistance to vancomycin and daptomycin and cross-susceptibility to β-lactams i.e. the "seesaw effect" among clinical strains of MRSA.

Materials/methods: Using a well-described in vitro PK/PD model we simulated average post-distributional, free-drug exposures of oritavancin 1200mg IV once (fCmax 11.2 μg/mL, β-elimination t½ 240h) against 4 strains of clinical MRSA. Pharmacodynamic samples were taken at 0h, 8h, and 24h, and then daily for 672h. Samples were serially diluted in cold sterile saline and spiral-diluted onto tryptic soy agar for colony enumeration or TSA enriched with oritavancin and polysorbate 80. Surviving colonies were subjected to repeat MIC testing against oritavancin, vancomycin, daptomycin and a panel of β-lactams to investigate the seesaw effect as well as whole genome sequencing.

Results: Oritavancin was bactericidal against all strains for at least 48h but as long as 408h before regrowth of less susceptible subpopulations. Isolates with reduced susceptibility to oritavancin were detected as early as 120h but increased above the susceptibility breakpoint of 0.25mg/L in all models by 672h. Vancomycin and daptomycin MICs increased by 2-8-fold but did not exceed the susceptibility breakpoints in most isolates. β-lactam MICs were largely unchanged among the recovered isolates with reduced oritavancin susceptibility. Many mutations were observed among resistant isolates including walK, saeS, and apt, but the most commonly mutated gene was purR, with over 10 unique variants identified.

Conclusions: These observations suggest that oritavancin is less likely than dalbavancin to select for cross resistance to other important classes of agents. It is unclear why oritavancin does not seem to select for cross resistance but is likely related to differences in the mechanisms of action and the different genotypes that were selected for, especially the many purR mutations relative to the genes more commonly implicated in glycopeptide resistance.

Abstract 5826

Retrospective analysis of intravenous fosfomycin use at Florence University Hospital, Italy: clinical and microbiological analysis

Nicoletta Di Lauria1, Elisabetta Mantengoli1, Noemi Aiezza1, Alberto Antonelli1, Silvia Bresci2, Tommaso Giani1, Filippo Lagi1, Keith S. Kaye4, Payal Patel4;5, Gian M. Rossolini1;3, Alessandro Bartoloni1;2

1University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy, 2Careggi University Hospital, Infectious and Tropical Diseases Unit, Florence, Italy, 3Careggi University Hospital, Microbiology and Virology Unit, Florence, Italy, 4University of Michigan, Department of Internal Medicine, Division of Infectious Diseases, Ann Arbor, United States, 5Veteran Affairs, Ann Arbor Veterans Affairs Medical Center, Ann Arbor, United States

Background: Intravenous fosfomycin may be used as last-resort therapy of infections caused by multidrug-resistant pathogens. We conducted a retrospective analysis of intravenous fosfomycin use at Careggi University Hospital in Florence (Italy) evaluating clinical indication, efficacy, antimicrobial susceptibility and safety.

Materials/methods: Retrospective observational study of adult patients who received at least a single dose of intravenous fosfomycin between January 2016 to July 2019 at a single hospital in Florence, Italy. Fosfomycin susceptibility was tested by reference agar dilution method according to ISO 20776-1,2006 and results interpreted according to EUCAST clinical breakpoints (v. 9.0 2019).

Results: 54 patients were included, 37 (68.5%) were male, median age 48 years (IQR=37-67). Indications were pulmonary exacerbations of Cystic Fibrosis (CF) (26, 42.6%); other indications were for treatment of infections in non-CF patients (28, 45.9%). Among non-CF infections, urinary tract infections (UTI) (13, 46.4%) and pneumonia (7, 25%, including 2 cases of hospital-acquired pneumonia and 5 cases of ventilator-associated pneumonia) were the most common types of infections. Carbapenem-resistant Klebsiella pneumoniae (CR-KP) (12, 44.4%) and Pseudomonas aeruginosa (9, 33.3%) were the most frequently treated pathogens. Antimicrobial susceptibility testing was performed on 20 isolates (74%). 41.6% of CR-KP were resistant, all Pseudomonas aeruginosa isolates presented MIC ≤ 128 mg/L (interpreted as susceptible for the purposes of this study). Combination therapy was prevalent (n=24, 85.7%) with tigecycline (7, 29.1%), ceftazidime/avibactam (6, 25%) and carbapenems (6, 25%) administered concomitantly. High dose fosfomycin (24 g/day) was used in 28.6% of cases. Doses adjusted for renal insufficiency were required in 46.4% of patients. Renal toxicity was reported in 3.6% of cases and electrolytes disorders in 21.4% of cases, neither resulting in fosfomycin discontinuation. Clinical success and mortality rates were 50% and 21.4%, respectively. Assessing outcomes according to microbiological susceptibility, clinical cure was achieved in 54% of patients with susceptible pathogens and 43% of resistant ones.

Conclusions: In this case series, intravenous fosfomycin had good in vitro activity against resistant Gram-negative pathogens mostly used in combination. Intravenous fosfomycin was safe. Fosfomycin was used primarily as salvage therapy for infections where there were few other treatment options.

Abstract 5830

**Cytomegalovirus in intensive care unit immunocompetent patients: mortality and clinical aspects**

Adrian Lazo¹, Carlos Ramírez ²*, José Castro¹, Teresita Somogyi¹, Juan Villalobos¹, Luis Montero¹, Rolando Arguedas¹

¹Costa Rica, Hospital Mexico, San José, Costa Rica

**Background:** A controversial point nowadays is whether to treat or not the critically ill patient who has Cytomegalovirus (CMV) replication, since there are different opinions and no consensus about whether treatment generates a benefit in prognosis. In Costa Rica, the CMV seroprevalence is around 90%. The aim of this study is to evaluate the clinical characteristics of CMV infection in the immunocompetent population of the medical and neurointensive care units and to determine the intensive care unit (ICU) and 30-day mortality.

**Materials/methods:** An observational, descriptive and retrospective cohort was undertaken in Costa Rica´s Mexico Hospital, from April 2019 to October 2019. No sample calculation was performed, since all the patients meeting the inclusion criteria during this period of time were included. The quantitative real-time PCR detection of CMV DNA was detected using Qiagen Artus PCR Kits. All patients with viral load above 1000 copies/mL (3.2 log10 IU/mL) received antiviral therapy.

**Results:** A total of 37 patients were included. Pneumonia (29.7%), neurosurgical procedure (24.3%) and Diabetes mellitus II (24.3%) were the most frequent comorbidities. The mean SOFA score was 8 and the APACHE II score of 19. The incidence of CMV viremia was 16% (n=6) and the mean age was 47.9 years old. The mean viral load at which treatment was initiated was 9217 copies/mL (4.18 log 10 UI/mL). The clinical features associated with positive viremia were the use of steroids (p=0,011, 95% CI), diagnosis of sepsis or septic shock at admission (p = 0,003, 95% CI), Pa/FiO2 ratio of 120 (p <0,001) and ICU length stay of 51,7 days (p<0,001). There was no statistical difference in ICU (p=0,74) and 30-day mortality (p=0,66) between the patients with or without CMV replication.

**Conclusions:** Despite the presence or not of viral replication, the mortality was not different between both groups. One possible cause is that the treatment with ganciclovir equalized the outcome of this patients. Further studies are needed to compare patients with and without treatment.

Abstract 5831

Safety and efficacy of triazole use for prophylaxis and treatment of invasive fungal diseases in patients receiving gilteritinib, a novel tyrosine kinase inhibitor for the treatment of acute leukaemias

Muneerah Aleissa*, Marlies Luskin1,2, Bashayer Alshehri1, Houry Leblebjian3, Anne Mcdonnell1, Francisco Marty1,2

1Brigham and Women’s Hospital, Boston, United States, 2Dana-Farber Cancer Institute, Boston, United States

Background: Gilteritinib is a novel selective oral tyrosine kinase inhibitor approved for the treatment of relapsed or refractory acute myeloid leukemia with FMS-like tyrosine kinase 3 (FLT3) mutation. Because gilteritinib is primarily metabolized via CYP3A, concomitant use of gilteritinib with strong CYP3A inducers or inhibitors is not recommended. Pharmacokinetic analyses have shown that itraconazole and fluconazole increased gilteritinib’s Cmax and area under the curve when administered concomitantly. We sought to evaluate the safety and efficacy of concomitant gilteritinib and triazole therapy in patients with hematological malignancies.

Materials/methods: We included all patients with acute leukemia who received ≥1 dose of gilteritinib with or without triazole therapy at Brigham and Women’s Hospital and Dana-Farber Cancer Institute between 28Nov2018 – 27Nov2019. The primary outcome was the number of patients who experienced any potential gilteritinib-related adverse events in the concomitant gilteritinib and triazole group compared with the gilteritinib group. Secondary outcomes include clinical outcomes of gilteritinib therapy, incidence of gilteritinib discontinuation, and 90-day mortality.

Results: Twenty-seven patients were included in the study. Twenty patients (74%) had a history of allogeneic hematopoietic-cell transplantation. The median starting dose of gilteritinib was 120 mg/day with a median duration of 135 days (IQR, 71-225). Fifteen patients (55.5%) received concomitant triazole therapy with fluconazole (8), isavuconazole (5), posaconazole (1), or voriconazole (1). Nine patients (33%) received triazole therapy for treatment of suspected or confirmed pulmonary or sinus IFD, or mucosal candidiasis, and 6 patients (22%) for antifungal prophylaxis in the setting of concurrent graft-versus-host disease. Median time of concomitant gilteritinib and triazole therapy was 72 days (IQR, 14-171). Two patients (13.3%) who received concomitant gilteritinib and triazole therapy had their gilteritinib dose reduced due to initiating triazole therapy or renal impairment. The number of patients who experienced any gilteritinib-associated adverse events [100% vs 75%; p=0.08] and 90-day mortality [26.7% vs. 8.3%, p=0.34], in the gilteritinib-triazole group was numerically higher compared to the gilteritinib group, likely due to baseline comorbidities.

Conclusions: This preliminary analysis suggests that concomitant gilteritinib and triazole therapy is feasible without routine dose reductions when required for clinical care and not associated with clinically-meaningful increase in adverse outcomes.

Impact of different antimicrobial exposures on the gut microbiome and resistome characterised by metagenomic sequencing

Leon Peto*1,2, Nicola Fawcett1,2, Tim Peto1,2, Derrick Crook1,2, Martin Llewelyn3,4, A. Sarah Walker1,2

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2National Institute for Health Research (NIHR) Health Protection Research Unit on Healthcare Associated Infections and Antimicrobial Resistance, John Radcliffe Hospital, Oxford, United Kingdom, 3Brighton and Sussex Medical School, Department of Global Health and Infection, Brighton, United Kingdom, 4Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom

Background: Selection of antimicrobials is guided in part by perceived differences in the extent to which they disrupt the gut microbiome and select for antimicrobial resistance. However, there is a lack of clinical data quantifying this disruption and comparing different antimicrobials. Comparative data could promote stewardship by focussing prescribing on less disruptive antimicrobials.

Materials/methods: Single stool samples were collected from healthy volunteers and patients at Oxford University Hospitals, UK, and data on antimicrobial exposure from electronic records. Metagenomic sequencing was performed with Illumina HiSeq at 3.5 million reads/sample. MetaPhlAn2 was used for taxonomic classification. Resistance gene detection was performed with ARIBA using the CARD database.

We considered associations with Shannon diversity in multivariable regression models. The proportion of the past week in which patients received each antimicrobial was used as the primary exposure, simultaneously for each antimicrobial received by >5 participants, adjusting for age, sex, participant type, and measures of comorbidity and acute illness. We also considered log relative abundance of specific taxa and classes of resistance genes.

Results: Data were available from 225 participants; 33 (15%) healthy volunteers and 192 (85%) inpatients. 119 (53%) had received antibiotics in the past week.

Exposure to several antibiotics was associated with substantially lower diversity, including piperacillin-tazobactam (-1.7 if received continuously for the last week, [95%CI -2.2 to -1.2], p<0.001), meropenem (-1.1, [-1.7 to -0.5], p<0.001), intravenous co-amoxiclav (-1.3, [-2.2 to -0.3], p=0.008), oral co-amoxiclav (-0.7, [-1.1 to -0.2], p=0.004), and oral ciprofloxacin (0.9, [1.9 to 0.0], p=0.05).

In contrast, antibiotics associated with minimal changes in diversity included doxycycline (+0.5, [-0.5 to 1.5], p=0.4) and gentamicin (+0.1, [-0.7 to 0.9], p=0.8). No antifungal or antiviral was associated with a significant change in diversity.

Meropenem, piperacillin-tazobactam and ceftriaxone significantly increased the relative abundance of Enterococcus faecium, and also the vanA glycopeptide resistance gene, but decreased Enterobacteriaceae (as did ciprofloxacin).

Conclusions: Our data provide simultaneous quantification of gut microbiome disruption by many different antimicrobials in the same study. The disruptive effect of some broad-spectrum beta-lactams contrasts markedly with several less disruptive antimicrobials. Larger studies using this approach would allow accurate comparison between even the more disruptive antimicrobials, and could greatly aid stewardship.

Abstract 5834

Evaluation of antimicrobial susceptibility testing assays for ceftazidime-avibactam and ceftolozane-tazobactam with Gram-negative bacteria directly from positive blood culture on the Pheno system

Niels Oppermann¹, Anyangatia Ndobegang¹, Aaron Sikorski¹, Aimee Taku¹, Dulini Gamage¹, Christina Chantell¹, Romney Humphries*¹

¹Accelerate Diagnostics, Inc., Tucson, United States

Background: New antibiotics recently FDA-approved for multidrug-resistant organisms include: ceftolozane-tazobactam (C/T), a compound with activity against multidrug-resistant *Pseudomonas aeruginosa* and ceftazidime-avibactam (CZA), a beta-lactam/beta-lactamase inhibitor compound with activity against class A and D carbapenemase-producing organisms. AST performance for these compounds with Enterobacterales and *P. aeruginosa* directly from positive blood culture (PBC) was evaluated using the Accelerate Pheno™ system, compared to broth microdilution (BMD).

Materials/methods: 294 clinical isolates (100 *P. aeruginosa*, 82 *Klebsiella* spp., 56 *E. coli*, 24 *Citrobacter* spp., 15 *Proteus* spp. and 3 *S. marcescens*) were tested with CZA and C/T. Aliquots of BD BACTEC™ Standard Aerobic media containing healthy donor blood were seeded with 10-100 bacterial cells and incubated until positivity. PBC aliquots were run using the Accelerate PhenoTest™ BC kit on the Accelerate Pheno™ system according to manufacturer instructions for use and results compared to BMD. Only samples with valid results from both methods were included in analysis. Essential agreement (EA), categorical agreement (CA), very major error (VME) and major error (ME) rates were calculated using EUCAST 2019 breakpoints.

Results: EA/CA for all antimicrobial/organism combinations were >90%. CZA had 1 VME and 6 ME. CZA does not have an intermediate range with *P. aeruginosa* and Enterobacterales, and 3 of 6 CZA ME were in EA. For C/T, there were 2 VME and 2 ME.

Conclusions: Results demonstrate the tests for CZA and C/T on the Accelerate PhenoTest™ BC kit are good. A limitation of this study is only 27 CZA-resistant organisms were tested. Further work will evaluate a larger number of resistant isolates.

**Abstract 5835**

**Two antibiotics are better than one: using functional genomics to elucidate mechanisms of action in combination therapy**

Geraldine Sullivan*, Ram Maharjan, Natasha Delgado, Amy Cain

1Macquarie University, North Ryde, Australia

**Background:** Antimicrobial resistance is a serious threat, with the 2014 O’Neill Report on antimicrobial resistance stating resistance-associated deaths worldwide are expected to rise to 10 million by 2050. The use of combinations of antibiotics in clinical and agricultural settings has been shown empirically to be effective, yet their precise mechanisms of action remain elusive. One of the most commonly used antibiotic combinations is trimethoprim and sulfamethoxazole (co-trimoxazole), first marketed in 1974. Despite its ubiquity in clinical settings, the mechanisms underlying its efficacy require further elucidation to improve treatment outcomes and predict trends in resistance to combination therapy. This project aims to identify genes responsible for synergistic antibiotic combinations, using *E. coli* as a model organism.

**Materials/methods:** Minimum and fractional inhibitory concentrations (MICs and FICs) were determined following the Clinical and Laboratory Standards Institute guidelines for antimicrobial susceptibility testing. The functional genomics technique TraDIS (transposon directed insertion-site sequencing) was used in *E. coli* K12 MG1655 to identify all genes that convey altered fitness in the presence of antibiotics individually or in combination at sub-inhibitory concentrations (¼ MIC/FIC).

**Results:** A dense library of random *E. coli* mutants was constructed using a Tn5 transposon yielding 340,000 unique mutants (1 insertion site per 13 bp). Challenges against the mutant library identified genes involved in survival under antibiotic stress. These included expected resistance genes (e.g. efflux pumps *acrAB/tolC*), as well as novel resistance modifiers. Genes with increased insertions, i.e. sensitivity genes and negative regulators, such as *aroK* and the sulfurtransferase complex *tusBCD*, helped identify novel interaction pathways (e.g. amino acid synthesis pathways). Confirming the roles of these genes with the KEIO collection knockouts allowed us to validate key findings in an *in vivo* context.

**Conclusions:** These genes can be used to finally understand mechanisms of action of an important antibiotic combination therapy, ultimately helping to improve treatment with antibiotic combination and also mitigating adverse side effects.

Abstract 5836

**Evaluation of the clinical economic efficacy of the antibiotic therapy of inpatients with community-acquired pneumonia**

Anna V. Demchuk*, Yuriy Mostovoy

1National Pirogov Memorial Medical University, Vinnytsya, Propedeutic department to internal medicine, Vinnytsia, Ukraine

**Background:** The economic evaluation of effectiveness of antibiotic treatment community-acquired pneumonia (CAP) has great importance. In routine medical practice, antibacterial therapy does not always meet the guidelines, which can lead to failure in the treatment of CAP and increase its cost. We analyzed the clinical and economic efficacy of antibiotic combinations, most commonly administered to patients with CAP, according to their compliance with guidelines.

**Materials/methods:** The observational study of 438 inpatients with CAP (male 231 (48.6%), mean age 56.1±1.79) was performed. Most of patients (399 (91.1%)) had moderate severe CAP and 39 (8.9%) – severe CAP. We assessed CAP outcome (recovery – success, without recovery - failure), compared direct cost, cost-effectiveness index (CE), incremental coefficient for recommended by guidelines and not recommended antimicrobial therapy.

**Results:** Adherence to the recommendations was accompanied by significantly higher efficacy compared to not recommended antibiotics (74.2% [132 patients out of 178] versus 73.5% [191 patients out of 260], p = 0.013). Combination of ceftriaxone or co-amoxicillin with clarithromycin was most advantageous clinically and economically (CE were lowest - UAH 25.13 % and UAH 28.90 %, respectively). Levofloxacin were economically least profitable (CE - 32.24 UAH %). In the case of severe CAP, the combination of meropenem, levofloxacin and amikacin (CE ratio of 44.36 UAH %) was at 1.5 times most economical than levofloxacin with beta-lactams [64.69 UAH %]. Non-compliant antibiotic therapy was characterized by using ceftriaxone with levofloxacin for patients with moderate severe CAP (CE 25.31 UAH %). Incorrect using amikacin, combinations of levofloxacin + ceftriaxone + amikacin or macrolide for patients with moderate severe CAP resulted in clinical failure in 7 (63.6%) patients and 12 (44.4%) patients, respectively, and the highest economic cost – (amikacin - 59.56 UAH %, combination of 3 antibiot-ics - 70.39 UAH %). The incremental coefficient was 409.31 UAH of the additional cost of treatment recommended in national guidelines compared to the non-recommended one.

**Conclusions:** The CE analysis of the recommended and non-recommended antibiotic regimens confirmed the higher clinical and economic feasibility of choosing the appropriate to guidelines therapy.

Septic shock and age are risk factors for mortality in bacteraemia by multidrug-resistant pathogens in a Brazilian cohort of critical patients

Luciana Campos¹, Camila Rizek², Marina Farrel Côrtes², Sânia Santos², Ana Paula Marchi², Katia Gonçalves¹, Silvia Figueiredo Costa*²

¹Hospital Municipal José Carvalho Florence, São José dos Campos, Brazil, ²University of São Paulo, São Paulo, Brazil

Background: multidrug-resistant bacteria (MDR) is an established public health threat and bloodstream infection by these agents is associated with high mortality. We aim to identify the risk factors for mortality in patients with MDR organisms bacteraemia hospitalized in an Intensive Care Unit (ICU) in a Brazilian trauma reference hospital during an 18 month period.

Materials/methods: in this observational cohort study, during the period of May 2017 to August 2018, all patients admitted in the ICU with the first episode of bacteraemia by the following MDR organisms - carbapenem resistant Gram negative bacteria, methicillin resistant *S.aureus* (MRSA) and vancomycin resistant enterococcus - had clinical and demographic data collected in order to investigate if any of these measurements were associated with death. Data were compared among the patients who survived and died and variables with p < 0.05 were analyzed in a logistic regression model using stepwise forward to identify risk factors for death. The isolates of *K.pneumoniae* e MRSA were investigated for carbapenemase production and presence of mec gene, respectively.

Results: 1528 fulfilled the inclusion criteria; 66 patients had bacteraemia by a MDR pathogen and 77.27% died during hospitalization. Age, systemic hypertension, quick SOFA score, Pitt bacteremia score and septic shock were associated with mortality. Trauma and bacteraemia by MRSA showed a tendency to be protective factors and were not associated with mortality. In the multivariate analysis, age (OR 1.08 CI95% 1.0 – 1.16; p 0.03) and septic shock (OR 27.82 CI95% 2.36 – 326.9; p 0.0082) remained independently associated with death. Prescription of antibiotics with in vitro activity against these agents in less than 24 hours was not associated with survival. We identified 71 isolates: 26 (36.82%) *K.pneumoniae* and 27 (40%) MRSA. 83.8% of *K.pneumoniae* strains were positive for KPC and all MRSA carried mecA gene.

Conclusions: age and septic shock were independent risk factors for mortality in patients with bacteremia by MDR organisms in a Brazilian ICU with a very high mortality where the predominant agents were *S.aureus* and *K.pneumoniae*. The better outcome of bacteremia by MRSA could be explained by the existence of an effective available treatment.

Evaluation of a culture surveillance application for the detection of methicillin-resistant Staphylococcus aureus in the clinical setting

Michael Bois 1, Erin Mcelvania 2, Mike Gosnell 1, Cédrick Orny 3, Volle Jean-Marc 1, Jaap Lemstra 4, Mariska Van Der Lei 4*, Raphael Marcelpoil 3

1 Becton Dickinson and Company, Sparks Glencoe, United States, 2 NorthShore University HealthSystem, Evanston, United States, 3 Becton Dickinson and Company, Pont de Claix, France, 4 Becton Dickinson and Company, Drachten, Netherlands

Abstract third-party references: Becton Dickinson and Company

Background: The currently available BD Kiestra™ platform offers a modular approach to automating the clinical microbiology laboratory, including specimen processing, plate inoculation, streaking, image acquisition, and automated analysis of images by a suite of imaging applications. The aim of this study was to demonstrate the performance of the BD BBL™ CHROMagar™ Surveillance Application (CSA) for the detection of growth and colony color for Methicillin-Resistant Staphylococcus aureus (MRSA) on chromogenic media.

Materials/methods: Six hundred and thirty nine (639) isolates from de-identified, remnant anterior nares specimens from NorthShore University HealthSystem were processed on BD BBL™ CHROMagar™ MRSA II (CHROM MRSA) plates for detection of growth and color associated with the presence of MRSA. Plates were imaged using the BD Kiestra™ ReadA Compact and Optis™ imaging software. All 18-24 hour images were manually reviewed by two microbiologists for growth and presence of color consistent with MRSA. For discrepant results, a third reader served as an arbitrator. BD CSA algorithm results were determined for growth versus no growth, and presence or absence of color consistent with MRSA for comparison to manual image reading results.

Results: Of the 639 samples, 37.8% (n=242) were growth positive with an observed MRSA prevalence of 94.6% (n=229). The application demonstrated a 95% [0.934 – 0.966] accuracy for growth detection with a positive predictive accuracy rate of 99.2% [0.979 – 1.000]. The MRSA CSA was able to detect color consistent with MRSA for 98.7% (n=228) of the growth positive samples, demonstrating a positive predictive accuracy rate of 99.6% [0.986 – 1.000].

Conclusions: The MRSA CSA can help differentiate between growth positive and negative CHROM MRSA plates, with capabilities to further discriminate plates with growth consistent with the presence of MRSA. Typically, approximately 80% of MRSA surveillance samples will be growth negative in the clinical setting. The MRSA CSA may help streamline workflows in the clinical laboratory, automatically segregating growth negative cultures, preventing laboratorians from spending time screening negative cultures, and enabling microbiologists to focus on tasks that require their expertise.

Impact of rapid antimicrobial susceptibility testing on antimicrobial stewardship and clinical outcomes of patients with Gram-negative rod bloodstream infection

Catherine Hogan*1,2, Bertrand Ebunji1,3, Nancy Watz2, Kristopher Kapphahn4, Joseph Rigdon4, Emily Mui5, Lina Meng5, William Alegria2, Marisa Holubar5,6, Stan Deresinski5,6, Niaz Banaei1,2,6

1Department of Pathology, Stanford University School of Medicine, Stanford, United States, 2Clinical Microbiology Laboratory, Stanford Health Care, Stanford, United States, 3Meharry Medical College, Nashville, United States, 4Quantitative Sciences Unit, Stanford University School of Medicine, Stanford, United States, 5Department of Quality, Patient Safety and Effectiveness, Stanford University School of Medicine, Stanford, United States, 6Division of Infectious Diseases and Geographic Medicine, Department of Medicine, Stanford University School of Medicine, Stanford, United States

Background: Clinical justification for rapid antimicrobial susceptibility testing (AST) in patients with Gram-negative rod (GNR) bacteremia is compelling; however, supporting empirical evidence is sparse. We investigated the impact of rapid AST for GNR bacteremia on initiation of appropriate antimicrobial therapy, de-escalation of antibiotics, and patient outcomes in a real-world clinical setting.

Materials/methods: We performed a before and after quasi-experimental study from February 2018 to July 2019 at a tertiary hospital to assess the clinical impact of the continuous implementation of the direct VITEK®2 AST method for GNR bacteremia coupled with real-time, electronic isolate-specific de-escalation comments, and antibiotic stewardship program (ASP) intervention during regular working hours. The primary outcome was time from positive blood culture Gram stain to appropriate antibiotic escalation or de-escalation (hazard ratio 1.41; 95% CI 1.07-1.87; p=0.01), with median times of 46.0 (IQR 32.4-64.6) vs 31.8 hours (IQR 23.3-54.9). There was no significant difference in median time to oral antibiotic step-down (56.2 vs 49.3 hours), hospital length-of-stay (96.1 vs 115.2 hours), 30-day all-cause mortality (7.1 vs 4.8%), 7-day acute kidney injury incidence (17.3 vs 13.1%) and 30-day C. difficile infection (2.1 vs 1.8%).

Conclusions: Rapid AST in GNR bacteremia led to improved stewardship measures but did not impact LOS and other clinical patient outcomes. These results highlight that other variables in addition to the timing of AST result contribute to clinical outcomes and warrant further investigation to identify interventions that justify rapid AST implementation.

Abstract 5851

Outcomes of scaling down vancomycin-resistant Enterococcus surveillance in a tertiary hospital in Singapore
Isaac Low1, Emily Xier Yeo2, Hwang Ching Chan1, Revathi Sridhar1, Dale A. Fisher1,3, Natasha Bagdasarian*1,3

1National University Hospital, Singapore, Singapore, 2Alexandra Hospital, Singapore, Singapore, 3National University of Singapore, Singapore, Singapore

Abstract third-party references: National University Hospital [Singapore]

Background: Infection prevention priorities at National University Hospital, a 1200-bed hospital in Singapore, were re-evaluated due to a growing issue with gram-negative resistance, in the face of relatively stable Vancomycin-resistant Enterococcus (VRE), and Methicillin-resistant staphylococcus aureus rates. This led to a scaling down of active surveillance measures for VRE starting in 2017. This study aims to assess the impact of reducing these VRE surveillance measures.

Materials/methods: A retrospective review was conducted using surveillance data collected between January 2015 and September 2019. The data was divided into three periods: “pre-transition” (January 2015 to December 2016), “transition” (January 2017 till March 2018), and “post-transition” (April 2018 to September 2019). During the transition period, the hospital VRE surveillance policy was amended – contact tracing ceased, and screening criteria were revised. Epidemiological analysis was conducted to compare trends in positive screens and infections. An audit in September 2019 was done to assess compliance to revised surveillance policies.

Results: 233 VRE cases pre- and post-transition were analyzed. After scaling down surveillance measures, the average number of screening samples per month reduced from 359 to 172, but rate of VRE carriers detected through screening increased from 9.29 per 1,000 screens to 18.2 per 1,000 screens. An audit on September 2019 on a sample of 53 hospital-wide VRE screens showed that 12 (22%) screens were inappropriate. There was an increase in VRE infections in the post-transition period: 34 cases pre-transition to 44 post-transition cases post-transition, or from 0.46 to 0.79 cases per 10,000 patient days, rate ratio (RR) 1.70 (95% Confidence Interval (CI) 1.06 to 2.74). However, hospital onset VRE bacteremia remained essentially unchanged: 6 pre-transition cases versus 5 post-transition cases, or 0.08 versus 0.09 per 10,000 patient days, RR 1.09 (CI 0.26 to 4.30).

Conclusions: Scaling down VRE surveillance has improved VRE screening efficiency, though this could be further improved with better compliance to revised screening practices. While no significant increase in VRE bacteremia incidence was noted, further follow up will be required to ensure that rates of VRE infection remain stable after scaling down of VRE surveillance practices.

**Evaluation of an investigation-use-only prototype of the BIOFIRE FILMARRAY Blood Culture Identification 2 (BCID2) panel for detection of bacteria, yeast, and antimicrobial resistance markers from positive blood cultures**

Alexandra Vasilakopoulou, Aikaterini Tarpatzi, Sophia Vourli, Paraskevas Tsilikis, Yang Lu, Kristen Holmberg, Usha Spaulding, Kerrin Koch, Alexandra Alvanidi, Nikoletta Koumasi, Spyros Pournaras

1Athens Medical School/Attikon University Hospital, Clinical Microbiology Laboratory, Athens, Greece, 2BioFire Diagnostics LLC, Salt Lake, UT, United States

**Background:** Bacteremia and candidaemia are important causes of mortality in the hospital. Rapid identification of pathogens and resistance genes from positive blood cultures (PBCs) can help in the early selection of appropriate antimicrobial therapy. The Investigation-Use-Only (IUO) BioFire FilmArray Blood Culture Identification 2 (BCID2) Panel (BioFire, Salt Lake City, UT) simultaneously detects 33 pathogens and 10 resistance genes in approximately one hour. The performance of the BCID2 Panel during a prospective evaluation study is compared to standard of care (SoC), as well as to independent PCR comparator assay (compPCR) results.

**Materials/methods:** Eighty-four aerobic and anaerobic de-identified PBCs from 84 patients with at least one gram-negative bacterium or fungus detected by Gram stain were tested using the BCID2 Panel. SoC included culture, standard biochemical identification and antimicrobial susceptibility testing (AST) of pathogens. Aliquots of residual PBCs and isolates were frozen for compPCR testing and discrepancy resolution. Sensitivity/positive percent agreement (PPA) and specificity/negative percent agreement (NPA) were determined for each BCID2 Panel analyte as compared to SoC.

**Results:** The BioFire BCID2 Panel results matched SoC results in 162/171 detections. The nine results that were initially categorized as false-positives were favorably resolved by compPCR as true-positives. Sensitivity/PPA and specificity/NPA of the BCID2 Panel with SoC identification methods were 97.9% and 99.8%, respectively. Twelve out of 13 Candida were identified by the BCID2 Panel (5 Candida albicans, 4 Candida parapsilosis, 2 Candida krusei, 1 Candida tropicalis) while only 1 case of Candida lusitaniae remained unidentified since it is not included in the panel's analytes. Six Enterobacterales species that exhibited resistance to 3rd generation cephalosporins by SoC, were correctly detected as CTX-M positive by the BCID2 Panel. Furthermore, eight Enterobacterales species resistant to carbapenems tested positive for carbapenemase genes (4 KPC, 3 VIM, 1 NDM) by the BCID2 Panel.

**Conclusions:** The BCID2 Panel with its new expanded menu has exhibited high sensitivity and specificity for pathogen identification. Consequently, the BioFire BCID2 Panel is expected to provide rapid and accurate results for key pathogens, as well as important antimicrobial resistance genes. Data presented are from assays that have not been cleared or approved for diagnostic use.

Clinical impact of metagenomics next-generation sequencing in patients with suspected central nervous system infection: a real-world study

Qiran Zhang*, Jingwen Ai, Wenhong Zhang

1Huashan Hospital, Department of Infectious Diseases, Shanghai, China

Background: Previous studies have already shown metagenomics next generation sequencing (mNGS) can enhance pathogen identification in central nervous system (CNS) infection. However, it has not been assessed yet whether mNGS results convinced the clinical practitioners and had impact on clinical decisions in real world.

Materials/methods: We conducted two prospective cohorts of patients with suspected CNS infection at admission, to investigate the impact of the mNGS on diagnosis, management and clinical outcomes. In the mNGS-assisted cohort, a total of 220 patients had their CSF specimens tested in parallel by mNGS and culture, and also other diagnostic tests decided by practitioners. The mNGS results were provided to clinical practitioners in 72 hours, and the results of culture or other laboratory tests were also provided as soon as they came out. In the control cohort, a total of 86 patients had CSF specimens tested in exclusively conventional diagnostic assays, and the patients included were 1:2 paired with NGS-assisted cohort in diagnosis. No intervention was given to either cohorts. Medical records were reviewed retrospectively to collect information including the final diagnosis, initial regimen selection and adjustment, length of stays and clinical outcomes.

Results: Within 81 mNGS positive results, 57 (70.4%) detected pathogens were considered as culprits of CNS infections. All these patients had their diagnosis supported or guided by mNGS results, but only about 1/3 (24, 29.6%) had therapy adjustment guided by mNGS. Within 139 mNGS negative results, 44 (31.7%) supported final diagnosis as non-infection CNS disorders. Only 12 (8.6%) had therapy adjustment based on the negative mNGS results. Compared with the control cohort, the mNGS-assisted cohort showed a shorter median length of stays (18 days vs 23 days, P<0.001), but the mortality was similar (P =0.93).

Conclusions: For suspected CNS infection cases, positive results of mNGS were frequently considered meaningful and had significant impact on diagnosis in practice, but negative results of mNGS were less relied on. The impact on therapy adjustment was limited. The mNGS results contributed to a shorter length of stay, but had no significant impact on patient outcomes.

A case of sepsis from a novel pathogen: Haematospirillum jordaniae

Pavan Annamaraju1, Scott Wade2, Bharath Raj Varatharaj Palraj*3

1Loma Linda University School of Medicine, Loma Linda, United States, 2Lynchburg General Hospital, Lynchburg, United States, 3Mayo Clinic College of Medicine and Science, Rochester, United States

Background: We report a case of sepsis from leg cellulitis caused by a novel pathogen Haematospirillum jordaniae

Materials/methods: A 69-year-old Caucasian man was admitted for progressive right leg swelling, pain, and erythema of seven-day duration. Four days before the onset of symptoms, he reported cleaning grass standing in brackish water at a lake. On arrival, he had fever, tachycardia, hypotension and was diagnosed to have sepsis from right leg cellulitis. No open wound or drainage was evident. Laboratory data showed leukocytosis. Blood cultures were drawn, and empiric intravenous vancomycin was initiated. At 48 hours, blood cultures showed no growth, and the antibiotic regimen was de-escalated to intravenous ceftriaxone. The patient continued to improve clinically with this therapy. On hospital day four, the blood cultures unexpectedly returned positive for a slow-growing gram-negative bacterium. The isolate could not be identified by hospital day six and, therefore, was sent to the reference laboratory (LabCorp, Burlington, NC, USA). The patient was discharged before the identification of the isolate, on oral ciprofloxacin and cefadroxil. Genetic sequencing of 16S rRNA identified the strain as Haematospirillum jordaniae. Antibiotic susceptibilities of the organism are shown in Table 1.

Results: Haematospirillum jordaniae, is a novel human pathogen, recognized as a new bacterial genus and species in 2016 by the Centers for Disease Control (CDC). So far, 15 human infections with H. jordaniae have been reported in the literature, with our patient being the 16th case. H. jordaniae is a gram-negative spiral-shaped aerobe in the family of Rhodospirillaceae. It’s a common environmental microbe rarely implicated as a human pathogen, as in our patient. There are concerns that slow-growing gram-negative rods identified in blood culture could be potential bioterrorism agents.

Conclusions: Haematospirillum jordaniae is a novel organism with pathogenic potential. Physicians should be aware of this organism and the need for genetic sequencing to identify this pathogen.

Table 1: Antibiotic susceptibilities of Haematospirillum jordaniae.

Comparing *Klebsiella pneumoniae* isolates from invasive infections versus carriage in Vietnam: genotypes and capsule types

Bich Vu Thi Ngoc*, Sylvain Brisse*, Kathryn Holt*, Huong Tran Thi Kieu2, Diep Nguyen Thi Ngoc2, Trinh Dao Tuyet1, Trung Nguyen Vu1, Hindrik Rogier Van Doorn2,7, Heiman Wertheim1

1Radboud University Medical Center, Nijmegen, the Netherlands, Nijmegen, Netherlands, 2Oxford University Clinical Research Unit and Wellcome Trust Major Overseas Programme, Vietnam, Hanoi, Vietnam, 3Institute Pasteur, Biodiversity and Epidemiology of Bacterial Pathogens, Paris, France, 4Centre for Systems Genomics, Department of Biochemistry & Molecular Biology, University of Melbourne, Melbourne, Australia, 5National Hospital Of Tropical Diseases, Hanoi, Vietnam, 6Hanoi Medical University, Hanoi, Vietnam, 7Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom

**Background:** *Klebsiella pneumoniae* (Kp) is an important cause of community-acquired blood stream infections in Asian countries. This study aims to compare the population structure and capsule types of Kp isolates from patients and healthy people in northern Vietnam.

**Materials/methods:** We characterized Kp isolates from patients with invasive Kp infection admitted to the National Hospital of Tropical Diseases, Vietnam between 2007 and 2011. We included 93 isolates from patients and 110 isolates from throat swabs from healthy volunteers living in the referral area of the hospital. We determined the sequence types by multi-locus sequence typing (MLST) and capsule typing by PCR. Susceptibility testing to antibiotics was performed by disk diffusion.

**Results:** The population structure of Kp in our study population was diverse. CG23 (63/203; 30%) was the most common clone in both invasive and carriage isolates (28/93, 30.1% versus 35/110, 31.8%, p=0.791). CG65 was significantly higher in invasive isolates (17/93, 18.3%, versus 6/110, 5.5%, p=0.004). In both invasive and carriage isolates, the most common capsule types were: K1 (39/203, 19.2%, mainly ST23) and K2 (29/203, 14.3%, multiple STs: ST65, ST86, ST380). We also detected 11 invasive isolates with capsule type K64, which had not been reported before. The resistance to Trimethoprim/Sulfamethoxazole (SXT) was 14.3%, to ciprofloxacin 3.4%, and imipenem 0.5%. We identified 15 (5.4%) ESBL – producing Kp, which included 11 invasive isolates.

**Conclusions:** In general, the population structure of Kp in our study population was diverse, with a remarkably high frequency of clone CG23 in carriage. Capsule type 64 is possibly a novel virulent capsule type but requires confirmation.

Abstract 5869

**Does herd immunity from conjugate vaccines alter the epidemiology of invasive pneumococcal disease in adults?**

Allison Mcgeer*1, Agron Plevneshi2, Kazi Hassan2, Wallis Rudnick3, Sarah Nayan1, Nataly Farshait4, Wayne Gold5, Kevin Katz6, Krystyna Ostrowska7, Jeff Powis8, Dan Ricciuto9, Debbie Yamamura10, Greg Tyrrell11

1University of Toronto - St. George Campus, Toronto, Canada, 2Sinai Health System, Toronto, Ontario, Toronto, Canada, 3Sinai Health System, Toronto, Canada, 4Humber River Hospital, Toronto, Canada, 5University Health Network, Toronto, Canada, 6North York General Hospital, Toronto, Canada, 7Trillium Health Partners - Mississauga Hospital, Mississauga, Canada, 8Toronto East Health Network, Toronto, Canada, 9Lakehead Health Oshawa, Oshawa, Canada, 10Hamilton Health Sciences - King West, Hamilton, Canada, 11Alberta Public Laboratories, Edmonton, Canada

**Abstract third-party references:** Toronto Invasive Bacterial Diseases Network

**Background:** There are many factors that affect the presentation and severity of pneumococcal disease. Several studies in the pre-conjugate vaccine era demonstrated that organism characteristics, including serotype, are associated with variability in disease presentation and severity. We undertook an analysis of population based surveillance for invasive pneumococcal disease (IPD) to assess whether herd immunity from PCVs will change the presentation and severity of IPD in adults.

**Materials/methods:** The Toronto Invasive Bacterial Diseases Network has performed population-based surveillance for IPD in Toronto and Peel region (pop’n 4.5M) since 1995. All sterile site isolates of *S. pneumoniae* are reported to a central study laboratory, isolates are serotyped, and clinical and vaccination data are collected via patient and physician interview and chart review. Population data are obtained from Statistics Canada. Backwards stepwise logistic regression assessed patient characteristics, illness features, and isolate factors associated with clinical presentation and case fatality.

**Results:** Between 1995 and 2018, 8815 episodes of IPD were identified in adults. Patients infected with PCV10not7 serotypes were younger, more likely male and without underlying illness. Patients with infections due to non-vaccine types were more likely to be immunocompromised. Case fatality in IPD declined from 177/754 in 1995/6 to 113/554 in 2017/8; OR 0.67, 95%CI0.51-0.86, P<.0001 and in all serotype groups (Figure). In multivariable models adjusted for host factors, relative to infections caused by PCV7 serotypes, those caused by PCV10not7 were less likely to be fatal (OR 0.65, 95%CI 0.46-0.91); those caused by PCV13not10 were more likely to be fatal (OR 1.6, 95%CI 1.3-1.9). Bacteremic pneumonia as a proportion of presentations is highest in IPD due to PCV10not7 and PCV13not10 serotypes (85% and 83%, respectively), and lowest in IPD due to non-vaccine serotypes and PCV20not15 (59% and 68%, P<.0001). Meningitis is least common in IPD due to PCV10not7 serotypes (2.6%), and highest in cases due to non-vaccine types and PCV20not15 (9.0% and 8.0%, respectively, P<.0001).

**Conclusions:** In our population, herd immunity from PCVs will result in a higher proportion of adult IPD occurring in immunocompromised cases, and a shift from bacteremic pneumonia to bacteremia without focus and meningitis.

**Abstract 5873**

**A novel plasmid-mediated RND family efflux pump confers tigecycline resistance in Klebsiella pneumoniae**

Shijun Sun*, Hua Gao, Yudong Liu, Longyang Jin, Ruobing Wang, Xiaojuan Wang, Qi Wang, Hui Wang

1Peking University People’s Hospital, Beijing, China

**Background:** Colistin and tigecycline are considered the last-resort antimicrobials, especially for treating infections involving multidrug-resistant *K. pneumoniae*. To date, the plasmid-mediated colistin resistance gene (*mcr*) has spread to a global scale, while it remains unclear the machnisms of tigecycline resistance in *K. pneumoniae* except for the recently reported *tet(X3)* and *tet(X4)*.

**Materials/methods:** A total of 14 tigecycline-resistant *K. pneumoniae* with unknown resistance mechanisms were identified by screening of 199 tigecycline-resistant *K. pneumoniae*. Whole genome sequencing and bioinformatics analysis were performed to investigate the unknown resistance mechanisms. Transconjugants experiment was utilized to test the transferrability of the novel tigecycline resistant plasmid.

**Results:** A novel plasmid-mediated tigecycline resistance gene, an RND family efflux pump pmexAB-oprY, which has never been reported in *K. pneumoniae* was identified. This pump was found to be co-existed with other resistance genes such as *mcr* and *blaNDM*. Interestingly, *pmexAB-oprY* co-existed with *mcr-8* in the same plasmid were identified in 4 strains. Importantly, the plasmid co-harboring *pmexAB-oprY* and *mcr-8* was able to transfer to the recipient strains, leading to a significant increase in the resistance to colistin and tigecycline. Bioinformatics analysis suggested that the *pmexAB-oprY* efflux pump was transferred to *Klebsiella pneumoniae* by *tnS393*.

**Conclusions:** Our findings revealed a novel mechanism in tigecycline-resistant *K. pneumoniae*, highlighting an urgent need for global efforts to control the spread of these resistant genes.

Impact of safety alerts and warnings on fluoroquinolone and alternative antibiotic use in Colombian outpatient care
Melissa Silva-Medina Weil*, Pawell Ricardo1, Mauricio Palacios1
1Universidad Del Valle, Cali, Colombia

Background: Fluoroquinolones have been associated to several adverse drug effects and have been the object of various FDA warnings and an EMA suspension and restriction report. In Colombia FDA warnings are widely spread among healthcare personnel.

Materials/methods: The objective of this study was to evaluate the impact of FDA and EMA warnings in the outpatient fluoroquinolone use and on the use of alternative antibiotics. Information about dispensation of outpatient antibiotics from 2015-2019 pertaining 3 Colombian public health insurance companies was obtained. Variables collected were: number of formulas, number of patients, DDD (defined daily doses) dispensed and number of patients insured. DHD (DDD/100,000 inhabitants/day) were calculated. Antibiotics were categorized in groups and using monthly data the trends were analyzed. Annual averages were calculated and variability was assessed for fluoroquinolone and alternative outpatient antibiotics.

Results: Figure 1 shows the antibiotic use during the study period. Fluoroquinolone use decreased during the study period while alternative antibiotics had non significant variations. Annual average variability showed a 20% decrease in fluoroquinolone dispensation while the other antibiotics remained stable. However when antibiotic groups were analyzed separately urinary agents, cotrimoxazole and cephalosporins had an upward trend while tetracyclines, macrolides and aminoglycosides dispensation decreased. Penicillin/B lactamse inhibitor combinations increased alongside fluoroquinolone decrease but then the trend reverted.

Conclusions: Safety alerts are a warning system that allows changes in prescription trends as new evidence emerges about drug use. Several warnings regarding fluoroquinolones were edited during the study period and a downward trend in the use of this antibiotic is clear. Alternative outpatient antibiotics surprisingly showed no increase, perhaps owing to antibiotic stewardship that has had an impact in overall antibiotic use, though the use of several groups of antibiotics, particularly those with indication for UTI, increased associated to a decrease in fluoroquinolone use. Warnings and restrictions edited by international agencies seem to have an impact in the use of fluoroquinolones in outpatient care in Colombia.

Abstract 5878

Characterising the incidence and outcomes of endogenous endophthalmitis in hospitalised patients with Staphylococcus aureus bacteraemia

Lynn Wardlow*, Mohammad Mahdee Sobhanie

1The Ohio State University Wexner Medical Center, Columbus, United States

Abstract third-party references: The Ohio State University Wexner Medical Center

Background: Staphylococcus aureus bacteraemia (SAB) is a leading cause of morbidity and mortality in the United States with metastatic disease such as endocarditis and septic joint commonly reported. Ocular spread may occur in select circumstances, with recent literature describing Staphylococcus aureus as a major pathogen in cases of bacterial endogenous endophthalmitis (BEE). Given the need for directed therapeutic intervention and serious disease-related complications, this study sought to describe the incidence of SAB BEE and clinical outcomes in affected patients.

Materials/methods: This retrospective descriptive study included patients aged 18-89 years hospitalized with SAB at an academic medical center from November 1, 2011 to August 30, 2019. Prisoners were excluded due to protected status. Individuals with Ophthalmology service consults during a SAB-related admission underwent chart review to elucidate patient demographics, infection characteristics, ocular findings, and medical and surgical therapies provided. The primary outcome of this study was to determine the percentage of BEE cases in the entire SAB population.

Results: During the study time period, 2435 patients with SAB met inclusion criteria with 182 (7.5%) patient encounters paired with Ophthalmology service consultation. An infectious concern was listed as the reason for consult in 60.4% (n=110) of cases, with 21.4% (n=39) for concomitant fungemia as part of a care bundle. Twenty patients were given a diagnosis of BEE representing 11.0% of consults and 0.82% of the SAB population. The BEE cohort was predominately male (85%) with a median age of 51 years (IQR 36-60). Common comorbidities included diabetes mellitus (35%, n=7) and substance abuse disorder (25%, n=5). Median time to Ophthalmology service evaluation following presentation was 1 day (IQR 0-1.5). The primary source of SAB was endocarditis (30%, n=6). Vitreous and/or aqueous cultures were collected on all patients with organism growth in 25% (n=5). All patients received intravitreal and systemic antimicrobials. Five patients underwent vitrectomy and one patient required enucleation.

Conclusions: The incidence of BEE was low in a large cohort of hospitalized patients with SAB (0.82%). Larger studies evaluating BEE in all patients who present with SAB are required to further characterize the impact of this condition.

Evaluation of in vitro activity of new polymyxin B analog SPR206 against clinical multidrug-, colistin- and tigecycline-resistant Gram-negative bacilli

Yawei Zhang*, Chunjiang Zhao, Qi Wang, Xiaojuan Wang, Hongbin Chen, Henan Li, Feifei Zhang, Hui Wang

1Peking University People’s Hospital, Beijing, China

Background: SPR206 is a novel polymyxin analog that is active against multi-drug-resistant Gram-negative pathogens such as A. baumannii, P. aeruginosa and Enterobacteriaceae. The aim of the study was to assess activity of SPR206 against a diverse collection of isolates collected in China in 2016-17.

Materials/methods: A contemporaneous (2016-2017) collection of 200 drug-sensitive and multidrug-resistant (MDR), including carbapenem-resistant, tigecycline-resistant, and colistin-resistant clinical isolates of A. baumannii, P. aeruginosa, K. pneumoniae, E. coli, E. cloacae, and S. maltophilia were obtained from 50 centers across China. Isolates were derived from respiratory tract, urine, and blood samples, and purposely selected on a basis of phenotypes, genotypes, and specimen origins. MICs of SPR206 and other antimicrobials were determined and interpreted in accordance with CLSI.

Results: Except for colistin-resistant isolates, SPR206 displayed potent, broad spectrum antimicrobial activity against the Gram-negative clinical isolates tested. All colistin-resistant strains were also resistant to SPR206, with MIC\text{50/90} of 16/128 mg/L vs. 8/128 mg/L for SPR206 and colistin, respectively. SPR206 demonstrated potent activity against colistin-susceptible OXA-producing A. baumannii (MIC\text{50} 0.064/0.125 mg/L), NDM-producing Enterobacteriaceae (MIC\text{50} 0.125/0.25 mg/L), and KPC-2-producing Enterobacteriaceae (MIC\text{50} 0.125/0.5 mg/L). Indeed, SPR206 was the most potent agent assessed, exhibiting 2- to 4-fold greater potency than colistin and polymyxin B against A. baumannii, P. aeruginosa, and Enterobacteriaceae and 16- to 32-fold lower (MIC\text{50/90} 0.064/0.125 mg/L) than tigecycline (MIC\text{50} 2/2 mg/L) for tigecycline-susceptible carbapenem-resistant A. baumannii.

Conclusions: SPR206 showed potent in vitro activity against MDR (carbapenem-resistant and tigecycline-resistant) and non-MDR clinical isolates. Additionally, SPR206 exhibited in vitro antimicrobial activity comparable to or better than colistin and polymyxin B, with MIC\text{50/90} consistently 2- to 4-fold lower. These promising in vitro data suggest SPR206 could be an effective option for multidrug-resistant Gram-negative infections.

Risk factors for *Clostridioides difficile* infection among hospitalised patients in Brazilian centres: a multi-centre prospective study

Evelyne Girão*1, Bruno Tavares2, Cecilia Costa1, Daniele Viana1, Geovania Maciel1, Janete Romão4, Gessica Gamarra5, Camila Rizek2, Tatiana Orsi2, Sânia Santos1, Lauro Perdigao Neto1, Icaro Boszczowski6, Hugo Manuel Paz Morales7, Keite Nogueira6, Adriane Maestri8, Roberta Cristina Ruedas Martins5, Gerly Anne Brito1, Silvia Figueiredo Costa5

1Federal University of Ceará - UFC, Fortaleza, Brazil, 2University of São Paulo- USP, São Paulo, Brazil, 3Hospital Universitario Walter Cantidio, Fortaleza, Brazil, 4Hospital São José, Fortaleza, Brazil, 5University of São Paulo- USP, São Paulo, Brazil, 6Hospital Alemão Oswaldo Cruz, São Paulo, Brazil, 7Federal University of Paraná, Curitiba, Brazil, 8Federal University of Paraná, Curitiba, Brazil, 9Federal University of Ceará - UFC, Fortaleza, Brazil

**Abstract third-party references:** Pfizer and bioMerieux

**Background:** *Clostridioides difficile* infection (CDI) is the leading cause of health care-associated diarrhea worldwide. However, risk factors for CDI are not fully understood in Brazil.

**Materials/methods:** Prospective, multicenter study that evaluated the prevalence and risk factors for healthcare associated CDI in 5 Brazilian hospitals. Hospitalized patients >18 years with diarrhea (> 3 soft stools /24 hours) were included. All the samples were tested for glutamate dehydrogenase (GDH) and toxins A and B, using a rapid membrane enzyme immunoassay (*C. difficile Quick Chek Complete*), and for of toxin B gene (*tcdB*), binary toxin gene (*cdtA*), and deletion of 117 nucleotides in the *tcdC* gene, using the real-time polymerase chain reaction (PCR) kit (*Xpert C. difficile test, Cepheid*). Culture was also performed, and the identification was confirmed by matrix-assisted laser desorption/ionization mass spectroscopy (MALDI-TOF/MS). We performed whole genome sequencing (WGS) of the isolates. CDI case was defined as a positive ELISA test for toxins A and B or a positive PCR.

**Results:** From April 2018 to June 2019, 377 samples from 361 patients were included. The overall CDI prevalence was 15%. 94% of CDI patients received antibiotics in the past 3 months. Ceftriaxone, meropenem, vancomycin, piperacillin-tazobactam, ciprofloxacin and clindamycin were the most frequently used antimicrobials. Risk factors for CDI, by univariate analysis, was previous use of ceftriaxone (RR, 2.07; 95% CI, 1.14-3.78), meropenem (RR, 3.41; 95% CI, 1.83-6.35) and onset of diarrhea before hospitalization (RR, 4.38; 95% CI, 1.69-11.2). HIV infection (RR, 0.14; 95% CI, 0.01-1.04) and lung disease (RR, 1.12; 95% CI, 0.01-0.95) were factors of protection. Multivariate analysis identified as independent risk factors for CDI: age (OR, 1.01; 95% CI, 1.00-1.038) and previous use of meropenem (OR, 4.9, 95% CI, 2, 45-10.09). CDI patients had more mucus in stool (OR, 3.2; 95% CI, 1.36-7.57) and left shift with > 20% of rods (OR, 4.07; 95% CI, 1.37-12.04). The classical hypervirulent strains ST1/RT027 and ST11/RT078 were not identified in our cases.

**Conclusions:** The prevalence of CDI is 15% in our study. Independent risk factors associated with CDI in our study were age and previous use of meropenem.

Population pharmacokinetics of cefazolin in paediatric patients undergoing cardiac surgery

Suzanne Parker*1, Gregory Moloney2, Benjamin Bierbach3, Jacobus Ungerer4, Jessica Suna5, Nelson Alphonso6, Jason Roberts1

1UQ Centre for Clinical Research, The University of Queensland, Brisbane, 2Department of Anaesthetics, Queensland Children's Hospital, Brisbane, Australia, 3Asklepios Kinderklinik, Sankt Augustin, Germany, 4Department of Chemical Pathology, Queensland Health, Brisbane, Australia, 5Centre for Children's Health Research, South Brisbane, Australia, 6Mater Research Institute, The University of Queensland, Brisbane, Australia

Background: Limited data exist regarding pharmacokinetics of cefazolin in children undergoing cardiac surgery. This study aimed to describe the population pharmacokinetics of unbound cefazolin concentrations and assess the appropriateness of doses recommended for paediatric patients undergoing cardiac surgery.

Materials/methods: In a prospective observational study, paediatric (<16 years) patients undergoing cardiopulmonary bypass and receiving a 50 mg/kg bolus dose of prophylactic cefazolin, followed by 3-hourly intra-operative 25 mg/kg doses and 8-hourly post-operative 25 mg/kg doses received in the paediatric intensive care unit (PICU) were enrolled. Fourteen serial plasma samples were collected peri and post-operatively and used for measurement of unbound cefazolin concentrations by LC-MS/MS. A non-parametric population pharmacokinetic analysis was performed using Pmetrics® in R, with subsequent Monte-Carlo dosing simulations (n=1000) to estimate the probability of target attainment of 90% time above MIC (fT>MIC). The fractional target attainment (FTA) was estimated based on the EUCAST MIC distribution for Staphylococcus aureus.

Results: Sixty-six patients, including 23 neonates (25 female) with median (IQR) weight 6.2 (3.5 – 16.2) kg, albumin concentration 30 (22-47) g/L and serum creatinine 35.6 (30-97) µmol/L, were enrolled. A two-compartment model adequately described the concentration-time data for unbound cefazolin. Mean (SD) parameter estimates for cefazolin clearance 3.7 (2.2) L/h and 4.7 (3.3) L/h; Vc 6.2 (3.8) L and 7.2 (4.3) L for during surgery and while in the paediatric intensive care unit (PICU), respectively. The dose described in the protocol failed to achieve the 90% fT>MIC target (for MICs <2 mg/L) for FTA for patients <45 kg for up to 30 h after the commencement of surgery. Simulations found all patients receiving a 50 mg/kg bolus dose of prophylactic cefazolin, followed by 3-hourly intra-operative 25 mg/kg doses and 6-hourly post-operative 50 mg/kg doses received in the PICU were adequate to achieve 90% fT>MIC exposure for all patient weight ranges.

Conclusions: A 50 mg/kg bolus dose of prophylactic cefazolin, followed by 3-hourly intra-operative 25 mg/kg doses and 6-hourly post-operative 50 mg/kg doses is appropriate for achievement of target exposures for paediatric patients undergoing cardiopulmonary bypass.

Abstract 5894

**Delayed diagnosis and increased length of stay in patients requiring hospitalisation with influenza who present without fever**

Benjamin John Smith1, Mark Putland1, Bruce Garbutt1, Douglas Johnson1, Louis Irving1,2, Steven Y. C. Tong*,1

1Royal Melbourne Hospital, Melbourne, Australia; 2University of Melbourne, Melbourne, Australia

**Background:** Case definitions for influenza-like illness typically include fever. However, many patients who require hospitalisation with influenza will present without fever as part of their clinical syndrome. While the recently updated Infectious Diseases Society of America guidelines for seasonal influenza no longer require fever as part of their testing algorithm, the impact of fever or lack of fever on clinical decision-making and patient outcomes has not been studied.

**Materials/methods:** We conducted a retrospective review of adult patients admitted to our tertiary health service with laboratory-confirmed influenza within 72 hours of arrival between April 2016 and June 2019 who had been recruited as part of local influenza surveillance. Demographic and symptom data were linked to hospital database extracts containing patient comorbidities, diagnoses, and emergency department (ED) observations. Data were analysed using Pearson’s Chi-squared test, Wilcoxon rank-sum test, and multivariate logistic regression.

**Results:** Of 578 patients meeting inclusion criteria, 359 (62.1%) had fever, defined as a temperature greater than or equal to 37.8°Celsius, while in the ED.

Patients without fever had lower rates of testing for influenza in the ED (64.8% vs 77.2%, p = 0.002) and increased hospital length of stay (median 2.4 days, IQR 1.3 - 4.5) compared to those with fever (median 1.9 days, IQR 1.0-4.0).

Fever was less likely in individuals with age greater than 65 years (adjusted [a] OR: 0.37, 95% CI [0.25, 0.54]), a non-respiratory presentation (aOR: 0.44, 95% CI [0.25 - 0.76]), Influenza B infection (aOR: 0.45, 95% CI [0.29,0.72]), symptom duration of greater than two days (aOR: 0.53, 95% CI [0.36, 0.78]), chronic lung disease (aOR: 0.55, 95%CI [0.37, 0.81]), and female sex (aOR: 0.68, 95% CI [0.47, 0.98]).

Patients without fever were less likely to receive antiviral treatment (55.7% vs 65.6%, p=0.02) and more likely die in hospital (3.2% vs 0.6%, p=0.03) although the difference in mortality was not significant after adjustment for age and comorbidities.

**Conclusions:** Using case definitions including fever to identify patients with influenza in the hospital setting may lead to delays in diagnosis and poorer outcomes including lower rates of antiviral treatment and longer length of stay.

Quantitative detection of bacterial resistance by meropenem hydrolysis using MALDI-TOF MS

Camila Wilhelm*, Maiara Carneiro1, Priscila Wink1, Afonso Barth1

1Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Background: Carbapenem resistant bacteria (CRB) are considered the main problem, by the World Health Organization, regarding antimicrobial resistance. As the main resistance mechanism of CRB in Brazil is carbapenemase production, such as KPC and NDM, the development of rapid methods to detect these determinants of resistance is necessary. The aim of this study was to develop a quantitative methodology to rapidly detect bacterial resistance to meropenem by MALDI-TOF/MS among Klebsiella pneumoniae.

Materials/methods: Thirty-three isolates carrying blaKPC or blaNDM gene and 25 isolates without carbapenemase genes were evaluated. Detection of carbapenemase genes was performed by High Resolution Melting-PCR. Meropenem minimum inhibitory concentration (MIC) was determined for all isolates. The hydrolysis test was performed as follows: a 1 µL loopful of bacteria was suspended in a meropenem solution (1 mg/mL); the suspension was incubated at 37°C for 2 hours, centrifuged and the supernatant (1 µL) was spotted onto a MALDI-TOF/MS target plate; the spot was dried and overlaid with 1 µL of HCCA matrix. Spectra were obtained by a Microflex LT mass spectrometer (Bruker Daltonics) and peak analysis was performed using flexAnalysis 3.4. Intensities of the peaks at 384 m/z (intact meropenem molecule) and at 401 m/z (matrix) were compared to evaluate meropenem hydrolysis. Hydrolysis index (HI) was calculated as follows: HI = (Peak intensity 384 Test / Peak intensity 401 Test) / (Peak intensity 384 Control / Peak intensity 401 Control). HI close to zero indicates maximum hydrolysis; HI close to 1 indicates minimum hydrolysis. Escherichia coli ATCC 25922 was used as control (HI = 1).

Results: Twenty-three isolates were positive for blaKPC (KPC) and 10 for blaNDM (NDM) with MICs varying from 16 to >1 28 µg/mL; 12 isolates negative for carbapenemase genes had MICs ≤0.5 µg/mL (NegS) and 13 had MICs from 4 to 16 µg/mL (NegNS). All isolates with carbapenemase genes presented a HI <0.5 and the isolates without carbapenemase genes (NegS and NegNS) presented a HI >0.5 (Figure 1).

Conclusions: These preliminary results indicate that this technique is a promising quantitative method to detect meropenem resistance due to carbapenemase production.

Figure 1. Hydrolysis index of isolates according to carbapenemase presence and MIC.

**Abstract 5897**

**Hepatitis B virus epidemiology among chronic kidney disease patients under haemodialysis**

Livia Villar*, Ketlyn Araujo Fraga, Juliana Miguel, Elisangela Ferreira Da Silva, Bianca Leires Marques, Ana Carolina Da Fonseca Mendonça, Lia Laura Lewis-Ximenez

1Fiocruz, Oswaldo Cruz Institute, Rio de Janeiro, Brazil

**Background:** Hepatitis B virus (HBV) can be transmitted through the parenteral route and the group of patients with chronic kidney disease (CKD) undergoing hemodialysis (HD) treatment is more vulnerable to infection due to increased exposure to invasive procedures. The objective of this study was to evaluate the prevalence of HBV infection markers in serum samples from patients with CKD in HD from the Southeast region of Brazil.

**Materials/methods:** A total of 644 patients with CKD underwent regular HD in dialysis units located in Rio de Janeiro State were recruited from 2013 to 2017. Samples were tested for HBsAg, anti-HBs and anti-HBc using commercial immunoenzymatic assays. HBsAg reactive or anti-HBc isolated samples were subjected to Semi-Nested PCR for HBV surface/polymerase gene amplification and nucleotide sequencing to determine genotypes and resistance to antivirals.

**Results:** Mean age was 50.3 ± 15.2 years and most of them was male (346/644). The prevalence of current infection (HBsAg +), previous contact (anti-HBc +), immunity for hepatitis B (anti-HBs +), and susceptibility to HBV (anti-HBc- / anti-HBs- / HBsAg-) were 5.9%, 36.0%, 57.3%, 34.3%, respectively. HBV DNA was detected in 36.8% (14/38) of the HBsAg reactive individuals indicating infection with active replication. Anti-HBc isolated was found in 18 individuals, where 6 had HBV DNA indicating 0.94% prevalence of occult HBV infection (OBI). We found a higher prevalence of genotype A (76.4%) followed by genotype D (23.5%) regardless of infection characteristic (current infection or OBI). Isolates of HBV were phylogenetically close to isolates from hemodialysis patients of Brazil, as well as some strains from the same unit had homology above 90%. All subjects in the study did not present resistance mutations to lamivudine, tenofovir, entecavir, adefovir and telbivudine.

**Conclusions:** We found high prevalence of HBV infection and low number of individuals immune to infection indicating the need for vaccination in this group. There was a higher prevalence of genotype A and the presence of closely related strains in the same dialysis unit, which reinforces the need for laboratory monitoring for hepatitis B among hemodialysis patients.

The DECISIVE study: defining beta-lactam concentration in intensive care unit patients - pharmacokinetics of cefepime, meropenem and piperacillin in critically ill patients across Malaysian intensive care units

Mohd-Hafiz Abdul-Aziz¹, Muhammad Azrai Rozali², Mohamad-Irfan Dthman-Jailani², Azrin-Nurul Abd Rahman⁴, Helmi Sulaiman¹, Nadia Atiya¹, Santosh Adiraju¹, Steven Wallis¹, Wan-Rahiza Wan-Mat⁵, Mohd-Zulfakar Mazlan³, Muhammad Fadhil Hadi Jamaluddin¹, Shahnaz Hasan¹, Basri Mat Nor², Jason Roberts¹

¹University of Queensland Centre for Clinical Research (UQCCR), The University of Queensland, Brisbane, Australia, ²International Islamic University Malaysia (IIUM), Kuantan, Malaysia, ³University Malaya Medical Centre (UMMC), Kuala Lumpur, Malaysia, ⁴Queensland Institute of Medical Research (QIMR), Brisbane, Australia, ⁵Universiti Kebangsaan Malaysia (UKM), Kuala Lumpur, Malaysia, ⁶Universiti Sains Malaysia (USM), Kota Bharu, Malaysia

Abstract third-party references: Supported by Malaysian Fundamental Research Grant Scheme [FRGS16-048-0547], Supported by Australian National Health & Medical Research Council (NHMRC) REDUCE - Centre of Research Excellence (CRE)

Background: Critically ill patients often demonstrate extreme physiological changes. Conventional antibiotic dosing may lead to sub-therapeutic exposure and therapeutic failure.

Materials/methods: This is a preliminary report from the DECISIVE Study, a prospective, multi-centre pharmacokinetic (PK) study aiming to describe the PK of seven beta-lactam antibiotics and the pharmacokinetic/pharmacodynamic (PK/PD) target attainment of critically ill patients across three Malaysian ICUs. Serial blood samples were collected across seven predetermined time-points. Two PK/PD targets were tested; achieving trough concentrations of 1xECOFF (conventional target) and 4xECOFF (aggressive target) of Pseudomonas aeruginosa. PK parameters were estimated using non-compartmental method. Univariate and multivariate analyses were applied.

Results: Ninety-five patients were included; 51 received piperacillin/tazobactam, 33 received meropenem and 11 received cefepime. The median 24-hour antibiotic dose for piperacillin/tazobactam was 18.0 g [9.0-18.0], 3.0 g [2.0-4.0] for meropenem, and 6.0 g [2.0-6.0] for cefepime. The median age was 56.5 years, body mass index was 23.2 kg/m², serum albumin was 24.0 g/L, and the estimated Cockcroft-Gault creatinine clearance (CLcr) was 65.2 mL/min. The median APACHE II and SOFA scores on admission were 14.0 and 6.0, respectively. Twenty-four patients (25.3%) underwent surgery 24 hours prior to study inclusion. Beta-lactam concentrations were highly-variable with coefficient of variation of ≥65%. The volume of distribution (Vd) and clearance (CL) of piperacillin were 0.42 L/kg [0.13-0.93] and 0.18 L/hr/kg [0.01-0.47], 0.37 L/kg [0.17-0.84] and 0.14 L/hr/kg [0.04-0.57] for meropenem, and 0.37 L/kg [0.16-0.67] and 0.11 L/hr/kg [0.03-0.39] for cefepime, respectively. Older age was significantly associated with increasing Vd and CLcr, and higher CLcr was significantly associated with faster CL, for all beta-lactam antibiotics. Additionally, higher serum albumin and recent surgery were significantly associated with higher CL of piperacillin and meropenem. Eighty-two (86.3%) and 55 (57.9%) patients achieved the conventional and aggressive PK/PD targets, respectively, and they tend to be older, with slower CLcr and receiving continuous infusion. Based on the most parsimonious logistic regression model, higher CLcr and intermittent infusion were significant predictors of sub-optimal target attainment for both PK/PD targets. The 30-day mortality was 33.7%.

Conclusions: Beta-lactam antibiotic concentrations were highly-variable in the ICU leading to variable PK/PD target attainment in this patient cohort.

Abstract 5907

Standardization of a pncA gene complementation in Mycobacterium tuberculosis pncA-knockout: tool for the study of the relationship between mutations in pncA and phenotypic parameters

Yudith Cauna*, Mirko Zimic¹, Patricia Sheen¹

¹Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru

Background: Mutations in the pncA gene, which encode pyrazinamidase, are the major cause of resistance to pyrazinamide (PZA), but there are alternative mechanisms that also promote resistance. The objective of the study was to standardize the pncA gene complementation in Mycobacterium tuberculosis H37Rv pncA-knockout to evaluate the effect of mutations in the pncA, in a scenario controlled by the genetic variability of clinical isolates.

Materials/methods: Strains complemented with pncA genes wild type and mutant were generated through the pNIT-1 expression system to evaluate pyrazinoic acid (POA) production through quantitative Wayne test, pncA gene expression level and PZA susceptibility under non-induced and induced conditions. Also, these parameters were evaluated to the clinical isolates where we identified the mutations D49N, H51R, G78C, and F94L.

Results: The pNIT-pncA expression system restored the susceptible phenotype of the pncA-knockout strain. The basal expression levels of wild type and mutants pncA were constant and similar to that H37Rv strain. The pncA wild type complemented strain, non-induced, showed POA production and Minimum Inhibitory Concentration of PZA similar to H37Rv (0.6 uM and 100 ug/mL, respectively). Although the overexpression of pncA wild type in the complemented strain, that was nine times greater than H37Rv strain, and it promoted higher production of POA than H37Rv strain (3 uM), the susceptibility was same. By contrast, the mutant pncA complemented strains non-induced did not produce POA, but in the induced condition the F94L and G78C complemented strains produced POA (0.8 and 1.4 uM, respectively); however, they were lowest than pncA wild type complemented strain-induced. Additionally, these strains were resistant in both conditions. The clinical isolates with the respective mutations were resistant (>1000 ug/mL), and no produced POA, except the clinical isolate with F94L mutation (0.5 uM).

Conclusions: The complementation of the pncA-knockout strain with the pncA wild type, through pNIT expression system, allowed the restoration of the susceptible phenotype, and the D49N, H51R, G78C and F94L mutations in the complemented strains really conferred resistance to PZA, and we verified that the overexpression of these mutants allowed to verify the total or partial loss their enzymatic function of the mutant pyrazinamidase.

Abstract 5914

**A simple cleaning intervention to prevent transmission of carbapenemase-producing Enterobacterales from hospital sinks**

Jason Kwong1, Marcel Leroi1, Trudi L. Bannam1, Deidre Edmonds1, Elizabeth Grabsch1, Shanti Narayanasamy1, John Greenough1, Courtney Lane1, Marion Easton1, Benjamin Peter Howden2, Paul Johnson1, M. Lindsay Grayson1

1Austin Hospital, Heidelberg, Australia, 2University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, 3Department of Health and Human Services Victoria, Melbourne, Australia

**Background:** A prolonged outbreak of carbapenemase-producing *Serratia marcescens* (CPSM) was identified in our quaternary healthcare centre over a two-year period from 2015-2017. A reservoir of IMP-4-producing *S. marcescens* in sink drains of clinical hand basins (CHB) was implicated in propagating transmission, supported by evidence from whole-genome sequencing (WGS). We assessed the impact of manual bioburden reduction intervention on further transmission of CPSM.

**Materials/methods:** Environmental sampling of frequently touched wet and dry areas around CPSM clinical cases was undertaken to identify potential reservoirs and transmission pathways. After identifying CHB as a source of CPSM, a widespread annual CHB cleaning intervention involving manual scrubbing of sink drains and the proximal pipes was implemented, with pre- and post-intervention point prevalence surveys (PPS) of CHB drains performed to assess for CPSM colonisation. Surveillance for subsequent transmission was conducted through weekly screening of patients and annual screening of CHB in transmission areas, and six-monthly whole-hospital PPS of patients. All CPSM isolates were assessed by WGS.

**Results:** A total of six patients were newly identified with CPSM from 2015-2017 (4.3 transmission events per 100,000 surveillance bed days [SBD]; 95% CI 1.6–9.4). All clinical CPSM isolates were linked to CHB isolates by WGS. The CHB cleaning intervention resulted in a reduction in CHB colonisation with CPSM in transmission areas from 72% colonisation to 28% (ARR 0.44; 95% CI 0.25–0.63). A single further clinical case of CPSM linked to the CHB isolates was detected over two years of surveillance from 2017-2019 following the implementation of the annual CHB cleaning program (0.7 transmissions per 100,000 SBD; 95% CI 0.0–3.9). No transmission events occurred as a direct result of the cleaning intervention.

**Conclusions:** A simple intervention targeted at reducing the biological burden of CPSM in CHB drains at regular intervals was effective in preventing transmission of carbapenemase-producing Enterobacterales from the hospital environment to patients over a prolonged period of intensive surveillance. This highlights the importance of detailed cleaning for controlling the spread of multidrug-resistant organisms from healthcare environments.

Detection of high rates of HIV-seropositivity in urban university hospital emergency department
Larissa May¹, Tasleem Chechi¹, Stephanie Voong¹, Nam Tran²

¹University of California Davis Medical Center, Sacramento, United States, ²University of California Davis Medical Center, Sacramento, United States

**Background:** With the ongoing public health impact of undetected human immunodeficiency virus (HIV), routine universal screening of HIV in the emergency department may identify populations who are not getting tested in other settings. The objectives of this analysis were to evaluate opt-out HIV screening and determine the number of new and known HIV-positive individuals out-of-care at an academic emergency department in Sacramento, California.

**Materials/methods:** From November 27, 2018 through October 31, 2019, electronic medical record (EMR) based HIV screening was implemented in a quaternary care emergency department in Northern California. EMR best practice alerts (BPA) were developed based on a combination of local and CDC guidelines and screening for persons aged 18-64 years (excluding persons with a confirmatory HIV+ test in their medical record) was implemented using a 4th generation HIV antigen/antibody assay. Upon notification of a positive test result through EMR, a patient navigator is responsible for coordinating an in-person notification/counseling and linking patients to receive medical follow-up.

**Results:** Over a period of 11 months, 14,068 individuals were tested for HIV, resulting in 22 (22%) new HIV diagnoses, of whom 17 (77%) were successfully linked to care. Universal screening also identified 23 out-of-care for >12-months HIV+ individuals of whom 14 (61%) were successfully relinked to care. Testing initiated either by physician on the basis of perceived HIV risk behaviors and/or clinical manifestation or through the screening program yielded an HIV seroprevalence of 0.9% with 29 percent self-reported history of intravenous drug use (IVDU).

**Conclusions:** The emergency department (ED) has unfortunately become the primary medical provider for HIV-at-risk populations. ED setting has been demonstrated to be effective for HIV screening. One of the major commonly identified risk factors for HIV is men having sex with other men (MSM), but with the rising opioid epidemic IVOD has been noted to contribute to an increase of new HIV infections thus contributing to the epidemic of viral hepatitis. Screening based on commonly known risk factors, such as MSM, captures missed opportunities to identify HIV-seropositive patients. The high seroprevalence in northern California is uncommon and indicates that HIV-1 infection is widespread in this population.

Heuristic identification of carbapenemase-encoding plasmids by short-read sequencing data: validation by ONT long-read hybrid assembly of a large Singaporean carbapenem-resistant Enterobacteriaceae collection

Weizhen Xu*1,2, Sridatta Sr. Prakki1,2, Natascha May Thevasagayam1,2, Liang De Wang1,2, Kalisvar Marimuthu1,2, Indumathi Venkatachalam1, Jeanette Teo4, Oon Tek Ng1,2

1Tan Tock Seng Hospital, Department of Infectious Diseases, Singapore, Singapore, 2National Centre for Infectious Diseases, Singapore, Singapore, 3Singapore General Hospital, Department of Infectious Diseases, Department of Infection Prevention & Epidemiology, Singapore, Singapore, 4National University Hospital, Department of Laboratory Medicine, Singapore, Singapore

Background: Alike the previous rapid global spread of extended-spectrum β-lactamases (ESBLs), transmission of carbapenem resistance across Enterobacteriaceae strains is facilitated by horizontal-gene-transmission of carbapenemase-encoding plasmids. Plasmid structures are difficult to resolve by short-read sequencing – a recent study benchmarking short-read plasmid analysis tools suggested that the resolution of large plasmids of >50kbp in size remains a challenge (Arredondo-Alonso et al., 2017). Long-read sequencing (e.g. PacBio and Oxford Nanopore Technologies (ONT)) is able to address the difficulty in plasmid assembly but is currently not as widely available as short-read sequencing within clinical/research institutions. Our study presents a heuristic short-read pipeline for plasmid identification based on the existing Plasmidseeker tool (Roosaare et al., 2018).

Materials/methods: We tested our pipeline on MiSeq short-read sequence data for 1251 Singaporean CPE isolates, of which ~700 have been sequenced using ONT. Best-match plasmid identities were assigned from carbapenemase-specific reference plasmid databases, based on query identity of the carbapenemase-bearing short-read assembly contig (qcov), and isolate kmer coverage of the reference plasmid (kcov). Plasmid predictions were validated against ONT hybrid assemblies based on sequence and replicon/antimicrobial resistance (AMR) gene profile similarity, and plasmid-matching rules were fine-tuned accordingly.

Results: Best-match carbapenemase-encoding plasmid identities were assigned for 487/541 (90.0%) blaNDM, 500/535 (93.5%) blaKPC and 60/150 (40%) OXA-48-family isolates. Preliminary validation of blaNDM plasmid calls indicate 391/409 (95.6%) are in agreement with actual structures based on a Mash distance threshold of 0.01; replicon and AMR gene profiles were also largely concordant. Difficulties in distinguishing between similar reference structures were observed and addressed by clustering reference plasmids based on kmer similarity. The blaNDM plasmid pNDM-ECS01 (n=305) and a novel 71,861bp blaKPC plasmid (n=344) were predominant in our dataset.

Conclusions: While our short-read pipeline does not produce the exact plasmid structures and is highly dependent on the coverage of existing databases, it is nonetheless able to assign best-match identities that are functionally representative of the actual isolate plasmids, allowing the epidemiological tracing of specific plasmid structures and their associated AMR genes. Coverage gaps in the pipeline will be addressed with the increasing availability of novel complete plasmid structures through long-read assembly.

Abstract 5918

**Epidemiology of Neisseria gonorrhoeae antimicrobial resistance and evaluation of alternative antibiotics**

Jing Yan*1, Stijn Van Der Veen1

1Zhejiang university, Department of Microbiology and Parasitology, School of medicine, Zhejiang University, Hangzhou, China

**Background:** Development of resistance in *Neisseria gonorrhoeae* to ceftriaxone monotherapy or ceftriaxone plus azithromycin dual therapy is a global public health concern, alternative clinically approved antimicrobials are urgently needed for future alternative therapies. Resistance against ceftriaxone is related to mosaic penA alleles. In addition, penicillinase-producing *N. gonorrhoeae* (PPNG) expressing the TEM-135 β-lactamase variant are alarming as this variant requires only a single amino acid substitution to develop into an extended-spectrum β-lactamase (ESBL). In this study, we analyzed the trend in antimicrobial susceptibility of clinical isolates from Hangzhou, China, over the period 2015-2017 to previous and current antimicrobial therapies and to several alternative clinically approved antimicrobials.

**Materials/methods:** The antimicrobial susceptibility of in total 379 clinical isolates was determined by the agar dilution method. Phylogenetic and clustering analysis was determined using porB and tbpB sequences. PPNG isolates were investigated by nitrocefin test and representative isolates were investigated by qPCR, western blot analysis and in vivo β-lactamase activity assays.

**Results:** Ceftriaxone resistance, decreased susceptibility to ceftriaxone and azithromycin resistance were observed in 3%, 17% and 21% of the isolates and resistance levels to ceftriaxone and azithromycin increased over the study period. Phylogenetic and cluster analysis showed the emergence and expansion in 2017 of a clonally related cluster containing strains with high abundance of decreased susceptibility to ceftriaxone, which was related to the presence of the mosaic penA allele X. Screening of alternative antimicrobials identified tigecycline and ertapenem as antibiotics with excellent activity and limited cross-resistance with previously used antibiotics. Finally, PPNG isolates consisted of three major clusters, and isolates of the Asian plasmid/blaTEM-135 cluster showed the highest penicillin resistance and β-lactamase activity, which was explained by higher blaTEM gene expression and higher TEM stability.

**Conclusions:** Resistance levels to ceftriaxone, which was related to presence of the mosaic penA allele X, were rising over the study period. Furthermore, we identified tigecycline and ertapenem as possible alternative clinically approved antimicrobials for future therapies. Finally, we showed that the blaTEM-135 gene is commonly present on the Asian plasmid in PPNG isolates from Hangzhou, posing major treat to the development of ESBLs in *N. gonorrhoeae*.

Abstract 5926

Analysis of outcomes by geographic region of enrolment in STRIVE, the phase II of rezafungin for the treatment of candidemia and invasive candidiasis

Jesus Fortun Abete*,1, Athanassios Skoutelis2, Rolando Viani3, Taylor Sandison3

1University Hospital Ramon y Cajal, Madrid, Spain, 2General Hospital of Athens Evangelismos, Athens, Greece, 3Cidara Therapeutics, San Diego, United States

Background: Rezafungin is a novel echinocandin in Phase 3 development. STRIVE (NCT02734862) is the global, Phase 2 trial of rezafungin once-weekly for treatment of candidemia and/or IC versus standard of care. Results of STRIVE were evaluated by geographic region to assess for differences in the complete trial population.

Materials/methods: Data were stratified by region of enrollment (EU vs North America [NA]) and analysed for differences in patient demographics and baseline characteristics, treatment patterns, and efficacy outcomes.

Results: Patients enrolled in EU (N=131) were older than in NA (N=76) (mean, 64 vs 52 years, respectively) and were predominantly male (61.1%) and White (93.1%). The NA population was 50% male and comprised 23.7% Black or African-American patients. On average, NA patients weighed more and had higher BMI (+2.3 kg/m²).

The same leading Candida species were isolated at baseline in both regions but with differing distribution. Candida albicans comprised 44% of EU isolates, and proportions of Candida parapsilosis, Candida glabrata, and Candida tropicalis were similar (13-18%). In NA, C. albicans accounted for 52% of isolates, followed by 25% C. glabrata and 7% each for C. parapsilosis and C. tropicalis.

In both regions, 55% of patients received 8-14 days of IV treatment; 27% of EU patients received >14 days versus 18% in NA. Fewer patients in EU were switched to oral step-down (24.4% vs 42.7% NA). The NA population had a higher proportion of patients with IC (26.3% vs 17.6% EU).

Outcomes were comparable between regions except for higher rates of overall success in EU patients treated with rezafungin 400 mg in Week 1 followed by 200 mg once weekly, compared with the NA cohort (Table).

Conclusions: The Phase 2 STRIVE trial demonstrated few differences by region in demographic and baseline characteristics. The EU population was slightly older, and NA patients were generally heavier. Non-albicans species were predominant in the EU and comprised almost half of the NA isolates. Efficacy by region showed no consistent trends, although interpretation of efficacy-related differences are limited by group size. Results of this analysis may inform future evaluation of data from the rezafungin clinical trial program.

Influence of biofilm formation on clinical outcome and their associated genetic virulence factors in *Klebsiella pneumoniae* bloodstream infections in India

Devanga Ragupathi Naveen Kumar¹,², Kalaiarasi Asokan², Karthick Vasudevan², Dhivya Murugan², Esther Karunakaran¹, Peter Monk³, Veeraraghavan Balaji²

¹The University of Sheffield, Department of Chemical and Biological Engineering, Sheffield, United Kingdom, ²Christian Medical College, Department of Clinical Microbiology, Vellore, India, ³The University of Sheffield, Department of Infection, Immunity & Cardiovascular Disease, Sheffield, United Kingdom

**Abstract third-party references:** Department of Infection, Immunity & Cardiovascular Disease, The University of Sheffield, Sheffield, UK, Department of Clinical Microbiology, Christian Medical College, Vellore, India, Department of Chemical and Biological Engineering, The University of Sheffield, Sheffield, UK

**Background:** *Klebsiella pneumoniae* is one of the leading causes of nosocomial infections. Carbapenem-resistant (CR) *K. pneumoniae* are on the rise in India. The biofilm forming ability of *K. pneumoniae* further complicates the patient management. There is still a knowledge gap on association of biofilm formation with patient outcome and carbapenem susceptibility, which is investigated in the present study.

**Materials/methods:** *K. pneumoniae* isolates from patients with blood stream infections admitted in critical care units with catheters were included. *K. pneumoniae* (n = 18) were tested for antimicrobial susceptibility as recommended by CLSI 2019 and subjected to 96-well titre plate biofilm formation assay. Based on optical density at 570 nm isolates were graded as strong, moderate and weak biofilm formers. Strong biofilm formers were subjected to whole genome sequencing with IonTorrent PGM. Core genome phylogeny using Roary and RaxML, and association of known biofilm virulence genes with other virulence genes by cytoscape network modelling were performed. Biofilm formation was compared for their association with the carbapenem susceptibility and outcome of the patients. Statistical significance, correlations and graphical representation were performed using SPSS v23.0 and Prism v8.2.0.

**Results:** Infections by stronger biofilm forming pathogen significantly (P<0.05) resulted in fewer ‘average days alive’ for the patient (4.43), in comparison to moderate (4.63) and weak biofilm formers (5.66). Among the strong, moderate and weak biofilm formers, 100%, 75% and 66% were carbapenem resistant respectively, thereby showing a positive correlation. Gene network model revealed close association of biofilm genes allS, iutA and rmpA2 with other genetic virulence factors. These genes might significantly contribute to the biofilm mechanism. Further analysis, also revealed association of CR gene, *bla*NDM with biofilm factors.

**Conclusions:** Biofilm forming ability of clinical *K. pneumoniae* isolates had a significant association with the morbidity/mortality. The strong biofilm formation significantly reduced the number of days alive for the patient (5.66 to 4.43). These results highlight the importance of biofilm testing, especially for nosocomial pathogens which are difficult to clear in vivo. As *K. pneumoniae* nosocomial infections require additional treatment which might effectively help in improving the patient outcome.
Abstracts 2020

**A M R genes and plasmids**

Figure 1:
A) Depicting biofilm formation efficiency of *K. pneumoniae* from bloodstream infections (left Y axis), and length of hospital stay from the date of admission (right Y axis). L1 depicts the cut off for weak biofilm formers, and L2 the cut off for moderate and strong biofilm formers, respectively.

B) Core phylogeny of *K. pneumoniae* depicting distinct AMR genes and plasmid profile for the two separate clones.

C) Comparison of strong biofilm study *K. pneumoniae* with known global-carbapenem resistant clones. Showing match between Indian and global resistant isolates.

Abstract 5935

Clinical implementation of routine whole genome sequencing for hospital infection control of multidrug-resistant pathogens

Patrick Harris*,1,2, Brian Forde1, Amy Jennison4, Krispin Hajkowicz5, Geoffrey Playford6, Julia Clark7,8, Scott Beatson3, David L. Paterson1,5

1University of Queensland, UQ Centre for Clinical Research, Brisbane, Australia, 2Pathology Queensland, Central Microbiology, Herston, Australia, 3University of Queensland, School of Chemistry and Molecular Biosciences, Brisbane, Australia, 4Forensic and Scientific Services, Coopers Plains, Australia, 5Royal Brisbane and Women’s Hospital, Infectious Diseases Unit, Herston, Australia, 6Princess Alexandra Hospital, Infection Management Services, Woolloongabba, Australia, 7Queensland Children’s Hospital, Infection management and prevention service, South Brisbane, Australia, 8Centre for Children’s Health Research, South Brisbane, Australia

Background: Every year ~200,000 Australians experience a healthcare-associated infection (HAI). The impact is exacerbated by increasing rates of antibiotic resistance. There is limited capacity in clinical laboratories to routinely track pathogens causing HAI in real-time or to detect cross-transmission events. We established a pre-emptive whole-genome sequencing (WGS)-based surveillance program to identify clustering of clinically relevant multi-drug resistant (MDR) bacteria, suggesting in-hospital transmission, before outbreaks can become established.

Materials/methods: We prospectively collected methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), carbapenem-resistant Acinetobacter baumannii (CRAB), extended-spectrum beta-lactamase (ESBL) and carbapenemase-producing Enterobacterales (CPE) isolated from sterile sites or screening specimens across three tertiary referral hospitals (2 adult, 1 paediatric). Whole genome sequencing (Illumina NextSeq) was used to determine in silico multi-locus sequence typing (MSLT) and resistance gene profiling via a bespoke genomic analysis pipeline. Putative transmission events were identified by comparison of core genome single nucleotide variants (SNVs). Combined with automated transfer of clinical meta-data from the laboratory information system, the genomic analyses were collated into hospital- and pathogen-specific reports and distributed to infection control teams at least monthly.

Results: Over two years (November 2017 to November 2019) more than 1700 MDR isolates were sequenced. This included MDR gram-negative bacilli (n=142 CPE, n=868 ESBL and n=27 other), MRSA (n=477) and VRE (n=249). Core genome SNV data identified that 21% of isolates formed 51 distinct clusters that were not identifiable using traditional surveillance techniques. Of 51 clusters, 18 were contained to one of three target hospitals suggesting ongoing transmission within the clinical environment. One cluster was related to a previous outbreak of CRAB, thought to have been resolved, prompting a targeted engineering response preventing further transmission. The remaining 33 clusters represented inter-hospital transmission events or strains circulating in the community acquired prior to hospital admission. In one hospital, diversity of non-multi-resistant MRSA strains and the lack of hospital transmission enabled changes to infection control policy. The effectiveness of this policy change will be assessed prospectively by ongoing WGS.

Conclusions: Implementation of routine WGS for MDR pathogens in clinical laboratories is feasible and reveals previously unknown transmission events, which can enable targeted infection control responses.

Abstract 5939

An agent-based simulation of hand hygiene and contact precautions for the control of Clostridioides difficile in an intensive care unit setting

Michael Rubin*,1,2, Molly Leecaster1,2, William Ray1,2, Karim Khader1,2, Damon Toth1,2

1University of Utah School of Medicine, University of Utah, Salt Lake City, United States, 2VA Salt Lake City Health Care System, Salt Lake City, United States

Abstract third-party references: US Centers for Disease Control and Prevention

Background: Clostridium difficile (CD) is one of the most common nosocomial infections. Strict adherence to hand hygiene (HH) and contact precautions (CP) by healthcare providers (HCP) is believed to be critical to controlling CD spread, particularly in hospital intensive care units (ICUs).

Materials/methods: We collected data from two ICUs (cardiovascular and medical/surgical) over several weeks each, using wireless sensors to track HCP movements, patient and room object interactions, and HH adherence, and daily microbiological cultures of patients, objects, and HCP hands. We then used these data to design and parameterize a high-fidelity agent-based simulation of nosocomial CD transmission in a single 20-bed ICU. The model was calibrated against local and published data and validated internally and externally.

Scenarios exploring the full range of HCP HH compliance were simulated 100 times each over a one-year period. Additional scenarios were performed exploring HH compliance based on the intensity of the HCP room visit, defined by the combination of time spent near the patient and number of patient/object touches per visit. Scenarios employing universal CP were also explored. Model output was expressed as CD infections per 10,000 patient-days (PD).

Results: When overall HH adherence was dropped below base-case values established from data collection, CD acquisition and infection rates increased rapidly; alternatively, raising HH adherence brought relatively little return (Figure). Interestingly, raising HH for visits of low intensity (no near-patient time/no touches) had the most pronounced effect, likely because these are the most frequent HCP visits. Implementing universal contact precautions (CP), without changing HH adherence from baseline, had a moderate impact on outcomes (mean 8.4 vs. 14.5 CD infections/10,000 PD).

Conclusions: Our model results suggest that, although typical overall HH rates may seem suboptimal, improving them may have a limited impact on CD infection rates, even when improvement is focused on high-intensity visits. At the same time, universal CP can have a moderate but incomplete effect on CD infections. This highly granular simulation can be used to explore the costs and benefits of infection control strategies otherwise difficult to assess in real-world settings, providing valuable input for targeting specific interventions to control CD transmission.

**Bacteriological study of kidney stones**

Hugo Filipe Bento Da Cruz*, Cláudia Santos1, Helena Ramos1

1Centro Hospitalar Universitário do Porto, Porto, Portugal

**Background:** Urolithiasis remains a significant cause of morbidity and mortality due to the high rate of recurrent urinary tract infections and the progressive deterioration of renal function. Although the pathophysiological mechanisms underlying the formation of kidney stones (KS) are not yet fully understood, some studies indicate the possible involvement of bacteria in this process.

**Materials/methods:** Prospective study of KS surgically extracted by nephrolithotomy over a 1-year period [from 1 November 2018 to 31 October 2019]. The chemical composition of KS was obtained by infrared spectroscopy. After 18 to 24 hours of incubation in 5 mL of thioglycolate broth, the bacteriological study of previously macerated KS was done by a quantitative sub-culture in blood agar and MacConkey agar [cutoff ≥ 10^5 CFU/mL]. Bacterial identification was performed by MALDI-TOF mass spectrometry.

**Results:** 75 KS from individuals with a mean age of 52 years were studied, 43% [n=32] belonging to males and 57% [n=43] to females. The chemical composition of KS included calcium oxalate, calcium phosphate, uric acid, magnesium ammonium phosphate [struvite], apatite and cystine, and most had a mixed composition. The bacteriological study of KS was sterile in 40% [n=30] and revealed bacterial growth above the cutoff in 60% [n=45], 45% [n=34] demonstrating a monomicrobial culture and 15% [n=11] a polymicrobial culture. In decreasing order of prevalence, the isolates were Enterobacterales, Staphylococcus spp. [mostly coagulase-negative staphylococci], Enterococcus spp., Pseudomonas aeruginosa and Streptococcus spp. [all viridans group streptococci].

**Conclusions:** The bacteriological study of KS allowed the isolation of well-recognized pathogens in a significant proportion of cases, particularly *Escherichia coli* and urease-producing bacteria [such as *Staphylococcus* spp., *Klebsiella* spp., *Proteus* spp. and *Pseudomonas* spp.]. Since these can survive in the interstices of KS [where antimicrobial agents have poor penetration], the bacteriological study of KS seems to provide valuable information that is representative of the renal pelvis; thus, it is possible to initiate targeted antimicrobial therapy for urinary tract sterilization and for prevention of recurrence or re-growth of residual KS after initial removal and treatment of postoperative infections.

A rare case of paragonimiasis infected by Paragonimus ohirai
Yao Zhang*,1, Wenting Jin1, Qing Miao1, Jue Pan1, Bijie Hu1

1Fudan University/Zhongshan Hospital, Shanghai, China

Background: Paragonimiasis is a zoonotic disease caused by lung flukes of the genus Paragonimus. Humans usually acquire infection via consumption of undercooked or raw freshwater crab or crayfish. More than 50 species of Paragonimus have been described and the best known is P. westermani. The P. ohirai is phylogenetically distinct from the well-known P. westermani. It is known from Japan, Korea and China with very occasional human infections reports. Here we report a rare case of P. ohirai infection simultaneously affecting pulmonary, hand and chest wall.

Case report: A 17-year-old girl from Zhejiang Province, China, presented with right chest pain and dry cough for 2 months. She was a high school student, and denied a history of hemoptysis, fevers, appetite suppression, or weight loss. There were no unusual food or animal exposures. The biological examination showed a hypereosinophilia (8,890 cells/mm3) and a raised C-reactive protein and ESR. The IgE was normal. Chest computed tomography (CT) revealed multiple migratory pulmonary infiltrates, cavities and pleural effusion. Sputa for mycobacterial, T-SPOT. TB, serology for Cryptococcus, all were negative. In the course of disease, she developed subcutaneous swellings in left index finger. She received a surgical drainage of left index finger and antibiotics treatment, but the chest CT showed no improvement. Even worse she presented with subcutaneous swelling in left palm and right chest wall, then she was referred to our hospital. We performed lung and chest wall biopsies, and the anatomopathology revealed large amounts of eosinophils. We could not observe characteristic parasite eggs in stool, sputum, bronchoalvelolar lavage fluid, lung tissue or chest wall tissue. The antibodies against P. westermani was negative. However, polymerase chain reaction (PCR) on the chest wall tissue was positive for P. ohirai. The girl received 4 course of praziquantel therapy, with rapid resolution of symptomatology and a decrease of eosinophil count. A follow-up chest CT at 2 months after treatment revealed normal.

Conclusions: To date, P. ohirai has not been observed in human infections, and this is the first report of Paragonimiasis infected by Paragonimus ohirai. PCR might be a useful tool for species diagnosis of Paragonimiasis.

Background: Members of the Enterobacter cloacae complex (ECC) have gained major clinical significance in the last decade, becoming difficult-to-treat nosocomial pathogens due to the increasing presence of bla_{KPC}. Polymyxins are important “last-line” antibiotics to treat infections caused by carbapenem-resistant Enterobacteriaceae (CRE), especially in KPC-endemic countries like Colombia. We report the first clinical set of carbapenem resistant Enterobacter spp. isolates (CRE) coharboring bla_{KPC-2} and the mobile resistance colistin gene mcr-9 from Colombia.

Materials/methods: A total of 67 ECC isolates carrying bla_{KPC} were obtained from an archived library of clinical samples collected between 2007 and 2017 in 7 Colombian cities. Paired-end Illumina whole genome sequencing (WGS) and de novo assembly was performed for all isolates. Species confirmation, resistome and plasmid typing, were obtained from the assemblies. For the 5 isolates where mcr-9 was identified, polymixin B (PolB) antimicrobial susceptibility testing was performed using the broth macrodilution method and long read WGS (Oxford Nanopore MinION) was carried out to identify the elements harboring bla_{KPC} and mcr-9.

Results: The mcr-9 harboring isolates were collected from 3 different cities; 3/5 were identified as E. asburiae, and 2/5 E. hormaechei (subsp. xiangfangensis and subsp. hoffmannii, respectively). All isolates carried bla_{KPC-2} in plasmids of different sizes and replicon types. For E. asburiae isolates mcr-9 was chromosomally encoded, and their PolB MIC was ≥ 8 mg/L; while E. hormaechei isolates harbored mcr-9 in multi-replicon plasmids and displayed low PolB MICs (0.25 and 0.125 mg/L; Table 1). Analysis of the genetic context of mcr-9 revealed that this gene was flanked by insertion sequences from the IS5 and IS481 families followed downstream by wbuC (encoding a putative enzyme of the cupin superfamily), the qseBC [two-component system], and an ATPase gene.

Conclusions: This study highlights the increased likelihood of a wide, sometimes silent dissemination of the newly identified mobile colistin resistance gene mcr-9 among ECC. Mobile genetic elements play a key role in mobilization, by aiding it to insert not only into plasmids, but also into the chromosome. Further surveillance is urgently needed to understand the prevalence and dissemination of mcr-9, especially taking into account its inducible nature.

Abstract 5944

**Do DNA based NAAT tests lead to over diagnosis of Chlamydia trachomatis infections?**

Alison Todd*1,2, Wilhelmina Huston1, Nicole Lima1,2

1SpeeDx Pty Ltd, Sydney, Australia, 2University of New South Wales, Sydney, Australia, 3University of Technology Sydney, Sydney, Australia

Abstract third-party references: University of Technology, Sydney, SpeeDx Pty Ltd, University of New South Wales

**Background:** Since NAATs are so sensitive and specific, reliance on DNA detection alone may overestimate infectivity and lead to overtreatment of CT. Further, both DNA and RNA can remain detectable after pathogens are dead. VITA RT-PCR is a novel method which determines viability by quantifying the ratio of RNA to DNA thus using transcriptional vigour of the pathogens as a surrogate “index of life”.

**Materials/methods:** A cohort of 20 asymptomatic MSM, who tested positive for rectal CT DNA using the Roche cobas CT/NG test, provided self-collected rectal specimens upon return visits to the clinic at (i) commencement of 7 days of doxycycline treatment, (ii) conclusion of treatment, and (iii) 4 weeks post treatment. Samples were assessed for viable CT by VITA and culture; and CT DNA was detected by an in-house PCR (and cobas CT/NG at the final visit). VITA results were reported as Alive/Viable (RNA>DNA; Index>2), Dead (DNA only; Index<2) or Negative (No RNA or DNA).

**Results:**

(i) VITA indicated 35% of patients did not have viable CT infections (6 negative/1 dead). Of samples deemed “alive” by VITA, 61.5% grew in culture, whereas no negative/dead samples grew.

(ii) No samples were viable by VITA (PCR confirmed DNA in 1 dead sample)

(iii) No samples were viable by VITA (PCR & cobas test confirmed DNA in 1 dead sample).

Overall, DNA detection by VITA was 94% and 100% concordant with PCR and the cobas test respectively.

**Conclusions:** This pilot study indicated up to 35% of the 20 patients did not have viable CT at visit (i) and may therefore have received unnecessary doxycycline treatment. Since the cobas CT/NG had detected CT DNA ≤6 days previously, it is hypothesised the test may have detected residual DNA associated with dead CT from infections in the process of self-clearing at the time of diagnosis, or between then and visit (i); or may detect DNA associated with CT exposure which did not result in infection. Support for the hypothesis includes studies showing pre-treatment samples where 18-20% had cleared, or where 17-24% where found to be non-viable by V-PCR or RNA analysis respectively.

Clonality of regional *Candida auris* isolates identified by whole genome sequencing

Scott Roberts*1, Egon Ozer1, Chao Qi1

1Northwestern Memorial Hospital, Chicago, United States

**Background:** *Candida auris* is a novel emerging fungal species capable of both antifungal resistance and person-to-person transmission. Research into the epidemiology and genotypic characteristics of *Candida auris* is limited.

**Materials/methods:** 16 *Candida auris* isolates from Northwestern Memorial Hospital (NMH) and ACL Laboratories (ACL) in Chicago, Illinois from 2017 to 2019 and 10 international isolates from the Centers of Disease Control and Prevention (CDC) were obtained. Antifungal susceptibility testing and whole-genome sequencing (WGS) were performed. Nanopore-long read sequencing was obtained on one NMH sample with the remainder of strains aligned to this reference.

**Results:** 26 samples were collected and underwent WGS. A maximum of 35 single-nucleotide variants (SNV) were present between any two non-CDC strains. NMH and ACL isolates were not genomically distinct. All isolates differed from the nearest genomic clade, South America, by 185 – 204 SNVs. Amongst regional strains, fluconazole minimum inhibitory concentrations ranged from 2 to 256 µg/mL. Phylogenetic trees of all sequenced isolates, and isolates compared to the closest clade, are shown in Figure 1.

**Conclusions:** There is high genomic similarity between local *Candida auris* strains in spite of varying antifungal resistance patterns. No grouping patterns were observed when comparing NMH to ACL strains. Regional isolates appear distinct from previously identified clades but are most closely related to the South American clade. Further study is needed to clarify this evolutionary pattern.

Figure 1: Phylogenetic tree of NMH clinical (purple), NMH environmental (green), and ACL (red) isolates when compared to the South American clade (black).

Perceptions of general practitioners on antimicrobial stewardship: a nation-wide survey in Australia

Sajal Saha*1, David Kong2, Karin Thursky1, Danielle Mazza1

1Monash University, Department of General Practice, Victoria, Melbourne, Australia, 2Monash University, Centre for Medicine Use and Safety, Victoria, Melbourne, Australia, 3University of Melbourne, National Centre for Antimicrobial Stewardship, Melbourne, Australia

Background: Establishing antimicrobial stewardship (AMS) programs in general practice is central to optimise antimicrobial prescribing in primary care. To date, the views of Australian general practitioners (GPs) on the national antimicrobial resistance strategies, uptake of AMS strategies when prescribing antimicrobials and GP-pharmacist collaboration to improve AMS remains unknown. This evidence gap hinders the development of models for implementing AMS strategies by improved GP-pharmacist collaboration in primary care. This study explored GPs’ AMS awareness and practices and attitudes towards GP-pharmacist collaborative approaches to optimising AMS in Australia.

Materials/methods: Across Australia, 3000 GPs derived from AMPCo database using a stratified random sampling method were invited to participate in a paper-based survey with two reminders between January to May 2019. Outcomes included awareness of AMS, uptake of evidence-based AMS strategies, attitudes towards GP-pharmacist collaboration and future AMS improvement strategies. Descriptive statistics and regression analysis were performed.

Results: Responses from 386 GPs (16.8%) were included for analysis. Participants were familiar with the term AMS (68.9%) and positively perceived the objectives of AMS: reduction of inappropriate antimicrobials use (61.7%) and treatment costs (70.8%). The most frequently used AMS strategies were Antibiotics Therapeutic Guidelines (TG) (83%) and delayed prescribing strategy (72%). Point of care testing (18.4%), patient leaflets (20.2%), peer prescribing reports (15.5%) and audit-feedback (9.8%) were poorly utilised. GPs who completed antimicrobial prescribing courses showed greatest awareness of AMS (p<0.002) and better uptake of AMS strategies (p=0.000). GPs were receptive to pharmacists’ recommendations on the choice (55%), and dose (63%) of antimicrobials. More than 60% of GPs would support a policy fostering GP-pharmacist collaboration. Most GPs were willing to be trained on AMS (72%), supported integration of electronic TG with prescribing software (87.3%) and a policy that would limit the prescribing of selected antimicrobials (74.4%).

Conclusions: GPs in Australia are aware of AMS but shows poor uptake of some evidence-based AMS strategies when prescribing antimicrobials. The majority of GPs hold positive attitudes towards GP-pharmacist collaboration to furthering AMS. GPs’ poor adoptions of AMS strategies and feasibility of GP-pharmacist collaborative AMS strategies can be further investigated to optimally design effective AMS strategies in Australian primary care.

Abstract 5948

Induction of erythromycin resistance in *Bordetella* sp. confirmed by whole genome sequencing

Winkie Fong*\(^1,2\), Verlaine Timms\(^1,2\), Eby Sim\(^1\), Trang Nguyen\(^3\), Vitali Sintchenko\(^1,2\)

\(^1\)University of Sydney, Sydney, Australia, \(^2\)Westmead Hospital, CIDM-PH, Westmead, Australia, \(^3\)Westmead Hospital, CIDMLS, Westmead, Australia

**Background:** *Bordetella pertussis*, the etiological agent of whooping cough, is highly infectious and re-merging globally despite widespread vaccination. The recommended antibiotics for treatment of *B. pertussis* infections and post-exposure prophylaxis are macrolides, Erythromycin and Azithromycin. However, mutations have occurred in the 23S rRNA gene resulting in macrolide resistance. While still uncommon, macrolide-resistant *B. pertussis* have been reported in Europe and Asia. The mechanism of resistance was identified as an A-to-G transition SNP mutation at position 2037 according to the *B. pertussis* Tohama I 23S rRNA gene.

The target sequence IS481 for routine clinical diagnosis has been found in both *Bordetella holmesii* and *B. pertussis* genomes. *B. holmesii* is often the main cause of false-positive results when screening symptomatic patients for Pertussis with routine PCR methods. Previous studies have shown that *B. holmesii* infections range from 0-32% of nasopharyngeal samples from patients with pertussis-like illnesses. Given the causative agent of Pertussis-like illnesses can be caused by other *Bordetella* sp. we aimed to examine the development of macrolide resistance in *B. pertussis*, *B. holmesii*, *Bordetella parapertussis*.

**Materials/methods:** To generate resistance in four *B. pertussis*, three *B. holmesii* and three *Bordetella parapertussis* strains, these isolates were grown on CBA or HBA media with an Erythromycin E-test or disc for 15 weeks and subcultured every 3-4 days. Passaged isolates were sequenced on an Illumina NextSeq500 every 4 weeks. Long reads were obtained using Nanopore MinION.

**Results:** *B. parapertussis* isolates developed resistance (>256 µg/mL) within three to seven weeks. *B. holmesii* isolates took six to twelve weeks to develop resistance (>256 µg/mL), from an initial MIC ranging from 0.047-0.25 µg/mL. However, following 15 weeks, *B. pertussis* MIC fluctuated between 0.032 to 0.38 µg/mL and did not gain resistance. Sequencing results revealed mutations in the 23S rRNA gene in *B. holmesii*. However, sequencing of *B. parapertussis* did not resolve any differences between susceptible and resistant strains.

**Conclusions:** This study was able to demonstrate a potential resistance mechanism for *B. holmesii*. Although *B. parapertussis* developed a resistant phenotype on subculture, no mechanism was found. Fortunately, a resistant *B. pertussis* phenotype could not be induced by this method.

Abstract 5956

**In vitro activity of cefepime-taniborbactam (VNRX-5133) against genetically-diverse, largely multidrug-resistant, *Pseudomonas aeruginosa* clinical isolates**

Ryan Shields*, Chlesea Jones1, Ellen Kline1, Abigail Rubio1, Yohei Doi1

1University of Pittsburgh, Pittsburgh, United States

**Background:** Cefepime-taniborbactam is in phase 3 clinical development. Taniborbactam (VNRX-5133) is a cyclic boronate β-lactamase inhibitor that inhibits Ambler class A, B, C, and D β-lactamases. Our objective was to assess the in vitro activity of cefepime-taniborbactam against *Pseudomonas aeruginosa* clinical isolates, including those resistant to ceftazidime-avibactam and ceftolozane-tazobactam.

**Materials/methods:** Aztreonam, ceftazidime, ceftazidime-avibactam, ceftolozane-tazobactam, imipenem, and piperacillin-tazobactam minimum inhibitory concentrations (MICs) were determined in triplicate by broth microdilution. Cefepime was tested alone and with a fixed concentration of taniborbactam (4µg/mL). All isolates underwent whole-genome sequencing (Illumina).

**Results:** 100 *P. aeruginosa* isolates representing 58 different sequence types (ST) were tested; ST241 (*n*=7), ST129 (*n*=6), ST244 (*n*=6), and ST348 (*n*=6) were most common. All isolates harbored *bla*OXA-50. Other β-lactamase genes included *bla*OXA-2 (*n*=11), *bla*ORB (*n*=4), *bla*QMB (*n*=3), and *bla*VIM-2, *bla*OXA-10, *bla*VIM-1 (*n*=1 each). Thirty-two unique Pseudomonas-derived cephalosporinase (PDC) variants were identified, including PDC-338 (*n*=13), PDC-382 (*n*=10), and PDC-51 (*n*=8). MICs are shown in the Table. 74% of isolates were MDR (R to ≥3 agents) or XDR (R to ≥1 agent from all classes), including 29 isolates non-susceptible (NS) to ceftazidime-avibactam and/or ceftolozane-tazobactam. 70% of isolates were R to cefepime (MIC≥16µg/mL). Following the addition of taniborbactam, R rates were reduced to 27%; the median MIC fold-change was 2 (range: 0–32). 69% and 45% of MDR/XDR or isolates NS to ceftazidime-avibactam or ceftolozane-tazobactam were susceptible to cefepime-taniborbactam, respectively. In subsequent experiments we evaluated serial isolates from 24 patients who developed R to ceftolozane-tazobactam. Baseline (*n*=27) and post-exposure (*n*=40) isolates exhibited median ceftolozane-tazobactam MICs of 2 and 64µg/mL, respectively. Corresponding median MICs of ceftazidime-avibactam were 4 and 64µg/mL, demonstrating cross-resistance (median 16-fold MIC increase). Median cefepime-taniborbactam MICs increased 4-fold post-exposure (from 8 to 32µg/mL), however, 20% retained susceptibility.

**Conclusions:** Against a challenging largely MDR/XDR collection of *P. aeruginosa* clinical isolates, cefepime-taniborbactam demonstrated similar in vitro activity to ceftazidime-avibactam and ceftolozane-tazobactam. Importantly, the combination retained susceptibility against some isolates NS to ceftazidime-avibactam and ceftolozane-tazobactam. These data support the potential role for cefepime-taniborbactam against MDR *P. aeruginosa* infections, for which therapeutic options remain limited and the emergence of resistance to other novel agents has been documented.

Evaluation of a liquid chromatography and tandem mass spectrometry-based Carba detection method using the Acrion system for clinical isolates expressing multiple carbapenemases

William Mcgee*1, Scott Kronewitter1, Jaakko Haakana2, Jason Neil1, Mark Hutchins3, Soniya Gurung1, Marjaana Viirtola2, Arvind Verma2, Jim Stephenson1

1Thermo Fisher Scientific, Cambridge, United States, 2Thermo Fisher Scientific, Vantaa, Finland, 3Thermo Fisher Scientific, Basingstoke, United Kingdom

Background: Carbapenem resistance among Gram negative bacteria is a significant health threat due to the nature of carbapenems being considered antibiotics of last resort. Within this broad group are carbapenemase-producing organisms [CPOs], which distinguish themselves by actively expressing enzymes to inhibit carbapenems. Successful therapy is frequently dependent on identifying those specific mechanisms. In the majority of CPOs, a single carbapenemase is expressed, such that the challenge is to determine which carbapenemase is produced, and to respond accordingly, however, in recent years there has been an increase in CPOs that produce more than a single carbapenemase, leading to multiple, sometimes synergistic combinations of resistance. Having the ability to identify the full extent of carbapenemases expressed by a single isolate is critical for both successful therapy and epidemiological surveillance.

We present a method herein that offers the ability to detect multiple carbapenemases of the "big five", KPC, NDM, OXA-48-like, VIM and IMP, from within a single isolate and using high resolution mass spectrometry.

Materials/methods: Samples are prepared in an automated fashion following harvesting of cell colonies from culture. Cells are mechanically lysed, proteins are extracted from supernatant following centrifugation, and subjected to a short chromatographic separation with subsequent electrospray ionization and mass spectrometric analysis.

Results: Isolates of Enterobacteriales and Pseudomonas aeruginosa were evaluated for the presence of multiple carbapenemases. To date, we were able to detect combinations of KPC/OXA-48-like (2 strains), KPC/NDM (1 strain), NDM/OXA-48-like (2 strains) based on strain availability. These resistances were identified by leveraging tandem mass spectrometry to fragment intact carbapenemase proteins and detecting diagnostic fragments produced, each fragment having a specific mass-to-charge (m/z) and charge state and being produced from a specific intact protein m/z. Multiple carbapenemases are constantly sought for the majority of the method by alternating between different m/z, each corresponding to different intact carbapenemases.

Conclusions: We present a method that offers automation from sample preparation all the way to results. Following the use of liquid chromatography for sample simplification, the use of tandem mass spectrometry allows for multiple targets to be probed in rapid succession, allowing for detection of multiple carbapenemases in a single method.

Phenotype or genotype: association between mortality and minimum inhibitory concentration or beta-lactamase genes for patients with ceftriaxone non-susceptible *Escherichia coli* or Klebsiella spp. treated with piperacillin/tazobactam compared with meropenem.

Andrew Henderson1,2, David L. Paterson3, Mark Chatfield4, Paul Tambyah5, David Lye6,7, Partha Pratim De8, Raymond Tzer-Pin Lin9, Ka Lip Chew10, Yin Mo11,12,13, Tao Hong Lee11,12,13, Mesut Yilmaz14,15, Rumeya Lakmaki, Thamer Alenazi16,17, Yaseen Arabi18,19,20, Marco Falcone20, Matteo Bassetti20,21, Elida Righi20,21, Benjamin Rogers20,21,22, Souha S. Kanji23, Hasan Bhally23, Jonathan Iredell23,24, Marc Mendelson23, Tom Bouley23, David Looke24, Naomi Runnegar25,26, Spiros Miyakis27,28,30,31, Genevieve Walls32,33, Mohammed Al Khamis34, Ahmed Zikri35, Amy Crowe36, Paul Ingram36,37, Nick Daneman38, Paul Griffin39,40, Eugene Athan41, Leah Roberts42, Scott Beaton42, Anton Peleg43,44, Kyra Cottrell42, Michelle Bauer42, Khin Chaw45,46,47, Graeme Robert Nimmo48,49, Tiffany Harris-Brown49, Patrick Harris1,2.

**Background:** This study aims to assess the association of piperacillin/tazobactam and meropenem minimum inhibitory concentration (MIC) and beta-lactamase resistance genes with mortality from patients with ceftriaxone non-susceptible *E. coli* and *Klebsiella* spp. bloodstream infections.

**Materials/methods:** Blood culture isolates from patients enrolled in the MERINO trial were tested by broth microdilution, Vitek 2, disk diffusion and whole genome sequencing at a central laboratory. Classification and regression tree (CART) was performed to determine the optimal MIC cut point for 30-day mortality based upon broth microdilution. Multivariate logistic regression was performed to account for confounders. Absolute risk increase for 30-day mortality between treatment groups was calculated for the primary analysis (PA) and the microbiologic assessable (MA) populations.
Results: 320 isolates from 379 enrolled patients were available with susceptibility to piperacillin/tazobactam 94% and meropenem 100% by broth microdilution. Very major error, major error and minor error for piperacillin/tazobactam were 67%, 5% and 17% for Vitek 2 and 44%, 1% and 13% for disk diffusion. The piperacillin/tazobactam non-susceptible breakpoint (MIC > 16 mg/L) best predicted 30-day mortality after accounting for confounders (odds ratio 2.0, 95% CI 1.3 – 3.4). The absolute risk increase for 30-day mortality for patients treated with piperacillin/tazobactam compared with meropenem was 9% (95% CI 3% – 15%) and 8% (95% CI 2% – 15%) for the original PA population and the post-hoc MA populations, which reduced to 5% (95% CI 1% – 10%) after excluding strains with piperacillin/tazobactam MIC values > 16 mg/L. ESBL and OXA co-harbouring strains showed a higher absolute risk increase for patients treated with piperacillin/tazobactam compared to ESBLs only (14%, 95% CI 2% – 28% vs 5%, 95% CI -3% – 14%).

Conclusions: 30-day mortality was significantly higher for patients treated with piperacillin/tazobactam with MICs > 16 mg/L. After excluding non-susceptible strains, 30-day mortality difference was less pronounced for piperacillin/tazobactam. Poor reliability in susceptibility testing performance for piperacillin/tazobactam and mortality differences from the MERINO trial suggest that meropenem remains a preferred choice for definitive treatment of ceftriaxone non-susceptible *E. coli* and *Klebsiella*.

In vitro susceptibility of multidrug-resistant *Pseudomonas aeruginosa* following treatment-emergent resistance to ceftolozane-tazobactam

Abigail Rubio*,1, Ellen Kline1, Chelsea Jones1, Minh-Hong Nguyen1, Cornelius Clancy1, Ryan Shields1

1University of Pittsburgh, Pittsburgh, United States

**Background:** Multidrug-resistant (MDR) *Pseudomonas aeruginosa* is a major public health threat. Treatment with ceftolozane-tazobactam improves patient outcomes compared to salvage therapy; however, resistance has emerged in ~15% of patients following courses ranging from 7 to 53 days. Our objective was to study the *in vitro* activity of other β-lactams agents in the setting of ceftolozane-tazobactam resistance to evaluate cross-resistance or collateral sensitivity.

**Materials/methods:** Serial isolates from 15 patients in whom ceftolozane-tazobactam resistance emerged were selected for analysis. Minimum inhibitory concentrations (MICs) were determined by standard broth microdilution in triplicated and interpreted by CLSI breakpoints. Mechanisms of resistance were explored through whole-genome sequence (WGS) analysis.

**Results:** 20 baseline and 23 post-treatment isolates were included. The median baseline ceftolozane-tazobactam MIC was 1.5 µg/mL (range: <0.25 – 8 µg/mL). 75%, 55%, 50%, and 15% of baseline isolates were resistant to imipenem, piperacillin-tazobactam, ceftazidime, and ceftazidime-avibactam respectively. Following a median 20 (range: 4-52) days of therapy, the median post-treatment ceftolozane-tazobactam MIC was 128 µg/mL (range: 8 – >256 µg/mL). Resistance was predominantly associated with mutations in AmpC. 45%, 40%, 90%, and 65% of post-treatment isolates were resistant to imipenem, piperacillin-tazobactam, ceftazidime, and ceftazidime-avibactam [Figure]. The corresponding MIC fold-changes were -8, -2, 6, and 16, respectively. Median imipenem-relebactam MICs did not change before or after treatment with ceftolozane-tazobactam (median = 2 µg/mL for both) and 83% were classified as susceptible (MIC ≤ 2).

**Conclusions:** Our findings show that resistance to ceftolozane-tazobactam impacts the susceptibility of other β-lactams. Cross-resistance was evident between ceftolozane-tazobactam and ceftazidime-avibactam [median 16-fold MIC increase]. On balance, imipenem and piperacillin-tazobactam MICs were decreased suggesting that AmpC mutations alter the substrate profile of the enzyme. Importantly, imipenem-relebactam MICs were unchanged providing evidence that the agent may be a reasonable therapeutic option in the setting of ceftolozane-tazobactam resistance.

**Figure 1:** Distribution of β-lactam MICs against baseline and post-treatment isolates. The red bar denotes the median. As MICs increased for ceftolozane-tazobactam, median MICs increased for ceftazidime and ceftazidime-avibactam, decreased for imipenem and piperacillin-tazobactam, and were unchanged for imipenem-relebactam.

The diagnostic accuracy of cryptococcal antigen detection in serum and cerebrospinal fluid in HIV patients with suspected cryptococcal meningitis: systematic review and meta-analysis

Elvis Temfack*, Jean Joel Bigna Rim, Rene Spinnaker, Angela Loyse, Tom Chiller, Peter George Pappas, John Perfect, Tania C. Sorrell, Tom Harrison, Jeremie F. Cohen, Olivier Lortholary

1Hospital, Douala General Hospital, Douala, Cameroon, 2Hospital, Centre Pasteur du Cameroun, Yaounde, Cameroon, 3University, University Medical Centre Utrecht, Amsterdam, Netherlands, 4University, St. George’s University of London, London, United Kingdom, 5University, Tulane School of Public Health and Tropical Medicine, Atlanta, United States, 6University, University of Alabama at Birmingham, Alabama, United States, 7University, Duke University Medical Centre, Durham, United States, 8University, University of Sydney, Sydney, Australia, 9University, Necker Hospital, AP-HP, Paris Descartes University, Paris, France, 10Hospital, Hôpital Necker - Enfants malades, AP-HP, IHU Imagine, Paris, France

Background: Delayed diagnosis of HIV-associated cryptococcal meningitis (CM) is a major determinant of poor outcome. Cryptococcus spp. characterised by a capsular polysaccharide known as cryptococcal antigen (CrAg), detectable as a biomarker of infection could ensue timely institution of induction antifungal therapy.

Materials/methods: To determine the diagnostic accuracy of CrAg, we searched MEDLINE, EMBASE, and Web of Science (1981 – 2019) for studies comparing CrAg detection in blood (serum or plasma) or cerebrospinal fluid (CSF) to Indian ink staining and fungal culture of CSF in HIV-positive adults with symptoms suggestive of CM. CrAg detection was with either latex agglutination, enzyme-linked immunosorbent assay or by lateral flow assay. We used quality assessment of diagnostic accuracy studies (QUADAS-2) to evaluate risk of bias (RoB) and concerns about applicability of included studies. Through random-effects meta-analysis, we obtained summary estimates of the prevalence of serum CrAg positivity, prevalence of confirmed CM as well as the sensitivity and specificity of serum and CSF CrAg and agreement between CSF CrAg and CSF culture in diagnosing CM.

Results: We included eleven studies from eight countries on 3600 participants, 5 of which were judged at low RoB. The summary prevalence of serum CrAg was 63% (95%CI: 45 – 81) and of confirmed CM was 43% (95%CI: 26 – 59). Summary sensitivity and specificity of serum CrAg detection were 97% (95%CI: 87 – 100) and 92.6% (95%CI: 89 – 98), respectively. Summary sensitivity and specificity of CSF CrAg detection were 98.8% (95%CI: 96.2 – 99.6) and 99.3% (95%CI: 96.7 – 99.8), respectively. There was very high agreement between CSF CrAg and CSF culture at 98% (95%CI: 97 – 99) in classifying patients with and without CM.

Conclusions: In HIV-positive adults with symptoms suggestive of CM, negative serum CrAg may rule-out CM while positive serum CrAg should prompt lumbar puncture (LP) for CM confirmation. If LP is not feasible, symptomatic serum CrAg positive patients should be considered for induction antifungal therapy. In settings where LP is feasible, patients who present with a first episode of symptoms suspicious of CM, CrAg detection in CSF is diagnostic.

Abstract 5969

The epidome: a species-specific approach to quantify population dynamics and heterogeneity of Staphylococcus epidermidis colonisation and infection in primary samples

Amalie Rendboe1, Thor Bech Johanssen1, Emeli Månsson2, Søren Iversen1, Sharmin Baig1, Jørgen Skov Jensen1, Bo Söderquist2, Paal Skytt Andersen1, Marc Stegger*1

1Statens Serum Institut, København, Denmark, 2Örebro University, School of Medical Sciences, Örebro, Sweden

Background: Staphylococcus epidermidis has gained attention as an increasingly important multidrug-resistant nosocomial pathogen in infections related to foreign body infections. Identification of S. epidermidis as an invasive agent is not trivial, and recent research suggests that heterogeneity is a common phenomenon in both carriage and infection. To elucidate clonality of S. epidermidis communities, we developed the “Epidome” assay, a culture-independent method based on targeted-sequencing of S. epidermidis-specific targets that provide information on quantity and diversity of S. epidermidis from primary samples.

Materials/methods: Based on >850 S. epidermidis genomes, core genes from representatives of all major lineages were parsed for highly conserved and variable regions suitable as PCR targets. These amplicon targets were evaluated for their ability to discriminate the entire population before designing primers for best candidates. For validation, DNA from S. epidermidis representing 15 sequence types and from 49 other common skin commensals, including 25 Staphylococcal species, were used for laboratory validation. Even and staggered genomic mock communities were subjected to a duplex PCR before applying paired-end Illumina sequencing. In addition, a qPCR probe was designed and validated for quantification of total genomic copies of S. epidermidis. Application of the method was demonstrated on human samples collected by ESwab from skin and nose of healthy carriers to investigate heterogenicity.

Results: No single target sufficiently differentiated the S. epidermidis population, so two targets (493/521-bp) were selected and optimized in a duplex PCR. The qPCR probe for one of the S. epidermidis gene targets revealed a sensitivity of ~100 S. epidermidis/μL template. Applying next-generation sequencing revealed a high level of reproducibility on even- and staggered-mock communities that allowed reliable differentiation of the S. epidermidis population. The primary samples from nares and skin showed high levels of S. epidermidis heterogeneity.

Conclusions: The Epidome approach provides information on S. epidermidis quantity and diversity well beyond species-level in primary samples. Our targeted sequencing method allows rapid differentiation and identification of clinically important nosocomial lineages in samples with low abundance. The method can be useful for investigating clonality of S. epidermidis communities, population dynamics and temporal stability or niche selection due to antimicrobials.

Meropenem versus piperacillin-tazobactam for definitive treatment of bloodstream infections caused by AmpC beta-lactamase-producing Enterobacter spp., Citrobacter freundii, Morganella morganii, Providencia spp., or Serratia marcescens: a pilot multi-centre randomised controlled trial (MERINO-2)

Abstract third-party references: University of Queensland Centre for Clinical Research

Background: Enterobacter spp., Klebsiella aerogenes, Citrobacter freundii, Morganella morganii, Providencia spp., and Serratia marcescens possess chromosomally encoded AmpC beta-lactamases that may hydrolyse third-generation cephalosporins [3GC]. Whether piperacillin-tazobactam is effective carbapenem-sparing therapy for bloodstream infection (BSI) caused by these organisms is uncertain. We undertook a pilot randomised controlled trial (RCT) (ACTRN12614001211651; NCT02437045) to assess feasibility and inform the design of a larger definitive trial.

Materials/methods: We enrolled adult patients from 7 sites in Australia and Singapore with BSI caused by chromosomal AmpC beta-lactamase producers. Participants were randomized within 72 hours of initial blood culture collection 1:1 to piperacillin-tazobactam 4.5g 6-hourly or meropenem 1g 8-hourly for a minimum of 3 days. Treating clinicians were not blinded to treatment allocation. The primary outcome was a composite of death within 30 days post randomisation; or clinical failure at day 5 post-randomisation; or microbiological failure on days 3-5; or microbiological relapse from day 5 to 30.

Results: Interim results are presented here. Between July 2015 and May 2019 a total of 56 patients were enrolled, from 575 screened. Of these, 50 were randomized appropriately, received at least one dose of study drug and were included in the primary analysis population (piperacillin-tazobactam=26; meropenem=24). No patients were lost to follow-up. The mean age was 65.0 years [range 19-93], 26% were female and 78% of BSI were healthcare-associated. The most common source was line-related [24%], biliary [20%] or urinary tract [18%]. A total of 10/26 [38.5%] met the composite primary outcome in the piperacillin-tazobactam group, and 5/24 [20.8%] in the meropenem group [P=0.174]. Only 1 death occurred in a patient randomised to meropenem. There were 4 microbiological failures, all occurring in patients randomised to piperacillin-tazobactam, of which two demonstrated emergent resistance. Recruitment will continue until 31 Dec 2019 to a maximum of 100 patients. Final outcome results will be available for presentation at ECCMID.

Conclusions: This is the first RCT to specifically compare treatment options for BSI caused by Gram-negative species with chromosomally encoded AmpC beta-lactamases. The results of this pilot trial will help inform larger definitive trials to define carbapenem-sparing options for these infections.

Impact of the Spanish Bacteraemia Zero project on central line-associated bloodstream infection rates

Sulamita Carvalho Brugger*1,2, Montserrat Vallverdú1,2, Mar Miralbés1,2, Begoña Balsera1,2, Silvia Rodriguez1,2, Silvia Iglesias1,2, Jesús Caballero1,2

1University Hospital Arnau de Vilanova, Lleida, Spain, 2Institut de Recerca Biomèdica de Lleida Fundació Dr. Pifarré, Lleida, Spain

Background: Central line associated bloodstream infection (CLABSI) is an important cause of hospital-acquired infection associated with morbidity, mortality and cost, and one of the most common infections acquired in ICU. In 2009 was launched in Spain the Bacteriemia Zero (BZ) project, based on specific measures related to the insertion and management of central venous catheter (CVC), and on other measures to promote a daily safety culture on ICU. This work aims to describe the impact of CLABSI rates after the implementation of BZ project in a Spanish ICU and the CLABSI etiology in our unity.

Materials/methods: Descriptive retrospective study, based on data from ENVIN-HELICS database, from an 18-bed polyvalent ICU. We analyzed CLABSI rates in the last 19 years, divided in 2 periods: P1 before BZ implementation, from January 2001 to July 2009; and P2, from August 2009 to October 2019, after BZ implementation. The difference between rates in the 2 periods was analyzed with Fisher’s exact test (signification with p<0.01).

Results: In P1 99 CLABSI were recorded, for 26449 days of stay, while in P2 there were 79 CLABSI for 57630 days of stay. The rates for P1/P2 were 3.7/4.17 for 1000 days of stay, 4.92/1.79 for 1000 days with CVC and 3.73/1.4 CLABSI for 1000 catheters days (CVC + arterial catheter). This is a reduction of 60.97%, 64.23% and 62.46%, respectively. The distribution by microorganisms was, in both periods: Staphylococcus epidermidis 34.0%/38.9%, methicillin-sensitive Staphylococcus aureus 10.7%/13.0%, methicillin-resistant Staphylococcus aureus 2.9%/1.2%, Acinetobacter baumannii 7.8%/1.3% (p<0.001), Pseudomonas aeruginosa 6.8%/7.8%, other gram-negative bacilli 23.3%/14.3%, Enterococcus 6.8%/6.5%, Candida spp 8.7%/9.1%, and other microorganisms 8.7%/8.8%. In 2018, there were just 2 cases of CLABSI in our unit (0.41/1000 days of stay), and 4 cases in 2019 until October.

Conclusions: Starting from a CLABSI rate superior than the one recommended by the quality standard, after the implementation of BZ project there was a significantly reduction on CLABSI in our unity, bigger than 60%, reaching values below the Spanish rates. The microbiological etiology was similar in both periods, except for the almost disappearance of A baumannii.

Abstract 5985

Antimicrobial stewardship opportunities at discharge: current prescribing at Boston Medical Centre
Nicholas Rebold*1, Karrine Brade1

1Boston Medical Center, Boston, United States

Background: Most antimicrobial stewardship interventions target inpatient prescribing; however, the majority of individual treatment courses are completed following hospital discharge. Additionally, data suggests antibiotics prescribed during this transition of care are often inappropriate. The objective of this study was to assess the appropriateness of antimicrobials prescribed upon hospital discharge at Boston Medical Center in order to guide future stewardship opportunities at the institution.

Materials/methods: Data on antimicrobials prescribed at discharge were collected between August 4th to 17th, 2019. Discharge antibiotics were assessed for overall appropriateness, defined as a composite of appropriateness of drug choice, dose, and duration. Antibiotic indication, inpatient, outpatient, and total days of therapy were collected and excess antibiotic days were calculated. Excluded prescriptions were those sent from the emergency department, or those from the observation or pediatric care teams.

Results: A total of 203 patients were included with 250 unique prescriptions. Overall appropriateness (as a composite of drug choice, dose, and duration) was only 40.4% (101/250). The most common antibiotics prescribed were cefpodoxime (14%), trimethoprim-sulfamethoxazole (12.8%), and amoxicillin-clavulanate (10.8%). Drug choice was appropriate in 85.6% (214/250) of prescriptions, however for urinary tract infections and community-acquired pneumonia only 62.2% (28/45) and 69.2% (18/26) were appropriate, respectively. The drug with the highest inappropriate selection was cefpodoxime at 54.3% (19/35), followed by levofloxacin at 35% (7/20). Overall, doses were prescribed appropriately in 97.6% of cases (244/250); however the duration of therapy was appropriate in only 48.0% of prescriptions (120/250), resulting in an average excess duration of 3.6 days. Inpatient and outpatient days of therapy were 5.0 and 10.9 days, respectively, for a total average days of therapy of 15.9 days.

Conclusions: Antibiotics at discharge are an important area of focus for antimicrobial stewardship interventions. Shortening durations of therapy remains the largest target, followed by appropriate antimicrobial selection, specifically for urinary tract infections and community-acquired pneumonia. This data highlights a significant need for antimicrobial stewardship interventions on prescribing upon hospital discharge with a focus on drug selection and duration.

Abstract 5987

**C-reactive protein patterns by age, sex and pathogen in patients with Gram-negative bacteraemia**

Virginie Prendki1,2*, Elodie Von Dach1, Werner Albrich2, Anne-Sophie Brunel1,2, Clémence Cuvelier1, Domenica Flury2, Angèle Gayet-Ageron1, Benedikt Huttner1, Philipp Patrick Kohler1, Eva Lemmenmeier2, Stephan J. Harbarth1, Laurent Kaiser1, Pierre-Yves Bochud2, Angela Huttner1

1Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland, 2Kantonsspital St.Gallen, St. Gallen, Switzerland, 3Lausanne University Hospital, Lausanne, Switzerland

**Background:** C-reactive protein (CRP) levels have been reported to differ by sex and age in healthy volunteers, but acute-phase patterns have been poorly characterized in patients with bloodstream infections. We explored differences in CRP kinetics by age, sex, and infecting pathogen.

**Materials/methods:** The multicenter non-inferiority PIRATE trial (NCT03101072) randomized 504 adult patients with gram-negative bacteraemia to an individualized/CRP-guided duration, 7 days, or 14 days of antibiotic therapy. Patients with complicated infections and/or non-fermenting bacteria were excluded. Per local practice, CRP levels were drawn daily from onset of illness until a descent from peak was documented; in the individualized arm, antibiotic therapy was discontinued when CRP levels decreased by 75%. Plasma CRP concentrations are measured via immunoturbidimetry.

**Results:** Among 498 patients with CRP data, median age was 79 years (IQR 68-86); 304 (61%) were women. Median peak CRP was 164 mg/l (IQR 105-247) and occurred median 1 day after bacteremia (IQR 0-2). While peak concentrations did not differ between men and women (median 164 mg/l for both), the very elderly (≥85 years, n=154) trended toward lower values (median 151 mg/l [IQR 104-216] versus 167 mg/l [IQR 103-262], ns), and experienced a significantly slower CRP descent thereafter (odds ratio for CRP>50% of peak by day 5: 1.78 [95% CI 1.21-2.63]). Patients with *Escherichia coli* infections (370/498, 74%) had significantly higher peak values (median 174 mg/l [IQR 117-251] versus 167 mg/l [IQR 103-262], ns), and experienced a significantly more rapid CRP descent (OR for descent by ≥50% by day 5: 1.98 [95%CI 1.31-2.98]). Patients with other Enterobacteriaceae followed the same pattern, with the notable exception of *Klebsiella* spp.: these (81/498, 16%) had significantly lower peak CRP values (median 118 mg/l [IQR 78-191] versus 174 mg/l [IQR 114-253], P=.0002) that declined significantly more slowly (OR for CRP>50% of peak by day 5: 2.00 [95% CI 1.22-3.29]).

**Conclusions:** The very elderly trend toward lower peak CRP concentrations and have significantly slower return to normal levels. Patients with *E. coli* infections have significantly higher peak CRP values and significantly more rapid CRP descent, while those with *Klebsiella* infections have significantly lower peak CRP values and significantly slower descent.

Abstract 5989

**Rapid identification of positive blood culture, short-incubation subcultures by MALDI-TOF MS comparing pre-conditioned and non-conditioned culture media adapted to laboratory automation**

Caitlin Reimers¹, Elizabeth Grabsch², Kit Lui², Amy Batey², Kyra Chua*², Marcel Leroi²

¹RMIT University Bundoora Campus East, Mill Park, Australia, ²Austin Health, Heidelberg, Australia

**Background:** Rapid identification methods, including short incubation subcultures utilising MALDI-TOF-MS, have been developed to decrease positive blood culture (posBC) turnaround times. Short-incubation subcultures often utilize pre-conditioned media but there are no reports comparing pre-conditioned and non-conditioned media. This study assessed early MALDI-TOF-MS identification of posBC isolates from pre-conditioned agar (CO₂-35°C) and non-conditioned media (room-temperature) used for short-incubation MALDI-TOF-MS methods, that were adapted to a laboratory automation system.

**Materials/methods:** One drop of neat posBC was inoculated manually onto each of two CBA pre-conditioned agar (CO₂-35°C minimum 4 hrs), and incubated (pCBA-S, in standard CO₂-35°C incubator; pCBA-K in CO₂-35°C automated laboratory incubator [BD-Kiestra-WCA, first inoculation protocol]). Similarly, a third CBA agar (CBA-K, room-temperature) was inoculated and incubated in CO₂-35°C BD-Kiestra-WCA incubator. MALDI-TOF-MS (4 wells each with 0.5 µl formic acid [BioMerieux]) was performed from all short-incubation CBA, if any visible growth was present on any these CBA (checked at 2, 3 and/or 4 hrs). Results of all short-incubation methods were compared to MALDI-TOF-MS identification at 18-24 hrs from standard subcultures. All MALDI-TOF-MS testing was performed on Vitek MS [BioMerieux].

**Results:** A total of 110 posBC bottles from 83 patients were assessed, and of these 106/110 (96.4%) were mono-microbial. Gram-positive bacteria (GP) were isolated from 53/110 (48.2%) posBC, and Gram-negative bacteria (GN) from 52/110 (47.3%) posBC. After 4 hrs incubation, the concordance rates (compared to MALDI-TOF-MS from standard cultures, 24h) for identification were similar for all short-incubation CBA. Early GP identification rates were 40/53 (75.5%), 40/53 (75.5%), 41/53 (77.4%) for pCBA-S, pCBA-K and CBA-K respectively. Similarly GN rates were 52/52 (100%), 50/52 (96.2%), 51/52 (98.1%). Yeast were isolated from 5/110 (4.5%) but none were identified from any short-incubation CBA. There were no differences in yield between different genera for conditioned and non-conditioned plates.

**Conclusions:** Concordance rates for early identification of GP and GN using MALDI-TOF MS on posBC isolates from all short-incubation cultures were high. Pre-conditioning media did not improve concordance and routine use may not be required. Short-incubation culture can be adapted to laboratory automated systems, streamlining workflow whilst maintaining reduced turnaround times.

**Presenter email address:** kyra.chua@austin.org.au
Metagenomics analysis of novel viruses in dromedaries from the Middle East
Hwei Huih Lee*, Jade Li Teng1,2, Joshua Fung1, Kai Yan Yeong1, Kwok-Hung Chan1, Susanna K. P. Lau1,2,3,4, Patrick C. Y. Woo1,2,3,4

1The University of Hong Kong, Department of Microbiology, Hong Kong SAR, Hong Kong, 2State Key Laboratory of Emerging Infectious Diseases, The University of Hong Kong, Hong Kong SAR, Hong Kong, 3Carol Yu Centre for Infection, The University of Hong Kong, Hong Kong SAR, Hong Kong, 4Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The University of Hong Kong, Hong Kong SAR, Hong Kong

Background: Viruses in dromedary camels have been extensively studied over the past decades since the emergence of Middle East Respiratory Syndrome Coronavirus (MERS-CoV) outbreak in the Arabian Peninsula and its surroundings. They are known as carriers of many viral pathogens, however, fundamental aspects of other novel infectious virus communities in dromedaries remains poorly described.

Materials/methods: Next generation sequencing (NGS) has made metagenomics a gold standard in microbiome studies and it had become the main tool for virus discovery. Camels at Middle East were regularly checked for MERS-CoV since its outbreak and these upper respiratory samples were cultured intensively as there might be potential unidentified viruses that can cause disease in humans. Those with high cytopathic effect (CPE), which is not typical to MERS-CoV were collected for further investigation. The cultured samples were extracted and sequenced on an Illumina HiSeq platform. Reads were filtered, assembled and aligned from short fragments of contigs with DIAMOND. They were annotated and then analysed with MetagenomeAnalyzer (MEGAN) producing metagenomics tree as belonging to the virus groups or other undefined viruses. Contigs matched to groups of viral families especially those previously unknown to dromedaries were selected for further studies.

Results: Cellular organisms were often the most abundance group. In this study, we had successfully obtained complete genome of Avian avulavirus infecting dromedary which is not common and non-occurrence in camels but is a common disease in bird species. Investigation shows that these viruses are lethal to dromedaries. The host of infection belong to the Family of Paramyxoviridae which consist of 6 genes in the order 5’-N-P-M-F-HN-L-3’. Currently, there is no evidence on how does the virus transmits to dromedaries, it is likely that the routes of transmission were through the droppings, sharing of foods and water and also mix farming.

Conclusions: Overall, our studies provide insights that cross transmission among camels and other animals (in this context not only mammalian) are possible, highlighting the importance of in depth studies in camels as a secondary host. Understanding the cross transmission of diseases from other animals presents the basis towards developing a better management strategies in camel farming.

Metagenomic sequencing to identify environmental reservoirs of carbapenem-resistant Acinetobacter baumannii associated with clinical outbreaks

Brian Forde*, Leah Roberts1, Patrick Harris2,3, Amy Jennison4, Krispin Hajkowicz5, Trish Hurst5, Michelle Doidge5, Scott Beatson1, David L. Paterson2,5
1The University of Queensland, School of Chemistry and Molecular Biosciences, Saint Lucia, Australia, 2The University of Queensland, Centre for Clinical Research, Herston, Australia, 3Pathology Queensland, Central Microbiology, Herston, Australia, 4Queensland Health, Forensic and Scientific services, Brisbane City, Australia, 5Royal Brisbane and Women’s Hospital, Infectious Diseases Unit, Herston, Australia

Abstract 6000

Background: Metagenomics is an emerging technology that has wide-ranging potential for use in clinical and public health settings for outbreak management, pathogen detection and for antimicrobial resistance gene surveillance. Metagenomics bypasses the cultivation bottleneck by directly sequencing the DNA of all organisms within a sample, allowing for relatively unbiased pathogen detection and resolution of the resident microbial community. However, questions over detection sensitivity and cost have seen the technology remain largely under-utilised in clinical research. Here we report the use of metagenomics sequencing to identify environmental reservoirs of pathogenic bacteria associated with an ongoing carbapenem-resistant Acinetobacter baumannii (Cr-Ab) outbreak in a burns unit.

Materials/methods: Environmental swabs and water samples were collected from the ICU and Burns ward of a single hospital and subjected to traditional culturing methods and shotgun metagenomic sequencing. Sequence read data for all samples were screened against a database of complete bacterial genomes, seeded with the complete genomes of a representative outbreak strain. Positive metagenomics samples were confirmed by culture and isolate sequencing.

Results: Over a four-month period a total of 54 environmental swabs and water samples were collected from areas of presumed high bacterial load (e.g. floor drains, plumbing, burns bath drains). Of 54 environmental samples only two were culture positive for A. baumannii, while five were positive for A. baumannii based on preliminary analysis of the metagenomic sequencing data. Culturing and metagenomics where only concordant in one case indicating that high sequencing depth (~5 gigabase pairs) is required to reliably discriminate specific species from the background population. Enrichment of metagenomic samples by filtering for A. baumannii sequence reads enabled strain level sequence typing by MLST profiling and phylogenetic analysis. Targeted cleaning of plumbing and decommissioning of contaminated burns baths resulted in no new positive cases being reported.

Conclusions: Here we demonstrate the feasibility of using metagenomic sequencing for targeted surveillance during an active outbreak. The identification of the outbreak strain in the plumbing enabled a precision infection control response resulting in resolution of the outbreak and cost savings which offset sequencing costs.

Co-infection with Mycoplasma or Ureaplasma spp. among HIV-positive men who have sex with men in Taiwan

Tai-Fen Lee*, Kuan-Yin Lin, Wen-Chun Liu, Yi-Jing Chen, Hsin-Yun Sun, Yu-Chung Chuang, Un In Wu, Sui-Yuan Chang, Chien-Ching Hung, Po-Ren Hsueh

1National Taiwan University Hospital, Taipei, Taiwan, 2National Taiwan University Hospital Jin-Shan Branch, New Taipei, Taiwan, 3National Taiwan University, Taipei, Taiwan

Abstract 6004

Background: Mycoplasma and Ureaplasma spp. have recently been recognized as pathogens causing urethritis and infertility. However, the data on coinfection with Mycoplasma and Ureaplasma spp. are limited among HIV-positive patients. We aimed to evaluate the prevalence of and associated factors with mycoplasmal and ureaplasmal coinfection among at-risk HIV-positive patients.

Materials/methods: From May to November 2019, we prospectively included HIV-positive men who have sex with men (MSM) with a history of sexually transmitted infections (STIs) or symptoms suggestive of STI. Urine and rectal specimens were collected and tested for Chlamydia trachomatis (CT), Neisseria gonorrhoeae (NG), Trichomonas vaginalis (TV), Mycoplasma genitalium (MG), Mycoplasma hominis (MH), Ureaplasma urealyticum (UU), Ureaplasma parvum (UP) with the use of multiplex real-time PCR assay.

Results: During the 6-month study period, 114 HIV-positive MSM (median age, 37 years) were included. All patients had been receiving combination antiretroviral therapy (cART) with a median CD4 count of 623 cells/µL and 85.1% having achieved plasma HIV RNA load <20 copies/mL. Among 26 patients having symptoms at screening, only 7 (26.9%) had symptoms suggestive of proctitis and 2 (7.7%) had urethritis. The prevalences of CT, NG, TV, MG, MH, UU, and UP infections among the 114 patients were 50.0% (n=57), 20.2% (23), 0%, 11.4% (13), 15.8% (18), 39.4% (45), and 5.3% (6), respectively. The prevalences of MG, MH, UU, and UP infections were even higher among patients coinfected with CT and/or NG (15.6%, 23.4%, 51.6%, and 4.7%, respectively) than that without (6.0%, 6.0%, 24.0%, and 6.0%, respectively). More than half of Mycoplasma and Ureaplasma spp. were detected from rectal swab specimens: 71.4% for MG, 85.0% for MH, 54.5% for UU, and 83.3% for UP. The factors associated with acquisition of UU were concurrent gonorrheal (adjusted odds ratio [AOR], 3.19; 95% CI, 1.11-9.20) and anal sex in 6 months (AOR, 2.89; 95% CI, 1.11-7.48).

Conclusions: Rectal mycoplasmal and ureaplasmal coinfections were common among at-risk HIV-positive MSM. The high rate of UU positivity and association with gonorrhea support the use of multiplex testing for detection of concurrent, multiple STIs.

**Adherence to routine monitoring guidelines for people living with HIV is poorer in higher-volume outpatient settings: when more is not better!**

Dorothy Ng*1, Ian Liang En Wee1, Edwin Chong Yu Sng1, Simon Kiat Loon Lee1, Zhu Ling1, Limin Wijaya1, Yii Ean Teh1

1Singapore General Hospital, Singapore, Singapore

**Background:** Potent antiretroviral therapy (ART) has transformed HIV from a fatal disease to a manageable chronic condition. Treatment goals for people living with HIV (PLHIV) have shifted from achieving durable viral suppression to person-centred healthy aging. Regular monitoring of biochemical parameters and vaccination uptake are essential components of care for PLHIV, but adherence to monitoring guidelines in our institution are currently unknown.

**Materials/methods:** A cross-sectional study of PLHIV who were initiated on ART between Jan 2012 – Dec 2015, and followed-up in the general Infectious Diseases clinic, was conducted. Adherence to monitoring for cardiovascular health, bone health, vaccination uptake, and renal disease, over the time period of June 2017- June 2019, was assessed. Optimal monitoring frequency was defined as per 2019 DHHS Guidelines. Correlation between patient and/or physician characteristics with adherence to monitoring were evaluated. Additional correlations were made after differentiating high- and low-volume physicians by median number of PLHIV seen per physician.

**Results:** A total of 163 PLHIV were recruited, of which, 91.4% were male; 53.4% were employed, 14.1% had social issues. 89.6% were compliant to ART and 68.7% were virologically suppressed. 42.9% received recommended vaccinations; 63.2% underwent bone health screening, and 55.2% underwent regular cardiovascular screening. Of those on a tenofovir-containing regimen (71.2%), 28.4% (33/116) had regular renal function monitoring. PLHIV followed up with lower-volume physicians had significantly higher cardiovascular screening rates (71.9% vs 51.1%, p=0.047) compared to higher-volume physicians. Vaccination frequency (56.3% vs. 39.7%, p=0.112) and bone health screening (68.8% vs 61.8%, p=0.543) were comparable in both groups. On multivariate analysis, being on followup with higher-volume physicians was independently associated with poorer compliance to metabolic screening (aOR=2.55, 95%CI=1.01-6.64). Other factors independently associated with poorer compliance to metabolic screening included current employment; being on a tenofovir-containing regimen, and physician seniority.

**Conclusions:** Surprisingly, PLHIV followed up by higher-volume physicians in the outpatient setting tended to have lower rates of regular cardiovascular screening, despite greater presumed physician familiarity with PLHIV care. Creating streamlined pathways for PLHIV care may improve physician adherence to regular monitoring of biochemical parameters and vaccination uptake.

Abstract 6009

**Efficacy of CD377, a novel antiviral Fc-conjugate, against influenza A(H1N1) in a lethal mouse model of Severe Combined Immunodeficiency (SCID)**

James Levin1, Karin Amundson1, Kim Shathia1, Allen Borchardt1, Thanh Lam1, Wanlong Jiang1, Zhi-Yong Chen1, Tom Brady1, Simon Döhrmann1, Voon Ong1, Leslie W. Tari1*

1Cidara Therapeutics, San Diego, United States

**Background:** Cidara’s AVCs (antiviral Fc-conjugates) are novel, immunotherapeutic conjugates of potent, antiviral agents with the Fc domain of human IgG1. These long-acting AVCs directly inhibit viral replication while simultaneously engaging the immune system. CD377 is an AVC development candidate being evaluated for seasonal and pandemic influenza, including in immune-deficient populations who are unable to benefit from vaccination. We evaluated CD377 in SCID mice to determine the impact of compromised immune status on its efficacy.

**Materials/methods:** Efficacy was evaluated in female BALB/c or BALB/c scid mice challenged intranasally with 3x the LD95 of influenza A/Puerto Rico/8/1934 (H1N1) [3E2 or 2E2 pfu/mouse respectively]. Mice were treated with a single subcutaneous dose of CD377 (between 0.01 and 10 mg/kg) two hours after viral challenge. The SCID study included baloxavir as comparator, at 3 or 10 mg/kg, bid x 1 day. Body weights (BW) were monitored daily for 14 or 28 days, with 20% BW loss recorded as mortality.

**Results:** In a benchmark study with immune-competent mice, CD377 was protective at 0.1 mg/kg (P=0.0031 relative to vehicle) accompanied by a transient drop in BW of less than 7%. Full recovery to starting BW was observed by study end (Day 14). Groups treated with vehicle or Fc-only control fully succumbed to infection by Day 6.

In a similar study with immune-compromised scid mice challenged with the same virus, CD377 dosed at 0.1 mg/kg was fully protective for 21 days. At 0.3 mg/kg, mice were fully protected for the entire study (28 days) (P=0.0020). In contrast, mice treated with 6 mg/kg [total dose] of baloxavir were only protected until Day 13, reaching 40% mortality by study end on Day 28. The potency of CD377 was further supported by BW data; scid mice treated at 0.3 mg/kg demonstrated only a transient BW drop of <3% [Day 4].

**Conclusions:** CD377 demonstrated robust efficacy in immune-competent and severely immunodeficient mouse infection models. The dose necessary to protect lethally challenged mice from both studies for 14 days was equivalent. This result supports further development of CD377 as a novel antiviral for prevention against influenza, including high-risk patients with immunodeficiencies.

Abstract 6013

Effect of the capsule exchange between serotype K1 and K20 *Klebsiella pneumoniae* on serum killing, neutrophil phagocytosis and mice lethality

Esther Yip-Mei Liu1, Jen-Chang Chang2, Jung-Chung Lin3, Feng-Yee Chang*4,5

1National Defense Medical Center, National Defense Medical Center, Taipei City, Taiwan, 2National Health Research Institutes, National Health Research Institutes, Miaoli, Taiwan, 3National Defense Medical Center and Tri-Service General Hospital, National Defense Medical Center and Tri-Service General Hospital, Taipei, Taiwan, 4Tri-Service General Hospital, National Defense Medical Center and Tri-Service General Hospital, Taipei City, Taiwan, 5National Defense Medical Center and Tri-Service General Hospital, Taipei City, Taiwan

**Background:** Capsular polysaccharide (CPS, K-antigen) of *Klebsiella pneumoniae* (Kp) is one of the major factors for hypervirulence. In this study, we investigate the effect of capsule exchange between serotype K1 and K20 Kp on serum killing, neutrophil phagocytosis and mice lethality.

**Materials/methods:** Capsule exchange strains between serotype K1 and K20 (K1∆K1cps::K20cps and K20∆K20cps::K1cps) and cps knockout strains (K1∆cps_{wzx-gnd} and K20∆cps_{wbaP-gnd}) were constructed to perform the experiment of serum killing, neutrophil phagocytosis and mice lethality.

**Results:** Capsular type of K1 and K20 ∆K20cps were confirmed as K1 whilst K20 and K1∆K1cps::K20cps were typed as K20. Neither K1∆cps nor K20∆cps had agglutination with K1-antiserum/K20-antiserum. The thickness and form of the capsule of the cps exchange strains shown in electron microscopy (EM) resemble to the type of cps it received. No capsule was found in K1∆cps and K20∆cps. Except the parental K20 strain, the parental K1 and the switched cps clones of K1 and K20 had shown hypermucoviscous (hmv) phenotype in the string test. In serum killing experiment, K1, K1∆cps and K1∆K1cps::K20cps were serum resistant (grade 5-6) whilst K20, K20∆cps and K20∆K20cps::K1cps were serum sensitive (grade 1-2). With the presence of the lipopolysaccharide (LPS), changing capsular type in Kp did not affect much in serum susceptibility. In neutrophil phagocytosis, K1, K20 and K1∆K1cps::K20cps were phagocytic resistant whilst K20∆K20cps::K1cps, both cps knockout strains were phagocytic susceptible. K1∆K1cps::K20cps would not alter its phagocytic susceptibility. Vice versa, K20∆K20cps::K1cps would turn from phagocytic resistant to sensitive. Likewise, LD_{50} of K1∆K1cps::K20cps [5.4x10^{1} CFU] in mice lethality was comparable to that of K1 [5.0x(10^{1}-10^{2}) CFU]. K20∆K20cps::K1cps [LD_{50}=3.1x10^{4} CFU] was attenuated when compared to K20 [LD_{50}=6.1 x (10^{3}-10^{4}) CFU]. LD_{50} of both cps knockout strains were higher than 10^{6} CFU. Under K1 genetic backbone, K1 could support K20 CPS expression and hence the virulence of K1∆K1cps::K20cps would keep. However, with K20 genetic backbone, K20 was unable to fully support K1 CPS expression resulting to the decline in virulence of K20∆K20cps::K1cps.

**Conclusions:** Switching capsular type in Kp could affect CPS expression, but retain its serum susceptibility. Effect on phagocytosis or mice lethality would depend on the genetic backbone of the recipient Kp.

Abstract 6019

**The effectiveness of two rapid identification technologies in Gram-negative bacteraemia without antimicrobial stewardship interventions**

Lee Nguyen*,1, Donna Chong1, Jenee Vo1, Joseph Lee1, Trina Ho1

1Loma Linda University, Loma Linda, United States

**Background:** Rapid diagnostic technologies provide faster organism identification with subsequent antimicrobial susceptibilities, which would improve antimicrobial therapy selection or optimization. This quality improvement study consists of four parts: 1) no rapid diagnostic technologies (nRDT) 2) implementation of Verigene (VG) 3) implementation of Accelerate Pheno (AP), 4) AP with antimicrobial stewardship (ASP) intervention. The study aim is to compare the first three phases prior to implementing the last phase utilizing RDT with ASP interventions.

**Materials/methods:** We evaluated the first 100 cases of gram-negative bacteraemia (GNB) in the baseline period (2016) and intervention period (VG:2018, AP:2019) using quasi-experimental design. The subjects were divided into three groups based on the method of gram-negative organism identification: no RDT (nRDT), Verigene (VG), and Accelerate Pheno (AP). Vitek-2 was used for antimicrobial susceptibility testing. Inclusion criteria were patients with the first incidence of GNB and age ≥18-years-old. Patients with a hospital length of stay <2 days or those with GNB caused by organisms not detectible by either VG or AP were excluded. Study outcome measures include all-cause hospital mortality, length of hospitalization after positive blood culture (LOS), time to effective antibiotics, time to clinical stability, and incidence of VG/AP misidentification/detection failure. Electronic medical records were reviewed for patient specific factors and desired outcomes data.

**Results:** The study included 222 subjects (nRDT, n=67; VG, n=86; AP, n=69). All-cause mortality differed between groups, (nRDT, n=2(3%); VG, n=11(13%); AP, n=2(3%), p=0.02). LOS were similar between groups, (mean days±SD, nRDT, 6.1±6.9; VG, 6.5±5.8; AP, 7.6±10.9, p=0.64). Time to effective antibiotics was shortest in the AP group, (mean hours±SD nRDT, 5.5±8.8; VG, 5.2±13 ; AP, 3.6±9.3, p<0.001). Achievement of clinical stability were similar (nRDT, n=58(87%); VG, n=73(85%); AP, n=57(83%), p=0.81). A difference was detected in the time to clinical stability (mean days±SD nRDT, 1.9±2.8; VG, 4.4±8; AP, 1.6±2.2, p=0.004). Incidence rates of misidentification/detection failure were similar, (VG, n=2(2%); AP, n=6(9%), p=0.14).

**Conclusions:** We found outcome differences including, mortality, time to effective antibiotics, and time to clinical stability between the groups. Further evaluations of RDT with ASP interventions is needed to determine if further optimization RDT can be achieved.

Adequacy of antibiotic treatment in patients with negative blood cultures: identifying a novel target for antimicrobial stewardship (NOBACT study)

Raquel Fernández Guerrero*1,2, José Antonio Girón Ortega1,2, Elena Morte Romea1, Pilar Luque Gómez1, Claudio Sánchez Tembleque1, Montse Montes De Oca1, Francisca Maria Guerrero-Sanchez1, Marina De Cueto-López1,2, Lorenzo Roberto Suardi4, Zaira Palacios Baena1,2, Silvia Jiménez-Jorge2,6, Jesús Rodríguez-Baño1,2, Pilar Retamar Gentil1,2

1Hospital Universitario Virgen Macarena, Sevilla, Spain, 2Ibis-Biomedicine Institute of Sevilla, Sevilla, Spain, 3Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain, 4Hospital Universitario Puerta del Mar, Cádiz, Spain, 5University of Florence, Firenze, Italy, 6Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background: There are scarce data about patients with negative blood culture (NBC) and how often they receive inadequate antimicrobial treatment. The objective of this study was to characterize the inadequacy of antibiotic treatment in patients with NBC with the aim of evaluating this as an easy-to-detect population that may be a good target for antimicrobial stewardship (AS) interventions.

Materials/methods: A multicenter, prospective cohort study conducted in 3 tertiary hospitals with active AS programmes in Spain, from October 2018 to July 2019 was performed. The features of randomly selected patients with NBC were collected. Adequacy of antibiotic treatment on day 2 was evaluated according to local guidelines. Chi-squared or Fisher, and Mann-Whitney U tests were used for comparisons.

Results: 499 patients were included. Antibiotic treatment on day 2 was considered inadequate in 204 (40%) of cases, due to insufficient coverage in 84 (41.2% of inadequate ones), too broad coverage in 76 (37.6%), unnecessary treatment in 34 (16.7%) and other causes in 10 (4.9%). There were no significant differences between patients with inadequate and adequate treatment in terms of demographics, underlying conditions, type of acquisition, suspected infection site or severity. Among patients with inadequate treatment, only 4% had undergone a specific AS intervention according to the local programmes. Overall, 30-day mortality was 19% (N=16) and 6.7% (N=8) among patients with insufficient (N=84) and sufficient coverage (N=120), respectively (OR, 3.29; 95% CI: 1.34-8.11).

Conclusions: Patients with NBC often received inadequate antimicrobial treatment, which may have clinical relevance, and had not been captured by other AS interventions. Therefore, this population may be a convenient and novel target for AS activities. No specific features of the patients were associated with inadequate treatment.

Abstract 6025

Aetiology and outcome of children hospitalised for acute respiratory tract infections in Europe: findings from a multi-country combined case-control and cohort study

Malte Kohns Vasconcelos*

1St. George’s, University of London, Paediatric Infectious Diseases Research Group, Institute for Infection and Immunity, London, United Kingdom, 2Heinrich-Heine-University Düsseldorf, Institute for Medical Microbiology and Hospital Hygiene, Düsseldorf, Germany

Abstract third-party references: on behalf of the PED-MERMAIDS Study Group

Background: Recently, major aetiology and outcome studies on paediatric acute respiratory tract infections (ARI) have been reported from LMICs. In contrast, studies using standardised protocols across Europe are lacking.

Materials/methods: The EU-funded Paediatric Multi-centre EuRopean study of MAjor Infectious Disease Syndromes (PED-MERMAIDS) enrolled children under 5 years hospitalised for ARI and well controls across 11 EU countries. Information on symptoms, course of disease and clinical management was collected prospectively. Admission day nasopharyngeal swabs were analysed for influenza, parainfluenza, rhinovirus, coronavirus, metapneumovirus, bocavirus, respiratory syncytial virus (RSV), parechovirus, enterovirus and adenovirus and Streptococcus pneumoniae (Sp), Haemophilus influenzae, Mycoplasma pneumoniae, Chlamydia pneumoniae and Staphylococcus aureus.

Results: 353 ARI children, median age 1.13 years (IQR:0.44-2.56) and 352 controls, median age 1.76 years (IQR:0.96-3.73) were enrolled over 2½ years. Swabs were analysed from 327 ARI children and 302 controls. No potential pathogen was detected in 4.6% of ARI, only bacteria in 10.9%, only viruses in 33.9% and both bacterial and viral potential pathogens in 51.4%. Codetection of multiple (up to 4) viruses occurred in 31.2% of ARI and codetection of multiple bacteria in 16.9%. The most commonly detected pathogens are listed in table 1. Respiratory pathogens were detected in 62.8% of controls. Of the frequently detected pathogens, only RSV and influenza were strongly associated with hospitalisation for ARI (table 1). The population attributable fractions (PAF) were 33.6% for RSV and 18.0% for Sp.

OR: odds ratio, 95%-CI: 95%-confidence interval; *% of detected in cases

209 ARI children (60.6%) received antibiotics, but this was not associated with detection of bacterial pathogens in study samples (OR=0.78, 95%-CI:0.48-1.28). Length of stay in hospital ranged between 0 and 49 days (median 3, IQR:2-5) and no child in the study died after admission for ARI.

Conclusions: Similarly to LMIC studies, RSV had the highest PAF for ARI hospitalisation in Europe, but with considerably lower mortality.

**Resistome analysis of new bacterial species isolated at the Institut Hospitalo-Universitaire Méditerranée**

Sami Khabthani1, Mouna Hamel1, Seydina Diene1, Vicky Merhej1, Jean-Marc Rolain1,2*

1Aix Marseille Univ, IHU Méditerranée Infection, Marseille, France, 2IHU Méditerranée Infection, Marseille, France

**Background:** The discovery of new bacterial species is always a source of curiosity and new input for the scientific community. The era of high throughput sequencing and the subsequent easy access to the bacterial genomes open up a new field of research. In this work, we are exploring antibiotic resistance in new bacterial species isolated at the Institut hospitalo-universitaire méditerranée infection.

**Materials/methods:** The work included 352 new bacterial species including 78 actinobacteria, 45 bacteroidites, 213 firmicutes, 2 fusobacteria, 14 proteobacteria. The bioinformatic analysis was performed by the ARG-ANNOT software. Genes showing low similarity results with available sequences in ARG-ANNOT database are analysed using the blast program against the NCBI database. Bacteria with potential novel resistance genes were selected for in vitro antibiotic sensitivity tests.

**Results:** Of the 352 analyzed genomes, 261 bacteria had at least one resistance gene showing a minimum of 30% identity and coverage. The sequences identity exceeded 70% in only 188 bacteria. When the antibiotic sensitivity was tested, 44 of the predicted resistance genes showed a resistance profile in vitro. Five out of these 44 genes appear to be novel resistance genes with no significant similar sequences in the NCBI database. Among these, three genes encoding for fosfomycin resistance were found in Bacillus genus, one gene encoding for tobramycin resistance was found in Paenibacillus genus and one gene encoding for clindamycin was found in Enterococcus genus.

**Conclusions:** The results obtained during this work are mainly based on a bioinformatic approach. The new sequences encoding for potential resistance can be added to ARG-ANNOT database to strengthen our ability to identify genes involved in antibiotic resistance. Further in vitro experiments, like complementation cloning are needed to validate the resistance activity.

Epidemiological and clinical characteristics among HIV adults with invasive fungal infections in north-eastern Mexico

Gloria Mayela Aguirre García*, Jonathan Isaí Cázares González, Michel Fernando Martínez-Reséndez, Reynaldo Lara-Medrano, Christian Gerardo Alfaro-Rivera, Natalia Gaona Chavez, Juan Rodríguez, Hiram Villanueva-Lozano

1Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico

Background: HIV-infected patients are at great risk of developing invasive fungal infections (IFIs), most of them AIDS-defining illnesses. Despite antiretroviral treatment, IFIs contribute to high mortality in this population. We aimed to evaluate the clinical characteristics (viral load, CD4+ cell counts and previous antiretroviral treatment) of IFIs among HIV-infected patients in North-eastern Mexico.

Materials/methods: We conducted a retrospective study including HIV-infected adults with suspected or confirmed IFI who were hospitalized from 2013 to 2019 in Hospital Universitario “Dr. José Eleuterio González” in Monterrey, México. Viral load, CD4+ cells count, the number of patients on antiretroviral therapy and intrahospital mortality were assessed.

Results: A total of 149 patients were included. The mean age was 39.8 years (±10.8) and 77.2% (n=115) were men. 98% (n=147) were born in Northeastern México. 20.1% (n=30) were already on antiretroviral therapy, with NNRTI as regimen base in 65.4% (n=17) of the cases. The median viral load was 152,000 copies/mL (IQR 2,620-350,000), and only 7.4% (n=6) of patients with available viral load were undetectable (<50 copies/mL). 81.8% of the patients had less than 200 CD4+ cells/µL. The most frequent fungal infection was Pneumocystis jirovecii pneumonia in 67.8% (n=101) of the cases, diagnosis was primarily made by clinical characteristics (20.8% [n=21] had P. jirovecii identification in bronchoalveolar lavage). Cryptocococcal meningitis was diagnosed in 21.5% (n=32) patients, 31 of 32 had positive CSF Indian ink stain, 11 of 32 had positive CSF culture and 1 of 32 had a positive PCR test. A higher incidence of histoplasmosis was noted with 8 of 10 cases seen in the last year in a non-endemic area, all of them with disseminated disease. Intrahospital mortality was 27.5% (n=41), and length of stay was a median of 10.5 days (IQR 6–19).

Conclusions: Although most IFIs are considered opportunistic infections in HIV-infected adults, 16.8% (n=13) had CD4+ cell counts higher than 200 cells/µL and 7.4% (n=6) had undetectable viral loads. Interesting data was found with the number of cases of histoplasmosis vs coccidioidomycosis despite epidemiological reports in Northeastern México. Intrahospital mortality remains high in our studied population making an argument for improving the diagnostic approach.

Abstract 6032

**Gram-negative screening the neonatal unit: can we predict bloodstream infections?**

Vivien Price*1, Jonathan Swindells2

1University Hospitals Birmingham, Birmingham Heartlands Hospital, Birmingham, United Kingdom, 2Sandwell and West Birmingham Hospitals, Black Country Pathology Services, Birmingham, United Kingdom

**Background:** Gram-negative bacilli (GNB) account for 20-40% of cases of neonatal sepsis. Routine screening for colonisation with antimicrobial-resistant GNB is standard practice in many neonatal units (NNUs), however evidence supporting a positive impact on clinical care is lacking.

We aimed to assess whether the causative organism in GNB blood-stream infection (GNB BSI) could be predicted from prior colonisation screening results, and to calculate the number needed to screen in order to pre-emptively optimise antimicrobial treatment choice.

**Materials/methods:** Rectal and umbilical swabs were performed on admission to NNU and weekly thereafter as standard care. Retrospective search of four years of laboratory records from 2015-2019 for all neonatal screening samples and all clinical isolates was performed. Case notes were reviewed for babies with GNB BSI.

**Results:** 2835 neonates were screened, of which 1267 (45%) were found to be colonised with at least one GNB. There were 10 (0.4%) babies who developed GNB BSI, of whom six had a preceding colonisation screen that yielded the same species, with a median time difference of 11.5 days (range: 3-27). Of these, in one case ESBL-producing E coli was isolated on screening and consequently empiric antibiotic therapy with meropenem was used to treat them for suspected sepsis, prior to confirmation of the BSI. In this case blood cultures were taken on the day that the screening result became available.

**Conclusions:** In our NNU, GNB colonisation was very common (45%), but GNB BSI was rare (0.4%). We found only six GNB BSI cases preceded by proven colonisation with the same organism species, with significant treatment impact in only one case. The number needed to screen to pre-emptively optimise treatment was therefore 2835. These results suggest that colonisation screening may be of limited usefulness in guiding antimicrobial choice in suspected neonatal BSI, although rising carbapenem usage and antibiotic administration prior to blood culture sampling may be confounding factors. Other potential benefits, such as guiding infection prevention, and harms, such as over-use of broad spectrum antimicrobials, were not explored in this study but merit further work.

Partnering with bedside nurses: questionnaire-based approach during an outbreak of carbapenem-resistant Acinetobacter baumannii in two separate intensive care units

Sunjung Kim1, Hyemin Seo1, Sunseon Oh1, Younghee Seo1, Byounghoon Lee2, Byeongwook Eun3, Jeongdon Chae4, Kideok Lee5, Taeun Kim*1,5

1Nowon Eulji University Hospital, Office for Infection Control, Seoul, South Korea, 2Nowon Eulji University Hospital, Division of Pulmonology, Department of Medicine, Seoul, South Korea, 3Nowon Eulji University Hospital, Department of Pediatrics, Seoul, South Korea, 4Nowon Eulji University Hospital, Department of Laboratory Medicine, Seoul, South Korea, 5Nowon Eulji University Hospital, Division of Infectious Diseases, Department of Medicine, Seoul, South Korea

Background: Although bedside nurses are essential participants in the infection control, there are limited studies to understand their attitudes, practices, and barriers regarding infection control measures. This study aimed to assess attitudes and barriers to hospital infection prevention and control policies among intensive care unit (ICU) nurses.

Materials/methods: Carbapenem-resistant Acinetobacter baumannii (CRAB) was endemic in the two adult ICUs comprising 38 beds (19 in medical; 19 in surgical ICU) before 2019. A change in the clinical manifestation of CRAB infection was noted during the first 14 weeks of 2019 with 8 CRAB bacteremia episodes (5 in medical; 3 in surgical ICU). Following the ICU outbreak, aggressive infection control interventions were instituted. Despite reinforced infection control, CRAB has resurged, predominantly in medical ICU (Figure 1). An anonymous survey consisting of 30 questions, including 13 questions about compliance with infection control measures (point 1: do not consider, to 5: always perform), was administered to both ICUs.

Results: Thirty-two nurses (16 from each ICU) responded to the survey. Characteristics of responders were comparable between ICUs (Table 1). Surgical ICU nurses tended to perform infection control procedures more perfectly (p=0.15). Overall rate of 5-points responses (always perform) for the 13 questions on infection control procedures was significantly higher in surgical ICU than in medical ICU (82% vs. 69%, p=0.002). The scores for leader nurses regarding infection control in surgical ICUs were also higher (10 vs. 8, p=0.02), and the scores for physicians showed lower values than those of nurses in both ICUs. Although half of nurses thought that environmental cleaning was the most effective strategy, the rate of 5-points responses for daily surface cleaning and terminal cleaning was suboptimal (63% and 72%). Shortage of staff (28%) was the top-cited factor contributing to spread of infection.

Conclusions: CRAB outbreak is difficult to terminate and requires understanding the behaviors of bedside nurses. During the predominant resurgence of CRAB in medical ICU, we observed better compliance of nurses and better insights of leader nurses for infection control policies in surgical ICU than medical ICU. Infection preventionists should make more effort to partner with nurses for effective infection control.

Abstract 6037

Environmental epidemiological survey of carbapenem-resistant Klebsiella pneumoniae in 5 intensive care unit
Qingfeng Shi¹*, Yingnan Huang¹, Wei Sun¹, Yangwen Cui¹, Bijie Hu¹, Xiaodong Gao¹

¹Zhongshan hospital, Fudan university, Shanghai, China

Background: Carbapenem-resistant Klebsiella pneumonia (CRKP) is one of the nosocomial infection pathogens in hospital intensive care units (ICU), causing 26%-44% attributable death. The hospital environment, especially high-touch surfaces, is considered as potential reservoir for CRKP transmission.

Materials/methods: Chromogenic medium [mSuper CARBA] was used to sample in high frequency contact surface, common area surface, tank wall and drainage hole in five surgical ICU, and 24-hour positive culture were identified by MALDI-TOF Mass Spectrometer. Double disk diffusion test was used to detect phenotype, EDTA was used to detect metalloproteinase synergistically, and PCR was used to detect KPC and NDM resistance genes.

Results: The isolation of CRKP from high frequency contact surface (1/66), common area surface (1/89), or workers’ clothes (1/24) was rare. However, contamination of CRKP in drainage hole (25/29) was common. The phenotypic identification of carbapenemase showed that 5 strains produced class A enzyme, 11 strains produced class B metalloproteinase. PCR results confirmed that 2 strains produced KPC resistance gene and 3 strains produced NDM resistance gene.

Conclusions: CRKP contamination in high frequency contact surface is low, but high in drainage hole. The phenotypic identification of carbapenemase and PCR results indicated that CRKP may not be endemic by transmission in ICU.

**Abstract 6039**

**Coverage of influenza vaccination in patients over 64 years hospitalised for severe acute respiratory infection according to their chronic diseases**

Latorre Millán Miriam1, Amparo Larrauri2, Alin Manuel Gherasim2, Clara Mazagatos2, Nieves Martínez Cameo1, María Pilar Hernández1, Yolanda Gracia1, Silvia Pina1, Vanessa Guerrero1, Antonio Rezusta1, Ana María Milagro Beamonte1

1Miguel Servet University Hospital, Aragon Health Research Institute (IIS Aragon), Zaragoza, Spain, 2National Epidemiology Center, Carlos III Health Institute, Madrid, Spain

Abstract third-party references: Miguel Servet University Hospital (Microbiology and Parasitology Service), Zaragoza, Spain. National Center for Epidemiology (Carlos III Health Institute), Madrid, Spain. Research group on infections difficult to diagnose and treat (Aragon Health Research Institute).

**Background:** The flu vaccination is the most appropriate protection measure for patients over 64 years old and people with chronic diseases. Knowledge of the coverage of influenza vaccination and the presence of influenza in patients over 64 years with chronic pathologies can provide useful information for their clinical management.

**Materials/methods:** Data of the patients included by the Miguel Servet University Hospital in the European IMOVE+ study, during the 2016/17, 2017/18, and 2018/19 seasons, were analyzed. Patients older than 64 years hospitalized with symptoms of Severe Acute Respiratory Infection (SARI), not institutionalized, provided a sample of pharyngeal smear in which the presence of influenza was detected by PCR-RT. The frequency of distribution of their most frequent chronic pathologies was studied according to the influenza vaccination status and diagnosis, using the chi-square test ($\chi^2$) adjusted by Monte-Carlo methods.

**Results:** 1314 patients with SARI were recruited, of which 57.45% were vaccinated. Compared to those not vaccinated, a higher proportion of respiratory disease presence and a lower one of morbid obesity was observed in those vaccinated patients (both $p<0.05$). No significant differences were found for these comparisons between those diagnosed with flu.

Complete genome sequencing of extended-spectrum beta-lactamase (ESBL) producing Escherichia coli isolated from dairy cattle in Japan

Hayami Kudo*1,2, Masaru Usui1, Kentaro Oka1, Motomichi Takahashi2, Yutaka Tamura1

1Rakuno Gakuen University, Laboratory of Food Microbiology and Food Safety, Department of Health and Environmental Sciences, School of Veterinary Medicine, Hokkaido, Japan, 2Miyarisan Pharmaceutical Co., Ltd., Tokyo R&D Center, Saitama, Japan

Background: Beta-Lactam antimicrobials are used worldwide in both human and veterinary medicine due to their little reported side effects and broad spectrum activity. The plasmid-mediated Extended-Spectrum Beta-Lactamase (ESBL) genes, which can confer resistance to third-generation cephalosporins, have been observed in isolates derived from livestock animals. Here, we present the complete genome sequence of ESBL-producing E. coli isolated from dairy cattle in Japan assembled using a combination of short- and long-read sequencing techniques.

Materials/methods: Ceftiofur resistant E. coli previously isolated from bovine feces: strain TC7-1, was used. Bacterial DNA was extracted using chemical and enzymatic lysis methods. ESBL genes were identified by PCR. The short- and long-read sequencing were performed using Illumina Miseq platform and Oxford Nanopore Technologies MinION platform, respectively. The long-read sequences were corrected with short-read sequences using LoRDEC v0.9 and assembled using Canu v1.7. The final assemble was annotated using Prokka. The plasmids and specific genes were identified with the bioinformatic pipeline of the Center for Genomic Epidemiology (CGE).

Results: The complete genome of TC7-1 comprises a 4,711,313 bp chromosome with 4,427 coding sequences. CGE revealed that TC7-1 belongs to the multilocus sequence type ST10 and harbors genes (wzy and filC) specific for O28ac/O42:H37 serotype. According to PlasmidFinder and ResFinder, TC7-1 contains a self-transmissible plasmid carrying the antimicrobial resistance (AMR) genes including blaCTX-M-2 and sul1. The incompatibility groups of AMR genes encoding plasmid of TC7-1 was IncN.

Conclusions: The first complete genome sequence of ESBL-producing E. coli, TC7-1, which includes IncN plasmid carrying blaCTX-M-2 isolated from livestock animal in Japan was obtained. A previous study reported that blaCTX-M-2 has been detected in E. coli isolated from humans in Japan. Further investigations are planned using the other two ESBL-producing E. coli isolated from livestock animals, which contains plasmids belonging to several Inc groups, to determine the genetic differences of ESBL-producing E. coli between human and animal origins.

Hospital related factors associated with multidrug-resistant organism acquisition: a multilevel case control study
Nosheen Nasir*,1, Sarah Khan1, Shafquat Rozi1, Nila Baig-Ansari2, Naveera Khan1, Noman Rehmani1, Rozina Roshan1, Bushra Jamil1, Faisal Mahmood1

1Aga Khan University, Karachi, Pakistan, 2The Indus Hospital, Karachi, Pakistan

Background: Antimicrobial resistance was recently declared a major global problem by World Health Organization. Such alarming rates of prevalence and transmission pose a public health problem as there are extreme limitations in the choice of antibiotics for treating patients with these infections. Association of modifiable hospital-related factors such as average ward/unit length of stay, understaffing and bed occupancy rates to multidrug-resistant organism acquisition remains unexplored. We aimed to determine the association of hospital-related factors with multidrug-resistant organism acquisition.

Materials/methods: We conducted a case-control study (1:2 ratio) at a tertiary care center in Karachi, Pakistan. Cases included patients with culture-proven multidrug-resistant organism after more than three days of hospitalization, while controls did not have a multidrug-resistant organism in any culture specimen. Data was collected on a structured proforma from hospital records for patient demographics and clinical data including admission diagnosis, type of infection and exposure to invasive devices. Ward/unit length of stay was the main hospital factor, defined as number of patient days per monthly number of patients in ward unit. Other hospital ward related risk factors included bed occupancy rate, 24 hour nurse to patient ratios and hand hygiene compliance. Multilevel logistic regression was performed to assess the individual and joint effects of patient- and hospital-related variables.

Results: 154 cases and 302 controls were included in the analysis. The odds of acquiring multidrug-resistant organism increased with the length of stay (OR 1.50, 95%CI 1.04-2.17) controlling for other factors. Among the patient related factors, MDRO acquisition was associated with presence of nasogastric tube, (OR 4.31, 95%CI 2.44-7.91), use of (OR 10.07, 95%CI 5.19-19.53), use of glycopeptide (OR 3.06, 95%CI 1.61-5.83), use of beta lactam/beta lactam inhibitor (OR 2.60, 95%CI 1.46-4.63) and central nervous system disease on admission (OR 3.75, 95%CI 1.65-8.51). MDRO acquisition decreased with increased hand hygiene compliance rate (OR 0.96, 95%CI 0.92 – 0.99). The intra class correlation was 0.94.

Conclusions: In conclusion, average length of stay in an individual ward is a modifiable hospital-related risk factor for multidrug-resistant organism acquisition. Moreover, it is also associated with empiric use of broad spectrum antibiotics whereas hand hygiene compliance is protective.

Abstract 6044

Background: Human cystic echinococcosis (CE) is a zoonotic infection caused by the cestode, Echinococcus granulosus. CE is believed to be endemic in Central Asia. We present findings from an ultrasound-based survey to estimate the prevalence of CE in the Turkistan region, where an incidence of 10.5/100,000 population was previously reported based on surgical records.

Materials/methods: The survey was carried out in October 2019 in six villages chosen following reported cases of surgically treated CE. Inhabitants 5 to 90 years of age were invited to undergo a free abdominal ultrasound to screen for CE cysts. All identified cysts were staged according to the World Health Organization-Informal Working Group on Echinococcosis (WHO-IWGE) classification. During the survey, information was also collected on individuals who had been previously diagnosed and surgically treated for CE.

Results: Of the 22,206 inhabitants, 2,252 (9.8%) underwent ultrasound screening (62.7% female). Twenty-two (0.97%) patients had CE, with a combined total of 33 cysts: 25 (73.5%) inactive (14 CE4, 11 CE5) and 8 (23.5%) active/transitional (2 CE1, 1 CE2, 3 CE3a, 2 CE3b). One additional patient had a post-surgical cavity. Of the 2,252 evaluated individuals, 68 (3.0%) reported prior surgical treatment for CE: 45 with hepatic cysts, 12 with lung cysts, and 5 with cysts in more than one location. Thirty-four (50.0%) patients were treated surgically in the last five years. In the same time period, the official surveillance system recorded 36 cases in the Turkistan region. In 25 patients, prophylaxis with albendazole was either not used or expert recommendations on dosing regimen and duration were not followed. Of the 22 current CE cases, 5 (22.5%) were under 18 years of age. Of the 68 patients who previously underwent surgical treatment for CE, 18 (26.5%) were under 18 years of age at the time of their surgery.

Conclusions: CE is endemic in the study area and the presence of active cysts suggests ongoing E. granulosus transmission. The large number of surgical patients suggests an underestimation of disease burden by the current surveillance system. Further studies on local CE epidemiology and the implementation of expert treatment recommendations are needed.

Simplification of direct MALDI-TOF MS identification from positive blood culture broth

Jessica Brotto¹, Elizabeth Grabsch¹, Kyra Chua*², Marcel Leroi²

¹RMIT University Bundoora Campus East, Mill Park, Australia, ²Austin Health, Heidelberg, Australia

Abstract: Rapid identification of positive blood culture (posBC) isolates has the potential to improve patient treatment and outcomes. Utilisation of Matrix-assisted Laser Desorption Ionization-Time of Flight Mass Spectrometry (MALDI-TOF MS) is well established for rapid identification of positive blood culture (posBC) isolates, but may have significant impact on laboratory workflow. A previously reported simple direct method using saponin-lysis has potential to reduce blood culture turn-around times (TAT). We evaluated MALDI-TOF MS identification for saponin-lysis and pre-warmed short incubation chocolate blood agar (pCBA) methods, and compared these results to the reference standard of MALDI-TOF at 24 hours.

Materials/methods: PosBC broths were subcultured on pCBA (manually), and standard culture media (automated BD Kiestra system). As previously described, 1 ml of posBC broth was added to 200 µl 5% saponin, vortexed for 1 minute at its maximum setting, centrifuged for 1 minute (13000 rpm) and the pellet resuspended in 1 ml deionised water, and the suspension was re-centrifuged. The final spun pellet was spotted onto 4 target wells [each with 0.5 µl 70% formic acid (in-house)]. MALDI-TOF (4 wells each with 0.5 µl formic acid [BioMerieux]) was performed from pCBA when visible growth was present [checked at 2, 3 and/or 4 hours]. Results of both early identification methods were compared to MALDI-TOF identification at 18-24 hours. All MALDI-TOF testing was performed on Vitek MS (Biomerieux).

Results: Overall, 227 mono-microbial and 20 poly-microbial posBC were analysed. In the mono-microbial posBC group, saponin-lysis was concordant with 24-hour MALDI-TOF in 92/158 (58%) Gram-Positive (GP) and 49/58 (85%) Gram-Negative (GN) culture samples. pCBA concordance rates were 85/158 (54%) and 45/58 (78%) for GP and GN posBC respectively. 2/227 (2.2%) of isolates were misidentified using saponin-lysis, and none with pCBA. Labour time for saponin-lysis method was 7.4 min compared to 4.5 min for pCBA. Notably, results using the saponin-lysis method were available 2-4 (median 4) hours earlier.

Conclusions: Our study confirmed that saponin-lysis provides acceptable rates of identification for GP posBC, and high rates for GN posBC. Saponin-lysis and pCBA identification rates were comparable but saponin-lysis was more rapid, with expected benefits in patient management and anti-microbial stewardship.

Abstract 6054

**Characterisation of phage obtained from methicillin-resistant Staphylococcus aureus**

Ozlem Ulusan*1, Fikret Sahin2, Mehmet Kiyat2

1Departments of Parasitology, Ege University Medical Faculty Hospital, Izmir, Turkey, 2Department of Microbiology, Ankara University Medical Faculty, Ankara, Turkey

**Background:** Antimicrobial resistance is increasing despite new treatments being employed. Bacteriophages (phages) are one of the most promising alternatives to antibiotics for clinical use. Phage therapy is the use of lytic phages to treat pathogenic bacterial infections. However, there are limitations for the use of lytic phages, such as, rapid toxin release by the lytic action of phages, and difficulty in dose determination in clinical situations. Therefore, the use of recombinant phages has gained importance. In this study, we investigated small size lysogenic phage that can be easily manipulated.

**Materials/methods:** Previously, we isolated 23 temperate phages of 27 MRSAs isolated from the hospital. One of 23 phages is much smaller than the others. We characterized the small phage after cutting with a restriction enzyme and cloning into pBSK vector. The primer walking sequencing method was followed to complete the whole sequence of the phage. Obtained sequences were investigated by using the NCBI Blast program.

**Results:** The phage genome is around 20 kb in size and contains 41 ORFs. The phage contains genes related to tail, DNA packaging, and head structure, lysis, and DNA metabolism. The gene map of the phage is given in the figure (below). In addition to the genome size, sequence results indicate that the phage is more similar to the family of Podoviridae. The members of the Podoviridae family are characterized by a small genome and short noncontractile tail. When sequences were investigated by using the NCBI BLAST program, 41.4% of the ORFs were found to encode a protein, with 43.9% could not be identified, and the remaining 6 (14.6%) were evaluated as a hypothetical protein. In a study in which Pelletier et al. studied genomes and proteins belonging to 27 staphylococcal phages; 2170 ORFs were examined, 35% of them could be found for protein equivalent, 44% of these genes were matched with none of the proteins. The results of the study are close to our scientific results.

**Conclusions:** Here we described a new phage obtained from MRSA. Due to its small size, we assume that it will be useable for the genetic engineering of phages.

**Presenter email address:** drozlemulusan@gmail.com
Abstract 6056

**Basophil activation test use for identification of fungal sensitisation in severe asthma patients**

Yana Kozlova¹, Ekaterina Frolova², Aleksandra Uchevatkina², Larisa Filippova², Oleg Aak², Galina Solovjeva², Valeriy Kuznetsov¹, Natalya Vasilyeva¹, Nikolai Klimko*¹

¹North-Western State Medical University named after I.I. Mechnikov, Department of Clinical Mycology, Allergy and Immunology, Saint-Petersburg, Russian Federation, ²North-Western State Medical University named after I.I. Mechnikov, Kashkin Research Institute of Medical Mycology, Saint-Petersburg, Russian Federation

**Background:** Identification of fungal sensitization is important for the diagnosis of allergic bronchopulmonary aspergillosis (ABPA). Recently, much attention has been paid to in vitro methods, the advantage of which is patient safety, specificity and the possibility of standardization. To study the possibility of using the basophil activation test (BAT) with Aspergillus fumigatus allergen using flow cytometry for identification of fungal sensitization in asthma patients.

**Materials/methods:** In prospective study included 76 severe asthma patients with median age 36 years (23 – 78). All patients underwent skin tests with six fungal allergens, determination of total IgE, specific serum IgE to fungal, domestic and epidermal allergens level (by enzyme immunoassay) and BAT by flow cytometry (Allergenicity kit, Beckman Coulter, USA). For basophil stimulation were used allergens A. fumigatus (AlcorBio, Russia). ABPA diagnosis was made according R. Agarwal et al (2013) criteria.

**Results:** Severe asthma with fungal sensitization (SAFS) was detected in 17 patients, severe asthma without fungal sensitization (SAwFS) - 39, ABPA – 20.

The amount of activated basophils A. fumigatus allergen in patients with ABPA was 81.9 (53.1-93.0) %.

The stimulation index (IS) in patients with ABPA was significantly higher 21.6 (18.0-32.2) compared with patients with SAFS and SAwFS: 4.4 (1.9-16.3) and 1.0 (0.8-1.4), p = 0.001, p = 0.000, respectively.

To evaluate the diagnostic value of IP in the detection of fungal sensitization, a ROC analysis was performed. The area under the curve (AUC) was 0.94, the sensitivity and specificity was 86.1% and 89.7%, (p<0.0001). The optimal cut-off value for IP was 2.55.

Among all patients with fungal sensitization, a direct correlation was found between IgE and the percentage and absolute number of eosinophils (r = 0.42, r = 0.46, p < 0.05), the level of sIgE to A. fumigatus (r = 0.47, p < 0.05), the percentage of basophils activated by the allergen A. fumigatus (r = 0.41, p < 0.05) and IP (r = 0.41, p < 0.05), as well as the inverse correlation with FVC (r = -0.35, p < 0.05).

**Conclusions:** Basophil activation test is a promising method for the laboratory diagnosis of fungal sensitization.

Abstract 6057

**Development of an antimicrobial stewardship programme for post-acute and long-term care centre by the use of telemedicine**

Silvia Gómez-Zorrilla*, Mónica Marín, Pilar García, Daniel Echeverría-Esnal, Nuria Prim, María Pilar Gracia-Arnillas, Eduardo Padilla, Olga Vázquez, Juan P. Horcajada, Santiago Grau

1Hospital del Mar-Parc Salut Mar, Barcelona, Spain, 2Centro Forum-Parc Salut Mar, Barcelona, Spain, 3Laboratorio Referencia Cataluña-Hospital del Mar, Barcelona, Spain

Abstract third-party references: On behalf PROA-PSMAR group

**Background:** Post-acute care (PAC) and long-term care (LTC) facilities represent important areas of antibiotic consumption. Our objective was to develop an interdisciplinary AMS program in a PAC-LTC setting.

**Materials/methods:** Prospective study was conducted in a 148-bed PAC-LTC center linked to a tertiary-level university hospital (January-October 2019). AMS-team was composed of a geriatrician and pharmacist from the PAC-LTC setting and an Infectious Diseases (ID) physician from the tertiary-level hospital. Previous years [2017-2018], formal AMS training was given to geriatrician. All patients under antimicrobial therapy admitted in the Post-Acute Unit (70 beds) were detected by the pharmacist through computer-generated data. Pharmacist and geriatrician reviewed and optimized these prescriptions. When complex patients, ID physician electronically reviewed them and made recommendations.

**Results:** 221 patients under antimicrobial therapy were evaluated by the AMS-team: 121 (54.8%) female, age 83 (IQR 73-88); 103 (46.6%) had prior surgery and 43 (19.5%) indwelling urinary catheter. Median Barthel index at admission and discharge were 33 (IQR 21-47) and 69 (IQR 31-88), respectively. Source of infection were: urinary 74 (33.5%), respiratory 63 (28.5%), soft tissue 34 (15.4%), bone 31 (14.0%), abdominal 6 (2.7%), catheter 3 (1.4%), unknown/others 10 (4.5%). Main microorganisms isolated were: *Enterobacteriaceae* 70 (31.7%), *Pseudomonas aeruginosa* 16 (7.2%), *Enterococcus* 13 (6%), *Staphylococcus aureus* 8 (3.6%), *Streptococcus* 4 (1.8%), others 11 (5.0%) and 17 (7.7%) polymicrobial. 17 (7.7%) had negative cultures and 65 (27.4%) not available. Regarding MDR profile, 13/70 (18.6%) *Enterobacteriaceae* were extended-spectrum-beta-lactamase (ESBL) carrying isolates and 2/70 (2.9%) had an acquired AmpC beta-lactamase. 8/16 (50%) *P. aeruginosa* isolates were XDR and 6/8 (75%) S. aureus MRSA. Main antibiotics used: 68 (30.8%) amoxicillin-clavulanate, 60 (27.1%) fluoroquinolones, 30 (13.6%) antipseudomonal-penicillins, 28 (12.7%) carbapenems and 25 (11.3%) cephalosporins. 63/221 (28.5%) were subsequently evaluated by the ID physician who made recommendations regarding: 48/63 (76.2%) duration (including stop unnecessary treatments), 31/63 (49.2%) antibiotic choice, 13/63 (20.6%) de-escalation, 6/63 (9.5%) intravenous-to-oral switch therapy and 5/63 (7.8%) dose adjustment.

**Conclusions:** The implementation of an interdisciplinary antimicrobial stewardship program in Post-Acute and Long-Term care facilities may be an effective intervention to improve antimicrobial use in these facilities. Telemedicine infectious diseases consultations may be useful in this setting.

Abstract 6058

Evaluation of the performance of Vitek MS and Bruker MS on the identification of *Candida haemulonii* species complex

Xin Hou

1Peking Union Medical College Hospital, Beijing, China

**Background:** To evaluate the results of original identification, Vitek MS and Bruker MS identification of *Candida haemulonii* species complex collected from National China Hospital Invasive Fungal Surveillance Net (CHIF-NET) 2010-2015.

**Materials/methods:** A total of 40 *Candida haemulonii* and five *Candida duobushaemulonii* were collected from all hospitals in China as part of CHIF-NET 2010-2015. The original identification results were evaluated by setting the review results as “gold-standard”, and the performances of Vitek MS and Bruker MS matrix assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF MS) in the identification of the *C. haemulonii* species complex were observed.

**Results:** As compared with the molecular identification, the accurate rate of original identification of *C. haemulonii* was 47.5%, while 15% of the strains were mistakenly identified as *Kodamaea ohmeri* and *Cryptococcus neoformans* by CHROMagar chromogenic media, ATB Rapid ID32C, API 20C or Vitek 2 Compact system; *C. duobushaemulonii* could not be identified by using routine identification methods. As for the identification of the *C. haemulonii*, the accurate rate of the Vitek MS IVD2.0 and Bruker MS DB 5989 were 100% and 57.5%, respectively. There were no reference spectra for *C. duobushaemulonii* in the Vitek MS IVD 2.0 database, so it could not be identified by Vitek MS IVD 2.0 and misidentified all *C. duobushaemulonii* as *C. haemulonii* with confidence value >90%. There were no reference spectra for *C. haemulonii* complex in the Vitek MS RUO database, so this complex could not be identified by Vitek MS RUO. 20% of *C. duobushaemulonii* were identified correctly to species level by Bruker MS DB 5989. After complementation with the “in-house” database, all of the remaining isolates were correctly identified to species level (score >2.00).

**Conclusions:** This is the first study to evaluate the performances of Vitek MS and Bruker MS in the identification of *C. haemulonii* species complex in China. MALDI-TOF MS can provide rapid and accurate identification but is reliant on a robust mass spectra database. The performance of MALDI-TOF may be improved by adding mass spectral profiles (MSPs) into the current databases.

Abstract

Background: direct-acting antivirals (DAA)-regimens are associated with failure in about 5% of the cases. The failure was associated with the emergence of resistance associated substitutions (RASs) within the viral quasispecies. This real-life study characterized the virological patterns in genotype 3 patients failing to DAA and evaluated the efficacy of retreatment.

Materials/methods: all the consecutive 51 HCV patients genotype 3 failed to DAA observed at the laboratory of infectious diseases of University of Campania, Naples were enrolled. All the patients were treated according to HCV genotype, international guidelines and local availability. Sanger sequencing of NS3, NS5A and NS5B was performed at failure by home-made protocols.

Results: Patients enrolled were mainly males (88,2%) with median age of 55 years (range, 31-80). HCV RNA, IU/ml median value was 1,0 x 10^6 (range, 1,3x10^3-2,2x10^7), 56,8% of patients had a diagnosis of cirrhosis, 80,4% were relapse, 19,6% were non responder.

Out of the 51 patients enrolled, 26 (51%) were re-treated. Table 2 shows the epidemiological, clinical and virological characteristics of the 26 retreated patients. At failure, 61,5% of patients presented one RAS and 19,2 % had 2 or more RAS. At retreatment 84,6% obtained SVR and 15,4% were relapse. In table 3 we analyze the SVR prevalence according to previous/latest DAA regimens, RASs distribution and Resistance-Guided Therapy (RGT). Patients retreated with the latest DAA regimen most frequently obtained SVR than patients retreated with previous generation of DAA (94,4% vs 62,5%, p<0.05). Patients with SVR most frequently had RGT (77% vs 25%, p<0.05).

Conclusions: The prevalence of RASs was high in our real-life population. Failed patients have at least one RAS in one HCV region. The latest DAA regimen more frequently obtained SVR despite previous regimen. Patients with RGT more frequently obtain SVR. NS3, NS5A and NS5B sequencing seems mandatory in the choice of re-treatment DAA.

Abstract 6063

How long do patients with undiagnosed Chlamydia infection remain test positive? A lesson from the Finnish new variant of Chlamydia trachomatis

Kaisu Rantakokko-Jalava*1, Niina Hieta2, Marika Havana3, Sakari Jokiranta3

1Turku University Hospital, Clinical Microbiology, Turku, Finland, 2Turku University Hospital, Clinic of Dermatology, Turku, Finland, 3Synlab Finland, Helsinki, Finland

Background: The Finnish new variant of Chlamydia trachomatis (Fi-nvCT) is characterized by a mutation (C1515T) in its 23S rRNA gene. Until its discovery in the spring of 2019, this variant caused false-negative test results in Aptima Combo 2 screening test (AC2). Since June, Hologic recommends reflex testing for negative/equivocal samples with relative light units (RLUs) ≥15 by a test with an alternative target, and ECDC recommends recalls of patients who may have received false negative results, with an initial look-back period of six months.

In southern Finland about 8% of chlamydia cases have been missed because of Fi-nvCT. The look-back period was set at six months prior to the earliest confirmed case, i.e. January 2018. Based on data collected in three Finnish laboratories using AC2, we expected that during this period, up to 96% of samples with RLUs ≥20 would have been positive for CT by Aptima CT.

Materials/methods: Probable false-negative samples were traced from the instrument and laboratory data. 101 patients (71 females and 30 males) were invited to give a new specimen.

Results: By the end of October, 49 (69% of invited) females and 24 (65%) males have been retested. Of them, 31 (42 %) have been positive for CT, all variant-type (AC2 RLU 11-52 and ACT≈6000). Results according to the interval between the samples are shown in the table. Clinical data on symptomatic treatments are pending.

Conclusions: Our results suggest that a 6 to 12-mo look-back period may be feasible. However, among all patients diagnosed with Fi-nvCT in 2019, the earliest samples with AC2 RLU≥20 date 24 and 36 months prior to the diagnostic one in a female and a male patient, respectively.

Presence and distribution of fungal species and dermatophytes in nail and skin samples

Lilla Marki1, Andreas Brachner2, Bernhard Ronacher2, Helena Enroth*1

1Unilabs laboratory medicine, SkaS, Skövde, Sweden, 2Cube Dx GmbH, St. Valentin, Austria

Background: Cube Dx’s test hybcell Fungi DNA xB detects 6 fungal genera and 33 species by amplifying 28S DNA followed by the proprietary compact sequencing process. The limit of detection of this test is about 20 CFU/sample. This study examines the abundance of other (potential pathogenic) fungal species besides dermatophytes in healthy and patients’ skin samples.

Materials/methods: In total 192 skin and nail samples were analysed in this study, thereof 172 clinical dermatological samples from patients and 20 samples from individuals without signs of disease (healthy controls). Samples were lysed and total DNA was isolated using the automated MagnaPure96 system (Roche Diagnostics). All samples have been verified for dermatophytes with a lab-developed test using real-time PCR and melting point analysis (Unilabs AB). The relative frequencies of tested fungal species in patient samples and samples from healthy individuals were calculated and are shown in the illustration below.

Results: Of the clinical samples 34% were positive for dermatophytes by the conventional lab method. In the hybcell Fungi DNA positive samples could be identified by Tm peaks > 89°C. Some species were only detected in the patient group: Trichophyton spp., some Aspergillus species, Candida tropicalis, Zygosaccharomyces rouxii, Pichia kudriavzevii and Cryptococcus neoformans. Most others were found in both groups at similar ratios, but in different combinations for individual samples. Two fungal species exhibited exceptional patterns: Saccharomyces cerevisiae was identified in all samples of healthy individuals and in about 80% of patient samples, whereas Candida albicans was positive in more than 60% of patient samples but in only about 15% of samples from healthy individuals.

Conclusions: Trichophyton spp., Aspergillus spp., Candida tropicalis, Zygosaccharomyces rouxii, Pichia kudriavzevii and Cryptococcus neoformans were only found among the clinical samples, as expected. No difference in abundance was observed for most non-dermatophyte fungal species in nail and skin samples of patients and healthy individuals. These species were detected at individual ratios in all samples and should be regarded as normal flora of human skin and nails. Further investigation and inclusion of more samples is necessary to validate initial results.

Abstract 6069

Comparison of clinical spectrum and outcomes of patients with extremely drug-resistant Salmonella enterica with multidrug-resistant strains

Fivzia Herekar*, Samreen Sarfaraz, Saba Shahid, Marvi Mahesar, Nida Ghouri

1The Indus Hospital, Karachi, Pakistan, 2The Indus Hospital, Karachi, Pakistan, 3The Indus Hospital, Karachi, Pakistan

Background: With the emergence of the Extensively Drug Resistant (XDR) strain of Salmonella Enterica, due to the H58 haplotype mutation identified in 2016 in Hyderabad Pakistan, there is a growing threat of complicated Enteric fever. Statistics from Sindh from November’ 2016 to July’ 2019 have reported 14297 cases of Enteric fever, of which 9822 were XDR, making the treatment challenging and leaving only carbapenems and azithromycin as the last resort.

Materials/methods: A retrospective chart review of culture positive Salmonella Typhi, in all age groups, was conducted, at the Indus Hospital Karachi from 1st July’ 2017 to 31st December’ 2018, capturing details of demographics, clinical features, treatment, complications and outcomes.

Results: 1518 Enteric fever patients were included in the study, 1341 pediatric and 177 adults. 50.5% [n=767] were XDR, 46.6% [n=707] Multi Drug Resistant (MDR) and 2.9% [n=44] Drug Sensitive (DS) enteric. 264 (17.4%) required admission (233 pediatric and 41 adults); 177 of which were XDR, 79 MDR and 8 DS. Definite outcomes are known for only 34.1% [n=517] patients, while 60.8% [n=923] were lost to follow or left against medical advice and 5.1% [n=78] were referred out due to non-availability of bed. Of the known outcomes, 33.7% [n=511] were cured, while 0.4% [n=6] died. In XDR cases, 37.2% [n=108] were cured on monotherapy, while 62.8% [n=182] were cured on multiple drugs. In MDR 59.1% [n=91] were cured on monotherapy, while 40.9% [n=63] were cured on multidrug therapy. Whereas, in DS, 50% [n=6] cases were cured on either of the regimens. Curiously, 4 cases of XDR Salmonella were cured with ceftriaxone monotherapy.

Conclusions: Due to shift of Salmonella Enterica towards the XDR strain, treating patients is delayed and sometimes unaffordable, especially in a resource limited country, leading to increasing morbidity and mortality. Further swift action and research needs to be undertaken to tackle this rapidly spreading disaster.

Comparative genomics of global linezolid-resistant Enterococcus faecalis strains unveils a chromosomal hotspot for optrA acquisition

Ana Raquel Freitas, Ana P. Tedim, Carla Novais, Val Fernandez Lanza, Luisa Maria Vieira Peixe

1 Faculdade de Farmácia do Porto, UCIBIO-Requimte, Porto, Portugal, 2Hospital Universitario Rio Hortega, Instituto de Investigación Biomédica de Salamanca (IBSAL), Valladolid, Spain, 3Ramón y Cajal University Hospital (IRYCIS), Madrid, Spain

Abstract third-party references: The work was supported by UID/MULTI/04378/2019 with funding from FCT/MCTES through national funds.

Background: Linezolid-resistant Enterococcus faecalis (LREfs) carrying optrA are increasingly reported globally from multiple sources, but we still lack a comprehensive analysis of human and animal optrA-LREfs strains. We aimed to compare the genomic content of publicly available optrA-Efs genomes to give insights about the pathogenic potential of circulating clones and optrA mobilization.

Materials/methods: We investigated the phylogenetic structure, genetic content [ABR/virulence/prophages/plasmidome] and optrA-containing platforms of 28 publicly available optrA-positive E. faecalis genomes from different hosts in 7 countries through CGE tools [http://www.genomicepidemiology.org]. In house databases with 57 virulence and 391 plasmid-replication genes were tested using MyDbFinder-CGE. PHASTER identified the presence of prophages. Genomic data for 23S rDNA and rplC/rplD/rpIV mutations were compared to Efs-V583 (Geneious-Prime BLASTN). optrA-platforms were compared (Geneious;Easy-fig-v2.2.2;VectorNTI-advance-v11) and gene functions annotated [eggNOG4.5.1,http://eggnogdb.embl.de/#/app/home].

Results: Our analysis showed a diversity of clones and adaptive gene sequences related to a wide range of genera, mainly but not exclusive from Firmicutes. Epidemiologically unrelated clones [ST476-like and ST21-like] obtained from human clinical and animal hosts in different continents over 5 years [2012-2017] were phylogenetically related [3-122 SNPs difference]. optrA was located on the chromosome within a Tn6674-like element [n=9] or on medium-size plasmids [30-60 kb; n=14] belonging to main plasmid families [RepA_N/Inc18/Rep_3]. In most cases, the immediate gene vicinity of optrA was identical in chromosomal [Tn6674] and plasmid [impB-fexA-optrA] backbones. Tn6674 was always inserted in the same ∆radC integration site and embedded in a 32 kb chromosomal platform common to diverse strains [patients/healthy-humans/animals] in Europe/Africa/Asia during 2012-2018 (Figure). This platform is conserved among hundreds of Efs genomes and proposed as a chromosomal hotspot for optrA integration.

Conclusions: The finding of optrA in strains enriched in different adaptive traits and sharing common genetic backgrounds across different hosts/countries suggests the occurrence of common and independent genetic events occurring in distant regions, and might explain the easy de novo generation of optrA-positive strains. It also highlights the relevance of genomic studies exploring the dissemination and reservoirs of optrA at a global and One Health scales in order to anticipate a dramatic increase of optrA carriage and spread, with a serious impact in linezolid’s efficacy.

Species distribution and antifungal susceptibility of yeast bloodstream isolates in adult patients at three university hospitals in South Korea

Yeon Jeong Jeong*1, Si-Hyun Kim1

1Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Incheon St. Mary’s Hospital, Incheon, South Korea

Abstract third-party references: The authors wish to acknowledge the financial support of the Catholic Medical Center Research Foundation made in the program year of 2017.

Background: Echinocandin antifungals are the agents of choice for the treatment of invasive candidiasis. Widespread echinocandin usage has been accompanied by reports of emerging drug resistance among clinical Candida isolates.

Materials/methods: In a prospective multicenter study, we analyzed 106 of bloodstream isolates identified by yeast from three university hospitals in South Korea. For the molecular identification of yeast isolates, we performed an internal transcribed spacer (ITS 1 & 4 regions) PCR, sequencing, and blast searching. The alignment of their sequences was performed by clustal omega method, and phylogenetic analysis was performed using the Maximum Likelihood method based on the Tamura-Nei model of MEGA7. Also, we sequenced and analyzed hot spot regions (HS1 & HS2) mutation of the β-(1,3)-D-glucan synthase for the correlation of echinocandin susceptibility in C. albicans and C. tropicalis isolates.

Results: The sequencing analysis of ITS showed that C. albicans, C. parapsilosis, C. glabrata, and C. tropicalis isolates were prevalent in the yeast bloodstream infections. In addition, Clavispora lusitaniae, Cyberlindnera fabianii, Kodamaea ohmeri, Meyerozyma guilliermondii, Pichia kudriavzevii, Saccharomyces cerevisiae, and Wickerhamomyces anomalus were identified. The genetic distance in non-candida yeasts arranged from 0.00 to 0.25, and the phylogenetic analysis exhibited four of major clades diverged from that of major Candida species (C. albicans, C. parapsilosis, and C. tropicalis) except for C. glabrata. In the analysis of HS regions, there were no mutations (641-FLTLSRD-G-649 & 1357-DWIRRTYL-1364) in C. albicans and C. tropicalis isolates except for a few silent mutations of HS1 (5 isolates in C. albicans).

Conclusions: Rare yeast species accounted for about 10% of yeast bloodstream isolates. Despite the increased use of echinocandin antifungals, echinocandin resistance among C. albicans and C. tropicalis was still low among bloodstream isolates in South Korea.

Estimation of the prevalence of the plasmid-encoded septicolysin gene in carbapenem-resistant Acinetobacter baumannii

Nadya Rakovitsky1,2*, Sammy Frenk1,2, Polet Elmalih1,2, Reut Rov2,2, Elizabeth Temkin2, David Schwartz1,2, Yehuda Carmeli1,2,3, Jonathan Lellouche1,2

1Ministry of Health, Tel Aviv-Yafo, Israel, 2Ministry of Health, Tel Aviv, Israel, 3Tel-Aviv University, Tel Aviv, Israel

Abstract 6082

Background: Septicolysin is a member of the thiol-activated cytolysin family, a prominent group of bacterial toxins. The cytolysin mechanism of action is the formation of pores in the cell membrane, resulting in the lysis of host cells. The role of cytolysins in the pathogenesis of infections by a number of Gram-positive pathogens is well described. However, the prevalence of septicolysin in Gram-negatives such as A. baumannii is unknown. Recently, fatal clinical cases involving carbapenem-resistant A. baumannii (CRAB) harboring a plasmidic septicolysin gene were reported in Israel. In this study, we aimed (1) to compare the prevalence of the septicolysin gene in CRAB isolated from blood in 2019 vs. previous years; and (2) to evaluate the relationship between clonality and septicolysin gene prevalence.

Methods/Results: The sample consisted of 49 randomly selected CRAB blood isolates from 3 hospitals and one post-acute care facility in 2019 and 106 CRAB blood isolates from 1 hospital in 2008-2011, all in Israel. Septicolysin gene presence was detected by PCR; primers were designed using a core genome alignment analysis of three septicolysin-positive CRAB genomes. PCR products were sequenced to confirm septicolysin gene presence. CRAB clonality was determined by sequencing of the blaOXA-LIKE gene. Periods were compared using a test of proportions or a chi-square test.

Results: The septicolysin gene was detected in 95.9% [47/49] of the specimens from 2019 and in 79.2% [84/106] of the specimens from 2008-2011, representing a 17% increase (P=0.01) The distribution of variants among the 2019 isolates was oxa-66 53.1% [26/49], oxa-71 44.9% [22/49], and oxa-94 2.0% [1/49]. The distribution of variants among the older isolates was oxa-66 64.2% [68/106], oxa-71 16.0% [17/106], and blaOXA-LIKE 19.8% [21/106] (P<0.001). Comparing the earlier period to 2019, the prevalence of the septicolysin gene among oxa-66-type variants increased nonsignificantly from 86.8% [59/68] to 96.2% [25/26] (P=0.19). The presence of septicolysin among the oxa-71-type variants increased markedly from 41.2% [7/17] to 100.0% [22/22] (P<0.001).

Conclusions: The plasmidic septicolysin gene appears to have played a role in the spread of a hypervirulent CRAB clone.

Abstract 6085

Faecal carriage of carbapenem-resistant *Acinetobacter baumannii*: comparison to clinical isolates from the same period

Bence Balázs*\(^1\)\(^2\)\(^3\), Zoltán Tóth\(^1\)\(^2\)\(^3\), Fruzsina Nagy\(^1\)\(^2\), Renátó Kovács\(^1\), Hajnalka Tóth\(^1\)\(^3\), József Bálint Nagy\(^1\)\(^2\), Akos Toth\(^4\), Gábor Kardos\(^1\)

\(^1\)University of Debrecen, Faculty of Medicine, Department of Medical Microbiology, Debrecen, Hungary, \(^2\)University of Debrecen, Doctoral School of Pharmaceutical Sciences, Debrecen, Hungary, \(^3\)Ostalb-Klinikum Aalen, Aalen, Germany, \(^4\)National Public Health Center, Budapest, Hungary

Abstract third-party references: Bence Balázs, Zoltán Tóth, Fruzsina Nagy were supported by New National Excellence Pro- gram of the Ministry for Innovation and Technology (UNKP-19-3-1.), Gábor Kardos was supported by Bolyai Scholarship of the Hungarian Academy of Sciences

Background: Increasing incidence of *Acinetobacter baumannii* was documented in a tertiary-care hospital between 2010-2014, with increasing prevalence of carbapenem resistance mediated by *bla*\(^\text{OXA-23}\) carbapenemase. The dominant carbapenem resistant strain (ST2) was replaced by *bla*\(^\text{OXA-72}\) carriers (ST636; ST492) in 2015 among clinical isolates, as confirmed by whole genome sequencing. We investigated the prevalence of *A. baumannii* in faecal samples of inpatients in this high-incidence setting, and characterised faecal and clinical isolates collected between January and April 2017.

Materials/methods: Identification of *A. baumannii* faecal isolates was carried out by Microflex MALDI-TOF-MS. *A. baumannii* were not detected from any other samples of the patients. Susceptibility of isolates was determined by disk-diffusion method, according to EUCAST guidelines; carbapenemases were sought for by PCR. Whole genomes of 16 faecal isolates from 2017, 2018 and 2019 were sequenced by Illumina MiSeq; resistome and MLST types were determined. Time-kill assays were performed with meropenem, imipenem (16 and 128-1024 mg/L) and colistin (2-32 mg/L) and killing rates (k) were calculated.

Results: Twenty-four non-duplicate *A. baumannii* isolates were found in the examined period out of 2042 faecal samples (1.18%), contrasting previous years, when only one isolate was found in 4285 samples collected between February 2011 and February 2013 (0.02%). The prevalence of carbapenem resistance was lower among faecal than among clinical isolates (33.3% vs. 95.4%). The occurrence of *bla*\(^\text{OXA-72}\) was similar (70.8 % vs. 76.9% respectively), while *bla*\(^\text{OXA-23}\) occurred in 3.1% of clinical isolates and was completely lacking in faecal isolates. Among faecal isolates only the ST636 and ST492 have been detected; the ST2 and ST49, previously dominant in clinical isolates, were absent. Against carbapenem resistant faecal isolates, meropenem was bactericidal only at ≥256 mg/L against ST492, but against ST636 even 1024 mg/L remained ineffective. Imipenem at ≥256 mg/L and colistin at ≥2 mg/L were bactericidal against both Sfs.

Conclusions: The prevalence of the *bla*\(^\text{OXA-72}\) gene in faecal isolates, the absence of *bla*\(^\text{OXA-23}\) gene and the ST pattern suggests that the microbiota of the patients may serve as a source of the new, but not for the previously dominant strains.

Abstract 6088

**Improving culture of Neisseria gonorrhoeae, by immediate plating and incubation at a venereology clinic**

Linn Merete Brendefur Corwin*, Patricia Campbell1, Kirsti Jakobsen1, Miriam Sare Ledaal1, Behrouz Moayeri1, Gaute Syversen1, Fredrik Müller1,2, Truls M. Leegaard1,2, Jørgen Vildershøj Bjørnholt1,2, Anne Olaug Olsen4

1Oslo University Hospital, Oslo, Norway, 2Akershus University Hospital, Lørenskog, Norway, 3Oslo University, Institute of Clinical Medicine, Oslo, Norway, 4Institute of Health and Society, Oslo, Norway

**Background:** Culture of *Neisseria gonorrhoeae* is necessary for surveillance of antimicrobial resistance. Total culture success rate of *N. gonorrhoeae* was 20% in 2014 at the Department of Microbiology, Oslo University Hospital, Norway. We hypothesized that immediate plating and incubation of patient samples would significantly improve culture rates of *N. gonorrhoeae*.

**Materials/methods:** From May 2016 to October 2017, a quality improvement study was performed at the Venereology Clinic of Oslo University Hospital. For 684 consecutive PCR positive samples of *N. gonorrhoeae* two samples were taken for culture:

1) Immediate culture involved plating of material from the site of infection directly on pre-warmed CLAT plates (selective enriched chocolate agar plates containing colistin, lincomycin, amphotericin B, and trimethoprim) and immediate incubation at 35°C, 5% CO₂, in moist atmosphere, for 48 hours. Plates were then transported to the Department of Microbiology for identification and antimicrobial susceptibility testing.

2) Standard culture involved transport of swabs (Puritan Liquid) to the Department of Microbiology for plating according to the routine procedure.

Culture success rate of immediate versus standard routine was compared.

**Results:** Overall culture rate was 59% during the study period. The immediate culture success rate was 55.6% (95% CI; [51.8 - 59.3]) versus the standard culture success rate 39.3% (95% CI; [35.7 - 43.0]). Culture results of PCR positive samples, immediate culture versus standard culture according to sample site are shown in table 1.

**Conclusions:** The total culture success rate was significantly improved when samples were plated and incubated immediately at the Venereology Clinic. We recommend immediate plating and incubation of samples from patients with gonorrhoea to optimize culture rates of *N. gonorrhoeae*

Abstract 6090

**Benchmarking blood culture turnaround times in an automated laboratory, at a tertiary teaching hospital**

Megan Sullivan1, Elizabeth Grabsch1, Kyra Chua*1, Marcel Lerol1

1Austin Health, Heidelberg, Australia

**Background:** Blood cultures (BCs) detect blood-borne bacteria/fungi that may be causing an infection with serious and life threatening implications. Rapid and accurate (BC) results are essential in providing best patient outcomes and reducing hospital-associated costs. Positive-blood culture turnaround times (BC-TATs) for Austin Pathology Microbiology Laboratory (AuPath-Micro) were compared against recently published benchmarks for microbiology laboratories [with/without automated systems] for reporting; Gram stain (GS), organism identification (Org-ID) and antibiotic susceptibility testing (AST).

**Materials/methods:** AuPath-Micro utilises advanced technology to standardise specimen/culture processing and improve workload efficiency. Technology/automation includes Bactec-FX BC-System (BD), Kiestra-Work Cell Automation (BD), MALDI-TOF mass spectrometry (Vitek MS, Biomerieux) identification and automated antimicrobial-susceptibility (Vitek2-XL Biomerieux). BCs collected January-February 2019 from Austin Health patients (N=7838 bottles, 3976 requests, 1391 patients; 508/7838 [6.5%] positive) were reviewed. Detailed analysis of all first positive bottles (n=220, 184 patients) was performed, as these results have the most impact on patient management and are given highest priority.

**Results:** The median [Interquartile Range [IQR]] BC-TATs [hours from BC collection] to GS, preliminary results for Org-ID and AST were 21.1 [14.9-31.2], 24.2 [19.2-32.4] and 36.0 [32.9-43.4], respectively. Similarly, final-results for Org-ID and AST reporting were 35.3 [27.1-46.6] and 49.4 [40.3-65.3]. Respective benchmark results [in hours] for automated and non-automated laboratories were GS 19.2 [14.6-28.3], 19.2 [15.4-25.9]; final Org-ID 36.0 [22.3-43.7], 43.4 [32.2-59.0]; final AST 60.0 [45.4-73.0], 65.0 [59.0-71.8]. Unlike AuPath-Micro, both laboratories reported GS results 24/7. GS BC-TATs during AuPath-Micro business hours [BH] were 18.7 [13.4-26.6] and after hours [AH] 23.3 [19.0-37.7]. During BH AuPath-Micro reported BC-GS TATs 0.5hrs earlier than the benchmark. Facilitated by Kiestra-Automation and standardised incubation, final Org-ID and AST are set up where possible using 6hr subcultures from positive-BCs, potentially explaining rapid BC-TAT.

**Conclusions:** Measuring TATs against benchmarks is an important quality exercise that assists in optimising workflow and reporting in clinical laboratories. Method development and monitoring of BC-TATs will ensure that improvements in reporting of BC results are ongoing.

Abstract 6093

**Carbapenem-resistant Enterobacteriaceae: a 7-year surveillance at Keimyung University Dongsan Hospital and changes after moving to a new location**

Namhee Ryoo*1, Heyin Kang1, Do Hoon Kim1, Wonmok Lee1, Jung Sook Ha1, Dong-Seok Jeon1, Seong Il Suh2

1Keimyung University School of Medicine, Department of Laboratory Medicine, Dongsan Hospital, Daegu, South Korea, 2Keimyung University School of Medicine, Department of Microbiology, Daegu, South Korea

**Background:** Carbapenem-resistant Enterobacteriaceae (CRE) is increasing within healthcare facilities and causing an important concern for health care and infection control globally. We described the epidemiologic and genetic characteristics of CRE isolated from patients at a tertiary care university hospital in 7 years, and compared any changes after moving to a new location.

**Materials/methods:** All CRE isolates were collected from patients between Oct 2012 and Oct 2019. The hospital was moved to a new location (10 km apart) on Apr 2019. The isolates were identified by automated identification system, subsequently confirmed by matrix-associated laser desorption ionization-time of flight mass spectrometry and antimicrobial susceptibility tests then, multiplex real-time PCR was used for identifying the types of carbapenemase of CRE.

**Results:** A total of 379 non-duplicated CRE were isolated: 241 isolates between Oct 2012 and Mar 2019 before moving, and 138 isolates during 7 months after moving. Carbapenemase producing CRE (CPE) was accounted 72.6% (275/379) in total, and the prevalence has increased significantly from 0% (0/2) in 2012 to 81.1% (150/185) in 2019. The comparisons of CPE prevalence before and after moving were 68.9% (166/241) and 79.0% (109/138), respectively. The types of carbapenemase-encoding genes were blaKPC 88.4% (243/275), blaNDM 4.7%, blaNDM with blaOX4-48 like 3.6%, blaOX4-48 like 1.8%, blaVIM 1.1%, and blaKPC with blaOX4-48 like 0.4%. The CPE with blaKPC genes was increased from 1.4% in 2017 to 94.0% in 2018 and was 94.5% after moving. The most common CRE species were in the order of *Klebsiella pneumoniae*, *Escherichia coli*, *Enterobacter cloacae* and *E. aerogenes*. Most common specimen type was sputum followed by urine and stool.

**Conclusions:** The incidence of CRE has risen significantly at this hospital since 2018 which was correlated with the overall incidence within Korea and continued its high prevalence even after moving to new place. While knowing new hospital started with newly admitted patients from emergency room and outpatient clinic, it may be worthwhile to evaluate the reason for this trend. Monitoring of hospital environment and enforced education for CRE could be important applications in infection control and prevention of unrecognized dissemination of CRE in the new hospital.

Abstract 6094

Evaluation of a Point-of-Care molecular system for rapid detection of toxigenic *Clostridioides difficile* in paediatric patients: impact on diagnostic yield and time to result

Jesica Saucedo1, Selene Garcia1, Mariona Fernandez De Sevilla1,2,3, Silvia Simó1,2,3, Estefania Albero1, Manuel Monsonis1, Carmen Muñoz-Almagro1,2,3,4, Pedro Brotons De Los Reyes1,2,3

1Hospital Sant Joan de Déu, Esplugues de Llobregat (Barcelona), Spain, 2Institut de Recerca Sant Joan de Déu, Esplugues del Llobregat (Barcelona), Spain, 3Centro de Investigación Biomédica en Red Epidemiología y Salud Pública, Madrid, Spain, 4Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain

Abstract third-party references: Supported by Roche Diagnostics

**Background:** *Clostridioides difficile* is the main etiological cause of bacterial infectious diarrhoea in hospitalised patients. The standard microbiological diagnostic algorithm for detecting toxigenic *C. difficile* in our hospital is based on a two-step procedure that includes use of an enzyme immunoassay (EIA) targeting antigen glutamate dehydrogenase (GDH), enterotoxin-A, and Cytotoxin-B, followed by a point-of-care PCR targeting toxigenic *C. difficile*. This easy algorithm requires re-testing EIA GDH-positive and toxin-negative samples by PCR to distinguish toxigenic vs. non-toxigenic strains. As a consequence, time to result (TAT) of algorithm implementation may range from minutes to > 1 hour. cobas® Liat® Cdiff is a new single-step automated system for molecular detection of toxigenic *C. difficile* in 20 minutes. Our objective was to evaluate diagnostic yield of Liat compared to our two-step standard microbiological diagnostic algorithm.

**Materials/methods:** Prospective study including fresh stool samples collected from patients between 2 and 18 years of age suspected of toxigenic *C. difficile* infection attended in Hospital Sant Joan de Deu (Barcelona, Spain) during the period December 2018 - August 2019. Liat performance was compared with performance by the Cdiff quik check complete® EIA (TAT~30 minutes) combined with targeted Xpert® *C. difficile* PCR (TAT~47 minutes) in EIA GDH-positive and toxin-negative samples.

**Results:** A total of 122 stool samples were collected from 91 patients [mean age, 8 years] during the study period. Liat identified 24 (19.7%) positive samples. The EIA yielded 97 (79.5%) GDH- and toxin-negative results, 11 (9%) GDH- and toxin-positive results, and 14 (11.5%) GDH-positive and toxin-negative results, of which 11 (78.6%) were confirmed as positive for the toxin by PCR. Overall GDH- and toxin-positive samples by the standard algorithm were 22 (18.0%). There were 2 results positive by Liat and GDH- and toxin-negative by EIA: one result was confirmed as positive by PCR after re-testing the sample while another was confirmed as positive by the standard algorithm after testing a second stool sample from the patient 3 weeks later.

**Conclusions:** cobas® Liat® Cdiff, a rapid system for detection of toxigenic *C. difficile*, increased diagnostic yield in paediatric patients compared to a two-step standard microbiological diagnostic algorithm.

Prevalence and genetic diversity of *Blastocystis* in asymptomatic and symptomatic individuals from Puducherry, India

Shashiraja Padukone*1, Ajay P. Selvarathinam1, Manochitra Kumar1, Jharna Mandal1, Nonika Rajkumari1, Ballambattu Vishnu Bhat2, Rathinam Palamalai Swaminathan3, Subhash Chandra Parija1

1Department of Microbiology, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, 2Department of Neonatology, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, 3Department of Medicine, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

**Background:** *Blastocystis*, an intestinal parasite, consists of 17 subtypes (ST), of which nine are capable of inhabiting humans. *Blastocystis* pathogenicity is controversial as it harbours both symptomatic and asymptomatic individuals. In India, molecular studies on *Blastocystis* are meagre. Hence, large scale molecular epidemiological studies are required to unveil genetic diversity and pathogenicity of *Blastocystis*.

**Materials/methods:** In this cross-sectional analytical study, a total of 752 stool samples (379 male; 373 female) were collected from asymptomatic (group I, n=384) and symptomatic (group II, n=368) individuals. Group II was subcategorized based on the specific clinical presentations: diarrhoea (n=152), inflammatory bowel disorder (IBD, n=83), dysentery (n=75), irritable bowel syndrome (n=31), and colorectal cancer (n=27). 18SSU rDNA was targeted in PCR for the detection and sub-typing of *Blastocystis*. 83 representative samples were sequenced and phylogenetic analysis was performed using MEGA 7 software. The subtypes and allele types were determined using [http://www.pubmlst.org/Blastocystis](http://www.pubmlst.org/Blastocystis) database. Fisher’s exact test was employed for the comparison between the groups. At 95% CI, p-value < 0.05 was considered statistically significant.

**Results:** Asymptomatic individuals had higher occurrence of *Blastocystis* (n=135; 33.7%) compared to the symptomatic patients (n=117; 31%) but statistically insignificant (p=0.33). Within-group II, patients having diarrhoea had the highest detection rate of *Blastocystis* (n=57; 37.1%) and the least in patients having IBD (n=18; 21.6%). A Comparison between subgroup IBD and asymptomatic group yielded statistically significant results (p=0.016). Out of the 252 samples positive for *Blastocystis*, ST1 (n=79), ST2 (n=23), ST3 (n=145), and ST1+ST3 mixed infections (n=5) were identified. ST3 was predominant subtype in both groups. Sequenced samples were deposited in NCBI GenBank (Accession. No. MK719604-MK719686). Allele 31, 34, and 36 of ST3, allele 9 and 11 of ST2 and allele 4 and 80 of ST1 were detected. The phylogenetic tree showed no distinct segregation of sequences of symptomatic and asymptomatic isolates.

**Conclusions:** This study largely contributes to *Blastocystis* molecular epidemiology in India. For the first time, ST2 was identified from India. However, the existence of all three subtypes in both symptomatic and asymptomatic individuals infers that inter-subtype variation may not be a reliable marker to assess the pathogenicity of *Blastocystis*.

**Short- and long-term outcomes of infective endocarditis admission in adults: a population-based registry study in Finland**

Elina Ahtela*, Jarmo Oksi, Tero Vahlberg, Päivi Rautava, Jussi Sipilä, Ville Kytö

1Turku University Hospital, Turku, Finland, 2University of Turku, Turku, Finland

**Background:** Infective endocarditis (IE) is a disease associated with high mortality. However, data of factors associated to length of stay (LOS) in hospital due to IE is scarce. In addition, long-term mortality of more than one year is inadequately known. In this large population-based study we investigated age and sex differences, temporal trends, and factors affecting the LOS due to IE and in-hospital, 1-year, 5-year and 10-year mortality of IE.

**Materials/methods:** Data of patients (≥18 years of age) admitted to hospital due to IE in Finland during 2005-2014 were collected retrospectively from the nationwide obligatory registries.

**Results:** We included 2166 patients in our study. Of the patients 67.8% were men. The mean age of the patients was 60.7 years (SD 18.2, range 18-97). The median LOS was 20.0 days (20.0 days in men and 18.0 in women, p=0.015). In the youngest patients (18-39 years) the median LOS was significantly longer than in the oldest patients (24.0 vs. 16.0 days, p=0.014). Patients with Charlson Comorbidity Index (CCI) score of 0 had significantly longer LOS compared to the patients with CCI score of ≥1 (p=0.008). The in-hospital mortality was 10%. The 1-year mortality was 22.7%, 5-year and 10-year mortality 37.5% and 48.5%. The 5-year and 10-year mortality was higher in women (HR 1.18, p=0.034; HR 1.18, p=0.021). Both the in-hospital and long-term mortality increased significantly with aging and comorbidity burden. Both the mortality and LOS remained stable over the study period and no seasonal variation was found.

**Conclusions:** Men had longer hospital stays due to IE compared to women. The youngest patients had the longest admissions. The 5- and 10-year mortality was higher in women. No seasonal variation was found in the LOS or mortality of IE. The mortality of IE or LOS did not change over time.

Abstract 6106

**Diagnosis of deep cutaneous mycoses in kidney transplant recipients by clinical metagenomics approach**

Emilie Sitterlé¹, Guillaume Gricourt², Demontant Vanessa², Anne Scemla¹, Jean-Michel Pawlotsky³, Marie Elisabeth Bougnoux¹, Christophe Rodriguez*²

¹Necker, Paris, France, ²Hôpital Henri-Mondor Ap-Hp, Créteil, France

**Background:** Deep cutaneous mycoses in transplant recipients are infections frequently caused by fungal invasion of the skin and subcutaneous tissue frequently arising after traumatic inoculation. They often involved rare or emerging opportunistic fungal pathogens originated from soil, yielding the species identification difficult. Clinical Metagenomics (CMg) could be a comprehensive method for pan-pathogen detection and particularly accurate identification of fungi from clinical samples. However, fungal infections have been little explored by these techniques because of incomplete genetic knowledge and the low percentage of genome informativeness for its identification. We propose in this study to validate the CMg on a cohort of kidney transplant patients, presenting a subcutaneous fungal infection.

**Materials/methods:** Biopsies of 13 kidney transplant patients with fungal subcutaneous infection characterized by conventional mycology techniques (microscopy, culture, mass spectrometry, molecular biology) were tested by CMg. An ISO 15189 accredited CMg pan-pathogens technics routinely used was performed with specific pan-pathogen extraction, DNA/RNA library prep followed by sequencing with NextSeq500 (Illumina) and analysed with MetaMIC software. An algorithm including informative fungal genes was developed to allow accurate species identification.

**Results:** Based on DNA, only 7/13 patients could be diagnosed positive while 13/13 patients were screened with a correct identification to the genus from the RNA including dematiaceous molds (n = 6), hyphomycetes (n = 3), dermatophyte (n = 2), and Mucorales (n = 2). Among these 13 patients, 9 were identified to the species level with a high confidence. Fungal loads could be established and showed a median of 1.93 log higher with RNA compared to DNA explaining the difference in sensitivity between the two markers.

**Conclusions:** Metagenomics using unbiased RNA sequencing improves the efficiency of CMg method to identify fungal pathogens even from cutaneous biopsies which are a difficult matrix because of the low fungal genetic materials compared with human. We were able to show that under extreme conditions, CMg had the ability to establish a reliable fungal identification, confirming its pan-pathogenic spectrum. Moreover, this accredited routinely used technic demonstrates that it can be perfectly adapted in complex cases of infection involving rare pathogens.

Background: During the last decade, some changes in the epidemiology of invasive infections have been reported; however, specific studies with patient-level data are scarce. The aim of this study is to describe and evaluate the epidemiologic changes in bloodstream infections (BSI) during the last decade in Andalusia, Spain.

Materials/methods: Data from two prospective cohorts of BSI in adults with the same methodology performed ten years apart in 11 hospitals (8 tertiary and 3 community) in Andalusia, Spain were compared; the 2006/2007 cohort was performed between October 2006 and March 2007, and the 2016/2017 cohort between October 2016 and March 2016. Population-based incidence rates were calculated and extrapolated for 1 year. Relative risk ratios were calculated between the 2 periods. Multivariate analyses were performed by logistic regression.

Results: Overall, 1,262 episodes of BSI were included, 563 (44.6%) in 2006/2007 and 699 (55.3%) in 2016/2017. Incidence was 91 and 113 cases per 100,000 population-year in 2006/2007 and 2016/2017, respectively. The incidence increased for community (15 and 35 in 2006/2007 and 2016/2017, respectively) and healthcare-associated episodes (21 and 30), and was reduced for nosocomial ones (53 and 47). Similar changes were seen for incidence rates based on admissions. Multivariate models selected the following changes in patients’ features in 2016/2017, after controlling for type of acquisition: higher age (OR=1.02,95%CI:1.01-1.03), lower urinary catheter (OR=0.37,95%CI:0.26-0.48) and lower Pitt score (OR=0.76,95%CI:0.71-0.82). Crude comparisons in aetiology showed an increase in Gram negative organisms (51.5% in 2006/2007 vs 58.8% in 2016/2017, RR=1.14,95%CI:1.03-1.26), and specifically in Klebsiella and Proteus spp.; and a reduction in Gram positives (45.6% vs 35.8%, RR=0.78,95%CI:0.69-0.90), specifically in coagulase-negative staphylococci. The proportion of methicillin-resistance among S. aureus decreased from 32% to 15.3%, and of ESBL-producers among Enterobacterales from 15.1% to 11.2%. There were no cases of carbapenemase producers in 2006/2007 and one in 2016/2017. Adjusted estimations considering patients’ features and exposure to procedures showed a reduction in coagulase-negative staphylococci (OR=0.47,95%CI:0.32-0.69); and an increase in Proteus spp. (OR=3.12,95%CI:1.18-8.23) and Candida spp. (OR=3.01,95%CI:1.03-8.86).

Conclusions: We found relevant epidemiological changes in BSI in our area, including rates, frequency of acquisition types, changes in patient's profiles and in aetiologic agents.

Abstract third-party references: On behalf of ITUBRAS-2 study group, GEIH/GEMARA groups of the Spanish Society of Infectious Diseases and Clinical Microbiology (SEIMC), Supported by MSD

Background: The ITUBRAS-2 project is a Spanish prospective multicenter study of bacteraemic urinary tract infections (BUTI). The aim of this study was to compare community-onset healthcare-associated (CO-HCA) with hospital-acquired (HA) BUTI.

Materials/methods: A multicenter cohort observational study was conducted at 12 Spanish hospitals. All consecutive CO-HCA-BUTI and HA-BUTI episodes were prospectively included [September 2017-April 2019]. Susceptibility results were interpreted according to 2019 EUCAST criteria. MDR profile was defined as non-susceptibility to ≥1 agent in ≥3 antimicrobial categories and XDR profile as resistance to ≥1 agent in all but ≤2 antimicrobial categories

Results: 445 episodes were included: 224 CO-HCA-BUTI and 221 HA-BUTI. Regarding CO-HCA-BUTI group, Friedman criteria were: 146 (65%) prior hospitalization, 71 (32%) receiving specialized ambulatory care, 93 (42%) indwelling urinary devices, 50 (22%) residency in long-term care facility, 21 (9%) receiving chemotherapy, 4 (2%) haemodialysis and 4 (2%) day-hospital patients.

Table 1 summarizes main differences between groups.

Causative microorganisms isolated in the cohort were: 221 (50%) *Escherichia coli* (68% MDR), 103 (23%) *Klebsiella spp.* (46% MDR, 5% XDR), 64 (14%) other *Enterobacteriaceae* (39% MDR, 3% XDR), 38 (9%) *Pseudomonas aeruginosa* (29% MDR, 18% XDR) and 22 (5%) *Enterococcus spp.* (32% MDR).

</tbody>
</table>

Clinical cure was independently associated with HA-BUTI [OR 1.88; 95%CI 1.23-2.85]. In an adjusted logistic regression analysis, Charlson Comorbidity Index [OR 1.26; 95%CI 1.021-1.55] and being immunosuppressed [OR 7.05; 95% 1.56-31.83] were identified as independent risk factors for mortality.

Conclusions: A worrying high rates of MDR were observed in healthcare-associated BUTI in our country, higher than 50% in both CO-HCA and hospital-acquired infections. Although no differences were observed in mortality, patients with CO-HCA-BUTI presented a worse clinical cure than hospital-acquired BUTI.

Abstract 6110

**Persister response of Klebsiella pneumoniae to colistin exposure**

Cansel Vatansever1, Nazli Atac1, Berna Özer1, Bilge Kaan Kiliçoğlu2, Metehan Berkkan2, Ulas Guler2, Defne Baskurt2, Egemen Sever2, Ozlem Dogan1, Fusun Can1

1Koç University, Department of Medical Microbiology, School of Medicine, Istanbul, Turkey, 2Koç University, School of Medicine, Istanbul, Turkey

**Background:** Persister cells are responsible for chronic recurrent infections. During antibiotic therapy small population of bacteria, known as persisters, can survive and become a source of relapsing resistant infections. Our aim was to investigate the response of starvation induced and colistin induced K. pneumoniae persister cells to colistin exposure.

**Materials/methods:** One carbapenem resistant, colistin susceptible clinical K. pneumoniae isolate (K1251) was studied. Two types of persister cells were generated with starvation of cultures [16 hours of incubation] and colistin stress [10XMIC, 1 hour]. Wild type cells were used as control group for the experiment. Time kill assay was performed with exposure of 10XMIC colistin and at time points of 0th, 1st, 2nd, 4th, 6th and 24th hours colony counts (CFU/ml) were determined. Meanwhile, cells were examined for viability with resazurin assay and NPN assay was performed for membrane integrity of the cells.

**Results:** In time kill assays, 10XMIC colistin did not cause growth inhibition on both general persister (log10 cfu/ml 7.25; 7.0; 6.90; 6.85; 7.19 at 0th, 1st, 2nd, 4th, 6th, respectively) and colistin persister (log10 cfu/ml 3.26; 1.99; 2.27; 1.96; 2.88 at 0th, 1st, 2nd, 4th, 6th, respectively) cells in 6 hours. However, in wild type cells 4-log decrease in colony counts was detected within one hour (log10 cfu/ml 7.50; 3.31 at 0th, 1st, respectively). In resazurin assay, viability of the both types of persister cells was constant until 6th hour of experiment. In NPN [1-N-phenyl-naphthylamine] uptake assay, membrane integrity was less than growth control in colistin induced persister cells however increased membrane integrity was found in general persister cells.

**Conclusions:** K. pneumoniae persister cells may have different types of phenotypic response to colistin stress depending on their triggering factors. General and colistin induced persister cells resist to high concentration of colistin however only colistin induced persister cells lose their membrane permeability.

**Presenter email address:** cvatansever17@ku.edu.tr
Secular trends in the epidemiology and clinical characteristics of *Enterococcus faecalis* infective endocarditis in a referral centre (2007-2018)

Laura Escolà-Vergé¹, Nuria Fernandez-Hidalgo*, Nieves Larrosa¹, Benito Almirante¹

¹Vall d’Hebron University Hospital, Barcelona, Spain

**Background:** Recent studies suggest that *Enterococcus faecalis* infective endocarditis (EFIE) is more frequent than expected. The aim of this study was to analyze the epidemiological and clinical changes of EFIE between 2007 and 2018 in a referral centre for IE.

**Materials/methods:** First, all definitive IE episodes treated in our centre during the study period were registered prospectively. The Mantel-Haenszel (MH) trend test was used to verify trends in the percentage of aetiologies over time.

Second, definite EFIE episodes were divided into three 4-years periods. The clinical differences between periods were studied using $\chi^2$ or Fisher exact test for qualitative variables, and Kruskal-Wallis for continuous variables.

Third, we collected retrospectively all episodes of *E. faecalis* monomicrobial bacteraemia diagnosed in our centre between 2010 and 2018, the number of echocardiograms performed in that patients and the number of definite EFIE diagnosed. The MH trend test was used to verify trends in the percentage of echocardiograms performed and EFIE diagnosed over time.

**Results:** Between 2007 and 2018, 648 definite IE episodes were treated in our centre. We detected an increase in the percentage of EFIE (from 15% in 2007 to 25.3% in 2018, $P=0.038$), currently being the first cause of IE.

We studied 108 episodes of definite EFIE (2007-2010 n=30, 2011-2014 n=22, 2015-2018 n=56). Patients from the last period were older (median 70.9 vs 66.5 vs 76.3 years, $P=0.015$), abdominal origin was established more frequently (20% vs 13.6% vs 42.9%, $P=0.014$), they had less indication of surgery (63.3% vs 54.6% vs 32.1%, $P=0.014$), and a non-statistically significant lower in-hospital mortality (30% vs 18.2% vs 12.5%, $P=0.139$).

There was an increase in the percentage of echocardiograms performed in *E. faecalis* monomicrobial bacteraemias between 2010 and 2018 [30% in 2010, 51.2% in 2018, $P=0.014$], as well as in the percentage of definite EFIE diagnosed [15% in 2010, 32.6% in 2018, $P=0.004$].

**Conclusions:** *E. faecalis* is a frequent and increasing cause of IE. Its greater diagnosis seems to be linked to an increase in the percentage of echocardiograms performed. The multiple factors that justify changes in the clinical characteristics of EFIE should be thoroughly studied.

Abstract 6113

**Mutations variability of KPC-3 carbapenemase related to ceftazidime/avibactam resistance found in Klebsiella pneumoniae strains isolated in Verona, Italy**

Sara Cavallini¹, Ilaria Unali¹, Irene Di Nolfo¹, Anna Bertoncelli¹, Annarita Mazzariol*¹

¹University of Verona, Department of Diagnostics and Public Health, Verona, Italy

**Background:** Avibactam is a non-β-lactam β-lactamase inhibitor, active against KPC enzyme, approved, in combination with ceftazidime. Ceftazidime-avibactam (CZA) resistance is an emerging threat. Porins mutations, efflux overexpression usually accounts for resistance in clinical isolates. Recent reports showed the involvement of KPC mutations in the CZA resistance.

This study focused on the analysis of KPC sequence of KPC producers *Klebsiella pneumoniae* resistant to CZA, isolated from purulent specimens.

**Materials/methods:** 9 KPC producer *K. pneumoniae* resistant to CZA were studied. Antimicrobial susceptibility was performed by broth micro dilution with a fixed concentration of avibactam of 4 mg/L. Phenotypic determination of carbapenemase production was based on Carba NP test and immune-chromatographic Carba5 test. Molecular characterization of carbapenemase genes (*blaKPC*, *blaVIM* and *blaIMP*, *blaNDM*) and ESBL genes (*blaCTX-M*, *blaTEM*, and *blaSHV*) was performed through PCR. Bioinformatics analyses were performed by Illumina sequencing to determine genetic mutations.

**Results:** All 9 strains confirmed CZA resistance and amplification of *blaKPC* gene. Eight out of 9 strains showed KPC production by immune assay.

Two strains showed the same deletion of 6 nucleotides in position 498-503, corresponding a deletion of a glutamic acid and leucine in position 167 and 168. The amino-acid in position 167 is involved in the proton acceptor active site.

One strain showed the mutation D179Y bringing to KPC-31 variant, known to be responsible for CZA resistance. The amino acids 163-179 in KPC include the omega-loop involved in the proton acceptor active site.

One strain showed the mutation T243M, mutation that is comprise in the region close to the hinge-loop that surrounds the active site of KPC.

All isolates showing deletion/mutation in the *blaKPC* gene had no carbapenems hydrolysis activity, presented low carbapenems MICs. The strain harboring KPC-31 confirmed also a negative immune-chromatographic assay.

5 strains had a KPC-3 variant without mutations, all of them harbor *blaSHV* and *blaCTX-M1* group.

**Conclusions:** We confirmed the variability of mutations, responsible for CZA resistance, affecting KPC-3 variant.

We found three different mutations in 9 strains.

Point mutations seems to drive the emergence of CZA resistance, probably related to drug exposition.

Further investigation on the ESBL genes is needed.

The appropriateness of prescribing antimicrobials in an infectious emergency outpatient department

Mateja Logar*1,2, Iza Korpar2, Meta Uršič2

1University Medical Center, Ljubljana, Department of Infectious Diseases, Ljubljana, Slovenia; 2University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Abstract 6116

Background: Overuse of antibiotics has contributed significantly to antimicrobial resistance, and antimicrobial stewardship is among important measures to reduce its spread. Despite up-to-date guidelines, adherence is questionable and should be regularly assessed. We aimed to assess the rationality of antibiotic prescription and adherence to recommendations at our infectious emergency outpatient department.

Materials/methods: In this retrospective study, antibiotics prescribed to adult patients in the outpatient department were analysed. Recorded prescription parameters - suitability of drug choice, prescription correctness, and overall rationality, including right diagnosis, drug suitability, prescription correctness and concomitant diseases - were assessed for adherence to local recommendations by an experienced infectious disease specialist.

Results: 896 patients were included in the period from January 1st and October 31st 2018. There were 452 (50.4%) males and 444 (49.6%) females, with a mean age of 59 ± 20.6 years. We included outpatients with new antimicrobial prescription (first or changed from another antimicrobial). Co-amoxicillin was most frequently prescribed (n=224; 25.0%), followed by doxycycline (n=139; 15.5%) and ciprofloxacin (n=110; 12.3%). Overall, the diagnosis was correct in 692 (77.8%) cases, antibiotic suitable in 721 (80.5%) cases, and prescription correct in 629 (70.2%) cases. Prescription was most often incorrect due to wrong or unspecified duration, as observed in 220 (24.6%) cases. Significant differences were observed for drug suitability with regards to patient age (p=0.042), (more errors made in younger patients), organ system affected (p<0.001) (the most errors in respiratory infections), and antibiotic class (p<0.001) (the most errors when prescribing moxifloxacin and azithromycin). No association was observed between doctors’ gender and drug suitability (p=0.074), prescription correctness (p=0.628) or overall rationality (p=0.693), while differences were observed for levels of specialization with regards to prescription correctness (p<0.001), but not drug suitability (p=0.704) or rationality (p=0.248). Overall, in 467 (52.1%) cases, at least one prescription parameter was flawed.

Conclusions: Despite it being previously pointed out, antibiotics are still often not prescribed rationally. Certain broad-spectrum antibiotics are overprescribed, with drug choice even more questionable in certain age groups of patients or organ systems affected.

Abstract 6117

Combinations activity of azidothymidine and colistin against colistin-resistant *Klebsiella pneumoniae* in a murine model of urinary tract infection

Rajesh Odedra1, David Corbett1, Anthony Coates2, Dennis Molnar2, Yanmin Hu3, Peter Warn1, Pia Thommes*1

1Evotec (UK) Ltd, Macclesfield, United Kingdom, 2Helperby Therapeutics, London, United Kingdom, 3St George’s, University of London, London, United Kingdom

**Background:** Repurposing drugs or using combinations are attractive approaches to identify critically required therapies to treat MDR infections. We showed previously that azidothymidine (AZT) and colistin acted synergistically *in vitro* and *in vivo*. In this study, the therapeutic effect of azidothymidine with colistimethate sodium (CMS) was tested in a murine model of *K. pneumoniae* urinary tract infection (UTI).

**Materials/methods:** Female C3H/HeN mice were pre-conditioned by 5% glucose in drinking water from day -5. On day 0, mice were infected with *K. pneumoniae* B817, a recent MDR colistin resistant clinical isolate (MIC 16µg/mL), by transurethral administration into bladders. Treatment was initiated 24h post infection with CMS (3, 10 and 30mg/kg/dose), AZT (3, 15, 75mg/kg/dose) or 3 and 10mg/kg/dose CMS in combination with 3, 15 or 75 mg/kg/dose AZT. All treatments were intravenous and continued q8h for 9 doses. Mice were euthanized 96h post infection and bacterial burden quantified in urine, bladder and kidneys.

**Results:** We had shown previously that AZT and CMS acted synergistically against *K. pneumoniae* B817 *in vitro*. The murine UTI model maintained a robust infection over 96h with bacterial burden >4.8 log10 CFU/g in urine, bladder and kidney.

Monotherapy with CMS at 3, 10 and 30mg/kg showed a dose dependent reduction in burden in all tissues and urine. AZT monotherapy at 3, 15 and 75mg/kg was also dose dependent in reduction of bacterial counts in urine and bladder, but no clear dose response was seen in the kidneys.

Significant additional reductions in burden were achieved when the two drugs were dosed concomitantly. Combination treatment with CMS at 3mg/kg or 10mg/kg plus AZT at a dose range of 3, 15 and 75mg/kg showed a reduction in bacterial burden in urine and kidneys when compared monotherapy treatment. However, this additional effect was not observed in bladder.

**Conclusions:** When tested in a murine model of UTI with the colistin resistant strain *K. pneumoniae* B817, combinations of CMS and AZT achieved efficacy superior to single agents as measured in kidney and urine burden. These results support continued investigation of combination treatment with AZT and colistin for the treatment of MDR Gram-negative infections.

Abstract 6119

**Diagnostic value of the IMMY Aspergillus LFA on bronchoalveolar lavage fluid of intensive care patients**

Albert Dunbar1, Toine Mercier*2, Vincent Veldhuizen1, Bart Rijnders3

1Erasmus Medical Center, Rotterdam, Netherlands, 2Universitair Ziekenhuis Leuven, Leuven, Belgium

**Background:** The diagnosis of invasive pulmonary aspergillosis (IPA) is challenging, especially in the intensive care unit (ICU) setting, where clinical symptoms as well as imaging are mostly aspecific. Recently, Aspergillus lateral flow tests were developed to decrease the time to diagnosis of IPA. Several studies evaluated the value of these new tests in the hematology population. We aimed to evaluate the value of a new lateral flow test for Aspergillus in ICU patients.

**Materials/methods:** Using left-over bronchoalveolar lavage fluid (BALf) from patients previously admitted to the ICU of a university hospital, we studied the performance of the sōna Aspergillus galactomannan lateral flow assay (LFA, IMMY, Norman, Oklahoma, USA). Patients included were >18 years of which BALf stored at ≤ -20°C was available. The Platelia™ Aspergillus EIA test was used to measure galactomannan. Based on the result of the fungal culture and galactomannan, the patients were classified according to 2 frequently used definitions: the EORTC-MSG criteria and the modified AspICU criteria (=AspICU criteria in which galactomannan is incorporated as well). For each case of IPA, we aimed to include 2 aspergillus negative controls. BALf was tested with the LFA according to the manufacturer’s instruction. The LFA was read out visually and with a digital reader by researchers blinded to the clinical diagnosis and IPA classification.

**Results:** Seventy-two patients were included of which 14 had probable or proven IPA according to the EORTC/MSG definitions, 24 had IPA according to the modified AspICU criteria and 48 served as IPA negative controls. Depending on the definitions used, sensitivities and specificities varied between 0.79 and 0.86 (table 1). The area under the ROC curve of the LFA was 0.85.

**Conclusions:** In ICU patients, the IMMY LFA performed well on BALf and can be used as a rapid screening test while waiting for culture results and conventional galactomannan results.

Abstract 6120

Comprehensive analysis of evolutionary dynamics of circulating strains and immunopathogenesis and co-infections of human metapneumovirus associated acute lower respiratory tract infections in children

Radha Kanta Ratho*, Subhabrata Sarkar†, Meenu Singh‡, Amarjeet Singh§, Mini P. Singh∥

1Post Graduate Institute of Medical Education and research, Chandigarh, India

Background: The study explored the role of circulating genotypes, evolutionary dynamics, co-infections, viral load and host cytokines in hMPV mediated ALRTI.

Materials/methods: Npas of 349 children were collected between the year 2013-2017. Samples positive for hMPV PCR were subjected for viral load estimation by Real Time PCR and co-infections by FTD Respiratory 21. IL-17A, IFN-Ɣ, TNF-α, IL-10, IL-6, MMP-9 and TIMP-1 levels in NPA samples were determined by CBA and ELISA. The viral load and cytokine levels were correlated with the WHO specified criteria for ALRTI severity. 'F' gene region of hMPV(n=12) was sequenced for phylodynamics analysis and potential N-glycosylation and O-glycosylation sites prediction.

Results: hMPV positivity was 6.59% (23/349). Twelve hMPV strains were analyzed and classified as hMPV A (n=8) and B (n=4) which contained 98% nucleic acid identity. The hMPV-A strains (n=8) phylogenetically belonged to hMPV A2a cluster whereas hMPV-B strains (n=4) belonged to lineage B1. The global time scaled evolutionary rate of hMPV A and B strains were 3.52X10-4 substitutions/site/year and 6.67X10-4 substitutions/site/year respectively. The potential O and N glycosylation sites in F gene were conserved among reference and test strains and without any variation in both hMPV A and B strains. hMPV A strains revealed two non-synonymous amino acid mutations. R82K mutation was seen to be conserved among all the strains and A185D mutation was seen in 7 strains and 1 strain contained A185N mutation. Only one strain of hMPV B contained R189K mutation in comparison to hMPV B reference strains. In 50% (11/22) of the infections hMPV was the sole pathogen. RSV was the most common virus (n=5) present along with hMPV followed by Rhinovirus (n=3) and Human Bocavirus (n=3). The Concentration of TNF, IL-6 and IL-10 levels in hMPV infected patients were significantly higher in severe ALRTI patients. The concentrations of TNF, IL-6, IL10, MMP-9 were (29.5±6.5 vs 5436.7±4473.7), (3432.3±1952.2 vs 15365.9±6013.9), (62.47±32.6 vs 290.2±135.3) and (33.9±33.02ng/ml and 1058.7±349.3ng/ml) in ALRTI and severe ALRTI patients respectively.

Conclusions: This study highlights the phylodynamics of circulating hMPV strains in Indian subcontinent where Th2 cytokine bias has been observed towards disease severity of ALRTI in Children.

Abstract 6121

**Impact of the D26N amino acid substitution in the RND-type efflux regulator AdeR on antimicrobial susceptibility of Acinetobacter baumannii**

Kai Lucassen*1, Kyriaki Xanthopoulou1,2, Thorsten Wille1, Harald Seifert1,2, Paul G. Higgins2,3

1University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 3University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany

**Background:** The Acinetobacter baumannii RND efflux pump AdeABC is regulated by the 2-component regulator AdeRS. In previous studies the AdeR amino acid substitution D26N was supposed to increase AdeABC expression, since it was found frequently in tigecycline resistant isolates [1]. The objective of this study was to determine the impact of the AdeR amino acid substitution D26N, identified in the tigecycline resistant clinical isolate MB-R112, on the antimicrobial resistance phenotype of A. baumannii.

**Materials/methods:** Deletion of adeRS in A. baumannii ATCC 17978 and complementation with adeRS of ATCC 19606 and MB-R112 was done by markerless mutagenesis. D26N substitution in AdeR19606 was achieved by site directed mutagenesis. Minimal inhibitory concentrations (MICs) for azithromycin (AZI), ciprofloxacin (CIP), gentamicin (GEN) meropenem (MEM), tetracycline (TET), and tigecycline (TGC) were determined by agar dilution. AdeRS of MB-R112 was aligned to A. baumannii reference strains for detection of additional amino acid substitutions.

**Results:** Introduction of the amino acid substitution D26N in AdeR19606 increased the MIC for AZI, CIP, GEN, and TET by one dilution step. Complementation with adeRSMB-R112 had a more noticeably effect by increasing the MIC fourfold for CIP, eightfold for TET and TGC, and 16-fold for AZI and GEN (Table 1). Analysis of the AdeRS amino acid sequences did not reveal unique amino acid substitutions in MB-R112 beyond D26N.

**Conclusions:** This study shows that the D26N amino acid substitution in AdeR does have an impact on antimicrobial susceptibility in A. baumannii. However, the single amino acid substitution had less impact than introduction of the entire adeRSMB-R112 construct, although it did not contain another unique substitution. Therefore, we hypothesise that accumulation of mutations in AdeRS, we assumed as silent, may actually facilitate AdeABC expression.

**Evaluation of the carbapenem inactivation method (CIM) as a predictor for carbapenemase-producing Gram-negative bacteria**

Frances Hurren¹, Kyra Chua*¹, Marcel Leroi²

¹Austin Hospital, Heidelberg, Australia

**Background:** The CIM test is now widely used to phenotypically detect carbapenemases in Gram negative bacteria due to its greater sensitivity compared to commercial methods. The specificity of the assay and its performance in specific genera are less well characterised. The aim of this study was to evaluate the specificity of the CIM for the detection of carbapenemase producing Gram-negative bacteria.

**Materials/methods:** A total of 37 clinical and screening isolates that had reduced meropenem susceptibilities were assessed.

Three variations of the CIM test were assessed;

1) The first described method by Van der Zwaluw et al (oCIM)

2) A modification of the Van der Zwaluw et al method that included a prolonged incubation of the meropenem disk in the bacterial suspension (aCIM)

3) The modified CIM described in the 27th edition of the CLSI (mCLSI)

The Blue-Carba test was performed as previously described. A multiplex PCR to detect a panel of carbapenemase genes was performed by the Microbiological Diagnostic Unit Public Health Laboratory.

**Results:** There were 9 isolates that were CIM negative, Blue-Carba negative and carbapenemase genes not detected.

0 of the 18 isolates that contained various carbapenemase genes, all yielded a positive CIM result. The three isolates that demonstrated a negative Blue-Carba result contained blaOXA genes.

10 isolates (8 Enterobacter cloacae complex, 1 Morganella morganii and 1 Citrobacter amalonaticus) yielded a positive CIM result using both oCIM and aCIM methodology, however no resistance genes were detected via molecular methods. These were considered false positive CIM tests.

7/9 isolates, all Enterobacter cloacae complex, that were considered false positives were susceptible to non-β-lactam agents. In contrast, all of the carbapenemase producing Gram negative bacteria had multi-drug resistance except one isolate with isolated ciprofloxacin resistance.

**Conclusions:** The increased inoculum used in the oCIM and aCIM increased the sensitivity for the detection of carbapenemases in Acinetobacter species, which may be due to lower expression of these genes. However, this increased sensitivity is at the expense of reduced specificity in Enterobacterales, specifically Enterobacter species. The absence of multidrug-resistance may flag the possibility of a false positive oCIM and aCIM result.

Collateral treatment effects in *Pseudomonas aeruginosa* on antibiotic susceptibility and virulence mechanisms

Thomas Ewout Van Der Schalk$^1$, Basil Britto Xavier$^1$, Christine Lammens$^1$, Samir Kumar-Singh$^2$, Herman Goossens$^1$, Surbhi Malhotra-Kumar$^1$

$^1$University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, Antwerpen, Belgium, $^2$University of Antwerp, Molecular Pathology Group, Cell Biology & Histology, Antwerpen, Belgium

**Background:** *P. aeruginosa* causes serious nosocomial infections and rapidly develops resistance against most antibiotics. This development of resistance has collateral effects that change the susceptibilities to other antibiotic. We treated PAO1 reference strains with ciprofloxacin and imipenem, and studied the collateral effects on antibiotic susceptibilities and genetic modifications.

**Materials/methods:** The PAO1 reference strains (MI and DTU) were treated with either ciprofloxacin (Cip) [0.05-256 µg/ml] or imipenem (Imi) [0.5-128 µg/ml], for 20 passages. Passages performed in 24-well plates contained three 2-step dilutions of antibiotics. Antibiotic concentrations were increased maximum 4-fold between passages. Minimal inhibitory concentration (MIC) testing was done for Cip, Imi, tobramycin (Tob), ceftazidime (Cef), and azithromycin (Azm) with E-tests (bioMérieux) and colistin (Col) with MIC-Strips Colistin (Merlin). The final passages were plated on a 4-fold dilution of the passages’ antibiotic concentration before sequencing 2×250bp PE, (MiSeq, Illumina). Parental strains were sequenced using Pacbio Sequel (PacificBio Sciences). Analysis was done using in-house developed pipeline BacPipe v.1.2.6 and CLC Genomics Workbench 9.5.1 (CLCbio, Qiagen).

**Results:** In the Cip-treated populations (>256-fold MIC increase) mutations were found in *gyrA, gyrB, parC* and *parE* (fluoroquinolone targets) and in *nfxB* and the *nfxB* binding site (MexCD-OprJ regulator). Increased efflux accounted for increased resistance against Azm (>32-fold MIC increase), a substrate of the MexCD-OprJ efflux pump. Cip treatment also resulted in increased susceptibility to Tob (4- to 6-fold MIC decrease) and Imi (< 2-fold MIC decrease) due to increased outermembrane permeability caused by the increased MexCD-OprJ expression. In the Imi-treated populations (>32-fold MIC increase), mutations were found in *oprD* (encoding an outer-membrane porin) (figure c). Both Cip- and Imi-treated populations showed mutations in lipopolysaccharide (LPS) synthesis genes of which, *tagO* (initiates O-polysaccharide synthesis) showed a G229 deletion leading to a frameshift (figures c and d).

**Conclusions:** Cip and Imi treatments increased susceptibilities to tobramycin. Prolonged and increasing exposure to ciprofloxacin and imipenem led to novel alterations in genes involved in synthesis of LPS, a major virulence factor of *P. aeruginosa*, that could lead to a potential lack of O-antigen and impact the organisms’ ability to cause infection.

Abstract 6128

Evaluation of ceftolozane-tazobactam disk diffusion testing of *Pseudomonas aeruginosa* in a multi-centre UK study

Joanna Diggle¹, Irene Monahan², Adela Alvarez Buylla³, Eric Manu⁴, Mike Allen⁴, Timothy Planche², Mandy Wootton*¹

¹University Hospital of Wales, Specialist Antimicrobial Chemotherapy Unit, Public Health Wales, Cardiff, United Kingdom, ²St George’s, University of London, London, United Kingdom, ³Merck Sharp & Dohme Limited, Hoddesdon, United Kingdom, ⁴Merck Sharp & Dohme Limited, Hoddesdon, United Kingdom

**Background:** *Pseudomonas aeruginosa* (PAER) is an important pathogen in healthcare associated infections, including nosocomial pneumonia, urinary tract (UTI) and bloodstream infections. It is adept at developing antimicrobial resistance, which impacts treatment options and patient outcomes. Ceftolozane/tazobactam (C/T) is an anti-pseudomonal cephalosporin combined with an established inhibitor licensed for complicated intra-abdominal infections, hospital & ventilator acquired pneumonia, complicated UTI and acute pyelonephritis. Susceptibility testing should be accurate, especially for drugs not tested routinely. We have evaluated locally performed disk diffusion (DD) on 6 antimicrobials including C/T against broth microdilution (BMD).

**Materials/methods:** Clinically significant PAER, from Cystic Fibrosis (CF) & non-CF, were tested locally at 14 laboratories in the UK as part of the INVICTUS study. EUCAST DD was performed on C/T (MAST), piperacillin/tazobactam (TZP), ceftazidime (CAZ), aztreonam (ATM), imipenem (IMI) & meropenem (MEM). Triplicate DD tests were performed at a reference laboratory on a percentage of isolates as part of quality Control (QC) as well as BMD on 159 non-CF isolates. Categorical agreement (CA), Major Errors (ME) and Very Major Errors (VME) were calculated.

**Results:** CA were C/T (79%), PT (85%), CAZ (86%), ATM (91%), IMI (90%) & MER (81%). ME, where DD result was resistant (R) but BMD susceptible (S), for C/T DD were 18.9% (n=30), whilst VME were 2.5%. Of the 30 ME, 9 were re-tested, 6 confirmed S results whilst 3 had zone diameters near the DD breakpoint. ME & VME for TZP, CAZ, ATM, IMI & MEM were 0%, 1 2.6%, 5.9%, 5.7% & 1.9% and 1 2%, 1.9%, 3.8%, 4.4% & 0% respectively. MEM also had 17% minor errors (mE). Five PAER exhibited TZP DD results in the area of technical uncertainty (ATU), 4 with R MIC results and 1 with S.

**Figure 1:** Ceftolozane/tazobactam histogram of local DD zone diameters versus MIC

**Conclusions:** Categorical agreement was lowest for C/T at 79% with high levels of MEs, suggesting high rates of false resistance in local laboratories with DD (Figure 1). However, CA improved upon re-testing of some isolates in the reference laboratory. CA was also low for TZP, CAZ and MEM. TZP showed a high VME rate.

Metagenomic analyses of antibiotic resistance genes in gut microbiome of healthy people in Korea: high carriage rate of blaCTX-M, blaCMY-2 and plasmid-mediated quinolone resistance genes

Jieun Kim*, Mi-Ran Seo, Kye-Yeung Park, Hoon-Sik Hwang, Bongyoung Kim, Mina Rho, Hyunjoo Pai

Hanyang University, Seoul, South Korea

Abstract third-party references: This research was supported by a fund [2017N-ER5407-00] by Research of Korea Centers for Disease Control and Prevention.

Background: To characterize carriage of antibiotic resistance genes (ARGs) in gut microbiome of healthy people.

Materials/methods: We investigated fecal carriage of ARGs in gut microbiome in healthy Koreans by using whole metagenome sequences and targeted metagenomics approach. Sixty-one Koreans aged 30 to 59 without underlying diseases were included.

Results: The median age was 46 and 47.5% were female. Eighteen (29.5%) carried blaCTX-M or plasmid-mediated AmpC or both alleles in their gut: blaCTX-M 23% (14/61), blaCMY2 13.1% (8/61) and blaDHA 3% (2/61). None carried plasmid-mediated carbapenemase alleles. Regarding plasmid-mediated quinolone resistance (PMQR) alleles, 36 (59%) carried PMQR, and 30 of 36 (83%) harbored 2-4 PMQR alleles: qnrB 44.3% (27/61), qnrD 4.9% (3/61), qnrS 47.5% (29/61), and aac(6’)-ib-cr 13.1% (8/61), respectively.

Based on ARGs abundance in gut microbiome, 61 people were categorized into high, medium, and low ARGs, and characteristics of people in each group were analyzed; high ARG group [relative abundance of ARGs ≥ 120 gene per million] were found to have visited hospitals more often \( (p = 0.039) \), particularly for upper respiratory tract infections \( (p = 0.047) \), and carry more blaCTX-M \( (p \text{ for trend}=0.008) \) than other groups. Presence of CTX-M alleles correlated with abundance of most ARG groups such as \( \beta \)-lactam, aminoglycoside, macrolide in gut resistome \( (p =0.006, p =0.034, p =0.009, \text{ respectively}) \). Unlike blaCTX-M, PMQR alleles existed irrelevant to abundance of ARGs \( (p \text{ for trend}=0.176) \). PMQR and blaCMY2 existed in association with individual PMQR alleles.

Conclusions: Fecal carriage of PMQR alleles were broad and multiplex, which might indicate a frequent exposure during daily life.

Diagnosis of invasive pneumococcal disease in children by using a classification method based on nasopharyngeal microbiota signatures

Desiré Henares-Bonilla*, Raul Cabrera-Rubio, Natalia Timoneda, Mariona Fernandez De Sevilla, Ana Fernandez, Pedro Brotons De Los Reyes, Alex Mira, Carmen Muñoz-Almagro

1Sant Joan de Déu University Hospital, Sant Joan de Déu Research Institute, Barcelona, Spain, 2CIBER Center for Epidemiology and Public Health (CIBERESP), Carlos III Health Institute, Madrid, Spain, 3Teagasc Food Research Centre [TEAGASC], Moorepark, Fermoy, Cork, Ireland, 4APC Microbiome Institute, University College Cork, Cork, Ireland, 5Pediatrics department, Sant Joan de Déu University Hospital, Barcelona, Spain, 6Department of Health and Genomics, Center for Advanced Research in Public Health, FISABIO, Valencia, Spain, 7School of Medicine, Universitat Internacional de Catalunya, Barcelona, Spain

**Background:** Streptococcus pneumoniae is a pathobiont that colonizes children's nasopharynx asymptomatically and has the potential to cause Invasive Pneumococcal Disease (IPD). IPD microbiological diagnosis is based on isolation/DNA detection of pneumococcus in sterile body fluids but this approach is invasive and yields limited sensitivity. This study aims to evaluate the utility of non-invasive nasopharyngeal microbiota for children IPD diagnosis.

**Materials/methods:** Prospective double-case-control study including all IPD cases <18 years pre-exposed <24h to antibiotics attending Hospital Sant Joan de Déu (Barcelona, Spain) during 2014-2018, paired by age/sex/seasonality with at least 2 healthy controls (HC) and 1 control with upper viral respiratory infection (UVRI). Nasopharyngeal DNA pneumococcal detection/quantification/serotyping (different multiplex real-time PCRs), DNA/RNA viral detection (Allplex-Respiratory-Panel, See gene) and microbiota characterization by sequencing V3-V4 region from 16S rRNA (Miseq, Illumina) was performed. Results were used for building a case-control classification model with Random Forest.

**Results:** A total of 140 children were selected (IPD=27, HC=65, UVRI=48). Viral RNA/DNA was detected in 100% of UVRI, 81.5% of IPD and 60.0% of HC (p-value=0.081). Pneumococcal DNA was detected in 100% of IPD, 61.5% of HC and 52.1% of UVRI (p-value<0.001). PCV13 serotypes (IPD=51.8%, HC=6.1%, UVRI=16.0%; p-value<0.001) and invasive serotypes (IPD=51.8%, HC=12.5%, UVRI=16.0%; p-value<0.001) were more prevalent in IPD. Independently of case-control grouping, viral infection was associated to decreased Shannon diversity (p-value=0.012) and a trend for richness (Observed species, p-value=0.065). When stratified by viral detection, cases presented lower richness than HC among viral-positive samples (Observed species, p-value=0.022). Beta-diversity showed an evident separation between viral-positive IPD, viral-negative IPD, viral-positive HC, viral-negative HC and UVRI groups (Adonis p-value=0.002), more notably between viral-negative HC and viral-positive IPD. This separation was confirmed by hierarchical cluster analysis. Deep insight at microbiota patterns with LEfSe revealed specific bacterial-biomarkers: Neisseria-Streptococcus pneumoniae in IPD, Dolosigranulum-pigrum-Gemella in HC and Moraxella in UVRI. Random forest model demonstrated high performance in distinguishing cases-controls, with AUCs of 0.87 for IPD-HC (accuracy=0.79 [95% CI: 0.54-0.94]) and 0.92 for IPD-UVRI (accuracy=0.88 [95% CI: 0.69-0.97]).

**Conclusions:** Integrated analysis from viral DNA/RNA detection, pneumococcus detection/quantification/characterization and microbiota composition of nasopharyngeal samples is a promising tool for easy non-invasive IPD diagnosis in children.

Abstract 6135

**Lensless imaging for non-destructive and label-free identification directly on agar**

Inès Zamoun1, Alexis Maire1,2, Patrick Schiavone1, Pierre R. Marcoux3, Tonatiuh Yescas González6, Emmanuel Picard2, Marc Zelsmann1, Emmanuel Hadji2, David Peyrade1

1Université Grenoble Alpes, CNRS - LTM, Grenoble, France, 2Université Grenoble Alpes, CEA, IRIG, PHELIQS, SINAPS, Grenoble, France, 3Université Grenoble Alpes, CEA, LETI, DTBS, Grenoble, France

**Background:** The pursuit of non-invasive and non-destructive identification methods has raised an increasing interest for label-free optical techniques, e.g. vibrational spectroscopies (infrared and Raman), elastic light scattering and lensless imaging. Among these technologies, elastic scattering and lensless imaging can be performed directly on agar plates, making them particularly compatible with the growing need for automated methods. Both techniques use a coherent or partially coherent light source to illuminate the Petri dish. Resulting scatterograms are then processed by pattern recognition algorithms, resulting in identification. Contrary to elastic scattering, lensless imaging can provide the simultaneous identification of several colonies.

**Materials/methods:** We report here the very first example of identification down to species with a widefield lensless imaging device, namely 22.3mm x 14.9mm (pixel size 4.335µm). Considering this large field of view, several hundreds of colonies can be analysed simultaneously. A partially coherent green light emitting diode (main wavelength 523nm) illuminated different microbial cultures growing on tryptic soy agar at 36°C. Cultures of Gram-positive, Gram-negative and yeast reference strains were imaged every 10 minutes, for 22 to 23 h of incubation. An example image of *E. coli* culture is given at 14h of incubation. For the automatic analysis of scatterograms, classical machine learning algorithms (i.e. Support-Vector Machine), as well as some deep learning models (i.e. Convolutional Neural Network), were developed.

**Results:** Deep learning algorithms, as well as classical machine learning, were investigated for the analysis of the collected database (5 reference strains). Six convolutional neural network models were assessed including transfer learning models such as VGG16, MobileNet etc., with up to 2000 samples (i.e. images of colonies) per species. The algorithms yielded unambiguous identification of the five species, with at least 98% accuracy.

**Conclusions:** This very first database paves the way towards a future imaging device for the simultaneous identification of all the isolated colonies on a 90mm Petri dish. Furthermore, as culture growth is being recorded in situ, the technique is capable of identification during the early stages of incubation. An extended database, including clinical isolates, will soon be collected.

**Presenter email address:** pierre.marcoux@cea.fr
Abstract 6140

Differentiation of Blastocystis subtypes by PCR and Sanger sequencing versus NGS-based total ribosomal DNA analysis

Kassandra Ascuña Durand1, Renzo Salazar Sanchez1, Lee O’brien Andersen2, Jorge Ballon Echegaray1, C. Rune Stensvold2

1Universidad Nacional de San Agustín, Arequipa, Peru, 2Statens Serum Institut, Copenhagen, Denmark

Background: Blastocystis may be the most common intestinal parasite in the world, infecting both human and a vast variety of non-human hosts. Based on SSU rDNA analysis, at least 17 subtypes of Blastocystis (arguably separate species/genera) are known, of which at least nine have been found in humans. State-of-the-art differentiation of Blastocystis subtypes relies on ‘barcoding’ (PCR and Sanger sequencing); however, novel technology may prove better subtype resolution and ease the identification of subtypes in mixed subtype infections. In this study, we compared barcoding with ILLUMINA-based sequencing and differentiation of ribosomal genes amplified by broad-specificity eukaryotic primers.

Materials/methods: We used 51 stool samples from symptomatic and asymptomatic individuals living in periurban communities from Arequipa, Peru. All DNAs were extracted by the Stool DNA Isolation kit (Norgen) and processed by i) state-of-the-art barcoding (PCR using the primers BhRDr and RD5 and Sanger sequencing), and ii) a microbiome assay using amplicon-based sequencing of total nuclear ribosomal genes, automated data clean-up and annotation to genus/species level by the in-house software BION. Sequences obtained by Sanger sequencing were edited manually and BLASTed against a curated Blastocystis database to gain information on subtype. Blastocystis-specific sequences identified by BION were clustered and consensus sequences for each cluster were BLASTed against the NCBI Database. Subtype identification as called by the two methods was compared.

Results: By barcoding, an unambiguous and single-peak DNA sequence reflecting a single subtype was observed in 77% of the samples. By the microbiome assay, subtype results were available for 96% of the samples. The results of the microbiome assay were in accordance with those obtained by barcoding, and the microbiome assay moreover allowed resolution of mixed subtype carriage in those samples where DNA sequence traces obtained by Sanger sequencing were ambiguous.

Conclusions: Based on Sanger sequencing, barcoding produced unambiguous results for 77% of the samples, possibly giving the DNA sequence of the most predominant subtype. Meanwhile the microbiome assay was able to subtype 96% of the samples and moreover enabled the detection and differentiation of mixed Blastocystis subtype infection. The microbiome assay therefore appears to be a useful supplement or alternative to barcoding.

Intracellular persistence of uropathogenic Escherichia coli is undetectable in urinary bladders from mecillinam-treated pigs

Kristian Stærk*, Rasmus Birkholm Grønnemose, Yaseelan Palarasah, Hans Jørn Kolmos, Lars Lund, Thomas Emil Andersen

1 Odense University Hospital, Department of Clinical Microbiology, Odense, Denmark, 2 University of Southern Denmark, Research Unit of Clinical Microbiology, Odense, Denmark, 3 University of Southern Denmark, Department of Cancer and Inflammation, Odense, Denmark, 4 Odense University Hospital, Department of Urology, Odense, Denmark, 5 University of Southern Denmark, Odense, Denmark

Background: Type-1 pili dependent invasion of bladder epithelial cells by uropathogenic Escherichia coli (UPEC) is suggested to serve as reservoirs for recurrent urinary tract infections (rUTI). However, the intracellular pathogenic cascade has only been observed in murine models, and its relevance for human rUTI has been a subject of debate and remains to be demonstrated. To provide a missing link between mice and humans, the aim of this study was to investigate the influence of type-1 pili on experimentally induced cystitis in pigs, and whether UPEC survives conventional antibiotic treatment by invading the bladder epithelium of this animal.

Materials/methods: The study was based on a recently developed porcine model of cystitis. Pigs were inoculated with the reference cystitis strain, UTI89, in different concentrations; 10^8 CFU/ml, 10^6 CFU/ml, 10^4 CFU/ml, and 10^2 CFU/ml (4 pigs in each group). Another group (n = 4) was inoculated with the type-1 pili deficient mutant UTI89ΔfimH in a concentration of 10^2 CFU/ml. In a separate experiment, six pigs were subjected to a three-day peroral treatment with the extracellular drug, mecillinam, to investigate if intracellular UPEC could survive antibiotic treatment in vivo. Regular urine and blood samples and clinical parameters were collected to monitor the infection. Whole bladders were removed and analyzed for the presence of intracellular UPEC using ex vivo gentamicin protection assays.

Results: Successful bladder colonization was achieved by all pigs infected with UTI89, however only 25% (1 of 4) of pigs became colonized upon inoculation with UTI89ΔfimH. Intracellular bacteria were present in low numbers in whole bladders following 14 days of persistent bacteriuria, however, no viable UPEC were detectable in the bladders of mecillinam-treated pigs.

Conclusions: Type-1 pili is non-essential but highly advantageous for UPEC to surpass initial bottlenecks during acute UTI in pigs. Also, UPEC is capable of invading the bladder epithelium of pigs, however, they fail to survive conventional antibiotic treatment in vivo suggesting that intracellular colonization does not serve as reservoirs of rUTI.

Abstract 6144

Gliotoxin, a new candidate against methicillin-resistant Staphylococcus aureus showing synergistic effect with classical antimicrobial drugs in Caenorhabditis elegans infection model

Patricia Esteban*, Sergio Redrado1, Laura Comas1, Cristina Seral2, Julián Pardo Jimeno1,4,5, Maykel Arias2, Eva María Gálvez2

1Fundación Instituto de Investigación Sanitaria Aragón (IIS Aragón), Biomedical Research Centre of Aragón (CIBA), Zaragoza, Spain, 2Instituto de Carboquímica (ICB-CSIC), Zaragoza, Spain, 3Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain, 4Fundación Agencia Aragonesa para la Investigación y el Desarrollo (ARAI), Zaragoza, Spain, 5University of Zaragoza, Department Biochemistry and Molecular and Cell Biology and Dept. Microbiology, Preventive Medicine and Public Health, Zaragoza, Spain

Background: Multidrug-resistant bacteria such as methicillin-resistant Staphylococcus aureus (MRSA) is among the major causes of hospital-acquired and community infections, and pose a challenge to the human health care system. Therefore, it is important to find new drugs that show activity against these bacteria, both in monotherapy and in combination with other antimicrobial drugs. Gliotoxin is a mycotoxin produced by Aspergillus fumigatus and other fungi of the Aspergillus genus. Some evidence suggests that gliotoxin shows antimicrobial activity, especially against S. aureus.

This work aims to evaluate the antibiotic efficacy of gliotoxin as monotherapy or in combination with other therapeutic against MRSA in vitro and in vivo using a C. elegans infection model.

Materials/methods: MRSA ATCC700699 sensitivity against gliotoxin was analysed by different methods: disc diffusion, time-mortality curves, microdilution assays. The synergistic effects of gliotoxin with others anti-staphylococcal drugs (vancomycin, fusidic acid and linezolid) were tested by a checkerboard assay.

Transformed synchronized C. elegans L4 worms were infected with MRSA. The culture was supplemented separately with gliotoxin, vancomycin or its combination to different concentrations. The survival rate of C. elegans was scored manually every 12h for 4 days.

Results: Sensitivity analysis of MRSA against gliotoxin showed that gliotoxin has a potent antimicrobial activity (MIC = 2 µg/ml). In addition, synergistic activity was observed, when the gliotoxin was combined with vancomycin and fusidic acid, using checkerboard and time-kill assays. This synergistic effect was confirmed by CalcuSyn software (CI = 0.15 for 1 µg/ml of gliotoxin combined with 2 µg/ml of vancomycin).

The in vivo study of S. aureus infection in a C. elegans model showed that combined treatment of vancomycin with gliotoxin increased 70% in survival rate of the MRSA-infected worms.

Conclusions: Our results suggest that gliotoxin is effective against MRSA strains indicating their potential use as a new drug against MRSA infections.

Abstract 6145

Hepatitis B and hepatitis D virus infection in immigrants living in south Italy: epidemiological and virological characteristics

Mariantonietta Pisaturo*1,2, Lorenzo Onorato1, Loredana Alessio3,4, Caterina Monari1, Luciano Gualdieri5, Carmine Minichini6, Giovanni Di Caprio2, Mario Starace1, Mara Caroprese1, Laura Occhiello6, Gaetano Scotto1, Margherita Macera6, Evangelista Sagnelli6, Nicola Coppola1,6

1. Sezione di Malattie Infettive, Dipartimento di Salute Mentale e Medicina Pubblica, Università della Campania Luigi Vanvitelli, Napoli, Italy, 2Centro sociale ex canapificio Caserta, Italy, 3UOC di Malattie Infettive, AORN Sant’Anna e San Sebastiano, Caserta, Italy, 4Centro Suore Missionarie della Carità, Napoli, Italy, 5Centro per la Tutela della Salute degli Immigrati, Napoli, Italy, 6Sezione di Malattie Infettive, Dipartimento di Salute Mentale e Medicina Pubblica, Università della Campania Luigi Vanvitelli, Napoli, Italy, 7UOC di Malattie Infettive, Foggia, Italy

Background: in several European countries, there has been an increase in migration from countries with a high prevalence of HBV. In Italy epidemiological data relating to HBV and HDV infection in the migrant population are scanty. Aim of our study was to investigate the demographic and virological characteristics of HBV and HDV infection in a cohort of migrants living in Southern Italy.

Materials/methods: Between January 2012 and december 2018 all the migrants attending to one of the 5 first-level centers, 2 in Naples, 2 in Caserta and 1 in Foggia were tested for HBV. Data for demographic characteristics and risk factors for HBV infection were collected. All HBsAg positive subjects were tested for HDV. HBV genotype was evaluated in viremic subjects. For all HDV positive subjects was performed HDVRNA.

Results: 3184 subjects were tested; the 243 (7.6%) HBsAg positive subjects had median age of 26 (range 15-55) years and 227 (94%) were males; 214 (88%) came from Sub-Saharan Africa, 3 (1.2%) from North Africa, 17 (7%) from Eastern Europe, 8 (3.2%) from IndoPakistan area, one from South America (table 1); 8 of 243 subjects (3.2%) were HDVAb positive. Table 2 shows the characteristics of the 243 HBsAg positive patients enrolled and stratified according HDV serostatus.

We found that HDVAb negative subjects lived in Italy for a longer period (p = 0.001) compared to HDVAb positive patients. No variables independently associated with HDVAb positivity were identified (table 3). HBV-DNA levels were similar in the two groups. The HBV genotype was available for 90 samples in the group of HDVAb negative patients; genotype A was present in 17%, C in 3%, D in 12% and E in 69%. HDV-RNA was performed for all HDV Ab positive patients but only one patients (12.5%) was found HDV-RNA positive genotype-1. None of the patients was aware of their HBV or HDV serostatus.

Conclusions: In this study we found a high prevalence of HBV and HDV in a cohort of migrants living in our geographical area. This data suggests the need to adopt a universal screening and vaccination strategy for HBV in this vulnerable category.

Novodiag CarbaR+ assay for the detection of carbapenemase-producing bacteria

Sandra Bernabeu*, Delphine Girlich1, Warda Bouchahrouf2, Saoussen Oueslati2, Isabelle Langlois1, Nicolas Arangia1, Christine Begasse1, Te-Din Huang3, Pierre Bogaerts1, Youri Glupczynski1, Thierry Naas1,2

1Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, 2Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 3Hospital Mont-Godinne, Yvoir, Belgium

Abstract 6146

Background: Carbapenemase-producing Gram-negatives organisms (CPOs) represent a global concern for public health. The rapid implementation of infection control measures at the hospital requires easy, efficient and reliable detection tools of carbapenemase positive isolates.

Materials/methods: The NOVOdiag® CarbaR+ is a fully automated random access, multiplex nucleic acid based diagnostic test for the detection carbapenemases and mcr-1 genes on bacterial culture or fecal swabs in eNAT™ tubes. It is based on real-time PCR and microarray hybridisation with detection by contact fluorescence imaging and evanescent excitation all performed within a single cartridge. The CarbaR+ cartridge targets 9 carbapenemase encoding genes including blaKPC, blaNDM, blaVIM, blaIMP, blaOXA-48-like, the Acinetobacter OXA-carbapenemase genes including blaOXA-23-like, blaOXA-24-like, blaOXA-58-like, the chromosomally-encoded blaOXA-51-like genes with upstream inserted ISAb1 and the plasmid-mediated colistin resistance gene mcr-1. 201 cultured colonies of Gram-negatives organisms (61 Pseudomonas, 60 Acinetobacter and 80 Enterobacterales) with characterized β-lactamase content and 80 clinical rectal swabs collected from hospitalized high-risk patients for CPE colonization were tested.

Results: Globally, the NOVOdiag® CarbaR+ assay detected carbapenemase and MCR-1 encoding genes with a 98.8 % Sensitivity (Ss) and 99.7 % of Specificity (Sp). When breaking down these results by main bacterial species, a 100% Ss and Sp was obtained for Pseudomonas spp.; 96.7 % Ss and 99.4 % Sp for Acinetobacter sp.; 100 % Ss and 99.7 % Sp for Enterobacterales. On clinical fecal swabs 97.8 % Ss and 98.6 % Sp were correctly identified, when using culture as gold standard. 1 swab with E. coli OXA-181 was not detected (FN), and 1 NDM/OXA-48 PCR positive swab from a patient formerly known as OXA-48 carrier could not be confirmed by culture, and was considered FP.

Conclusions: The Novodiag® CarbaR+ is an easy to use sample in-answer out technology. The instrument is random access with results obtained in 80 minutes. The test allows the detection of the most frequently encountered carbapenemases and their variants among Enterobacteriales and non-fermenters but unfortunately excluding GES carbapenemases. Performance directly on fecal swab are very good but further evaluation on a larger number of clinical samples and from countries with different CPEs than those encountered in France.

Presenter email address: sandrine.bernabeu@aphp.fr
Extensively drug-resistant Klebsiella pneumoniae ST383 co-harbouring OXA-48 and NDM-5 outbreak at a tertiary care centre in Lebanon

Omar Zmerli*1;2, Amanda Chamieh1;3, Sanaa Saliba1;2, Ziad Daoud1;2, Claude Afif1;2, Eid Azar1;2

1Saint George Hospital University Medical Center, Division of Infectious Diseases, Beirut, Lebanon, 2University of Balamand, Faculty of Medicine and Medical Sciences, Beirut, Lebanon, 3Aix-Marseille University, Marseille, France

Background: Carbapenem-resistant Enterobacteriaceae (CRE) are a heterogenous group of MDR organisms harboring multiple different mechanisms of resistance. In November 2017, we accepted two patients transferred for management of gunshot wounds who had no major risk factors for MDR carriage. However, screening admission cultures grew extensively drug resistant Klebsiella pneumoniae (XDR-Kp). Shortly later, multiple cases of XDR-Kp were identified with a similar profile of resistance. This prompted an outbreak investigation.

Materials/methods: The outbreak investigation occurred at Saint George Hospital, a 333-bed tertiary care center in Lebanon. The two index cases grew XDR-Kp found to be resistant to cephalosporins, quinolones, aminoglycosides, carbapenems, colistin, and susceptible to tigecycline. All cultures growing XDR-Kp with this susceptibility profile from any clinical specimen in the period November 2017 - June 2018 were extracted from the laboratory electronic database. Charts of these patients were reviewed for clinical data including outcome, infection control measures, and antibiotic use. A subset of five isolates from the index cases were further identified with MALDI-TOF MS and genotypic analysis with PCR and MLST.

Results: A total of 25 cases were identified. The isolates overall came from sputum, urine, surgical wounds, and blood. Despite this extensive resistance profile, none of the patients experienced any related severe sepsis. Crude mortality rate at 30 days was 12% (3/25). Two deaths were due to non-infectious complications and one was due to a polymicrobial bacteremia. In light of the few therapeutic options available, a special effort was made to distinguish colonization from infection. Strict infection control practices were enforced.

The five isolates were co-harboring OXA-48 and NDM-5 carbapenemase genes and were part of the ST383 clone. The last identified case of this clone was in June 2018.

Conclusions: Our outbreak combines an unexpected high-level of resistance mediated by two notorious mechanisms of resistance coupled with a relatively benign clinical presentation. Infection control measures may have helped in containing this clonal spreading. Efficient diagnostic efforts eliminated the need for unnecessary therapy and was helpful when faced with a lack of therapeutic options. High level antimicrobial resistance should be tackled by deep investigation rather than empirical broad-spectrum combinations.

Abstract 6149

Catheter-associated bloodstream infections: Empirical antibiotic recommendations based on microbiological data

Carmen Collado Giner1, Mercedes García-Gasalla1, María Arrizabalaga Asenjo1, Lola Ventayol-Aguiló1, Mari Cruz Perez-Seco2, Maria Carmen Gallegos Alvarez1, Antoni Payeras1

1Hospital Universitari Son Llàtzer, Palma, Spain

Background: Central line and peripheral venous catheter-associated bloodstream infections (CA-BSIs) increase patient morbidity, length of stay, and hospital costs. Every hospital should have its own policy to control and prevent CA-BSIs. The collection of microbiological data in a CA-BSI register improves knowledge of the local epidemiology and allows for recommendations to be made regarding prevention and empirical antibiotic therapy.

Materials/methods: We collected microbiological data (microorganisms, susceptibility profiles), in addition to clinical data, from the CA-BSI register of Son Llàtzer Hospital, a 350-bed university hospital in Majorca (Spain), for the period from August 2015 to June 2019.

Results: 212 episodes of CA-BSIs were identified; 115 (54.2%) were peripheral venous catheter-associated bloodstream infections (PVC-BSIs) and 97 (45.8%) were central line-associated bloodstream infections (CLA-BSIs). The incidence rate was 0.26/1000 patient-days for PVC-BSIs and 0.24/1000 patient-days for CLA-BSIs. All PVC-BSIs and 59/97 CLA-BSIs occurred in non-intensive care units.

A polymicrobial aetiology was found in 19 cases. Gram-negative (GN) rods were isolated in 109 (47.2%) cases (86 Enterobacteriaceae and 22 non-fermentative), gram-positive (GP) rods in 112 (48.5%), and yeasts in 10 (4.3%). GN rods were more frequently isolated in PVC-BSIs than in CLA-BSIs (55.2% vs 37.7%), and yeasts were found in all CLA-BSIs.

GN susceptibility rates of 78% to cefotaxime (only Enterobacteriaceae), 80% to piperacillin/tazobactam, and 96.1% to meropenem were found. Among the GN microorganisms, 12 were ESBL producers (6 from CLA-BSIs and 6 from PVC-BSIs), 3 CAmpCs producers, and 2 Pseudomonas XDR non-carbapenemase-producing.

Among Staphylococcus aureus isolates, methicillin resistance was present in 8/51 (16.7%) isolates, 4 from CLA-BSIs and 4 from PVC-BSIs. Vancomycin MIC was ≤1 µg/mL in all cases. Candida spp. was identified in 10 cases (C. albicans in 7 cases and C. glabrata in 3 cases), and no resistance to echinocandins was found.

Conclusions: The incidence rate of CA-BSIs is high in our institution. GN bacteria were isolated more frequently than GP bacteria in PVC-BSIs. Based on the local epidemiology, when a CA-BSI is suspected, antimicrobial therapy should be initiated with a bactericidal agent active against S. aureus and CoNS, and GN coverage with piperacillin/tazobactam or in selected cases meropenem should be mandatory.

Abstract 6151

Whole genome sequencing and phenotypic characterisation of non-typeable Haemophilus influenzae in Hong Kong: 2000-2016

Carmen Li1, David Cleary2-3, Yun Kit Yeoh1, Jeffery Ho1, Nannur Rahman4*, Dulmini Nanayakkara1, Jun Yang1, Norman Lo1, Stuart Clarke4, Margaret Ip1,5

1Department of Microbiology, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong, 2NIHR Southampton Biomedical Research Centre, University Hospital Southampton Foundation NHS Trust, Southampton, United Kingdom, 3University of Southampton, Faculty of Medicine and Institute for Life Sciences, Southampton, United Kingdom, 4Faculty of Medicine and Institute for Life Sciences, University of Southampton, Southampton, United Kingdom, 5Prince of Wales Hospital, Shatin, Hong Kong

Background: Non-typeable H. Influenzae (NTHi) is increasingly recognized to play an important role in respiratory tract infections. Increasing reports of ampicillin- and β-lactamase-negative ampicillin-resistance are also noted. We aimed to study the epidemiology and characteristics of NTHi from a collection of archived Haemophilus influenzae (HI) strains from Hong Kong using whole genome sequencing. We also examined the antibiotic susceptibilities of these isolates to characterize genetic determinants of resistance phenotypes.

Materials/methods: 391 non-duplicate isolates of HI archived from carriage and respiratory diseases of children and adults were whole genome sequenced using NextSeq (Illumina) 2 x 150bp paired-end read chemistry. These included 231 isolates from NPAs of children’s carriage, 132 from sputa of adults with pneumonia/COPD and 26 from blood/body fluids saved during 2000-2016. Sequence Types (STs) were identified using ‘mlst’ (https://github.com/tseemann/mlst) and population structure analysed using PopPUNK. Minimum inhibitory concentrations (MICs) of ampicillin, amoxicillin-clavulanate, cefuroxime, cefotaxime, imipenem, azithromycin, tetracycline, doxycycline, minocycline and ciprofloxacin were determined according to CLSI (2019).

Results: Three serotypeable strains were identified based on in silico analysis of capsular loci – one each of serotypes A, B and F. From the remaining 388 NTHi, 86 known STs were identified. In addition, 32 novel STs comprising known allele sequences and six fuculose kinase (fucK) isolates were found. The remaining 32 isolates had novel STs defined by new allele sequences. The most common ST was 107 (8.0%; n=25) followed by ST12 (6.4%; n=20) and ST159 (6.0%; n=19). Preliminary analysis revealed a population structure contained within six clusters. Overall, 27% (n=104/385) of NTHI were ampicillin-resistant (MIC ≥4.0, MIC50/90 0.5/16 mg/L), 1% (4/385) amoxcillin/clavulanate-resistant (MIC≥4/2mg/L), 5.7% (22/385) cefuroxime-nonsusceptible (MIC≥8.0 mg/L), 7% (28/385) tetracycline NS (MIC≥4 mg/L). No statistical difference in percentage of ampicillin resistance between sputa vs NPA isolates (p>0.3) were obtained. Single isolates were resistant to cefotaxime, azithromycin, and imipenem. All isolates were susceptible to ciprofloxacin.

Conclusions: This represents the first in-depth analysis of NTHi from Hong Kong. The population epidemiology is diverse based on ST but can be defined within a minimal number of genome-level clusters. A moderate rate of ampicillin-resistance (27%) was observed and resistance to amoxicillin-clavulanate remains low (1%).

Effects of mutations in the hepatitis B virus genome on viral loads testing

Ayelet Keren Naus1, David Yardeni2,3, Haim Ben Zvi4, Ohad Etzion1, Michal Cohen-Naftaly3, Shoshana Rozenberg3, Yonat Shemer-Avni*5

1Hospital, Laboratory of Clinical Virology, Soroka University Medical Center, Beer-Sheva, Israel, Beer Sheva, Israel, 2hospital, Department of Gastroenterology and Liver Diseases, Soroka University Medical Center, Beer-Sheva, Israel, Beer Sheva, Israel, 3hospital, Department of Gastroenterology and Liver Diseases, Soroka University Medical Center, Beer-Sheva, Israel, Beer Sheva, Israel, 4Hospital, Microbiology Laboratory Rabin Medical Center, Beilinson Hospital, Petah-Tikva, Israel, Petach Tikva, Israel, 5Hospital, The Liver Institute, Rabin Medical Center, Beilinson Hospital, Petah-Tikva, Israel, Petach Tikva, Israel, 6Soroka University Medical Center, Laboratory of Clinical Virology, Soroka University Medical Center, Beer-Sheva, Israel, Beer Sheva, Israel

Background: Disease management of patients with chronic infection of hepatitis B virus (HBV) is largely dependent on HBV viral load (VL) monitoring. Many commercial tests were developed in recent years to test VLs, based on real time PCR or TMA (transcription-mediated amplification) technology: e.g. Xpert® HBV Viral Load and COBAS HBV Test are based on RTPCR, while Aptima™ HBV Quant Assay of Hologic is based on TMA technology. The tests also use different target-genes for amplification: while the first two amplify the precore/core region Aptima is directed to amplify the S/polymerase region. Aim: Comparing the 3 methods for HBV-DNA-monitoring.

Materials/methods: 36 sera were tested for HBV-VL by 3 kits: Xpert® HBV Viral Load, COBAS HBV, and Aptima™ HBV Quant Assay of Hologic. In 2 cases the precore/core region of HBV was amplified using specific primers, and the amplicons were analyzed further.

Results: In most cases there was a good agreement between the three methods. Out of 36 patients that were tested only two exhibited dramatic variations between COBAS/Genexpert VLs and the Aptima results (5562 IU/mL by the Panther vs. <20 by Roche, and 3825 IU/mL by the Panther vs. <20 by Roche). Further investigations have shown a deletion in the precore/core region in the genome of HBV that was isolated from these two patients. This deletion probably contributed to decrease VLs when the patients were tested by a method that is based on amplification of precore/core region.

Conclusions: Health care providers should be aware of deletions and sequence variation of HBV genome that accumulates during chronic infection with HBV. Depending on the circumstances, in certain cases, testing patients for HBV VLs by more than one method should be recommended.

Chronic pluripathological patients in over 64 years old with flu or serious acute respiratory infection, according to flu vaccination status

Latorre Millán Miriam1*, Amparo Larrauri2, Alin Manuel Gherasim3, Clara Mazagatos2, Nieves Martínez Cameo1, Mª Pilar Hernández1, Yolanda Gracia1, Silvia Pina1, Ana Martinez-Sapiña2, Antonio Rezusta1, Ana María Milagro Beamonte1

1Miguel Servet University Hospital, Aragon Health Research Institute (IIS Aragon), Zaragoza, Spain. 2National Epidemiology Center, Carlos III Health Institute, Madrid, Spain

Abstract third-party references: National Center for Epidemiology (Carlos III Health Institute), Madrid, Spain, Miguel Servet University Hospital (Microbiology and Parasitology Service), Zaragoza, Spain., Research group on infections difficult to diagnose and treat (Aragon Health Research Institute).

Background: Influenza virus infections should be considered in all older adults with risk factors, as they may be associated with higher mortality. Knowledge of the distribution of chronic diseases present in these patients can help in their clinical management.

Materials/methods: Data of the patients included by the Miguel Servet University Hospital (HUMS) in the European IMOVE+ study, during the 2016/17, 2017/18, and 2018/19 seasons, were analyzed. Patients older than 64 years hospitalized with symptoms of Severe Acute Respiratory Infection (SARI), not institutionalized, provided a sample of pharyngeal smear in which the presence of influenza was detected by PCR-RT. The number of the most frequent chronic pathologies was studied according to the influenza vaccination status and diagnosis, using the chi-square test ($\chi^2$) adjusted by Monte-Carlo methods.

Results: Among the three studied seasons, 1314 patients with SARI were recruited, of which 35.9% were diagnosed of flu, and 94.2% were considered pluripathological patients according to OMS definition. More than three quarters of them had three or more chronic diseases, and approximately a third had five or more. No significant differences were found when comparing the number of diseases according to the vaccination status, neither in the presence of flu.

Conclusions: There is a high number of pluripathological patients over 64 years unvaccinated for the flu who needed hospital admission for SARI [with or without flu]. This should be taken into account in clinical practice, especially during epidemic periods of influenza, and reinforce the importance of vaccination in this population.

Performance of a commercially available LAMP assay and RDT for diagnosing *Plasmodium falciparum* malaria at very low parasitemias in a controlled human malaria infection trial

Ruth Payne*1,2, Nick Edwards1, Katherine Ellis1, Yrene Themistocleous1, Sarah Silk1, Jordan Barrett1, Amy Flaxman1, Duncan Bellamy1, Richard Morter1, Thomas Rawlinson1, Simon Draper1, Angela Minassian1

1University of Oxford, The Jenner Institute, Oxford, United Kingdom, 2University of Sheffield, Department of Infection, Immunity and Cardiovascular Disease, Sheffield, United Kingdom

**Background:** Malaria is the most common imported tropical infection in European travellers with short-term exposure, with roughly 1500 infections annually in the UK. Current UK guidelines for diagnosis recommend thick and thin film microscopy and state that a rapid diagnostic test (RDT) alone cannot be used to exclude malaria. The accuracy of microscopy is dependent on operator experience and RDTs have variable performance with reduced sensitivity at low parasitaemias. Nucleic acid amplification techniques, in particular loop-mediated isothermal amplification (LAMP), have been developed to try to improve sensitivity compared with traditional microscopy or RDTs. Performance of RDTs and LAMP assays at low parasitaemias is typically assessed by diluting blood samples with a known parasite density. Controlled human malaria infection (CHMI) provides an opportunity to assess these diagnostics with serial, undiluted clinical samples with very low parasitaemias compared with qPCR.

**Materials/methods:** Eleven participants took part in a *P. falciparum* CHMI trial in which infection was administered intravenously. Participants were monitored twice daily for symptoms, with blood taken to assess parasitaemia by qPCR at each visit. Participants were treated once they had a parasitaemia of >5000 parasites/mL if symptomatic, or >10,000 parasites/mL if asymptomatic. Based on previous data and qPCR results, we assessed blood samples from day 6 post-CHMI (C+6) for malaria positivity using the Carestart™ Malaria (Pan) RDT and from C+4 using the illumigene Malaria® LAMP assay.

**Results:** Daily samples were tested for the eleven participants until the pre-defined qPCR thresholds for treatment were reached. LAMP assay positivity in relation to parasitaemia by qPCR (parasites/mL) in serial samples from malaria-infected individuals is shown in the attached figure.

**Conclusions:** To our knowledge, this is the first time the illumigene Malaria® assay has been assessed using serial samples from infected individuals at very low parasitaemias. Our data show that assay is 100% sensitive at the published detection limit of 2 parasites/µL in this setting, and reliably detected *P. falciparum* at parasitaemias well below this, although LAMP remains less sensitive than qPCR. This supports its use as a method for excluding malaria in returning travellers, although it has limitations for diagnosis.

**Presenter email address:** r.o.payne@sheffield.ac.uk
Phenotypic and molecular investigation of ST11 NDM-1-producing Klebsiella pneumoniae isolates persisting between 2015 and 2018 in a Bulgarian hospital

Tomislav Kostyanev1, Rossitza Vatcheva-Dobrevska1, Basil Britto Xavier1, Violeta Dicheva1, Petja Stefanowa1, Christine Lammens1, Herman Goossens1, Surbhi Malhotra-Kumar1

1University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, Antwerp, Belgium, 2University Hospital ‘Tsaritsa Yoanna’ ISUL, Sofia, Bulgaria

Background: A surveillance was conducted in “Tsaritsa Yoanna” University Hospital, Sofia, Bulgaria, between August 2015 and January 2018 to estimate the burden of carbapenem-resistant (CR) Gram-negative pathogens in the hospital.

Materials/methods: During the surveillance period (Aug2015-Jan2018), samples from high-risk wards (i.e. ICU, surgery and haematology) were plated also on selective media for detection of carbapenems (BD BBL CHROMagarTM CPE). Identification and antimicrobial susceptibility testing (AST) were performed by VITEK and conventional methods. Double disk synergy test IMP/MER-EDTA and CarbaNP test were conducted. AST of isolates resistant to carbapenems was (re-)confirmed with gradient MIC testing method and interpreted according to EUCAST guidelines. All CR isolates were sent for whole-genome sequencing (WGS). Identification was reconfirmed by MALDI-TOF. Genomic DNA was extracted using MasterPureTM DNA Purification Kit and sequenced via 2×250b PE sequencing (Miseq, Illumina). Comparative genome analysis was performed using in-house developed pipeline BacPipe v.1.2.6. wg/cgMLST scheme was generated and compared using chewBBACA and visualized in PHYLOViZ.

Results: A total of 21,151 samples were processed and 533 Klebsiella pneumoniae isolates were identified throughout the surveillance period. We detected 30 CR K. pneumoniae and 1 CR E. coli isolates. All CR K. pneumoniae isolates had MICs of imipenem and meropenem >32 mg/L, except one which showed MICs of 2 and 4, respectively. The MICs for both carbapenems in E. coli was 32. The isolates were also resistant to gentamicin, amikacin, piperacillin/tazobactam and ciprofloxacin. WGS analysis showed that all 31 isolates carried \( \text{bla}_{\text{NDM-1}} \) in combination with other beta-lactamases such as \( \text{bla}_{\text{CMY-4}} \), \( \text{bla}_{\text{CTX-M-3}} \) or \( \text{bla}_{\text{CTX-M-15}} \) and \( \text{bla}_{\text{SHV-11}} \). Majority of the K. pneumoniae isolates were ST11 (n=29, 96.7%). The E. coli isolate was ST101. The wg/cgMLST comparison indicated that a single clone was circulating within the surveillance period and that it evolved slightly (23 allelic loci differences) (Figure).

Conclusions: We could highlight the spread of a persisting NDM-1-producing ST11 K. pneumoniae clone in our hospital. This clone and the ST101 E. coli have already been reported in Bulgaria and their dissemination is causing local outbreaks in several hospitals. This is a worrisome trend which demands robust infection control measures and concerted action at a national level.

The rates of antimicrobial resistance in leprosy are higher among cases diagnosed in France than in those diagnosed in African countries [WHO sentinel surveillance network]

Aurelie Chauffour*1, Emmanuel Lecorche2, Faïza Mougari2,3, Alexandra Aubry4,5, Andriamira Randrianantoandro6, Kodio Mamoudou7, Moussa Gado8, Bertrand Cauchiox1, Roch Christian Johnson9, Vincent P. Jarlier1,5, Emmanuelle Cambau2,3

1Sorbonne Université, INSERM U1135, Centre d’Immunologie et des Maladies Infectieuses, Cimi-PARIS, Paris, France; 2Université de Paris, INSERM, IAME UMR1137, Paris, France, 3AP-HP, Groupe hospitalier Lariboisière - Fernand-Widal, Service de Bactériologie, Paris, France, 4Sorbonne Université, INSERM U1135, Centre d’Immunologie et des Maladies Infectieuses, Cimi-PARIS, Paris, France, 5APHP, Groupe Hospitalier Universitaire Sorbonne Université, Hôpital Pitié-Salpêtrière, Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux, Paris, France, 6Ministère de la Santé Madagascar, Tananarive, Madagascar, 7Centre National d’Appui à la Lutte Contre la Maladie, Bamako, Mali, 8Programme National de Lutte contre la Lèpre, Ministry of Public Health, Niamey, Niger, 9Fondation Raoul Follereau, Paris, France, 10Centre Interfacultaire de Formation et de Recherche en Environnement pour le Développement Durable, University of Abomey-Calavi, 03 BP 1463 Jericho, Cotonou, Benin

Background: Since leprosy is still a prevalent infectious disease with 210 000 new cases in 2018, WHO new strategy recommends monitoring resistance rates in new and retreated cases. As Mycobacterium leprae doesn’t grow in vitro, studying its antimicrobial resistance can be done either phenotypically by using the mouse footpad model, which requires qualified persons and is time consuming, or genotypically by detecting mutations in the genes involved in resistance. Our laboratory is mandated for leprosy as National Reference Center in France and as supranational for African countries.

Materials/methods: M. leprae strains from patients diagnosed in France [Metropolitan and overseas territories] between 2001 and 2019 and in 7 endemic African countries between 2009 and 2019 were screened for resistance genotypes using the GenotypeLepraeDR® kit [Hain Lifescience] and confirmed by PCR sequencing in case of mutations.

Results: We studied 240 cases [from 206 new cases and 34 relapses] diagnosed in France, and 374 [316 new cases, 48 relapses, 10 unknown] diagnosed in African countries. Molecular detection of resistance showed that the resistance rate was 6.9% in cases diagnosed in France whereas it was 3.2% in cases from African countries. In France and African countries, there were 13 and 9 strains resistant to dapsone, 3 and 1 strains resistant to rifampicin, and 2 and 2 strains resistant to fluoroquinolones, respectively. No multiresistance was detected. Mutations conferring resistance were the following [France cohort, African cohort]: P55L [6 and 6], T53R [0 and 2], T53A [1, 1], T53I [4, 0] in folP1 for dapsone, S456L [2, 1] and S456F [1, 0] in rpoB for rifampicin, and A91V [2, 2] in gyrA for fluoroquinolones. The resistance rate was significantly different between primary and secondary resistance [4.8% vs. 23.5%, p<0.001] for cases diagnosed in France. On the contrary, there was no secondary resistance in African countries, but 3.8% primary resistance.

Conclusions: antimicrobial resistance rates for leprosy were significantly higher in cases diagnosed in France than in African countries. This might be explained by a specific WHO programmatic organization in African countries contrary to France and/or by the lower use of antimicrobials in Africa.

**HHV-6A infection and systemic sclerosis: clues of a possible association**

Elisabetta Caselli, Irene Soffritti, Maria D’accolti, Daria Bortolotti, Roberta Rizzo, Dilia Giuggioli, Clodoveo Ferri

1University of Ferrara, Department of Chemical and Pharmaceutical Sciences, Section of Microbiology, Ferrara, Italy, 2University-Hospital Policlinico of Modena, Modena, Italy

**Background:** Systemic sclerosis (SSc) is a very severe autoimmune disease characterized by vasculopathy and fibrosis of the connective tissues, which is often fatal. Its etiology remains unknown, and several infectious agents, including human herpesvirus 6 [HHV-6], have been suggested as possible triggering factors, although direct association between infection and SSc is still missing. Since HHV-6 infection/reactivation has been associated to many autoimmune conditions, including thyroid disease that is often present in SSc, the aim of our study was to investigate such possible association.

**Materials/methods:** Twenty-six SSc patients were analyzed for the presence of HHV-6 in tissues and blood by a specifically designed digital droplet PCR allowing the distinction between 6A and 6B species. Anti-HHV6 humoral and cellular immune responses were also analyzed respectively by ELISA and Fluorospot assays. HLA-G plasma levels, and KIR typing were also analyzed. Furthermore, as endothelial cells (EC) have a main role in the disease pathogenesis and are a target for HHV-6 infection, we analyzed by quantitative real-time PCR microarray the expression of pro-fibrotic factors in HHV-6 infected EC.

**Results:** HHV-6A was detected at the skin level in all available SSc biopsies, whereas no control skin samples harboured the virus. HHV-6B was detected at the blood level in 80.7% of SSc patients (vs 40% of controls). Increased virus loads were associated with disease severity and poor natural killer (NK) response against the virus, particularly in subjects exhibiting a KIR2 phenotype. SSc patients also displayed a higher frequency and titer of antibodies directed against the HHV-6 U94 product. SSc patients also displayed a higher frequency and titer of antibodies directed against the virus, particularly in subjects exhibiting a KIR2 phenotype. HLA-G plasma levels were significantly higher in HHV-6/KIR2 positive SSc patients, and in vitro HHV-6 infection-induced pro-fibrosis factors expression in EC, supporting its role in the development of the fibrosing process

**Conclusions:** Our data suggest an association between virus infection/reactivation and disease, opening the way to future studies to understand the mechanisms by which HHV-6 might contribute to the multifactorial pathogenesis of SSc.

**Presenter email address:** sffrni@unife.it
Abstract 6173

Novel qPCR demonstrates azole-resistant TR34/L98H and TR46/Y121F/T289A Aspergillus fumigatus, in air spore-samplings around Danish agricultural fields

Rasmus Krøger Hare*, Thies Martin Heick†, Lise Jørgensen‡, Maiken C. Arendrup§,||

1Statens Serum Institut, Mycology Unit, Copenhagen, Denmark, 2Aarhus University, Flakkebjerg Agricultural Sciences, Slogelse, Denmark, 3Copenhagen University Hospital, Rigshospitalet, Clinical Microbiology Laboratory, Copenhagen, Denmark, 4Copenhagen University, Department of Clinical Medicine, Copenhagen, Denmark

Background: Azole-resistant (AR) Aspergillus fumigatus is increasing worldwide and arise through medical and environmental azole use. Environmentally driven AR today accounts for the majority of AR cases in Denmark. We developed a novel Taqman qPCR for detection of the two dominating environmental AR mechanisms (TR34/L98H and TR46/Y121F/T289A) and applied the assay on spore-trap samples from air.

Materials/methods: Primers and probes were designed specifically for the promotor of cyp51A in A. fumigatus based on in-silico analysis covering >800 cyp51A Genbank sequences including >200 sequences from 44 Aspergillus non-fumigatus species. Three probes was included specific for A. fumigatus, TR34 and since 2018 also TR46. Sensitivity was evaluated by 10-fold dilution series of normalized DNA concentrations and by CFU experiments with spore suspensions subjected to bead-beating and Nuclisens easyMag (biomérieux, Denmark) DNA extraction. Environmental air-sampling was performed using Burkhard spore collectors, with tape-strips corresponding to 24-hour samplings. Three sampling-periods were included, 2012-2014 (N=512), 2016 (N=645) and 2018 (N=439), collected across Denmark. DNA was extracted from tape as previously described (Duvivier et al. 2013).

Results: Based on DNA quantification and CFU experiments, the limit of detection (LOD) was estimated to 50 fg (<20 copies) and 50-200 CFU/mL, respectively with no differences between the three probes (A. fumigatus, TR34 and TR46). A. fumigatus cyp51A was detected in 47 (9%), 87 (13.5%) and 122 (28%) samples in 2012-2014, 2016 and 2018, respectively. Increased detection rate may be correlated to improved DNA processing and continuous optimisation of the PCR assay. Two samples with TR34 were discovered in 2016, four TR34 in 2018 but none in 2012-2014 (Table).

AR: Azole resistance, NA: Not available, ND: Not done

Conclusions: Environmental AR A. fumigatus was detected in 2016 and 2018 despite low content of A. fumigatus on tape samples. This is probably underrepresented as the AR spores constitute a minority among total A. fumigatus spores and thus potentially often below LOD. Although, this assay (single-copy gene target) displays lower sensitivity than diagnostic Aspergillus PCRs (multi-copy gene target) and lack extensive specificity testing, the assay offers a novel method for direct detection of TR34 and TR46 in clinical samples and for screening of environmentally driven azole resistance in complex specimens.

Abstract 6174

**Change of gut microbiome and resistome of the patients with *Clostridioides difficile* infection and those with chronic obstructive pulmonary diseases compared with healthy population**

Jieun Kim1*, Mi-Ran Seo1, Mi-Hyun Bae1, Bongyoung Kim1, Mina Rho1, Hyunjoo Pai1

1Hanyang University, Seoul, South Korea

**Abstract third-party references:** This research was supported by a fund [2017N-ER5407-00] by Research of Korea Centers for Disease Control and Prevention. This research was supported by the National Research Foundation of Korea [NRF] grant funded by the Korea government [MSIT] [No. 2015R1C1A1A01055646].

**Background:** The aim of this study is to investigate the change of gut microbiome and resistome in the patients with different exposure to antibiotics

**Materials/methods:** As for models of different antibiotic exposure, we selected 3 groups of people; healthy person without exposure to antibiotics within 2 months, chronic obstructive pulmonary disease patients [COPD] as people with frequent but subacute exposure to antibiotics, and Clostridioides difficile infection patients [CDI] who had dysbiosis caused by antibiotics. Whole metagenome sequences and targeted metagenomics approaches were performed.

**Results:** A total 61 healthy, 16 COPD, and 26 CDI patients were enrolled. Median days of antibiotic use within 2 months were 0, 8, and 12.5 days respectively (p < 0.001 by Kruskal Wallis). Median days of antibiotic-free within 2 months were 60, 39, and 0 days respectively (p < 0.001 by Kruskal Wallis). Bifidobacterium was the most prevalent genus in healthy gut microbiome and Ruminococcus in COPD and Enterococcus in CDI with statistical significance (p value by Kruskal Wallis < 0.001, each). Person who were exposed to antibiotics showed a positive correlation with abundance of Enterococcus (rho 0.773, p <0.001) and negative correlation with Faecalibacterium (rho -0.722, p <0.001), Bifidobacterium (rho -0.579, p <0.001), and Ruminococcus (rho -0.555, p <0.001).

Relative abundance of antibiotic resistance genes [ARGs] showed a significant difference between the groups [median 100 GPM in healthy vs 138 GPM in COPD vs 384 GPM in CDI with p < 0.001 by Kruskal Wallis]. Aminoglycoside was the most abundant ARGs [median 16.1 GPM in healthy, 21.7 GPM in COPD, and 70 GPM in CDI with p < 0.001 by Kruskal Wallis] and followed by beta-lactam [median 9.9 GPM in healthy, 20.6 GPM in COPD, and 50.8 GPM in CDI with p < 0.001 by Kruskal Wallis] and polymyxin (figure).

**Conclusions:** The bacterial composition of gut microbiome and resistome differed according to different antibiotic exposure.

Renal manifestations of severe fever with thrombocytopenia syndrome

Seongman Bae1, Joung Ha Park1, Moonsuk Bae1, Jiwon Jung1, Min-Jae Kim1, Yong Pil Chong1, Sang-Oh Lee1, Sang-Ho Choi1, Yang Soo Kim1, Jun Hee Woo1, Sung-Han Kim1

1Asan Medical Center, Seoul, South Korea

Background: Severe fever with thrombocytopenia syndrome (SFTS) is a tick-borne hemorrhagic fever caused by the SFTS virus (SFTSV), a newly discovered phlebovirus of family Phenuiviridae, which was previously classified as family Bunyaviridae. SFTS is characterized by high fever, leukopenia, and thrombocytopenia and often leads to multiorgan dysfunction, including kidneys. However, there are limited data on renal involvement of SFTS. We thus investigated the frequency and characteristics of kidney involvement of SFTS.

Materials/methods: All the PCR-confirmed SFTS patients who were admitted to Asan Medical Center, a tertiary hospital, Seoul, South Korea, between January 2013 and October 2018 were retrospectively enrolled. Patients with a history of previous urologic or chronic kidney disease were excluded. Proteinuria was defined as urinary albumin greater than two plus in dipstick urine test, and hematuria was defined as urinary blood greater than two plus in dipstick test and/or accompanying microscopic hematuria [≥5 red blood cells per high-power field].

Results: Of a total 43 patients with SFTS, 13 (30%) experienced acute kidney injury during the hospitalization. Proteinuria and hematuria were observed at 74% (32/43) and 79% (34/43), respectively. Both proteinuria and hematuria occurred at median 7.5 days (range, 2-13 days) after symptoms onset and lasted for 4 days (range, 1-21 days) and 4 days (range, 1-23 days), respectively. According to the degree of the proteinuria or hematuria, patients who had renal manifestation showed significantly higher frequency of septic shock or ICU admission than who did not (Table 1). Increased creatinine level, proteinuria, and hematuria were observed to be transient and fully recovered during the follow-up.

Conclusions: Reversible renal involvement was commonly observed among the patients with SFTS. The level of proteinuria and hematuria may reflect the severity of the viral illness. Regular monitoring of kidney function test with urinalysis is warranted in the management of SFTS patients.

Table 1. Clinical characteristics of patients with SFTS according to proteinuria or hematuria.

Abstract 6177

Comparison of in vivo pathogenicity of four Candida auris clades in a neutropenic bloodstream infection murine model

Zoltán Tóth*1;2, Lajos Forgács1;2, Andrew Borman3, Adrien Szekely3, Shawn R. Lockhart4, Ronen Ben-Ami5, Gábor Kardos1, Fruzsina Nagy1;2, Bence Balázs1;2, Renátó Kovács1, Laszlo Majoros1

1University of Debrecen, Faculty of Medicine, Department of Medical Microbiology, Debrecen, Hungary, 2University of Debrecen, Doctoral School of Pharmaceutical Sciences, Debrecen, Hungary, 3Public Health England South-West, UK National Mycology Reference Laboratory (MRL), Bristol, United Kingdom, 4Centers for Disease Control and Prevention, Atlanta, United States, 5Tel-Aviv Sourasky Medical Centre, Infectious Disease Unit, Tel-Aviv, Israel

Abstract third-party references: Bence Balázs, Zoltán Tóth, Fruzsina Nagy were supported by New National Excellence Program of the Ministry for Innovation and Technology (ÚNKP-19-3.1.)

Background: Candida auris is an emerging worldwide concern and while many studies focus on virulence and pathomechanisms of this peculiar fungus, data are scarce regarding the behaviour of different C. auris lineages in mammalian hosts.

Materials/methods: Different isolates of the four prevalent C. auris clades (South Asian/Indian n=5, South African n=5, South American/Israeli n=5 and Japanese/Korean n=4) were compared to assess their virulence in a mammalian host using a neutropenic murine bloodstream infection model (10 animals/group). The infecting dose was 10^7 CFU/mice. Primary endpoint was mortality 21 days postinfection. Fungal tissue burden and histopathological examination were also performed two and six days postinfection (five animals at each time point) of relevant organs (kidney, heart, liver, spleen) using a similar infection protocol with two C. auris isolates of each clade chosen based on lethality experiments.

Results: Highest overall mortality at day 21 was observed for the South American/Israeli clade (96%, range 90%-100%), followed by South-Asian/Indian isolates (80%, range 50%-100%), while infection with Japanese/Korean and South-African isolates resulted in significantly lower cumulative lethality (44% and 45%, ranges 30-70% and 0-90%, respectively; Figure 1.). Survival differed significantly among isolates of all clades except the Japanese/Korean clade.

The highest fungal burden at day six was also found with the South American clade in all examined organs, while it was comparable for the other three tested clades. Fungal tissue burden varied with South Asian/Indian and South African clade isolates, but not in case of the South American or Japanese/Korean clades. Histopathological examination revealed a surprisingly high myocardial fungal burden with all lineages, which is less common for other clinically relevant Candida species.

Conclusions: Hereby we present the first comparison on the in vivo virulence of the four worldwide distributed C. auris lineages in a mammalian host. High fungal burden in the myocardium is notable. Isolates of the same clade showed differences in virulence in mice, but a markedly higher virulence of the South American/Israeli clade was clearly demonstrated.

University Hospital Virgen Macarena, Sevilla, Spain, 6Hôpitaux Universitaires de Genève (HUG), Infection Control Program, Genève, Switzerland, 7Hospital Universitario Virgen Macarena, Department of Infectious Diseases, Sevilla, Spain, 8UMC Utrecht, Department of Medical Microbiology, Utrecht, Netherlands

Background: ESBL-producing E. coli (ESBL-Ec) and K. pneumoniae (ESBL-Kp) have been widely isolated from humans, anthropogenic environment (AE), and food. The circulation of these isolates between the different sources is not well-understood and could differ between countries. Here, we compare the population structure of ESBL-Ec and ESBL-Kp in AE and food from five European cities.

Materials/methods: 1329 samples were collected between April 2017 and November 2019 in France, Switzerland, Spain, Germany, and The Netherlands. U-bends of long-term care facilities (LTCF) were sampled twice. LTCF sewers, water inflow of wastewater treatment plants (WWTPs), and river downstream from WWTPs were sampled 8 times over 32 weeks. Food samples were collected in supermarkets and LTCF kitchens. 328 ESBL-producing Enterobacteriaceae were retrieved: 266 ESBL-Ec (168 from AE and 98 from food) and 62 ESBL-Kp (49 from AE and 13 from food), of which genomes were sequenced using Illumina NextSeq. Sequence types (STs) and blaESBL were identified in silico.

Results: The predominant STs and the prevalent ESBL genes depending of their origins are shown in Table 1. ST131 ESBL-Ec was only found in the AE. Half (48.8%) of isolates retrieved in AE harbored blaCTX-M-15 while only 12.2% of food-isolated strains carried this gene. One third (28.6%) of the food-isolated strains harbored blaCTX-M-1 against 12.2% for AE-isolated strains. ST10 clade was in similar proportion in both AE- and food-isolated strains but harbor different blaESBL (blaCTX-M-15 or blaSHV-12, respectively). blaCTX-M-15 was overrepresented in ESBL-Kp (77.4%), with comparable proportions in food- and AE-isolated strains. ST405 and ST307 isolates were specifically retrieved in Spain while ST233 were found only in France.

Table 1

<td>ST155 (9.2%)</td>
<td>blaCTX-M-4 (28.6%)</td>
</tr>
<tr>
<td></td>
<td>ST69 (8.2%)</td>
<td>blaCTX-M-65 (12.2%)</td>
</tr>
</tbody>
</table>

Conclusions: Our results suggest that the population structure of ESBL-Ec retrieved from AE differs from foodborne ESBL-Ec for the European cities studied. In contrast, ESBL-Kp population seems to be structured by geography.

Abstract 6183

Characterisation of *Pseudomonas aeruginosa* isolates co-harbouring IMP-18 and VIM-2 metallo-beta-lactamases from Peru

Katherine Yauri1,2, Saoussen Oueslati2, Laurent Dortet3, Edgar Gonzales4, Thierry Naas2,3

1National University of San Marcos, Center of Technological, Biomedical and Environmental Research - CITBM, Lima, Peru, 2Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 3Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, 4National University of San Marcos, Lima District, Peru

**Background:** Antimicrobial resistance is increasing worldwide, including the Americas. *Pseudomonas aeruginosa* (PA) is a major pathogen responsible of nosocomial infections, especially in immunosuppressed patients. Carbapenem-resistance (CR) due to production of carbapenemases is an increasing problem in PA. VIM and IMP are the most frequent Metallo-β-lactamases (MBL) identified in PA. In Peru, molecular characterizations of CR in PA are very rare. The aim of the study was to characterize PA isolates co-expressing IMP and VIM MBLs.

**Materials/methods:** 81 non-duplicate carbapenem non-susceptible PA were collected from clinical specimen: blood (29), urine (21) and bronchial and tracheal secretions (31) of patients hospitalized at the National Institute of Neoplastic Diseases (INEN) of Peru from January to December 2017. Bacterial identification and antimicrobial susceptibility testing were performed using the Phoenix system (BD Diagnostics, Sparks, MD). Disc diffusion antibiograms were also performed. NG-test Carba 5 was used to detect the 5 main carbapenemases. Carbapenemase genes were sought by PCR and WGS.

**Results:** Out of the 81 PA of this study, 52 (64%) were carbapenemase producers: 34 (42%) were harboring *bla*<sub>IMP</sub> gene, 4 (5%) *bla*<sub>VIM</sub> gene and 14 (17%) *bla*<sub>IMP</sub> and *bla*<sub>VIM</sub> genes together. All PA isolates co-expressing *bla*<sub>IMP</sub> and *bla*<sub>VIM</sub> genes were resistant to all tested antibiotics except aztreonam and colistin. WGS revealed that the IMP-producers corresponded to IMP-74-producing ST357 or IMP-16-producing ST176 PA, while the co-producers corresponded to IMP-18-VIM-2 ST111 PA. The *bla*<sub>IMP-18</sub> and *bla*<sub>VIM-2</sub> genes were present on two different integrons, suggesting the acquisition of *bla*<sub>IMP-18</sub> gene by the VIM-2 producing ST111 PA. Despite repeated attempts, no plasmids could be evidenced in these isolates. NG-test Carba 5 was positive to all strains except PA with IMP-18, nevertheless, those could be detected with the second version of NG-test Carba 5v2.

**Conclusions:** To the best of our knowledge this is the first report of PA co-harboring VIM-2 and IMP-18 MBLs in Peru. Our results show that these isolates were highly resistant to most antimicrobials, except to colistin and aztreonam. Preliminary results revealed that the co-MBL producing isolates belong to single clone, while for the IMP producers, several unrelated clones were detected.

**Presenter email address:** kyauri.c@gmail.com
The Insertion Sequence (IS) disruption of mgrB gene is critical for colistin susceptibility testing efficiency of Sensititre in carbapenem-resistant *Klebsiella pneumoniae*

Berna Ozer*1, Cansel Vatansever1, Beliz Gundogdu2, Ozlem Dogan1, Fusun Can1

1Koc University, Department of Medical Microbiology, School of Medicine, Istanbul, Turkey, 2Koc University, School of Medicine, Istanbul, Turkey

Background: The broth microdilution (BMD) method is currently the recommended technique for antimicrobial susceptibility testing of colistin by both EUCAST and CLSI. In routine microbiology laboratories, BMD method is often not implementable. Sensititre (EURGNCOL, SensititreTM, Thermo Fisher) are considered as an alternative method. The aim of the study was to evaluate the performance of Sensititre for antimicrobial susceptibility testing of colistin in *Klebsiella pneumoniae* and to find molecular mechanisms of discordant results.

Materials/methods: A total of 210 carbapenem resistant *K. pneumoniae* clinical isolates were included in this study. The colistin minimum inhibitory concentration (MIC) were determined by both BMD according to the recommendations of EUCAST and Sensititre EURGNCOL according to the manufacturer’s instructions. In colistin resistant isolates, the *mgrB* gene was amplified by PCR and sequenced by Sanger sequencing to determine truncation, insertions and mutations in the gene. Carbapenamase genes were examined by PCR.

Results: In total of 210 *K. pneumoniae*, OXA-48 was found in 187 (89%), NDM-1 was in 30 (14.28%), KPC-2 was in 9 (4.28), both OXA-48 and NDM-1 was in 24 (11.42) isolates. In BMD method, 144 (68%) isolates were resistant to colistin however 66 (31.3%) were found to be resistant to colistin by Sensititre. All colistin resistant isolates (144) had alterations in *mgrB* gene. The IS disruption in *mgrB* gene was detected in 38 (26.38%), point mutations and intragenic deletions were found in 106 (73.6%) isolates. Sensititre revealed false-resistant results in two isolates (0.95% major errors, ME) and 54 false-susceptible results (25.71% very major errors, VME) were detected. Among the 54 isolates with ME, 52 (96.3%) had no IS in *mgrB* gene.

Conclusions: The mechanism of *mgrB* disruption affects the efficiency of Sensititre in colistin susceptibility testing of carbapenem resistant *K. pneumoniae*.

Abstract 6185

**Impact of the Spanish Neumonía Zero project on ventilator-associated pneumonia rates**

Sulamita Carvalho Brugger*¹², Mar Miralbés¹², Begoña Balsera¹², Silvia Rodríguez¹², Montserrat Vallverdú¹², Jesús Caballero¹²

¹University Hospital Arnau de Vilanova, Lleida, Spain, ²Institut de Recerca Biomèdica de Lleida Fundació Dr. Pifarré, Lleida, Spain

**Background:** Ventilator associated pneumonia (VAP) is the most common healthcare associated infection in intensive care. It is associated with increased morbidity, mortality, length of stay and costs. The Spanish Neumonía Zero project (NZ) is a multifactor intervention proposal based on the application of evidence based interventions in patients receiving mechanical ventilation (MV) to prevent VAP and reduce its incidence in the ICUs. This work aims to describe the impact of VAP rates after the implementation of NZ in a Spanish ICU and the VAP etiology in our unity.

**Materials/methods:** Retrospective descriptive study, based on data from ENVIN-HELICS database, from an 18-bed polyvalent ICU. We analyzed VAP rates in the last 19 years, divided in 2 periods: P1 before NZ implementation, from January 2001 to March 2011; and P2, from April 2011 to October 2019, after NZ implementation. The difference between rates was analyzed with Fisher´ s exact test (signification with p<0,01).

**Results:** In P1 258 VAP were recorded, for 37351 days of stay and 25706 days of VM, while in P2 there were 87 VAP for 47330 days of stay and 25473 days with MV. The rates for P1/P2 were 6,91/1,84 for 1000 days of stay and 10,04/3,41 for 1000 days with MV. This is a reduction of 73.4% and 66% respectively (p<0,01). The distribution by microorganisms was, in both periods: Acinetobacter baumannii 25,2%/8%(p<0,01); Pseudomonas aeruginosa 19,4%/19,3%; methicillin-sensitive Staphylococcus aureus 13,6%/13,8%; methicillin-resistant Staphylococcus aureus 4,3%/2,3%; Escherichia coli 6,6%/2,3%; Klebsiella spp 5,4%/5,7%; Candida spp 1,9%/1,15%; Aspergillus 0,77%/0; Haemophilus influenza 3,1%/0; Enterobacter 5,8%/5,7%; Streptococcus pneumonia 2,7%/1,1%; other gram-negative 7,7%/10,3%; other gram-positive 1,9%/2,3%. On the last 12 months there was a rate of 4,1 VAP/1000 days of MV, against 10,8/1000 on the same period 10 years ago.

**Conclusions:** Starting from a VAP rate superior that the one recommended by the quality standard, after the implementation of NZ project there was a significantly reduction on VAP in our unity, bigger than 65%, reaching values below the Spanish rates. The microbiology was similar in both periods, except for A. baumannii.

The risk of microbial contamination associated with nine different needle-free connectors
Qingfeng Shi*, Yangwen Cui1, Wei Sun2, Yan Shen1, Xiang Chen1, Jiabing Lin1, Bijie Hu1, Xiaodong Gao1

1Zhongshan Hospital, Fudan University, Shanghai, China

Background: Needle-free connectors (NFCs) are widely used in clinical practice, and they can significantly reduce the incidence of catheter-related bloodstream infection (CRBSI) in critically ill patients. However, no study ascertain whether surface undulations of NFCs is a key factor for microbial decontamination, and subsequently allow microorganisms to enter the fluid pathway.

Materials/methods: The cap surface of 9 commercially available NFCs were inoculated with *Staphylococcus aureus* (*S. aureus*) for 15 seconds, cleaned for 30 seconds with a 70% (v/v) isopropyl alcohol wipe, and allowed to dry for 30 seconds. Syringes were used to activate each NFC and to flush with 10 ml aseptic saline, and all saline flushes were collected and pooled in a sterile filter cup to collect any *S. Aureus*. Then, the filter papers were aseptically transferred to blood agar plates with incubation for 48 hours at 37 °C.

Results: The standard NFC with decontamination had associated negative culture, while median log10 CFU counts in the standard NFC without decontamination after inoculation with *S. aureus* were 3.2, 2.8, 3.3, 3.5 on days 1 to 4, respectively. *S. aureus* isolated from 9 commercially available NFCs after decontamination for 15 seconds with 70% (v/v) isopropyl alcohol wipe at day 1 to day 4 is shown in table 1.

Conclusions: This finding suggested that there may be differences in the risk of internal microbial contamination with different surface undulations and even 15 seconds of decontamination may not eradicate microorganisms from these devices.

Abstract 6187

**Susceptibility to bacteriophage K, biofilm formation, presence of ica operon and adhesins among staphylococci**

Maria Plet (=), Foteini Gkartziou, Nikolaos Giormezis, Fevronia Kolonitsiou, Iris Spiliopoulou

1University of Patras, Department of Microbiology, School of Medicine, Patras, Greece, 2University of Patras, National Reference Centre for Staphylococci, School of Medicine, Patras, Greece, 3Institute of Chemical Engineering Sciences, FORTH/ICE-HT, Patras, Greece

**Background:** Staphylococci, mainly *Staphylococcus aureus* and *S. epidermidis*, are frequent etiologic agents of hospital infections. Among the virulent factors implicated, are the adhesion mechanisms used by the bacteria to anchor to the surface of various materials. Of importance is the production of an intercellular polysaccharide adhesin encoded by the ica operon, and biofilm formation. Due to the increasing antimicrobial resistance, there is a resurgence of interest into bacteriophages. In this study, *S. aureus* and *S. epidermidis* were tested in terms of phage and antimicrobial resistance, biofilm formation, ica and adhesins' genes carriage.

**Materials/methods:** In total, 179 staphylococci (106 *S. aureus* and 73 *S. epidermidis*) recovered from patients with staphylococcal infections, were identified at species level by Vitek 2 Advanced Expert System (bioMerieux, France). Biofilm formation was performed by the microtiter dish assay method. Antimicrobial resistance was tested by the disk diffusion and a gradient method, according to EUCAST guidelines. Susceptibility to bacteriophage K (ATCC19685-B1) was tested using two concentrations of phage suspensions (10⁴ and 10⁶ pfu/ml) on agar plates. The presence of ica operon and adhesins' genes [aap, fnbA in *S. aureus* and atlE, fbE in *S. epidermidis*] was investigated by PCRs.

**Results:** Among 179 strains, 64 (35.8%) produced biofilm (35 *S. aureus* and 29 *S. epidermidis*), whereas 70 (39.1%) were methicillin-resistant (10/106 *S. aureus* and 54/73 *S. epidermidis*). Statistically significant difference was observed for ica operon and both adhesins genes carriage in biofilm-positive *S. epidermidis* strains and for aap among *S. aureus*, as compared to biofilm negative ones (p<0.05, Figure 1). Susceptibility to phage K was detected in 83 strains: 64/106 *S. aureus* (60.4%) and 19/73 *S. epidermidis* (22%). Carriage of fnbA in *S. aureus* was positively associated with phage K susceptibility (97% vs 90.5%), whereas, both adhesins in *S. epidermidis* were more often found in phage K-resistant strains.

**Conclusions:** In our hospital, methicillin-resistant staphylococci are a major cause of infections. Phage susceptibility is more frequent in *S. aureus* and biofilm-negative strains. Methicillin resistance is observed more frequently in biofilm-positive strains that carry the ica operon and adhesins genes as compared to biofilm negative ones, enhancing their virulence capacity.

Abstract 6191

**Direct MALDI-TOF MS identification from positive blood cultures: rapid Sepsityper**
Miriam Cordovana*1, Simone Ambretti1

1Policlinico Sant’Orsola-Malpighi, Bologna, Italy

**Background:** The rapid identification of the causative agent of sepsis plays a key role for the adoption of an appropriate antibiotic therapy, and hence is crucial for the patients’ clinical outcome.

In this study, we evaluate the implementation into the routine workflow of the Rapid Sepsityper kit for the rapid bacterial identification by MALDI-TOF MS directly from positive blood culture bottles.

**Materials/methods:** From February 2018 to October 2019, a total of 5,271 routine positive blood cultures samples underwent direct MALDI identification by Rapid Sepsityper (Bruker Daltonik).

The bacterial pellet extracted from 1 ml of positive blood culture by the lysis/centrifugation Sepsityper protocol was spotted directly onto the MALDI target for the species identification.

For 1,648 samples, the same pellet was then used to set up the antibiotic susceptibility testing by Microscan WalkAway (Beckman Coulter) broth microdilution panels.

**Results:** Overall, the Rapid Sepsityper enabled the direct identification of 4,493/5,060 (88.7%) monomicrobial samples. It showed a very good performance for enterobacteria, non-fermenting gram-negative rods, staphylococci and enterococci. The missed identifications were restricted mainly to a few groups of microorganisms (streptococci, corynebacteria, Bacteroides spp. and yeasts).

Among the polymicrobial samples, in 68/211 samples both species were identified, in 76/211 only one species, in 65 samples none of them.

Susceptibility testing was successful for 2489/2648 samples (94%) (for 159 samples the growth in the panel was insufficient).

**Conclusions:** The Rapid Sepsityper proved to be a reliable and robust method for the bacterial identification directly from positive blood cultures, with an excellent efficacy (near to 100%) for the most clinically relevant causative agents of sepsis (enterobacteria, S. aureus, enterococci). It delivered a result in a very short time (around 1 h for a batch of 10-15 samples).

Further, the same bacterial pellet used for the MALDI identification proved to be suitable to set up the antibiotic susceptibility testing, simplifying and speeding up the routine workflow and the time-to-report.

Abstract 6192

**Uncovering cryptic clusters of Group B streptococcal infant disease in the UK and Ireland through genomic analysis**

Simon Collin1, Natalie Groves1, Catherine O'Sullivan2, Elita Jauneikaite3, Robert Cunney4\&5, Mary Meehan5, Andrew Smith4, Diane Sj Lindsay6, Ruth Campbell7, Lorraine Doherty2, Victoria Chalker1, Peter Lamb1, Baharak Afshar1, Sooria Balasegaram1, Juliana Coelho1, Derren Ready1, Colin Brown1, Kirsty Le Doare2, Shiranee Sriskandan3, Paul Heath2, Theresa Lamagni*1

1Public Health England, London, United Kingdom, 2St George's University of London, London, United Kingdom, 3Imperial College, London, United Kingdom, 4Health Service Executive Health Protection Surveillance Centre, Dublin, Ireland, 5Temple Street Children's University Hospital, Dublin, Ireland, 6Scottish Microbiology Reference Laboratory, Glasgow, United Kingdom, 7Public Health Agency Northern Ireland, Belfast, United Kingdom

**Background:** A recent systematic review of hospital outbreaks of invasive group B streptococcal (iGBS; *Streptococcus agalactiae*) disease identified 30 documented outbreaks worldwide since 1966. Whilst this suggests that these are rare events, prolonged serial intervals between cases pointed to likely under-recognition. To assess the frequency of infant iGBS clusters in the UK and Ireland, whole genome sequencing (WGS) data from isolates collected during a period of enhanced surveillance were analysed alongside epidemiological data.

**Materials/methods:** Potentially linked (<10 single nucleotide polymorphisms, SNP) iGBS cases from infants with early (<7 days of life) or late-onset (7 - 90 days) disease were identified from WGS (HiSeq 2500 platform, Illumina) data from clinical sterile site isolates between April 2014 and April 2015. We assessed accompanying time/place data to determine an appropriate SNP threshold for clustered cases. Data for cases in England were augmented through linkage to national hospital admission data to determine admission/discharge timelines and identify hospital transfers of cases.

**Results:** Through analysis of sequences of 753 iGBS isolates, coupled with time/place information, we adopted ≤5 SNP differences as cut-off to define likely clusters. We identified 7 clusters comprising 16 cases over the 13-month period consistent with intra-hospital horizontal transmission. Of these, 15 were late-onset cases (of 192 late-onset cases with sequenced isolates) and one an early-onset index case. Six clusters were pairs and one cluster involved 4 infants. Serial intervals between cases ranged from 0 to 59 days (median 12 days). In one cluster, the iGBS infections were diagnosed by two different hospitals, the second infant being readmitted to a different hospital to their place of birth. Only 3 of the 7 clusters had been previously identified.

**Conclusions:** Our study identified that approximately 1 in 12 late-onset infant GBS cases formed part of a hospital cluster and most clusters were previously unrecognised. Routine submission of iGBS isolates to the national reference laboratory is essential to identify potential clusters, ensuring timely investigation and confirmation through genomic analysis.

Severity of chronic diseases in patients over 64 years old with flu or serious acute respiratory infection, according to flu vaccination status

Latorre Millán Miriam*1, Amparo Larrauri2, Alín Manuel Gherasim3, Clara Mazagatos4, Nieves Martínez Cameo1, Mª Pilar Hernández1, Yolanda Gracia1, Vanessa Guerrero1, Ana Martínez-Sapiña1, Antonio Rezusta1, Ana María Milagro Beamonte1

1Miguel Servet University Hospital, Aragon Health Research Institute (IIS Aragon), Zaragoza, Spain, 2National Epidemiology Center, Carlos III Health Institute, Madrid, Spain

Abstract third-party references: Miguel Servet University Hospital (Microbiology and Parasitology Service), Zaragoza, Spain. Research group on infections difficult to diagnose and treat (Aragon Health Research Institute). National Epidemiology Center (Carlos III Health Institute), Madrid, Spain.

Background: Influenza virus infections should be considered in all older adults with risk factors, as they may be associated with higher mortality. Knowledge of the distribution of chronic diseases present in these patients can help in their management in clinical practice.

Materials/methods: Data of the patients included by the Miguel Servet University Hospital (HUMS) in the European IMOVE+ study, during the 2016/17, 2017/18, and 2018/19 seasons, were analyzed. Patients older than 64 years hospitalized with symptoms of Severe Acute Respiratory Infection (SARI), not institutionalized, provided a sample of pharyngeal smear in which the presence of influenza was detected by PCR-RT. The severity of their chronic diseases was studied as the number of their related previous hospitalizations in the last year, according to the flu vaccination status and diagnosis, using the chi-square test \( \chi^2 \) adjusted by Monte-Carlo methods.

Results: Among the three studied seasons, 1,314 patients with SARI were recruited, of which 424 were unvaccinated, and 35.9% were diagnosed of flu. Approximately, a half of them had some hospitalization related to their chronic diseases in the last year, and more than a quarter had two or more. No significant differences were found when comparing the number of previous hospitalizations according to the vaccination status, regardless of the presence of flu.

Conclusions: There is a high proportion of patients over 64 years unvaccinated for the flu between those who needed a hospitalization for SARI [with or without flu] and had some previous hospitalizations for their chronic diseases in the same year. This reinforce the importance of highlighting vaccination in this population.

Abstract 6194

Rapid phenotypic susceptibility testing of *Neisseria gonorrhoeae* using Graver-Wade medium, broth microdilution, and the flow cytometry-assisted susceptibility test (FAST)

Malgorzata Kopczyk¹, Teagan Paton¹, Kieran Mulroney², Timothy Inglis¹,², Christine Carson*¹,²

¹PathWest Laboratory Medicine WA, Perth, Australia, ²The University of Western Australia, Perth, Australia

**Background:** Gonococci are immensely challenging to existing antimicrobial susceptibility test (AST) regimes. No international reference AST method for *Neisseria gonorrhoeae* exists. Improved methods would better support gonorrhoea treatment recommendations. The fastidious physiology of gonococci complicates AST development. We demonstrate use of Graver-Wade (GW) broth medium in both a broth-microdilution (BMD) assay and a Flow Cytometry-Assisted Susceptibility Test (FAST) application for rapid susceptibility profiling of *N. gonorrhoeae*.

**Materials/methods:** 24 isolates of *N. gonorrhoeae* were tested by BMD and FAST using GW medium in Sensititre™ HPB1 plates. The range of antimicrobial agents on the plate was not ideal for gonococci but included ceftriaxone, penicillin, tetracycline and agents from other drug classes used to treat gonorrhoea. Isolates selected for inclusion had a range of ceftriaxone, penicillin and tetracycline MICs previously determined by agar-dilution (AD) method. Overnight cultures in GW broth were adjusted to approximately $5 \times 10^5$ cfu/ml in GW broth and inoculated into HPB1 plates using a Sensititre™ auto-inoculator. Plates were incubated at 35°C with 5% CO$_2$; 18-24 h for the BMD, 5 hours for FAST. At 5 h, FAST plates were diluted 1:2 with a staining buffer containing 5 µM SYTO® 9, and read using an Attune™ NxT flow cytometer with an autosampler. Flow data were analysed using bespoke software to predict MIC and susceptibility in ≤ 6 hours from antimicrobial plate inoculation.

**Results:** Concordance between AD and BMD results was 90% (penicillin), 96% (tetracycline), and 100% (ceftriaxone). Across 18 antimicrobials tested, essential agreement between FAST and BMD was 91.44%. Categoric agreement for ceftriaxone, penicillin and tetracycline was 100%, 79.17% and 75%, respectively. Using the EUCAST v9.0 breakpoints, 11 errors were present. For penicillin, 5 minor errors overestimated resistance of the discordant isolates, while for tetracycline, 6 minor errors underestimated resistance. The flow cytometry data suggested transition of cells to a quiescent state during measurement on the autosampler stage may be influencing results.

**Conclusions:** Graver-Wade medium should be reconsidered as a fully defined, liquid culture medium suitable for gonococcal ASTs. FAST results using GW broth are encouraging but would likely benefit from better control of the antimicrobial challenge and measurement conditions.

**Presenter email address:** christine.carson@uwa.edu.au
Comparative inflammatory cytokines gene expression in culture of human macrophages infected with Leishmania tropica and Leishmania major parasites

Fatemeh Darzi*, Mahmoud Nateghi Rostami1, Roshanak Davoodian1

1Pasteur Institute of Iran, Department of Parasitology, Tehran, Iran

Background: Human cutaneous leishmaniasis is mainly caused by two species Leishmania tropica and L. major in Old World. The type of skin lesion, its duration, severity and appearance is different between Anthropogetic Cutaneous Leishmaniasis [ACL] due to L. tropica and Zoonotic CL [ZCL] due to L. major. Since Pro- and anti-inflammatory cytokines significantly contribute in severity and outcome of CL lesion, this experiment aimed to compare the gene expression changes of these cytokines in culture of human macrophages infected with L. major and L. tropica parasites.

Materials/methods: Peripheral blood mononuclear cells were isolated from a healthy individual without the history of CL from non-endemic region and macrophages were prepared by culture of adherent monocytes in 6well flat-bottomed plates for 6 days in 37°C incubator with 5% CO2. Macrophages (3x10⁵/well) were stimulated with either live L. major or live L. tropica promastigotes (Parasite:MQ ratio of 10:1) or unstimulated. At three time points T1=4, T2=10 and T3=24 hours after stimulation, RNAs were extracted and gene expression of TNF, IL-1B, IL-6, TGF-B, and IL-10 were measured by relative real-time RT-PCR method using ∆∆Ct calculation.

Results: Significant upregulation of TNF, TGF-B and IL-1B genes was shown in stimulated macrophages. The expression of IL1B in macrophages stimulated with L. major was significantly higher than that of L. tropica. In L. tropica stimulated macrophages the expression of TNF was 93.05 fold higher in T2=10 hr compared to T1=4 hr and significantly decreased after 24 hr. In L. major stimulated macrophages the expression of TGF-B was 213.78 fold higher in T2=10 hr compared to T1=4 and significantly decreased after 24 hr, but in L. tropica stimulated macrophages TGF-B expression was significantly higher in T3=24 hr culture.

Conclusions: This study suggested alterations in pro-inflammatory cytokine IL1B and anti-inflammatory cytokine TGF-B associated with L. major vs. L. tropica infection in vitro. Changes in pro- and anti-inflammatory cytokines seems to play a role in differences occur between severity/appearance of ACL and ZCL lesions.

**Abstract 6205**

**Hypervirulent Klebsiella pneumoniae bloodstream infections in adults: results from a retrospective study in a French intensive care unit**

Cécile Gonnin, Paul Jaubert, Claire Poyart, Julien Charpentier, Hélène Poupet, Alexandra Doloy, Jean-Paul Mira, Asmaa Tazi, Nabil Gastli

1University of Paris, Paris, France, 2Cochin Hospital, Assistance Publique des Hôpitaux de Paris, Bacteriology Laboratory, Paris, France, 3Cochin Hospital, Assistance Publique des Hôpitaux de Paris, Medical Intensive Care Unit, Paris, France

**Background:** Hypervirulent variants of Klebsiella pneumoniae (hvKp) have been initially reported in the Asian Pacific Rim in 1986. Although reports of invasive infections due to hvKp in Western countries is increasing, European data remain limited. The objective of our study was to describe hvKp bacteremia prevalence in intensive care unit (ICU) patients of a French university hospital.

**Materials/methods:** We retrospectively screened all K. pneumoniae bloodstream infections in adult ICU patients between January 2016 and June 2019. Clinical features were collected from hospitalization reports. The hypermucoviscous phenotype was defined by a positive string-test (ST). We performed a multiplex PCR detecting K1/K2 capsular genotypes and genes encoding for the following virulence-related factors: regulator of mucoid phenotype (rmpA), aerobactin receptor-encoding gene (iutA), enterobactin (entB) and yersiniabactin (ybtS), allantoin metabolism (allS), and type-3 fimbriae (mrkD). Isolates positive for the rmpA gene were defined as hypervirulent.

**Results:** A total of 53 non-redundant K. pneumoniae isolates was collected. Prevalence of hvKp was of 13% (7/53), mainly belonging to K1/K2 serotypes (5/7, 71%), all harboring iutA, mrkD and entB virulence genes. Classical K. pneumoniae (cKp), i.e. non hypermucoviscous, strains, were mainly non-K1/K2 (44/46, 96%, p<0.001) and iutA-negative (45/46, 98%, p<0.001). All hvKp strains displayed a wild-type susceptibility profile to antibiotics. Compared to molecular hvKp definition, the ST had a sensitivity and a specificity of 86% and 94%, respectively. Bacteremic patients with hvKp were all males and seem younger than patients with cKp (mean age 53 vs. 64 yrs). None of them was Asian and no recent travel to endemic countries was reported. The portal of entry in hvKp bacteraemia was the respiratory tract in 5/7 cases including community-acquired pneumonia (n=3) and aspiration pneumonia (n=1). Although not statistically significant, mortality was higher in the hvKp group (57% vs. 39%).

**Conclusions:** Our study confirms the burden of hvKp invasive infections in Europe in patients without usual associated risk factors (travels to Asia and Asian ethnicity). The prevalence might be underestimated by the ST performances and a consensus definition of hypervirulence must be established, together with guidelines for the management of patients suffering from hvKp infections.

**Abstract 6210**

**Gut microbiota of healthy volunteers with or without stool carriage of Klebsiella pneumoniae in an area with invasive Klebsiella pneumoniae syndrome**

Yu-Tsung Huang*1, Chun Hsing Liao1

1Far Eastern Memorial Hospital, New Taipei, Taiwan

**Background:** Invasive Klebsiella pneumoniae syndrome (IKS) is an important endemic disease in Taiwan. Intestinal carriage of certain clones causing IKS in asymptomatic adults has been demonstrated. Data comparing healthy adults and children with or without stool KP carriage was rarely reported.

**Materials/methods:** Healthy volunteers without antibiotic exposure within three months were recruited from medical staff and their family in a Taiwanese medical center. Stool samples were sent for gut microbiota analysis. The gut microbiota was analyzed using amplification of the V4 hypervariable regions of the 16sRNA followed by high-throughput sequence. Rectal swab was sent for *K. pneumoniae* culture and identification by MALDI-TOF method.

**Results:** A total of 55 adults (Age: 23.13-72.14, 45.97) and 20 children (Age: 0.09-5.81, 2.29) were enrolled. 29 adults and 6 children had positive rectal swab of *K. pneumoniae*. Children had lower diversity compared with adults with higher relative abundance of *Streptococci* and *Bifidobacterium* spp. The relative abundance of *Klebsiella* spp. were (1.56E-02, 0.00E+00-3.06E-01) among adults and (6.74E-03, 0.00E+00-4.33E-02) among children. Relative abundance of *Klebsiella* was significantly higher in personnel with positive rectal swab (*p*<0.0001, analyzed with linear discriminant analysis effect size). Interestingly, rectal swab positive for *Klebsiella* is strongly negatively correlated with *Enterobacter* spp. (*p*<0.0001). Difference in the relative abundance of the three major intestinal genus including *Bacteroides*, *Prevotella* and *Bifidobacterium* was also noted among *Klebsiella* carrier and non-carrier. However, there is no known demographic factors correlated to positive rectal swab positive for *Klebsiella*.

**Conclusions:** *Klebsiella* species could be found in early days of life. Competition of *Klebsiella* spp. and *Enterobacter* spp. might occur.

Abstract 6212

Outbreaks of multidrug-resistant *Klebsiella pneumoniae* in neonatal intensive care units in Ghana: a case for improved surveillance and infection control

Appiah-Korang Labi Labi*1,2, Karen Leth Nielsen1, Rasmus Marvig2, Stephanie Bjerrum2, Christabel Enweronu-Laryea4, Mercy Newman5, Prosper Ayibor6, Leif Percival Andersen3, Jørgen Kurtzhals1

1Copenhagen University, Copenhagen, Denmark, 2Korle-Bu Teaching Hospital, Accra, Ghana, 3Rigshospitalet, Copenhagen, Denmark, 4Department of Child Health University of Ghana Medical School, Accra, Ghana, 5Department of Medical Microbiology University of Ghana Medical School, Accra, Ghana, 6Department of Child Health 37 Military Hospital, Accra, Ghana

**Background:** Hospital outbreaks are rarely reported from sub-Saharan Africa. Using whole genome sequencing we describe two outbreaks involving carbapenemase- and ESBL-producing *Klebsiella pneumoniae*, respectively, in two neonatal intensive care units (NICUs) in Ghana.

**Materials/methods:** Two outbreaks were detected during a hand hygiene intervention programme at the NICUs of the Korle-Bu Teaching Hospital (KBTH) and 37 Military Hospital (37MH) in Ghana between September 2017 and March 2019. We conducted surveillance of bloodstream infections, screened neonates for carriage of multi-drug resistant Gram-negative bacteria and sampled for bacterial contamination of the environment. We sequenced the genomes of all sampled carbapenemase-producing *K. pneumoniae* from KBTH. Likewise we sequenced 10 ESBL positive *K. pneumoniae* randomly selected from 126 positive blood cultures with growth of this organism at 37MH. Genome sequences were analysed for antibiotic resistance genes, presence of plasmids, multi-locus sequence typing and single nucleotide polymorphisms (SNPs).

**Results:** Twenty-nine carbapenemase-producing *K. pneumoniae* were isolated from KBTH, 18 from external carriage, 8 from bloodstream infections and 3 from the environment. All were multi-drug resistant with reduced susceptibility to carbapenems but susceptible to colistin. Carbapenemase production was mediated by *bla-oxa-1*81. Ninety-seven percent (28/29) of the isolates belonged to ST 17 and *in silico* defined capsular type KL25. The 28 ST 17 isolates differed by 0-32 SNPs in their core genome suggesting they constitute a clonal outbreak. Plasmid incompatibility groups IncX3, F1B[Mar], O1, ColKP3 were present in all the isolates. At 37MH all 10 *K. pneumoniae* isolates were multi-drug resistant but susceptible to amikacin, meropenem and tigecycline. ESBL production was mediated by *bla-CTX-M-15*. Nine of the isolates (90%) belonged to ST 25, and *in silico* defined capsular type KL2. Core genome phylogeny revealed that they belonged to an outbreak with a maximum SNP distance of 7 across the tree. None of these outbreak strains carried plasmids.

**Conclusions:** We documented two outbreaks of MDR *K. pneumoniae* from two NICUs in Ghana over a 19-month period. Improved clinical microbiology services, enhanced surveillance and access to newer molecular diagnostic tools is likely to improve outbreak detection and control in sub-Saharan African hospitals.

Abstract 6217

The microbiome of nasal samples from an all-age, healthy, UK cohort reveals the epidemiology of potentially protective bacterial genera

David Cleary*1,2, Masanori Asai3, Karen Moore4, Stuart Clarke1

1University of Southampton, Faculty of Medicine and Institute for Life Sciences, Southampton, United Kingdom, 2NIHR Southampton Biomedical Research Centre, University Hospital Southampton Foundation NHS Trust, Southampton, United Kingdom, 3Imperial College London, London, United Kingdom, 4University of Exeter, College of Life and Environmental Sciences, Exeter, United Kingdom

Background: Respiratory infections remain significant contributors to global morbidity and mortality yet there is increasing evidence that certain microbiota compositions are beneficial to health. Carriage of Corynebacterium and Dolosigranulum sp. predict the absence of Staphylococcus aureus carriage, and a decrease in carriage of both Streptococcus pneumoniae and Haemophilus influenzae leading to reduced incidence of acute otitis media. These interactions suggest that the modification of the microbiome may be beneficial, however significant fundamental knowledge gaps remain.

Materials/methods: Nasal self-swabs (n=471) were collected from individuals attending general practitioners (GP) practices from the South-East (UK) hub of the Wessex Primary Care Research Network between May to August 2012 and February to April 2013. DNA was extracted from 200µL STGG-stored swab contents and the 16S rRNA gene was amplified using V4 primers 515FB and 806RB. Sequencing was done on a MiSeq (Illumina, UK) with 2 × 300bp paired-end V3 chemistry. Microbiome analysis was done using the R package Phyloseq v1.29.0. Sample metadata included bacterial culture, age, antibiotic usage, recent respiratory infection and vaccination status.

Results: Nasal microbiome profiles were dominated by Proteobacteria, Firmicutes and Actinobacteria. The richness and evenness of the microbiota compositions sampled during winter months was significantly lower than spring (p = 0.022) and summer (p = 0.034). No clustering based on participant age was observed. No age-related differences in the relative abundance Corynebacterium sp. were observed. In contrast, the relative abundance of Alloiococcus sp. (also commonly referred to as Dolosigranulum sp.) was significantly higher in both children less than five years old and adults (18 to 65) compared to children and adolescents between the ages of 5 and 18. The prevalence of both genera was significantly higher in respiratory samples that were culture negative for Staphylococcus aureus. In all cases the culture of a pathobiont (H. influenzae, S. pneumoniae or Moraxella catarrhalis) was associated with a higher prevalence of each of Corynebacterium sp. and Alloiococcus sp.

Conclusions: The prevalence of Corynebacterium and Alloiococcus sp. exhibit different epidemiological prevalence across age-groups. The central posit that the presence of Corynebacterium and Alloiococcus sp. predicts lower prevalence’s of pathobiont colonisation requires further examination.

Multi-centre whole genome sequencing bioinformatic outbreak analysis proficiency test conducted in The Netherlands

Jordy Coolen*1, Casper Jamin2, Paul H.M. Savelkoul2, Heiman Wertheim1, John W. A. Rossen3, Sébastien Matamoros4, Lieke Van Alphen2

1Radboud University Medical Center, Department of Medical Microbiology and Radboudumc Center for Infectious Diseases, Nijmegen, Netherlands, 2Maastricht University Medical Center, Department of Medical Microbiology, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands, 3University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands, 4Amsterdam University Medical Center, Department of Medical Microbiology, Amsterdam, Netherlands

Abstract third-party references: SIG Bioinformatics in Medical Microbiology NL Consortium

Background: The introduction of Whole-genome sequencing (WGS) for outbreak detection, made other methods to analyse outbreaks almost deprecated. Nevertheless, the reproducibility and comparability of WGS based outbreak analysis among different centres using distinct analysis tools, has not been fully explored. Furthermore, centres that are performing these complicated outbreak analyses need external validation of their methods in order to meet health care standards. To accommodate these issues, the SIG Bioinformatics consortium has setup a Multi-centre proficiency test.

Materials/methods: 40 paired-end Illumina Klebsiella pneumoniae and Enterococcus faecium sequence read sets were obtained from the Sequence Read Archive. To the best of our knowledge, no publicly available outbreak analysis was conducted previously on these samples. These samples together with standardized result forms were distributed to 16 centres in the Netherlands via a secure data share. Centres were asked to perform WGS Outbreak analysis and report the detected outbreak clusters as they would report to their own Infection and Prevention Control. Additionally, centres were asked to specify their methodology and outbreak cluster definitions. Results were reported back and uploaded to a secure data share. The reported outbreak clusters were reconstructed per centre and compared to each other by using pairwise distances and multidimensional scaling.

Results: 13 out of 16 (81.25%) centres participated in this proficiency test and reported outbreak clusters for both the K. pneumoniae and the E. faecium dataset. A majority voting strategy was employed to assess performance of each centre. Preliminary analysis reveals only small variations in the reported clusters. Furthermore, some similarity in methodology among centres was observed, 8/13 used Ridom SeqSphere+, 4/10 a fully custom approach and 1/13 BioNumerics.

Conclusions: This proficiency test is the first step to EQA/proficiency testing and validation of WGS based outbreak analysis and gives us clear insights inside the variability in outcome and methodology. Furthermore, the analysis strategy used in this proficiency test can be adopted by WGS outbreak analysis proficiency tests in the future. The study demonstrates that even though a wide variety in methodology is employed for WGS based outbreak surveillance, similar clusters are defined, demonstrating harmonisation of methodology is not essential.

Presenter email address: jordy.coolen@radboudumc.nl
Typing of *Salmonella enterica* by Fourier-transform infrared spectroscopy

Miriam Cordovana, Norman Mauder, Stefano Pongolini, Laura Soliani, Simone Ambretti, Markus Kostrzewa

1 Policlinico Sant’Orsola-Malpighi, Bologna, Italy, 2 Bruker Daltonik GmbH, Bremen, Germany, 3 Istituto Zooprofilattico Sperimentale Della Lombardia e dell’Emilia Romagna - Sezione di Parma, Parma, Italy.

**Background:** *Salmonella enterica* is one of the leading causes of foodborne diseases worldwide and represents a major public health burden. Differentiation of *S. enterica* at intra-species level is crucial, for epidemiological investigations and to control foodborne outbreaks, as well as from the clinical point of view (identification of typhoid/non-typhoid serovars). Several methods are currently used for this purpose (serotyping, phage typing, molecular methods), but they all are laborious and cost-intensive.

In this study, we investigated the discriminatory power of the Fourier Transform Infrared Spectroscopy for *S. enterica* typing, in comparison with classical serotyping methods based on somatic and flagellar antigens.

**Materials/methods:** A total of 148 well characterized clinical, foodborne, veterinary and environmental *S. enterica* isolates, belonging to 19 different serogroups, were analysed by the IR Biotyper system (IRBT - Bruker Daltonik). This dataset includes also 24 *S. Typhi* isolates.

Infrared absorption spectra were acquired in transmission mode from a bacterial suspension in water/ethanol, placed in three technical replicates on a silicon sample plate, and let air dry.

Using the IRBT software, spectra relation within a wavenumber range from 1300 to 800 nm was analysed applying hierarchical cluster analysis (HCA) with Euclidean metric and single linkage.

**Results:** Congruence of IR Biotyper HCA and O-serogroups was evaluated with adjusted Wallace algorithm, indicating that IRBT can predict the O serogroup with 95% accuracy.

The 19 different serogroups were clustered separately at a threshold of 0.20. In addition, at a lower threshold, further intra-serogroup clustering was possible for some serotypes, in particular the separation of *S. Typhi* from the other 0:9 serotypes was observed.

**Conclusions:** IR Biotyper enabled an accurate discrimination of *Salmonella enterica* isolates at serogroup level, and in some cases also at serotype level, the most clinically relevant of which is the reliable discrimination of *S. Typhi* from other 0:9 serovars.

This technique has the capability to be a reliable, fast, high throughput and low-cost alternative typing methodology, suitable for implementation into routine microbiology laboratories for both diagnostics and epidemiological investigations.

The REAnimation Low Immune Status Markers study: phenotypic and functional alterations of adaptive immune response in critically ill patients

Virginie Moucadel, Fabienne Venet, Julien Textoris, Sophie Blein, Mary Luz Rol, Bertrand Canard, Pierre Cortez, Craig Tippé, Maina Lazou, Andrew Griffiths, Estelle Peronnet, Alexandre Pachot, Guillaume Monneret, Thomas Rimmelé

1EA 7426 « Pathophysiology of Injury-Induced Immunosuppression » (Université Claude Bernard Lyon 1 - Hospices Civils de Lyon - bioMérieux), Joint Research Unit HCL-bioMérieux, Immunology Laboratory & Anesthesia and Critical Care Medicine Department, Edouard Herriot Hospital, Lyon, France, 2Bioaster Technology Research Institute, Lyon, France, 3Sanofi Aventis, Chilly-Mazarin, France, 4GlaxoSmithKline, Cambridge, United Kingdom, 5Sanofi Pasteur, Marcy-l’Étoile, France, 6ESPCI Paris, Paris, France

Background: Immune response to sepsis is complex and dynamic. Several alterations of the adaptive immune response have been already described and some even observed in other severe injuries like trauma. However, the comprehensive description of phenotypic and functional immune alterations development overtime in a large cohort of patients has never been done. In addition, it is not known whether these alterations depend on the type of injury (infectious vs sterile) and if they are associated with an increased risk of deleterious outcomes.

Materials/methods: A prospective longitudinal, single-center observational study was set up in Edouard Herriot Hospital (Lyon, France) between December 2015 and March 2018. A total of 354 ICU patients suffering from sepsis, severe trauma or after major surgery, and 175 healthy volunteers were enrolled. Blood specimens were collected once for volunteers and three times for patients during the first week of ICU stay. The adaptive response was measured by concomitantly assessing cellular phenotypes (circulating lymphocyte subpopulations) and functions (proliferation, cytokine production), and mRNA levels (CD3D, CD127, PD-1) with standardized tests.

Results: Injury-induced adaptive immune profile was similar in the 3 groups of patients and characterized by a major decrease in the number of circulating effector cells affecting every lymphocyte sub-populations except for regulatory T cells. Remaining circulating T cells were dysfunctional as illustrated by their decreased effector responses ex vivo. Intensity of these injury-induced alterations was maximal at D1 and decreased overtime. The persistence at the end of the first week after injury of profound lymphocyte alterations measured by the decreased CD3D mRNA level was associated with an increased risk of death and an increased risk of secondary infections independently of exposure to invasive devices.

Conclusions: Our results show that the adaptive immune response induced after injury is not dependent on the type of injury and is characterized by major alterations of T cell number and functions that are present from D1 in patients. When persisting, they are associated with deleterious outcomes in accordance with the development of delayed injury-acquired immunodeficiency. Our data support the rational for an immune intervention to restore functional immune response in these patients.

The Red Flag Sepsis Screening tool and Sepsis Six. defining the New Zealand Red Flag Sepsis population and introducing the change

Katie Walland1*, Paul Huggan1,2, Odette Paul1, Ros Morell1, Anna Gwynne1, Sean Munroe1, Mo Neville1

1Waikato District Health Board, Hamilton, New Zealand, 2University of Auckland, Auckland, New Zealand

**Background:** The Red Flag Sepsis (RFS) Screening Tool and Sepsis Six resuscitation bundle were first introduced in the UK. Although bundle adherence is associated with superior clinical outcomes, concerns have been raised that protocolisation could lead to antibiotic overuse. We collected clinical and microbiologic data whilst implementing the RFS tools at a tertiary academic medical centre in New Zealand.

**Materials/methods:** A whole-of-system multi-disciplinary quality improvement initiative (the "Sepsis Ready Program") was launched in August 2018. Impact on time to delivery of each bundle component was assessed through retrospective chart review targeting randomly selected adult, non-palliative, sepsis patients identified using a published coding algorithm. Clinical, demographic and microbiological information were collected to describe the key features of RFS.

**Results:** Bundle adherence (excluding urine output measurement) was assessed preintervention and at two time periods post-intervention. Adherence increased from 50% at baseline (n=40) to 76% post intervention (n=42) and was maintained at 65% in the final period (n=43). The time to administration of bolus fluid improved from a median of 50mins (IQR 15-85) at base-line to 15mins (IQR 0-25). Median time to first doctor review reduced from 35mins (IQR 4-74mins) to 15mins (IQR 0-35mins).

224 pathway-eligible patients with at least one red flag were reviewed. Māori were over-represented in the 15-64 year age group and under-represented in older age groups. 164 patients [73%] had two or more Red Flags. 53 [24%] died within 30 days and of these, 11 [21%] died within the first 24 hours. At least one set of blood cultures were submitted in 199 cases, of which 91 cases [46%] were demonstrated to have significant bacteraemia. Predominant organisms were *Escherichia coli* (32.6%), β haemolytic streptococci (22%), and *Staphylococcus aureus* [including MRSA] (10%).

**Conclusions:** This study supports the use of the RFS Screening Tool to target urgent intervention to patients with a high probability of bacteraemia and poor outcomes. A multidisciplinary approach to sepsis education and awareness based around the concept of Red Flag Sepsis is associated with improvements in the administration of sepsis care. Frequent sepsis presentations amongst Māori demonstrates health inequity in New Zealand.

Outcomes of candidaemia caused by biofilm-forming isolates in haematological patients
Galina Klyasova*, Anna Malchikova1, Kristina Tandilova1, Sergey Kravchenko1, Parovichnikova Elena1, Valeriy Savchenko1
1National Research Center for Hematology, Moscow, Russian Federation

Background: The goal of this study was to evaluate the etiology, risk factors, outcome of candidemia caused by biofilm-forming Candida (BFC) spp.

Materials/methods: The prospective study was conducted in 2006-2017. Only the first episode of candidemia was included. Mortality was estimated within 30 day of the onset of candidemia.

Results: A total of 75 patients with candidemia were enrolled, of them 34 (45%) were infected by BFC isolates (C.krusei-24%, C.tropicalis-21%, C.parapsilosis-18%, C.albicans-14%, C.lusitaniae-9%, C.guilliermondii-6%, C.pelliculosa-6%, C.kefyr-3%) and 41 (55%) non-BFC isolates (C.albicans-51%, C.parapsilosis-22%, C.guilliermondii-15%, C.tropicalis-5%, C.glabrata-5%, C.krusei-2%). Overall, biofilm production was most frequently observed for C.krusei (24% vs 2%, p=0.01), C.tropicalis (21% vs 5%, p=0.04), more young patients (42 years vs 50 years, p=0.04). Biofilm production by C.albicans was less frequent (14% vs 51%, p=0.001).

The 34 patients with BFC were more likely to have candidemia caused by Candida non-albicans than 41 patients with non-BFC (85% vs 49%, OR 6.09, p=0.001), persistence of Candida spp in blood (44% vs 15%, OR 5.47, p=0.01), septic shock (44% vs 29%, OR 1.91, p=0.03). Other characteristics were comparable. Central venous catheter (CVC) had 97% patients in each group. For treatment of candidemia with BFC and non-BFC were administered echinocandins 47% and 37%, azoles 9% and 19%, amphotericin B 20% and 34%, accordingly. Antifungal therapy was not used in 2 (6%) patients with BFC and in 4 (10%) patients with non-BFC.

The 30 days survival was lower in patients with candidemia caused by BFC than non-BFC (49.5% vs 62.3%, p=0.2) (Fig.a). Survival was comparable in patients treated by echinocandins (74%) (Fig.b) and differed in amphotericin B therapy. All patients with BFC treated with amphotericin B died (Fig.c). Cure rates were higher in patients with BFC treated by echinocandin as 1st line therapy (81% vs 28%, p=0.002) and CVC has been removed (62% vs 0%, p=0.01).

Conclusions: Candidemia caused by BFC is associated with Candida non-albicans, persistence in blood, septic shock and with increased mortality especially in patients treated with amphotericin B. Better outcomes were seen for patients with BFC who received echinocandin therapy and CVC has been removed.

Abstract 6226

Investigation of Candida parapsilosis outbreaks by microsatellite genotyping and emergence of clonal antifungal drug-resistant strains in a multi-centre surveillance in China

Zhang Li1,2, Shu-Ying Yu1, Sharon Chen3, Meng Xiao1, Fanrong Kong2, Yingchun Xu3

1Department of Laboratory Medicine, Peking Union Medical College Hospital, Beijing, China, 2University of Sydney, Westmead Hospital, Sydney, Australia, 3Department of Laboratory Medicine, Peking Union Medical College Hospital, Beijing, China

Background: Candida parapsilosis is an important species causing invasive candidiasis in China. Our study aims to conduct a national multicenter study of the molecular epidemiology and susceptibility profiles of C. parapsilosis.

Materials/methods: Non-duplicate C. parapsilosis isolates were collected from 10 hospitals across China in the CHIF-NET program 2016-17. C. parapsilosis isolates were genotyped using four highly polymorphic microsatellite markers, and susceptibility profiles were determined using Sensititre YeastOne™ Y010.

Results: A total of 319 C. parapsilosis from separate patients with invasive candidiasis were studied; 49.2%, 33.2%, and 10.3% isolates were from patients in surgical departments, intensive care units (ICUs) and neonatal ICUs, respectively. C. parapsilosis showed good susceptibility to nine antifungals. Microsatellite analysis identified 122 microsatellite (MT) types for 319 isolates. There were four major MT types prevalent in three hospitals: MT48, MT95, MT29, and MT42. There were four MT types (84 isolates) involved in outbreak in hospital H01 and one MT type (38 isolates) prevalent in hospital H10, mainly affecting surgical departments and ICUs. MT42 was prevalent in hospital H06 (all 22 patients were from NICU). Of 16 fluconazole-resistant isolates, seven from hospital H02 shared the same genotype MT70, and three from hospital H04 shared genotype MT47. For 37 5-flucytosine non-WT isolates, 29 isolates from hospital H01 hospital were of genotype MT48.

Conclusions: The present study, the first to conduct a nationwide molecular epidemiology study of C. parapsilosis in China, identified several unrecognized outbreak cases including antifungal resistant isolates. The findings provided important data for Candida infection control in China.

Prevalence of virulence factors in colonising and infecting Klebsiella pneumoniae isolates obtained from a German multi-centre surveillance study

Kai Lucassen*1, Kyriaki Xanthopoulou1;2, Julia Wille1;2, A. Sarah Walker1;2, Yvonne Stelzer1;2, Vivien Persy1;2, Harald Seifert1;2, Paul G. Higgins2;3

1University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, 2German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 3University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany

Abstract third-party references: for the DZIF-R-NET Study Group

Background: Virulence enables Klebsiella pneumoniae (Kpn) to overcome physical and chemical barriers, and evade host defenses. Cases of hypervirulent strains causing severe infections have been reported [1]. The objective of this study was to compare the prevalence of virulence factors in third-generation cephalosporin-resistant (3GCR) and carbapenem-resistant (CR) Kpn isolated from rectal swabs of patients obtained on hospital admission and from those with bloodstream infections (BSI) in Germany.

Materials/methods: Isolates were obtained from rectal swabs upon hospital admission (n=71), or from BSI (n=64) between 2016 and 2018 from 6 German university hospitals and selected using chromID ESBL (bioMérieux) and MAST CHROMAgar mSuperCARBA (Mast Diagnostica). Whole-genome sequencing was performed by Illumina MiSeq. Assembled genomes were used for MLST to identify sequence types (ST) associated with high-risk clones (HiR). Genes encoding for virulence factors; type I fimbriae (adherence), type 3 fimbriae (biofilm formation), siderophores (iron acquisition), and colibactin (toxin) were identified using BacWGSTdb [2]. Capsular locus types (KL) were assigned using Kaptive Web [3].

Results: We identified 54 KL-types, which varied between colonizing and invasive isolates. In both cohorts KL107 was the most prevalent and was mainly associated with HiR ST307 and ST17. KL2, which is common in hypervirulent isolates, was often found in isolates belonging to HiR ST14. The same pattern of virulence factors like type I fimbriae and type 3 fimbriae was found in colonizing and BSI isolates. Colibactin encoding genes were only detected in two colonizing isolates. The hypervirulence associated capsular polysaccharide synthesis activator rmpA was found in a single BSI isolate, which further harboured genes coding for the siderophore aerobactin and belonged to HiR ST17.

Conclusions: In this study, we found that KL107 was the most common capsular type and correlated with HiR. However, KL-types were diverse in colonizing and BSI isolates. In terms of virulence factors contributing to adherence, biofilm formation, iron acquisition and toxins, there was no difference between colonising and infecting isolates. In conclusion, our results indicate that hypervirulent genotypes are rare among these German K. pneumoniae clinical isolates.

Abstract 6229

**Antimicrobial susceptibility of medically important Nocardia species in Korea**

Kyu-Hwa Hur*, Kuengyoul Park, Mi-Na Kim, Heungsup Sung

1Department of Laboratory Medicine, University of Ulsan College of Medicine and Asan Medical Center, Seoul, South Korea

**Background:** *Nocardia* species is the most commonly recognized human pathogen of aerobic actinomycetes which are ubiquitous in the environment. There are often geographic differences in epidemiology and antimicrobial susceptibility by *Nocardia* species. This study first investigated species distribution and antimicrobial susceptibilities of medically important *Nocardia* species in Korea.

**Materials/methods:** From 2008 to 2019, clinical isolates of *Nocardia* species were consecutively collected in Asan Medical Center. Species identification was confirmed by 16S rRNA gene PCR sequencing and antimicrobial susceptibility was determined by Sensititre RAPMYCOI Plate (Thermo Scientific, Waltham, MA).

**Results:** A total of 43 isolates were collected, including 16 *N. farcinica* (37.2%), 11 *N. cyriacigeorgica* (25.6%), 3 *N. brasiliensis*, 3 *N. kroppenstedtii*, 3 *N. nova*, 2 *N. abscessus*, and 1 *N. concava*, *N. elegans*, *N. exalbida*, *N. pseudobrasiliensis* and *N. puris* respectively. While only one *N. farcinica* isolates had minimum inhibitory concentration (MIC) to trimethoprim-sulfamethoxazole of 4 μg/mL and five *N. farcinica* and all *N. kroppenstedtii* isolates had MIC of 2 μg/mL, all isolates of other than *N. farcinica* and *N. kroppenstedtii* had MIC of lower than 1 μg/mL. All *Nocardia* species were susceptible to amikacin and linezolid but frequently resistant to clarithromycin, doxycycline and minocycline, whereas *N. nova* and *N. pseudobrasiliensis* isolates were consistently susceptible to clarithromycin. A half of *N. farcinica* and all *N. kroppenstedtii* isolates were susceptible to fluoroquinolone but the other *Nocardia* species were resistant to ciprofloxacin. All *Nocardia* species except *N. abscessus* and *N. puris* showed various susceptibilities to β-lactams.

**Conclusions:** In Korea, *N. cyriacigeorgica* and *N. kroppenstedtii* are more prevalent than western countries. High prevalence of sulfonamide resistance-prone species, *N. farcinica* and *N. kroppenstedtii* raised the issue of species identification and antimicrobial susceptibility testing for all clinically relevant isolates.

**Presenter email address:** sampg@naver.com
Abstract 6230

**Characterisation of the human gut microbiome in a high antibiotic use and resistance setting in Vietnam**

Bich Vu Thi Ngoc*, Hai Ho Bich1, Melissa Oomen3, Tran Huy4, Hindrik Rogier Van Doorn1,5, Heiman Wertheim2,5, John Penders3

1Oxford University Clinical Research Unit and Welcome Trust Major Overseas Programme, Hanoi, Vietnam, 2Radboud University Medical Center, Nijmegen, Netherlands, 3School for Nutrition and Translational Research in Metabolism (NUTRIM) and Care and Public Health Research Institute (Caphri), Department of Medical Microbiology, Maastricht University Medical Center, Maastricht, Netherlands, 4National Institute of Hygiene and Epidemiology, Ha Noi, Vietnam, 5Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom

**Background:** Repeated exposure to antibiotics may drive the microbiome into a steady-state that is different from the original one, particularly in a high antibiotic use and resistance setting like Vietnam. Here, we studied the microbiome and resistome in relation to recent antibiotic use and we compared the results with a low use and resistance Dutch cohort.

**Materials/methods:** We characterised the microbiome from 102 participants using 16S rRNA amplicon sequencing and obtained their antibiotic use history. We used Qiime2 and vegan R package to compare the diversity and differential abundance in a gradient of antibiotic exposure (<1 month, 1-4 months, and >4 months of no exposure) and in the presence of three ESBL genes (CTX-M-1, 2 and 9), assessed metagenomically.

**Results:** Among 102 participants 40 had used antibiotics, mostly cephalosporins (n=39), at least once in the past 4 months and 78% carried ESBL genes. Overall, we found a reduced richness and diversity when compared to a Dutch cohort in a low use and resistance background. Within the group of Vietnamese participants who used antibiotics, we observed a significantly reduced species richness (Chao1, p<0.05), but not diversity (Shannon). The microbiota, as measured using Bray-Curtis dissimilarity, were partially shaped by age group, antibiotic exposure, and the presence of ESBL genes [adonis2, total R² of 11%, p-values < 0.05]. In particular, we found a decrease in the abundance of Lachnospiraceae spp. among antibiotic users (ANCOM, W=168) and a higher abundance of the class of Bacillales and the Enterobacteriaceae family in CTX-M-2 carriers (n=18 vs 84, ANCOM, W=23 and W=395, respectively), but no different abundance across compositions with and without mcr-1 (n=84 vs 18).

**Conclusions:** We characterized the human gut microbiome in a rural community in Vietnam where antibiotic use and resistance are high. A reduced overall diversity and richness was observed compared to a low use and resistance setting, while richness was further reduced among antibiotic users. These perturbations may be caused by the high background use of antibiotics.

Screening research of antibacterial potential of selected released-active forms of antibodies

Nataliia Petrova1,2, Elena Don1,2, Alexandra Emelyanova1,2, Elena Kardash1,2, Sergey Tarasov1,2

1Institute of General Pathology and Pathophysiology, Moscow, Russian Federation, 2OOO “NPF “Materia Medica Holding”, Moscow, Russian Federation

Abstract third-party references: Institute of General Pathology and Pathophysiology, Moscow, Russian Federation, OOO “NPF "MATERIA MEDICA HOLDING", Moscow, Russian Federation

Background: Products based on released-active forms of antibodies (RAF Abs) are a fundamentally new approach to treating a number of diseases. Their safety and efficacy are supported by preclinical and clinical data making them an attractive tool for further application. A growing resistance of bacterial strains is one of the most important medical problems worldwide. Considerable attention in this field is devoted to the products whose mechanism of action is aimed at enhancing host immunity. Thus, the purpose of the study was to conduct screening research and examine antibacterial properties of several RAF Abs targeted at a variety of molecules involved in the host immune response to bacteria.

Materials/methods: Nonlethal infection with Neisseria meningitidis A-208 was chosen as a screening model. Before infection, outbred mice (n=10/group) were randomised for treatment with the test samples (11 groups) or distilled water used as a control. The examined substances targeted at either host immune molecules (RAF Abs to MHC II, AIM2, TRL7, etc.) or pathogen (RAF Abs to beta-lactamase, VacA, etc.) were given 5 days before and 10 days after infection via drinking bowls in a 1:1 ratio. The survival rate was recorded during 10 days after contamination; colony-forming units (CFU) circulating in blood were assessed in acute phase, 24h after bacterial challenge.

Results: Administration of RAF Abs to MHC class II resulted in a statistically significant reduction in bacterial load compared to the control group. Survival rate for this group and a group of the animals treated with water equaled 100%. However, as for the other tested substances, mortality was still observed. Nevertheless, our findings indicate that eight molecules were ineffective, one possessed a moderate activity and the other two were the most effective ones suggesting their protective role in disease progression.

Conclusions: The study results have shown that out of all tested substances RAF Abs to MHC class II was the most efficient and thus seems to be a worthy candidate for further preclinical investigation as antibacterial agents. However, additional experiments are essential to validate this proposal.

Evolutionary insights into carbapenem-resistant and sensitive Acinetobacter baumannii isolates from India

Kanika Bansal*, Prashant Patil1, Tanu Saroha2, Amandeep Kaur1, Sanjeeet Kumar2, Satinder Kaur3, Vikas Gautam4, Prabhu Patil4
1CSIR - Institute of Microbial Technology, Chandigarh, India, 2University of Washington, Seattle, United States, 3Max Planck Institute for the Science of Human History, Jena, Germany, 4Post Graduate Institute of Medical Education & Research, Chandigarh, India

Background: Carbapenem resistance Acinetobacter baumannii is a major nosocomial pathogen which is widely studied at the global level. However, comprehensive whole genome investigation of A. baumannii from India is lacking. Prevalence of carbapenemases, their allelic diversity in context of genome diversity amongst carbapenem resistant/sensitive A. baumannii (CRAB/CSAB) will be of utmost evolutionary importance. Since, India have highest usage of antimicrobials and heavy patient load, allelic variations of these beta-lactamases will be significant. In the present study, we carried out whole genome comparative studies of CRAB/CSAB isolates.

Materials/methods: Thirty A. baumannii isolates (one isolate per patient) were collected from blood, body fluid or CSF during 2013 to 2016 in Indian tertiary care unit. Carbapenem sensitivity for imipenem, meropenem and doripenem was performed by Kirby Bauer Disk diffusion method. Whole genome sequencing was carried out using Illumina MiSeq platform with pair-end sequencing. Reads were error corrected and assembled using SPAdes v3.13.0 and annotated using NCBI-PGAP pipeline. Multilocus sequence typing (MLST) was performed using PubMLST database (https://pubmlst.org/). Resistome of the strains was fetched by ABRicate v0.9.8 (https://github.com/tseemann/abricate).

Results: Out of thirty isolates, twelve were CSAB and remaining eighteen were CRAB. Clonal complexes and sequence types were confirmed with whole genome level recombination analysis. Interestingly, 10/18 CRABs were forming a distinct clonal complex with one of the CSABs as its closest ancestor. At the same time significantly enriched and differential resistome was found for CRAB/CSAB isolates. Among carbapenemases, class C and D were present in all the CRAB/CSAB isolates while, class A and B carbapenemases were present only in CRAB. Three out of four groups of class D, blaOXA-51 family, blaOXA-23 and blaOXA-58 were present in CRAB/CSAB. Genomic investigation of carbapenemase alleles reveals multiple novel allele amongst the set of isolates. Further, resistome of CRABs was enriched for sulfonamide and aminoglycoside resistance. Comparative genomic analysis of these isolates to investigate genomic differences and correlations among CRAB/CSAB is being analysed.

Conclusions: Systematic genome wide association studies are allowing us to uncover critical knowledge related to emergence, evolution and spread of CRAB/CSAB isolates both at regional and global level.

Phenotypic susceptibility testing for vancomycin-resistant enterococci in less than 4 hours using the flow cytometry-assisted susceptibility test

Kieran Mulroney¹, Teagan Paton*², Malgorzata Kopczyk¹, Aron Chakera¹,³, Christine Carson²,⁴, Timothy John Jay Inglis²,⁴

¹The University of Western Australia, Harry Perkins Institute of Medical Research, Crawley, Australia, ²PathWest Laboratory Medicine WA, Nedlands, Australia, ³Sir Charles Gairdner Hospital, Nedlands, Australia, ⁴The University of Western Australia, Marshall Centre for Infectious Diseases Research and Training, Crawley, Australia

Background: Enterococci are commensal flora of the gastro-intestinal tract. The rise of vancomycin resistance has increased the necessity for rapid vancomycin susceptibility testing for nosocomial infections caused by enterococci. The intrinsic ability of enterococci to acquire and/or evolve new forms of vancomycin resistance underscores the need for phenotypic testing. We present the use of the Flow Cytometry-Assisted Susceptibility Test (FAST) to rapidly assess antimicrobial susceptibility in enterococci.

Materials/methods: 21 Enterococcus faecalis and 5 E. faecium were tested by FAST and broth microdilution (BMD) against 18 antimicrobials using Sensititre™ GPN3F plates. Isolates deliberately represented a diverse range of vancomycin MICs, including two PCR-confirmed vanA positive and 3 vanB positive isolates. Three colonies from blood agar purity plates were inoculated into trypticase soya broth overnight. Bacterial suspensions were standardised to 0.5 McFarland using a Sensititre™ nephelometer and inoculated into paired Sensititre™ plates using a Sensititre™ auto-inoculator module. Both plates were incubated at 35°C. One plate was incubated for 18-24 h followed by visual recording of MIC results. The other plate was incubated for 3 hours after which well contents were diluted 1:4 with a staining buffer containing 5 µM SYTO® 9 and read using an Attune™ NxT flow cytometer with an autosampler. Data were analysed using bespoke software to predict MIC and susceptibility in ≤ 4 hours from antimicrobial plate inoculation.

Results: Across all 18 drugs tested, there was 95.34% essential agreement between FAST and BMD. There was 98.40% categoric agreement for the 8 agents with breakpoints. Three minor errors were reported for quinupristin/dalfopristin. For vancomycin, all vanA and vanB isolates were reported as resistant. Remaining isolates were reported as susceptible with one exception: a single isolate of E. faecalis demonstrated a vancomycin MIC > 128 mg/L [both by FAST and BMD across multiple replicates]. Investigative molecular testing found no known vancomycin resistance mechanisms in this isolate.

Conclusions: FAST can provide phenotypic AST results for enterococci in ≤ 4 hours with excellent accuracy. The correct prediction of MIC and susceptibility for the vancomycin-resistant E. faecalis isolate with no known resistance mechanism underscores the need for phenotypic AST to capture all resistant isolates.

**Abstract 6236**

**Characterisation of vaginal microbiota in pregnant women with preterm prelabor rupture of the foetal membranes**

Andrea Vergara*,1, Teresa Cobo*,2, Elisa Rubio García1, Jordi Bosch4, Jordi Vila Estape4, Climent Casals-Pascual1

1Department of Clinical Microbiology, CDB, Hospital Clinic of Barcelona – University of Barcelona, Barcelona, Spain, 2BCNatal - Barcelona Center for Maternal-Fetal and Neonatal Medicine (Hospital Clinic and Hospital Sant Joan de Deu), Fetal i+D Fetal Medicine Research Center, IDIBAPS, University of Barcelona, Barcelona, Spain, 3Department of Clinical Microbiology, CDB, Hospital Clinic of Barcelona, Barcelona, Spain, 4Department of Clinical Microbiology, CDB, Hospital Clinic of Barcelona – University of Barcelona – Institute for Global Health (ISGlobal), Barcelona, Spain

**Background:** Preterm prelabor rupture of the fetal membranes (PPROM) is a leading cause of preterm birth and is associated with high morbi-mortality. Vaginal dysbiosis can cause PPROM by activation of the local immune system. Moreover, one third of PPROM cases are associated with microbial invasion of the amniotic cavity (MIAC) and/or intraamniotic inflammation. The purpose of this study was to characterize and compare the vaginal microbiome in patients with PPROM with and without MIAC.

**Materials/methods:** One hundred pregnant women with PPROM were included and categorized into 2 groups according to amniotic fluid (AF) analysis: patients with MIAC [positive amniotic fluid culture and/or detection of microbial 16S ribosomal RNA] and Non-MIAC group. The AF concentration of IL-6 was assessed by enzyme-linked immunoassay (Biosource; Invitrogen, Carlsbad, CA). Vaginal swabs from these patients were collected. DNA was extracted (PureLink™ Microbiome, Invitrogen) and a 16S rRNA sequencing library was constructed (Nextera XT, Illumina) targeting the V3 and V4 hypervariable regions. Sequencing was performed on a MiSeq platform. Bioinformatics and statistical analyses were performed using QIIME2 and R version 3.4.2 software.

**Results:** A total of 28 women presented MIAC, being *Ureaplasma* spp. the microorganism most frequently isolated (N=15). We did not find significant differences regarding alpha-diversity between groups. The compositional analysis at the genus level, revealed that *Atopobium* spp., *Gardnerella* spp., *Streptococcus* spp., and *Ureaplasma* spp. were overrepresented in the MIAC group, whereas *Lactobacillus* spp. were underrepresented (Fig 1). A low-rank approximation analysis (biplot) revealed that the family Lactobacillaceae was associated with gestational age and was inversely related with microbial diversity (Faith PD), presence of inflammation [IL-6], presence of MIAC, and relative abundance of the family Mycoplasmataceae [which includes *Ureaplasma* spp].

**Conclusions:** Changes in the vaginal microbiota correlate with clinical and biological phenotypes and may provide new insights into the pathophysiology of PPROM. Further studies will be required to establish the potential role of the vaginal microbiome to predict the outcome in patients with PPROM.

---

**Figure 1. Differences in genus relative abundance between MIAC and Non-MIAC group.**

Stable mutants and persisters variants are involved in heteroresistance to colistin in wild-type *Klebsiella pneumoniae* of clinical origin

Irene Sánchez León*, Cristina Elias-Lopez*, Luis Martínez-Martínez

1University of Cordoba / IMIBIC, Córdoba, Spain, 2IMIBIC, Córdoba, Spain, 3Service of Microbiology, H.U. Reina Sofía, University of Cordoba / IMIBIC, Córdoba, Spain

**Background:** Heteroresistance (HR) can be defined as the presence of bacterial subpopulations with various susceptibilities to an antibiotic within an isolate. This can be related to the emergence of persisters (organisms can survive the lethal action of antibiotics without a minimum inhibitory concentration [MIC] change) or the selection of stable mutants (stable increment of MIC). The objective of this study is to evaluate if clinical isolates of *K. pneumoniae* with a wild-type (Wt) phenotype (resistant only to aminopenicillins; susceptible to colistin), express HR to colistin.

**Materials/methods:** Ten Wt clinical strains isolated from different patients were evaluated. MICs of colistin were determined by standardized broth microdilution (BMD; CLSI-EUCAST). The activity of colistin was also tested with gradient strips, using different inocula \(10^8\) and \(10^{10}\) UFC/mL, incubating plates at 35 °C for 7 days to evaluate the emergence of colonies within the inhibition zone. The minimum bactericidal concentration (MBC) was determined by subculturing supra-MIC wells in BMD on colistin-free agar plates. Colistin HR was determined by population-analysis-profiling (PAP), performing bacterial counts on media with increasing concentrations of colistin (up to 64 mg/L). Up to 8 colonies were selected from PAP plates; bacteria were subcultured twice in antibiotic-free medium and BMD were again subsequently performed.

**Results:** All isolates were susceptible (BMD) to colistin (MICs: 0.125 and 0.25 mg/L). MBC values were one dilution step higher than the MIC. MICs of colistin with gradient strips ranged 0.094 to 0.125 mg/L \(10^8\) and 0.094 to 0.25 mg/L \(10^{10}\). No colonies observed in the inhibition zones in any isolate. PAP indicated that all strains contained colistin-heteroresistant subpopulations with colonies growing up to 32 (1 isolate) or 64 mg/L (9 isolates). In all isolates, the organisms growing in supra-MICs were stable mutants (MIC: 16-128 mg/L). Additionally, in 6 of the 10 isolates some colonies from plates containing only 1-2 mg/L of colistin were persisters.

**Conclusions:** Wt *K. pneumoniae* contain colistin heteroresistant subpopulations. HR is more frequently related to the selection of stable mutants, but it is also related to the emergence of persisters at low supra-MIC of colistin.

**Presenter email address:** ire2595@hotmail.com
Evidence of high prevalence, transmission rate and persistence of *Escherichia coli* ST131-Rx among residents of nursing homes in south Spain (JPI-ST131TS project)

Elena Salamanca*1, Lorena Lopez-Cerero2, Mercedes Delgado-Valverde2, Jesús Rodríguez-Baño2, Alvaro Pascual Hernandez2

1Infectious Diseases, Microbiology and Preventive Medicine. University Hospital Virgen Macarena., Sevilla, Spain, 2Infectious Diseases, Microbiology and Preventive Medicine. Hospital Universitario Virgen Macarena, Sevilla, Spain

Abstract third-party references: Award no. “AC16/00072 funded by Instituto de Salud Carlos III, integrated in the national I+D+i 2013-2016 through AES 2016 and within the JPI-EC-AMR framework

**Background:** A sublineage of the *E. coli* ST131 clone, which carries mutations in *gyrA* and *parC* (subclone H30-R), has been found as a dominant ExPEC strain. Our aim was to study the prevalence of this lineage and transmission dynamics among nursing home (NH) residents.

**Materials/methods:** Rectal swabs were collected from 2 NH, A and B (55 individuals in NH-A and 31 in NH-B) in Sevilla during 10-month-period (two 3-month cohorts with a 4-month separation-period). Eight samples (S1-S8) per individual were taken (baseline and 1, 4 and 12 weeks later in each cohort). Sampling of sinks and bathroom surfaces were also carried out. Bath sharing among residents was 100% and 45% (14/31) in NH-A and NH-B, respectively. Samples were inoculated on UTI-agar (Oxoid®) with 2 mg/L ciprofloxacin after a a enrichment step. Up to three morphologically different colonies of *E. coli* were selected per plate for ST131 screening by PCR. Isolates with <2 bands of difference with *XbaI*-PFGE were considered the same pulsotype.

**Results:** Fifty (58%) individuals were found to be colonized by ST131 FQR at any time: 28 (33%) at S1, 28 (33%) at S2, 24 (28%) at S3, 28 (33%) at S4, 21 (24%) at S5, 21 (24%) at S6, 13 (15%) at S7 and 9 (10%) at S8. Twenty-two negative individuals (26%) became colonized and 12 (24%) positive individuals acquired a new pulsotype at any time of study. Among the positives individuals, 4 (5%) were colonized by the same pulsotype during the 10-month study period, and 13 (23%) during the first 3-month cohort. Eight clusters in NH-A (79% of positive cases) and 7 in NH-B (88% of positive cases) were identified. At least two of the individuals from each cluster share the same bathroom in 6/8 clusters in NH-A and 1/7 clusters in NH-B. Twenty-two (15%) environmental samples (6 NH-A and 16 NH-B) were positive, and 15 (68%) isolates were identical to those of residents.

**Conclusions:** 1) Half of nursing homes residents in our area were found colonised by ST131 FQR *E. coli*. 2) A third remained colonized during the first 3-month period. 3) Bathroom-sharing seems to be a risk factor for cross-transmission among residents.

Abstract 6241

Application of logistic regression model in the identification of potential HIV-1 drug resistance-associated mutations

Ting-En Wang*1, Jia-Ming Chang2, Pi-Han Lin3, Chien-Ching Hung1, Sui-Yuan Chang4

1National Taiwan University Hospital, Taipei, Taiwan, 2National Chengchi University, Taipei, Taiwan, 3National Taiwan University, Taipei, Taiwan, 4National Taiwan University, Taipei, Taiwan

Background: Many software has been applied to predict HIV-1 drug resistance by detection of major drug-resistance associated genetic mutations, defined by in vivo clinical observation and in vitro cell culture-based experiments. In this study, the logistic regression model was designed to detect the presence of amino acid mutations which might not be recognized as major mutations, but its presence is significantly associated with drug resistance.

Materials/methods: A total of 6214 RT sequences (aa 1-250), 6200 protease sequences (aa 1-99), and 2563 integrase sequences (aa 1-288) from HIV-1 infected patients recruited at National Taiwan University Hospital between 2008 and 2019 were analyzed. Each sequence was encoded to a binary vector of corresponding features (independent variables in regression) where the corresponding a.a. is mutated or not compared with the HXB2 reference. The resistance level of the sequence (dependent variable) was labeled as 0, susceptible or potential low-level, and 1, low to high-level, based on the Stanford drug-resistance database regarding to protease inhibitors (PI), nucleoside RT Inhibitors (NRTI), or non-nucleoside RT inhibitors (nNRTI) and integrase inhibitors (INSTI). The logistic regression model is implemented by Python 3.6 scikit-learn package.

Results: After each logistic regression model fitting by thousands of samples in this study, we narrowed down the resistance-associated amino acid residues about ten. The amino acid residues and their related p values. For NRTI, all of the eight amino acid mutations were defined as the major mutations by the Stanford database, while for nNRTI and INSTI, only five and six of eight and eleven were the previously defined major mutations. For PI, only one of eight was not in previously defined major mutations. Nevertheless, the regression models generated great accuracy ranging from 0.64 to 0.94, in prediction of drug resistance as compared with the Stanford database.

Conclusions: The regression methods gave great prediction of drug resistance. It can identify the major mutations and also implicate the potential association of novel non-polymorphic mutations which have not been addressed before. The interaction between the major mutations and these non-polymorphic mutations will be investigated by further modeling analysis and in vitro characterization.

Abstract 6243

The frequency and clinical implications of Epstein-Barr virus DNA in the cerebrospinal fluid of immunocompetent and immunodeficient patients diagnosed with meningoencephalitis

Neven Papic1,2, Josip Begovac1,2, Adriana Vince1,2, Snjezana Zidovec Lepej1

1University Hospital for Infectious Diseases Zagreb, Zagreb, Croatia, 2School of Medicine, University of Zagreb, Zagreb, Croatia

Background: The role of Epstein-Barr (EBV) virus in central nervous system (CNS) infections and the clinical significance of EBV-DNA in the cerebrospinal fluid (CSF) are not fully understood. The aim of this study was to investigate clinical implications of positive CSF EBV-DNA PCR results in the context of the patients’ final diagnosis.

Materials/methods: From January 2008 to October 2019, a total of 54 CSF samples from 37 patients were positive for EBV DNA (of 646 samples tested). Clinical and laboratory data extracted from patient’s medical records were available for 31 patients that were included in our cohort. Data are presented as frequencies (%) and medians with interquartile ranges (IQR).

Results: Of the 31 patients included, 12 had advanced HIV infection (11 males, age 43.5, IQR 35-48.7 years) with low CD4+ counts (23, IQR 27-49) and HIV viral load of 372,500 (IQR 125,794-829,250 copies/mL). Clinical diagnoses in HIV-infected patients included: biopsy-proven primary CNS lymphoma (PCNSL, n=4; EBV DNA of 99,325 copies/mL, IQR 7,112-201,125), toxoplasmosis (n=3, including 1 suspected PCNSL; EBV DNA 226,500 copies/mL, IQR 174,750-226,500), cryptococcal meningitis (n=1), tuberculous meningitis (n=2) and 2 patients with HIV-encephalopathy (including 1 patient with CMV coinfection).

HIV-negative patient group included 4 children (2 with acute EBV infection and ME, 1 with entroviral ME and 1 with chronic EBV infection) and 15 adults (11 males; age 51, IQR 37-67). Of two solid-organ transplant recipients, one had invasive CNS aspergillosis (EBV DNA 5,700 copies/mL) and other EBV reactivation (EBV DNA 402,000 copies/mL). Among the remaining 13 immunocompetent adults, viral etiology was diagnosed in 5 (HSV-1=2, VZV=2, enterovirus=1), postinfectious ME in 3, neurotuberculosis in 1, PCNSL in 1 (EBV DNA 186,500 copies/mL). In 3 patients etiology remained unknown. Patients with viral ME had lower CSF EBV DNA (7,550 copies/mL, IQR 6550-8900) than patients with postinfectious ME (15,050 copies/mL, IQR 10675-21025) or unknown etiology (19,025 copies/mL, IQR 12712-254750).

Conclusions: While detection of EBV is associated with PCNLS and toxoplasmosis in HIV+ patients, in immunocompetent adults it is frequently associated with other infectious agents or postinfectious syndrome.

A systems thinking methodology for evaluating interventions to optimise antibiotic use along the surgical pathway and minimise AMR

Fabia Edathadathil*, Mohamed Lebcir

1Amrita Institute of Medical Sciences, Kochi, India, 2University of Hertfordshire, Hertfordshire, United Kingdom

Background: The integration of Antimicrobial stewardship (AMS) across the surgical pathway can optimize antimicrobial use for managing infectious complications like Surgical Site Infections (SSI) and thereby reduce Antimicrobial Resistance (AMR). Systems thinking (ST) is a holistic novel approach that accounts for health system behavior and utilizes quantitative as well as qualitative data to model the integration of AMS and interventions to reduce AMR. ST methodology utilizes system dynamic (SD) tool, a resource efficient method that can evaluate prospective interventions and assess the impact on incidence of performance indicators.

Materials/methods: Clinical and operational information on managing post-surgical infectious complications were collected. The ’cause-effect links’ generated using ST methodology that incorporate prospective interventions and elements of AMS influencing performance indicators would be converted into a quantitative SD model. Cultural and contextual factors would be integrated into the model as part of wider research inputs from ethnographic observations on antimicrobial prescriptions along surgical pathway and macrolevel policy analysis. The simulation of the model at the base line level and post inclusion of specific interventions would enable comparison of the effect on SSI and other performance indicators.

Results: The patient flow along surgical pathway was initially developed by mapping the requisite procedures, medical investigations, administrative requirements and relevant stake holders across the pre-surgical, surgical and post-surgical phases. Interventions selected for simulation are ensuring hand hygiene compliance to reduce SSI and recording right indication for antimicrobial prescription and feedback of audit data as part of AMS. Performance indicators identified to assess the impact of interventions span clinical, operational and economic domains for evaluating both implementation effectiveness and clinical effectiveness.

Conclusions: ST modeling would aid decision makers in optimizing and selecting the best interventions that could prove as effective solutions. ST is a potentially novel application in the field of evaluating interventions across surgical pathway for optimizing antimicrobial use and emerges promising in supporting clinical systems as ST is an evidence based decision making methodology.

Molecular epidemiology of leptospirosis in Tahiti, French Polynesia, during the 13-year-time spanning from 2007 to 2019

Hilde Angermeier*,1,2,3, Linda Grillová1, Stephane Lastere4, Marc Levy4, Mathieu Picardeau2,3
1European Programme for Public Health Microbiology (EUPHEM), European Centre for Disease Prevention and Control (ECDC), Solna, Sweden, 2National Reference Laboratory for Leptospirosis, Institut Pasteur, Paris, France, 3Biology of Spirochetes Unit, Institut Pasteur, Paris, France, 4Centre hospitalier de Polynésie française, Papeete, French Polynesia

Background: Leptospirosis, caused by spirochetes of the genus Leptospira, is the zoonosis with the widest global distribution causing more than one million severe cases resulting in 60,000 deaths every year. Rodents have been considered to be the main animal reservoir, however, leptospirosis is ubiquitously present within the animal kingdom. This study describes the molecular epidemiology of leptospirosis in Tahiti, French Polynesia - a hotspot for this disease - in the 13 years-time span from 2007 to 2019.

Materials/methods: We collected in total 418 serum samples from patients diagnosed with leptospirosis at the Centre hospitalier in French Polynesia. Using a combination of traditional and nested PCR followed by Sanger sequencing, we determined the sequences for secY locus in 249 serum samples (60%). In addition, 16 Leptospira strains isolated from patient blood were fully characterized at species and serogroup levels and used as references for the association of different phylogenetic branches with respective serogroups. The secY sequences were compared with sequences from wild rats, farm pigs and domestic dogs from a previous study in French Polynesia (Guernier et al. 2017).

Results: The phylogenetic analyses divided our sample set into 18 genotypes clustering into 4 lineages. Lineage 2 (L. weilii associated with serogroup Mini) was found exclusively in human patients. Its source remained unknown. Lineage 3 (L. interrogans associated with serogroup Canicola) was correlated with its co-isolation from human patients and farm pigs (Sus scrofa, p-value=0), while lineage 1 (L. borgpetersenii associated with serogroup Ballum) was correlated with its co-isolation from rats (Rattus exulans and Rattus norvegicus, p-value=0). The most prevalent lineage 4 (L. interrogans) consisted of two central genotypes, 9 (associated with serogroup Icterohaemorrhagiae) and 10 (associated with serogroup Australis). Remarkably, genotype 9 predominated each year (2007-2019). The ability to survive in a wide host range (dogs, rats and pigs) might have facilitated its high prevalence and predominance over the 13 years period.

Conclusions: With this study we shed light on the population dynamics of leptospires circulating among patients in Tahiti during 2007 to 2019 and on the role potential animal reservoirs (pigs, rats and dogs) play in leptospirosis transmission to humans.

**Bismethylgliotoxin is detected in serum from oncohaematological neutropaenic paediatric patients: presentation of two cases of probable IPA with negative galactomannan and positive bmGT**

M. Pilar Domingo¹, Patricia Esteban², Sergio Redrado³, Concepcion Lopez³, Lourdes Roc Alfaro³, Yurena Aguilar³, Olga Algara³, Ana Milagro¹, Carlota Calvo³, Julián Pardo Jimeno²,³, Antonio Rezusta⁴,⁵, Eva María Gálvez¹

¹Instituto de Carboquímica (ICB-CSIC), Zaragoza, Spain, ²Fundación Instituto de Investigación Sanitaria Aragón (IIS Aragón), Biomedical Research Centre of Aragón (CIBA), Zaragoza, Spain, ³Hospital Universitario Miguel Servet, Zaragoza, Spain, ⁴University of Zaragoza, Department Biochemistry and Molecular and Cell Biology and Dept. Microbiology, Preventive Medicine and Public Health, Zaragoza, Spain, ⁵Fundación Agencia Aragonesa para la Investigación y el Desarrollo (ARAID), Zaragoza, Spain, ⁶University of Zaragoza, Dept. Microbiology, Preventive Medicine and Public Health, Zaragoza, Spain, ⁷Hospital Universitario Miguel Servet, Zaragoza, Spain

**Background:** Invasive pulmonary aspergillosis (IPA) is a leading cause of morbidity and mortality in immunocompromised oncohaematology pediatric patients. This is mainly due to the absence of optimal diagnostic modalities, which hamper early specific disease detection and treatment. Thus, diagnosis of IA is still challenging and constitutes a major problem during management of pediatric patients at risk of infection, where the number of studies validating different diagnosis biomarkers is more limited. In a previous study, we demonstrated the high diagnostic accuracy of bis(methyl)gliotoxin (bmGT) compared to GM for IPA diagnosis in adults. The objective of this study is to show bmGT suitability for IPA diagnosis in oncopediatric patients in comparison with GM, monitoring the course of bmGT concentration in serum during voriconazole treatment.

**Materials/methods:** The presence and concentration of bmGT and voriconazole in sequential serum series from 9 oncopediatric patients with febrile neutropenia (retrospective and prospective samples) were simultaneously quantified by High Performance Thin Layer Chromatography (HPTLC) and confirmed using LC/MS/MS by an independent lab.

**Results:** HPTLC allowed simultaneous sensitive detection of bmGT and voriconazole in serum and BAL of pediatric patients confirmed by LC/MS/MS. We present two patients [17 and 36 months]. In the phase of prolonged neutropenia, fever, hypoxemia and pulmonary infiltration compatible with Aspergillosis in high resolution CT are started. In one patient, bmGT was detected earlier than GM, allowing early initiation of treatment, with the voriconazole treatment the GM was negativized and the bmGT levels decreased. In the second patient, GM was negative and bmGT positive in serum and BAL, so treatment with voriconazole was started, then a decrease in bmGT values was detected coinciding with the patient clinical improvement.

**Conclusions:** The determination of bmGT in pediatric patients allowed the early diagnosis and effective treatment of two cases of IA, being a promising tool in neutropenic pediatric patients at risk of IPA. Identification of bmGT by HPTLC has been confirmed by LC/MS/MS indicating the presence of this biomarker during IPA in pediatric population. Analyses to establish the performance of serum bmGT detection together with beta-d-Glucan, PCR and IL8 to diagnose IPA in pediatric oncohaematological patients are ongoing.

Abstract 6254

**Early empirical anidulafungin therapy reduces the prevalence of invasive candidiasis in critically ill sepsis patients: a retrospective study**

Md Jahidul Hasan*, Sharmind Neelotpol, Raihan Rabbani

1Square Hospitals Limited, Dhaka, Bangladesh, 2BRAC University, Dhaka, Bangladesh

**Abstract third-party references:** Square Hospitals ltd.

**Background:** Invasive candidiasis (IC) in critically ill patients is a serious infection with high rate of mortality. Like empirical antibiotics, the use of antifungals empirically is not common in intensive care units (ICUs). The practice of anidulafungin empirically in critically ill patients is very limited worldwide. The objective of this study was to evaluate the clinical outcomes of empirical anidulafungin therapy in critically ill ICU patients with sepsis and/or septic shock.

**Materials/methods:** This retrospective case-control study was conducted on 149 (N) sepsis/septic shock ICU patients. The patients of 'empirical anidulafungin therapy (EAT)' group [case] (n = 77) found empirical anidulafungin in early hospitalization hours with standard dose. On the other hand, 'no empirical anidulafungin therapy (NEAT)' group's [control] patients (n = 72) received no empirical antifungal therapy including anidulafungin. The clinical outcome of empirical anidulafungin therapy was evaluated in terms of prevalence rate of IC, mortality rate and ICU leaving rate.

**Results:** Patients in EAT group received empirical anidulafungin and showed less incidences of IC (5.19%, n = 77) than that of NEAT group’s patients (29.17%, n = 72) with the relative risk of 0.175 (95% CI, 0.064-0.493, p value <0.05) and the risk difference (RD) rate was 24% (95% CI, 12.36%-35.58%) among the groups. The 30-day mortality rate in NEAT group was higher (19.44%, n = 72) than that of EAT group (10.39%, n = 77) (p value = 0.04). Within the first 10-ICU-days, patients in EAT group left ICU in higher rate (62.34%, n = 77) than that of NEAT group (54.17%, n = 72).

**Conclusions:** IC in critically ill patients is a life-threatening event. Sepsis patients with early empirical anidulafungin therapy showed better clinical outcome, lower mortality rate and higher ICU leaving rate within the first 10-ICU-days than the sepsis patients received no anidulafungin therapy empirically.

Prevalence and antibiotic resistance of ESKAPE pathogens isolated in the emergency department of a tertiary care teaching hospital in Hungary: a 5-year retrospective survey

Ria Benko1, Máró Gajdács*2,3, Mária Matuz1, Gyöngyvér Sós1, Lazar Andrea4, Edit Hajdú5, Péter Hannauer6, Zoltan Peto6

1University of Szeged Faculty of Pharmacy, Department of Clinical Pharmacy, Szeged, Hungary, 2University of Szeged Faculty of Pharmacy, Department of Pharmacodynamics and Biopharmacy, Szeged, Hungary, 3Hungarian Society of Clinical Microbiology and Infectious Diseases, Budapest, Hungary, 4University of Szeged Faculty of Medicine, Institute of Clinical Microbiology, Szeged, Hungary, 5University of Szeged Faculty of Medicine, 1st Department of Internal Medicine, Infectious Disease Ward, Szeged, Hungary, 6University of Szeged Faculty of Medicine, Department of Emergency Medicine, Szeged, Hungary

Abstract

Background: Emergency departments (EDs) have a central role in the triage and early management of patients with potentially severe bacterial infections. ESKAPE pathogens are one of the key contributors to multidrug resistance and excess mortality worldwide. The purpose of this study was to characterize the epidemiology and susceptibility patterns of ESKAPE bacteria isolated in an ED of a tertiary-care teaching hospital in Hungary over a 5-year period.

Materials/methods: Data collection was carried out retrospectively by reviewing the microbiology record database of the Department of Clinical Microbiology (University of Szeged), corresponding to ESKAPE isolates. Only the first isolate per ED patient was analysed during the designated study period (2014.07.01-2019.07.01.). Bacterial identification was performed using MALDI-TOF MS (Bruker Daltonics). Antibiotic susceptibility-testing, phenotypic detection of resistance mechanisms and interpretation of drug resistance (MDR/XDR) categories were based on ESCMID/EUCAST standards. The classification of Gram-negative isolates into usual drug resistance (UDR) and difficult-to-treat resistance (DTR) categories were based on the criteria defined by Kadri et al.

Results: During the study period, the number of ED admissions was 39,146±477/year. Out of the 7681 individual isolates, 67.2% (n=5161) were ESKAPE bacteria. Most of the isolates originated from urine specimens [catheter-specimen: 30.6%, midstream: 15.0%], blood cultures (29.0%), wound samples (13.1%) and abscesses (4.2%). The distribution of ESKAPE bacteria and their classification into resistance categories is presented in Table 1.

Conclusions: EDs are essential components of the healthcare system, presenting as gateways for many patients to inpatient units; however, due to the significant flux of patients, they may also have pronounced roles in the emergence and spread of resistant bacterial strains. The number of MDR and XDR Gram-negative isolates (both Enterobacterales and non-fermenters) presents a worrisome therapeutic challenge to clinicians.

Abstract 6260

An epidemiological description of Panton-Valentine-leukocidin-positive Staphylococcus aureus (PVL-SA) at ambulatory health units of the Rhine-Ruhr metropolitan region in North Rhine-Westphalia, Germany

Carlos J. Tellez-Castillo*, Marcena Griego1, Philipp Göcke1, Rostislav Rujbr1, Ulrike Scharmann2, Claas Scharmann1

1Praxis für Labormedizin und Mikrobiologie - MedLab, Microbiology Laboratory, Bochum, Germany, 2Universitätsklinikum Essen, Institut für Medizinische Mikrobiologie, Essen, Germany

Background: Staphylococcus aureus (SA) is known to cause severe skin and soft tissue infections by producing the virulence factor Panton-Valentin-leukocidin (PVL). The prevalence of PVL-positive SA (PVL-SA) isolates differs in geographical regions. We determine the percentage of PVL-SA in skin swabs and analyse epidemiological variables of outpatients with PVL-SA from health centres of the Rhine-Ruhr region in North-Rhine-Westphalia, Germany.

Materials/methods: A retrospective study was performed to analyse the presence of PVL-SA in random skin specimens. We included patients with clinical manifestations in skin with the positive results of SA. Identification and susceptibility testing of SA-isolates were done using the VITEK 2-system (bioMérieux®, France). The presence of PVL was determined by in-house real-time PCR assay according to Pichon et al. [2012] by MVZ Dr. Eberhard & Partner Dortmund, Germany. Demographic and clinical characteristics of the patients were obtained from the patient records.

Results: 8355 SA in clinical samples were identified (5954 Methicillin-sensitive SA (MSSA) and 2401 Methicillin-resistant SA (MRSA)) from January 2017 to September 2019. Of these samples, the detection of PVL-SA was performed in 122 specimens (52.5% abscess swabs, 20.5% skin swabs, 15.6% wound/ ulcer swabs, 7.4% nose/throat swabs and 4% other samples) of 114 patients (36.9% women and 63.1% men). The PVL-SA-PCR was positive in 41.8% of all specimens analysed, which inferred a prevalence of 0.61% of all identified SA, 0.55% in MSSA and 0.75% in MRSA. 78.4% of positive PVL-SA were from men (p<0.05). The highest rate in total of PVL-positive results was detected in patients 16-47 years of age (58.8%). The mean age of the PVL-positive patients was 33 years. Of the swabs 66.7% (p<0.05) were PVL-SA-PCR positive abscesses. These came from mainly the axilla (20.6%), the leg (20.6%) or the head (14.7%).

Conclusions: Our study revealed that men were significant more often infected with PVL-SA. In the Rhine-Ruhr metropolitan region the highest rate of PVL-positive was found in patients 16-47 years of age and especially in swabs taken from abscesses. This analysis highlights sample types which are often PVL-SA positive and thereby informing laboratories on when to perform examination for PVL-SA.

Abstract 6262

Development of a predictive score for Enterococcus spp. in biliary tract-related bloodstream infections: Results from the PROBAC study

1University of Pavia, Pavia, Italy, 2Hospital Universitario Virgen Macarena, Sevilla, Spain, 3Complejo Asistencial Universitario de León, León, Spain, 4Hospital Universitario Central de Asturias, Oviedo, Spain, 5Hospital Universitario Mútua de Terrassa, Barcelona, Spain, 6Hospital de Jerez de la Frontera, Jerez de la Frontera, Spain, 7Hospital General Granollers, Barcelona, Spain, 8Hospital Universitario Arnau de Vilanova, Lleida, Spain, 9Hospital Universitario Reina Sofia, Córdoba, Spain, 10Hospital Universitario de Vigo, Vigo, Spain, 11Hospital de Cruces, Bilbao, Spain, 12Hospital Regional de Málaga, Málaga, Spain, 13Hospital Universitario Virgen de Valme, Sevilla, Spain, 14Hospital Universitario Marqués de Valdecilla, Santander, Spain, 15Hospital Universitario de Burgos, Burgos, Spain, 16Hospital Universitario Puerta del Mar, Cadiz, Spain, 17Hospital Costa del Sol, Marbella, Spain, 18Hospital el Bierzo, Ponferrada, Spain, 19Hospital de l’Esperit Sant, Santa Coloma de Gramenet, Barcelona, Spain, 20Hospital Clínico San Cecilio, Granada, Spain, 21Complejo Hospitalario Ciudad de Jaén, Jaén, Spain, 22Complejo Hospitalario Torrecárdenas, Almería, Spain, 23Hospital de Poniente, Almería, Spain, 24Hospital del SAS de La Línea de la Concepción, La Línea de la Concepción, Spain, 25Hospital San Juan de la Cruz de Úbeda, Jaén, Spain, 26Hospital Punta de Europa, Algeciras, Spain, 27Hospital General Universitario de Alicante, Alicante, Spain

Abstract third-party references: Supported by Instituto de Salud Carlos III [PI16/01432], On behalf of PROBAC REIPI/GEIH-SEIMC/SAEI group.

Background: Enterococcus spp. represent the third cause of bloodstream infection from a biliary tract source (BT-BSI) following E. coli and Klebsiella spp. Several studies have demonstrated that enterococcal BT-BSI are related to inadequate antimicrobial treatment and worse outcome. Our aim is to investigate risk factors for enterococcal BSI in patient with biliary tract infections.

Materials/methods: PROBAC is a prospective multicentric cohort collecting patients with bloodstream-infection older than 14 years from 26 Spanish hospitals, between October 2016 and April 2017. Patients with BT-BSI were included in this analysis. Bivariate comparisons were done using Chi square or Fisher test for categorical variables and Mann-Whitney for continuous variables; independent predictors were identified by logistic regression. A score was developed, by providing weighted points to each variable; positive and negative predictive values (PPV, NPV) were calculated.

Results: 850 episodes of BT-BSI were included, 73 (8.5%) were due to Enterococcus spp., of which 50 (68%) were due to Enterococcus faecalis and (23) 32% due to Enterococcus faecium; in 51% of the cases, Enterococcus spp. were isolated in polymicrobial infection. In univariate analysis, the factors associated with Enterococcus spp. were [RR (95%CI)]: liver disease [2.23 (1.36-3.62)], moderate-severe chronic kidney disease [1.83 (1.01-3.32)], cancer [1.69 (1.09-2.63)], cholangiocarcinoma [5.35 (2.80-10.20)], immunosuppressive therapy [2.30 (1.29-4.05)], biliary prosthesis [2.23 (1.41-3.52)], hospital acquisition [3.59 (2.35-5.52)], previous surgery [2.35 (1.25-4.42)], upper gastrointestinal tract endoscopic procedure other than esophago-gastroduodenoscopy [1.69 (1.09-2.63)] and previous antimicrobial treatment [2.25 (1.45-3.73)]. By multivariate analysis, the variable associated with Enterococcus spp. were cholangiocarcinoma [5.47 (3.75-18.43)], moderate-severe CKD [2.71 (1.30-5.68)], biliary prosthesis [2.05 (1.11-3.83)] and hospital acquisition [3.57 (2.06-6.19)]. The AUC of the model was 0.73 [95% CI 0.66-0.79]. A score was developed, with 3, 1, 1 and 2 points for these variables, respectively. For a score ≥4, the PPV was 66.7%, and for a score <2, the NPV was 94.7%.

Conclusions: A moderately predictive score for enterococcal aetiology of BT-BSI was developed. A high punctuation in the score may be used to consider empirical coverage against these pathogens in patients with severe presentation of the infection. The score would need to be externally validated.

Geodes Antibiotiques: restituting French antimicrobial consumption in the ambulatory sector using two indicators and an interactive website

Philippe Cavalie*, Marjorie Boussac¹, Sylvie Maugat¹, Etienne Lucas², Anne Berger-Carbonne¹, Laurence Watier³, Bruno Coignard²

¹Santé Publique France, Direction des Maladies Infectieuses, Saint Maurice, France, ²Santé Publique France, Direction Appui, Traitements et Analyses de données, Saint Maurice, France, ³Institut Pasteur, Paris, France, ⁴INSERM, UMR 1181, Paris, France

Background: In France, surveillance of antibiotic consumption in the ambulatory sector started in the early 2000s, based on pharmaceutical sales data. The indicators were expressed in defined daily doses (DDD) per 1000 inhabitants per day, as recommended by WHO. However, they were only available at national level and did not allow stratifying consumptions by age group or place of residence.

Materials/methods: We used data from the National Health Data System [i.e., all reimbursements to outpatients of drugs in the J01 ATC classes] in order to assess antibiotic consumption in the ambulatory sector from 2009 to 2018. We produced two annual indicators: the first one as the number of DDDs and the second one as the number of prescriptions, both expressed per 1 000 inhabitants per day. These indicators were broken down for eight age groups and by region or department.

Results: At national level, although overall antibiotic consumption expressed in number of DDD remained stable over the study period (22.5 DDD per 1 000 inhabitants per day in 2018), the number of prescriptions decreased by 15% (2.81 vs 2.38 per 1 000 inhabitants per day, in 2009 and 2018 respectively). This downward trend was particularly noticeable in children < 5 years old [-31%] but not in the elderly (> 65 years old). A switch of prescriptions from other beta-lactams (including cephalosporins; -54.5%) to broad-spectrum penicillins (including amoxicillin; +28.8%) mainly explains different trends for each indicator, as the DDD for amoxicillin remains lower than doses usually prescribed by French medical doctors. In addition, fluoroquinolone prescriptions decreased by 41.7% over the study period. Last, both indicators [numbers of DDD and prescriptions] reveal important variations in antibiotic consumption by region or department [map].

Conclusions: The prescription indicator is a very useful addition to the number of DDD in order to better monitor and understand antibiotic use in France. Particularly, it highlights trends that suggest changes in specific prescription behaviours. Both indicators are now publicly available through an interactive web site [https://geodes.santepubliquefrance.fr/] for better assessing and guiding antimicrobial stewardship actions.

Abstract 6264

Preliminary data on initial antimicrobial regimen from a prospective cohort study of sepsis in hospitalised neonates: the NeoOBS study

Wolfgang Stöhr*1

1University College London, MRC Clinical Trials Unit at UCL, Institute of Clinical Trials & Methodology, London, United Kingdom

Abstract third-party references: on behalf of the NeoOBS Study

Background: NeoOBS is a prospective, multinational, multicentre, observational cohort study of the inpatient management of neonatal sepsis and was set up to collect high-quality observational data to inform future clinical trials. One important aim was to explore which antibiotics are routinely given empirically in neonatal sepsis internationally (standard of care) in order to define the comparators for trials to assess the efficacy of novel antibiotic regimens in areas with high endemic rates of antimicrobial resistance.

Materials/methods: Hospitalised infants aged <60 days [post-natal] with a primary diagnosis of sepsis were enrolled in 19 sites in 11 countries across Asia, Africa, Europe and South America. Antibiotics started within 24h of the blood culture being taken were classified based on coverage; associations with birth-weight, age, central line/indwelling catheter, and time of hospitalisation were estimated using multivariable logistic regression with site-level random effects.

Results: 1760 neonates enrolled between Aug 2018-Aug 2019 with known antimicrobial regimen were included in this analysis. Antibiotic regimens received fell into five broad groups: 1) 1st-line penicillin (mostly ampicillin) in 19% (73% also started gentamicin), 2) 3rd generation cephalosporin (mostly cefotaxime) in 15%, 3) antipseudomonal penicillin/cephalosporin/quinolone with incomplete ESBL coverage (mostly ceftazidime or piperacillin/tazobactam) in 32%, 4) ESBL-covering regimen (mainly meropenem) in 26%, and 5) carbapenem-resistant organism-covering regimen (mainly colistin) in 3% of participants; 4% started another regimen. In group-3, 63% also started amikacin (11.14% in the other groups). Regimen varied considerably between sites (Figure). In sites with at least 10% of neonates starting group-1 or group-2 regimens (8 sites, 828 neonates), these regimens were independently less frequently prescribed in neonates aged ≥7days [OR=0.17 [95% CI 0.11-0.27] p<0.001], with lower birth weight [OR 0.08 [0.03-0.21], 0.18 [0.10-0.32] and 0.44 [0.28-0.67] for birth-weight <1000g, 1000-1500g, ≥1500-2500g versus ≥2500g, respectively, p<0.001], with a central line/indwelling catheter [OR=0.15 [0.04-0.53] p=0.004], and not born in the recruiting hospital [OR=0.45 [0.25-0.78] p=0.005].

Conclusions: Initial antibacterial regimens vary widely across sites, and are associated with important patient characteristics. Further analyses will explore additional factors to better assess the impact of disease severity on choice of empiric regimen.

**Risk factors for colonisation with multiple species of extended-spectrum beta-lactamase producing Enterobacteriales: a case-case-control study**

Isabelle Vock*1, Lisandra Aguilar Bultet1, Adrian Egli1, Pranita Tamma2, Sarah Tschudin-Sutter1

1University Hospital Basel, Basel, Switzerland, 2Johns Hopkins University School of Medicine, Baltimore, United States

**Background:** Colonization with multiple species of extended-spectrum beta-lactamase producing Enterobacteriales (ESBL-PE) has been reported in up to 11% of carriers. Risk factors for colonization with ESBL-PE have been investigated in several studies, yet further information on patients at risk of colonization with multiple ESBL-PE species is lacking. We therefore investigated risk factors associated with multiple- rather than single-species ESBL-PE colonization.

**Materials/methods:** We performed a retrospective case-case-control study at the University Hospital Basel, Switzerland. Hospitalized patients colonized with multiple species of ESBL-PE between 01/2008 and 12/2018 were included in case group 1. Case group 2 consisted of hospitalized patients with ESBL-PE and an additional ESBL-PE species within a following hospitalization. Controls (i.e. patients with detection of only one species of ESBL-PE within different hospitalizations) were frequency-matched 1:3 to cases of the second group according to the time-period between isolate-dates to standardize duration of colonization. Risk factors differentiating these three groups were determined using conditional logistic regression analyses.

**Results:** 154 cases met eligibility criteria (67 in group 1, 22 in group 2, 65 in group 3). Univariable analysis revealed recent stay abroad (OR1 2.3, 95%CI3.49-43.37, p=0.000), hospitalization abroad (OR2 3.51, 95%CI3.03-182.21, p=0.003) and prior antibiotic exposure within the last three months (OR2.88, 95%CI1.42-5.84, p=0.003) to be associated with carriage of multiple ESBL-PE-species. Recent stay abroad (OR1 2.57, 95%CI3.48-45.45, p=0.000) and prior antibiotic exposure (OR2.96, 95%CI 1.37-6.41, p=0.006) independently predicted multiple species-ESBL-PE-colonization as determined by stepwise backward/forward regression and selection by Akaike information criterion. Admission from another acute-care facility was the only predictor of a shift of ESBL-PE species (OR6.02, 95%CI1.15-31.49, p=0.003) within the same patient. Analyses regarding genetic relatedness of respective strains, plasmids, and ESBL-genes are ongoing.

**Conclusions:** In addition to antibiotic selection pressure, acquisition of specific strains and/or plasmids of ESBL-PE in settings with differing ESBL-epidemiology may be associated with an increased likelihood of co-colonization with ESBL-PE, either by transmission of ESBL-encoding plasmids to colonizing non-ESBL-PE or by direct acquisition of multiple strains of ESBL-PE. These findings point to strain-related factors being the main drivers of co-colonization with different ESBL-PE and may support stratification of infection prevention and control measures according to ESBL-PE species/strains.

Abstract 6268

**Comparative in vitro activities of eravacycline and various antibiotics against multidrug-resistant clinical strains of Acinetobacter baumannii isolated from intensive care units**

Merve Ataman*, Emel Mataraci-Kara, Berna Özbek Çelik

1Istanbul Aydın University, Istanbul, Turkey, 2Istanbul University, Istanbul, Turkey

**Background:** Acinetobacter baumannii is an opportunistic pathogen that often causes nosocomial infections. Increased antibiotic resistance including carbapenems and the absence of alternative antimicrobials have made the treatment of multidrug-resistant (MDR) A. baumannii infections difficult. On 27 August, 2018, FDA approved eravacycline is a synthetic tetracycline derivative antibiotic agent that has shown activity against Gram-positive and Gram-negative pathogens, including multidrug-resistant bacteria. The aim of the present study was to evaluate the in vitro activity eravacycline and various antibiotics against MDR Acinetobacter baumannii strains.

**Materials/methods:** The antimicrobial activities of eravacycline and various antibiotics were studied against 80 MDR A. baumannii strains isolated from an intensive care unit between 2018-2019. Minimum inhibitory concentration (MIC)s were determined by microdilution method according to CLSI.

**Results:** The in vitro activities of the studied antibiotics against 80 MDR A. baumannii strains are summarized in Table 1. Susceptibility testing demonstrated that the MIC ranges for tobramycin, levofloxacin, meropenem, cefepime, colistin, and eravacycline were 0.25- >256, 2- 256, 8- >256, 32- >256, <0.125- >256 and 0.25- 128 mg/l, respectively. Based on MIC results, 75% of the A. baumannii strains were resistant to tobramycin, although 20% of the tested isolates were resistant to colistin. Additionally, all of the studied isolates were resistant to meropenem, and cefepime. Versus comparator antibiotics, eravacycline showed the lowest MIC90 values against tested isolates.

**Conclusions:** Based on MIC90, eravacycline was the most potent antibiotic of those tested against MDR A. baumannii, including isolates that were resistant to meropenem or/and colistin. Eravacycline has been evaluated as a good treatment option against MDR A. baumannii isolates.

Abstract 6270

**A retrospective analysis of ceftriaxone-resistant *Neisseria gonorrhoeae* isolated in Japan nation-wide surveillance in 2013**

Hanao Mami*1,2, Kotaro Aoki1, Yoshikazu Ishii1, Kazuhiro Tateda1

1Department of Microbiology and Infectious Diseases, Toho University School of Medicine, Ohtaku, Japan, 2Department of Medical Technology, Division of Health Science, Tokyo University of Technology, Ohtaku, Japan

**Background:** Reduced susceptibility to ceftriaxone of *Neisseria gonorrhoeae* is a public health concern in the world. In 2009, high-level ceftriaxone-resistant H041 emerged in Japan. Since then, we have paid attention to the clonal spreading of H041.

**Materials/methods:** To analyze the clonal spreading of H041, we used 55 gonococcal strains which were collected from 25 hospitals in Japan in 2013 by the levofloxacin surveillance group. This surveillance was funded from DAIICHI SANKYO COMPANY, LIMITED. Antimicrobial susceptibility testing (AST) was performed by the agar dilution method. Multilocus sequence typing (MLST) and full-length of penA sequence encoding penicillin-binding protein 2 were determined by the draft whole-genome sequencing (WGS). The penA which affected to reduced susceptibility to ceftriaxone was evaluated by the transformation of full-length penA PCR amplicon DNA and by the AST.

**Results:** Antimicrobial-resistance rate was 98% [54/55], 80% [44/55], and 2% [1/55] for benzylpenicillin, cefixime, and ceftriaxone, respectively. The only one ceftriaxone-resistant strain (TUM15748) showed the minimum inhibitory concentration (MIC) of 0.5 mg/L of ceftriaxone. The strain belonged to sequence type (ST) 7359 which was different ST from H041 strain. The other ST7359 strains (n=10) were susceptible to ceftriaxone. The amino acid sequence of TUM15748 PenA (encoded penA-TUM15748) was novel and consisted of two amino acid substitutions (A311V and T483S). By the transformation with penA-TUM15748, the ceftriaxone MIC of the transformant showed 30-fold higher than that of ceftriaxone-susceptible recipients (NG9807 and another ST7359 strain).

**Conclusions:** Although the H041 clone was not found, we found a ceftriaxone-resistant strain which was another genotype with H041 and had a novel penA in Japan in 2013.

Evaluation of the combined use of galactomannan antigen and \textit{Aspergillus} DNA real-time PCR detection in laboratory diagnosis of invasive aspergillosis among haematological patients

Georgia Vrioni*1, Constantinos Tsiamis1, Maria Mavrouli1, Kalliopi Theodoridou1, Violetta Kapsimali1, Athanassios Tsakris1

1National and Kapodistrian University of Athens, Department of Microbiology, Medical School, Athens, Greece

\textbf{Background:} Diagnosis of invasive aspergillosis (IA) still remains a critical issue among hematological patients. According to the guidelines released by the European Organization for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group (EDRTC/MSG), the serological detection of galactomannan (GM) has been considered as the mycological diagnostic standard method. Nevertheless, \textit{Aspergillus} DNA detection has not been included in the guidelines, due to the lack of standardization and validation.

\textbf{Materials/methods:} In the current study the combined use of \textit{Aspergillus} GM and \textit{Aspergillus} DNA detection was evaluated as a useful practice for diagnosis of suspicious invasive IA. The study includes 1,041 samples by 454 patients with hematological malignancies (59 adults and 395 children) from five hematologic units of tertiary care Greek hospitals during 2012-2018. The measurements were made by GM immunoenzymatic method Platelia \textit{Aspergillus} (Bio-Rad, Hercules, CA) and PCR \textit{Aspergillus} (Standard Real-Time PCR detection kit for \textit{Aspergillus}, PrimerDesign). In the immunoenzymatic method, positive samples were considered those with a cut-off index $\geq 0.5$ and $\geq 1.0$ in serum and bronchoalveolar lavage (BAL), respectively.

\textbf{Results:} GM and PCR-\textit{Aspergillus} DNA investigation showed that 44 from 454 patients (9 from 59 adults and 35 from 395 children) were positive for IA. 17 patients (6 adults and 11 children) were found positive using both assays (GM+/PCR+), 2 adults and 16 children were positive by GM only (34 sera & 1 BAL), while 1 adult and 8 children were positive by PCR only (12 sera) (Table). The results’ agreement of GM+/PCR+ and GM-/PCR- were found in 427 patients and 993 samples (94% of the total patients and 95% of the total samples). Respectively, discrepant results were found in only 27 patients (48 samples; 4.6% of total), in which the positive result in any of the two methods was evaluated as true positive, in conjunction with the clinical and radiological findings.

\textbf{Conclusions:} Our findings indicate that the combination of GM-antigen and PCR-\textit{Aspergillus} DNA detection could be an important laboratory tool for the diagnosis of IA in conjunction with clinical, radiological and other laboratory findings of the patient.

Abstract 6274

**Bacterial STI-testing in the private sector in France, 2006-2018**

Delphine Viriot*, Ndeindo Ndeikoundam, Etienne Lucas, Nicolas Dupin, Bertille De Barbeyrac, Antoine Bertolotti, Charles Cazanave, Sébastien Fouere, Corinne Pioche, Florence Lot

1Santé publique France, Saint-Maurice, France, 2National Reference Centre for bacterial STI (Syphilis), Cochin Hospital, Paris, France, 3National Reference Centre for bacterial STI (Chlamydia, Mycoplasma), Pellegrin Hospital, Bordeaux, France, 4Sud Réunion Hospital, Saint-Pierre, France, 5Pellegrin Hospital, Bordeaux, France, 6Saint-Louis Hospital, Paris, France

**Background:** Protective barrier methods, testing and efficient treatments are main strategies to control the transmission of bacterial sexually transmitted infections (STIs). This study aims to analyze the evolution of STIs testing in private laboratories in France by exploring health insurance reimbursement data.

**Materials/methods:** In France the national health insurance covers 95% of the population. This system contains data on healthcare reimbursements and socio-demographic information. Reimbursement data of the national health insurance enable to monitor the number of persons tested for syphilis, *Chlamydia trachomatis* (*Ct*) or gonococcal infections in private laboratories. National and regional testing rates were calculated per 1,000 inhabitants aged 15 and over, by age and sex. Trends were described since 2006 with a focus on the 2016-2018 period.

**Results:** In 2018, 2.1 million people (39 per 1,000 inhabitants) were tested for *Ct* (figure). The annual number of tests increased by 9% from 2016 to 2018. Nearly 1.6 million people were tested for gonorrhea, with a rate of 30 per 1,000 inhabitants and a sharp increase of 18% since 2016.

For these two STIs, testing rates are higher in populations aged 25 and over. However the testing activity was twice higher in 2018 compared to 2016 in younger people (men or women < 25 years).

In 2018, 1.8 million syphilis tests (33 per 1,000 population) were carried out, with a 14% decrease compared to 2017. Future data will enable further interpretation of this point. The testing rates of these STIs in 2018 were twice higher in most French overseas territories (French West Indies, Reunion Island and French Guiana) than those in mainland France.

**Conclusions:** The increase in the number of tests for *Ct* and gonococcal infections from 2006 to 2018 might result from a better testing offer by health professional following prevention campaigns. The reimbursement of combined *Ct* and gonorrhea tests and the systematic *Ct* screening for young women (< 25 years) extended to general practitioner since 2018 should improve testing in France. However, epidemics remained uncontrolled. Condom use, improvements of the testing offer and its diversification toward most exposed populations are crucial to prevent STIs transmission.

Abstract 6275

WGS-based characterisation of clinical Pseudomonas aeruginosa isolates obtained from teaching and specialist hospitals in Lagos, Nigeria

Adesola Olalekan1*, Bamidele Iwalokun2, Baris Bader3, Sophia Vogt4, Adobi Dike5, Morounke Mannie-Udoh6, Albert Lalremruata6, Matthias Marschal3, Philipp Oberhettinger3, Jan Liese3, Silke Peter7

1University of Lagos, Department of Medical Laboratory Science of College of Medicine, Lagos, Nigeria, 2Molecular Biology & Biotechnology Department, Nigerian Institute of Medical Research, Lagos, Nigeria, Lagos, Nigeria, 3Institute of Medical Microbiology and Hygiene, University of Tübingen, Tübingen, Germany, 4Department of Microbiology, Lagos University Teaching Hospital, Iđi-Araba, Lagos, Lagos, Nigeria, 5Medical Microbiology Unit, National Orthopedic Hospital, Lagos, Lagos, Nigeria, 6Institute of Tropical Medicine, University of Tübingen, Tübingen, Tübingen, Germany

Background: Pseudomonas (P.) aeruginosa is one of the most frequently involved pathogens in serious infections of hospitalised patients. These infections are difficult to treat due to limited treatment options in particular when multidrug resistant (MDR) strains are encountered. Infections with MDR Paeruginosa have become a major concern of public health and infection control experts worldwide, emphasizing the need for detailed surveillance data on a global scale.

Materials/methods: In the present study, we obtained non-duplicate clinical P. aeruginosa isolates (n=124) from three large hospitals in Lagos, Nigeria. Identification was achieved by MALDI-TOF (Microflex LT, Bruker Daltonics, Germany), antimicrobial susceptibility was performed using the VITEK2 (bioMérieux SA, France) supplemented with E-Tests (bioMérieux SA, France), All 124 isolates were subjected to whole genome sequencing using a NextSeq instrument (Illumina, San Diego, USA).

Results: Overall 92 (74%) isolates were resistant to fluoroquinolones, 74 (60%) to piperacillin-tazobactam, 65 (62%) to ceftazidime or cefepime and 54 (44%) to carbapenems. Co-resistances to fluoroquinolones, piperacillin-tazobactam, cephalosporins and aminoglycosides were frequently observed in the carbapenem resistant strains.

In the 54 carbapenem resistant isolates a carbapenemase gene was detected in 53 (98%) of the strains, with blaNDM-1 (34=64%) and blaVIM-5 (11=21%) being the most prevalent ones.

Phylogenetic analysis revealed a broad diversity of the isolates, but also indicated clusters of closely related strains suggesting possible transmission events. Extraction of the multilocus sequence types (STs) revealed the presence of three important STs, namely ST773, ST2613 and ST233. Interestingly, the predominant ST encountered in our strain selection was ST773, which has been frequently reported from different areas around the world.

Conclusions: To the best of our knowledge, this is the first report of application of whole genome sequencing on a larger scale to understand resistance mechanism and epidemiology of clinical P. aeruginosa isolates obtained from Nigeria. The alarmingly high percentage of carbapenemase carrying isolates warrants further investigation. Long-read based analysis is currently being conducted to distinguish between plasmid and chromosomal location of the resistance genes and to elucidate the genetic environments of blaNDM-1 and blaVIM-5.

Abstract 6276

Epidemiology of dengue, chikungunya, Zika and West Nile diseases from 2012 to 2019: data from an Italian regional reference centre

Nadia Zanchetta1, Alberto Rizzo1,2, Carla Bossi1, Cecilia Pontoriero1, Romualdo Grande*, Giulietta Venturi2, Maria Rita Gismondo2

1Sacco Hospital, Lab of Clinical Microbiology, Virology and Bioemergency, Milan, Italy, 2University of Milan, Postgraduate School of Microbiology and Virology, Milan, Italy, 3Department of Infectious Diseases, Istituto Superiore di Sanità, National Reference Laboratory for Arboviruses, Rome, Italy

Background: Arboviral infections represent an important public health problem. In the recent years many elements favoured their spreading. Increasing travels, emigrations from endemic zones, introduction of vectors at other latitudes, contributed to the onset of autochthonous infections. Many countries, including Italy, introduced surveillance programs in order to control and prevent these diseases. The aim of this study is to analyse epidemiological data of Dengue (DENV), Chikungunya (CHKV), Zika (ZIKV) and West Nile (WNV) infections diagnosed at the Laboratory of Clinical Microbiology, Virology and Bioemergencies, L. Sacco University Hospital, Milan.

Materials/methods: We searched for DENV, CHKV, ZIKV and WNV in 4091 samples of 1191 patients in 2012-2017, 4066 samples of 1132 patients in 2018-2019. For detection of IgM and IgG antibodies serum samples were used and the positive ones were confirmed by Plaque Neutralization test (PRNT). The presence of viral RNA was investigated in serum, urine, whole blood, liquor and saliva samples. Medical and epidemiological informations were collected in a data sheet. Data obtained in 2012-2017 have been compared with those from January 2018 to September 2019.

Results: Comparing 2012-2017 with 2018-2019, an increased number of cases of DENV (+153%: 27 vs 41.5), CHKV (+125%: 4.4 vs 5.5), WNV (+232%: 2.8 vs 6.5) and a decreased number of ZIKV cases (-11%: 5.6 vs 5) have been recorded. Positive patients in 2012-2017 came from: 49.5% South-East Asia, 30% Central America, 9.1% South America, 6.4% Europe, 5% Africa; while in 2018-2019 they were from: 54% South and East Asia, 23% Central America, 5% South America, 10% Europe, 4% Africa and 4% Oceania.

Conclusions: A remarkable increase in number of arboviral diseases in the recent years has been observed. South and East Asia, Central America (including Caribbean), can still be considered as the main endemic zones. According to data, a surveillance system proved to be essential. In fact, in order to control the spreading of the diseases, effective measures must be initiated as soon as possible.

Abstract 6277

The global burden of sepsis in adults: updated systematic review and meta-analysis
Carolin Fleischmann-Struzek*, Lisa Mellhammar1, Norman Rose1, Alessandro Cassini1, Kristina Rudd2, Peter Schlattmann3, Benedetta Allegranzi3, Konrad Reinhart1,6,7

1Jena University Hospital, Center for Sepsis Control and Care, Jena, Germany, 2Lund University, Department of Clinical Sciences, Division of Infection Medicine, Lund, Sweden, 3World Health Organization HQ, Infection Prevention and Control Hub, Integrated Health Services, Geneva, Switzerland, 4University of Pittsburgh, Department of Critical Care Medicine, Pittsburgh, United States, 5Jena University Hospital, Department of Medical Statistics, Computer Sciences and Documentation, Jena, Germany, 6Charité Universitätsmedizin, Department of Anesthesiology and Operative Intensive Care Medicine (CCM, CVK), Berlin, Germany, 7Berlin Institute of Health, Berlin, Germany

Abstract third-party references: World Health Organization

Background: Sepsis is a major global health threat, but its burden remains largely unknown, in particular in low- and middle-income-countries (LMIC). We investigated the global burden of sepsis in adults by updating and expanding a systematic review and meta-analysis [Fleischmann AJRCCM 2016].

Materials/methods: 13 electronic databases were searched for studies on the population-level sepsis incidence defined according to clinical criteria (sepsis-1, sepsis-2 or sepsis-3) or relevant ICD-codes. The search of the original systematic review was updated for studies published between 06/2016-02/2019 and complemented by a search targeting LMIC studies published between 01/1979-02/2019. We performed a random-effects meta-analysis with sepsis incidence and proportion of deaths among sepsis cases as outcomes. The model accounts for the potential heterogeneity in the outcomes across studies by the between-study standard deviation (τ).

Results: Our search yielded 4,746 results, of which 32 met the inclusion criteria. 25 studies contributed complete data and were pooled with the 38 studies of the original meta-analysis. The resulting 63 studies were from 4 WHO-regions and 22 countries (Fig. 1). 58/63 studies were from high-income-countries. We found a pooled incidence of 261.16 [95% CI, 199.01, 342.65, τ=0.653] hospital-treated sepsis and 196.83 [142.97, 270.92, τ=0.882] hospital-treated severe sepsis cases per 100,000 person-years. An estimated 22.7% [18.7%, 27.2%, τ=0.411] and 27.4% [24.1%, 30.9%, τ=0.597] sepsis and severe sepsis patients died, respectively. There was a higher incidence of both sepsis and severe sepsis incidence observed in the past decade (+22% and +68% compared to the overall time frame, respectively). Random-effects estimators for ICU-treated sepsis and severe sepsis were 46.88 [23.76, 92.44, τ=1.284] and 65.99 [47.32, 92.03, τ=0.682] per 100,000 person-years, respectively. An estimated 52.6% [34.5%, 70.1%, τ=0.333] of ICU-treated sepsis and 39.0% [32.5%, 45.8%, τ=0.331] of ICU-treated severe sepsis patients died until hospital discharge.

Conclusions: The burden of hospital-treated sepsis is high. Extrapolating the recent estimates on a global scale, we estimate 25 million global hospital-treated severe sepsis cases per year with 6.8 million patients dying from or with sepsis. Data on sepsis epidemiology is lacking from the vast majority of LMICs. Improved epidemiological sepsis surveillance is urgently needed.

Abstract 6278

Evaluation of the rapid antimicrobial susceptibility testing (RAST) from positively-flagged blood cultures

Tingyu Ko*, Pei Chien Chuang¹, Chen-Ching Hsu¹, Tai-Fen Lee¹, Po-Ren Hsueh²

¹National Taiwan University Hospital, Department of Laboratory Medicine, Taipei, Taiwan, ²National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan

Background: Antibiotic-resistant pathogens are of growing concern to public health. The disk diffusion method and VITEK2 automated drug sensitivity test currently used clinical microbiology laboratories both require 18-24 hours to obtain the results. Development of rapid antimicrobial susceptibility testing (RAST) is important for patient care and improving clinical outcomes.

Materials/methods: Microorganisms from 142 positively flagged blood culture bottles were directly identified by Bruker MALDI-TOF Biotyper using the saponin pretreatment methods. RAST recommended by the EUCAST (European Committee on Antimicrobial Susceptibility Testing) were performed for E. coli, K. pneumoniae, S. aureus, E. faecalis, E. faecium, P. aeruginosa. The results obtained by RAST were interpreted at 4, 6, and 8 hours and were compared with those analyzed by the routine AST method (VITEK 2).

Results:

Table 1. Accuracy (agreement) rates of RAST as compared with the results from VITEK 2 AST

</tbody>
</table>

Interpretation of RAST and VITEK 2 AST results to selected antimicrobial agents was based on the guidelines recommended by the EUCAST. The high MIEs of E. faecalis and E. faecium were due to fuzzy zone edges of vancomycin. VME, very major error; ME, major error, and MIE, minor error.

Conclusions: RAST were useful (>85% agreement) for early detection of susceptibilities at 8 hours for E. coli, K. pneumoniae, and P. aeruginosa. However, several isolates of these species exhibited VMEs. Using MALDI-TOF MS and RAST from positive blood cultures, the entire time for bacterial identification and AST was shortened from 36-48 hours to 4.5-8.5 hours. It is expected to effectively reduce patient mortality, shorten hospital stay, and reduce medical costs.

Abstract 6280

Comparative evaluation of CHROMagar COL-APSE, MicroScan Walkaway, ComASP Colistin, and Colistin MAC test diagnostic efficiencies in detecting colistin-resistant Gram-negative bacteria

Arnold Sephpfane1, Nontombi Mbelle1, John Osei Sekyere*1

1University Of Pretoria, Higher education, Pretoria, South Africa

Abstract third-party references: National Health Laboratory Service (NHLS) for their generous support in cash and kind, Department of Medical microbiology, University of Pretoria

Background: Colistin belongs to the polymyxin class of antimicrobials. Subsequent to its successful introduction however, its use was halted due to its side effects. Increasing antimicrobial resistance has led to the resurgence of colistin as the last-resort antimicrobial agent to treat multidrug-resistant (MDR) Gram-Negative Bacteria (GNB). Colistin resistance was reported after identification of a mobile colistin resistance (mcr-1) gene in E. coli isolates from patients, food and food-producing animals. To date, the mcr-1 gene and its variants have spread globally. Owing to the threat posed by colistin-resistant (COL-R) GNB, it is crucial that patients are quickly diagnosed and treated accordingly. However, this requires diagnostic assays that can rapidly and timeously detect COL-R GNB. Currently, only the Broth Microdilution (BMD) is the accepted colistin antimicrobial susceptibility (AST) testing technique for routine diagnostic laboratories.

Materials/methods: A total of 84 GNB were screened with the BMD to determine their colistin Minimum Inhibitory Concentrations (MICs). A multiplex PCR (M-PCR) was used to screen all isolates to detect the presence of the mcr-1 to mcr-5 genes. CHROMagar COL-APSE was challenged for the recovery and identification of COL-R organisms. The MicroScan® was challenged with all isolates to determine their colistin MICs and species taxon. The ComASP™Colistin, was also challenged with the isolates. A novel screening assay, the Colistin MAC Test (CMT) was used to identify mcr positive isolates.

Results: The M-PCR detected a single mcr-1 positive E. coli isolate. CHROMagar recovered 45% COL-S and 55% COL-R isolates with a sensitivity of 82.05% and specificity of 66.67%. The MicroScan® had a specificity and sensitivity of 92.31% and 76.92%. The ComASP™Colistin had a sensitivity and specificity of 100% and 88.89% respectively. The CMT detected one mcr-positive isolate. The MicroScan® was the most expensive at a cost (per sample tested) of R221.59, followed by CHROMagar COL-APSE, M-PCR, CMT and ComASP™Colistin at R119.33, R75.08, R20.12 and R2.64 respectively. CHROMagar was the easiest to perform, followed by ComASP™, M-PCR, MicroScan®, CMT AND BMD.

Conclusions: The ComASP™ Colistin was the best performing diagnostic test and is therefore recommended as a potential commercial BMD assay that can improve routine colistin AST in clinical laboratories.

First European outbreak of eosinophilic meningitis in travellers returning from Cuba

Sílvia Roure1, Gema Fernández Rivas*2,3, Belen Rivaya Sanchez1, Gemma Lladós1, Laia Grau4, Laura Guarro5, Seven Poppert1, Marie-Therese Ruf5, Lluís Valerio2, Beatrice Nickel6, Lurdes Matas Andreu8

1Hospital Universitari Germans Trias i Pujol, North Metropolitan International Health Unit PROSICS, Infectious Diseases Department, Badalona, Spain, 2Hospital Universitari Germans Trias i Pujol, Microbiology Department, Badalona, Spain, 3Universitat Autònoma de Barcelona, Genetics and Microbiology Department, Bellaterra, Spain, 4Hospital Germans Trias i Pujol, Neurology Department, Badalona, Spain, 5Hospital Germans Trias i Pujol, Emergency Department, Badalona, Spain, 6Swiss Tropical And Public Health Institute, Basel, Switzerland, 7Institut Català de la Salut, North Metropolitan International Health Unit PROSICS, Santa Coloma de Gramenet, Spain, 8Hospital Germans Trias i Pujol, Microbiology Department, Badalona, Spain

Background: Angiostrongyliasis caused by the rat lungworm Angiostrongylus cantonensis (AC) is endemic in Asia, the Pacific Islands and the Caribbean. Humans become infected by ingestion of larvae contained in raw or undercooked snails, prawns or contaminated vegetables. Infection can lead to eosinophilic meningitis with CNS involvement. We report the first imported outbreak in the European Union of eosinophilic meningitis caused by AC. Diagnosis of four cases was based on clinical symptoms and confirmed by serology.

Materials/methods: An 18-year-old woman (Case 1) and her sister aged 23 (Case 2) were admitted to the Emergency Department due to severe occipital and retro-orbicular headache and vomiting in the last 4 days. Two weeks earlier they had returned from a trip to Cuba. From asking for potentially exposures, the patients reported to have eaten raw freshwater prawns, salad and half-cocked pork (“ropa vieja”). Few days later, other members of the family developed similar symptoms and in addition intense conjunctivitis (Case 3) and paraesthesia/dysesthesia (Case 4). Clinical and analytical data suggested the diagnosis of eosinophilic meningitis.

Results: Laboratory tests displayed blood eosinophilia with normal acute phase parameters. CSF was collected from two patients (1, 3) and CSF examinations were consistent with aseptic meningitis: lymphocytic predominance with 18-36% eosinophils. Serum samples of three patients were collected during acute phase and convalescence phase for serological analysis. All samples were tested in the following tissue helminth serology: Trichinella, Toxocara, Fasciola, Filaria, Schistosoma and Strongyloides with ELISA, and Angiostrongylus spp. with EITB. The acute phase samples were additionally tested for Gnathostoma serology (EITB).

All serologies were negative except for the Angiostrongylus. The acute phase samples were all negative, while all convalescence phase samples were positive for specific IgG antibodies directed against the 31 kDa protein of A. cantonensis. In all cases seroconversion took place within three weeks after onset of symptoms. Patients were treated with systemic prednisolone.

Conclusions: These results show the importance of repeated testing for specific antibodies in patients with suspected angiostrongyliasis. AC infections should always be considered in cases of eosinophilic meningitis, even outside of endemic areas. Travel counseling is mandatory to avoid the infection.

Abstract 6288

Using dried blood spots in drug dependency treatment centres to diagnose active hepatitis C infection
Magdalena Lara1, Diego García Martínez De Artola*, Julia Alcoba Flores1

1Hospital Universitaria Nuestra Señora de Candelaria, Department of Clinical Microbiology, Santa Cruz de Tenerife, Spain

Background: Patients attending drug dependency treatment centres (DDTC) have high prevalence of hepatitis C virus (HCV) active infection in Spain, as well as low connection with health system environment. If no new diagnostic and treatment strategies are implemented, eradication of this disease will not be possible. The purpose of this study was to evaluate the use of dried blood spots samples (DBS), obtained in DDTC, in hepatitis C diagnosis in a clinical microbiology laboratory in Tenerife, Spain.

Materials/methods: 254 DBS were collected and treated with different protocols in order to obtain an eluate to perform a serology to detect anti-hepatitis C virus antibodies (Alinity, Abbott Diagnostics), or to perform a rtPCR to measure the viral load (Cobas 6800, Roche Diagnostics). In the positive viral load cases, the patients were scheduled for a doctor appointment 1-2 weeks later, where plasma sample was obtained and treatment was started.

Results: Seventy-one DBS gave positive results in serology and quantitation, diagnosing an active infection. 183 were negative in the rtPCR, ten of them treatment controls, previously diagnosed by normal algorithms. Other five DBS were treatment controls, previously diagnosed also by DBS technique.

Correlation of the 71 positive results between DBS and normal detection of the antibodies were 97.18%, and 100% with viral load results. In DBS technique, viral loads were 2.24 log on average lower [International Units/mL], from the results obtained 1-2 weeks later in plasma in untreated patients.

Conclusions: DBS based techniques are very useful methods to detect active hepatitis C infection in these communities. Our results showed that amount of viral load should not be considered when performing DBS techniques, as it normally results in lower detection of HCV RNA. However, lower results of viral loads of DBS may be due to lower volume of blood used in blotting DBS as compared to plasma.

Further investigation and validation studies need to be performed to address these problems, as DBS techniques have showed promising results in detection of hepatitis C active infection, and could substantially improve worldwide screening, diagnosis and access to care.

Predicting co-amoxiclav resistance in *Escherichia coli* bloodstream infections using machine learning methods and bacterial genome-wide association studies

Karina-Doris Vihta1, Timothy Davies1, Nicole Stoesser1, Sarah Earle2, Daniel Wilson2, David Eyre1, Sam Lipworth1, David Clifton3, Samaneh Kouchaki3, Derrick Crook1,4,5, Tim Peto1,4,5, A. Sarah Walker1,4,5

1University of Oxford, Nuffield Department of Clinical Medicine, Oxford, United Kingdom, 2University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom, 3University of Oxford, Biomedical Engineering, Oxford, United Kingdom, 4Oxford National Institute for Health Research Health Protection Research Unit, Oxford, United Kingdom, 5University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

**Background:** Several methodologies have been developed to predict antimicrobial susceptibilities from whole genome sequencing (WGS) data. Levels of performance vary. However, predictions of beta-lactam/beta-lactamase inhibitor susceptibility in Enterobacteriaceae have proved challenging. This is partly driven by the modest reproducibility of laboratory phenotypes and differences in reference methodologies. We investigated if alternative approaches using machine learning (ML) could improve resistance prediction for co-amoxiclav in *Escherichia coli*.

**Materials/methods:** We investigated *E. coli* isolated from blood (January 2013-August 2015, Oxfordshire, UK). For each isolate, WGS was used to identify genetic features relevant to co-amoxiclav resistance and MICs were measured by microbroth dilution (BD Phoenix). Input genetic features were constructed both from presence/absence of known resistance elements (Resfinder database), and by creating agnostic patterns of k-mer presence/absence (using 31-mers) with bacterial genome-wide association studies for feature selection. We predicted susceptible/resistant phenotypes (using EUCAST breakpoints) using regularized logistic regression, support vector machines, and ensembles of decision trees (random forests, gradient boosting). For MICs we considered regularized multinomial logistic regression, generalization of regularized logistic regression for ordered outcomes (ordinal regression), regularized regression and ensembles of trees.

**Results:** Of 976 *E. coli* bloodstream infections, 36% were phenotypically co-amoxiclav resistant. For susceptible/resistant prediction the best-performing model, determined using cross-validation, included the 5561 most significant 31-mer patterns of presence/absence using L2-regularised logistic regression [accuracy 89%, sensitivity 88%, specificity 89%, AUC 96%].

The best-performing model for essential agreement (MIC within a doubling dilution) utilised ordinal regression with known co-amoxiclav resistance determinants and their DNA copy-number as input features [essential agreement 92%, accuracy 58%, sensitivity 74% and specificity 98% [sensitivity/specificity against the predicted binary phenotype]]. The same ML algorithm with the top 5088 31-mer presence/absence patterns had similar performance (Figure).

**Conclusions:** The largest improvement in performance was obtained through feature engineering (e.g. DNA copy-number, Figure); choice of ML algorithm further improved this. Agnostic 31-mers were able to achieve similar predictive performance as that obtained using known resistance gene databases, despite not accounting for copy-number, suggesting further improvement may be possible.

Abstract 6292

Dealing with the current dengue viral fever outbreak: an experience from a tertiary care hospital in Karachi

Samreen Sarfaraz*1, Fivzia Herekar1, Sundus Iftikhar1

1The Indus Hospital, Karachi, Pakistan

Background: Pakistan is currently facing its worst outbreak of Dengue Viral Fever (DVF) since 1994 with over 42,120 confirmed cases and 75 mortalities. In Sindh alone, 12,053 cases were confirmed and 33 deaths were reported. More than 90% cases of Sindh were recorded in Karachi, with heavy rainfall, hot, humid weather, overflowing sewage and garbage dumps being the perfect breeding ground for the mosquito vector. The Indus Hospital, located in Korangi, Karachi, deals with DVF cases all year round but received an enormous surge in cases over the past two months.

Materials/methods: A retrospective review of confirmed DVF cases of all age groups was conducted at The Indus Hospital Karachi from August till October 2019 capturing details of demographics, clinical features, investigations and outcomes.

Results: A total of 1,631 confirmed cases were reported during August to October 2019 (August: 211, September: 321 and October: 1289 cases respectively). Detailed analysis was performed on data from Oct-2019, out of which 79.3% (n=1,022) were diagnosed on positive Dengue NS1 antigen test and 21% (n=270) on positive Dengue IgM antibodies with 7.21% (n=93) of the latter showing concomitant IgG positivity. Fifty-three patients (4.1%) presenting with severe Dengue Fever were admitted and recovered uneventfully. Five (0.4%) patients presenting with Dengue Haemorrhagic Fever expired within hours of presentation to the Emergency Department. Demographics are shown in figure 1. Thirty-nine (3.13%) patients had platelets <20 x 10^9/L, lowest reported being 4 x 10^9/L. The lowest total leukocyte count was 1.13 x 10^9/L (mean±SD of 5.35±3.53 x 10^9/L). Haemoglobin ranged from 4 gm/dl- 20.1 gm/dl and highest haematocrit recorded was 60.1% (Mean± SD: 40±5.9%). Malaria and dengue co-infection was observed in 8 (0.62%) patients, one of which (with falciparum parasitic load of 16%) survived after prolonged ventilatory, haemodynamic and dialysis support.

Conclusions: In this 2019 outbreak, DVF has caused significant morbidity, overwhelming our resource limited hospital. Vector control in high burden areas and better preparedness at hospital level can help curtail future seasonal outbreaks.

Abstract 6294

Initial clinical features from preliminary analyses of a global multi-centre prospective observational cohort of sepsis in hospitalised neonates: the NeoOBS study

Neal Russell*1

1St George’s, University of London, Paediatric Infectious Diseases Research Group, Institute of Infection & Immunity, London, United Kingdom

Abstract third-party references: on behalf of the NeoOBS Study Team

Background: Neonatal sepsis is estimated to be responsible for 680,000 deaths per year, with an estimated 214,000 deaths attributable to antimicrobial resistance, demonstrating a need for new treatment strategies. However, the lack of a universally accepted and workable definition of neonatal sepsis, particularly for low-middle income countries (LMIC), undermines estimates and is a challenge for designing sepsis trials. This multi-country observational study is the largest to link clinical presentation, microbiology, response to antibiotic treatment and outcomes in LMIC settings.

Materials/methods: Hospitalised infants aged <60 days, with a primary diagnosis of sepsis, fulfilling at least 2 clinical or laboratory sepsis criteria (at least 1 clinical) were enrolled over 2018-19 in 19 sites in 11 countries across Asia, Africa, Europe and South America (up to 200 cases per site). Infants were included after a decision to treat with new antibiotics for a sepsis episode, and were excluded if an alternative primary diagnosis was suspected to be more likely.

Results: 1826 neonates for whom preliminary clinical data could be analysed were included. 43% are female, with median birth weight 2270g and postnatal age 6 days. The median number of clinical signs was 4, the most common being shown in figure 1. The frequency of most signs varied with birth weight and (post-natal) age. In particular, respiratory signs were more frequent at lower birth weights (54%<2500g vs 94%<1000g, P<0.001), younger age (78%<7d vs 57%>7d, P<0.001) and for inborn newborns who had remained in hospital since birth (OR=1.8, 95% CI 1.6-2.0, P<0.001 after adjustment for birth weight and age). The most common laboratory criteria was CRP, which was >10mg/L in 725 (62%) of 1,177 infants in whom it was measured (64% of total), and more commonly raised in infants >7d old (71% vs 51%, P<0.001).

Conclusions: In this preliminary analysis, infant factors such as birth weight and age were associated with different frequencies of common signs of sepsis, with implications for clinical sepsis definitions and neonatal sepsis trial design. Further analyses will explore how such factors influence the sensitivity and specificity of signs for prediction of culture positivity, response to therapy and outcomes.

Abstract 6296

**Phenotypic and molecular characterisations of carbapenem-resistant *Acinetobacter baumannii* isolates collected within the EURECA study**

Tomislav Kostyanev1, Basil Britto Xavier1, María García-Castillo1, Christie Lammens1, Jose María Bravo-Ferrer Acosta4, Jesús Rodríguez-Baño5, Rafael Canton Moreno1,2, Herman Goossens3

1University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, Antwerp, Belgium, 2Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain, 3Red Española de Investigación en Patología Infecciosa (REIPI), Madrid, Spain, *Unidad de Gestión Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Hospital Universitario Virgen Macarena – IBIS and Departamento de Medicina, Universidad de Sevilla, Seville, Spain

**Abstract third-party references:** on behalf of the EURECA study team

**Background:** Carbapenem-resistant *Acinetobacter baumannii* (CRAB) isolates were collected from patients with sepsis from 50 European sites that participated in the EUropean prospective cohort study on Enterobacteriaceae showing REsistance to CArbapenems (EURECA) (May 2016 to November 2018).

**Materials/methods:** Local laboratories stored all *A. baumannii* blood isolates resistant to carbapenems (MIC ≥ 16 mg/L for imipenem or meropenem, and/or disc diffusion zone diameter ≤17 mm and/or ≤15 mm, respectively). Patients with CRAB bacteremia were enrolled into the study. The isolates were shipped to the central lab (University of Antwerp) for identification (MALDI-TOF) and phenotypic (disc diffusion) confirmation. In addition, MIC testing was performed by broth microdilution and interpreted by EUCAST guidelines. Genomic DNA was extracted using MasterPure™ DNA Purification Kit and sequenced via 2×250b PE sequencing (Miseq, Illumina). Comparative genome analysis was performed using an in-house developed pipeline (BacPipe v.1.2.6). Since *A. baumannii* isolates have a high genetic diversity, we performed a gene-by-gene approach-based allelic loci comparison using chewBBACA by generating a study-specific wg/cg MLST scheme and visualized it using PHYLOViZ.

**Results:** A total of 227 CRAB strains from 29 sites were collected. The identification and susceptibility testing results of almost all isolates (n=225; 99.1%) were confirmed at the central lab. Whole-genome sequencing data revealed 26 diverse ST-types according to the Oxford MLST scheme, the most common being ST195 (n=75; 33.2%). ST-type could not be assigned to 19 isolates (8.4%). Pasteur MLST scheme identified 12 different STs; the most prevalent was ST2 (n=153; 67.7%). A majority of the isolates harboured the *bla*OXA-23 (n=153; 67.7%), while the main oxacillinase in 70 isolates (30.1%) was *bla*OXA-72. The *bla*OXA-66 gene was present in 179 isolates (79.2%, usually in conjunction with *bla*OXA-23 (n=138; 61.1%). Four isolates from Serbia that had *bla*OXA-72 and *bla*OXA-66 also co-harboured *bla*NDM-1. Genetic relatedness based on cgMLST allelic loci distances showed that isolates were scattered in various clusters despite belonging to the same ST-type (Fig. 1).

**Conclusions:** Findings from the local labs were confirmed at an excellent rate which underlines the importance of training microbiology labs in clinical trials on anti-infectives. *bla*OXA-23 was the most predominant oxacillinase. The most common ST types were ST195/ST2.

![Fig. 1. Phylogenetic tree showing the clonal relatedness of Acinetobacter baumannii isolates within the EURECA study. Isolates from participating countries are shown in different colors.](image-url)

Quantitative detection of human cytomegalovirus and Epstein-Barr virus using the real-time PCR STAT-NAT CMV and STAT-NAT EBV assays

Davide Rigamonti1, Alessandro Mancon2, Giulia Ferri1, Alessandro Di Cosimo1, Luigi Spinelli1, Giacomo Torini1, Laura Bavagnoli1, Isabella Merli2, Maria Loreto Incandela1, Maria Rita Gismondo2, Maurizio Gramegna*1, Valeria Micheli2

1Sentinel Diagnostics, Milan, Italy, 2Clinical Microbiology, Virology and Bioemergencies - L. Sacco Hospital - ASST FBF Sacco, Milan, Italy

Background: Human Cytomegalovirus (HCMV) and Epstein-Barr virus (EBV) are two Herpesviridae family DNA viruses, widely spread in human population, with estimated seroprevalence up to 80% and above. Despite being generally asymptomatic in healthy subject, HCMV and EBV infection represents a leading cause of morbidity and mortality in non-immunocompetent subjects (i.e.: transplant recipients, newborns, children). Molecular methods demonstrated to be rapid, sensitive and reliable tools for viruses detection. The aim of this work was to evaluate the performance of new quantitative freeze-dried and ready-to-use Real-Time PCR assays (STAT-NAT CMV and STAT-NAT EBV) for HCMV and EBV DNA detection in human samples.

Materials/methods: Both assays were developed as ready-to-use lyophilized mix, combining viruses specific primers and probes, primers and probes for the detection of Internal Control (exogenous for HCMV, endogenous for EBV) and other reagents. In the present study, a total of 50 HCMV and 50 EBV whole-blood samples were extracted by means of QIAamp DSP Virus Spin Kit (QIAGEN) and then processed using CFX96 Real-Time PCR Detection System (Bio-Rad Laboratories, Inc.); results were compared to those previously obtained with the routine method used at L. Sacco Hospital (ASST FBF Sacco – Milan, Italy), CMV and EBV ELITe MGB® Kit (ELITechGroup).

Results: All samples were successfully amplified for both targets, as confirmed by ICs results. HCMV and EBV-DNA values were comparable with those obtained with ELITe MGB® Kits; in particular, a difference >0.5 Log was found in <5% of samples. From analytical studies the CMV test resulted in a LLoQ of 102 cps/rxn, a LoD of 30 cps/rxn and linearity range between 102 and 106 cps/rxn. Analytical studies of EBV showed a LLoQ of 101 cps/rxn, a LoD of 5 cps/rxn and linearity range between 101 and 107 cps/rxn. Cross-reactivity studies did not show evidences of spurious amplification.

Conclusions: These novel Real-Time PCR assays proved their effectiveness for detection and quantification of HCMV and EBV DNA in clinical samples. The high sensitivity and specificity, the ready-to-use setup and the possibility to storage at room temperature make these assays suitable for molecular monitoring in patients management.

Abstract 6300

A high-throughput real-time liquid-based Caenorhabditis elegans model for assessing the virulence of clinical encapsulated multidrug-resistant Klebsiella pneumoniae isolates

Ayala Gancz1, Dorit Cohen-Eli1, Shiri Navon-Venezia1

1Ariel University, Department of Molecular Biology, Ariel, Israel

Background: MDR Klebsiella pneumoniae (Kpn) is an important pathogen responsible for life-threatening infections. There is an urgent need for a rapid in vivo model for virulence assessment of this pathogen. Caenorhabditis elegans nematode is a powerful model for studying host-pathogen interactions. The standard nematode killing assay (NKA) is an agar-based method performed with nematodes placed on a bacterial lawn and virulence is assessed by following nematode survival. This model is suitable for various pathogens but is inapplicable for highly mucoid encapsulated bacteria such as Kpn. We aimed to develop a high-throughput real-time nematode liquid-based killing assay (NLKA) that enables rapid virulence assessment of multiple MDR Kpn strains.

Materials/methods: NLKA experiments were performed in 96-multiwell plates with manual live/dead counting of nematodes [strain AL98] using an inverted-light microscope. Nematodes (L4 larvae) were inoculated (15-20 worms/well) into BM2 broth-containing wells (150µL) with the tested K. pneumoniae strain (~10^7 CFU/well). High throughput NLKA experiments were developed in 384-multiwell-plates (50µL medium) placed in an automated microscope imaging system (WiScan® Hermes, 7.5 min time-laps). Image analysis was performed using CellProfiler™. Escherichia coli strain OP50 was used as a non-virulent control strain. Survival curves and statistics were performed using Log-rank test (GraphPad-Prism).

Results: Agar-based NKA experiments are irrelevant for encapsulated Kpn strains. Therefore, NLKA experiments were carried out to enable a feasible nematode survival follow-up (Figure). Virulence assessment of eight ESBL-producing MDR Kpn strains on BM2 medium demonstrated their killing ability compared to E. coli OP50 (100% survival). LT50 values ranged from 4.75 to 6.0 hr ± 0.39 hr. An automated rapid NLKA experiment was developed and applied on KpnU95 UTI strain. Virulence was assessed on two growth media- BM2 and artificial urine. KpnU95 showed enhanced virulence when grown on artificial urine compared to BM2 (LT50 of 2.82 ± 0.25 hr and 3.37 ± 0.42 hr, respectively, p<0.05).

Conclusions: We present here a high-throughput real-time assay for comparative virulence assessment of highly encapsulated K. pneumoniae strains. This method allows the simultaneous screening of a high number of bacterial isolates and is highly valuable for comparative virulence assessment of mutants and host-pathogen in vivo studies of Klebsiella.

Abstract 6301

The impact of medical drugs on the acquisition of ESBL-producing Enterobacterales: a matched case-control study

Paula Klauke*, Frank Schwab1, Petra Gastmeier1, Friederike Maechler1

1Charité - Universitätsmedizin Berlin, Institute of Hygiene and Environmental Medicine, Berlin, Germany

Abstract third-party references: R-GNOSIS WP5 study group

Background: Little is known about the impact of non-antimicrobial agents on the selection of ESBL-producing Enterobacterales (ESBL-E). The aim of this study was to investigate medical drugs as potential risk factors for ESBL-E acquisition.

Materials/methods: We conducted a retrospective, exploratory, matched case-control study based on a larger trial in a 3000-bed University Hospital carried out between 2014 and 2016. Rectal surveillance cultures were obtained on admission and at least once before discharge to screen patients for ESBL-E carriage.

Patients with ward-acquired ESBL-E were matched one-to-one with Non-ESBL-E carriers. Matching was based on ward, number of rectal cultures, number of days at risk (ESBL-E free days), and Charlson Comorbidity Score (CCS). Medication prescription data were collected from paper charts and patient data management system and documented according to Anatomical Therapeutic Chemical Classification System (ATC). Multivariable conditional logistic regression was used to calculate independent risk factors for ESBL-E acquisition.

Results: In total, 232 cases and 232 controls from eight non-ICU wards were analyzed. Baseline characteristics such as patient age (median years 65; IQR 52-74), gender (Male 56.9%), number of samples (median 3; IQR 2-4), number of days from admission to first sample (median 2, IQR 1-2), number of days at risk (median 8; IQR 6-11), and CCS (median 4; IQR 2-6) were similar between cases and controls.

There was no difference between cases and controls with regard to the use of systemic antimicrobials, particularly fluoroquinolones (J01M) and third-generation cephalosporins (J01DD) in univariate analysis, all p>0.05.

Multivariable analysis showed that use of pantoprazole (proton pump inhibitor) and ipratropium bromide (anticholinergic agent) independently increased the chance to detect ESBL-E (OR 1.96; CI95% 1.19-3.23; P=0.047, and OR 16.36; CI95% 2.03-131.82; p<0.01, respectively), while bisacodyl (laxative) and citalopram (selective serotonine-reuptake inhibitor) decreased it (OR 0.13; CI95% 0.04-0.44; P<0.01, and OR 0.21; CI95% 0.06-0.75; P=0.026, respectively).

Conclusions: In a non-ICU-setting, medicinal agents other than antimicrobials were determined as independent risk factors for ESBL-E acquisition. Interestingly, substances with side effects favouring intestinal motility were determined as protective, while substances with constipating effects were risk factors. However, uncertainty was large as some drugs were prescribed to only few patients.

Abstract 6303

Paediatric invasive pneumococcal disease in Portugal: dominance of serotype 3 and increase in serotype 8 four years after PCV13 inclusion in the national immunization plan

Catarina Silva-Costa¹, Joana Gomes-Silva¹, Lucia Prados¹, Mario N. Ramirez*, José Melo-Cristino¹

¹Universidade de Lisboa, Faculdade de Medicina, Lisboa, Portugal

Abstract third-party references: Portuguese Study Group of Invasive Pneumococcal Disease of the Paediatric Infectious Disease Society, Portuguese Group for the Study of Streptococcal Infections

Background: In Portugal, vaccination with pneumococcal conjugate vaccines (PCVs) of infants in the private sector led to significant decreases in the incidence of pediatric invasive pneumococcal disease (pIPD). We aimed to determine serotype distribution and antimicrobial susceptibility patterns of pneumococci causing IPD between July 2015 (when PCV13 was introduced in the National Immunization Plan - NIP) and June 2019 to determine the impact of PCV13 on pIPD.

Materials/methods: A total of 196 Streptococcus pneumoniae isolates recovered from pIPD cases in 62 hospitals in Portugal between July 2015 and June 2019 were characterized by serotyping and antimicrobial susceptibility testing. In 96 cases with culture-negative CSF or pleural fluid samples, real-time PCR identified and serotyped S. pneumoniae.

Results: Most pIPD cases were caused by serotypes not included in PCV13 (55%, n=161), with serotypes 8 (n=19), 10A (n=20), 15B/C (n=13), 15A (n=11) and 33F (n=9) being the most frequent. Among PCV13 serotypes, serotype 3 was the most frequent overall (27%, n=78) followed by serotypes 14 (5%, n=15) and 19A (4%, n=12). Other PCV13 serotypes detected included 19F (n=8), 6B (n=6), 1 (n=5), 23F (n=4) and 18C (n=3), together accounting for 9% of the cases. Comparing with the period prior to the inclusion of PCV13 in the NIP, PCV serotypes 1 and 7F showed significant decreases, while the opposite was true for serotypes 3, 8 and 33F. Susceptibility to penicillin and erythromycin was found in 75% of the isolates, while 10% were simultaneously resistant to erythromycin and penicillin non-susceptible (MIC>0.06 mg/L). Overall, 12% of the isolates were penicillin non-susceptible and 18% were resistant to erythromycin, mostly associated with serotypes 1, 19F, 33F and 6B.

Conclusions: Despite universal vaccination with PCV13 for more than 4 years, serotype 3 is still the dominant serotype in pIPD while other PCV13 serotypes decreased significantly, suggesting that vaccination is not equally effective against all serotypes. Furthermore, the increase of serotypes not included in PCV13 such as serotypes 8, 33F and, to a lesser extent, 10A and serogroup 15 is of concern because NVTs may begin to erode the benefits of vaccination.

3 Division of Infectious Diseases, Department of Internal Medicine, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan,
4 Division of Infectious Diseases, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan,
5 Division of Infectious Diseases, Department of Internal Medicine, Chang Gung Memorial Hospital Kaohsiung Branch, Chang Gung University College of Medicine, Kaohsiung, Taiwan

Background: Trichosporon species is an emergent opportunistic pathogen that might cause life-threatening invasive infections, and exhibit an intrinsic resistance to echinocandins. Very little is known regarding whether epidemiology, clinical characteristics and therapeutic management differences are associated with the clinical outcomes of Trichosporon fungaemia. The aim of this study was to determine the Trichosporon species distribution, genotypes, antifungal susceptibilities, and predictors of clinical outcomes of Trichosporon fungaemia.

Materials/methods: This was a multicenter, retrospective study enrolled patients with a positive culture for Trichosporon species between January 2010 to December 2018 identified from records of the microbiology laboratory at four medical centers in Taiwan. Isolates were identified to the species level by sequence analysis of the ribosomal DNA ITS region and IGS1 region. In vitro susceptibility against antifungal agents were determined by the Sensititre YeastOne panel.

Results: Among the enrolled 117 isolates, blood cultures (n=53) were the majority. Trichosporon asahii was the most frequently isolated species (72.6%), followed by T. dermatis, T. montevideense, and T. faecales. Of the 85 T. asahii isolates, genotype 1 was the most predominant (41.2%). Generally, T. asahii isolates had higher MIC geometric means value than non-asahii Trichosporon isolates. New azoles had good in vitro activity, and voriconazole was the most potent. After excluding 11 patients from fungemia analysis (2 with incomplete data, and 9 who died within the first 48 hours), the overall 14-day mortality was 54.8%. Kaplan-Meier plot revealed that patients with voriconazole treatment had a significantly better survival rate compared with those who did not (p=0.036). Compared with those without antifungal treatment, voriconazole was associated with better 14-day survival rate in cox regression model (odds ratio: 0.29, 95% confidence interval: 0.10-0.84, p = 0.22). In the multivariate analysis, SOFA score, septic shock, source control and voriconazole use were independent predictors of 14-day mortality.

Conclusions: Our study demonstrated that Trichosporon asahii was the most frequently isolated species, and the most predominant genotype of T. asahii is genotype 1. Among patients with Trichosporon fungaemia, T. asahii remains the main isolates. Voriconazole use is the optimal choice and predicts the positive outcome of 14-day mortality.

Abstract 6305

Clinical and bacterial characteristics of paediatric invasive infections caused by Streptococcus pyogenes

Catarina Gouveia1, Luís Varandas1, Mario N. Ramirez*,2, José Melo-Cristino2, Ana Friães2

1Infectious Diseases Unit, Área da Mulher, Criança e Adolescente, Hospital de Dona Estefânia, CHULC - EPE, Lisbon, Portugal, 2Instituto de Microbiologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: In industrialized countries, Streptococcus pyogenes (Group A Streptococcus, GAS) is mostly associated with pediatric tonsillopharyngitis, but it may also cause severe invasive disease (iGAS), especially among infants and the elderly. This study aimed at performing a clinical, epidemiological and molecular characterization of pediatric iGAS in Portugal.

Materials/methods: During 2014-2018, the pediatric departments and microbiology laboratories of 36 hospitals throughout Portugal were asked to report all pediatric (<18 years) cases of iGAS and to submit the corresponding isolates. Relevant demographic and clinical data were recorded. The emm type and the presence of 11 superantigen (SAg) genes was determined for all available isolates.

Results: We identified 129 children with iGAS, with an average annual incidence of 1.45/100,000 (3.97/100,000 in patients <4 years old), 56% males, and a median age of 3 years (range 2 days-15 years). Clinical information was available for 118 cases. The most frequent diagnosis was bacteremia without focus (38%), osteoarticular infection (21%), skin/soft tissue infection (20%), and pneumonia (14%). STSS occurred in 13% of the patients. The case-fatality ratio was 5% (20% among STSS patients, p=0.027). Risk factors for mortality were diarrhea (p=0.042), higher cardiac rate at presentation (p=0.027), and STSS (p=0.040). Ninety non-duplicate isolates were available for molecular characterization, comprising 10 emm clusters, 14 emm types and 23 SAg profiles. Three emm types accounted for 66% of the isolates, namely emm1 (37%), emm3 (19%), and emm6 (10%). There were no significant associations between individual emm types or clusters and STSS or mortality.

Conclusions: The incidence of pediatric iGAS determined herein is lower than that reported in other European countries, but with a higher associated mortality. The most frequent lineages in this study are among the leading lineages causing iGAS in the general population in Portugal up to 2015, but with a higher prevalence of emm1 and emm3. The second most common emm type among all iGAS in 2010-2015 (emm89), accounted for only 3% of the pediatric isolates. Further studies are necessary to evaluate if these lineages have a different ability to cause iGAS in children and adults, or if their prevalence changed among all iGAS since 2016.

Global multi-centre prospective observational cohort of sepsis in hospitalised neonates highlights complex case mix: the NeoOBS Study

Aislinn Cook*

1St George’s, University of London, Paediatric Infectious Diseases Research Group, London, United Kingdom

Abstract third-party references: on behalf of the NeoOBS study team

Background: Nearly half of global deaths in children under 5 years occur in neonates and sepsis is a major cause of neonatal mortality. Antimicrobial resistance is a significant challenge to reducing neonatal mortality. Understanding patient characteristics and current neonatal sepsis management in areas where the WHO recommended first-line ampicillin+gentamicin is not used due to resistance is key to designing future clinical trials of antibiotic regimens.

Materials/methods: A prospective longitudinal observation cohort study of infants with significant sepsis has been recruiting at 19 predominantly tertiary hospitals in 11 countries [5 WHO regions] since August 2018. Infants <60 days presenting with clinical sepsis, defined as the presence of at least two clinical or one clinical and one laboratory predefined signs are eligible. Daily clinical and antimicrobial data, as well as all routinely obtained laboratory and microbiology data, are collected for up to 28 days while the neonate is hospitalised and receiving antimicrobial treatment. Outcome data on day 28 is collected. Recruitment target is 2500-3000 babies. Here we describe patient characteristics of neonates with sepsis at global tertiary hospitals.

Results: 1853 neonates from 18/19 site included in this analysis; 57% [1047/1839] are male. The median postnatal age at enrolment is 6 days [IQR:2-15]. 46% [854/1841] of neonates are inborn and 54% [987/1841] are admitted from elsewhere (e.g. other hospital or community). The median gestational age is 36 weeks [IQR:30-39 weeks] and birth weight is 2272 grams [IQR:1295–3044 grams]. 51% [936/1837] of neonates were delivered by spontaneous vaginal birth and 46% [850/1837] were born via caesarean. Neonates with sepsis had a wide range of admission diagnoses including respiratory distress [56%, 1038/1853], prematurity [45%, 833/1853], low birth weight [41%, 757/1853] and infection [40%, 733/1853]. 8% [138/1808] have a congenital anomaly, of which heart [28%, 39/138] and gastrointestinal [23%, 31/138] are the most common systems affected. Comorbidities are summarised in table 1.

Conclusions: To our knowledge, this is the largest study of hospitalised neonates with sepsis to date. Hospitalised neonates with sepsis have a wide range of comorbidities at diagnosis. Future antimicrobial clinical trials will need to account for the variation and complexity of these patients.

Abstract 6308

Optimised standard of care for Ebola virus disease patients in eastern Congo: a mandatory effort associated with specific therapies

1INSERM 1219, Bordeaux, France, 2ALIMA, Paris, France, 3ALIMA, Kinshasa, Democratic Republic of Congo, 4University of Bordeaux, Bordeaux, France

Abstract third-party references: INSERM, ALIMA

Background: The current Ebola outbreak in Democratic Republic of the Congo (DRC) has been reported since August 2018. The lethality rate for hospitalized patients remains high despite increasing access to vaccines, innovative treatments and patient management. We have been running the EVISTA cohort (Ebola Virus STAndard of care) on three Ebola Treatment Center (ETC) in eastern DRC.

Materials/methods: All patients admitted into participating sites with a positive Ebola RT-PCR were included in the study providing informed consent. Clinical and biological data, as well as information regarding supportive care were collected through medical records prospectively when possible, otherwise retrospectively.

Results: 835 Ebola confirmed patients were included, which represent almost one third of the total amount of cases diagnosed during this outbreak. All of them received specific treatment through investigational therapeutic evaluation efforts. Median age was 28 years [IQR 18,40], 57% female. The overall mortality was 45%, 81% occurred during the first 5 days of hospitalization (cf fig. 1). The median hospitalization duration was 2 days [IQR 1, 5] when outcome was death, and 17 days [IQR 14, 21] when patients were discharged. Among the 63 children (≤ 5 years old) included, mortality was 52%. The 8% of pregnant women experienced a 50% mortality rate. On the 186/835 (22%) previously vaccinated patients, median delay between vaccination and positive RT-PCR was 8 days [IQR 5,12]. Mortality amongst vaccinated participants was 31%. Descriptors for standard of care and clinical and biological issues are generated.

Conclusions: Even with the development of specific treatment, lethality during this outbreak remains quite high. This feature highlights the paramount for optimizing standard of supportive care efforts, especially resuscitation procedures. In the cohort, several patients were managed with an optimized level for intensive care (e.g., oxygen, vasoactive drugs, point-of-care ultrasound and vital parameter monitoring), which might contribute to the overall decrease of mortality in our ETCs and in comparison with reports from West Africa outbreak. This effort needs to be evaluated for evolving decision-making procedures, insofar specific drugs and vaccine will not be the only support for saving more lives.

Role of the gut microbiota in the anastomotic leakage after colorectal surgery

Patricia Hernández1,2, Manuel Ponce-Alonso1,2, José Barquín1, Alejandra Caminoa-Lizarralde4, Elisa Conde1, Beatriz Romero1,2, Juan Carlos García-Pérez3, Rosa Del Campo1,2

1Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain, 2Hospital Universitario Ramón y Cajal. Servicio de Microbiología Clínica, Madrid, Spain, 3Hospital Universitario Ramón y Cajal. Servicio de Cirugía General y Digestivo, Madrid, Spain, 4Hospital Universitario Ramón y Cajal. Servicio de Anatomía Patológica, Madrid, Spain

Abstract third-party references: Supported by the Spanish Network for Research in Infectious Diseases (REIPI) and Instituto de Salud Carlos III.

Background: Colorectal cancer is one of the most frequent oncologic processes with an incidence of 1.8 million new cases every year. Despite surgery is the selective treatment, it presents serious complications such as anastomotic leakage that leads to septic shock, multiple organ failure, and death. Factors that could predict this complication has not yet been described, however, several recently studies suggest that gut microbiota may be involved.

Materials/methods: A total of 108 patients diagnosed of colorectal cancer give their informed consent and contributed each one with a fecal sample and biopsies (proximal and distal tissue of the tumor) after surgical resection. Bacterial composition was determined by PCR amplification and sequencing of the V3-V4 region (16S rDNA) using a MiSeq platform (Illumina). Bioinformatics was performed using QIIME2. Differential abundance was assessed by LEfSe. The indexes for calculating the Alpha-diversity were Chao1, Shannon and Faith-phylogeny, while, for Beta-diversity were Bray-Curtis and UniFrac distances.

Results: Only 10 out of the 108 patients developed anastomotic leakage (10.8%). Microbiota analysis showed no statistical significance for Alpha-diversity in any of the samples, showing that gut microbiota near the tumor (both proximal and distal) and feces were equally diverse in patients with and without anastomotic leakage. Regarding Beta-diversity, Bray-Curtis index showed a statistical significance in the proximal (p=0.033) and distal (p=0.016) tissue between patients with and without anastomotic leakage. However, when phylogenetic distances were taken into account by Weighted and Unweighted UniFrac, no significant differences were found. LEfSE analysis (Figure 1) decipher that in proximal tissue there was an increase of Enterobacteriaceae in patients with anastomotic leakage. In distal tissue samples, also an Enterobacteriaceae enrichment was linked to anastomotic leakage, whereas Bifidobacterium and Faecalibacterium seems to protect from developing this complication. Microbiota from feces only showed an increase of Firmicutes in patients with no anastomotic leakage.

Conclusions: A particular microbiota profile, and probably the expression of particular virulence factors, may be related to the development of anastomotic leakage more in concrete with the presence of Enterobacteriaceae. Additionally, Bifidobacterium and Faecalibacterium may have a protective character probably related to their metabolism and the production of short chain fatty acids.

Microbiological Point-of-Care analysis of endotracheal aspirate from intubated patients admitted to the intensive care unit

Dorthe Ørsnes Christensen*1,2, Dår Kristian Kur3, Jeppe Brandt1,2, Mathias Hindborg1,2, Christian Dalby Sørensen1, Mette Kolpen4, Claus Jensen1, Frederik B. Hertz5, Jette Bangsborg5, Morten H. Bestle1,2

1Northzealands Hospital - Hillerød, Dept. of Anaesthesiology and Intensive Care, Hillerød, Denmark, 2Copenhagen University, Dept. of Clinical Medicine, København, Denmark, 3Northzealnds Hospital - Hillerød, Dept. of Clinical Biochemistry, Hillerød, Denmark, 4Rigshospitalet, Dept. of Clinical Microbiology, København, Denmark, 5Herlev Hospital, Dept. of Clinical Microbiology, Herlev, Denmark

Background: The paraclinical diagnosis of lower respiratory tract infection (LRTI) still relies heavily on culturing of respiratory tract samples, which are quite insensitive, hence resulting in false negative response. There is a growing market for commercially available multiplex polymerase chain reaction (PCR) assays promising fast turnaround time (TAT) and high sensitivity towards a variety of common pathogens, which may improve antibiotic stewardship. The purpose of this study was to assess the applicability of the FILMARRAY® Pneumonia Panel Plus (PP) in the clinical setting of an Intensive Care Unit (ICU).

Materials/methods: Tests were performed on undiluted specimens from mechanically ventilated patients at the ICU on the first day of intubation. The FILMARRAY® Pneumonia Panel Plus was used to test 76 endotracheal aspirate samples frozen in a biobank. Comparison with pathogen detection using conventional microbiological methods (CMM) was performed, and concordance rates between methods was assessed taking into account incomplete investigation by conventional methods. Evaluation on the usage of antibiotics was done retrospectively by a clinical microbiologist and an Intensive Care physician assessing a potential change in treatment based on FILMARRAY® results and patient status.

Results: In 42 (55.3%) samples PP and CMM are in full concordance. Additional findings by CMM were seen in 2 (2.6%) samples. Additional findings by PP were seen in 31 (40.7%) samples. Complete discrepancy between methods were seen in 1 (1.3%) sample. In 2 samples, PP detected methicillin resistant Staphylococcus Aureus, even though CMM showed methicillin sensitive Staphylococcus Aureus. By CMM, extended virus panel TAT was a median of 111.28h. TAT for culture and susceptibility a median 52.82h. PCR for atypical 40.04h. PP TAT was estimated 2h, making de-escalation possible in 35 (46.1%) patients, among these discontinuation of macrolide would have been possible in 24 (31.6%).

Conclusions: The FILMARRAY® Pneumonia Panel Plus may offer valuable information, however it detected several additional pathogens compared to conventional microbiological methods and the interpretation of results appears difficult in terms of disease causality and antibiotic resistance. The biggest impact may be on fast-delivered negative results, which resonated in the possible discontinuation of macrolide. Even though our study showed potential for the FILMARRAY® Pneumonia Panel Plus, further investigations on clinical effect should be performed prospectively.

Abstract 6312

**Do bacterial growth conditions affect antibiotic resistance evolution?**

Jenny Littler*, Freya Harrison

1University of Warwick, Coventry, United Kingdom

**Background:** It is well known that sub-inhibitory levels of antibiotics are a selector for antibiotic resistance genes in bacterial species. However, it is unclear whether varying levels of sub-inhibitory concentrations have an effect on natural selection for resistance mutations. Different strengths of selection pressure could lead to a different spectrum of resistance mutants arising, with different effects on bacterial fitness [benefits and costs of the mutations]. This will affect how the bacterial population evolves during exposure to antibiotics, and when the antibiotic is removed. The effect of the growth medium on the resistance rate and costs and benefits is also not well established. These could also be very different in different environments. *In vitro* tests are regularly performed in standard laboratory media; however, it is unclear whether resistance rates would vary in a more clinically realistic model. We hypothesize that evolution in standard lab media such as Mueller Hinton Broth may lead to different resistance levels when compared with bacteria evolved in artificial cystic fibrosis sputum.

**Materials/methods:** We grew two species of pathogenic bacteria which infect the lungs of people with CF, in the presence of colistin in either Mueller Hinton broth or artificial sputum [ASM]. First, we assessed if there was a difference in the minimum inhibitory concentrations [MICs] between the different media used. Following this, the clinical isolates were evolved in the various media with increasing concentrations of antibiotic.

**Results:** Evolution in both MHB and ASM led to increases in MIC. Although isolates evolved in ASM survived at higher concentrations of antibiotic than those grown in MHB, the MIC for MHB was double that for ASM.

**Conclusions:** The data suggests that the growth conditions can have an effect on the resistance phenotype and potentially genotype of bacteria. Further tests will assess the effects of phenotypic tolerance and evolved, genetic resistance. Whole genome sequencing will be used to assess whether there are any differences in the mutations formed from the bacterial growth conditions.

**Abstract 6313**

**A prolonged incubation time is not needed for cultures obtained from acute periprosthetic joint infections**

Ditmer Tjitze Talsma*, Joris Ploegmakers, Paul Jutte, Greetje Kampinga, Marjan Wouthuyzen-Bakker

1University of Groningen, University Medical Center Groningen, Groningen, Netherlands

**Background:** A prolonged incubation time (i.e. 10-14 days) is generally recommended for diagnosing periprosthetic joint infections (PJIs). However, in literature, no distinction is made between acute and chronic infections. In this study we investigated whether time to positivity differs between acute and chronic PJIs.

**Materials/methods:** All patients that underwent surgical debridement or revision of the prosthesis between November 2015 and February 2019 were retrospectively evaluated. Synovial fluid and an average of 5 periprosthetic tissue samples were obtained during surgery and the prosthetic implant and/or mobile components were sent for sonication. Sonication fluid and synovial fluid was incubated in blood culture bottles, while tissue cultures were directly incubated on culture plates and in fastingidious broth. All cultures were incubated for 9-14 days. Acute and chronic PJIs was diagnosed according to the criteria proposed by the Musculoskeletal Infection Society (MSIS).

**Results:** A total of 62 patients were analyzed, including 21 with an acute PJI (incl. 36 isolates) and 41 with a chronic PJI (incl. 52 isolates). In acute PJIs, all isolates grew within 4 days [Figure 1A], while this took 11 days for chronic PJIs [Figure 1B]. *Staphylococcus aureus*, Gram negative rods, enterococci and streptococci all grew within 2 days, while *Cutibacterium acnes*, Gram positive rods and coagulase negative staphylococci grew within 9 days. Sonication fluid incubated in blood culture bottles showed the highest culture yield and shortest time to positivity for chronic PJIs, but no difference was observed for acute PJIs [Figure 1C-D].

**Conclusions:** In contrast to cultures from chronic PJIs, acute PJIs do not need a prolonged incubation time and no clear time to positivity benefit is observed for sonication in this patient category. These results need to be confirmed in a larger cohort of patients.

Genomic investigation of *Klebsiella pneumoniae* complex isolates recovered from pigs and humans in Thailand

Thongpan Leangapichart1, Kamonwan Lunha2, Jatesada Jiwakanon3, Sunpetch Angkititrakul1, Josef Järhult4, Ulf Magnussen2, Marianne Sunde1

1Norwegian Veterinary Institute, Section for Food Safety and Antimicrobial resistance, Oslo, Norway, 2Swedish University of Agricultural Sciences, Department of Clinical Sciences, Uppsala, Sweden, 3Khon Kaen University, Research Group Preventive Technology Livestock, Khon Kaen, Thailand, 4Uppsala University, Section for Infectious Diseases, Uppsala, Sweden

**Background:** *Klebsiella pneumoniae* complex members are common bacteria living in animal and human guts and in natural environments. Antibiotic-resistant *Klebsiella* species and hypervirulent *Klebsiella* species have been reported as the causative agent of human infections worldwide. Here, we report on the characterization of *K. pneumoniae* complex isolates from healthy pigs and humans in Thailand based on their antibiotic resistance, virulence, and genetic relatedness.

**Materials/methods:** *K. pneumoniae* complex species were isolated from rectal swabs of pigs (97-pooled samples) and human feces (134 humans) from 97 farms in Thailand by plating out on SCAI agar. Antibiotic susceptibility testing using disc diffusion (EUCAST) and Illumina whole-genome sequencing (WGS) were performed. Antibiotic resistance genes, virulence genes, and plasmids were extracted from WGS data. Genomic typing was assessed and compared with public core genome multi locus sequence typing (cgMLST) schemes.

**Results:** Among the 231 *K. pneumoniae* complex isolates, two mcr positive strains (ST290/mcr-1 and ST761-1LV/mcr-8) and one ESBL-producing strain (ST500/blaCTX-M-3) were isolated from pigs. MLSTs of our 231 strains showed high genetic diversity, comprising 175 different STs and 89 K-loci. However, some STs were shared between pigs and humans. ST111-2LV the most prevalent ST was found from both hosts suggesting the possibility of transmission between pigs and humans living in the same district area.

**Conclusions:** Our data demonstrate high genetic diversity and low level of ESBL and colistin resistance among *K. pneumoniae* complex isolates from pigs and humans in Thailand. ST111-2LV was found in both hosts in the same district area indicating zoonotic transmission of this particular ST.

Clinical evaluation of FASTinov kits for ultra-rapid antimicrobial susceptibility testing directly from positive blood cultures

Ana Silva-Dias\(^1\), Blanca Pérez-Viso\(^2\), Rosário Gomes\(^3\), Inês Martins-Oliveira\(^1\), Acácio Gonçalves Rodrigues\(^1\), Rafael Canton Moreno\(^2\), Cidália Pina-Vaz*\(^{1,3}\)

\(^1\)FASTinov, SA., Porto, Portugal, \(^2\)Hospital Universitario Ramón y Cajal, Instituto Ramón y Cajal de Investigación Sanitaria (IRY-CIS), Servicio de Microbiología, Madrid, Spain, \(^3\)Faculty of Medicine, University of Porto, Division of Microbiology, Department of Pathology, Porto, Portugal

Abstract third-party references: This project received funding from the H2020 FTI pilot 2016, project number 730713 "FAST-bact". A novel fast and automated test for antibiotic susceptibility testing for Gram positive and Gram negative bacteria.

Background: Bloodstream infections (BSI) remain a major public health concern with high rates of morbidity and mortality. Antimicrobial susceptibility testing (AST) of microorganisms causing BSIs is crucial for optimal antimicrobial therapy. Current conventional methods require sub-culture of positive blood cultures (BCs) to begin AST, taking nearly 2 days for definitive results. New approaches can reduce time-to-result avoiding this sub-culture but are still growth-based taking at least 6 hours to report. The objective of this work was to evaluate the clinical performance of the Fastinov\(^\circ\) kits (Porto, Portugal), an ultra-rapid AST assay performed directly on positive BCs, based on flow cytometry analysis.

Materials/methods: An internal validation was performed using spiked BC with bacteria with well-characterized resistance phenotypes. Two kits were evaluated, one for Gram-negative (Enterobacterales, Pseudomonas and Acinetobacter) and another for Gram positive (Staphylococcus and Enterococcus) organisms by testing primary drugs used to treat sepsis. In parallel a proof-of-concept in an external clinical environment was performed at Ramon y Cajal hospital in Madrid (Spain), using patients’ BC. A total of 480 positive BC (257 Gram-negative and 223 Gram-positive bacteria) were included with 98 patient samples (64 Gram-negative and 34 Gram-positive). After extracting microorganisms from positive BC, bacteria were incubated for 1 hour at 37ºC with antibiotics together with fluorescent probes followed by flow cytometric analysis with CytoFLEX (Beckman Coulter) platforms. Both CLSI and EUCAST criteria were followed and a dedicated software used to produce a report. The obtained phenotype, as well as ESBL detection and screening for the presence of AmpC and carbapenemases, were compared with reference methods and categorical agreement (CA), quantification and classification of errors determined.

Results: The overall CA for the FASTgramneg panel was 95.9% and 95.6% respectively for EUCAST and CLSI. The FASTgrampos panel CA was 98.4% and 98.2% respectively for EUCAST and CLSI. A maximum of 2/266 very major errors was found for FASTgrampos and 8/872 errors for FASTgramneg, mainly due to beta-lactam-beta-lactamase inhibitors combination.

Conclusions: FASTinov\(^\circ\) kits represent an alternative for direct ultra-rapid AST of Gram-negative and Gram-positive bacteria in bloodstream infections showing time-to-result <2 hours versus nearly 2 days with current methodology.

Abstract 6320

**An updated analysis of the burden of fungal diseases in Uganda**

Felix Bongomin¹, Bruce Kirenga¹, Richard Kwizera², David Meya², David W. Denning³

¹Gulu University School of Medicine, Gulu, Uganda, ²Makerere University, Kampala, Uganda, ³The University of Manchester, Manchester, United Kingdom

**Background:** It is of utmost importance to monitor any change in the epidemiology of fungal diseases that may arise from a change in the number of the at-risk population or availability of local data. We sought to re-evaluate the incidence and prevalence of major fungal diseases in Uganda.

**Materials/methods:** Using the Leading International Fungal Education methodology, we reviewed published data on fungal diseases and drivers of fungal diseases in Uganda. Regional or global data were used where there is no Ugandan data.

**Results:** With a population of ~45 million, overall we estimate annual burden of severe fungal diseases at 981,680 cases (2.2% of the population), excluding cases of tinea capitis. Estimates for the annual incidence of HIV-related life-threatening fungal disease include cryptococcal meningitis (17,859 cases), Pneumocystis pneumonia (4,962 cases in adults and 2,888 cases in children), oral candidiasis (29,772), oesophageal candidiasis (79,924 cases), and invasive pulmonary aspergillosis (920 cases). We estimate 656,340 cases of recurrent vulvovaginal candidiasis and 6,084 cases of fungal keratitis annually. The overall prevalence of post-tuberculosis chronic pulmonary aspergillosis is 8,905 cases (annual incidence of 1,291 cases) and the burden of fungal asthma at 171,863 cases (allergic bronchopulmonary aspergillosis, 74,079 cases and severe asthma with fungal sensitisation, 97,784 cases). Candida peritonitis and candidaemia are estimated at the rate of 0.8/100,000 (343 annual incidence) and 5/100,000 (2,287 annual incidence), respectively. The neglected tropical fungal disease mycetoma is uncommon with an annual incidence rate of 0.3/100,000 (79 cases annually).

**Conclusions:** Fungal diseases affect a significant proportion of Ugandans every year. Tuberculosis and HIV remains the most important predisposition to fungal disease in this population. The burden of fungal diseases in Uganda has remained stable for the past five years, calling for accelerated preventive, diagnostic and therapeutic interventions for the management of these diseases.

Investigation of skin microbiota reveals Mycobacterium ulcerans-Aspergillus sp. trans-kingdom communication

Nassim Hammoudi1*, Cassagne Carole2, Matthieu Million1, Stephane Ranque3, Michel Drancourt2, Odilon Kabore1, Dezemon Zingue1,3, Amar Bouam2

1Aix Marseille Univ., IRD, MEPHI, IHU Méditerranée Infection, Marseille, France, IHU Méditerranée Infection, Marseille, France,
2Aix Marseille Univ., IRD, AP-HM, SSA, VITROME, IHU Méditerranée Infection, Marseille, France,
3Centre Muraz, Bobo-Dioulasso, Burkina Faso

Background: Mycobacterium ulcerans secretes a series of non-ribosomal-encoded toxins known as mycolactones that are responsible for causing a disabling ulceration of the skin and subcutaneous tissues named Buruli ulcer. The disease is the sole non-contagious mycobacteriosis among the three most common mycobacterial diseases in humans. Direct contact with contaminated wetlands is a risk factor for Buruli ulcer, responsible for M. ulcerans skin carriage before transcutaneous inoculation with this opportunistic pathogen.

Materials/methods: Initially, we used molecular biology to study the possibility of asymptomatic skin carrying of M. ulcerans in farmers in Burkina Faso using two IS2404 IS2606 insertion sequences and the Kr-b genes specific to M. ulcerans. In a second step, we analysed the bacterial and fungal skin microbiota in individuals exposed to M. ulcerans in Burkina Faso. Then, we cultured the skin microbiota of asymptomatic M. ulcerans carriers and negative control individuals, all living in the region of Sindou.

Results: We showed that M. ulcerans-specific DNA sequences were detected on the unbreached skin of 6/52 (11.5%) asymptomatic farmers living in Sindou versus 0/52 (0%) of those living in the non-endemic region of Tenkodogo. A total of 84 different bacterial and fungal species were isolated, 21 from M. ulcerans-negative skin samples, 31 from M. ulcerans-positive samples and 32 from both. More specifically, Actinobacteria, Aspergillus niger and Aspergillus flavus were significantly associated with M. ulcerans skin carriage. We further observed that in vitro, mycolactones induced spore germination of A. flavus, attracting the fungal network.

Conclusions: These unprecedented observations suggest that interactions with fungi may modulate the outcome of M. ulcerans skin carriage, opening new venues to the understanding of Buruli ulcer pathology, prophylaxis and treatment of this still neglected tropical infection.

Abstract 6324

**Hepatic phaeohyphomycosis due to Pleurostoma hongkongensis, a novel species**

Ka-Fai Chan*1, Chi-Ching Tsang1, Jasper Chan1,2,3, Antonio Ngan1, Walton Chan1, Susanna K. P. Lau1,2,3, Patrick C. Y. Woo1,2,3

1Department of Microbiology, The University of Hong Kong, Pokfulam, Hong Kong, 2State Key Laboratory of Emerging Infectious Diseases, The University of Hong Kong, Pokfulam, Hong Kong, 3Collaborative Innovation Centre for Diagnosis and Treatment of Infectious Diseases, The University of Hong Kong, Pokfulam, Hong Kong

**Background:** The genus *Pleurostoma* houses Phialaphora-like fungi which possess a creamy white-to-pale yellow colony appearance with no diffusible pigment and produce small-to-large, subspherical-to-allantoid conidia at the phialide tips. These fungi are mainly found in soil, woody plants, and sewage. Within this genus, *P. repens*, *P. richardsiae*, and *P. ootheca* have been reported to cause phaeohyphomycosis in humans. In this study, we isolated a novel dematiaceous mould pathogen, HKU44T, from a 65-year-old Chinese male patient. Preliminary morphological analysis and ITS sequencing showed that this fungus belonged to the genus *Pleurostoma* but its exact species identity could not be ascertained.

**Materials/methods:** The clinical history of the patient was reviewed. The colony and microscopic morphologies of strain HKU44T was examined for its phenotypic characteristics. The ITS, 18S rDNA, 28S rDNA, and β-tubulin gene of HKU44T, along with an additional 28 strains of the species *P. richardsiae*, *P. ochraceum*, *P. repens*, and *P. ootheca* were amplified by conventional PCR and sequenced. The DNA sequences were then compared with each other by pairwise alignment and the phylogenetic relationship of HKU44T and other *Pleurostoma* species were inferred using the maximum likelihood method.

**Results:** Histological examination of the abscess wall biopsy collected from the patient showed numerous fungal hyphae. HKU44T, the mold recovered from the abscess sample, exhibited typical phenotypes shared by *Pleurostoma* species, including hyaline-to-pale brown colonies as well as branched, septate hyphae and subspherical, hyaline-to-brown conidia. Pairwise alignment of the ITS sequence of HKU44T and those of the type strains of *P. richardsiae*, *P. ochraceum*, *P. repens*, and *P. ootheca* showed 87.32%, 86.49%, 88.57%, and 88.87% similarities, respectively. Phylogenetic trees of all the four DNA markers showed that HKU44T is phylogenetically distinct from all four *Pleurostoma* species, although it is most closely related to *P. ootheca* and *P. repens*. The results suggested that HKU44T is a novel species of the genus *Pleurostoma*, which we propose to name it *Pleurostoma hongkongensis* sp. nov.

**Conclusions:** A novel fungal pathogen, *Pleurostoma hongkongensis*, was discovered from the subhepatic abscess of a liver failure patient in Hong Kong, and this fungus is capable of causing invasive phaeohyphomycosis.

Abstract 6326

**Evaluation of Genomera CDX system for influenza and respiratory syncytial virus infections**

Emeline Choquet¹, Céline Chessa¹, Manon Prat¹, Andy Larivières¹, Agnès Beby Defaux¹, Nicolas Lévêque¹, Maxime Pichon*¹

¹Poitiers University Hospital, Infectious Agents Department, Poitiers, France

**Background:** Performances comparison [Concordances (κ), sensitivity (Se), specificity (Sp)] of RT-qPCR assays detecting major viral respiratory pathogens on the GenomEra®CDX system, using the GenomEra® FluA/B+RSV assay (Influenzavirus (IAV/IBV), or Respiratory Syncytial virus (RSV)) to our standard of care process (Allplex Respiratory; Seegene).

**Materials/methods:** Prospective assays on fresh samples (n = 299; 116 nasal swabs (NS), 129 combined nasal and throat swabs (NTS) and 54 nasopharyngeal aspirates (NPA)) collected for 2018 - 2019 winter season, from patients hospitalized in the University Hospital of Poitiers, France. Samples with discrepant results were tested with a 3rd method: a real time PCR method (Rgene, Biomérieux®). Our referential consider concordance of ≥2 molecular testing specific for a specific viral target (including the result of the third method if needed). Inclusivity, cross-reactivity and reproducibility testing were associated to analyses on clinical samples.

**Results:** Performances could be obtained for each viral target (no IBV-positive sample during the epidemics). On NS, Se, Sp, and κ were: i) 100%, 95% and 0.89 for IAV; ii) undetermined, 97%, and undetermined for IBV; iii) 100%, 100%, and 0.91 for RSV. On NTS, performances were: i) 100%, 99% and 0.96 for IAV; ii) undetermined, 98% and undetermined for IBV; iii) 95%, 100% and 0.92 for RSV. On NPA performances were: i) 86%, 100% and 0.91 for IAV; ii) undetermined, 100% and undetermined for IBV; iii) 97%, 100% and 0.92 for RSV.

**Conclusions:** With 1 false negative and 5 false positive (including one IBV) results, performances for Influenza detection are very good but remain perfectible. With 1 false negative result, performances for RSV detection are very impressive.

Abstract 6327

Cutaneous lesions due to *Staphylococcus aureus* in inflammatory bowel disease patients undergoing anti-TNFα treatment: molecular characteristics and strains comparison in different niches

Somar Hoche¹, Catherine Dunyach-Remy², Emily Schowb³, Olivier Dereure¹, Romain Altwegg⁴, Aurélie Du-Thanh³, Jean Philippe Lavigne⁵

¹University Hospital Nîmes, Department of Microbiology, Nîmes, France, ²University Hospital Nîmes, Department of Microbiology, INSERM, U1047, Nîmes, France, ³Department of Dermatology, University Hospital Saint Eloi, Montpellier, France, ⁴Department of Gastroenterology, University Hospital Saint Eloi, Montpellier, France

**Background:** *Staphylococcus aureus* is a common inhabitant of the skin microflora and colonizes the nares and other human mucosa. This is also an opportunistic bacterium capable of causing a wide range of severe diseases when it gains access to underlying tissues. Among patients with inflammatory bowel disease (IBD), those treated with anti-TNFα therapy present frequently particular cutaneous lesions associating nasal and retroauricular fissures, alopecia and the presence of *S. aureus*. The aim of this study was to describe the molecular characteristics of *S. aureus* isolated from these skin lesions and at different body sites (anterior nares, post-auricular, umbilical and axillary, anal throat and mouth) in this population.

**Materials/methods:** IBD patients undergoing anti-TNFα therapy and presenting cutaneous lesions were included between January 2018 and June 2019 in Department of Dermatology in Montpellier University Hospital (France). “Control” patients with IBD treated with anti-TNFα therapy, but without any cutaneous wound were also included. A screening of *S. aureus* in the lesions and in different mucosa niches was performed. After identification by Maldi-tof (Vitek MS⁶), all the isolates were analyzed using DNA micro-arrays (Clondiag⁷) and MLST (https://pubmlst.org).

**Results:** Twenty-two IBD patients with cutaneous lesion and 42 controls were included. The IBD patients with lesions harbored a significantly higher *S. aureus* colonization rate (15, 68.2%) vs controls (10, 23.8%) (p<0.001). Among these patients, 13 had positive *S. aureus* cultures in cutaneous lesions samples (59.1%), with 12 co-colonized in anterior nares (92.3%). Eighteen isolates, including different morphotypes, were definitively collected. All of them were methicillin-sensitive and belonged to 9 different clonal complexes (CC), with a predominance of STS-MSSA (50%). Eleven out of 13 patients (84.6%) had similar clones in lesion and at least one niche (mainly the anterior nares).

**Conclusions:** The role of *S. aureus* nasal colonization in IBD patients with anti-TNFα medication seems particularly important in the development of cutaneous lesions. Screening of this nasal carriage before treatment could be considered.

Latent tuberculosis infection among household contacts of pulmonary tuberculosis cases in Nairobi, Kenya

Susan Akinyi Odera*, Marianne Mureithi1, Omu Anzala1, Julius Oyugi1

1University of Nairobi, Nairobi, Kenya

Background: Tuberculosis (TB) is a major health problem in sub-Saharan Africa and other developing countries including Kenya, which is ranked among the top 30 countries with the highest burden TB. Household Contacts (HHCs) of Pulmonary Tuberculosis (PTB) patients have a higher risk of LTBI. However, its prevalence and risk factors among adults living with PTB patients are poorly documented in Kenya.

Materials/methods: An analytical cross-sectional study was conducted to establish the prevalence and risk factors of LTBI in a cohort of adult HHCs of active PTB patients who were seeking health care services in a per-urban public district hospital in the Kenyan capital, Nairobi. Informed consent was obtained. A structured questionnaire was used to capture socio-demographic data of the study participants and thereafter 3 blood samples collected by venipuncture from each HHCs directly into the blood collection tubes provided in the QuantiFERON®-TB Gold In-Tube kit (QFT-GIT) for Interferon-gamma release assays (IGRAs).

Results: A total of 166 PTB patients yielded 175 adult HHCs of whom 29.7% (52/125) were males and 70.3% (123/125) were females. A majority of HHCs (65.7% [115/175]) lived in a single-room house with the patient and (37.7% [66/175]) were in the age group 30-39-years. The overall prevalence of LTBI was 55.7%, peaking among spouses of the patients (70.0% [14/20]) and the 30-39 year age group (63.5% [42/66]). Potential risk factors for LTBI included cohabiting with a TB patient for 8 to 12 weeks [OR= 3.6 (0.70-18.5), p=0.107], being a spouse of the patient [OR=2.0 (0.72-5.47), p=0.173] and sharing a single room with the patient [OR=1.58 (0.84-2.97), p=0.158].

Conclusions: There is an increasing awareness of the problem LTBI poses to HHCs of PTB patients. In Kenya, however, data on LTBI is mainly anecdotal, which hinders its active management. Overall, it was evident that LTBI is a common yet neglected problem for HHCs, with factors such as age, relation to TB patients, and the length of time spent cohabiting with or caring for TB patients leading to repeated exposure and thus the risk of developing LTBI. The findings demonstrate the need for targeted contact-screening programs in high TB transmission settings.

Abstract 6332

Integrated diagnosis by metagenomic and host transcriptomic of pulmonary infection in solid organ transplant patients

Louise Castain*1,2, Guillaume Gricourt3, Demontant Vanessa1, Audrey Rodallec1, Céline Bressollette-Bodin1,2, Berthe-Marie Imbert-Marcille1,2, Christophe Rodriguez3,4

1University of Nantes, Transplantation and Immunology Research Center (UMR1064); ITUN, INSERM, Nantes, France, 2Nantes University Hospital Hotel-Dieu, Virology Dpt., Nantes, France, 3Hôpital Henri-Mondor Ap-Hp, Platform NGS, IMRB, INSERM U955, Créteil, France, 4Hôpital Henri-Mondor Ap-Hp, Microbiology Dpt, Créteil, France

Background: Pulmonary infection is a common complication after solid organ transplantation but diagnosis can be difficult because symptoms may be attenuated and the presence of microorganisms is sometimes difficult to interpret (infection, commensalism…). In this context, developing host-based exploration assays associated to broad spectrum micro-organisms detection methods may help to better understand, manage and treat infection/disease. Our aim is to evaluate a combined approach which allows both infection diagnosis by metagenomic and host transcriptomic profile determination in the same single assay in solid organ transplant (SOT) patients.

Materials/methods: Bronchoalveolar lavages were collected from 13 patients (12 lung and 1 heart transplant patients). Conventional bacterial and virological diagnostic methods were performed according to the standard recommendations. In parallel, accredited routine metagenomic next-generation sequencing MetaMIC (mNGS) was used and combined a DNA/RNA extraction protocol adapted for all types of pathogens and human, DNA/RNA libraries preparation with Nextera XT and Stranded Total RNA (Illumina), and sequencing on NextSeq500 (Illumina). Metagenomic and transcriptomic data were analysed using a dedicated software (MetaMIC). The first gave a final automatic report of presence of micro-organisms while the second provided a transcriptome profiling identifying over/underexpressed genes in different patients.

Results: Among the patients, 9/13 were considered infected by at least one micro-organism. Conventional microbiology and mNGS were fully concordant in 9 cases (4 negative and 5 positive) and partially discordant in 4 cases (2 Streptococcus pneumoniae found only by mNGS and 2 low viral load CMV found only by PCR). Transcriptomic analysis revealed a different host transcriptional signature in infected vs uninfected patients and between CMV DNA positive and CMV DNA negative patients. Ontology analysis with over/under expressed genes in infected patients revealed activated immunity pathways.

Conclusions: The mNGS technique has demonstrated its ability to explore both hosts and pathogens in a single analysis. Thus, it offers an unprecedented opportunity to explore the host-pathogen relationship, to better understand the physiopathology of infections, while allowing the detection of microorganisms. Integrating unbiased pathogen detection and host transcriptomic may be a promising alternative to pathogen-based diagnostics, in order to understand and manage infectious complications in SOT patients.

**Effectiveness and cost-effectiveness of antimicrobial stewardship programmes in French acute care hospitals**

Anne Perozziello*\(^1\), Xavier Lescure\(^1,2\), Sylvie Deuffic-Burban\(^1\), Lidia Kardas-Sloma\(^1\), Liem Binh Luong Nguyen\(^1\), Yazdan Yazdanpanah\(^1,3,4\), Jean-Christophe Lucet\(^3,4\)

\(^1\)INSERM, IAME UMR 113? - DeSCID team, Paris, France, \(^2\)Hôpital Bichat, Service des maladies infectieuses et tropicales, Paris, France, \(^3\)INSERM, IAME UMR 113? - DeSCID team, Paris, France, \(^4\)Hôpital Bichat, UHLIN, Paris, France

**Background:** Multidrug resistant (MDR) infections represent a growing burden for patients and healthcare system. Antimicrobial stewardship programs have been implemented to improve antibiotic use to prevent the expansion of MDR. The objective of this study was to assess the effectiveness and cost-effectiveness of different antimicrobial stewardship (AMS) strategies in a hospital setting.

**Materials/methods:** We used a decision tree incorporating a Markov model to simulate the trajectory of patients admitted to hospital for a urinary tract infection. We evaluated three AMS strategies: Strategy 1 (S1) implemented on day 1, at admission, strategy 2 (S2) implemented on day 2 or 3, when antibiotic treatment is reassessed, while strategy 3 (S3) combined S1 and S2. These strategies were compared to a baseline scenario (BSL), with no ASP intervention. Effectiveness was assessed by the number of life-years (LY) gained. An incremental cost-effectiveness ratio (ICER) less than French annual gross domestic product per capita was considered cost-effective (30,100€).

**Results:** All AMS strategies were more expensive than the baseline scenario. S1 and S3 were associated with 310 LY gained when compared to BSL, while S2 did not lead to additional LY gained. S2 and S3 were dominated by S1: less effective and more expensive for S2; equally effective and more costly for S3. ICER comparing S1 to BSL was of 2169€/LY gained. Probabilistic sensitivity analyses indicated that 91% of the ICER comparing S1 to baseline were under 5000€/LY gained.

Abstract 6339

Whole genome sequencing of bloodstream isolates of *Staphylococcus aureus* reveals prolonged transmission chains within neonatal intensive care units

Cosmika Goswami1, Stephen Fox2, Matthew Holden3, Alistair Leanord2, Thomas John Evans*2

1University of Glasgow, Glasgow, United Kingdom, 1University of Glasgow, Glasgow, United Kingdom, 3University of St Andrews, St. Andrews, United Kingdom

**Background:** *Staphylococcus aureus* is one of the commonest agents of nosocomial bacteremia. Outbreaks in neonatal intensive care units are frequent, typically identified if the organism is methicillin-resistant or produces unusual clinical syndromes. To identify potential transmission of this organism, we have completed whole genome sequencing (WGS) of bloodstream isolates of *S. aureus* from across Scotland.

**Materials/methods:** 1545 bloodstream isolates of *S. aureus* from across Scotland from the years 2015 to 2017 were collected, with complete coverage of isolates from the Greater Glasgow area. WGS using the Illumina platform was performed for all isolates. Single-nucleotide polymorphisms (SNPs) in the core genome were identified using SMALT and VarScan software. A threshold of 50 SNPs or fewer was used to identify highly related strains.

**Results:** We found 150 pairs of isolates with 50 or fewer pairwise SNP differences. Associated clinical data identified persistent transmission chains within neonatal intensive care units; we focused on those within areas where all bloodstream isolates had been collected within the time frame studied. In one unit over a 20-month period, we discovered 10 neonates with bloodstream *S. aureus* ST30 infection with fewer than 50 SNP differences. 9 of the isolates were methicillin sensitive; one isolate acquired methicillin resistance. For 8 of these infections the patients had overlapping hospital admissions but for 2 patients there was no overlap, and the sequential differences in SNPs could not be explained by simple transmission from patient to patient, strongly suggesting intermediate carriers of this strain or environmental contamination. None of these cases were flagged as possible outbreaks. Similar prolonged transmission chains of strains of methicillin-sensitive *S. aureus* were found in other neonatal intensive care units.

**Conclusions:** The high resolution of WGS allowed us to identify previously unsuspected transmission of *S. aureus* strains producing bloodstream infection within neonatal intensive care units within Scotland. Carriage by patients, carers and staff seem the most likely source, although environmental contamination cannot be excluded. Routine WGS of bloodstream isolates of *S. aureus* within neonatal intensive care units would allow early identification of similar transmission events and thus allow measures to prevent further transmission to be instituted.

**Circulation of ST30 in a hospital in Scotland between years 2015 and 2017**

Abstract 6342

**Evaluation of carbapenem-resistant *Enterobacteriaceae* treatment outcomes in a quaternary hospital in the United Arab Emirates**

Asma Ali*, Rania El Lababidi, Maher Balkis, Rami Ismail, Farah Kablaoui

1Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates

**Background:** Carbapenem-resistant *Enterobacteriaceae* (CRE) infections are on the rise and they’re internationally known to be among the major public health threats associated with high rates of mortality exceeding 50% in some reports. Current clinical evidence for treatment guidance and options and their possible outcomes are limited. This study aims to evaluate the efficacy of different treatment options for CRE infections.

**Materials/methods:** This study is an observational retrospective chart review study from January 2015 to December 2018 aiming to investigate the outcomes of different CRE therapy. This study was conducted at Cleveland Clinic Abu Dhabi, Abu Dhabi, UAE. Data of all adult patients with at least one culture positive for CRE infection were electronically extracted from January 2015 until December 2018. Ambulatory patients with CRE isolates were excluded from the data. Patient demographics, colonization with CRE, risk factors for CRE, as well as different antimicrobial regimens and their treatment outcomes were collected. Descriptive statistics were used to analyze the data.

**Results:** A total of 96 cases with CRE were included for the analysis. Twenty-seven outpatient isolates were excluded from the study. Sixty-nine cases were included for the final analysis. Colistin monotherapy was used in 28.9% (20/69). Seventy-one percent (49/69) of the patients received combination therapies with other antimicrobial agents such as colistin-carbapenem (9/49), colistin-ceftazidime/avibactam (14/49), colistin-tigecycline (12/49) and other regimens (14/49). Re-occurrence of infection within 2 weeks was observed in 23% (16/69) of all cases. The overall 30-day mortality was 50% (10/20) among the monotherapy treated patients and the among the patients who received combinations treatments mortality was up to 26.5% (13/49).

**Conclusions:** Over the past few years CRE infections significantly increased and it poses a threat to public health. There hasn’t been an ultimate guideline for the treatment of CRE Infections, but our study suggests that the combination antimicrobial therapies may be associated with lower mortality rates than monotherapy.

Abstract 6348

**Probability of target attainment by conventional pharmacokinetic/pharmacodynamic targets is overestimated in obese patients receiving linezolid and meropenem**

David Busse*1,2, Lisa Ehmann1,2, Philipp Simon3,4, David Petroff5, Niklas Hartung6, Robin Michelet1, Wilhelm Huisenga6, Hermann Wrigge3,4,7, Charlotte Kloft1

1Freie Universitaet Berlin, Dept. of Clinical Pharmacy and Biochemistry, Institute of Pharmacy, Berlin, Germany, 2Graduate Research Training program PharMetrX, Berlin, Germany, 3University of Leipzig Medical Center, Department of Anaesthesiology and Intensive Care, Leipzig, Germany, 4University of Leipzig, Integrated Research and Treatment Center [IFB] Adiposity Diseases, Leipzig, Germany, 5University of Leipzig, Clinical Trial Centre Leipzig, Leipzig, Germany, 6University of Potsdam, Institute of Mathematics, Potsdam, Germany, 7Bergmannstrost Hospital Halle, Department of Anaesthesiology, Intensive Care and Emergency Medicine, Pain Therapy, Halle, Germany

**Background:** Clinical pharmacokinetic/pharmacodynamic (PK/PD) targets represent a proxy for exposure at the infection site and are typically based on studies in non-obese patients. Due to lack of alternatives, they are often also employed in probability of target-attainment (PTA) analysis in various other populations, including the obese. Since drug penetration into the target-site might differ, it remains unclear if these targets are valid for obese patients. This analysis aimed at evaluating the adequacy of PK/PD targets in obese patients based on PTA analysis.

**Materials/methods:** Previously, two nonlinear mixed-effects PK models had been developed based on plasma and target-site data obtained via microdialysis from 15 obese (BMI mean±SD=49±11 kg/m\(^2\)) and 15 non-obese patients (BMI mean±SD=24±2 kg/m\(^2\)), receiving a standard 30-min infusion of 1000 mg meropenem and 600 mg linezolid before abdominal surgery [1,2]. Here, Monte-Carlo simulations were performed for concentration-time profiles in plasma and at target-site for obese and non-obese patients (n=1000, NONMEM version 7.4.3). PTA was calculated for the PK/PD targets "unbound concentrations exceed MIC=2 mg/L during 95% of dosing interval" (meropenem) and "AUC/MIC≥80 for MIC=4 mg/L" (linezolid) in plasma and target-site.

**Results:** In obese versus non-obese patients PTA increased for meropenem whereas PTA decreased for linezolid (Table 1). For both drugs, the difference in PTA between plasma and target-site was larger for obese compared to non-obese patients (relative reduction, meropenem: -65% versus -55%, linezolid: -97% versus -71%), reflecting population dependent differences in the relevant exposure at target-site.

**Conclusions:** The discrepancy between PTA in plasma and target-site for obese and non-obese patients indicated altered penetration into target-site and therefore inadequacy of conventional PK/PD targets in obese patients leading to overestimated PTA in plasma. Thus, there is the necessity to develop new targets for obese patients which can then be investigated in clinical studies.

**Table 1:** Probability of target-attainment in obese versus non-obese patients for meropenem and linezolid for the standard dosing regimens.

Abstract 6349

Exploring social links and networks of communication in relation to infection prevention and control and antibiotic stewardship across surgical specialties in South Africa

Candice Bonaconsa1, Oluchi Mbamalu*, Adam Boutall2, Mark Hampton3, Alison H. Holmes4, Marc Mendelson1, Tim Pennel5, Esmita Charani6

1Division of Infectious Diseases and HIV Medicine, Department of Medicine, Groote Schuur Hospital, University of Cape Town, Cape Town, South Africa, 2Division of Colorectal Surgery, Groote Schuur Hospital, University of Cape Town, Cape Town, South Africa, 3Dr Matley & Partners, Cape Town, South Africa, 4Imperial College London and Imperial College Healthcare NHS trust, National Centre for Infection Prevention and Management / Medicine, London, United Kingdom, 5Chris Barnard Division of Cardiothoracic Surgery, University of Cape Town, Cape Town, South Africa, 6Imperial College London, Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, London, United Kingdom

Background: Cultural differences exist between medical and surgical specialties that determine antibiotic prescribing outcomes, which require contextually-fit interventions. We investigated communication and team dynamics in relation to antibiotic stewardship (AS) and infection prevention and control (IPC) across two surgical teams at a tertiary hospital.

Materials/methods: Data were collected between May to November 2019, by direct observations of ward rounds, and face-to-face interviews with ward round participants. Field notes from observations and the transcripts of interviews were analysed using a grounded theory approach. Additionally, graphs (sociograms) were drawn plotting the content and flow of communication and the social links between individual participants. Sociograms enabled data triangulation and validation, and were a powerful visual illustration giving participants a global view of interactions and team dynamics on ward rounds.

Results: 60 hours of observations, including 1024 individual patient discussions were gathered. Seven patients and 60 healthcare professionals were interviewed. Discussions about antibiotic prescriptions and IPC are inconsistent across specialties and depend on the leadership style of the consultant. Communication flow is mainly between the consultants and registrars, and seldom includes input from the nurse, or wider team members. Although consultants facilitate key decision-making, individual leadership styles determine how decisions are assigned to team members. Mapping the communication flow using sociograms (Fig 1) demonstrates that whereas AS (e.g. initiating an antibiotic) and IPC (e.g. removing indwelling lines) actions are verbalised between the consultants and registrars, little direct communication occurs with nurses who are responsible for activating or maintaining decisions. Similarly, patients often remain passive recipients of care with little details about decisions on AS and IPC communicated with them.

Conclusions: AS and IPC discussions on ward rounds occur predominantly between consultants and registrars with little interaction noted with patients and nurses. Nurses activate decisions made on ward rounds and the lack of directed communication may result in delayed or missed AS and/or IPC interventions. The sociograms identified positive examples of practice and engagement with the wider team which can be developed into a model of effective communication on ward rounds in relation to AS and IPC.

Figure: Sociogram mapping communication flow on consultant round

Integrated molecular surveillance of carbapenem-resistant Enterobacterales in Germany

Rolf Kramer1, Katrin Kremer2, Joerg B. Hans3, Sebastian Haller1, Annicka Reuss1, Niels Pfennigwerth3, Yvonne Pfeifer1, Bernd Neumann4, Guido Werner4, Tim Eckmanns1, Sören G. Gatermann3

1Robert Koch Institute, Berlin, Germany, 2Robert Koch Institute, Postgraduate Training for Applied Epidemiology (PAE), Berlin, Germany, 3National Reference Centre for Multidrug-resistant Gram-negative Bacteria, Department for Medical Microbiology, Ruhr-University Bochum, Bochum , Germany, 4Robert Koch Institute, Wernigerode, Germany

Background: Carbapenem-resistant Enterobacterales (CRE) are an important cause of healthcare-associated infections. Although prevalence in Germany is low, case numbers significantly increased over the past years. CRE are notifiable and national guidelines recommend sending all isolates to the national reference centre (NRC) for analyses of resistance mechanisms. Enzyme-mediated resistance by carbapenemases is particularly worrisome. To control their spread, routes of transmission need to be identified. The Robert Koch-Institute (RKI) and the NRC are joining their efforts for an integrated molecular surveillance (IMS) of CRE in Germany by combining microbiological and epidemiological data with whole-genome sequencing (WGS) to improve identification of otherwise undetected outbreaks.

Materials/methods: All CRE cases have to be notified to local health authorities and pseudonymized patient data is forwarded to the RKI. Likewise, the NRC receives CRE isolates from diagnostic laboratories with pseudonymized patient information. In a suspected outbreak, an IMS approach was tested: Available data sources were screened to detect irregular upsurges of carbapenemases (local, temporal or both). WGS was performed for selected isolates followed by core genome multi locus sequence typing (cgMLST) and SNP analysis. If microbiological analyses indicated clonal spread, related isolates were matched with notified cases and responsible health authorities were contacted for outbreak investigations.

Results: The NRC detected an increase of OXA-244-producing Escherichia coli from 2017 (n=32) to 2019 (n=101). WGS analyses revealed that 59 isolates belonged to a cluster of closely related E. coli ST38 of which 39 were successfully matched with notified cases from ten federal states throughout Germany. No specific age group was affected (0-90 years). Exploratory questionnaires showed two possible common exposures: stay/family abroad and previous hospital admissions. Investigations are currently ongoing to identify specific circumstances of strain acquisitions and transmissions.

Conclusions: Our use case for IMS shows that a combined approach of microbiological technologies and epidemiological methodologies can be applied to identify otherwise unrecognizable relations between CRE cases. IMS is likely to detect more suspected outbreaks in the future as the detection algorithms will be automatized and analyses’ methodologies continue to improve. Detailed outbreak investigations, as for OXA-244, will help identifying potential sources and deciphering common transmission routes.

Abstract 6351

**Polyphasic validation of a nisin-biogel aiming at the control of canine periodontal disease**

Eva Cunha*, Ferdinando Bernardino De Freitas¹, Berta São Braz¹, Jorge Moreira², Luís Tavares¹, Ana Salomé Veiga³, Manuela Oliveira¹

¹CIISA - Centro de Investigação Interdisciplinar em Sanidade Animal, Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisboa, Portugal
²Virbac de Portugal Laboratórios, Lda., Sintra, Portugal
³Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

**Background:** Periodontal disease (PD) is one of the most frequent inflammatory diseases in dogs. It results from a complex interaction between the polymicrobial biofilm in the dental surface (dental plaque), and consequent host inflammatory response. Previous work showed that nisin incorporated in a guar-gum biogel (nisin-biogel) can inhibit and eradicate pre-formed canine oral enterococcal-biofilms, being a promising alternative for canine PD control[1]. This project aimed to evaluate if (1) the nisin-biogel maintained its antimicrobial activity in a simulated oral environment; if (2) it kept its antimicrobial activity during a 24-month storage at different temperatures; and if (3) its application is safe towards eukaryotic cells.

**Materials/methods:** To achieve the first objective, a previously characterized collection of 20 canine oral enterococci was used in a spot-on-lawn assay, to evaluate the antimicrobial activity of nisin and nisin-biogel in the presence of canine saliva. Nisin and nisin-biogel were diluted in filtered saliva, collected from healthy dogs, achieving nisin concentrations of 12.5, 25, 50 and 100μg/mL.

To evaluate the influence of storage in the nisin-biogel antimicrobial activity, 62.5, 250 and 500μg/mL solutions were stored in different conditions (-20ºC, 4ºC, room temperature and 37ºC) during 1, 3, 6, 9, 12, 15, 18 and 24 months, after which a spot-on-lawn assay was performed.

Finally, a cytotoxicity assay, using a Vero cell line and a canine primary small intestinal fibroblast cell culture, was performed to evaluate nisin and nisin-biogel safety in eukaryotic cells[2].

**Results:** The presence of saliva didn’t inhibit nisin antimicrobial activity, but this activity was expressed at higher concentrations. Regarding the influence of storage, a significant reduction (p<0.05) in nisin’s antimicrobial activity towards the canine enterococci under study was observed at 37ºC, over the 24-month period, regarding all solutions tested. The cytotoxicity assay revealed absence of toxicity (cell viability higher that 90%) of the nisin and nisin-biogel solutions with concentrations lower than 200μg/mL.

**Conclusions:** Nisin-biogel kept its antimicrobial activity in a simulated oral environment and after 24h-month storage at freezing, refrigeration and room temperatures, being safe to be applied to eukaryotic cells. This work supports nisin-biogel as a promising compound for the control of canine PD.

Results from the 2019 antimicrobial susceptibility testing External Quality Assessment (EQA) exercise organised for EARS-Net participants

E. J. Fagan*, Shila Seaton1, Puja Shah1, Natasha Bundock1, Shabana Bi1, Paul Chadwick1

1UK NEQAS, Public Health England, London, United Kingdom

Background: The United Kingdom National External Quality Assessment Service (UK NEQAS) for Microbiology provides the annual external quality assessment (EQA) for antimicrobial susceptibility testing to the EARS-Net. The aim is to assess and monitor the comparability of results between laboratories and countries and thus justify the pooling and comparison of routinely collected antimicrobial susceptibility test data across Europe.

Materials/methods: An analysis was carried out on the performance of participants in the EQA exercise. Participation was invited from 954 laboratories in 30 countries. Six organisms were distributed: Acinetobacter baumannii complex, Klebsiella pneumoniae, Escherichia coli, Staphylococcus aureus, Pseudomonas aeruginosa and Streptococcus pneumoniae. Participants’ results for identification and antimicrobial susceptibility testing were collated and assessed.

Results: Eight hundred and eighty-five participants returned results. The level of performance with these EQA specimens was generally satisfactory, with >80% consensus [at the ‘S, I, R’ level] with the intended results of 88.5%. Poor performance was noted for an isolate of E. coli expressing discrepant resistance to third generation cephalosporins, for an isolate of K. pneumoniae expressing resistance to amoxicillin-clavulanate. Furthermore, difficulties were again seen with categorising resistance to benzylpenicillin, cefotaxime and ceftriaxone in an isolate of S. pneumoniae which expressed intermediate susceptibility to third generation cephalosporins. Two challenging bug-drug combinations from the 2017 and 2018 EQAs were distributed again in 2019. Specimen 5586 contained a strain of S. aureus resistant to beta-lactam agents, clindamycin, linezolid and tetracycline. Resistance to linezolid was correctly reported by 84.1% of participants, a significant improvement compared to 16.3% participants in the 2017 EQA. Specimen 5587 contained a strain of S. pneumoniae with intermediate susceptibility to cefotaxime. Only 59.3% of participants reported a susceptible result, but this was also an improvement compared to 65.7% when the same isolate was distributed in 2019.

Conclusions: The overall concordance between participating laboratories was satisfactory. However, difficulties arose where there was borderline susceptibility to the agents and there were several areas where discrepancies were found in susceptibility testing. There was an improvement in performance for some challenging bug-drug combinations.

Abstract 6354

**Faecal microbiota transfer in real-life is more effective for recidivant *Clostridioides difficile* infection than for highly resistant bacteria decolonisation**

Pascaline Choinier*1, Hassane Sadou-Yaye1, Gentiane Monsel1, Elie Haddad1, Émilie Vallet1, Jerome Robert1, Agnès Bellanger1, Laurence Drieux-Rouzet1, Eric Caumes1, Nathalie Kapel4, Alexandre Bleibtreu1

1University Hospitals Pitié Salpêtrière - Charles Foix, Infectious and Tropical Diseases Departement, Paris, France, 2University Hospitals Pitié Salpêtrière - Charles Foix, Central Pharmacy, Paris, France, 3University Hospitals Pitié Salpêtrière - Charles Foix, Infection Control Unit and Bacteriology departement, Paris, France, 4University Hospitals Pitié Salpêtrière - Charles Foix, Fonctionnal Coprology, Paris, France

**Abstract third-party references:** Groupe Français de Transplantation Fécale, GFTF

**Background:** Fecal microbiota transplantation (FMT) is effective in recurrent *Clostridioides difficile* infections (rICD) for which antibiotic therapy have shown limitations. New indications are discussed such as the decolonization of emerging highly resistant bacteria (eHRB).

**Materials/methods:** Demographics, rICD characteristics, treatments and FMT procedures for patient who received FMT produced in a TMF center between 2016 and 2019 were collected prospectively. Donor screening was performed according to GFTF guidelines including BLSE and eHRB screening in donor’s feces. The FMT was performed according to the recommendations in rICD cases or as compassionate in case of eHRB decolonization. The final end point for evaluation was at 90 days after FMT. All patients consent for FMT procedures and for data collection.

**Results:** During the study period 41 independent FMT were performed for 32 patients. rICD was the main indication (81%) followed by compassionate eHRB colonization (19%). Median age was 68.3 years old [min=19-max=90] and sex ratio [F/M] was 0.88. Forty percent of the patients were immunocompromised, due to chemotherapy (8/13) or immunosuppressive therapy (5/13). Patients were hospitalized in medicine departments, intensive care unit (25) or hematology department (6%). FMT was mostly performed for second relapse (81%) to 5 relapses (3%). They had received 1 FMT (88%), two (12%) or three (3%) independent FMT. FMT was administered through oral route using capsules (72%), upper way (gastrostomy or nasogastric tube (25%) and one per coloscopy (3%). All FMT were performed with anonym donor frozen feces following pre-FMT antibiotherapy (vancomycin (77%)). For eHRB decolonization no antibiotics were used. Bowel lavage using classic colic preparation was performed the day before FMT. rICD cure was obtained in 85% after a unique FMT. There was no difference in terms of route, pre-FMT antibiotic regimen, FMT route or immunocompromised status, respectively.

**Conclusions:** FMT is a highly effective therapy for rICD including in patients with numerous risk factors for ICD relapse. FMT was safe in our study with no side effects in particular no bacteremia, no death and no evidence for resistant bacteria transmission. In contrast in real life FMT for eHRB decolonization in compassionate use was not effective with 100% of failure.

Comparative metabolomics of Pseudomonas aeruginosa in response to polymyxin B
Maytham Hashim Hussein*1, Meiling Han2, Brian Tsuji3, Robert Hancock4, Tony Velkov1, Jian Li2

1The university of Melbourne, School of Biomedical Sciences, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, 2Monash University, Monash Biomedicine Discovery Institute, Melbourne, Australia, 3University at Buffalo, Department of Pharmacy Practice, NY, United States, 4University of British Columbia, Department of Microbiology and Immunology, BC, Canada

Background: P. aeruginosa is the most commonly cause of life-threatening lung infections. Polymyxins are last-line antibiotics which retain efficacy against this MDR pathogen. Despite their clinical utility, the exact antibacterial killing mechanism of polymyxins is not completely understood. Herein, for the first time, we employed untargeted metabolomics to decipher the mechanism(s) of action of polymyxin B against three P. aeruginosa strains.

Materials/methods: Two polymyxin-susceptible P. aeruginosa strains [PA01 and PA14] (polymyxin B MIC=2 mg/L) and one polymyxin-resistant strain the Liverpool epidemic strain LESB58 (polymyxin B MIC=16 mg/L) were grown in M9 minimal media and treated with polymyxin B: 2 mg/L for polymyxin-susceptible strains and 4 mg/L for polymyxin-resistant strain (n=4). Samples were collected at 15 and 60 min and processed through LC-MS. The significant cellular metabolites (≥1.0-log2-fold; P≤0.05; FDR≤0.1) were determined using multivariate and univariate analyses and reconstructed using IDEOM and KEGG Mapper to elucidate the perturbed metabolic pathways.

Results: In line with the putative mode of action of polymyxin B via disorganising the outer membrane, at 15 and 60 min the bacterial cell envelope biogenesis was markedly perturbed due to polymyxin B treatment particularly in P. aeruginosa PA01 and PA14. This is manifested by a marked decline (≥ -1.0 log2FC) in the complex interrelated pathways of amino and nucleotide sugar (e.g. N-acetyl-D-glucosamine 6P), peptidoglycan (e.g. L-Ala-γ-D-Glu-m-DAP-D-Ala) and lipopolysaccharide biosynthesis (e.g. 3-Deoxy-D-manno-octulosonate). In P. aeruginosa LESB58, only peptidoglycan biosynthesis (e.g. D-Alanyl-D-alanine) was significantly perturbed at 15 and 60 min (-0.98 log2-fold). Consequently, the abundance of the main precursors of bacterial membrane glycerophospholipids (e.g. sn-glycerol-3-phosphate) and fatty acids (e.g. palmitoleylCoA) underwent a considerable decreased (≥ -1.0 log2FC) following polymyxin B treatment in all tested strains. Furthermore, at 15 min and 60 min, polymyxin B caused significant changes in the cellular antioxidant network pool, TCA cycle and the downstream arginine pathway mainly in polymyxin-susceptible strains.

Conclusions: Our results indicated that the killing effect of polymyxin B was largely due to the inhibition of cell envelope biosynthesis, the cellular antioxidant network, TCA cycle and its downstream pathways. This study shed lights on key mechanistic information for optimisation of polymyxin B in clinical setting.

Abstract 6356

Patterns of antimicrobial treatment of health-acquired infections in France
Thibaud Sevin1, Daniau Côme1, Anne Berger-Carbonne1, Stephane Le Vu*1
1Santé publique France, Saint-Maurice, France

Background: Monitoring the use of antimicrobial drugs within hospitalized patients is critical owing to the risk of resistance selection following exposure to broad-spectrum molecules. This study aims to describe the patterns of antimicrobial prescription for the most frequent health-acquired infections (HAI) in France, relating drugs selection and potentially resistant microorganisms.

Materials/methods: We used data from 2017 point-prevalence survey of HAI and antimicrobial use in France - a large nationally representative sample survey of hospitalized patients. We sought unambiguous correspondence between individual indications of antibiotic regimen and HAI sites to determine which molecules (individually or in combination) are directed towards which pathogen (by resistance profile).

Results: Of 75698 adult patients from 401 hospitals, 5.1% had an active HAI and 4.3% had a curative treatment for an HAI. The two most frequent therapeutic indications of treatment were lower respiratory tract (LRTI, 27.7%) and urinary tract infections (UTI, 18.4%) and could be matched with corresponding HAI sites. For LRTI, the most prescribed antimicrobial was amoxicillin-clavulanic acid (27.8%) and most frequently isolated pathogens were in equivalent proportions (~17%) Staphylococcus aureus, Pseudomonas aeruginosa and Escherichia coli. Methicillin-resistant Staphylococcus aureus LRTI were more likely treated by linezolid (see figure-A). For UTI, ofloxacin, ceftriaxone and amoxicillin (with or without clavulanic acid) were mostly prescribed (f13% each) and Escherichia coli predominantly isolated (52.0%). Extended-spectrum beta-lactamase-producing Escherichia coli UTI were more likely treated by fosfomycin, pivmecillinam, piperacillin-tazobactam or ertapenem (see figure-B). We estimated that f56% of LRTI/UTI were treated by broad-spectrum antimicrobials and f75% of prescriptions in absence of microbiological information ("empirical treatment") complied with national guidelines.

Conclusions: In this study, we provide a baseline of antimicrobial use in relation to microbiological information in patients with the most common HAI. Our results can serve to direct future effort of antimicrobial stewardship. Also, we leveraged a type of data that is available in many countries, notably in Europe where similar surveys have been conducted, and as such our work could be extended to a broader population.

Figure: Proportion of antimicrobial prescription according to pathogen resistance for MRSA LRTI (subfigure A) and ESBL-producing E. Coli UTI (subfigure B).

1Austin Hospital, Department of Infectious Diseases, Heidelberg, Australia, 2University of Melbourne, MDU Public Health Laboratory, Parkville, Australia, 3University of Melbourne, Department of Microbiology & Immunology at Doherty Institute, Parkville, Australia, 4Monash Health, Department of Infectious Diseases, Clayton, Australia, 5Monash University, Department of Medicine, Clayton, Australia, 6Melbourne Health, Department of Infectious Diseases, Parkville, Australia, 7University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, 8Austin Hospital, Departments of Microbiology & Infectious Diseases, Heidelberg, Australia, 9Peter MacCallum Cancer Centre, Department of Infectious Diseases, Melbourne, Australia, 10Melbourne Health, Department of Microbiology, Parkville, Australia, 11University of Melbourne, Department of Medicine, Austin Hospital, Heidelberg, Australia

Abstract third-party references: Supported by Melbourne Genomics Health Alliance

Background: Multidrug-resistant organisms (MDROs) are associated with significant morbidity, mortality and costs in hospital patients, yet routine microbiological methods have limited ability to detect nosocomial MDRO transmission. This study aims to evaluate the feasibility and potential clinical impact of applying whole genome sequencing (WGS) of multiple MDROs, across multiple healthcare institutions, to characterise and detect transmission of MDROs in hospitals, and identify challenges for implementation.

Materials/methods: Prospective multi-centre study (8 university hospitals) conducted over 15 months (2 month pilot phase, 13 month implementation phase). Hospital inpatients with positive clinical or screening cultures for MDROs (MRSA, vanA VRE, ESBL Escherichia coli or Klebsiella pneumoniae) were included. Isolates were collected prospectively, underwent usual testing in hospital laboratory, then sequenced (Illumina NextSeq) in parallel. Core genome pairwise single nucleotide polymorphism (SNP) distances were used to infer phylogenetic relationships within same species/ST. Epidemiological information was assessed for pairs of patients with genomically related isolates (below specified SNP distance threshold) to assess likelihood of hospital MDRO transmission. Results were presented to hospitals in the implementation phase, and changes to infection control practices were monitored.

Results: 2285 isolates from 1873 patients were included (41% ESBL E. coli, 36% MRSA, 15% VRE, 8% ESBL K. pneumoniae); 63% of isolates were from clinical samples. Hospital transmission (isolates genomically and epidemiologically-related to another patient) was demonstrated for all MDRO species, including 33% of patients overall, most of which would not have been detected without genomics. This varied from 87% of patients with vanA VRE to 19% for MRSA. Genomic data influenced infection control practices, contributing to management of outbreaks, directing focused infection control interventions, and altering cleaning practices. Critical analysis of genomics workflows identified contributors to delays in turnaround times, including difficulties accessing digital patient data, delays in isolate transfer, and need for innovative data visualisation methods to report genomic data to hospitals.

Conclusions: Prospective genomic workflows offer unparalleled resolution for infection control MDRO surveillance, allowing hospitals to more effectively target their infection control interventions, and potentially decrease MDRO transmission. This study has identified some of the key challenges and inputs required for future implementation of this promising technology.

Usefulness of reverse transcriptase nested polymerase chain reaction in clinical specimens for the diagnosis of haemorrhagic fever with renal syndrome

Jun-Won Seo*1, Choon-Mee Kim2, Na-Ra Yoon1, You Mi Lee2, Merlin Jayalal Lawrence Panchali2, Dong-Min Kim1

1Chosun University Hospital, Gwangju, South Korea, 2Premedical Science, College of Medicine, Chosun university, Gwangju, South Korea

Background: Hemorrhagic fever with renal syndrome (HFRS) is confirmed by Hantavirus isolation in serum, virus-specific immunoglobulin M antibody detection, or 4-fold increase in immunoglobulin G antibody titer in the acute and convalescent period, using immunofluorescence antibody assay (IFA). However, these tests are imperfect for early diagnosis. The aim of this study was to investigate the usefulness of the reverse transcriptase nested polymerase chain reaction (RT N-PCR) in HFRS diagnosis in clinical samples such as whole blood and urine.

Materials/methods: The clinical and laboratory data of 6 HFRS confirmed patients were collected from medical records, between May, 2016 and July, 2017, at the Chosun University Hospital, an 828-bed, University-affiliated, tertiary referral center in Gwangju, Korea. The 6 patients confirmed with HFRS using IFA and RT N-PCR from clinical specimens (whole blood, urine, saliva, sputum).

Results: The virus was detected in all 6 patients, using RT N-PCR targeting the early phase large segment of genus Hantaan virus. Importantly, the virus was identified in urine as well as blood, using RT N-PCR. Our data shows that the virus can be detected in the blood for over a month, which is long, and in urine for up to 3 or 4 weeks, but not in saliva.

Conclusions: We report 6 HFRS cases diagnosed using RT N-PCR targeting the L-segment, with whole blood and urine samples, but not in saliva. Hantaan virus RNA detection by RT N-PCR in whole blood and urine may be helpful in confirming rapid diagnosis in the early phase disease, and useful for routine HFRS diagnosis.

Clinical benefits of Point-of-Care rapid molecular influenza test at a hospital emergency service

Johan Nordh*1, Håkan Janson2

1Region Kronoberg, Infectious Diseases, Växjö, Sweden, 2Region Kronoberg, Clinical Microbiology, Växjö, Sweden

Background: Early diagnosis of influenza should help physicians at the emergency service to decide if a patient with symptoms of respiratory tract infection needs isolation, can be cohorted, should be given antibiotics or oseltamivir. In our county there is access to influenza PCR once daily weekdays and a multiplex PCR that tests for several different respiratory tract viruses and some bacteria (run office hours weekdays and before midday at weekends).

In prospective trials commercially available rapid molecular point-of-care tests have been found to lower hospitalization frequency, decrease use of antibiotics, increase correct use of oseltamivir, shorten stay at emergency service and help sort which patients need isolation. Although common in Swedish hospitals there has been no local prospective evaluation. Therefore, this trial aims to evaluate potential benefits of having access to a rapid molecular point-of-care influenza test in the hospital emergency service, and to evaluate the performance of the test.

Materials/methods: In the spring of 2018 a rapid molecular point-of-care test for influenza was made available every other week in the hospital emergency service. Patients tested for respiratory tract viruses (influenza PCR, multiplex PCR or point-of-care test) were included to the test group (n=230) when point-of-care test was available, or to the control group (n=187) when it was not.

Results: There was a significantly lower frequency in the test group of:

- Antibiotic treatment (62.17% vs 74.87%, p<0.01)
- Multiplex PCR (34.35% vs 57.75%, p<0.00001).

There was no significant difference between the test group and the control group in:

- Hospitalization (72.17% vs 79.14%)
- Oseltamivir treatment (13.04% vs 12.30%)
- Stay at emergency service (4.45 vs 4.57 hours)
- Stay at hospital (6.16 vs 5.87 days)
- Time to antibiotics (8.23 vs 10.45 hours)
- Length of antibiotic course (9.30 vs 7.98 days)
- Time to oseltamivir (13.34 vs 8.42 hours)

The sensitivity and specificity of the point-of-care test was 91.7% and 99.0%, for influenza A and 95.5% and 98.5% for influenza B, respectively.

Conclusions: Preliminary results from this trial suggest that access to rapid molecular point-of-care influenza test in the hospital emergency service offers limited clinical benefit.

**Abstract 6361**

**Q fever endocarditis among patients with culture-negative infective endocarditis in South Korea**  
Moonsuk Bae*, Choong Eun Jin, Jong Ha Park, Seongman Bae, Sang-Oh Lee, Sang-Ho Choi, Yang Soo Kim, Jun-Hee Woo, Yong Shin, Sung-Han Kim

1Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

**Background:** Q fever is the common pathogen of culture-negative infective endocarditis (CNIE), but there are only limited reports in South Korea that Q fever is the cause of CNIE. We thus investigated the incidence of Q fever endocarditis in patients with suspected CNIE in South Korea by using Q fever PCR assay in blood and tissue valves as well as 0 fever serology.

**Materials/methods:** All adult patients with infective endocarditis classified by modified Duke criteria or with large vessel infection at clinical imaging enrolled from December 2016 through September 2019. Of them, the patients with positive for blood or valve tissue culture were excluded. Q fever endocarditis was defined as 1) positive Q fever PCR of a cardiac valve, or 2) positive Q fever PCR of the blood or single phase I IgG antibody titer ≥ 1:6400 with evidence of endocardial involvement. Q fever vascular infection was defined as meeting the same microbiological criteria as endocarditis with the evidence of the aneurysm or vascular graft infection. We performed serologic test by indirect immunofluorescence assay and PCR targeting the transposase gene insertion element IS1111a of C. burnetii for blood and cardiac valve tissue from the patients.

**Results:** Of the 115 patients with endocarditis and 7 patients with vascular infection, 16 patients with culture-negative endocarditis and vascular infection were included in this study. Of 16 patients, 6 (38%) had predisposing heart condition and 5 (36%) had valve surgery. PCR results from blood and heart valve tissue was positive in 3 and 2 patients, respectively. Four patients (25%, 95% confidence interval 7–52%) was diagnosed with definite Q fever endocarditis. None of these patients received treatment for C. burnetii, but 2 patients had been stable after cardiac valve surgery. One patient died due to the development of surgical site infection after five months from heart valve surgery and the other one died due to worsening underlying disease.

**Conclusions:** These data suggest that Q fever endocarditis in South Korea is probably underestimated and further studies are needed to examine the epidemiology and outcomes of Q fever endocarditis patients in South Korea.

**Early Lyme borreliosis in patients with chronic inflammatory bowel disease**

Vera Maraspin Carman*1, Petra Bogovic2, Katarina Ogrinc3, Eva Ruzic-Slabjic3, Franc Strle2

1 University Medical Centre Ljubljana, Slovenia, Department of Infectious Diseases, Ljubljana, Slovenia, 2University Medical Centre Ljubljana, Slovenia, Department of Infectious Diseases, Ljubljana, Slovenia, 3Medical Faculty, University of Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia

**Background:** Information on the course and outcome of Lyme borreliosis (LB) in patients with chronic inflammatory bowel disease (CIBD) is limited.

**Materials/methods:** The source of information for the present study was database on 14,891 patients, diagnosed with EM at our institution from 1993–2018. The data were obtained prospectively using a structured questionnaire. EM was defined according to modified CDC criteria. Symptoms that had newly developed or worsened since the onset of the EM and had no other known medical explanation were regarded as LB-associated constitutional symptoms. Pre-and post antibiotic treatment characteristics in patients with EM and underlying CIBD were assessed and compared with sex-, age-, and antibiotic therapy-matched immunocompetent individuals diagnosed with EM in the same year; for each patient with CIBD two immunocompetent patients were chosen.

**Results:** During 26-year period, 50 patients (33 with Crohn’s disease and 17 with ulcerative colitis) with typical EM were diagnosed. There were 29 females and 21 males, aged 48 (20–74) years; 37/50 (74%) patients were receiving immunosuppressive therapy (mesalazin-20, azathioprine-2, corticosteroids-2, biological drugs-2, combined treatment-11). 12/50 (24%) patients had signs/symptoms of disseminated LB (multiple EM-8; meningitis-1; pronounced LB-associated symptoms-3), and in 2 patients with multiple EM *Borrelia afzelii* was isolated from blood. In contrast, only 2/100 (2%) immunocompetent patients had indications of disseminated borrelial infection (multiple EM-1, solitary EM without constitutional symptoms but with spirochtemia-1). The difference was statistically significant (12/50, 24% vs. 2/100, 2%; p<0.0001). Treatment failure was found in 4/50 (8%) patients with CIBD (persistence of EM >2 months after antibiotic treatment-2, development of severe LB-associated constitutional symptoms during follow-up-2) and in 1/100 (1%) immunocompetent patients (persistence of EM >2 months after antibiotic treatment) (p=0.0425). All 5 patients recovered after re-treatment with an alternative antibiotic and had smooth subsequent clinical course during one year follow-up.

**Conclusions:** In contrast to immunocompetent patients with EM, patients with CIBD had more common signs/symptoms of disseminated LB and more frequently needed re-treatment because of treatment failure. However, identical antibiotic treatment approach for EM in patients with CIBD as used in immunocompetent patients, including re-treatment with alternative antibiotics, resulted in favourable outcome of LB.

Yellow fever enquiries to a national telephone advice line regarding travellers who are pre-conception, pregnant or breastfeeding

Charlotte Patterson*, Sanch Kanagarajah, Dipti Patel

1Guys and St Thomas’s NHS Foundation Trust, London, United Kingdom, 2University College London Hospitals NHS Foundation Trust, National Travel Health Network and Centre (NaTHNaC), London, United Kingdom

Background: NaTHNaC (The National Travel Health Network and Centre) was set up with the broad goal of protecting the health of UK travellers. It provides advice for healthcare professionals advising those with complex itineraries or specialist health needs. NaTHNaC’s telephone advice line receives numerous enquiries relating to yellow fever vaccine (YFV), which is contra-indicated in certain patient groups and should be used with caution in others, making advice regarding vaccination risk challenging.

Materials/methods: We performed a retrospective audit of all electronic records of telephone enquiries to NaTHNaC between January 2016 – September 2019 relating to pre-conception, pregnancy or breastfeeding and YFV. Data were collected on traveller demographics, travel destination, purpose of travel and trimester of pregnancy. The aim was to quantify the frequency of telephone calls to NaTHNaC for YFV advice, travel destination, and identify the training needs of callers.

Results: There were 2,104 telephone enquiries to NaTHNaC between January 2016 – September 2019. 8,996 (43%) were related to YFV administration. 514 (6%) calls related to YFV in peri-partum travellers as summarised in figure 1. The majority of enquiries were related to pregnancy 250/514 (51%), with the first trimester of pregnancy accounting for most calls at 132/250 enquiries (50%). 42% related to 2nd trimester travellers, and just 2% 3rd trimester travellers. 155/514 (30%) enquiries related to breastfeeding, 47/514 (8%) to pre-conception and 7/514 1% related to miscarriage.

416/514 (81%) of phone calls were from GP practices. The most popular travel destinations were in West Africa, with Nigeria making up 19% of calls and Ghana 17%. The commonest reason for travel was visiting friends and relatives (VFR) 351/482 (73%).

Conclusions: Enquiries relating to YFV make up almost half of the calls to NaTHNaC, with a significant proportion relating to peri-partum enquiries. The commonest reason for travel was VFR in West Africa in 1st trimester pregnancy. This highlights training needs for those providing travel advice and the importance of raising awareness in this patient group to improve vaccination outside the peri-partum period.

Figure 1: Telephone Enquiries to NaTHNaC related to YFV and pregnancy, pre-conception, breastfeeding and miscarriage from January 2016 – September 2019

Abstract 6370

Protective role for cytomegalovirus-specific neutralising antibodies in kidney transplant recipients treated with T-cell-depleting agents

Mario Fernandez Ruiz1, Virginia Sandonis2, Tamara Ruiz Merlo1, Patricia Parra1, Francisco Lopez-Medrano1, Rafael San Juan Garrido1, Laura Corbella Vazquez1, Isabel Rodriguez Goncerc, Amado Andrés1, David Navarro1, Jose M. Aguado Garcia1, Pilar Pérez-Romero2

1Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” [imas12], Unit of Infectious Diseases, Madrid, Spain, 2National Center of Microbiology, Instituto de Salud Carlos III, Majadahonda, Spain, 3Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” [imas12], Department of Nephrology, Madrid, Spain, 4Hospital Clinico Universitario, Fundación INCLIVA, Department of Microbiology, Valencia, Spain

Abstract third-party references: Supported by the Spanish Ministry of Science, Innovation and Universities, Instituto de Salud Carlos III [FIS] P17/00014.

Background: Induction therapy with lymphocyte-depleting agents such as antithymocyte globulin (ATG) increases the risk of cytomegalovirus (CMV) infection after kidney transplantation (KT). Most previous studies have analyzed the predictive value of CMV-specific cell-mediated immunity (CMV-CMI) in this population. The contribution of CMV-specific neutralizing antibodies blocking infection of epithelial cells (AbNEI) remains unclear.

Materials/methods: Prospective cohort study of 105 CMV-seropositive KT recipients that received induction therapy with ATG and valganciclovir prophylaxis for a median of 92 days [IQR: 90 - 114]. AbNEI titers were measured at baseline and post-transplant months 3 and 6 using microneutralization assays. Experiments were performed in duplicate for each patient. CMV-CMI was assessed at months 3 and 6 by means of the QuantiFERON-CMV® assay (Qiagen, Hilden, Germany) as per manufacturer’s instructions.

Results: One-year cumulative incidence of CMV infection and disease were 40.9% and 6.7%, respectively. All the episodes of disease occurred after discontinuation of prophylaxis. AbNEI titers increased from baseline through month 6 (geometric mean of 295.3 and 409.4; P-value for trend = 0.032). Patients with AbNEI titers ≥160 at baseline had lower incidence of CMV disease than those with titers <160 [3.5% [3/85] vs. 22.2% [4/18]; log-rank P-value = 0.003], with no differences in the occurrence of overall CMV infection. Similar differences in the subsequent incidence of CMV disease were observed for AbNEI titers ≥160 at months 3 (P-value = 0.006) and 6 (P-value = 0.038). Patients with baseline AbNEI titers above this threshold were more likely to exhibit a reactive QuantiFERON-CMV assay at months 3 [73.7% [56/76] vs. 33.3% [4/12]; P-value = 0.015] and 6 [81.4% [48/59] vs. 46.2% [6/13]; P-value = 0.014]. After adjusting for clinical covariates (including age and CMV-CMI) by Cox regression, baseline AbNEI titers ≥160 remained protective for the development of CMV disease (hazard ratio: 0.148; 95% confidence interval: 0.030 – 0.732; P-value = 0.019). No association was found between CMV disease and the results of the QuantiFERON-CMV assay.

Conclusions: High baseline AbNEI titers are protective against CMV disease among CMV-seropositive KT recipients receiving ATG induction, suggesting a role for humoral immunity independent of CMV-CMI in the setting of ATG-induced lymphodepletion.

Molecular characterisation of *Escherichia coli* isolated from children admitted with bloodstream infection in Dar es Salaam, Tanzania

Sabrina Moyo1,2, Joel Manyahi*2,3, Alasdair Hubbard4, Björn Blomberg5,6, Adam Roberts4, Nina Langeland3,5

1University of Bergen, University of Bergen, Bergen, Norway, 2Muhimbili University of Health and Allied Sciences, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, 3University of Bergen, University of Bergen, Bergen, Norway, 4Liverpool School of Tropical Medicine, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 5Haukeland University Hospital, Haukeland University Hospital, Bergen, Norway

**Background:** *Escherichia coli* is one of the leading bacterial causes of blood stream infection in children and antimicrobial resistance rates among *E. coli* is increasing worldwide. This study aimed to understand the molecular characteristics of clinical *E. coli* isolates identified between March 2017 and July 2018 from children admitted with fever in four hospitals of Dar es Salaam, Tanzania.

**Materials/methods:** A total of 28 *E. coli* were isolated from blood cultures drawn from 2226 children, and identified by MAL-DI-TOF. Whole genome sequencing of the 28 identified isolates were performed using an Illumina platform and the sequencing reads were assembled using SPAdes. Acquired antibiotic resistance genes present in the assembled genomes were identified using ResFinder, sequence type of each isolate was determined using Multilocus Sequence Type (MLST) and the plasmids were characterized using plasmid incompatibility groups (Inc) and pMLST-type (IncF).

**Results:** Extended Spectrum Beta-Lactamase (ESBL) genes were found in twelve of the 28 isolates (42.8%). *blaCTX-M* was present on the majority of isolates (10/12, 83.3%), of which nine and one were *blaCTX-M-15* and *blaCTX-M-27*, respectively. All 10 *blaCTX-M* carrying isolates also harboured either *blaOXA-1* and/or *blaTEM-1B*. The remaining two ESBL isolates carried *blaSHV-106* and *blaACT-16*. We did not identify any carbapenemase resistance genes present on any of the 28 isolates. However, resistant genes towards aminoglycosides e.g., *aac(3)-Ila*, fluoroquinolones e.g., *aac(6′)-Ib-cr/qnrS1*, sulphonamides e.g. sul1/sul2, trimethoprim e.g., *dfra17/dfrA8*, tetracyclines tet(A)/tetB, and chloramphenicol e.g. catA1/catB3 were detected. Among all 28 *E. coli* isolates, thirteen different sequence types (STs) were identified, ST1193 was the most common (n=4), followed by ST131 (n=2), ST617 (n=2), ST216 (n=2) and ST2141 (n=2). Other STs only occurred once, and seven isolates were found to be novel STs.

All the ten *blaCTX-M* carrying isolates contained an IncF plasmid replicon type and different IncF pMLST types were detected; F31:A4: B1 (n=3), F1:A2: B20 (n=2), F29: A: B10 (n=1) and F-: A1:B10 (n=4).

**Conclusions:** Our study shows high prevalence of ESBLs among *E. coli* isolated from children with blood stream infection in Dar es Salaam, Tanzania, with *blaCTX-M* being the most prominent. Diversity of the STs obtained showed that the strains are not clonally related.

**Performance evaluation of a novel BKV Quant Assay in plasma and urine specimens**

Maurizio Gramegna*1, Giulia Ferri1, Alessandro DI Cosimo1, Giacomo Torini1, Lijie Gong2, Daniel Krause2, Cameron Butcher2, Michelle Mastronardi2, Betty Wu2, Sundu Brahmasandra2

1Sentinel Diagnostics, Milan, Italy, 2NeuMoDx Molecular, Ann Arbor, United States

**Background:** BK virus (BKV) infection is linked to two major complications: BKV associated nephropathy (BKVAN) in kidney transplant patients and BKV associated hemorrhagic cystitis in hematopoietic stem cell transplant patients. Consequently, active screening of BKV replication in urine and blood combined with preemptive modulation of immunosuppression therapy are essential measures to prevent complications from BKV infections. The NeuMoDx BKV Quant Assay, developed by Sentinel Diagnostics, enables rapid quantitative detection of BKV in plasma and urine matrices to assist in monitoring BKV infections in such patients.

**Materials/methods:** Performance of the NeuMoDx BKV Quant Assay was characterized in urine (550µL) and two different input volumes (100 µL and 500 µL) of plasma. The performance of the NeuMoDx BKV Quant Assay were demonstrated across key analytical metrics including analytical sensitivity (LoD), linearity, precision, turnaround time, and specificity. Evaluation of the analytical sensitivity was performed using the 1st WHO International Standard for BKV, and the limits of quantitation (LLoQ/ULoQ) were determined using the TAE ≤ 1.0 criterion.

**Results:** Using an input specimen volume of 550µL, the NeuMoDx BKV Assay demonstrated a limit of detection (LoD) and lower limit of quantitation (LLoQ) of 60 IU/mL in plasma and an LoD/LLoQ of 100 IU/mL in urine. With lower specimen volume, 100µL, the NeuMoDx BKV Assay demonstrated a LoD/LLoQ of 350 IU/mL in plasma. The NeuMoDx BKV Quant Assay also showed excellent linearity across a ~8-log dynamic range with a ULoQ of 9 Log10 IU/mL. Excellent quantitative precision across 3 systems over 6 days, as well as quantitative equivalency across multiple reagent lots was demonstrated. Turaround time was ~60min and no cross-reactivity was observed against >20 relevant non-target pathogens tested. The test performed efficaciously in the presence of endogenous/exogenous interfering moieties. Finally, equivalent quantitative performance (equivalence slope >0.95 with absolute bias < 0.25 Log10 IU/mL) was demonstrated across 100µL and 550µL input specimen volumes of plasma.

**Conclusions:** The NeuMoDx BKV Quant Assay is well suited for implementing BKV viral load monitoring using plasma and urine specimens in normal and low specimen volume settings.

Abstract 6374

New approach for determination of antimicrobial susceptibility to amoxicillin by an acoustic sensor-based on a slot mode

Olga Guliy*, Boris Zaitsev, Olga Karavaeva, Irina Borodina

1Institute of Biochemistry & Physiology of Plants & Microorganisms RAS, Saratov, Russian Federation, 2Kotelnikov Institute of Radio Engineering and Electronics, Russian Academy of Sciences, Saratov Branch, Saratov, Russian Federation

Abstract third-party references: This work was partially supported by the Russian Foundation for Basic Research [grants № 19-07-00300 and 19-07-00304].

Background: The use of antibiotics leads to a decrease of the number of deaths from infectious diseases. Traditional microbiological methods, based on inhibiting the growth of microorganisms in the presence of antibiotics, are characterized by high detection sensitivity, but require a long time. Therefore, the development of new technologies and methods for testing the activity of the antibiotic against bacteria is very relevant.

Materials/methods: The experiments were carried out using the developed acoustic sensor, consisting of two piezoelectric plates separated by an air gap. Using two interdigital transducers located on one of the plates, a piezoactive acoustic wave was excited and received. The second plate served as the bottom of a liquid container with a suspension of test cells. Excitation of the slot mode in such a structure led to the appearance of resonance absorption peaks in the frequency dependence of the insertion loss. The change in the frequency and depth of these peaks when an antibiotic was added to nonresistant/resistant cells was used as an informative analytical signal.

Results: For the first time, a rapid method was proposed for determining the susceptibility of Escherichia coli cells to antibiotics by the example of amoxicillin by the acoustic sensor. It has been established that an indicator of the activity of an antibiotic in relation to microbial cells is the difference between the recorded sensor signal for cell suspension without exposure to the antibiotic and after exposure. The depth and frequency of the peaks of resonant absorption in the frequency dependence of the insertion loss of sensor varied after adding an antibiotic with different concentrations (2-18 μg/ml) to the cells. A criterion for the sensitivity of E. coli cells to amoxicillin for using an acoustic sensor was established.

Conclusions: These results demonstrate the possibility of using a device with a slot mode in an acoustic delay line for determining the susceptibility of microbial cells to antibiotics. The advantages of this method are the ability to carry out the analysis directly in the liquid, the short time of the analysis (within 15 min) and the possibility of multiple use of the sensor.

A multi-year decline of multidrug-resistant Escherichia coli in French nursing homes and primary care: are we on the good track?

Sonia Thibaut*, Thomas Coeffic, David Boutoille, Gabriel Birgand, Jocelyne Caillon, Primo Network

1Cpias Pays de la Loire, Nantes, France; 2CHU de Nantes, Nantes, France

Abstract 6376

Background: Since 2012, a French national system surveys the antimicrobial resistance among Enterobacteriaceae in primary cares and nursing homes (NH). This study describes characteristics and temporal and geographical trends of multi-drug resistant Escherichia coli.

Materials/methods: From 1st January 2012 to 31st December 2018, antibiograms of E.coli isolated from urine samples were collected in a large network of laboratories across France. Administrative and microbiological data were downloaded by laboratories on an e-platform dedicated to the surveillance. Strains isolated from patients living at home or NH residents were included in the analysis. Hospitalised patients and screening samples were excluded. The multi-drug resistant E.coli rates were the number of third generation cephalosporins (3GC) resistant or/and extended spectrum beta-lactamase (ESBL) E.coli strains by divided by the total number of strains. Statistical analyses were performed using Student test or variance analysis as appropriate.

Results: The total number of E.coli antibiograms included varied from 94,164 in 2012 (147 laboratories) to 381,141 in 2018 (742 laboratories across 11 French regions). When accommodation was notified, 95.3% (n=32,710) of patients were living at home and 4.7% (n=1,598) were residents in NH in 2012 vs 96.1% (n=335,338) and 3.9% (n=13,720) in 2018, respectively. Among patients living at home, the proportion of E.coli resistant to 3GC was 3.0% in 2012, 4.2% in 2015, and 3.2% in 2018 (p<0.001), and the proportion of ESBL-E.coli was 2.3%, 3.7% and 2.8% (p<0.001), respectively. In 2018 in the same population, the proportion of ESBL-E.coli varied from 2.2% to 3.6% according to regions. Among residents living in NH, the proportion of E.coli resistant to 3GC was 8.0% in 2012, 11.1% in 2015 (p<0.01) and 8.6% in 2018 (p<0.001), and the proportion of ESBL-E.coli was 6.6%, 9.7% and 7.7% (p<0.001), respectively. In 2018 in NH, the proportion of ESBL-E.coli varied from 15.1% to 28.6% according to regions. (Figure)

Conclusions: This study suggests a multi-year decrease of multi-drug resistance among E.coli both in the French community and NH. An analysis of potential associations with results obtained from national hand hygiene and antibiotic consumption surveillances is ongoing. Figure: Temporal and geographical trends for ESBL-E.coli in NH and the community.

1Geneva University Hospital, Infection Control Program, Geneva, Switzerland, 2University Medical Centre Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands, 3University Hospital Tübingen, Infectious Diseases, Tübingen, Germany, 4University Hospital Besançon, Infection Control Unit, Besançon, France, 5Infectious Diseases, Microbiology and Preventive Medicine. University Hospital Virgen Macarena., Sevilla, Spain, 6Tübingen University Hospital, Institute of Medical Microbiology and Hygiene, Tübingen, Germany, 7Geneva University Hospital, Bacteriology Laboratory, Geneva, Switzerland, 8University Hospital Tübingen, Institute of Medical Microbiology and Hygiene, Tübingen, Germany, 9University Medical Centre Utrecht, Department of Medical Microbiology, Utrecht, Netherlands, 10Virgen Macarena University Hospital, Infectious Diseases, Sevilla, Spain

**Background:** Human-to-human transmission of ESBL-producing *Enterobacteriaceae* (ESBL-PE) may play an important role in their dissemination, especially within households. This study aimed to determine rates and dynamics of ESBL-PE acquisition and transmission in households after hospital discharge of an ESBL-PE index patient.

**Materials/methods:** We conducted a prospective, observational cohort study between Nov 2017 and Aug 2019 in 5 European cities. ESBL-PE-positive index patients and their household contacts were recruited at index patients’ hospital discharge (baseline). During 4-month follow-up, all participants were asked to provide personal information and 4 stool samples or rectal swabs (at baseline, 1 week, 2 & 4 months). ESBL-producing *E. coli* (ESBL-EC) and *K. pneumoniae* (ESBL-KP) were identified by conventional methods and MALDI-TOF. Genomes were obtained with Illumina NextSeq and phylogenetic trees were built per species by PopPUNK. Incidence rates of acquisition [new ESBL-PE detection in a previously negative household contact] and transmission [acquisition of a similar strain previously detected in another household member] were estimated at pheno- and genotypic level overall and per species.

**Results:** 71 index patients were enrolled carrying ESBL-EC (n=46), ESBL-KP (n=20) or both (n=5). 29/95 household contacts (31%) in 26 households were ESBL-PE positive at baseline and 18 participants (18%) in 16 households became positive during follow-up. Based on phenotypical assessment, the overall incidence rate of ESBL-PE acquisition was 1.9/100 participant-weeks at risk [ESBL-EC: 1.1; ESBL-KP: 0.6; RR 1.7, 95%CI 0.7-3.9] and the overall rate of transmission was 1.3 events/100 participant-weeks of follow-up [ESBL-EC: 1.3; ESBL-KP: 1.0; RR 1.3, 95%CI 0.5-4.0]. Transmission rates varied between 0.2 and 2.1 event/100 weeks across cities. ST131 [41%] and ST1537 [13%] were the most frequent sequence types in ESBL-EC and ESBL-KP, respectively. *blaCTX-M-15* was the predominant ESBL gene in both species [57-67%]. 67% of strains phenotypically suspected of transmission shared the same MLST and ESBL genes.

**Conclusions:** Half of the households had secondary ESBL-PE cases, with a third of family members already positive at baseline. Transmission rates were similar for ESBL-EC and ESBL-KP. Two thirds of putative ESBL-PE transmission events were associated with genetically related strains.

Abstract 6381

Antimicrobial resistance surveillance in low- and middle-income countries: can we estimate resistance in bloodstream infections from other types of specimen?

Karina-Doris Vihta1, Nicola Claire Gordon1, Nicole Stoesser1, T Phuong Quan1, Carina Tyrrell1, David Eyre1, Nicholas White4, Derrick Crook1,5,6, Tim Peto1,5,6, A. Sarah Walker1,5,6

1University of Oxford, Nuffield Department of Clinical Medicine, Oxford, United Kingdom, 2Mott MacDonald, London, United Kingdom, 3University of Cambridge, Cambridge, United Kingdom, 4University of Oxford, Mahidol Oxford Research Unit, Bangkok, Thailand, 5Oxford National Institute for Health Research Health Protection Research Unit, Oxford, United Kingdom, 6University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Background: Antimicrobial resistance (AMR) is a major global health threat. AMR surveillance is difficult in LMICs, where lack of laboratory capacity prevents routine patient-level antimicrobial susceptibility testing, and systematic invasive testing of individuals may not be feasible. Evaluation of AMR in non-invasive/colonisation samples may be of benefit in predicting AMR in invasive cases.

Materials/methods: We used data from Oxford University Hospitals, UK, 1998-2018, to investigate if AMR rates in Escherichia coli and Staphylococcus aureus isolates from blood could be predicted using only other types of specimen, more readily cultured in LMICs. We compared the proportion resistant in blood versus the proportion resistant in other sample types in each calendar year using time series cross-correlations, including all antibiotics for which both blood and non-sterile sites isolates were consistently tested between 1998-2018 (four for E. coli, six for S. aureus). We compared the proportion of resistant blood cultures versus the proportion of resistant other cultures across drug-years including an additional eight and ten antibiotics respectively, tested only after 2013, using four clinically relevant resistance thresholds (<5%, 5-10, 10-20%, >20%).

Results: 8080 E. coli bloodstream infections, 32207 E. coli urinary tract infections, 6926 S. aureus bloodstream infections and 11463 S. aureus non-sterile site cultures were included in the analyses. Trends over time in blood vs other specimens were strongly correlated [maximum cross-correlation 0.53-0.98 with strongest associations between proportions in the identical year for 8/10 bug-drug combinations]. Resistance prevalence was broadly congruent across drug-years for each species [Figure], particularly allowing for uncertainty in estimating proportions. 212/318 (67%) bug-drug-years had resistance prevalence in other sample types within ±5% of blood isolates, and 279/318 (88%) within ±10%. 218/318 (69%) bug-drug-years had the same resistance percentage threshold categorisation for both blood and other specimen types, 310/318 (97%) had either the same resistance categorisation or within ±1.

Conclusions: The rate of AMR in bloodstream infections and other less invasive infections are strongly related, implying the latter could be used as a surveillance tool for AMR in LMICs. These infection sites are easier to sample from and cheaper to carry out antimicrobial susceptibility testing on, and can provide evidence for decisions such as empiric antibiotic recommendations.

**A mobilisable plasmid spreads the blaGES-6 carbapenemase gene among multidrug-resistant Enterobacter cloacae complex isolates**

Jesús Rodríguez Lozano*1, María Pilar García Lloris2, María Lucas3, Luis Martínez-Martínez1, Jesús Aguerro1, Jorge Calvo-Montes1

1Marqués de Valdecilla University Hospital, Microbiology Service - IDIVAL, Santander, Spain, 2Instituto de Biomedicina y Biotecnología de Cantabria, Santander, Spain, 3Hospital Universitario Reina Sofia, Microbiology Service, Córdoba, Spain

**Background:** The clinical relevance of *Enterobacter* spp. is highlighted by its inclusion in the ESKAPE group. Resistance gene spreading through mobile genetic elements is of key importance to this group. One of the most important resistance mechanisms is the production of enzymes that hydrolyze carbapenem antibiotics.

Here we aimed at determining the genetic context of the *blaGES-6* carbapenemase gene found in a collection of multidrug-resistant *E. cloacae* complex (Ecpx) isolates, and the possible way for its dissemination.

**Materials/methods:** Nine clinical isolates of GES-6-producing Ecpx were selected for whole genome sequencing with Illumina MySeq. Genome assembly and plasmid reconstruction were carried out by using PLACNETw. Plasmid genome comparisons were performed with BRIG. Plasmid DNA was extracted with GeneJet plasmid kit (ThermoFisher), digested with restriction enzymes *BstBI*, *HpiI* and *MluI* to remove all plasmids but that encoding *blaGES-6* (*pGES-6*), and transformed into *Escherichia coli* strain DH5α. DH5α (*pGES-6*) was tested for antimicrobial susceptibility with Vitek2 (BioMerieux) or gradient strips, following the EUCAST recommendations. DH5α (*pGES-6*) derivatives, containing different conjugative plasmids (*pOX38, R100-1, R751, R388*, and *R64drd11*), were used as donors in mating experiments to test for *pGES-6* transfer. *E. coli* UB1637 was used as a recipient. Matings were carried at 37°C onto solid surfaces during 1h. The conjugation frequency was expressed as the number of transconjugants per donor cell.

**Results:** The carbapenemase gene *blaGES-6* is the single gene cassette of a class 3 integron encoded in a plasmid (*pGES-6*), which is 8259 bp in size and identical in all isolates (Figure 1). Susceptibility testing of DH5α (*pGES-6*) showed a MIC increase for amoxicillin, amoxicillin-clavulanate, cefuroxime, cefoxitin, ceftazidime and imipenem, compared to the empty strain. *pGES-6* is a MOBQ mobilizable plasmid that can be transferred between *E. coli* strains by different conjugative plasmids. The IncP1β plasmid R751 was the most efficient helper of *pGES-6* (mobilization frequency: 0.18).

**Conclusions:** Plasmid *pGES-6* circulates among Ecpx, spreading the *blaGES-6* carbapenemase gene. Its ability to replicate and transfer into other enterobacteria, such as *E. coli*, makes Ecpx bearing *pGES-6* a potential source for *blaGES-6* dissemination.

![Figure 1. Genetic map of the pGES-6 plasmid.](image)

Whole genome sequence analyses by a new easy-to-use software solution confirm a neonatal ward outbreak of MRSA CC22 being related to strains in the neighbouring region

Marie Louise Slott Jensen¹, Ming Chen², Marianne Nielsine Skov¹, Michael Kemp*¹

¹Odense University Hospital / University of Southern Denmark, Research Unit for Clinical Microbiology, Odense C, Denmark, ²Hospital Sønderjylland, Dept. Clinical Microbiology, Sønderborg, Denmark

Background: Effective monitoring of hospital transmission of pathogens requires efficient and detailed characterization of the microorganisms. Core genome MLST (cgMLST) based on whole genome sequencing allows bacteria to be divided into clusters with a unique resolution. 1928 Diagnostics is a new online cgMLST based software solution, which can be used to characterize and cluster selected bacteria, including S. aureus, by infection control units without bioinformatic assistance. We used 1928 Diagnostics to retrospectively test a neonatal ward outbreak of MRSA CC22 in 2014 after transfer of patients from a hospital in a neighboring area.

Materials/methods: We analyzed isolates of MRSA CC22 from 1) individuals considered part of the outbreak, 2) individuals living in the region, collected over the preceding seven years, and 3) individuals from the neighboring area in the same year as the outbreak. Two isolates from the region were from the same patient. Raw sequence data (.fastq.gz files) was uploaded to 1928 Diagnostics (https://www.1928diagnostics.com/).

Data processed by 1928 Diagnostics was presented with MLST sequence type (ST) and antibiotic resistance genes profiles. A core genome MLST (cgMLST) based cluster tree showed isolates of potential relatedness. Definite core genome MLST cluster types were not assigned to individual isolates.

Results: Sequence data from ten outbreak isolates, ten isolates previously obtained from individuals in the region, and twenty-six isolates from individuals in neighboring region passed the quality control step and were identified as MRSA ST22. The isolates were all SCCmec type IV. Genes for PVL, TSST and ETS were not detected. blaZ and mecA genes were present in all isolates and ermC gene was detected in six isolates. Cluster analyses revealed that all supposed outbreak isolates were within one cluster and that five of the isolates from the neighboring area were in the same cluster (Figure).

Conclusions:

- Online whole genome sequence analyses by 1928 Diagnostics characterized the isolates and separated outbreak isolates from local non-outbreak isolates.
- The results are in accordance with introduction of the outbreak strain with patients transferred from a hospital in a neighboring area.
- 1928 may prove valuable to infection control units without bioinformatic expertise.

Unexpected genetic diversity among KPC-producing Klebsiella pneumoniae in France

Remy Bonnin*, Agnes Jousset¹, Adriana Chiarelli², Emeraud Cécile¹, Philippe Glaser², Thierry Naas¹, Laurent Dortet¹

¹Paris-Sud University, Le Kremlin-Bicêtre, France, ²Pasteur Institute, Paris, France

Background: The worldwide spread of KPC-producing K. pneumoniae (KPC-Kp) isolates was reported to be due to the dissemination of one clonal complex, i.e. CG258 (including ST258 and ST512). However, recent epidemiological European study is not available. The aim of this study was to deeply characterize the epidemiology of KPC-producing K. pneumoniae circulating in France in 2018.

Materials/methods: During 2018, 1,259 isolates of carbapenem non-susceptible K. pneumoniae clinical isolates were received by the french NRC for carbapenem-resistance in Enterobacterales. Among this collection, 63 KPC producing K. pneumoniae were fully sequenced by Illumina’s technology and further analyzed. Resistomes, susceptibility testing and clonal relationship at a nationwide scale were determined.

Results: Among the 63 KPC-producing isolates, 16 different STs were identified including two main clones, representing 41% of all isolates. These two STs, ST147 and ST307, represented 19 and 22% respectively. Analysis of resistomes indicated that the main variant was bla_{KPC3} (73%). In addition, one isolate co-harboured bla_{KPC2} and bla_{NDM4} genes and one co-harboured bla_{KPC2} and bla_{VIM-1}. The bla_{KPC} genes were mostly carried by Tn_{4401a} and Tn_{4401d} structures and 4 new NTE [Non Tn_{4401} Element] were characterized. These structures were carried mostly by three types of plasmids being IncN ST15, pKPQIL-like and an Inc-FIA-family plasmid. Epidemiological investigations highlighted that the emergence of these non-CG258 KPC-Kp in France was linked to the dissemination of these clones from Portugal.

Conclusions: This study described the unexpected wide genetic diversity of KPC-producing K. pneumoniae in France. Thus, KPC-producing Kp epidemiology has changed in Europe, at least in several not endemic countries of the West Europe such as France and Portugal, where CG258 is not the most prevalent clone anymore.

Abstract 6392

**Identification of Mycobacterium species with MALDI-TOF mass spectrometry**

Zeynep Saribas1, O. Kaya Koksalan2, Hazal Gur*1, Selay Demirci1, Alpaslan Alp1

1Hacettepe University Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey, 2Istanbul University, Aziz Sancar Institute for Medical Experimental Research (DETAIE), Istanbul, Turkey

**Background:** The identification of *Mycobacterium* to species level is important since the genus *Mycobacterium* consists of non-pathogenic environmental species as well as pathogenic species causing serious diseases. Matrix-assisted laser desorption ionization–time of flight mass spectrometry (MALDI-TOF MS) is an inexpensive, reliable way of identifying microorganisms. The aim of this study was to evaluate MALDI-TOF MS method in identification of *Mycobacterium* species so that appropriate treatment can be given when indicated.

**Materials/methods:** A total of 36 clinical isolates (24 species) of nontuberculous mycobacteria (NTM), that were identified with hsp65 gene restriction enzyme analysis, were included in the study. The isolates were subcultured onto both MGIT broth and Lowenstein-Jensen media. Heat inactivation and MALDI-TOF MS (Bruker MALDI Biotyper) procedures were applied, as it is recommended by the manufacturer, to the mycobacteria that were grown on both MGIT and Lowenstein-Jensen media.

**Results:** Among 36 isolates, 31 of them (20 species) were identified correctly with MALDI-TOF MS. These species were *M. gordoa*, *M. elephantis*, *M. peregrinum*, *M. cosmeticum*, *M. simiae*, *M. engbaekii*, *M. phocaicum*, *M. avium*, *M. kansasii*, *M. chelonae*, *M. xenopi*, *M. arupense*, *M. nonchromogenicum*, *M. abscessus*, *M. intracellulare*, *M. mageritense*, *M. celeriflavum*, *M. fortuitum*, *M. neoaurum*, *M. europaeum*. Five isolates (4 species) were misidentified. *M. smegmatis*, *M. senuense*, *M. monocense*, and *M. porcinum* species were misidentified as *M. mageritense*, *M. avium/terrae complex*, *M. fortuitum*, *M. septicum* respectively. Same MALDI-TOF MS results were obtained from cultures of MGIT and LJ media.

**Conclusions:** MALDI-TOF MS is a correct, relatively rapid, inexpensive way of identification of *Mycobacterium* species. Although results of MALDI-TOF MS had a high concordance with the results of hsp65 gene restriction enzyme analysis, it should be kept in mind that some genetically close species can be misdiagnosed with MALDI-TOF MS.

A study of virulence factors and antimicrobial resistance in Staphylococcus epidermidis isolates from ocular infections

Nishat Hussain Ahmed*, Arkendu Basu2, Gita Satpathy2, Bimal Tezpur2, Namrata Sharma2, Rohan Chawla2

1All India Institute of Medical Sciences, New Delhi, India, 2All India Institute of Medical Sciences, New Delhi, India

Background: Staphylococcus epidermidis is part of commensal flora of the conjunctiva. It is also the most common bacterial pathogen causing ocular infections. Ocular infections occur due to some breach in ocular defence mechanisms; of which endophthalmitis and keratitis are the most common and most dreaded infections due to their effect on patient’s vision. The extent and course of infection depends on virulence and antimicrobial susceptibility of the infecting strain. The study was planned to speciate coagulase negative staphylocci (CoNS) isolated from keratitis and endophthalmitis patients, and to study the virulence factors and resistance profile of the S. epidermidis isolates.

Materials/methods: Culture isolates of CoNS from 86 cases of keratitis and endophthalmitis, and 20 healthy controls were included in the study. Speciation of CoNS was done using conventional methods and Matrix Assisted Laser Desorption Ionisation – Time of Flight Mass Spectrometry (MALDI TOF MS).

S. epidermidis was the most common CoNS isolated. The virulence attributes determined were ability to cause hemolysis and biofilm formation; and production of protease, gelatinase, lipase and DNase enzymes. Resistance profile was studied using disc diffusion, e-test for minimum inhibitory concentration (MIC) of vancomycin and polymerase chain reaction (PCR) for mec A gene causing methicillin resistance.

Results: Most common CoNS isolated was S.epidermidis (n= 48, 56% in test and n=9, 45% in control groups) followed by S.hemolyticus.

Production of lipase enzyme (96% isolates), biofilm formation (81% isolates) and alpha-hemolysis (58% isolates) were the most important virulence factors. Methicillin resistance was found in 67% and 56% of isolates in test and control groups respectively. Macrolide and fluoroquinolone resistance was seen in 63% and 35% of isolates respectively. Vancomycin-resistance was not seen in any of the isolates; however ‘creeping MIC’ phenomenon was seen in five test isolates. PCR for mec A gene was found positive in 65% of test and 56% of control strains.

Conclusions: The study has elucidated important virulence factors and resistance profile of the most common ocular bacterial pathogen. Also, to the best of our knowledge this is the first study co-relating methicillin resistance with presence of mec A gene in S. epidermidis isolates from ocular infections.

Epidemiology and differential diagnosis of chikungunya and O’nyong-nyong virus: many gaps of knowledge to be filled
Laura Pezzi*1,2, Issa Diarra2
1University of Corsica, EA7310 BIOSCOPE, Laboratoire de Virologie, Corte, France, 2University of Aix-Marseille, Unité des Virus Émergents (UVE: Aix-Marseille Univ-IRD 190-Inserm 1207-1HU Méditerranée Infection), Marseille, France

Abstract third-party references: On behalf of GloPID-R chikungunya, o’nyong-nyong and Mayaro virus Working Group

Background: In the last 15 years, chikungunya virus (CHIKV) has impacted human health globally, with local transmission reported in Asia, Africa, Americas, Pacific region and, transiently, in Europe. The recent occurrence of extensive CHIKV epidemics has highlighted the need for improved capacity for diagnosis and surveillance, especially when the co-circulation of closely related viruses increases the chance of misdiagnosis. In particular, o’nyong-nyong virus (ONNV) is phylogenetically close to CHIKV, it causes a similar clinical presentation and its geographic spread overlaps with CHIKV in Africa. Serological tests are hampered by massive cross-reactivity between CHIKV and ONNV; among available assays, virus neutralization test (VNT) is actually the gold standard to distinguish the two viruses in sero-epidemiological studies.

Materials/methods: The GloPID-R (Global Research Collaboration for Infectious Disease Preparedness) CHIKV Working Group investigated gaps of knowledge about the diagnosis and the epidemiology of these viruses and aimed to provide adapted recommendations for future research. Data from available scientific literature were combined with experts' experience.

Results: The experts established that to improve diagnosis of CHIKV and ONNV at the acute phase, both molecular and serological assays require further evaluation, standardized protocols, reference panels and international standards. Moreover, available seroprevalence data on CHIKV and ONNV distribution are largely affected by cross-reactivity and in areas of potential co-circulation both viruses should be tested with VNT. In a cross-sectional study performed in Mali in 2016, CHIKV ELISA seroprevalence mean value was 48%, reaching up to 65-69% in some regions. When retested with VNT, the large majority of CHIKV+ samples was in reality ONNV+. These results highlight that high-throughput assays that can distinguish among the two viruses are necessary to perform large-scale epidemiological studies of public health relevance.

Conclusions: Overlapping clinical presentations, wide geographic spread and cross-reactivity among CHIKV and ONNV highlight the need for laboratory supports to unambiguously identify etiological agents and to obtain strong epidemiological data. This is important to ensure an early detection of cases and to support a clinical and public health response. Considering the high risk of future CHIKV and ONNV outbreaks, a major effort should be done to fill the existing diagnostic gaps.

Abstract third-party references: On behalf of the ZENITH study group

**Background:** We aimed to assess the characteristics and outcomes of neutropenic cancer patients with *Pseudomonas aeruginosa* (PA) bloodstream infection (BSI) treated with ceftolozane-tazobactam.

**Materials/methods:** We performed a descriptive, multicenter, international, retrospective cohort study including onco-hematological neutropenic patients with BSI due to PA who received ceftolozane-tazobactam as empirical and/or definitive therapy across 13 centres from 4 countries (January 2016 - October 2019).

**Results:** We included 31 episodes of PA BSI, of which 90.3% and 41.9% were caused by multidrug-resistant (MDR) or extensively-resistant strains, respectively. All patients had a underlying hematological disease, most commonly myeloid leukaemia (61.3%). 32.3% of patients were allogeneic hematopoietic stem cell transplant recipients, and 76.7% had profound neutropenia (<0.1x10⁹/L). Two episodes were polymicrobial. Pneumonia was the most frequent source of BSI (25.8%), followed by catheter infection (19.4%). Septic shock at onset was present in 29% of patients. Inadequate empirical antibiotic therapy was administered to 41.9% of patients, mainly with meropenem or piperacillin/tazobactam monotherapy. Ceftolozane-tazobactam was administered empirically in 8 patients; 4 in combination with other drugs (aminoglycosides 3, and colistin 1) and 4 in monotherapy. Five of these 8 patients were known to be previously colonized by a MDRPA strain. Ceftolozane-tazobactam was used as definitive therapy in 30 patients; 14 in combination with other drugs (aminoglycosides 11, fosfomycin 1, ciprofloxacin 1, and colistin + fosfomycin 1) and 16 as monotherapy. The main reason for antibiotic change was the identification of a MDRPA strain. Three patients with susceptible PA BSI received ceftolozane-tazobactam due to septic shock in 2 cases, and as a carbapenem-sparing alternative in 1. In 4 patients, it was administered in extended infusion. Seven patients required ICU admission and 4 mechanical ventilation. Only one patient had persistent BSI after 48 hours of antibiotic treatment. Early [7-day] and overall [30-day] case-fatality rates were 3.3% and 16.1%, respectively. No related adverse events were observed.

**Conclusions:** In this real-life experience, ceftolozane-tazobactam was used in patients with BSI due to PA, mostly in patients with infection due to MDR strains and pneumonia. Ceftolozane-tazobactam appears to be safe and efficacious for the treatment of these extremely high-risk patients.

1ALIMA, Paris, France, 2INSERM 1219, Bordeaux, France, 3ALIMA, Kinshasa, Democratic Republic of Congo, 4University of Bordeaux, Bordeaux, France

**Abstract third-party references:** ALIMA, INSERM

**Background:** The largest Ebola epidemic of the Democratic Republic of the Congo has been ongoing since August 2018, with an overall mortality rate of over 65%. New vaccines and specific immunotherapies implemented during this outbreak allowed starting post exposure prophylaxis (PEP) management for high risk viral contact. Considering the gap between vaccine administration and individual protectiveness, those specific therapeutics based on monoclonal antibodies were to be used. ALIMA (French medical NGO) health care workers (HCW) with high risk contact were managed with PEP using specific immune-therapeutics through compassionate use (MEURI, for monitored emergency use of investigational drugs).

**Materials/methods:** After being exposed to intermediate (Intact-skin-only contact) or high risk (broken skin contact) with an Ebola positive patient, participants provided consent through MEURI protocol. Ebola RT-PCR and clinical examination was performed at D0, then mAb114 or REGN-EB3 drug was injected once negative RT-PCR results were confirmed. Clinical follow-up was done by phone at D7. Subsequently, D14 evaluation was implemented for clinical status and Ebola RT-PCR as to confirm patient status for infection.

**Results:** 33 participants were included (31 adults (30 HCW), 2 babies). Median (IQR) age was 31 (25, 39) years old, 58% male. Vaccination status was known for 31/33 participants, and all adults (29/31) were vaccinated. Mean (SD) time between contact and administration was 2.2 (1.2) days. On the 18/33 (55%) on which the exact dates of vaccination were known, median (IQR) time between vaccine and PEP administration was 173 (19, 427) days. 70% received the mAb114. Report suggest that no participants developed Ebola at D14.

**Conclusions:** With specific treatments raising proof of efficacy, it is considered now unethical on a field carer perspective not to propose the best individual strategy to avoid developing Ebola when being exposed to high risk contact. While ALIMA has been the first NGO to propose this solution to his personal, extending the PEP outside compassionate use will be of higher interest for next outbreaks. Good quality studies are needed to answer important questions, in particular about interaction with vaccines, both treatments sharing the same target as the vaccine strategy currently used in the field.

The interplay of resistance mechanisms associated with reduced susceptibility and resistance to imipenem and ceftazidime-avibactam in clinical *Pseudomonas aeruginosa* isolates from Switzerland

Baharak Babouee Flury*1,2, Anja Bösch1, Valentin Gisler1,2; Michael Oberle1, Hans Fankhauser3, Vladimira Hinic5, Adrian Egli5,6, Salome Seiffert7, Nolte Oliver7, Jacqueline Findlay8

1Division of Infectious Diseases and Hospital Epidemiology, Cantonal Hospital St. Gall, St. Gall, Switzerland, 2Medical Research Centre, Cantonal Hospital St. Gall, St. Gall, Switzerland, 3Institute for Laboratory Medicine, Cantonal Hospital Aarau, Aarau, Switzerland, 4Clinical Infectious Diseases and Hospital Hygiene, Cantonal Hospital Aarau, Aarau, Switzerland, 5Clinical Bacteriology and Mycology, University Hospital Basel, Basel, Switzerland, 6Department of Biomedicine, University of Basel, Basel, Switzerland, 7Division of Human Microbiology, Centre for Laboratory Medicine, St. Gall, Switzerland, 8University of Bristol, University Walk, School of Cellular & Molecular Medicine, Bristol, United Kingdom

**Background:** Increasing reports of multidrug resistance (MDR) in clinical *Pseudomonas aeruginosa* have led to a necessity for new antimicrobials. The beta-lactamase/inhibitor combination, ceftazidime-avibactam (CAZ-AVI), is indicated for use against MDR *P. aeruginosa* against a broad range of infection types and particularly those that are carbapenem resistant. This study sought to determine the mechanisms of CAZ-AVI and imipenem (IPM) resistance in clinical *P. aeruginosa* isolates obtained from Swiss hospitals

**Materials/methods:** Increasing reports of multidrug resistance (MDR) in clinical *Pseudomonas aeruginosa* have led to a necessity for new antimicrobials. The beta-lactamase/inhibitor combination, ceftazidime-avibactam (CAZ-AVI), is indicated for use against MDR *P. aeruginosa* against a broad range of infection types and particularly those that are carbapenem resistant. This study sought to determine the mechanisms of CAZ-AVI and imipenem (IPM) resistance in clinical *P. aeruginosa* isolates obtained from Swiss hospitals

**Results:** Fifteen STs were identified amongst the 15 isolates in this study. No carbapenemases were detected but one isolate harboured the ESBL *bla*<sub>PER-1</sub>. Seven isolates were CAZ-AVI-R with MICs ranging from 1-2 to 64 mg/L, and the remaining eight isolates had either low/wildtype MICs (n=6; 1-2 mg/L) or reduced susceptibility (n=2; 4-6 mg/L). Six isolates were IPM-R, four of which had mutations resulting in truncations of OprD, and the remaining six IMP-S isolates had intact *oprD* genes. Within CAZ-AVI-R isolates, and those with reduced susceptibility, mutations resulting in *ampC* derepression, OprD loss, *mexAB* overexpression and ESBL (*bla*<sub>PER-1</sub>) carriage were observed in various combinations. Within the six wildtype isolates no mutations were found that would affect any AMR genes of interest when compared to PAO1. Just one isolate, with a CAZ-AVI MIC of 12 mg/L, had none of these mechanisms at play and requires further investigation

**Conclusions:** This preliminary study highlights that CAZ-AVI-R in *P. aeruginosa* is multifactorial and could be caused by the interplay between different resistance mechanisms including ESBL carriage, increased efflux, loss of permeability and derepression of its intrinsic AmpC enzyme. IPM-R appears to be mainly due to OprD loss as previously reported. This area warrants further study to prevent the selection of CAZ-AVI-R and the risk of subsequent therapy failure

Abstract 6403

Background: Emerging extensively drug-resistant (eXDR) bacteria is a growing public health concern. Infection control measures are essential to limit their spread among hospitalized patients. The objective was to describe the trends of eXDR bacteria cases between 2015 and 2019 at Lyon University hospitals.

Materials/methods: Incident eXDR bacteria cases, including carbapenemase-producing Enterobacteriaceae (CPE) and vancomycin-resistant Enterococcus faecium (VRE) were monitored prospectively from January 1, 2015 to June 30, 2019 at Lyon University hospitals (5,300 beds). The microbiology laboratory alerts the infection control teams for each new eXDR bacteria isolated. A case was a colonized or an infected patient diagnosed with an eXDR bacteria. An outbreak was at least 1 secondary case due to the same bacteria with the same resistance mechanism, in the same unit within an acceptable interval time. Molecular identification might not be part of the definition in the emergency context. Incidence was reported for 10,000 hospital days.

Results: Since 2015, 667 incident eXDR bacteria cases were diagnosed, among them 575 (86.2%) CPE and 92 (13.8%) VRE. The mean age was 67.3 years. Overall, 368 (55.2%) cases were detected in medical wards, 146 (21.9%) in surgery wards and 83 (12.4%) in intensive care units. Sixty four (69.6%) VRE cases developed vanA resistance and 28 (30.4%) vanB resistance. Among CPE cases, 384 (66.8%) developed OXA-48 resistance, 135 (23.5%) VIM, 50 (8.7%) NDM, 5 (0.9%) KPC and 1 (0.2%) IMI. Regarding CPE species, 147 (24.5%) were Citrobacter freundii, 128 (22.3%) Enterobacter cloacae, 112 (19.5%) Klebsiella pneumoniae and 97 (16.9%) Escherichia coli. A total of 563 (84.4%) eXDR cases were colonized against 104 (15.6%) infected; 59 outbreaks occurred during the study period generating 200 (30.0%) secondary cases. The incidence rate increased from 0.44/10 000 hospitalization days in 2015 to 2.39/10000 in 2019 (p=0.003). Figure 1 shows the epidemic curve of eXDR bacteria cases from 2015 to 2019.

Conclusions: From 2015 to 2019, the incidence of eXDR bacteria cases and outbreaks increased dramatically. Further studies are needed to understand/explore the dynamics of this trend. Current recommendations might be improved to help infection control units to better control the spread of eXDR bacteria.

**Investigation of waterborne outbreaks due to drinking water consumption in Greece, 2004-2019 (1st semester): time to learn our lessons**

Kassiani Mellou1, Myrsini Tzani1,2, Theologia Sideroglou1, Anthi Chrysostomou1, Theano Georgakopoulou1, Sotirios Tsiodras*3

1Hellenic National Public Health Organization (EODY), Athens, Greece, 2EPIET (European Programme for Intervention Epidemiology Training) fellow-MS track-Cohort 2018, Athens, Greece, 34th Academic Department of Medicine, National and Kapodistrian University of Athens, Medical School, Athens, Greece

**Background:** Waterborne outbreaks (WBOs) remain a public health concern as large numbers of people can be infected within a short time. We summarize Greek data on WBOs from January 2004 to June 2019 and the conducted investigations and identify points for improvement.

**Materials/methods:** WBOs are mandatorily notified in Greece. Data on outbreak characteristics (type, size, duration, demographics, hospitalization, outcome) and conducted investigations (epidemiological, laboratory, environmental) were analyzed.

**Results:** Overall, 33 WBOs were recorded (mean 2.1 outbreaks per year). Analytical epidemiological studies were conducted in seven (21%) and suggested tap water consumption as the probable vehicle of infection. Environmental investigation was performed in 23 (70%). Clinical specimens were tested in 24 (73%) and water samples in 14 outbreaks (42%).

The median number of cases per WBO was 54 (range: 2-1,640); eight had more than 200 recorded cases each with a total number of 4,892 cases (81% of total recorded cases); 56% of cases were women. Most WBOs (72%) affected more than one household and affected people from all age-groups. Clinical manifestations were compatible with gastrointestinal illness and 194 cases were hospitalized (7%). No deaths were recorded. Outbreaks’ duration ranged from 1 to 44 days.

Clinical samples were positive in 79.2% (19/24) of the outbreaks; *Salmonella* spp., *Norovirus*, *Shigella* spp., *Campylobacter* spp., and *Rotavirus* were isolated in 6 (31.6%), 6 (31.6%), 3 (15.8%), 2 (10.5%) and 2 (10.5%) outbreaks respectively and in one multiple pathogens (*Norovirus, Campylobacter jejuni*, and Enterohemorrhagic *Escherichia coli*, EHEC) were detected. Water samples tested positive in 35.7% (4/11) of the outbreaks investigated. In two outbreaks samples were collected after chlorination and consequently results were negative. Environmental investigation identified factors that led to water contamination, such as failures in water treatment and disinfection, in 17/33 (52%) WBOs.

**Conclusions:** WBOs, although rare in Greece, pose a significant public health burden due to their usually large size. Environmental investigation often fails to identify the contributing factors. An integrated plan is needed to ensure water safety based on WHO recommendations, water sample collection before water treatment and testing of samples for a wide spectrum of pathogens.

**Abstract 6406**

**Outbreak of Arcobacter butzleri? An emerging enteropathogen**

Carlos Ruiz De Alegria Puig*, Marta Fernández-Martínez1, Daniel Pablo-Marcos1, Jesus Aguero1, Jorge Calvo-Montes1

1Universitary Hospital Marqués de valdecilla-IDIVAL, Santander, Spain

**Background:** Arcobacter butzleri, previously named Campylobacter butzleri, is a gram-negative rod oxidase positive, with microaerobic growth at an optimal temperature of 37ºC unlike the genus Campylobacter, which grow at 42ºC. A. butzleri was reported to be the fourth most common Campylobacter-like organism isolated from patients with diarrhea, which is usually watery in case of Arcobacter and bloody in case of Campylobacter.

The aim of this study was to characterize a potential outbreak of A. butzleri detected in a short period of time in the University Hospital Marqués de Valdecilla.

**Materials/methods:** Eight strains of A. butzleri were detected in our hospital in only two months (October-December 2018). Isolates were identified by MALDI-TOF MS Vitek-MS™ system and 16S ribosomal DNA sequencing.

Enterobacterial repetitive intergenic consensus-PCR (ERIC-PCR) and Pulsed Field Gel Electrophoresis (PFGE) with KpnI were carried out to assess clonal relationship.

Erythromycin (ERY), ciprofloxacin (CIP), imipenem (IPM), fixed 2:1 ratio amoxicillin-clavulanic acid (AMC) and tetracycline (TET) gradient strips (Etest) were used to determine susceptibility by agar diffusion. Susceptibility categories were defined according to EUCAST [CIP, ERY, TET] and PK-PD EUCAST breakpoints [IPM, AMC] for Campylobacter jejuni. Cefazoline [CFZ], used as internal control because of its intrinsic resistance, was assessed by disk-diffusion method.

**Results:** During the analyzed period 328 stool samples were collected and the following microorganisms were recovered: Campylobacter jejuni (34), Salmonella enterica (28), Aeromonas sp. (7), Campylobacter coli (6) and Yersinia enterocolitica (1). Analysis of ERIC-PCR and PFGE confirmed the lack of clonal relationship between strains. Antimicrobial susceptibility is shown in Table 1.

**Conclusions:** Eight A. butzleri isolates were collected in our hospital during a 2-month period, although clonal relationship was not confirmed.

A. butzleri is an emerging pathogen with increasing incidence, and may be underestimated mainly because of the unique growth temperature at 42°C of most of laboratory at the time to isolate Campylobacter spp.

Imipenem could be an alternative treatment for multidrug resistant Arcobacter.

**Table 1: Antimicrobial susceptibility testing for the eight strains of Arcobacter butzleri.**

**Molecular detection of cytomegalovirus in intestinal tissue**

Natalia Bastón Paz *, María Araceli Hernández-Betancor¹, Mónica Peñate Bolaños², Pilar Michelle Hernandez Cabrera³, Tomas Tosco-Núñez¹

¹Hospital Universitario Insular de Gran Canaria, Department of Microbiology and Parasitology, Las Palmas de Gran Canaria, Spain, ²Hospital Universitario Insular de Gran Canaria, Department of Gastroenterology and Hepatology, Las Palmas de Gran Canaria, Spain, ³Hospital Universitario Insular de Gran Canaria, Department of Infectious Diseases and Tropical Medicine, Las Palmas de Gran Canaria, Spain

**Background:** Cytomegalovirus (CMV) re-activation can occur anywhere along the gastrointestinal tract, though it seems that this virus prefers the colonic mucosa when there are injuries or inflammation. The introduction of molecular techniques has led to an improvement in the diagnosis of CMV when compared to cell culture, but there is no cut-off of CMV viral load (CMV-VL) in order to distinguish latent infection from disease. The aim of the study is to describe the positive-CMV cases detected in intestinal tissue in our hospital.

**Materials/methods:** The study (2018-2019) included 64 patients in whom the presence of CMV in rectal and colonic biopsy samples was qualitatively determined (SmartCycler®, Cepheid). Those samples with positive detection were re-analyzed by CMV-VL (COBAS® AmpliPrep/TaqMan, Roche). In addition, clinical setting and pathological examinations were reviewed.

**Results:** CMV was detected in 10 patients (15.6%). The CMV-VL was positive in 6 of them (60.0%) (average: 14,882.7 IU/mL; range: 631-57,603 IU/mL). Seventy percent of the patients were men (average age: 46.6 years; range: 17-86 years). All of the patients had some immunosuppressive risk factor: 2 (20.0%) HIV-infection, 6 (60.0%) inflammatory bowel disease chronically treated with corticosteroids and/or immunomodulators, 1 (10.0%) bone marrow aplasia and 1 (10.0%) advanced age. Moderate to intense colonic or rectal inflammation was present in all of them. Blood CMV-VL was requested for 6 (60.0%) patients, which was negative in all of the cases. Furthermore, CMV was ruled out for 6 patients (60.0%) by immunohistochemistry exam, with negative result in all of them. Finally, valganciclovir was administered in 7 patients (70.0%). All episodes were resolved favorably.

**Conclusions:** All of the patients had some immunosuppressive risk factor. All positive-CMV patients presented a moderate-intense inflammation of the intestinal mucosa. PCR qualitative detection of CMV in biopsy samples is more sensitive than the quantitative technique. Antiviral treatment was required in 7 patients with clinical improvement in follow-up.

Abstract 6409

Comparison of colistin-resistant Klebsiella pneumoniae strains in five Greek hospitals

Maria Maisi*1, Georgios Tsioulos2, Emmanouela Maisi3, Irene Choudalaki4, Panagiota Giakkoupi5

1venizeleio hospital, Heraklion, Greece, 2venizeleio hospital, Heraklion, Greece, 3pagni hospital, Heraklion, Greece, 4National School of public health, Athens, Greece, 5University of West Athens, Athens, Greece

Background: Klebsiella pneumoniae causes severe hospital infections. In Greece, since 2008, isolation of multi-resistant strains that produce Klebsiella pneumoniae Carbapenemase (KPC) with resistance to all beta-lactamic antibiotics including carbapenemes, has been reported. Thus, polymyxins (polymyxin B and colistin) are the treatment of choice. Despite of their recent entry in clinical practice, resistance to polymyxins has already been developed.

Materials/methods: Molecular identification and comparison of 18 colistin resistant K.pneumoniae strains that were sent to the Central Laboratory of Public Health from five Greek hospitals during the period 01/01/2011 until 30/07/2012, was performed. The 18 K.pneumoniae strains were sent from two hospitals of Athens, one of Thessaloniki and two of Western Greece. Antimicrobial Susceptibility Test to colistin and meropenem was performed by the E-test method. The gene of blaKPC was detected with PCR. The strains were identified with the molecular method of PFGE (Pulsed Field Gel Electrophoresis) and the imprints were compared with the GelCompar2 system.

Results: All of the 18 strains were resistant to colistin and meropenem and all of them produced beta-lactamase KPC. After performing PFGE the strains were categorized in nine types/subtypes. The dendrogram revealed that there were three different dispersions in different hospitals and different time. These dispersions referred to 2 strains of subtype A1, 2 strains of subtype C and 8 strains of subtype A4. The rest of 6 strains revealed heterogeneity which corresponds to sporadic isolations.

Conclusions: In Greece, K.pneumoniae resistance to colistin is not clonal, but is due to the dispersion of sporadic resistant isolates that are probably created during antibiotic treatment.

Usefulness of sputum for the identification of the viral aetiology in adults with community-acquired pneumonia

Judith Berastegui Cabrera1,1, Manuela Aguilar-Guisado2, Juan Carlos Crespo Rivas2, Macarena López Verdugo2, Laura Merino2, Ana Escoresca Ortega2, Carmen Calero2, Laura Carrasco Hernandez2, Javier Ignacio Toral Marín2, María Abad Arranz2, Nieves Ramírez Duque1, Bosco Barón Franco2, Javier Sánchez Céspedes2, Jeronimo Pachon-Diaz2

1Institute of Biomedicine of Seville (IBiS), Seville, Spain, 2University Hospital Virgen del Rocio, Seville, Spain

Background: Despite the molecular approaches developed in diagnosis, the identification of the causative agent of community-acquired pneumonia (CAP) remains a challenge; thus, only in approximately 50% of the CAP a definitive diagnosis of the etiologic agent is reached. Our goal was to know the value of sputum in the diagnosis of the viral etiology of CAP in adults.

Materials/methods: Prospective cohort study of consecutive adult patients hospitalized with CAP. Blood, nasopharyngeal swabs and sputum were taken in the first 24 h after hospitalization. From these samples, DNA/RNA was extracted and viruses were identified by a multiplex PCR (Allplex, Seegene, Madrid, Spain). Viral loads in sputum and blood were quantified using commercial standard curves of complete viral genomes (Amplirun, Vircell, Granada, Spain). Bacterial identification was carried out by standard blood and representative sputum cultures. Demographics and clinical data of the patients were collected. Data were compared by chi-square or Mann Whitney U tests; a \( p < 0.05 \) was considered significant.

Results: Two hundred and fifty adult patients with CAP have been included (January 2018-September 2019): 58 (23.2%), 37 (14.8%), and 34 (13.6%) with bacterial, viral, and mixed etiologies, respectively; in 121 (48.4%) patients an etiological diagnosis was not reached. Out of the 250 patients, 4 (1.7%, n=241) showed viremia (5.5x10^4 to 1.2x10^7 copies/ml). Fifty-seven (22.9%, n=249) and 28 (53.8%, n=52) had a virus detected in nasopharyngeal swabs and representative sputum, respectively. The mean viral loads in sputum ranged from 3.88x10^5 to 1.87x10^7 copies/ml. The most frequent viruses were rhinoviruses in 23 (9.2%) and influenza in 19 (7.6%) patients. Bacterial/virus co-infections were detected in 34 (13.6%) patients and virus-virus in 1 (0.4%). No differences were observed regarding hospital stays (5 [3.25-8] vs. 4.5 [4-5.75] days, \( p=0.58 \)) or mortality (6.3% vs. 1.1%, \( p=0.26 \)) between cases of bacterial and viral etiologies.

Conclusions: The frequency of viral etiology in hospitalized adults for CAP (mono- or co-infections) was 28.4%, with rhinovirus and influenza virus as the main etiologies. Viral detection and quantification in representative sputum is more sensitive than nasopharyngeal swabs for the etiological studies in viral CAP in adults. As expected, the frequency of viremia was low.

Phylogenetic and geographical analyses of bat Coronaviruses
Tat Yin Chan*,1, Cheuk Pui Wong1, Hayes Luk1, Susanna K. P. Lau1,2,3,4,5, Patrick C. Y. Woo1,2,3,4,5

1Department of Microbiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, 2State Key Laboratory of Emerging Infectious Diseases, The University of Hong Kong, Hong Kong, Hong Kong, 3Research Centre of Infection and Immunology, The University of Hong Kong, Hong Kong, Hong Kong, 4Carol Yu Centre for Infection, The University of Hong Kong, Hong Kong, Hong Kong, 5Collaborative Innovation Centre for Diagnosis and Treatment of Infectious Diseases, The University of Hong Kong, Hong Kong, Hong Kong

Background: Coronaviruses (CoVs) are classified into four genera, namely Alphacoronavirus, Betacoronavirus, Gammacoronavirus and Deltacoronavirus. Similar to other single-stranded RNA viruses, CoVs possess a high tendency for recombination and high mutation rates. Hence, they have a broad host tropism. Notably, Alphacoronavirus and Betacoronavirus encompassing Rhinolophus bat coronavirus HKU2, Severe acute respiratory syndrome-related coronavirus, Middle East respiratory syndrome-related coronavirus, etc. are found in bats. As bats are capable of sustained flight and are globally distributed, it is important to study bat CoVs’ global epidemiology in order to understand CoVs evolution and their interspecies transmission pathways.

Materials/methods: Respiratory and alimentary samples of various bat species from different geographical locations were collected for viral RNA extraction. Extracted RNAs were then reverse transcribed and amplified by polymerase chain reaction for detection of CoVs and complete genome sequencing. The sequences obtained, together with those available in GenBank, were then used for phylogenetic analyses, recombination studies and geographical analyses.

Results: Only members of Alphacoronavirus and Betacoronavirus were found in bats. When analyzing the origins of different bat CoVs, it was revealed that both Alphacoronavirus and Betacoronavirus were globally distributed. However, members of Alphacoronavirus seems to be more prevalent, with a two-fold higher detection rate, and more widespread than members of Betacoronavirus. The distribution of CoVs was closely related to their hosts’ habitats as Merbecovirus which infected bats of the family Vespertilionidae possessing distinct and diverse habitats was more geographically widespread than Norbecovirus and Sarbecovirus. The higher the number of bat species with overlapping habitats there were, the more frequent coronaviral recombination events took place. Locations in which a high diversity of bats resided such as Yunnan Province in China were the regions with higher bat CoV diversity. More recombination events were observed in the bat CoV strains in these areas. Last but not least, a positive correlation between the diversity of CoVs and that of bats was indicated in Merbecovirus and Vespertilionidae.

Conclusions: A wide variety of bat CoVs belonging to Alphacoronavirus and Betacoronavirus were identified. Diversities, geographical distributions and habitats of bats were shown related to the diversity of CoVs through recombination studies and geographical analyses.

Abstract 6413

Carbapenem-resistant *Acinetobacter baumannii* and its genotypic profile in a tertiary hospital South Sulawesi, Indonesia

Rizalinda Sjahri*1, Lisa Tenriesa1, Andi Rofian Sultan1, Munawir Muhammad1, Firdaus Hamid2

1Hasanuddin University, Department of Microbiology, Faculty of Medicine, Makassar, Indonesia

**Background:** *Acinetobacter baumannii* is one of the most important bacteria isolated from among hospitalized patients worldwide due to its high propensity to antibiotic resistance, including carbapenem antibiotics. Since surveillance report for this resistance from the eastern region of Indonesia is still not available, therefore, we aimed to determine the phenotypic prevalence and the molecular detection of carbapenemase genes among *A. baumannii* isolated at tertiary hospital in South Sulawesi Indonesia.

**Materials/methods:** Specimens from patients with signs of infection were collected for standard bacterial identification. Bacteria were identified to species level and antibiotic sensitivity test performed by an automated bacterial identification system. Isolated *A. baumannii* were subsequently extracted for DNA, and amplification of carbapenemase encoding gene by PCR was performed targeting bla-Oxa23, bla-Oxa51, Bla-NDM and Bla-IMP genes. In addition, gene sequencing was also performed.

**Results:** During eight months period, 106 *A. baumannii* were isolated. Majority of samples were sputum (62.3%), followed by pus (23.6%), urine (5.6%), and the rest; blood, bronchial lavage, body fluids, and ear exudates (8.5%). Among these isolates, phenotypically; 38 (35.8%) were resistant to carbapenem antibiotics. Further genotypic identification revealed 100%, 45.3%, 33.9%, and 11.3% of the isolates harboring the bla-Oxa51, bla-Oxa23, Bla-NDM, and Bla-IMP genes, respectively.

**Conclusions:** There is a high prevalence of carbapenem-resistant *A. baumannii* isolated in Tertiary Hospital of South Sulawesi within short period of time. Therefore, an extensive surveillance and preventative measures need to be implemented, immediately.

Continuous genomic surveillance of the third generation cephalosporin-resistant Enterobacteriaceae circulating in intensive care units of a 1600 bed university hospital, France

François Gravey1, Marguerite Fines-Guyon2, Christophe Isnard1, Frédéric Ethuin1, Desire Samba2, Damien Du Cheyron1, Cedric Baubin1, Audrey Mouet1, Claire Lesteven1, Olivier Join-Lambert1, Michel Auzou2, François Guérin1, Simon Le Hello1

1Normandie Univ, UNICAEN, UNIROUEN, GRAM 2.0, EA2656, Caen, France, 2Caen University Hospital, Service de microbiologie, Caen, France, 3Caen University Hospital, reanimation chirurgicale, Caen, France, 4Caen University Hospital, reanimation medicale, Caen, France, 5Caen University Hospital, Hygiene hospitaliere, Caen, France

Background: Third generation cephalosporin resistant Enterobacteriaceae (C3G-E) are disseminating worldwide leading to increased mortality in intensive care units (ICU). The aim of this study was to determine C3G resistant-Escherichia coli (Ecol), Klebsiella pneumoniae (Kpn) and Enterobacter cloacae complex (ECC) clonal populations circulating in two ICU at the university hospital of Caen, France for nine months in 2019 using routine whole genome sequencing (WGS) analysis.

Materials/methods: The first C3G-E was collected from any clinical specimens or systematic faecal carriage screening. Identification was performed by mass-spectrometry (MALDI-TOF) and antimicrobial susceptibility testing by disk diffusion method according to the EUCAST guidelines. WGS was carried out on all Ecol, Kpn and ECC strains using NextSeq 500 platform. In silico sequence type (MLST) and antimicrobial resistance genes were searched. Core genome Multi locus Sequence Type (cgMLST) was realized using web-dedicated schemes for Kpn and Ecol and homemade scheme for ECC. Furthermore, mapping against genome references allowed single nucleotide polymorphisms approach for grouped cases investigation.

Results: For nine months, 126 patients were included (sex ratio M/F was 2, average age was 66 years old). Strains were isolated from rectal swabs (n=106, 84%), respiratory samples (n=9, 7%) and blood cultures (n=2, 2%). Ecol was the main species recovered (n=48, 38%), followed by ECC (n=40, 32%) and Kpn (n=38, 30%). CTX-M-15-producing C3G-E represented 66% of all strains. Ecol populations were diverse with 30 distinct ST with the ST131 (n=13, 27%) as the dominant one. Regarding the eleven ST ECC and Kpn populations found for each, ST66 and ST11 were the main ST for ECC (n=20, 50%; n=7, 18% respectively) and ST405 was major for Kpn (n=24, 63%). Furthermore, cgMLST and SNP analyses confirmed the homogenic ECC ST66 population and Kpn ST405 population (differed by 50 maximum SNP). Cross-transmissions between patient-to-patient and medical equipment contaminations have been revealed for ST114 and ST66 ECC and ST405 Kpn populations.

Conclusions: The diffusion of C3G-E into ICUs of our hospital was mainly clonal for ECC and Kpn whereas it was more diverse for Ecol. Implementation of systematic genomic surveillance could improve hygiene procedures by outbreaks, cross-transmissions and contaminated material detections.

Abstract 6417

**High rate of microbiological clearance using intravenous fosfomycin combined regimens in infections caused by multidrug-resistant non-fermenting Gram-negative bacilli: clinical experience in an intensive care unit in Rome**

Alessandro D’Avino*1, Stefania Mazzocchetti2, Elena Paciacconi3, Damiano Menghetti4, Arcangelo Schiattarella5, Daniela Grande6, Paolo Dionisi2, Angela Maria Mastromatteo2

1Cristo Re General Hospital GIOMI S.p.a, Department of Internal Medicine and Hospital Acquired Infections Committee, Rome, Italy, 2Cristo Re General Hospital GIOMI S.p.a, Intensive Care Unit Department, Rome, Italy, 3Cristo Re General Hospital GIOMI S.p.a, Clinical Pathology and Microbiology Department, Rome, Italy, 4Cristo Re General Hospital GIOMI S.p.a, Central Pharmacy Department, Rome, Italy, 5Cristo Re General Hospital GIOMI S.p.a, Hospital Direction, Risk Management, Rome, Italy

**Background:** Infections due to MDR non-fermenting Gram-negative bacilli are characterized by a high mortality rate, and few therapeutic strategies. In this setting intravenous fosfomycin, thanks to synergistic activity with several antimicrobials could represent a feasible option for the treatment of these infections. We report our clinical experience in Intensive Care Unite (ICU) patients.

**Materials/methods:** A retrospective case-control study was designed, enrolling patients, from March 2018 until August 2019 admitted in ICU of “Cristo Re” General Hospital in Rome with infections caused by MDR *Pseudomonas aeruginosa* (MDR-PA) or *Acinetobacter baumannii*. Cases were defined as patients treated with fosfomycin combined regimens, controls were patients exposed to other regimens. All causes and infection-related mortality at 28 days and microbiological resolution (defined as a negative control at the end of treatment) were evaluated in both groups. Chi-square test was used to compare frequencies, t-test to compare means between groups.

**Results:** 41 patients were enrolled (24 pt with MDR-*Acinetobacter baumannii* and 17 with MDR-PA). 18 (43.8%) were male, with median age of 74 years (C.I 62.5-80.0). 18 pt (43.8%) showed septic shock at diagnosis. Most of infections detected were pneumonia (27 pts, 65.9%, HAP and VAP included), followed by BSIs (13 pts, 31.7%), UTIs (6 pts, 14.6%) and surgical infections (5 pts, 14.2%). Fosfomycin was used in 19 patients in combination with other antimicrobials. No differences in baseline characteristics were found between groups except for mean duration of treatment, significantly shorter for fosfomycin group (9.6 days vs 11.7 of controls p=0.03).

Any cause mortality was 36.8% and 45.5% in cases and controls respectively (p=0.58), but only 15.9% of patients treated with fosfomycin had an infection-related death (vs 22.7 of controls, p=0.57). Microbiological clearance was achieved in 84.7% of cases and 59.1% of controls (p=0.07). Moreover, a significant higher microbiological outcome was found for MDR-PA infections, in patients exposed to fosfomycin [100% vs 62.5% of controls p=0.04].

**Conclusions:** Our data show a high rate of microbiological success in treating MDR non-fermenting Gram-negative bacilli infections with intravenous fosfomycin based-regimens, especially in MDR-PA infected-patients. Furthermore better outcomes are achieved with a shorter duration of therapy.

Efficacy of a carbapenem-sparing regimen for treating post-surgical intra-abdominal infections: a case-control study

Francesca Giovannenze*, Eleonora Taddei1, Rita Murri2, Lucia Cerolini3, Emanuela Birocchi1, Francesco Taccari1, Roberto Cauda2, Massimo Fantoni2

1Catholic University of Sacred Heart, Infectious Diseases Institute, Rome, Italy, 2Università Cattolica del Sacro Cuore, Fondazione Policlinico Gemelli IRCCS, Rome, Italy, 3Catholic University of Sacred Heart, Rome, Italy

Background: Intra-abdominal infections (IAIs) are a common surgical complication that frequently leads to broad-spectrum and long-duration antibiotic therapy. The increasing prevalence of extended-spectrum beta-lactamases (ESBL) producing Enterobacterales raises concern about the choice of optimal antibiotic treatment. Objective of this study was to evaluate the clinical efficacy of a carbapenem-sparing empiric antibiotic therapy in post-surgical IAIs.

Materials/methods: We conducted a retrospective monocentric case-control study on patients diagnosed with localized post-surgical IAI admitted to Fondazione Policlinico IRCCS Gemelli in Rome, from January 2013 to December 2018. Patients with intra-parenchymal (i.e. liver or kidney) abscess, IBD or pancreatitis and patients who received empiric therapy different from carbapenem or piperacillin/tazobactam mono or combination therapy were excluded. We defined two groups: patients who received a carbapenem-based empiric antibiotic regimen (Carb-B) and those who received a carbapenem-sparing regimen with piperacillin/tazobactam (Carb-S). The primary outcome was adverse clinical outcome, defined as overall mortality and/or IAI relapse. Secondary outcomes were duration of therapy (DOT) and length of hospital stay (LOS). A multiple logistic regression analysis was performed to evaluate factors independently related to adverse clinical outcome.

Results: We included 265 patients, 113 in the Carb-B group and 152 in the Carb-S group. Patients in the two groups did not differ for sex, age, clinical severity at onset (SOFA score) and microbial etiology. The rate of adverse clinical outcomes was similar in the two groups: 21 (18.6%) in the Carb-B group and 22 (14.5%) in the Carb-S group, p=0.37. Median DOT (Carb-B: 20 days, IQR 14–28; Carb-S: 17 days, IQR 11–25; p=0.03) and median LOS (Carb-B: 19 days, IQR 12.5–37; Carb-S: 16 days, IQR 11–27; p=0.04) were significantly longer in the Carb-B group. At multiple logistic regression analysis, only SOFA score (OR 1.25, p=0.03) and Candida spp etiology (OR 3.19, p=0.01) were independently related to adverse clinical outcome, while receiving a Carb-B empiric antibiotic therapy had no impact on clinical outcome (OR 0.89, p=0.76).

Conclusions: A carbapenem-sparing empiric antibiotic treatment seems not to affect clinical outcome in patients with localized post-surgical IAI. These findings support the implementation of carbapenem-sparing hospital and local policies for treatment of post-surgical IAI.

Abstract 6420

Infections in patients colonised with extended-spectrum beta-lactamase-producing Enterobacteriales: a retrospective cohort study

Isabelle Vock1, Lisandra Aguilar Bultet1, Adrian Egli1, Pranita Tamma2, Sarah Tschudin-Sutter1

1University Hospital Basel, Basel, Switzerland, 2Johns Hopkins University School of Medicine, Baltimore, United States

Background: Patients colonized with extended-spectrum beta-lactamase-producing Enterobacteriales (ESBL-PE) have an increased risk of subsequent ESBL-PE infections compared to patients without prior ESBL-PE colonization. Concerns regarding this risk have led to a significant rise in carbapenem consumption. The likelihood of ESBL-PE versus non-ESBL-PE (nESBL-PE) infections in ESBL-PE colonized patients, however, is unclear. We investigated these relative proportions as well as relevant risk factors, as this knowledge may improve empiric antibiotic decision making for patients known to be colonized with ESBL-PE.

Materials/methods: We conducted a retrospective cohort study at the University Hospital Basel, Switzerland. Hospitalizations of patients with detection of ESBL-PE and at least one infection within the same hospitalization between 01/2016 and 12/2018 were included. The main outcome was the proportion of ESBL-PE and nESBL-PE infections. Secondary outcomes were risk factors differentiating patients with non-ESBL-PE-infections from patients with ESBL-PE-infections as determined by logistic regression analyses.

Results: 572 hospitalizations of patients colonized with ESBL-PE met eligibility criteria. Overall 684 infections occurred, of which 307 were caused by ESBL-PE (44.9%) and 377 were caused by non-ESBL-PE (55.1%). 8.2% of patients had ESBL-PE-infections as well as nESBL-PE-infections within the same hospitalization, yet most patients were affected either by only ESBL-PE-infections (44.4%) or nESBL-PE-infections (47.4%). 74.6% of ESBL-PE-infections occurred in the urinary tract whereas nESBL-PE-infections mostly affected the lower respiratory tract (42.7%). Non-ESBL-producing Escherichia coli was most frequently identified as causative bacterial pathogen in nESBL-PE-infections (16.4%). Multivariable analysis revealed dialysis to be associated with ESBL-PE-infections (OR 8.88, 95%CI 1.06-74.51, p=0.044), whereas age (OR 1.01, 95%CI 1.00-1.02, p=0.017), current ICU-stay (OR 0.58, 95%CI 0.33-0.95, p=0.033) travel abroad (OR 0.33, 95%CI 0.17-0.66, p=0.002), active immunosuppressive therapy (OR 0.42, 95%CI 0.28-0.64, p<0.001) were associated with nESBL-PE-infections. Overall mortality was higher and hospital stay longer in patients with nESBL-PE infections (OR 0.39, 95%CI 0.17-0.89, p=0.026 and OR 0.98, 95%CI 0.96-0.99, p<0.001).

Conclusions: In our cohort, ESBL-PE were not the causative pathogen in the majority of infections in hospitalized patients known to be colonized with ESBL-PE. Site of infection as well as patient-related exposures may be useful predictors of nESBL-PE infections in ESBL-PE carriers, potentially guiding empiric treatment recommendations aiming to restrict carbapenem consumption.

**Abstract 6421**

**Beyond the minimal inhibitory concentration: novel pharmacokinetic/pharmacodynamic metrics quantify the exposure-effect relationship of levofloxacin against fluoroquinolone-resistant *Escherichia coli* based on *in vitro* infection models**

Johanna Seeger*1, Robin Michelet1,2, Sebastian Guenther1, Charlotte Kloft1

1Institute of Pharmacy, Dept. of Clinical Pharmacy & Biochemistry, Berlin, Germany, 2Universitaet Greifswald, Institute of Pharmacy, Greifswald, Germany

**Background:** Dosing optimisation is crucial to tackle the challenge of antibiotic resistance and is mostly based on pharmacokinetic/pharmacodynamic (PK/PD) indices, linking PK metrics of an antibiotic to a pathogen’s minimal inhibitory concentration (MIC) [1]. However, their informative value is limited, because a dynamic component is lacking [2]. To derive novel PK/PD metrics, the exposure-effect relationship of levofloxacin (LEV) against *Escherichia coli* (Ec) was investigated utilising *in vitro* infection models (IVIM).

**Materials/methods:** Three LEV resistant clinical *E. coli* isolates (sequence type 58 (ST58), MIC=8 mg/L; ST88, MIC=2 mg/L; ST167, MIC=8 mg/L) with different *gyrA* and *parC* mutations were exposed to static LEV concentrations (n_total=35) and dynamic target site LEV concentration-time (C(t)) profiles (n_total=12). Bacterial concentrations over time were determined and the antibiotic effect was quantified as cumulative area between the growth control and the bacterial killing and regrowth curve, normalised to the cumulative area under the growth control curve. As dynamic exposure metric, the cumulative area under the LEV C(t) curve (cumAUC) was assessed. The exposure-effect relationship was analysed in R 3.6.0.

**Results:** An inhibition model, including the cumAUC50 as initial bacterial reduction parameter and cumAUCreg as a regrowth metric, best described the exposure-effect relationship under static and dynamic LEV exposure. Different model structures were compared by Akaike Information Criterion. Parameter values were precisely estimated and in accordance with observed time-kill behaviour. Lower cumAUC50 values represented a larger extent of initial bacterial reduction and lower cumAUCreg values described a more pronounced bacterial regrowth. Despite equal MIC, differences in exposure-effect relationship of ST58 and ST167 were captured in a 5-fold higher cumAUC50 for ST58 compared to ST167.

**Conclusions:** Beyond conventional PK/PD indices, our novel metrics characterised the differences in resistance and persistence mechanisms between the isolates. Different pre-existing genotypic resistance mechanisms resulted in increased cumAUC50 values. Additionally, differences in extent of phenotypic adaptation were represented by cumAUCreg estimates. The larger effect for continuously high concentrations in the static IVIM, compared to higher Cmax values in the dynamic IVIM, showed benefits of higher cumAUC values, which can be achieved by prolonging infusion times in the clinics.

Abstract 6423

**Two in three final-year veterinary students demand improved education in rational antimicrobial use**

Carmen Espinosa-Gongora*, Lisbeth R. Jessen, Oliver J. Dyar, Bojana Beovic, Alain Bousquet-Melou, Bruno Gonzalez-Zorn, Patrizia Nebbia, Rosangela Odore, Céline Pulcini, Giovanni Re, Sara Sacristán, Stefan Schwarz, Pierre-Louis Toutain, Luca Guardabassi

1 University of Copenhagen, Department of Veterinary and Animal Sciences, Frederiksberg, Denmark; 2 University of Copenhagen, Department of Veterinary Clinical Sciences, Frederiksberg, Denmark; 3 Karolinska Institute, Public Health Sciences, Stockholm, Sweden; 4 University Medical Centre Ljubljana, Department of Infectious Diseases, Ljubljana, Slovenia; 5 INThERES, Université de Toulouse, INRA, ENVT, Toulouse, France; 6 Complutense University of Madrid, Veterinary School and VISAVET, Madrid, Spain; 7 University of Turin, Department of Veterinary Sciences, Grugliasco, Italy; 8 CHRU de Nancy, Service de Maladies Infectieuses et Tropicales and Université de Lorraine, Nancy, France; 9 Spanish Agency of Medicines and Medical Devices, Coordinator Unit of the Spanish National Plan against Antibiotic Resistance, Madrid, Spain; 10 Freie Universität Berlin, Institute of Microbiology and Epizootics, Berlin, Germany; 11 University of Liverpool, Institute of Veterinary Science, Cheshire, United Kingdom; 12 University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom

**Background:** Education plays an essential role in the fight against antimicrobial resistance (AMR) in both human and veterinary medicine. Previous studies have shown that final year medical students in Europe are not satisfied with the quality of education on antibiotic use. PREPARE-VET was a joint initiative by the ESCMID study groups for veterinary microbiology (ESGVM) and antimicrobial stewardship (ESGAP) to evaluate the education of final year European veterinary students on AMR and antibiotic use.

**Materials/methods:** We invited all veterinary schools in 31 European countries to participate in a survey using the online platform SurveyMonkey®. Schools were enrolled in the study if at least 10% of their students participated in the survey. Only students that answered all questions were taken into account. The survey included questions addressing the students’ perception of quality of education on key topics related to AMR and antibiotic use as well as questions testing their knowledge and preparedness on these topics. All calculations and visualizations were performed in R.

**Results:** Thirty countries and 89 veterinary schools were included in the final analysis, accounting for 3423 students. Average participation was 45% (12-100%). Overall, 75% of the students demanded improved teaching on rational antibiotic use, of which approximately half also demanded improved teaching on general knowledge about antibiotics [see figure]. Indeed, we observed a strong lack of consensus in selecting treatment strategies towards some of the most common animal infections. For example, while Scandinavian students choose local antiseptic for treatment of canine superficial pyoderma, most students from other countries choose local antibiotics alone (31%) or combined with systemic therapy (22%). Moreover, less than half of the students knew the definition of ESBL, only 22% could recognize practices that minimize the emergence of AMR, and only one in four students was familiar with guidelines [national or international] for antibiotic use.

**Conclusions:** Veterinary students demand better education on AMR and antibiotic use. The lack of familiarity with common AMR threats, treatment guidelines, and treatment strategies that minimize AMR, calls for urgent harmonization and in-depth review of veterinary curricula in this field.

Same-day diagnosis of severe pneumonia on intensive care using long-read whole gene 16S rRNA gene sequencing on single-sample flowcells

Rossella Baldan1, Penny Cliff2, Sarah Burns3, Rahul Batra3, Graeme Smith2, Natalie Groves4, Albert Cerda2, Shona Lewis2, Jonathan Edgeworth*3, Meera Chand5

1King’s College London, London, United Kingdom, 2St Thomas’ Hospital, Viapath, London, United Kingdom, 3St Thomas’ Hospital, London, United Kingdom, 4Public Health England, London, United Kingdom, 5Guy’s and St Thomas’ NHS Foundation Trust AND Public Health England, London, United Kingdom

Background: Nanopore sequencing allows real-time analysis, but has yet to be harnessed in clinical laboratories for rapid diagnosis. 16S rRNA whole gene sequencing improves discrimination compared to variable region assays. We investigated nanopore-based whole 16S rRNA gene sequencing (np16s) for same-day diagnosis of severe pneumonia in our ICU, the largest Severe Respiratory Failure service in the UK.

Materials/methods: A 2 phase study was conducted: (1) speciation accuracy and pipeline development; (2) performance on clinical samples. Phase 1: 167 clinically relevant species were tested (R9.4 flowcells/Guppy v2.0.5, Oxford Nanopore Technologies). Sequencing accuracy, reproducibility and limit of detection (LOD) were assessed. Multiple taxonomic classification tools, databases and read correctors were evaluated to construct a pipeline. Phase 2: 71 culture-positive and 26 culture-negative bronchoalveolar lavages were tested on novel single-sample flowcells (Flongle, ONT) using high accuracy basecalling (Guppy v3.0.6, ONT) and the Phase 1 pipeline. Analyses at 5 time-points across 16 hours were compared.

Results: Sequencing accuracy was 89% (Phase 1), 85% (Phase 2). The LOD was 55 genome copies per reaction, or 3 copies within a mixture; reproducibility was satisfactory. 140 (84%) isolates were speciated correctly. The only misclassified respiratory pathogen was Bordetella pertussis, identified as Bordetella spp. Read correction did not improve classification due to disparities between gene copies within the genome. Of 71 culture-positive BALs: 54 (76%) were concordant with culture; 12 failed quality control; 5 were discrepant including 4 misidentified Gram-negative bacteria. Of 26 culture-negative BAL: 10 had insufficient bacterial DNA for classification; 5 were positive with fastidious or easily-killed species (e.g. Mycoplasma pneumoniae); 3 contained mixed commensal organisms. Analysis at 1 hour of sequencing was equivalent to 16 hours, including composition of mixtures. A same-day automated workflow was approved for clinical service pilot commencing December 2019.

Conclusions: Np16S can be used for same-day diagnosis of severe pneumonia. New basecallers do not compensate for the reduction in sequencing accuracy from single-sample flowcells but classification remains adequate. Nanopore sequencing is sufficiently robust and consistent for routine use in a clinical diagnostic service, paving the way for the introduction of novel assays.

A novel method for preparing structurally preserved toxoids of TcdA and TcdB from Clostridioides difficile
Aria Aminzadeh1,2, Manish Kumar Tiwari1, Srwa Satar Mamah Mustapha1, Sandra Junquera Navarrete1, Morten Jannik Bjerrum2, René Jørgensen1

1Statens Serum Institut, Department of Bacteria, Parasites and Fungi, København, Denmark, 2Copenhagen University, Department of Chemistry, København, Denmark

Background: Clostridioides difficile is a Gram-positive, spore-forming and anaerobic bacterium and is the most common cause of healthcare-associated diarrhea in the western world. The disease results in tens of thousands of deaths annually, and carries an economic burden up to US$ 6.3 billion every year in the United States alone. Following intestinal colonization, C. difficile secretes the two cytotoxins, Toxin A (TcdA) and Toxin B (TcdB), which degrade the actin cytoskeleton in epithelial cells causing diarrhea, and may lead to pseudomembranous colitis and death.

Materials/methods: Metal-catalyzed oxidation (MCO) was used to irreversibly detoxify TcdA and TcdB, creating inactive toxoids. The cytotoxicity of the toxoids was tested on Vero cells, and the structural integrity studied using both far- and near-UV circular dichroism. Conservation of the immunogenic epitopes were assessed with an array of toxin-specific monoclonal antibodies in an indirect ELISA. Antibiotic-treated C57BL/6J mice were used to assess the immunogenic efficacy of the toxoids in a C. difficile challenge study.

Results: Here, we describe an efficient and safe method for preparing immunogenic and irreversible toxoids of TcdA and TcdB. We demonstrate that MCO using submillimolar concentration of an oxidant in combination with a pH-dependent conformational change, results in more than 6 log10 reductions in cytotoxicity of both toxoids relative to the native toxins. The toxoids are structurally similar to native toxins and highly recognized by monoclonal antibodies. Injection of the toxoids fully protected mice against disease symptoms and death following a C. difficile infection, and elicited substantial serum IgG responses against both toxins.

Conclusions: Using an optimized MCO method on TcdA and TcdB, we developed structurally intact and immunogenic toxoids, with highly conserved immunogenic epitopes. A vaccine comprising the toxoids were capable of fully protecting mice against C. difficile infection and inducing IgG antibodies against both toxins. This method is very suitable for the creation of safe toxin-based antigens and for future vaccine development should be considered as a potential replacement for cross-linking reagents.

Presenter email address: aram@ssi.dk
Abstract 6431

Polymerase chain reaction-based active surveillance of multidrug resistant pathogens in a paediatric intensive care unit: to screen or not to screen?

Óscar Martínez Expósito1, Elvira Morteruel Arizkuren1, José Luis Barrios Andrés1, Francisco Javier Pilar Drive1, Maitane Aranzamendi Zaldumbide*

1University Hospital Cruces, Biocruces Bizkaia Health Research Institute, Barakaldo, Spain

Abstract third-party references: Biocruces Bizkaia Health Research Institute

Background: An increasing number of children at our institution with Multi-Drug Resistant (MDR) pathogens fostered by the limited information available on molecular surveillance, isolation, and clearance protocols, led us to delve into the rationale use of direct molecular screening of resistance genes into routine policies. Conventional culture methods take a few days, and their sensitivity and usefulness also need to be improved towards active surveillance as the use of the polymerase chain reaction (PCR).

Materials/methods: We carried out prospective admission and follow-up double surveillance comparing PCR and culture on 48 patients resided in the Pediatric Intensive Care Unit [PICU]. From February 2019 to October 2019 AllPlexTM Entero-DR assay [Seegene] which simultaneously detects eight antibiotic-resistance genes, including CPE (blaKPC, blaVIM, blaNDM, blaIMP and blaOXA-48), VRE (vanA, vanB) and ESBL (blaCTX-M) was performed directly on 207 swabs collected: 69 were from pharynx (33.3%), 68 nasal (32.8%), 64 rectal (30.9%) and 6 inguinal (2.9%).

Results: Among 207 samples, 21 (10.1%) from 10 patients were positive: 1 for a CPE type blaVIM-2 and 20 blaCTX-M (18 blaCTX-M 15 like, 2 blaCTX-M 14 like) all confirmed by sequencing. Furthermore, there was a tendency for younger age (< 15 months in 80%) although no differences were found on the basis of gender neither according to days of stay. 7 samples belonging to 4 patients were PCR-negative but culture-positive to microorganisms not targeted by the PCR (S. maltophilia, A. ursingii, S. multivorum, E. meningoseptica and C. amalonaticus). Overall, Positive Predictive Value of PCR was 100%.

Conclusions: Admission prompt surveillance identified a substantial proportion of MDR positive patients in our PICU gaining from 72 to 24 hours, although controlled comparative data were frequently lacking. Follow-up cultures drive out and patients cleared per protocol might enact more active routine programs that could reduce the prevalence of MDR and pre-emptive therapy. Resource limitations and uncertainty regarding the optimal approach may have kept many facilities to implement rigorous molecular screening programs that remain open to debate, enclosing a boarder amount of targets such as MRSA, S. maltophilia, P. aeruginosa MDR, A. baumannii, etc.

Presenter email address: maitanearanzamendi@yahoo.es
Collateral responses to fluoroquinolone resistance in *Streptococcus pneumoniae*

Apostolos Liakopoulos*, Matteo Buffoni1, Daniel Rozen1

1Leiden University, Institute of Biology, Leiden, Netherlands

**Background:** *Streptococcus pneumoniae* is the major cause of community-acquired pneumonia and meningitis, responsible for high morbidity and mortality. Of increasing concern is the global dissemination of multi-resistant *S. pneumoniae* clones compromising treatment efficacy. A promising approach to address this problem is collateral sensitivity (CS) cycling. The aim of this study was to determine the CS and collateral resistance (CR) responses of fluoroquinolone-resistant *S. pneumoniae*.

**Materials/methods:** Eight isogenic fluoroquinolone-resistant *S. pneumoniae* R6/D39 mutants were selected at concentration of ciprofloxacin equal to EUCAST ECOFFs and were whole-genome-sequenced using Illumina MiSeq to identify resistance mechanisms and causal factors underlying CS/CR. In addition, nine *S. pneumoniae* R6/D39 transformants carrying clinically relevant *gyrA* and/or *parC* mutations were created. Minimal inhibitory concentrations (MICs) of 13 commonly used antibiotics were determined for each strain via broth microdilution. CS/CR was determined by comparing the MICs of resistant strains to the isogenic antibiotic-sensitive wild type strain.

**Results:** Although independently isolated resistant strains varied in their collateral responses, generated mutants exhibited extensive collateral sensitivity responses to penicillin (50% of the isolates), co-trimoxazole (62.5%) and several protein synthesis inhibiting antibiotics, mainly tetracycline (75%). CR responses were limited to daptomycin (50%). WGS analysis of mutant strains revealed the presence of the S79Y mutation in *parC* accompanied by mutations in different genetic loci in each spontaneous mutant, suggesting the pleiotropic effect of these secondary mutations on CS/CR phenotypes. Similar CS/CR responses were observed among isogenic transformant isolates exclusively carrying single or combination of mutations in *parC* (S79F, S79Y, D83N, D83Y and E85G) and *gyrA* (S81F) loci. Interestingly, double-mutants (*parC* and *gyrA*) exhibited differences in CS/CR responses and in some cases even in the intensity of responses compared to single mutants carrying identical mutations, suggesting epistatic effects influence collateral responses. In addition, nucleotide mutations resulting in different non-synonymous mutations at the same amino-acid caused distinct CS/CR responses.

**Conclusions:** Fluoroquinolone-resistant *S. pneumoniae* exhibit conserved CS responses to several antibiotics, especially tetracycline. Our data provide evidence that combination therapy based on CS responses may be a promising approach to eliminate *de novo* emergence of fluoroquinolone-resistance and/or treat *S. pneumoniae* infections.

**Stepwise in vitro daptomycin resistance selection of Staphylococcus aureus: accumulation mutations and heteromutations**

Vladimir Gostev*1;2, Olga Kalinogorskaya1, Julia V. Sopova1;3, Irina Tsvetkova1, Maria Velizhanina3, Sergey Sidorenko1;2

1Pediatric Research and Clinical Center for Infectious Diseases, Saint Petersburg, Russian Federation, 2North-Western State Medical University named after I.I Mechnikov, Saint Petersburg, Russian Federation, 3Saint Petersburg State University, Saint Petersburg, Russian Federation, 4St. Petersburg branch of Vavilov Institute of General Genetics, Saint Petersburg, Russian Federation

**Background:** Daptomycin (DAP) is one of the last-resort agents for treatment of MRSA infections. DAP resistance is rare, but frequently associated with heteroresistance or/and decreased susceptibility to vancomycin. In this study we followed genetic events during in vitro selection of DAP resistance in S. aureus of different genotypes.

**Materials/methods:** Five clinical MRSA strains and MSSA [ATCC29213] with initial MIC of DAP \(\leq 1\) mg/L were included in the study. Resistant mutants were selected during 40 passages in media with daptomycin. Whole genome sequencing was performed for derivative strains after 5, 20, and 40 passages. Hetero-mutations were calculated using Breseq as: the number of reads with mutational events in derivative strain in comparison with parental strain/number of reads in this point. Hetero-mutations were considered at a frequency of > 5% and < 91%.

**Results:** After 5-20 passages all derivative strains demonstrated MIC in range 132 mg/L due to mutations in \(mprF\), and at 20-40 passages level MIC increasing up to >64 mg/L due to additional mutations in \(cls2\). Mutation in \(pgsA\) and \(fabF\) were identified in two strains. In 3 of 5 stains mutations were identified in hypothetical protein \(YfhP\) which is localized in peptidoglycan biosynthesis locus. Distribution of hetero-mutations in the genomes was associated with the different genes of general metabolism (Table). Some hetero-mutations were eliminated during passages, other were converted to homologous (marked with * in the Table). In parallel passaging in antibiotic free media these mutations were not detected.

**Conclusions:** Main DAP resistance mechanisms are associated with mutations in \(mprF\), additional mutations in \(cls2\) promoted high level MIC. Mutations in potential gene \(yfhP\) can be regarded as new markers of DAP resistance. Detected hetero-mutations are a consequence of appearance a subset of a microbial population during resistance selection.

Abstract 6435

Phase II clinical data showed that lower recurrence of *Clostridioides difficile* infection with ridinilazole is associated with minimal impact on the gut microbiota and bile acid composition

Esther Duperchy*1, XI Qian2, Karin Yanagi3, Anne Kane4, Nicholas Alden3, Ming Lei5, David R. Snydman5,6, Richard Vickers1, David Roblin1, Kyongbum Lee3, Cheleste Thorpe5,6

1Summit Therapeutics, Abingdon, United Kingdom, 2Tufts University, The Tufts Clinical and Translational Science Institute, Boston, United States, 3Tufts University, Department of Chemical & Biological Engineering, Boston, United States, 4Tufts Medical Center, Boston, United States, 5Tufts Medical Center, Boston, United States, 6Tufts University School of Medicine, Boston, United States

**Background:** In 2019 the US CDC listed *Clostridioides difficile* as one of the five urgent public health threats. The key clinical challenge is high risk of recurrent *C. difficile* infection (rCDI), typically 25% after a first episode. CDI is generally associated with gut dysbiosis. Treatment of CDI with antibiotics can further damage the microbiota and increase the risk of recurrence. Ridinilazole (RDZ) is a novel targeted spectrum antibiotic under investigation to treat CDI and reduce rCDI. Phase 2 clinical data presented here review the effect of RDZ and vancomycin (VAN) therapy on rCDI, gut microbiota and bile acid (BA) composition.

**Materials/methods:** The Phase 2 clinical trial was a double-blind study of 100 patients randomized 1:1 for 10 days RDZ or VAN treatment. Stool samples were collected from baseline (BSL) up to 30 days post-end-of-treatment (EOT) and analysed for gut microbiota and BA composition using 16S rDNA sequencing and LC-MS², respectively.

**Results:** The Phase 2 clinical study showed a 60% reduction of the recurrence rate in the RDZ-treatment arm compared to VAN. Microbiota analysis at RDZ EOT showed a significant reduction of relative abundance of two Firmicutes families including *C. difficile* compared to BSL. At VAN EOT significant losses were observed in four Firmicutes families (often to below detection), in Actinobacteria (70% drop) and in Bacteroidetes (> 3 log decrease). These changes were associated with a 25-fold increase in Proteobacteria. RDZ had minimal impact on the microbiota-associated BA composition. In contrast, VAN EOT samples showed increased levels of conjugated primary BAs (100-fold) which can mediate *C. difficile* spore germination, and, decreased levels of secondary BAs (10-fold) which generally inhibit *C. difficile* growth. Secondary BAs result from the hydrolysis and transformation of conjugated BAs by the gut microbiota. Altogether these data correlate with the leading hypothesis that preserving the gut microbiota and its ability to transform BA can lower the rate of rCDI.

**Conclusions:** These data demonstrate that RDZ preserved both the gut microbiota and BA composition in CDI patients. This likely contributed to the lower rate of recurrence compared to VAN. RDZ is currently being evaluated in Phase 3 trials.

**Presenter email address:** esther.duperchy@summitplc.com
Leukocytes apoptosis in pulmonary tuberculosis patients with different treatment schemes

Olga Hovardovska*

1Kharkiv National Medical University, Kharkiv, Ukraine

Background: Anti-tuberculosis (TB) immune response depends from activity of phagocytosis by blood cells, formation of specific antibodies and delayed-type hypersensitivity, all this processes are performed or depends from leukocytes. Thus, study of apoptosis process in TB patients has high practical and theoretical interest.

Materials/methods: The study was performed on 30 patients with pulmonary tuberculosis: 1 group – 12 patients treated by standart regimen with I line drugs; 2 group treated by individual regimen with I and II line drugs. Control group included 12 healthy donors. The study was performed by flow cytometry on a flow cytometer FACS Calibur with addition of markers CD45+, AnnexinV FITC detection KIT I, 7AAD.

Results: Analysis of state of cytoplasmic membranes of leukocytes in the blood of pulmonary TB patients of 1 and 2 groups showed that the proportion of live intact cells was 71.05± 3.66 % that is lower by 20.75 % from the results of control group. Comparative analysis of results between 1 and 2 groups showed significant differ between amount of alive cells that was not involved in apoptosis process. In 2 group the proportion of alive cells was lower by 12.9 % than in 1 group (p<0.05). In the same time, the proportion of leukocytes on the late of apoptosis/necrosis, that have deep damages of cell structure, was higher by more than 10 % than in 1 group (p<0.05). The differences between proportion of leukocytes on other stages of apoptosis were not significant (p≥0.05).

Conclusions: Our results suggest that treatment of pulmonary tuberculosis is accompanied with externalization of phosphatidylserine in the phospholipid leaflet of the plasma membrane of CD-45+ leukocytes. Significant difference between groups of patients in the proportion of absolutely alive leukocytes and cells on the late stage of apoptosis/necrosis can be a prove ment of higher activation of apoptosis process by individual treatment regimen that included I and II lines drugs, comparing with standart I line regimen. The obtained data allow us to recommend the study of influence of different antituberculosis drugs and regimens to apoptosis process of immune-competent cells to evaluate efficacy of pulmonary tuberculosis treatment.

Presenter email address: olgasencheva@yandex.ru
Can UF-5000 body fluid mode be an alternative for cerebrospinal fluid cell count?

Esra Baran*, Arzu Ilki

1Marmara University Faculty of Medicine, Istanbul, Turkey

Background: Cellular analysis of cerebrospinal fluid (CSF) provides diagnostic information in meningitis or encephalitis. The aim of the study was to evaluate performance of UF-5000-BF (Sysmex Co., Kobe Japan) body fluid mode and compare the obtained results with cytometric analysis of CSF with optical counting as reference method.

Materials/methods: A total of 426 CSF samples from patients with suspected cases of central nervous system infection submitted to our clinical microbiology laboratory, were enrolled in the study. Specimens were counted with Thoma cell counting chamber and they were simultaneously analyzed with UF-5000 body fluid mode based on flow cytometry principle. The results were evaluated according to CLSI document H56-A. The manual white blood cell (WBC) counts were grouped into nine categories. The comparison of the manual method and the automated system according to these categories were determined with Pearson’s correlation coefficient.

Results: The study group consisted of 223 (52.3%) children and 203 (47.7%) adult patients. Of the 107 samples classified as positive (> 7 WBC/µL) in pediatric patients by manual counting, 90 were also determined as positive by UF-5000-BF. Sensitivity and specificity were 84.1% and 73.2%, respectively. In adults, 95 samples were counted as positive (>5 WBC/µL) by optical microscopy whereas 87 were analyzed as positive with UF-5000. Sensitivity and specificity were determined as 91.5% and 62.0%, respectively. The comparison between UF-5000 and light microscopy differentiation cell counts showed a Pearson’s correlation of 0.84 for WBC with p<0.0001 and results of UF-5000-BF displayed good agreement with light microscopy optical counting for WBC (Table 1).

Conclusions: The comparison between UF-5000-BF results and optical microscopy counts showed a good correlation for WBC. Particularly the performance of UF-5000-BF was very good at ≤20 cells/µL and 400 cells/µL. This result is meaningful for our laboratory, since WBC counts were detected in this range for 76% of the samples. Thus, UF-5000-BF can be rapid, effective and automated method for CSF samples in clinical microbiology laboratory.

Table 1: UF-5000-BF WBC counts corresponding to optical microscopy results

Co-occurrence of mcr and blaCTX-M genes in Escherichia coli from healthy pigs and humans in Thailand

Thongpan Leangapichart1, Rachel A. Hickman2, Kanonwan Lunha1, Jatesada Jiwakanon4, Sunpetch Angkititrakul4, Ulf Magnussen3, Josef Järhult2, Marianne Sunde1

1Norwegian Veterinary Institute, Section for Food Safety and Antimicrobial resistance, Oslo, Norway. 2Uppsala University, Department of Medical Sciences, Uppsala, Sweden, 3Swedish University of Agricultural Sciences, Department of Clinical Sciences, Uppsala, Sweden, 4Khon Kaen University, Research Group Preventive Technology Livestock, Khon Kaen, Thailand

Background: The plasmid-mediated colistin resistance mcr-1 was initially described from China and have increasingly been reported in humans, animals and from the environment. Until now, bacteria harboring mcr, mainly mcr-1 and its family mcr-2 to -9, have been reported across the world. Moreover, coexistence of mcr with extended-spectrum beta-lactamase (ESBL), blaCTX-M genes has become an established and an increasing treat of horizontal gene transfer (HGT) mediated antibiotic resistance. Here, we investigate the presence of mcr and coexistence with blaCTX-M genes in Escherichia coli isolated from pig farms in Thailand.

Materials/methods: Rectal swabs were collected from 847 pigs (166-pooled samples) from 166 pig farms. Fecal samples were provided by from 159 farmers and 114 humans in proximity to farms but without direct contact with pigs. Isolation of multi-drug resistant (MDR) E. coli was done by use of selective methods. Minimum inhibitory concentrations and whole-genome sequencing (WGS) were performed for all isolates.

Results: Overall, 492 E. coli were isolated from 439 pooled-swab and fecal samples of which 33.7% (166/492) were mcr-positive. The predominant mcr genes were mcr-1 (109/166, 65.6%), mcr-3 (70/166, 42.1%), and mcr-9 (1/166, 0.6%). mcr-positive E. coli with blaCTX-M14 (54/103) and blaCTX-M55 (49/103) were detected among the isolates. Interestingly, coexistence of mcr-1, mcr-3, and a blaCTX-M gene was found in 15 isolates. WGS analysis of mcr-positive E. coli revealed high genomic diversity, comprising 64 sequence types (STs) and 24 new STs. A variety of plasmid backbones carrying mcr genes were identified including IncHI1, IncHI2, IncFI1, IncI2, IncP1, IncX1, and IncX4. Our results also indicate evidence of transmission of MDR bacteria between pigs and humans.

Conclusions: High prevalence of mcr-positive E. coli including the evidence of coexistence with blaCTX-M gene indicated high MDR bacteria in pig and human origins in Thailand. This study highlights the importance for more substantial monitoring which can aid in developing more appropriate antimicrobial stewardship. Also, there is a need to provide the knowledge of using antibiotics in both human and animal sectors.

Phenotypic and genotypic comparison between *Escherichia coli* isolates causing recurrent and sporadic cystitis

Vautrin Nicolas*1, Sandrine Dahyot1,2, Marie Leoz1, François Caron1,2, François Gravey1, Simon Le Hello3, Roland Fabre4, Kévin Alexandre1,2, Martine Pestel-Caron1,2

1 Normandie Univ, UNIROUEN, UNICAEN, GRAM 2.0 EA2656, Rouen, France, 2 Rouen University Hospital, Rouen, France, 3 Normandie Univ, UNICAEN, UNIROUEN, GRAM 2.0 EA2656, Caen, France, 4 Laboratoire d’analyses de biologie médicale, Elbeuf, France

**Background:** *Escherichia coli* is by far the predominant agent of urinary tract infection. Half of women suffer from recurrent cystitis in the year following the index episode. However, their physiopathology is still poorly understood. Thus we aimed to analyse genomic and phenotypic markers associated with recurrent *E. coli* cystitis compared to sporadic ones.

**Materials/methods:** 343 *E. coli* prospectively collected over 18 months were analyzed; 124 from recurrent cystitis (49 patients with ≥2 episodes over 6 months) and 217 from sporadic cystitis. Genetic diversity was studied by Clermont phylo-typing and CH-typing (*fimH* and *fumC* sequencing). Afterwards, 80 isolates were selected: 43 from recurrent cystitis (9 patients, each with ≥4 episodes over 12 months) and 32 from sporadic cystitis (matched on CH-type). These isolates were further characterized by whole genome sequencing (wgs) by Illumina® technology, in silico MultiLocus Sequence Typing (MLST), analysis of the virulome (VirulenceFinder) and resistome (ResFinder, PointFinder), biofilm production measurement (crystal violet assay), antimicrobial susceptibility testing (disk diffusion method) and fitness (growth curve analysis).

**Results:** Phylotyping of the 343 isolates revealed that B2 was the most prevalent phylogroup (53%) followed by D (14%) and A (13%). 120 unique CH-types were identified with no specific lineage associated with recurrent or sporadic event. Despite this genetic diversity, half of the 49 patients with recurrent cystitis were infected at least 2 times with the same strain (identical phylogroup and CH-type). Interestingly, 100% of the 9 patients with ≥4 episodes in 12 months relapsed at least once with the same strain, consistent with MLST results. This must be confirmed by wg single nucleotide polymorphisms analysis. Comparative analysis of isolates from recurrent and sporadic cystitis has not shown significant differences in terms of virulome (genes involved in adhesion, iron capture or biofilm formation), biofilm production and fitness. Antibiotic resistance to amoxicillin, cotrimoxazole and ciprofloxacin was significantly more frequent in recurrent cystitis and correlated to resistome analysis.

**Conclusions:** Sporadic *E. coli* cystitis are due to a large diversity of strains. Recurrent ones mix episodes with unique strains and episodes with indistinguishable strains by classical typing methods. The reasons of such dual dynamic request further studies.

Abstract 6442

**Personal experience and availability of surveillance data, diagnostics and therapeutics are the main drivers for treating carbapenem-resistant Gram-negative bacteria infections**

Alessia Savoldi*, Elena Carrara¹, Laura Piddock², François Franceschi², Sally Ellis², Evelina Tacconelli¹

¹University of Verona, Verona, Italy, ²Global Antibiotic R&D Partnership [GARDP], Geneve, Switzerland

**Background:** The GARDP COHERENCE survey aims at assessing prescription habits among clinicians who routinely treat infections due to carbapenem-resistant Gram-negative bacteria (CR-GNB) including *Acinetobacter*, Enterobacterales, *Pseudomonas* in adults and pediatric populations worldwide accounting for surveillance data, diagnostic and treatment availability.

**Materials/methods:** A 36-item anonymous web-based questionnaire was developed and validated by a multidisciplinary team. A core-expert group of 101 members from 70 countries facilitated the survey distribution through 50 international networks to prescribers via a SurveyMonkey link. Differences in responses across three main prescribers’ characteristics (geography, income and prescription frequency) were computed using Chi-square test with level of significance <0.05.

**Results:** In 10-week period, 1020 respondents from 95 countries and 687 hospitals completed the questionnaire. Twenty per cent (204) of respondents were from low and lower-middle income countries (LIC/LMIC), 14.4% (145) had experience in treating children or neonates. In 38% of the surveyed countries (33/95), clinicians could not rely on national/regional surveillance systems tracking carbapenem-resistance rates. Income status substantially affected the availability of diagnostics and therapeutics: 94% of LIC/LMIC countries had access solely to standard antimicrobial susceptibility tests, while molecular diagnostic tools were more frequent in HIC compared to LIC/LMIC. Molecules licensed in the last five years (ceftazidime-avibactam, meropenem-vaborbactam, plazomicin, eravacycline) were available only in 19 (20%) countries. Therapeutic schemes included 40 combinations in *Acinetobacter* up to 178 in Enterobacterales. In general, dual-antibiotic schemes were preferred over single and triple-antibiotic schemes, irrespective of sepsis source and bacterial species. The most prescribed dual-antibiotic scheme was carbapenem plus polymyxin. Empirc coverage for CR-GNB was mainly dictated by infection severity and less by epidemiological data and/or risk factors for CR-GNB acquisition. Eighty per cent of respondents prescribed combination therapy driven by the personal perception of higher clinical efficacy. In 62% of respondents, the choice of prescribing combination over monotherapy did not rely on evidence but on experts’ recommendation and personal experience.

**Conclusions:** The heterogeneity of prescription habits across the world seems to be mostly influenced by personal experience and unequal access to diagnostics and therapeutics. The development of guidelines for CR-GNB infections should consider these data when issuing recommendations targeting a global audience.

**Abstract 6444**

**Persistence of serotype 19F and the importance of non-vaccine serotypes in paediatric non-invasive pneumococcal pneumonia in Portugal, 2015-2018**

Catarina Silva-Costa¹, Joana Gomes-Silva¹, Mario N. Ramirez*, José Melo-Cristino¹

¹Universidade de Lisboa, Faculdade de Medicina, Lisboa, Portugal

**Abstract third-party references:** Portuguese Group for the Study of Streptococcal Infections

**Background:** The introduction of pneumococcal conjugate vaccines (PCVs) into routine infant immunization programs led to significant changes in serotype distribution and antimicrobial susceptibility patterns of pneumococci causing IPD, but little is known about the epidemiology of non-invasive pneumococcal pneumonia (NIPP) in children. Given this, we aimed to characterize the pneumococcal population causing NIPP in children (<18 years) in Portugal from 2015 to 2018, after the inclusion of PCV13 in the National Immunization Plan, by serotyping and antimicrobial susceptibility testing.

**Materials/methods:** A total of 190 *Streptococcus pneumoniae* isolates recovered from sputum, bronchial secretions or bronchoalveolar lavage of pediatric patients in 62 hospitals in Portugal between January 2015 and December 2018 were characterized by serotyping and antimicrobial susceptibility testing.

**Results:** The majority of the NIPP cases were caused by serotypes not included in PCV13 (70%), with serotypes 11A (n=23), 23B (n=17) and 21 (n=9) being the most frequent. Among PCV13 serotypes, serotype 19F was the most frequent (n=19) followed by serotypes 3 (n=15) and 19A (n=10). Other PCV serotypes detected included 14 (n=7), 23F (n=2) and 4, 6A, 6B and 18C (n=1 each). In the same time period, the proportion of cases caused by PCV13 serotypes was significantly lower in NIPP than in IPD (30% vs 45%, p<0.001). 56% of the isolates were susceptible to penicillin and erythromycin, while 15% of the isolates were simultaneously resistant to erythromycin and penicillin non-susceptible (MIC>0.06 mg/L). Overall, 21% of the isolates were penicillin non-susceptible and resistance to erythromycin was expressed by 23% of the isolates, mostly associated with serotypes 14, 19A and 19F. When considering the current non-meningitis breakpoints, no strain would be resistant to penicillin.

**Conclusions:** Despite the use of PCV7 >15 years, serotype 19F is still an important serotype in pediatric NIPP in Portugal. In recent years, pediatric NIPP was mostly caused by non-vaccine serotypes in contrast to the dominance of PCV13 serotypes in IPD, suggesting different effects of vaccination on these two presentations. Continued pediatric NIPP surveillance is crucial to understand the full effect of vaccination.

Squamous cell carcinoma of the anus screening in people living with HIV: HPV genotyping is as important as cytology in anal cancer early diagnosis

Margherita Digaetano1, Carlotta Rogati1, Marianna Menozzi*1, Aurora Bonazza2, Francesco Spatafora2, Alberto Farinetti2, Roberta Gelmini2, Monica Pecorari2, Sara Tagliazucchi2, Luca Reggiani Bonetti2, Roberto Paolo Iachetta2, Roberto Villani2, Cristina Mussini2,3,6

1Policlinico of Modena University Hospital of Modena, Clinica di Malattie Infettive, Modena, Italy, 2Policlinico of Modena University Hospital of Modena, Chirurgia Generale d’Urgenza e Oncologica, Modena, Italy, 3Policlinico of Modena University Hospital of Modena, Microbiologia e Virologia, Modena, Italy, 4Policlinico of Modena University Hospital of Modena, Anatomia Patologica, Modena, Italy, 5Nuovo Ospedale Civile, Unità operativa di chirurgia proctologica, Sassuolo, Italy, 6University of Modena and Reggio Emilia, Modena, Italy

Background: Squamous cell carcinoma of the anus is one of the most common non-AIDS-defining malignancy among people living with HIV (PLWH). Our project aimed to evaluate the incidence of precancerous lesions in high-risk patients, in order to assess the best screening method.

Materials/methods: All MSM and women with history of CIN PLWH, aged >18, outpatients attending the Infectious Diseases Clinic have been offered to perform a first level screening including anal Pap test and HPV genotyping followed by high resolution anoscopy (HRA) in Pap test positives or high risk HPV (HRHPV) carriers.

Results: 87 Pap tests (41.5% of 209 enrolled) were positive for HPV-related lesions, 78 (37.3%) low grade squamous intra-epithelial lesions (LSIL) and 5 (2.4%) atypical squamous cells of undetermined significance (ASCUS) while high grade lesions (HSIL) were found in 4 patients (1.9%). 157 of 209 screened (75.1%) performed also HPV genotyping and 123 (58.8%) carried least one high risk HPV (HRHPV). 169 screened (80.8% of 209) had the indication for second level screening. Among 68 HRAs performed until today (51 in Pap test positive and 17 in HRHPV carriers with Pap test negative), 29 (42.6%) showed LSIL and 12 HSIL/CIS (17.6%). In 4 patients HSIL was diagnosed only thanks to a high-risk genotype. Statistical significance was only achieved in the univariate analysis by correlating the positive pap test alone as an indication for HRA with biopsy confirmation of LSIL even with anoscopic examination. HPV16 is the most frequently isolated genotype (38 cases, 24.4%). Of note is the high frequency of isolation of genotypes considered to be possible / probable high risk as HPV 53 which was the second most prevalent genotype (21%) followed by HPV 66 (15.9%) and HPV 70 (14%).

Conclusions: We can state that anal carcinoma screening including anal Pap test, HPV genotyping and second level surveillance with HRA is currently the most complete and reliable method. It is expected that with the expansion of the present study it will be possible to establish the sensitivity and specificity of the cytology and genotyping performed during the Pap test and even to modify the current screening protocol.

Impact of recent vaccine schedule changes on pertussis epidemiology in France

Juliette Paireau¹, Sophie Guillot¹, Fatima Ait El Belghiti², Sabine Trombert Paolantoni³, Véronique Jacomo⁴, Henrik Salje¹, Sylvain Brisse², Daniel Levy Bruhl², Simon Cauchemez³, Julie Toubiana*¹⁵

¹Institut Pasteur, Paris, France, ²Santé Publique France, Paris, France, ³Cerba, St Ouen L'Aumone, France, ⁴Eurofins Biomnis, Lyon, France, ⁵Necker, Université de Paris, Paris, France

Background: Despite widespread acellular vaccine implementation, pertussis is resurgent in several parts of the world including Europe. In France, Santé publique France, with the support of the National Reference Center (NRC) of whooping cough and other bordetelloses, is responsible for pertussis surveillance and collaborates with 2 outpatient laboratories (Cerba and Biomnis) that ensure the biological diagnosis of outpatient pertussis cases throughout the country. In 2017 and 2018, an increase of nasopharyngeal samples positive for Bordetella spp. was observed, mainly in the 2-5 years group. The aim of this study was to assess the effect of the French immunization schedule modification in 2013 (from a 2/3/4 + 16-18 months to a 2/4 + 11 months doses schedule) on pertussis epidemiology.

Materials/methods: We analysed outpatient laboratory results from nasopharyngeal swabs from symptomatic patients between 2012 and 2018, tested for Bordetella spp using PCR targeting insertion sequences IS481. The data analysis was based on a Poisson regression model, in which all positive cases by year and age depended on the year, the age group, the vaccine effectiveness and duration of protection, and the size of each age group. Different models were tested, in which vaccine effectiveness and duration of protection could depend on the type of vaccine schedule.

Results: The number of pertussis cases increased in 2017 and 2018 (x 2.4 compared to 2014-2016), with an increase in the proportion of the 2-5 years [1% in 2017-2018 vs. 7% in 2014-2016]. The models supporting a rapid decrease of vaccine protection following vaccination with the new vaccine schedule gave the best fit to epidemiological data. The predicted age distribution of cases for 2019 using the best model showed good correlation (r=0.96, p<0.001) with the observed age distribution reported between January and September 2019.

Conclusions: The increase of pertussis cases observed in 2017-2018 in children born after 2013 and aged 2-5 years, and the larger proportion of this age group among all pertussis cases, could be explained by a short-lived protection induced by the novel vaccine schedule recommended in France since 2013. A preliminary analysis of 2019 data seems to confirm this finding.

Elevated tolerance to disinfectants in a carbapenemase-producing Klebsiella pneumoniae isolate obtained from a duodenoscopy-associated outbreak

Katharina Konrat1, Melanie Brunke2*, Yvonne Pfeifer1, Laura Becker2,3, Christoph Schaudinn1, Brar Piening4, Ingeborg Schwebke1, Mardjan Arvand1

1Robert Koch-Institute, Berlin, Germany, 2Robert Koch-Institute, Wernigerode, Germany, 3Hessisches Landesprüfungs- und Untersuchungsamt im Gesundheitswesen, Dillenburg, Germany, 4Charité – Universitätsmedizin Berlin, Institute for Hygiene and Environmental Medicine, Berlin, Germany

Background: Nosocomial outbreaks of carbapenemase-producing Klebsiella (K.) pneumoniae (CPKP) have become a major concern in healthcare facilities worldwide. In some cases duodenoscopes have been identified as a source of transmission. In 2014 a duodenoscopy-associated outbreak affecting 13 patients occurred in a German hospital. We investigated the efficacy of disinfectants used for the reprocessing of duodenoscopes in inactivating the CPKP outbreak strain.

Materials/methods: Genetic relationship of CPKP isolates obtained from 13 patients and one duodenoscope was confirmed by PFGE. Antimicrobial susceptibility testing was performed. MLST type, resistance and virulence genes were extracted from whole genome sequencing (WGS) data.

The efficacy of different disinfectants was tested in suspension tests based on DIN EN 13727 comparing the CPKP outbreak strain with a K. pneumoniae reference strain (ATCC 13883). Efficacy of peracetic acid (PAA)-based disinfection was further assessed in a biofilm assay developed at Robert Koch-Institute. Successful disinfection was defined as a reduction of ≥ 5 log10 recoverable mean CFUs.

Results: The CPKP outbreak strain was resistant to fluoroquinolones, aminoglycosides, cephalosporins and carbapenems but sensitive to tigecycline and colistin. WGS analyses revealed a ST101 K. pneumoniae strain with genes encoding the carbapenemase OXA-48 and ESBL CTX-M-15. Furthermore, genes involved in iron uptake systems (ybt, kfu) and biofilm formation (mrk) were detected.

The suspension tests showed no difference between the outbreak and reference strain in terms of efficacy of disinfection by H2O2, glutaraldehyde and isopropanol. However, we found decreased susceptibility of the outbreak strain towards PAA. We further pursued this phenomenon by testing efficacy of PAA disinfection in biofilm. Here, 0.15% PAA, the concentration used in reprocessing of the duodenoscope from which the outbreak strain was obtained, was sufficient to achieve disinfection of the reference strain but not of the outbreak strain.

Conclusions: We report a CPKP strain of a major epidemic clonal lineage that exhibited enhanced tolerance to PAA-based disinfection, which was performed for reprocessing of duodenoscopes at the time of the outbreak. This phenomenon has probably contributed to the transmission of the outbreak strain. Tolerance against disinfectants might contribute to nosocomial spread of epidemic K. pneumoniae and needs to be further studied.

Abstract 6453

Potential impact of removing metronidazole from the treatment armamentarium for mild acute Clostridioides difficile infections

Shani Zilberman-Itskovich1, Ilan Youngster1, Tzilia Lazarovitch1, Marina Bondorenco1, Limor Toledano1, Yael Kachlon1, Bethlehem Mengesha1, Ronit Zaidenstein1, Dror Marchaim*1

1Shamir (Assaf Harofeh) Medical Center, Beer Yaacov, Israel

**Background:** The epidemiology of Clostridioides difficile infection (CDI) has rapidly evolved, with increasing rates of resistances, toxin production, and recurrences. This, in addition to limited clinical data, resulted IDSA guidelines, to recommend removing metronidazole from the treatment armamentarium, even for mild CDI. However, superiority of vancomycin over metronidazole specifically for mild CDI, has not been firmly established, and extensive use of vancomycin, might lead to detrimental outcomes, including possible emergence of vancomycin-resistant enterococci (VRE).

**Materials/methods:** We conducted a retrospective cohort analysis (2010-15) at Shamir (Assaf Harofeh) medical center, Israel. Adult patients with acute CDI (first and single episodes) per IDSA definitions were enrolled. CDI severity was determined based on established criteria. Cox and Logistic regressions were used to analyze post-CDI VRE rates (up to 18 months), and in a sub-analysis (using propensity score matched analysis), the efficacy of metronidazole vs. vancomycin for mild cases, respectively.

**Results:** 409 patients were enrolled during the 6-year study period (median age 78 years). There were 13 post-CDI VRE acquisitions, all among patients treated solely with vancomycin during their acute CDI. In a multivariable controlled analysis, independent predictors of post-CDI VRE acquisition were recent exposure to proton-pump inhibitors (aOR=6.6, p=0.04), severe level of sepsis at CDI onset (aOR=5.2, p < 0.001) and treatment with oral vancomycin [alone or in combination, aOR=6.7, p=0.03]. Of 164 patients with mild CDI, 131 received monotherapy. In univariable analysis among these patients, all clinical outcomes were favorable in the metronidazole group. After propensity score matched analyses, metronidazole remained non-inferior to vancomycin in all 16 morbidity and mortality outcomes that were captured and analyzed (e.g., mortality, length of stay, functional deterioration, re-hospitalizations, institutionalization).

**Conclusions:** The recent shift in CDI treatment recommendations, might lead to increased usage of oral vancomycin, also for mild cases. We showed a significant independent association between treatment with oral vancomycin and later acquisition of VRE, and non-inferiority of metronidazole for mild cases. in first episodes of mild acute CDI, metronidazole should still be considered a valid treatment option and vancomycin should be restricted and used judiciously.

**Presenter email address:** drormarchaim@shamir.gov.il
Molecular characterisation of carbapenemase-producing Enterobacterales (CPE) in London, UK

Bharat Patel*, Katie Hopkins1, Daniele Meunier1, Nazim Mustafa1, Nicholas Ellaby1, Michel Doumith1, Susan Hopkins1, Neil Woodford1

1Public Health England, National Infection Service, London, United Kingdom

Background: Whole-genome sequencing (WGS) was applied over 30 months to determine the pattern of high-risk globally-dominant clones amongst CPE isolates submitted by London laboratories to the national reference laboratory for investigation of carbapenem resistance.

Materials/methods: WGS was applied between 1st Jan ‘14 and 30th June ‘16 to the first confirmed CPE referred by London laboratories from each new patient. Additional isolates from a patient were included only if harbouring a different carbapenemase or of a different species. WGS was performed on an Illumina HiSeq 2500 and the data analysed using an in-house bioinformatics pipeline, which determined species identification, MLST profile and resistance gene content.

Results: WGS data were obtained for 927 isolates, and 96.3% (892) were of five species: Klebsiella pneumoniae (504, 54.4%), Escherichia coli (267, 28.8%), Enterobacter cloacae (47, 5.1%), Citrobacter freundii (42, 4.5%) and Klebsiella oxytoca (32, 3.5%). The most common sequence types (ST) identified in K. pneumoniae were ST14 (119), ST147 (56), ST231 (35), ST11 (30) and in E. coli ST38 (60), ST416 (27), ST405 (26), ST162 (22), ST131 (8). The most common carbapenemase detected was OXA-48 (248, 26.8%) followed by NDM-1 (247, 26.6%), OXA-181 (99, 10.7%), OXA-232 (65, 7.0%), and NDM-5 (64, 6.9%). Other minor mechanisms (<5%) included NDM-1+OXA2-32 (25, 2.7%), IMP-1 (23, 2.5%), VIM-4 (22, 2.4%), NDM-7 (21, 2.3%), GES-5 (19, 2.0%) and KPC-2 (17, 1.8%). Most CPE were detected from rectal swabs or faecal samples (459, 49.5%), followed by urine (168, 18.1%), blood cultures (53, 5.7%) and wound swabs (52, 5.6%).

Multiple species/ST/carbapenemase mechanism combinations were detected:

K. pneumoniae ST14/NDM-1 was detected from four laboratories \{n=37\}, \{n=21\}, \{n=6\}, \{n=5\}.
K. pneumoniae ST147/NDM-1 from two laboratories \{n=9\}, \{n=7\}.
K. pneumoniae ST405/OXA-48 \{n=10\},
K. pneumoniae ST834/IMP-1 \{n=10\},
K. oxytoca ST13B/GES-5 \{n=14\},
E. coli ST38/OXA-48 from three laboratories \{n=13\}, \{n=6\}, \{n=5\}.
E. coli ST38/NDM-1 \{n=20\}.

Conclusions: K. pneumoniae ST14 and E. coli ST38 were the dominant clones associated with NDM-1 and/or OXA-48 carbapenemases. However, diverse combinations of species/ST/carbapenemase were detected in London over the 30-month period.

Abstract 6455

mcr-8-mediated colistin resistance in a carbapenem-resistant Klebsiella pneumoniae isolate
Remy Bonnin¹, Sandrine Bernabeu¹, Francoise Jaureguy², Thierry Naas¹, Laurent Dortet*¹
¹Paris-Sud University, Le Kremlin-Bicêtre, France, ²Hospital Avicenne, Bobigny, France

Background: During the last two years, resistance to polymyxin is increasingly reported in Gram negatives. In Gram negative bacteria, colistin resistance results mostly from addition[s] of cationic groups such as 4-amino-L-arabinose [L-Ara4N] and/or phosphoethanolamine [pETN] on the lipid A. These modifications could be chromosome- (mainly through mgrB alteration) or plasmid-encoded [mcr gene acquisition]. Here, we characterized the mechanism responsible for colistin resistance in a carbapenem-resistant K. pneumoniae isolate.

Materials/methods: Colistin susceptibility testing using broth microdilution, as recommended by EUCAST. Multiplex PCR was performed for the detection of mcr-1, -2, -3, -4 and -5. A recently described rapid [15 min] MALDI-TOF-based test [named MALDIXin test] was performed to detect modified lipid A responsible for colistin resistance. Whole genome sequencing (WGS) was performed using Illumina technology. ResFinder3.1 was used to identify acquired resistance determinants. Direct transfer of the colistin resistance gene mcr-B into E. coli J53 was attempted by liquid mating-out assays at 37°C. Selection was performed on agar plates supplemented with colistin (4 µg/ml) and sodium azide (100 µg/ml).

Results: A K. pneumoniae isolate with decreased susceptibility to carbapenems and resistant to colistin (MIC = 16 mg/L) was recovered from an immunocompromised patient with recent history of travel to Morocco. Carbapenemase production was excluded using Carba NP test and NG-test Carba5 immunochromatographic assay. Regarding colistin resistance, multiplex PCR for the detection of mcr-1, -2, -3, -4 and -5 remained negative. The MALDIXin test revealed the presence pETN-modified lipid A suggesting the production of an MCR-like enzyme. WGS data analysis revealed the presence of mcr-B gene. Transconjugants were obtained that harbored the ca. 130-kb plasmid carrying the mcr-B gene. This transconjugative E. coli J53 isolate was resistant to colistin with MIC at 8 mg/L but remain susceptible to all other antimicrobials. This self-conjugative plasmid does not carry other antimicrobial resistance genes.

Conclusions: This is the first report of MCR-B-producing K. pneumoniae clinical isolate that is not related to China.

Presenter email address: laurent.dortet@aphp.fr
Genetic architecture of interspecies hybrids

Katrin Bartke, Linnéa Garoff, Douglas Huseby, Gerrit Brandis, Diarmaid Hughes

1 Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden

Background: Bacterial acquisition of foreign genetic material is closely associated with virulence and resistance to antibiotics. High frequency mechanisms of gene transfer are dedicated to promote the movement of mobile genetic elements such as plasmids and integrative conjugative elements. Chromosomal DNA can also be mobilised, for example when a conjugative plasmid is integrated into a chromosome. Intra-species chromosomal transfers have resulted in the creation of virulent and drug-resistant clinical isolates of *Klebsiella pneumoniae* and *Escherichia coli*. Classical experiments, mapping the repair of chromosomal mutations, have demonstrated Hfr-mediated intra- and inter-species conjugation involving *E. coli* and *Salmonella enterica* serovar Typhimurium. Very little is known about the genetic architecture and relative fitness of these hybrid strains.

Materials/methods: Using conjugation we created a set of *E. coli*-*Salmonella* hybrid strains. Hybrids were selected for the transfer of markers at different distances from the transfer origin. The relative growth fitness of hybrids was measured using Bioscreen and colony spot assays. Experimental evolution was used to address the rate and mechanisms of fitness cost amelioration. Whole genome sequencing was used to analyse the genetic architecture of the hybrids, before and after evolution.

Results: Almost all inter-species hybrids acquired a contiguous segment of donor chromosome replacing an equivalent region of recipient chromosome, with lengths ranging from ~100kb up to >4000kb. The length of acquired DNA did not correlate with relative fitness but most hybrids had reduced growth rate relative to the parental strains. Evolution to ameliorate fitness costs selected predominantly strains with mutations affecting global transcriptional regulators, and strains with increased mutation rates, suggesting that for low-fitness hybrids there is no simple path to high fitness. A very interesting observation is that several hybrid strains, in which 45% - 90% of the *Salmonella* chromosome was replaced with *E. coli* DNA, showed no reduction in growth fitness.

Conclusions: These data show that most *E. coli* – *Salmonella* hybrids suffer a severe reduction in fitness with no simple path to restore growth fitness. However, a significant fraction of hybrids retained parental levels of fitness suggesting that barriers to creating high-fitness inter-species hybrids may be significantly lower than generally appreciated.

Faecal carriage of extended-spectrum beta-lactamase-producing members of order Enterobacterales among patients in Bulgarian hospitals

Petya Stankova1*, Rumyana Markovska-Davidkova2, Temenuga Stoева1, Lyudmila Boyanova1, Marianna Murdjeva4, Atanaska Petrova4, Dobrinka Ivanova1, Dobromir Dimitrova1, Marija Sredkova6, Yuliya Marteva-Proevska2, Tzvetan Velinov5, Ivan Mitov2

1Medical University - Sofia, София, Bulgaria, 2Medical University - Sofia, Sofia, Bulgaria, 3Medical University of Varna, Varna, Bulgaria, 4Medical University - Plovdiv, Plovdiv, Bulgaria, 5Second Multiprofile Hospital for active treatment, Sofia, Bulgaria, 6Medical University - Pleven, Pleven, Bulgaria, 7Aleksandrovska University Hospital, Sofia, Bulgaria

Background: The fecal carriage of extended-spectrum β-lactamase/carbapenemase-producing Enterobacterales (ESBL/CPE) isolates remains an important risk factor for their dissemination and is poorly investigated in Bulgaria. The objective of this study was to determine the prevalence of ESBL/CPE fecal carriage in Bulgarian hospitalized patients.

Materials/methods: In total, 537 stool samples were collected from hospitalized patients in 6 hospitals in Bulgaria from December 2017 to December 2018. Species identification was done by MALDI-TOF mass spectrometry. ESBL selective agar was used for initial screening. Later the ESBL production was confirmed by the double-disc synergy test and the carbapenemase production - by the combined discs. The beta-lactamases were identified by PCR and sequencing. The disk diffusion method and MIC strips for tigecycline were used for antimicrobial susceptibility testing.

Results: Third generation cephalosporin resistant fecal carriage isolates were detected in 43.6 %: Escherichia coli (n=121), Klebsiella pneumoniae (n=66), Klebsiella oxytoca (n=7), K. michiganensis (n=3), Enterobacter cloacae complex (n=21), Citrobacter freundii complex (n=13) and Morganella morganii (n=3). Among all 537 collected isolates, PCR and sequencing identified 176 ESBL-producing isolates (32.8%). CPE fecal carriage was 2.6% (14 from 537). BlaCTX-M genes were identified in 99% of all ESBL-producing enterobacteria (n=176): blaCTX-M-1gr in 86.4% (152/176) and blaCTX-M-9gr in 11.9% (21/176). Only two isolates harboured blaSHV. The following blaESBL genes were found: blaCTX-M-15, blaCTX-M-3, blaCTX-M-1, blaCTX-M-9, blaCTX-M-14, blaCTX-M-27 and blaSHV. BlaKPC-2 and blaNDM-1 were detected in 3 and 11 isolates respectively. Twenty one AmpC hyperproducers and 13 plasmid mediated AmpC producers (7 DHA-1 and 6 from EBS family) were identified too. The susceptibility testing showed the following rates of resistance: cefotaxime(91.9%), amoxicillin/clavulanic acid(91.9%), ceftazidime(85%), cefepime(91.9%), cefoxitine(32.2%), meropenem(8.1%), imipenem(9.1%), piperacillin/tazobactam(71.8%), tobramycin(87.7%), gentamicin(56%), amikacin(47.9%), ciprofloxacin(67.1%), levofloxacin(60.7%), tigecycline(34.2%), trimetoprim/sulfamethoxazole(50%), chloramphenicol(21.4%). Only six colistin resistant isolates of K. pneumoniae was found.

Conclusions: The presented data showed a high rate of third generation cephalosporin resistant fecal carriage isolates. Most of these isolates carried ESBLs, while plasmid mediated AmpC enzymes were identified in single isolates only. The fecal carriage could be an important reservoir for various resistance determinants. The detection of carbapenemases producing fecal isolates clearly showed the need for strong infection control measures.

Abstract 6462

**Delayed haemolytic anaemia following artesunate treatment in a returning African traveller**

Roisin Oconnor¹, Fiona Carroll*¹, Caitriona Doyle¹, Ceppie Merry¹, Ciaran Bannan¹

¹St. James’s Hospital, Dublin, Ireland

**Background:** At our institution malaria is relatively uncommon with an average of 7 cases per year from 2014 to 2018. Nationally 59 cases were notified in Ireland in 2018. Over a 2 year period in our institution the majority of cases treated were *Plasmodium* (*P*) *Falciparum* (*n* = 10); five were treated as severe and received IV Artesunate followed by oral Artemether-Lumefantrine. We present the case of a patient with delayed haemolysis post IV Artesunate.

**Materials/methods:** Inpatient, outpatient medical records and laboratory results were reviewed.

**Results:** A 27 year old male presented to the Emergency Department with a 4 day history of fever, myalgia and headaches after returning to Ireland from a visit to Angola. He had not taken malaria chemoprophylaxis. His initial parasite count was 14%. He was diagnosed with severe *Plasmodium Falciparum* infection and admitted to the intensive care unit for monitoring. He was treated initially with IV Artesunate for 4 days followed by oral artemeter/lumefantrine for 3 days and was discharged after 7 days.

He was seen a week later in Infectious Diseases outpatient clinic where he had complained of dizziness, shortness of breath and palpitations. His haemoglobin (Hb) had decreased from 14.8g/dL to 9.8g/dL. He was admitted 5 days later with a Hb 8.0g/dL. Reticulocytes were elevated (11.7%), LDH was high (703IU/L) and haptoglobins were low (<0.24g/L) in keeping with a diagnosis of haemolytic anaemia. His folate level was low (4.0 µg/L) and was started on replacement therapy. He did not require blood transfusion. His haemoglobin improved and recovered within 9 days.

**Conclusions:** This case of delayed haemolytic anaemia highlights the importance of follow-up of patients treated with IV Artesunate. The pathophysiology of this syndrome is not fully understood but appears to occur with hyperparasitemia. It has been thought that it is the result of the splenic process of pitting - the normal removal of infected erythrocytes whose parasites have been killed by artemesunate. These once-infected erythrocytes have a decreased lifespan, leading to delayed onset haemolysis. Although the course of haemolysis was self-limiting we routinely follow these patients for 1 month post treatment for surveillance of this syndrome.

Efficacy of ribavirin in post-exposure prophylaxis in Crimean-Congo haemorrhagic fever

Imran Hasanoğlu*, Muge Ayhan1, Bircan Kayaaslan1, Ayse Kaya Kalem1, Selma Karaahmetoğlu1, Seval Izdes1, Rahmet Guneri1

1Yıldızım Beyazıt University Ankara City Hospital, Ankara, Turkey, 2Ankara City Hospital, Ankara, Turkey

Abstract 6463

Background: Ribavirin is the only drug of choice for post-exposure prophylaxis (PEP) in Crimean Congo hemorrhagic fever (CCHF), however its usage is not absolutely recommended.

Materials/methods: In this study, we report the management of healthcare workers’ (HCW) exposure to one fatal CCHF patient. Exposures are grouped into 3 categories according to recently published meta-analysis. The high-risk group consisted of HCWs who were directly exposed to blood or body fluids. We also included HCWs who participated in CPR without wearing appropriate personal protective equipment (PPE) to the high-risk group. The moderate-risk group consisted of HCWs without a visible exposure to blood or body fluids but handled patient or performed physical examination without appropriate PPE. The low risk group consisted of HCWs who cared the patient when she had no bleeding but didn’t perform physical examination or participate in aerosol-producing procedures.

Results: At least 38 HCWs had contact with the index fatal patient. The patient was admitted to the emergency department, followed up in the internal medicine clinic (IMS) and intensive care unit (ICU). She had 1 CPR in IMS, 2 CPRs in ICU. Despite warnings about the suspicion of CCHF, physician who intubated did not wear mask or any other PPE, except gloves. During the ICU follow-up, she had severe bleeding. Two resuscitations of the patient in the ICU lasted approximately more than 1 hour. Physician who inserted femoral artery sheath and femoral catheter didn’t wear goggles and her gown was short-sleeved. An ICU nurse intervened her uterine prolapse due to severe bleeding with gloves but without a protective gown. None of the HCWs who had contact with the patient had appropriate PPE. Patient’s PCR and IgM were positive for CCHF. She died 48 hours after her admission. Among all known contacts, all HCWs in high and moderate risk groups (n=24) received PEP with ribavirin after within the 48 hours of the exposure. Non-severe side effect was observed in 3 (12.5%) HCWs. None of the HCWs developed nosocomial CCHF.

Conclusions: Ribavirin seems effective and well tolerated for nosocomial transmission of CCHF which has high mortality rate.

Reconstruction of plasmids by shotgun sequencing of various environmental DNA: from hospital biofilms to wastewater treatment plants

Genevieve Bricheux*, Cecile Hilpert1, Florence Bernard1, Claire Hennquin1,2, Christane Forestier1,2, Dusmane Traore1,2, Didier Debroas1

1Université Clermont Auvergne, LMGE, Aubière, France, 2Chu Gabriel-Montpied, Clermont-Ferrand, France, 3Faculté de Pharmacie, Clermont-Ferrand, France

Background: Plasmids play important roles in microbial evolution and also in the spread of antibiotic resistance. Plasmid sequences are extensively studied from clinical isolates but rarely from the environment with a metagenomic approach focused on the plasmid fraction referred to as plasmidome. We defined a workflow for discriminating plasmids from chromosomic contaminants. This pipeline named PlasPredict was tested on 2 types of environment, hospital biofilm and waste water treatment plant (WWTP) receiving hospital and urban effluents, in terms of Mobile genetic elements (MGEs) involved in the transport of genetic information between genomes in different bacterial species

Materials/methods: PlasPredict pipeline: we benchmarked existing tools from assembling to the detection of the plasmids by reference-free methods (cBar and PlasFlow) and database-guided approaches. DNA extraction was optimized to enrich in plasmid DNA with conservation of large plasmids.

Results: From the WWTP assembly, 6.5 % of contigs were identified as chromosomes from the database approach [chromosomes and phylogenetic markers]. The detection of plasmid markers, circular sequences and whole plasmid sequences identified 2.16 % of contigs considered to be “true” plasmids corresponding to plasmids referenced in public databases. We also considered circular contigs to be plasmids. From the biofilm assembly, 21.27 % of contigs were identified as chromosomes and 7.02 % of contigs as plasmids. After PlasFlow treatment, 4.9 % of the remaining contigs were defined as chromosomes for WWTP and 9.3 % for biofilm. 5.4 % of the remaining contigs were defined as plasmids from WWTP and 17.1 % from biofilm. Concerning the biofilm, the reliability of the pipeline was confirmed by searching for plasmid markers such as MOB, MPF, OriT and rep sequences. A total of 9490 linear plasmids and 381 circular plasmids [size 1.4 kb to 235 kb] were reconstructed, with 2 of them already in databases. The sequences associated with antibiotic resistance mechanisms were mainly efflux pump [EmrE], ABC transporter and beta-lactamase-encoding genes.

Conclusions: This study highlights the major potential role of biofilms in hospital effluents as providers of resistance genes to urban effluents, adding new traits potentially generating dangerous multidrug-resistant pathogens and pose a hazard to environmental and public health.

**Abstract 6468**

**Bacterial contamination of umbilical cord blood collected at Ankara University cord blood bank**

Pinar Yurdakul-Mesutoglu*, Emine Begum Gencer-Oncul1, Hasan Yalım Akin2, Meral Beksac3

1TOBB University of Economics and Technology, Faculty of Medicine Department of Medical Microbiology, Ankara, Turkey, 2Ankara University Faculty of Medicine, Cord Blood Bank, Ankara, Turkey, 3Ankara University, Faculty of Medicine Department of Hematology, Ankara, Turkey.

**Background:** Cord blood (CB) is a unique graft source with the potential to be used as an alternative for bone marrow or hematopoietic stem cell transplantation. To make sure that full potential of a CB unit (CBU) is met, it is of crucial importance that every single unit is traced from donor to the recipient with very strict quality control measures. Microbial sterility is essential for the safety of the CB product. The aim of this particular study was to retrospectively analyze bacterial contamination rates in CBUs and the impact of delivery method on contamination frequencies.

**Materials/methods:** A total of 1653 CBUs collected in utero from consented maternal donors between June 2011 and October 2019 were enrolled in this study. BACTEC automated culture system was used to monitor bacterial growth. Ten individual units which were discarded due to microbial growth were thawed and re-cultured for the assessment of the impact of cryopreservation on bacterial growth.

**Results:** Microbial culture results of 1653 CBUs were evaluated to determine culture positivity and to specify contaminating microorganisms. Of the 1653 CBUs analyzed, 41 (2.5%) were found to be contaminated with 44 bacterial strains. Of those 41 units 68% were collected from cesarean section (C/S) and 32% from vaginal deliveries. Methicillin-susceptible coagulase-negative *Staphylococcus* (CoNS) was the most frequent microorganisms detected (12 out of 44 [27.3%]) followed by methicillin-resistant CoNS (10 out of 44 [22.7%]) (Figure 1). Most of the CoNS growth (91%) of was detected in CBUs collected from C/S (20/22). Post thaw analysis of 10 individual units revealed that 50% of formerly positive units were culture negative after cryopreservation. Three of the survivors were methicillin-susceptible CoNS, one was methicillin-resistant CoNS and the remainder was a member of *Actinomyces* genus.

**Conclusions:** A very low overall contamination rate (2.5%), mostly from CBUs collected from C/S, was determined in the CBUs investigated and the pre-dominant microorganism was found to be CoNS. Delivery method had a significant effect on contamination rates. Our results also indicated that some bacteria do survive after cryopreservation while some don’t, the precise mechanism being still unknown.

![Figure 1. Bacterial isolation rates of 41 contaminated CBUs](image)

Abstract 6469

**In-host evolution of methicillin-resistant Staphylococcus aureus within individual carriers using core genome multi-locus sequence typing and single-nucleotide polymorphism analysis**

Amaya Campillay Lagos*, Martin Sundqvist1, Fredrik Dyrkell2, Marc Stegger3, Bo Söderquist1, Paula Mölling1

1Department of Laboratory Medicine, Clinical Microbiology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden, 21928 Diagnostics, Gothenburg, Sweden, 3Statens Serum Institut, Department of Bacteria, Parasites and Fungi, Copenhagen, Denmark

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) colonize humans but also causes serious infections associated with poor outcome, which makes the pathogen highly topical in outbreak investigations. Intra-host evolution in carriers through mutations and recombination events are either best traced using whole-genome sequencing data where analysis are often performed using single nucleotide variants (SNV) presented as core genome multi-locus sequence typing (cgMLST) or single nucleotide polymorphisms (SNPs). In this study we aimed to evaluate the in-host evolution of MRSA in long term carriers as measured with cgMLST and SNP based analysis.

**Materials/methods:** MRSA isolates (n=94) from 20 individual long-term MRSA-carriers were collected from 2003 to 2019. The isolates were sequenced using Illumina Miseq (600-cycle). The sequence data were analyzed with two commercially available software; SeqSphere+ (Ridom GmbH) for cgMLST- and SNV-analysis, 1928D (1928 Diagnostics, Sweden) for cgMLST- and SNP-analysis but also using the bioinformatic tool NASP (https://github.com/TGenNorth/NASP) for a non-commercial, well validated, SNP-analysis. Calculations of mean, median and standard deviation were performed with Statistical software SPSS version 25.

**Results:** Three patients were excluded (n=13 isolates) due to an obvious change of MRSA strain during the follow up. For the remaining 17 patients the cgMLST analysis using SeqSphere+ showed a median of 4.1 (range 1.4-26) allele variants and a median of 1.4 (range 6-46) SNV/year. The cgMLST analysis by 1928D showed a median of 2.3 (range 0.6-20.3) allele variants/year and the SNP-analysis (including recombination events) showed a median of 112.5 (range 6.75-239.8) SNPs per individual/year. The NASP pipeline (excluding recombination events) results of the SNP-analysis showed a median of 5.5 (range 2.4-35.3) SNPs/year.

**Conclusions:** The estimated within host evolution for a MRSA isolate was less than 6 genetic changes per genome and year, according to the two cgMLST methods and the NASP SNP-based analysis used. However, using the 1928D SNP-analysis, which also includes recombination events, a much higher SNP variability was observed. These findings supports previous estimates and adds to the clinical utility of the tested bioinformatics tools.

Abstract 6472

Development of LAMP-based multiplex real-time assay for rapid detection of genes of NDM, VIM, KPC and OXA-48 carbapenemase groups

Anastasiya Nosova*, Yulia Savochkina1, Amina Ibragimova1, German Shipulin1

1Federal State Budgetary Institution «Center for Strategic Planning and Management of Medical and Biological Health Risks», Moscow, Russian Federation

Background: Carbapenem resistance caused by acquired carbapenemases is a global public health concern and represents a serious problem for the treatment of related infection. Loop-mediated isothermal amplification (LAMP) can be used as a rapid and effective technique for detection of acquired antimicrobial resistance genes. The aim of this study was to develop a LAMP based assay for detection of genes encoding the most common for Enterobacterales spp carbapenemase of NDM, VIM, KPC and OXA-48-like groups.

Materials/methods: LAMP technique with real-time detection provided by fluorogenic loop primers (assimilating probes) was used to develop a new multiplex assay. The primer sets for target genes (VIM, KPC, NDM, OXA-48-like) were designed using PrimerExplorer V5 (Eiken Chemical Co., Ltd.). The LAMP reaction was performed at 65°C using CFX-96 instrument. The assay was validated using a panel of strains carrying the genes of the known carbapenemases (VIM-1, -2, -4, -10, NDM-1, -2, KPC-2, -3, OXA-48, -181, -244) on natural plasmids or recombinant vectors. Thirty-eight previously characterized clinical isolates of different Enterobacterales spp and Pseudomonas aeruginosa, 10 positive blood cultures with the same bacterial species and DNA extracted from 30 sputum samples from patients with nosocomial pneumonia were tested by the LAMP assay in comparison with commercial IVD real-time PCR assays «AmpliSens MBL-FL» and «AmpliSens KPC/OXA-48-FL» (CRIE, Russia).

Results: The assay composed of two multiplex real-time LAMP tests, was developed for detection of genes encoding four groups of carbapenemases. The first test allows the detection and discrimination of NDM and OXA-48-like carbapenemase genes and includes exogenous internal control (IC). The second test allows differential detection of VIM and KPC carbapenemase genes. Both LAMP-based tests produced correct results for strains carrying the known carbapenemase genes. The limit of detection corresponded to (1-4) x 10^3 copies per ml for all target gene groups. The LAMP based assay results for all tested clinical isolates, blood cultures and sputum samples were concordant with these produced by IVD real-time PCR assays.

Conclusions: The developed multiplex real-time LAMP assay allows the rapid and effective detection of VIM, KPC, NDM, OXA-48-like carbapenemase genes both in bacterial cultures and sputum.

Abstract 6473

**Major changes detected in penicillin-binding proteins of vancomycin-resistant Enterococcus faecalis by sequencing and homology modeling**

Nese Caglayan¹, Banu Sancak², Esma Aybakan¹, Zeynep Kanlidere³, Ofcan Ofılaz⁴, Tanıl Kocagöz*¹,⁵

¹Acıbadem Mehmet Ali Aydinlar University, Department of Medical Biotechnology, Istanbul, Turkey, ²Hacettepe University, School of Medicine, Department of Medical Microbiology, Ankara, Turkey, ³Acıbadem Mehmet Ali Aydinlar University, Department of Pharmaceutical Basic Sciences, Istanbul, Turkey, ⁴Hacettepe University, Department of Molecular Biology, Ankara, Turkey, ⁵Acıbadem Mehmet Ali Aydinlar University, School of Medicine, Department of Medical Microbiology, Istanbul, Turkey

**Background:** Vancomycin-resistant enterococci (VRE) are currently one of the most common species that cause serious, hard to treat, hospital-acquired infections. Resistance to vancomycin is due to the change of the D-Alanine-D-Alanine group to D-Alanine-D-Lactate at the end of the pentapeptides forming cross-links of bacterial cell wall. Due to this change vancomycin can no longer bind to terminal dipeptide. The question of how penicillin-binding proteins (PBPs) bind D-Alanine-D-Lactate groups instead of D-Alanine-D-Alanine has not been studied until now. In this study, we have investigated possible changes in the PBPs of VRE for functioning properly with D-Ala-D-Lac group.

**Materials/methods:** We have studied the genes of PBPs of 3 clinical vancomycin resistant and 3 vancomycin susceptible (VSE) strains of Enterococcus faecalis. All the genes belonging to PBPs were amplified by PCR, sequenced by Sanger sequencing and compared to each other. The structural changes due to identified amino acid changes were evaluated by homology modeling using Swiss model portal for sequencing.

**Results:** The same amino acid changes which were identified in PBPs of VRE compared to VSE were present in all VRE strains investigated. It was identified 4 amino acid changes in PBP1B, 2 in PBP2A, and 5 in PBP3. Homology modeling of PBPs suggested that the changes were related to the active sites that bind to D-Ala-D-Lac which is also the binding site for beta-lactam antibiotics. We did not find any amino acid changes related to the catalytic region of PBP1A, PBP2B and PBP4.

**Conclusions:** We have identified significant changes related to the catalytic regions of PBP1B, 2A and 3 in VRE as we expected since the PBPs in VRE should use D-Ala-D-Lac instead of D-Ala-D-Ala for building cross links in the cell wall. These PBPs may have lower affinity to beta-lactam antibiotics creating further resistance to these drugs. Identification of these changes may give the opportunity to develop new beta-lactam drugs by redesigning there structure using homology modeling. The knowledge about the function of each PBP is quite limited. Further investigation about these, using large number of clinical strains is needed.

This project is supported by TUBITAK {Project No:118S502}.

Abstract 6474

Nanopore metagenomic sequencing of influenza virus directly from respiratory samples: diagnosis, drug resistance and nosocomial transmission

Yifei Xu*, Kuiama Lewandowski, Louise Downs, James Kavanagh, Thomas Hender, Sheila Lumley, Katie Jeffery, Dona Foster, Nicholas Sanderson, Ali Vaughan, Marcus Morgan, Richard Vipond, Miles Carroll, Tim Peto, Derrick Crook, A. Sarah Walker, Philippa Matthews, Steven Pullan

1University of Oxford, Oxford, United Kingdom, 2Public Health England, Salisbury, United Kingdom, 3Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: Influenza virus presents a significant public health challenge, causing seasonal epidemics and occasional pandemics. Nanopore metagenomic sequencing has the potential to be deployed for near-patient testing, providing rapid diagnosis of infection, rationalising antimicrobial therapy, and supporting interventions for infection and transmission control. This study aimed to evaluate the applicability of Nanopore sequencing as a routine laboratory test for influenza in clinical settings.

Materials/methods: We conducted Nanopore metagenomic sequencing for 180 respiratory samples from a UK hospital, including 90 influenza-positives and 90 influenza-negatives based on routine molecular diagnostic testing using Cepheid Xpress or BioFire FilmArray® Respiratory Panel. Samples were taken between October 2018 (first laboratory diagnosis of influenza from the hospital in the 2018/19 season) and February 2019, plus a putative clinical cluster on the ID ward. We investigated drug resistance, genetic diversity, and nosocomial transmission.

Results: Metagenomic sequencing was 83% (75/90) sensitive and 93% (84/90) specific for detection of influenza A viruses compared with the diagnostic standard. Viral reads were detected in all 58 samples with Ct≤31. HA subtype was determined for 59/75 (79%) samples (40 H1, 19 H3), and all samples with Ct≤27. 28/75 (37%) consensus sequences were assembled with genome coverage ≥70%. One H3N2 genome had the oseltamivir-resistant S331R mutation in the NA protein, potentially associated with the emergence of a distinct intra-subtype reassortant. Whole genome phylogeny refuted suspicions of a transmission cluster on the ID ward. It identified two other clusters that likely reflected nosocomial transmission of a dominant strain circulating in the community. We detected a range of other potentially pathogenic viruses and bacteria from the metagenome.

Conclusions: Nanopore metagenomic sequencing can detect the emergence of novel variants and drug resistance in influenza virus, providing timely insights for antimicrobial stewardship and vaccine design. Generation of full genomes can contribute to investigation and management of nosocomial outbreaks. While substantial work is still needed to refine the sequencing protocol and bioinformatic analysis, Nanopore metagenomic sequencing has the potential to become an applicable point-of-care test for infectious diseases in clinical settings.

Optimisation of the MALDIxin test for the rapid identification of colistin resistance in *Klebsiella pneumoniae* using MALDI-TOF MS

Laurent Dortet*1, Sandrine Bernabeu1, Pierre Bogaerts2, Remy Bonnin1, Thierry Naas1, Alain Filloux3, Gerald Larrouy-Maumus3

1Paris-Sud University, Le Kremlin-Bicêtre, France, 2UCL Louvain, Yvoir, Belgium, 3Imperial College London, London, United Kingdom

Background: With the dissemination of carbapenemase producers, a revival of colistin was observed for the treatment of infections caused by multidrug-resistant Gram-negatives. Unfortunately, the increasing usage of colistin led to the emergence of resistance. In *Klebsiella pneumoniae*, colistin resistance arises through addition of L-arabinose 4N (L-Ara4N) or phosphoethanolamine (pEtN) on the native lipid A. The underlying mechanisms involve numerous chromosome-encoded genes or the plasmid-encoded phosphoethanolamine transferase MCR. Currently, detection of colistin resistance is time consuming since it still relies on MIC determination by broth microdilution. Recently, a rapid diagnostic test based on MALDI-TOF detection of modified lipid A was developed (the MALDIxin test) and tested on *Escherichia coli* and *Acinetobacter baumannii*.

Objectives: Optimize the MALDIxin test for the rapid detection of colistin resistance in *Klebsiella pneumoniae*.

Materials/methods: This optimization consists on an additional mild-acid hydrolysis of 15 min in 1% acetic acid. The optimized method was tested on a collection of 81 clinical *K. pneumoniae* isolates including 49 colistin resistant strains among which 45 correspond to chromosome-encoded resistance, 3 MCR-related resistance and one isolate harbouring both mechanisms.

Results: The optimized method allowed the rapid (< 30 min) identification of L-Ara4N and pEtN modified lipid A of *K. pneumoniae* which are known to be the real triggers of polymyxin resistance. In the same time, it discriminates between chromosome-encoded and MCR-related polymyxin resistance.

Conclusions: The MALDIxin test has the potential to become an accurate tool for the rapid diagnostic of colistin resistance in clinically-relevant Gram negative bacteria.

*Candida auris* species and lineage identification from plate and blood cultures applying Orbitrap ultra high-resolution mass spectrometry

Azadeh Jamalian*1,2, Joanna Freeke1,2, Benjamin Stielow1,2, Ivan Moser2, Alejandra Giraldo Lopez2, Herdis Friedrich3, Jacques F. Meis4, Sybren De Hoog2,5

1Thermo Fisher Scientific, Microbiology Mass Spectrometry, Landsmeer, Netherlands, 2Westerdijk Fungal Biodiversity Institute, Utrecht, Netherlands, 3Thermo Fisher Scientific, Microbiology Mass Spectrometry, Helsinki, Finland, 4Canisius Wilhelmina Hospital, Nijmegen, Netherlands, 5Radboud University Medical Center, Nijmegen, Netherlands

**Background:** Candidiasis, which includes both superficial and systemic infections, is the most common cause of fungal infection worldwide. Although *Candida albicans* remains the most frequently isolated species in the clinical setting, in some countries a dramatic shift to other species, such as *C. auris* is observed, emerging as a multidrug-resistant pathogen that can cause outbreaks of invasive infections. *C. auris* is identified in >35 countries, many of which have documented healthcare-associated spread. While many nosocomial outbreaks of *C. auris* have been reported worldwide (India, South Korea, Venezuela & Colombia, South Africa, Europe, USA and Middle East), the exact affiliation of a strain genotype to a lineage is highly time, cost and labor intensive and currently only possible by NGS research only (RUO) applications. It remains a pivotal element to clinical microbiology to develop cost-effective molecular epidemiological surveillance techniques beyond species identification, to track microbial spread and major clones circulating among global geographies, which are potentially prone to rapidly acquire resistances.

**Materials/methods:** High resolution mass spectrometry integrated in the Acrion™ system, was applied to protein extracts from *C. auris* strains originating from major outbreaks in East Asia, Central Asia, Africa, Europe, South America, Middle East and Arabian Peninsula. Strains were characterized using standard molecular barcodes and AFLP sequence typing. High resolution mass spectra were evaluated for the individual protein masses detected. Different identification approaches were compared.

**Results:** Applying the proposed rapid and easy workflow and benefiting from high resolution Orbitrap™ mass analyzer, accurate masses of multiple protein classes were detected. Across diverse strains of the *C. auris* complex the variation in the presence of proteins enabled searching for lineage specific protein masses that were used to delimit the tested entities.

**Conclusions:** The user friendly workflow with the high resolution database enabled rapid and accurate identification of *C. auris* species from plate and blood in Acrion™ system. Moreover lineage delimitation in a time-efficient manner is demonstrated for the first time using Orbitrap™ mass spectra, revealing equivalent typing-identification capabilities to NGS which is crucial for epidemiological tracking and dissemination prevention.

In vitro activity of commonly used antimicrobial agents against clinical Gram-negative bacterial isolates from ATLAS Indian centres in 2018

Shweta Kamat¹, Akshata Mane*, Prithwijit Kundu¹

¹Pfizer Limited, Mumbai, India

**Background:** Anti-microbial resistance is a huge concern in India while tackling gram negative organisms. ATLAS [Antimicrobial Testing Leadership and Surveillance], which is the integration of three surveillance programs (TEST, AWARE, INFORM), initiated in 2004, detects trends in multi-drug resistance longitudinally over time. This report analyses the susceptibility of gram negative nosocomial isolates from ATLAS to commonly used agents against MDR organisms.

**Materials/methods:** Non-duplicate clinical Gram negative nosocomial isolates (n= 788) were collected in 2018 from eight Indian tertiary care centers. Organisms were identified and susceptibility tested, by conventional methods. Susceptibility was confirmed at an IHMA (International Health Management Associates) laboratory using supplied broth microdilution panels [Microscan], according to CLSI guidelines, for all antibiotics. Selected isolates were screened for acquired beta-lactamase genes by PCR and sequencing. In-vitro activity of Cefoperazone sulbactam [C/S], piperacillin-tazobactam [P/T], ceftazidime-avibactam [C/A], meropenem, tigecycline, colistin and aztreonam was assessed for Enterobacteriaceae, Pseudomonas spp. and Acinetobacter spp. isolates from various clinical samples.

**Results:** Of the 788 gram negative isolates, 567 belonged to Enterobacteriaceae. Of the 221 non enterobacteriaceae, 66 belonged to Acinetobacter spp. and 151 to Pseudomonas spp.. Below is the in-vitro activity of the isolates to commonly used antibiotics against Gram negative organisms:

<table>
<thead>
<tr>
<th>Organisms</th>
<th>Percentage susceptibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>C/S</td>
</tr>
<tr>
<td>Enterobacteriaceae (n=567)</td>
<td>368 (65%)</td>
</tr>
<tr>
<td>Acinetobacter spp. (n=66)</td>
<td>15 (23%)</td>
</tr>
<tr>
<td>Pseudomonas spp. (n=151)</td>
<td>109 (72%)</td>
</tr>
</tbody>
</table>

Meropenem resistance was 23% in Enterobacteriaceae, 80% in Acinetobacter spp. and 27% in Pseudomonas spp. The susceptibility of Ceftazidime-Avibactam to Meropenem resistant Enterobacteriaceae and Meropenem resistant Pseudomonas spp. was 34% and 32% respectively.

**Conclusions:** Based on percentage susceptibility, C/S, P/T, C/A, meropenem and colistin exhibited good in-vitro activity against Enterobacteriaceae and Pseudomonas isolates. Tigecycline showed good susceptibility to Enterobacteriaceae. Higher resistance was seen among Acinetobacter spp. for which Colistin was the most active agent. Ceftazidime-avibactam may be a useful agent in meropenem resistant Enterobacteriaceae and Pseudomonas isolates.

**Background:** Despite the availability of evidence based Quality Standards [QS] in Vietnam for patients hospitalised with community-acquired pneumonia (CAP), there remains wide variation in care, providing opportunities for improvement. The pilot implementation of QS for CAP aims to test whether a co-designed improvement programme using PDSA methodology would result in better adherence to QS for CAP patients in a provincial hospital and better understanding of the barriers to QS adoption that could be applied to larger scale implementation.

**Materials/methods:** The QS implemented were designed to reduce unnecessary admissions and use of intravenous antibiotics and included CURB65 severity score documentation and use to guide hospital admission, timely diagnosis including early radiology, and in-patient antibiotic treatment review to limit the duration of intravenous antibiotic use. The implementation package was agreed during a staff workshop and included data collection on care quality, onsite updated-training to medical staff and tools to facilitate documentation in patient records. The piloted package was deployed in a 600-bed hospital in northern Vietnam over 10 months (from July 2018 to April 2019) following two iterations of the Plan-Do-Study-Act (PDSA) cycle methodology. In parallel we interviewed staff to understand factors that were inhibiting implementation.

**Results:** The pilot interventions resulted in limited change in QS adherence with improvements made only in CURB65 score documentation (68% versus 80% and 96%, p<0.05) and chest X-ray results available within 4 hours (39% versus 88% and 76%, p<0.05). We documented change barriers ranging from individual cultural to system blocks e.g. perceptions held by doctors regarding the evidence for CURB65, and lack of health insurance reimbursement for out-patient care, leading to over-admission and unnecessary longer intravenous antibiotic treatment.

**Conclusions:** Whilst specific solutions will differ by context, the dual approach of engendering local ownership of quality improvement activities whilst proactively understanding barriers to implementation of best practice to inform further improvement approaches will be applicable in other low and middle income countries (LMIC) s.

Phylogenetic groups and virulence factors of uropathogenic Escherichia coli in pregnant and non-pregnant women in St. Petersburg, Russia

Maria Razinkova1, Tatiana Khusnutdinova1,2, Elena Shipitsyna1, Olga Budilovskaya1,2, Anna Krysanova1,2, Kira Shalepo1,2, Alevtina Savitcheva1,2

1D.O. Ott Research Institute of Obstetrics, Gynaecology and Reproductology, St. Petersburg, Russian Federation, 2St. Petersburg State Paediatric Medical University, St. Petersburg, Russian Federation

Background: Uropathogenic Escherichia coli (UPEC) is responsible for a large majority of urinary tract infections (UTIs). UTIs are more prevalent in women, and in pregnancy can cause significant morbidity. Physiological changes in pregnancy are considered a major contributor to UTI-associated complications, and very little focus has been placed on the role of specific UPEC virulence factors. Molecular epidemiological studies are necessary for identifying UPEC traits predicting UTI severity, with identifying pregnant women with asymptomatic bacteriuria (ABU) who are at risk of developing pyelonephritis being of particular clinical relevance. This study aimed to determine the UPEC phylogenetic groups and virulence profiles in pregnant and non-pregnant women with different UTIs.

Materials/methods: UPEC strains were routinely isolated from women attending the D.O. Ott Research Institute of Obstetrics, Gynaecology and Reproductology from October 2017 to November 2019 for gynaecological and obstetrical care. E. coli phylogenetic groups and 15 genes encoding toxins (hly, cnf1, sat1), adhesins (papA, -EF, -C, focG, hra, fimH, afp), siderophores (fyu, iroN, iucD), invasin (ibeA), bacteriocin (usp) were determined using PCR assays (Clermont et al., 2013, Johnson & Stell, 2000; Yamamoto et al., 1995; Vila et al., 2002; Takahashi et al., 2006; Bingen-Bidois et al., 2002).

Results: In total, 73 UPEC strains were isolated from women aged 19-50 (median 31) years, 44 pregnant and 29 non-pregnant. ABU was diagnosed in 16 women (15 pregnant, one non-pregnant), cystitis in 23 women (4 pregnant, 19 non-pregnant), pyelonephritis in 34 women (25 pregnant, 9 non-pregnant). The distribution of the phylogenetic groups and virulence factors in pregnant women was similar to that in non-pregnant women, whereas significant differences were observed between UTIs (Table). Phylogenetic group A isolates were more frequent in pyelonephritis, and hlyA, cnf1, hra, iroN positive isolates – in cystitis, compared to the other UTIs. Group F isolates were more frequent in pregnant women with ABU compared to pyelonephritis.

Conclusions: The distribution of UPEC phylogenetic groups and virulence factors was mainly similar in pregnant and non-pregnant women, whereas significant differences were revealed between different UTIs. Cohort studies into UPEC traits in pregnant women are needed to identify predictors of UTI-associated pregnancy complications.

ABU, asymptomatic bacteriuria; significant values are in bold letters (chi-square test or Fisher’s exact test)
Evidence from in vitro pharmacokinetic/pharmacodynamic studies on polymyxin-based combination therapies to treat infections due to carbapenem-resistant Gram-negative bacteria

Margherita Chiamenti1, Damiano Bragantini1, Luigia Scudeller2, Laura Piddock1, François Franceschi3, Sally Ellis3, Maurizio Sanguinetti4, Giulia Menchinelli4, Alessia Savoldi1, Elda Righi1, Evelina Tacconelli1

1University of Verona, Verona, Italy, 2IRCCS Ca’ Granda Ospedale Maggiore Policlinico di Milano Foundation, Milano, Italy, 3Global Antibiotic R&D Partnership (GARDP), Geneva, Switzerland, 4Università Cattolica del S. Cuore, Rome, Italy

Background: Poor-quality evidence from clinical trials supports the use of combination therapy (CoT) against carbapenem-resistant Gram-negative bacteria (CR-GNB). The objective of this systematic review and meta-analysis, performed within the GARDP COHERENCE project, was to assess the evidence on in vitro synergy of any CoT (old and new drugs) against CR-GNB in pharmacokinetic/pharmacodynamics (PK/PD) studies.

Materials/methods: Pre-clinical PK/PD studies targeting any CoT in CR-Acinetobacter baumannii (AB), CR-Klebsiella pneumoniae (KP), CR-Pseudomonas aeruginosa (PA) and other CR-Enterobacterales (Ent) were systematically searched in PubMed, Scopus, Web of Science and relevant conference proceedings from the inception until 12/2018 without language restriction. Synergism was defined as >2-log10 reduction in colony-forming unit for a CoT compared to that of the most active single agent; while antagonism as >2-log10 increase. The effect size was defined as pooled proportion (with 95%CI) of CoT showing synergy for each species (significance: p<0.05).

Results: Among 3754 records screened, 42 PK/PD studies reporting data on 100 bacterial isolates were included: 37 (37%) on KP, 35 (35%) on AB, 14 (14%) on PA and 14 (14%) on Ent. Twenty-one antibiotic agents belonging to 12 classes were combined in 41 different CoT (132 tests). Pooled data were available for 8 polymyxin-based CoT, accounting for 32 tests and 67 strains. Seven CoT showed synergism. Antagonism was not detected. In AB, colistin-based CoT showed significant synergism with rifampicin (0.99, 95%CI 0.92-1.06, three tests, six strains) and with tigecycline (0.64, 95%CI 0.32-0.96, two tests, eight strains); in KP, fosfomycin showed high synergism with polymyxinB (0.99, 95%CI 0.93-1.06, four tests, six strains) and colistin (0.67, 95%CI 0.40-0.95, five tests, 16 strains); in PA, colistin with doripenem showed significant synergism (0.66, 95%CI 0.23-1.09, six tests, eight strains). No PK/PD studies tested antibiotics approved in the last decade. High inter-studies heterogeneity was detected, associated with dosages and strains' differences.

Conclusions: To our knowledge this is the first systematic review and meta-analysis of PK/PD studies assessing the synergy of polymyxin-based CoT in CR-GNB. The evidence is limited and does not include any recently marketed drug. These results should be considered for the strategic research agenda for the assessment of CoT against CR-GNB.

Abstract 6483

**Validation of FASTmar kit, a flow cytometric assay for detection of main mechanisms of beta-lactams resistance directly from positive blood cultures**

Inês Martins-Oliveira1, Rosário Gomes1, Blanca Pérez-Viso2, Ana Silva-Dias1, Luisa Maria Vieira Peixe3, Angela Novais3, Rafael Canton Moreno2, Acácio Gonçalves Rodrigues3, Cidália Pina-Vaz*1,4

1FASTinov S.A., Porto, Portugal, 2Hospital Universitario Ramón y Cajal, Instituto Ramón y Cajal de Investigación Sanitaria (IRY-CIS), Servicio de Microbiologia, Madrid, Spain, 3Faculty of Pharmacy, University of Porto, Laboratory of Microbiology, Porto, Portugal, 4Faculty of Medicine, University of Porto, Division of Microbiology, Department of Pathology, Porto, Portugal

Abstract third-party references: This work received funding from the H2020 FTIPilot 2016 project nº 730713 ‘FAST-bact—A novel fast and automated test for antibiotic susceptibility testing for Gram positive and negative bacteria’.

**Background:** Detection of main mechanisms of resistance such as ESBL, AmpC and carbapenemases is recommended, not only to treat the patient accordingly but also for infection control. Most laboratories perform ESBL detection on Enterobacterales such as *Escherichia coli* and *Klebsiella* spp or *Proteus* spp but not on group II-Enterobacterales including *Enterobacter* spp, *Serratia* spp, *Citrobacter freundii*, *Morganella morganii*, *Providencia* spp or *Hafnia alvei*. AmpC are often underestimated and carbapenemases are usually identified using molecular assays targeting already described genes. FASTinov developed a rapid phenotypic method for detection of diverse class A, B, C and D beta-lactamases directly from positive blood cultures.

**Materials/methods:** Eighty-four blood cultures [80] were spiked with well characterized bacterial strains; 29 ESBL, 16 AmpC and/or 39 carbapenemases. When flagged positive, the microorganisms were extracted using a previously optimized protocol. Strains were either incubated with: i) serial concentrations of cefepime with and without clavulanic acid (for ESBL on group II-Enterobacterales); ii) serial concentrations of cefotaxime or ceftazidime with cloxacillin (for AmpC) and iii) serial concentrations of meropenem associated with different inhibitors [EDTA for metallo-carbapenemases and boronic acid for KPC] or considering susceptibility to temocillin for OXA-like 48 enzymes. After incubation of 1h together with a membrane potential probe, the cells were analyzed using CytoFLEX flow cytometer (Beckman Coulter). A dedicated software developed by FASTinov® gave automatically the result that was compared with phenotypic criteria according to EUCAST protocols. The proportion of agreement (PA) was calculated, as well as the sensitivity and specificity of the assay.

**Results:** Regarding ESBL detection, the PA was 90% with 100% specificity and 88% sensitivity (2 false negatives). For AmpC, the PA was 100% (100% sensitivity and specificity). Regarding carbapenemases the PA for KPC was 97.7% (100% specificity and 94% sensitivity) (1 false negative); the PA for metallo-beta-lactamases was 93% (100% specificity and 77% sensitivity) (3 false negatives); the PA for OXA-48-like was 100% (100% specificity and sensitivity).

**Conclusions:** A new, fast and accurate detection [time-to-results <2h] of main beta-lactams mechanisms of resistance on diverse Enterobacterales species is described showing an excellent correlation with the reference method with time-to-results of 2 days.

Abstract 6485

The PCV13 serotypes still account for a large fraction of invasive pneumococcal disease in adults three-years after PCV13 introduction in the paediatric vaccination schedule (Portugal: 2015-2018)

Catarina Silva-Costa1, Joana Gomes-Silva1, Inês Teodoro1, Mario N. Ramirez*1, José Melo-Cristino1

1Universidade de Lisboa, Faculdade de Medicina, Lisboa, Portugal

Abstract third-party references: Portuguese Group for the Study of Streptococcal Infections

Background: In Portugal, the uptake of pneumococcal vaccines by the adult population (≥18 years) has been low, but changes in invasive pneumococcal disease (IPD) were detected, possibly by herd protection from the pediatric population. We aimed to determine serotype distribution and antimicrobial susceptibility patterns of pneumococci causing adult IPD between 2015 and 2018, after PCV13 introduction in the National Immunization Plan (NIP) for children.

Materials/methods: A total of 2135 Streptococcus pneumoniae isolates recovered from IPD cases in 62 hospitals in Portugal between January 2015 and December 2018 was characterized by serotyping and antimicrobial susceptibility testing. In one case, S. pneumoniae was identified and serotyped in a culture-negative CSF sample by real-time PCR.

Results: Most cases were caused by serotypes included in PPV23 (n= 1689, 79%) with serotypes found exclusively in this vaccine being among the most frequent – serotype 8 (n=408), 22F (n=143), 9N (n=94), 11A (n=73) and 20 (n=72). PCV13 serotypes represented 37% of the cases, with serotype 3 being the second most frequent overall (n=329), and serotypes 14 (n=137) and 19A (n=115) also ranking among the most frequent. All other PCV13 serotypes, except serotype 5, were also detected: 19F (n=53), 7F (n=40), 23F (n=29), 4 (n=27), 9V and 18C (n=13 each), 6B and 6A (n=10 each) and 1 (n=4). Comparing to the period prior to the inclusion of PCV13 in the NIP, PCV13 serotypes 1 and 7F showed significant decreases, while the opposite was true for serotype 8. Overall, 14% of the isolates were penicillin non-susceptible (MIC>0.06 mg/L) and 15% were resistant to erythromycin, mostly associated to serotypes 14, 19A and 19F. Simultaneous expression of erythromycin and penicillin non-susceptibility was found in 8% of the isolates and susceptibility to both these antimicrobials was found in 71% of the isolates.

Conclusions: The increase in proportion of IPD cases caused by serotype 8 and the resilience of serotype 3 and of other PCV13 serotypes, contribute to the dominance of isolates expressing PPV23 serotypes suggesting a potential role of more widespread vaccination in the prevention of adult pneumococcal invasive disease.

Abstract 6486

Detection of colistin resistance in Pseudomonas and Acinetobacter by the ATB PSE EU strips

Sandrine Petre¹, Edwige Pillon*, Martelin Roland¹

¹bioMérieux, La Balme-les-Grottes, France

**Background:** Colistin is a last line antibiotic for treating severe infections due to multi-resistant Gram negative bacilli. Disc-diffusion and gradient based methods do not allow reliable detection of colistin resistance for *Pseudomonas* spp. and *Acinetobacter* spp., only liquid methods seem to be satisfactory. The aim of the study is to evaluate the colistin test (COL) that is present in the ATB™ PSE EU strips. This test consists in one single well containing 2 mg/L of colistin sulfate in Mueller Hinton broth.

**Materials/methods:** The susceptibility of 69 isolates with known reference MICs by broth micro-dilution (BMD), comprising 38 *Pseudomonas aeruginosa*, 1 *Pseudomonas fluorescens* [9 S, 30 R] and 31 *Acinetobacter* spp. [8 S, 23 R], was determined by the COL test of the ATB™ PSE EU strip. Category agreement (CA), Major Errors (ME) and Very Major Errors (VME) were calculated following the EUCAST breakpoints [mg/L]: *Pseudomonas aeruginosa*: ≤2 [S] and >2 [R] with an area of technical uncertainty (ATU) at 4, *Acinetobacter*: ≤2 [S] and >2 [R].

**Results:** Results are summarized in the Table below. With this challenging panel (75% of R isolates), the colistin resistance detection by ATB™ PSE EU is good for *Acinetobacter*, and promising for *Pseudomonas*. Among the 6 isolates with a BMD MIC at 4 mg/L (R-ATU), 3 are S and 3 are R by ATB™ PSE EU.

**Conclusions:** This study shows that the ATB™ method has the potential to well detect colistin-resistant *Pseudomonas* and *Acinetobacter*, thus making possible the development of an ATB MIC test.

Molecular characterisation of blaNDM-1 from an Acinetobacter baumannii outbreak in a German university hospital

Kyriaki Xanthopoulou\textsuperscript{1,2,}*, Julia Wille\textsuperscript{1,2}, Janine Zweigher\textsuperscript{2,3}, Kai Lucassen\textsuperscript{1}, Harald Seifert\textsuperscript{1,3}, Paul G. Higgins\textsuperscript{1,2}

\textsuperscript{1}University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany, \textsuperscript{2}German Center for Infection Research (DZIF), Partner site Bonn-Cologne, Cologne, Germany, \textsuperscript{3}University Hospital Cologne, Department of Infection Control and Hospital Hygiene, Cologne, Germany

**Background:** New-Delhi metallo-\(\beta\)-lactamase (NDM) producing *Acinetobacter baumannii* are associated with nosocomial outbreaks worldwide, however, in Germany these outbreaks are rare. The aim of this study was the molecular characterization of bla\textsubscript{NDM-1} from an *A. baumannii* outbreak in a university hospital in Germany.

**Materials/methods:** Between May and September 2019, ten *A. baumannii* isolates from nine patients and six environmental samples were collected from different wards in the clinic for internal medicine. Antimicrobial susceptibility testing was performed using Vitek2 and Etest (bioMérieux). Sequencing libraries were prepared using the Nextera XT kit for a 250bp paired-end sequencing run on a MiSeq (Illumina). Additionally, three isolates were sequenced using the MinION (Nanopore) platform. Hybrid- and non-hybrid methods were used for de novo genome assembly. The molecular epidemiology was investigated using the core-genome MLST (cgMLST) scheme from Ridom® SeqSphere+. The assembled genomes were used for 7-loci MLST (Pasteur) and resistome analysis.

**Results:** A total of 15 carbapenem-resistant *A. baumannii* isolates encoding both bla\textsubscript{NDM-1} and bla\textsubscript{OXA-23} were identified. One of the patients was found colonized with a carbapenem-resistant *A. baumannii* which harboured bla\textsubscript{OXA-23} and bla\textsubscript{NDM-1} and another carbapenem-resistant *A. baumannii* that was bla\textsubscript{OXA-23} positive but lacked bla\textsubscript{NDM-1}. All *A. baumannii* harboured the intrinsic bla\textsubscript{OXA-66} and were assigned as international clone (IC) 2 and ST570. By cgMLST analysis the isolates differed in less than 3 alleles indicating clonal transmission. Investigation of the bla\textsubscript{NDM-1} genetic environment using long-read sequencing revealed that it was encoded within a 19Kb Tn1\textsubscript{25} like transposon and was located in the chromosome upstream of IS\textsubscript{Aba14-aphA6} (Figure 1). This transposon was missing in the bla\textsubscript{NDM-1}-negative *A. baumannii* indicating its loss by a transposition event.

**Conclusions:** In this study we described the transmission of a bla\textsubscript{NDM-1} positive carbapenem-resistant *A. baumannii* in the clinic for internal medicine. One of these isolates lost bla\textsubscript{NDM-1} but remained carbapenem-resistant because of the presence of bla\textsubscript{OXA-23}. These results indicate that mobile genetic elements can lead to genetic variation within an outbreak and that the presence or absence of resistance genes should not be used to determine clonality.

**Figure 1.** Schematic diagram of the genetic environment of bla\textsubscript{NDM-1} in *A. baumannii* (19Kb).

Study of the humoral response against adjuvanted and non-adjuvanted influenza vaccine in the elderly by age groups

Laura Sanchez De Prada¹,²; Iván Sanz²; Sonia Tamames³; Ana Lopez¹; Jose Manuel Méndez-Legaza¹; Silvia Rojo¹; Raúl Ortiz De Lejarazu¹; Jose María Eiros⁴

¹University Clinical Hospital of Valladolid, Valladolid, Spain; ²’National Influenza Centre Valladolid, Valladolid, Spain; ³’Consejería de Sanidad- Junta de Castilla y León, Valladolid, Spain; ⁴Hospital Universitario Rio Hortega, Valladolid, Spain

Background: Immune-senescence makes elderly people one of the main targets of seasonal influenza vaccination campaigns. Non-Adjuvanted influenza vaccines (NAIV) present limitations to reach desirable humoral responses in elderly. For improving these, adjuvanted influenza vaccines (ADIV) are used. The aim of this study is to compare the humoral response in elderly people

Materials/methods: A retrospective study was performed in 2,513 healthy individuals ≥65years vaccinated with NAIV and ADIV, recruited from 1990-2018. Of them, 1,018 were 65-74years, 1,003 were 75-84 and 492 were 85-94years old. Sera were obtained before and 28 days after vaccination. For analyzing antibodies titers, haemagglutination inhibition assay was performed at the National Influenza Centre of Valladolid(Spain) against classical-A(H1N1)(from 1990 till 2010), A(H1N1)pdm09(from 2010 till 2018), A(H3N2) and for both B/Yamagata and B/Victoria lineages. Statistical analysis was performed calculating Geometric Mean Titers increase induced by NAIV and ADIV. Differences were analyzed using Student-T test (α<0.05).

Results: A total of 1,467(58.37%) individuals were vaccinated with NAIV and 1,046(41.62%) with ADIV. GMTi was significantly higher using ADIV for A(H3N2) and classical-A(H1N1) among 75-84 and 85-94 years old respectively. Elderly among 65-74 showed significantly higher GMTi in NAIV for classical-A(H1N1)subtype. Results showed no significant differences between both vaccines for A(H1N1)pdm09subtype or B-lineages in any age groups. Results are shown in the following table.

</table>

Conclusions: ADIV induced higher humoral responses against some influenza viruses as A(H3N2) and classical-A(H1N1) in 75-84 and 85-94 years respectively, while NAIV induced higher humoral response for classical-A(H1N1) subtype in 65-74 years. No differences were found for A(H1N1)pdm09 or B-lineages. ADIV is more useful than NAIV for inducing higher humoral responses in older groups, especially against A(H3N2) subtype which is the virus that present higher mortality among the elderly.

Abstract 6494

**Discovery of convergent mutations associated with *Mycobacterium tuberculosis* clinical and microbiological characteristics**

Olga Lebedenko1, Mikhail Rotkevich1, Viatcheslav Zhuravlev2, Ekaterina Chernyaeva1, Peter Yablonsky1,3

1Saint Petersburg State University, Saint Petersburg, Russian Federation, 2Barcelona Supercomputing Center (BSC), Barcelona, Spain, 3St.Petersburg Research Institute of Phthisiopulmonology, Saint Petersburg, Russian Federation

**Background:** Understanding of genetic mechanisms for *Mycobacterium tuberculosis* drug resistance is important to provide correct treatment plan. GWAS became well-established instrument for discovering genetic associations in many organisms, however it requires adaptation to bacterial genome analysis due to relatively strong population structure. The current study presents alternative algorithm convPhy based on detection of convergent mutations. Significantly, developed application can be expanded to identification genetic associations for any binary traits in evolutionary context

**Materials/methods:** The main goal of convPhy is detection of convergent mutations. convPhy assumes reconstruction phylogenetic tree, prediction ancestral genotype and phenotype. Phylogenetic tree branches lead to resistant or sensitive phenotype descendant labeled respectively. For each testing SNP sensitive and resistant branches are counted. Statistical significance is evaluated by permutation test. The source code of the project is available on github: https://github.com/OOLebedenko/convPhy. We validated conPhy on well characterized dataset PRJNA23585 consisting of 233 Indian *M. tuberculosis* isolates and applied to 71 pulmonary and 66 extrapulmonary Russian isolates PRJNA352769. Both datasets have experimentally determined drug susceptibility profile to rifampicin, isoniazid and ethambutol. Raw reads aligned on the reference genome H37Rv (NC_000962.3) with bwa mem 0.7.15-r1140. SNPs calling was performed with GATK ver. 4.0.1.2. SNPs were filtered by QD>30 and DP>20. Phylogenetic tree was constructed using RAxML with CTRCAT nucleotide substitution model, *M. canettii* (NC_015848.1) as outgroup and concatenated filtered SNPs as input.

**Results:** convPhy demonstrated high level of concordance with associations described in Indian validation SNPs set. In Russian isolates convPhy revealed association pathogen localization with mutations in PE/PPE genes, presumably participating in virulence. Moreover, convPhy detected mutation previously not associated with drug resistance in esxV, pks12, lppa, lppb, pknH, fadD19, glyA1, rpfA genes and cooperative interaction of single SNPs in isolates *M. tuberculosis* whose resistance to isoniazid and rifampicin are not explained by known mutations S315T katG and S450L rpoD.

**Conclusions:** convPhy seems promising tool for discovering resistance-related mutations in bacterial genome. The preference convPhy against previously described similar approaches is available source code with clear technical realization and module for detection interaction between single SNPs.

Abstract 6495

Prospective study of breakthrough invasive fungal infections in haematologic patients in Spain

Estela Moreno1, Pedro Puerta1, Juan Carlos Soto-Debrán2, Cecilia Martín Gandul3, Montserrat Batlle4, Jon Badiola5, Ana Fernández-Cruz6, Marina Machado7, Juan Carlos Ramos Ramos8, Lucía Gomez9, Carlota Gudiol10, Isabel Ruiz11, Mariana Chumbita1, Pilar Martín-Dávila12, Lucrècia Yañez13, Lourdes Vázquez14, Nicole Garcia-Pouton15, Jesus Fortun Abete16, Julio García Rodríguez17, Pedro González18, Francesc Marco Reverte1, Isabel Sanchez-Romero9, María Dolores Quesada1, Jesús Guinea Ortega2, Manuela Aguilar-Guisado1, Alex Soriano1, Ana Alastruey-Izquierdo1, Carolina García Vidal1

1Hospital Clínic, Barcelona, Spain, 2Instituto de Salud Carlos III, Madrid, Spain, 3Hospital Universitario Virgen del Rocío, Seville, Spain, 4Hospital Universitari Germans Trias i Pujol, Badalona, Spain, 5Hospital Universitaria Virgen de las Nieves, Granada, Spain, 6Hospital Puerta de Hierro, Madrid, Spain, 7Hospital Gregorio Marañón, Madrid, Spain, 8Hospital Universitario La Paz, Madrid, Spain, 9Hospital Universitario Mutua Terrasa, Terrasa, Spain, 10Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat, Spain, 11Hospital Universitario Vall d’Hebron, Barcelona, Spain, 12Hospital Ramón y Cajal, Madrid, Spain, 13Hospital Universitario Marqués de Valdecilla, Santander, Spain, 14Hospital Universitario de Salamanca, Salamanca, Spain

Background: Breakthrough invasive fungal infections (BtIFI) are an emerging problem; however prospective epidemiological data are lacking. We aimed to describe the current epidemiology, treatment and outcomes of BtIFI in hematological patients in Spain.

Materials/methods: Prospective descriptive cohort study of all consecutive BtIFI diagnosed according to the revised EORTC criteria in 13 Spanish hospitals from September 2017 to July 2019 [22 months]. BtIFI was defined as any IFI occurring in patients with ≥5 days of antifungals within the last week. Antifungal susceptibility was tested in the Spanish National Center for Microbiology.

Results: 84 BtIFI were diagnosed: 25 [29.8%] proven, 36 [42.9%] probable and 21 [25%] possible. Most common underlying diseases were acute myeloid leukemia (44%) and hematopoietic stem cell transplantation (19%). Table 1 details the microbiological characteristics of the proven cases. Most frequent prior antifungals were posaconazole [31%], fluconazole [27.4%] and echinocandins [22.7%]; administered for primary prophylaxis [71.4%], secondary prophylaxis [10.7%] and preemptive therapy [6%]. Antifungal therapy was usually changed [84.5%], commonly to liposomal Amphotericin B [42.9%]. 100-day mortality was 51.2%.

Conclusions: Aspergillosis is still the most frequent cause of BtIFI but the appearance of rare fungi like Mucorales, Geotrichum or Fusarium and non-albicans Candida infections was evidenced. Most proven BtIFI were resistant to the prior antifungal administered. Mortality rate was high.

Table 1. Microbiological characteristics.

Abstract 6497

**Innovative diagnosis strategy for pneumococcal infections in children using an immunochromatographic test in respiratory specimens**

Cyrille Haddar*1,2, Johan Joly3, Anne Carricajo1,3, Paul Oswald Verhoeven1,3, Grattard Florence1,3, Olivier Mory4, Evelyne Begaud2, Yves Germani2, Aymeric Cantais1,4, Pozzetto Bruno1,3

1GIMAP EA3064, University of Lyon, Saint-Etienne, France, 2BioSpeedia, Paris, France, 3Department of Microbiology and Hygiene, University Hospital of Saint-Étienne, Saint-Priest-en-Jarez, France, 4Department of Paediatric Emergency, University Hospital of Saint-Étienne, Saint-Priest-en-Jarez, France

**Background:** Despite vaccination programs, *Streptococcus pneumoniae* remains among the main microorganisms involved in bacterial pneumonia, notably in terms of severity. The prognosis of pneumococcal infections is conditioned by the precocity of the diagnosis. This study evaluated the impact of a Rapid Diagnostic Test (RDT) targeting *S. pneumoniae* cell wall polysaccharide and performed directly in respiratory samples, on the strategy of diagnosis of pneumococcal respiratory infections in children.

**Materials/methods:** Upper-respiratory tract samples from 196 children consulting at hospital for respiratory infection were tested for *S. pneumoniae* using a newly-designed RDT (PneumoResp, Biospeedia), a semi-quantitative culture and two PCR assays. If positive on fluidized undiluted specimen, the RDT was repeated on 1:100-diluted sample. The clinical data analysis was conducted retrospectively.

**Results:** The RDT was highly specific when tested on non-*S. pneumoniae* strains. By comparison to culture and PCR assays, the RDT on undiluted secretions exhibited sensitivity (Se) and negative predictive value (NPV) over 98%.

</tbody>
</table>

* These thresholds were shown to correspond to approximately 10⁷ CFU/ml by qPCR.

By comparison to criteria of *S. pneumoniae* pneumonia combining typical symptoms, X-ray image and culture ≥ 10⁷ CFU/ml, the Se and NPV of RDT on diluted specimens were 100% in both cases.

**Conclusions:** In case of negative result, the excellent NPV of RDT on undiluted secretions allows excluding *S. pneumoniae* pneumonia at day 0 and orientates towards the search for another pathogen. In case of positive result, the excellent sensitivity of RDT on diluted secretions for the diagnosis of *S. pneumoniae* pneumonia allows proposing an anti-pneumococcal treatment at day 0.

Abstract 6499

**Polymicrobial species identification from positive blood cultures with high-resolution Orbitrap mass spectrometry**

Hannu Peltoniemi1, Martin Damsbo1, Ilja Ritamo1, Marjaana Viirtola*1, Anssi Rantakari1

1Thermo Fisher Scientific, Vantaa, Finland

**Background:** Polymicrobial blood cultures occur due to co-infection, or as an incidence of skin contamination from blood sampling. Approximately 5-10% of positive blood cultures are polymicrobial and contain two or more species. Identification of all species present in polymicrobial blood cultures has remained challenging for diagnostic methods, as the ratio of different organisms can vary.

**Materials/methods:** Diagnostic protein markers were determined for seven common blood culture taxa including Enterococcus faecalis, E. faecium, Escherichia coli, Klebsiella pneumoniae, Staphylococcus aureus, S. epidermidis and Pseudomonas aeruginosa. Initially, monoculture protein profiles were measured with top-down data dependent acquisition (DDA) LC-MS2. Given the identified proteins, the potential markers were deduced by comparing predicted protein prevalence across strains of publicly available genomes [NCBI]. Preferred marker candidates displayed exclusivity to a clinical category, a high prevalence across strains of the targeted species, as well as a high propensity for detection with mass spectrometry [MS]. To test the approach and simulate polymicrobial cultures, seeded, positive blood culture of E. coli was mixed with corresponding blood cultures of S. epidermidis and E. faecalis. Microbial cells were enriched and lysed, and produced protein extracts were measured with targeted 2.5 min LC-MS2 method, using Acroion ProTrap™ columns and Orbitrap™ mass spectrometer. True microbe ratio in each sample was determined based on CFU in positive blood cultures and mixing ratio.

**Results:** The protein markers and corresponding species were identified based on diagnostic MS2 fragments. The approach to use targeted protein markers with a short LC-MS2 method for polymicrobial species identification was shown to be feasible, even with high mixing ratios (f1:100).

**Conclusions:** High-resolution targeted LC-MS2 is a promising method to identify species in polymicrobial blood culture samples, and can be utilised on a high-resolution MS platform such as Acroion™. Simultaneous detection of multiple species in one analysis facilitates diagnosis of bacteremia, and may have a significant impact to patient outcome.

Abstract 6501

Impact of enteric viral co-infections on gastroenteritis among hospitalised children in Palermo, Italy, during a 10-year surveillance

Simona De Grazia*, Floriana Bonura1, Leonardo Mangiaracina2, Chiara Filizzolo1, Celestino Bonura1, Vito Martella2, Giovanni Giammanco1

1University of Palermo, ADUP; Dipartimento di Promozione della Salute, Materno-Infantile, di Medicina Interno e Specialistica di Eccellenza “G. D’Alessandro”, Palermo, Italy; 2Università Aldo Moro di Bari, Dipartimento di Medicina Veterinaria, Valenzano, Italy

Background: Acute gastroenteritis is one of the most common illnesses in humans worldwide. Four viruses account most of the cases of childhood gastroenteritis: rotavirus, norovirus, adenovirus 40/41 and astrovirus. The recent availability of syndromic assays simultaneously detecting several pathogens allows to easily reveal co-infections.

The aim of this study was to investigate the extent and epidemiological features of concurrent rotavirus, norovirus, adenovirus and astrovirus infections in children hospitalized with acute gastroenteritis.

Materials/methods: A total of 4161 stools from children <5 years of age hospitalized in Palermo, Italy, from January 2008 to December 2018, collected for the sentinel surveillance activity of the Italian Study Group for Enteric Viruses (ISGEV; http://isgev.net), were investigated for the presence of rotavirus, norovirus, adenovirus and astrovirus.

Results: At least one enteric virus was detected in 55.5% of the patients, and the rate of co-infection was 4.06%, with a maximum of three different viruses being simultaneously detected. Rotavirus was the most prevalent virus in symptomatic children (24.8%) followed by norovirus (20.31%), adenovirus (7.4%) and astrovirus (2.84%). Astrovirus infections frequently also involved other enteric viruses (27.12% of co-infections), but rotavirus was most commonly detected in mixed infections, notably with norovirus G1P[8] (66.86%), astrovirus (10.06%) and adenovirus (4.73%). G1P[8] was the predominant rotavirus genotype found in co-infections (55.7%), followed by G9P[8] (14.7%) and G2P[4] (5.7%). Mixed infections involving more than one rotavirus genotype were seldom detected (6.5%). GIIP4 was the main norovirus genotype (41.3%) detected in co-infections, followed by GII.Pe (12.3%) and GII.P16 (15.2). In most cases, a significant difference in Ct values was observed among the co-infecting viruses, and rotavirus was generally detected at a lower Ct value compared to the concomitant norovirus or astrovirus (indicating 1 to >3 log higher viral load).

Conclusions: The systematic detection of four viruses allowed us to evaluate their involvement in co-infections. As detection of co-infections still represents a challenge for the diagnostic laboratory, further studies should be performed to understand if co-infection can increase the severity of enteric disease and the role of each pathogen involved.

Presenter email address: simona.degrazia@unipa.it
Clinical outcome of early central venous catheter removal in children with candidaemia: a retrospective multi-centre study

Nora Poey*, Marion Caseris¹, Albert Fayet, Stephane Bonacorsi², Mathie Lorrot, Julie Toubiana³, Patricia Mariani³

¹Hopital Robert Debré, Paris, France; ²Hopital Armand Trousseau, Paris, France; ³Hopital Necker enfants malade, Paris, France

Background: Candida spp. is third leading organism of nosocomial bloodstream infection in pediatrics preceded by coagulase-negative staphyloccoci and Staphylococcus aureus. Vascular catheters are a risk factor of candidemia and its withdrawal is considered to be a standard. Pediatric specific data on the impact of central venous catheter (CVC) retention are limited.

Materials/methods: We have led a retrospective study in 2 pediatrics Parisians centers which aimed to study the impact of central venous catheter (CVC) retention beyond 72 hours in candidemia in children, between 2007 and 2017. We defined catheter-related bloodstream infection (CRBSI) according to IDSA definitions. The primary study outcome was clinical failure, defined as mortality within 30-days, persistent positive blood culture for ≥72 hours after the initiation of antifungal therapy, new sites of infection or relapse within 12 weeks.

Results: We included 93 patients. Median age was 4.4 years old. 58 patients (62.4%) benefited from a removal of CVC within 72h after the positive blood culture and 35 patients (37.6%) had conservative treatment of CVC. C. albicans, C. parapsilosis and C. tropicalis were the three most represented. 3 strains were resistant to fluconazole: 1 C. tropicalis, 1 C. krusei, et 1 C. haemulonii. None were resistant to echinocandins. 57 patients had criterion of clinical failure: 28/58 (48.3%) with removal CVC and 29/35 (82.9%) in conservative group (p=0.002). Mortality was 15 % : 7/58 (12%) in removal group, 7/35 (20%) in conservative group (p=0,46), 40 patients had persistent fungemia : 20/58 (34,5%) in removal, 20/35 (57%) in conservative group (p=0,054), 16 patients had new infection site : 6/58 (10,3%) in removal group, 10/35 (28,6%) in conservative group (p=0,048). Predictive factors of clinical failure were neutropenia (p=0,003), intensive care needed (p= 0,007) and retention of CVC (p=0.02).

Conclusions: Results of this pediatric cohort confirms guidelines for Candida CRBSI and reminded us the need to remove CVC as early as possible even if venous access is more complex in children. Maintained CVC seems to be associated with clinical failure.

Abstract 6505

Comparison of antimycotic activity against clinical isolates of Candida albicans and Candida glabrata of originator and generics of voriconazole and anidulafungin

Alina Karoline Nussbaumer-Pröll*, Sabine Eberl1, Brigitte Selitsch1, Christoph Dorn2, Frieder Kees2, Tiziana Gasperetti1, Jana Marx1, René Welte1, Romuald Bellmann3, Jana Marx3, René Welte3, Romuald Bellmann3, Markus Zeitlinger1

1Medical University of Vienna, Wien, Austria, 2University of Regensburg, Regensburg, Germany, 3Medizinische Universität Innsbruck, Innsbruck, Austria

Background: Concerns have been expressed about the interchangeability of innovator and generic antimycotics regarding their activity, stability and their susceptibility towards fungi.

Materials/methods: Activity of 2 different antimycotics was tested each with 1 originator and 2 generics. For voriconazole [fungistatic] the originator VFEND® from Pfizer and the two generics from Ratiopharm and Stada were used to test against 21 clinical isolates of Candida albicans (C. albicans) with reference strain ATCC-90028. For anidulafungin [fungicidal] the originator ECALTA® from Pfizer and the two generics from Stada and Pharmore were used and tested against 20 clinical isolates of Candida glabrata (C. glabrata) and reference strain ATCC-22019 Candida parapsilosis (C. parapsilosis). MIC testing was performed in triplicate for both settings in RPMI growth media in compliance with the EUCAST protocol for MIC testing of antifungal agents. Time Kill Curves (TKC) with concentrations above and below the respective MIC were performed for 1 representative clinical isolate and the corresponding ATCC-strain in Sabouraud broth (SAB). Samples were drawn at defined time points, and dilutions were plated on Sabouraud agar plates (SAG) to evaluate the CFU/mL. Stability testing of the antimycotics stored at 4°C and at room temperature over 24 hours was done with HPLC analysis.

Results: MIC results of clinical isolates and ATCC strains showed no significant difference in activity of generic and innovator antimycotic in all settings. The median MIC ratios of originator and generic [all combinations showed a ratio of 1] confirm the interchangeability of the drugs. Colony counts per mL in TKCs verify these findings as seen in figure 1 (a) and (b). HPLC analysis demonstrated stability of the tested antimycotics despite originator or generic.

Conclusions: This study showed that antimycotic activity of generics was identical to the originator for both settings with voriconazole and anidulafungin. Further, antimycotic stability within approved storing conditions could be confirmed. The present study demonstrates interchangeability of generic and originator antimycotic in-vitro potentially leading to broader public acceptance for generic antimycotics.

Figure 1: TKC of (a) voriconazol against C. albicans and (b) anidulafungin against C. glabrata tested with originators (O) from Pfizer (blue symbols), generics-1 (G1a and G1b) from Strada (red symbols), generic-2 (G2) from Ratiopharm and generic-3 (G3) from Pharmore (green symbols) with standard deviations over 72 and 24 hours, respectively are shown.

Transglutaminase 2 inhibitors as a future intervention against non-tuberculous mycobacteria

Ivana Palucci*1, Alessandro Salustri2, Michela Salì1, Flavio De Maio1, Linda Petrone3, Gianmaria Firmia4,5, Maurizio Sanguinetti1, Delia Goletti3, Mauro Piacentini5,6, Giovanni Delogu2,7

1Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Institute of Microbiology, Rome, Italy, 2Università Cattolica del Sacro Cuore, Institute of Microbiology, Rome, Italy, 3L. Spallanzani National Institute for Infectious Diseases (INMI) IRCCS, Rome, Italy, 4Sapienza University of Rome, Department of Molecular Medicine, Rome, Italy, 5Spallanzani” National Institute for Infectious Diseases (INMI) IRCCS, Electron Microscopy and Cell Biology Unit, Department of Epidemiology and Preclinical Research, Rome, Italy, 6University of Rome “Tor Vergata”, Department of Biology, Rome, Italy, 7Mater Olbia Hospital, Olbia, Italy

Background: Diseases caused by Non Tuberculous Mycobacteria (NTM) are on the rise worldwide, including immunocompetent adults. The current treatment against NTM infections is based on the combined use of antibiotics that are administered for 6-12 months. Despite these aggressive regimens, success rate barely exceed 50% due to the intrinsic and acquired NTM drug resistance. Host-directed therapies (HDTs) are emerging as a promising area of research and are opening new avenues in the treatment of mycobacterial infection. We recently demonstrated that genetic or pharmacological inhibition of transglutaminase 2 (TG2), a multifunctional ubiquitous enzyme that catalyses post-translational modifications of proteins in eukaryotic cells, results in the reduction of Mycobacterium tuberculosis replication in murine and human primary macrophages. In this study we aim to assess the anti-mycobacterial activity of the TG2 inhibitors cystamine and cysteamine against a panel of NTM.

Materials/methods: To test the potential activity of TG2-inhibitors, human monocyte-derived macrophages (THP-1) were infected with clinical isolates of NTM (Mycobacterium avium (MAV), Mycobacterium abscessus (Mabs), Mycobacterium intracellulare (MAI)) and then treated with antibiotics currently used in the standard therapy or with cystamine or cysteamine. We also evaluate cysteamine and cystamine activity in the human ex vivo model of granuloma-like structures (GLS).

Results: Intracellular CFUs were determined at day 2 and a significant reduction was observed following treatment with these inhibitors. Interestingly, when THP-1 cells were infected with the two colony variants of Mabs (Smooth and Rough), the treatment with cystamine and cysteamine turns out to have a superior antimicrobial response compared with the drug streptomycin and especially against the most virulent R variant of Mabs. The study in the GLS model further confirmed the ability of these drugs to restrict NTM replication (reduction of 1.2 log CFU for Mabs; ≈ 2 log CFU for MAV and 1.3 for MAI) and to reduce the size of GLS.

Conclusions: The antimicrobial activity of the TG2-inhibitors synergized with a standard drug as amikacin in human mono-ocyte-derived macrophages and in the GLSs model. Overall, the results of this study support the potential usefulness of the TG2-inhibitors cysteamine and cystamine as HDTs in NTM disease.

Omitting the nightly dose of selective digestive tract decontamination provides equally effective decontamination of potential pathogenic bacteria: a cost reducing and sleep-promoting intervention

Jara De La Court*1,2, Thomas Groot1, Kim Sigaloff2, Hans Van Der Spoel3, Rogier Schade1

1Amsterdam University Medical Center (AUMC), Department of Medical Microbiology and Infection Control, Amsterdam, Netherlands, 2Amsterdam UMC, location VUmc, Department of internal medicine, Amsterdam, Netherlands, 3Amsterdam University Medical Center (AUMC), Department of Intensive Care, Amsterdam, Netherlands

Background: Selective digestive decontamination (SDD), targeting potential pathogenic microorganisms (PPMs), has been shown to prevent ICU-acquired infections and improve patient survival. SDD consists of application of non-absorbable antibiotics (colistin, tobramycin and amphotericin B) in the oropharyngeal cavity and the stomach, four times daily of which one dosage is at night, combined during the first four days with intravenous cefotaxim. Surveillance cultures are collected weekly to assess the effectiveness of decontamination. We aimed to demonstrate that omitting the nightly SDD dosage does not influence the effectiveness of decontamination.

Materials/methods: Retrospective equivalence study with a before-and-after design performed at a tertiary ICU that omitted the nightly dose of SDD three years earlier. We defined effective decontamination as the time-point at which surveillance cultures became negative for PPMs and remained so during the remainder of the ICU stay. Inclusion criteria were admission duration ≥72h and ≥2 surveillance cultures collected on different dates.

Results: In total 1958 ICU admission were included in the analysis, 1236 before (q.i.d.) and 722 after (t.i.d.) the change in SDD application frequency. Effective decontamination was achieved in 73.2% of the admission with q.i.d. versus 71.6% in t.i.d. SDD application (p-value = 0.4398). The proportion difference of effective decontamination between the two regimens was equivalent (-0.016, 99% CI: -0.07; 0.038). There was no significant difference in time to decontamination between the two regimens (log-rank test p-value = 0.55).

Conclusions: Omitting the nightly SDD dosage provided equally effective decontamination of PPMs. Sleep is essential for adequate immune, metabolic, and endocrine functioning. No formal cost analysis was performed but a 25% reduction of costs of the medication can be expected. These findings justify implementation of a t.i.d. SDD frequency as a cost reducing and sleep-promoting intervention.

Clinical application of polyomavirus detection by metagenomic next-generation sequencing in urinary tract infection
Na Li1*, Bijie Hu1

1Zhongshan Hospital, Fudan University, Shanghai, China

Background: Urinary tract polyomavirus replication is common, while the clinical significance of polyomavirus detection in the urine of patients with urinary tract infections remains elusive. We aimed to analyze the clinical value of polyomavirus detection in the urine by metagenomic next generation sequencing.

Materials/methods: Urine specimens were collected from 30 patients diagnosed with urinary tract infection in Zhongshan Hospital of Fudan University from September 2018 to October 2019. The random amplification, DNA nanoball, BGI-500 sequencing platform, and BWA were used for next generation sequencing and analysis of nucleic acid extracts from urine. The number of virus sequences in urine samples >100 was included in the study, and indexes of virus types, depth, coverage rate, abundance and reads number were observed.

Results: JC polyomavirus was detected in 26.7% (8/30) urine samples, with BK polyomavirus co-detected in one of them. 7 of the 8 patients were made a designation of complicated urinary tract infection, and only one of them had positive urine culture (Escherichia coli). All cases were immunocompromised patients, including rheumatic autoimmune diseases, tuberculosis, rheumatic heart disease, liver transplantation, T-lymphocyte tumor hyperplasia, and poorly controlled type 2 diabetes. The mean value of depth, coverage rate, relative abundance and stringently mapped reads number of JC polyomavirus were 40.2, 97.5%, 90.8% and 3464, respectively. Nucleic acid sequences of bacteria, fungi, other viruses and mycobacteria were also detected in some cases. There was a negative linear correlation between the RPM parameter (reads per megabyte of data) and the number of CD4+ T cells. In one case, the urinary irritation symptoms and urine test indexes were obviously improved after treatment with cidofovir, and the reads and RPM value of JC polyomavirus were significantly decreased during follow-up.

Conclusions: The possibility of infection should be considered upon JC polyomavirus detected in the urine of immunocompromised hosts. The metagenomic next generation sequencing is of great value in the diagnosis of viral urinary tract infection. Cidofovir may be effective in the treatment of urinary tract polyomavirus infection.

Abstract 6510

Impact of infectious diseases consultation and appropriate empirical antibiotic therapy on mortality in patients with *Staphylococcus aureus* bloodstream infection: a two-year retrospective analysis

Andrea Cona*1, Lidia Gazzola1, Ottavia Viganò1, Roberto Castoldi1, Andrea Renzelli1, Teresa Bini1, Giulia Marchetti1, Antonella D’arminio Monforte1

1Infectious Diseases Unit, San Paolo Hospital, University of Milan, Milan, Italy

**Background:** Guidelines on *Staphylococcus aureus* Bloodstream Infection (SA-BSI) recommend the implementation of bundles of interventions, including follow-up blood culture, echocardiography, source control, specific antibiotic therapy with appropriate length and Infectious Diseases consultation (ID-cons) to reduce mortality of SA-BSI. We aim to evaluate the adherence to the bundles for SA-BSI and the impact of ID-cons and empirical appropriate antibiotic therapy on in-hospital mortality.

**Materials/methods:** Two-years (2017-2018) analysis of all the SA-BSI diagnosed at San Paolo Hospital, Milan. Data on clinical characteristics, adherence to bundles of interventions and in-hospital mortality for any cause (by Kaplan-Meier) were collected. Factors associated with mortality were analyzed by uni- and multivariate Cox regression models adjusted for potential confounders.

**Results:** A total of 117 patients with SA-BSI diagnosed in 2017-18 were included; 41 (35%) were sustained by MRSA. Median age was 77 years (IQR:64-82); median Charlson score was 7 (5-10). 32.7% (38/117) of the SA-BSI were hospital-acquired and 51% were sepsis at onset; ID-cons was requested in 88 (79.2%) of cases. Overall adherence to the bundle protocol was 37.5%. High adherence was recorded for source control (72%); conversely, adherence to diagnostic work-up and to follow-up blood culture was 49% and 21%. Overall, 44% of the SA-BSI resulted complicated. Empirical antibiotic therapy was appropriate in 69.8% of the cases (86% MSSA vs 39% MRSA, p<0.0001). At survival analysis, the 30 days-probability of in hospital mortality was of 29% [95%CI 15.7-42.3], ID-cons was associated with a reduced 30 days-probability of mortality [ID-cons: 22%[95%CI 8-36] vs no ID-cons 52%[95%CI 28-75]; p=0.002] (Figure 1a). Similarly, appropriate empirical antibiotic therapy was associated with a reduced 30 days-probability of mortality [appropriate: 15%[95%CI 3-27] vs inappropriate 45%[95%CI 22-68]; p=0.002] (Fig. 1b). By multivariate analysis adjusted for MRSA, ID-cons (aHR 0.2, 95%CI 0.07-0.6. p=0.004) and appropriate empirical antibiotic therapy (aHR 0.1, 95%CI 0.02-0.4. p=0.006) were associated to a reduced risk, whereas high Charlson score (aHR 1.2, CI95% 1.0-1.4. p=0.03) and sepsis at onset (aHR 6.9, CI95% 1.7-28. p=0.007) were associated to increased risk of in-hospital mortality.

**Conclusions:** Our study confirms that ID-cons and appropriate empirical therapy result in a reduced SA-BSI-related in-hospital mortality.

![Figure 1. Kaplan-Meier curves for survival analysis: probability of in-hospital mortality with (A) and without (B) ID-cons (Fig 1a); probability of in-hospital mortality with (C) and without (D) appropriate empirical therapy (Fig 1b).](image)

Evaluation of different commercial methods for fosfomycin susceptibility testing of Staphylococcus aureus

Floriana Campanile¹, Ausilia Aprile*, Carmelo Bonomo¹, Clarissa Imbrosciano¹, Alessia Mirabile¹, Dafne Bongiorno¹, Stefania Stefani¹, Maria Lina Mezzatesta¹

¹University of Catania, Catania, Italy

Background: Recent studies demonstrated a good in vitro activity of fosfomycin against MRSA clinical isolates can cause a wide spectrum of diseases, including bacteremia, pneumonia, osteomyelitis, endocarditis, septic shock and other infectious diseases.

The clinical use of fosfomycin requires the in vitro testing of the drugs in order to be categorized correctly in the clinical reports. According to EUCAST, the only approved MIC method for testing the fosfomycin susceptibility is the agar dilution (AD) method, which is cumbersome and not routinely performed.

Our aim was to compare the AD reference method, Gradient test (GT) and a rapid AD commercial test for fosfomycin susceptibility against Staphylococcus aureus clinical isolates.

Materials/methods: Fosfomycin antimicrobial susceptibility testing was performed on 70 MRSA and n.10 MSSA clinical isolates, according to the GT and AD as described by the CLSI 2014. The gradient test was carried out on Mueller Hinton agar with strips containing fosfomycin and Glucose-6-Phosphate (Liofilchem, Roseto degli Abruzzi, Italy). The susceptibility testing by commercial AD method was performed as recommended by the manufacturer (Liofilchem, Roseto degli Abruzzi, Italy). The fosfomycin-resistance-related genes fosB, murA, glpT and uhpT were analyzed to explore the molecular mechanism of resistance.

Results: According to the selected breakpoints, fosfomycin, performed by AD reference method, inhibited 60% of the tested strains (n.49 MRSA and n.9 MSSA). fosB gene was detected in fosfomycin resistant strains with MICs >256 mg/L.

The results of the commercial AD method, compared with those obtained from the AD, used as reference method, demonstrated a Categorical agreement (CA) of 100% and an Essential agreement (EA) of 91%.

The comparison between GT and AD reference method showed a CA of 82,5% for all staphylococci tested.

Conclusions: The results obtained comparing the commercial AD method and AD reference method confirmed the feasibility to characterize fosfomycin susceptibility by Liofilchem panels, while the GT method was not suitable as an alternative to the AD. High-level resistance to fosfomycin was due to the presence of fosB gene.

In conclusion, the new commercial method was easy and rapid to use, resulting a valid alternative to the AD reference method in the routine laboratory.

Clinical and epidemiological features of patients presenting with Crimean-Congo haemorrhagic fever at a tertiary care hospital in Karachi

Kiren Habib*1, Iffat Khanum1, Safia Awan1, Bushra Jamil1

1Aga Khan University Hospital, Karachi, Pakistan

Background: Crimean Congo Haemorrhagic fever (CCHF) is a life threatening tick borne zoonotic infection caused by an arbovirus from the family Bunyaviridae. An increasing number of cases have been reported from Pakistan since 2007 and environmental changes such as movement of human and animal populations and increase in temperature and humidity have been identified as contributing factors. We describe the clinical and epidemiological features and laboratory findings of patients presenting with CCHF at a tertiary care hospital in Karachi.

Materials/methods: This retrospective observational study was conducted at Aga Khan University Hospital, Karachi. Medical records of all patients admitted with CCHF confirmed by PCR from 2000-2018 were reviewed.

Results: A total of 58 patients were admitted of which 89.7% were male. The mean age was 34.4 years. 41.4% had exposure to livestock and 12.8% had exposure to a patient with CCHF. The number of patients is higher in the months of May, July and August. Mean duration of symptoms from onset to hospitalization was 6.2 days. All patients had fever. The other common symptoms on presentation were bleeding (87.9%), vomiting (70.7%), headaches (65.5%) and myalgias (51.7%). A total of 41.4% of all cases were from Karachi and 39.7% were from Balochistan province. Almost all patients had thrombocytopenia and elevated aspartate aminotransferase (AST) and alanine aminotransferase (ALT). The mortality was 34.5%. As compared to survivors, non-survivors had a higher aPTT, ALT, AST and acute kidney injury. Shock and haemorrhage was seen in almost all patients who died.

Conclusions: Early diagnosis and management may lead to better outcomes. The population needs to be educated about the signs and symptoms of CCHF and mode of transmission to encourage them to seek early healthcare and prevent household exposures.

Whole genome sequencing reveals differences between previously indistinguishable isolates of tobramycin resistant *Staphylococcus aureus*

Sara Mernelius*,1, Anna Jogenfors1, Linda Berglind1, Andreas Matussek1,2

1Ryhov County Hospital, Laboratory Medicine, Jönköping, Sweden, 2Karolinska University Hospital Huddinge, Division of Clinical Microbiology, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden

**Abstract third-party references:** Futurum - the Academy for Health and Care

**Background:** We have a collection of 250 tobramycin resistant *Staphylococcus aureus* (TRSA), spa type t084. The strains were collected from May 2012 until June 2019 from 140 neonates, hospitalized at the neonatal ward at Ryhov County hospital, Jönköping, Sweden.

In this study we used whole-genome sequencing (WGS) to clarify the similarity between a subset of the TRSA t084 strains.

**Materials/methods:** DNA was extracted from 21 TRSA isolates, using the EZ1 DNA Tissue kit on the EZ1 Advanced XL (Qiagen). Library preparation was performed using Nextera XT library prep kit (Illumina). Paired-end sequencing (2*250 cycles) was performed on a Miseq instrument (Illumina). Assembly and cluster analysis by core genome multilocus sequence typing (cg-MLST) based on 1861 genes was performed using SeqSphere (Ridom GmbH). The cluster alert difference was set to 24 allelic differences by default.

**Results:** Out of the 21 isolates, 19 passed quality control after WGS and cgMLST.

The isolates were divided into two distinct, but closely related, cluster types; 3008 and 18810. The majority of isolates (n=17) belonged to cluster type 3008. The remaining two isolates belonged to cluster type 18810. The two neonates with TRSA of cluster type 18810 were born at another hospital than Ryhov County hospital. They were culture positive immediately upon arrival at the neonatal ward at Ryhov County hospital and were therefore concluded to be colonized at the hospital where they were born.

**Conclusions:** WGS revealed two outbreaks among isolates that where considered indistinguishable in regards to the antibiotic susceptibility pattern combined with spa typing. This proves that WGS is more discriminatory than previous typing methods, even when they are combined.

The two neonates with the TRSA of cluster type 18810 were born and colonized at another hospital. It therefore seems as if cluster type 3008 is endemic to the neonatal ward at Ryhov County hospital.

Genomic and structural protein characterisation of mutations conferring bedaquiline resistance in *Mycobacterium tuberculosis* clinical strains

Andrea Spitaleri\(^1\), Simone Battaglia\(^2\), Joshua Carter\(^2\), Arash Ghodousi\(^{3,4}\), Andrea M. Cabibbe\(^1\), Philip Fowler\(^2\), Sarah Hoosdally\(^3,4\), Daniela M. Cirillo\(^1\)

\(^1\)IRCCS San Raffaele Scientific Institute, Milan, Italy, \(^2\)University of Oxford, John Radcliffe Hospital, Nuffield Department of Medicine, Oxford, United Kingdom, \(^3\)University of Oxford, John Radcliffe Hospital, Headington, United Kingdom, \(^4\)CRyPTIC Consortium, Oxford, United Kingdom

**Background:** The increasing incidence of multi- and extensively-drug resistant tuberculosis (MDR/XDR-TB) represents a global emergency. Many mutations conferring drug resistance have been characterized for first- and second-line drugs, and their detection offers a means of rapidly assessing drug susceptibility patterns to improve patient management. Mutations putatively involved in resistance to Bedaquiline (BDQ) were found in *atpE* and *Rv0678* genes. The aim of this work is to characterize mutations conferring BDQ resistance at genomic and structural protein levels and their association with strain phenotypes.

**Materials/methods:** A collection of *Mycobacterium tuberculosis* (*Mtb*) strains representing all different lineages and drug susceptibility profiles were included in the study: minimal inhibitory concentrations (MICs) of BDQ was determined by using microtiter plates. MIC values of resistant strains were confirmed by Bactec 960 MGIT system and resazurin microtiter assay as reference methods. For whole genome sequencing, paired-end libraries were prepared using Nextera XT-DNA Library Prep Kit and sequenced on NextSeq500. Data analysis was performed by MTBseq pipeline. Protein structure analyses were performed using Molecular Docking and Molecular Dynamics simulations.

**Results:** WGS analysis on these strains revealed the presence of previously uncharacterized non-synonymous mutations in the screened genomic loci. The analysis revealed the presence of non-synonymous mutations (80%), frameshift mutations (14%) and also synonymous mutation (6%) considering all BDQ genomic targets. Most of the resistance-conferring mutations on the on-target proteins are far from the drug binding site (> 10Å), implying allosteric effect in the resistance mechanism. Network analysis shown that the mutations in the off-target protein are involved in the resistance mechanism. Molecular dynamics simulations together with normal mode analysis shown that the long range mutations induce allosteric effect impairing the drug binding.

**Conclusions:** The comparison between the genotypic-structural protein and the phenotypic allowed to identify and discriminate SNPs correlated to DR phenotype from SNPs without any DR correlation. It is worth nothing that *Mtb* strains were isolated from patients never exposed to BDQ, confirming that resistance phenotypes are pre-existing in *Mtb* circulating strains. The structural protein analysis revealed that most of the mutations raised far from the binding site and few close to the binding site.

Abstract 6527

Investigating the prevalence of ESBL-producing Escherichia coli in rooks (Corvus frugilegus) wintering in an urban area and comparing these isolates to contemporary human faecal and clinical isolates

József Bálint Nagy1,2*, Bence Balázs1,2, Ivelina Damjanova3, Akos Toth1, Péter Gyüre1, László Kövér4, Gábor Kardos1

1University of Debrecen, Department of Medical Microbiology, Faculty of Medicine, Debrecen, Hungary, 2University of Debrecen, Doctoral School of Pharmaceutical Sciences, Debrecen, Hungary, 3National Public Health Center, Budapest, Hungary, 4University of Debrecen, Department of Nature Conservation, Zoology and Game Management, Debrecen, Hungary

Background: During winter, Rooks (Corvus frugilegus) gather at a university clinic. Prevalence of ESBL-producing Escherichia coli was investigated in these birds and, in line with the One Health concept, compared them to contemporary human faecal and clinical isolates.

Materials/methods: During the winter of 2016-2017, cloacal swabs from 112 live-captured Rooks together with all 2455 contemporary human faecal samples sent for culture were examined for asymptomatic carriage of ESBL-producers. The isolates found were compared to 42 ESBL-producing E. coli from infections of contemporary inpatients. Resistance genes bla_SHV and bla_CTX-M were identified by sequencing. E. coli phylogroups and the ST131 clonal lineage were detected by PCR. Clonal relatedness was analyzed by pulse field gel electrophoresis.

Results: From Rook samples 43 (38%) and from human faecal samples 42 (2%) ESBL-producing E. coli were isolated. In Rook isolates the bla_CTX-M-55 was dominant (16/43) followed by bla_CTX-M-27 (13/43), while bla_CTX-M-15 was most prevalent in human clinical (18/42) and faecal isolates (20/42) followed by bla_CTX-M-27 (13/42 and 10/42, respectively). Of the isolates carried by birds and humans 56% and 68% belonged to commensal E. coli phylogroups (A, B1, C, E), respectively, while 74% of the clinical isolates belonged to phylogroup B2. Two, ten and 15 of Rook, human faecal and clinical isolates belonged to ST131 C1-M27 clade, while none, one and ten isolates belonged to ST131 C2 clade, respectively. Human clinical and faecal isolates clustered frequently together but Rook isolates tended to cluster separately. A cluster of ten human clinical and eight faecal isolates belonged to the ST131 pandemic clonal lineage; this cluster also contained the two Rook isolates from the ST131 C1-M27 clade. A small cluster consisted of three clinical, one faecal and one bird isolates; another cluster dominated by Rook isolates also contained one human faecal isolate.

Conclusions: Rooks are significant reservoirs of ESBL-producing E. coli and carry isolates of the pandemic clone ST131. However, ESBL genes and pulsotypes were shared infrequently between Rook- and human-derived isolates, suggesting that Rooks are important as reservoirs and potential long-distance vectors of resistant bacteria and resistance genes rather than as direct sources of human infections.

Improvements in HIV-1 transmitted drug resistance surveillance in Ireland

Martha Neary1*, Melissa Brady1, Joanne Moran1, Jeff Connell1, Suzie Coughlan1, Sarah Doyle1, Orla Ennis4, Fionnuala Cooney4, Nick Eichler4, Shay Keating5, Caroline Hurley6, Erin Nugent7, Siobhan O’dea8, Lysander Preston9, Helen Tuite10, Fiona Lyons11, Kate O’donnell2, Derval Igoe2, Cillian Degascun12

1UCD National Virus Reference Laboratory, Dublin, Ireland, 2Health Protection Surveillance Centre (HPSC), Dublin, Ireland, 3Department of Public Health, HSE Southeast, Dublin, Ireland, 4Department of Public Health, HSE East, Dublin, Ireland, 5Society for the Study of Sexually Transmitted Diseases in Ireland, Dublin, Ireland, 6Sexual Health and Crisis Pregnancy Programme, Dublin, Ireland, 7HIV Ireland, Dublin, Ireland, 8Gay Men's Health Service, Dublin, Ireland, 9Positive Now, Dublin, Ireland, 10Galway University Hospital, Galway, Ireland, 11St. James’s Hospital, Dublin, Ireland, 12UCD National Virus Reference Laboratory, Dublin, Ireland

Background: HIV is of global public health concern and a priority European Centre for Disease Prevention and Control (ECDC) pathogen for molecular surveillance. This is imperative to reduce the risk of treatment failure at both an individual and population level. Trends in HIV transmitted drug resistance (TDR) can inform national treatment guidelines and contribute to Europe-wide surveillance.

Materials/methods: In 2017 and 2018, case-based, de-identified HIV epidemiological data on all newly notified HIV cases from the Computerised Infectious Diseases Reporting (CIDR) system were linked to antiviral resistance data generated by Sanger sequencing. Drug resistant mutations (DRM) were identified using the WHO 2009 surveillance DRM list for 2017, and the ECDC recommended DRM protocol for 2018.

Results: Sequencing was performed in 58% (n=283) of HIV diagnoses in 2017 and in 51% (n=266) in 2018. In the remainder, sequencing was not performed due to low viral load, a consequence of being on treatment at time of first diagnosis in Ireland. Of those sequenced, exposure to prior antiretroviral therapy could be determined for 73% in 2017 and 81% in 2018. TDR prevalence to any drug class was 8.6% in 2017 and 19.1% in 2018.

Non-nucleoside reverse transcriptase inhibitor (NNRTI) resistance (7.5% & 15.5%) was significantly higher than nucleoside reverse transcriptase inhibitor (NRTI) resistance (1.1% & 2.1%) and protease inhibitor (PI) resistance (1.6% & 3.1%) for both study years. Integrase inhibitor (INI) resistance (1.6%) was identified by the ECDC protocol in 2018 only. TDR rates increased across all patient groups.

Conclusions: The increased TDR rate observed in 2018 was mainly due to changes in DRM identification, but requires close monitoring, as the introduction of next-generation sequencing and enhanced TDR surveillance may increase rates further. Comprehensive surveillance of TDR in HIV remains a public health priority in Ireland.

Abstract 6532

**Comparison of native and a new recombinant fusion protein (AgB8/1+AgB8/2+Ag5) for serological diagnosis of cystic echinococcosis**

Fatma Bilgic*1, Derya Dirim Erdogan1, Cumhur Gunduz1, Eylum Akdur Ozturk2, Metin Korkmaz2

1Izmir Katip Celebi University, Faculty of Medicine, Department of Microbiology, Izmir, Turkey, 2Ege University, Faculty of Medicine, Department of Parasitology, Izmir, Turkey

**Background:** Cystic echinococcosis (CE) is one of the most common helminthic infections and is caused by larvae of the tapeworm *Echinococcus granulosus*. Diagnosis and monitoring CE is based on imaging and serologic methods. In our study, recombinant fusion protein (Ag5+AgB8/1+AgB8/2) consisting of AgB8/1, AgB8/2 and Ag5, all of which having a high sensitivity and specificity, was compared to cyst fluid using total Immunoglobulin G (IgG) ELISA test. Also, the usefulness of the recombinant fusion protein in the diagnosis and follow-up of CE patients was investigated.

**Materials/methods:** Two hundred fifty two patient sera belonging to 182 CE patients whose diagnoses were confirmed radiologically, serologically and/or surgically were tested. Together with 252 CE sera, 160 patient sera from individuals who received a positive clinical, serologic or parasitological diagnosis with regards to other parasitic infections such as alveolar echinococcosis (AE), fascioliasis, toxocariasis, toxoplasmosis, visceral leishmaniasis, and trichinellosis were also tested. Finally, 30 serum samples from healthy individuals were tested bringing the total number of tested serum samples to 442.

**Results:** The sensitivity of cyst fluid and recombinant antigen tested by ELISA were 86.5% and 29.3%, respectively, whereas, the specificity of cyst fluid and recombinant antigen were 82.6% and 94.2%, respectively. Cyst fluid ELISA showed low percentage of positivity in patients with inactive cyst stage (CE4-CE5). However, before treatment or in patients with post-operative relapse seropositivity was higher compared to those who were cured after treatment. In recombinant antigen ELISA no significant difference was found between cyst stages (P=0.085), however, significant difference was found between the presence of cyst in the liver and in other organs (P=0.030).

**Conclusions:** Fusion protein consists of promising antigens in the diagnosis and follow-up of CE patients, contrary to expectations, it was found to have low sensitivity and seropositivity rates. It was thought that studies using wider serum panel must be carried out to investigate the reasons of the low diagnostic performance of the antigen and to make necessary adjustments.

Abstract 6535

**Biochemical description of seven putative novel species of the genus Yersinia identified by core-genome multilocus sequence typing (cgMLST)**

Hilde Angermeyer*1,2, Anne-Sophie Le Guern2, Sylvie Bremont2, Cyril Savin2, Javier Pizarro-Cerda2

1European Programme for Public Health Microbiology (EUPHEM), European Centre for Disease Prevention and Control (ECDC), Solna, Sweden, 2Yersinia Research Unit and National Reference Laboratory, Institut Pasteur, Paris, France

**Background:** A phylogenetic analysis based on cgMLST of the genomes of 238 strains belonging to 18 Yersinia species performed by the French National Reference Laboratory evidenced seven putative novel Yersinia species being mainly derived from human stool samples (91.7%) besides veterinary (4.2%), environmental (1.4%), alimentary (0.7%) or undefined source of origin (2.0%): Y. frederiksenii 2 and 3, Y. kristensenii 2 and 3 as well as Y. new 2, 3 and 4 with the last two species clustering phylogenetically at the root of the Y. enterocolitica strains. We aimed in this study for a biochemical characterization of these species to better distinguish them phenotypically from the disease-causing Yersinia strains for a first estimation of their pathogenic potential.

**Materials/methods:** We performed O-serotyping and biochemical tests to obtain the phenotypical characteristics of the putative new Yersinia species. The results were compared to the characteristics of the already described Yersinia species. The significance of the observed biochemical patterns was tested via Fisher’s exact test. The strains of the putative novel species were highly variable in sample size: Yersinia new 2 (n=2), Y. new 3 (n=3), Y. new 4 (n=35), Y. frederiksenii 2 (n=11), Y. frederiksenii 3 (n=62), Y. kristensenii 2 (n=5), Y. kristensenii 3 (n=6).

**Results:** The new Y. kristensenii species showed differential characteristics in D-arabitol (p≤0.0109), indole (p≤0.0311), L-fucose (p≤0.0411), lipase (p≤0.0137), gluconate and 5-colo-gluconate (p=0.0049). Within the new Y. frederiksenii species lipase (p<0.0001) and citrate (p≤0.002) varied. Strains of Y. new 4 differed in Voges-Proskauer (p=0.0019), L-fucose (p=0.0183) and D-arabitol (p=0.0071). They were strongly associated with the O:10,34 serotype. Sample sizes of the species Y. new 2 and 3 were too low to determine significant characteristics. However, Y. new 2 was found to be negative for pyrazinamidase-activity which is usually associated with virulence in Yersinia.

**Conclusions:** Biochemical characteristics were successfully applied to discriminate the putative novel Yersinia species, as strong phenotypical associations were found. However, the low number of strains in some species requires larger studies. As a next step, the association of the species with epidemiological and clinical characteristics will be evaluated via descriptive analysis to further assess their pathogenic potential.

Evaluation of a sub-culturing solution directly from manual blood cultures in low-resource settings

Alessandra Natale1, Saoussen Oueslati2, Sien Ombelet3, Jean-Baptiste Ronat1, Olivier Vandenbergh4, Thierry Naas2, Jan Jacobs3

1 Médecins Sans Frontières, Paris, France, 2 Hospital Le Kremlin-Bicêtre, Paris, France, 3 Institute of Tropical Medicine, Antwerp, Belgium, 4 LHUB - ULB, Pôle Hospitalier Universitaire de Bruxelles (PHUB), Brussels, Belgium

**Background:** The Mini-Lab is a Médecins Sans Frontières project for the development of an all-in-one basic clinical bacteriology laboratory deployable in low-resource settings. In a previous laboratory evaluation study, the manual bi-phasic blood culture bottles (Autobio Diagnostics Co., Zhengzhou, China) chosen to be integrated in the Mini-Lab prototype for field-testing, showed insufficient growth on agar slant for downstream analyses; hence the need for a sub-culturing solution. The InTray® systems (Biomed Diagnostics Inc, OR, United States) were chosen for their ready-to-use compact format, the choice of media available and their 12 months shelf-life.

**Materials/methods:** Following a proof-of-concept study, the InTray® Müller-Hinton (MH) chocolate agar was chosen. In this study, this media was further tested against standard agar media (PolyViteX, bioMérieux) in two different settings: (1) In the clinical bacteriology laboratory of the Bicêtre Hospital (Paris), adult and paediatric blood culture bottles (BCBs) (BacT/ALERT, bioMerieux) were sub-cultured after positivity indicated by the automate and (2) at the Institute of Tropical Medicine in Antwerp, Belgium, Autobio bi-phasic and BacT/ALERT BCBs spiked with 2 mL of human blood (paediatric formulation) and clinical samples from low-resource settings (LRS) were sub-cultured after overnight incubation.

**Results:** Out of 70 BacT/ALERT positive BCBs sub-cultured (n=65 adults and n=5 paediatrics), InTray MH chocolate agar showed growth in 97% (n=68) with 100% agreement with standard media. Time to detection (TTD) was <20h in 97% of positives. When BCBs were spiked with LRS clinical samples (n=326), InTray MH chocolate agar showed growth in 96.6% and 99% (vs 100% of standard media) respectively, with a TTD of <24h in 100% of positives. In both settings suboptimal growth was observed when Streptococcus species were incubated in CO2 atmosphere. Presence of lawn (2-1%) as opposed to >10 isolated colonies (54%) on InTrays was probably due to condensation in the cassettes.

**Conclusions:** InTray MH chocolate agar is a valid sub-culturing solution, as it shows good performance after overnight incubation independently of type of BCB used. Elimination of condensation, optimization of the inoculation method, and incubation in air atmosphere to allow growth of most species were recommended.

Accurate identification species of Enterobacter cloacae complex with Acrion system
Jake D’Addiego*1, Jarkko Räbinä2, Soniya Gurung3, Otso Niiranen2, Juha Knuuttila2, Naomi Chant1, Pirjo Wacklin2
1Thermo Fisher Scientific, Basingstoke, United Kingdom, 2Thermo Fisher Scientific, Vantaa, Finland, 3Thermo Fisher Scientific, Basingstoke, United Kingdom

Background: E. cloacae complex is comprised of closely related Enterobacter asburiae, E. cloacae, E. hormaechei, E. kobei, E. ludwigii, and E. roggenkampii species. Discrimination of the species of the complex is challenging in clinical settings and requires molecular methods such as sequencing of the 16S rRNA, rpoB and hsp60 genes.

Species of the E. cloacae complex, especially E. cloacae, E. asburiae and E. hormaechei, are causing severe infections e.g. sepsis, pneumonia and urinary tract infections, in community and nosocomial outbreaks. Recently increase of prevalence of carbapenem resistance in E. cloacae complex species has been reported. Broad-spectrum antibiotic resistance, including the recent emergence of resistance to last-resort carbapenems, has led to increased interest in rapid and accurate identification and resistance detection in these species.

Materials/methods: Novel microbial diagnostic technique, Acrion™ system [Thermo Fisher Scientific] was applied to identification of E. cloacae complex species. Acrion identification and carbapenem resistance [CARBBA] detection is based on high resolution accurate mass spectrometry. Identification and CARBA resistance detection of the strains was compared with sequencing of seven house-keeping and blaKPC, blaNDM and blaOXA-48-like resistance genes as reference methods. The strains were recent clinical isolates or originated from culture collections. The strains were cultivated on agar media and as spiked blood cultures.

Results: Acrion Identification of species of E. cloacae complex from both positive blood cultures and agar media was accordance [96.9%] with the classification results based on sequencing of multiple genes. In addition, carbapenem resistance markers were correctly detected from E. cloacae and E. hormaechei strains. Both sequencing and Acrion showed that several strains from culture collections were originally misidentified, indicating the need for improved identification techniques for E. cloacae complex species.

Conclusions: The Acrion identified strains of E. cloacae complex, E. cloacae, E. asburiae, E. hormaechei, E. kobei, E. ludwigii, and E. roggenkampii correctly with high specificity from both positive blood cultures and isolated colonies. Carbapenem resistance was shown to be successful for the most common pathogens of the complex, E. cloacae and E. hormaechei. These results demonstrate accurate identification of E. cloacae complex species and carbapenem resistance detection with novel Acrion system.

One-year surveillance report of carbapenem- and colistin-resistant Gram-negative bacteria within the MERCyCAT project

Marta Mari Almirall¹, Laura Muñoz¹, Nuria Ferrando¹, Clara Cosgaya Castro¹, Victor Moya¹, Maria Piquet¹, Raul Rodríguez¹, Frederic Ballester¹, Pilar Ciruela Navas²,³, Yuliya Zboromyrska¹, Cristina Pitart¹, Jordi Vila Estape¹, Ignasi Roca*¹

¹ISGlobal-Hospital Clinic, Department of Clinical Microbiology, Barcelona, Spain, ²Hospital Universitari Sant Joan de Reus, Department of Microbiology, Reus, Spain, ³Generalitat de Catalunya, Department of public Health, Barcelona, Spain, *CIBER de Epidemiología y Salud Pública, (CIBERESP), Madrid, Spain

Abstract third-party references: On behalf of the MERCyCAT study group

Background: This study aimed at performing a prospective study to evaluate the prevalence, epidemiology and dissemination of carbapenemase-producing and/or colistin-resistant GNB circulating in hospitals from Catalonia, Spain.

Materials/methods: The first GNB isolate/per patient was collected from 26 participating centers according to inclusion criteria: for Enterobacterales, MICs of >0.125 mg/L to meropenem and/or ertapenem and/or >1 mg/L imipenem, or disk inhibition zones of <25 mm to meropenem and/or ertapenem and/or <23 mm to imipenem; for A. baumannii, MICs of >2 mg/L to meropenem and >1 mg/L imipenem, or inhibition zones of <23 mm to meropenem and imipenem; for P. aeruginosa, MICs of >2 mg/L to meropenem and >4 mg/L imipenem, or inhibition zones of <24 mm to meropenem and <20 mm to imipenem. Species were identified by MALDI-TOF/MS, susceptibility was tested by disk diffusion and broth microdilution. Screening for carbapenemases and their genes was performed by mCIM method and PCR. Genetic relatedness was evaluated by PFGE and MLST.

Results: From January-2018 through May-2019, 118,041 isolates of GNB were reported, of which 0.67% and 0.19% were carbapenem- and colistin-resistant, respectively. E. coli isolates represented 60.8% of the total followed by K. pneumoniae and P. aeruginosa (13.3% and 9.7%), while A. baumannii constituted 0.16% of the total isolates. Among CarbR-isolates K. pneumoniae was predominant (53.6%) followed by P. aeruginosa (21%) and E. coli (11%). ColR-isolates were dominated by P. aeruginosa (46.9%) followed by E. coli (33.8%) and K. pneumoniae (14%). OXA-48 was the most abundant carbapenem-resistant gene (46.1%) and recovered in all hospitals mainly from K. pneumoniae. Among VIM-producers (16.9%) we distinguished the broad distribution of VIM-producing Enterobacterales, in terms of hospitals and species, and that of VIM-producing P. aeruginosa, more clonal and restricted to a few settings. KPC- and NDM-producers (16.7% and 3.5%) were associated with a few K. pneumoniae clones, causing small-sized outbreaks in one or two settings, and with sporadic cases of E. coli isolates due to horizontal-plasmid-transfer. Colistin-resistance was heterogeneous in its epidemiology and distribution.

Conclusions: Carbapenem and colistin resistance in Catalonia is still low but active surveillance should be continued to monitor the spread of major circulating clones.

Unravelling HIV proviral latency by comparing HIV-1 and HIV-2 expression and reactivation with single round, double reporter constructs

Anne Bruggemans*1,2; Gerlinde Vansant2; Zeger Debyser2

1UZ Leuven, Department of Internal Medicine, Leuven, Belgium, 2KU Leuven, Molecular Virology and Gene Therapy, Leuven, Belgium

Abstract third-party references: Fonds Wetenschappelijk Onderzoek Vlaanderen

Background: Antiretroviral treatment does not cure HIV as the virus can persist in reservoirs of latently infected cells. Yet, the mechanisms governing proviral latency remain poorly understood. Like HIV-1, HIV-2 can cause AIDS but clinical data show slower disease progression and lower viremia, while the proviral DNA load is similar, suggesting HIV-2 may be more latent. By comparing HIV-1 and HIV-2 latency in vitro, we hope to learn more about the mechanisms governing HIV expression on a cellular level.

Materials/methods: The OGH double reporter construct contains an LTR driven eGFP gene and a constitutively active EF1a promoter, driving an mKO2 gene (Chavez et al., 2015), allowing detection of both silent and productively infected cells. We cloned the OGH cassette from the existing HIV-1 OGH construct, into an HIV-2 backbone. Next, we infected cell lines (SupT1, Jurkat) and primary cells (peripheral blood mononuclear cells and CD4+ T cells) with these single round HIV-1 and HIV-2 OGH viruses and measured reporter gene expression via flow cytometry, p24 levels in the supernatant and copy number via real-time quantitative PCR. Secondly, cells were treated with latency reactivating agents to measure reactivation.

Results: The fraction of latently infected cells was similar for HIV-1 and HIV-2. Yet HIV-2 median eGFP intensity was higher and over time, remaining HIV-2 expression was seen for higher eGFP intensities, where HIV-1 eGFP expression decreased uniformly. Upon reactivation with tumor necrosis factor alpha (TNFα), HIV-1 reactivated regardless of eGFP expression. HIV-2 was overall less sensitive to reactivation, and reactivated mostly at low eGFP intensity levels.

Conclusions: HIV-1 and HIV-2 have different expression and reactivation patterns. While HIV-2 is less sensitive to reactivation than HIV-1, median expression of eGFP was higher for HIV-2. Possible explanations for these differences include differences in the LTR promoter, Tat/TAR regulation, integration site selection and/or differences in toxicity. We continue to investigate the roles of each of these factors.

Abstract 6544

Differences in nasopharyngeal microbiota composition according to the severity of human rhinovirus infection in the first 1000 days of life

Natalia Timoneda1, Desiré Henares-Bonilla1,2, Raul Cabrera-Rubio1,2, Ana Fernandez2,5, Daniel Penela6,5, Pedro Brotons De Los Reyes1,2, Yolanda Jordan García1,2,6, Alex Mira7, Carmen Muñoz-Almagro1,2,8, Cristian Launes1,2,8

1Centro de Investigacion Biomédica en Red de Epidemiología y Salud Publica (CIBERESP), Instituto de Salud Carlos III, Madrid, Spain, 2Institut de Recerca Sant Joan de Déu, Hospital Sant Joan de Déu, Barcelona, Spain, 3Teagasc Food Research Centre (TEAGASC), Cork, Ireland, 4APC Microbiome Institute, University College Cork, Cork, Ireland, 5Pediatrics Department, Hospital Sant Joan de Déu, Barcelona, Spain, 6Universitat de Barcelona, Barcelona, Spain, 7Fundació per al Foment de la Investigació Sanitària i Biomèdica de la Comunitat Valenciana (FISABIO), València, Spain, 8Universitat Internacional de Catalunya, Barcelona, Spain

Background: Human Rhinovirus infection (HRVi) in early ages ranges from asymptomatic or mildly symptomatic infection to be often the only etiological agent in patients requiring advanced life support in intensive care units (ICU). The underlying determinants that contribute to the varying severity of HRVi are unknown. The objective of this study was to investigate the relationship between bacterial nasopharyngeal microbiota and the severity of HRVi in children <2 years old.

Materials/methods: Triple case-control study with patients <2 years old matched by gender and sex that were attended in Hospital Sant Joan de Déu (Barcelona, Spain) during the period 2014-2019. Cases (Group-A) were patients with severe lower respiratory tract infection (LRTI) associated with HRVi requiring admission to the ICU. A first control group (Group-B) included non-hospitalized patients with banal common cold symptomatology and confirmed HRVi. Healthy children with asymptomatic HRVi were the second control group (Group-C) and healthy children without HRVi were the third control group (Group-D). Nasopharyngeal aspirate samples were collected from participants and the variable V3-V4 region of 16S rRNA gene was analyzed using Illumina-Miseq. HRV was detected by a multiplex real-time PCR (AnyplexII-RV16, Seegene).

Results: Forty specimens from participants allocated to Group-A (n=9), Group-B (n=12), Group-C (n=8), and Group-D (n=11) were analyzed. No major differences between groups were observed in epidemiology variables. Richness values were also similar across groups. However, the diversity of Group-A was significantly lower to that of Group-D (p-value=0.012) and a trend for significance was observed when comparing Group-B vs. Group-D (p-value=0.07). Principal Coordinates Analysis showed a separation between the study groups (Adonis=0.009).

Analysis of the nasopharyngeal microbiota composition using LEfSe revealed that presence of Streptococcus pneumoniae was associated with Group-A, Moraxella genus with both Group-B and Group-C, and Dolosigranulum pigrum and Staphylococcus genus with Group-D. Additionally, all pairwise comparisons showed that Escherichia coli was associated with severe HRVi (Group-A).

Conclusions: The presence of HRV was associated with decreasing nasopharyngeal microbiota diversity. Patients with severe LRTI requiring admission to ICU were characterized by an increased abundance of Streptococcus pneumoniae and Escherichia coli. The absence of HRV was characterized by the presence of Dolosigranulum and Staphylococcus.

Abstract 6551

Sexual behaviour and incidence of sexually-transmitted infections in high-risk men who have sex with men following pre-exposure prophylaxis commencement Sophocles-P4G demonstration study

M. Psichogiou*, Martha Papadopoulou1, Vana Sypsa1, Sotiris Roussos2, Sophocles Chanos3, Nikos Dedes3, George L. Daikos1, John Schneider4, Angelos Hatzakis2

1Laiko General Hospital, National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Athens, Greece, 2Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 3Positive Voice, Athens CheckPoint, Athens, Greece, 4University of Chicago, Public Health Chicago, Chicago, Unit-
ed States

Abstract third-party references: GILEAD SCIENCES INTERNATIONAL, University of Chicago, Public Health Chicago, USA, Laiko General Hospital, National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Positive Voice, Athens CheckPoint, Athens, Greece

Background: Pre-exposure prophylaxis (PrEP) is an important tool to prevent HIV acquisition. Nevertheless, there is an aris-
ing concern that PrEP may result in a high burden of disease related to Sexually Transmitted Infections (STI). Our aim was to
determine the sexual behavior and the incidence of STIs among men who have sex with men (MSM) within the first 1 2 months
following commencement of PrEP.

Materials/methods: Sophocles-P4G, the first pilot PrEP study conducted in Athens, Greece, was designed to identify the
population at highest risk of HIV transmission among the MSM networks who would be eligible for receiving PrEP. Peer-driven
chain-referral was used to reach the population (Respondent-Driven Sampling). In total, 100 high-risk MSM were enrolled and
received daily PrEP for 12 months. Participants were scheduled for six visits every 1-3 months. Diagnosis for STI was based on
serology for syphilis, syndromic diagnosis and management for the other STIs. The number and type of sexual contacts during
PrEP was collected through daily diaries.

Results: From the 100 MSM participants with a mean age (SD) of 33.2 (9.3) years, 74 completed the 12-month study with a
discontinuation rate of 2.5 discontinuations per 100 person-months. At study entry, participants reported a median (25th, 75th)
of 13.3 (7.8, 21.0) sexual contacts per month and of 2.3 (0, 6.8) anal receptive sexual contacts without condom per month.
Sixty-seven per cent reported history of an STI. Following PrEP commencement, no change in the number of sexual contacts
(p=0.167), in the proportion of participants reporting sex without condoms (p=0.405), or in the number of receptive anal sexual
contacts without condom (p=0.935) was identified. During follow up, 36% experienced a new STI with an incidence rate (95% CI)
of 4.15 STIs per 100 person months (2.93, 5.87), while no HIV seroconversion was noted.

Conclusions: PrEP is a precious tool in reducing HIV new infections. Unsafe sex and the risk of STI were high, although no
change was observed during the 1-year PrEP period. These data underline the importance of routine STI screening and the need
of counselling to reduce high risk sexual behavior among PrEP users.

Bone density, microarchitecture and tissue quality after 1 year of treatment with dolutegravir-abacavir-lamivudine

Jade Soldado1, Elisabet Lerma-Chipirraz1, Itziar Arrieta1, Alicia Gonzalez-Mena1, Ignacio Domingo1, Hernando Knobel1, Roberto Güerri Fernandez*1

1Hospital del Mar, Infectious Diseases, Barcelona, Spain

Background: People living with HIV (PLWHIV) suffer a decrease in Bone Mineral Density (BMD), a condition associated with antiretroviral treatment (ART) among other causes. There is little information about other components of bone strength.

Objective: To study the impact of Dolutegravir-Abacavir-Lamivudine-based therapy on bone health parameters—apart from BMD—in ART-naïve individuals with HIV after 48 weeks of treatment.

Materials/methods: Observational, prospective and analytical study of treatment-naïve patients with HIV undergoing a DTG-ABC-3TC-based regimen at 48-week follow-up. A Mann-Whitney U test was performed to evaluate changes in bone strength parameters (bone mineral density, bone microarchitecture and bone tissue quality measure).

Results: 20 naïve HIV individuals starting DTG-ABC-3TC were included. Three patients were withdrawn because of corticosteroid initiation. One individual was lost in the follow-up. After 48-weeks of treatment the median lumbar spine BMD showed a significant decrease from 1.013 g/cm² (IQR 0.964, 1.08) to 1.024 g/cm² (0.951, 1.065) (-2.25%, p=0.007) respectively as well as in femoral neck BMD from 0.835 g/cm² (0.797, 1.023) to 0.81 g/cm² (0.778, 1.006) (-4.1%, p=0.03). Bone microarchitecture, as measured by TBS, decreased from 1.359 (1.334, 1.371) to 1.321 (1.318, 1.329) (-2.5%, p=0.03). In contrast, bone quality measured by microindentation was significantly higher with respect to baseline [84 (82.75, 90) to 91.5 (87 , 94); +6.53%, p<0.001]. This result was indicative of improved bone material properties after the initiation of treatment (Figure 1). No significant changes were found in bone turnover markers. We did however find a significant decrease of -73% (p=0.02) in inflammation, as measured by an unspecified marker erythrocyte sedimentation rate (ESR). In addition, a positive significant correlation between CD4/CD8 ratio at baseline and changes in BMSi after 48 weeks of treatment was observed [Spearman's Rho=0.4974, p=0.04]

Conclusions: After a 48-week treatment with DTG-ABC-3TC-based ART, BMD and TBS decreased while bone tissue quality, as measured by microindentation, improved significantly. The state of the immune system—how balanced it is before infection, that is—seems to impact bone quality recovery. An overarching approach to assess bone toxicity in ART-treated patients is needed

Flat lining of nine-year deaths rate throughout various carbapenem-resistant Gram-negative outbreaks at Saint George Hospital, Lebanon

Amanda Chamieh1,2, Omar Zmerli1, Sanaa Saliba1,3, Claude Afif1, George Juvelekian1,4, Jean-Marc Rolain2, Eid Azar2

1Saint George Hospital, Infectious Disease Department, Antimicrobial Stewardship, Beirut, Lebanon, 2Aix-Marseille University, Marseille, France, 3Saint George University Hospital, Saint George University Hospital, Bayrut, Lebanon, 4Saint George Hospital, Pulmonary and Critical Care Department, Beirut, Lebanon

Background: Infamous reports attributing exceedingly high rates of mortality to antimicrobial resistance have been circulating for the past few years. Clear evidence is missing, probably due to the diverse consensus concerning attributable mortality and the difficulty of accurately gathering harmonious antimicrobial resistance data.

Materials/methods: We look at the rates of mortality and antimicrobial resistance from Jan 1, 2010 - Dec 31, 2018, at the 333-bed tertiary care center Saint George Hospital (SGH) in Beirut to understand the local and regional reality of the situation. We retrieved from our electronic antimicrobial stewardship database [ASP] the yearly number of: total deaths in the hospital and the Intensive Care Unit (ICU) - deduplicated top four isolated organisms resistant to carbapenems: Acinetobacter baumanii (Ab), Escherichia coli (Eco), Klebsiella pneumonia (Kp), and Pseudomonas aeruginosa (Pae) - Hospital (HD) and ICU (ID) Days. Rates were expressed as number/1000 days. Time series analysis (TSA) was used. No patient records accessed.

Results: A total of 642,564 HD, 27,307 ID and 2,886 isolates included throughout the study. No significant yearly variation in HD and ID. In 2010, we had 4.2 deaths/1000 HD, staying flat until 2018 at 4.4 deaths/1000 HD. The highest mortality reported in 2012 at 5.17 deaths/1000 HD [Figure 1]. No trend detected by TSA. Despite variations ranging from 34 deaths/1000 ID in 2010 dropping to 25 deaths/1000 ID in 2018, no significant trend was detected as well. Ab started at 0.74/1000 HD in 2010, peaked at 3.2/1000 HD in 2014-2015 during an outbreak and then significantly dropped to 0.98/1000 HD in 2018 after ASP implemented carbapenem sparing and colistin monotherapy strategies in 2016. As for Eco and Kp, both significantly trend upwards 2 and 3-fold starting 2016, reaching 0.48/1000 HD and 0.94/1000 HD, respectively. Pae had no signification variations throughout the study period, ranging from 1.44/1000 HD in 2010 to 1.78/1000 HD in 2018. No correlation between isolation densities of multidrug-resistant isolates and mortality by TSA.

Conclusions: The 9-year, flat death rate hospital wide and in the ICU, despite the witnessed multidrug-resistant outbreaks, and the lack of existing correlations indicate a so far independent relationship. Real-time factual data is needed to provide a balanced, solid ground and relieve the anxiety of antimicrobial resistance.
**Abstract 6554**

**Antimicrobial resistance among urinary Enterobacteriaceae from patient living in nursing homes**

Sonia Thibaut*,1, Thomas Coeffic1, David Boutoille1, Gabriel Birgand1, Jocelyne Caillon2, Primo Network1

1 Cpias Pays de la Loire, Nantes, France, 2 CHU de Nantes, Nantes, France

**Background:** Urinary tract infections are common problems in patient living in nursing home and important reason for consulting physicians, resulting in substantial financial burden to community. There are few data on resistance surveillance among these patients. So the PRIMO national reference center under the supervision of Public Health France follows the antimicrobial resistance of Enterobacteriaceae in nursing homes (NH). This surveillance is based on the e-tool MedQual-Ville, allowing the prospective collection of antibiotic patterns from strains isolated within a network of microbiology laboratories (ML).

**Materials/methods:** All the urinary Enterobacteriaceae strains isolated in these laboratories, from January 2018 to December 2018, were included in the investigation. All patients from private hospitals and emergency departments were excluded. Distribution of bacterial species and study of antibiotic resistance for fosfomycin (FOS), nitrofurantoine (NF), cotrimoxazole (SXT), mecillinam (MEC), 3rd generation cephalosporins (3GC). Exact Chi2 and Fischer tests were applied.

**Results:** In 2018, 421353 antibiograms performed on urinary Enterobacteriaceae strains were provided by the 742 ML across 11 French regions, of which 15896 (3.8%) were isolated from resident in NH. Escherichia coli was the majority bacterial species (86.3%, n=13720), followed by Klebsiella pneumoniae (9.2%, n=1459) and 1.9% of Enterobacter cloacae complex (n=304). Other Enterobacteriaceae isolates accounted for 2.6%. Less than 2.0% of E. coli strains were resistant to NF (1.0%) and FOS (1.8%). 10.6% of E. coli was resistant to MEC, 22.6% to SXT and 8.6% to 3GC. Klebsiella pneumoniae strains were significantly more resistant to antibiotics compared to E. coli strains (23.6% to NF, 19.1% to FOS, 41.3% to MEC, 19.8% to SXT and 21.2% to 3GC; p<0.001 for all antibiotics instead for SXT p=0.024). The overall proportion of ESBL-producing E. coli was 7.7%, significantly lower than for K. pneumoniae (18.8%, p<0.001).

**Conclusions:** The proportion of urinary strains resistant to 3GC isolated from resident living in nursing home was higher than urinary strains among primary care patients. For the French national survey PRIMO, it is planned to compare these results with those observed in medico social structures from 2019.

Streptococcus pneumoniae: serotype distribution in adults with invasive disease after 8 years of systematic vaccination of children with PCV13

Pedro Miguel Juiz González1, Susana Mendez Lage1, Natividad Somaza Serantes1, Isabel Losada2, María Rodríguez Mayo3, Gema Barbeito4, Francisco Vidal Vidal5, Isabel Paz Vidal6, Fernando García Garrote7, Victoria Pulián Moráis8, Marta Serrano López9, Javier Alba10, Pedro Alonso Alonso11, Irene Rodríguez Conde12, Jose Andres Agulla Budiño1

1Hospital Arquitecto Marcide, Ferrol, Spain, 2Conselleria de Sanidade, Santiago de Compostela, Spain, 3Complexo Hospitalario Universitario da Coruña, A Coruña, Spain, 4Complexo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain, 5Hospital Universitario Álvaro Cunqueiro, Vigo, Spain, 6Complexo Hospitalario Universitario de Ourense, Ourense, Spain, 7Hospital Universitario Lucas Augusti, Lugo, Spain, 8Complexo Hospitalario Universitario de Pontevedra, Pontevedra, Spain, 9Hospital de Costa Burela, Burela, Spain, 10Hospital do Barco de Valdeorras, O Barco de Valdeorras, Spain, 11Hospital Comarcal de Monforte de Lemos, Monforte de Lemos, Spain, 12Hospital POVISA, Vigo, Spain

Background: Vaccination against Streptococcus pneumoniae with polysaccharidic 23-valent antipneumococcal vaccine (PPSV23) was authorized in 2000 in Galicia (Spain) for ≥65 years-old belonging to risk groups. In 2001 vaccination with antipneumococcal 7-valent conjugated vaccine (PCV7) was authorized for children in risk groups. In 2011, systematic vaccination in children with antipneumococcal 13-valent conjugated vaccine [PCV13] was established. The aim of this study is to analyze the behavior of PCV13 and PPSV23 serotypes through the study period.

Materials/methods: Every invasive pneumococcal disease (IPD)-causing isolate in adults was collected from sterile bodily fluids (2088 samples) between 2011 and 2018. Serotyping was performed by latex agglutination and Quellung reaction (Statens Serum Institut latex/antisera, Copenhagen, Denmark). Incidences were described in cases/100,000 inhabitants.

Results: IPD incidence has increased from 10.69 in 2011 to 15.55 in 2018. PCV13 incidence has decreased from 6.70 to 2.72, but non-PCV13/PPSV23 has increased from 1.83 to 8.43.

Regarding to PCV13/non-PCV7, serotype 3 has maintained its incidence, and serotypes 19A and 7F have decreased drastically. 1, 5 and 6A weren’t almost present from the beginning of the study. PCV7 were also less present, except 14 and 4, which decreased.

For PPSV23/non-PCV13, 12F, 9N and 22F have increased, and specially serotype 8, becoming the most prevalent in 2018 (29.72% of all cases). Data are shown in table below.

Conclusions: After 8 years of systematic children vaccination with PCV13, IPD incidence in adults has increased, but PCV13-related IPD has decreased substantially.

There’s been an increase in the PPSV23 serotypes not included in PCV13, specially serotype 8, the most prevalent in 2018.

Abstract 6556

**Saccharomyces cerevisiae fungaemia: a 10-year review in the CHU of Liege (Belgium)**

Coumba Diop*, Julie Descy, Cécile Meex, Rosalie Sacheli, Marie-Pierre Hayette

1Chu De Liège, Liège, Belgium

**Background:** *Saccharomyces cerevisiae* is a yeast which has been used for decades mainly as probiotic in the medical field. For a long time, it was considered as safe and non-pathogenic but recently, the number of infections caused by this yeast has been rising particularly in immunocompromised patients. This study presents a review of cases of deep infection caused by *S. cerevisiae* during the last 10 years including the clinical relevance and therapeutic management.

**Materials/methods:** The systemic infections due to *Saccharomyces cerevisiae* that occurred at the University Hospital of Liege from January 2000 to January 2019 were reviewed by using the Glims laboratory database. The minimal inhibitory concentrations (MICs) obtained by microdilution with Sensititre YeastOne YO10 test (Trek, USA) was compared to the therapeutic management applied.

**Results:** During this period, from 2016 to 2019, 11 patients were diagnosed with fungemia due to *S. cerevisiae*. All the systemic infections occurred in patients presenting one or multiple risk factors: 4 out of 11 were oncologic patients upon chemotherapy, corticoids or radiotherapy, 3 were under Enterol® and 9 patients received broad-spectrum antibiotics prior to fungemia. Only 3 patients who were immunocompromised had multiple positive blood cultures (9, 5 and 3 respectively) contrary to the others, which had only one positive bottle. High MIC values were obtained for fluconazole (4-256 µg/mL), while MICs for amphotericin B were low (0.002-2 µg/mL). Among the 11 patients, 4 were treated with fluconazole, 2 with Amphotericin B and 5 only by catheter removal. All had a favorable outcome, except 2 oncologic patients who were under fluconazole (MIC = 8 µg/mL) and one who wasn’t treated due to her critical state.

**Conclusions:** The last 3 years, we noticed the emergence of blood infections caused by this yeast. They progressed into invasive conditions only in immunocompromised patients, who had been directly in contact with Enterol® or indirectly by caregivers. Therefore, it is necessary to limit the contact of fragile patients with probiotics containing the yeast. About the treatment, Amphotericin B seems to be the best option but due to its toxicity, fluconazole is preferably used, the outcome depending on the case.

**Presenter email address:** csdiop@chuliege.be
Background: Section Flavi within genus *Aspergillus* includes a large number of species that may behave as opportunistic pathogens in humans or animals and/or may produce mycotoxins. Morphological similarities between Flavi section members make precise identification difficult. In this study, we present data on antifungal susceptibility profile of molecularly characterized French clinical isolates of Flavi section.

Materials/methods: Sixty-one isolates, phenotypically identified as *A. flavus*, were included in the study. These clinical isolates were recovered over a 15-year period (2001-2015). For all isolates, specific identification was confirmed by sequencing a part of the β-tubulin and calmodulin genes. The isolates were first screened for their susceptibility to azoles antifungal agents by using 3-sectors agar plates containing itraconazole, voriconazole and a drug-free control. Susceptibility to 8 antifungal drugs was further determined by using EUCAST reference microdilution broth technique.

Results: Out of 61 isolates, molecular analysis of the partial β-tubulin and calmodulin sequences showed that 59 isolates were *A. flavus sensu stricto* and one isolate each was *A. parasiticus* and *A. nomius*. One isolate was azole-resistant by the screening test. The geometric mean MIC values (range) of amphotericin B, itraconazole, voriconazole, posaconazole, isavuconazole, caspofungin, micafungin, and anidulafungin were 3.32 (1-16), 0.36 (0.1-25-2), 1.02 (0.5-8), 0.4 (0.1-25-1), 1.26 (0.25-8), 0.066 (0.03-0.125), 0.016 (0.016-0.03), 0.017 (0.016-0.03) µg/mL for the *A. flavus sensu stricto*. For *A. parasiticus* and *A. nomius*, MICs were in the same range. Only one *A. flavus sensu stricto* isolate had voriconazole and isavuconazole MICs at 8 µg/mL.

Conclusions: Antifungal susceptibility to 8 drugs was determined on a large collection of clinical isolates belonging to *Aspergillus* Flavi section. Most of the isolates were identified as *A. flavus sensu stricto* and most of them were susceptible to antifungal drugs. Nevertheless, the occurrence of one resistant isolate highlights the need for susceptibility testing for any *Aspergillus* section.

Abstract 6558

Monocyte progenitors are effector cells in mycobacterial infections
Anne Loesslein1, Philipp Henneke*1

1University Medical Center Freiburg, Freiburg, Germany

Background: Mycobacterial tissue infections are characterized by formation of granulomas harboring a unique macrophage species, so-called multinucleated giant cells (MGC). The presence of MGC in the tissue has been associated with mycobacterial containment and immunocompetence. In order to identify cellular biomarkers for the immunological state in *M. tuberculosis* infections, we embarked on defining the hitherto unknown MGC progenitors.

Materials/methods: 1) An in vitro system for glycolipid-induced MGC formation to analyze MGC forming properties (transcriptome, metabolome, function) in macrophage progenitors isolated from mouse bone marrow; 2) Mouse models of *M. tuberculosis* lung infection and BCG liver granuloma; 3) Cell transfer in vivo.

Results: We found the common monocyte progenitor (cMoP) to have the highest potential to form MGC in response to mycobacterial glycolipids or whole mycobacteria. Moreover, mycobacteria induced robust formation of TNFα and nitric oxide in cMoP. Transcriptome analysis revealed a sustained synthesis and accumulation of cholesterol and fatty acid metabolism in cMoP undergoing transformation into MGC. Oxidation and depletion of cholesterol decreased MGC formation by >70%, but not cytokine formation in cMoP. Thus, the observed changes in lipid metabolism were a specific prerequisite for the MGC transformation program. In *M. tuberculosis* lung infection and in a BCG liver granuloma model, we identified a new c-kit-low cMoP descendent, which we denominated induced monocyte progenitor (iMoP), to circulate in the blood at significantly higher frequency (> 0.6% of CD45-pos. cells) than in controls (< 0.2%). By adoptive transfer we found iMoP to differentiate in vivo and preferentially localize to mycobacterial granulomas, i.e. > 75% of transferred cells reaching the liver were granuloma associated in BCG model.

Conclusions: A novel macrophage progenitor denominated iMoP circulates in the peripheral blood during mycobacterial infections and may seed MGC in the infected tissue. iMoPs exhibit a specific metabolic program that underlies their MGC forming properties. iMoPs are likely to contribute to mycobacterial immunity and may serve as cellular biomarkers in the future.

Abstract 6560

MRSA from skin and soft tissue infections in Poland
Monika Orczykowska-Kotyna1, Dorota Żabicka1, Anna Skoczyńska1, Joanna Empel1

1National Medicines Institute, Warsaw, Poland

Background: The aim of this study was to examine the antimicrobial resistance and genetic diversity of Polish methicillin-resistant S. aureus (MRSA) from skin and soft tissue infections (SSTIs).

Materials/methods: 213 MRSA isolates, collected between 2013-2014 in 28 Polish hospitals were assigned to MLST-CC based on spa-typing and MLST analysis. MRSA, MLSB phenotypes and MICs of selected antimicrobials were determined according to the EUCAST guidelines. Presence of selected virulence and resistance genes was tested by PCR.

Results: Isolates were classified to 11 clonal complexes (CCs) with predominant, comprised over 80.0% of the isolates, CC59/ST338 (27.2%), CC5 (26.8%), CC30 (16.9%) and CC8 (12.2%). Amongst isolates, 62.0% were assigned to HA-MRSA and 32.0% to CA-MRSA. CA-MRSA isolates were significantly more predominant in children in comparison to older population (90.0% vs. 26.3%, p<0.0001). The PVL coding genes and ACME element were identified in CA-MRSA clones exclusively [pvl genes in ST338-V(5C2&5), ST8-IVa and ST30-IVc, while the ACME in ST8-IVa].

Only 7.0% isolates were susceptible to all antibiotics tested with the exception of β-lactams. Resistance in vitro to erythromycin, clindamycin, ciprofloxacin, tetracycline, doxycycline and gentamicin was found in 83.1%, 72.8%, 67.1%, 33.3%, 17.4% and 14.6% of isolates, respectively. Amongst erythromycin-resistant isolates, 87.6%, 9.0% and 3.4% represented cMLSb, iMLSb, and MSb phenotype, respectively. cMLSb phenotype was prevalent amongst isolates from CC30 (94.4%), CC5 (89.5%), and CC59/ST338 (84.4%).

Forty-six resistance profiles were identified. The most frequent OX-ERY-CLI-CIP (34.2%) comprised mainly CC5 (53.4%) and CC30 (39.7%) isolates, while the second ERY-CLI-CIP-SXT-TE-DK-MIN-GEN (8.9%) - exclusively CC59/ST338.

Resistance to erythromycin was mediated by single ermA gene (CC5, CC8, CCB/239 and CC30), ermC (CC1, CC8, CC22, CC45, CC97 and CC398), or both (CC30), and ermB gene (CC59). Tetracycline resistance was associated with tetK (69.0%), tetM (4.2%), tetL (2.8%) genes; both of the tetK and tetM genes (22.5%) were found mainly in CCB/239. All gentamicin resistant isolates carried aacA-aphD gene.

Conclusions: The present study revealed considerable heterogeneity of MRSA clones from SSTIs in Poland with predominance of ST338-V(5C2&5) clone. Different S. aureus clones causing SSTIs were associated with specific antimicrobial resistance and virulence gene profiles.

**Investigation of increased prevalence of IMP carbapenemases by next-generation sequencing in Wales**  
Mandy Wootton*1, Massimo Mentasti1, Kerry Prime1, Swati Khan1, Kirsty Sands1, Joanne Watkins1, Sally Corden1, Thomas R. Connor2, Lim Jones3

1University Hospital of Wales, Specialist Antimicrobial Chemotherapy Unit, Public Health Wales, Cardiff, United Kingdom, 2Cardiff University, Cardiff, United Kingdom, 3University Hospital of Wales, Pathogen Genomics Unit, Public Health Wales, Cardiff, United Kingdom

**Background:** Carbapenemase producing Enterobacterales [CPE] cause serious infections and outbreaks which are increasingly difficult to treat. In Europe NDM/KPC/OXA-48 are the most common, whilst IMP/VIM are isolated less frequently. In Wales, 17 IMP producing CPE were isolated in five different hospitals between 2017-2019, compared to six between 2008-2016. The isolates were analysed by NGS to characterise resistance markers and sequence type (ST).

**Materials/methods:** DNA was extracted using eMAG (Biomerieux), libraries prepared using Nextera XT and sequenced using the V2 assay on the MiSeq sequencers (Illumina). Assemblies were run through Resfinder to determine resistance markers and MLST to establish the MLST.

**Results:** IMP-4 and IMP-70 were the two identified variants. At Hospital A, five *K. pneumoniae* ST20 were epidemiologically linked (EL). At hospital B, two *E. coli* ST224 were EL and also contained KPC-2. All isolates were resistant to ertapenem, while a significant number were susceptible to imipenem and meropenem (Table). In 3 other hospitals 2x and 1x ECL containing IMP-4 and 1x K/O with IMP-70 were found. A variety of other beta-lactamases (AmpC/ESBL), aminoglycoside modifying enzymes and in ST 20 *K. pneumoniae* isolates, a mcr-9 gene. These tested colistin susceptible, although inducible resistance (ICR) is associated with this gene, analysis did not suggest the putative regulatory genes needed for ICR were present.

**Conclusions:** IMP incidence have increased over the last 3yrs in Wales, however many isolates remain susceptible to IMI and MER. Only two IMP variants out of the 80+ so far described were identified. ST analysis showed spread of IMP+ CPE between different patients. KPC was also found in two EL isolates.

Abstract 6563

**Mycobacterium mucogenicum in hospital water: a potential source for human infection**

Jerome Ory*, Claire Aumeran†, Ousmane Traore‡, Emmanuel Lecorche§, Cécilia Enault∥, Emmanuelle Cambau∥, Jean Philippe Lavigne*, Alix Pantel*

†CHU de Nîmes, Nîmes, France, ‡CHU de Clermont-Ferrand, Clermont-Ferrand, France, ∥APHP, Paris, France

**Background:** Non tuberculous mycobacteria (NTM) are a major cause of opportunistic infections. *Mycobacterium mucogenicum* is a rapidly growing mycobacteria, rarely but increasingly involved in infections, especially in immunocompromised patients.

The objectives of the study were to describe an outbreak of *M. mucogenicum* catheter-related bloodstream infections and investigate the potential environmental reservoir of this NTM.

**Materials/methods:** In 2018, patients diagnosed with NTM bacteremia by conventional bacteriological cultures (BACTEC™ FX, BD) were included. Identification was performed by mass spectrometry (Vitek MS, bioMérieux), 16S rRNA and rpoB genes sequencing. Clinical data were recorded from electronic clinical charts. Physicochemical and microbiology parameters were analyzed in the water of the hospital network during several sampling campaign. The presence of NTM was investigated by a membrane filtration (0.45 µm) followed by culture on Middlebrook 7H10 Agar.

**Results:** From Mars to November 2018, four patients were diagnosed with NTM catheter-related bloodstream infections. All patients were immunocompromised and hospitalized in the Oncology Unit. The species identified was *M. mucogenicum*. In this Unit, this NTM was also isolated from several water sources including tap water from sinks and showerheads in rooms patients (1-150 UFC/100 mL). However, *M. mucogenicum* was not found in the city water supplied to the hospital. Levels of chlorine in the water were intermittently low (<0.3 mg/l) and may have contributed towards bacterial growth. Corrective actions have been implemented: self-purging, UV and heat shock disinfection. No other cases have been identified since this period.

**Conclusions:** The cause of the *M. mucogenicum* outbreak seemed to be the water contamination of central venous catheter during bathing. Environmental survey and corrective actions allowed to control the outbreak. This study underlined the major role of the investigation of environmental sources, especially water supply, in NTM outbreaks.

**Abstract 6565**

**Inhibition of metabolic signalling pathways controls inflammatory tissue destruction in tuberculosis**

Radha Mukul Asher*, Jon S. Friedland

1Imperial College London, London, United Kingdom, 2St George’s, University of London, London, United Kingdom

**Background:** Tuberculosis (TB) is a global infectious threat, complicated by rising drug resistance. The clinical manifestations of TB are due to severe inflammatory tissue destruction driven by pro-inflammatory cytokines and matrix metalloproteinase (MMP) enzymes. Patients also experience profound metabolic changes, notably weight loss. TB-infected macrophages demonstrate the Warburg effect, a metabolic shift from oxidative phosphorylation to aerobic glycolysis. However, little is known about metabolic control of inflammatory tissue damage in TB.

**Materials/methods:** Primary monocyte-derived macrophages (MDM) or normal human bronchial epithelial cells (NHBE) were pre-treated with specific metabolic inhibitors, or transfected with siRNA. Cells were then either infected with live, virulent *Mycobacterium tuberculosis* (*M.tb*) or stimulated with conditioned media from *M.tb*-infected monocytes (CoMTB). MMP and cytokine gene expression, secretion and activity were investigated by qPCR, ELISA, luminex, zymography, Western blot and confocal microscopy. Immunohistochemistry was performed on human TB lymph nodes.

**Results:** 2-deoxyglucose (2DG), a hexokinase inhibitor which impedes the rate-limiting step in glycolysis, decreased gene expression and secretion of the key collagenase, MMP-1. There was a 7-fold fall in MMP-1 secretion in CoMTB-stimulated NHBE (from 5852±1090 to 774±17 pg/ml; p<0.0001) and a 5-fold fall in *M.tb*-infected MDM (from 34733±2911 to 6709±506 pg/ml; p<0.0001). TB-enhanced expression of the transcription factor, HIF-1α, was attenuated by 2DG. 2DG decreased IL-1β secretion (p=0.0001), but increased TNF-α secretion (p=0.0012), in *M.tb*-infected MDM. Immunohistochemical staining of human TB lymph nodes demonstrated increased expression of hexokinase 2 within granulomas. Inhibition of the PI3-kinase-Akt-mTOR pathway enhanced MMP-1 and MMP-9 gene expression and secretion in CoMTB-stimulated NHBE. There was an associated functional increase in fluorescent collagen and gelatin degradation, confirmed by confocal microscopy. PI3 kinase-Akt-mTOR inhibition also increased IL1β and TNF-α secretion in *M.tb*-infected MDM. Inhibiting the metabolic regulator, AMPK, reduced MMP-1 gene expression and secretion, IL-1β and TNF-α secretion, and HIF-1α expression, in *M.tb*-infected MDM.

**Conclusions:** We show that glycolysis is an important modulator of MMP-1, pro-inflammatory cytokine and HIF-1α activity in TB. The PI3-kinase-Akt-mTOR axis and AMPK also have key regulatory roles. Metabolic pathways are potential targets for novel host-directed therapies in TB.

**Presenter email address:** rmasher@gmail.com
**First outbreak of colistin-resistant OXA-23/NDM-1-producing *Acinetobacter baumannii* (France, 2019)**

Guillaume Miltgen, Maxime Bour, Pauline Triponney, Olivier Belmonte Garcia, Marie-Christine Jaffar Bandjee, Nathalie Lugagne, Patrick Plésiat, Anais Potron

1University Hospital of La Réunion Island, Department of Bacteriology, Saint-Denis, Reunion, 2University Hospital of Besançon, National Reference Center of Antimicrobial Resistance, Besançon, France, 3University Hospital of La Réunion Island, Department of Infection control, Saint-Denis, Reunion

**Background:** Over the last decade, polymyxin resistance has been reported for a growing number of *Acinetobacter baumannii* strains worldwide. In this species, colistin resistance mainly results from mutations occurring in the pmrCAB operon, and that lead to the overproduction of phosphoethanolamine transferase PmrC and subsequent decrease in the net negative charge of the bacterial surface. The spread of XDR colistin- and carbapenem-resistant *A. baumannii* (CCRAB) strains in the European overseas territory of La Réunion Island (Indian Ocean) is reported here.

**Materials/methods:** Between April and August 2019, 7 clinical and 1 environmental CCRAB strains were isolated in the university hospital of La Réunion Island. Demographics, clinical data and diffusion dynamics of CCRAB cases were collected. Antibiotic susceptibilities were determined by broth microdilution or E-tests according to EUCAST recommendations. Whole genome sequencing (WGS) was performed to fully characterize the resistome of these isolates and the genetic context of *β*-lactamase-encoding genes. The selected strains were then compared to each other by cgMLST.

**Results:** The clinical CCRAB strains were recovered from 7 patients hospitalized in 3 different wards. Four patients were colonized and 3 infected (two resulting in death). The index case had been previously admitted to the hospital of Mayotte Island (The Comoros). The environmental strain was isolated from a chair in a nephrology room. An epidemiological link could be established for 6 patients who had stayed in two wards. All of the collected isolates displayed the same multidrug resistance profile, including carbapenems, colistin and aminoglycosides except tobramycin. They all produced the class D carbapenemase OXA-23, intrinsic class D *β*-lactamase OXA-69, and metallo-beta-lactamase NDM-1. Likely accounting for their resistance to colistin, a mutation (D82N) was detected in the response regulator PmrA of PmrAB two-component system. Genotyping experiments revealed that the 8 isolates belonged to the international clonal complex ST1 and were phylogenetically indistinguishable.

**Conclusions:** This study which relates the emergence and intra-hospital spread of an XDR *A. baumannii* emphasizes the need of strict application of prevention and control measures in institutions where the risk of imported XDR-bacteria is high.

**Presenter email address:** patrick.plesiat@univ-fcomte.fr
Nanopore metagenomic sequencing to investigate nosocomial transmission of human metapneumovirus from a unique genetic group among haematology patients in the United Kingdom

Yifei Xu1, Kuiama Lewandowski2, Katie Jeffery3, Louise Downs1, Dona Foster1, Nicholas Sanderson1, James Kavanagh1, Ali Vaughan1, Claudia Salvagno3, Richard Vipond2, Miles Carroll2, Robert Danby3, Tim Peto1, Derrick Crook1, A. Sarah Walker1, Philippa Matthews1, Steven Pullan*2

1University of Oxford, Oxford, United Kingdom, 2Public Health England, Salisbury, United Kingdom, 3Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: Human metapneumovirus (HMPV) infection causes a spectrum of respiratory tract disease, and is recognised as a significant pathogen in the context of immunocompromise. In Spring 2019, a group of patients under the care of the haematology unit in a UK teaching hospital were diagnosed with HMPV infection (BioFire FilmArray RP2), raising concerns of an outbreak. This study aimed to investigate whether nosocomial transmission occurred among these patients, and to elucidate genetic relationships between circulating strains in this setting.

Materials/methods: We conducted direct-from-sample Nanopore metagenomic sequencing of 25 respiratory samples submitted to the hospital’s microbiology laboratory. Samples came from 13 patients under the care of haematology over 20-days in Spring 2019 (two patients sampled twice), and ten patients elsewhere in the hospital between 2017-2019 to provide broader representation of sequence diversity in our patient population. We performed phylogenetic analyses for the complete genomes.

Results: We generated HMPV reads from 20/25 samples (sensitivity 80% versus routine diagnostic testing) and retrieved complete HMPV genomes from 15 samples. Consensus sequences from Nanopore data were identical to those generated by Illumina, and represented HMPV genomes from two distinct sublineages, A2b and B2. Sequences from 10/13 haematology patients formed a unique genetic group in the A2b sublineage, not previously reported in the UK. Among these, eight HMPV genomes formed a cluster (differing by ≤3 SNPs), likely reflecting nosocomial transmission, while two others were more distantly related and may represent independent introductions to the haematology unit. Two other A2b sequences from elsewhere in the hospital were >80 SNPs away from all other sequences; as were two B2 sequences from elsewhere in the hospital.

Conclusions: This study increases knowledge of UK HMPV lineages and demonstrates that Nanopore metagenomic sequencing can be used for HMPV detection, although more work is required to optimise sensitivity. Generation of full genome sequences can be used to support or rule out nosocomial transmission, contribute to improve infection prevention and control practices, and inform antimicrobial stewardship.

Abstract 6570

Investigation of carbapenemases by RESIST-4 O.K.N.V immunochromatographic lateral flow assay in Enterobacteriaceae isolates

Melike Yasar1, Feriha Cilli1, Yamac Tekintas1, Furkan Polat1, Mine Hosgor-Limoncu2

1Ege University, Faculty of Medicine, Department of Medical Microbiology, Izmir, Turkey, 2Izmir Katip Çelebi University, Faculty of Pharmacy, Department of Pharmaceutical Microbiology, Izmir, Turkey

Background: Carbapenem resistance in Enterobacteriaceae poses a significant threat to patients and healthcare systems. In the last years, several methods for detecting carbapenem resistance have become available. These methods include phenotypic-based methods that detect the activity of carbapenemase enzymes such as growth-based assays, immunochromatographic (IC) assays, and molecular-based methods. Here we evaluated the performance new immunochromatograph test, RESIST-4 O.K.N.V. test.

Materials/methods: One hundred and fifteen (115) carbapenem resistant Enterobacteriaceae isolates, isolated in 2016-2019 at Ege University Hospital Bacteriology, Laboratory of Medical Microbiology Department were studied. Escherichia coli ATTC 25922 and three carbapenem susceptible clinical isolates were included as negative control. VITEK MS and VITEK 2 Compact® automated systems were used for identification and antibiotic susceptibilities respectively. Minimum inhibitor concentration’s (MIC) of meropenem were determined by gradient test, according to EUCAST recommendations. The RESIST-4 O.K.N.V. test were used for detection of carbapenemase detection. The presence of blaOXA-48, blaVIM, blaNDM and blaKPC genes were also investigated by polymerase chain reaction (PCR) in the isolates.

Results: 90.8% of the isolates were identified as K. pneumoniae. At least one resistance gene was detected in all but one of the 115 resistant isolates included in the study. According to PCR results, co-existance of blaOXA-48 and blaNDM genes was the most common (41.17%) resistance mechanism. RESIST-4 O.K.N.V. test did not detect the presence of blaNDM in eleven (11) isolates which are already containing blaOXA-48.

Conclusions: Resist-4 O.K.N.V. stands out as a method that can be applied in the detection of carbapenemases on cultures. However, it should not be ignored that it can give false negative results in the detection of blaNDM.

Abstract 6571

Routine use of genotype Genotype MTBDRsl assay on clinical samples in a high TB burden setting in South Africa: a descriptive analysis

Keeren Lutchminarain*1, Afsana Kajee1, Nomonde Ritta Mvelase1, Khine Swe Swe Han1

1University of KwaZulu-Natal - Nelson R. Mandela School of Medicine, National Health Laboratory Service, Berea, South Africa

Abstract third-party references: University of KwaZulu Natal, National Health Laboratory Service

Background: Following WHO recommendations for the shortened multi-drug resistant TB (MDR) treatment regimen and use of the GenoType MTBDRsl Line Probe Assay (SL-LPA), the South African Department of Health developed a "DR-TB reflex" testing laboratory algorithm. The rationale for this algorithm is to identify those MDR or rifampicin-resistant TB patients who can be commenced on, and continue the shortened MDR-TB treatment regimen. This study aims to analyse the performance of the Genotype MTBDRsl in smear positive and negative samples; and describe common mutations detected in XDR isolates.

Materials/methods: We performed a retrospective data analysis of Genotype MTBDRsl results on 1841 MDR/Rif resistant clinical samples over 1 year (January – December 2018). DR-TB reflex testing comprises a panel of tests: Auramine-O smear, MGIT960 culture, Genotype MTBDRplus, Genotype MTBDRsl and where necessary phenotypic drug susceptibility testing. GenoType MTBDRsl assays were routinely performed on smear positive and negative samples.

Results: Of the 1841 clinical samples, 38% (701/1841) were smear negative and 62% (1172/1841) were smear positive. Of the smear negative samples, 67% (471/701) had inconclusive MTBDRsl results. 33% (230/701) showed good banding patterns with 25% (178/701) MDR TB diagnosed 5% (34/701) pre-XDR TB and 2% (18/701) XDR TB diagnosed.

For smear positive samples, 6% (77/1172) had inconclusive results. The remaining 93% (1095/1172) showed good banding patterns with 77% (930/1172) MDR TB diagnosed 12% (111/1172) pre-XDR TB diagnosed and 5% (54/1172) XDR TB diagnosed. Of the 72 XDR isolates, the commonest gyrA fluoroquinolone mutation pattern was an absent WT 2 with MUT 1 present; followed by absent WT 3, with MUT 3C present; indicating A90V and D94G respectively as the predominant mutations. The commonest rrs mutation was an absent WT 1 with MUT 1 present indicating A1401G as the commonest second line injectable drug mutation. No gyrB and eis mutations were detected.

Conclusions: Our data shows that the Genotype MTBDRsl performed sub optimally on smear negative samples with 67% having inconclusive results. gyrA and rrs gene mutations are the prevalent mutations observed. These findings question the routine use of Genotype MTBDRsl in smear negative samples in a high TB burden setting.

Abstract 6577

**Epidemiology of serotypes of *Streptococcus pneumoniae* in patients older than 18-years in Russia**

Roman Kozlov*, Alexander Muraviov, Aida Chagaryan, Anastasia Kurkova, Natali Ivanchik

1Smolensk State Medical University, Institute of antimicrobial chemotherapy, Smolensk, Russian Federation

**Abstract third-party references:** MSD

**Background:** Introduction the PCV to the the National Immunization Program in Russia in 2014 and beginning of use of PPV in adults, could potentially change distribution of serotypes of *S. pneumoniae* in patients older than 18-years with non-invasive and invasive forms of pneumococcal infection in Russia.

**Materials/methods:** Collection of *S. pneumoniae* strains and identification was provided by the participating laboratory. Only clinical isolates that met the study criteria as defined by protocol, was stored and submitted to reference laboratory of the Institute of Antimicrobial Chemotherapy of Smolensk State Medical University (IAC, Smolensk). Re-identification of *S. pneumoniae* strains was initially carried out to the species level at the IAC laboratory using classic bacteriologic methods and MALDI Biotyper. Serotyping of *S. pneumoniae* was performed using Real-Time PCR.

**Results:** 192 consecutive non-duplicate strains of *S. pneumoniae* have been analyzed – 7 strains from middle ear fluid, 161 – from respiratory samples, and 24 – from blood samples and cerebrospinal fluid. The most common serotypes of *S. pneumoniae* were: 3 (14.1%), 6AB (9.9%), 19F (9.4%), 14 (5.7%), 9NL (5.7%), 23F (5.2%), 11AD (3.6%) and 15AF (3.6%), and 25% were nontypeable. Moreover, 14 and 19F serotypes were prevalent in patients with AOM and sinusitis - 28.7%. Causative for pneumonia were serotypes 3 (13.1%), 6AB (11.2%), 19F (9.3%), 14 and 9NL (5.6% each) and 23F (4.3%). IPD dominant serotype was 3 (25%), followed by 23F, 12F and 9NL (each 8.3%).

**Conclusions:** PCV13 immunization reduces an incidence of vaccine serotypes of *S. pneumoniae*, however there is an increase of non-vaccine serotypes circulation, which are covered by PPV-23.

**Presenter email address:** roman.kozlov@antibiotic.ru
Possible horizontal transfer of enterococcal IS1216V-mediated composite transposon between enterococci and methicillin-resistant Staphylococcus aureus

Wei-Chun Hung*, Chen-Chia Chang

1Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Sequence type 59 (ST59), the dominant community-associated methicillin-resistant Staphylococcus aureus (MRSA) in Taiwan, is multiresistant to non-β-lactams due to the acquisition of MES, a highly composite transposon flanked by enterococcal insertion sequence IS1216V. Majority of ST59/staphylococcal cassette chromosome mec (SCCmec) IV MRSA acquires MES6272-2 encoding IS1216V-ermB [erythromycin resistance]-[aph(3’)-IIIa] [kanamycin resistance]-ΔaadE-[aacA-aphD] [gentamicin resistance]-IS1216V-IS1216V-cat [chloramphenicol resistance]-IS1216V-IS1216V. ST59/SCCmec V MRSA acquires MESPM1, encoding IS1216V-ermB-[aph(3’)-IIIa]-aadE [streptomycin resistance]-IS1216V-IS1216V-cat-IS1216V-IS1216V. Because the rearrangement of MES is mediated by enterococcal IS1216V, we hypothesize ST59 MRSA may acquire the transposon from enterococci.

Materials/methods: A total of 270 enterococcal species collected in Taiwan were analyzed. Presence of MES structures were screened by PCR. Sequences of the MES were determined by next-generation sequencing. Genetic relationships among the strains were explored by multilocus sequence typing and pulsed-field gel electrophoresis (PFGE). Horizontal gene transfer was tested by filter mating. Pheromone response was detected by clumping inducing assay.

Results: Two E. faecalis strains isolated in 1993 were found to carry MESPM1 structure; one E. faecium strain isolated in 2003 and ten E. faecium strains isolated in 2014 were found to carry MES6272-2-like structures. Both of the two E. faecalis strains were sequence type 64 (ST64), and had nearly identical PFGE patterns. The 11 E. faecium strains had four different pulsotypes but all belonged to clonal complex 17. Sequence analysis revealed that the MESPM1 in ST64 E. faecalis displayed 99.9% DNA sequence homology to that in ST59/SCCmec V MRSA; the MES6272-2-like structures in the E. faecium strains showed >99.7% identity in IS1216V-ermB-[aph(3’)-IIIa]-aadE-[aacA-aphD] cluster compared with that in ST59/SCCmec IV MRSA. The conjugative transfer ability of MES to E. faecalis JH2-2 was tested. MESPM1 in ST64 E. faecalis produced the highest frequency (3.7 x 10⁻²), probably due to pheromone-like response.

Conclusions: MESPM1 and MES6272-2-like structures were found in the enterococcal species isolated in Taiwan. The MESPM1 in ST64 E. faecalis showed 99% DNA similarity to that in ST59/SCCmec V MRSA, implying the highly composite transposon may undergo recombination in E. faecalis and spread to MRSA through the mediation of enterococcal IS1216V.

Identification of microorganisms in polymicrobial blood culture bottles using short-term culture MALDI-TOF MS
Alicia Wong*, Måns Ullberg1, Volkan Özenci1
1Karolinska Institutet, Stockholm, Sweden

Background: Polymicrobial bloodstream infections (BSI) have been reported to comprise of 6-32% of all BSI incidents, and has double the mortality rate of monomicrobial sepsis. Since the prognosis of sepsis is correlated with the rapid administration of effective antimicrobial treatment, there is need for rapid identification methods for identification of microorganisms from polymicrobial blood cultures. Here, we assess the performance of short-term culture followed by MALDI-TOF MS in identifying microorganisms in polymicrobial blood cultures (BCs).

Materials/methods: Both simulated and clinical polymicrobial BCs were used for this study. Simulated samples were derived using two methods, either by inoculating known clinical isolates directly into new BC bottles and incubating in the BC system, or by mixing broth from two clinical monomicrobial BC bottles. Short-term culture followed by MALDI-TOF MS was performed by culturing broth directly from positive polymicrobial BC bottles for 6 hrs at 37 °C on four different agar plates ie. desoxycholate citrate agar, colistin nalidixin acid agar, cromogenic UTI agar, and cystine lactose without electrolytes agar. Aztreonam and linezolid antibiotic discs were used on blood agar. Observed growths from different plates and antibiotic inhibition zones were analyzed by MALDI-TOF MS. Samples were tested using short-term culture followed by MALDI-TOF MS and the results were compared to conventional culture-based methods.

Results: A total of 27 clinical samples and 112 simulated polymicrobial samples were analyzed. Short-term culture followed by MALDI-TOF MS identified at least one microorganism in almost all BC samples tested, and was able to identify all microorganisms in 84/124 (68%) and 3/15 (20%) of bottles that contained two or three microorganisms respectively. 229/292 (78%) of isolates that were identified by conventional methods were successfully identified by short-term culture followed by MALDI-TOF MS. Time to identification by short-term culture followed by MALDI-TOF MS took 7 hrs compared to 48-72 hrs by conventional methods.

Conclusions: Short-term culture followed by MALDI-TOF MS has high performance in rapid identification of microorganisms from polymicrobial BCs, and the method can be implemented in the clinical routine.

Evaluation of a new automated Acrion system for rapid identification of microorganisms and detection of antimicrobial resistance markers directly from blood cultures in an Italian hospital

Flora Marzia Liotti¹,², Marjaana Viirtola¹, Jemiina Salo³, Otso Niiranen², Maurizio Sanguinetti¹,³, Brunella Posteraro⁴,⁵

¹Institute of Microbiology, Università Cattolica del Sacro Cuore, Rome, Italy, ²Thermo Fisher Scientific, Ratastie 2, Vantaa, Finland, Vantaa, Finland, ³Dipartimento di Scienze di Laboratorio e Infettivologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, ⁴Institute of Medical Pathology and Semeiotics, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy, ⁵Dipartimento di Scienze Gastroenterologiche, Endocrino-Metaboliche e Nefro-Urologiche, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Background: As a recent advance in bloodstream infection diagnostics, the Acrion™ system (ThermoFisher) provides a fully automated workflow for rapid detection of microorganisms and their critical antimicrobial resistance gene products [i.e. mecA product PBP2a] directly from positive blood culture (PBC) broths. The system combines liquid chromatography (LC) with high-resolution mass spectrometry (HRMS) for microbial protein analysis. We comparatively evaluated the Acrion™ system workflow and an in-house diagnostic workflow, where PBC broths were analyzed with the MALDI BioTyper® system (Bruker Daltonics) and/or FilmArray® blood culture ID panel (bioMérieux) for microorganism identification and with the eazyplex® MRSA assay (Amplex Diagnostics GmbH) for mecA gene detection.

Materials/methods: Using the two workflows, we separately tested broth aliquots from 218 (199 monomicrobial and 19 polymicrobial) PBCs that were consecutively (clinical, n = 195) or ad hoc (simulated, n = 36) obtained. Results by each workflow were compared with those of culture-based identification and antimicrobial susceptibility methods (here used as the reference method), and were reported as correct detections, misdetections or no detections, respectively. The time to results were calculated for each workflow.

Results: Of 199 monomicrobial PBCs, 190 (95.5%) yielded results by the Acrion™ system workflow that were concordant with those of the reference method, whereas there were 9 no detection results. In parallel, 192 (96.5%) of the 199 PBCs yielded results by the in-house diagnostic workflow that were concordant with those of the reference method, whereas 7 yielded misdetection results. The overall agreement between the workflows was 92.0%. Furthermore, the Acrion™ system detected at least one microorganism, whereas the in-house diagnostic workflow detected all the microorganisms, in the 19 polymicrobial PBCs. Interestingly, all the 7 mecA-positive Staphylococcus aureus were correctly detected, 2 Salmonella species were correctly identified as S. enterica and, ultimately, overall results by the Acrion™ system were available more shortly than those by the in-house diagnostic workflow.

Conclusions: The Acrion™ system is an easy, fast and reliable tool for the laboratory diagnosis of bloodstream infections and integrates multiple crucial tests into a single, effortless workflow.

Laboratory capacity for the diagnosis of leishmaniasis in Greece, 2018: a national surveillance study
Myrsini Tzani1,2, Kassiani Mellou2, Theologia Sideroglou2, Anthi Chrysostomou2, Annita Vakali2, Theano Georgakopoulou2, Danai Pervanidou2, Sotirios Tsiodras*3

1EPIET (European Programme for Intervention Epidemiology Training) fellow-MS track-Cohort 2018, Athens, Greece, 2Hellenic National Public Health Organization, Athens, Greece, 34th Academic Department of Medicine, National and Kapodistrian University of Athens, Medical School, Athens, Greece

Background: Leishmaniasis is a public health problem in many parts of the world. The most common forms of the disease are visceral (VL) and cutaneous (CL) leishmaniasis. Greece is endemic for zoonotic VL. Reported cases of anthroponotic CL are sporadic. The mean annual notification rate of domestic VL and CL cases was 0.49/100,000 and 0.05/100,000, respectively for the period 2004-2018. We evaluated the laboratory capacity of Greek hospitals to diagnose leishmaniasis, in order to explore areas for improvement.

Materials/methods: A structured questionnaire was dispatched to microbiological laboratories of all country’s public hospitals. Diagnostic methods used, typing capacity and collaboration with other laboratories for diagnosis of leishmaniasis were recorded. Data were analysed as a whole, by region and by method of testing, i.e. parasitological testing, which is the reference diagnostic method used for the disease, serological and molecular testing.

Results: Feedback was provided by 56 of 110 hospitals (response rate 51%); of these, 25 (45%) reported they had the capacity to diagnose the disease. Capacity varied among different regions of the country with hospitals in Attica [area of the capital of the country Athens] reporting the highest [52%] capacity overall.

Serology was performed by 16/56 (64%) hospitals, followed by parasitology (52%). PCR capacity was low (1 hospital). Three (12%) hospitals could type leishmania species, all located in Attica region; two of them reported capacity for typing L. donovani complex, one L. donovani donovani and one L. donovani infantum. No hospital could type L. tropica or other species.

Conclusions: There is suboptimal capacity to diagnose leishmaniasis in Greece with significant geographical variation. Future efforts should focus on enhancing diagnostic capacity preferably through the development of a network of specialised laboratories coordinated by a national reference lab, including the development of typing methods for the timely detection of new species that may emerge in Greece.

The distribution, transmission and adaptation of Klebsiella species in multiple clinical and non-clinical settings

Harry Thorpe1, Jukka Corander1, Teemu Ville Sakari Kallonen1, Sylvain Brisse2, Virginie Passet2, Juan Sebastian Lopez Fernandez2, Carla Parada Rodrigues2, Louise Matthews3, Sonia Mitchell3, Richard Reeve3, Sophia David4, Cristina Merla5, Marta Corbella5, Carolina Ferrari5, Davide Sassera5, Edward Feil*6

1Institute of Biostatistics, University of Oslo, Oslo, Norway, 2Institut Pasteur, Paris, France, 3University of Glasgow, Glasgow, United Kingdom, 4Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 5University of Pavia, Pavia, Italy, 6Milner Centre for Evolution, University of Bath, Bath, United Kingdom

Background: Species belonging to the genus Klebsiella, and in particular K. pneumoniae (Kp), are pathogens of increasing notoriety. Treatment options are limited by the spread of resistance to carbapenems (CRKP) and other antibiotics. K. pneumoniae and related species are ecological generalists and reside in multiple non-clinical and environmental sources. A “One-Health” perspective is therefore warranted to better understand the contribution of environmental reservoirs to the public health burden.

Materials/methods: Over 6,000 samples from hospitals, community carriage, farm, companion and wild animals, surfaces, soil and water were taken near the Italian city of Pavia from July 2017 to October 2018. 3510 Klebsiella colonies recovered from selective media were sequenced. Kleborate was used to confirm species, ST, and to assay for virulence and resistance genes. GWAS analysis was performed using Pyseer, and transmission events inferred using a bespoke clustering method.

Results: 1705 (48.6%) of the samples were K. pneumoniae, with the remaining samples corresponding to 15 other Klebsiella / Raoultella species (including at least two novel species). K. pneumoniae was enriched in human derived samples, Raoultella spp were dominant in soil and plants, and the K. oxytoca-like clade was marginally enriched in animals. No CRKP was detected outside of the hospital environment, but different classes of beta-lactamase genes were common in animals and in multiple Klebsiella species. Isolates from pigs were found to be associated with aerobactin, an important virulence factor. GWAS analysis pointed to a strong host adaptive role for genes conferring resistance to metals. Transmission for all species was predominantly inferred within, rather than between niches. Many Kp isolates recovered from hospital carriage and disease shared a high level of relatedness.

Conclusions: Although most Klebsiella species were observed in most settings, species distribution is not random. GWAS analysis points to a strong genetic component for host adaptation, and broadly supports the view that human and bovine Klebsiella strains represent distinct populations. Although most transmission occurs within a single setting, occasional transmission between hosts or environmental niches may still play a significant role in the emergence of new resistant or virulent strains over the long term.

Study of the serological efficacy of influenza vaccine along 28 consecutive seasons
Laura Sanchez De Prada*1, Iván Sanz2, Sonia Tamames3, Ana Lopez1,2, Jose Manuel Méndez-Legaza1, Silvia Rojo1, Raúl Ortiz De Lejarazu2, Jose María Eiros4

1University Clinical Hospital of Valladolid, Valladolid, Spain, 2National Influenza Centre Valladolid, Valladolid, Spain, 3Consejería de Sanidad- Junta de Castilla y León, Valladolid, Spain, 4Hospital Universitario Rio Hortega, Valladolid, Spain

Background: The classical serological criteria of the European Medicament Agency (EMA) for the evaluation of vaccine efficacy determine different parameters for analysis the efficacy in people below and >60 years. For 18-59 or >60 that encloses a sero-protection rate (SPR) ≥70%/60%, a seroconversion rate (SCR) ≥40%/30% and a geometric mean titre (GMT) increase between post and pre-vaccination serum samples ≥2.5/2.0 respectively. The aim of these study is to apply those criteria to analyze vaccine efficacy in population ranging from 15 to >95 years old.

Materials/methods: A retrospective study was performed in 4,008 individuals vaccinated against influenza recruited from 1990 until 2018. This population was divided by age groups [15-30,31-40,41-50,51-64,65-74,75-84,85-94 and ≥95 years old]. Sera were obtained before and 28 days after vaccination. For analyzing the antibodies titers in both sera, haemagglutination inhibition assay (HAI) was performed at the National Influenza Centre of Valladolid (Spain) against classical A(H1N1) [from 1990 till 2010], A(H1N1)pdm09 [from 2010 till 2018], A(H3N2) and for both influenza B/Yamagata and B/Victoria lineages. The analysis was performed calculating the Seroprotection Rate (SPR), Seroconversion Rate (SCR) and Geometric Mean Titers increase (GMTi). The current consensus was followed and a titre of 1:40 was considered as protective. Seroconversion was defined as a titre increase of at least four-fold between pre and post-vaccination sera. We applied those criteria considering 15-64 and ≥65 as the cut-off.

Results: Against A(H1N1)pdm09, the efficacy criteria were fulfilled in all age groups. For classical-A[H1N1] SCR criteria were not achieved in 15-30, 41-50 and ≥95. For A(H3N2) subtype SCR criteria were below 40% for all groups between 15 and 50 years. In the case of Influenza B viruses, no SCR criteria were achieved in either Victoria or Yamagata lineages, and GMTi only met the criteria for 31-40 in B/Yamagata and 31-40 and 65-74 in B/Victoria lineages. In all cases SPR was over 75%.

Conclusions: For A[H1N1]pdm09 and A[H3N2] subtypes, influenza vaccine showed great results fulfilling all EMA criteria in individuals >50 years old but not for younger individuals in the case of A[H3N2] subtype. B lineages have more difficulties to achieve the criteria proposed for most of the age groups.

Abstract 6587

Trends in invasive pneumococcal disease in Italy, 2010-2018

Romina Camilli*1, Maria Del Grosso1, Fabio D’ambrosio1, Monica Monaco1, Fernanda Pimentel De Araujo1, Giulia Errico1, Stefano Boros1, Roberta Urciuoli1, Maria Grazia Caporali1, Martina Del Manso1, Fortunato D’ancona1, Stefania Iannazzo2, Flavia Riccardo1, Annalisa Fantosti1

1Istituto Superiore di Sanità, Department of Infectious Diseases, Rome, Italy, 2Ministry of Health, Directorate General for Health Prevention, Rome, Italy

Background: In Italy, the 13-valent conjugate vaccine (PCV13) was used for children vaccination against pneumococcal diseases since 2010, and in 2017 it was introduced at national level for vaccination also in the elderly. Data regarding Invasive Pneumococcal Diseases (IPD) are collected through the nationwide surveillance system of invasive bacterial diseases (MIB).

Materials/methods: All IPD cases reported in the MIB surveillance in the period 2010-2018 were included in this analysis, mainly focusing on the two high-risk age classes, children <5 years and elderly ≥65 years. Total IPD incidence and serotype distribution were analyzed.

Results: During 2010-2018, an overall increasing IPD incidence was observed, from 1.4 cases in 2010 to 2.6 cases/100,000 inhabitants in 2018. The impact of PCV13 vaccination in children was more evident in the age <1 year, with an IPD incidence decreasing from 5.3 cases in 2010 to 3.5 cases/100,000 inhabitants in 2013. Starting from 2014, IPD incidence began to increase again, reaching 5.3 cases/100,000 inhabitants in 2018. PCV13 serotypes decreased from 83% in 2010 to 23% in 2018, while NVS became the most frequent cause of IPD in children during the last years. Among NVS, serotypes 10A, 12F, 8, 11A, 15B/C, 22F, 23B, and 24F are the most frequently reported. Regarding elderly ≥65 years, IPD incidence increased from 5.3 in 2010 to 6.7 cases/100,000 inhabitants in 2018. Although PCV13-related IPD decreased also in this age group due to herd protection, from 70% in 2010 to 31% in 2018, serotypes 3, 19A, and 14 still represent a frequent cause of IPD in the elderly. NVS IPD increased consistently, mainly due to serotypes 8 and 22F.

Conclusions: The overall IPD increasing trend observed during the study period is likely influenced by the progressive implementation in the sensitivity of the surveillance system. PCV13 immunization in children was effective in reducing PCV13-related IPD not only in vaccinated children but also in older unvaccinated individuals. NVS accounted for the majority of IPD cases in the last years under study, indicating the occurrence of a serotype replacement phenomenon. Continuous implementation of the IPD surveillance is warranted to better evaluate the overtime IPD epidemiology changes.

Abstract 6589

Three-dimensional in vitro Staphylococcus aureus abscess communities are not affected by antibiotics or neutrophils

Marloes Hofstee*1,2, Martijn Riol1, Keith Thompson1, Martin Stoddart1, Sebastian Zaat2, Fintan Moriarty1

1 AO Research Institute Davos, Davos Platz, Switzerland, 2 Amsterdam UMC, Amsterdam, Netherlands

Background: Staphylococcus aureus is a prominent pathogen in skin, soft tissue and bone-related infections where it can form staphylococcal abscess communities (SACs). Given the specificity of a number of virulence factors for human targets (e.g. leukocidins), working with human host cells should provide a more accurate estimation of pathogenicity. Advanced three-dimensional (3D) in vitro cell culture models enable the incorporation of human cells and can resemble structures observed in vivo. However, no in vitro models, 2 or 3 dimensional, for full grown SACs have been described in the literature to date. Generation of a 3D in vitro SACs model would enable studies into host cell-pathogen interactions, antibiotic tolerance, new drug targets and treatment efficacy.

Materials/methods: We developed a 3D in vitro model of SACs grown in a collagen gel supplemented with human plasma. Characterization of the model was done by transmission and scanning electron microscopy, and immunofluorescent stainings were preformed to determine whether the pseudocapsule around SACs consist of fibrin. Antibiotic tolerance of SACs was assessed with 100x the minimal inhibitory concentration (MIC) of gentamicin. Bacterial clearance of non-establised SACs and established SACs with or without pseudocapsule was determined by exposure to differentiated PLB neutrophil-like cells (dPLB) or primary neutrophils.

Results: The 3D in vitro SACs were on average 200 micrometers in diameter, consisted of 8 log10 CFUs and were surrounded by an inner and outer fibrin pseudocapsule. The in vitro grown SACs tolerated 100x the MIC of gentamicin for 24h and bacterial numbers did not significantly differ from control SACs (p=0.1000). dPLB neutrophil-like cells or primary neutrophils were unable to clear established in vitro SACs (p=0.1102 and p=0.8767, respectively). When the fibrin pseudocapsule was degraded by the enzyme plasmin, dPLB neutrophil-like cells or primary neutrophils caused a significant decrease in total CFU compared the SACs that did had a pseudocapsule (p=0.0333 and p=0.0272, respectively).

Conclusions: The 3D in vitro SACs were not affected by the antibiotic treatment nor neutrophils. The in vitro SACs model offers a tool for host-pathogen interaction and drug efficacy assessments, and is a valuable starting point for future research.

Evolution of cutaneous bacterial microbiota of pressure ulcers in patients with spinal cord injury

Catherine Dunyach-Remy*1, Anthony Gélis2, Sophie Bastide3, Alex Yahiaoui-Martinez1, Jean Philippe Lavigne1, Albert Sotto4

1University Hospital Nîmes, Department of Microbiology, INSERM U1047, Nîmes, France, 2Centre Mutualiste Neurologique PROPARA, Montpellier, France, 3University Hospital Nîmes, Department of BESPIM, Nîmes, France, 4University Hospital Nîmes, Department of Infectious Diseases, INSERM U1047, Nîmes, France

Background: Chronic wounds are naturally colonised by bacteria from the cutaneous microbiota. Very few data have described the evolution of the microbiota of pressure ulcers (PU) after management and the influence of bacteria species in the chronicity of the lesion. The aim of this study was to characterize the evolution of the cutaneous microbiota of PU in spinal cord injury (SCI) patients during wound management.

Materials/methods: Patients admitted in a French reeducation centre and harboring stage 3/4 PU were prospectively included between May 2015 to December 2016. PU tissular biopsies were performed at baseline (D0) and 28 days after (D28). The PU microbiota were analysed by a metagenomic approach using 16S rRNA gene-based sequencing analysis of the V3-V4 region and interpreted with the clinical evolution of PU.

Results: Twenty-four patients with 24 pelvic PU were included (15 males; median age: 62.5 years [31 -89]). Twelve PU were ischial [50.0%], 11 sacral [45.8%] and one trochanterial [4.2%]. Most of PU belonged to stage 3 [66.7%]. Analysis of the evolution of bacterial communities at D0 and D28 showed an increase of the Firmicutes phylum at D28 ([76.3% [D0] vs 94.7% [D28]]) and a decrease of the Proteobacteria phylum [22.7% [D0] vs 5.0% [D28]]. This evolution is observed whatever the clinical evolution of the PU [degradation/stagnation and improvement]. The main bacterial genera present at D0 were Staphylococcus [30.8% of Firmicutes], Anaerococcus [24.0% of Firmicutes], Streptococcus [21.4% of Firmicutes] and Escherichia [88.8% of Proteobacteria]. At D28, no evolution in bacterial genera could be noted. Interestingly, according to the clinical evolution, the association Anaerococcus and Finegoldia had a statistically higher relative abundance at D0 for wounds that have stagnated or deteriorated at 28 days [0.77% vs 4.98%, p=0.056 and 1.50% vs 53.89%, p=0.036 respectively]. Moreover, at D28, Proteus were significantly detected in these worsened wounds [0.00% vs 32.02%, p=0.001].

Conclusions: This study shows that the association of Anaerococcus/Finegoldia could be a prognostic tool of the wound evolution and Proteus a marker of wound degradation. The knowledge of skin microbiota could represent an interesting tool to manage PU.

**Epidemiological and genomics insights into the first outbreak of an extensive drug-resistant NDM-1-producing *Klebsiella pneumoniae* in Portugal**

Angela Novais*, 1, Rita Ferraz2, Mariana Viana2, Paula Martins Da Costa2, Luisa Maria Vieira Peixe1

1University of Porto, UCIBIO-Requimte. Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, 2Centro Hospitalar do Tâmega e Sousa, Penafiel, Portugal

**Background:** In Portugal, carbapenems resistant *Klebsiella pneumoniae* (Kp) rates increased ~80% since 2014, essentially by expansion of KPC-3-producing ST147 till very recently. Here, we provide epidemiological and comparative genomics analysis on the first noticed outbreak of an extensive drug-resistant NDM-1-producing Kp in hospitalized patients.

**Materials/methods:** NDM-producing Kp were detected by GeneXpert-CarbaR in rectal colonization screenings of seven patients (Nov 2018-Mar 2019), two of them simultaneously in infection sites (urine, bile). Bacterial identification/susceptibility testing were performed by standard methods and PCR/sequencing (carbapenemases). Fourier Transform Infrared (FTIR) spectroscopy was used to assess isolates’ relationships in less than 24h and support infection control. Whole genome sequencing (n=1) and available bioinformatics tools allowed characterization of antibiotic resistance and virulence genes, K/O-locus [KLEBORATE/BiGsdB/Center for Genomic Epidemiology] and phylogenetic analysis (SNP-based CSI-phylogeny).

**Results:** The index case is from a patient with no history of previous hospitalization or travel abroad, 5 cases were detected in contact screenings of patients hospitalized in the same unit/period of time, and the last one from a household resident with no epidemiological link. Reinforcement of carrier screening, cleaning/disinfection practices, patients’ cohort and antibiotic stewardship prevented new cases. All isolates were considered identical by FTIR and belonged to ST11 with KL105 capsular type, a lineage that had caused long-term outbreaks as a DHA-1 producer in our country [Ribeiro et al. IJAA 2019]. They were resistant to all antibiotics tested (n=21) except amikacin and colistin, and carried several resistance (*bla*\(_{\text{NDM-1}}, \text{bla}_{\text{CTX-M-15}}, \text{aac}, \text{aph}, \text{qpxAB}, \text{qnrB1}, \text{catB3}, \text{sul2}, \text{tetD}, \text{dfra14}\) and virulence (*fuyA-mkr-ybtS-entB-kfuBC-ureA-fimH-iutA*) genes. Comparative genomics revealed high relatedness with 29 ST11-KL105 NCBI genomes (120-300 SNPs) from multiple countries worldwide, including previous DHA-1-producing Portuguese strain, and typical *bla*\(_{\text{NDM-1}}\) backbones (\(\Delta\text{Tn125}\) identical to pNDM-MAR, IncHI1B plasmid). These data suggests wide dissemination of ST11-KL105 lineage carrying either DHA-1, CTX-M-3/-15, KPC-2/-3 and/or NDM-encoding plasmids.

**Conclusions:** FTIR is an extremely powerful tool to support surveillance and infection control. Data from the first outbreak of NDM-1-Kp in our country raises the alarm for the potential silent dissemination of NDM through unnoticed carriage, and the need to implement active surveillance for early recognition of colonization/infection by NDM-producers to prevent wide dissemination.

Abstract 6593

A glance at the endothelial activation in complicated and uncomplicated malaria

Nikita Makkar*1, Pankaj Malhotra1, Jasmina Ahluwalia2, Ram Singh4, Rakesh Sehgal2

1PGI Hospital, Chandigarh, PGIMER, Chandigarh, India, 2PGIMER Chandigarh, Chandigarh, India, 4PGIMER Chandigarh, Chandigarh, India

Abstract third-party references: pgimer, icmr

Background: Malaria is one of the major public health problems that cause millions of deaths each year across the world. The pathogenesis of malaria is complex. Even with greater understanding of pathogenesis and treatment available, complicated malaria still occur leading to increase in morbidity and mortality. We studied endothelium activation as one of the pathogenetic mechanism responsible for complications in malaria.

Materials/methods: In a case control study of 30 patients with vivax malaria, endothelial activation was studied in the form of measurement of VWF. The diagnosis of malaria was made by microscopy and/or Rapid Diagnostic tests. Nested PCR was performed for confirmation of microscopy and/or Rapid Diagnostic tests positive cases. The presenting symptoms, physical examination and investigations were noted as per protocol. Patients were classified into complicated and uncomplicated category according to WHO criteria. The levels of vwf were measured in citrated plasma of P. vivax malaria patients using the commercial ELISA and analyzed using the chi-square test. The patients were followed up till discharge/death.

Results: The median age of study participants was 31 years, ranged from 16 - 65 years with 21 (70%) being males. The presenting clinical features were fever (n=30), bodyache (n=30), vomiting (n=10), headache (n=30), abdominal pain (n=3), decreased urine output (n=2) and loose stool (n=1). 22 patients were diagnosed to have complicated malaria. Median hemoglobin in malaria patients was 11.8gm/dl (range 7.2 – 14.4 gm/dl) and median platelet count in complicated and uncomplicated malaria patients were 24000 (range 5000 – 57000), 36000 (range 18000 – 78000) respectively. Levels of VWF in healthy control ranged from 50-150% whereas 95 % of complicated and 77 % uncomplicated cases had levels of VWF ≥150%.

Conclusions: The outcome of our study indicates that the malaria parasite has the potential to activate the endothelium. Although increased VWF levels in malaria insights the alteration in coagulation, but couldn’t differentiate between the complicated and uncomplicated malaria. Therefore to define the role of VWF in malaria, further investigations with more sample size are required.

**Abstract 6594**

**Methenamine: an audit of its use for recurrent UTIs in a large UK trust**

Naina Mccann*1, Mauricio Arias1, Nikki Sweeney1, Preet Panesar1, Mahreen Pakzad1, Sarah Logan1

1University College Hospital, London, United Kingdom

**Background:** Patients with recurrent urinary tract infections (rUTI) present frequently to primary and secondary health care services. These patients commonly receive prophylactic antibiotics, driving antimicrobial resistance and reducing antimicrobial treatment options. Non-antibiotic prophylaxis has the potential to reduce these risks. There is evidence that methenamine hippurate (MH), a urinary antiseptic, has a role in rUTI prophylaxis, and has been approved for use in our trust since 2017. We retrospectively described the use of MH to ascertain efficacy and adherence to local protocol.

**Materials/methods:** A list of MH prescriptions from April 2017 to September 2018 at University College London Hospital was gained from pharmacy records. A total of 220 prescriptions were issued during this time. Of these, 100 patients were randomly chosen for analysis across different prescribers. Patients’ electronic records were reviewed and data inputted and analysed in Excel.

**Results:** Ninety-one percent of patients were female (median age =59). MH was prescribed by different specialties, mainly Urology, Neurology and Gynaecology. Renal tract abnormalities were absent in 59% patients. Prophylactic antibiotics were used in 61% of patients prior to starting MH. Bacteriuria was confirmed in 73% of patients - 23% of these isolates had significant resistance. Urine pH was measured in 31% patients prior to starting MH, with 13% undergoing urinary acidification with ascorbic acid.

MH was relatively well-tolerated with only 14% of patients reporting side effects and 17% discontinuing MH earlier than planned. Number of rUTI’s during treatment was documented in 63% of patients, with 25% reporting no UTIs during the initial 6 months’ therapy.

**Conclusions:** We describe MH use in rUTIs in a large UK tertiary hospital. MH appears to be widely used by different specialties in patients with evidence of rUTIs and prior use of prophylactic antibiotics. 25%of patients who were on MH therapy were free of rUTI for a minimum of 6 months, suggesting a reduction in antibiotic treatment prescriptions. Importantly, MH appears to be well-tolerated with minimal side effects. The impact of a new electronic prescribing protocol for MH and the effect that this has on recording of MH outcomes, including subsequent antibiotic prescriptions, will be shown.

Detection rates of bacterial vaginosis and sexually-transmitted pathogens associated with genital discharge syndrome in the South-African private sector

Chanel Kingsburgh*1, Kathy-Anne Strydom2, Marleen Kock3

1University of Pretoria, Ampath Laboratories, Pretoria, South Africa, 2University of Pretoria, Ampath Laboratories, Centurion, South Africa, 3University of Pretoria, National Health Laboratory Services, Pretoria, South Africa

Abstract third-party references: National Health Laboratory Services, Ampath Laboratories, University of Pretoria

Background: Sexually transmitted infections (STIs) and bacterial vaginosis (BV) are associated with poor reproductive outcomes as well as increased transmission of HIV. In South-Africa, a high HIV prevalence setting, limited data are available regarding the prevalence of STIs and BV mainly due to the syndromic management of these conditions. We present the findings of a retrospective analysis of detection rates of pathogens responsible for the genital discharge syndrome amongst males and females as well as BV rates amongst females.

Materials/methods: The detection rates of Chlamydia trachomatis, Neisseria gonorrhoeae, Mycoplasma genitalium, Trichomonas vaginalis, Mycoplasma hominis, Ureaplasma urealyticum and Ureaplasma parvum using the Anyplex II STI-7 multiplex PCR (Seegene) as well as the BV rate determined using Nugent scores were calculated by retrospectively analyzing laboratory data for the period 1 February 2014 to 29 June 2019.

Results: A total of 11,413 specimens [urine and genital swabs] were available for analysis of multiplex PCR results and Nugent scores were available for 50,342 vaginal swabs. Detection rates were as follows amongst females (n=7082): C. trachomatis 5.2%, N. gonorrhoeae 1.5%, M. genitalium 1.9%, T. vaginalis 1.9%, M. hominis 16.9%, U. urealyticum 16.6% and U. parvum 42.8%. Sixty percent of the vaginal swabs submitted for microscopy had a Nugent score of 0-3 (normal); 31% of swabs had a Nugent score of 4-6 (indeterminate); and 9% of swabs had a Nugent score of 7-10 (BV). Detection rates were as follows amongst males (n=4331): C. trachomatis 10.2%, N. gonorrhoeae 6.3%, M. genitalium 4.2%, T. vaginalis 1%, M. hominis 5.3%, U. urealyticum 13.2% and U. parvum 13.2%.

Conclusions: High rates of C. trachomatis and N. gonorrhoeae were observed amongst males and females. Mycoplasma genitalium is an emerging pathogen with the potential for multi-drug resistance; the high rates observed especially amongst males is therefore concerning. The role of the Ureaplasma species and M. hominis in the genital discharge syndrome is unclear; however, the high rates observed in female patients indicate that symptomatic pregnant females should be screened and treated for these bacteria as they are associated with poor pregnancy outcomes.

**Abstract 6597**

**Drugs repurposing: in vitro testing of licensed drugs to assess role against MDR/XDR-TB**

Ximena Gonzalo*1, Francis Drobniewski1,2

1Imperial College London, London, United Kingdom, 2Faculty of Medicine, Imperial College London, London, United Kingdom

**Background:** Carbapenems inhibit mycobacterial L,D-transpeptidases but they are inactivated by beta-lactamases. The addition of clavulanate improves carbapenem activity.

Clavulanate is available in the UK combined with amoxicillin whose addition to meropenem-clavulanate was synergistic against *Mycobacterium tuberculosis* (MTB). Unfortunately, meropenem requires IV administration 3 times a day. Ertapenem, faropenem and tebipenem have a better administration profiles. Faropenem showed good killing activity *ex vivo*. Tebipenem and ertapenem showed activity against multi-drug resistant (MDR) and extensively drug resistant (XDR) MTB isolates.

**Materials/methods:** Susceptibility was performed in microtiter plates in a final volume of 0.1 mL of Middlebrook-7H9. 8 concentrations of carbapenems (faropenem: 0.064 - 16 mg/L; ertapenem, meropenem and tebipenem: 0.125 – 32 mg/L) were tested combined with fixed concentrations of clavulanate (2.5 mg/L) and amoxicillin (2mg/L).

The plates were incubated at 37° CO₂ and read every 7 days. Susceptibility was interpreted when visible growth was seen in the growth control (GC) well.

**Results:** 82 fully susceptible, MDR and XDR MTB isolates were tested.

Faropenem/clavulanate minimal Inhibitory Concentration (MIC) 50 was 2 mg/L and the MIC90 was >16 mg/L. The addition of amoxicillin did not change these values. Meropenem/clavulanate MIC50 was 8 mg/L while the addition of amoxicillin produced a value of 4 mg/L; MIC90 was >32 mg/L. Tebipenem/clavulanate MIC50 was 2 mg/L and 1 mg/L after the addition of amoxicillin. Ertapenem showed MIC50 of 32 mg/L and MIC90 >32 mg/L with no changes after the addition of amoxicillin.

**Conclusions:** Meropenem, tebipenem and faropenem showed modest activity against some MTB strains. Resistant pattern was not associated with resistance to other drugs so being fully susceptible, MDR or XDR could not predict susceptibility to these drugs. Synergy, if present, was strain specific rather than a drug-combination phenomenon. Ertapenem testing remains a challenge as it degrades quickly.

Since these drugs are increasingly used, further research is required to determine ecological cut-offs, breakpoints and the best methodology for testing.

Information regarding clinical use and outcomes in humans is emerging, showing results suggestive of activity against MTB. However, the contribution of these beta-lactams to the outcome remains uncertain.

Clinical evaluation of an investigational use only Aspergillus galactomannan lateral flow assay at a tertiary cancer care centre

Krupa Jani1, Tracy Mcmillen1, Esther Babady*1

1Memorial Sloan Kettering Cancer Center, New York, United States

Background: Invasive Aspergillosis is the most common fungal infection in immunocompromised hosts, including oncology patients. Diagnosis is currently limited due in part to slow and/or insensitive methods. One method includes the detection of Aspergillus galactomannan (GM) antigen using an enzyme-linked immunosorbant assay (EIA). EIA can be time-consuming, laborious and requires batching for cost-effective testing, delaying results. The IMMY Aspergillus Galactomannan Lateral Flow Assay (GM LFA), is an immunochromatographic test that recently became commercially available for the rapid detection (30 minutes) of GM. In this study, we evaluated the accuracy of the IMMY Aspergillus GM LFA to the PLATELIA™ Aspergillus EIA Antigen assay (GM EIA).

Materials/methods: This was a single-center, retrospective study. All clinical samples (serum and Bronchoalveolar lavages (BAL)) received for testing by the GM EIA between March 2019 and August 2019 were included, except if remaining sample volume following testing by GM EIA was insufficient. Samples were stored at -20 °C prior to testing by the GM LFA. Performance characteristics including positive (PPA) and negative percent agreement (NPA) were calculated. Discrepant analysis was performed by review of patients medical records for evidence of fungal infections.

Results: 565 samples were collected for this evaluation, including 90 BAL and 475 serum samples. Overall, 10/565 and 541/565 samples were positive and negative respectively by both tests for a PPA of 100% (95% CI: 69.2-100%) and a NPA of 97.5 % (95% CI: 95.8-98.6%). PPA and NPA by specimen types were 100% (95% CI: 15.8-100%) and 93.2% (95% CI:85.8-97.5%) respectively for BAL and 100% (95% CI: 63.1-100%) and 98.3% (95% CI: 96.4-99.3%) respectively for serum. 11/14 discordant samples were collected from patients with supporting evidence of fungal infection (e.g. culture, BD glucans, histopathology).

Conclusions: In our oncology patients, the Aspergillus GM LFA outperformed the Aspergillus GM EIA for the detection of the galactomannan antigen. Furthermore, the simplicity and rapid time to results makes the Aspergillus GM LFA easy to implement in a wide range of laboratory settings. Further studies will determine the impact of additional positive samples detected by the Aspergillus GM LFA on patient outcomes.

Mechanisms of resistance and virulence of azole-resistant *Aspergillus flavus* clinical isolates

Elie Djenontin*1,2, Bita Mousavi2, Nguyen Lin3,4, Laurence Lachaud5,6, Muriel Cornet7,8, Jacques Guillot2, Laurence Delhaes3,4, Françoise Botterel2,9, Eric Dannaoui2,10,11

1Hôpital Universitaire Mondor, laboratoire de Parasitologie-Mycologie, Créteil, France, 2UPEC, Dynamyc UPEC, EnvA, UIC Anses, Faculté de Médecine de Créteil, Créteil, France, 3Université de Bordeaux, INSERM U1045, Bordeaux, France, 4CHU de Bordeaux, Laboratoire de Parasitologie-Mycologie, Bordeaux, France, 5Université de Montpellier, Montpellier, France, 6Centre Hospitalo-Universitaire de Montpellier, Laboratoire de Parasitologie-Mycologie, Montpellier, France, 7Université Grenoble Alpes, Grenoble, France, 8CHU Grenoble, Laboratoire de Parasitologie-Mycologie, Grenoble, France, 9Hôpital Universitaire Mondor, Laboratoire de Parasitologie-Mycologie, Créteil, France, 10AP-HF, Hôpital Européen Georges Pompidou, Unité de Parasitologie-Mycologie, Paris, France, 11Université Paris Descartes, Faculté de Médecine, Paris, France

**Background:** Resistance to azole drugs is an emerging problem in *Aspergillus fumigatus* but has been rarely evaluated in *Aspergillus flavus*, the second most important species of *Aspergillus* in human and animal infections. Only few azole-resistant *A. flavus* isolates have been reported and the mechanism of resistance remains poorly understood. As in *A. fumigatus*, the resistance mechanism may be related to alteration in the *Cyp51* genes coding for 14-alpha-demethylase.

**Materials/methods:** Six clinical isolates morphologically identified as *A. flavus* and presumed to be azole-resistant by an agar screening test, were included. Partial sequencing of β-tubulin and calmodulin genes identified the isolates as *A. flavus sensu stricto*. Resistance was confirmed by EUCAST. The virulence was evaluated in a *Galleria mellonella* model for 2 resistant and 2 susceptible isolates. *Cyp 51C* was sequenced for all resistant isolates.

**Results:** Voriconazole MIC was 8 mg/l for 2 strains and itraconazole MIC of was 16 mg/l for 4 strains. There was a cross-resistance between voriconazole and isavuconazole and between itraconazole and posaconazole. The two resistant isolates tested in *G. mellonella* were less pathogenic than the susceptible isolates. Among the 6 resistant isolates, eight substitutions were detected in *Cyp 51C* (Table). All but one (S399I) of these substitutions were also present or have been previously reported in susceptible isolates.

**Conclusions:** The presence of *A. flavus* azole-resistant isolates in France is confirmed. Resistant isolates were less virulent than susceptible ones. Most of Cyp 51C substitutions were also present in susceptible strains. The role of Cyp 51C mutations in *A. flavus* azole-resistance in our isolates is unlikely and therefore, other mechanisms of resistance needs to be further evaluated.

**Abstract 6601**

**Viral versus bacterial infection diagnosis: Affimer proteins as alternative molecular recognition reagents**

Modupe Ajayi*, Darren Tomlinson1, Michael McPherson1

1School of Molecular and Cellular Biology, Faculty of Biological Sciences, University of Leeds, Leeds, United Kingdom

**Background:** The lack of point-of-care diagnostic tools for infectious diseases leads to inappropriate prescribing of antimicrobial agents, which had been associated with the increasing prevalence of antimicrobial resistance (AMR). Therefore, robust platforms for clinicians to distinguish between viral and bacterial infections at point of care are vital. This will help reduce the inappropriate use of antibiotics and decrease the prevalence of AMR. Antibodies are the major molecular recognition reagents used in commercially available diagnostic kits. However, the inherent limitations of antibodies including cost, production time and batch-to-batch variation, directly impact the performance of antibody-based immunoassays. The sensitivity and specificity of such assays is critically dependent on the quality of the molecular recognition reagents used.

**Materials/methods:** Leeds has developed a non-antibody binding protein called Affimer type II. From phage display libraries, Affimer binders against >500 targets have been identified. Here, using phage display, the Affimer library was screened to identify sensitive and non-cross-reactive Affimer proteins against specific biomarkers of (i) bacterial infection (procalcitonin and CRP) (ii) viral infection (TRAIL and IP-10) and (iii) nosocomial infection such as *Clostridium difficile* (toxin A, toxin B and GDH). Selected Affimers were characterised for specificity, sensitivity, binding kinetics and thermostability. To test for improved sensitivity, performance of Affimers were compared with commercially available diagnostic kit.

**Results:** Phage display screening yielded high affinity and specific Affimers against all the targets tested. The Affimers were expressed in *E. coli*, with soluble protein yield as high as 250 mg/L. A combination of ELISA and SPR has shown that these Affimer proteins bind their targets with low nanomolar affinity. Affimer pairs that bind different epitopes on monomeric targets were identified and used as both capture and detection reagents in immunoassays. The pairs show high specificity and retained 96% of binding in complex matrices. These Affimer-based assays have shown increased sensitivity and specificity compared to current ELISA kits.

**Conclusions:** This study shows that Affimers are robust molecular reagents for the identification of high affinity and specific binders against the panel of targets tested. The selected Affimers have potential for use in point-of-care differential diagnostics for viral and bacterial infection.

Abstract 6602

The natural history of gonorrhoea infection: an illustrative review

Jane Whelan*, Ekkehard Beck

1GSK, Amsterdam, Netherlands, 2GSK, Wavre, Belgium

Abstract third-party references: Funding: GlaxoSmithKline Biologicals SA

Background: Gonorrhoea is a sexually transmitted infection of the urogenital, pharyngeal or anorectal tract, or the eye. The natural history is complex and infection results in diverse clinical presentations and health outcomes in men, women and newborns, the scope of which is incompletely characterized in the literature. Traditional systematic literature searching based on broad search queries and multitudinous hits, may be too resource intensive to capture all related clinical and psychosocial outcomes. Using novel artificial intelligence-(AI)-assisted search methods we address this challenge, providing a single, evidence-based compendium of identified outcomes and a summary of related pathogenic processes.

Materials/methods: We combined traditional systematic review methodology using standard search engine technology with innovative AI Medline screening. The AI tool uses natural language pre-processing to screen abstracts for ‘topic-words’ associated with a query (‘gonorrhoea’), which are then weighted based on term and supporting-document frequency. Topic-words were screened independently by two reviewers for relevance to clinical and psychosocial gonorrhoea-related health outcomes, and key references selected according to an objective quality score. A systematic search of the literature combining pre-specified medical subject headings and keywords was also conducted to identify health outcomes and related key pathogenic processes (English, no time limit).

Results: Ninety-seven clinical conditions relating to Ng were first identified through a targeted search of works by seminal authors, websites of public health institutes (CDC, PHE/NHS and RKI) and gonorrhoea-related ICD9/10 and Read diagnostic codes. AI screening identified 18,289 Medline citations, of which 10,022 containing an abstract were included, incorporating 10,324 topic-words. Of 10,324 topic words manually screened, 230 outcome-related topic-words were selected, categorized by organ systems or outcomes and by quality score for supporting references (n=57 urogenital, n=20 anorectal, n=6 oropharyngeal, n=14 eye, n=26 psychosocial, n=25 coinfections, n=6 disseminated infection, n=2 antibiotic resistance, n=74 systemic/non-specific health domain). Pathogenic processes were summarized based on 35/101 full text articles reviewed.

Conclusions: Combining novel and traditional systematic search methodologies, we comprehensively identified evidence-based clinical and psychosocial health outcomes associated with gonorrhoea infection. This review informs clinicians, public health practitioners and policy makers, ultimately facilitating an evidence-based summary of the burden of gonorrhoea infection.

Burden of viral infections among autologous stem cell transplant patients: a prospective longitudinal study

Grégory Destras*1,2, Antonin Bal1,2, Pierre Sesques4, Clementine Sarkozy1, Laurence Generaz1, Guy Oriol1, Gilles Salles1, Bruno Lina1,2, François Mallet3, Alexandre Pachot1, Genevieve Billaud2, Laurence Josset1,2, Trouillet-Assant Sophie1,2, Valérie Cheynet3, Karen Brengel-Pesce3, Florence Morfin1,2

1Université Claude Bernard Lyon 1, CIRI - INSERM U1111 - CNRS UMR5308 - Virpath, Lyon, France, 2Groupement Hospitalier Nord, Hospices Civils de Lyon, Laboratoire de Virologie, Institut des Agents Infectieux, Lyon, France, 3Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Laboratoire Commun de Recherche Hospices Civils de Lyon - bioMérieux, Pierre-Bénite, France, 4Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Service d’Hématologie Clinique, Pierre-Bénite, France

Background: Hematopoietic stem cell transplantation remains the only curative treatment for many hematological disorders. Surrounding this immunosuppressive therapy, viral reactivations caused by herpesviruses, adenovirus, BK virus require particular attention to prevent organ damages. Despite some severe cases reported in autologous stem cell transplant (ASCT) patients, only few recommendations regarding the management of viral infections have been established so far. We aimed to investigate viral infections in patients who underwent ASCT in a large prospective longitudinal study.

Materials/methods: A systematic screening of plasma viral load, targeting 9 viruses at 11 time-points (from diagnosis to 90 days post transplantation), was performed on 477 samples from 48 patients (n=42 multiple myeloma, n=6 lymphoma) prospectively enrolled. Clinical criteria and hemogram values were collected. All patients received antiviral prophylaxis with valaciclovir.

Results: Of 4293 PCRs performed, 86 (2.0%) were positive corresponding to 75/477 (15.7%) samples. While sixteen patients (35%) had no virus detected during follow-up, most of positive samples (56%) were found after aplasia and 30 days after transplantation. Patients mainly presented CMV reactivation (59% of CMV seropositive patients). Overall, low viral loads (<3 log copies/mL) were found except for one patient with parvovirus B19 primary infection [11.85 log copies/mL], and for two patients with HHV6 [3.84 log copies/mL] and CMV [4.50 log copies/mL] clinical reactivations. For this latter patient, CMV was also the unique pathogen identified in the bronchoalveolar lavage collected during an interstitial pneumonia episode requiring 6 days of hospitalization. No specific reactivation was associated with clinical or biological criteria. Interestingly, no reactivation was found in multiple myeloma patients treated with daratumumab, a cd-38 monoclonal antibody for which an increase in viral reactivations was previously reported.

Conclusions: This is the largest prospective study reported so far describing viral detections during the whole follow-up of ASCT patients. We found a limited clinical impact of viral reactivations in these patients treated with valaciclovir, suggesting a potential benefit of administering an antiviral prophylaxis in all ASCT patients [even not yet recommended]. However, CMV testing should be systematically considered in case of infectious complications. This study might contribute to upgrade guidelines regarding ASCT patient management.

Abstract 6610

Spectrophotometric detection of azole-resistant *Aspergillus fumigatus* clinical isolates with EUCAST broth microdilution method. Is it time for automating EUCAST antifungal susceptibility testing of *Aspergillus* spp.?

Ioanna Efstathiou¹, Hein Van Der Lee², Maiken C. Arendrup³,⁴,⁵, Paul E. Verweij², Joseph Meletiadis*¹,⁶

¹"Attikon" University General Hospital, Clinical Microbiology Laboratory, Athens, Greece, ²Radboud University Medical Centre, Department of Medical Microbiology, Nijmegen, Netherlands, ³Statens Serum Institut, Unit of Mycology, Copenhagen, Denmark, ⁴Rigs Hospsitalet, Department of Clinical Microbiology, Copenhagen, Denmark, ⁵University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark, ⁶Erasmus Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands

**Background:** Timely detection of azole-resistant *Aspergillus* isolates is a significant challenge. EUCAST antifungal susceptibility testing of *Aspergillus* spp. requires visual inspection of microplates, which is time-consuming, subjective and requires experienced staff. We compared spectrophotometric and visual reading of EUCAST microplates for the detection azole resistant *A. fumigatus* in a large collection of isolates including resistant isolates with different mechanisms of resistance.

**Materials/methods:** The following *Aspergillus fumigatus* (n=181) were examined: 63 WT isolates, 60 isolates harboring TR34/L98H mutation and 58 harboring TR46/Y121F/T289A mutation. Susceptibility testing was performed following the EUCAST E.Def 9.3.1 methodology for amphotericin B, itraconazole, voriconazole, posaconazole and isavuconazole. The MICs of the isolates were determined after 48h of incubation visually and spectrophotometrically at 405 nm as the lowest concentration corresponding to 1, 3, 5, 10 or 15% OD increase above the conidia-free background OD. The essential agreement EA (±1 twofold dilution) and categorical agreement CA (based on the classification of the isolates as susceptible/intermediate/resistant using EUCAST breakpoints) were calculated. The best spectrophotometric endpoint (SPE) was chosen based on the highest CA and fewer very major (VME), major (ME) and minor errors (mE).

**Results:** The median (range) MICs of amphotericin B, itraconazole, voriconazole, posaconazole and isavuconazole were 0.5(0.25-1), 0.25(0.063-2), 0.25(0.125-1), 0.063(0.031-0.25) mg/l for WT, 0.5(0.25-2), >16(2->16), 4(2-16), 0.5(0.125-1), 8(2->16) mg/l for TR34/L98H and 0.5(0.125-4), 2(0.25->16), 16(0.5->16), 0.5(0.016-16), 32(0.5->16) mg/l for TR46/Y121F/T289A isolates. The best performing SPE was the 10% growth endpoint with EA 98%, 96%, 95%, 93% and 93% and CA 98%, 95%, 90%, 90% and 98% for amphotericin B, itraconazole, voriconazole, posaconazole and isavuconazole, respectively. The VME were 0% for all drugs except for itraconazole (1%). The ME and mE were 1-2% and 0-10%, respectively for all drugs.

**Conclusions:** Spectrophotometric reading of EUCAST microplates can be used for amphotericin B and azole antifungal susceptibility testing of *A. fumigatus* and particularly in detecting azole resistance. Spectrophotometric readings will lead to automation and increase objectivity of EUCAST E.Def 9.3.1 protocol.

Abstract 6613

Definite prolonged antibiotic treatment in complicated prosthetic valve endocarditis with absolute contraindication to surgery: a single-centre retrospective analysis

Novella Cesta*1, Tizana Mulas1, Vincenzo Malagnino1, Marco Iannetta1, Margherita De Masi1, Giovanni Ruvolo1, Massimo Andreoni1, Loredana Sarmati1

1Università degli Studi di Roma "Tor Vergata", Infectious Disease Unit, Department of Systems Medicine, Roma, Italy, 2Università degli Studi di Roma "Tor Vergata", Unit of Cardiac Surgery, Department of Experimental Medicine, Roma, Italy

Background: Prosthetic valve endocarditis (PVE) is a serious complication after heart valve replacement. In case of complicated infections, Staphylococcus spp or peripheral embolism, the recommended treatment is the antibiotic therapy combined to surgery. Antibiotic therapy alone is not commonly recommended for complicated PVE. Here we retrospectively describe a case collection of patients with complicated PVE, conservatively treated with antibiotics because of the presence of absolute contraindication to surgery.

Materials/methods: We retrospectively collected complicated PVE cases diagnosed (according to Duke criteria) in our institution, between 2009 and 2017. Demographic data, antibiotic therapy, complications, radiologic and microbiologic findings were reported. All patients had an absolute contraindication to valve replacement and were treated with a definite prolonged antibiotic therapy (first intravenously and then orally). After antibiotic discontinuation, a one-year follow up was conducted.

Results: 28 patients (22 males, 78.5%) were included in the analysis. Median age at time of diagnosis was 72 (IQR: 65-76). In our cohort the prosthetic:biologic valve ratio was 1:1. Aortic valve was the most involved (17/28, 61%) and 21 patients (75%) had a late (> 1 year after surgery) PVE. Staphylococcus spp was responsible for infection in 11 patients (39.2%). A vegetation size of >10 mm was present in 8 patients (28.5%), a valvular abscess in 6 (21.4%) and 4 patients (14.2%) had a periprosthetic leak. Embolic phenomena were observed in 9 patients (39.1%). During hospitalization the median time of antibiotic treatment was 6 weeks (IQR: 5.75-7) whereas the median weeks for the outpatient antibiotic treatment (OPAT) were 24 (IQR: 10-24). After one year of follow up, 22 patients (78%) had no recurrence of infection.

Conclusions: In our study, we observed that a prolonged antibiotic treatment, together with a close follow-up, can be a valid option for those patients with complicated PVE, when surgery is contraindicated. A median of 30 weeks of treatment (6 intravenously and 24 orally) seems to reduce the recurrence of infections after one-year follow up. More studies on wider populations with longer follow up periods are needed to address the issue of definite conservative antibiotic treatment for complicated PVE.

Abstract 6614

**Reference evaluation of two manual blood culture bottles for low-resource settings**

Sien Ombelet*1,2, Alessandra Natale3, Jean-Baptiste Ronat1, Thierry Naas4, Olivier Vandenberg5,6, Jan Jacobs1,2

1Institute of Tropical Medicine Antwerp, Antwerpen, Belgium, 2Katholieke Universiteit Leuven, Leuven, Belgium, 3Doctors Without Borders, Paris, France, 4Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, 5CHU Saint-Pierre, Bruxelles, Belgium, 6Université Libre de Bruxelles, Bruxelles, Belgium

**Background:** The Mini-lab is a Médecins Sans Frontières project for the development of an all-in-one basic clinical bacteriology laboratory deployable in low-resource settings (LRS). Blood cultures are considered priority specimens in this laboratory. An extensive evaluation of two “manual” (i.e., visually read) blood culture bottles (BCB) was done, in parallel to automated incubation of BCB (Bact/ALERT system, bioMérieux). In a previous pilot evaluation of five different manual BCB (n=112 for each BCB type), the Autobio Bi-State BCB (biphasic bottle – agar slant and broth) as well as the “manual” BacT/ALERT FA Plus/PF Plus BCB had shown the best performance.

**Materials/methods:** Both bottle types were further evaluated with a panel of 122 representative bacterial isolates from LRS comprising most clinically relevant bloodstream pathogens (16 bacterial species). Bottles were inoculated with spiked human blood in triplicate, both for pediatric and adult bottles and blood volumes. In total, 552 bottles of each type were inoculated, of which 354 in pediatric experiments and 198 in adult experiments. Bottles were visually inspected twice daily for signs of growth, such as turbidity and hemolysis. For BacT/ALERT bottles, color change of the CO₂ Indicator at the bottom of the bottle was also assessed. For the Autobio bottles, signs of growth on the agar slant as well as in the broth were recorded.

**Results:** The yield (% of inoculated bottles grown) of combined experiments was 95% for the automated BacT/ALERT incubation, 94% for Autobio bottles and 93% for manual BacT/ALERT bottles. Yield was lower in pediatric experiments (93%, 92% and 90% for automated BacT/ALERT, Autobio and manual BacT/ALERT BCB respectively) than in adult experiments (98%, 98% and 97%, respectively). Difference in yield between Autobio and manual BacT/ALERT bottles was not significant (p=0.07). All automated bottles showed growth after overnight incubation. For Autobio bottles, 91.3% showed growth after overnight incubation, versus 82.4% of manual BacT/ALERT bottles (p<0.001).

**Conclusions:** Yield of manual BCB was comparable to that of the automated bottles in our experiments. Autobio bottles showed similar yield but significantly faster growth than manual BacT/ALERT bottles. Visual signs of growth were more easily detectable in the Autobio bottles.

Abstract 6615

Whole genome sequencing clarifies potential outbreak with extended-spectrum beta-lactamase-producing *Escherichia coli*

Sara Mernelius*1,2, Linda Berglind1

1Ryhov County Hospital, Laboratory Medicine, Jönköping, Sweden

**Background:** Between March and October 2019 we isolated Extended Spectrum Betalactamase (ESBL)-producing *Escherichia coli* from eight neonates in the neonatal ward at Ryhov County Hospital, Jönköping, Sweden. All of the neonates were colonized with ESBL-*E. coli*, none of the isolates were retrieved from clinical cultures.

By whole-genome sequencing (WGS) we clarified the similarity between the ESBL-*E. coli* isolates and used the information to elucidate whether transmission of bacteria between neonates had occurred or not.

**Materials/methods:** DNA was extracted from the eight ESBL-*E. coli* isolates, using the EZ1 DNA Tissue kit on the EZ1 Advanced XL (Qiagen). Library preparation was performed using Nextera XT library prep kit (Illumina). Paired-end sequencing (2*250 cycles) was performed on a Miseq instrument (Illumina). Assembly and cluster analysis by core genome multilocus sequence typing (cgMLST) based on 1602 genes was performed using SeqSphere (Ridom GmbH). The cluster alert distance was set to 10 allelic differences.

**Results:** The eight isolates were divided into five different clusters. Three of the clusters consisted of one isolate each. The remaining two clusters consisted of two and three isolates, respectively (Figure 1).

ESBL-*E. coli* isolates 1 and 2 were highly dissimilar although they were retrieved the same day.

Isolates 4, 5 and 6 were indistinguishable. Two of the isolates were collected from a pair of twins and the third isolate from a neonate cared for at the ward simultaneously as the twins.

The isolates from neonate 3 and 7 were indistinguishable. The neonates were not cared for simultaneously at the ward.

**Conclusions:** WGS shows that highly dissimilar ESBL-*E. coli* can be obtained from different patients simultaneously cared for in one ward. Epidemiological data alone indicated that transmission could have occurred.

The opposite is also shown by WGS, neonates with no overlap in hospitalization had the same type of ESBL-*E. coli*, indicating long survival in the environment and a possible delayed transmission.

In conclusion, WGS can be used both to rule out and detect bacterial transmission between patients in hospital care.

**Figure 1:** Minimum-spanning tree of the eight ESBL-*E. coli* isolates.

Abstract 6616

**Designing and structure evaluation of uropathogenic *Escherichia coli* multi-epitope subunit vaccine**

Maryam Rezaei*, Mehri Habibi1, Mohammad Reza Asadi Karam1, Parastoo Ehsani1, Neda Moazzezy1, Saeid Bouzari*

1Pasteur institute of Iran, Tehran, Iran

**Background:** Urinary tract infections (UTIs) are a severe public health problem and usually caused by UPEC. According to the increasing rate of antibiotic resistance, precaution strategies such as vaccination can be useful for UTI management. Immunoinformatics methods overcome the problems of traditional vaccinology such as high cost, time duration, and accuracy and has been applied successfully in vaccine design.

**Materials/methods:** To design a novel multiepitope subunit vaccine against UTI, FdeC, Hma, UpaB were selected. Different online tools such as IEDB, ABCpred, Net MHCI and Net MHCII were used to predict Bcell linear epitopes and T cell epitopes. Some physicochemical characteristics of the vaccine constructs were investigated by ProtParam tools and solubility was checked by the ccSOL omics server. Third structure of our designed constructs were modeled by I-Tasser and molecular docking was done by patchdock server using HLA alleles and GM1. Antigenicity and allergenicity of selected construct were evaluated by VaxiJen and AlgPred server respectively.

**Results:** In this study two constructs were designed: a construct which contains Bcell epitopes and a construct contains Tcell epitopes. According to the performed analysis, constructs which had best physicochemical characteristics and best c-score in I-tasser results were selected. Docking results of selected constructs with related receptors were desirable and constructs were found to be non-allergen.

**Conclusions:** Since humoral and cellular immunity are required for effective protection against UTI, we designed two constructs containing B-cell and T-cell epitopes and CTB as a build-in adjuvant. Computational analysis showed that our construct could induce effective immune responses. This study could be useful in achieving an ideal epitope based vaccine against UTI.

Abstract 6617

Understanding the pathogenicity of Scedosporium species, the emerging cystic fibrosis pathogens
Mónika Homa*1,2, Csilla Szebenyi1,2, Olivér Jáger1,2, Csaba Vágvölgyi2, Tamás Papp1,2

1University of Szeged, MTA-SZTE “Lendület” Fungal Pathogenicity Mechanisms Research Group, Szeged, Hungary, 2University of Szeged, Faculty of Science and Informatics, Department of Microbiology, Szeged, Hungary

Background: Scedosporium species are ubiquitous saprophytic hyaline filamentous fungi, which are commonly associated with anthropogenic habitats. As opportunistic human pathogens, these species are capable to cause a wide spectrum of infections (e.g., they are the second most frequently isolated filamentous fungi from the sputum of patients with cystic fibrosis), while known to be resistant against numerous clinically used antifungal drugs. The incidence of clinically relevant species does not reflect their environmental distribution, moreover, some species has not been associated with clinical samples at all. These observations suggest, that the different Scedosporium species might possess unique properties (e.g., a specific set of virulence factors) allowing them to colonize distinct environmental niches. These virulence factors might serve as novel targets for antifungal strategies.

Materials/methods: We investigate host-pathogen interactions using in vitro and in vivo model systems in order to compare the pathogenic potential of Scedosporium apiospermum, S. boydii, S. aurantiacum, S. angustum, S. dehoogii, S. ellipsoideum, S. minutisporum, S. fuscosporeum and S. desertorum. To reveal differences in the killing potential of macrophages against various Scedosporium species and to describe the immune cell damaging capacity of these fungi, cytotoxicity and imaging flow cytometry-based phagocytosis assays are performed. Alternative invertebrate infection models are also applied in order to compare the in vivo pathogenic potential of scedosporia.

Results: Our preliminary observations suggest some fundamental differences between the volatile sulfur and nitrogen metabolism of S. aurantiacum and other Scedosporium species (e.g., S. apiospermum and S. boydii). As sulfur metabolism has been previously associated with the virulence of other filamentous fungi, we assume that the observed metabolic differences is reflected in the virulence properties of scedosporia as well. Additionally, we observed significant differences in the in vitro and in vivo pathogenic potential of the tested species. The results of this ongoing project may reveal novel aspects of the background of pathogenicity mechanisms (e.g., virulence factors) and the main risk factors for the emergence and spread of scedosporia in our immediate environment.

Conclusions: This comprehensive study facilitates the understanding of the pathogenicity of filamentous fungi through the investigation of the emerging pathogenic Scedosporium genus.

A study comparing the performance of an eravacycline Oxoid antimicrobial susceptibility testing disc against an FDA-cleared predicate device

Katherine Church*, Darcie Carpenter², Melanie Olesky³

1Thermo Fisher Scientific, Basingstoke, United Kingdom, ²IHMA Europe Sàrl, Monthey, Switzerland, ³Tetraphase Pharmaceuticals Inc, Watertown, United States

Abstract third-party references: Tetraphase Pharmaceuticals, 480 Arsenal St Ste 110, Watertown, USA, Thermo Fisher Scientific, Wade Road, Basingstoke, RG24 8PW, IHMA Europe Sarl, Rte de l'Ile-ai-Bois 1A, Switzerland

Background: An evaluation was designed to determine the accuracy and reproducibility of the new eravacycline Oxoid Antimicrobial Susceptibility Testing disc against the FDA cleared eravacycline disc from Hardy Diagnostics (the predicate device). Eravacycline is a synthetic halogenated tetracycline antibiotic from tetraphase and is indicated for the treatment of complicated intra-abdominal infections (cIAI) caused by the following susceptible microorganisms: Escherichia coli, Klebsiella pneumoniae, Citrobacter freundii, Enterobacter cloacae, Klebsiella oxytoca, Enterococcus faecalis, Enterococcus faecium, Staphylococcus aureus, Streptococcus anginosis group, Clostridium perfringens, Bacteroides species and Porabacteroides distasonis, in patients 18 or older.

Materials/methods: Two lots of investigational use only Oxoid eravacycline disks provided by Thermo Fisher were tested with 375 (300 clinical + 75 challenge) isolates using Clinical and Laboratory Standards Institute (CLSI) M02-A13 (2018) method with Mueller Hinton agar (Oxoid MHA). One lot of Hardy eravacycline disks were tested alongside as a predicate device. Quality Control (QC) was carried out daily as per CLSI M02-A13 and M100-S29 documents using American Type Culture Collection (ATCC) strains.

Results: When compared with the predicate device, five minor errors were observed (four challenge isolates, one clinical isolate) with categorical agreement of 98.67%. Reproducibility was calculated as the percent of results which were within plus or minus 3 mm of the modal value. All data was shown to be 100% reproducible both within-reader and between-reader. QC results were within range 100% of the time for each batch and each reader.

Conclusions: The results show that the Oxoid eravacycline disc demonstrates an equivalent level of performance compared to the predicate device. The high level of agreement obtained by the Oxoid eravacycline disc suggests this is an acceptable method for susceptibility testing of eravacycline.

Abstract 6623

Relatedness of European Clostridioides difficile strains from humans, food and animals by whole genome sequencing, ribotyping and toxinotyping; results from COMBACTE-CDI

Kerrie Davies*, Virginie Viprey¹, Valerija Tkalec², Nathalie Devos³, Emmanuelle Santiago-Allexant⁴, Duncan Ewin¹, William Spittal¹, Jonathan Vernon¹, Warren Fawley², Jill Dombrecht⁴, Anthony Benson¹, Georgina Davis¹, Beatrice Sente³, Maja Rupnik², Philippe Cleuziat⁴, Mark H. Wilcox¹

¹Healthcare Associated Infections Research group, University of Leeds, Leeds, United Kingdom, ²National laboratory for Health, Environment and Food, NLZOH, Maribor, Slovenia, ³GSK, Rixensart, Belgium, ⁴bioMérieux, chemin de l’Orme, Marcy l’Etoile, France, ⁵National Infection Service, Public Health England, Leeds, United Kingdom

Abstract third-party references: on behalf of the COMBACTE-CDI consortium

Background: Previous data from human-derived Clostridium difficile (CD) strains indicates country-specific clustering for some but not all ribotypes. COMBACTE-CDI provides the opportunity to explore this further with the addition of food/animal strains

Materials/methods: On two days, all diarrhoeal samples (regardless of tests requested, n=3163) from 119 sites in 12 European countries, were CD cultured at the coordinating laboratory (positive=287). Contemporaneous CD isolates were collected from animals (n=126) and food (n=67) in the same countries. All isolates underwent PCR-ribotyping, toxinotyping, and whole genome sequencing (WGS); dendrograms were constructed in BIOMÉRIEUX EPISEQ® CS using wgMLST with 95% cut-off and virulome compared between strains.

Results: Using WGS, isolates clustered by ribotype and toxinotype, although matches were not exact. Some ribotypes had within-country clustering (027, 181) while others did not (002, 015, 014, 020). Similarity threshold was increased to 99% to analyse highly-related ribotype 078 and 126 strains, demonstrating five distinct clusters with no within-country clustering for human isolates; animal and food isolates did cluster by country (Figure 1). Analysis highlighted one UK 027 isolate, clustered within 027 isolates from Poland; one 181 isolate from UK clustered within 181 isolates from Romania; one 018 isolate from an Italian community patient clustered next to an isolate from an Italian hospital patient. Virulome analysis on EPISEQ® CS aligned with toxinotyping, with two discrepancies (PaLoc not detected by EPISEQ® CS). Both parts of the binary toxin genes were present in all isolates from ribotypes 027, 181, 078 and 126; however several ribotypes only had cdtB (015, 001 and 005). All isolates from ribotypes 078 and 126 were deficient in fliA, which was ubiquitous in almost all other ribotypes.

Conclusions: There was not an exact match between WGS and ribotype, probably because these are two distinct typing schemes examining different parts of the genome. Previous data on strains that show within-country clustering was confirmed, while in contrast to previous data there was some country-specific clustering of 078 and 126 strains, however this was for food or animal source isolates only. EPISEQ® CS analysis highlighted potential transmission events for further investigation, and differences in virulence factors between ribotypes.

Abstract 6624

**Species distribution and antifungal susceptibility profile of the emerging yeast pathogen Blastobotrys**

Hamid Badali, Connie Gibas, Hoja Park Patterson, Dora Mccarthy, James Mele, Hongxin Fan, Nathan Wiederhold

1UT Health San Antonio, San Antonio, United States

**Background:** The genus *Blastobotrys* (order Saccharomycetales) consists of a group of uncommon, fluconazole-resistant yeasts. Although infrequently cultured from clinical samples, these fungi can be isolated from cystic fibrosis patients or those with chronic bronchitis and have been associated with respiratory deterioration. However, many clinical laboratories do not routinely identify yeasts in respiratory specimens, and antifungal susceptibility profiles against this genus is not well-understood. Our objective was to evaluate the species distribution and antifungal susceptibility profile of clinically available agents and the novel inositol acyltransferase inhibitor manogepix against *Blastobotrys* isolates in the U.S.

**Materials/methods:** A panel of 22 clinical *Blastobotrys* isolates, mostly respiratory isolates comprised of 14 human and 8 animal specimens, received by the Fungus Testing Laboratory at the UT Health Science Center San Antonio for identification and antifungal susceptibility testing were included. Identification was determined by DNA sequencing and phylogenetic analysis of ITS rDNA region and LSU gene. *In vitro* susceptibility against 20 isolates was performed by the CLSI M27 broth microdilution method.

**Results:** Of the 22 *Blastobotrys* isolates, the majority (n=21) were identified as *B. raffinosifermentans*, while one was identified as *B. adeninivorans*. Of the clinically available antifungals the most potent activity was observed with micafungin (range ≤0.015 - 0.5 mg/L, GM MIC 0.268 mg/L), isavuconazole (0.06-8 mg/L, 0.287 mg/L), and amphotericin (0.25- 1 mg/L, 0.448 mg/L). The other extended-spectrum azoles (i.e., voriconazole, posaconazole, and itraconazole) also demonstrated activity although the GM MICs were at least 2 dilutions higher than that of isavuconazole (GM MIC range 0.896 - 1.04 mg/L; p <0.01 for each comparison vs. isavuconazole). Manogepix also demonstrated potent in vitro activity (range ≤0.015 - 0.03 mg/L; GM MIC 0.016 mg/L). In contrast, limited activity was observed with fluconazole (16 - >64 mg/L, 46.1 mg/L).

**Conclusions:** Of the clinical isolates tested, *B. raffinosifermentans* was the most prevalent species, which was cultured from both human and animal specimens. Potent *in vitro* activity was observed with the investigational agent manogepix and the clinically available antifungals micafungin, isavuconazole, and amphotericin B. Further studies are warranted in order to determine the clinical implications of these findings.

Does vaccines need a gender perspective? Influenza says yes!

Laura Sanchez De Prada*1, Iván Sanz2, Sonia T amames3, Ana Lopez1,2, Silvia Rojo1, Raúl Ortiz De Lejarazu4, Jose María Eiros4

1Hospital Clinico Universitario de Valladolid, valladolid, Spain, 2National Influenza Centre Valladolid, Valladolid, Spain, 3Consejería de Sanidad- Junta de Castilla y León, Valladolid, Spain, 4Hospital Universitario Rio Hortega, Valladolid, Spain

Background: In the era of gender equality there are studies showing different responses to infectious diseases based on gender. This has been related to hormones and their impact on the immune system. The aim of this study is to compare the humoral response to influenza vaccination in men and women

Materials/methods: A retrospective study was performed in 2,077 individuals vaccinated with influenza vaccine recruited from 1990 till 2018. Population of study was divided by gender and age (14-64 and ≥65 years old). Serum samples were obtained before and 28 days after vaccination. For analyzing the antibodies titer in both sera, haemaglutination inhibition assay (HAI) was performed at the National Influenza Centre of Valladolid (Spain) against classical A(H1N1) (from 1990 till 2010), A[H1N1]pdm09 (from 2010 till 2018), A(H3N2) and for both influenza B/Yamagata and B/Victoria lineages. The statistical analysis was performed calculating the Geometric Mean Titters increase (GMTi) and the Seroconversion Rate (SCR). Differences by age and sex were analyzed using Student-T and chi-square tests (p<0.05).

Results: HAI was performed in 966(46.5%) men and in 1,111(53.5%) women. GMTi was significantly higher in women (14-64 years) for classical A(H1N1) (p=0.019) while GMTi were significantly higher in women ≥65 for both classical A(H1N1) (p=0.004) and A[H1N1]pdm09 (p=0.001) subtypes. The SCR was significantly higher in women ≥65 for both classical A(H1N1) (p=0.005) subtype and A[H1N1]pdm09 (p=0.001) subtypes but also for B/Victoria lineage (p=0.039). No other statistical significances were found. Values of GMTi and SCR are shown in the following table.

Conclusions: Our results showed that women experience higher humoral responses after influenza vaccination specially in the elderly against some influenza viruses as classical A(H1N1) and A[H1N1]pdm09 subtypes. These results confirm that there are biological differences between men and women affecting the humoral response induced by vaccination.

**Association between first episode Clostridioides difficile infection management and recurrence in a tertiary hospital**

Ledicia Alvarez Paredes¹, Maria Andrés Franch¹, Cristina Labayru Echeverría², María Ángeles Mantecón *, Cristina Losa Pérez¹, María Ortega Lafont¹, Eleda Coletta¹, Gregoria Megias Lobon¹

¹Hospital Universitario de Burgos, Burgos, Spain

**Background:** Inadequacy of treatment to guidelines and specific risk factors (advanced age, duration of hospitalization, exposure to antibiotics, underlying diseases and comorbidities, cancer chemotherapy, immunosuppression, gastrointestinal surgery, tube feeding, proton pump inhibitor [PPI]) are associated with recurrent cases of CDI (rCDI). The aim of the study was to analyze factors associated with recurrence in our health area.

**Materials/methods:** Between 2010 and 2018, patients >2 years old with unexplained and new-onset ≥3 loose stools in 24 h were included. Microbiological diagnosis of toxigenic strains was confirmed by EIA (C. diff Quik Chek®) or PCR (Xpert® C. difficile). Recurrence was defined as a relapse of CDI symptoms within 2-8 weeks of successful treatment of the initial episode. Clinical and microbiological risk factors associated with recurrence, as well as adjusted treatment to guidelines (IDSA 2010-2018, ESCMID 2014) were analyzed. Chi-square or Fisher and U-Mann Whitney were performed to investigate association between variables. Odds ratio and 95% confidence intervals [CIs] were calculated.

**Results:** 273 patients were included. Mean age was 64.90 year old, and 153 (56%) were women. Higher mortality rates were not found in recurrent patients. Clinical and microbiological risk factors significantly associated with recurrence, are shown in Table 1.

¹IDSA 2010-2018, ESCMID 2014

²Ct: cycle thresholds.

**Conclusions:** Although finding association between some of the clinical and microbiological variables, our sample size wasn’t enough to achieve a robust recurrence predictor score. However, it seems that in the future these factors will be included in recurrence prediction algorithms. Furthermore, distribution of current guidelines would minimize the prevalence of recurrence.

The population structure of extended-spectrum beta-lactamase-producing Enterobacteriaceae in households following hospital discharge and long-term care facilities is species dependent: MODERN-studies from 5 European countries (2017-2019)

Tess Daniëlle Verschuuren1, Julia Dick2, Maria Eugenia Riccio1, Elena Salamanca4, Stefanie Bunk3, Nadine Conzelmann1, Daniel Martak6, Didier Hocquet6, Evelina Tacconelli5, Jesús Rodríguez-Baho7, Stephan J. Harbarth3, Ingo B. Autenrieth2, Ad Fluit8, Silke Peter2, Jan A. J. W. Kluytmans1

1University Medical Centre Utrecht, Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands, 2University Hospital Tübingen, Institute of Medical Microbiology and Hygiene, Tübingen, Germany, 3Geneva University Hospital, Infection Control Program, Geneva, Switzerland, 4Infectious Diseases, Microbiology and Preventive Medicine. University Hospital Virgen Macarena., Sevilla, Spain, 5University Hospital Tübingen, Department of Infectious Diseases, Tübingen, Germany, 6University Hospital Besançon, Infection Control Unit, Besançon, France, 7University Hospital Virgen Macarena, Department of Infectious Diseases, Seville, Spain, 8University Medical Centre Utrecht, Department of Medical Microbiology, Utrecht, Netherlands

Background: Limited evidence is available on how the molecular population structure of extended spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-PE) differs between European countries, and to which extent transmission dynamics depend on bacterial species. Here we describe the molecular results of the MODERN-studies performed in 5 European countries between 2017 and 2019.

Materials/methods: In total, 728 ESBL-PE (Escherichia coli and Klebsiella pneumoniae) isolates were prospectively collected in two observational cohort studies. Firstly, isolates from 83 residents and 12 employees from six Long Term Care Facilities (LTCF). Secondly, isolates collected from 112 household members from 71 households. The first isolate of a specific sequence type (ST) per study participant was selected to prevent dependency between longitudinal measurements. This led to a selection of 201 E. coli and 89 K. pneumoniae isolates (127 from Spain, 59 from Switzerland, 38 from France, 44 from Germany, and 22 from the Netherlands) whose genomes were sequenced with Illumina NextSeq. Neighbour joining trees were constructed using PopPUNK.

Results: In total, 84 unique STs were found. For E. coli, ST131 predominated in 41% (n=82) of isolates, followed by ST10 in 12% (n=24), and ST38 with 4% (n=8) of isolates, following a similar pattern for all countries. In contrast, K. pneumoniae showed distinct clustering based on geographical origin, with ST405 and ST307 predominating in Spain, ST1537 in Switzerland, and ST405 in France. Fourteen unique blaESBL were detected, 9 genes from the blaCTX-M family, in 92% of isolates, and 5 genes from the blaSHV family, in 10% of isolates. For both species, blaCTX-M-15 was the most frequent (62% of all isolates). Phylogeny (figure 1) revealed clustering of K. pneumoniae isolates based on epidemiological setting (LTCF [in red and green] versus households [in blue]), while for E. coli a more heterogeneous pattern was seen.

Conclusions: In the MODERN-studies performed in six LTCFs and 71 households in 5 European countries, ESBL-producing E. coli has a similar ST distribution, while ESBL-producing K. pneumoniae demonstrates clustering based on geography and epidemiological setting. ESBL gene content shows a limited diversity, with large overlap between K. pneumoniae and E. coli, with a relatively even distribution across countries.
Figure 1. Core genome Neighbour Joining Trees for ESBL *E. coli* (left), and ESBL *K. pneumoniae* (right).

Abstract 6631

Interactive access to current regional and national antimicrobial resistance data: the INFECT framework
Felix Steiner¹, Lina M. Van Der Weg¹, Silvio D. Brugger², Andreas Kronenberg³, Pascal Frey*⁴

¹Joinbox GmbH, Department for Biomedical Innovation, Bern, Switzerland, ²University Hospital Zurich, University of Zurich, Department of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland, ³University of Bern, Institute for Infectious Diseases, Bern, Switzerland, ⁴Bern University Hospital (Inselspital), University of Bern, Department for General Internal Medicine, Bern, Switzerland

Background: Empirical antimicrobial therapy is a vital and widely applied concept in clinical medicine that relies on the availability of local antimicrobial resistance data and evidence-based guidelines. To support the availability of such data, we initiated the open-source project INFECT (INterface For Empirical antimicrobial Chemotherapy), aimed at informing and assisting clinicians with empirical antimicrobial treatments.

Materials/methods: NFECT is a web application that works with all major internet browsers, and a stand-alone mobile app. As data source for INFECT we used anonymized susceptibility test data from the Swiss Center for Antibiotic Resistance (anresis.ch). Each month, INFECT imports resistance information of the past 12 months, which is aggregated and shown in a substance-by-organism matrix. The matrix can be filtered by multiple characteristics. In order to handle the heavy computational load of combining filters, we have introduced a real-time data analytics service (RDA) that distributes load to multiple servers. To enhance the clinical usability of INFECT, we have developed an additional guideline module that combines third-party empirical antimicrobial treatment guidelines (e.g., Swiss national treatment guidelines) with the regional resistance data.

Results: Overall, by processing anresis.ch data our "INFECT by anresis.ch" web application now handles approximately 2 million antimicrobial resistance test results, from eight representative regions of Switzerland. Data can be filtered by users according to microbial (e.g., Gram stain), antimicrobial (e.g., substance class) or population (e.g., region, age) properties. Susceptibility is displayed as percentage in a coloured circle, with the circle colour showing the proportion of susceptibles while the circle size represents sample size (Figure). With RDA, aggregations for filters take only ~200ms. The additional guideline module provides a further diagnosis filter, which highlights expected pathogens and the guideline's recommended substances for the respective diagnosis.

Conclusions: With the INFECT framework it is now possible to routinely assist empirical antimicrobial therapies with state-of-the-art information technology using the latest epidemiological data and third party guidelines. Due to its flexible modular design, INFECT may be adjusted to other data sources, or extended with further modules as needed. The Swiss application "INFECT by anresis.ch" is available on infect.info and as mobile app for iOS and Android.

Abstract 6634

Diagnostic yield of pharyngeal, axillary, inguinal and rectal swab samples for multidrug-resistant Gram-negative detection in intensive care patients

Sergio Román Soto*, Marina Alguacil Guillén1, Almudena Quintás-Viqueira1, Ana Robustillo1, Guillermo Ruíz-Crrascoso1

1University Hospital La Paz, Madrid, Spain

Background: Colonization screening of multidrug-resistant microorganisms has been implemented in intensive care units (ICU) to prevent outbreaks and nosocomial infections. Multidrug-resistant Gram-negative bacteria (MDR-GNB) can be isolated from skin, respiratory and intestinal mucosa. Our aim is to assess pharyngeal (PSS), axillary (ASS), inguinal (ISS) and rectal (RSS) swab samples for recovering MDR-GNB in ICU patients at La Paz-Cantoblanco-Carlos III University Hospital (Madrid, Spain).

Materials/methods: Colonization screening was performed obtaining RSS, ISS, ASS and PSS on the same day, from January 2015 to December 2018. Samples were cultured on MacConkey agar supplemented with 4 mg/L of cefotaxime and/or CHROMID® CARBA SMART. Gram-negative isolates were identified using MALDI-TOF. Phenotypical and molecular methods were performed for bacterial resistance characterization.

Results: We analyzed 396 screening (1,584 samples) from 259 adult patients admitted to the burn ICU and post-operative ICU. MDR-GNB were isolated in 18% (72/396) of screening: 86% (62/72) from RSS, 55% (40/72) from ISS, 20% (15/72) from ASS and 19% (14/72) from PSS. The resistance mechanisms detected were: 46% extended-spectrum beta-lactamase (ESBL), 22% VIM, 14% OXA 48, 1% OXA 48+VIM producers and 17% MDR Acinetobacter baumannii. The isolates were 65% Klebsiella spp., 17% Acinetobacter baumannii, 14% Enterobacter spp., and 4% Serratia marcescens. Cumulative percentages of positive MDR-GNB are shown in table 1.

<table>

</table>

Table 1: Yield of swab samples for recovering MDR-GNB.

Conclusions: RSS was the best sample for recovering MDR-GNB and, to a lesser extent, ISS for GNB ESBL/carbapenemase producers and PSS for MDR Acinetobacter baumannii. ASS did not contribute to the recovery of any MDR-GNB compared to other swabbed sites. Therefore, ASS cultures are not advisable for MDR-GNB colonization screening in ICU patients.

An outbreak of Ralstonia pickettii bloodstream infection among paediatric leukaemia patients

Tugba Bedir Demirdag, Aslı Nur Parlakay, Fatma Bayrakdar, Belgin Gulhan, Saliha Kanik, Serap Süzük, İpek Mumcuoğlu*, Bedia Dinc, Neşet Yarıli

1Ankara City Hospital, Ankara, Turkey, 2National Molecular Microbiology Reference Laboratory, Ankara, Turkey

Background: Ralstonia pickettii is a non-fermentative Gram-negative bacillus and an opportunistic pathogen in both hospital settings and environment. It is waterborne and can survive in any kind of water sources and contaminate intravenous drugs and solutions used in hospitals. Herein an outbreak of Ralstonia pickettii related to contaminated saline infusion is reported.

Materials/methods: An outbreak occurred in Pediatric Hematology and Oncology Unit between 28.08.19-13.09.2019. Eleven leukemia patients affected by the outbreak were included. All these cases had a central venous catheter. They had minimum one positive blood culture for R. pickettii. Environmental samples such as tap water, saline, hand soap, total parenteral nutrition fluids were collected to find out the source of outbreak. Automated BactAlert 3D blood culture system (bioMerieux/France) was used for incubation of blood culture bottles. Bacterial identification and antibiotic susceptibility were performed with Vitek MS and Vitek 2 system (bioMerieux/France) respectively. Pulse Field Gel Electrophoresis (PFGE) was performed for all isolates.

Results: Eleven patients, seven of which were male and 4 were female and the median age was 6.5 years had positive cultures. All R. pickettii isolates were susceptible to ceftazidime, ciprofloxacin, imipenem, meropenem and resistant to aztreonam, cefepime, gentamicin, amikacin and piperacillin tazobactam. Four, 3, 2 and 2 cases were treated with meropenem, piperacillin tazobactam, cefepime and ciprofloxacin respectively. R. pickettii was also isolated in saline solution culture. PFGE showed that R. pickettii clones of saline solution and blood cultures were identical. The outbreak lasted in two weeks, and was controlled due to ending of usage and collecting back the saline solutions from the same manufactured batch.

Conclusions: A highly unusual outbreak of R. pickettii bloodstream infections occurred among 11 patients with leukemia. All of the clinical isolates were suggesting a sole source due to the identical PFGE pattern. To our knowledge, this is the first outbreak reported in pediatric leukemia patients. It’s important that clinicians and microbiology laboratory should be aware of the possibility of contamination of intravascular solutions with R. pickettii and infection control practices should involve sampling of these fluids directly, so further contamination and new cases can be prevented.

Abstract 6638

Antimicrobial stewardship in Cambodia: the importance of antimicrobial point prevalence survey and lessons learned from the field

Gaetan Khim*1, Frances Daily1, Phalkun Pen2, Rithy Kong2, Sovannrith Sok2, Sovannra Yim1, Sopheaktra Oung1, Joe Hessell1, Joanne Letchford1, John Ferguson1

1Cambodia, Diagnostic Microbiology Development Program, Phnom-penh, Cambodia, 2Cambodia, Siem Reap Referral Hospital, Siem Reap, Cambodia

Abstract third-party references: Diagnostic Microbiology Development Program, Defense Threat Reduction Agency

Background: Antimicrobial resistance in Cambodia is a significant concern with antimicrobial misuse a major driver. Diagnostic Microbiology Development Program works alongside physicians, nurses, microbiology staff, pharmacists and hospital management in provincial hospitals to improve rational prescribing through development and appropriate use of diagnostic bacteriology laboratories and antimicrobial stewardship (AMS) programs.

Materials/methods: Diagnostic bacteriology was established in Siem Reap Referral Hospital (SRRH) in June 2014. From December 2016-February 2017, SRRH undertook a hospital wide antimicrobial point-prevalence survey (PPS+). The tool (PPS+) also included information on use of microbiology laboratory, antibiotics prescribed prior to the survey, percentage of correct prescriptions and other parameters. Simultaneously, measurement of WHO standard defined daily doses (DDD) were calculated. Post survey, an AMS committee was established and three major interventions were developed and implemented. These were: surgical prophylaxis, restricted empirical treatment in emergency and directed treatment in all wards. A follow up survey was repeated 2 years later.

Results: A reduction in antimicrobial prescribing and an increase in microbiology specimen requests was observed. There was also a significant decrease in antimicrobial consumption during that period, which was reflected in an overall decrease in DDD.

Conclusions: Implementing an AMS program in a low-middle income country requires a systematic approach with effective management and multidisciplinary healthcare staff engagement. The PPS+ was key to providing data to healthcare staff, which was used as a learning tool as well as a powerful instrument for promoting engagement with these staff when proposing interventions for quality improvement. The interventions required engagement and training of healthcare staff, local guideline development, logistics, monitoring and feedback for these positive results.

Assessment of the performance of the Vaginosis kit Aptima BV on Panther system from vaginal samples during a 3-month period at Nantes university hospital

Louise Ruffier D’epenoux1, Aurélie Guillouzouic1, Pascale Bemer1, Stéphane Corvec*1

1Nantes University Hospital Hotel-Dieu, Nantes, France

Background: In France, Bacterial vaginosis (BV) affects 20% of women. This pathology, benign for non-pregnant women, manifests increased concentrations of Gardnerella vaginalis, Mobiluncus sp and Atopobium vaginae paired with decreased level of Lactobacillus bacteria.

Over a three-month period, we gauged the impact of the Aptima BV kit on Panther for the detection of BV. The experiment was conducted using vaginal samples (VS), taken from non-pregnant women, above 18.

Materials/methods: From June to August 2019, vaginal samples (VS) were tested with the Aptima BV kit using Transcription Mediated Amplifications (TMA) to detect bacteria associated with BV, namely Gardnerella vaginalis and Atopobium vaginae with reduction of Lactobacillus sp. Results were compared to the Nugent score (more or less culture). A Nugent score (NS) of 3 or less was considered BV negative whereas a score of 7 or more was considered BV positive.

Results: 454 VS were included. 30 VS were excluded due to technical problems. 181 VS had a NS below 3, of which 171 with a negative test (94.5%). 47 samples showed a score between 4 and 6, 28 with a negative score (59.6%). Finally 49 samples displayed a score higher than 7. Among these, 45 with a positive test (91.8%).

After performing a curve analysis, among 91 VS, with various bacteria (excluding vaginal flora), the PCR results correspond to culture results in 84.6% of the cases. The correlation indexes are 94.3% and 71.4% respectively for VS with insufficient bacterial density (35 VS) and predominance of yeasts (21 VS). Sensitivity, specificity, positive and negative predictive value were 91.8%, 94.5%, 81.8%, 97.7% respectively.

Conclusions: Results provided by this new kit show a 90.4% correlation with NS and culture, excluding intermediary scores. This outcome demonstrates the analytical performance of this kit.

Among other benefits, this system would allow for faster analysis times (3h on average) and could provide a bacteriological help in the interpretation of intermediary NS, depending on the medical institution where it is used.

Abstract 6641

Varicella zoster virus seroepidemiology in Caribbean Netherlands: implications for vaccine policy
Regnerus Albertus Vos*1,2, Liesbeth Mollema1, Michiel Van Boven1, Alies Van Lier1, Gaby Smits1, Alcira Janga-Jansen3, Sharda Baboe-Kalpoe1, Koen Hulshof2, Ymke Stienstra2, Van Der Klis Fiona1, Hester De Melker1
1National Institute for Public Health and Environment, Bilthoven, Netherlands, 2University Medical Center Groningen, Groningen, Netherlands, 3Public Entity Bonaire, Kralendijk, Netherlands Antilles, 4Public Entity St. Eustatius, Oranjestad, Bonaire, Sint Eustatius and Saba, 5Public Entity Saba, the Bottom, Bonaire, Sint Eustatius and Saba

Background: In Caribbean Netherlands [CN], infection with varicella-zoster virus (VZV) is reported regularly in adolescents and adults. Among them, disease more often runs a severe course, including increased risk of complications such as pneumonia and encephalitis. Hence, the aim of this seroepidemiological study was to obtain insight into VZV susceptibility and its determinants in the general island populations of CN.

Materials/methods: In this cross-sectional population-based study, participants from Bonaire, St. Eustatius and Saba (n=1,829, aged 0-90 years, randomly selected via five age strata from the population registry) donated a blood sample and completed a health-related questionnaire, including characteristics possibly related to VZV disease. VZV-specific IgG antibodies were determined using a bead-based multiplex immunoassay. Risk factors for VZV seronegativity were analyzed using a logistic regression model.

Results: Overall seroprevalence in CN was 78% and did not differ between sexes. Estimates were lowest on St. Eustatius (73%) and highest on Bonaire and Saba (both 79%). Between different ethnic backgrounds, lowest overall seroprevalence was seen among people from the [former] Dutch overseas territories (71%), followed by Latin America and other non-Western countries (88%) and highest in those from Western countries (95%). Among people from the [former] Dutch overseas territories, seropositivity increased gradually with age, with 60% and 75% at ages 10 and 30 years, respectively, and ranging between 75-90% thereafter. Moreover, higher odds for seronegativity were seen among persons who were born in CN or resided there since early childhood as well as being a single-person household. Furthermore, the positive predictive value of self-reported history of VZV disease in this population appeared to be high (92%).

Conclusions: VZV susceptibility is relatively high among adolescents and adults in CN, in particular among those originating from the [former] Dutch overseas territories. This susceptibility pattern and the occurrence of severe varicella reflects the epidemiology on islands in tropical regions. These results ask for a swift consideration of routine varicella vaccination among islands populations – including a possible catch-up campaign in those susceptible – to reduce the burden of disease from VZV infection.

Investigating the contribution of the RND-type efflux pump AdeABC in tolerance to chlorhexidine digluconate in Acinetobacter baumannii ATCC 19606

Christina Meyer*1,2, Kai Lucassen2, Kyriaki Xanthopoulou1,2, Thorsten Wille2, Harald Seifert1,2, Paul G. Higgins1,2

1German Center for Infection Research (DZIF), Partner Site Bonn-Cologne, Cologne, Germany, 2University of Cologne, Institute for Medical Microbiology, Immunology and Hygiene, Cologne, Germany

Background: The RND-type efflux pump AdeABC in Acinetobacter baumannii is regulated by the two-component system AdeRS [1]. We have previously shown that A. baumannii ATCC 19606 adeRS knockout (∆adeRS) does not express adeABC and reveals increased susceptibility to various antibiotics. Furthermore, overexpression of RND-type efflux pumps contributes to triclosan resistance in Acinetobacter baumannii [2]. In Klebsiella pneumoniae, efflux pumps mediate resistance to chlorhexidine digluconate (CHX), an antiseptic used for wound and pre-operative skin disinfection, mouthwash and hand washing [3]. In this study, we have investigated the contribution of AdeABC to CHX tolerance in A. baumannii.

Materials/methods: ∆adeRS was produced through a markerless deletion. Minimal inhibitory concentrations for CHX of 19606 wild-type (wt) and ∆adeRS were determined by microbroth dilution in Mueller-Hinton broth. For a time-kill assay, bacterial strains were grown in Luria-Bertani medium until mid-log phase. CHX was added to a final concentration of 16 mg/L. 1 mL samples were taken before CHX addition and after 30, 60 and 180 minutes of CHX exposure. Cells were pelleted and washed with 0.9% sterile saline solution. CFUs were counted from appropriate dilutions on Mueller-Hinton plates after 24h-incubation at 37°C.

Results: Deletion of adeRS produces a four-fold decrease in the MIC for CHX (wt: MIC: 16 mg/L; ∆adeRS: MIC: 4 mg/L). In the time-kill assay, CFUs of 19606 ∆adeRS decrease under CHX exposure until reaching 1% of the initial amount after 180 min. CFUs of 19606 wt show an initial decrease, but begin increasing after 30 min until reaching 270% of the initial amount of CFUs after 180 min [Figure 1].

Conclusions: This study suggests that adeABC expression may enable A. baumannii ATCC 19606 to survive chlorhexidine digluconate exposure. Therefore, addressing efflux pump regulators could be a possibility to increase disinfectant susceptibility and impair persistence of A. baumannii in the hospital environment.

Figure 1. Time-kill curves with chlorhexidine digluconate (16 mg/L)

Abstract 6643

**Local anti-Pseudomonas IgY therapy prevents pyelonephritis in a novel murine experimental Pseudomonas aeruginosa urinary tract infection model**

Maria Pals Bendixen*, Franziska Angelika Schwartz†, Sarah Baekdahl‡, Lars Jackie Christophersen‡, Ida Bull Rasmussen‡, Mette Joergensen‡, Christian Johann Lerche‡, Kim Thomsen‡, Niels Haiby‡, Claus Moser‡

1Rigshospitalet, Department of Clinical Microbiology, København Ø, Denmark, †University hospital of Copenhagen, Rigshospitalet, Department of Clinical Microbiology, Copenhagen East, Denmark, ‡University of Copenhagen, Department of Immunology and Microbiology, Copenhagen N, Denmark

**Background:** Previously, gargling egg yolk antibodies (IgY) targeting *Pseudomonas aeruginosa* (PA) reduced chronic infections in patients with cystic fibrosis. Spinal cord injured (SPI) patients are in risk of recurrent and chronic urinary tract infections (UTIs), due to intermittent catheterization. The chronic UTIs indicates biofilm growth and risk of developing antibiotic resistance. Therefore, our aim was to investigate the effect of IgY in a UTI model in mice.

**Materials/methods:** Female BALB/c mice (n=50) and PA PAO1 were used for the experiments. Firstly, 15 mice received 5x 10^6 CFU and 18 mice received 2.5x 10^7 CFU PA in the bladder through a temporarily inserted urethral catheter. Mice were sacrificed at day 1, 6, 9 or 13 after infection. In the second experiment 27 mice were injected with 5x 10^7 CFU PA in the bladder, and randomized in to three IgY intervention groups and one control group. IgY 10% was administered through a temporarily inserted catheter at day 0, 1 or 3, and all mice were sacrificed at day 7 after infection. Experiments were evaluated by means of quantitative bacteriology in the urine, the bladder and the kidneys.

**Results:** In general, quantitative bacteriology was non-statistically increased in the urine, bladder and kidneys in the high as compared to the low infectious dose group. However, there were more mice with a positive urinary (6 vs. 2, day 6, p<0.05, and 7 vs. 3, day 9, p<0.025), bladder (4 vs. 0, day 6, p<0.005) and kidney culture (4 vs. 0, day 6, p<0.005) in the 2.5x 10^7 CFU group. There was no significant difference between the IgY intervention and the control group regarding quantitative PA. However, in the control group 5 out of 7 mice (71.4%) had PA in the kidneys, compared to 5 out of 20 mice (25%) in the three intervention groups pooled (p≤0.03).

**Conclusions:** This study indicates that topical anti- *Pseudomonas* IgY have a preventive effect regarding ascending PA pyelonephritis. In SPI patients using intermittent catheterization, adjunctive IgY therapy seems a promising antibiotic reducing strategy. Accordingly, similar strategy may be attractive in a selected group of patients with urinary catheters.

**Presenter email address:** mariapals@hotmail.com
Characterisation of a cfr gene variant in multidrug-resistant (MDR) livestock-associated methicillin-resistant Staphylococcus aureus (LA-MRSA), isolated from Italian pig herds

Elena Lavinia Diaconu*1, Patricia Alba1, Manuela Iurescia1, Virginia Carfora1, Andrea Caprioli1, Alessia Franco1, Antonio Battisti1

1Experimental Zooprophylactic Institute of Lazio and Tuscany, Department of General Diagnostics-National Reference Laboratory for Antimicrobial Resistance, Roma, Italy

Background: Linezolid belongs to the oxazolidinone family, an antibiotic class classified among Highest Priority Critically Important (HPCIA) for humans. Gram-positive microorganisms, as methicillin-resistant Staphylococcus aureus (MRSA) can develop resistance to linezolid by several mechanisms, including the acquisition of the plasmid-borne cfr gene. cfr encodes a methyltransferase mediating multidrug resistance (MDR) towards phenicols, lincosamides, oxazolidinones, pleuromutilins, streptogramin A and 16-membered macrolides.

Materials/methods: Three cfr-positive Livestock-Associated (LA)-MRSA, with two of them belonging to Clonal Complex (CC)1 and one to CC398, detected in different Italian pig herds (2008-2011), in the frame of the EMIDA-ERANET project (acronym “LA_MRSA”), were retrospectively in-depth characterized by WGS (Illumina technology). Isolates were previously tested for their antimicrobial susceptibility by broth microdilution, using a panel of drugs recommended by EFSA. Results were interpreted according to EUCAST epidemiological cut-offs. Regarding WGS analysis, de novo assembled scaffolds were analysed with different bioinformatic tools to detect accessory resistance genes and plasmid replicons (https://cge.cbs.dtu.dk/services/). Presence of cfr mutations was investigated by mapping reads to the reference sequence AM408573 (S. warneri) and “variant calling” was performed using bwa mem v0.7.12, samtools v1.7 and IGV 2.0.1.

Results: The three LA-MRSA were phenotypically MDR, displaying a common resistance pattern to beta-lactams, amphenicols, fluoroquinolones and tetracyclines. 2/3 isolates were also macrolide (erythromycin), lincosamide (clindamycin) and pleuromutilin (tiamulin) resistant. All isolates tested cfr-positive, but just one CC1 LA-MRSA was phenotypically linezolid-resistant. Apart from this exception (Table 1), MDR phenotypes were confirmed by their genetic background. Variant calling analysis indicated that both linezolid-susceptible isolates presented a cfr gene with a single T nucleotide deletion (position 384), whereas linezolid-resistant LA-MRSA harboured a cfr sequence identical to the reference one. This mutation causes a reading frame-shift and consequently a truncated protein.

Conclusions: This study describes for the first time CC1 and CC398 LA-MRSA presenting different cfr variants and linezolid-resistant phenotypes. Considering its potential transmissibility of cfr and increasingly isolation in animal productions in Europe, these preliminary results have significant Public Health implications and backdate cfr presence in LA-MRSA from Italian pigs at least to 2008. Further studies are needed to better understand cfr characteristics and their relationships to different resistance patterns.

Abstract 6645

**The impact of delayed analysis of positive blood cultures on the performance of short-term culture followed by MALDI-TOF MS**

Alexander Johnsson¹, Alicia Wong*, Volkan Özenci¹

¹Karolinska Institutet, Stockholm, Sweden

**Abstract third-party references:** On behalf of Alexander Johnsson.

**Background:** Rapid identification of bacteria is crucial for early appropriate antimicrobial treatment in sepsis patients. Transport time of blood culture (BC) bottles to the laboratories has been one of the major problems causing unnecessary delay in total turnaround time. Therefore, many central laboratories establish so called satellite BC systems and place them in clinics and other hospitals. BC bottles can therefore be incubated right after sampling. However, the positive BC bottles still need to be transported to the clinical microbiology laboratory for analysis. The aim of this study was to investigate how delayed analysis of positive BC bottles would affect the short-term culture followed by Maldi-ToF MS method.

**Materials/methods:** To simulate the effect of transportation and delayed analysis of BC bottles, 51 positive blood culture bottles were left to incubate for 0, 2, 4 and 24 hours at room temperature (RT). After each time-interval, a 2-4-hour short-term culture followed by Maldi-ToF MS was performed. In addition, 257 prospective clinical positive blood culture bottles were analysed with the same method after a 24 h incubation at RT.

**Results:** In the simulated samples, all (120/120) Gram-negative bacteria (GNB) and 77/84 (92%) Gram-positive bacteria (GPB) were accurately identified at species level after a 2-hour short-term culture, regardless of the duration of simulated transport time. In the clinical samples, 100/116 (86%) GNB and 44/141 (31%) GPB were accurately identified at species-level after a 2-hour short-term culture. When the contaminants were excluded, 39/71 (56%) of the GPB could be identified after 2h. After a 4-hour short-term culture, 112/116 (96%) of GNB and 107/141 (76%) GPB were accurately identified at species-level. Of the clinically relevant GPB, 68/71 (96%) were identified at species-level after 4 h.

**Conclusions:** Short-term culture followed by Maldi-ToF can provide fast and accurate results for identification of clinically relevant bacteria, despite long transportation times from satellite laboratories. The method can be used for identification of microorganisms from positive blood cultures transported from satellite BC systems.

First report of colistin resistance in *Salmonella* spp. isolated from fresh minced meats and poultry faeces from primary production phase in Bosnia and Herzegovina

Amir Ibrahimagic*1, Majda Fetahagić1, Jasmin Dizdarević1, Emina Idrizović1, Selma Uzunovic1, Ajna Kapidžić1, Aida Šanjta-Reis1, Muhamed Gladan1

1Institute for Health and Food Safety Zenica, Zenica, Bosnia and Herzegovina

Abstract third-party references: Ministry of Agriculture, Forestry and Water Management of Zenica-Doboj Canton

Background: Colistin has been used in animal production plants in several countries for therapeutic, prophylactic and growth promotion purposes. Colistin is clearly associates with selection of resistant strains in livestock which can spread from animals to humans by direct contact, or indirectly, by the food chain.

Materials/methods: Thirty-two *Salmonella* spp. strains were isolated. Food samples and poultry faeces in primary production phase were analysed according to Rulebook which is in accordance with the International Standards (EN ISO 6579-1:2018) and Manual for Reporting 2018 - Data on antimicrobial resistance Decision 2013/652/EU. The isolates were identified by colony morphology, standard biochemical and serological tests. Antimicrobial sensitivity testing was carried out using disk-diffusion and minimal inhibitory concentration (MIC).

Results: Among 32 *Salmonella* spp. strains, seven were isolated from food samples – fresh minced meats from the markets, and 25 from the poultry faeces. Using agar dilution method test, seven (21.9%) *Salmonella enteritidis* strains were resistant to colistin, two (out of 7; 28.6%) from fresh minced meats and five (out of 7; 71.4%) from poultry faeces. MICs values for seven colistin-resistant isolates were in the range 4 to 8 µg/mL. Six isolates (out of seven) were resistant to cefazolin (85.0%) and one isolate were resistant to ciprofloxacin and nalidixic acid with the MIC values of 0.25 and ≥128 µg/mL.

Conclusions: In food animals, colistin is frequently used as oral medication for prevention and treatment of gastrointestinal tract infection. There is need for careful monitoring of colistin usage in animal husbandry, as well as to seek for alternative, effective, less expensive antibiotics, competitive with colistin in the treatment of animal gastrointestinal infections. Considering the importance of colistin usage in control of animal infections, and large use of this drug in animal production, colistin-resistance prevalence in *Salmonella* spp. of animal origin have to be monitored more closely. Detection mcr genes should be introduced as well.

Mitigating the fitness costs of carbapenemase-encoding clinical plasmids in Escherichia coli: Piggy-backing on environmental adaptation

Julia Kloos1, João Pedro Alves Gama*1, Joachim Hegstad1, Ørjan Samuelsen2, Pål Johnsen1

1UiT The Arctic University of Norway, Department of Pharmacy, Faculty of Health Sciences, Tromsø, Norway, 2University Hospital of North Norway, Norwegian National Advisory Unit on Detection of Antimicrobial Resistance, Department of Microbiology and Infection Control, Tromsø, Norway

Background: Acquisition of carbapenemase-encoding plasmids limits treatment options for Gram-negative infections. Resistance plasmids often decrease bacterial fitness in unselective environments, but adaptive processes may mitigate such plasmid cost. Investigating the mechanisms improving plasmid-host relationships is thus crucial for understanding the selection and spread of antibiotic resistance in clinical isolates.

Materials/methods: Two plasmids encoding carbapenem-resistance (bla\_NDM-1 and bla\_VIM-1) were respectively transferred from Klebsiella pneumoniae and Escherichia coli into a ST537 E. coli uropathogenic isolate. Plasmid-carrying and -free strains were evolved for ~300 generations in four parallels each in antibiotic-free medium. Evolved populations were whole genome sequenced and plasmid-cost was measured in head-to-head competitions for ancestral, evolved clones and knockout mutants.

Results: An initial fitness cost of 5% was observed for both plasmids. These costs were fully, and partially mitigated after experimental evolution in ST537 E. coli hosts harbouring bla\_VIM-1 and bla\_NDM-1 encoding plasmids, respectively. Independently of plasmid carriage, all evolved populations displayed chromosomal mutations in the same genes: crp, cpdA, arcA and arcB, previously associated with environmental adaptation. The bla\_VIM-1 plasmid still imposed a cost in parental and ΔarcA Keio collection E. coli strains but not on the ΔcpdA strain.

Conclusions: Mutations in global transcriptional regulators mitigate fitness costs of carbapenemase-encoding plasmids, suggesting that niche-adaptation can affect the plasmid-host potential of E. coli lineages. Our findings provide an explanatory frame-work for understanding why certain E. coli lineages appear to be predisposed to the acquisition of specific antibiotic resistance determinants and plasmid backbones.

Toxigenic Corynebacterium ulcerans isolated from an Italian hunter

Giulia Zambolin,*1 Barbara Saccani2, Gabriele Tomasoni3, Nicola Latronico3, Angiola Spinetti3, Luana Signorini3, Francesco Castelli3, Zhou Youliang3, Zugni Nicola3

1Brescia, Spedali Civili, Brescia, Italy, 2Brescia, Spedali Civili, Brescia, Italy, 3Brescia, Spedali Civili, Brescia, Italy

Background: Corynebacterium ulcerans (C. ulcerans) has become an emerging pathogen today. In many European countries, cases of respiratory diphtheria and systemic infections have been increasing in recent years. Here we report the clinical course of a man affected by C. ulcerans diphtheritis with confirmed production of diphtheria toxin.

Case report: In late December 2018 a 65 year-old Italian man had been complaining of dysphonia, pharyngeal pain and mild fever for 5 days; symptoms worsened over a few hours with the onset of dyspnea and inspiratory retraction. He was a hunter and owned three dogs: one had died two days before and another one had cutaneous ulcerations; all dogs were subjected to swabs, that resulted negative for C. ulcerans. The patient was transported to the intensive care unit (ICU) of a tertiary care centre in Italy [Brescia]. Blood exams showed neutrophilic leukocytosis (24500 cell/μL, 93.5%). An arterial blood gas analysis was performed and revealed PO2 57 mmHg. Chest radiography was negative. Massive white and yellowish exudate (pseudomembrane) was observed in tracheal lumen through the bronchoscope. CT scan of the neck showed pharyngeal and soft palate edema, so the patient underwent surgical tracheostomy. Suspecting respiratory diphtheria infection, penicillin was administered and pseudomembranes were removed as much as possible. Vaccination history of the patient was unknown. Cultural exam of pseudomembranes revealed a toxin-producing strain of C. ulcerans. Diphtheria antitoxin (100,000 IU) was administered and in the following days the patient presented respiratory improvement. One week after he complained an acute chest pain with elevated troponin levels and progression of renal failure: cardiovascular magnetic resonance revealed an acute myopericarditis. Two months after, a progressive neuromuscular weakness developed and a diagnosis of polyneuropathy was done. After one month of intensive care the patient was discharged from the ICU.

Conclusions: Polyneuropathy, myocarditis and renal failure are well described complications caused by exotoxin-producing strains of Corynebacterium. In fact, diphtheria toxin is the major virulence factor of toxigenic C. ulcerans strains. This case report supports the idea that pathogenicity of corynebacteria is a multifactorial process; early diagnosis is essential for management and implementation of control measures.

Abstract 6652

**Predictive value of sepsis scores for in-hospital mortality in patients with left-sided infective endocarditis**

Bianca Leal De Almeida*, Tania Strabelli, Marcio Sommer Bittencourt, Alfredo Jose Mansur, Milena Ribeiro Paixao, Lucas Zoboli Pocebon, Danielle M. Gualandro, Flora Goldemberg, Rinaldo Focaccia Siciliano

1Clinical Hospital, Hospital das Clinicas da Faculdade de Medicina da USP, São Paulo, Brazil, 2Heart Institute, University of São Paulo, Heart Institute, University of São Paulo, São Paulo, Brazil, 3Unidade Morumbi - Hospital Israelita Albert Einstein, Hospital Israelita Albert Einstein, São Paulo, Brazil

**Background:** Unlike other bacterial infectious diseases, death related to infectious endocarditis (IE) are likely to be associated to non-septic conditions, such as heart failure or embolization. However, pilot studies have suggested that sepsis scores have good accuracy in IE Patients. The aim of our study was to evaluate the accuracy

**Materials/methods:** We prospectively enrolled 517 patients diagnosed with left-sided IE from 2010 to 2019 admitted to a tertiary cardiology hospital. Inclusion criteria were age > 18 years and “possible” or “definite” IE according to Modified Duke Criteria. Patients in use of intravenous antibiotics for more than 3 days before enrollment were excluded. Univariate and multivariate analysis were performed to test association between clinical and laboratory results and in-hospital mortality. The sepsis scores evaluated were: SIRS, severe sepsis, qSOFA and SOFA. Receiver operating characteristic curves (ROC) were constructed to assess the accuracy of sepsis scores for prediction of in-hospital mortality.

**Results:** Patients included had median age of 57 years (range 18 to 87), 65% were male, 435 (84%) had pre-existing heart valve disease, and the overall mortality was 28%. Microorganisms most frequently isolated were: Streptococcus spp. (36%), Enterococcus spp. (10%) and S. aureus (9%). After multivariate analysis variables evaluated at admission that were associated with in-hospital death were: heart failure NYHA III/IV (aOR 2.37, CI95% 1.497-3.751, p<0.001) embolism (aOR 1.91, CI95% 1.091-3.324, p=0.022), diabetes mellitus (aOR 2.45, CI95% 1.490-4.345, p=0.001), low hemoglobin level (aOR 0.860, CI95% 0.773-0.956, p=0.005) and SOFA≥2 (aOR 3.26, CI 95% 2.056-5.137, p<0.001). The accuracy for sepsis scores to predict in-hospital mortality were: qSOFA (ROC 0.601, CI95% 0.522-0.681) and SOFA (ROC 0.699, CI95% 0.602-0.756). A sub-group analysis in patients with and without pre-existing valve disease for SOFA showed ROC curve of 0.627(CI95% 0.563-0.690) and 0.775(CI95% 0.594-0.956), respectively.

**Conclusions:** Overall, qSOFA and SOFA at admission presented low accuracy to predict in-hospital death in patients with IE. However, SOFA≥2 could be a useful predictor for mortality in patients with IE without preexistent valvar disease.

**Presenter email address:** bianca.almeida@hc.fm.usp.br
Role of TAC1 orthologs in Candida auris azole resistance

Jizhou Li*1, Alix Coste1, Daniel Bachmann1, Dominique Sanglard1, Frederic Lamoth1,2

1Lausanne University Hospital, Microbiology Institute, Lausanne, Switzerland, 2Lausanne University Hospital, Infectious Diseases Service, Lausanne, Switzerland

Background: Candida auris has emerged as a novel yeast pathogen in all continents with ability to cause nosocomial outbreaks and to develop antifungal resistance. Acquired azole resistance is a hallmark of most C. auris isolates. Mutations in hotspots of the azole target gene ERG11 have been associated with azole resistance in C. auris. However, other non-ERG11-related mechanisms of resistance to azoles may be involved, such as overexpression of drug transporters including ABC-transporters Cdr1 and Cdr2. Indeed, overexpression of CDR1 has been observed in some azole-resistant C. auris isolates. In C. albicans, CDR1 expression is controlled by the transcription factor Tac1 and azole resistance has been linked to gain-of-function mutations in TAC1. In this work, we investigated in C. auris the role of the TAC1 ortholog in azole resistance.

Materials/methods: Two putative TAC1 orthologs of C. auris were identified by nBLAST with C. albicans (30% homology). Deletion of these two TAC1 orthologs was performed by Crispr-CAS9 in an azole-resistant C. auris isolate (South American clade) not carrying ERG11 mutations. We also complemented a TAC1-deleted C. albicans mutant by the two TAC1 C. auris orthologs. Susceptibility to azole drugs (fluconazole, voriconazole) was tested by microbroth dilution method (CLSI protocol) and spotting assay. CDR genes expression in C. auris was analyzed by real-time reverse transcription PCR (RT-PCR).

Results: Deletion of both putative TAC1 genes in C. auris resulted in modest decrease of resistance to both fluconazole and voriconazole. Expression of CDR1 and CDR2 in the TAC1-deleted mutant was similar to the parental wild-type strain under basal conditions and after induction by fluconazole. Complementation of C. albicans-TAC1 by the two C. auris-TAC1 orthologs did not restore wild-type phenotype in C. albicans.

Conclusions: This work suggests that, contrarily to observations in C. albicans, the C. auris TAC1 orthologs have only a modest role in azole resistance of this C. auris isolate. Other azole resistance mechanisms should be involved and deserve further investigations.

Abstract 6662

Emerging piperacillin-tazobactam resistance in Indian hospital settings
Madhumathi Jayaprakasam*, Kamini Walia

1Indian council of medical research, New Delhi, India

Background: Resistance to beta-lactam antibiotics is effectively tackled by the use of beta-lactam/beta-lactamase inhibitor combinations. However, there is increasing evidence for emergence of resistance against one of the promising combination, piperacillin/tazobactum (TZP) worldwide. Recent report showed hyperproduction of blaTEM-1 causing resistance to piperacillin/tazobactam in Escherichia coli (Hansen et al., Zhou et al., 2019). Gram negative bacteria P. aeruginosa and A. baumannii have been reported to show resistance to TZP in India in similar studies (Anuradha et al., 2007). Here we present comprehensive TZP non-susceptibility data over three years.

Materials/methods: Antimicrobial susceptibility data from about 18674 isolates was collected from 2016-2019 through the AMR surveillance network of Indian Council of Medical Research (ICMR) from 20 tertiary care hospitals across the country. Antibiotic sensitivity and phenotypic assays of resistance are carried out as per the standard protocols of Bacteriology SOP of ICMR. MIC/DD data of the isolates is entered into the iAMRSN data management portal developed by ICMR and analyzed location-wise or specimen-wise through the data analysis system. Data from Gram negative organisms A. baumanii, K. pneumoniae, P. aeruginosa and E. coli that showed increasing resistance to TZP are given here.

Results: Our data showed high percentage of TZP non-susceptibility in gram-negative bacteria especially in ICUs. A. baumanii showed highest percentage non-susceptibility in ICU [92%] followed by K. pneumoniae [73%] and E. coli [55%]. The trend of percentage non-susceptibility showed was significant increase in A. baumanii [72-83%], from 2016-2018, which is of great concern [Fig 1].

A. baumanii showed higher non-susceptibility in isolates from lower respiratory tract (LRT) specimen, deep & superficial infections and cerebrospinal fluid (CSF) specimen, while K. pneumoniae showed higher non-susceptibility in isolates from CSF and blood. Region-wise analysis of data revealed that percentage non-susceptibility in A. baumanii [86-92%] and K. pneumoniae [72-78] was consistently high in Northern part of the country.

Conclusions: Increasing prevalence of piperacillin/tazobactam resistance in Indian hospital settings warrant implementation of better stewardship efforts in rational use of TZP. Antibiotic use and resistance rate was correlated in a retrospective observational study (Cusini et al., 2018) for TZP in E. coli emphasizing need for urgent interventions to optimize antibiotic prescribing.

Detection rates of the bacterial causes of gastroenteritis using a multiplex molecular assay in the South-African private sector

Chanel Kingsburgh*, Kathy-Anne Strydom

1University of Pretoria, Ampath Laboratories, Pretoria, South Africa

Abstract third-party references: University of Pretoria, Ampath Laboratories

Background: Infectious diarrhea remains a significant cause of morbidity and mortality globally. Many of the bacterial pathogens implicated in the causation of acute infectious diarrhea are fastidious in nature and stool cultures are positive in only about 2-4% of cases, consequently multiplex molecular panels are emerging as useful diagnostic tools.

Materials/methods: A 5 year retrospective analysis was performed on clinical stool specimens submitted for bacterial gastroenteritis multiplex PCR testing (BD MAX™ Enteric Bacterial Panel, Becton Dickinson, United States) performed at Ampath private laboratories, South Africa. Where available, stool culture results were compared to that of PCR.

Results: Of the 1498 stool specimens submitted for PCR testing, 305 (20%) tested positive for a pathogen. Campylobacter was the most commonly identified (42%), followed by Salmonella (24%), Shigella/Enteroinvasive E. coli (21%), Shiga toxin-producing E. coli (9%), Enterotoxigenic E. coli (5%), and Yersinia enterocolitica (4%). Of the positive samples, 223 (73%) were submitted for culture. An additional 54 (57%) Campylobacter spp., 16 (30%) Salmonella spp., 36 (78%) Shigella spp./EIEC, and seven (78%) Yersinia enterocolitica were detected by PCR. None of the 21 PCR positive STEC isolates were identified by culture. Campylobacter species were cultured from 41 specimens (34 Campylobacter jejuni, six Campylobacter coli, and one Campylobacter species). Of the campylobacters isolated, 39% were susceptible to ciprofloxacin, 97% to erythromycin, and 46.3% to tetracycline. Non-typhoidal Salmonella were cultured from 37 specimens with 97.3% susceptible to ampicillin and ceftriaxone and 100% susceptible to ciprofloxacin and cotrimoxazole. Shigella species were cultured from 10 specimens PCR positive for the ipaH gene of which 50% were susceptible to ampicillin, 30% to cotrimoxazole and all were susceptible to ceftriaxone and ciprofloxacin.

Conclusions: Multiplex molecular panels are valuable tools for the identification of stool pathogens, many of which remain undetected by culture. Drawbacks include cost, lack of susceptibility data and species level identification. Azithromycin remains a valuable treatment option for the empiric management of diarrhoea due to Campylobacter species. Ciprofloxacin and ceftriaxone remain good empiric choices for the management of disease due to Salmonella and Shigella species. Use of multiplex molecular panels should be limited to patients with severe disease.

Abstract 6666

Genetic characterisation of multidrug-resistant *Klebsiella pneumoniae* harbouring colistin resistance gene *mcr-1* from North India

Ashutosh Pathak*1, Sanjay Singh1, Kashi Nath Prasad1

1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**Background:** Multi drug resistant (MDR) *Klebsiella pneumoniae* accounts for a significant proportion of nosocomial infections. Colistin is considered as the drug of last resort for treatment of infections caused by MDR *K. pneumoniae*. The emergence of plasmid encoded mobile colistin resistance (*mcr-1*) gene has breached the barrier. Moreover, association of *mcr-1* gene with other resistance markers is a matter of concern. Here we report genetic characterisation of nineteen *mcr-1* producing *K. pneumoniae* isolates.

**Materials/methods:** The study investigated 19 *mcr-1* harbouring *K. pneumoniae* recovered from patients. Minimum inhibitory concentration was determined using broth microdilution method. The presence of various resistance markers and virulence factors were detected by PCR. Pulsed field gel electrophoresis (PFGE) and MLST was done to analyse the genetic relatedness among *mcr-1* producers. Conjugation assay was performed for Strains harboring *mcr-1* and *bla*$_{NDM}$. S1-nuclease-PFGE followed by Southern blotting was done to determine their genetic location.

**Results:** Among 19 *mcr* isolates; *bla*$_{NDM}$ was present in five isolates, all the strains harboured multiple resistance traits. Virulence factors were also present in all isolates. Diverse PFGE profiles were found among *mcr* producers and MLST revealed presence of eight unique STs. Conjugation assays showed that *mcr-1* and *bla*$_{NDM}$ containing plasmid could be transferred into *Escherichia coli* J53. S1-PFGE revealed that strains carried multiple plasmids, Southern blot showed that *mcr-1* and *bla*$_{NDM}$ gene were present on plasmid and chromosome simultaneously or alone.

**Conclusions:** Co-occurrence of *mcr-1* with *bla*$_{NDM}$ and other resistance genes in *K. pneumoniae* indicates towards evolution of multi-drug resistance to an extent where no treatment options are available against infections caused by such organisms.

**Presenter email address:** ashutoshsgpgi@gmail.com
Evaluation of various stool collection devices for gut microbiome analysis

Manuela Castro Camargo*1, Agapi Theodoridou1, Lucinda Hillary1, Humphrey Bacchus1, Jaspal Patil1

1Phylo Bioscience, Bristol, United Kingdom

Background: Various stool collection devices are available in the market. However, it is necessary to evaluate their user friendliness for customers and effectiveness for the use in lab. Currently there is no such comparative data available for choice of tools, which can guide customers towards better understanding of available devices. Hence, at Phylo bioscience we decided to evaluate three different stool collection devices for their ability of preserving microbial DNA and analyze relative abundance of microbial copy numbers.

Materials/methods: Three different collection vials were used for evaluation, 1: TOTAL-FIX stool collection vial (Medical Chemical Corporation (MCC), CA, USA), 2: C&S Stool Transport Vials (Meridian bioscience, USA), 3: µb-eNAT (Copan Italia, Brescia, Italy). Stool sample was donated by six anonymous volunteers by using these 3 collection devices. Volunteers were asked to score the user friendliness of each device. Samples were stored at room temperature for 24hr. DNA extraction was carried out by using KingFisher Flex DNA extraction instrument based on magnetic beads technology. DNA quantification was performed by using Qubit fluorometer. Extracted DNA were normalized for 1 nano gram per micro liter and were further analyzed for selected gut microbes. By using quantitative real time PCR (qRT-PCR) following bacterial targets were analyzed Bifidobacterium spp., Eubacterium spp, Bacteroides spp., Bacteroides vulgatus, Bacteroides ovatus, Bacteroides uniformis, Bacteroides thetaiotaomicron, Bacteroides dorei and endogenous control.

Results: The µb-eNAT stool collection device received better average score for user friendliness. As per the volunteer’s comments, the collection device uses a swab and low volume of preservation media which makes it easy to handle and less risky. qRT-PCR results for various bacterial targets did not show any significant deference between all three devices, figure shows result from one donor out of six.

Conclusions: Microbial copy number did not show any significant difference between devices, however µb-eNAT had better user friendliness score. Additional time points at room temperature should be accessed for the further evaluation of the devices.

Abstract 6669

**Yersinia enterocolitica-associated diarrhoea: descriptive epidemiology in a low-prevalence setting (Barcelona, Spain) from January 2016 to October 2019**

Lidia Goterris Bonet1, Carme Crespo1, Silvia Mota1, Sara Isabel Gomez Calvo-Parras1, Jose Luis Virto1, Ana M. Sáiz1, Thais Cornejo Sanchez1, Rosa Rubio Leal1, Virginia Rodriguez1

1Vall d’Hebron University Hospital, Microbiology Department, Barcelona, Spain

**Background:** *Yersinia enterocolitica* is widespread in nature and its infection in humans is mostly considered as a zoonotic disease. Reservoirs range from mammals, avian and cold-blooded species, but most of the human pathogenic serogroups, principally O:3 and O:9, are recovered from porcine sources. The main objective is to describe the epidemiology of *Yersinia enterocolitica* diarrhea diagnosed in the Microbiology Laboratory of the Vall d’Hebron University Hospital in Barcelona in a 4-year period.

**Materials/methods:** From January 2016 to October 2019, all stool samples asking for bacterial diarrheal etiology were included. Conventional culture with selective plates, included CIN agar, was conducted. Combined biochemical and mass spectrometry methods were applied to species level identification. Specific anti-sera were used to serogroup investigation. Demographics (age, sex), travel report, seasonality and co-infection with other pathogens were registered.

**Results:** During the study period, 55,463 stool cultured samples were included and 47 *Yersinia enterocolitica* isolates were recovered from 46 patients [24 male and 22 female; median age 6.5 years old (range 0.5-79). Most cases [61%] occurred in patients aged ≤ 10 years old. Global frequency of isolation was 0.85 ‰. An increased frequency was observed: from 0.59 ‰ in 2016 to 1.49 ‰ in the 2019 period. Serogroup O:3 was the most frequent [65.2%] during all the study period. Minority serogroups [O:5, 6.4%; O:8, 4.3%] were only isolated in 2019. Most of the isolations [76%] occurred in spring and summer seasons. Six [13%] presented co-infection with other diarrheal pathogens: *Campylobacter jejuni* (2/6), *Salmonella typhimurium* (2/6) and *Dientamoeba fragilis* (2/6). Detailed data are shown in the table. Non previous travel history was reported.

**Conclusions:** *Yersinia enterocolitica* is a low prevalence diarrheal agent in our setting involving 0.85 ‰ of stool samples cultured. Nevertheless, increment prevalence was observed in the study period: in 2019 was 2.5 folds than 2016. According to the literature, *Yersinia enterocolitica* infection was more frequent in children and infants and serogroup O:3 was the most prevalent. Contrary to previously described, no serogroup O:9 was detected but we found more incidences in spring and summer seasons than in the coldest ones. No travel-related episode was detected.

**Rapid MALDI-TOF MS-based pneumococci confirmation by a standardised semi-automated workflow**

Markus Peer1, Ilka Davina Nix4, Evgeny A. Idelevich1, Irene Burckhardt2, Stefan Zimmermann2, Katrin Sparbier3, Karsten Becker, Markus Kostrzewa*3

1University Medicine Greifswald, Friedrich Loeffler-Institute of Medical Microbiology, Greifswald, Germany, 2University Hospital Heidelberg, Department of Medical Microbiology and Hygiene, Heidelberg, Germany, 3Bruker Daltonik GmbH, Bremen, Germany, 4University Hospital Münster, Institute of Medical Microbiology, Münster, Germany

**Background:** Rapid and reliable differentiation of the clinically important pneumococci from other Streptococcus mitis group streptococci (SMGS) using the proven bile solubility test (BST) remains challenging for routine laboratories. MALDI-TOF mass spectrometry (MS) may allow a standardized rapid workflow with easy and objective result interpretation. In this multi-center study, we investigated the performance of a standardized and (semi-) automated MALDI-TOF MS-based direct-on-target BST using a novel tool set available for rapid routine microbiological applications.

**Materials/methods:** Overnight plate culture colonies of in total 21 S. pneumoniae isolates belonging to 7 distinct serotypes (3, 6B, 8, 9V, 19A, 19F and 23F) and 9 non-S. pneumoniae isolates (3 S. mitis, 3 S. oralis, 3 S. pseudopneumoniae) as controls were suspended in water. 1-µL aliquots were transferred to a MALDI Biotarget96 (Bruker Daltonik), dried and subsequently subjected to direct-on-target bile acid lysis by adding 4 µL of a 7.5% sodium deoxycholate solution followed by incubation at 35 °C for 60 minutes under controlled humidity conditions using a dedicated incubation chamber prototype. For growth controls, 4 µL water were added before incubation. Liquid removal of supernatant and subsequent washing step was performed using a dedicated liquid removal stamp prototype. Analysis was performed using the MALDI Biotyper® (Bruker Daltonik) and a dedicated software prototype. To test for robustness and reproducibility of the workflow, the bacterial isolate panel was tested at two different sites.

**Results:** 100% sensitivity and 100% specificity were obtained at both test sites for classification of the tested pneumococci and other SMGS with 60 minutes incubation. All tested S. pneumoniae serotypes were correctly confirmed as pneumococci using this rapid and easy to handle method.

**Conclusions:** Using dedicated semi-automated hardware tools, software and standardized workflows allows the application of a rapid and accurate MALDI-TOF MS based BST in routine laboratory environments with minimal hands-on time providing an objective and traceable evaluation.

Identifying the drivers of multidrug-resistant *Klebsiella pneumoniae* at a European level

Viacheslav Kachalov*1;2, Huyen Nguyen1;2, Suraj Balakrishna1;2, Luisa Salazar Vizcaya3, Rami Sommerstein1, Stefan P. Kuster2, Anthony Hauser4, Pia Abel Zur Wiesch5;6, Eili Klein7;8, Roger Kouyos1;2

1University of Zurich, Institute of Medical Virology, Zürich, Switzerland, 2University Hospital of Zürich, Division of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland, 3Bern University Hospital Inselspital, Department of Infectious Diseases, Bern, Switzerland, 4University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, 5UiT The Arctic University of Norway, Department of Pharmacy, Faculty of Health Sciences, Tromsø, Norway, 6Nordic EMBL Partnership, Centre for Molecular Medicine Norway, Oslo, Norway, 7Johns Hopkins University, Department of Emergency Medicine, Baltimore, United States, 8Center for Disease Dynamics, Economics & Policy, Washington, D.C, United States

**Background:** Beta-lactam- and in particular carbapenem-resistant Enterobacteriaceae represent a major public health threat. Despite variation in resistance rates both across geographical settings and over time, there is only limited understanding of the underlying drivers: while antibiotic consumption is a primary driver of resistance, countries with similar consumption can have different resistance rates. Improved understanding of other possible drivers such as consumption structure, particular hospital vs. community, can aid in combatting this public health threat.

**Materials/methods:** We developed a transmission model of cephalosporin- and carbapenem-resistant *Klebsiella pneumoniae* based on antibiotic consumption and demographic data from eleven European countries and fit the model to resistance rates for *Klebsiella pneumoniae* across countries. The impact of consumption structure and nosocomial transmission on resistance was then assessed in counterfactual analyses.

**Results:** Based on reported consumption data, the model could simultaneously fit the prevalence of extended-spectrum beta-lactamase-producing and carbapenem-resistant *Klebsiella pneumoniae* (ESBL and CRK) across eleven European countries over eleven years (Figure). The model fits suggest thus that hospital transmission rates and consumption patterns can explain the large between-country variability of resistance. Based on this fit, a counterfactual analysis suggested that reducing nosocomial transmission and antibiotic consumption in the hospital would have the strongest impact on ESBL and CRK prevalence. Community antibiotic consumption also affected ESBL prevalence, but the relative impact was weaker than nosocomial consumption. Finally, we used the model to estimate a moderate fitness cost of CRK and ESBL at the population level.

**Conclusions:** Our study highlights the disproportionate role of antibiotic consumption in the hospital and of nosocomial transmission for resistance in gram-negative bacteria at a European level. This indicates that infection control and antibiotic stewardship measures should play a major role in limiting resistance even at the national or regional level.

![Figure: Model fit of ESBL and CRK. The model was fitted to the data of the annual prevalence of resistance in *Klebsiella pneumoniae* reported by ECDC from 2005 to 2015. Circles represent the reported data and solid and dotted lines represent the fit with variable between-country and uniform hospital transmission rates respectively.](image)

Within-patient evolution of a clinical isolate of *Escherichia coli* uncovers an IS26-linked amplification of *bla*TEM-1 leading to piperacillin-tazobactam resistance

Thomas Edwards*, Jenifer Mason¹, Paul Roberts¹, Chris Parry¹, Jon Van Aartsen¹, Alex Howard¹, Adam Roberts¹, Emily Adams¹, Alasdair Hubbard¹

¹Liverpool School of Tropical Medicine, Liverpool, United Kingdom, ²The Royal Liverpool University Hospital, Liverpool, United Kingdom, ³Alder Hey Children’s Hospital - Liverpool, Liverpool, United Kingdom

**Background:** The emergence of invasive strains of *Escherichia coli* resistant to Piperacillin/tazobactam (TZP), but susceptible to carbapenems and cephalosporins has been identified in the Royal Liverpool University Hospital, Liverpool, UK. We sought to understand this mechanism of resistance to TZP, initially focussing on isolates obtained from individual patients to identify within-patient evolution of resistance.

**Materials/methods:** We identified 5 instances where two *E. coli* isolates had been obtained from the same patient, with TZP resistance detected only at the second point of isolation, post-antibiotic treatment. Potential clonality of these paired isolates was assessed using RFLP and confirmed with whole genome sequencing, using hybrid assembly of Oxford Nanopore long-reads and Illumina short-reads with Unicycler. Hyperproduction of beta-lactamase and efflux pumps was determined using a nitrocefin-based assay and the efflux inhibitor phenylalanine-arginine β-naphthylamide, respectively. All remaining 21 isolates with this resistance phenotype identified between 2016 and 2017 were sequenced in order to confirm the prevalence of the identified mechanism, and describe involved sequence types and genetic resistance profiles.

**Results:** Only one pair of *E. coli* isolates were confirmed to be clonal. The resistant isolate (MIC 64/4µg/ml) did not have increased efflux, or beta-lactamase promoter region mutations, but was found to hyperproduce *bla*TEM-1. Hybrid assembly of both isolates revealed an 11Kb resistance module present in the susceptible isolate was excised from the genome between two IS26 flanked repeat regions, forming a circular translocatable unit (TU) containing multiple resistance genes. This TU was amplified in the resistant isolate to a copy number of 8.5, likely due to multiple IS26 mediated re-insertion and excision events into the chromosome, increasing the copy number of all resistance genes present on the TU including *bla*TEM-1 and *bla*OXA-1. Sequencing of the remaining isolates revealed increased *bla*TEM-1 copy number in 50%, ranging from 5 to 210 copies. This increase was associated with IS26 in 70% of occurrences.

**Conclusions:** This study underlines the role of IS26 mediated amplification of beta-lactamase genes as a mechanism for overcoming beta-lactamase inhibitors, and highlights the importance of gene copy number and expression levels when inferring susceptibility to beta-lactam/beta-lactamase inhibitor combinations from genomic data.

**Presenter email address:** thomas.edwards@lstmed.ac.uk
**Bordetella pertussis in the Netherlands, 2015-2019: a sharp increase in prn-deficient isolates**

Rob Mariman*1, Corrie Schot1, James Groot1, Frans Reubsae1, Ramón Noomen1, Thijs Bosch1

1Rijksinstituut voor Volksgezondheid en Milieu, RIVM, Bilthoven, Netherlands

**Background:** In the Netherlands, pertussis notifications resurged since 1996, likely due to strain adaptation. We apply molecular methods to characterize *B. pertussis* clinical isolates with emphasis to vaccine antigens. Here, we report on the surveillance data from 2015 to 2019.

**Materials/methods:** All *B. pertussis* samples were cultured and suspected colonies were subjected to MALDI-TOF MS and phenotypical tests for species confirmation, followed by whole genome sequencing (WGS). The resulting data were used for identifying the pertussis toxin (*ptxA, ptxP*), fimbriae (*Fim3*) and pertactin (*Prn*) genotypes. Furthermore, core-genome MLST, using an in-house scheme consisting of 3,180 genes, was used to infer genetic relationships between the isolates.

**Results:** WGS revealed that 99% of all our 223 *B. pertussis* isolates that have been collected the past 5 years had a *ptxA1* and *ptxP3* genotype. A minimum spanning tree (MST) based on cgMLST, showed limited variation within the Dutch *B. pertussis* population with an average distance of 5 genes between two neighbouring isolates (range 0–56 genes). There was no clustering in the MST based on year of isolation or age, but there was a clear distinction between fim3-1 (39%) and fim3-2 (60%) isolates with a higher genetic diversity among fim3-1 isolates. The majority of isolates were prn-2, but no prn allele could be determined in 12% of the isolates isolated between 2015-2017. In 2018 and 2019, a sharp increase of Prn-deficient isolates was observed (24% of all), caused by multiple changes including inversion of ~22 kb in the promotor, IS481 element in the prn-gene, and the insertion of a stop codon.

**Conclusions:** The current Dutch *B. pertussis* population represents a homogenous group dominated by isolates that harbour *ptxP3* and *prn-2* as genotypes. In 2018-2019, a sharp increase in prn-deficiency strains was observed.

Abstract 6678

**Early syphilis infection: a clinical case**
Milena Bozhilova1, Desislava Velcheva*1

1MDL Cibalab, Sofia, Bulgaria

**Background:** Serology is the most widely used approach for the diagnosis of Syphilis. Often discrepant results are obtained in practice using different methods of analysis. The purpose of this work is to present a clinical case of a proven very early syphilitic infection to highlight the benefits of newer generations of automated treponemal screening tests for the disease.

**Materials/methods:** used are: The first analytical step is automated enzyme-linked immunosorbent assay [ELISA/Gemini/Biokit] or chemiluminescent immunoassay [CLIA/LiaisonXL/DiaSorin]. If a positive result is obtained, the second confirmatory step is the T. pallidum hemagglutination test [TPHA/Biotec]. In case of ambiguous results, T.Pallidum IgG/IgM immunoblot test/Mikrogen is used for confirmation.

**Results:** A 46 years old man, who has been tested 7 times for syphilis and other STIs [HIV, HSV2, chlamydia] in the period 02.2017-06.2019. His results have always been negative. On 12.08.2019, the following results were obtained in syphilis test: ELISA 1.002 OD [c.off 0.250], CLIA 11.0 Index [c.off 1.0], TPHA 1:20. ELISA and CLIA results are positive and TPHA is negative. This required immunoblot confirmation. The results are: Immunoblot IgG negative and IgM positive. This is a very early syphilitic infection, where tests with higher recognition sensitivity [ELISA, CLIA] are positive earlier. A positive Immunoblot IgM strongly confirms the early phase of the infection. The VDRL [Veneral Disease Research Laboratory] test is positive (+++). The patient reports a risk contact in the middle of July 2019. A course of treatment with Benzathine penicillin G has been conducted. Control tests on 01.10.2019: ELISA 1.880 OD, CLIA 22.5 Index, TPHA 1:40, Immunoblot IgG positive, VDRL (++) show specific dynamics with increasing treponemal values tests and a decrease in the non-treponemal values resulting from the therapy.

**Conclusions:** The following clinical case confirms the data in the literature for higher sensitivity of ELISA and CLIA in the diagnosis of early syphilis compared to TPHA.

The use of Immunoblot IgM/IgG in difficult to interpret cases, with ambiguous results from the various methods used, can aid diagnostics by eliminating false positive results due to the high specificity of this method.

**Presenter email address:** desislavasv@abv.bg
Abstract 6680

**Changing epidemiology of Clostridiodes difficile infection in a French university hospital**

Nagham Khanafer*1,2, Luc Oltra1, Veronique Pergay1, Olivier Dauwalder2, François Vandenesch2,3, Philippe Vanhems1,2

1Hopital Édouard Herriot-HCL, Lyon, France, 2Université de Lyon, Lyon, France, 3Hôpital La Croix-Rousse - HCL, Lyon, France

**Background:** *C. difficile* infection (CDI) weighs heavily on healthcare system due to increased incidence, morbidity and mortality, as well as costs. CDI is mainly considered as a health-care associated (HCA) after exposure to broad-spectrum antibiotics. However, CDI has been reported outside health care institutions in people previously thought to be at low risk. The objective of this study was to compare characteristics of CDI cases regarding the infection presumed acquired in the community or in the hospital.

**Materials/methods:** Between November 2006 and October 2019, a prospective surveillance study of CDI was conducted in a 900-bed French university hospital. National and European definitions of CDI case, relapses and origin of acquisition were applied. Standardized questionnaire was used for data collection.

**Results:** A total of 1000 (=1031 episodes) patients were included with a mean incidence rate of 2.1 per 1000 hospital-stays. Most of episodes were HCA (76.7%). The remaining cases were community-acquired (CA) (17.8%) or indeterminate origin (5.5%). The mean age of patients was 59.8 and 67.7 years for CA and HCA cases respectively (P<0.001) and 31.3% of CA patients were ≤45 years (P<0.001). In CA cases, women were more prevalent (59.8% vs 49.4% in HCA-CDI, P=0.01). CA-CDI group had lower rate of recent antimicrobial exposure (40.9% vs 79.3%, P<0.001), antivirals (1.1% vs 6.8%, P<0.001) proton pomp inhibitor (39.5% vs 61.6%, P<0.001) and gastrointestinal surgery (2.3% vs 7.8%, P=0.008). Fever (>38°C), abdominal pain and ileus were significantly more frequent in CA cases (36.7% vs 26.3%; 45.5% vs 24.0% and 4.4% vs 1.2% respectively). Pseudomembranous colitis and admission in intensive care unit were more frequent in CA cases (7.7% vs 4.6%, P=0.06; 6.6% vs 1.7%, P<0.001 respectively). However, death was more frequent in HCA-CDI (11.4% vs 6.6%, P<0.001). The detection of free toxins A&B was similar between CA and HCA cases (P=0.85).

**Conclusions:** We found that approximately 20% of all CDI cases were CA with 60% of them not exposed to antimicrobial or proton pomp inhibitor drugs. Monitoring and active surveillance of CDI is needed to improve our understanding of the changing epidemiology of the disease.

Pan-pathogen microbiological diagnosis by accredited routine clinical metagenomics: one-year experience

Paul-Louis Woerther*, Raphael Lepeule1, Demontant Vanessa1, Guillaume Gricourt1, Claudie Lamoureux1, Vincent Fihman1, Slim Fourati1, Françoise Botterel1, Cécile Angebault1, Jean-Michel Pawlotsky1, Christophe Rodriguez1

1Hôpital Henri-Mondor AP-Hp, Créteil, France

Background: Clinical metagenomics (CMg) is a high-throughput sequencing technique dedicated to the etiological diagnosis of infectious diseases, regardless of the nature of the pathogen involved (bacteria, viruses, fungi, parasites). This technique has been implemented in 2018 at the Henri Mondor University hospital as part of routine diagnosis for "undiagnosed" suspected infections and accredited according to the ISO15189 standard in 2019.

Materials/methods: All of the CMg prescriptions prospectively received during year 2019 in the laboratory and validated by the biologists have been included in this retrospective analysis. The clinical indications and type of sample were collected. Samples have been processed by our in-house MetaMIC protocol including pre-extraction by bead-beating, QiaSymphony extraction, DNA and RNA library preparation (Illumina), NextSeq500 sequencing (Illumina) and MetaMIC software analysis. Results were interpreted in the light of the clinical context by a multidisciplinary microbiologist and clinician group.

Results: 208 CMg prescriptions have been received between January and November 2019. The clinical indications for CMg prescriptions included suspicions of: central nervous system infections (40%; 85/208), disseminated infections (25%; 51/208), hepatitis (9%; 18/208), pneumonia (7%; 14/208), cardiovascular infections (6%; 13/208), soft and skin tissue infections (5%; 11/208), bone and joint infections (4%; 8/208) and genitourinary infections (4%; 8/208) (Figure 1). The samples were found positive in 33% of cases (69/208), of which 65% (45/69) contained bacteria, 55% (38/69) contained a virus and 13% (9/69) contained a fungus. In total, 47 of the 69 positive cases (23% of the 208 tests) were considered to be clinically relevant by providing the final diagnosis of infection. CMg was particularly relevant in cases of decapitated infections, or with infrequent, difficult-to-detect or thus far unknown microorganisms.

Conclusions: In this study, prescriptions for CMg sent to the laboratory generally corresponded to situations of suspected infection with failure of usual techniques to detect an infectious agent. CMg identified this agent with excellent performance in a substantial proportion of cases, especially those with rare infections and/or unusual situations. Thus, CMg appears as a promising second-line option for the diagnosis of infectious diseases.

Figure 1: total number of samples analyzed by CMg.

Presenter email address: paul-louis.woerther@aphp.fr
In vitro susceptibility of fosfomycin in Aerococcus spp. isolated from urine samples

Itziar Angulo López*, Estibaliz Ugalde Zarraga1, Julia Aragón-Díez1, Domingo Fernández-Vecilla1, Lourdes Lasa Epelde1, José Luis Díaz De Tuesta1

1Hospital Universitario Basurto, Bilbao, Spain

Background: The introduction of matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) in routine microbiology laboratories has led to an increased isolation of Aerococcus urinae and Aerococcus sanguinicola from human urine. Both these species have been reported to cause urinary tract infections (UTIs), being isolated from urinary cultures in only 0.2–0.8% of cultures sent to different laboratories.

The EUCAST established species-specific clinical breakpoints for aerococci in 2017 for penicillins, carbapenems, vancomycin, quinolones and nitrofurantoin. Fosfomycin, despite being the first-line empirical treatment option for uncomplicated UTIs in Europe, has no clinical breakpoint yet. The aim of this study was to evaluate the in vitro activity of fosfomycin against the Aerococcus spp. strains recovered from urine samples throughout this year.

Materials/methods: 51 nonduplicate isolates [37 A. urinae, 14 A. sanguinicola] collected from urine samples between January 2019 and November 2019 at the Clinical Microbiology Laboratory of the University Hospital Basurto (Bilbao) were analyzed. Species identification was obtained by using MALDI-TOF MS (Bruker Daltonics). Minimum inhibitory concentrations (MICs) of fosfomycin were determined by Liofilchem® MIC Test Strips using a McFarland 0.5 inoculum on BD Mueller Hinton agar plates with 5% sheep blood and incubated at 35±1°C in 5% CO₂ for 16-20 hours. MICs were interpreted using EUCAST 2019 breakpoints established for Staphylococcus spp., as there is no fosfomycin breakpoint in related bacteria such as viridans group streptococci.

Results: MIC distributions are shown in Figure 1.

According to EUCAST criteria for Staphylococcus spp., 31 A. urinae (83.8%) would be categorized as susceptible (MIC₅₀ =16 mg/L, MIC₉₀ =64 mg/L), whereas only 42.8% (6 isolates) of A. sanguinicola would be susceptible (MIC₅₀ =64 mg/L, MIC₉₀ =256 mg/L).

Conclusions:
- Our results indicate that fosfomycin demonstrates a good in vitro activity against A. urinae, in contrast to A. sanguinicola.
- Further multicentre surveillance studies should be carried out to better define the susceptibility of Aerococcus spp. clinical isolates to fosfomycin and for establishing an EUCAST breakpoint.
- In order to clarify if the in vitro results are applicable to the in vivo situation, clinical trials investigating the efficacy of fosfomycin in uncomplicated UTI due to Aerococcus spp. are needed.

Presenter email address: itzupitzu@gmail.com
Abstract 6688

**Endemic situation regarding OXA-48-producing *Klebsiella pneumoniae* in north-west Spain**

Eva Gato*1, María José Gude Gonzalez2, Felipe Fernández-Cuenca3, Alvaro Pascual Hernandez3, Astrid Pérez1, Ana Fernández González4, Germán Bou Arevalo5

1Hospital Universitario A Coruña, Instituto de Investigación Biomédica A Coruña (INIBIC), A Coruña, Spain, 2Hospital Lucus Augusti, Lugo, Spain, 3Hospital Universitario Virgen Macarena, Sevilla, Spain, 4Hospital Arquitecto Marcide, Ferrol, Spain, 5Hospital Universitario A Coruña, A Coruña, Spain

**Background:** *Klebsiella pneumoniae* belongs to **Enterobacterales** family being considered one of the most relevant pathogen causing important disseminated infections. Emergence of plasmid-encoded carbapenemases along with the ability to spread and persist in clinical and community setting could favor the current epidemiology of carbapenem-resistant *K. pneumoniae*. In 2013, an OXA-48-producing *K. pneumoniae* (OXA-48-kp) was isolated from 23 patients admitted to a hospital in A Coruña, Spain. This strain spread rapidly causing a large outbreak that has persisted to date. In this work, we report microbiological and clinical details of this outbreak.

**Materials/methods:** MALDI-TOF MS (Bruker) was used for isolate identification. MIC determination was performed in MicroScan WalkAway (Siemens HealthCare Diagnostics Inc.). The detection of carbapenemase was performed by Xpert® Carba-R Kit (Cepheid) and home-made PCR. Molecular typing was performed in 50 representative isolates by SpeI-PFGE and MLST (Multi Locus Sequence Type) analysis. Whole Genome sequencing (Miseq, Illumina) was performed in a representative epidemic clone. The resistome and virulome were analyzed using ResFinder (Center for Genomic Epidemiology) and VFDB (Virulence Factors Database), respectively.

**Results:** During the 6-year study, 5340 *K. pneumoniae* non-duplicate isolates were detected in clinical and/or colonization samples. A total of 682 harbored OXA-48 carbapenemase. From 462 patients tested we found that 431 (93.3%) were intestinal-ly colonized by OXA-48-kp. The urinary tract was the most common source for OXA-48-kp isolation. Forty-six isolates were recovered from blood samples. Most of cases (62.6%) were nosocomially acquired. Colistin, gentamycin and tigecycline were the most active antibiotics. Susceptibility to fosfomycin and meropenem was 66.6% and 67.5%, respectively. Most isolates (86%) belonged to ST-15. We detected additional resistance genes against aminoglycoside and fluoroquinolones (aac(6’)-Ib-cr), and betalactams (blaCTX-M-15), together with adherence-related virulence factors including a novel fimbriae system. Virulence factors involved in iron acquisition, secretion systems and capsule production were also detected.

**Conclusions:**

1) The colonization rates by OXA48-producing *Klebsiella pneumoniae* in this study are alarming, which makes difficult to control the outbreak promoting an endemic situation beyond the hospital environment.

2) Convergence of resistance and virulence determinants, particularly adherence-related virulence factors, could be favoring the progression of outbreak despite intensive intervention controls.

**Presenter email address:** eva.gato@hotmail.com
Abstract 6690

Impaired membrane integrity as a marker for colistin susceptibility: a flow cytometry method for rapid AST in Pseudomonas aeruginosa and Acinetobacter spp.

Oskar Ekelund1, Erik Sturegård2, Thomas Schön3, Sofia Somajo*

1Department of Clinical Microbiology, Region Kronoberg, Karlskrona/Växjö, Sweden, 2Department of Translational Medicine, Lund University, Lund, Sweden, 3Department of Clinical Microbiology and Infectious Diseases, Kalmar County Hospital, Linköping University, Kalmar, Sweden

Background: Colistin constitutes an important last resort therapeutic for multi-drug resistant Pseudomonas aeruginosa and Acinetobacter species, which, in a global perspective, are common hard-to-treat agents in nosocomial infections. However, antimicrobial susceptibility testing for colistin remains cumbersome and broth microdilution (BMD) is still the only accepted method for determination of the minimal inhibitory concentration [MIC]. In this study we could within 2.5 hours, distinguish between wild type (WT) isolates and isolates with reduced susceptibility to colistin by detecting impaired membrane integrity using flow cytometry analysis.

Materials/methods: A collection of Pseudomonas aeruginosa (n=28) and Acinetobacter species (n=22, including 16 A. baumannii) with colistin MICs between 0.5-16 mg/L was assembled. Bacterial suspensions were inoculated in Mueller-Hinton broth and, after a pre-incubation step, dispensed in the wells of a microtiterplate containing freeze-dried colistin (0.06-64 mg/L). After 30 minutes, a fluorescent dye (YoPro-1 (Thermo Fisher Scientific)) for detection of impaired membrane integrity was added, followed by flow cytometry (Attune NXT) analysis. Non-linear regression analysis with the fraction of membrane-compromised cells as a function of colistin concentration was performed, and the colistin concentration required for 70% of maximum effect (EC70) was calculated.

Results: The colistin concentration needed to achieve 70% of maximum cellular effect (EC70 median [quartile range]) of the susceptible (MIC≤2) Pseudomonas strains was significantly lower (0.8 [0.2-0.5]) mg/L as compared with 16.6 [5.2-30.3] mg/L in the resistant (MIC>2) population. The corresponding figures for Acinetobacter were 0.4 [0.2-0.4] and 2.9 [1.1-7.0] mg/L. In one Pseudomonas and two Acinetobacter the estimated EC70 misclassified resistant isolates (MIC 4 mg/L) as susceptible. However, the epidemiological cut-off (ECOFF) for Pseudomonas is 4 mg/L, and it is possible that this isolate actually should belong to the WT population. For the two discrepant Acinetobacter isolates re-analysis resulted in MICs of 2 mg/L (susceptible according to EUCAST breakpoints) implying a correct classification by flow cytometry analysis.

Conclusions: Rapid detection of compromised membrane integrity after colistin exposure can be achieved by flow cytometry. Estimation of EC70 could be used as a cut-off to distinguish between WT and non-WT isolates for both P. aeruginosa and Acinetobacter spp.

Presenter email address: sofia.somajo@kronoberg.se
An ex vivo pig lung model demonstrates potential to distinguish key aspects of chronic and acute infection in the cystic fibrosis lung.

Esther Sweeney*1, Niamh Harrington2, Branagh Crealock-Ashurst2, Freya Allen2, Freya Harrison2

1University of Warwick, Life Sciences, Coventry, United Kingdom, 2University of Warwick, Life Sciences, Coventry, United Kingdom

Background: Robust laboratory models of chronic infections are needed to investigate determinants of chronic pathology and antimicrobial susceptibility in a complex in vivo environment. We previously described an ex vivo pig lung model (EVPL) of cystic fibrosis that demonstrates the influence of host tissue interaction and biofilm structure on growth and persistence of Pseudomonas aeruginosa infection. Here we present developments suggesting the model recapitulates important aspects of chronic S. aureus or P. aeruginosa infection including antibiotic tolerance and regulation of virulence factor production. The model has potential as a tool to investigate the switch from acute, antibiotic susceptible to chronic, antibiotic tolerant infection in the CF lung.

Materials/methods: Using an established EVPL model (pig bronchiole sections plus artificial CF sputum, ASM), growth of bacteria and antibiotic susceptibility was monitored over periods up to 48h. Lung-associated biofilms and/or bacteria growing in surrounding ASM were exposed to antibiotic solutions and viable cell numbers and virulence factor production quantified in treated and untreated model infections.

Results: S. aureus may adopt a silent persister phenotype in the EVPL: After 48h incubation, CF isolates of S. aureus tolerated clinically relevant levels of linezolid (12µl/ml), hemolysin production was down regulated and production of AIPs under agr regulation was not detectable. We also monitored the emergence of antibiotic tolerance in P. aeruginosa; clinical isolates showed tolerance to several antibiotics. They survived colistin concentrations that exceed MIC (planktonic culture in ASM) and in vitro MBEC (Calgary device with ASM), due in part to reduced penetration into biofilm. Some isolates also developed tolerance to meropenem following 8 H incubation in the EVPL, well before biofilm is established, suggesting that altered cell physiology also plays a role in tolerance. Meropenem tolerance correlated with an increase in pyoverdine production.

Conclusions: EPVL is a potentially important model to study key aspects of chronic or persistent infections in the CF lung and provides a more clinically relevant environment than standard in vitro models of infection for assessing virulence and antibiotic tolerance.

Abstract 6694

**Prospective, non-interventional, multi-centre clinical study of the T2Resistance system for detection resistance genes in bacterial bloodstream infections: an interim analysis**

Thomas J. Walsh*, Antonella Mencacci, Riccardo Paggi, Evangelia Douka, Charikleia Vrettou, Oscar Guzman, Roger Smith, Tom Lowery

1Weill Cornell Medicine of Cornell University and New York Presbyterian Hospital, New York, United States, 2Medical Microbiology, Department of Medicine, University of Perugia, Perugia, Italy, 3First Department of Critical Care, University of Athens, Evangelismos General Hospital, Athens, Greece, 4T2Biosystems, Lexington, United States

**Background:** The incidence of blood stream infections (BSIs) caused by multi-drug resistant organisms (MDROs) is growing at an unprecedented pace. BSIs caused by MDROs are associated with high attributable mortality and increased healthcare costs. Rapid and reliable direct-from-blood pathogen identification remains an unmet healthcare need that may guide early-targeted therapy. The T2Resistance Panel provides direct-from-blood identification of resistance genes in both Gram-positive and Gram-negative pathogens within 3 to 5 hours of sample collection: \( \text{bla} \text{KPC}, \text{bla} \text{OXA}, \text{bla} \text{NDM}, \text{bla} \text{VIM}, \text{bla} \text{IMP}, \text{bla} \text{CTXM-14}, \text{bla} \text{C-TXM-15}, \text{bla} \text{CMY}, \text{bla} \text{DHA}, \text{vanA/B} \) and \( \text{mecA/C} \). The main objective of this study is to evaluate the diagnostic accuracy of T2Resistance in patients with BSIs in comparison to standard methods of blood culture diagnosis and to determine if T2Resistance results would impact treatment decisions in the enrolled patient population.

**Materials/methods:** This is a prospective, non-interventional, multicenter clinical study conducted in whole blood samples (4mL) that were collected in K2 or K3 EDTA tubes and analyzed using the T2Resistance and T2Bacteria panels and compared to standard pathogen phenotypic, and genotypic detection methods including direct from positive blood culture species identification via matrix-assisted laser desorption/ionization time-of flight mass spectrometry – MALDI-TOF.

**Results:** Among the 13 cases enrolled to date and of the 7 blood cultures that were positive, five cases demonstrated 100% concordance between the T2Resistance system and conventional methods. Results from the other two cases are pending blood culture results. The median time (range) to identification of resistance genes via T2Resistance was 3.7 h (3.5 – 8.8 h) versus 98 h (16 - 233 h) by conventional microbiological methods shown to be significant (p<0.001). The resistance genes identified by the T2Resistance system were NDM, VIM, CTX, KPC, AmpC, and MecA/C.

**Conclusions:** An interim analysis of the data from a prospective, multicenter clinical study of the T2Resistance system for detection of resistance genes in bacterial blood stream infections demonstrates a high concordance with the results of conventional microbiological methods but with results available in real time to physicians within 4 to 9 hours from the time of processing blood cultures.

Oral vancomycin prophylaxis for primary and secondary prevention of *Clostridioides difficile* infection in patients treated with systemic antibiotic therapy: a systematic review and meta-analysis

Alberto Enrico Maraolo*,1, Emanuela Zappulo1, Riccardo Scotto1, Guido Granata1, Roberto Andini2, Emanuele Durante Mangoni3, Nicola Petrosillo2, Ivan Gentile1

1Section of Infectious Diseases, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy, 2Clinical and Research Department for Infectious Diseases, Unit Systemic and Immunedepression-Associated Infections, National Institute for Infectious Diseases L. Spallanzani, Rome, Italy, 3Internal Medicine, University of Campania ‘L. Vanvitelli’ & Unit of Infectious and Transplant Medicine, AORN Ospedali dei Colli-Monaldi Hospital, Naples, Italy

**Background:** There is an increasing interest in the role of oral vancomycin prophylaxis (OVP) to prevent *Clostridioides difficile* infection (CDI).

**Materials/methods:** A systematic review and meta-analysis was performed. The search was run up to 30 September 2019 through MEDLINE and Embase to include full-text studies comparing the use of OVP with no intervention in adult patients exposed to systemic antibiotics. Main outcome was CDI occurrence (first episode or relapse). Risk ratio (RR) estimates with 95% Confidence Interval (CI) were computed using random effects model. Sensitivity, subgroup analyses and meta-regression were carried out as appropriate. Statistical analysis was performed with RevMan (v 5.3) and Comprehensive Meta-analysis (v 3).

**Results:** Ten studies were selected: 4 addressing primary and 6 secondary prevention. All studies but one (a randomized controlled trial) were observational and retrospective, in different populations (elderly, solid organ transplantation, hematology). Overall, 2809 patients were included (2816 observations). Follow-up ranged from 30 days/in-hospital to 1 year. OVP regimens varied from 125 mg once-daily to 125 mg each 6 hours, from 2 up to 80 days, in parallel with antibiotic exposure. OVP was associated with a significant decrease in CDI risk (RR 0.29; 95% CI, 0.13-0.63), but heterogeneity was high ($I^2$ = 78%). Significant interaction ($p = 0.02$) existed between the subtotal estimates for the two main subgroups, primary (RR 0.09; 95% CI, 0.03-0.31; $I^2$ 0%) and secondary prophylaxis (RR 0.49; 95% CI, 0.24-0.99; $I^2$ 76%). In the latter, adjusted analysis (3 studies) showed a non-significant difference between OVP and control (aRR 0.66, 95% CI 0.36-1.22, $I^2$ = 70%). Meta-regression demonstrated decrease of CDI risk as OVP duration (days, mean) increases: slope coefficient was $-0.1546$ ($p < 0.001$), explaining a high portion of between-study variance ($R^2$ analog 82%). Only 4 studies reported infections/new colonization by vancomycin-resistant *Enterococcus spp.*, without differences between OVP and control.

**Conclusions:** OVP seems promising in decreasing CDI risk in patients receiving systemic antibiotic therapy, especially for primary prevention in selected populations. Nevertheless, caution is needed since current evidence relies mainly on observational studies, prone to bias and with high heterogeneity regarding OVP schedules, follow-up, baseline features of patients.

Epidemiology and treatment outcome of Neisseria gonorrhoeae infections

Jill Parkes-Smith, Cheryn Palmer, Amy Jennison, Vicki Hicks, Lawrence Ariotti, Sara Bell, David Whiley, Lawrence Ariotti, Andrew Henderson

1 Princess Alexandra Hospital, Infection Management Services, Woolloongabba, Australia, 2 Forensic and Scientific Services, Coopers Plains, Australia, 3 The University of Queensland, Centre for Clinical Research, Saint Lucia, Australia

Background: Infection due to Neisseria gonorrhoeae is increasing in incidence worldwide. In Australia, resistance to recommended antimicrobials remains relatively uncommon. The aim of this study was to describe the epidemiologic distribution, choice of treatment and clinical outcomes of N. gonorrhoeae episodes over a 10 year period at a large metropolitan sexual health service.

Materials/methods: A retrospective cohort study from a prospective clinical database of all patients presenting to the Princess Alexandra Hospital Sexual Health (PASH) service over a ten-year period from January 1st 2008 to 31st of December 2017 with N. gonorrhoeae infection was performed. Patient characteristics and demographics were collected along with treatment choice, test of cure (TOC) and antimicrobial susceptibility testing results.

Results: Of the 36,212 tests performed during the period, N. gonorrhoeae was identified in 803 (2.2%) specimens from 621 individual cases. Of the 621 cases, 469 (75.5%) occurred in patients with attributable symptoms. Infection was predominantly identified in male patients between the age of 20-29 (n = 554, 89.2%), with 504 (91%) of male patients identifying as men who have sex with men (MSM). TOC was performed for 421 (67.8%) of those treated and was positive in 25 (6%) cases. Treatment choice or reduced susceptibility to ceftriaxone or resistance to azithromycin were not associated with a positive TOC. Overall rates of susceptibility to these agents remained high in the cohort. The highest rate of positive TOC was seen from cervical infections (18% of cervical infections treated).

Conclusions: N. gonorrhoeae infection during the 10-year period was predominantly identified in males with MSM history, however female patients with cervical infections had a higher positive TOC which may reflect treatment failure, non-viable DNA or reinfection. Further surveillance of gonorrhoea infection with additional molecular methods may help to shed light on transmission and persistent or recurrent infection.

Abstract 6701

The clinical impact of extended blood culture incubation time

Rose Willemze1, Ans Kwakernaak2, Ted Koster1, Vishal Hira*2

1Groene Hart Ziekenhuis, Department of Internal Medicine, Gouda, Netherlands; 2Groene Hart Ziekenhuis, Department of Medical Microbiology and Infection Prevention, Gouda, Netherlands

Background: When suspecting endocarditis, it is still common practice in most Dutch hospitals to prolong incubation of blood cultures to ten or 14 days in order to increase the chance of finding fastidious bacteria that are able to cause endocarditis. However, recent literature questions the added value of incubation longer than five days with modern blood culture methods. In this study, we evaluated whether prolonged incubation led to clinical consequences, in terms of both benefit and harm to the patient.

Materials/methods: We analysed all blood cultures that became positive between five and ten days and were cultured in the microbiology laboratory of the Groene Hart Ziekenhuis in The Netherlands between November 14th 2014 and April 30th 2019. Medical records were used to determine the clinical consequences of the blood cultures. Furthermore, we randomly (using randomizer.org) selected 36 culture sets (two aerobic, two anaerobic) from the year 2018 (three per month) that did not grow any bacteria after ten days (i.e. negative) and searched the medical records to determine if these cultures had clinical consequences.

Results: From November 14th 2014 till April 30th 2019, 65697 blood cultures were processed of which 2353 were incubated for ten days and from the latter 188 became positive (8,0%). Only five of those positive blood cultures, from three different patients, became positive after five days (2,7%). Clinical record analysis of these three patients showed that one patient suffered from consequences of the positive culture, as blood cultures were repeated. No treatment changes were made based on these five positive blood cultures.

In 36 culture sets that were negative after incubating ten days, one had clinical consequences, as intravenous antibiotic treatment was continued until the end of the incubation period.

Conclusions: In accordance with previous studies, there was no benefit from prolonged incubation of blood cultures in our hospital. More importantly, prolonged incubation may even be harmful to patients, as it may lead to extra blood cultures or even prolonged antibiotic therapy. Our study supports that unnecessary diagnostics are a serious problem in current medicine and diagnostic tools and their relevance should constantly be re-evaluated.

Abstract 6702

Reference-setting evaluation of MicroScan panels for identification of bloodstream pathogens in low-resource settings

Sien Ombelet*1,2, Alessandra Natale3, Jean-Baptiste Ronat1, Thierry Naas4, Jan Jacobs1,2

1Institute of Tropical Medicine Antwerp, Antwerpen, Belgium, 2Katholieke Universiteit Leuven, Leuven, Belgium, 3Doctors Without Borders, Paris, France, 4Bicetre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: The Mini-Lab is a Médecins Sans Frontières project for the development of an all-in-one basic clinical bacteriology laboratory deployable in low-resource settings, where bacterial identification is challenging. The MicroScan identifications panels by Beckman-Coulter were selected, based on target product profiles and market analysis. Their advantage consists in including all tests into one panel, ease of use and long shelf-life.

Materials/methods: The PID3 panels (reference B1017-221) for Gram-positive organisms, NID2 panels (reference B1017-27) for Gram-negative organisms and HNID panels for Neisseria and Haemophilus species (reference B1012-10B) were assessed with a broad selection of common bloodstream pathogens, originating from low-resource settings. In total, 151 Gram-positive isolates (representing 28 species), 180 Gram-negative isolates (20 species), 12 Neisseria and 13 Haemophilus influenzae isolates were tested. Among the species tested, 13 species (35 isolates) were not registered in the MicroScan database; they included mainly Gram-positive rods (Bacillus and Corynebacterium spp.) and Streptococcus suis, endemic to Asian regions. All panels were read visually using the manufacturer’s instructions. The MicroScan autoSCAN-4 reader was used in addition to visual reading for 42% of isolates tested.

Results: Of Gram-negative species registered in the MicroScan database, 89% (153/172) of isolates were correctly identified up to species level. Of Gram-positive species registered, 76% (94/124) of isolated were identified correctly up to species level. Among fastidious species, performance was better for Haemophilus species (85%) than Neisseria species (33%). As expected, species not registered in the database were not identified correctly; moreover 12 Gram-positive (comprising Bacillus spp. and S. suis) and 4 Gram-negative (Burkholderia thailandensis) isolates were incorrectly identified and generated high probability scores (> 80%). Among the isolates with both visual and autoSCAN-4 reading, agreement between readings was 72%, with automated and visual reading leading to correct identifications in 64% versus 68% respectively. Testing of Gram-positive isolates on Gram-negative panels and vice versa resulted in misidentification (with occasionally high probability scores) of 65% of tested isolates.

Conclusions: Performance of the MicroScan PID3 and NID2 panels for isolates from LRS was lower than previously described in high-resource settings. The HNID panel showed low performance for Neisseria.

Restriction modification systems affect the ability of Escherichia coli ST73 to acquire plasmids

João Pedro Alves Gama†1, Julia Kloos1, Pål Johnsen1, Ørjan Samuelsen2
1UiT The Arctic University of Norway, Department of Pharmacy, Faculty of Health Sciences, Tromsø, Norway, 2University Hospital of North Norway HF, Norwegian National Advisory Unit on Detection of Antimicrobial Resistance, Department of Microbiology and Infection Control, Tromsø, Norway

Background: The spread of antibiotic resistance is frequently linked to the dissemination of multi-drug resistant high-risk clones and specific plasmid backbones. Yet, some clones display worldwide success despite being susceptible to virtually all antibiotics. Such is the case of Escherichia coli sequence type (ST) 73, a dominant ExPEC (Extraintestinal Pathogenic E. coli) lineage that is generally regarded as antibiotic-susceptible and plasmid-free. We aimed to understand the determinants responsible for this behavior of ST73.

Materials/methods: We transferred a clinical blaNDM-1 plasmid into 2 genetically diverse clinical E. coli strains representing 14 different STs, concomitantly measuring its conjugative efficiency. Transconjugants were propagated for ~300 generations to assess plasmid maintenance. Growth rates of transconjugants and isogenic plasmid-free strains were determined to evaluate the effect of the plasmid on host fitness. We downloaded all E. coli genomes belonging to the experimentally tested STs from GenBank and mined them for the presence of plasmids, restriction modification systems and CRISPRs.

Results: The plasmid transferred with lower efficiency to ST73 strains, where it also imposed higher fitness costs. The plasmid was maintained in most strains for 300 generations and its stability did not differ between ST73 and non-ST73 strains. Analysis of E. coli genomes belonging to the studied STs revealed lower frequency of plasmids in ST73 genomes than in other STs. ST73 genomes are often devoid of CRISPR, but exhibit changes in their restriction-modification repertoire. Specifically, such genomes tend to encode type III restriction-modification systems more frequently than other STs.

Conclusions: A plasmid encoding resistance to last resort antibiotics was fairly stable and did not impose detectable fitness cost in several genetic backgrounds. Additionally, ST73 strains exhibit a weaker ability to acquire plasmids than other STs. We suggest that type III restriction-modification systems may pose a barrier to plasmid acquisition in ST73. Our experimental data combined with an extensive bioinformatic approach may explain, at least in part, why molecular epidemiology studies suggest that ST73 is less associated with antibiotic resistance determinants.

Abstract 6708

Mapping the roles and responsibilities for infection prevention and antibiotic prescribing along the surgical pathway in India and South Africa: case studies

Sanjeev Singh1, Marc Mendelson1, Surya Surendran1, Candice Bonaconsa2, Oluchi Mbamalu2*, Vrinda Nampoothiri1, Adam Boutall3, Mark Hampton3, Puneet Dhar2, Tim Pennel4, Carolyn Tarrant5, Alison H. Holmes3, Esmita Charani10

1Department of Infection Control and Epidemiology, Amrita Institute of Medical Sciences, Amrita Vishwa Vidyapeetham University, Kochi, India, 2Division of Infectious Diseases and HIV Medicine, Department of Medicine, Groote Schuur Hospital, University of Cape Town, Cape Town, South Africa, 3Department of Infection Control and Epidemiology, Amrita Institute of Medical Sciences, Amrita Vishwa Vidyapeetham University, Kochi (Kerala), India, 4Colorectal Unit, Groote Schuur Hospital, University of Cape Town, Cape Town, South Africa, 5Dr. Matley & Partners Surgical Practice, Cape Town, South Africa, 6Department of Gastrointestinal Surgery, Amrita Institute of Medical Sciences, Amrita Vishwa Vidyapeetham University, Kochi (Kerala), India, 7Chris Barnard Division of Cardiothoracic Surgery, University of Cape Town, Cape Town, South Africa, 8Department of Health Sciences, University of Leicester, Leicester, United Kingdom, 9Health Protection Research Unit in Healthcare Associated infections and Antimicrobial Resistance, Department of Medicine, Imperial College London, London, United Kingdom, 10Health Protection Research Unit in Healthcare Associated infections and Antimicrobial Resistance, Department of Medicine, Imperial College London, London, United Kingdom

Background: The surgical pathway remains a hard to reach, but critical target for antibiotic stewardship (AS) globally. There is a need to develop contextually appropriate AS interventions, targeting the surgical pathway in different resource settings. We aimed to characterise the roles and responsibilities of various stakeholders for infection prevention and control (IPC) and AS along the surgical pathway, in two academic institutions in South Africa (SA) and India.

Materials/methods: Between July 2018 and August 2019, we conducted an ethnographic study across cardiac and thoracic (CTS) and gastrointestinal surgical teams utilizing non-participant observations, face-to-face interviews, and in-depth case-studies including patient and healthcare provider narratives on infection management and antibiotic prescribing along the surgical pathway. Data were analysed using an inductive-deductive approach, applying thematic framework informed by existing evidence.

Results: Over 100 hours of observations comprising shadowing of healthcare staff, attendance to meetings, and observation of ward activities and ward rounds were conducted. Across both sites, 14 patient SA) and 11 3 healthcare professional) interviews, and 5 case studies were recorded. These highlighted the multiple steps in IPC and antibiotic prescribing, and the implicit roles and responsibilities of different healthcare professionals involved in IPC and AS, along the surgical pathway. Despite available policies and guidelines on IPC, the patient case-studies highlighted the vulnerability to infections in settings where there are high patient numbers, low staff numbers and surgery with high risk for infection. The environment and resources, including the availability and level of training of staff, the nature of patient illness and level of demand, and the limited infrastructure, all present significant challenges for IPC.

Conclusions: Identifying the implicit existing roles in IPC and AS is critical, as historically most AS interventions target junior doctors, by-passing the existing roles of the wider range of healthcare professionals. In mapping the existing implicit roles along the surgical pathway in relation to IPC and AS, this study provides opportunities for using existing resources, including the workforce, to develop sustainable and context-sensitive interventions.

Figure 1: Roles and Responsibilities in relation to antibiotic prescribing and infection prevention and control

Abstract 6709

**Cefepime 2g plus enmetazobactam 0.5g administered IV q8h achieves high probability of target attainment in patients with complicated urinary tract infections**

Jannik Vollmer¹, Matthias Machacek¹, Adam C Belley², Philipp Knechtle*²

¹LYO-X, Allschwil, Switzerland, ²Allegra Therapeutics, Saint-Louis, France

**Background:** Enmetazobactam is a novel penicillanic acid sulfone β-lactamase inhibitor targeting extended-spectrum β-lactamases, the principal mechanism causing resistance to 3rd-generation cephalosporins (3GC) in Enterobacterales. The combination of enmetazobactam with cefepime is currently being investigated in a Phase 3 trial of patients with complicated urinary tract infections (cUTI) or acute pyelonephritis (AP). This study determined the joint probability of target attainment (PTA) of cefepime-enmetazobactam in adult cUTI/AP patients with varying degrees of renal function.

**Materials/methods:** Pharmacokinetic-pharmacodynamic (PK-PD) targets were 60% of the dosing interval during which free cefepime was above the minimal inhibitory concentration (ft > MIC), and 45% of the dosing interval during which free enmetazobactam was above a threshold concentration (ft > CT) of 2 mg/L. Population PK models for cefepime and enmetazobactam were established from cUTI/AP patients, healthy volunteers, and subjects with varying degrees of renal function. Monte-Carlo simulations (n = 4000 per group) were done accounting for between-patient variability and joint PTAs were defined as the fraction of simulated individuals who attained both targets. Covariate effects on probability of target attainment were predicted to assess if any of the statistically significant covariates require dose adjustments.

**Results:** The cefepime-enmetazobactam MIC distribution of 7168 recent clinical isolates of Enterobacterales was plotted as a histogram and overlaid with joint cefepime-enmetazobactam PTAs [Figure]. Glomerular filtration rate was identified as a covariate requiring dosing adjustment. A dose of cefepime 2 g enmetazobactam 0.5 g administered q8h as 2h IV infusion achieved high PTAs (≥98.3%) in patients with normal renal function or mild renal impairment up to a cefepime-enmetazobactam MIC of 8 mg/L. Half the dose administered q8h, q12h, and q24h achieved PTAs > 99% in patients with moderate and severe renal impairment, and end-stage renal disease, respectively.

**Conclusions:** High PTAs are achieved across the cefepime-enmetazobactam MIC distribution for Enterobacterales. Comparable pharmacokinetic properties of cefepime and enmetazobactam facilitate dosing-adjustment in patients with varying degrees of renal impairment. Cefepime-enmetazobactam may prove to be an important empiric, carbapenem-sparing therapy for the treatment of serious Gram-negative infections in settings where ESBLs are endemic.

**Presenter email address:** philippknechtle@bluewin.ch
Evaluation of plasma lipocalin-2 as a biomarker of community-acquired pneumonia

Andrea Vergara*1, Lucía Boix-Palop2, Emma Padilla3, Esther Calbo4, Ana Blanco Suárez3, Pepita Perez3, Jordi Vila Estape5, Climent Casals-Pascual5

1Departamento de Microbiología, Centro de Diagnóstico Biomédico (CDB)-Universidad de Barcelona-Hospital Clínic, Barcelona, Spain, 2Unidad de Enfermedades Infecciosas - Servicio de Medicina Interna -Hospital Universitari Mútua de Terrassa, Terrassa, Spain, 3Departamento de Microbiología, CATLAB, Viladecavalls, Spain, 4Universitat Internacional de Catalunya, Barcelona, Spain, 5Departamento de Microbiología, Centro de Diagnóstico Biomédico (CDB)-Universidad de Barcelona-Hospital Clínic-Instituto de Salud Global (ISGLOBAL), Barcelona, Spain

Background: Community-acquired pneumonia (CAP) is an infection of the respiratory tract associated with high morbimortality. Although the classical presentation of pneumonia typically includes symptoms like cough, sputum production, dyspnea, fever and pleuritic pain, in many cases these symptoms are absent, particularly in elderly patients with other underlying conditions. In this context, a rapid and more specific diagnosis is critical to accelerate treatment and improve prognosis of CAP. We evaluated the use of lipocalin-2 (LCN2), a well-characterised neutrophil-secreted protein, as a potential biomarker of CAP.

Materials/methods: A total of 130 patients with CAP were included in the study and classified into two groups: 71 bacterial infections (including 34 co-infections with virus); and 59 non-bacterial infections (17 viral and 42 with unknown etiology). Clinical (respiratory rate, heart rate, oxygen saturation, presence of symptoms and CURB-65, among others) and laboratory parameters (leukocytes, PCR, urea and creatinine, among others) were collected. LCN2 in plasma was determined using a modified enzyme immunoassay coupled with chemiluminescence (Architect). Statistical analyses were performed using RStudio (R version 3.4.0).

Results: The median (IQR) concentration of LCN2 was 122 ng/mL (62.6-192.6) in the bacterial group and 89.7 ng/mL (59.8-130.5) in the non-bacterial group \( p=0.03 \) (Fig1A). In patients with pneumococcal CAP there was a strong direct correlation between LCN2 concentration and pathogen copies/mL detected in blood \( R = 0.74 \), \( p=0.005 \) (Fig1B). Moreover, we observed a strong correlation between LCN2 concentration and CURB-65 index \( R = 0.37 \), \( p<0.001 \) (Fig1C).

Conclusions: LCN-2 could be a useful biomarker to identify bacterial CAP, allowing more responsible use of antibiotics. It could also play an important role in the discrimination between colonization and infection by \textit{S. pneumoniae}. Moreover, LCN2 concentration could be used as a complementary test to determine the severity of patients with CAP. Studies with a larger number of patients are necessary to corroborate the results obtained.

Figure 1. Lipocalin-2 concentration in plasma according to etiological group \( A \) and CURB index \( B \) and Spearman correlation between lipocalin-2 concentration and number of copies/mL of \textit{S. pneumoniae} target detected by PCR \( C \).

Abstract 6712

Quality of documentation on antibiotic treatment in medical records: evaluation of the long-term impact of an antimicrobial stewardship intervention

Christelle Vercheval*, Pierre Damas1, Frederic Frippiat1

1CHU de Liège, CHU de Liège, Liège, Belgium

Background: In 2016, the antimicrobial stewardship team (AST) of the University Hospital of Liège, Belgium published a prospective, uncontrolled, interrupted time series study demonstrating the successful implementation of a combined intervention strategy from the AST to improve the quality of documentation on antibiotic therapy in the computerized medical records between 2012 and 2014. Since 2016, the AST repeated a point prevalence surveys (PPS) twice a year about that topic.

Materials/methods: We aimed to evaluate if the impact of the interventions remained stable over time on the documentation rate of 3 quality indicators: (1) the indication (2) the antibiotics prescribed and (3) the expected duration or review date, with a goal of achieving 90% compliance on each indicator. Using the PPS approach, a clinical pharmacist and physician, both from the AST, identified patients receiving one or more antibacterial agents from the Medication Administration Record (MAR). Patients seen in the outpatients or dialysis department or the emergency room, and those who underwent a specific medical intervention or surgery the same day were excluded.

Results: From 2016-2019, six PPS were performed. Overall 4691 patient MARs were reviewed from a total of 34 wards: 1118 (23.8%) took one or more antibiotics, 84.9% for the treatment of an infection, which was slightly lower than previous results (26-28% and 82-83%, respectively). The medical records of 949 patients receiving antibiotics for infection were carefully reviewed and analyzed. On average, 90.4% (vs 90.3% in comparison with our previous results) had an indication documented; 95.1% (vs 95.6%) had documentation of the antibiotics prescribed; and 65.2% (vs 67.7%) had a duration or review date documented.

Conclusions: In our institution, the quality of documentation on antibiotic therapy remained stable over a 5 years period of time, with 90% or more compliance on average for two quality indicators: the indication and the antibiotics prescribed, but less than 70% for duration or review date. This last point should be analyzed and new interventions should be considered to reach 90% compliance for this quality indicator.

Presenter email address: christelle.vercheval@chu.ulg.ac.be
A comparative study to assess the prevalence and risk factors for *Clostridioides difficile* infection in patients with and without inflammatory bowel disease in a tertiary care hospital in northern India

Ujjala Ghoshal*, Nidhi Tejan1, Romya Singh1, Ankita Pandey1, Uday C. Ghoshal1

1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**Background:** The incidence of *Clostridiodes difficile* infection (CDI) is high among patients with inflammatory bowel disease (IBD) and is responsible for increased morbidity and mortality. In this study, we aim to describe the prevalence and risk factors in patients with IBD as compared to diseased controls (diarrhoea due to causes other than IBD).

**Materials/methods:** This study was conducted between June 2017 to June 2019 in a tertiary care hospital. Cases and controls were diarrhoeal patients with IBD and without IBD respectively. History was taken on a predesigned proforma. Stool samples were processed for routine microscopy and staining for opportunistic parasites. For *C. difficile* diagnosis, Glutamate dehydrogenase (GDH) assay and toxin detection by enzyme linked immunoassay (ELISA), culture and PCR were done. A diagnosis of CDI was made if both ELISA and PCR were positive. Statistical analysis was done using SPSS software version 21.0 (SPSS Inc., Chicago, IL, USA). Study was approved by institutional Ethical committee.

**Results:** A total of 160 cases and 108 age and gender matched control patients were included in IBD group and non-IBD group respectively. Six of 160 (3.8%) and none of controls had CDI (p value = 0.04). In IBD, 136/160 (85%) and 24/160 (15%) patients had ulcerative colitis (UC) and Crohn’s disease (CD) respectively. Only UC patients had CDI, all of which had active disease (3 mild and 3 severe UC), i.e. 6/73 (8.2%) compared to patients in remission (n=63, p value = 0.02). Exposure to levofloxacin (p < 0.001), cephalosporins (p = 0.03), proton pump inhibitors (PPI, p < 0.001) and infliximab (p = 0.02) were found significant risk factors. Using PCR as gold standard, the sensitivity and specificity of GDH ELISA and ELISA for toxins were 100%; 96.8% and 85.7%; 100% respectively.

**Conclusions:** This is first prospective study from India estimating *C. difficile* prevalence among IBD patients and showed prevalence of 3.8% which is lower than that reported from West. Exposure to antibiotics like fluoroquinolones and cephalosporins as well as PPI use are important risk factors for CDI development. An IBD flare and CDI have similar presentations therefore an early diagnosis is important.

**Presenter email address:** ujjalaghoshal@yahoo.co.in
Abstract 6715

**Cefotaxime-resistance in *Escherichia coli* strains isolated from poultry faeces in primary production phase**

Majda Fetahagic*1, Amir Ibrahimagic1, Jasmin Dizdarevic1, Selma Uzunovic1, Aida Šanjta-Reis1, Ajna Kapidžić1, Muhamed Gladan1

1Institute for Health and Food Safety Zenica, Zenica, Bosnia and Herzegovina

**Abstract third-party references:** Ministry of Agriculture, Forestry and Water Management in Zenica-Doboj Canton

**Background:** Antimicrobial resistance is a serious public health problem worldwide. There is increasing evidence that animals constitute a reservoir of antimicrobial resistance. The aim of this study was to investigate the prevalence of cefotaxime-resistance in *Escherichia coli* strains isolated from poultry feces in primary production phase in Zenica-Doboj Canton, Bosnia and Herzegovina.

**Materials/methods:** Between September and October 2019, 108 fecal samples (cloacal swabs) were obtained from 25 different poultry farms of Zenica-Doboj Canton. The swabs were subcultured on MacConkey agar supplemented with cefotaxime (2 g/L). Antibiotic susceptibility was determined using the disk-diffusion method. Phenotypic detection of extended spectrum beta-lactamases (ESBL) and AmpC production was performed using double disk synergy and the phenyl-boronic acid test, respectively.

**Results:** Among 108 swabs, 75 (69.4%) were positive on *E. coli*, of which 27 (36.0%) were cefotaxime-resistant. All cefotaxime-resistant *E. coli* isolates were positive in phenotypic test for ESBLs and five (out of 27; 18.5%) were positive on AmpC beta-lactamase production. More than 70% of cefotaxime-resistant isolates were resistant to cephalosporins 1st, 2nd, 3rd and 4th generation, and more than 30% of isolates were resistant to fluoroquinolones. Low prevalence of resistance was observed for aminoglycosides and sulphamethoxazole-trimethoprim. There was no isolates resistant to imipenem, meropenem and colistin. Twelve (44.4%) of the cefotaxime-resistant isolates were multi-resistant [more than three classes of antibiotics].

**Conclusions:** The wide production of chicken meat and consequently a presence of their fecal waste likely have to an impact on an increase of development of antibiotic resistance. Poultry production systems represent a hotspot for development of antimicrobial resistance, possibly mediated by extensive use of antibiotics in production plants. Also, it is very important to develop national surveillance system of resistance in order to prevent a possibility of emergency and spread of multiple resistant strains between animals, as well as between animals and people.

Identifying nosocomial transmission of influenza and associated deaths: a prospective, observational study

Luke Blagdon Snell*1,2, Jasper Vink1,2, Hannah Mitchell1, Csaba Beviz1, Morloh Kabia1, Jonathan Edgeworth1,2, Gaia Nebbia1,2

1Dept of Infection, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 2Centre for Clinical Infection & Diagnostics Research, King’s College London, London, United Kingdom

Abstract 6717

**Background:** The extent and burden of disease from nosocomial transmission of influenza is not well defined. Nosocomial transmission is of particular importance as hospitalised patients are often at risk of complications and death due to existing comorbidities. This study seeks to identify the burden of influenza in our hospital, as well as the extent of nosocomial transmission, and associated morbidity/mortality outcomes.

**Materials/methods:** Adult patients admitted to our hospital with a laboratory diagnosis of influenza were enrolled in the prospective study (Dec to March). Inpatients who shared a bay with a laboratory-confirmed case of influenza were defined as contact. Contacts were followed up for 5 days, to monitor for signs and symptoms of influenza. Those contacts who became symptomatic were tested for influenza. Demographic, co-morbidity and outcome data (mortality, HDU/ITU admission) was collated for both cases and contacts.

**Results:** We enrolled 405 influenza cases during our study period, representing 95% of those eligible by the inclusion criteria.

360 cases were community-associated cases (diagnosed <48 hours of hospital attendance), with 39/363 (11%) admitted to HDU/ITU and 11/363 (3%) deaths. 45 cases were diagnosed >48 hours after admission and designated hospital-associated. In this group there was a significantly higher mortality (7/45, 15%) and admissions to HDU/ITU (14/45, 30%) (p<0.001).

We identified 298 contacts from 73 cases, of which 23 acquired influenza (8% attack rate). In this influenza-positive contact group there were 5 deaths (28%) and 6 (26%) admissions to HDU/ITU. This was significantly greater than for influenza-negative contacts (275/298), in which there were 11/275 (4%) deaths (p=0.001) and 20/275 (7%) admissions to HDU/ITU (p=0.003).

Multivariate analysis including factors like age, ward, co-morbidity and length of stay suggests that influenza acquisition in hospitalised contacts is a major risk factor for death.

**Conclusions:** Hospital-associated influenza carries greater morbidity and mortality, compared to community-acquired influenza. A large number of contacts were identified suggesting suboptimal clinical suspicion and infection control response. The high rate of influenza acquisition in contacts and the poor outcomes highlight the need for improved strategies to prevent nosocomial transmission. Whole genome sequencing is underway and may be able to corroborate our epidemiological data.

Abstract 6718

**Epidemiology of carbapenem resistance genes in clinical isolates in South India**

Anusha Rohit*, Jagandeesan P1, Balaji Raghuraman1, Dhinakaran I1, Sureshkumar Dorairajan1, Karunasagar Iddya2

1Hospital, The Madras Medical Mission, Chennai, India, 2University, Nitte University, Mangalore, India

**Background:** The most clinically important carbapenemase genes are molecular class A (KPC type), Amber class B (NDM, VIM and IMP types) and class D (OXA-48 like). After the first discovery of NDM-1 in India and epidemiological studies that followed, indicated that the Indian subcontinent and Balkan region are reservoirs of NDM-1 producing bacteria and Turkey and surrounding Mediterranean basin is the reservoir of OXA-48-like producing bacteria. Both NDM and OXA-48 are carried on plasmids and other mobile genetic elements and have potential to spread rapidly. The objective of this study was to understand the epidemiology of carbapenem resistance genes in clinical isolates in a tertiary care hospital settings in South India.

**Materials/methods:** We studied 112 clinical isolates from blood (108), endotracheal secretions (1), urine (1), sputum (1), perigraft abscess (1) for the presence of carbapenamases by molecular and phenotypic testing over one year. Blood cultures from sepsis patients growing gram negative bacilli and isolates from above samples were subjected to Gene Xpert Carba (Cepheid) to look for the presence of KPC, Oxa-48, NDM, VIM and IMP. Disk diffusion and MIC’s for carbapenems were also determined simultaneously.

**Results:** Of the 108 blood culture isolates, phenotypic cabapenem resistance was found in 22 (21.3%) cases. This correlated with our hospital antibiogram pattern. Of the 23 isolates showing carbapenemase resistance, 11 had OXA-48, 4 had NDM and 5 isolates had both OXA-48 and NDM. One isolate from urine had Oxa-48. Two isolates that were carbapenem sensitive possessed both OXA-48 and NDM. In two phenotypically carbapenem resistant isolates, no carbapenemase genes could be detected suggesting other mechanisms of resistance. Oxa-48 was the most common carbapenamase in our study followed by joint presence of OXA-48 and NDM (Figure 1).

**Conclusions:** Our data indicates that OXA-48 carbapenemase gene is rapidly spreading in India overtaking NDM. Co-presence of NDM and OXA-8 possibly suggests acquisition of OXA-48 plasmids by isolates possessing NDM plasmids. This study also brings to relevance that ceftazidime avibactam can be used as a colistin sparing agent when presence of Oxa-48 is confirmed in clinical isolates.

**Percentage prevalence of carbapenemase resistance genes in clinical isolates**

Abstract 6720

**Longitudinal large-scale survey on blaCTX-M faecal carriage in children from Bolivian Guaraní indigenous communities**

Selene Rebecca Boncompagni*1, Tiziana Di Maggio1, Antonia Mantella2, Maria Micieli1, Ana Liz Villagrán3, Michele Spinicci2, Marianne Strohmeyer2, Martina Cecchetti2, Herlan Gamboa Barahona4, Veronica Poma2, Alessandro Bartoloni2, Gian Maria Rossolini2,6, Lucia Pallecchi1

1University of Siena, Department of Medical Biotechnologies, Siena, Italy, 2University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 3Hospital Básico Villa Montes, Villa Montes, Bolivia, 4Universidad Rene Moreno, Facultad Politecnica del Chaco, Camiri, Bolivia, 5Escuela de Salud Tekove Katu, Gutierrez, Bolivia, 6Careggi University Hospital, Microbiology and Virology Unit, Firenze, Italy

**Background:** CTX-M extended-spectrum beta-lactamases represent a huge challenge to healthcare. Community fecal carriage of CTX-M-producing enterobacteria has dramatically increased worldwide over the last two decades, with resource-limited countries being the most affected settings for reasons related to poverty and poor sanitation. Here we reported on a recent rapid increase of bla-CTX-M fecal carriage in healthy children from Bolivian Guaraní indigenous communities.

**Materials/methods:** School-aged children from four communities (Ivamirapinta and San Antonio del Parapetí, Santa Cruz Department; Chimeo and Tarairí, Tarija Department) were enrolled in 2016 (n=194) and 2019 (n=215). Of these, 23 were found to be included in both surveys. Stool samples (stored in fecal swab (Copan, Brescia, Italy) until processed) were plated as a first step onto MacConkey Agar (MCA), and then onto MCA plus cefotaxime 2 µg/ml (MCA-CTX). The bacterial growth on MCA-CTX was used as the template for the detection of group 1, 2, 8/25 and 9 blaCTX-M variants by mRT-PCR.

**Results:** Growth onto MCA-CTX was obtained with 318/409 stool samples (170/194, 2016; 148/215, 2019). Overall, a relevant increase of bla-CTX-M fecal carriage was observed in the study period (19.6%, 2016; 40.9%, 2019). Nonetheless, a discordant trend was observed in Tarairí, where prevalence of bla-CTX-M fecal carriage lowered from 41.5% in 2016 to 16.3% in 2019. Group 1 bla-CTX-M variants were found to have a major epidemiological impact (14.9%, 2016; 25.8% 2019, \(p < 0.05\)), and were the main responsible for the decreasing trend observed in Tarairí (31.7%, 2016; 7%, 2019, \(p < 0.01\)). Group 9 variants increased from 4.6% in 2016 to 14% in 2019 (\(p < 0.01\)), and group 8/25 variants appeared 2019 (3.7%, \(p < 0.05\)). Interestingly, no group 2 variants was detected. In 17 (N=4, 2016; N=13, 2019) samples (4.2%; 1%, 2016; 3.2%, 2019), the presence of bla-CTX-M variants of diverse groups was observed. Data from the 23 children enrolled in both surveys, did not suggest long-term colonization by CTX-M-producing enterobacteria.

**Conclusions:** High prevalence and rapid spread of CTX-M-producing enterobacteria were observed in the study setting, which encourages further studies to unravel the strains features and dissemination dynamics.

Prevalence of positive serology for Trypanosoma cruzi in a sample population of migrants from El Salvador and Honduras living in the Metropolitan Area of Milan (MAM)

Romualdo Grande*, Anna Maria Villa¹, Maria Rita Gismondo¹, Laura Galimberti³, Alkis Pilafas¹, Alberto Rizzo¹,², Sara Fadelli², Rosa Cimmino², Emanuela Ciriaco³, Chiara Fiammanti², Spinello Antinori²

¹Sacco Hospital, Lab of Clinical Microbiology, Virology and Bioemergencies, Milan, Italy, ²OSF Opera S. Francesco per i Poveri, Outpatient Clinic for not Guaranteed People, Milan, Italy, ³DIBIC L. Sacco University Hospital University of Milan, Infectious and Tropical Diseases University Clinic, Milan, Italy, ⁴Postgraduate School of Microbiology and Virology, University of Milan, Milan, Italy

Background: Studies on Chagas Disease (CD) among Latin Americans living in Europe Union (EU) calculated a pool seroprevalence of Trypanosoma cruzi (TC) of 4.2%. MAM is home to the largest Italian El Salvador Community. The aim of this study is to improve data in previous surveys about TC seroprevalence in Central American migrants living in MAM, especially El Salvador and Honduras.

Materials/methods: 385 migrants from Central America Area (CAA) (El Salvador, Honduras and Dominican Republic) were enlisted by OSF outpatient clinic (OSF) by interview. A serum sample was collected by all subjects enlisted and assayed by two serological methods (EIA Lisado Weiner - Effegiemme Italy; EIA Recombinant Weiner - Effegiemme Italy). Samples with discordant results were tested by Western Blot Method (WB) (LDBio - Effegiemme Italy). All subjects positive for at least two tests were attended to University Clinic (DIBIC) for clinical assessment.

Results: 9 subjects were positive for at least one assay (1 M, 8 F). Five were confirmed positives by WB and went for clinical examination. All positives were 2.3% of the sample population and all ones were Salvadorians. All patients with confirmed serology by WB were asymptomatic and their clinical assessment and follow up is in progress.

Conclusions: These preliminary results confirm seroprevalence for TC in El Salvador community dwelling in MAM. The screening is still in progress and so the clinical assessment and follow up of the patients seropositive for TC.

Variation in strain types of extended spectrum beta-lactamase-producing Enterobacteriaceae in long-term care facilities: a multi-centre, prospective cohort study

1University Hospital Tübingen, Department of Internal Medicine I, Division of Infectious Diseases, Tübingen, Germany, 2University Hospital Tübingen, Institute of Medical Microbiology and Hygiene, Tübingen, Germany, 3University Hospital Besançon, Infection Control Unit, Besançon, France, 4Infectious Diseases, Microbiology and Preventive Medicine, University Hospital Virgen Macarena, Sevilla, Spain, 5University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Epidemiology of Infectious Diseases, Utrecht, Netherlands, 6University Hospital Virgen Macarena Sevilla, Clinical Unit for Infectious Diseases, Microbiology and Preventive Medicine, Sevilla, Spain

Abstract third-party references: This research project receives support from the Joint Programming Initiative on Antimicrobial Resistance (JPIAMR) under the funding reference 01KI1 701 resources of Bundesministerium für Bildung und Forschung.

Background: While transmission of ESBL-producing Enterobacteriaceae (ESBL-PE) has been extensively studied in hospitals, prospective collected data in long term-care facilities (LTCF) are scarce and usually limited to single center studies.

Materials/methods: A longitudinal observational study was carried out in six LTCFs in four European countries. In a 34-week study period residents and staff were screened or provided stool samples for detection of ESBL-producing Escherichia coli (ESBL-EC) and Klebsiella pneumoniae (ESBL-KP) at eight defined time points. Individual, clinical and epidemiological data were collected at each point prevalence survey (PPS). Residents had a daily diary to note relevant risk factors for ESBL-PE acquisition. Environmental surfaces of the LTCF living areas were screened at two time points. ESBL production was detected using selective media and confirmed phenotypically by double disc synergy tests. blaESBL determinants were identified using Whole Genome Sequencing (WGS). Continuous carriage was defined as at least 7 out of 8 samples positive.

Results: 300 residents were enrolled, 1958 rectal swabs or stool samples and 707 surface samples were analyzed. ESBL-KP and/or ESBL-EC were isolated from 83 residents (27%) in 294 samples (15%). Prevalence at first PPS varied substantially among residents ranging from no cases to 41%. Dominant sequence type was ESBL-EC ST131 (34%), dominant ESBL gene blaCTX-M-15. Continuous ESBL carriage occurred in 15 residents (17.9%): 3 (20%) had a change in species (EC/KP), 1 (6.7%) had a change both in species and sequence type (within EC), 2 (13.3%) had a change in sequence type, and 1 (6.7%) had 5 different EC sequence types in 7 samples. Among 35 transient carriers, 15 (42.8%) had a change in species and/or sequence type. 6 (17.1%) had a change in species (EC/KP), 5 (14.3%) had a change both in species and sequence type, and 4 (11.4%) had a change in sequence type. Environmental screening was positive only from the center with highest prevalence (15/146).

Conclusions: Variation in prevalence and diversity of strains among the LTCFs was extremely high. Contamination of surface samples was limited. Transmission in LTCFs seems complex and linked to multiple patient’ risk factors which require consideration before starting infection control interventions.

Duration and sampling schedule of the 4 European study centres

**Colonisation and infection with carbapenemase-producing Enterobacteriaceae (CPE) in high-risk patients in a private hospital setting in Istanbul, Turkey**

Melda Ozdamar*1, Elif Hakko2, Ipek Karaman1, Muazzez Topaloglu1, Salih Turkoglu1

1Anadolu Medical Center, Kocaeli, Turkey, 2Anadolu Medical Center, Kocaeli, Turkey

**Background:** Infections associated with carbapenemase-producing Enterobacteriaceae (CPE) is getting a growing problem worldwide. An important risk factor of nosocomial infections is colonization.

**Materials/methods:** The study was done in a private foundation hospital specialized in the field of hematology/oncology and accepting international patients from July 2014 to September 2019. High risk patients according to the algorithm were screened at admission for CPE to attempt preemptive isolation. All rectal swabs were inoculated in ChromID CARBA agar (Biomerieux, France), identified by Vitek2 compact automated system (Biomerieux, France). The CPE positive colonies were tested with CarbaNP simultaneously. Genotypic characterization of CPE was done by real-PCR for blaVIM, blaIMP, blaNDM-1, blaKPC, and blaOXA-48 genes.

**Results:** A total of 849 patients were screened for CPE with rectal swabs. Of these 65 patients were positive (7.5%). Geographical distribution of patients were 420 from Turkey, 158 from North Africa, 117 from Eastern Europe, 97 from former Soviet Union countries, 66 from Middle East countries (Table1). From CPE positive patients, 9 patients (13.8%) were infected with CPE and 6 (66.6%) of them died. The patients who were infected had mostly hematologic cancer as underlying disease. Two of these infections were pneumonia and 7 were bloodstream infection. All the deceased patients had sepsis. In infected patients; the pathogens were mostly *Klebsiella pneumoniae*, one was *Enterobacter cloacae*. Only in one there was colistin resistance. Even if four of them had colistin in their empirical therapy, all of them died.

**Conclusions:** The rate of 7.5 % CPE colonization is high. Therefore, it is worthy to screen patients at admission for preemptive isolation and determining empirical treatment. However, even if colistin was included in empirical therapy and 66% of patients were died of sepsis. In conclusion, we should make attention to infection control measures and we need new antibiotics which are effective for CPE.

Abstract 6727

**Does trichomonas hurt? A five-year comprehensive full-region study**
Matthijs S. Berends*1, Daphne W.L. Scoop2, Jan Weel2, Theo A. Schuurs2

1Certe Medical Diagnostics & Advice, Groningen, Netherlands, 2Izore Centre for Infectious Diseases, Leeuwarden, Netherlands

Trichomonas vaginalis (TVG) is the etiological agent of trichomoniasis, the most prevalent non-viral sexually transmitted disease worldwide and a widespread, global health concern. The relatively mild symptoms have historically led to this disease being under diagnosed, and under researched. However, growing evidence that TVG infections are associated with high morbidity in both men and women, has increased the efforts to diagnose and treat patients harbouring this parasite. In this study, we aimed to assess this burden of disease.

Between 1 May 2012 and 31 January 2017, we routinely screened all patients for TVG where any STD diagnostics were requested by a GP, gynaecologist or social health care service in the region. All samples were tested using real-time PCR. The patient catchment area covered the whole of Friesland, one of the twelve provinces of the Netherlands, comprising ~645,000 inhabitants. All requesters were asked to supply clinical information about their patients.

In total, 47,735 patients were screened, of which 69% was female. The median age was 27 (IQR: 22-38). Out of 67,774 samples, 540 (0.8%) were positive for TVG, with a median cycle threshold (Ct) of 22.47 (IQR: 18.33-29.15). As a comparison, 9.7% tests were positive for Chlamydia trachomatis (CTR) and 1.4% was positive for Neisseria gonorrhoeae (NGO). Compliance of the supply of clinical information was 87%. TVG was found in both women (489/540, 91%) and men (51/540, 9.4%), although the median DNA load was almost 300 times higher in women (Ct 21.6) then in men (Ct 29.8). In women, presence of vaginal discharge and/or irritation was predictive only for presence of TVG and, opposingly, predictive for absence of both CTR and NGO.

To our knowledge this is the first full-region approach to study on the prevalence of TVG in relation to clinical complaints. Although our study results corroborate previous findings in the Netherlands, they contrast the high prevalences seen worldwide. Vaginal discharge appeared to be predictive for presence of TVG, and this reason for clinical burden is probably easily overlooked by physicians. Additional, in-depth analyses will be necessary to further specify how TVG infections are associated with other disease states.

Abstract 6728

Predictors of mortality in invasive pneumococcal disease: a meta-analysis

Tuna Demirdal*, Pinar Sen1, Busra Emir2

1Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Infectious Diseases and Clinical Microbiology, Izmir, Turkey
2Izmir Katip Celebi University, Department of Biostatistics, Izmir, Turkey

Background: Invasive pneumococcal disease (IPD) is responsible for life-threatening invasive infections such as bacteremia, meningitis and sepsis. Several risk factors have been identified that predict IPD-related mortality in some potential risk groups. However, mortality-related risk factors have not yet been systematically identified among all patient groups with IPD. In this meta-analysis, we aimed to determine the risk factors for mortality in IPD.

Materials/methods: We conducted a systemic literature search to January 2019 in MEDLINE/PubMed, ISI Web of Science and Cochrane Central Register of Controlled Trials databases. After reviewing 2514 potentially relevant records, remaining 190 articles were included in the analysis. The study protocol was registered in PROSPERO (CRD42019120189). Summary estimates were evaluated as odds ratios (OR) with 95% confidence intervals (CI) by using random-effects model. The main outcome measure included death within 30 days after diagnosis of IPD.

Results: Male sex (OR: 1.12), age ≥45 years (OR: 0.97), alcohol abuse (OR: 1.82), previous tuberculosis (OR: 2.33), severe sepsis (OR: 3.12), septic shock (OR: 8.6), hospital acquired infection (OR: 2.17), acute respiratory failure (OR: 2.56), mechanical ventilation (OR: 5.21), altered mental status (OR: 2.69), coma/convulsion (OR: 4.28), admission to the internal care unit (OR: 7.02), multilobar infiltrate or effusion (OR: 2.79), Pitt bacteremia score ≥4 (OR: 5.59), Pneumonia Severity Index ≥4 (OR: 2.68), solid organ malignancy (OR: 2.13), underlying clinical conditions (OR: 2.5), immunocompromising conditions (OR: 1.43), diabetes (OR: 1.2), chronic cardiovascular disease (OR: 2.27), chronic kidney disease (OR: 1.99), chronic liver disease (OR: 2.25), neurological disease (OR: 2.14), Charlson Comorbidity Index ≥2 and ≥3 (OR: 1.95 and 2.5), dialysis (OR: 7.35), serotype 3 (OR: 1.84), serotype 6B (OR: 1.3), serotype 9N (OR: 1.38), serotype 10A (OR: 1.57), serotype 11A (OR: 2.44), serotype 16F (OR: 1.94), serotype 17F (OR: 1.37), serotype 19 and 19F (OR: 1.81), serotype 22F (OR: 1.2), serotype 23A (OR: 1.33), serotype 23F (OR: 1.37), serotype 31 (OR: 2.59), serotype 35F (OR: 1.94), penicillin resistant (OR: 1.27), previous antibiotic use (OR: 1.6), inappropriate initial antimicrobial therapy (OR: 1.95) and vancomycin use (OR: 2.09) were found as predictors of 30-day mortality in IPD.

Conclusions: The results of this meta-analysis highlight the most important variables in determining outcome of IPD. Understanding the risk factors for mortality in IPD will help to define the potential pneumococcal vaccine benefits and treatment schedules with increased coverage that might target risk factors associated with higher mortality.

Migration and outbreaks of vaccine-preventable disease in Europe: a systematic analysis (1990-2019)

Anna Deal*, Mary Ramsay², Michael Edelstein², Sandra Mounier-Jack¹, Ines Campos-Matos³, Kieran Rustage¹, Sally Hayward¹, Azeem Majeed⁴, Felicity Knights¹, Jessica Carter¹, Jon S. Friedland⁴, Sally Hargreaves¹

¹St George’s University of London, Institute for Infection and Immunity, London, United Kingdom, ²Public Health England, London, United Kingdom, ³LSHTM, London, United Kingdom, ⁴Imperial College London, London, United Kingdom

Background: Migrant populations (defined as foreign-born) in the EU/EEA may be one of several under-immunised populations associated with outbreaks of vaccine-preventable diseases (VPDs). We synthesised existing EU/EEA data to explore whether migrants are involved in outbreaks and which particular subpopulations are at increased risk.

Materials/methods: We did both a systematic review (PROSPERO CRD42019157473; Medline, EMBASE, and Global Health January 1990 to October 2019) adhering to PRISMA guidelines, and a temporal analysis to map published reports of migrant-related outbreaks against data from the ECDC’s Surveillance Atlas of Infectious Disease. Studies on VPD outbreaks (measles, mumps, rubella, diphtheria, pertussis, polio, hepatitis A, N meningitidis, and H influenzae) in migrants residing in the EU/EEA and Switzerland were included.

Results: 54 studies were included, reporting on 55 VPD outbreaks across 13 EU/EEA countries, of which 96.4% (n=53) occurred since January 2000. Measles had the highest number of reports of outbreaks involving migrants (n=2; 5043 cases), followed by varicella (n=10; 595 cases), hepatitis A (n=8; 1082 cases), diphtheria (n=5; 35 cases), rubella (n=4; 512 cases), mumps, N meningitidis, polio (all n=2; 147, 7 and 15 cases, respectively), and pertussis (n=1; 10 cases). 21 (40%) of outbreaks were reported from camps or shelters for asylum seekers and refugees (mainly varicella or measles). Of 27 outbreaks where the index case was defined and reported, 20 (74.1%) were migrants, including 9 (33.3%) from Eastern Europe and 6 (22.2%) from Africa. When mapped against the ECDC timeline of measles outbreaks, migrant-related outbreak studies coincide with Europe-wide peaks in measles incidence, particularly in 2006, 2010, and 2017/2018 (shown in Figure 1).

Conclusions: Migrants represent one key group involved in VPD outbreaks in Europe, with refugees and asylum seekers residing in shelters or camps particularly at risk. Measles accounted for 38% of all reported outbreaks. Regional targets for elimination and control of vaccine-preventable diseases will not be met if we don’t better engage migrant populations in vaccination, alongside other under-immunised groups. Improved data collection is crucial to understanding the complex relationship between migration and occurrence of VPD outbreaks to inform policy decisions on the most effective strategies to prevent future outbreaks.

Figure 1. Published reports of outbreaks of measles involving migrants, mapped against the ECDC Surveillance Atlas of Infectious Disease timeline of all European measles outbreaks (1999-2018).

*Migrant-related outbreaks are marked as orange circles with the relevant reference.

Abstract 6730

**Application of MALDI-TOF MS for identification of helminths in clinical samples**

Issa Sy\(^1\*\), Tabea Wendel\(^1\), Maureen Feucherolles\(^1,2\), Anna Nimmesgern\(^1\), Anna Stuermann\(^3\), Yvette Endriss\(^1\), Juerg Utzinger\(^3\), Sven Poppert\(^1\), Sören Leif Becker\(^1,4\)

\(^1\)Saarland University, Institute of Medical Microbiology and Hygiene, Saarland University, Homburg/Saar, Germany, Homburg/Saar, Germany, \(^2\)Luxembourg Institut of Science and Technology, Environmental research and innovation (ERIN) department, Belvaux, Luxembourg, \(^3\)University of Basel, Swiss Tropical and Public Health Institute, Basel, Switzerland, Basel, Switzerland, \(^4\)University of Basel, Basel, Switzerland

**Abstract third-party references:** Luxembourg Institute of Science and Technology, Environmental Research and Innovation Department, Belvaux, Luxembourg, Institute of Medical Microbiology and Hygiene, Saarland University, Homburg/Saar, Germany, Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland

**Background:** Matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry is the standard diagnostic technique for identification of bacteria, mycobacteria and fungi. Preliminary data suggest that MALDI-TOF might also be used for helminths. At present, their identification is mainly based on microscopy, but exact species differentiation cannot always be achieved. Hence, we evaluated the capacity of MALDI-TOF MS to identify helminths from clinical samples, and analysed the influence of different sample storage conditions.

**Materials/methods:** All experiments were carried out with a MALDI-TOF mass spectrometer (Bruker Daltonics), using the software Maldi Biotyper Compass Explorer\(^2\) and FlexAnalysis\(^2\). We analysed proglottids of *Taenia saginata* stemming from two different patients and one serum sample from a patient with active *Schistosoma mansoni* infection. The acquired raw MALDI spectra were tested with a commercially available database for bacteria and fungi as well as a previously developed in-house database for helminths. Log-score values (LSVs) of ≥2.00 were considered as reliable species identification. Additionally, proglottids of *T. saginata* were placed in tubes containing different fixatives (water, 0.45% sodium chloride, 70% ethanol, and formalin), and spectral profiles were visualized after 12 weeks.

**Results:** When employing our in-house database for helminths, the two new *T. saginata* samples and the *S. mansoni* serum specimen were correctly identified with average LSVs of 2.04, 2.10 and 2.21, respectively. In contrast, no identification was achieved with the commercially available database. The quality of acquired spectra was best if ethanol or sodium chloride solution were used as fixatives, whereas formalin-preserved samples did not yield any spectra [Figure].

**Conclusions:** MALDI-TOF MS can be employed to identify helminths in different sample types. Further research and database validation is needed to confirm its potential as diagnostic tool for parasitic pathogens. Formalin-fixed specimens cannot be subjected to MALDI-TOF analysis.

**Figure:** MALDI-TOF mass spectrometry profile of *Taenia saginata* proglottids in different fixatives after a storage period of 12 weeks. A decrease of the peak intensity at 3827 m/z and at 7065 m/z for samples stored in water (first row) as compared to ethanol (second row) can be observed. Third row: 0.45% sodium chloride. Fourth row: formalin.

Abstract 6733

Examining the modified Duke criteria in infective endocarditis: a comparison of outcomes for ‘typical’ and ‘atypical’ bacteria

Ravi Mehta*1, Punam Pabari1, Adam Hartley1, Yousuf Razvi2, Bushra Rana1, Anan Ghazy1, Monicka Shehata1, Aula Abbara1

1Imperial College Healthcare NHS Trust, London, United Kingdom, 2Imperial College London, London, United Kingdom

Background: The 2000 modified Duke criteria remain the most often used internationally for the stratification of infective endocarditis (IE) as definite, possible or rejected. This study aimed to assess the sensitivity of the modified Duke criteria in IE and compare clinical outcomes between different infections and patient populations.

Materials/methods: This retrospective cohort review included all patients diagnosed with IE between 2016 and 2018 at a tertiary centre for Infectious Diseases, Cardiology and Cardiothoracic Surgery in London, UK. Detailed demographic, clinical, microbiology, imaging, management and outcome data were extracted from electronic health records and analysed in Excel. Modified Duke criteria was noted for each patient.

Results: 129 patients met the inclusion criteria, of whom 109 (85.8%) had positive blood cultures. 91 (70.5%) were male; median age was 67 (IQR: 51-76). Modified Duke criteria identified 81 (62.8%) cases as definite, 43 (33.3%) as possible and missed five (3.9%) of our cohort. 24/109 (22.0%) were infected with an ‘atypical’ organism, as per the modified Duke criteria; 20/129 (15.5%) were culture negative. The most common ‘atypical’ organisms were coagulase negative staphylococcus (six patients), group B streptococcus (five), and Streptococcus pneumoniae (two). When compared with ‘typical’ infections, ‘atypical’ infections led to lower mortality rates (31.8% vs 20.0%) but longer admissions (mean 32 versus 46 days). Staphylococcus aureus had the highest mortality rate (41.9%) of all infections. Intravenous drug users (IVDUs) had a better inpatient survival rate than non-IVDUs (75.0% vs 63.3%), despite fewer patients undergoing surgery (25.0% vs 34.9%).

Conclusions: Our study showed that in a large cohort of patients with IE, the modified Duke criteria showed a high sensitivity. However, an unexpectedly high proportion of infections did not fall into the ‘typical’ category as defined by these criteria; the largest groups were coagulase negative staphylococcus and group B streptococcus, which are both increasingly reported in the literature as causes of IE. The outcomes for ‘typical’ and ‘atypical’ bacteria differed in terms of mortality, which was lower in the ‘atypical’ group. 15.5% of patients were culture negative, supporting the need for improved diagnostics.

1Institut Supérieur des Professions Infirmières et Techniques de Santé de Tanger, Hôpital Al Kortobi, Tanger, Morocco, 2Équipe de Recherche en Biotechnologies et Génie des Biomolécules, Faculté des Sciences et Techniques de Tanger, Tanger, Morocco, 3Centre National de Référence des Staphylocoques, Institut des agents Infectieux, Hospices Civils de Lyon, Lyon, France

**Background:** Data concerning the molecular epidemiology of *S. aureus* infections in Morocco, particularly methicillin-resistant *S. aureus* (MRSA), are very limited. The aim of the study was to perform the molecular characterization of *S. aureus* isolates recovered in respiratory specimens of children hospitalized in the Mohammed V Hospital in Tangier, Morocco.

**Materials/methods:** A total of 97 *S. aureus* isolates collected from respiratory tract infections between 2013 and 2014, were retrospectively identified and analyzed. Information was retrieved from the database of the bacteriology laboratory and through the medical record review. The antimicrobial susceptibility phenotypes were determined by disk diffusion according to EUCAST 2016. The presence of mecA (encoding PBP2a and methicillin resistance), lukS/F-PV (encoding PVL toxin), and tst (encoding TSST-1 toxin) genes were determined by PCR for all isolates. To describe the clonality of MRSA, genotyping was performed using Alere StaphType DNA microarray (Alere Technologies GmbH, Jena, Germany). Statistical analyses were performed using SPSS statistics version 20.0 software; p-values of ≤0.05 were interpreted as statistically significant.

**Results:** Susceptibility testing of the 97 investigated *S. aureus* isolates resulted in 89 (91.75%), methicillin susceptible *S. aureus* (MSSA) and eight (8.25%) MRSA isolates. All *S. aureus* isolates were found to be susceptible to rifampicin, pristinamycin, and vancomycin. The lukS/F-PV and tst genes were found respectively in 22 (22.7%) and 25 (25.7%) isolates. Of note, the lukS/F-PV genes were not detected in MRSA. The most prevalent MRSA genotype was the CC22-IV (UK-MRSA-15 / Middle Eastern variant; n=3) harbouring tst, egc genes followed by CC5-MRSAV+SCCfus (n=2), harbouring seb, egc, and three singletons belonging to CC88-MRSA-IV, CC5-MRSA-V, CC5-MRSA-IV Pediatric clone.

**Conclusions:** This study provides, for the first time, data on the genetic background of *S. aureus* isolates involved in respiratory infections among children in Tangier. Our results highlight the high prevalence of PVL+ MSSA as well as the high prevalence of MRSA in respiratory tract specimen in children.

Antibiotic resistance in *Staphylococcus pseudintermedius* associated with skin and soft tissue infections in dogs and cats

Catarina Morais*1, Sofia Santos Costa1, Patrícia Abrantes1, Maria Constança Pomba2, Isabel Couto1

1Global Health and Tropical Medicine (GHTM), Instituto de Higiene e Medicina Tropical (IHTM) - Universidade NOVA de Lisboa, Lisboa, Portugal, 2Laboratory of Antimicrobial and Biocide Resistance, CIISA, Faculty of Veterinary Medicine, University of Lisbon, Lisbon, Portugal

**Background:** Antimicrobial resistance in staphylococci causing skin and soft tissue infections (SSTIs) in companion animals is a growing public health concern. In this study we characterized a collection of *S. pseudintermedius* causing SSTIs in pets to document their phenotypic and genotypic profile towards antibiotics.

**Materials/methods:** The collection comprised 163 *S. pseudintermedius* associated with SSTIs in dogs and cats, collected between 2014 and 2018 at two veterinary laboratories in Lisbon (Portugal). Identification was confirmed by species-specific *spsJ* PCR approach and the susceptibility profile determined by Kirby-Bauer. The results were interpreted according to the VET08 CLSI guidelines or other, when necessary. Resistance determinants were screened for all isolates (*blaZ* and *mecA* genes) or for those showing a resistance phenotype (e.g. *erm*, *tet*, *aadD*, *vga*(C), *dfrA*(S1), *aph3-IIIa*).

**Results:** Among the 163 *S. pseudintermedius* tested, 136 (83.4%) were resistant to penicillin, all of which carried the *blaZ* gene. Methicillin resistance (MRSP) was detected in 52 isolates (31.9%), 51 of which carried *mecA* and 48 showed a multidrug resistance (MDR) phenotype. In general, multidrug resistance was detected in 77 isolates (47%) and the most common pattern was resistance to beta-lactams, aminoglycosides, macrolides and lincosamides. Resistance to aminoglycosides (39.3%) and macrolides/lincosamides (37.4%) was mostly associated with carriage of *aph3-IIIa* and *erm*(B) genes, respectively. Resistance to tetracyclines was found in 55.2% of the isolates, mostly related to *tet(M)* gene. We also detected resistance to trimethoprim-sulfamethoxazole (30.7%), fluoroquinolones (25.8%), chloramphenicol (14.7%) and fusidic acid (4.9%). No resistance was observed for linezolid, tigecycline or quinupristin-dalfopristin.

**Conclusions:** This ongoing study revealed a high frequency of MDR and MRSP strains and, in comparison with previous studies, an increasing trend of antibiotic-resistant *S. pseudintermedius* associated with SSTIs in pets. The close contact between these animals and humans may be a possible source for transmission of antibiotic resistant staphylococci, reinforcing the need of a One Health perspective in their study. These results also highlight relevant therapeutic limitations for the treatment of SSTIs in pets, which already include critically important antibiotics.

Abstract 6738

Diagnosing disseminated histoplasmosis in an AIDS patient: the role of bone marrow evaluation
Naseelah Yunus Mussa1, Dinah Carvalho1, Sara Ismail2, José Melo-Cristino1

1Hospital de Santa Maria, Lisboa, Portugal; 2Hospital Santa Maria, Lisboa, Portugal

Background: Histoplasmosis (HP) is a micosis caused by a dimorphic fungus *Histoplasma capsulatum*. HP represents a HIV-defining condition and in AIDS patients the pathogen can invade the bloodstream and spread to other organs and tissues leading to progressive disseminated histoplasmosis (PDH), a fatal disease in untreated patients. There are multiple methods for the diagnosis of histoplasmosis including histopathology/cytology and cultures, specific fungal stains, antigen detection, serological tests and molecular biology tests. The gold standard for identification of the pathogen is the culture demonstrating the thermal dimorphism of the fungus.

Materials/methods: A 52 year old male with HIV-1 infection (CDC-C3, CD4+: 4.5%, 27 cel/μl, HIV-RNA: 5640000 copies/mL) and a recent trip to Brasil, was admitted in the ICU with a diagnosis of *Pneumocystis jirovecii* pneumonia (under co-trimoxazole treatment) and haemophagocytic lymphohistiocytosis. A bone marrow (BM) aspirate, BM cultures (on Columbia blood agar, Sabouraud dextrose agar (SDA), SDA with gentamicin/chloramphenicol, SDA with cicloheximide incubated at two temperatures-25ºC and 35ºC), and BM PCR were requested.

Results: Stained May-Grunwald-Giemsa films revealed numerous yeast-like bodies inside and outside macrophages with morphology suggestive of *Histoplasma spp.* After 7 days the cultures revealed: at 35ºC- growth of white, smooth, creamy and yeast-like colonies and microscopic examination of a lactophenol blue mount preparation showed round to oval, small, budding, and thin-walled yeast-like cells. At 25ºC- growth of velvety/cottony white colonies with yellow reverse and a lactophenol blue mount preparation showed hyphae hialine and septate, with short conidiophores. Macroconidia were large, round, one-celled, hyaline, thick-walled and tuberculate. The isolate was identified as *Histoplasma capsulatum* based on its morphological features growth. Molecular results (bone marrow PCR) confirmed the microbiological diagnosis- *Histoplasma capsulatum*. Despite the diagnosis, due to several comorbidities the patient died 24 hours after the marrow morphology report.

Conclusions: PDH carries a poor prognosis, especially when the diagnosis is delayed. Giving its rarity in non endemic areas it poses a real challenge but should be always considered, specially in AIDS patients. In our case the prompt diagnosis was possible through direct microscopy and culture (for PDH cases the sensitivity of bone marrow culture is 75%).

Efficacy and safety of tedizolid in difficult-to-treat osteoarticular infections: results of a multi-centre experience

Eva Benavent Palomares*1, Francesc Escrihuela-Vidal2, Laura Morata3, Esteban Reynaga4, Alex Soriano3, Dolors Garcia-Somoza5, Xavier Cabo6, Laia Albiach7, Ariadna Padulles8, Oscar Murillo1

1Bellvitge University Hospital, Departament of Infectious Diseases - IDIBELL, L’Hospitalet de Llobregat, Spain, 2Bellvitge University Hospital, Department of Infectious Diseases, L’Hospitalet de Llobregat, Spain, 3Hospital Clinic de Barcelona, Department of Infectious Diseases - University of Barcelona, Barcelona, Spain, 4Hospital Universitari Germans Trias i Pujol, Department of Infectious Diseases, Badalona, Spain, 5Bellvitge University Hospital, Microbiology Department, L’Hospitalet de Llobregat, Spain, 6Bellvitge University Hospital, Orthopedic Surgery Department, L’Hospitalet de Llobregat, Spain, 7Hospital Clinic de Barcelona, Department of Infectious Diseases, Barcelona, Spain, 8Bellvitge University Hospital, Pharmacy Department, L’Hospitalet de Llobregat, Spain

Background: Linezolid is widely used against Gram-positive osteoarticular infections (OAsI) but has limitations in particular scenarios. Tedizolid, a newer oxazolidinone drug, present a higher in vitro activity and less drug-interaction and toxicity. We aimed to describe our experience using tedizolid in difficult-to-treat OAsIs.

Materials/methods: Multicenter retrospective study (3 Spanish referral centers). Cases with OAI (prosthetic joint infections -PJIs-, osteoarthritis, and diabetic foot infections -DFIs-) receiving Tedizolid (200mg/d) for at least 7 days, were included (January 2017-March 2019). Failure: reappearance of signs of infection after treatment, absence of improving or suppressive treatment.

Results: 51 patients were enrolled (59% women), mean age was 65±14.3. Mean adjusted Charlson Index was 4.9±3.4.

27 (53%) cases presented with osteoarthritis, 17 (33%) with PJIs, and 9 (18%) with DFIs. 30 cases (59%) had device-related infection (DRI). 39.2% (n=20) were polymicrobial infections (55% combining Gram-positive bacteria). Most frequent isolates were coagulase-negative staphylococci (36%, n=26) followed by Staphylococcus aureus (29%, n=21 with 48% of MRSA), and Enterococcus faecium (n=4, 6%).

Potential interaction was main reason for tedizolid treatment (n=32, 63%) followed by cytopenia (n=28, 55%), and toxicity or failure with previous treatment (n=11). 24% cases received rifampin concomitantly.

Median days of treatment was 29 (IQR 15-44). Adverse events were scarce (vomits, n=2) and did not require discontinuation. Hemoglobin value and platelet count (overall cohort) stayed stable along treatment (from 110.3g/L to 120g/L, p=0.03 and 242x10⁶/mL to 239x10⁶/mL, p=0.88 respectively); cases with anemia or thrombocytopenia initially (n=28) did not worsen with treatment (from 94.7g/L to 107.7g/L, p=0.001 and 72x10⁶/mL to 218x10⁶/mL, p=0.001, respectively).

41 (80.4%) underwent surgery; 33% of DRI cases were managed with implant retention. Three cases [6%] were not evaluated due to non-related death after 30 days of infection. Median follow-up was 371 days (IQR 177-644) with a cure rate of 81.3% (n=39) and 4.2% of improvement while 7 cases (14.6%) failed (4 DRI).

Conclusions: Tedizolid proved safety in patients receiving anti-depressants and having relevant cytopenia. High efficacy of tedizolid alone and in combination with rifampicin was observed in difficult-to-treat OAsIs and DFIs. Tedizolid seems to be a suitable alternative for OAsIs while waiting for further experiences in this setting.

Whole genome sequencing in an outbreak of Serratia marcescens in a neonatal intensive care unit of a tertiary care centre in Italy

Barbara Saccani*, Luana Signorini¹, Francesco Castelli¹, Evelyn Van Hauwermeiren¹, Roberto Marzollo¹, Maria Motta¹, Mauro Ricca¹, Simona Fiorentini¹, Arnaldo Caruso¹, Ramona Pezzotta¹, Claudio Bandi², Piero Marone³

¹Brescia, Spedali Civili, Brescia, Italy, ²Milano, Milano, Italy, ³San Matteo, Pavia, Italy

Background: Many outbreaks due to Serratia marcescens [S. marcescens] among hospitalised neonates have been described. In neonatal intensive care units, colonized or infected newborns are the main potential reservoir of S. marcescens, particularly in the gastrointestinal tract. The objective of this outbreak report was to establish the clonal relationships between different isolates of S. Marcescens and identify the source, using whole genome sequencing (WGS).

Materials/methods: In late July 2018 three neonates hospitalised in the neonatal intensive care unit (NICU) of a tertiary care centre in Italy (Brescia), were found to be colonised/infected with S. marcescens. It was considered a possible outbreak and an investigation was started with extensive environmental sampling. Ten patient isolates and two environmental samples positive for S. marcescens underwent WGS, using Illumina Miseq instrument. After alignment, cores of Single Nucleotide Polymorphisms (SNPs) were identified using GATK BestPractice to define genetic clusters with a minimum distance of 5 SNPs. Diffusion of bacterial strains was then analyzed using R Outbreaker2 package and presence of resistance genes was investigated using SRST2 software.

Results: Ten neonates were colonised with S. marcescens; 3 of these had invasive infection due to S. marcescens and 2 neonates had a localized infection (a conjunctivitis and an urinary tract infection). Of 353 environmental samples collected over the study period, S. marcescens was only isolated from the soap dispenser, sink in the lactaction room and soap in the kitchen of NICU. Clinical and environmental samples were closely related with an average of 4.8 SNPs (minimum: 1; maximum: 8); thus they belonged to a unique cluster (Figure 1).

Conclusions: Genotyping confirmed that our outbreak has been caused by a single clone of S. marcescens. The main source were the colonized/infected neonates; transmission was due to the hands of health care workers and parents; while liquid soap resulted ongoing reservoir. We believe that ample evidence is available to support the benefits of integrating WGS into outbreak investigations.

Figure 1 Heatmap of the SNP distances between the 12 isolates of S. marcescens. Heatmap color indicates the number of SNPs between isolates [red corresponds to 0 SNPs, white to 8 SNPs].

Manipulation of raw pig meat is a risk for transmission of carbapenem-resistant *Pseudomonas fluorescens* to humans in the community

Mariana Adriao Camoez*, Ana Botelho1, Ons Bouchami1, Helena Fernandes2, Nuno Alexandre Faria1, Opeyemi U. Lawal1, Maria Joao Fraqueza2, Maria Miragaia1

1Universidade NOVA de Lisboa, Laboratory of Bacterial Evolution and Molecular Epidemiology, ITQB-UNL, Oeiras, Portugal, 2Universidade de Lisboa, DEIIA, Faculty of Veterinary Medicine, University of Lisbon, Lisboa, Portugal

Abstract third-party references: Project financed by FCT (reference PTDC/CVT-CVT/29510/2017)

**Background:** Carbapenem-resistant gram-negative bacteria (CRGNB) such as *Enterobacter*, *Klebsiella*, *Serratia*, and *Pseudomonas* species became one of the main causes of nosocomial infections worldwide, and colonize persons in the community. Although carbapenems are not used in animal farming, CRGNB have been reported in production animals. However, the prevalence of the different gram-negative bacterial species in production animals and the occurrence of transmission to humans through the food production chain are unknown.

**Materials/methods:** To determine the prevalence of carbapenem-resistant *Pseudomonas* spp. (CRP) and the potential of transmission to humans in pig production chain, we have sampled live pigs (ear and rectum) at slaughterhouse entrance, workers, equipment, raw and cooked meat and hands of human consumers before and after meat manipulation (*n*=90 samples) in Portugal (2019). Samples were screened for presumptive CRP by culturing in selective media with and without 4mg/L of meropenem; up to 5 colonies per sample (*n*=201) were selected for confirmation of carbapenem-resistance through growth in different meropenem concentrations (2, 4, 8 and 16 mg/L). Forty-six CRP isolates, collected from all sampling sites, were selected for species identification by sequencing an internal fragment of *rpoB*.

**Results:** Carbapenem resistant *Pseudomonas* spp. were detected in 46% (41/90) of the samples. Notably, the raw pig meat samples had the highest load of CRP (average: 1.19x10⁵ CFU). No resistant isolates were detected in pig rectum and equipment samples. A total of 60% (6/10) of the human consumers became colonized with CRP only after manipulation of the pig raw meat. The most frequent CRP species were *P. fluorescens* (74%, 34/46 isolates; 23%, 21/90 samples) followed by *P. aeruginosa* (13%, 6/46 isolates; 2%, 2/90 samples). *P. fluorescens* was detected in all sampling sites, whereas *P. aeruginosa* was only detected in the pig ear.

**Conclusions:** The pig food processing chain is a large reservoir for carbapenem-resistant *P. fluorescens*. Manipulation of raw pig meat constitutes a risk of transmission of carbapenem-resistant *P. fluorescens* to humans in the community and might aid in the spread into healthcare settings. Also, foodborne carbapenem-resistant *P. fluorescens* can be a reservoir of carbapenemase resistance genes to other more pathogenic species like *P. aeruginosa*.

Abstract 6753

Activity of cefiderocol and comparator antibiotics on an Italian multi-centre collection of carbapenem-resistant Gram-negative clinical isolates

Marco Coppi¹, Alberto Antonelli¹, Chiara Cervini¹, Lara Mosconi¹, Eleonora Riccobono¹, Giulia Baldi¹, Francesco Luzzaro¹, Teresa Lopizzo¹, Teresa Spanu⁴, Tommaso Giani¹,²,⁵, Gian M. Rossolini¹,²,⁵

¹University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, ²Alessandro Manzoni Hospital, Clinical Microbiology and Virology Unit, Lecco, Italy, ³A.O.R. San Carlo Hospital, Clinical and microbiological analysis laboratory, Potenza, Italy, ⁴Università Cattolica del Sacro Cuore, Institute of Microbiology, Roma, Italy, ⁵Careggi Florence University Hospital, Clinical Microbiology and Virology Unit, Florence, Italy

Background: The recent worldwide spread of carbapenem-resistant Gram-negative pathogens underlined the need for novel antimicrobial therapies. Cefiderocol (Shionogi & Co) is a siderophore cephalosporin recently approved by FDA against complicated urinary tract infections caused by Gram-negative pathogens with limited treatment options. No data are available about the activity of cefiderocol against carbapenem-resistant clinical isolates in Italy. The aim of this work was to evaluate the in vitro activity of cefiderocol and comparator antibiotics against carbapenem-resistant Gram-negative isolates prospectively collected from four Italian hospitals (Lecco, Florence, Rome, Potenza).

Materials/methods: Non-duplicate carbapenem-resistant clinical isolates (surveillance samples excluded) of Enterobacteriales and Gram-negative non-fermenters (Pseudomonas aeruginosa, Acinetobacter baumannii and Stenotrophomonas maltophilia) were included in a period of 5 months during 2018. The most common carbapenemases were detected by Real-Time PCR. The susceptibility testing of cefiderocol and comparators (including ceftazidime/avibactam, ceftolozane/tazobactam, amikacin, gentamicin, tigecycline, colistin and trimethoprim/sulfamethoxazole) was performed using frozen broth microdilution plates with iron-depleted Mueller-Hinton broth for cefiderocol. MICs of cefiderocol and comparators were interpreted according to CLSI (29th ed; susceptibility ≤4 mg/L) and EUCAST (v 9.0) clinical breakpoints, respectively.

Results: Among the 234 isolates collected, 159 were confirmed as producers of acquired carbapenemases by molecular methods, including 87 KPC-producing Enterobacteriales, one VIM-producing Enterobacter cloacae, one VIM-producing Citrobacter spp, five VIM-producing P. aeruginosa, five GES-producing P. aeruginosa, one NDM-producing K. pneumoniae, one NDM-producing E. coli, 49 OXA-23-producing A. baumannii, 8 OXA-23- and ISAb1-OXA-51-coproducing A. baumannii and one NDM-producing A. baumannii. Excellent activity of cefiderocol was observed with all tested isolates. In particular, 99.1% of all isolates [N=232/234] exhibited MIC≤4 mg/L, including 98.9% of KPC producers and 90.0% of metallo-β-lactamase producers. Among Enterobacteriales, the cefiderocol MIC₅₀ and MIC₉₀ [2 and 4 mg/L, respectively] were lower than those of comparators, except for colistin and tigecycline. Moreover, non-fermenters, P. aeruginosa and S. maltophilia especially, had lower MIC values for cefiderocol than Enterobacteriales isolates. The highest MIC of cefiderocol was 8 mg/L, corresponding to an intermediate susceptibility, observed in a KPC-producing K. pneumoniae and a NDM-producing A. baumannii.

Conclusions: Cefiderocol showed a potent activity in vitro against multidrug-resistant Gram-negative bacteria, including carbapenemase producers of all classes.

Abstract 6754

**Recurrent community-acquired bacterial meningitis in adults**
Liora Ter Horst*, Matthijs Brouwer¹, Arie Van Der Ende², Diederik Van De Beek⁴

¹Amsterdam University Centers, location AMC, Amsterdam, Netherlands

**Background:** Recurrent episodes of bacterial meningitis episodes have been described in 5% of cases and was previously associated with a relatively favorable prognosis. Due to changes in population and epidemiology of bacterial meningitis risk factors and clinical characteristics may have changed. It is unclear whether this is done and if vaccine failures occur.

**Materials/methods:** We analyzed adult patients with recurrent episodes of bacterial meningitis from a prospective nationwide cohort study of community-acquired bacterial meningitis.

**Results:** We identified 143 recurrent episodes of community-acquired bacterial meningitis (5%) out of 2264 episodes in 123 patients. The median age was 57 years and 57 episodes (46%) occurred in men. The median duration between a first episode and the current episode was 5 years. For 78 of 122 patients [64%] the current episode was a second episode, 30 patients [25%] had between 1 and 5 previous episodes, 3 patients [3%] had 5 to 10 episodes, 1 patient had more than 10 recurrent episodes. Predisposing factors were identified in 86 of 123 patients [70%], and most commonly consisted of extra-meningeal foci of infections [45/123 [37%]] and cerebrospinal fluid leakage [36/122 patients [30%]]. The most common causative agents were Streptococcus pneumoniae in 80 patients [65%] and Haemophilus influenzae in 16 patients [13%]. The outcome was unfavorable [Glasgow outcome scale score <5] in 22 patients with recurrent bacterial meningitis [18%] versus 806 patients [40%] for non-recurrent meningitis patients [P<0.001]. Five patients [4%] died compared with 363 patients [18%, P<0.001].

**Conclusions:** Recurrent meningitis frequently occurs due to predisposing factors, most commonly extra-meningeal foci of infection and CSF leakage. Recurrent episodes are predominantly caused by S. pneumoniae and H. influenzae and the disease course is less severe with a lower mortality rate compared with non-recurrent bacterial meningitis patients.

Evaluation of STANDARD E TB-Feron ELISA for the diagnosis of latent tuberculosis infection in healthcare workers

Mi-Kyung Lee*, Oh Joo Kweon¹, Yong Kwan Lim¹, Hye-Ryoun Kim¹, Tae-Hyoung Kim²

¹Department of Laboratory Medicine, Chung-Ang University College of Medicine, Seoul, South Korea, ²Department of Urology, Chung-Ang University College of Medicine, Seoul, South Korea

Background: Laboratory diagnosis of latent tuberculosis infection (LTBI) is mainly performed with interferon-gamma release assays (IGRAs). We compared the performance of a new ELISA-based IGRA, STANDARD E TB-Feron ELISA (TBF; SD Biosensor, Gyeonggi-do, Republic of Korea), and a widely used assay, QuantiFERON-TB Gold In-Tube (QFT-GIT; Qiagen, Hilden, Germany), in a population of 425 healthcare workers (HCWs).

Materials/methods: All HCWs were screened with both assays per the manufacturers’ protocols and in a “cross-manner,” where tube sets from one assay were used with the alternative ELISA. Results were compared both qualitatively and quantitatively.

Results: TBF and QFT-GIT identified 11.3% (48/425) and 12.9% (55/425) positive samples, respectively. TBF demonstrated 81.6% positive and 97.4% negative percentage agreement with QFT-GIT, with a Cohen’s kappa value of 0.78 (strong agreement). Discordant results were detected in 20 subjects (4.3%): 13 samples (65.0%) were TBF(-)/QFT-GIT(+), 6 (30.0%) were TBF(+)/QFT-GIT(-), and one provided TBF/QFT-GIT indeterminate/negative results. We observed a statistical significant degree of correlation between interferon-gamma reactivity between both assays ($r_s=0.551$, $P<0.01$) and between standard assays and cross-manner tests ($r_s$ ranging from 0.449 to 0.816, $P<0.01$ for all combinations). Cross-manner tests also revealed that the ELISA kit of TBF provided higher TB antigen and nil values than ELISA of QFT-GIT under the same conditions ($P<0.01$), although these differences disappeared in the TB antigen minus nil value.

Conclusions: TBF showed a comparable and acceptable clinical performance in detecting LTBI comparing to QFT-GIT. TBF represents a useful alternative tool of ELISA-based IGRA, especially in large-scale LTBI screening in HCWs.

Rapid simultaneous detection of TB and first line drugs gene mutations onto direct paediatric samples
Cristina Russo*, Leonarda Gentile

Ospedale pediatrico Bambino Gesù, Healthcare and Research Institute, Roma, Italy

Background: The great challenges in diagnosing childhood TB are: low burden bacterial load, lack of sign and symptoms and high prevalence of Extrapulmonary TB.

Despite the incredible advances in the field of technological innovations, a major bottleneck in controlling tuberculosis is still the Turn-Around-Time to obtain a TB laboratory confirmed diagnosis. On the other hands, in the last few years we are witnessing the evidence of multidrug and extremely resistant TB strains pan-spread. Rifampicin resistance is mostly due to mutations in an 8bp "hot-spot" region of the rpoB-gene, while isoniazid resistance is due to mutations of several genes as catalase-peroxidase-

Materials/methods: we evaluated a new real-timePCR combined with automated platform [MDR/MTB-ELiTé-InGenius] able to perform simultaneous DNA extraction, detection of MTB and rifampicin-isoniazid resistance direct onto various samples. The DNA extraction is based on magnetic-beads technology and heat treatment using a low sample volume, while the RT-PCR amplification is performed independently. Within one session, one-to-12 samples are processed.

In order to evaluate robustness of MDR/MTB-PCR and platform feasibility, we selected a list of 12 well-known frozen positive samples [NAT and/or culture confirmed].

Afterwards, we tested 62 pediatric routine samples [51 patients] examined with PCR/ cultures/DST.

Results: A broad spectrum of samples was investigated: biopsy(4), gastric aspirate(19), sputum(16), BAL(22), exudate(1). No cross-reaction with non-tuberculous mycobacteria (5) was observed, 27 patients received a diagnosis other-than-TB, while 19 patients were TB positive.

Conclusions: Despite a low DNA Mycobacterial load in pediatric samples, the new assay MDR/MTB-ELiTé-InGenius could be a valid support for a rapid TB and drug-resistance detection.

Abstract 6757

Potential coverage of invasive pneumococcal disease by current and next generation of anti-pneumococcal vaccines in children and adults in Spain

Sara De Miguel1, Mirian Domenech2, Julio Sempere2, Idoia Del Rio2, Beatriz López Ruiz2, Fernando González Camacho3, José Yuste3

1Instituto de Salud Carlos III y Dirección General de Salud Pública CAM, Madrid, Spain, 2Instituto de Salud Carlos III. Centro Nacional de Microbiología y CIBER Enfermedades Respiratorias (CIBERES), Madrid, Spain

Background: Introduction of pneumococcal conjugate vaccines (PCVs) has shown a marked reduction in the disease caused by vaccine serotypes in children providing herd protection to the elderly group. However, the emergence of non-vaccine serotypes is of great concern worldwide. The main goal of this study was to evaluate the serotype distribution of invasive pneumococcal disease (IPD) by age group in Spain to assess the potential coverage of the different pneumococcal vaccines.

Materials/methods: This study includes national laboratory data from IPD cases affecting pediatric and adult population for the last 10 years corresponding to the period 2009 to 2018. We show the potential coverage by age group of the different PCVs (PCV13, PCV15, PCV20) and also by the 23-valent polysaccharide vaccine (PPV23) comparing the years 2009 (pre-PCV13 period in private market) vs 2015 (pre-PCV13 in pediatric vaccination calendar) vs 2018 (late period).

Results: A total of 22978 laboratory-confirmed IPD cases were included in the study. In 2009, just the year before the introduction of PCV13 in the private market for the pediatric population, the coverage rates of IPD cases by PCV13, PCV15 and PCV20 in children under 5 years old were 78%, 80% and 86% respectively. In adults aged 65 years or older the coverage by PCV13, PCV15, PCV20 and PPV23 were 65%, 70%, 80% and 78% respectively. In 2015 coverages for children under 5 years old were 30%, 39% and 59% for PCV13, PCV15 and PCV20 respectively whereas for adults aged 65 years or older were 35%, 43%, 63% and 69% for PCV13, PCV15, PCV20 and PPV23 respectively. In the late period 2018, the potential coverages for PCV13, PCV15 and PCV20 in children under 5 years old were 24%, 33% and 53% respectively and for adults aged 65 years or older were 29%, 37%, 62% and 68% for PCV13, PCV15, PCV20 and PPV23 respectively (Figure 1).

Conclusions: The two new PCVs could provide additional increased coverage in the late period 2018 in Spain, with PCV15 and PCV20 potentially protecting against 33% or 53% of IPD pediatric cases respectively whereas in adults the coverage would be 37% or 62% respectively.

Figure 1: Potential coverage of IPD cases by pneumococcal conjugate vaccines in children and adults in the year 2018 in Spain

Prediction Model for carbapenemase-producing Enterobacterales colonisation upon admission to hospital in an endemic geographic area

Chrysanthe Papafotiou*, Sofia Bampali, Sotiris Roussos, Vana Sypsa, Tania Moussouli, Michail Samarkos, M. Psichogiou, Kalliopi Spyridopoulou, A. Karapanou, George L. Daikos

1“Laikon” General Hospital, First Department of Medicine, National and Kapodistrian University of Athens, Athens, Greece, 2Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Carbapenemase producing Enterobacterales (CPE) have been established as important nosocomial pathogens worldwide. These organisms are sustained in healthcare facilities by continuous influx of already colonized patients. The timely detection of CPE carriers by active surveillance cultures is considered pivotal in controlling CPE. Universal screening, however, is unfeasible in resource-limited settings. We aimed to develop a prediction score to identify patients upon admission to the hospital who are at greater risk for colonization.

Materials/methods: The study was conducted between January 2014 and December 2015 in a tertiary-care 500-bed hospital located in a CPE endemic area, Athens, Greece. Rectal swabs were obtained from consecutive patients upon admission, periodically at different departments and inoculated on McConkey agar No.3 plates containing 0.5 mg/L meropenem. After incubation for 48 hours, all isolated enterobacterales were examined for the presence of \( \text{bla}_{\text{VIM}}, \text{bla}_{\text{KPC}}, \text{bla}_{\text{NDM}}, \text{bla}_{\text{OXA-48}} \) by PCR using specific primers. Relevant demographic and epidemiologic information were collected in a pre-designed form. Logistic regression analysis was used to identify factors associated with increased risk for CPE carriage. A points score was developed and the area under the Receiver Operating Curve (AUROC) was estimated to assess its discriminative ability. The predictive performance of the model was validated in a different cohort that took place in the same hospital between May and October 2016.

Results: Among 2199 patients examined, 95 (4.3%) were CPE carriers. Eight predictors were identified: Karnofsky score, prior hospitalization in previous six months, duration of prior hospitalization (\( \geq 10 < 10 \) days), stay in a long-term health care facility, history of \( \geq 2 \) different interventional procedures, known CPE colonization or infection, renal replacement therapy, and diabetes with complications. The developed points score to predict CPE risk ranged between 0 and 79 points with a corresponding risk estimate of 0% to 83.6% and an AUROC of 0.83. The AUROC of the score in the validation cohort of 1506 patients was 0.84.

Conclusions: This study provides useful information to help us limit the pre-active infection control measures and the active surveillance cultures to high-risk patients in CPE endemic areas and resource-limited settings.

Abstract third-party references: Supported by Instituto de Salud Carlos III (PI16/01 432), On behalf of PROBAC REIPI/GEIH-SEIMC/SAEI group

Background: Biliary prosthesis (BP) is a well-recognized risk factor for biliary tract-associat ed bloodstream infections (BT-BSI). However, there are scarce data comparing BT-BSI with and without BP. Our aim is to provide information about BT-BSI in patients with BP.

Materials/methods: Patients with BT-BSI were selected from the PROBAC cohort, a prospective multicenter cohort collecting patients aged >14 years with BSI from 26 Spanish hospitals, between October 2016 and April 2017. Variable associated with BP were investigated through a bivariate analysis. Multivariate analysis using logistic regression was performed to estimate the adjusted risk of 30-day mortality associated to BP.

Results: We analyzed 850 episodes of BT-BSI; 153 (18%) were associated with BP. Beyond the reasons for having a BP, the variables associated with BP were younger age [70 years (IQR 59-84) vs 77 (IQR 67-84); p<0.01], moderate-severe liver disease [RR=2.34; 95%CI=1.64-3.44; p<0.001], and immunosuppressive therapy [RR=3.26; 95%CI=2.08-5.19; p<0.01]. Escherichia coli was the most frequent etiology in both groups but was less frequent in BP [56.9% vs 68.9%; RR=0.82; 95%CI: 0.71-0.96; p<0.01], while the following were more frequent: Enterococcus faecalis [9.2% vs 5%; RR=1.82; 95%CI: 1.00-3.30; p=0.05] and Escherichia (6.5% vs 2%; RR=3.26; 95%CI: 1.47-7.19; p<0.01). Pseudomonas aeruginosa [5.9% vs 1.4%; RR=4.10; 95%CI: 1.69-9.90; p<0.01] and polymicrobial BSI [22.9% vs 15.1%; RR=1.52; 95%CI: 1.08-2.13; p=0.02]. No difference in ESBL distribution was noted; carbapenem-resistance in Gram negatives was 3.1% and 1.1% [RR 2.83; 95%CI: 0.84-9.52; p=0.09]. Active empirical therapy was administered to 71.2% and 76.3% [RR=0.93; 95%CI:0.84-1.04; p=0.186]. BP was associated with worse outcomes in crude analyses: higher 30-day mortality [24.2% vs 13.1%; RR=1.85; 95%CI: 1.32-2.60; p<0.01], recurrence [RR=2.13; 95%CI: 1.15-3.91; p<0.01], persistent bacteremia [RR=3.65; 95%CI: 1.46-9.09; p<0.01] and secondary infection of endovascular or joint devices [RR=4.54; 95%CI: 1.33-15.65; p<0.01]. The risk of mortality adjusted by age, Charlson index, presentation with septic shock and inadequate empirical therapy was higher in patients with BP [OR=2.28; 95%CI: 1.45-3.58; p<0.01].

Conclusions: Our results highlight that BT-BSI in patients with BP was associated with specific pathogens and higher risk of death. Specific preventive and therapeutic strategies for BT-BSI must be investigated in these patients.

Differentiation of phenotypic and genotypic characteristics of uropathogenic *Escherichia coli* isolates in acute and recurrent phases of urinary tract infection

Mohammad Pooya*1, Moein Saleh1, Amin Abd1, Hoora Mazaheri1, Elham Khosravi1, Alireza Abdollahi1, Saeid Bouzari1, Masoud Mardani Bashti4

1Pasteur Institute of Iran, Molecular Biology Department, Tehran, Iran, 2University of Malaya, Department of Mechanical Engineering, Faculty of Engineering, Kuala Lumpur, Malaysia, 3Tehran University of Medical Sciences, Department of Pathology, Imam Hospital Complex, Tehran, Iran, 4Shahid Beheshti University of Medical Sciences, Infectious Diseases and Tropical Medicine Research Center, Tehran, Iran

**Background:** Urinary tract infection (UTI) is one of the most common infections worldwide, and uropathogenic *Escherichia coli* (UPECs) are the main causative pathogens. However, their characteristics may vary depend on the phase (acute or recurrent) of UTI.

This study was conducted to evaluate any probable differences between UPEC isolates in acute and recurrent phases of UTI in the same patient.

**Materials/methods:** The urine samples of patients suffering from UTI in two referral hospitals of Tehran, Iran were collected and the patients were under supervision for any probable recurrence during 6 months. The isolates were subjected for differential cultures to select *E. coli* strains. Then, phyl- and sero-grouping, antibiotic susceptibility test, biofilm formation assay, was performed, and the genes responsible for antibiotic resistance, biofilm formation and iron transferring were detected.

**Results:** Sixty isolates (one isolate from each phase) were selected from 30 patients (16 females, 14 males) at different ages. In two-third of patients, phylogroups of the *E. coli* isolates were identical in the acute and recurrent phases, 70% of them were B2/B2. Similarly, in 70% of the patients, serogroups of the isolates were alike in both phases, 85.7% of them have O25/O25 pattern. The isolates with O15 serotype were significantly seen more in recurrent phase. All of the isolates form biofilm. However, only one-third of them showed equal biofilm intensity in both phases (mostly weak/weak). The isolates with strong biofilm ability were mainly detected in recurrent phase. When comparing antibiotic resistance pattern of the isolates in two different phases, the isolates from Imam hospital had more antibiotics in common to be resistant to than the ones from Loghman hospital. Likewise, the isolates in Imam hospital had more antibiotic resistance, biofilm-related and iron transfer genes in common than the ones in Loghman hospital. Interestingly, distribution of two resistance genes, *sul1* and *qnrA*, was more predominant in Imam and Loghman hospitals respectively.

**Conclusions:** Although it seems that UPEC isolates that are responsible for acute or recurrent phases of UTI may belong to common phylo- or sero-groups, but they show different resistance and virulence characteristics. These characteristics may vary from hospital to hospital.

Abstract 6762

Pyogenic spinal infections in a tertiary care centre: trends in the last decade
Olga Dzupova*, Jiri Benes

Charles University in Prague, Third Faculty of Medicine, Na Bulovce Hospital, Prague, Czech Republic

Background: The incidence of pyogenic spinal infections is increasing in the last 20 years. The aim of the study was to compare two subgroups of patients treated for two consecutive five-year periods at the Department of infectious diseases of a tertiary care centre and to identify possible trends.

Materials/methods: A retrospective observational study carried out in 2010-2019 enrolled 137 adult patients with pyogenic spondylitis, discitis and facet joint infections. Recorded parameters included demographics, chronic comorbidities, time to diagnosis, radiological work-up, anatomical level of spinal infection, etiological agent, complications, treatment and outcomes. The periods 2010-2014 and 2015-2019 were evaluated and compared.

Results: In 2010-2014 and 2015-2019, there were 57 vs. 80 patients enrolled, median age 66 years. The proportion of patients with comorbidities increased (64 vs. 75%) as well as median time to diagnosis (9 vs. 14 days). Diagnosis was made using MRI in 81 vs. 59% and CT in 16 vs. 35%. Epidural abscess developed in 53 vs 48%, paravertebral abscess or empyema in 61 vs. 51% of patients. The pathogen was identified in 82 vs. 69% of patients, mainly by blood culture in both periods (72 vs. 58%). Staphylococcus aureus was the most common pathogen isolated in 54 vs. 48%; Gram-positive bacteria in total caused 70 vs. 59% of cases. Forty-two vs. 35% of patients were treated surgically. The median length of hospital stay was similar in both periods (46 vs. 42 days) as well as the median length of antibiotic treatment (58 vs. 52 days). Sixty-five vs. 73% recovered with no or mild sequelae, 14 vs. 6% with severe sequelae, and 21 vs. 20% of patients died.

Conclusions: When comparing the two periods, we observed an increasing incidence, chronic comorbidities and time to diagnosis, but also better outcomes. An adverse finding is a decreasing proportion of identified aetiology, probably due to early initiation of antibiotic therapy and the absence of CT-guided disc biopsy. Despite the decline in identified Gram-positive aetiology, which can be partly explained by a decrease in the proportion of overall identified aetiology, Gram-positives remain the major pathogens and empirical therapy should target it.

Abstract 6764

**A proof-of-concept evaluation of biphasic blood culture bottles for low-resource settings**

Sien Ombelet*1,2, Alessandra Natale3, Jean-Baptiste Ronat1, Thierry Naas4, Jan Jacobs1,2

1Institute of Tropical Medicine Antwerp, Antwerpen, Belgium, 2Katholieke Universiteit Leuven, Leuven, Belgium, 3Doctors Without Borders, Paris, France, 4Bicetre Hospital AP-HP, Le Kremlin-Bicêtre, France

**Background:** The Mini-lab is a Médecins Sans Frontières project for the development of an all-in-one clinical bacteriology laboratory deployable in low-resource settings. Blood cultures are priority specimens in this laboratory. Since automated blood culture systems are not yet feasible in these settings, biphasic "manual" blood culture bottles (BCB) were selected. They consist of a broth and an agar slant; the agar slant assists in recognizing growth and performing subcultures.

**Materials/methods:** Three biphasic BCB types (Zhuhai Encode Bi-State BCB, CD Rich Double Phase BCB and Autobio Bi-State BCB) were evaluated alongside visual reading of BacT/ALERT FA Plus and BacT/ALERT PF Plus (bioMérieux) BCB and a monophasic manual BCB (Hemo-aerobic culturing bottle and Hemo-aerobic culturing pediatric bottle, Liofilchem). They were inoculated with human blood spiked with ATCC strains representing 8 common bloodstream pathogens. For adult cultures, 10 ml blood per bottle (containing 1-10 colony forming units (CFU)/ml) was inoculated; for pediatric cultures, the volume was 2 ml (containing 2-25 CFU/ml).

**Results:** The yield (% of inoculated BCB grown) was 97.3% (109/112) for Autobio BCB, 89.3% (100/112) for CD Rich BCB (p=0.016 compared to Autobio), 84.8% (94/112) for Zhuhai Encode BCB (p=0.001), 95.5% (107/112) for Liofilchem BCB (p=0.47) and 100% (58/58) for manual BacT/ALERT BCB (p=0.21). More than 95% of grown bottles showed signs of growth within 48 hours of incubation, with similar results for all BCB types. Growth was more frequently observed in broth (91.7%) than on the agar slant (87.8%; n=336; p=0.006). First sign of growth was observed only in the broth in 51.0%, only on agar slant in 1.3% and in broth and agar slant simultaneously in 47.7% of grown biphasic BCB (n=304). At the moment of growth, only 6.3% – 10.1% of biphasic BCB showed sufficient bacterial growth on the agar slant to do further testing. Sufficient bacterial growth on the agar slant increased to 56.9 – 70% of grown biphasic BCB by the end of the 7 day incubation period.

**Conclusions:** Compared to a monophasic BCB, biphasic BCB had similar yield and speed of detection. The agar slant did not allow earlier detection and had insufficient growth to replace subculture.

Abstract 6768

**Stool multiplex PCR for Shiga toxin-producing *Escherichia coli* sufficiently equals with culture for clinical diagnosis and follow-up**

Anu Jääskeläinen*, Saara Salmenlinna, Jenni Antikainen, Anu Pätäri-Sampo

1Helsinki University Hospital Laboratory Services HUSLAB, Division for Clinical Microbiology, Helsinki, Finland, 2Finnish Institute for Health and Welfare, Department of Health Security, Expert Microbiology Unit, Helsinki, Finland

**Background:** STEC causes potentially severe gastrointestinal infections. Due to its public health importance, control measures are required, and carriers may need to refrain from work or day care when the spread risk to vulnerable people is high. We evaluated the usefulness of direct stool multiplex PCR compared to parallel stool culture for primary STEC diagnostics and for follow-up in order to update the national guidelines for STEC monitoring.

**Materials/methods:** At Helsinki and Uusimaa Hospital District, Finland, we identified 236 STEC PCR positive cases in 2016-2017. We included their follow-up samples, altogether 858 samples with stool PCR and corresponding culture. All STEC PCR positive samples were inoculated on non-selective BD™ CHROMagar™ Orientation agar plates (ORI). Culture positivity was confirmed from ORI culture sweeps by PCR.

**Results:** 211 (89%) of the cases were culture positive in their primary sample. Of all primary and follow-up samples 499 were PCR positive and of these 450 (90%) were culture positive. Ten cases (8%) had one PCR positive but culture negative ("intermediate") sample in between the culture positive and PCR negative sample(s), and one case (0.8%) had two such "intermediate" samples in between the culture positive and PCR negative samples. For 13 cases (10%), the initial sample was PCR positive, culture negative, followed by PCR negative samples. The remaining 15 cases (12%) had fluctuation of PCR and/or culture positivity in their follow-up samples. 89 cases were followed for at least three consecutive PCR negative samples. 2 cases (2%) had culture positive sample(s) after two consecutive PCR negative samples.

**Conclusions:** PCR is adequate for STEC diagnostics and follow-up in a clinical laboratory. When non-selective methodology is used, the vast majority of PCR positive samples (90%) are also culture positive. Furthermore, only two cases (2%) in our material had positive samples followed by two consecutive PCR negative samples. Consequently, to demonstrate the clearance from STEC infection, we consider two PCR negative follow-up samples sufficient. The Finnish national guidelines for STEC monitoring have recently been updated accordingly.

**Presenter email address:** anu.e.jaaskelainen@hus.fi
Background: *Streptococcus pneumoniae* is the most common pathogen causing community-acquired bacterial meningitis. We evaluated the impact of the implementation of adjunctive dexamethasone treatment in 2002 and the 7-valent and 10-valent pneumococcal conjugate vaccines (PCVs) in 2006 and 2011 on the clinical outcome and cause of death in pneumococcal meningitis.

Materials/methods: We included adult patients (≥16 years of age) with community-acquired pneumococcal meningitis from two large nationwide prospective cohort studies in the Netherlands (1998-2002, 2006-2018). Patients were identified by the surveillance of the Netherlands Reference Laboratory for Bacterial Meningitis or were notified by the treating physician. Deaths were categorized independently by two physicians as neurologic or systemic. Missing data were imputed for logistic multivariable models to assess prognostic factors for death and unfavorable outcome.

Results: A total of 1816 episodes in 1783 patients were included (median age 62 [IQR 51,70], 902 episodes in males [50%], 1739 CSF culture positive episodes [96%]). The classic triad of fever, neck stiffness, and altered mental status was present in half of episodes. 11 of 336 (3%) patients in the 1998-2002 cohort and 117 of 1437 patients (82%) in the 2006-2018 cohort received adjunctive dexamethasone. Clinical outcome at discharge was unfavorable (Glasgow Outcome Scale score <5) in 772 of 1816 episodes (43%), with death occurring in 363 episodes (20%). Adjuvant dexamethasone led to a lower death rate (175/585 [30%] vs. 178/1188 [15%], p<0.001), both due to neurologic (15% vs. 9%) and systemic causes of death (15% vs. 6%). Mortality among patients not treated with dexamethasone was similar in the 1998-2002 and 2006-2018 cohort (32% vs. 28%). Age ≥75 years, immunocompromising condition, higher heart rate, lower Glasgow Coma Scale score, cranial nerve palsy, CSF white cells <1,000/µL, CSF:blood glucose ratio <0.23, C-reactive protein >200mg/L, and thrombocytes <75,000 units/L were associated with death and unfavorable outcome. Particular serotypes were associated with clinical outcome adjusted for dexamethasone use and age (Figure 1).

Conclusions: Pneumococcal meningitis is still associated with high mortality and morbidity rates. Implementation of PCVs has not affected clinical outcome.
Effectiveness of monitoring colonisation by multidrug-resistant bacteria in polytrauma patients: 7 years of experience

Stefania Torri*1, Alessandra Bielli1, Valeria Cento1, Giulia Colombo1, Osvaldo Chiara2, Fabrizio Sammartano1, Chiara Silvia Vismara2, Carlo Federico Perno1, Ester Mazzola2

1ASSIT Grande Ospedale Metropolitano Niguarda, Milan, Italy

Background: Patients with polytrauma need prolonged hospitalization and intensive care, which are risk factors for nosocomial infection. A recent increase of these infections due to Multidrug-resistant bacteria (MDR) involves application of surveillance procedures.

Monitoring colonization is performed by Active Surveillance Cultures (ASC) with fecal, nasal and pharyngeal swab (Copan).

Aim of the study is the evaluation of effectiveness of ASC for prevention and control of infections by MDR.

Materials/methods: We analyzed 1011 patients with Major Trauma, evaluated with Injury Severity Score (ISS) >15 admitted in Emergency Room of GOM Niguarda in a period of 7 years.

Each patient is monitored with ASC at hospitalization time and, if negative, every 7 days.

We considered hospitalization and intensive care duration, mortality; we also evaluated colonization, infections and sepsis due to MDR.

Results: 867 (85.8%) patients resulted permanently negative (ASC-), while 144 (14.2%) resulted positive during hospitalization (ASC+).

ASC+ presented major clinical severity at entry than ASC-, in terms of ISS and visceral lesions (p<0.05). ASC+ needed a longer hospitalization (35 days) than ASC- (20 days) (p<0.001), and longer stay in Intensive Care Unit, 20 days respect 7 days (p<0.001). Infections due to MDR were most frequent in ASC+ (68.1% versus 11.2%, p<0.001).

There were 40 cases of sepsis, 7/867 (0.81%) ASC- patients, and 33/144 (22.9%) ASC+ (p<0.001), mainly caused by Acinetobacter baumannii MDR and Meticillin-resistant Staphylococcus aureus. In ASC+, 32/33 sepsis were caused by the same MDR that were previously isolated in surveillance culture.

Mortality rate in ASC- was 10.9% vs 6.3% in ASC+ (p=0.056), the former mostly in the first days of hospitalization.

Conclusions: Surveillance allows to evaluate risk of MDR-infection of each patient during hospitalization period. In addition, a positive surveillance test provides information to set up a targeted therapy in case of MDR-driven infections, with important consequences on clinical outcome, including a trend in decreased mortality in ASC+ despite a higher rate of sepsis.

Background: We aimed to describe the clinical characteristics and aetiology of bloodstream infections (BSI) in febrile neutropenic patients presenting with septic shock and analyze risk factors for mortality.

Materials/methods: All consecutive episodes of BSI in neutropenic patients were prospectively collected in two university hospitals [2010-2019]. Patients with septic shock, defined as hypotension requiring vasopressors despite adequate volume resuscitation, were compared with those without shock. Factors associated with 30-day mortality in patients with septic shock were assessed using univariate and logistic multivariate models.

Results: Out of 1563 BSI episodes, 257 (16.4%) presented with septic shock. The most frequent baseline diseases were acute leukaemia (45.2%), non-Hodgkin lymphoma (17.1%), and solid neoplasia (15.2%). Haematopoietic stem cell transplantation was undergone by 25.5% of patients. Patients presenting with septic shock were older (p=0.026), and had solid neoplasms (p<0.001) and other comorbidities (p=0.025) more frequently. Corticosteroid therapy, urinary catheter, and non-nosocomial acquisition (p<0.001 for all) were also more frequent. Pulmonary (p<0.001), abdominal (p=0.001) and urinary (p=0.027) sources of BSI were more common among patients with septic shock, whereas catheter and mucositis-related episodes (p<0.001 and p=0.001) were less frequent. Regarding aetiology, episodes with septic shock were more commonly caused by E. coli, K. pneumoniae and P. aeruginosa (p<0.001 for all), and less commonly by Enterococcus spp. and coagulase-negative Staphylococci (p<0.001 for both). Multidrug-resistant (MDR) Gram-negative bacilli (GNB) were the causative agents of septic shock in 15.2% of cases. 30-day mortality was higher among patients presenting with septic shock (54.9% vs 15.2%, p<0.001). Table 1 shows the independent risk factors for mortality in patients with septic shock.

Conclusions: Clinical and microbiological characteristics of neutropenic patients with shock are differential. Avoiding inappropriate empirical antibiotic treatment in those patients with GNB-BSI is the only modifiable factor in decreasing mortality.

Abstract 6779

Clinical characteristics and outcomes of respiratory syncytial virus infection among hospitalised adult patients: risk factors of intensive care unit hospitalisation and 30-day mortality

Choi Youngeun*, Jong Hun Kim1, Sun Bean Kim1, Young Kyung Yoon1, Jang Wook Sohn1, Min Ja Kim1

1Korea University College of Medicine, Seoul, South Korea

Background: Respiratory syncytial virus (RSV) can cause intensive care unit (ICU) hospitalization with significant morbidity among the susceptible populations. However, clinical burden of this infection may vary in adult risk groups. This study aimed to investigate risk factors to RSV-related ICU hospitalization and outcomes among hospitalized adult patients.

Materials/methods: A retrospective cohort study was conducted in a university hospital in South Korea from March 2013 to February 2019. Subjects included hospitalized adult patients (≥19 years) diagnosed with RSV infection by RT-PCR. The RSV-associated events (pneumonia, aggravation of chronic co-morbid illness, ICU admission, etc.) were defined as those episodes occurred within prior and after 2 weeks of the RSV detection.

Results: A total of 272 adults with RSV infection were enrolled. The median age was 72. The subjects were categorized into ICU (54/272, 19.9%) and non-ICU (218/272, 80.1%) hospitalization groups. There were no significant differences in terms of age, sex, nursing facility residency, types of RSV infection, and co-infection with other respiratory virus between two groups, while more patients with immunocompromised conditions (IC) were in the non-ICU group (35.5% vs. 13.2%, P=0.002). In contrast, presence of chronic kidney disease (≥stage 3) (28.3% vs. 14.2%, P=0.014), RSV-associated heart failure (25.9% vs. 11.9%, P=0.009), and RSV-associated pneumonia (33.3% vs. 17.4%, P=0.010) were more common in the ICU group. In a multiple logistic analysis, RSV-associated pneumonia [odds ratio (OR) 2.73, 95% confidence interval (CI) 1.31-5.69], RSV-associated heart failure (OR 2.46, 95%CI 1.10-5.50) and septic shock (OR 50.0, 95%CI 5.16-446.90) were significant risk factors for ICU hospitalization, while the presence of IC (OR 0.38, 95%CI 0.15-0.94) was inversely associated with ICU hospitalization. Thirty-day mortality was 6.3% (17/272). In a Cox regression model, chronic kidney disease (≥stage 3) [hazard ratio (HR) 4.66, 95%CI 1.73-12.54], nursing facility residency [HR 8.15, 95%CI 2.21-30.06], and ICU hospitalization [HR 7.96, 95%CI 2.96-27.79] showed higher risk of 30-day mortality.

Conclusions: This study indicates that patients with chronic kidney disease and cardiac disease may be vulnerable to high clinical severity from RSV infection and need to be considered for prompt recognition and preventive measures for RSV infection.

Abstract 6781

**Rapid, reproducible resistance analysis for all: the AMR package for R**

Matthijs S. Berends*1,2, Christian Luz2, Bhanu Sinha2, Alexander W. Friedrich2, Corinna Glasner2

1Certé Medical Diagnostics & Advice, Groningen, Netherlands, 2University of Groningen, University Medical Center Groningen, Groningen, Netherlands

**Background:** Antimicrobial resistance (AMR) is threatening healthcare on multiple levels worldwide, thus AMR surveillance is indispensable. However, analysis of antimicrobial resistance (AMR) is challenging due to the rapidly increasing amount of data, while microbiological laboratory systems are not equipped for thorough (epidemiological) data analysis. Smart analysis tools and scientifically reliable reference data are lacking, leaving analysts and clinicians with restricted and non-reproducible methods. To overcome this, we present a free and open-source software solution enabling a new standardised way of working with (anti-)microbial resistance.

**Materials/methods:** We developed the ‘AMR’ package in the increasingly popular statistical software R. By incorporating evidence-based methods and reliable reference data, the ‘AMR’ package is intended to simplify, facilitate, and automate AMR data cleaning, enhancing, and analysing. The software was tested by health care professionals of seven different public health institutes from three different countries.

**Results:** With intelligent rules, microbiological data can be transformed to valid, reproducible output within milliseconds. Antimicrobial resistance (rates) can be calculated, predicted, and plotted with integrated regression models, to which end empiric antimicrobial treatment could also be evaluated. The package can identify first isolates, apply EUCAST rules, and determine the presence of MDRs automatically based on different national and international guidelines. On top, the package contains the complete taxonomic tree of ~70,000 microorganisms and all names, tradenames, and defined daily doses (DDDs) of ~550 antimicrobial agents as reference data.

**Conclusions:** Being downloaded ~25,000 times from 74 countries since its release online last year (figure 1), the ‘AMR’ package is routinely used by epidemiologists and data scientists in many different microbiological laboratory institutes and universities worldwide. In organisations or countries with very limited resources this free and open-source package could also overcome a financial limitation that would otherwise hinder antimicrobial resistance analysis in these settings. Our new standard for clean and reproducible antimicrobial resistance data analysis can therefore empower epidemiological analyses to continuously enable surveillance in any setting.

Figure 1. World map showing all 74 countries (in blue) where the AMR package was downloaded from since its release last year.

Abstract 6784

**Genome analysis of mecC-harbouring methicillin-resistant *Staphylococcus aureus* and methicillin-sensitive *Staphylococcus aureus* CC130 strains from different origins**

Paula Gómez1, Laura Ruiz Ripa1, Rosa Fernández Fernández1, Haythem Gharsa1, Karim Ben Slama2, Myriam Zarazaga1, Mark Holmes3, Carmen Torres*1

1University of La Rioja, Logroño, Spain, 2University of Tunis el Manar, Tunis, Tunisia, 3University of Cambridge, Cambridge, United Kingdom

**Abstract third-party references:** Supported by project SAF3016_76571 R of the AEI of Spain and FEDER of EU

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) CC130 has been associated with the unusual mecC gene, and never so far with mecA gene. In this work, the molecular characteristics of MRSA and methicillin-susceptible *S. aureus* (MSSA) isolates of lineage CC130, from different origins, were analyzed by whole-genome-sequencing.

**Materials/methods:** Eighteen CC130 isolates (13 MRSA and 5 MSSA) from different origins (domestic ruminant and wild animals, human and environment) and with different sequence types (ST130, ST1945, ST1583, ST3061, ST1581, ST1571, ST700) were sequenced (Illumina HiSeq-2000) and analyzed using bioinformatics tools.

**Results:** All 13 MRSA-CC130 contained the mecC, blaZ-SSCMecXI, arsB, and arsC genes (SSCMecXI) and no other resistance genes were detected; contrarily, MSSA-CC130 harbored tet(K) (n=2) and blaZ (n=1) genes. All CC130 strains carried the virulence genes lukED, hlgAB, hlgCB, edinB, splA/B, and aur. The three ST700 strains carried sec, sel, lukMF, and tst-like genes. etD2 gene was present in all the strains, but in ST700. Six MRSA-mecC strains was immune-evasion-cluster (IEC) positive (type-E). The pan-genome study showed a high similarity in core genome, with 2318 genes shared by all strains, but 29 unique genes in MRSA (mainly SCCmecXI-related), and 21 unique genes in MSSA (mainly bacteriophage-related). No unique genes in IEC-positive versus IEC-negative strains were found (except for bacteriophage φ3 related-genes) and hlb gene was also truncated in 3 IEC-negative strains. The vwbp gene was found in four MSSA strains (domestic ruminants and red deer). Three MSSA among CC130 strains presented rep genes: rep1, rep2, rep3, and rep4. Phage analysis showed 12 different intact prophages, with an average of 2±2 prophage regions-genome; four MSSA strains (small ruminants and red deer) showed a scn-like gene. The 5 MSSA strains grouped separately in a phylogenic three from MRSA stains, and those of ST700 were really distant to all the others.

**Conclusions:** Differences between MSSA and MRSA CC130 were detected. The etD2 gene could be a genetic marker of CC130 lineage (MSSA and MRSA), except in ST700, what reinforce the idea of this lineage outside of CC130. The presence of IEC system in some of the MRSA-mecC from animals open questions about the mecC origin.

**Presenter email address:** carmen.torres@unirioja.es
Predictors of 30-day mortality rate in patients with *Pseudomonas aeruginosa* bacteraemia

Warren Rose*¹, Larae Bagnell¹, Laura Puzniak², Lucas Schulz³

¹University of Wisconsin-Madison: School of Pharmacy, Madison, United States, ²Merck & Co., Inc., Kenilworth, United States, ³UW Health University Hospital, Madison, United States

**Background:** *Pseudomonas aeruginosa* is a major cause of morbidity and mortality among nosocomial pathogens. The CDC reports a serious threat level for multidrug-resistant *Pseudomonas aeruginosa*. UW Health is an academic medical center that is unique in testing ceftolozane-tazobactam susceptibilities on *Pseudomonas aeruginosa* routinely. The purpose of this study is to determine factors contributing to the 30-day mortality rate in *Pseudomonas aeruginosa* primary bacteremia.

**Materials/methods:** A retrospective chart review included patients less than 90 years old with a blood culture positive for *Pseudomonas aeruginosa* at UW Health. Data collection included patient's baseline characteristics, chronic conditions, antibiotic regimen, susceptibilities, and outcome. Statistical analysis was performed using Fischer's exact test, T-test, and Mann-Whitney U tests as appropriate, followed by a logistic regression using STATA with a p value cut point of p<0.02.

**Results:** Eighty-four patients were included. The 30-day mortality rate was 26% (22/84). Of these mortality cases, they remained susceptible to anti-pseudomonal beta-lactams include meropenem, piperacillin-tazobactam, and cefepime. Logistic regression demonstrated higher PITT bacteremia scores increased mortality rate (OR 2.841, p = 0.016, 95% CI (1.218 – 6.625)) and CKD indicated decreased 30-day mortality rate (OR 0.026, p = 0.082, (0.0004 – 1.5902)).

**Conclusions:** This study helps to identify patients with bacteremia that are at high risk for mortality. These factors can help identify patients at greater risk for a poor outcome and may need optimization of treatment to enhance outcomes.

Abstract 6788

Emergence of resistance in Gram-negative bacteria and correlation with antibiotic use in 52 Swiss intensive care units

Stefanie Barnsteiner*, Florent Baty†, Werner Albrich†, Baharak Babouee Flury†, Catherine Pluess-Suard†, Andreas Kronenberg‡, Matthias Schlegel†, Philipp Patrick Kohler†

†Kantonsspital St. Gallen, St. Gallen, Switzerland, ‡Institut für Infektionskrankheiten, Bern, Switzerland

Abstract third-party references: Supported by project SAF3016_76571_R of the AEI of Spain and FEDER of EU

Background: Intensive care units (ICUs) constitute a high-risk setting for antimicrobial resistance (AMR). Besides horizontal dissemination of resistant pathogens, antibiotic (AB) selection pressure is considered a main driver of the AMR epidemic. We aimed to assess temporal trends regarding resistant Gram-negative bacteria in Swiss ICUs and to correlate resistance data with institutional AB use.

Materials/methods: We analyzed data on AMR and AB use sent to the Swiss Centre for Antibiotic Resistance ANRESIS from 2009 to 2018. The following pathogens were analyzed: extended-spectrum cephalosporin-resistant Escherichia coli (ESCR-EC) and Klebsiella spp. (ESCR-K), carbapenem-resistant Enterobacteriales (CRE) and Pseudomonas aeruginosa (CRPA). AMR (one sample per species/patient/year) was expressed as % of all isolates; the use of systemic AB was calculated as defined daily doses (DDD) per 100 beddays (BD). On the institutional level (only ICUs contributing data for at least 3 years), we correlated AMR (median proportion of resistant pathogens) and the use of the following pre-specified antibiotic substances/classes (median DDD/100 BD): quinolones, 3rd/4th generation cephalosporins, piperacillin/tazobactam, and carbapenems. Temporal trends and correlations were analyzed using linear regression.

Results: Among 52 institutions (20 ICUs from French/Italian- and 32 from German-speaking parts), we observed a significant increase of ESCR-EC from 8% to 16% (P < .001) among a total of 11,817 E. coli isolates and of ESCR-K from 7% to 13% (P < .001; n=6,313) between 2009 and 2018. CRE increased from 1% to 6% (P=.007; n=19,665), and CRPA remained stable over time at 26% (P=.72; n=4,774). Trends were similar between geographic regions. For the correlation analysis, we included 24 ICUs. Quinolone use correlated with CRE (P=.01) and CRPA rates (P=.04); carbapenem use correlated with CRPA only (P=.03) (Figure). Use of 3rd/4th generation cephalosporins and piperacillin/tazobactam were not associated with AMR.

Conclusions: In Swiss ICUs, resistant Gram-negative pathogens have been steadily increasing over the last decade. Correlation between AB use and AMR was weak, except for carbapenem-resistant bacteria. Antibiotic stewardship programs are most promising if aimed at reducing the use of quinolones and carbapenems in this setting.

Abstract 6790

**Long-term effect of dietary preferences and nutritional regimes on intestinal microbiota diversity and composition**

Mehmet Hora¹, Aycan Gundogdu*¹²

¹Erciyes University, Genome and Stem Cell Center, Kayseri, Turkey, ²Erciyes University, Faculty of Medicine, Kayseri, Turkey

**Background:** Long term effects of certain diet types on human gut microbiota is crucial for a better understanding how common dietary interventions modulate the microbiome. However, high variability of dietary effects and the technical difficulties of designing large cohorts of this sort constitutes a significant obstacle for wide-ranging studies. For this reason, we have investigated the modulatory effect of diet on a largest open-source datasets available, the American Gut Project data and reported the significant variations that might be undetectable or overlooked in small-cohort studies.

**Materials/methods:** After gathering the 16S rRNA sequencing gut microbiota data of around 16,000 participants in American Gut Project, the taxonomic profiles were obtained at genus level using QIIME pipeline. The metadata of the corresponding samples indicating the diet regime of a participant (i.e. omnivore, vegetarian, vegan, raw food diet, FODMAP diet, paleo diet, low grain-low processed food diet) were matched. Alpha diversities and genera relative abundances of each specific group were compared using Mann-Whitney U-test.

**Results:** Omnivores, dieters excluding raw sugar, dieters preferring low-processed food appeared to have significantly diverse microbiota; while vegetarians, vegans, raw food dieters, dieters excluding diary, low-grain dieters had significantly less diverse microbiota. Omnivores, vegetarians, vegans, paleo dieters, dieters excluding refined sugars, dieters excluding diary, dieters preferring low-processed food all had specific taxa significantly altered. Remaining diet populations did not have significant differences compared to the rest.

**Conclusions:** The analyses we conducted reveal that restrictions on animal products and grains might narrow the microbiome. In terms of high diversity and abundant beneficial taxa, cutting on raw sugar and processed food consumption while following a regular omnivore diet appears to be beneficial on gut microbiota.

Abstract 6791

Pharmacokinetics and pharmacodynamics of dalbavancin in the clinical setting

Giacomo Stroffolini1, Stefano Biffi1, Amedeo De Nicolò1, Ambra Barco1, Stefano Bonora1, Giovanni Di Perri1, Miriam Antonucci1, Antonio Briozzo2, Valeria Avataneo1, Giuseppe Cariti1, Antonio D’avolio1

1Hospital Amedeo di Savoia, Department of medical science, Infectious Disease Unit, Torino, Italy, 2Ospedale Mauriziano Torino, Ospedale Mauriziano Umberto I, Torino, Italy

Background: Dalbavancin is a potent lipoglycopeptide active against Gram+ bacteria with a favorable pharmacokinetic/pharmacodynamic [PK/PD] and safety profile, suitable for numerous challenging infections. Dalbavancin has been approved for ABSSSIs, but its range of application and the relative posology is still debated. Nowadays, little is known about its PK/PD profile in the real-life.

Materials/methods: A clinical and PK/PD study is ongoing on patients receiving one (group 1) or two 1500 mg doses (group 2) of Dalbavancin in 2 centers in Italy. Given informed consent, plasma Dalbavancin concentrations were measured through a LC-MS/MS analytical Kit (CoQuaLab) at the end of infusion, after one hour and then weekly. AUCs, Volume of Distribution (Vd) and half-lives (t1/2) were calculated through Kinetica® (Thermo) software in the two groups. AUC/MIC and the estimated T>MIC were calculated according to reported MIC for susceptible microorganisms. Results are expressed as median (IQR).

Results: Twelve patients were enrolled: age 62.5 (52.5-76); 3 ABSSSIs, 1 IE, 6 osteoarticular and 2 intravascular device infections. Microorganisms were Oxacillin-Resistant in 50% of cases. Reasons for treating with Dalbavancin were simplification (33%) or failure (66%) to previous regimens There were no adverse events. Nine patients (75%) had favorable outcome. Nine patients belonged to group 1 and three to group 2. Median plasma concentrations were 233.627 mg/L (2 10.004-425.645) at peak, 70.765 mg/L (30.953-109.020) at week 1 and 5.635 mg/L (5.313-5.957) at week 1 2. Vd was 9.3 L (7.6-12.3), while t1/2 was 240 h (222-259) in group 1 and 542 h (535-550) in group 2. AUCs were 55958 mg*h/L (41918-69998) for group 1 and 136948 mg*h/L (128138-145758) for group 2. AUC/MIC and T>MIC were 447667 mg*h/L (335345-559990) and 116 days (111-121) in group 1, 1095584 mg*h/L (1025104-1166064) and 261 days (258-265) in group 2, respectively.

Conclusions: This is among the first evaluations of Dalbavancin PK/PD profile in a real-life clinical setting. From a theoretical PK/PD perspective, our data support a potential longer antibiotic activity than previously considered both for single or double 1500 mg dose administration, with T>MIC estimated up to 3 and 8 months, respectively. These data deserve further clinical evaluation in a larger sample.

Abstract 6793

Prevalence and quantity of parvovirus B19 DNA among blood donors

Aylin Uskudar Guclu*, Soner Yilmaz2, Mehmet Baysalar2, Ismail Yasar Avci2

1Başkent University, Faculty of Medicine, ankara, Turkey, 2Gulhane Training and Research Hospital, ankara, Turkey

Background: Parvovirus B19 causes a range of diseases and morbidity in humans and is transmissible by transfusion of blood, blood components and plasma derivatives. This study aimed to investigate the prevalence and quantity of parvovirus B19 DNA and seropositivity in Turkish blood donors by using an in-house quantitative polymerase chain reaction method and ELISA respectively.

Materials/methods: Totally 1053 samples were collected from March to July 2016 at a blood bank for detection of Parvovirus B19 DNA and serological status of blood donors. Viral genomic DNA extraction from sera was performed by using viral nucleic acid extraction kit. Testing of the presence of viral DNA was performed by a quantitative real-time PCR with a 10^7 copies/ml detection limit. The primers and probe sequences targeting minor capsid protein VP1 gene of PB19. Enzyme Immune Assay for qualitative determination of IgM and IgG antibodies to Parvovirus B19 in human sera was performed for all DNA positive and randomly selected 267 (95% CI; 5% margin of error) PB19 DNA negative samples. The differences of Ig G serological status within different age groups and the differences of both parvovirus IgM and parvovirus IgG serological status within different age groups were analyzed statistically.

Results: Age distribution of donors was between 18-64; mean age was 27 and median was 23. Among the 1053 samples, 5 (0.47%) had PB19 DNA. All PB19 DNA positive donations had both B19 IgM and IgG antibodies. The DNA level for positive donations were between 0.9x10^2 to 3.1x10^4 copies/ml. IgG and IgM were present in 59.9% (160/267) and 0.74% (2/267) among the healthy donors without PB19 DNA. Two donors with positive results for IgM were also positive for IgG and negative for PB19 DNA.

Conclusions: Detected DNA concentration was less than 10^5 copies/ml. The presence of IgM in low level PB19 DNA positive donors may indicate that there might be a risk in transmission of PB19 to particularly immunosuppressed recipients. The clinical follow-up of blood donation with low level of PB19DNA should be considered to answer the questions about blood safety.

Abstract 6794

**Chemotherapies for acute lymphoblastic leukaemia may have a long-term impact on bacterial gut microbiota**

Mathilde Payen*1, Aurélie Cointe1,2, Alice Pascault1, Ghalaajini Mohamed1, Mony Fadh1, Sabine Delannoy1, Patrick Fach4, André Baruchel1, Auréy Monjault1, Stéphane Bonacorsi1, André Birgy1,2  

**Background:** The microbiota appears to play an important role in the fate of children with leukaemia, both in terms of response to anticanceral chemotherapy and infectious complications. Little is known about chemotherapies effects on the children microbiota with acute lymphoblastic leukaemia (ALL). Here, we describe the impact of anticanceral chemotherapy on 8 children's gut 16S microbiota.

**Materials/methods:** Stools from 8 patients with ALL were studied at different times of their management: one sample before chemotherapy (P1) and two after (P2 and P3). In total, 24 stools were analyzed. Amplicon libraries were prepared using QIAseq 16S/ITS Screening Panel kit (Qiagen®). Data generated by V2V3 region were analyzed using CLC Genomics Workbench 12 (Qiagen®) pipelines. All patients received antibiotics at some point during management.

**Results:** A significant decrease of α-diversity (Shannon index p=0.0078) between P1 and P3 was observed while no significant differences were found between P1 and P2. Similarly, β-diversity did not vary significantly between P1 and P2 but decreased from P1 to P3 (p=0.035). Microbiota before chemotherapy showed a majority of Clostridia and Actinobacteria that decreased over time. In turn, relative abundances of gamma-proteobacteria and Bacilli increased during management (Figure 1). Among the bacterial genera whose relative abundance has decreased, we can cite Faecalibacterium (p=0.008), Ruminococcus (p=0.016) and Ruminococcus torques group (p=0.008).

**Conclusions:** Our results suggest that all chemotherapies do not have a drastic effect on gut microbiota. However, a cumulative effect of several cycles of chemotherapy probably associated with antibiotic use may be responsible for the dysbiosis observed.

**Presenter email address:** mathilde.payen@aphp.fr
Moraxella keratitis: investigating emerging pathogenicity through clinical and microbiological findings and whole genome sequencing for virulence determinants

Gwendolyn Connolly*1,2, Anya Curry2, Daniel Jaen Luchoro3, Conor Murphy4, Terence Mcswiney4, Susan Knowles2,4
1 Technological University Dublin - City Campus, Dublin, Ireland, 2 The National Maternity Hospital, Dublin, Ireland, 3 CCUG, Gothenburg, Sweden, 4 Royal Victoria Eye and Ear Hospital, Dublin, Ireland

Abstract third-party references: Technological University Dublin, Ireland, Royal Victoria Eye and Ear Hospital, Dublin, Ireland, Culture Collection University of Gothenburg, Sweden, National Maternity Hospital, Dublin, Ireland

Background: Keratitis is an infection of the cornea. The most prevalent causative organisms are Staphylococcus aureus, Pseudomonas aeruginosa and Streptococcus pneumoniae. In recent years, there are increasing reports of Moraxella keratitis. In a tertiary hospital in Dublin, Ireland, specialising in ophthalmic care, Moraxella species are now the second most frequent organism implicated in keratitis after S. aureus.

Materials/methods: Fifty-two Moraxella isolates were collected from corneal scraping specimens from 2013 to 2018. Clinical findings, treatment and outcome data were extracted from medical records. Isolates were speciated by MALDI-TOF mass spectrometry. Antimicrobial susceptibility testing was performed by gradient testing for chloramphenicol, ciprofloxacin, ceftazadime, cefuroxime and gentamicin and interpreted using EUCAST guidelines. A non-specific assay to determine biofilm formation was used to investigate the potential for Moraxella to adhere to inert surfaces. Whole genome sequencing, followed by BLASTp analysis determined other potential virulence factors.

Results: The patients’ mean age was 65 years. The majority had systemic and/or ocular risk factors although none wore contact lenses. This infection led to blindness in one third of patients and 22% required surgical intervention including corneal grafting, transplantation and evisceration. The most prevalent organisms were M. lacunata (n=25) and M. nonliquefaciens (n=21) followed by M. osloensis (n=4) and M. catarrhalis (n=2). Antibiotic resistance was uncommon. The difference in biofilm formation ability was statistically significant (p ≤ 0.0001, 95% CI: 0.04-0.57) between M. lacunata, where 88% formed biofilms and M. nonliquefaciens, where 88% were non-biofilm producers. Biofilm formation does not appear to contribute to keratitis. BLASTp analysis of the genomes detected proteins involved in construction of the Type IV Pili system, degradative enzymes, toxins and antimicrobial efflux pumps.

Conclusions: Moraxella may cause opportunistic infection, however it is frequently associated with a poor outcome in keratitis. All but two isolates were found to be non-catarrhalis. The majority of isolates were susceptible to most, if not all, topical antibiotics tested. Biofilm formation was not a contributory factor to disease. The detection of other virulence factors appears to contribute to Moraxella’s pathogenicity in keratitis, although research on the functionality of the genes is required to fully determine the significance of these findings.

Indwelling time of peripherally inserted central catheters and incidence of bloodstream infections in haematology patients: a cohort study

Nick De Jonge1,2, Martine Caris1,3, Henk-Jan Punt1, Dorien Salet1, Birgit Lissenberg-Witte4, Sonja Zweegman1, Christina Vandenbroucke-Grauls2, Michiel Van Agtmael2, Jeroen Janssen4

1Amsterdam UMC, locatie VUmc, Department of Haematology, Amsterdam, Netherlands, 2Amsterdam UMC, locatie VUmc, Department of Medicine, Amsterdam, Netherlands, 3Amsterdam UMC, locatie VUmc, Department of Medical Microbiology and Infection Control, Amsterdam, Netherlands, 4Amsterdam UMC, locatie VUmc, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands

Background: A recurring dilemma in clinical practice is whether we should routinely replace central venous catheters (CVCs) to prevent Central Line Associated Bloodstream Infections (CLABSI), or wait and see if one occurs. In haematology patients, peripherally inserted central catheters (PICCs) are frequently used to provide long-term venous access. Previous studies have shown that bacterial colonization of intravascular catheters increases with prolonged use, leading to increasing risk of infection with longer indwelling time. This suggests that routine replacement of PICCs may prevent CLABSI. We aimed to assess whether longer PICC indwelling time increases risk of CLABSI and thus address whether scheduled PICC replacement could aid in preventing CLABSI in haematology patients.

Materials/methods: Multicentre retrospective cohort study among haematology patients receiving PICCs between 2013-2015. Occurrence of CLABSI based on Centers for Disease Control definitions was assessed. We calculated cumulative incidence and hazard of CLABSI and determined risk factors. The cumulative hazard function was assumed to follow a Weibull distribution. As the curve showed a change in slope after 28 days, cumulative hazard was estimated separately for the period up to and after 28 days of PICC indwelling time.

Results: 455 PICCs were placed in 370 patients, comprising 19063 catheter days. Median indwelling time was 26 days (range 0-385) and CLABSI incidence was 4.0 per 1000 catheter days. Aplastic anaemia was associated with increased risk of CLABSI, patients undergoing autologous stem cell transplantation were less likely to develop CLABSI (Panel A & B). For the first 28 days, the estimated cumulative hazard function showed an increasing cumulative hazard over time (estimated shape parameter 1.8), but a constant hazard with indwelling time thereafter (estimated shape parameter 1) (Panel C).

Conclusions: Our study shows that risk of CLABSI increases during the first 28 days after PICC-placement, but does not appear to increase with indwelling time thereafter. Routine replacement of PICCs therefore is unlikely to prevent CLABSI in this population.

Analysis and characterisation of rmtB-bearing plasmids disseminated in various species of Enterobacterales isolated from clinical specimens of hospitalised patients in Greece

Konstantina Nafplioti, Helen Moraitou, Panagiota Giannopoulou, Paraskevi Chra, Maria Damala, Evangelos Vogiatzakis, Eleftheria Trikka-Graphakos, Vasiliki Baka, Eleni Prifti, Maria Souli, Irene Galani

1 National and Kapodistrian University of Athens, Faculty of Medicine, Infectious Diseases Laboratory, 4th Department of Internal Medicine, Athens, Greece, 2 Sotiria Thoracic Diseases Hospital of Athens, Department of Clinical Microbiology, Athens, Greece, 3 Thriasio General Hospital of Elefsina, Microbiology Department, Athens, Greece, 4 Korgialenio Benakio Helenic Red Cross Hospital, Microbiology Department, Athens, Greece, 5 Alexandra General Hospital, Microbiology Department, Athens, Greece, 6 National and Kapodistrian University of Athens, Faculty of Medicine, 4th Department of Internal Medicine, Athens, Greece

Background: Methylation of 16S ribosomal RNA has emerged as a new mechanism of resistance against aminoglycosides among gram-negative pathogens. The aim of this study was to characterize rmtB-bearing plasmids from various genera of Enterobacterales isolated from hospitalized patients in Greece.

Materials/methods: Single-patient, clinical isolates of Providencia stuartii (n=31), Klebsiella pneumoniae (n=41), Proteus mirabilis (n=6) and Escherichia coli (n=2) all harboring rmtB, consecutively collected during 2015-2016 in five tertiary-care hospitals in Athens, were studied. ESBL and carbapenemase production was confirmed by PCR. Transferability of rmtB was investigated by transformation with at least one strain of each species/PFGE clone. Representative rmtB-carrying plasmids (based on donor/β-lactamase content detected by PCR/susceptibility testing) were selected for complete sequencing.

Results: All rmtB-bearing isolates were carbapenemase-producers. P. stuartii, P. mirabilis and E. coli produced VIM-type carbapenemases. K. pneumoniae produced mainly KPC-carbapenemases (n=34, 82.9%), but also OXA-48 (n=3, 7.3%), KPC- and VIM- (n=3, 7.3%), or only VIM-type (n=1, 2.4%) enzymes. In all cases other β-lactamases were also detected. Analysis of TOP10 transformants showed two groups of similar IncA/C plasmids, one harboring rmtB, bla_VEB, bla_OXA-10 and bla_TEM, and the second co-harboring bla_VEB and bla_SHV. The second group was detected in all VIM-producers except for four P. mirabilis, which carried a plasmid of the first group (Table). Sequencing revealed that these plasmids were multireplicons [IncA/C and IncR]. In all plasmids, rmtB-1 was located downstream of a Tn3-like transposon, and bla_VEB-1 was the first gene cassette of a class 1 integron followed by aadB, arr2, cmIa1, bla_OXA-10 and aadA1 gene cassettes, with an IS1999 located upstream of bla_VEB-1. bla_VIM-1 occurred as the first cassette of a class I integron along with the aacA7, dfrA1, and aadA1, similar to Ine541, the integron structure harboring bla_VIM-1 in K. pneumoniae previously reported in Greece.

Conclusions: A multireplicon [IncA/C and IncR] plasmid co-harboring rmtB1 and bla_VIM-1 along with other ESBL genes is responsible for the dissemination of rmtB in clinical isolates of Enterobacterales in Greece. Another similar multireplicon plasmid, lacking bla_OXA-10 and bla_SHV-5 is disseminated among KPC- or OXA-48 producing K. pneumoniae isolates. The co-dissemination of these genes poses a public health threat.

Abstract 6803

Frequency and severity of potential drug-drug interactions before, during and after an antifungal stewardship pilot project

Sarah Lachenmayr*1,2, Alicia Gretler2, Dorothea Strobach1,2, Hanna Mannell2, Karin Berger3, Helmut Ostermann3

1Hospital Pharmacy, University Hospital, LMU Munich, Munich, Germany, 2Doctoral Programme Clinical Pharmacy, University Hospital, LMU Munich, Munich, Germany, 3Department of Haematology/Oncology, University Hospital, LMU Munich, Munich, Germany

Background: Antifungal agents may lead to significant drug-drug interactions, which potentially impede the success of antifungal therapy or cause adverse or diminished clinical effects of concomitant drugs. After piloting an antifungal stewardship (AFS) project, we aimed to test the long-lasting effects on the awareness of potential drug-drug interactions of antifungal agents after termination of the project.

Materials/methods: AFS measures (medical training, pocket card with internal guidelines, daily pharmaceutical counselling on wards) were introduced for six months on two wards (68 beds) in the department of haematology/oncology in a German tertiary care centre. Frequency and severity of potential drug-drug interactions of antifungal agents with concomitant therapy was retrospectively analyzed before (phase I: 01-06/2016), during (phase II: 01-06/2017) and six months after termination of the AFS project (phase III: 01-06/2018). Severe and moderate potential drug-drug interactions were identified using the interaction databases Lexicomp® Stockley’s®, AiDklinik® and German SmPC (summary of product characteristics).

Results: We analyzed 104 patients (171 antifungal prescriptions; phase I), 103 patients (145 antifungal prescriptions; phase II) and 116 patients (166 antifungal prescriptions; phase III), respectively. Patients received on average 14 (phase I) and 13 (phase II and phase III) medications in addition to the antifungal agent. The number of patients with moderate and severe potential drug-drug interactions decreased from 22% (26 drug-drug interactions; moderate: 15, severe: 10) to 11% (13 drug-drug interactions; moderate: 9, severe: 4) during the AFS period, whereas an increase to 21% (36 drug-drug interactions; moderate: 27, severe: 9) was observed six months after the AFS project. Most common potential severe drug-drug interactions concerned the azol antifungal agents posaconazole and voriconazole, which were co-administrated with for example vinca alkaloids, statins (atorvastatin, simvastatin), apixaban and quetiapine.

Conclusions: Our data show that the implementation of AFS measures did not have sustained effects on frequency of potential severe and moderate drug-drug interactions after termination of the project. To obtain long-lasting effects regarding optimal quality of antifungal treatment, the implementation of AFS programmes in routine care is desirable. A precise evaluation of prescriptions regarding drug-drug interactions by a clinical pharmacist will reduce drug-related problems and ensure safe antifungal therapy.

**Background:** Although antimicrobial (AMC) stewardship is recommended by Brazilian government, data regarding prescription practices in Brazilian hospitals are scarce. This study aims to describe two point prevalence surveys on AMC consumption among 27 hospitals in Brazil.

**Materials/methods:** 27 Brazilian hospitals conducted the Global Point Prevalence Survey of AMC Consumption and Resistance (Global-PPS) in 2017 and / or 2018. A web-based program was used for data-entry of details on AMC prescriptions. The Global-PPS was developed by the University of Antwerp and funded by bioMérieux. Reporting one-day prevalence of AMC use and resistance in 2017 and 2018 are presented as risk ratios. The main outcomes are total AMC use and stratification of use for the classes separately, only carbapenems showed a decrease (10.2% to 8.6%, p=0.04). In 86 ICUs, 331 (60.0%) and 375 (52.4%) were on AMC treatment, in 2017 and 2018, respectively (p=0.03). Significant decrease of total AMC use was observed in four out of five most prescribed AMC: ceftriaxone (9.4% to 7.8%, p=0.03), meropenem (9.3% to 7.8%, p=0.04), vancomycin (7.6% to 5.6%, p=0.001), pipercillin-tazobactam (7% to 5.8%, p=0.07) and cefazolin (6.3% to 5.1%, p=0.05). Overall prevalence of MDRO infection was not different [5.6% to 5.8%, p=0.4]. Overall prevalence of AMC use to treat Gram negative MDRO decreased significantly (15.8% to 13.4%, p=0.01) although analyzing the classes separately, only carbapenems showed a decrease (10.2% to 8.6%, p=0.04). There was no significant change in prescriptions for Gram positive MDRO (10.7% to 9.3%, p=0.07). The most frequent diagnosis were pneumonia [16-18%], intra-abdominal sepsis [7-8%], skin and soft tissue infection [5-7%] and urinary tract infection [5-6%]. In 2018, there were significantly less AMC prescriptions for healthcare-acquired infections [HAI] [40.3% to 36.8%, p=0.02].

**Conclusions:** Although there was significant decrease in overall AMC use, especially for treatment of HAI, the prevalence of AMC prescribing among surveyed Brazilian hospitals remained high. These data may be helpful for further stewardship interventions and repetitive PPS to monitor their effects.

Abstract 6807

**Activity of imipenem-relebactam and meropenem-vaborbactam against ceftazidime-avibactam-resistant Klebsiella pneumoniae isolates producing KPC carbapenemases**

Irene Galani¹, Evdokia Angelidis¹, Vassiliki Papoutsaki², Ilias Karaioskis*³, Lamprini Galani¹, Helen Giamarellou¹, Maria Souli⁴, Anastasia Antoniadou⁶

¹National and Kapodistrian University of Athens, Faculty of Medicine, Infectious Diseases Laboratory, 4th Department of Internal Medicine, Athens, Greece, ²Hygeia, Microbiology Department, Marousi, Greece, ³Hygeia, 1st Internal Medicine & Infectious Diseases Clinic, Marousi, Greece, ⁴National and Kapodistrian University of Athens, Faculty of Medicine, 4th Department of Internal Medicine, Athens, Greece

**Background:** Ceftazidime-avibactam (CZA) is an effective new treatment, against KPC-producing Klebsiella pneumoniae. Resistance to CZA, although rare, has been reported, magnifying the problem of limited treatment options. Vaborbactam and relebactam, two other β-lactamase inhibitors are developed in combination with meropenem and imipenem respectively. Our objective was to determine their activity against 10 CZA-resistant K. pneumoniae isolates producing KPC carbapenemases.

**Materials/methods:** A total of 9 CZA-resistant K. pneumoniae isolates producing KPC, collected in 2018-2019, were tested for susceptibility by broth microdilution and MIC Test Strips and interpreted per EUCAST criteria. Strain KP-90 isolated in 2016, producing KPC-23 was also included. Isolates underwent whole-genome sequencing for the determination of MLST-type and resistance genes.

**Results:** MICs of CZA ranged from 16 to >256mg/L (MIC₅₀ / MIC₉₀; 64/128), with ceftazidime MICs being ≥1024mg/L in all cases. Nine isolates were resistant to carbapenems and the addition of relebactam or vaborbactam to imipenem (I/R) and meropenem (M/V), respectively, decreased resistance from 90% to 0%. I/R MICs ranged from 0.125 to 4mg/L (MIC₅₀ / MIC₉₀; 0.5/1), and M/V from 0.125 to 4mg/L (MIC₅₀ / MIC₉₀; 0.25/2). Isolates were resistant to all other antibiotics except colistin for which 40% were susceptible. The isolate that was susceptible to both imipenem (MIC 0.5mg/L) and meropenem (MIC 2mg/L) harbored the *bla*KPC-3 and belonged to ST39 and was isolated from rectal swab of a patient previously treated with CZA. Isolates resistant to carbapenems harbored the *bla*KPC-23 (n=1) or the *bla*KPC-2 (n=8) and were isolated from clinical or surveillance cultures of patients not exposed to CZA. KPC-23 isolate belonged to ST258, one of the KPC-2- to ST39 and the rest seven KPC-2-producers to ST147. Isolates of ST147 exhibited a truncated OmpK35_v1 (*1 73) and OmpK36_v3, which have been previously associated with ST147 K. pneumoniae isolates from Greece. ST39 isolates had an intact OmpK35 and an OmpK36_v3 variant, while ST258 isolate exhibited a truncated OmpK35_v1 (*89) and an OmpK36_v1 characteristic of this clone.

**Conclusions:** As emergence of ceftazidime-avibactam resistance is increasingly recognized, meropenem-vaborbactam and imipenem-relebactam, the two novel combinations already approved by FDA, may provide clinicians with an alternative option for the treatment of serious infections caused by KPC-producing Enterobacterales, including CZA-resistant isolates.

**Presenter email address:** ikaraioskis@hygeia.gr
Professional exposure to brucellosis and Q-fever in veterinarians in Bosnia and Herzegovina

Zeljana Sulaver*1, Jadranka Nikolic1, Sinisa Skocibusic1, Jurica Arapovic1

1University Clinical Hospital of Mostar, Mostar, Bosnia and Herzegovina

Background: Veterinarians are the most exposed demographic and professional group for acquiring brucellosis and Q fever. The aim of this study is to determine seroprevalence on brucellosis and Q fever in veterinarians in Bosnia and Herzegovina (B&H), to determine and quantify professional risk factors for acquiring diseases and to define required protective measures.

Materials/methods: Two groups of subjects were analysed and randomised by gender, age and socio-demographic characteristics. Examined group consisted of 180 veterinarians and 100 voluntary blood donors were used as a control group. Subjects' sera were tested on presence of antibodies on brucellosis (Rose Bengal test) and Q fever (ELISA). Considering the nature of their work, veterinarians were divided into two subgroups – terrain and office workers. They were also classified by numerous socio-demographic and professional data (regional presence, age, years of service and usage of standard safety measures in working environment) which were provided through questionnaire.

Results: Seroprevalence of brucellosis and Q fever in veterinarians was 12.2% (p=0.010) and 35.6% (p<0.001), respectively, while seroprevalence in the control group was 3.0% and 15.0%, respectively. Significantly more veterinarians who are seropositive on brucellosis (90.9%, p<0.001) and Q fever (93.8%, p<0.001) are male. They all do terrain work and are involved in vaccination of ruminants. Veterinarians which were seropositive on brucellosis and Q fever wore gloves most of the time (95.4% and 89.1%, respectively) and usually did not wear goggles (36.4% and 28.1%, respectively) and mask (54.5% and 43.7%, respectively) as safety work equipment. There was no statistical significance in seroprevalence of brucellosis and Q fever in veterinarians considering age groups and residence. Double infections were noted in seven terrain veterinarians.

Conclusions: The seroprevalence of brucellosis and Q fever in veterinarians in B&H is significantly higher compared to general population. Having in mind that all veterinarians positive on brucellosis were involved in vaccination, this study emphasised how important is to wear safety equipment for prevention of infectious diseases in professionally exposed workers. It is important to encourage further epidemiological and epizootiological studies emphasising the importance of interaction between veterinary and medical vocation and their contribution for public health.

Abstract 6810

**Diagnosis and sampling of human papilloma virus in men**

Jaqueline Muehlberger*, Angelika Stary1, Katharina Schwarz1

1Vienna, Pilzambulatorium, Vienna, Austria

**Abstract third-party references:** On behalf of Prof. Angelika Stary, Pilzambulatorium

**Background:** Recently it has been demonstrated that human papillomavirus (HPV) infections in men are highly prevalent, with up to 50% of men acquiring an HPV infection at least once in their lifetime. Unfortunately, male HPV testing has a high failure rate as there is no validated male sampling device currently available. The main reason for failure often is an insufficient amount of human cell material. Aim of this study was to evaluate 3 different sample collection devices in a smaller cohort in order to find a suitable collection device for HPV testing in men.

**Materials/methods:** For the preliminary evaluation of the optimal collection device, duplicate specimens from 79 male patients were collected. Three different collection devices have been compared; a brush from the PapilloCheck® Collection Kit (Greiner Bio-One GmbH), the FLOQSwabs® 552C (Copan Italia Spa) and the FLOQSwabs® 5E046S (Copan Italia Spa). Penile, perigenital and anorectal specimens were tested for HPV at the Outpatient’s Centre for Diagnosis of Infectious Venereodermatological diseases by using the PapilloCheck®, a microarray-based assay which allows the detection and identification of 18 high risk (hr) and 6 low risk (lr) HPV genotypes.

**Results:** Out of 79 samples collected with the brush, 49 were collected in parallel with the FLOQSwabs® 552C and 30 with the FLOQSwabs® 5E046S, respectively, and subsequently tested in duplicates. The brush produced 27.8% invalid results. Compared to that, 10.2% of samples collected with the FLOQSwabs® 552C were invalid. The best results so far were achieved with the FLOQSwabs® 5E046S displaying only 6.3% invalid test results. The results of high and low risk HPV types using different collection devices will be presented.

**Conclusions:** Due to its flocked swabs comprising of Nylon® fibers that are arranged in a perpendicular fashion, the FLOQSwabs® had a very low failure rate compared to the brush. These data are being further investigated with a larger cohort, which hopefully pave the way for a successful implementation of one of these swabs as HPV collection device for men.

Efficient long-term storage of mycobacteria using conventional laboratory reagents

Frédéric Schramm*, Émilie Talagrand-Reboul†, Pierre Boyer†, Angéline Chabaud‡, Benoît Jaulhac†, Christelle Koebel†

1CHRU Strasbourg, Department of Bacteriology, Strasbourg, France, †Laboratoire Schuh, Strasbourg, France

Abstract 6811

Background: Common procedures for long-term preservation of mycobacteria frequently use skim milk as a cryopreservative. Achieving methods verification according to ISO 15189 requirements for procedures including unstandardized reagents could be difficult. The aim of the study was to validate a simple protocol using only standardized reagents for long-term preservation of both *M. tuberculosis* and non-tuberculous mycobacteria (NTM).

Materials/methods: 9 strains were selected: *M. tuberculosis* (n=3), *M. kansasii* (n=3), *M. chelonae* (n=1), *M. avium* (n=1) and *M. abscessus* (n=1). For each strain, a 0.5 McF suspension was prepared in a cryopreservative medium composed of 7H9 broth, OADC (10% vol.) and glycerol (10% vol.); suspensions were aliquoted in two series of tubes, allowing comparison of two different cooling rate protocols: a "rapid" cooling (aliquotes directly placed at -80 °C), and a "slow" cooling (aliquotes placed in insulated aluminum blocks at room temperature, and closed devices placed overnight at -80 °C before transferring tubes in standard cryoboxes). Aliquots were then respectively stored at -80 °C for 1 day, 3 months, 1 year, 2 years and 3 years, and the viable count of bacteria for each duration was compared to the initial count before freezing.

Results: The cooling rate had no impact on the strain viability, as the evolutive profiles were similar for both "rapid" and "slow" cooling procedures. With a few exceptions, viable count of strains were always lower after freezing compared to T0, with a progressive loss of viability increasing with the duration of freezing. However, even after 3 years of storage at -80 °C, ≥10^4 CFU/mL were recovered for each strain.

Conclusions: Using easy to control reagents commonly used for mycobacterial cultures (7H9 broth and OADC) supplemented with glycerol, our cryopreservative media allows efficient long-term storage of both *M. tuberculosis* and NTM. The cooling rate has no impact on the recovery rate: once the strain is suspended in the media, cryotubes can be directly stored in -80 °C using standard cryoboxes.

An unusual case of recurrent lymphocytic meningitis
Mohammed Mansoor Raza*, Poonam Kapila, Kareem Omar, Rabinder Randhawa1

1Milton Keynes University Hospital NHS Foundation Trust, Milton Keynes, United Kingdom

Background: Recurrent lymphocytic meningitis is uncommon and requires detailed assessment to ascertain the cause. Risk factors including ethnicity and travel history is important to guide investigations along with multidisciplinary input to achieve a timely diagnosis.

Results: A 36 year old gentleman with no significant past medical history presented to his general practitioner with two days of headache. He was originally from South Africa who and moved to the UK in 2004. On examination, he had no other signs of meningeal irritation and no focal neurology. He subsequently presented to the accident and emergency department with worsening headache and vomiting. CT Head scan showed multiple cystic lesions with calcification likely to be neurocysticercosis. Magnetic Resonance Imaging confirmed CT findings but the lesions were considered to be inactive calcified lesions. A lumbar puncture showed his cerebrospinal fluid (CSF) had a lymphocytosis with high protein and a normal glucose. Despite negative viral PCR results he was treated conservatively for presumed viral meningitis and discharged. He presented on two further occasions 4 and 7 months later. On each admission his CSF had similar microscopy and biochemistry. TB and fungal cultures were done on the second admission and these were negative.

The diagnosis was clinched on his third admission on referral to the infectious diseases team. The imaging was reviewed with a neuro-radiologist and it was felt that the frontal lobe lesion had an enhancing wall and associated leptomeningeal enhancement indicating active disease. Specialist parasitology laboratory input was sought. The CSF Cysticercosis Immunoblot and ELISA were strongly positive as was the serum Cysticercosis Immunoblot suggesting antigen leak from this active frontal lesion was leading to his recurrent lymphocytic meningitis. The patient was successfully treated with Albendazole and Praziquantel.

Conclusions: This case highlights the difficulties with diagnosis of rare conditions in the absence of appropriate specialist input and the importance of multidisciplinary input. The specialist neuro-radiology and specialist parasitology laboratory input was key to clinching the diagnosis. Treatment for neurocysticercosis is not always required unless the lesions are active, as was clearly warranted in this case.

Evaluation of total and excess treatment duration for community-acquired pneumonia: experience from a tertiary centre in the UK

Lea Nadia Marvulli¹*, Reem Santos², Jessica Lilley², Cristiano Serra², Nicholas Brown², Theodore Gouliouris²

¹The University of Pavia, Pavia, Italy; ²Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Multiple randomized studies demonstrate non-inferior outcomes with shorter compared to longer durations of antibiotic therapy for a range of indications including community-acquired pneumonia (CAP). Despite national recommendations based on this evidence, clinical practice is often associated with longer courses, which carry an increased risk of harm. We evaluated total and excess durations of antibiotic treatment in patients with suspected community-acquired pneumonia (CAP) at Cambridge University Hospital (CUH).

Materials/methods: This was a retrospective single-centre cohort evaluation of all adult patients admitted with suspected CAP from 1st of September 2018 to 30th of June 2019. Patients were identified from electronic prescribing data and CURB-65 scores were calculated using a previously validated algorithm using the hospital electronic patient data records. Patients receiving less than 4 days total duration of therapy, those with underlying lung disease, those treated for multiple indications and those with a hospital discharge in the preceding 10 days were excluded. Records were deduplicated to only include the first episode. Excess days of treatment were calculated by subtracting the shortest recommended duration based on CURB-65 score (5 days for low scores (0-1) and 7 days for high scores (2-5)) from the actual duration.

Results: 1436 patients were included in the analysis [median age 78 (interquartile range (IQR) 61-87), 53% female]. Median total length of treatment was 8 days (IQR 7-10) and did not differ significantly between low and high CURB-65 scores. Only 577/1436 (40%) of patients received recommended durations of treatment. Patients with low CURB-65 scores were more likely to exceed recommended durations of treatment compared to those with high CURB-65 scores {470/577 (81%) vs. 389/859 (45%) respectively, p<0.001}. The median excess duration of treatment was 2 days (IQR 0-4), accounting for 3651 total excess days, 2056 (56%) of which were received on hospital discharge.

Conclusions: Antibiotic courses exceed recommended durations for most patients treated for suspected CAP in our hospital. Increased education is required to optimize course lengths for CAP, focusing on appropriate use of CURB-65 stratification and accurate calculation of discharge course lengths.

Epidemic of carbapenem-resistant *Klebsiella pneumoniae* in a tertiary referral hospital for an annual surveillance in China

Yan Jiang*, Qiucheng Shi, Dongdong Zhao, Ping Zhang, Yanfei Wang, Jingjing Ouan, Xinhong Han, Rushuang Yan, Haiyang Liu, Xueqing Wu, Xiaoting Hua, Yunsong Yu

1Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Department of Infectious Diseases, Hangzhou, China

**Background:** The nosocomial dissemination of carbapenem-resistant *Klebsiella pneumoniae* (CRKP) troubled the treatment of infectious diseases worldwide. The clonal CRKP isolates outbreak is a major problem in lots of hospitals of mainland China.

**Materials/methods:** An annual surveillance of CRKP was performed in a tertiary referral hospital that holds 2400 beds. Antimicrobial susceptibility testing against meropenem, imipenem and ertapenem and their MICs were determined by disk diffusion method. Next-generation high-throughput sequencing was applied for all non-duplicated isolates by using Illumina platform. Multiple locus sequence type (MLST), core genome- (cg-) MLST, and resistance genes of each strain was elucidated based on their assembly sequence data.

**Results:** A total of 281 non-duplicated CRKP isolates were collected in 2017. Most of CRKP isolates showed high resistant level against carbapenem and MIC90 to meropenem is >128 mg/L. The main source of isolates encompassed sputum (51, 18.1%), blood (46, 16.4%), drainage fluid (35, 12.5%), and urine (35, 12.5%). We found that Intensive Care Unit (ICU) is the most epidemic department, followed by department of general surgery, contributed 82/281 (29.2%) and 62 (22.1%) of CRKP isolates, respectively. This result suggested an ICU-centered nosocomial transmission route. The ST11 (237/281, 84.3%) and its derivative ST4496 (18/281, 6.4%) were the predominant clones that spread in the hospital. Moreover, carbapenemase-producing was found to be responsible for 98.9% (278/281) of CRKP isolates carbapenem-resistance, including the dominant type KPC-2 (274, 97.5%) and NDM-1 (3, 1.1%), IMP-4 (1, 0.4%). All ST11 isolates but one harbored bla\_KPC-2 gene.

**Conclusions:** A KPC-2-producing ST11-CRKP clone was emerged and spread widely in a typical tertiary referral hospital in China. The ICU is becoming a center of dissemination of multidrug resistant bacteria and posed a big challenge in hospital infection control. Therefore, public health efforts should focus on genomic pathogen surveillance, identifying the high-risk clones and their expansion early.

![Minimum spanning tree of all CRKP isolates base on cgMLST typing](image)

The nodes under a grey shadow represent a cluster of close lineages with the gene number difference less than 15. The red nodes are ST11-CRKP isolates.

Mapping a nosocomial outbreak of measles, coinciding with a period of sustained transmission in south London in 2018

Jasper Vink1,2, Luke Blagdon Snell*1,2, Karen Bernard3, Hannah Mitchell1, Rachel Thorn Heathcock1, William Newsholme1

1Department of Infection, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 2Centre for Clinical Infection and Diagnostics Research (CIDR), King’s College London, London, United Kingdom, 3South London Health Protection Team, Public Health England, London, United Kingdom

Background: We describe an outbreak affecting two large London hospitals over 8 weeks in 2018 infecting patients, staff and visitors. We map spread to the community within suburban London, with a secondary case also identified internationally. Immediately prior to this outbreak there were only sporadic cases of measles in South London. This sustained outbreak is a reminder that measles can spread easily and quickly within unvaccinated groups and in high risk settings.

Materials/methods: Patients were identified retrospectively based on hospital case logs and laboratory results from 2018. Clinical information was obtained from medical notes, infection control correspondence and supplementary data held by Public Health England (PHE). Cases were defined as per PHE guidelines.

Results: This outbreak involved 34 measles positive cases, primarily young adults, with age range 14 days to 54 years. 19/34 (56%) cases were male.

Measles was confirmed by either measles RNA or IgM in 28/34. 2/34 represented reinfections. 4/34 were epidemiologically confirmed cases.

19/34 had an unknown vaccination status, and 3/34 had received two doses of vaccine. Remaining cases (12/34) were either unimmunised, ineligible due to age under 12 months or suboptimally vaccinated.

Outbreak investigation showed that members of an undervaccinated community (Travellers) spent time on-site after visiting hours due to inclement weather. An individual infected an unvaccinated worker of the on-site, 24/7 retail shop, who propagated the infection to other members of staff. The company who managed this shop did not have a robust occupational health policy to ensure vaccination of employees working on healthcare premises.

Conclusions: Our investigation suggests multiple factors contributed to the outbreak, including under-vaccinated communities, deficiencies in occupational health policy, adverse weather conditions affecting human behaviour, and lack of resources in the local community. We show that transmission occurred within the hospital via unvaccinated retail shop employees managed by a third party, who currently fall outside the scope of hospital occupational health policies. Emerging from this, one practice point is to expand occupational health policies so that evidence of protection against infectious diseases is recommended to all non-clinical employees on the hospital site.

Gemelli IRCCS, Dipartimento di Scienze di Laboratorio e Infettivologiche, Rome, Italy, ²Azienda Ospedaliera Universitaria Integrata, Unità Operativa Complessa di Microbiologia e virologia, Verona, Italy, ³Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Gastroenterologiche, Endocrino-Metaboliche e Nefro-Urologiche, Rome, Italy

Background: Nowadays an efficient outbreaks surveillance relies not only on the rapid identification of the pathogen but also on the characterization below species level by diverse typing methods.

The FT-IR technology, recently introduced in this landscape, analyzes absorption bands due to the stretching vibrations of specific functional groups, resulting in different spectroscopic fingerprints depending on the differences existing in the biochemical composition of microorganisms.

The objective of the present study was to evaluate the potentiality of FT-IR spectroscopy in the subtyping of six isolates of the yeast S. clavata, collected from single patients’ episodes of candidemia occurred in an Italian hematological ward, and compared with the cluster analysis obtained by WGS and MALDI-TOF protein fingerprint.

Materials/methods: For all the isolates, four replicates’ profiles were obtained on a IR Biotyper system [Bruker Daltonics] running the IR Biotyper software and distance was evaluated using the Euclidean average linkage method.

For WGS analysis whole single nucleotide polymorphisms [SNPs] within each genome was performed and phylogenetic analysis was inferred by SNPrelate and Ape/Phangorn.

Finally, after the generation of the main spectrum profiles by mass spectrometry, the isolates relatedness was inferred by MALDI-TOF hierarchical cluster analysis.

The congruence of the FT-IR spectroscopy clustering was compared to those of WGS and MALDI-TOF mass spectrometry.

Results: WGS analysis showed that the six isolates belonged to the same clade with one isolate harbouring a higher number of mutations with respect to the remaining ones, interestingly this isolate clustered in a separate branch in the dendrogram obtained by the FT-IR spectra. The remaining isolates showed a very high clonality being grouped together basing on each of the three methods applied, including the MALDI-TOF MSP dendrogram.

Conclusions: FT-IR spectroscopy tool thanks to its easiness of use could be reasonably applied to the implementation of infection control measures, nonetheless, additional analysis including a higher number of isolates, will allow further evaluation of the discriminatory power of this subtyping method as screening technology for outbreaks’ investigation purposes.

Abstract 6822

**Molecular cpn60-targeted PCR sequencing to assess the diagnostic characteristics of the Nugent Score diagnosis of bacterial vaginosis in reproductive age Kenyan women**

Thomas Fear*1, Elinor Shvartsman1, Justen Russell2, Melika Richmond1,3, Catia Perciani4, Sarah Vancuren5, Janet Hill2, Paul Sandstrom1, Kelly Macdonald1

1University of Manitoba, Winnipeg, Canada, 2Insitut Pasteur, Paris, France, 3Public Health Agency of Canada, Winnipeg, Canada, 4University of Toronto, Toronto, Canada, 5University of Saskatchewan, Saskatoon, Canada

Abstract third-party references: KAVI-ICR Team

**Background:** The Nugent score (NS) is the gold standard microbiologic test to diagnose bacterial vaginosis (BV), but its performance in detecting abnormal vaginal microbiota is unclear. Analysis of the vaginal microbiome using cpn60-targeted sequencing, which characterizes Gardnerella vaginalis subtypes, improves upon 16S rRNA-sequencing. We compared the NS to the results of cpn60-sequencing.

**Materials/methods:** A cohort of non-pregnant reproductive age Kenyan women using contraception were followed in the KAVI-VZV-001 clinical trial [ClinicalTrials.gov identifier NCT02514018]. Over 48 weeks, monthly vaginal swabs were collected to determine NS, and for cpn60-sequencing. Bacterial sequencing reads were converted to proportions of each species per sample. Samples comprised by more than 80% bacteria species known to be BV-associated were considered to have ‘Molecular-BV’.

**Results:** A total of 362 samples were collected and included in the analysis. The NS was positive (NS ≥7) for a total 34 (9.4%) samples, and 81 (22.2%) were intermediate (NS 4-6). Multiple definitions of Molecular-BV were examined, such as BV-associated bacteria comprising 50% or 80% of the vaginal flora, but were not significantly different in relation to the NS. The 80% Molecular-BV definition was detected in 103 (28.5%) samples, and is compared to all NS thresholds in Table 1. The current NS interpretation (positive if ≥7) resulted in a sensitivity of 33%, specificity of 100%, and accuracy of 79%. If intermediate Nugent Scores (NS 4-6), were interpreted as positive the sensitivity was 66%, specificity was 95%, and accuracy was 85%.

**Table 1: Test characteristics of the Nugent score (NS) at all diagnostic thresholds compared against Molecular-BV.**

Molecular-BV: Microbiota comprised by more than 80% with bacteria of species reported in the literature to predominate in bacterial vaginosis; determined by cpn60-sequencing.

**Conclusions:** In a population of reproductive age women, the NS is highly specific but very insensitive for detecting vaginal microbiomes abundant in bacteria associated with BV, determined by cpn60-sequencing. The clinical diagnosis of BV requires correlation with symptoms; however, our results suggest the utility of the NS in research settings could be improved by using lower thresholds. The current threshold is insensitive, and lower thresholds do not yield excessive false positives.

No current standard exists for the molecular determination of BV. Our study describes a method for defining Molecular-BV using cpn60-sequencing. Further work is needed to correlate this molecular definition with clinical outcomes, and replicate these results in other populations.

Performance of two commercial multiplex PCR assays on the detection the aetiologies of sexually-transmitted infections in men who have sex with men
Tai-Fen Lee1*, Kuan-Yin Lin1, Sui-Yuan Chang1, Chien-Ching Hung2, Po-Ren Hsueh1
1National Taiwan University Hospital, Taipei, Taiwan, 2National Taiwan University Hospital Jin-Shan Branch, New Taipei City, Taiwan

Background: Data on the etiologies associated with sexually transmitted infections (STI) in men who have sex with men (MSM) in Taiwan are lacking. This study aimed to investigate the etiologies of STI from the urine and rectal swab samples of MSM in Taiwan.

Materials/methods: Two commercial multiplex PCR assays, including BD Max CT/GC/TV panel (Chlamydia trachomatis [CT], Neisseria gonorrhoeae [GC], and Trichomonas vaginalis [TV]) and Seegene STI panel 1 (N. gonorrhoeae [NG], Mycoplasma genitalium [MG], Mycoplasma hominis [MH], Ureaplasma urealyticum [UU], Ureaplasma parvum [UP], TV) were evaluated for HIV-positive adults and HIV-negative adults receiving pre-exposure prophylaxis (PrEP) for HIV infection in 2019. During the first period, urine and rectal swab samples from 91 patients were evaluated by both BD Max CT/GC/TV panel and the Seegene STI panel 1. During the second period, urine and rectal swab samples from 170 patients were evaluated initially by the BD Max CT/GC/TV panel and the Seegene STI panel 1 was applied only to patients (n=50) with positive results by the BD Max CT/GC/TV panel.

Results: Identical results for CT, GC (NG), and TV were found by the both methods during the two periods. For the first period evaluation, the positive rates of CT, GC (NG), MG, MH, and UU were 4.3%, 0%, 4.3%, 2.2%, and 12.1%, respectively for urine samples (n=91) and 16.4%, 6.5%, 9.9%, 13.2%, and 21.9%, respectively for rectal swab samples (n=91). TV and UP were not detected for all samples. During the second period, BD MAX was positive (≥ one of the CT, GC, TV tests) in 50 patients. The positive rates of CT, GC were 4.1%, 0.6% for urine and 22.3%, 10% for rental swab samples. TV were not detected for all samples collected. As for the Seege STI panel 1 results, positive rates of MG, MH, UU and UP were 6%, 4%, 26% and 0% for urine, and 10%, 26%, 38% and 6% for rental swab samples.

Conclusions: Using the multiplex PCR assays, high rates of etiologies associated with STIs were found in MSM. The positive detection rates were higher in rectal swabs than those from urine samples.

Abstract 6828

**An outbreak of carbapenem-resistant Serratia marcescens carrying blaKPC in an intensive care unit between 2010 and 2013: which is the role of environment?**

Marina Farrel Côrtes*, Gladys Melo¹, Andre Soares², Roberta Cristina Ruedas Martins¹, Thais Guimaraes³, Silvia Figueiredo Costa¹,³

¹Faculdade de Medicina da USP - FMUSP, Sao Paulo, Brazil, ²National Scientific computational laboratory LNCC, Rio de Janeiro, Brazil, ³Clinical Hospital, Sao Paulo, Brazil

**Background:** Healthcare associated infection is a major problem worldwide especially due to the emergence of multidrug-resistant pathogens, such as Serratia marcescens (Sm). Although, the environment has been associated with outbreak by Sm in hospital settings, its role on maintenance of endemic infections needs better investigation.

Thus, the aim of this study was to investigate the role of carbapenem-resistant Sm carrying KPC environmental isolates on the maintenance of Sm outbreak that occurred in our hospital.

**Materials/methods:** A Sm outbreak occurred between 2010 and 2013 in the bone marrow transplanted (BMT) patients and in the intensive care unit (ICU) of Hospital das Clínicas-São Paulo. A weekly surveillance swab culture was stablished to identify colonized patients and the hospital environment (HE). A total of 63 Sm isolates were analyzed. 20 clinical and 3 environmental isolates were sequenced using illumina technology. The resistome was analyzed using CGE and BLAST. The phylogenomic analysis was performed using BEAST and included 33 other Sm genomes available in NCBI (n=57).

**Results:** Sm was isolated in 63 patients and in two sinks in room 4151. The unit was then blocked for complete ICU emptying and terminal cleaning. At the end of 2013 it was decided to change the taps of room 4151. The bioinformatics analysis revealed the presence of genes related to quinolone, rifampicin, trimethoprim, tetracycline, sulphonamide, beta-lactam, phenicol and aminoglycoside resistance in most of the genomes. 82.6% (19/23) of the genomes carried kpc gene including the HE isolates. Bayesian analysis showed that HE isolates from this work grouped closely to most of the clinical isolates and apart from other environmental isolates. Most of the genomes grouped together with other genomes from different places in USA. The 4 kpc-negative isolates grouped in other cluster together with USA isolates and 1 isolate from Mexico.

**Conclusions:** Hospital environment can be an important source of nosocomial pathogens as Sm. The Bayesian tree suggests that clinical isolates contaminated the HE and this environment became a reservoir of multidrug-resistant Sm. These data highlight the importance of cleaning practices specially in HE and brings more insights to better understand this poorly studied emerging pathogen.

Heroes and villains: the dynamics of antibiotic-uropathogens interactions during recurrent urinary tract infections management

Maxime Vallée*1,2,3, Phillip Aldridge4,5, Aaron Mz Tan3,5, Catherine Mowbray4, Catherine Walton6, Christopher Harding7, Judith Hall8

1Poitiers, Poitiers, France, 2Newcastle upon Tyne, Centre for Bacterial Cell Biology, Baddiley-Clark Building, Newcastle University, Newcastle upon Tyne, United Kingdom, 3Newcastle upon Tyne, Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle upon Tyne, United Kingdom, 4Newcastle upon Tyne, United Kingdom, 5Newcastle upon Tyne, Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle upon Tyne, United Kingdom, Newcastle upon Tyne, United Kingdom, 6Newcastle upon Tyne, Microbiology Department, Freeman Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, Newcastle upon Tyne, United Kingdom, 7Newcastle upon Tyne, Urology Department, Freeman Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom

Abstract third-party references: Supported by European and French Association of urology (EAU and AFU)

Background: Urinary tract infections (UTI) are a growing public health problem, with high recurrence rates and increased antimicrobial resistance complicating clinical management. Uropathogenic Escherichia coli (UPEC) is associated with between 60-80% of UTI cases.

Materials/methods: Here we describe the analysis of UPEC clinical isolates from the clinical trial AnTIC. AnTIC was an open-label, randomised clinical trial that compared antibiotic prophylaxis versus no prophylactic treatment to manage recurrent UTIs in clean intermittent self-catheterised patients.

Results: A key outcome of AnTIC was that rUTI frequency was lower among prophylactic patients. Our analysis argues that prophylaxis correlates with stable UPEC colonisation, when UPEC was isolated. This suggests a commensal-like role in preventing more pathogenic strains/species from colonising the urinary tract.

To investigate the evolution of antimicrobial resistance (AMR), we performed whole-genome sequencing on UPEC isolates from 20 ANtic patients that acquired multi-drug resistant (MDR) UPEC during the trial. Phylogenetic analysis revealed that nine patients retained the same strain, arguing that in these cases MDR evolved rather than incidences of new MDR strain infections.

Conclusions: Our data provides a unique insight into the dynamics of microbial colonisation during antibiotic use for a specific UTI at-risk group. Our analysis is therefore a foundation to develop alternative strategies to manage UTI risk in clean intermittent self-catheterised patients.

AnTIC microbiological analysis

Acute antibiotics and trimethoprim prophylaxis promoted E. coli colonisation

Abstract 6831

**Pandrug-resistant Ralstonia mannitolilytica isolates from a cystic fibrosis patient after lung transplantation**

Marta Hernandez1, Borja Suberviola2, Laura Alvarez-Montes3, Catalina Díaz Ríos1, María Siller4, Jesús Rodríguez-Lozano4, Ana De Malet1, Inmaculada Perez Del Molino4, Leticia Armendariz2, Carmen Fariñas4, Jorge Calvo-Montes4, Alain Ocampo-Sosa3

1Laboratorio de Biología Molecular y Microbiología, Instituto Tecnológico Agrario de Castilla y León (ITACyL), Valladolid, Spain, 2Hospital Universitario Marqués de Valdecilla, Santander, Spain, 3Hospital Universitario Marqués de Valdecilla, Instituto de Investigación Sanitaria Valdecilla (IDIVAL), Santander, Spain, 4Hospital Universitario Marqués de Valdecilla, Santander, Spain

**Background:** Patients with cystic fibrosis (CF) are more prone to pulmonary infections with a wide range of bacteria. *Ralstonia mannitolilytica* (Rm) is an opportunistic pathogen that is becoming more common in CF infections. Little is known about antimicrobial resistance and virulence traits of Rm. The aim of this study was the phenotypic and genotypic characterisation of 16 pandrug-resistant Rm isolates from a CF patient.

**Materials/methods:** Sixteen consecutive Rm isolates recovered from blood, thoracic wounds and respiratory (including lung biopsy) samples of a CF patient after a bilateral lung transplantation were identified by MALDI-TOF. MICs of aztreonam, piperacillin-tazobactam, ticarcillin-clavulanate, ceftazidime, ceftazidime-avibactam, imipenem, meropenem, doripenem, gentamicin, tobramycin, amikacin, netilmicin, ciprofloxacin, levofloxacin, minocycline, tetracycline, colistin, trimethoprim-sulfamethoxazole, chloramphenicol, fosfomycin and cefiderocol were determined by broth microdilution, except for ceftazidime-avibactam and ceftolozane-tazobactam that were performed by Etest. EUCAST and/or CLSI breakpoints were applied accordingly. The Etest synergy test was performed by the MIC:MIC ratio method (Pankey et al., 2013) using combinations of meropenem, minocycline, fosfomycin and trimethoprim-sulfamethoxazole. The isolates were investigated for their antimicrobial resistant and virulence profiles by Whole-Genome Sequencing (WGS) on an Illumina MiSeq platform.

**Results:** Antimicrobial susceptibility test demonstrated that all the isolates were pandrug-resistant, as they were non-susceptible to all agents in all antimicrobial classes, including beta-lactam combination agents ceftazidime-avibactam and ceftolozane-tazobactam, and cefiderocol. Synergy was observed only for the meropenem-minocycline combination (ΣFIC=0.5). The rest of antibiotic combinations showed a ΣFIC between 1.4, considered indifferent. WGS analysis showed between 8 and 179 SNPs differences among the isolates, indicating a clonal evolution. The pan-genome was composed of 4401 core genes out of 47,488 total genes. All the isolates harboured the *bla*OXA-443 and *bla*OXA-60 genes. Two copies of *hcp* and *vgrG* genes were found, indicating the presence of a type VI secretion system (T6SS), a major virulence factor in several Gram-negative pathogens.

**Conclusions:** To the best of our knowledge this is the first report of pandrug-resistant *R. mannitolilytica* isolates from a lung transplant patient with CF. The occurrence of pandrug-resistant bacteria, including those resistant to cefiderocol, a last resort antibiotic, represents a new challenge for treatment of chronic infections such as the case of CF.

**Presenter email address:** hernandez.marta@gmail.com
Phylogenetic and resistome analysis of human and animal Acinetobacter baumannii ST25 isolates

Agnese Lupo*1, Benoit Valot2, Estelle Saras3, Maxime Bour3, Edouard Hirchaud4, Marisa Haenni1, Patrick Plésiat3, Jean-Yves Madec1, Anais Potron3

1Université de Lyon - ANSES Laboratoire de Lyon, ANSES-Laboratoire de Lyon, Lyon, France, 2University of Franche-Comté, Besançon, France, 3Centre hospitalier régional universitaire de Besançon, Centre National de Référence de la Résistance aux Antibiotiques, Besançon, France, 4ANSES, Ploufragan-Plouzané-Niort Laboratory, Viral Genetic and Biosecurity Unit, BP53, Ploufragan, France

Background: Acinetobacter baumannii ST25 is an emerging lineage disseminating globally. In France, ST25 isolates producing OXA-23 have been found also in animals. To investigate a possible epidemiological link among human and animal isolates and strengthen the knowledge of this epidemic lineage, we analyzed the genetic relationships and the resistome of 32 ST25 isolates sampled during the same study period in humans and animals in France.

Materials/methods: Isolates collected during 2011-2018 from animals (dogs, n = 9; cats, n = 12; horses, n = 5; and ferret, n = 1) through the Resapath (ANSES-Lyon), and from humans (n = 5) by the Reference Center for Antimicrobial Resistance in Acinetobacter spp. (University Hospital of Besançon), were sequenced using the Illumina technology. The phylogenetic and resistome analysis were conducted using pyMLST (https://github.com/bvalot/pyMLST) and ResFinder 3.2 (https://cge.cbs.dtu.dk/services/ResFinder). The genetic elements harboring antimicrobial resistance genes were investigated by chromosome walking PCR and Southern Blot.

Results: The phylogenetic analysis, including all the genomes belonging to ST25 available from NCBI, generated five groups including one constituted by the genomes of the current study together with ten from NCBI. In this group, two subgroups [I, II] comprised 19 out of 32 isolates of this study, which harbored the blaOXA-23 gene on the chromosome, mostly on an AbaR4 island. The subgroup I comprised exclusively human isolates (n = 3), the second (II) included isolates from humans (n=2), dogs (n=5), and cats (n=9). The remaining isolates generated a third subgroup (III). All the isolates harbored one plasmid sizing according to the phylogenetic subgroup: 200, 150, and 250 Kbp in subgroup I, II and III, respectively. Most of the plasmids harbored two acetylases encoding genes and a genetic island containing the genes sul2, strA-strB and tetB.

Conclusions: The OXA-23 producers from animals demonstrated clonal relation to some human isolates. A transmission or a common source of contagion for humans and animals with carbapenem-resistant A. baumannii cannot be excluded. The plasmid content of the ST25 isolates of this study seems to be clonally expanded and the presence of the resistance island might favor the selection and persistence of these isolates among animals.

Abstract 6835

High accuracy identification of ten common blood culture isolates by Acrion system

Herdis Friedrich*1, Marjaana Viirtola1, Hanne Amdahl1, Ilja Ritamo1, Juha Knuuttila1, Anssi Rantakari1, Pirjo Wacklin1

1Thermo Fisher Scientific, Vantaa, Finland, 2Amicus Therapeutics UK LTD, Marlow, United Kingdom

Background: Direct pathogen identification from blood culture specimen has remained to be challenging with current mass spectrometry (MS) methods due to low recovery of microbial cells, interfering blood components and/or low sensitivity of the methods. Novel MS-based system Acrion (Thermo Fisher Scientific) utilizes a standardized, automated sample preparation that decreases human errors and increases the robustness of identification direct from blood culture.

Materials/methods: Ten bacterial isolates representing common blood culture pathogens were seeded into blood culture bottles with human blood and incubated until positive signalling. An aliquot [100-200 µl] of positive blood culture was placed into Acrion for automated sample preparation and species identification against the Acrion blood culture database. Results were compared against reference data acquired from reference collection or sequencing.

Results: The ten common blood culture pathogens were successfully identified from positive blood culture samples including Escherichia coli (20/20), Staphylococcus aureus (19/20), S. epidermidis (18/20), Klebsiella pneumoniae (22/22), Enterobacter aerogenes (20/20), Enterococcus faecalis (20/20), Bacteroides fragilis (20/20), Pseudomonas aeruginosa (20/20), Streptococcus pneumoniae (16/18) and Proteus mirabilis (20/20). Overall sensitivity for detection was 97.5% (195/200). The sensitivity of detection for gram negative bacteria was 100% (122/122) and for gram positive bacteria 93.6% (73/78). Positive identification results were in agreement with previously acquired sequencing data and demonstrate the resolving power of the high-resolution MS identification applied in Acrion.

Conclusions: Acrion System demonstrates high accuracy comparable to sequencing methods for the ten commonly met blood culture organisms. The automated sample preparation used in Acrion provides significant time savings for clinical laboratories and reduces human errors during sample handling.

Fungal disease burden: an underestimated health challenge in Cote d'Ivoire

David Koffi*, Bonoumin Valerie Ira1, Offianan Andre Toure2, Ronan Jambou4, David W. Denning5

1Institut Pasteur de Cote d'Ivoire, Abidjan, Côte d'Ivoire, 2Institut Pasteur de Côte d’Ivoire, Abidjan, Côte d’Ivoire, 3Institut Pasteur de Côte d’Ivoire, Abidjan, Côte d’Ivoire, 4Institut Pasteur de Paris, Paris, France, 5University of Manchester, Manchester, United Kingdom

Background: Due to limited access to more powerful diagnostic tools, there are few data on the burden of fungal infections in Cote d'ivoire, despite a high HIV and TB burden and many cutaneous diseases. Here we estimate the burden of serious fungal infections in this sub-Saharan country.

Materials/methods: National demographics were used to perform a PubMed search and retrieve all published articles on fungal infections in Cote d'Ivoire and countries bordering West Africa. When no data existed, risk populations were used to estimate frequencies of fungal infections, using previously described methodology by LIFE (www.LIFE-Worldwide.org).

Results: The population of Cote d'Ivoire is around 24 millions; 37% are children, and 9% are >65 years. Tinea capitis in children is common, measured at 13.9% in the last epidemiological study [2013]. Considering the prevalence of HIV infection (2.7% of the population, a total of ~500,000) and a hospital incidence of 6% of cryptococcosis, it is estimated that 3726 patients per year develop cryptococcosis. For pneumocystosis, it is suggested that 6023 new cases occur each year with the prevalence of 14.1% in paediatric HIV infection. An estimated 156 new cases of chronic pulmonary aspergillosis occur after pulmonary tuberculosis [a 5 year prevalence of 4938 cases (20.3/100,000)]. Allergic bronchopulmonary aspergillosis (ABPA) and severe asthma with fungal sensitisation (SAFS) were estimated in 104/100,000 and 151/100,000 respectively, in 1,100,000 adult asthmatics. Vulvovaginal candidiasis (VVC) is common and recurrent VVC affects ~6% of women in their fertile years - 407,000 women. An unknown number develop candidaemia and invasive aspergillosis. There are no incidence data on fungal keratitis, histoplasmosis and chromoblastomycosis, although some cases of mycetoma and histoplasmosis have been reported.

Conclusions: The present study indicates that around to 6.8% (1.6 million) of the population is affected by a serious fungal infection, predominantly tinea capitis in children and rVVC in women. These data should be used to inform epidemiological studies, diagnostic needs and therapeutic strategies in Cote d'Ivoire.

Presenter email address: davidkoffi82@gmail.com
Background: Recently, the development of Multiple Sclerosis (MS) is associated with the influence intestinal microbiota. Supposed, it to be related to the capacity of bacteria to stimulate the differentiation of Th17 cells or regulatory T cells (Lee, 2010; Kosiewicz, 2011). Therefore, it is important to understand which bacteria dominate under various disorders and how they affect immune cells and microbial community members. Lack of Akkermansia muciniphila in the intestine is associated with metabolic diseases, but its excess is associated with autoimmune pathology. It was shown that the content of A. muciniphila increases in patients with MS (Jangi, 2016) and it had proinflammatory effect (Cekanaviciute, 2017). However, there is no evidence of direct relationship between A. muciniphila and MS.

The aim of study was to investigate the association of A. muciniphila level in gut microbiota with MS course and immune cells subpopulations.

Materials/methods: 110 stool samples from MS patients with disease duration 12.2±0.9 years and 30 healthy people were analyzed. Gut microbiome was determined by the Illumina / Solexa sequencing method and by real-time PCR. Immune cell phenotypes were determined by flow cytofluorimetry.

Results: Among MS patients, there were 3 groups, in accordance with the A. muciniphila level: similarly to the healthy people group (32.3%), increased up to 20-30% (40.3%), and content less than 0.1% (27.4%). Although there was no correlation between the level of A. muciniphila and severity of MS score (EDSS), the higher content of A. muciniphila was observed in patients with EDSS>3.5 or in progressive course of MS. The most unfavorable MS course was observed in patients when, high A. muciniphila level was combined with the presence of Euryarchaeota, increased content of Actinobacteria and reduced content of phylums Proteobacteria (<1%) and Bacteroides (<4%) in gut microbiome. The presence of A. muciniphila in the intestinal microbiota was accompanied by redistribution subpopulations of Th17, Th1 / Th22 and pre-GC cells in blood.

Conclusions: The negative effect of a high level of A. muciniphila on the course of MS is manifested in a certain surrounding microbial environment, and can be mediated by redistribution of Th17 subpopulations and B cells.

Infections due to multidrug-resistant bacteria among Swiss solid organ transplant recipients between 2012 and 2017

Philipp Patrick Kohler*1, Aline Wolfensberger2, Susanne Stampf3, Andreas Brönnimann1, Katia Boggian1, Christian Van Delden4, Cédric Hirzel5, Nina Khanna1, Stefan P. Kuster2, Dionysios Neofytos6, Oriol Manuel6, Silvio Ragozzino3, Peter W. Schreiber2, Laura Walti5, Nicolas Mueller7

1Kantonsspital St.Gallen, St. Gallen, Switzerland, 2University Hospital of Zürich, Zürich, Switzerland, 3University Hospital of Basel, Basel, Switzerland, 4Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland, 5Inselspital, Bern, Switzerland, 6Lausanne University Hospital, Lausanne, Switzerland

**Background:** Solid organ transplant (SOT) recipients are at particular risk for infections caused by multi-drug resistant (MDR) bacteria. We describe temporal trends, risk factors and outcome for such infections among SOT recipients in Switzerland.

**Materials/methods:** We extracted data on proven infections due to Enterobacterales and Staphylococcus aureus between 2012 and 2017 from the Swiss Transplant Cohort Study (STCS), a prospective cohort including all Swiss SOT recipients. Temporal trends were described for episodes caused by extended-spectrum beta-lactamase (ESBL)-producing Enterobacterales and methicillin-resistant S. aureus (MRSA). Chart review was performed i) for patients infected with ESBL-producing or extended-spectrum cephalosporin (ESC)-resistant Enterobacterales [used as a proxy for ESBL-production] between 2012 and 2016, and ii) for a selection of patients infected with non-ESBL and ESC-susceptible Enterobacterales from the same time period. Factors associated with ESBL-Enterobacterales infection and with unfavourable 30-day outcome (death, relapse of infection, and graft loss) were assessed using logistic regression.

**Results:** We identified 1400 episodes due to Enterobacterales and 160 episodes caused by S. aureus. ESBL-production was 14% among Enterobacterales in 2012 and increased to 19% in 2017 (P-value for trend 0.10); MRSA rates remained stable over time (mean 9%; P-value 0.45). Among 155 patients undergoing chart review, 112 (72%) were kidney transplant recipients; 73 (47%) were infected with ESBL isolates (72% urinary tract infections). Prior antibiotic treatment within the last 3 months was the only independent risk factors for ESBL-Enterobacterales infection (OR 3.5, 95% CI 1.6-8.2). Patients infected with ESBL-Enterobacterales were more likely to have involvement of an infectious disease specialist (OR 2.6, 95% CI 1.3-5.0), and less likely to receive adequate empiric treatment (OR 0.2, 95% CI 0.1-0.6). Unfavourable 30-day outcome - mostly (82%) relapse - was more common among patients with ESBL (44% vs 20%, P-value 0.002). This association remained significant in multivariable analysis after correction for important co-variables (OR 3.4, 95% CI 1.5-8.1) (Figure).

**Conclusions:** ESBL-Enterobacteraeae are less common among Swiss SOT recipients compared to patients from other European countries. Given the potentially unfavourable impact of resistance on patient outcome, further efforts are needed to protect this vulnerable patient population from colonization and infection with resistant pathogens.

Abstract 6842

Human-like miRNA detection of bacterial origin in human gut microbiome

Aysenur Soyturk¹, Aycan Gundogdu*¹,², Ufuk Nalbantoglu¹,²,³

¹Erciyes University, Genome and Stem Cell Center, Kayseri, Turkey, ²Erciyes University, Faculty of Medicine, Kayseri, Turkey, ³Erciyes University, Computer Engineering, Kayseri, Turkey

Background: MicroRNA (miRNA) are small noncoding regulatory RNA fragments of about 19-25 nucleotides in length. Whether bacterial miRNAs harbored in human microbiome affect human cells is a new and important research interest. The miRNA structure and the multiplicity of potential targets make experimental detection difficult and economically unfavorable. The aim of this study is to determine the presence of structures similar to human miRNA in human intestinal microbiota by developing an in silico approach mining the gut metagenomes.

Materials/methods: Pre-miRNAs, which constitute the structure of 1917 human miRNAs in Mirbase, all of which have experimentally proven to be miRNAs, were identified and used as a training set. A miRNA detector based on sequence features was developed. Several classification methods (Random forests, Support Vector Machines, Gradient boosted trees, k-Nearest Neighbors) have been experimented for the miRNA classification process and Gradient-Boosted Trees (GBT) gave the best accuracy value. A threshold of detection (0.98) was determined for a moderately sensitive, yet highly specific detector. Whole metagenome sequencing data from human feces from a cirrhosis cohort was scanned for human-like miRNA precursors of 70-110 nucleotides, which govern the secondary structure of miRNAs. The microbial contigs exceeding the threshold value were located and the species harboring that loci were determined using Kraken2 microbial taxonomic assignment method.

Results: 1141 different microbial species were found to contain human-like miRNA sequences. The number of putative miRNA for each species between the groups were tested statistically. *Streptococcus pluranimalium* (p=0.043), *Bacillus spp.* (p=0.036), *Limnochorda pilosa* (p=0.048), *Cellulophaga lytica* (p=0.024) were found to harbor differential number of putative sequences [Student’s t-test]

Conclusions: The study suggests that human gut microbiome contains abundant number of sequences resembling human miRNA, showing up in a broad biodiversity spectrum. In the context of disease, certain species exhibit variation in the putative miRNA sequences they harbor. Experimental validations should be carried out revealing to what extent these sequences are expressed and if they function in regulating human gene expression. In case of such validations, a new dimension in host-microbiome interactions will be in question, as well as a practical opportunity in the detection/treatment of disease with novel potential biomarkers.

Abstract 6844

**Current treatment pathways for Clostridioides difficile infection in Europe**

Nicola Petrosillo*1, Guido Granata1, Maria Adriana Cataldo1, Kerrie Davies2

1National Institute for Infectious Diseases "L. Spallanzani", Rome, Italy, 2Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom

Abstract third-party references: On behalf of the COMBACTE-CDI consortium.

**Background:** The aim of this study is to report on the current *C. difficile* infection (CDI) treatment pathways in Europe, showing the differences between European countries and comparing the adherence to the most recent international CDI guidelines.

**Materials/methods:** In 2018, in the framework of the European COMBACTE-CDI project, a questionnaire on the awareness and observance of any European or local CDI treatment guidelines and on CDI treatment pathways was sent to the participating sites from 12 different European countries.

**Results:** One-hundred fifty-five European facilities participated in the survey, including hospitals or hospital-based laboratory facilities, general practitioners, long-term healthcare facilities, private laboratories and residential care facilities. Overall, 63% (98/155) of all the participating sites reported awareness of any European CDI treatment guidelines and the majority (78/83, 94%) of these sites declared that they followed them. Italy, Romania and the Netherlands were the countries where awareness was lowest i.e. 27/55 (49%), 3/8 (38%) and 1/6 (17%), respectively. In different settings, residential care facilities and general practitioners had lower awareness than hospitals (50% and 26%, respectively, versus 75%). Eighty one% (106/131) of the participants declared that they stratified via severity criteria for the treatment of a primary case of CDI. For treating a mild/moderate primary case of CDI, 76/155 (49%), 49/155 (32%), 12/155 (8%) reported using metronidazole, vancomycin and fidaxomicin, respectively whereas for severe primary CDI, 29/155 (18.7%), 113/155 (72.9%), 20/155 (12.9%) used metronidazole, vancomycin and fidaxomicin, respectively. Antimicrobials other than vancomycin, metronidazole or fidaxomicin were used by 1.9% of the sites, mostly by residential care facilities and hospitals in Romania and the UK. For the treatment of recurrent cases of CDI, antimicrobials different from vancomycin, metronidazole or fidaxomicin were used in 10% (15/155) of cases.

**Conclusions:** The results of the European survey on CDI treatment shows that awareness of European CDI treatment varied according with different geographical areas and settings, thus a strategy to improve awareness needs to be developed. Interestingly, the use of “other” antimicrobials tends to increase when the treatment of recurrent CDI cases is considered, perhaps suggesting a lack of trust in conventional CDI antimicrobials in this patient population.

Background: The EUCAST rapid antimicrobial susceptibility testing (RAST) method, available to clinical laboratories since November 2018, lists breakpoints for seven common bloodstream infection pathogens. Acinetobacter baumannii is another important sepsis pathogen, especially in Southern Europe. This organism is often resistant to multiple agents. We aimed to evaluate the RAST method for A. baumannii.

Materials/methods: Blood culture (BC) bottles, BACTEC™ Plus Aerobic (BD), were inoculated with susceptible and resistant isolates of altogether 48 A. baumannii (Table). The EUCAST RAST method was performed on positive BC bottles for eight clinically relevant antimicrobial agents using Mueller-Hinton agar from two manufacturers (BBL/BD and Oxoid/Thermo Fisher Scientific) and Oxoid antimicrobial disks. Broth microdilution was performed according to ISO 20776-1 on custom Sensititre panels (Thermo Scientific) and used as a reference. MICs were interpreted according to EUCAST breakpoints v. 9.0 (2019). RAST breakpoints were set to correctly categorise as many isolates as possible and avoid false susceptible results.

Results: All inhibition zones could be read after 6 and 8h and all but one after 4h incubation (Table). Breakpoints were determined for all antimicrobials tested, but for amikacin at 4h only a resistant breakpoint was set. As for other pathogens in RAST, an Area of technical Uncertainty (ATU) was defined for all agents and reading times. With the proposed breakpoints 24, 4 and 3% of the inhibition zones were in the ATU after 4, 6 and 8h, respectively. One false susceptible result occurred with trimethoprim-sulfamethoxazole at 4h and four false resistant results occurred at 4h (n=3) and 8h (n=1) for different agents.

Conclusions: The EUCAST RAST method can be implemented for A. baumannii and breakpoints based on this study have been published on the EUCAST website. All but one zone diameters could be comfortably read after 4h. Seventy-five per cent of results after 4h could be categorised as S or R. Results read after 6 and 8h were only rarely (≤4 %) in the ATU. With the suggested breakpoints the number of errors was low when tested on a collection of both susceptible and resistant isolates.

Table. Theoretical and actual number of tests, the proportion of tests which could be read and interpreted after 4, 6 and 8 h, and the categorical errors with RAST at each reading time for 48 isolates of A. baumannii.

**Abstract 6846**

**Acinetobacter baumannii and Klebsiella pneumoniae: intelligent design of phage cocktails against multidrug-resistant pathogens**

Matti Jalasvuori*, Katarina Koskinen, Matti Ylänne, Reetta Penttinen

1University of Jyväskylä, Jyväskylä, Finland

**Background:** Multidrug-resistant Klebsiella pneumoniae and Acinetobacter baumannii are emerging as a cause of mortality worldwide. As such the need for alternative therapies are in high demand. Bacteriophages provide one potential mean to control the proliferation of pathogens that are insensitive to conventional antimicrobials. Yet, bacteria have developed multitude of ways to become resistant to phages, thus calling for efficient phage cocktail design.

**Materials/methods:** In this study, we investigated the response of K. pneumoniae and A. baumannii clinical isolates to various phages. Bacteria were exposed to multiple phages in different set-ups and the emerging phage-resistant pheno- and genotypes were determined.

**Results:** We show that the surviving K. pneumoniae exposed to multiple phages have severely impaired growth ability. Interestingly, K. pneumoniae strains harboring a CRISPR-system appears to respond to phage-selection via genomic mutations whereas closely related CRISPR-free strains become resistant by assuming only an alternative phenotype. Respectively, when phage selection is abolished, it takes significantly more time for genomic mutations to revert back into the wild-type (and likely pathogenic) form in comparison to exclusively phenotypic changes that readily return to their original form. We also demonstrate that phage isolation against first-line phage resistant phenotypes can help construct more efficient phage-cocktails.

In A. baumannii, exposure to first-line phages repeatedly select for a phenotype that is sensitive only to second-line phages. By combining first-line and second-line phages, the cocktail induces selection for less-fit and hence probably less-virulent pathogens.

**Conclusions:** Including phage isolation against first-line phage resistant K. pneumoniae and A. baumannii phenotypes can help develop antimicrobial formulations that may be more robust in reducing the pathogenicity in any surviving bacteria. Such evolution-predicting cocktails may improve the outcome of therapy trials and therefore help pave the way for adopting phages as emergency antimicrobials.

Epidemiology, risk factors and outcomes of infections caused by carbapenem-resistant Gram-negative bacteria in paediatric intensive care unit

Luigi Celani¹, Marco Ridolfi¹, Cristian Borrazzo¹, Maria Trancassini¹, Guido Antonelli¹, Paola Papoff¹, Claudio M. Mastroianni¹, Gabriella D’ettorre¹, Paolo Pavone*¹

¹Sapienza University of Rome, Department of Public Health and Infectious Diseases, Roma, Italy, ²Sapienza University of Rome, Department of Molecular Medicine, Roma, Italy, ³Sapienza University of Rome, Department of Pediatrics and Pediatric Neuropsychiatry, Roma, Italy

Background: Infections caused by gram-negative resistant bacteria have increased worldwide but there are few available data for the pediatric population. For these reasons, the objectives of our study were to describe the epidemiology, risk factors and outcomes associated to infections due to CR-GN in PICU.

Materials/methods: We performed a retrospective observational study at the PICU of a large Italian Hospital from 2017 to 2019. We enrolled patients under 18 years of age with an infection due to GN, we divided them in two groups according to the sensitivity of isolates to carbapenems and we compared them to assess risk factors and outcomes.

Results: We enrolled 65 patients, 32 presented a CR-GN infection due to: A. baumannii (16; 50%), S. maltophilia (3; 9.4%), P. aeruginosa (11; 34.4%), K. Pneumoniae (2; 6.2%). All isolates were MDR, 13 (39.4%) isolates were sensitive to fluoroquinolones, 12 (36.4%) to aminoglycosides, 28 (84.8%) to colistin, 5 isolates were sensitive to tigecycline and 5 to piperacillin/tazobactam. Lower respiratory tract infections were the most frequent infections (20; 62.5%). At the univariate analysis we identified the following risk factors for CR-GN infection: age ≥ 24 months (p = 0.004), central venous catheter (p = 0.029), urinary catheter (p = 0.024), nasogastric tube (p = 0.001), orotracheal intubation (p = 0.042), mechanical ventilation (p = 0.042), corticosteroids use in the previous 30 days (p = 0.048) and at the time of infection (p = 0.040), antibiotic therapy in the previous 30 days (p = 0.002), in particular, carbapenems and glycopeptides (p = 0.011 and p = 0.047 respectively); length of stay in PICU before the infection (p <0.001); rectal colonization by carbapenemase-producing microorganism (p = 0.026); Candida spp. Infection in the previous 30 days (p = 0.010). We did not observe deaths, but the length of hospitalization was significantly longer in the group of patients who had a CR-GN infection (p <0.001).

Conclusions: Antimicrobial resistance is an emerging problem even in the pediatric population. Optimization of antibiotics use and an improvement in the management of medical devices could be a strategy to try to prevent CR-GN infections in children.

Abstract 6849

Knowledge, attitude, and practice of Visiting Friends or Relatives (VFR) travellers towards prevention of malaria

Fabian Heinrich*1, Thomas Theo Brehm1,2, Marylyn Addo1,2, Thierry Rolling1,2

1University Medical Center Hamburg-Eppendorf, Division of Infectious Diseases, I. Department of Medicine, Hamburg, Germany,
2German Center for Infection Research (DZIF), Partner Site Hamburg/Lübeck/Borstel/Riems, Hamburg, Germany

Background: An average of 900 cases of malaria are reported yearly in Germany, with around 95% of cases occurring in travelers returning from Sub-Saharan Africa. People who travel to foreign countries in order to visit friends or relatives (VFR) make up almost half of those cases. However, no systematic survey of VFR on their knowledge, attitude, and practice (KAP) towards prevention of malaria has been conducted in Germany so far.

Materials/methods: We are conducting a questionnaire-based survey in VFR living in Hamburg, Germany with the aim to study issues in malaria prevention, chemoprophylaxis and non-drug preventive measures.

Results: At the time of this preliminary analysis a total of 32 VFR could be included in our study. The male:female ratio was 1.3:1 and the median age was 39 years (range: 20 - 67 years). Eight participants were second or third generation immigrants that were born in Germany, the rest were born in Western Africa and lived in Germany since a median of 15 years (range: 2 - 25 years). The individual risk to fall ill from Malaria when visiting their friends and relatives, was perceived as "low" or "not present in" 63% (n=20) of participants. A total of 56% (n=18) had sought medical advice prior to their last travel, 47% (n=15) had taken malaria chemoprophylaxis. Reasons not take chemoprophylaxis were low risk perception (n=6), no such recommendation by the medical practitioner (n=3), high cost of chemoprophylaxis (n=3) and doubt of effectiveness (n=1). While six patients did not adhere to any non-drug preventive measures, others used mosquito nets (n=7), skin-applied chemical repellents (n=11), window screening (n=11) and bright long clothes (n=3).

Conclusions: Among a substantial proportion of VFR travelers in Germany, a lack of perceived individual malaria risk appears to be the predominant reason for low rates of pretravel medical consultation and low uptake of chemoprophylaxis. This underlines the need for awareness-raising campaigns addressing the population of VFR in order to decrease rates of imported malaria.

Rescue diagnosis of a cerebral nocardiosis by accredited clinical metagenomics: a case report

Virginie Courbin¹, Quentin Riller¹, Guillaume Gricourt¹, Demontant Vanessa², Raphael Lepeule¹, Jean-Michel Pawlotsky¹, Christophe Rodriguez¹, Paul-Louis Woerther*¹

¹Hôpital Henri-Mondor Ap-Hp, Créteil, France

Background: Nocardia spp. are environmental Gram-positive rods responsible for rare and severe opportunistic infections in immunocompromised patients. Growth conditions of this bacterium require specific media and long culture duration. Microbiological documentation is mandatory to confirm the bacteriological identification and adapt antibiotic treatment according to the susceptibility profile of the strain. This case describes the exploration of a cerebral nocardiosis by Clinical Metagenomics (CMg).

Materials/methods: A 66 years-old man, with no past medical history, was admitted in intensive care unit for febrile coma. Flu-like symptoms, including headache, fever, asthenia and neurological impairment began 10 days before. Computed tomography (CT) brain scan revealed an abscess with hydrocephaly. Cerebrospinal fluid (CSF) showed meningitis with 750 elements (76 % neutrophils), hyperproteinorachia and hypoglycorachia. Conventional microbiological procedures (standard, mycobacterial and fungal cultures, 16S rDNA PCR, multiplex PCR (Film Array®)) failed to identify any pathogen. For that reason, the sample was submitted to CMg. Briefly, a specific extraction combining mechanical and enzymatical step was performed before DNA and RNA library prep using Nextera and Total RNA kits (Illumina), and sequencing with NextSeq500 (Illumina). Bioinformatic analysis was performed using the MetaMIC software.

Results: From a total of 36'882'731 reads generated from the CSL sample, 7'862 matched to Nocardia cyriacygeorgica genome, which corresponds to a high ratio of positivity (2.1 3x10⁻⁴) for our CMg method. This result was confirmed by PCR by the French Observatory of Nocardiosis (Hospices Civils de Lyon). Administration of imipenem-cilastatin associated with trimethoprim-sulfamethoxazol allowed the recovery of the patient. A posterior exploration of immunodeficiency showed antibodies against GM-CSF, treated successfully with anti-CD20. Two years later, the patient was considered cured under trimethoprim-sulfamethoxazol prophylaxis.

Conclusions: CMg is a new method based on new generation sequencing, which allows the detection of pathogens whatever their nature (bacteria, viruses, fungi). In our case, CMg was able to identify N. cyriacygeorgica as responsible for a brain abscess, whereas all other methods available in our laboratory were negative. This diagnosis allowed the adaptation of the antimicrobial treatment and also leaded to the detection of an acquired immunodeficiency, the medical care of which was then made possible.

Abstract 6853

Microbiology of tubo-ovarian abscess in a tertiary hospital in Spain
Cristina Aspichueta*,1, Eva Lozano1, Manuel Imaz Perez1, Felicitas Elena Calvo Muro1, Josebe Unzaga1, Maite Caceres1, José Luis Diaz De Tuesta1, Matxalen Vidal-Garcia1

1Basurto University Hospital, Bilbao, Spain

Background: Tubo-ovarian abscess (TOA) is a purulent collection involving the fallopian tube and/or ovary. Our aim is to describe the TOA microbiological characteristics.

Materials/methods: We reviewed medical records and microbiological results from confirmed cases of tubo-ovarian or tubarian abscess between January 2008 and November 2019. The microbiological diagnosis was studied by routine bacteriological culture and Sexually Transmitted Infections (STI) PCR assay (STI Essencial Assay, Allplex®, Seegene).

Results: 47 abscess and 40 peritoneal fluids were cultured from 74 women and 57 (77%) were tested by STI-PCR. The mean age was 40.4 years (SD=12.4). 30 (40%) had an intrauterine contraceptive device in situ. The median white blood recount was 14,748/µL (SD=5,703) and the median C reactive protein 168.4 mg/L (SD=121.7). The abscess localization was bilateral in 36 (48.6%), 19 left (25.7%) and 19 right (25.7%). The routine culture was positive in 42 (56.8%) patients: 20 (47.6%) aerobic flora, 15 (35.7%) anaerobic flora and 6 (14.3%) aerobic + anaerobic flora. In 2 patients with TOA culture negative, we also considered bacteria isolated in blood culture (BC). The STI-PCR was positive in 11/57 (19.3%) TOA samples, 10 (90.9%) Chlamydia trachomatis and 1 (9.1%) Neisseria gonorrhoeae. In 4 patients with this PCR negative or not realized, we also considered C. trachomatis detected in related endocervix (3) and DIU-PCR (1). Taking all these results into consideration, 55 (74.3%) patients had microbiological isolates, of which 15 (27.3%) had sexually transmitted bacteria implicated. The flora was polymicrobial in 13/50 (26%) cases and only 4 (7.3%) had mixed ST-bacteria + anaerobic flora. Ampicillin+gentamicin+clindamycin was used empirically in 52/62 (84%) consulted patients. About surgical management, drainage/washout was carried out in 11 (14.9%) women and salpingo/oophorectomy in 63 (85.1%).

Conclusions:

- It’s essential in TOA samples to ask not only for bacteriological culture but also for STI-PCR.
- Our study shows a high yield in the microbiological diagnosis of TOA samples with an important presence of STI (27.3%) and polymicrobial flora (26%).
- E.coli is the most common isolated pathogen (32.7%), followed by C.trachomatis (25.5%) and Bacteroides spp (14.5%).

Abstract 6854

**Identification of microorganisms direct from signal positive blood culture using Acrion system**

Jemiina Salo*,1, Soniya Gurung2, Otso Niiranen1, Naomi Chant2, Mark Wilks3

1Thermo Fisher Scientific, Vantaa, Finland, 2Thermo Fisher Scientific, Basingstoke, United Kingdom, 3Barts and the London School of Medicine and Dentistry, Queen Mary, University of London, London, United Kingdom

**Background:** Mass spectrometry (MS) has made a major impact in the field of clinical microbiology in recent years, but there is still a need for more rapid and accurate identification of microorganisms from positive blood culture. Direct detection is challenging and although several extraction protocols are commercially available, these are expensive, laborious and time consuming. A widely used method in clinical laboratories is to subculture positive blood cultures on solid medium and incubate for a few hours before identifying the isolate using MALDI-TOF. Not only does this delay the time to result, but identification can be of low discrimination between certain closely related species. Here we present a high resolution mass spectrometry device, Acrion™, that is able to rapidly identify microorganisms directly from positive blood cultures with high accuracy.

**Materials/methods:** A 1–2 mL aliquot of over 200 signal positive blood culture samples (BioMerieux Bactec) was removed and frozen within five hours of signal positivity. Each positive blood culture aliquot was thawed at room temperature and 150 µL sampled for Acrion™ analysis. All samples were subcultured onto solid media and incubated in appropriate conditions to evaluate growth. Identification was carried out using MALDI-TOF or DNA sequencing. Samples where there was no recovery of viable organisms or minimal growth were discarded from the analysis.

**Results:** Altogether, 161 positive blood culture samples representing 34 different bacterial and yeast species were included in the study. Acrion™ identified the correct microorganism with 95.03 % accuracy (153/161) directly from positive blood culture, with 123 Gram positive, 37 Gram negative and 1 yeast isolates tested (Table 1).

Abstract 6855

Molecular epidemiology of *Achromobacter xylosoxidans* in the airways of cystic fibrosis patients: a longitudinal study

Stefanie Kampmeier*, Alexander Mellmann†, Barbara Kahl‡

†University Hospital Münster, Institute of Hygiene, Münster, Germany, ‡University Hospital Münster, Institute of Medical Microbiology, Münster, Germany

**Background:** *Achromobacter xylosoxidans* are increasingly recognized in patients suffering from cystic fibrosis (CF). These pathogens are highly resistant to commonly used antibiotics due to intrinsic and acquired resistance mechanisms. Detection of these pathogens in the airways of CF patients is accompanied with an impaired pulmonary function. Here, we aimed to detect genomic clusters of *A. xylosoxidans* strains in different CF patients to elucidate genetic alterations of these pathogens over time.

**Materials/methods:** All *A. xylosoxidans* isolates from sputa of CF patients admitted to the University Hospital Münster were collected from 2006 to 2018, analyzed by whole genome sequencing and compared in a gene-by-gene approach (core genome multilocus sequence typing, cgMLST) using *A. xylosoxidans* NCTC 10807 (GenBank accession number NZ_LN831029.1) as a reference sequence. Genetic relation was displayed using the minimum-spanning tree algorithm, whereby close genetic relationship was assumed at 20 allele difference or less.

**Results:** In total, 131 *A. xylosoxidans* strains isolated from 24 patients were genetically analyzed resulting in 13 clusters of two to 14 close related genotypes, whereby one cluster harbors genotypes isolated from three different patients, indicating a possible transmission of this pathogen. All other clusters only harbor isolates derived from one and the same patient. In three patients, isolates showed a cluster of distantly related (21-350 alleles difference) genotypes. Ten isolates derived from one patient over time resulted in 2 different clusters of unrelated and distantly related genotypes.

**Conclusions:** In the majority of cases one *A. xylosoxidans* clone persist in the airway of CF patients and alters genetically over time. Transmissions of *A. xylosoxidans* from one patient to another are possible, making infections control approaches more important.

Abstract 6857

Results of a Zika virus screening programme in asymptomatic pregnant women in Spain

Cristian Castelló-Abietar1, Isabel Costales*1, Susana Rojo1, Marta E. Alavarez-Argüelles1, Santiago Melón-García1, Mercedes Rodriguez-Perez1

1Hospital Universitaria Central de Asturias, Microbiology, Oviedo, Spain

Background: Zika virus is a mosquito-borne flavivirus transmitted by Aedes. In Spain, a monitoring protocol was developed to detect the exposure to the virus in pregnant women who reside or have traveled to areas with active Zika virus transmission. Our objective was to evaluate the results of the screening programme in Asturias.

Materials/methods: A total of 229 pregnant patients (179 came from endemic zone and 50 traveled to those areas before pregnancy) were included in the study from 23/11/2017 to 10/10/2019 (medium age= 31.53 years, range 14-51). Zika immunoglobulin G (IgG) and immunoglobulin M (IgM) were analyzed by indirect chemiluminescent immunoassay (ZIKA VIRCLIA® MONOTEST, Vircell, Spain). Zika IgG positive samples were confirmed by plaque reduction neutralization test (PRNT) in the Spanish National Center for Microbiology (Madrid, Spain).

Dengue virus determination by indirect immunofluorescence was also performed to rule out other flaviviruses that could interfere with Zika result (Arbovirus Fever Mosaic 2, Euroimmun, Germany).

Results: Zika IgG were detected in 88 patients (medium age= 29.73 years, range 17-51). The most common origin countries were: Dominican Republic (12), Colombia (12), Brazil (10), Ecuador (9), Paraguay (7), Honduras (7), Venezuela (5), and Senegal (5). No pregnant woman who traveled to endemic zone presented antibodies against Zika. Three positive samples were confirmed by PRNT (probable cases), 53 were negative and 32 undetermined. In none of them Zika IgM was detected. Therefore there was a Zika probable cases incidence rate in the study of 1.31%.

All three patients with Zika infection also had dengue IgG positive, indicating previous contact with dengue and Zika. Two of them were from Dominican Republic and one from Senegal. No complications during pregnancy and newborn were observed.

Of those unconfirmed Zika cases, in 67 patients dengue IgG were detected (past dengue infection), 3 patients were negative for dengue and in 15 patients no data were available.

Conclusions: The study of Zika virus in pregnancy allowed detecting those with previous contact with the virus and subsequent pregnancy and newborn monitoring.

The percentage of positive IgG results that are confirmed with neutralization is low, which suggest the need to confirm these results.

Development of a high-throughput single nucleotide polymorphism (SNP) typing assay for Klebsiella pneumoniae

Elvira Shaidullina*, Eugene Sheck, Anna Mikotina, Ayslu Mardanova, Mikhail Edelstein

1Smolensk State Medical University, Institute of Antimicrobial Chemotherapy, Smolensk, Russian Federation, 2Kazan Federal University, Institute of Fundamental Medicine and Biology, Kazan, Russian Federation

Background: Multilocus sequence typing (MLST) is currently widely used for describing the population structure of many bacterial species including Klebsiella pneumoniae (KPN), one of the top priority pathogens on the WHO list, and for defining 'high-risk' clones associated with specific virulence and/or resistance traits. However, MLST, performed by conventional Sanger sequencing or next-generation sequencing, is still costly and laborious for analysis on large sample collections. Here, we aimed to develop a high-throughput real-time-PCR-based SNP-typing assay for KPN.

Materials/methods: The informative SNPs for typing were selected from concatenated sequences of MLST loci: gapA, infB, mdh, pgI, phoE, rpoB, tonB (https://bigsdb.pasteur.fr/klebsiella/) to achieve the maximum Simpson's index of diversity (D) for all known sequence types (STs). Additionally, two virulence genes, clbA and rmpA, commonly present en bloc in hypervirulent strains were included. Allele-specific real-time PCR with universal fluorescence-energy-transfer-labelled primers was used to detect SNPs. For each SNP, allele-specific primers were designed to contain a locked nucleic acid (LNA) at the 3’ end to improve specificity of priming, and the 5’-tail sequences, to introduce priming sites for the universal fluorogenic primers. Automated SNP calling was performed by detecting fluorescence generated upon amplification from differentially-labelled universal primers. The assay was validated on a panel of control strains representing various STs and SNPs combinations, and was applied for genotyping 179 carbapenemase-producing (CP) isolates from diverse sources.

Results: A set of 22 SNPs from seven loci was selected that provided a D-value of 0.997 by testing in silico 2440 unique MLST profiles (excluding those of K. variicola, K. quasipneumoniae and Raoultella terrigena). The developed SNP-typing assay permitted accurate and unambiguous identification of nucleotide bases at all selected SNP positions with typability of 100% for control strains. All CP isolates were successfully typed with majority of them being assigned to international multiresistant clones: CG395 (46.4%), CG147 (14.0%), CG307 (8.4%), ST11 (4.5%), ST340 (3.9%), ST258 (0.6%), and some to hypervirulent clone CG23 (1.1%), which was further confirmed by sequencing.

Conclusions: We developed a rapid, reproducible and cost-effective SNP-typing assay suitable for large-scale surveillance studies of KPN.

Abstract 6861

**Characteristics and outcome of acute viral encephalitis in an infectious disease unit**

Sakly Hela*, Marrakchi Wafa1, Ikbel Kooli1, Adnene Toumi1, Abir Aouam1, Mohamed Chakroun1

1Hôpital Fattouma Bourguiba, Infectious disease department, Monastir, Tunisia

**Background:** The main causes of infectious encephalitis are viruses. We performed a retrospective study to analyse the characteristics of adult patients with viral encephalitis.

**Materials/methods:** From January 2002 to October 2019, a retrospective study was conducted including patients hospitalized for viral encephalitis. All demographic and clinical data, as well as those regarding patient outcome were recorded.

**Results:** 93 patients were included. There were 67 males (72 %) and 26 females (28 %) with a mean age of 52.4 years ± 19.2 years (range 27–82 years). 82 patients (88.1%) had altered mental status, 48 (51.6%) focal neurological symptoms, 35 (37.6%) impaired level of consciousness and 42 (45.1%) seizures. Blood tests found moderate C-reactive protein increase in 65 patients (mean 13 mg/l). An elevated white blood cell count was found in 34 patients (mean 12,500/mm3 cells). Hepatic cytolysis was found in 27 patients (29%). Cerebral spinal fluid tests showed increased leukocytes > 10/mm3 in 90 patients (mean: 137/mm3 cells), and a majority of lymphocytes in 87 (93.5%). Moderate hyperproteinorachia was observed in 43 patients (46.3%). Hypoglycorrachia was observed in 67 cases (72%). The viral agent was identified in 42 cases: Herpes simplex virus (n=24, 25.8%), West Nile virus (n=10, 10.7%), rubelle (n=4, 4.3%), Cytomegalovirus (n=2, 2.1%), varicella-zona virus and VIH in respectively one case. 80 patients (86%) received antiviral drugs: aciclovir for 79 patients (73.4%) and ganciclovir for 2 (2.1%). The mean duration of antiviral treatment was 15 days ± 3.2 days. The outcome was good for 80 patients. Four patients died from acute viral encephalitis. Altered level of consciousness were noted in 8 of them (8.6%). One patient had developed a brain abscess needing surgery.

**Conclusions:** Our study describes the main characteristics of viral encephalitis. In order to increase the likelihood of positive results for a specific virus, it is important to know the best approach to collecting samples and to choose the best identification technique for each virus. Further studies are required to investigate defective mechanisms of defense against pathogens that might be genetically determined.

**Presenter email address:** helasakly89@gmail.com
A publicly accessible database for *Clostridioides difficile* genome sequences supports tracing of transmission chains and epidemics

Martinique Frentrup¹, Zhemin Zhou², Matthias Steglich¹, Jan Meier-Kolthoff³, Markus Göker¹, Thomas Riedel¹², Boyke Bunk⁴, Cathrin Spröer⁵, Jörg Overmann¹³, Marion Blaschitz⁴, Alexander Indra⁴, Lutz von Müller⁴, Thomas Kohl⁴, Stefan Niemann⁴, Christian Seybold², Frank Klawonn⁶, Nitin Kumar⁸, Trevor Lawley⁹, Sergio García-Fernández¹⁰, Rafael Cantón Moreno¹⁰, Rosa Del Campo¹⁰, Ortud Zimmermann¹¹, Uwe Groß¹¹, Mark Achtman¹², Ulrich Nübel*¹³

¹Leibniz Institute DSMZ, Braunschweig, Germany, ²University of Warwick, Warwick, United Kingdom, ³German Center of Infection Research (DZIF), Braunschweig, Germany, ⁴AGES, Vienna, Austria, ⁵Christophorus-Kliniken, Coesfeld, Germany, ⁶Research Center Borstel, Borstel, Germany, ⁷Friedrich-Loeffler-Institut, Jena, Germany, ⁸Helmholtz Centre for Infection Research, Braunschweig, Germany, ⁹Wellcome Sanger Institute, Hinxton, United Kingdom, ¹⁰Hospital Universitario Ramón y Cajal, Madrid, Spain, ¹¹University Medical Center Göttingen, Göttingen, Germany, ¹²University Warwick, Warwick, United Kingdom, ¹³Technical University Braunschweig, Braunschweig, Germany

**Background:** *Clostridioides difficile* (formerly called *Clostridium difficile*) is the primary infectious cause of antibiotic-associated diarrhea. Local transmissions and international outbreaks of this pathogen have been previously elucidated by bacterial whole-genome sequencing, but comparative genomic analyses at the global scale were hampered by the lack of specific bioinformatic tools.

**Materials/methods:** Here we introduce a publicly accessible database within EnteroBase (http://enterobase.warwick.ac.uk) that automatically retrieves and assembles *C. difficile* short-reads from the public domain, and calls alleles for core-genome multilocus sequence typing (cgMLST).

**Results:** EnteroBase currently contains 13,515 quality-controlled *C. difficile* genomes which have been assigned to hierarchical sets of single-linkage clusters by cgMLST distances. This hierarchical clustering is used to identify and name populations of *C. difficile* at all epidemiological levels, from recent transmission chains through to pandemic and endemic strains. Moreover, it puts newly collected isolates into phylogenetic and epidemiological context by identifying related strains among all previously published genome data. For example, HC2 clusters (i.e. chains of genomes with pairwise distances of up to two cgMLST alleles) were statistically associated with specific hospitals (\(p<10^{-4}\)) or single wards (\(p=0.01\)) within hospitals, indicating they represented local transmission clusters. In contrast, clustering at level HC150 was largely compatible with PCR ribotyping, thus enabling comparisons to earlier surveillance data.

**Conclusions:** EnteroBase enables contextual interpretation of a growing collection of assembled, quality-controlled *C. difficile* genome sequences and their associated metadata. Hierarchical clustering rapidly identifies database entries that are related at multiple levels of genetic distance, facilitating communication among researchers, clinicians and public-health officials who are combating disease caused by *C. difficile*.

Community antibiotic prescribing for children in France from 2015 to 2017: a prospective national study
Nhung Trinh*1,2, Robert Cohen3, Magali Lemaitre4, Pierre Chahwakilian5, Gregory Coulthard6, Tim Bruckner5, Dejan Milic2, Corinne Levy2, Martin Chalumeau1,6, Jérémie Cohen1,6

1University of Paris, CRESS UMR 1153, Paris, France, 2IQVIA France, Courbevoie, France, 3Association Clinique et Thérapeutique Infantile du Val de Marne, Créteil, France, 4Independent expert, Versailles, France, 5University of California, Irvine, Program in Public Health, Irvine, United States, 6Necker Hospital, Department of General Pediatrics, Paris, France

Background: To assess recent community antibiotic prescribing for French children and identify areas of potential improvement.

Materials/methods: We analyzed 223,506 pediatric (<15 years) visits in a nationally representative sample of 680 French general practitioners (GPs) and 70 community pediatricians (IQVIA's EPPM database), between March 2015 and February 2017, excluding well-child visits. We calculated antibiotic prescription rates per 100 visits, separately for GPs and pediatricians. For respiratory tract infections (RTIs), we described broad-spectrum antibiotic use and duration of treatment. We used Poisson regression to identify factors associated with antibiotic prescribing.

Results: Overall, antibiotic prescriptions rates were 26.1 and 20.1 per 100 visits, for GPs and pediatricians, respectively ($p<0.0001$). RTIs accounted for more than 80% of antibiotic prescriptions by GPs and pediatricians, respectively. For RTIs, antibiotic prescription rates per 100 visits were: otitis, 66.5 and 79.8; pharyngitis, 67.9 and 54.4; sinusitis, 67.9 and 77.3; pneumonia, 80.0 and 99.2; bronchitis, 65.2 and 47.3; nasopharyngitis, 21.7 and 11.6; other presumed viral RTIs, 23.3 and 11.7, respectively. For RTIs, GPs prescribed more broad-spectrum antibiotics (49.9% vs. 35.6%, $p<0.001$) and antibiotic courses of similar duration (6.9 vs. 7.1 days, $p=0.21$). After adjustment for diagnosis and season, antibiotic prescription rates were significantly higher in older children (3-14 years vs. <3 years) and older GPs (≥50 years vs. <50 years).

Conclusions: Future antibiotic stewardship campaigns should target presumed viral RTIs (notably bronchitis and nasopharyngitis), broad-spectrum antibiotic use, children 3-14 years old, and GPs ≥50 years.

Presenter email address: nhung.trinh@inserm.fr
Background: Inappropriate antibiotic use and antimicrobial resistance have posed huge threat to healthcare safety. However, there were few reports on antibiotic use and antimicrobial resistance in the provincial level in Mainland China. Therefore, this study aimed to describe current situation of antibiotic use and burden of antimicrobial resistance in Shaanxi province in 2017.

Materials/methods: 116 secondary and 45 tertiary hospitals voluntarily participated in the provincial surveillance project. All surveillance data (aggregated data) of antibiotic use and antimicrobial resistance from each hospital were submitted to local Ministry of Health for analysis. Two infection control specialists conducted the surveillance data validation.

Results: A hundred and sixty-one participating hospitals provided information about antibiotic use in 2,093,548 patients. A total of 950,138 (45.38%) received one or more antibiotics; 542,754 (25.93%) for treatment. Of those on antibiotics for therapeutic purposes, 247,875 (45.67%) had microbiology testing before receiving treatment. Among gram-negative bacteria, i.e. Enterobacteriaceae of 27,881 strains, Klebsiella pneumoniae of 18,256 strains, Pseudomonas aeruginosa of 14,553 strains, Acinetobacter baumannii of 11,788 strains, the proportions of carbapenem-resistant Acinetobacter baumannii (CRAB), carbapenem-resistant Pseudomonas aeruginosa (CRPA), carbapenem-resistant Klebsiella pneumoniae (CRKP), carbapenem-resistant Enterobacteriaceae (CRE) isolated from all samples were 51.32%, 13.76%, 7.09% and 1.80%, respectively. Among gram-positive bacteria, i.e. Staphylococcus aureus of 13,101 strains, Enterococci of 6,109 strains, the proportions of methicillin-resistant Staphylococcus aureus and vancomycin-resistant Enterococci (VRE) isolated from all samples were 35.11% and 1.17%, respectively. Furthermore, the proportions of CRAB, CRPA, CRKP, CRE, MRSA, and VRE isolated from blood samples were 51.22%, 13.76%, 10.26%, 2.86%, 33.48%, and 1.17%, respectively.

Conclusions: Clinical antibiotics use in the northwestern China largely relied on empirical treatment. Antimicrobial resistance was still one major concern in view of the relatively high rate of antibiotic-resistant bacteria, not only from all samples but also from blood samples.

Study of the relationship of infections of *Chlamydophila pneumoniae* and *Mycoplasma pneumoniae* with recurrent course of respiratory sarcoidosis

Diana Antipushina¹, Marina Smirnova², Andrey Zaytsev*³

¹National Medical Research Center for Preventive Medicine, Moscow, Russian Federation, ²National Medical Research Center for Preventive Medicine, Moscow, Russian Federation, ³Burdenko Hospital, Moscow, Russian Federation

**Background:** It was found that patients with respiratory sarcoidosis (RS) have elevated antibody titers (AB) to *Chlamydophila pneumoniae* (C.p.) and *Mycoplasma pneumoniae* (M.p.) more often than healthy people and patients with interstitial pneumonia. However, we did not find information about the impact of intracellular respiratory pathogens on the incidence of relapses RS.

**Materials/methods:** The prospective study of patients with newly diagnosed RS was performed. All patients underwent the paired blood serum study of the level of AB IgA and IgG to C.p. and M.p. using enzyme immunoassay initially and 2 weeks after. A positive increase in the AB titer was taken 2 or more times. We calculated the OR (95% CI) of the development of the recurrent course of RS taking into account each type of AB.

**Results:** 60 patients (55 men [91.7%] and 5 women [8.3%]) with morphologically confirmed RS were examined. The average age was 33.9±10.8 years. The stage II of RS was in 80% (48) of patient, stage I – in 18.3% (11), and generalized sarcoidosis - in 1.7% (1). Average follow-up was 24.6±10.8 months. Recurrent course of RS was observed in 7 patients (11.7%). Elevated AB titers were detected in 29 patients: isolated infections (either C.p. or M.p.), and combinations thereof. Signs of current infection were detected in 30% (20), transferred - in 35% (21). In patients with elevated titers of AB, no clinical manifestations of respiratory tract infection were observed. OR of recurrent course of RS was for AB IgA C.p. - 0.57 [95% CI 0.06-5.2], AB IgG C.p. - 1.72 [95% CI 0.13-4.5], AB IgA M.p. - 1.31 [95% CI 0.13 - 12.78], and AB IgG M.p. - 0.51 [95% CI 0.06-4.66]; p>0.05 for each parameter.

**Conclusions:** Elevated titers of AB to C.p. or M.p. can be detected in 48.3% of patients with RS, but these titers are not associated with the recurrent course of RS. Currently, there is no convincing data on the benefits of antibiotic therapy for the prevention of recurrent course of RS. Further studies explaining the relationship of C.p. and M.p. with RS are needed, including an assessment of immunological mechanisms.

**Presenter email address:** a-zaicev@yandex.ru
Abstract 6871

In vitro susceptibility of carbapenem-resistant Enterobacterales urinary isolates to nitroxoline and other oral urinary antibiotics

Agnes M. Sonnevend1, Akela Ahmed Ghazawi2, Tibor Pal2

1University of Pécs Faculty of Medicine, Pécs, Hungary, 2United Arab Emirates University, Al Ain, United Arab Emirates

Background: Nitroxoline is a recently re-introduced antibacterial agent to treat urinary infections. The aim of the study was to compare the in vitro efficacy of this drug to other orally administered urinary antibiotics against a collection of carbapenem resistant Enterobacterales (CRE) urinary isolates.

Materials/methods: MICs of nitroxoline, fosfomycin, nitrofurantoin, trimethoprim-sulfamethoxazole and ciprofloxacin for a collection of well-characterized CRE (n=222) isolated from urine in 5 hospitals in Kuwait (n=39) and 13 hospitals in the United Arab Emirates (n=183) were determined by broth microdilution. The collection comprised of OXA-48-like (n=75), VIM (n=5), NDM (n=80), KPC (n=3) producing, NDM and OXA-48-like (n=30) and NDM and VIM (n=2) co-producing isolates, as well as carbapenemase non-producing (n=27) strains, and it also included two previously characterized metallo-beta-lactamase producing pan-drug resistant Klebsiella pneumoniae. Susceptibility was interpreted using the EUCAST breakpoints for urinary Escherichia coli isolates.

Results: The MIC90/50 and susceptibility rates of the collection is shown in the Table.

<table>
<thead>
<tr>
<th>Antibiotic</th>
<th>MIC90</th>
<th>MIC50</th>
<th>Susceptibility rate %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ciprofloxacin</td>
<td>&gt;64</td>

<td>16</td>
<td>8</td>
<td>92.3</td>
</tr>
</tbody>
</table>

All E. coli (n=36) were susceptible to nitroxoline with 4/8 mg/L MIC50/90. Seventeen K. pneumoniae had MIC of nitroxoline >16 mg/L, nonetheless, the two pan-drug resistant K. pneumoniae exhibited nitroxoline MIC below the breakpoint (MIC 8 and 16 mg/L). Nitroxine MIC50/90 of K. pneumoniae (n=169) was 8/32 mg/L.

Conclusions: Of the five oral urinary antibiotics tested, nitroxoline exhibited by far the best in vitro efficacy against urinary CRE isolates. More than 90% of CRE (205/222), including two K. pneumoniae resistant to all other available antibiotics, would be classified as susceptible, if the current EUCAST susceptibility breakpoints for urinary E. coli were applied. Consequently, if clinically feasible, nitroxoline appears to be the best option for oral treatment of urinary tract infections caused by CRE.

Presenter email address: pal.agnes@pte.hu
Is Lactobacillus crispatus a marker of cytolytic vaginosis in women under 45-years old?

Leticia Fontan¹, Ayla Yarci Carrión¹, Sara Gómez De Frutos¹, Arturo Manuel Fraile Torres¹, Laura Cardeñoso*¹, Alicia García¹

¹Hospital de La Princesa, Madrid, Spain

**Background:** Cytolytic vaginosis (CV) occurs due to overgrowth of lactobacilli, which causes a decrease in vaginal pH. In gram staining, abundant gram-positive bacilli (GPB) compatible with *Lactobacillus* and citolysis with bare cell nuclei are observed. Clinically it is often confused with vulvovaginal candidiasis. Some studies have postulated the possibility that *Lactobacillus crispatus* could be a marker of this pathology. The objective of this study was to identify *L. crispatus* as a marker of CV by MALDI-TOF identification directly from the culture of vaginal exudates.

**Materials/methods:** Gram stains of vaginal exudates from 38 symptomatic women were studied. If the staining showed cytolysis along with a significant amount of GPB compatible with *Lactobacillus*, the patients became part of the CV group. If Gram staining showed GPB without the presence of cytolysis, the patients became part of the “normal microbiota” (NM) group. In all samples, MALDI-TOF MS was used for identification directly from the culture. Vaginal pH data was not available. Patients older than 45 years old (who may be in menopause) and MALDI-TOF interpretations with a score lower than 1.7 were excluded.

**Results:** Of the 22 patients belonging to the CV group, 7 were excluded. Average age: 31.7 years old. MALDI-TOF identifications: *L. crispatus* 73.3% [n=11], *Lactobacillus jensenii* 20% [n=3], *Lactobacillus iners* 6.6% [n=1]. Of the 16 patients belonging to the NM group, 4 were excluded. Average age: 37.1 years old. MALDI-TOF identifications: *L. iners* 58.3% [n=7], *L. jensenii* 16.6% [n=2], *Lactobacillus gasseri* 16.6% [n=2], *L. crispatus* 8.3% [n=1]. *L. crispatus* was the microorganism most frequently identified in the CV group [p<0.001] and so was *L.iners* in the NM group [p<0.01]. There was no statistically significant difference between the groups with the other *Lactobacillus* species.

**Conclusions:** Diagnosing CV is crucial to avoid unnecessary antifungal treatments that will increase vaginal microbiota disorders. That is why it is important to identify factors that help diagnosing this pathology. One of them could be the abundant presence of *L. crispatus* in the culture in combination with a gram stain suggestive of CV. Further studies will be required studying the pH to help confirming the diagnosis of CV.

Abstract 6876

**Evolution of multidrug-resistant organisms active surveillance strategy in a Portuguese acute care hospital, from 2015 to 2018**

David Peres, Ana Cipriano, Valquiria Alves, Fernanda Vieira, Ilda Devesa, Isabel Neves

1 Pedro Hispano Hospital, Matosinhos Local Health Unit, Matosinhos, Portugal, 2 Santo Antonio Hospital, Porto University Hospital Center, Porto, Portugal

**Background:** Multidrug-resistant organisms (MDRO) are a worldwide public health concern. Infection control guidelines advocate a strategy based on two central cornerstones: patient contact isolation and active screening tests, in order to contain MDRO dissemination. We describe the evolution of methicillin-resistant *Staphylococcus aureus* (MRSA) and carbapenemase-producing *Enterobacteriaceae* (CPE) active surveillance strategy in a Portuguese 340 bed acute care hospital, between 2015 and 2018.

**Materials/methods:** MRSA screening, through nasal swab, and CPE screening, through rectal swab, was implemented using real-time PCR methodology. A selected population for screening was defined, namely, in patients to be admitted: (1) from other hospitals/nursing homes, (2) with history of hospitalization (in national or abroad units), (3) antibiotic exposure in the last 6 months, (4) in intensive and intermediate care; (5) with chronic wounds (local swab for MRSA screening) and (6) doing haemodialysis. Direct contacts of newly detected inpatients were subjected to MRSA/EPC screening too. Every patient with suspicion/confirmation of MRSA/EPC was treated in contact isolation. In 2017 MDRO risk assessment was implemented to all patients to be admitted.

**Results:** A total of 13046 MRSA and 5905 EPC screening tests were completed, with a continuous rise in this time interval. The percentage of MRSA positive tests declined from 2015 to 2017 (10.9% to 6.4%) but, during 2018, increased to 7.8% (P=0.022) [Image 1]. The evolution of EPC positive screening tests is rising since 2016: from 3.5% to 4.1% in 2017 and 5.4% in 2018 (P=0.032). Considering a density of incidence, EPC increased continuously these four years, from 0.05 to 1.28 cases per 1000 patient-days (P=0.454) and MRSA increased since 2017 (2.09 versus 2.35, P=0.021). In these four years, MRSA positive patients were 8.6 years older than those who had negative test (P<0.001) and, in case of EPC, this difference was 4.7 years (P<0.001).

**Conclusions:** A screening strategy to MRSA and EPC in an acute healthcare setting is described. There is a tendency to the increase of this MDRO’s, which has important infection control implications in their management. Continuous active surveillance is needed, with periodical revision of risk criteria for screening.

Investigation of a hospital outbreak of multi-drug resistant *Klebsiella pneumoniae* ST307, including isolates producing OXA-244 carbapenemase

1University Hospital of Wales, Specialist Antimicrobial Chemotherapy Unit, Public Health Wales, Cardiff, United Kingdom, 2University Hospital of Wales, Pathogen Genomics Unit, Public Health Wales, Cardiff, United Kingdom, 3Cardiff University, Heath Park Campus, School of Medicine, Cardiff, United Kingdom, 4No 2 Capital Quarter, Public Health Wales, Cardiff, United Kingdom, 5Matrix House, Swansea Enterprise Park, Public Health Wales, Swansea, United Kingdom, 6Singleton Hospital, Public Health Wales, Sketty, United Kingdom

Abstract third-party references: Public Health Wales

**Background:** Carbapenemase producing *Kp* are becoming increasingly common. Antibiotic treatment options are limited and invasive infections are associated with significant mortality. Patient screening for Carbapenemase Producing Enterobacterales (CPE) was commenced on a surgical ward in a Welsh Hospital following isolation of CPE from two patient’s clinical samples. An outbreak investigation followed during which further OXA-48-like producing *Kp* were identified from clinical and screening samples.

**Materials/methods:** Susceptibility testing was performed according to EUCAST methods. OXA-48-like producing isolate were identified using in house RT-PCR. For NGS DNA was extracted using the eMAG (Biomerieux), libraries prepared using Nextera XT and sequenced using the V2 assaag on MiSeq sequencers (Illumina). Read assemblies were performed using Spades and run through Restfinder and PubMLST. The relationships of the Welsh isolates were contextualized by comparison with a previously published international dataset of 50 ST307 genomes. Sequence mapping used the software Snippy, against strain 616 (Accession CP0026495). Following the removal of regions that were putatively identified as repeats or mobile elements, variant sites were identified and phylogenetic trees produced using IQTree.

**Results:** The investigation identified a complex outbreak dominated by *Kp* ST307 producing OXA-244, identified in nine patients at the time of writing. All isolates were MDR, including resistance to ertapenem and variable activity against meropenem. All isolates were sensitive to amikacin, colistin and cefazidime-avibactam. Further NGS analysis confirmed that these isolates were closely related, forming a single, distinct, cluster on the global ST307 phylogenetic tree. This was compatible with epidemiological findings and isolation of cases, basic infection control and enhanced cleaning halted onward spread. During investigation further MDR, OXA-negative *K. pneumoniae* were also identified from clinical samples. These were predominantly either ST307 or ST1788. The ST307, OXA-negative isolates showed varying degrees of core genome identity to the outbreak strain.

**Conclusions:** *Kp* ST307 is an emerging high risk clone associated with nosocomial spread of infection and multi-drug resistant phenotype. Increasing reports of this organism acquiring carbapenemase genes are a public health concern. NGS can act as a useful adjunct to epidemiological investigations in understanding and controlling outbreaks, and can enhance our understanding of the epidemiology of nosocomial pathogens.

High prevalence of Lymphogranuloma venereum in men who have sex with men in Alicante, south-east Spain

Victoria Ortiz-De La Tabla*,1, Gregoria Gázquez1, Ana Infante1

1Hospital Universitari Sant Joan d’Alacant, Servicio de Microbiología, Sant Joan d’Alacant, Spain

Abstract third-party references: Ortiz de la Tabla, V, Infante Urrios, A, Gázquez Gómez, G

Background: Lymphogranuloma venereum (LGV) is a sexually transmitted infection (STI) caused by L serovars of Chlamydia trachomatis (CT). In developed countries LGV is predominantly associated with rectal infection in HIV-positive MSM. Data on the prevalence of LGV in Europe are sparse and not all laboratories have the capacity to identify LGV serovars. Alicante is a holiday town in Southeast Spain that receives travelers from many European countries, which can contribute to dissemination of STI. Our aim was to evaluate LGV prevalence and describe clinical and demographic characteristics of patients infected by CT LGV and non-LGV.

Materials/methods: From January to December of 2018, all anorectal samples positives for CT using the Cobas 4800 Real-Time CT/NG PCR (Roche®) were tested for LGV serovars. A confirmation LGV/non-LGV in house real-time PCR was performed.

Results: A total of 321 anorectal samples were tested (314 exudates and 7 biopsies).

Overall CT and LGV positivity was 11.8% (38/321) and 4% (13/321), respectively. Among 38 CT positive specimens, LGV positivity was 34.2% (13/38). All CT positives patients were MSM, with an average age of 33 years. Compared to CT non-LGV, patients with LGV were more likely to have rectal mucopurulent or bloody discharge (84.6% vs 39%; p=0.011), tenesmus and/or rectal pain (61.5% vs 5.6%; p=0.001) and inguinal lymphadenopathy (23% vs 0%; p=0.034). Three LGV positive biopsies specimens were from patients with symptoms suggestive of inflammatory bowel disease. More than half of non-LGV patients did not have symptoms at diagnosis, whereas only a single LGV case was asymptomatic.

Conclusions: We found a high prevalence of CT and LGV in MSM. The rate of LGV found in non-HIV patients was higher than expected. Unlike CT non-LGV, most cases of LGV were symptomatic and presented clinically with non-specific proctocolitis. Public health strategies should include testing for LGV on all CT positive samples from MSM, independently of their HIV status.

Assigning the plasmidome: a novel approach to compare plasmids independent of host and incompatibility type
Nikolaos Strepis*1, Juliëtte A. Severin1, Corné H. Klaassen1
1Erasmus MC, Rotterdam, Netherlands

Background: Plasmids carry a large diversity of antimicrobial resistance genes and are hosted in numerous species. Plasmids are nowadays considered the main protagonists for AMR transmission and other virulence factors. Epidemic plasmids can cause outbreaks which often remain undetected. In general, plasmids are complicated entities usually defined by high sequence versatility, which hampers their surveillance. In Enterobacteriales, plasmids can be identified by their incompatibility (Inc) type. In this study, we aim for an unbiased comparison including all currently available plasmid sequences, proposing a method to characterize plasmid sequences independent of host species and Inc type.

Materials/methods: A total number of 97,000 plasmid sequences were obtained from NCBI (08-10-2019). Prokka was used for annotation and Roary was utilized to generate the gene presence/absence information for all plasmids using 85% identity as cut-off for gene sequence without splitting paralogues. A text-mining algorithm in python was used for extracting metadata from Genbank records. RGI based on CARD was used for identifying resistome and Plasmidfinder for defining Inc types. An algorithm based on python was used to concatenate the data and apply filters for comparison. We applied our approach to plasmids carrying mcr (1-10) genes.

Results: Functional genomics comparison among all currently available plasmids was possible. We observed that every Inc type carried a specific backbone of genes. Each backbone was different regarding number and type of genes for plasmids with different size and Inc type (e.g. IncX4, IncI2 and IncHI2). A particular IncX4 mcr-1-carrying plasmid was present in more than nine species. Also, we observed plasmids carrying multiple Inc types. Our approach enabled comparison of plasmids from species where Inc types are unidentified. We were able to describe the evolution of mcr-containing plasmids and their global distribution including hosts.

Conclusions: Here, we propose a comparative collective method for characterizing plasmids independent of species and Inc type and show its applicability for mcr gene epidemiology. This unbiased approach can be applied for any gene of interest. Defining the plasmidome will provide more insight into the plasmidal epidemiology and the AMR landscape, which may contribute to new AMR prevention policies in local and global context.

Molecular epidemiology of carbapenemase-producing *Escherichia coli* in northern Spain studied by molecular typing techniques and next-generation sequencing

Xenia Vázquez1,2, Vanesa García Menéndez3, María De Toro4, Pilar Lumbreras Iglesias1,2,5, Jesús Rodríguez-Lozano6, Andrés Canut7, Pedro De La Iglesia8, Beatriz Iglesias9, Azucena Mora Gutiérrez3, Jorge Blanco1, M. Rosario Rodicio1,2, Javier Fernández2,5

1University of Oviedo Campus del Cristo, Oviedo, Spain, 2Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, 3Campus de Lugo USC, Lugo, Spain, 4Biomedical Research Center of La Rioja (CIBIR), Logroño, Spain, 5Hospital Universitario Central de Asturias, Oviedo, Spain, 6Marqués de Valdecilla University Hospital, Santander, Spain, 7Hospital Universitario de Cabueñes, Gijón, Spain, 8Hospital Universitario San Agustín, Avilés, Spain

**Background:** Carbapenemases have spread worldwide in *Enterobacteriaceae*, limiting the therapeutic options available to treat the infections they cause. These enzymes are becoming more frequent in *Escherichia coli*, and this is a cause of concern because of the importance of this species in hospitals and its potential role in the transmission of antimicrobial resistance in the community.

**Materials/methods:** In the present study, 42 clinical isolates of carbapenemase-producing *E. coli* recovered between March 2017 and March 2018 in four hospitals located in northern Spain, and primary care centers associated with them, were analyzed. Bacterial genomes were sequenced with Illumina in a HiSeq 1500 to generate 125 bp paired-end reads. Serotyping, MultiLocus Sequence typing (MLST), clonotyping, as well as identification of phylogenroups, resistance genes, virulence genes and their genetic context, were accomplished by PCR and bioinformatics analysis (SeqSero, MLST, ResFinder, CARD, ArgAnnot, pMLST and PLACNETw). A phylogenetic tree was constructed using RAxML, based on SNPs in the core genome.

**Results:** Forty isolates were positive for the *bla* <sup>OXA-48</sup> gene while the remaining two carried *bla* <sup>VIM</sup>. All of them were multidrug-resistant and 23.8% harbored genes encoding extended-spectrum-β-lactamases (*bla<sup>CTX-M-1</sup>, *bla<sup>CTX-M-15</sup>, *bla<sup>CTX-M-27</sup>, *bla<sup>CTX-M-55</sup>, *bla<sup>TEM-10</sup>, *bla<sup>TEM-30</sup>, *bla<sup>TEM-150</sup> and *bla<sup>SHV-102</sup>). A wide variety of determinants conferring important resistances, such as plasmid-mediated quinolone resistance (*qnrB2*, *qnrS1* and *qnrS2*) or fosfomycin resistance (*fosA7*) were also found. Isolates belonging to diverse phylogroups: A (10), B1 (12), B2 (14), C (4) and F (2), and sequence types (Figure 1). Three clonotypes were determined within the O25b:H4-B2-ST131 clonal group: CH40-22 (2), CH40-30 (7) and CH40-298 (1). Fifteen isolates conformed the ExPEC and another 15 the UPEC status. The phylogenetic tree based on SNPs correlated with the STs.

**Figure 1:** Phylogenetic tree of the carbapenemase-producing *Escherichia coli* genomes. The tree is based on the core genome SNPs (2,509,672 +/- 154 bp; 2,633 core CDS with 90% identity; 96% pairwise alignment coverage). Bootstrap support values of 1,000 replicates are shown at the nodes. The hospital of origin of the isolates is colored in red (Hospital Universitario Central de Asturias, HUCA), black (Hospital Universitario San Agustín, HUSA), green (Hospital Universitario Marqués de Valdecilla, HMV) and dark blue (Hospital Universitario de Cabueñes, HUCAB).

**Conclusions:** A wide variety of carbapenemase-producing *E. coli* strains are circulating in northern Spain. Some of them belong to high-risk international clones such as ST58, ST131, ST410, ST48, ST648 and ST1193, carrying other antimicrobial resistances of concern and with potentially spread capacity, hence representing a threat to patients both in hospitals and the community.

Abstract 6884

A high-resolution whole genome multilocus sequence typing (wgMLST) scheme for easy and scalable detection of *Streptococcus pyogenes* outbreaks

Dieter De Coninck¹, Katleen Vranckx*¹, Jill Dombrecht¹

¹bioMérieux, Sint-Martens-Latem, Belgium

**Background:** *Streptococcus pyogenes* is an infrequent, but usually pathogenic, component of the skin microbiota. Many important human diseases, which can range from mild skin infections to life-threatening systemic diseases, can be caused by *S. pyogenes*. Some strains are toxigenic causing infections that may lead to the potentially life-threatening streptococcal toxic shock syndrome. Typing based on whole genome sequencing data could help in quickly characterizing these toxigenic strains for outbreak analysis.

**Materials/methods:** We developed a whole genome Multi Locus Sequence Typing (wgMLST) scheme starting from 304 publicly available, annotated genomes that represent the known diversity of *S. pyogenes*. The scheme was validated against 7 recent published outbreaks characterized by whole genome Single Nucleotide Polymorphism (wgSNP) (Athey et al. 2016, Beres et al. 2017, Chalker et al. 2017, Chochua et al. 2017, Cornick et al. 2017, Davies et al. 2014, Engelthaler et al. 2016). Alleles were identified in BioNumerics 7.6.3 starting both from the assembled genome, using a BLAST based approach with 80% similarity threshold, and the raw sequencing data, using a k-mer based approach.

**Results:** In total, 991 strains were analyzed in less than two days. Using the wgMLST results we were able to reach the same conclusions regarding the outbreaks as the original authors did based on wgSNP results. wgMLST has the advantage that is more scalable than wgSNP. That is, each newly analyzed strain can be easily and directly compared to previous strains without the need of comparing it to a common reference. As such, we compared all 991 strains in one analysis to investigate whether the outbreaks could be linked with each other. The included strains originated from 5 different countries: Canada, Hong Kong, UK, USA and Scotland. In a few cases strains originating from different countries differing less than 10 loci were found, indicating possible links between the outbreaks.

**Conclusions:** The *S. pyogenes* wgMLST scheme developed in BioNumerics proved to be a valid and powerful tool for easy and scalable outbreak analysis. It enables finding possible worldwide links between different, individually described outbreaks.

Abstract 6888

**Role of PRAS40/mTOR/Akt in the intracellular development of Toxoplasma gondii tachyzoites**
Manuel González-Del Carmen1, Valeria Ailyn Cortés Mollinedo*1, Gilberto Aldair Rojas García1

1Universidad Veracruzana: Facultad de Medicina campus Cd. Mendoza, Ciudad Mendoza, Mexico

**Background:** *Toxoplasma gondii* is an obligate intracellular protozoan able to invade and proliferate in all nucleated cells. In immunocompromised patients they produce various diseases that can lead to death. The pathogenicity of this parasite depends directly on its ability to control cell proliferation through various biochemical signals. PRAS40 [Proline Rich Akt Sustrate 40 kDa] may be involved in the survivor of the parasite by activating mTOR pathway by phosphorylation.

**Materials/methods:** Tachyzoites extracted from peritoneal lavage of a murine BALB/c were used for Invasion experiments in 3T3 NIH cell cultures at different times: 0, 6, 12 and 18 hours. Some experiments included the use of mTOR inhibitors drugs [Torin-2] plus tachyzoites in the cultures using times: 6, 12 and 18 hours. We also have 2 control conditions using insulin, the cultures were stimulated for 15 minutes with insulin, and in one of them it was added Torin-2 for 30 minutes. The proteins were extracted and analyzed by poly acrylamide gel electrophoresis [PAGE] and Western Blot using antibodies for the proteins we were studying.

**Results:** It was found that the *Toxoplasma gondii* develop increases the phosphorylation of PRAS40 in cell cultures, especially in the incubated at 12 hours. This phosphorylation was observed dependent on mTOR and Akt.

**Conclusions:** Results from the study suggest that PRAS40 is involved in the intracellular development of *Toxoplasma gondii* Tachyzoites, apparently the pathway regulated by mTOR participates in this process, contributing to the arrest of the host cell division and providing stability to the intracellular niche to the parasit.

Abstract 6892

**Evaluation of QIAseq 16S/ITS screening panel kit sequencing 6 regions to analyse 16S microbiota**

Mathilde Payen*1, Bidet Philippe1, Sabine Delannoy1, Patrick Fach1, Aurey Monjault1, Stephane Bonacorsi1,2, André Birgy1,2

1Hôpital Robert-Debré, AP-HP, Service de Microbiologie, Centre National de Référence Escherichia coli, Paris, France, 2Université de Paris, IAME, INSERM, Paris, France, 3ANSES, Plateforme IdentyPath, Maisons-Alfort, France

**Background:** The advent of high throughput sequencing allows the study and the understanding of the bacterial microbiota. Most of the time, only one region of the 16S ribosomal RNA is sequenced and analyzed for the bacterial microbiota 16S study. Here, we evaluated the QIAseq 16S/ITS Screening Panel kit (Qiagen®) allowing the amplification and sequencing of six 16S rRNA regions: V1V2, V2V3, V3V4, V4V5, V5V7, V7V9.

**Materials/methods:** Stools from seven children with acute lymphoblastic leukaemia were studied at different times of their treatment: one sample before chemotherapy (P1) and two after (P2 and P3). In total 21 stools were analyzed. DNA extraction was performed by QIAamp DNA stool Mini (Qiagen®). Amplicon libraries were prepared using QIAseq 16S/ITS Screening Panel kit (Qiagen®) and sequencing was performed on MiSeq 2x300 bp V3 kit. Data were analyzed using CLC Genomics Workbench 12 (Qiagen®) pipelines.

**Results:** The number of reads obtained before trimming varied between 5,950,910 for V5V7 region and 2,491,512 for V3V4 region. After trimming, the remaining sequence percentages were 40% for V1V2 and only 26% for V3V4. The rarefaction curves were reached for all samples in all regions except for 2 samples in V2V3. The percentage of OTUs assigned to gender was comparable for all regions. In order to assess the microbiota composition and ensure that important families are not missed by any of the PCR primers, we compared the relative abundances of Lachnospiraceae, Enterococcaceae, Enterobacteriaceae and Bacteroidaceae. No significant differences between relative abundances were found and no significant families were missed. Finally, the choice of 16S rRNA regions does not seem to impact significantly the α-diversity of bacterial microbiota. However, the regions V3V4 and V4V5 had the lowest Shannon index (α-diversity).

**Conclusions:** Our study highlights that the use of 6 regions to analyze 16S microbiota may not be necessary. Few differences between regions were observed with slight differences in terms of diversity. In contrast, sequencing depth is crucial to have comprehensive data. V3V4 region was the least sequenced region suggesting that it may not be the best, with the primers used, to analyze 16S microbiota.

**Abstract 6896**

**Rapid detection of colistin-resistant *Klebsiella pneumoniae* using colistin drop test**

Verônica Rocha*1, Daniela Nascimento1, Matheus Sales2, Adson Martins1, Jailton Azevedo1, Allan Malheiros3, Ledilce Ataide3, Mitermayer Reis4, Joice Reis1,2

1Laboratory of Pathology and Molecular Biology (LPBM), Gonçalo Moniz Research Institute, Oswaldo Cruz Foundation, Salvador, Brazil, 2Faculty of Pharmacy, Federal University of Bahia, Salvador, Brazil, 3Bahia State Health Department, Salvador, Brazil, 4Federal University of Bahia; Gonçalo Moniz Research Institute, Oswaldo Cruz Foundation, School of Public Health, Yale University, Salvador, Brazil

**Abstract third-party references:** This study is supported by Laboratory of Pathology and Molecular Biology (LPBM), Gonçalo Moniz Research Institute, Oswaldo Cruz Foundation, Salvador, Bahia, Brazil and Faculty of Pharmacy, Federal University of Bahia, Salvador, Bahia, Brazil.

**Background:** The emergence and spread of carbapenem and colistin-resistant *Klebsiella pneumoniae* (ColR-KP) is an important threat to global health. At the diagnostic level, the only approved susceptibility testing method for colistin is broth microdilution (BMD). However, manual BMD is time consuming and often unfeasible in the clinical laboratory. During an outbreak of ColR-KP in a Tertiary Hospital of Salvador, Bahia / Brazil, was used the colistin drop, a less complex methodological alternative, and the BMD. In addition, the mechanisms of carbapenemic and colistin resistance were also evaluated.

**Materials/methods:** Phenotypic detection of carbapenemase production was performed using the Modified Carbapenemic Inactivation Method (mCIM) and the EDTA-Modified Carbapenemic Inactivation Method (eCIM) according to the CLSI standardized methodology. The PCR reaction was performed for *bla*OXA-48-LIKE, *bla*GES, *bla*KPC, *bla*IMP, *bla*VIM, and *bla*NDM. The colistin drop test was compared with BMD results.

**Results:** Fifty-nine ColR-KP were evaluated. The mCIM test was positive in 54 (91.5%) and the eCIM in 51 (86.4%). Nine (17.7%) of the eCIM positive strains were *bla*NDM and none was IMP or VIM, suggesting the possibility of another metallo-β-lactamase, currently under investigation. Fifty-one (86.4%) *bla*KPC were identified. The mCIM/eCIM showed 1 false negative in which the *bla*NDM gene was detected. One *bla*GES was detected in a negative mCIM/eCIM strain.

The *mgrB* gene was evaluated in 58 samples, being detected mutation in 43 (74.2%) and non-detection of the gene in 4 (6.9%). In 11 (19%) stains the *mgrB* gene was detected unchanged suggesting another mechanism of resistance. The mcr-1 test was negative in all samples. Of the 57 samples submitted to the drop colistin test, correlation with BMD were 98.2%. The only divergent case was a strain with a MIC of 2 mcg/ml and a drop colistin test positive and no detection of *mgrB* gene which would justify the resistance.

**Conclusions:** The colistin drop test showed a good correlation with BMD but a limitation is the non-determination of the colistin MIC. Although *bla*KPC was detected in 86.4%, the eCIM test suggested the presence of an unidentified metallo-beta-lactamase. The main mechanism of colistin resistance detected was the mutation of the *mgrB* gene.

**Presenter email address:** veronicarocha.infecto@yahoo.com
Synthesis and antibacterial evaluation of 9-substituted palmatine analogues as a novel class of anti-
H. pylori agents targeting urease

Wang Yanxiang*, Jing Pang¹, Tianyun Fan¹

¹Chinese Academy of Medical Sciences and Peking Union Medical College, Institute of Medicinal Biotechnology, Beijing, China

**Background:** Antibiotic-resistant *Helicobacter pylori (H. pylori)* was increasingly found in infected individuals, which resulted in treatment failure and required alternative therapeutic strategies. This research was mainly focused on discovering novel antibacterial candidates with unique scaffold for the treatment of infections arising from *H. pylori*.

**Materials/methods:** A library of 9-substituted palmatine derivatives constructed in our lab was screened for their anti-*H. pylori* potencies using phenotype screening assay. MICs of all prepared compounds were tested on seven *H. pylori* strains including standard strains and clinical isolates using agar dilution method according to Clinical and Laboratory Standards Institute (CLSI) guidelines. All prepared compounds were characterized by ¹H NMR, ¹³C NMR and ESI-HRMS.

**Results:** A series of new 9-substituted palmatine including ethers, amines and amides were synthesized and evaluated for their antibacterial effect. Among them, compounds HP-1 and PN-1 exhibited high potency against metronidazole-sensitive and resistant strains of *H. pylori* with MIC values of 2-8 μg/mL. Preliminary mechanism study indicated that compounds HP-1 and PN-1 significantly inhibited urease which neutralizes stomach acid in order to create a suitable pH environment that the bacterium requires to survive and colonize.

**Conclusions:** Therefore, we consider 9-substituted palmatine derivatives to be a novel class of anti- *H. pylori* agents worthy of further investigation.

**Presenter email address:** wangyanxiang@imb.pumc.edu.cn
Clinical performance of the novel multiplex real-time PCR ResistancePlus MG FleXible: a cartridge-based assay for simultaneous detection of *Mycoplasma genitalium* and macrolide resistance

Miguel Fernández-Huerta*1, Paula Salmerón1, Aroa Silgado Gimenez1, Tomàs Pumarola-Suñé1, Mateu Espasa2, Yannick Hoyos-Mallecot1, Judit Serra Pladevall1

1Vall d’Hebron University Hospital, Barcelona, Spain, 2Parc Taulí University Hospital, Sabadell, Spain

**Background:** *Mycoplasma genitalium* (MG) has a disturbing capacity to develop antibiotic resistance and may soon become untreatable. The resistance-guided treatment strategy has demonstrated very good efficacy against MG and prolongs the utility of existing antibiotics by optimizing antimicrobial stewardship. The aim of this study was to evaluate the clinical performance of the novel molecular cartridge-based test ResistancePlus® MG FleXible (SpeeDx Pty Ltd, AU) on the GeneXpert Infinity-48s Platform (Cepheid, USA) for detection of MG and mutations conferring macrolide resistance.

**Materials/methods:** The ResistancePlus® MG FleXible test detects MG through the *mgpB* gene and the macrolide resistance-associated mutations A2058G, A2059G, A2058T and A2058C in the 23S rRNA gene. Between March 2019 and April 2019, a total of 146 samples [95 MG positive and 51 MG negative], were collected at the Vall d’Hebron University Hospital in Barcelona, Spain. Specimens consisted of 18 vaginal swabs, 32 endocervical swabs, 15 urethral swabs, 38 first-void urines and 43 rectal swabs. Results were compared to the Allplex™ STI Essential assay (Seegene, SK) for MG detection, while Sanger sequencing of the 23S rRNA gene was used for confirmation of macrolide resistance-associated mutations.

**Results:** Results are displayed in table 1. Only 63/90 ResistancePlus® MG FleXible positives were suitable for subsequent Sanger sequencing.

*aThese were two rectal swabs reported as non-mutant by the ResistancePlus® MG FleXible assay but harbouring mutations A2059G and A2058G, respectively, according to Sanger sequencing.

**Conclusions:** The ResistancePlus® MG FleXible assay is a rapid, simple and accurate assay for simultaneous detection of MG and macrolide resistance. This novel test may facilitate the implementation of the resistance-guided therapy for MG in many clinical settings, significantly improving clinical management and limiting antibiotic resistance selection.

A real-world review on QIDP designation: what lessons can we learn?
Archita Kukreja*1, Nuno Antunes2, Wing Hui3, David Holman2

1Decision Resources Group, Gurugram, India, 2Decision Resources Group, Burlington, United States, 3Decision Resources Group, Toronto, Canada

Abstract third-party references: Decision Resources Group

Background: Antibiotic resistance is a global crisis that threatens public health. In response to increasing antibiotic resistance, numerous initiatives have been undertaken to accelerate antibiotic development by addressing the barriers associated with antibiotics innovation. One such initiative is the qualified infectious disease product (QIDP) designation, which grants priority review and market exclusivity, among other incentives, to certain antibiotics for a specific indication.

Materials/methods: This study assesses the impact of QIDP designation on development and approval timelines and evaluates the time to first patient and use across indications. We evaluated US patient-level data from a real-world, outpatient claims data repository as well as US hospital charge master data covering more than 350 hospitals across 37 states from April 2014 to June 2019. To evaluate the correlation between real-world use and QIDP-designated indications, we assessed the relative usage of drugs across indications. Antibiotic utilization date and off-label usage were evaluated for 9 novel antibiotics launched between 2012 to 2018 using relevant medical codes and evaluating their corresponding diagnosis.

Results: Despite all evaluated antibiotics being labeled as QIDP, review durations took an average of eight months, exceeding the FDA target goal of six months. Analysis of real-world data indicated, the first prescription occurred within three months following launch, frequently in the indication included in the FDA label. Generally, a higher antibiotic usage was noted for the QIDP designated indication, but exceptions occur. Similarly, off-label usage happened within two months of the first on-label use. First use in pediatric populations was more variable, ranging from one month (ceftolozane/tazobactam) up to 25 months (oritavancin).

Conclusions: Our study highlights limited impact of QIDP designation in expediting regulatory approval, suggesting it may not be as impactful as intended from a commercial and resource allocation perspective. Moreover, despite antibiotic stewardship measures, off-label use of antibiotics is common, and driven by needs for agents active against resistant pathogens, or with better safety/tolerability profiles or more convenient administration. We believe that along with QIDP, other initiatives like relaxation of government reimbursement policies and incentivizing innovation will together help accelerate future antibiotic drug development.

Abstract 6902

Cure rate comparison between rifampicin mono-resistant and multidrug-resistant tuberculosis: a retrospective multi-centre study from 1990 to 2017

Niccolò Riccardi1,2, Simone Villa*2, Maurizio Ferrarese2,3, Paola Castellotti5, Matteo Saporiti2,3, Alessandro Torre4, Fabio Franzetti4, Laura Saderi5, Mario C. Raviglione2,6, Giovanni Sotgiu2,5, Luigi Codecasa2,3, Giorgio Besozzi7

1IRCCS Sacro Cuore Don Calabria Hospital, Department of Infectious - Tropical Diseases and Microbiology, Negrar di Valpolicella, Italy, 2StopTB Italia Onlus, Milan, Italy, 3Regional TB Reference Centre, Villa Morelli Institute/ASST Niguarda, Milan, Italy, 4 Luigi Sacco Hospital, Infectious Disease Department, Milan, Italy, 5University of Sassari, Clinical Epidemiology and Medical Statistics Unit, Department of Medical, Surgical and Experimental Sciences, Sassari, Italy, 6University of Milan, Global Health Centre, Milan, Italy

Background: World Health Organization (WHO) recommended in 2016 that all cases of rifampicin-resistant tuberculosis (TB), regardless of isoniazid susceptibility, should have been managed as multidrug-resistant (MDR) TB. The current updated WHO guidelines recommend the administration of all-oral regimens, if feasible. The present study aims to assess treatment outcomes in rifampicin mono-resistant (RMR) and MDR-TB.

Materials/methods: An observational, retrospective, multi-centre study was conducted using data from two Italian TB reference hospitals. Patients admitted from 1st of January 1990 to 31st of December 2017 were consecutively recruited. Demographic, epidemiological, and clinical variables of RMR- and MDR-TB cases were statistically compared.

Results: A total of 301 patients were diagnosed with RMR- (73, 24.3%) or MDR-TB (228, 75.7%). Their median age was 33 years and they were mainly male (188, 62.4%); 44 (14.4%) were HIV co-infected and 276 (91.6%) showed a pulmonary TB. Extra-pulmonary TB was more prevalent in RMR-TB (37% vs. 11%; p<0.0001). Positive culture for Mycobacterium tuberculosis was obtained in 297/301 (98.7%) cases and DST was performed in all 297 cases. The majority of RMR-TB cases (37; 52.9%) were Italian, whereas patients from Eastern Europe (73; 35.1%) were mainly affected by MDR-TB. Co-infection with HIV (33.8% RMR VS. 9.0% MDR-TB; P <0.0001) and social exclusion (22.2% RMR VS. 7.9% MDR-TB; P= 0.0001) were more prevalent in patients with RMR-TB. The overall treatment success rate was 66.9% (56.2% in RMR- VS. 68.0% in MDR-TB; P= 0.027). A lower treatment success was observed in those socially excluded (e.g., homeless and intra-venous drug users; P= 0.044) and with HIV co-infection (P= 0.07). Treatment success was more prevalent in patients treated with fluoroquinolone-containing regimens (78.3%VS. 51.3%; P <0.001). Mortality rate was 7.1% and 4.3% in RMR- and MDR-TB, respectively (P= 0.352).

Conclusions: Regimens combined with appropriate management of comorbidities and socio-economic hardship may improve treatment outcomes. The role played by social and clinical factors should be further assessed in a larger sample, including a large number of vulnerable population groups.

Abstract 6904

**Mass visitation of show caves as a threat to human health**

Rok Tomazin*1, Tadeja Matos1, Janez Mulec2

1University of Ljubljana, Institute of Microbiology and Immunology, Faculty of Medicine, Ljubljana, Slovenia, 2Slovenian Academy of Sciences and Arts, Karst Research Institute, Postojna, Slovenia

**Background:** Karst caves have been an attraction since the Middle Ages, and some became a place of mass visitation. Tourists emit bioaerosols inside caves which give a detailed view on conditions and dynamics in the atmosphere, and estimate human impact. Human-borne microorganisms can also represent a threat to human and environmental health. Mass cave tourism can impact people visiting or working in caves as well as ecology of the underground ecosystem.

**Materials/methods:** Air was sampled from February 2017 to November 2018 along footpaths before and during tourist visits in Postojna Cave, Slovenia, which is visited by more than 750,000 tourists annually, and in Škocjan Caves, Slovenia, which attracts more than 150,000 tourists annually. 4.5m³ of air was sampled by Coriolis-Impinger (Bertin Technologies, France) into 10mL of saline. 0.2mL were inoculated onto nutrient and blood agar plates and incubated aerobically at 20°C and 37°C for seven and two days, respectively. Concentrations of airborne microbes were expressed in CFU/m³ and identified by MALDI-TOF MS (Bruker Daltonik, Germany).

**Results:** Tourists significantly increased concentration of airborne microbes above the background level. The highest microbial load was in August when microbial biomass exceeded 300CFU/m³ at all sampling sites. The highest value (1146CFU/m³) was in a smaller chamber in Postojna Cave in the section Vivarij. In the air, a mix of bacteria typically associated with humans and other natural habitats was identified before and during tourist visits at all sites. Several isolates belonged to clinically important genera: *Staphylococcus*, *Pseudomonas*, *Moraxella*, *Acinetobacter*, *Aerococcus* and *Bacillus*.

**Conclusions:** Tourists impact air in show caves in terms of quantity and quality of airborne particles. Despite large underground chambers and air movements, the air always contained representatives of human microbiome. In the peak season, the microbial loads exceeded the maximum recommended value of 300CFU/m³ for indoor environments. Constant presence of Risk-Group 2 microbes in the air should be further evaluated as cave natural conditions can prolong their viability and enhance their transmission on longer distances. Further investigations should also estimate the potential health risks in susceptible hosts visiting caves during the peak season when concentration of airborne microbes is significantly elevated.

Abstract 6906

**Zooming into the CoNS group on a species level exposes high heterogenicity in prevalence and antibiotic resistance: an in-depth data analysis in the MALDI-TOF era**

Matthijs S. Berends*1,2, Christian Luz2, Yvonne Roelofs1, Jan Arends2, Gunnar I. Andriesse1, Corinna Glasner2, Alexander W. Friedrich2

1Certe Medical Diagnostics & Advice, Groningen, Netherlands, 2University of Groningen, University Medical Center Groningen, Groningen, Netherlands, 3Izore Center for Infectious Diseases, Leeuwarden, Netherlands

**Background:** For years, coagulase-negative Staphylococci (CoNS) were not considered a cause of systemic illness and were often regarded as contamination. Yet, recent literature shows that CoNS lead to septicemia and high mortality rates. Still, little is known about the prevalence and resistance of the 39 species of the CoNS group. Therefore, we aimed at filling this gap by performing a region-wide, comprehensive species-specific prevalence and antibiotic resistance analysis.

**Materials/methods:** In this retrospective study, we analysed all CoNS isolates from blood cultures of 9,121 patients from all 14 hospitals in the Northern Netherlands between 2013 and 2019. All isolates were determined to the species level using MALDI-TOF. Using the 'AMR' package written in the open-source software R, we applied EUCAST rules, corrected for first isolates and analysed resistance of the bug-drug combinations of all isolates.

**Results:** In total, we included 12,587 isolates for epidemiological analysis from 24 different CoNS species. The five most prevalent species spanned 98% of all species. No vancomycin resistance was found, but teicoplanin resistance is increasing over the years in most species. Furthermore, we defined 'CoNS sepsis' as having at least 3 positive blood cultures with the same species within 60 days. Following this definition, 8.2% of all patients suffered from CoNS sepsis. The relatively most common causal agent to this end was S. haemolyticus (584/459 patients, 12.6%), followed by S. lugdunensis (9/72 patients, 12.5%) and S. epidermidis (538/4,315 patients, 11.1%). S. haemolyticus showed the highest resistance in the CoNS group for almost all antibiotic classes. Additionally, significant differences were found in both prevalence and resistance between patient gender, age groups and types of hospital.

**Conclusions:** To the best of our knowledge, this is the first comprehensive analysis of the CoNS group in a region-wide approach, using solely MALDI-TOF for species identification. Although S. epidermidis and S. hominis were 8-10 times more prevalent than S. haemolyticus, the latter was associated with higher morbidity (CoNS sepsis rate) than S. epidermidis and S. hominis. This study highlights how large in-depth epidemiological analyses can generate new insights on the species level, that could help increase awareness and evaluate treatment options.

Leishmaniasis in immunocompromised individuals without HIV: not so different. A comparative analysis of 60 patients

Cecilia Tortajada*, Lidia Castellano1, Eva Calabuig2, Carmen Carratala3, Amparo Farga4, Meritxell Fernandez5, Juan Flores1

1Hospital Arnau de Vilanova, Internal Medicine. Infectious Disease Unit. Hospital Arnau de Vilanova, València, Spain, 2University of Valencia, Internal Medicine. Hospital Arnau de Vilanova, València, Spain, 3Hospital Arnau de Vilanova, Internal Medicine. Hospital Arnau de Vilanova, València, Spain, 4Hospital Arnau de Vilanova, Microbiology Department. Hospital Arnau de Vilanova, València, Spain, 5Hospital Arnau de Vilanova, Department of Rheumatology. Hospital Arnau de Vilanova, València, Spain

Background: To evaluate the clinical characteristics and prognosis of leishmaniasis among immunocompetent (group1), immunocompromised without HIV (group2) and HIV-infected individuals (group3).

Materials/methods: We present an observational, retrospective study including all the patients with leishmaniasis who were attended in the Department of Health number 6 in Valencia, Spain from 2015 to June 2019. The records of the Microbiology Department were reviewed for identifying the patients. The variables were retrieved from the medical records. Median and IQR were calculated for quantitative variables and frequencies for qualitative variables. The t-test and chi-squared were applied.

Results: A total of 60 patients were included –see table-. Among group2: rheumatological and inflammatory bowel disease were the more frequent. Methotrexate, corticosteroids and anti-TNF were the more common treatments. Distribution of sex, age, visceral leishmaniasis (VL) and cutaneous (CL), atypical presentation and clinical cure is shown in table 1. In group 1, two patients died and 1 relapsed, in group 3 one patient died, and 1 patient relapsed in group 2. Time to diagnosis was 1[0.3-2.5] months for VL and 6[2-10] for CL for group 1 and 0.5[0-1.25] in VL and 4[2.75-8.5] in CL for group 2, differences were not significative. Bone marrow microscopy yielded diagnosis in a total of 17/26(65%) and PCR in 22/24(91%) of cases; skin biopsy microscopy was diagnostic in 9/27(33%) and PCR in 28/28(100%).

Conclusions: In our area, the Mediterranean Basin, half of the cases of leishmaniasis are seen among immunocompromised individuals without HIV. In this group, VL was more frequent than in the immunocompetent patients but we did not find more frequency of atypical presentations, longer time to diagnosis, less frequency of clinical cure or more relapses. Bone marrow and skin biopsy PCR was superior to microscopy examination for establishing the diagnosis in immunocompetent and immunocompromised without HIV patients.

Abstract 6908

Direct detection and identification of microorganisms from clinical urine specimens by high-resolution mass spectrometry

Marjaana Viirtola*1, Anssi Rantakari1, Ilja Ritamo1, Hanne Amdahl1,2, Juha Knuuttila1, Hannu Peltoniemi1, Herdis Friedrich1, Karita Haapasalo1, Sakari Jokiranta1,4

1Thermo Fisher Scientific, Vantaa, Finland, 2Amicus Therapeutics UK LTD, Marlow, United Kingdom, 3University of Helsinki, Department of Bacteriology and Immunology, Medicum, Helsinki, Finland, 4SYLAB Finland Oy, Helsinki, Finland

Background: Rapid and accurate identification of microorganisms from urine specimens is important to ensure that clinicians can select appropriate antimicrobial treatment for patients having urinary tract infections (UTIs). Conventional methods for microbial identification often include a culturing step that delays the identification roughly by 24 h. Furthermore, daily number of urine specimens is usually relatively high in hospitals and increases need of manual work and resources. Direct method to detect and identify microorganisms and antibiotic resistance markers from urine samples would ease the workflow and decrease the workload of laboratory personnel.

Materials/methods: Twenty clinical urine specimens (10 positive, 10 negative) were received from a Finnish service laboratory. Five milliliters of each specimen was concentrated by centrifugation and the cell pellet was washed and finally extracted by chemical lysis and sonication. Extracted proteins were subjected to solid phase extraction (SPE) followed by liquid chromatography and electrospray ionization mass spectrometry (LC-ESI-MS). MS1 data was examined for deconvoluted masses (here: proteoform counts) and MS2 was utilized to identify the ten most abundant proteins in each sample. MS2 data was analyzed using ProSightPC software and database searches were performed against UniProtKB/SwissProt. Protein identifications were imported to ProteinCenter which clustered the homological proteins to single entry.

Results: Less than 20 proteoforms were detected in UTI negative specimens by MS1, whereas more than 100 proteoforms were present in 7/10 (70%) of UTI positive specimens. Viable cell counts from the samples revealed that in remaining 3/10 UTI positive specimen, bacterial cells were present in less than 10^6 CFU/ml. Half of the UTI positive samples got matches with proteins specific to bacterial species in MS2. Four out of ten matched only with human proteins, and from one sample, no species specific proteins were detected by MS2.

Conclusions: The results suggest that SPE-LC-ESI-MS is a feasible option for direct detection of microbes in UTI positive specimens as long as the sample preparation is optimized to recover enough material to the analysis. Once optimized, the method could readily be transferred to already existing high-resolution MS platform such as Acrion™ System.

Abstract 6910

**Viral respiratory tract infections in children: epidemiology and impact of the implementation of a multiplex PCR**

Amina Amine Khodja, Djazia Boufedji, Bettina Mesplies, Luce Landraud, Marie Cotillon, Romain Basmaci, Flora Joannes

1Service de Pédiatrie-Urgences, Hôpital Louis Mourier, Colombes, France, 2Service de Microbiologie, Hôpital Louis Mourier, AP-HP, Colombes, France, 3Université de Paris, IAME, INSERM, Paris, France

**Background:** Viral respiratory tract infections are very common during childhood. In addition to immunochromatographic and real-time PCR assays, we recently implemented a multiplex PCR assay allowing a rapid identification of numerous pathogens. We aimed to describe the epidemiology of respiratory pathogens and the impact of the viral results on antibiotic prescription.

**Materials/methods:** All patients under 18 years old attending to the paediatric emergency department and/or hospitalised in the general paediatric unit between March 1st 2018 and February 28th 2019, who were tested for a respiratory pathogen either by: influenza A/B or respiratory syncytial virus (RSV) immunochromatographic assays, or influenza A/B-RSV PCR assay (GeneXpert®), or multiplex PCR assay (Filmarray respiratory panel®) were retrospectively identified by the microbiology unit. Clinical, laboratory and imaging characteristics of the patients were further collected from medical files as well as antibiotic prescriptions. Proportion of antibiotic prescription and duration of treatment were compared between patients regarding the presence or absence of a viral pathogen.

**Results:** A total of 300 respiratory tests were performed among 234 patients during 272 episodes, distributed as 142 immunochromatographic tests (116 influenza A/B, 26 RSV, and 158 PCR assays (50 influenza A/B-RSV PCR assays, 108 multiplex PCR assays). The main clinical features of the patients were: age under 3 years old (n=192; 70.5%), fever (n=217; 79.7%), and dyspnea (n=169; 62.1%). The most frequently identified viruses were influenza A (n=72; 26.4%), rhinovirus/enterovirus (n=35; 12.9%), and RSV (n=30; 11%). Of note, 5/116 (4.3%) influenza and 1/26 (3.8%) RSV immunochromatographic assays showed false negative results. Overall, antibiotic prescription rate was significantly higher when the patient had a negative respiratory test (107/111=96.4% vs. 70/161=43.5%, p<0.001), whereas no significant difference was observed when only multiplex PCR assays results were considered (17/27=62.9% vs. 48/81=59.3%, p=0.66). Surprisingly, patients with asthma and neonates received more frequently an antibiotic treatment when a virus was found (53.3% vs. 0%, p<0.001; and 53.8% vs. 33.3%, p=0.004, respectively), whereas no significant difference was observed among immunocompromised and sickle cell disease patients.

**Conclusions:** Population of patients undertaking viral respiratory test should be better defined in order to limit antibiotic prescription.
