Results: In period I 1,064 TB PCR tests were performed for 741 patients. In period II 1,451 tests were performed for 884 patients, (36.4% increase in PCR tests and 19.3% increase in patients tested). During Period I 21 (2.8%) patients had a positive PCR (1 high, 10 medium, 5 low, and 3 very low). 2 patients had a negative PCR with a positive culture. During period II 37 patients were positive (6 high, 9 medium, 8 low, and 14 very low), an increase of 76.2%. 14 additional patients had a trace result. In only one case the TB culture was positive. 5 (35.7%) of them were treated for TB in the past. In Period I and Period II 10 (47.6%) and 19 (37.3%) were African born, 6 (28.6%) and 17 (33.3%) were born in Eastern Europe, 5 (23.8%) and 14 (27.5) were born in Asia. Mean age was 47.0, and 53.2 years. 18 (85.7%) and 29 (78.4%) cases were susceptible to rifampicin Cultures susceptibility results were variable. All trace cases were not susceptible.

Conclusions: The Ultra assay enabled a higher diagnosis rate for TB. During the study there was no change in TB guidelines, nor in the epidemiology of patients served by the hospital. We suggest that this reflects a higher sensitivity of the Ultra test in patients with paucibacillary TB. Trace result pause a clinical challenge as it is not clear what is their clinical significance.

Enterococcus species involvement in vascular graft infections

Jules Bauer*1, Olivier Leroy1, Piervito Délia1, Jonathan Sobocinski2, Olivier Robineau1, Eric Senneville1

1 CH. Dron, Tourcoing, France, 2 Institut Cœur Poumon, Lille, France

Background: Vascular graft infections (VGI) are associated with significant mortality. Due to the lack of data and recommendations, treatment of VGI was historically regarded as similar to other material-related infections or endocarditis. Enterococcus species represent the second gram-positive cocci in VGI (10 to 15%) but are frequently involved in polymicrobial infections. This make them difficult to treat.

Materials/methods: We described vascular graft infections involving Enterococcus sp. from a cohort of 230 VGI followed in an infectious disease center between 2009 and 2019.

Results: We found 29 (13%) VGI associated with Enterococcus sp.. Patients were mostly men (86.2%) with a median age of 72 years. Most of the cases involved patients with few comorbidities (COPD = 17%; obesity = 20%; diabetes mellitus = 27%; moderate or severe kidney failure = 44%). Enterococcus sp. strains includes E. faecalis (75%), E. faecium (18%), E. avium (n=1) and E. casseliflavus (n=1). Only 3 VGI were monomicrobial (10%). The microbiological epidemiology of the polymicrobial cases is broken down as follows: Enterobacteriaceae (52%); Staphylococcus species (45%, including six strains of methicillin-sensitive Staphylococcus aureus and one strain of methicillin resistant Staphylococcus aureus); Streptococcus species (24%); Candida species (12%). VGIs concerned intra-cavitary prosthesis and extra-cavitary prosthesis in 16 (55%) and 13 (45%) cases, respectively. Infections were declared during the three months following surgery (76%) with few associated clinical symptoms and a mean rate of CRP at 94 mg/L. The mortality rate was 31%.

Conclusions: Enterococcus sp. vascular graft infections seem to occur in patients with few comorbidities and during the early period following surgery. Our study shows a high rate of intra-cavitary prosthesis infection. Taking all these factors into account could be of importance for choosing the right antibiotic regimen, for example Piperacilline-Tazobactam rather than Cefepim associated with Vancomycin or Daptomycin.

Abstract 8406

**Artesunate-containing therapies and abnormal haemoglobin: do we need to adapt the treatment?**

Ronan Jambou 1, Eric G Adji 2, Andre Toure 0, Albert Gnondjui 2, Stephane Koussou Tossea 2, Landry Tiacoh 2, Serge Assi 3, Ibrahima Sanogo 4

1 Institut Pasteur, Global health Department, Paris, France, 2 Institut Pasteur de Côte d’Ivoire, Parasitology Department, Abidjan, Côte d’Ivoire, 3 Institut Pierre Richet/Programme National de Lutte contre le Paludisme, Abidjan, Côte d’Ivoire, 4 Yopougon University Hospital, Abidjan, Côte d’Ivoire

**Background:** Patients with sickle cell anemia have a lower risk of severe disease, but are not protected for malaria. Sickle cells are very different from normal ones and efficacy of artesunate containing therapy can varies. This project aims to explore in vivo and in vitro drug responses of Plasmodium infecting red cells with or without abnormal hemoglobin.

**Materials/methods:** In vivo response was investigated through retrospective data obtained during standard 42 days lumefantrine-artesunate response protocol with a 6 hours decay (WWARN) or a 24H decay (WHO) follow-up. A, S or C genotypes were determined using electrophoresis or FRET molecular typing. The threshold of in vivo decrease of drug resistance was set at 5 hours for the decay slope (WWARN) and 48h for WHO test.

**Results:** For the in vivo study, data from 1003 patients were analyzed (268 and 735 for WWARN and WHO protocols respectively). For 804 of them, hemoglobin status was defined successfully (196 and 608 for the two protocols respectively), and 127 patients (15.7%) had abnormal hemoglobin (20 and 107 for WWARN and WHO). Overall, during the 42 days of follow up, 6 out of 127 (4.6%) and 52 out of 677 (7.7%) patients experimented a clinical drug failure. Patients with abnormal hemoglobin experimented more parasite clearance retardation (both for WWARN and WHO protocols) than others, especially before 5 years.

**Conclusions:** In conclusion abnormal hemoglobin seems not associated with a treatment failure with ACT, but clearance retardation could sustain occlusive crisis. In vitro experiments could suggest a specific resistance to artesunate which needs to be explored deeper.

Abstract 8408

Performance of XpertMTB/RIF Ultra assay on respiratory and extra-respiratory specimens in a high-resource setting with a low TB prevalence

Carmen Martín Higuera*, Maria Jesus Ruiz Serrano2, Carlos Toro-Diez3, Marta Tato4, Maria Simon5, Diego Domingo6, Paula Lopez-Roa1

1University Hospital 12 de Octubre, Madrid, Spain, 2Gregorio Marañón Hospital, Madrid, Spain, 3University Hospital La Paz, Madrid, Spain, 4Hospital Ramón y Cajal, Madrid, Spain, 5Central Hospital Gómez Ulla Defense, Madrid, Spain, 6Hospital de La Princesa, Madrid, Spain

Background: Tuberculosis (TB) is a worldwide public health threat, including in countries with a low prevalence. Rapid diagnosis of TB and determination of rifampicin resistance are essential for disease management and effective public health interventions. The Xpert MTB/RIF assay is an automated molecular test that has improved the detection of TB and rifampicin resistance. However, its sensitivity for TB detection is limited in patients with paucibacillary disease (patients with sputum smear-negative or extrapulmonary TB) or HIV. Xpert MTB/RIF Ultra has been recently developed to overcome this limitation. We compared the diagnostic performance of Xpert Ultra with that of culture for the detection of TB and rifampicin resistance in a high-resource setting with a low TB prevalence.

Materials/methods: This study was conducted in 6 tertiary hospitals in Madrid, Spain. Respiratory and extra-respiratory specimens were obtained as part of standard patient care between April 2018 and October 2019 and processed using Xpert Ultra, auramine acid-fast staining (AFB), conventional culture, and drug phenotypic susceptibility testing.

Results: Of the 1,268 clinical samples, 419 (33%) were extra-respiratory and 849 (67%) were respiratory. In total, MTB was isolated in 187 specimens, 173 of which were positive with Xpert Ultra. Trace-positive results were obtained in 15 samples, 8 of which were confirmed by culture. The sensitivity, specificity, PPV, and NPV of Xpert Ultra were: 94.7%, 97.7%, 90.5% and 98.8% for respiratory samples and 83.3%, 96.7%, 71.4% and 98.3% for non-respiratory. The sensitivity, specificity, and predictive values of Xpert Ultra for smear-positive and smear negative respiratory samples are detailed in Table 1. Xpert Ultra detected 5 RIF-resistant samples, also confirmed by DST.

Conclusions: XpertMTB/RIF Ultra demonstrates excellent diagnostic accuracy for TB detection and simultaneous detection of rifampicin resistance in a low prevalence setting, including in individuals with paucibacillary forms. Further studies are needed to evaluate the interpretation of trace-positive results.

Abstract 8411

Performance of the PBP2a (Alere-Abbott) immunochromatographic test on early primary cultures from positive MRSA/MR-CoNS blood cultures

Clement Munier1, Céline Dupieux1, Camille Kolenda1, Michele Bes1, Olivier Dauwalder1, François Vandenesch1, Anne Tristan1, Frédéric Laurent1

1Hospital La Croix-Rousse - HCL, Lyon, France

Abstract third-party references: Resistance detection rapid assays

Background: Early detection of methicillin resistance in staphylococci is crucial for optimal early treatment of infected patients. Alere™ PBP2a SA Culture Colony Test is an immunochromatographic test allowing the detection of the expression of PB-P2a directly from a primary culture in 5 minutes. We evaluated the use of this test on early primary cultures for methicillin-resistant S. aureus and methicillin-resistant coagulase-negative staphylococci (MRSA and MR-CoNS) from blood-culture bottles.

Materials/methods: The performance of the test was evaluated on early cultures (4h) on COS agar (bioMérieux) of MRSA or MRCoNS strains obtained from BactALERT-FA bottles reported positive using the BactALERT VIRTUO platform (bioMérieux):

- Artificial spiking with human blood and an inoculum of 100 bacteria per bottle using MRSA harbouring mecA [n=100] and mecC [n=2] representative of the various clones circulating in France and Europe.

- Artificial spiking with human blood and an inoculum of 100 bacteria per bottle using 36 mecA+ MRCoNS (S. epidermidis [n=11], S. capitis [n=4], S. hominis [n=4], S. haemolyticus [n=4], S. lugdunensis [n=4], S. saprophyticus [n=4], S. warneri [n=5]).

In addition, we tested prospectively MRSA (mecA+) positive blood cultures [n=36] from patients.

At the same time, identification using Maldi-tof VITEK® MS (bioMérieux) was performed on the same early culture.

When species identification was inconclusive and/or PBP2a was negative at t=4h, the tests were repeated after 6, or even after 24h of reincubation of the primary culture.

Results: The results highlighted an excellent ability to detect methicillin resistance at an early stage for S. aureus, except for MRSA harbouring mecC gene, which have a very low prevalence in France. For MRCoNS, 6% of methicillin-resistant strains were classified as susceptible after 4h of incubation on COS.

</table>

Conclusions: These results show that the Alere™ PBP2a SA Culture Colony Test can be used on colonies after short incubation (4h) of primary cultures from positive blood-cultures to detect methicillin resistance in S. aureus, in combination with Maldi-tof for identification.

For MRCoNS, a negative result after only 4h of incubation should be interpreted with more caution. In addition, species identification using Maldi-tof is also less effective.

Sero-prevalence and risk factors of brucellosis among suspected febrile patients attending a referral hospital in southern Saudi Arabia (2014-2018)

Abdullah Alkahtani1*, Mohammed Assiry2, Harish C. Chandramoorthy1, Ahmed Al-Hakami3, Mohamed E. Hamid1

1King Khalid University, College of Medicine, Abha, Saudi Arabia, 2Asir Central Hospital, Asir central hospital, Abha, Saudi Arabia, 3King Khalid University, college of Medicine, Abha, Saudi Arabia

Background: Human brucellosis is an infectious zoonotic disease caused by Brucella spp. It is one of the most public health problems that remains largely neglected in developing countries, including Saudi Arabia. Brucellosis is particularly prevalent among rural people who have constant contact with livestock. The Objectives To determine brucellosis prevalence and associated risk factors in suspected febrile human patients attending Aseer referral hospital between 2014 and 2018 in the Southern region of Saudi Arabia.

Materials/methods: A cross-sectional sero-epidemiological study conducted in Aseer Central Hospital, South Saudi Arabia, between 2014 and 2018 among 7567 patients. Serum samples were analyzed for Brucella antibodies using slide agglutination test. Serology results and patient’s demographic data were analyzed by GraphPad Prism. Results were presented as mean ± SEM and differences between two groups were assessed by t-test and p<0.05 was considered significant.

Results: The prevalence of brucellosis among the admitted suspected 7567 cases was 12.8% (10.4–15.7%; CI 95%). The highest prevalence rate was detected during 2015, the rate decreased to the lowest level during the last three years (p < 0.05). Higher rate of brucellosis was observed among males than females (p < 0.05) and most cases were reported during summer season (p < 0.05). The highest prevalence rate was observed in age group 21-40 year old (40.5%) followed by 41-60 years (27.7%). The lowest prevalence rate was noticed in old and young children (15 % and 3%, respectively). Cross-transmission of brucellosis was seen within family (1%) and high titers (>1280) was noticed in 22% of the hospitalized patients. The major symptoms were fatigue, hyperhidrosis, fever and joint pain.

Conclusions: Our findings showed a high prevalence of human brucellosis among suspected patients in Aseer region. This indicates that clinical suspicion is a valid criterion and the endemic nature of the disease. The disease status requires early laboratory detection and confirmation to start prompt

Background: The Dutch Working Party on Antibiotic Policy (SWAB), in collaboration with scientific societies for Medical Microbiology, Internal Medicine, Intensive Care, Surgery, Hospital Pharmacy and Emergency Medicine, has updated the guidelines on antibacterial therapy of sepsis in adults in the Netherlands.

Materials/methods: The guideline committee generated key clinical questions (Table 1). For each question we performed a pragmatic literature search to summarize the quality of evidence for clinically relevant outcomes, assessed according to GRADE from high to very low. The committee formulated recommendations after structured discussions as strong or weak. When evidence could not be obtained, recommendations could be provided on the basis of opinions (good practice statements).

Results: Forty-eight recommendations were generated. Overall, the committee formulated 21 strong and 27 weak recommendations. Eleven recommendations were based on moderate to high quality evidence, 28 on low to very low quality evidence and nine on good practice statements.

Conclusions: Our multidisciplinary committee formulated evidence-based recommendations for antibacterial therapy of adults with sepsis in the Netherlands. We will ask relevant scientific medical disciplinary organizations to review and endorse these guidelines. We will subsequently implement them in routine daily practice after dissemination through the national SWAB website and its antimicrobial formulary.

Abstract 8420

Performance of core genome multi-locus sequence typing compared to capillary electrophoresis PCR ribotyping of Clostridioides difficile

Amoe Baktash1, Bastian Hornung1, Jeroen Cover1, Céline Harmanus1,2, Wiel Klaas Smits1, Warren Fawley3, Mark H. Wilcox4, Nitin Kumar5, David Eyre6, Alexander Indra7, Alexander Mellmann8, Ed J. Kuijper1,2

1Department of Medical Microbiology, Section Experimental Bacteriology, Leiden University Medical Center, Leiden, Netherlands, 2National Reference Laboratory Clostridium difficile, National Institute of Public Health and the Environment, Leiden University Medical Center, Leiden, Netherlands, 3National Infection Service, Public Health England, and University of Leeds, Leeds, United Kingdom, 4Department of Microbiology, Leeds Teaching Hospitals & University of Leeds, Leeds, United Kingdom, 5Microbiota Interactions Laboratory, Wellcome Sanger Institute, Hinxton, United Kingdom, 6Big Data Institute, University of Oxford, Oxford, United Kingdom, 7Institute of Medical Microbiology and Hygiene, Österreichische Agentur für Gesundheit und Ernährungssicherheit (AGES), Vienna, Austria, 8Institute of Hygiene, University Hospital Münster, and National Reference Center for C. difficile, Münster Branch, Münster, Germany

Background: Clostridioides difficile is the most common cause of antibiotic-associated gastrointestinal infection. Capillary-electrophoresis (CE) PCR ribotyping is currently the gold standard for C. difficile typing, but lacks sufficient discriminatory power to fully resolve outbreaks. This study compares the performance of core genome (cg) and whole genome (wg) multi-locus sequence typing (MLST) with CE-PCR ribotyping.

Materials/methods: 528 sequenced C. difficile strains were obtained from the NCBI Sequence Read Archive (Illumina sequencing platform). Additionally, 74 known ribotypes from the Leeds-Leiden reference collection were included, resulting in 99 unique ribotypes [1-98 different strains/ribotype]. Two different cgMLST schemes [SeqSphere: 2270 genes; Enterobase: 2556 genes] and the Enterobase wgMLST scheme (pangenome; 13763 genes) were used. Backward compatibility and discordances between CE-PCR ribotyping and cgMLST were assessed. A neighbor-joining tree was produced (1 strain per ribotype) [Seqsphere]. Average inter- and intra-ribotype allele differences were calculated from produced distance matrices using the cg/wgMLST schemes. Discriminatory power of cgMLST was assessed in 3 outbreak settings with RT078, RT036/198 and RT181 in Europe [30 strains] using a threshold of ≤ 6 targets to define similarity.

Results: Of 99 ribotypes (n=602 strains), 78 ribotypes [78,8%] had a unique profile, whereas 21 ribotypes clustered [≤ 6 targets] with multiple ribotypes [ranging 1-4].These latter ribotypes belonged mainly to MLST Clades 2 and 5, followed by Clade 1. This clustering is shown in a neighbor-joining tree (Figure 1). Average intra-ribotype allele difference varied between different ribotypes, with RT001 (n=11) showing high average allele difference [56.7 with Seqsphere; 70.5 and 110.7 with Enterobase cg and wgMLST, respectively], contrary to RT027 [n=13] [8.5 with SeqSphere; 10.5 and 16.7 with Enterobase cg and wgMLST, respectively]. Application of cgMLST in outbreak settings of RT078, RT036/198 and RT181 showed clustering of the strains with unrelated control strains of the same ribotypes/Clades.

Conclusions: cgMLST has the potential to replace CE-PCR ribotyping of C. difficile as the standard typing method in centers where whole genome sequencing is accessible. The method is reproducible, easy to standardize and offers a higher discriminatory power, but its use is currently limited in an outbreak of strains belonging to MLST Clades 2 or 5.

Presenter email address: a.baktash.mm@lumc.nl
Enabling phyletic-based comParison and visualization of genomic islands for tens to hundreds of microbial genomes

Claire Bertelli\*1, Kristen Gray2, Adrian Lim2, Nolan Woods1, Geoff Winsor1, Adam Spencer2, James Peltier2, Fiona Brinkman2

1 Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, 2 Simon Fraser University, Burnaby, Canada

Background: Genomic islands (GIs), commonly defined as clusters of genes of probable horizontal origin, are of interest since they disproportionately encode environmental and medically important adaptations, including novel metabolic abilities, virulence factors (VFs) and certain antimicrobial resistance (AMR) genes. While microbial genome sequencing has become rapid and inexpensive, current computational methods for GI analysis are not amenable for rapid, user-friendly, and scalable analysis of the thousands of genomes being sequenced. To fill this gap, we have developed IslandCompare, an open-source computational pipeline and web-based visualization resource to compare GIs across several to hundreds of bacterial genomes.

Materials/methods: In IslandCompare, GI predictions are performed using two of the most accurate GI prediction tools based on nucleotide composition biases: SIGI-HMM\textsuperscript{\dagger}duplications or mutations. For a precise characterization, algorithms are needed that identify transfer events with high reliability. Frequently, the transferred pieces of DNA have a considerable length, comprise several genes and are called genomic islands (GIs and IslandPath-DIMOB v1.0.0). A bacterial core-genome phylogeny is computed using Parsnp\textsuperscript{\dagger}however existing whole-genome alignment methods are limited in their ability to perform sequence comparisons of multiple sequences simultaneously. Here we present the Harvest suite of core-genome, and visualization tools for the rapid and simultaneous analysis of thousands of intraspecific microbial strains. Harvest includes Parsnp, a fast core-genome multi-aligner, and Gingr, a dynamic visual platform. Together they provide interactive core-genome alignments, variant calls, recombination detection, and phylogenetic trees. Using simulated and real data we demonstrate that our approach exhibits unrivaled speed while maintaining the accuracy of existing methods. The Harvest suite is open-source and freely available from: http://github.com/marbl/harvest. The Harvest suite for rapid core-genome alignment and visualization of thousands of intraspecific microbial genomes and pairwise regions of similarity between isolates are calculated with Mauve\textsuperscript{\dagger}they undergo large-scale evolutionary processes that present a challenge to sequence comparison to other methods through extensive simulations of genome evolution. ComParison to other methods through extensive simulations of genome evolution.

Conclusions: IslandCompare will facilitate more robust, flexible analysis and comParison of GIs, complementing existing tools like IslandViewer\textsuperscript{\dagger}, and enabling more efficient larger-scale analysis of infectious disease outbreaks and microbial evolution. The genome visualization developed may be adapted to visualize any genome feature for hundreds of phyletically-organized linear genomes, with broad applications.

In vitro antimicrobial activity of liposomal ceftriaxone and liposomal amoxicillin and clavulanic acid against clinical strains isolated from companion animals with urinary tract infections

Maria Ogren*, Maria Manuela Gaspar1, Solange Gil1, Magda Ferreira1, Carla Carneiro1, Manuela Oliveira1, Luís Tavares1, Frederico Aires Da Silva1, Sandra Isabel Aguiar1

1Faculty of Veterinary Medicine, Lisboa, Portugal, 2Faculty of Pharmacy, University of Lisbon, Lisboa, Portugal

Abstract third-party references: Centro de Investigação Interdisciplinar em Sanidade Animal (CIISA)

Background: In the face of rising antimicrobial resistance and subsequent absence of effective antibiotics, new approaches are required. A promising strategy to increase the bactericidal efficacy of an antibiotic is through their entrapment in drug carriers, namely liposomes. This promotes antibiotic accumulation at the infection site and enhances binding to bacteria, while avoiding systemic exposure.

Materials/methods: The evaluation of the antimicrobial activity, in vitro, of free and liposome-encapsulated ceftriaxone and amoxicillin and clavulanic acid combination, against 14 susceptible and resistant clinical strains (8 strains of Escherichia Coli, 3 of Klebsiella pneumoniae and 3 of Pseudomonas Aeruginosa), isolated from companion animals with a confirmed diagnosis of urinary tract infections was performed. Their antimicrobial activity was measured by means of MIC determination, through the broth microdilutions method, whereas the assessment of the bacterial growth was achieved by a colorimetric method.

Results: Ceftriaxone and amoxicillin and clavulanic acid were successfully encapsulated, in a liposomal formulation of phosphatidylcholine and negatively charged phosphatidylglycerol (PC:PG). The liposome-encapsulated ceftriaxone showed bactericidal activity however the MIC values of the encapsulated ceftriaxone were 4 to 16 times higher than those of the corresponding free antibiotic, against the E. coli and K. pneumoniae strains. This result was probably due to a low liposome-bacterium interaction. The liposome-encapsulated amoxicillin and clavulanic acid didn't show bactericidal activity against any strain. None of the studied liposomal forms exhibited bactericidal activity against the P. aeruginosa strains owing to its bacterial resistance related to low permeability and enzymatic hydrolysis.

Conclusions: The liposomal encapsulation of the antibiotics ceftriaxone and amoxicillin and clavulanic acid combination didn't enhance the in vitro antibacterial activity when compared to the existing drug. Nevertheless, the liposomal formulation showed bactericidal potential, suggesting that for further investigation the extent of the interaction with the bacteria should be improved through the variation of the physicochemical properties of the liposome, namely surface charge, bilayer fluidity and fusogenic properties.

Abstract 8426

**Antimicrobial stewardship practices in Brazil: where are we?**

Rochele Menezes¹, Mara Gonçalves², Magda Costa², Eliane Krummenauer¹, Jane Dagmar Renner¹, Cézane Reuter³, Marcelo Carneiro¹,²,³,⁴,⁴

¹Hospital Infection Control Service - HICS and Stricto Sensu Health Promotion Program, University of Santa Cruz do Sul, Santa Cruz do Sul, Brazil, ²National Health Surveillance Agency – ANVISA/GVMS/GGTES, Brasília, Brazil, ³Stricto Sensu Health Promotion Program, University of Santa Cruz do Sul, Santa Cruz do Sul, Brazil, ⁴Brazilian Association of Infection Control and Hospital Epidemiology Professionals, São Paulo, Brazil

**Background:** To know the essential elements for the creation and implementation of the Antimicrobial Stewardship Program (ASP) becomes a necessary strategy to improve hospital care outcomes, related to the use of antimicrobials with a safe and cost-effective approach, minimizing the development of antimicrobial resistance.

**Materials/methods:** This was a prospective, cross-sectional, multicenter study. A total of 453 hospitals with adult Intensive Care Unit (ICU) from all 27 Brazilian states were included. The evaluation criteria of the institutions with ASP were grouped into six essential elements for the implementation of these programs in a National Guideline for Creation of the Antimicrobial Use Management Program in Health Services, with validation by specialists with satisfactory internal consistency (five elements with Alpha Cronbach classification “Good / Excellent”). The elements are: (E1) Institutional support from the senior management; (E2) Definition of the responsibilities of each professional involved; (E3) Education of professionals and family members; (E4) Strategic actions to rationalize antimicrobial prescription; (E5) Monitoring of ASP indicators and (E6) Dissemination of the results in the institution. The data were collected through an online government platform called FormSUS. This is an unprecedented study carried out between July and August 2019.

**Results:** It was observed that 62% (SD ± 24.1) of the hospitals have an ASP. Of the 27 Brazilian states, a significant implementation of the ASP was observed in the states of: São Paulo 96 (21.2%), Rio de Janeiro 63 (13.9), Paraná 47 (10.4%) and Minas Gerais 39 (8.6%), with the southeast region standing out in this unprecedented investigation. Regarding the evaluated elements of the 453 (47.5%) Adult ICUs that had the ASP implemented, the medians were: E1 = 65.3%, E2 = 35.7%, E3 = 15.2%, E4 = 78.4%, E5 = 72.2% and E6 = 58.7%.

**Conclusions:** The results show that Brazil needs to improve all Elements, but special attention should be given to E2 and E3. This study outlined an important Brazilian characteristic of the level of implementation of adult ICU bed hospital programs in Brazil.

Background: Thus far, only few sRNAs have been identified in the opportunistic pathogen Enterococcus faecium, and the study has been conducted only in laboratory conditions, to analyse the sRNA involved in antibiotic resistance. To gain insights on the sRNAs that may play a role during infection and/or in laboratory conditions, we conducted RNA-seq and Transposon sequencing (TN-seq) analysis on bacteria grown in laboratory condition and bacteria recovered after intraperitoneal infection.

Materials/methods: The study was conducted using the E. faecium strain AUS0004. RNA was extracted from bacteria grown in laboratory condition and from bacteria recovered after intraperitoneal infection. All reads from the in vitro and in vivo RNA samples were mapped on the AUS0004 genome. The transposon bank was constructed using the pZXL5 vector and the insertions were mapped on the genome.

Results: 35 intergenic small-RNAs and 40 antisense small-RNAs were identified by RNA-seq. The quantification of the expression of the sRNA candidates in the in vitro and in vivo conditions has been performed. E. faecium transposon bank grown over night, representing the input pool, and recovered after intra-peritoneal infection (output pool) was sequenced and transposon insertion sites were mapped onto the AUS0004 genome. The intergenic transcripts regions, identified above, were checked for the presence of transposon insertions. Six intergenic regions do not show reads neither in the input library nor in the output library, reflecting a putative essential or fitness function for bacterial growth in laboratory culture. Interestingly, two intergenic regions do not contain reads in the output pool, indicating a possible involvement in pathogenesis. Moreover, these two intergenic regions appear to be over-expressed in vivo in the RNA-seq analysis.

Conclusions: RNA-mediated regulation is an important aspect to understand bacterial response to different environments. This study allowed the identification of new sRNAs involved in E. faecium growth and infection process, using an innovative approach combining RNA-seq and TN-seq. The putative sRNAs identified will be confirmed by Northern-blot and RT-qPCR and their involvement in bacterial growth and virulence will be analyzed using deletion mutants. We expect this approach to stand as a powerful tool to predict bacterial essential sRNAs.

**Abstract 8429**

**Dananase: discovery of a novel *Pseudomonas aeruginosa* active polyketide type-1 synthetase**

Daniela Knafl*, Goran Mitulovic1, Peter Pichler1, Thomas Reiter1, Ludwig Wagner1, Wolfgang Winnicki1

1Medical University of Vienna, Vienna, Austria

**Background:** The urinary microbiome harbors a great repertoire of bacteria, which possess an immense potential for the biosynthesis of different biochemical products such as polyketide synthases. Traditionally such compounds have been utilized as pharmaceutical drugs, for example as antibiotics or cytostatic substances or agrochemical agents. While examining the urinary microbiome of patients during AKI and concomitant antibiotic treatment a remarkable decrease of *Candidatus solibacter usitatus* in one patient attracted our attention. Surprised about detecting a putative close relative of a bacterium, which originally has been found in Australian soil in our patient’s urine, we examined the genome and protein coding regions of *Candidatus solibacter usitatus*. Thereby we identified a biosynthetic pathway, which allowed us to clone and produce an up-to-now unknown polyketide type 1 synthase, which we named Dananase.

**Materials/methods:** The *dananase* gene was synthesized, cloned into the pEX-A258 for replication and inserted into the p-T0-PO-entry-D gateway vector following PCR amplification. The resultant insert was shifted into the pEXP1-DEST gateway vector. *E. coli* transformants were selected for *dananase* expression. BAP1- *E. coli* was transformed with the *dananase*-pEXP1-DEST expression plasmid and grown in liquid culture under induction with IPTG. The supernatant was filtered and utilized for antimicrobial activity testing against *Pseudomonas aeruginosa*. Metabolome analysis of BAP1- pEXP1-DEST-*dananase* following induction with IPTG was performed and compared to LB-media alone and supernatants of dummy plasmid transformed BAP1- *E. coli*. In addition, the molecular structure of *dananase* product was determined using trans-AT polyketide synthase predictor web application genome mining tool.

**Results:** The 1646 amino acid long polyketide synthase type 1 named *dananase* was cloned into pEXP1 expression vector and expressed in BAP1. The supernatant contained specific antimicrobial activity against clinical isolates of *Pseudomonas aeruginosa*. This highly active compound could be further purified by HPLC but not yet identified in its structure. In silico prediction analysis suggested a polyketide as follows CC[C(O)*]CC[CC][NC][K]CC[CC][CC][O]0=0=0. Mass spectrometric analysis revealed several Dananase-specific peaks representing most likely its product in the supernatant.

**Conclusions:** The *dananase* gene of *Candidatus solibacter usitatus* consists of 4941bp and encodes a polymodular polyketide synthase type-1, its product successfully inhibits growth of *Pseudomonas aeruginosa* in vitro.

Abstract 8431

**Epidemiology and risk factors for mortality in patients with *Pseudomonas aeruginosa* bacteraemia**

Inés Pérez-Camacho*, Juan Diego Ruiz-Mesa1, Ignacio Márquez Gómez1, Luis Francisco Caballero Martínez1, Beatriz Sobrino1, Lucía Valiente De Santis1, Antonio Plata Ciézar1, Jose Mª Reguera Iglesias1

1Regional Hospital of Málaga, Málaga, Spain

**Background:** Our study was conducted to identify the predictors of mortality in patients with *Pseudomonas aeruginosa* bacteraemia.

**Materials/methods:** A retrospective study was performed on data from patients (>16 years old) with confirmed clinical signs of *P. aeruginosa* bacteraemia between January 2010 and December 2017 at a tertiary teaching hospital in Spain. The data that were routinely collected included the patient’s age, sex, clinical service at the onset of bacteraemia, acquisition, source of infection, predisposing clinical conditions, as well as antimicrobial susceptibility of causative pathogens, antimicrobial therapy regimen and the outcome during hospitalization. To determine independent risk factors for mortality, a multiple logistic regression model was used to control for the effects of confounding variables.

**Results:** Overall, 349 episodes of *P. aeruginosa* bacteraemia were included, 67.9% of them were men with a median age of 61 years (range, 16–100 years). A predisposing condition was identified in 83.1% of episodes. The acquisition of bacteraemia was nosocomial in 153 (43.8%) cases and the most common primary site of infection was catheter-related [86 (24.6%)]. One hundred and thirty-one (37.5%) had a severe sepsis or septic shock. The isolates were multidrug-resistant in 20 (5.7%) cases and extremely-resistant in 13 (3.7%). Treatment was appropriate in 176 (50.4%) of episodes. The 30-day mortality rate was 26.6% (93 patients). By univariate analysis, variables significantly associated with mortality included having an underlying disease (COPD and heart failure) and a predisposing condition (chemotherapy or radiotherapy, steroids, neutropenia and parenteral nutrition), requiring invasive procedures (endotracheal intubation, nasogastric tube or urinary catheter), presentation with severe sepsis or septic shock, absence of fever, having pneumonia and an increasing SOFA score. Multivariate model is shown in table 1.

**Conclusions:** *P. aeruginosa* bacteraemia was a nosocomial acquired infection in nearly half of episodes and catheter-related was the most common primary site of infection. Presentation with septic shock, absence of fever, previous use of steroids and neutropenia were independently associated with mortality.

Typing of carbapenemase-producing Klebsiella pneumoniae: IR Biotyper meets NGS

Miriam Cordovana1*, Helena Seth-Smith2, Alessandro Deni1, Vladimira Hinic2, Adrian Egli2, Simone Ambretti1

1 Policlinico Sant’Orsola-Malpighi, Bologna, Italy, 2 University Hospital of Basel, Basel, Switzerland

Background: KPC- and NDM-producing Klebsiella pneumoniae (KPC-Kp and NDM-Kp) represent a serious public health concern. The high-resolution molecular epidemiology techniques required to track its spread are often unaffordable and laborious to perform. In this study, we evaluated the resolution power of the Fourier Transform Infrared Spectroscopy (FTIRS) based IR Biotyper in comparison to whole genome sequencing (WGS).

Materials/methods: We used WGS of 46 clinical and surveillance K. pneumoniae isolates (n=33 KPC-, n=11 NDM- and 2 ESβL-producers) from the Bologna University Hospital on a NextSeq500 (Illumina) with core genome MLST clustering (Ridom Seqsphere+ v 6.0.2) as reference method, and compared results to clustering using IR Biotyper (IRBT - Bruker Daltonik). Infrared spectra were acquired in transmission mode from bacterial suspensions in water/ethanol, placed onto a silicon sample plate, and air dried. The IRBT software evaluated spectra in the range 1300-800 nm, applying hierarchical cluster analysis (HCA) with Euclidean metric and single linkage. We compared IRBT results with core genome multi-locus sequencing typing (cgMLST). We explored the resolution power of IRBT with subclusters and the presence of bla genes.

Results: 14 Multilocus Sequence Types (ST) were identified in the samples: ST-258, 512, 1519, 307, 101, 189, 39, 45, 628 (KPC-producers); ST-11, 16, 147 (NDM-producers); and ST-15 and 37 (ESβL-producers). Using cgMLST these represent 9 different clusters and 4 unique isolates (using a 15-allele cut-off). IRBT classified the isolates in similar clusters using a cut-off value of 0.30. The comparison of the two trees showed a good congruence, with only minor differences in the location within the Clonal Group (CG) 258, and two ST-258 isolates clustered outside the CG-258. Lowering the cut-off value for IR Biotyper, further subclusters could be defined for CG-258 and ST-307. Subclusters correlated with presence of bla genes variants.

Conclusions: IR Biotyper showed a resolution power comparable to cgMLST for carbapenemase-producing K. pneumoniae typing, and a promising potential to be explored for a differentiation at a deeper level. Although further detailed investigations are necessary, these results suggest that IRBT represents a promising typing method for carbapenemase-producing K. pneumoniae.

Abstract 8434

One-year prospective analysis of carbapenem-resistant strains isolated from a tertiary urinary centre in Romania

Mădălina-Maria Muntean, Alexandru Muntean, Madalina Preda, Iulia Sandu, Viorel Jinga, Thierry Naas, Mircea-Ioan Popa

1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, 2Cantacuzino National Institute, Bucharest, Romania, 3Professor Dr. Theodor Burghele Hospital, Bucharest, Romania, 4Bicetre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: Urinary tract infections (UTIs) caused by carbapenem-resistant microorganisms are a major public health issue as they are difficult to treat, leading to high morbidity rates and high costs for the healthcare system. The prevalence of carbapenem-resistant bacteria in UTIs in Romania is not known. Here, we studied carbapenem-resistance among Enterobacterales and non-fermenters isolated over one year at a Tertiary Urinary Center in Bucharest, Romania.

Materials/methods: Antibiotic susceptibility testing was performed using disc diffusion antibiograms. All bacteria with reduced susceptibility to carbapenems and compatible with EUCAST criteria for carbapenemase confirmatory testing (MIC for meropenem > 0.125µg/ml) were screened using CarbaNP test and rCIM tests. NG-test Carba5 (NG biotech) was used to determine the type of carbapenemase involved.

Results: During the study period 392 Gram negative bacilli were studied. Upon interpretation of the antibiograms, 152 isolates met EUCAST screening criteria for carbapenemase production. Of these, 85 isolates were confirmed as carbapenemase producers on the basis of CarbaNP or rCIM positivity. NG-test Carba5 revealed that 54 isolates produced NDM (27 K. pneumoniae, 20 E. cloacae, 3 P. stuartii and 1 E. hormachei, S. marcescens, P. mirabilis, Acinetobacter baumannii), 11 isolates produced OXA-48 (all K. pneumoniae), 5 isolates produced VIM (all in P. aeruginosa), and 2 co-produced KPC and NDM (in K. pneumoniae). 13 isolates presented a positive CarbaNP or rCIM test, yet it was not identified through the lateral flow assay. These isolates will be subjected to WGS in order to identify the underlying carbapenem-resistance mechanism. In enterobacteria, carbapenem resistance was associated with Ciprofloxacin resistance (95% of strains), Nitrofurantoin (95% of strains) and Cotrimoxazole (75% of strains) – according to EUCAST guidelines.

Conclusions: Carbapenemase production in isolates from urinary tract infections appears to be high in Bucharest (22%). NDM is the main carbapenemase identified in Enterobacterales while VIM was predominant in Pseudomonas aeruginosa. Resistance to other antibiotics useful in UTIs such as fluoroquinolones, fosfomycin or nitrofurantoin is high as well, leaving few therapeutic options for these patients.

**Abstract 8436**

**Late presentation of HIV infection in a hospital in the community of Madrid**

Sandra Scarleth Mendoza Lizardo*, Rosa Escudero Sánchez, Elia Pérez Fernández, Leonor Moreno, María Velasco Arribas, Rafael Hervas Gómez, Oriol Martín Segarra, Natalia Mayoral Canalejas, Sonia Bellón Vallinot, Ana Vegas Serrano, Juan Emilio Losa García

1Hospital Universitario Fundación Alcorcón, Madrid, Spain, 2Hospital Universitario Ramón y Cajal, Madrid, Spain

**Background:** Late presentation (LP) has become the leading cause related to mortality in HIV-infected people in Western countries. It increases the risk of opportunistic infections and medical costs in the short and long term in the affected population.

**Materials/methods:** Retrospective, observational study conducted in a 400-bed hospital in the Community of Madrid. Epidemiological, clinical, analytical variables were collected from all patients over 18 years of age with diagnosis of HIV infection from 2008 to 2017. The patients were compared by area of diagnosis, transmission mechanism and place of origin. The LP was defined as <350CD4+ and advanced disease as the presence of an AIDS event or <200 CD4+ at diagnosis. The regression analysis identified the factors associated with LP.

**Results:** 186 patients were included. The average age was 36 years (SD 11.5), 74% were men and 54% were immigrants. The route of transmission was heterosexual (HTS) in 54% and 46% of the diagnoses were made in Primary Care. At diagnosis, the median of CD4+ and CV were 418/µL and 44,117 copies/mL respectively.

LP was found in 41.8% of patients. The frequency of advanced disease and WHO category C diseases at diagnosis were 30.3% and 14.1% respectively.

Women had a higher LP (52%) compared to men (38.2%), (p:0.98). HTS patients had a higher risk of LP (55%) compared to MSM (27.4%), (p: 0.001). Diagnosis during hospitalization (69.7%) compared to other areas was associated with a higher LP (p:0.001). African immigrants presented 66% of LP, followed by patients from Latin America (46.8%) and Europe (30.9%), (p: 0.01).

In the multivariate analysis, being an African immigrant was associated with LP, increasing the risk of LP by 2.9 times, 95% CI(1.06–8.34) (p:0.038).

In our cohort 88.2% of patients started ART. After 12 months of follow up the median of CD4 was 607 (IQR399-824). Among treated patients 96.2% had undetectable CV (<20 copies/mL) at 35 (20-40) weeks.

**Conclusions:** Late presentation remains an area of improvement in the cascade of care of HIV patients. In our cohort, African patients have a higher risk of LP. Attention should be given to HIV screening in this population.

**Abstract 8443**

**Laboratory evaluation of a cartridge-based multiplex PCR assay for the detection of gastrointestinal pathogens**

Christopher Holmes1, Paul Bird*1

1Clinical Microbiology, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

**Background:** Acute infectious gastroenteritis can be caused by a wide range of pathogens, but symptoms are rarely pathognomonic. Whilst many causes are self-limiting, certain pathogens have significant morbidity or infection prevention implications, for which rapid diagnosis can inform appropriate management. Traditional methods can be time-consuming and slow, delaying these management decisions. Multiplex PCR panels offer a rapid, simple solution to screen samples for a broad-range of pathogens in a single process. The aim of this study was to evaluate the utility of the Qiagen QIAstat Gastrointestinal Panel (QSGP) in a diagnostic laboratory.

**Materials/methods:** Stool specimens that had been sent for diagnosis of gastrointestinal pathogens using routine culture, antigen detection or PCR methods (depending on the pathogen) were retrospectively tested with the QSGP. The QSGP detects 24 bacterial, viral and parasitic pathogens by real-time PCR in an enclosed cartridge format. Stool samples were inoculated into phosphate-buffered saline using a flocked swab and 200 µL was immediately transferred to the cartridge. This was loaded onto the QIAstat DX instrument which completed nucleic acid extraction, amplification and interpretation of results.

**Results:** Forty-nine stool samples were included in the study, providing 324 individual comparisons between QSGP target results and reference methods. QSGP overall sensitivity was 78.7% and specificity was 98.5%. QSGP detected an additional 15 pathogens from 10 specimens, predominantly pathotypes of *Escherichia coli* not covered by the routine methods. Sensitivity for *Salmonella* spp. was particularly low at 58.3%, with 5 specimens negative by QSGP, but culture-positive following selenite broth enrichment. Two specimens were positive for shiga toxin-producing *E. coli* by QSGP, but negative by reference laboratory PCR. One specimen (2.0%) gave an invalid result. Hands-on time was <5 minutes per specimen and results were available within 75 minutes.

**Conclusions:** The QSGP is a simple and rapid test for syndromic gastrointestinal infection testing. Performance was similar to other nucleic acid-based assays for detection of GI pathogens, displaying the ability to detect a wider range of pathogens than culture, but having reduced sensitivity in the detection of *Salmonella* spp. The ability to obtain rapid results using this system has the potential to improve patient management.

**Presenter email address:** paul.bird@uhl-tr.nhs.uk
Abstract 8447

Detection of Legionella spp. and Legionella pneumophila in environmental samples using culture and live/dead-qPCR

Mihai Zamfir*, Sandra Walser-Reichenbach, Stefanie Heinze, Caroline Herr

1Bavarian Health and Food Safety Authority, Occupational and Environmental Health, Epidemiology, Munich, Germany

Background: Legionella spp. are found in water bodies but the typical route of infection is inhalation of bioaerosols. The distribution of such aerosols is commonly linked to evaporative cooling systems, cooling towers and wet separators, but also sewage treatment plants, composting plants and surface waters. The identification of a possible source is typically done by culture on selective nutritive medium (ISO 11731, 2017). For correct interpretation of results, 10 days are required and commensal bacteria often prevent detection of legionella colonies.

In an effort to establish a catalogue of measures which contribute to contain the threat to civil security as quickly as possible, we have evaluated molecular and immunological approaches to detect, quantify and characterize Legionella in environmental samples.

Materials/methods: Water and air samples were screened for Legionella spp. and L. pneumophila. The samples were tested in parallel with standard culture methods and with live/dead qPCR using propidium monoazide (PMA). Through treatment with PMA we were able to differentiate between the cells with an intact membrane (living) and those with a damaged membrane (dead).

Results: In total, 107 water samples and 28 air samples were collected between November 2015 and January 2019. Using qPCR, Legionella spp. was found in 115 samples. L. pneumophila was found using qPCR in seven cooling towers, three wastewater treatment plants, two industrial water samples in concentrations between 100-25000 GU/100mL and between 3-550 GU/m³ in three air samples. Using the culture method, only seven samples were positive for L. pneumophila. The concentration of PMA was adjusted based on the bacterial and organic load of the samples.

Conclusions: qPCR detection of Legionella spp and Legionella pneumophila shows higher sensitivity than the culture based methods. The methods described have been mentioned as part of the VDI (Verein Deutscher Ingenieure) guideline: “Catalogue of measures in case of suspicion of emission-related Legionellosis outbreaks - Identification and investigation of aerosol-emitting environmental sources in the context of legionellosis outbreaks” (VDI-MT 4259-1).

Presenter email address: famzamfir@gmail.com
Abstract 8449

Contrasting molecular epidemiology of Klebsiella spp. and Escherichia coli bloodstream infections in Oxfordshire (UK) 2009-2017

Sam Lipworth1*, Karina-Doris Vihta1, James Kavanagh1, Leanne Barker1, Kevin Kaibond Chau1, Sophie George1, Ali Vaughan1, Dai Griffiths1, Marcus Morgan1, Monique Andersson2, Katja Jefferies3, Tim Peto1, Derrick Crook1, Nicole Stoesser1, A. Sarah Walker1

1University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 2John Radcliffe Hospital, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: The incidence of Gram-negative bloodstream infections (BSI) in England continues to increase with significant associated morbidity and mortality; the genetic mechanisms underpinning this remain unclear.

Materials/methods: We performed short-read whole genome sequencing of all (90-day deduplicated) E. coli (n=2964) and Klebsiella spp. (n=651) BSIs in Oxfordshire, UK, 2009-2017. AMR genes were identified using Abricate; in silico MLST using BLASTn. Stacked negative binomial regression models were used to compare change in presence/absence of AMR genes/STs over time. Healthcare-associated was defined as nosocomial-onset or ≤ 30 days since last discharge.

Results: 1415/2964 (48%) of E. coli isolates belonged to four dominant STs (131/95/73/69); the proportion of BSIs caused by these did not change over time (p=0.25). Most cases were community-onset (1802 community vs 1162 healthcare-associated); ST131 was more likely than other STs (except ST69/95) to be healthcare-associated (p=0.005). There was a significant increase in incidence of the relatively drug-susceptible ST127 [rate ratio/year (RR) = 1.20, p=0.01], which became the sixth largest ST. In contrast for Klebsiella spp., only 87/651 (13%) of cases belonged to the top four STs and the proportion caused by these significantly decreased over time (RR=0.97, p=0.004). Klebsiella BSIs were more likely to be healthcare-associated than E. coli (p < 0.001). In E. coli, the incidence of isolates with genes encoding amoxicillin (RR=1.17, p=0.01) and/or ceftriaxone (RR=1.26, p=0.003) resistance increased significantly over time. Ceftriaxone resistance genes were more commonly found in healthcare-associated cases (136/1162 vs 147/1802, p=0.002). For Klebsiella spp. there was a significant decrease in the incidence of genes associated with co-amoxiclav (RR=0.92, p=0.03), gentamicin (RR=0.92, p<0.001) and ceftriaxone (RR=0.98, p=0.03) resistance. Carbapenemase genes were not observed until 2014; there was an increasing trend over the remaining study period (RR=1.59, p=0.03).

Conclusions: As expected, E. coli BSIs were predominantly community-onset, and associated with a largely clonal population structure and increasing AMR carriage. Somewhat paradoxically for the more healthcare-associated Klebsiella BSIs the opposite was true. This contrasting epidemiology likely reflects different environmental reservoirs and modes of acquisition, and may require different control strategies. The emergence of E. coli ST127, a strain associated with virulence, warrants vigilance.

Feedlot lambs, carcasses and nearby animals are implicated in the transmission of cephalosporin-resistant *Escherichia coli*

Caroline Silva¹, Marlon Barroso¹, Katia Suemi Gozi¹, Juliana Froes², Leticia Kalir Pradela³,⁴, Juliana Peiró⁴, Luiz Claudio Nogueira Mendes⁴, Mara Nogueira¹, Tiago Casella*¹,³

¹Faculdade de Medicina de São José do Rio Preto - FAMERP, São José do Rio Preto, Brazil, ²Centro Universitário de Rio Preto - UNIRP, São José do Rio Preto, Brazil, ³Hospital de Base de São José do Rio Preto, São José do Rio Preto, Brazil, ⁴Universidade Estadual Paulista, Faculdade de Medicina Veterinária, Araçatuba, Brazil

Abstract third-party references: FAPESP [#2018/02691-4, #2018/16147-4, #2019/16003-5], CAPES, CNPq

**Background:** Transmission of cephalosporin-resistant *Escherichia coli* through the food-production chain has been reported by studies concerning beef, chicken and pork meat. This represents a public health concern since those bacteria can cause hard-to-treat infections or horizontally transmit resistance genes to the intestinal microbiota. Studies with sheep are scarce, thus we initiated investigation in this field in Brazil.

**Materials/methods:** Ninety-nine and 93 lambs were rectal sampled during feedlotting in 2017 and 2018, respectively, different herds in the same stockyard. Carcasses were also sampled after slaughtering. In 2017, 10 other mammals dwelling nearby were also sampled. Faeces were inoculated in MacConkey agar supplemented with 4 mg/L ceftiofur. Suggestive colonies of *E. coli* were identified and submitted to antimicrobial susceptibility test by disk-diffusion. Genes responsible for cephalosporin-resistance were sequenced, and *bla*-carrying plasmids were characterized. Isolates were typed by *Xba*I-PFGE.

**Results:** Fifty-seven *E. coli* were isolated from 43 lambs, four carcasses and two surrounding animals in 2017, 82.5% of them multidrug-resistant, and 51 were isolated from 44 lambs and two carcasses in 2018, 100% of them multidrug-resistant. The *blaCTX-M-55* gene prevailed (56.1% in 2017, 62.7% in 2018), but *blaCTX-M-2* (12.3%, and 17.7%), *blaCTX-M-8* (10.5% in 2017), *blaCTX-M-14* (7.8% in 2018) and *blaCMY-2* (21.0%, and 9.8%) were also detected. *Xba*I-PFGE revealed identical isolates carrying *blaCTX-M-2*, *blaCTX-M-55*, or *blaCMY-2*, each gene in the same plasmid, recovered from lamb faeces in either years, showing that such strains remained in that environment throughout a year. Very similar isolates carrying *blaCTX-M-14*- in a unique plasmid were recovered from feedlot lambs and external animals in 2017, which supports that surrounding fauna is also involved in the transmission of cephalosporin-resistant strains to/from food-producing animals. Finally, identical *blaCTX-M-14*-carrying *E. coli* and plasmids were isolated from faeces and carcass in 2018, corroborating the transferring of resistant bacteria from animals’ intestine to ensuing products.

**Conclusions:** Commensal cephalosporin-resistant *E. coli* of food-producing animals contaminate carcasses after animals’ slaughtering, and such bacteria are also in close contact with animals nearby a herd, as well as they can remain subsequent years in a single stockyard. Our results corroborate the movement of resistant bacteria through the food chain.

**Presenter email address:** tiago_casella@yahoo.com.br
Brain abscess in children: a retrospective single-centre experience
Diana Didovic*1, Ivana Valenčak-Ignjatić1, Maja Stemberger Maric1,2, Srđan Roglić1, Goran Tešović1,3

1University Hospital for Infectious Diseases Dr. Fran Mihaljević, Zagreb, Croatia, 2University of Zagreb School of Dental Medicine, Zagreb, Croatia, 3School of Medicine, University of Zagreb, Zagreb, Croatia

Background: Brain abscess (BA) is an uncommon infection during childhood, occurring mostly in the 4-to-7-year age group. Most frequent causative pathogens are streptococci, usually from an otic focus or in patients with congenital heart disease (CHD). BA symptoms and signs vary. High index of suspicion, recognition of predisposing conditions and prompt radiologic evaluation are necessary for outcome improvement.

Materials/methods: Patients with BA aged <18 years, treated at University Hospital for Infectious Diseases “Dr. Fran Mihaljević” in the 10-year period (1 January 2009 – 31 October 2019) were included. Epidemiology, etiology and outcome were analysed.

Results: This study enrolled 21 patients with a male predominance of 71.4%, and the median age of 7.8 years (range 11 days - 17.2 years). The majority (52.3%) were older than 8 years, followed by 3-to-7-year (28.6%) and <3 years age group (19.0%). Predisposing conditions were identified in 16 (76.2%) patients. The most common were otitis/sinusitis (19.0%), followed by dental infection (14.3%), CHD (14.3%), previous neurosurgical procedure (14.3%), meningitis (14.3%), haematologic malignancy (9.5%), and brain trauma (4.8%). In majority of them initial symptom was fever (66.6%). The classic triad of headache, fever and focal neurological deficits was identified in 8 cases (38.1%). Median time from the onset of symptoms to the diagnosis was 7 days (range 0-30 days). 80.9% patients had a single BA. Among patients with multiple BA, 50% were newborns.

Causative pathogens were identified in 16 (76.2%) patients and included 12 bacterial and one fungal pathogen. Most frequently isolated bacteria were streptococci (43.8% of culture-positive cases), of which S.intermedius and S.gordonii were the most common. Mixed infections were detected in 6 cases (37.5% of culture-positive cases). In 76.2% of patients neurosurgical procedure was an integral part of treatment. Stereotactical puncture was performed in 10 and radical excision in 6 patients. The mortality rate was 14.3%.

Conclusions: BA remains a relatively rare disease in children. The spectrum of predisposing conditions is changing due to the increase in the number of postoperative cases and immunocompromised hosts. Early recognition of symptoms, radiologic evaluation and adequate microbiological culture techniques are necessary for positive outcome.

Abstract 8455

Immunotherapy in patients with relapsed/refractory HIV-related lymphomas

Marina Popova1, Yuliya Rogacheva*1, Ivan Tsygankov1, Kirill Lepik1, Anastasia Nekrasova1, Liilia Stelmah1, Ivan Moiseev1, Sergey Bondarenko1, Natalia Mikhaylova1, Vadim Bagkov1, Boris Afanasyev1

1Raisa Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation

Background: Immune check point inhibitors (ICIs) is a new option for salvage therapy in relapsed/refractory (r/r) Hodgkin lymphoma (HL) and non-Hodgkin lymphoma. Patients with HIV-related lymphoma may benefit not only anticancer activity of ICIs, but also from its potential anti-HIV effect [1]. The publications on ICIs in HIV-related lymphomas is limited by a few case reports [2,3].

Materials/methods: Nine patients with r/r HIV-related lymphoma were treated with nivolumab [nivo] between 2017-2019. Median follow-up time was 397 days [45-889]. The end points were response to therapy, immune-related adverse effects (IRAЕ) and overall survival (OS) at 12 months. LYRIC criteria for assessing FDG-PET/CT were applied.

Results: The main characteristics of study population and outcomes are presented on picture 1. Median number of prior lines of therapy was 3 (range, 2-4). Four patients received low dose of nivo as monotherapy [NCT03343665] with median N of courses 12 [7-12], 5 patients in combi with bendamustine and gemcitabine [NCT03259529] with median N of courses 4 [3-11]. The median of CD4+ was 382 c/mcl (range, 45-560). The only one patient didn’t receive cART due acute renal failure who died early from undetermined cause. Overall response rate (ORR) was 89% with the median time 104 days [73-517]; complete remission (CR) was 67% with the median time 107 days [75-265]. IRAЕ was not registered. OS at 12 months was 88.9%

Conclusions: Overall response rate to nivo in patients with HIV-related lymphomas was 89%, one-year OS – 88.9%. Immune-related adverse effects were not registered. Preliminary data provide that nivo seems to be an effective and safety treatment option for r/r HIV-related lymphoma.

Abstract 8461

Clinical characteristics and treatment outcome of patients with sepsis treated in an infectious disease intensive care unit

Rafaela Novak*1, Marta Popović1, Bruno Baršić1,2, Marija Santini1,2, Marko Kutlesa1,2, Vladimir Krajnović2

1School of Medicine, University of Zagreb, Zagreb, Croatia, 2University Hospital for Infectious Disease Zagreb, Zagreb, Croatia

Background: In most countries of the European Union patients suffering from sepsis are commonly treated in general intensive care units (ICU). By contrast, in some European countries, as well as in Zagreb, Croatia, these patients are admitted to a specialized infectious disease intensive care unit (IDICU). The study aimed to evaluate the clinical and epidemiological features of patients with severe sepsis admitted to an IDICU and compare treatment outcome in IDICU with literature data on the outcome of patients admitted to a non-IDICU.

Materials/methods: This research is a retrospective data analysis on 408 patients with the diagnosis of sepsis admitted to the 18-bed IDICU of the University Hospital for Infectious Diseases in Zagreb, Croatia over a three year period (January 2016 to December 2018).

Results: The admitting diagnosis of sepsis represented 35% of all admitting diagnoses in the IDICU. Nearly 2/3 of admitted patients with sepsis were men and the age median was 65 (IQR 55-75), whereas the median of Charlson Comorbidity Index (CCI) was 3 (IQR 2-5). Septic shock was present in 40% of patients, while the median of Sequential Organ Failure Assessment Score (SOFA) was 7 (IQR 4-11). In the IDICU the median patient length of stay was 8 (IQR 3-19) days. The most commonly associated infections were neurological (16%), endocarditis (15%) and urinary tract infections (12%). The specific mortality rate among patients with sepsis was 14%. Around 10% of admitted patients with sepsis were discharged from the IDICU as independent and mobile, while 23% of patients were left with reduced functional disability and 27% of patients were completely dependent and immobile, with case fatality rate of 40%.

Conclusions: The proportion of admitted patients with sepsis in the IDICU was 35%, which is higher than in other ICU-s in Croatia (10-20%) according to literature. The specific mortality rate of IDICU patients of 14% was though in the lower portion of the compared specific mortality range for sepsis (10-50%). Taken into consideration that the admitted patients had higher CCI and SOFA scores, we observed that the type of ICU may have had an impact on the treatment outcome.

Infectious complications in patients with relapsed/refractory Hodgkin's lymphoma during new agents' therapy

Yuliya Rogacheva1, Marina Popova1, Kirill Lepik1, Elena Kondakova1, Yurii Zalylov1, Lilia Stelmah1, Alisa Volkova1, Ilya Nikolaev1, Oleg Goloshapov1, Il'dar Barkhatov1, Sergey Bondarenko1, Ivan Moiseev1, Vadim Ba'ykov1, Natalia Mikhailova1, Nikolai Klimko1,2, Boris Afanasyev1

1Raisa Gorbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation, 2I.I. Mechnikov North-Western State Medical University, Ministry of Health of Russia, Saint Petersburg, Russian Federation

Background: Despite of many reports on anti PD-1 antibody and brentuximab vedotin (BV) therapy the risk of infections is still unknown. We are the first to present the study on infectious complications in large cohort r/r HL patients treated with nivolumab (nivo) or BV.

Materials/methods: Since 2012 to 2018 in our clinic 287 patients with r/r HL received salvage treatment with nivo (n=112) and BV (n=175). In nivo and BV groups median age was 31 and 27 y, median lines of chemo before therapy was 6 (range, 1-9) vs 5 (range, 1-12). The median number of chemo courses was 20 (range, 1-30) vs 4 (range, 1-16), with the median follow-up time 3 years. Infection episodes and outcome analysis considered events at one year after first nivo or BV administration and were censored at the date of allo-HSCT or auto-HSCT.

Results: In 26 r/r HL patients during salvage therapy 31 infection episodes were registered: bacterial infections – 35.5% (n=11), viral infections – 35.5% (n=11), and IFD – 29% (n=9). The incidence of documented bacterial infection in nivolumab group was 6%, in BV – 3.4%, (p=0.19). The main etiology agent was Klebsiella pneumoniae (45%). The incidence of viral infection in nivolumab group was 5.3%, in BV – 2.8% (p=0.28). The main etiology agent was CMV (90%). The incidence of IFD in nivolumab group was 3.2%, in BV – 2.8% (p=0.30). The main etiology agents were Aspergillus spp. (100%). Median time to infection episode was 98 days (12-365) after first nivo administration and 144 days (33-363) after BV. Primary chemoresistant disease before nivo therapy was the only risk factor for the infectious complications during salvage therapy of r/r HL (p=0.029). Overall survival (OS) at 1 year after first nivo administration was 96.5%, in BV group – 72.1%. The only one death was attributed to infection in nivo group.

Conclusions: Infections after BV and nivo developed in 10.8% of patients with r/r HL. There was no difference in incidence of different type of infections during salvage treatment for relapsed/refractory Hodgkin’s lymphoma in BV and nivolumab group. Infections after BV and nivolumab can be managed successfully.

Fecal lactoferrin is associated with severity at presentation but not relapse risk in *Clostridioides difficile* infection

Julia Origüen Sabater*1, Mario Agreda1, Mario Fernandez Ruiz2, Laura Corbella Vazquez1, Patricia Parra1, Jennifer Villa1, Ma Angeles Orellana Miguel1, María Ruiz-Ruigómez1, Tamara Ruiz Merlio1, Isabel Rodriguez Goncer1, Manolo Lizasoain1, Rafael San Juan Garrido1, Francisco Lopez-Medrano1, Jose M. Aguado Garcia1

1University Hospital 12 de Octubre, Madrid, Spain, 2Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain

**Background:** Fecal lactoferrin (FL) has been shown to correlate with the severity of inflammation in the gastrointestinal tract. Data relative to *Clostridioides difficile* infection (CDI) is scarce.

**Materials/methods:** We investigated the accuracy of FL values to predict CDI severity or relapse in a prospective cohort of consecutive patients diagnosed with CDI over a 10-month period. A stool sample was collected at diagnosis and frozen at -80ºC. The ELISA kit DRG EIA-6038 was used to assess FL levels after sample extraction with the system EIA-5674 (both from DRG Diagnostics, Marburg, Germany). According to manufacturer’s recommendations, the cut-off for test positivity was 7.2 µg/ml. Second [Q2 (67.4 µg/ml)] and third quartiles [Q3 (213.8 µg/ml)] were also explored as alternative cut-off values.

**Results:** Overall, 170 samples (146 first CDI episodes, 26 recurrences) were included. The presence of FL values below Q2 was more frequent in patients with diabetes mellitus [64.3% [27/42] vs. 44.5% [57/128], P-value = 0.03], immunosuppression (62.0% [31/50] vs. 44.2% [53/120], P-value = 0.04), solid organ transplantation (71.9% [23/32] vs. 44.2% [61/138], P-value = 0.005) and chronic renal failure (70.2% [33/47] vs. 40.6% [50/123], P-value = 0.02). On the contrary, FL test positivity was associated with solid organ cancer (96.7% [29/30] vs. 77.1% [108/140], P-value = 0.016) and patient age (67.4 ± 18.9 vs. 58.4 ± 16.3 years, P-value = 0.014), as well as with acute renal failure (90% [45/50] vs. 79.3% [98/121], P-value = 0.09), fever (88.8% [79/89] vs. 67.9% [55/81], P-value = 0.007) and leucocytosis at presentation (92.5% [37/40] vs. 78.5% [95/121], P-value = 0.04). Patients with non-severe CDI exhibit more frequently negative FL test than those with severe or fulminant episodes (25% [28/112] vs. 8.6% [5/58], P-value = 0.01). FL values below Q2 were more common among patients with non-severe CDI (58.0% [65/112] vs. 34.5% [20/58], P-value = 0.004). No association was observed between a positive FL test and CDI relapse in the subset of 146 first episodes (86.7% [13/15] vs. 79.4% [104/131], P-value = 0.5).

**Conclusions:** Although immunosuppressed patients presented lower FL levels, a positive test was associated with severity at presentation of CDI (but not relapse).

Phenotypic and genomic diversity of bacterial isolates from humans and healthy pigs in Thailand

Rachel Hickman*1, Thongpan Leangpichart2, Kamonwan Lunha3, Jatesada Jiwakanon4, Sunpetch Angkititrakul4, Ulf Magnussen3, Marianne Sunde2, Josef Järhult1

1Uppsala University, Department of Medical Sciences, Uppsala, Sweden, 2Norwegian Veterinary Institute, Section for Food Safety and Antimicrobial resistance, Oslo, Norway, 3Swedish University of Agricultural Sciences, Department of Clinical Science, Uppsala, Sweden, 4 Khon Kaen University, Research Group Preventive Technology Livestoc, Khon Kaen, Thailand

Background: Antibiotic drugs are frequently used in the rearing of farm animals in South East Asia either as direct treatments or as supplements in animal feed. However, there is limited information into the prevalence and dissemination antimicrobial resistance within these farms. Within this study we developed a bacterial isolate collection from small and medium sized pig farms in Thailand. Each farm had samples collected from the contact animal-handler (C), non-contact animal-rearing individual (NC), and from the health pigs (P) present on the farm.

Materials/methods: A total of 166 pig farms were included in this study, where 115 were from small-sized farms and 51 from medium sample farms. Farm size was categorized as, small-sized farms being <9 pigs and medium sized were categorized as ≥9 pigs. P samples were collected from rectal swabs, whilst all human (C and NC) samples were collected from fecal samples. Collected samples were cultivated on selective media plates, bacterial isolates were selected and species determined by MALDI-TOF. All bacterial isolates were tested for their antimicrobial susceptibility testing (AST) profile and whole-genome sequenced (WGS).

Results: Our bacterial collection consists of 492 E. coli and 43 K. pneumoniae isolates. From our AST testing we saw an abundance of multidrug resistance in both species (E. coli 358/492, 72.3% and K. pneumoniae 29/43, 67.4%). No significant differences between the three groups were found by using a three-way ANOVA statistical test of variance. From our WGS results, we observed a multitude of sequence types (ST) for both species (for E. coli 143 known and 51 novel STs whilst for K. pneumoniae 26 known and 10 novel STs) that will undergo further analysis for clonality and plasmid type testing.

Conclusions: MDR Gram-negative bacteria are prevalent in both small and medium sized Thai pig farms, amongst all sample groups. We demonstrate that NC individuals are at high MDR carriage risk due to close proximity but the societal risk needs to be explored further.

Background: Diagnostic criteria for IA are well validated in hematological patients, but their application to other population, including SOT patients, has several limitations.

Patients/methods: Retrospective study, carried out in 8 centers in Spain from 2010 to 2019. EORTC criteria, Blot et al criteria and a new diagnostic algorithm based on the combination of the above criteria (DIASPERTOS criteria) were compared.

Results: During the study period, 91 IA were diagnosed. The distribution of patients according the different criteria were: "probed" in the same 29 patients for the three criteria; "probable or putative" in 32, 49 and 60 patients, respectively; “possible” in 3, 0 and 1 patients respectively; and “not classified” in 26, 12 and 1 patient, respectively. The contribution of diagnostic techniques according to the type of SOT was as follows:

</tbody>
</table>

Conclusions: The diagnostic of IA in SOT requires a different approach than of the hematological patient. EORTC and Blot et al. criteria have poor sensitivity in SOT patients with IA. GM in blood and GM in BAL have a sensitivity of 52% and 68%, respectively, in these patients. The most frequent radiological features in CT in SOT were nodules, ground glass opacities and tree-in-bud pattern.

**Progressive multifocal leukoencephalopathy, still a challenge in the combined antiretroviral therapy era**

Irina Ianache¹, Alin Olaru¹, Roxana Radoi¹, Manuela Nica¹², Gratiela Tardei¹, Luminita Ene¹, Anca Cristiana Oprea*¹²

¹Victor Babes Hospital for Infectious and Tropical Diseases, București, Romania, ²Carol Davila University of Medicine and Pharmacy, București, Romania

**Background:** The aim of our study was to assess prevalence, clinical outcomes and survival in HIV-infected patients diagnosed with progressive multifocal leukoencephalopathy (PML) in a Romanian tertiary care facility.

**Materials/methods:** Retrospective study on HIV-infected patients hospitalized with PML at Victor Babes Hospital, Bucharest, between January 2006 and December 2018. PML diagnosis was based on clinical symptoms, neuroimaging, positive CSF PCR-DNA JC virus and neurohistopathology.

Statistical analysis was performed using SPSS vs. 20.0.

**Results:** During the study period 87 HIV-infected patients, 63.2% males, were diagnosed with PML, with a prevalence of 3.5/1000 PY [87/24,315]. Thirty patients were confirmed by positive CSF PCR-DNA-JCV. The median age at PML diagnosis was 27 years [IQR: 23, 33]. Modes of HIV acquisition were: parenteral, during early childhood (PI) 54.0%, sexual contact (SI) 40.2% and injecting drug use (IDU) 5.7%. The median CD4 cell count/µl and plasma HIV-RNA (log₁₀copies/mL) at PML diagnosis were 53 [IQR: 16,129] and 4.72 [IQR:2.92,5.40], respectively. The median HIV-RNA in CSF [log₁₀copies/mL] was 3.89 [IQR: 2.71,4.59]. Brain MRI showed lesions in brainstem and/or cerebellum in 25 (28.7%) patients and 4 were diagnosed with PML IRIS. Out of 62 patients previously diagnosed with HIV, 45 were on ART and 41 had severe immunosuppression due to poor adherence. PI patients were younger at PML and HIV diagnosis [p<0.0001] and had lower CD4 cell count [p=0.006] compared to SI and IDUs. The overall mortality and early mortality rates [within 3 months] were high, 49.4% and 29.8%, respectively. 44 patients (50.5%) were alive at the end of the study, with a median survival of 68.0 months [IQR: 41.4, 102.3]. The main risk factors for short survival were nadir CD4 cell count lower than 50/µl [p=0.014], severe immunosuppression [CD4 ≤ 80/µl] and HIV-RNA > 5.00 log₁₀copies/mL [p=0.006] at PML diagnosis [Figure].

**Conclusions:** PML prevalence was high due to late diagnosis and/or poor adherence to ART. SI and IDU patients were frequently diagnosed simultaneously with HIV and PML and had more severe immunosuppression, compared to PI. High HIV viral load at PML diagnosis was a predictor for short-term survival and increased mortality rate.

**Lower concentrations of immunoglobulins (IgM, IgG and IgA) in patients with septic shock compared with sepsis**

Dajana Lendak*1;2, Dunja Mihajlović1;2, Milan Ubavicić3, Aleksandra Novakov Mikic4, Jasmina Boban1, Igor Mitić1;2, Snezana Brkić1;2

1University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, 2Clinical Center of Vojvodina, Novi Sad, Serbia, 3Medlab, Novi Sad, Serbia, 4Poliklinika NOVAKOV i sar., Novi Sad, Serbia

**Background:** Septic shock is the subset of sepsis with the poorest prognosis. Early recognition of those patients is the keystone of successful treatment. Immune status is one of the key factors for sepsis outcome. We have hypothesized that concentrations of immunoglobulins at admission could reflect one part of the patients immune status, and might serve as biomarkers of sepsis severity. We aimed to compare immunoglobulin levels on the day of sepsis diagnosis in patients with sepsis and septic shock, and to compare immunoglobulin concentrations between the subgroups of survivors and non-survivors among the septic shock patients.

**Materials/methods:** 137 consecutive septic patients (Sepsis-3 definition) were included – 116 with sepsis and 21 with septic shock. All patients had available clinical and laboratory data: age, SOFA score, white blood cell count (WBC [$\times 10^9$]), C-reactive protein (CRP [mg/ml]), procalcitonin (PCT [ng/ml]), immunoglobulin levels (IgM, IgG and IgA [g/l]) on admission. Mann-Whitney test was used for comparison of evaluated parameters in two observed groups. For evaluation of sensitivity, specificity and cut-off values of immunoglobulin concentrations, we constructed ROC curves.

**Results:** IgM, IgG and IgA levels were significantly lower in patients with septic shock (Table 1). Despite the small number of patients in septic shock group, concentrations of immunoglobulins in survivors (n=12) and non-survivors (n=9) were compared. Significantly lower levels of both IgM (non-survivors: 0.36 [0.30-0.49] g/l; survivors: 0.64 [0.42-1.04] g/l; p=0.049) and IgG (non-survivors: 2.73 [2.12-3.94] g/l; survivors: 6.13 [3.01-10.89] g/l; p=0.023) were detected in non-survivors.

**Diabetes and obesity reduce weight gain on tuberculosis treatment**

Rishi Banerjee*1, Jessica Barrett2, Ashley Whittington2

1Imperial College London, Faculty of Medicine, London, United Kingdom, 2Department of Infectious diseases London North West University NHS Trust, London, United Kingdom

**Abstract third-party references:** Department of Infectious Diseases London North West University NHS Trust

**Background:** Weight gain is used as a clinical indicator of satisfactory response to anti-tuberculosis treatment (ATT). Here we review weight change on ATT for our TB cohort, with a high prevalence of Type 2 diabetes mellitus (17%), to identify correlates of poor weight gain, and the effect of diabetes on weight change.

**Materials/methods:** Retrospective case-control study of patients treated in a North West London tuberculosis unit between 01.01.2015 and 01.01.2018. Diabetic patients (DM) were age-matched to non-diabetic (non-DM), and pre-diabetic patients were excluded. Weights at 0, 2 months and 6 months of treatment were extracted from the clinical record, and percentage weight change for induction (0-2months), continuation (2-6months) and overall (0-6months) were calculated.

**Results:**

- Older age negatively correlated with both induction and overall percentage weight changes ($r(147) = -.301 \ p=.0007$ and $-.357 \ p=.00003$ respectively).
- Higher start weight negatively correlated with continuation and overall percentage weight changes ($r(113) = -.185 \ p=.048$, $r(129) = -.195 \ p=.027$ respectively).
- Male sex was associated with significantly higher mean weight gains during induction, continuation and overall.
- Percentage weight change was not associated with smear-positivity, ethnicity, HbA1c or good treatment outcomes.

Diabetic patients had significantly less percentage weight gain at all treatment stages than age matched non-diabetic patients:

*Mean ±standard deviation

No significant differences in smear-positivity, ethnicity, sex or outcomes between diabetic and non-diabetic groups.

**Conclusions:** In our cohort lower percentage weight increase was associated with diabetes, higher start weight, older age and female sex.

Treatment outcome was good for a large proportion of patients despite the lack of significant weight gain for many.

Diabetic TB patients have less weight gain during treatment despite similar starting weights possibly due to the metabolic effects of diabetes or effects of glycaemic treatment. Consequently, weight gain as an indicator of TB recovery may therefore be less valid in heavier, older and diabetic populations.

Abstract 8484

Evaluating the healthcare utilisation of undocumented migrants in the Helsinki and Uusimaa hospital district, Finland: a protocol for a register-based cross-sectional study

Kanerva Rautila*, Otto Helve1, Paula Tiittala3

1University of Helsinki, Helsinki, Finland, 2Children’s Hospital, Pediatric Research Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, 3National Institute for Health and Welfare (THL), Helsinki, Finland

Background: It is estimated that 3000-4000 undocumented migrants reside in Finland. The majority live in the capital region of Helsinki. Evidence on the health status and utilisation of health care services by undocumented migrants in Finland is scarce. Their entitlement to municipal health care and social services is severely restricted, although considerable variation exists between municipalities. A description of these services is currently missing. We aim to describe the tertiary level health system for undocumented migrants in Finland and present the first characterization of the use of tertiary level health care and the prevalence of routinely screened resistant bacteria (e.g. MRSA, VRE) in undocumented migrants.

Materials/methods: By using legislative and administrative documents, we map the current health system for undocumented migrants in Finland. In addition, we perform a register-based cross-sectional study of the undocumented migrant population’s use of outpatient and inpatient services in the Helsinki and Uusimaa Hospital District between 2010-2020. The data are collected using two different methods to maximise capture rate. Firstly, in addition to a temporary personal identification code, the financial documentation on hospital billing include a specific code in the case of an undocumented migrant. Secondly, hospitals apply for state reimbursement from the Social Insurance Institution with a specific form. Combining records allows for the tracking of selected personal identification codes from the electronic patient record system. Information is collected on, e.g., the length of hospital stay, number of hospital visits, related diagnoses, and screening results on colonising resistant bacteria.

Results: The tertiary level health system available to undocumented migrants in Finland is shown in Figure 1. We have identified and mapped the registering basis for undocumented migrants in the HUS area and are currently collecting data.

Conclusions: We have created a model to be used to evaluate health care utilisation and needs of undocumented migrants. We will assess the prevalence of routinely screened resistant bacteria to test the applicability of our model in this particularly hard-to-reach population. The results can be used in developing health care services for undocumented migrants and improving their access to necessary preventative health interventions.

Abstract 8487

Granulicatella sp. and Abiotrophia sp. as a rare cause of osteoarticular infections

Dorsaf Slama*, Philippe Morand*,1, Julien Loubinoux1,2, Anne-Laure Roux1, Luc-Jean Eyrolle1, Guillaume Aubeger1, Maya Enser3, Thomas Bauer4, Remy Gauzit1, Valérie Zeller5, Dominique Salmon-Ceron1

1CRIOAC-Ile de France, Cochin-associated Center, Paris, France, 2Laboratory of bacteriology, GHU APHP Centre-Université de Paris, Cochin Hospital, Paris, France, 3Laboratory of bacteriology, GHU APHP Université Paris Saclay Ambroise Paré Hospital, Boulogne Billancourt, Paris, France, 4Orthopedic department, GHU APHP Université Paris Saclay Ambroise Paré Hospital, Boulogne Billancourt, Paris, France, 5CRIOAC-Ile de France, Department of Internal Medicine and Rheumatology, GH Diaconesses-Croix Saint Simon, Paris, France

Abstract:

Granulicatella and Abiotrophia are two bacterial genus close to streptococci, formerly known as “nutritional variants of streptococci”. The purpose of this work is to describe the characteristics of osteoarticular infections (OAI) due to Granulicatella and Abiotrophia and their antibiotic resistance pattern.

Background:

The background section describes the context and rationale for the study.

Materials/methods:

The methods section details the study design, patient selection, data collection, and analysis methods.

Results:

The results section presents the findings of the study, including patient demographics, clinical characteristics, and outcomes.

Conclusions:

The conclusions section summarizes the key findings and their implications for future research and clinical practice.

Development of a new murine model for *Enterococcus faecium* intestinal colonisation

Sophie Reissier1, Valérie Bordeau1, Felden Brice1, Vincent Cattoir1,2, Matthieu Revest1,3

1Université Rennes 1, Unité Inserm U1230, ARN régulateurs bactériens et médecine, Rennes, France, 2CHU de Rennes, Service de Bactériologie-Hygiène hospitalière & CNR de la Résistance aux Antibiotiques (laboratoire associé ‘Entérocoques’), Rennes, France, 3CHU de Rennes, Service de Maladies Infectieuses et Réanimation Médicale, Rennes, France

**Background:** *Enterococcus faecium* is a ubiquitous organism usually present in normal human gut microbiota and natural environment, which is commonly responsible for healthcare-associated infections and hospital outbreaks. Understanding colonization mechanisms seems to be essential to manage those infections and to limit hospital spread. Several experimental models of intestinal colonization have been described using different antibiotic protocols. The aim of this study was to compare these different published models of intestinal colonization with a new one as close as possible to human conditions.

**Materials/methods:** Protocols were performed using 6-weeks specific-pathogen-free Swiss mice. Mice were treated with antibiotics to decolonize the intestinal tract, and then a calibrated suspension (ca. 10⁸ CFU/mL) of *E. faecium* was orally inoculated. The vancomycin-resistant vanB-positive Aus0004 reference strain (recovered from a bacteremic patient) was used. A fecal pellet was collected for each mouse before inoculation and at day (D) 3, D5, D7, D10 and D14 after colonization. Viable bacterial counts were determined in pellets by serially diluting homogenates and plating onto Trypticase-Soy agar and Bile-Esculin-Azide agar. Five antibiotic protocols were tested: clindamycin associated with gentamicin; ceftriaxone associated with cefoxitin; ceftriaxone alone; ceftriaxone associated with amoxicillin and cefoxitin; and ceftriaxone associated with amoxicillin. A group received no antibiotic as negative control.

**Results:** No *E. faecium* intestinal colonization was observed in the control group. At D3, fecal pellets contained on average 4.10⁹ CFU of *E. faecium* per gram of feces with all antibiotic protocols. With clindamycin-gentamicin association, we observed a decrease of about one log₁₀ CFU/g every two days from D3. With the other four antibiotic regimens, the bacterial load obtained at D3 was maintained and stable until D14. A concomitant colonization by *Enterococcus faecalis* was observed in groups treated with ceftriaxone alone and ceftriaxone-cefoxitin combination.

**Conclusions:** Both ceftriaxone-amoxicillin-cefoxitin and ceftriaxone-amoxicillin combinations provided significant and stable *E. faecium* colonization without co-colonization by *E. faecalis*. To be as close as possible to human situation, ceftriaxone-amoxicillin seemed to be the most appropriate for *E. faecium* intestinal colonization model. This model can be used to develop *in vivo* transcriptomic analysis by RNA-seq.

Abstract 8491

A study to investigate the utility of confirmatory testing of oropharyngeal samples positive for Neisseria gonorrhoeae by Cobas 4800 CT/NG test

Sophie Jones*1, Rachel Drayton2, Carys Knapper1, Michael Perry1

1Public Health Wales NHS Trust, Microbiology, Cardiff, United Kingdom, 2Cardiff & Vale University Health Board, Department of Sexual Health, Cardiff, United Kingdom, 3Aneurin Bevan University Health Board, Department of Sexual Health, Newport, United Kingdom

Abstract third-party references: Cardiff and Vale University Health Board, Aneurin Bevan University Health Board, Public Health Wales

Background: Neisseria gonorrhoeae (NG) is a sexually transmitted disease that infects the columnar epithelial cells of the urethra, cervix, rectum, conjunctiva and pharynx. We have previously shown that the positive predictive value for oropharyngeal swabs using the Roche cobas® 4800 CT/NG Test was 88.6% using an in-house assay for confirmation. In this study we set out to investigate the confirmation of cobas® 4800 CT/NG Test NG positive oropharyngeal samples using additional methods.

Materials/methods: Eighty-three patients with positive NG oropharyngeal cobas® 4800 samples from two Integrated Sexual Health clinics in Wales were consented for further NG investigations. Patients had two additional swabs taken for NG testing using the Hologic Aptima Combo 2® Assay and for culture using selective NG media. In-house confirmatory testing for opa and pap genes by real-time PCR was also performed on the remnant cobas 4800 specimens.

Results:

<table>
<thead>
<tr>
<th>Method</th>
<th>Agreement with cobas® 4800 CT/NG Test (n=83)</th>
</tr>
</thead>
<tbody>
<tr>
<td>In-house real-time PCR</td>
<td>73.5% (n=61)</td>
</tr>
<tr>
<td>Aptima Combo 2® Assay (Aptima NG confirmatory assay negative)</td>
<td>66.3% (n=55)</td>
</tr>
<tr>
<td>Aptima Combo 2® Assay (Aptima NG confirmatory assay positive)</td>
<td>56.6% (n=47)</td>
</tr>
<tr>
<td>Any molecular method</td>
<td>73.5% (n=61)</td>
</tr>
<tr>
<td>Culture</td>
<td>19.3% (n=16)</td>
</tr>
</tbody>
</table>

The agreement for all three molecular methods was 66.3%, falling to 56.6% when the Aptima® NG confirmatory assay was performed.

All samples that were negative by in-house real-time PCR were also negative by the Aptima Combo 2® Assay and by culture; all samples positive by the Aptima Combo 2® Assay were also positive by the in-house assay.

Conclusions: The agreement between all four methods for NG detection was low at 19.3%, primarily due to the low sensitivity of culture, and no culture positive samples were negative by any molecular method. Twenty-two samples (26.5%) did not confirm NG by any method, it is unclear if these are true positives or are due to cross-reactivity with non-gonococcal Neisseria species. The further lack of agreement between the molecular confirmatory methods casts doubt onto the utility of confirmatory testing for this sample type when screening high risk patients where high sensitivity is required. Further work is required to determine the true nature of the unconfirmed NG positive samples.

Abstract 8492

Microbiological performances and clinical impact of the FilmArray Pneumonia Panel Plus on critically ill with severe pneumonia
Alexia Verroken*1, Julien Favresse1, Hector Rodriguez-Villalobos1, Pierre-Francois Laterre1
1Cliniques universitaires Saint-Luc, Brussels, Belgium

Background: Following international recommendations, patients suspected with severe pneumonia receive broad-spectrum empirical antibiotherapy subsequently reviewed upon availability of microbiological results. However laboratory analysis on respiratory samples requires up to 48 hours to obtain final results allowing instauration of optimal antibiotherapy (OAT). Molecular testing aims to reduce time to results. In this study we evaluated the microbiological performances and clinical impact of the BioFire® FilmArray® Pneumonia Panel (FA-PNEU) [bioMérieux] on critically ill suspected with severe pneumonia. This multiplex PCR allows the detection of 27 bacteria and viruses within 1h15 minutes directly from the respiratory sample.

Materials/methods: This prospective interventional study is conducted at the Cliniques universitaires Saint-Luc university hospital. Conditions for inclusion are: all adult patients admitted/remaining at the intensive care with suspicion of community acquired pneumonia class IV [CAP IV] or hospital acquired pneumonia (HAP) for which a lower respiratory tract sample was obtained. The study started in May 2019 and will last for 1 year. FA-PNEU testing is performed immediately following sample collection 24h/24 7days/7. Results were compared with routine testing including urinary antigen detection, immuno-enzymatic viral assays and bacterial cultures performed during working hours. FA-PNEU results were used to tailor patient’s antimicrobial treatment and time to OAT was measured.

Results: At present 34 patients have been included, comprising 20 men and 14 women with a mean age of 63 years. Final diagnosis was bacterial CAP IV and HAP for respectively 15 and 9 patients while pneumonia diagnosis was uncorroborated for 10 patients. Mean time to FA-PNEU result was 2h10 compared to 52h to complete routine laboratory results. A 100% concordance with routine testing was observed for all FA-PNEU strains detected with a minimum quantity of 10^6 copies/ml. 18/34 (52.9%) included patients benefitted from a speeded-up initiation of OAT following FA-PNEU result availability consisting of 11 cases of antibiotic streamlining and 7 cases of complete antibiotic stop.

Conclusions: FA-PNEU results show optimal concordance with routine testing and speed up instauration of the OAT in more than 50% of the included patients. Incoming study results confirm these observations and will be included in the presentation.

Abstract 8495

Human metapneumovirus infections among patients with haematological malignancies including haematopoietic stem cell transplant: analysis of a 6-year period

Laura Labate1, Elisa Balletto1, Laura Magnasco*1, Anna Maria Raiola2, Fabio Guolo3, Emanuele Angelucci1, Lemoli Roberto Massimo1, Claudio Viscoli1,4, Matteo Bassetti1,4, Malgorzata Karolina Mikulska1,4

1University of Genoa, Division of Infectious Diseases, Department of Health Science DISSAL, Genoa, Italy, 2Ospedale Policlinico San Martino IRCCS, Division of Hematology and Bone Marrow Transplantation, Genoa, Italy, 3Ospedale Policlinico San Martino IRCCS, Division of Hematology, Genoa, Italy, 4Ospedale Policlinico San Martino IRCCS, Division of Infectious Diseases, Genoa, Italy

Background: The pathogenic potential of human metapneumovirus (hMPV) infection among severely immunocompromised patients has yet to be fully elucidated. Previous studies reported a prevalence of hMPV infection in hematopoietic stem cell transplant (HSCT) recipients of 5-9% and a mortality up to 27% among patients with lower respiratory tract infections (LRTI). The aim of this study was to report the characteristics and outcome of hMPV infection among patients with hematological malignancies.

Materials/methods: We conducted a retrospective, single-centre study at a University Hospital in Genoa, Italy during the years 2012 to 2018. All adult patients with hematological malignancies and detection of hMPV in respiratory specimens by molecular search (Seeplex RV12 Viral) were included. Upper respiratory tract infection (URTI) and LRTI were defined according to ECIL criteria.

Results: Fifty-two patients met the inclusion criteria. Median age was 52 years; 30 patients (58%) were females. The infection was mostly detected during late winter/early spring (February to April). Clinical characteristics of included patients, data about specific antiviral treatment and outcome are outlined in table 1. Overall, incidence of hMPV LRTI among patients receiving HSCT was 10%. Attributable mortality to hMPV infection was 3.9%, with a crude mortality of 29%.

Conclusions: hMPV infections are frequent among immunocompromised patients with hematological malignancies and undergoing HSCT during the cold season, with a high rate of LRTI and attributable mortality of 4%. The optimal management strategy remains to be defined.

Identifying drivers of acquisition of extended-spectrum beta-lactamase producing Enterobacterales in Malawi using whole genome sequencing and mathematical modelling

Joseph Lewis*1,2,3, Madalitso Mphasa1, Rachel Banda1, Emma Smith1,2, Christopher Jewell4, Brian Faragher1, Nicholas Thomson1, Nicholas Feasey1,2

1Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 2Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, 3Wellcome Sanger Institute, Hinxton, United Kingdom, 4Lancaster University, Centre for Health Informatics, Computing and Statistics, Lancaster, United Kingdom

Background: In Blantyre, Malawi, extended-spectrum beta-lactamase producing Enterobacterales (ESBL-E) are a significant public health challenge: limited access to carbapenems often renders these infections locally untreatable. Sparse data suggest ESBL-E gut mucosal colonisation is common, making interventions to reduce colonisation potentially attractive to tackle invasive disease - but drivers of carriage are not understood. We performed a prospective cohort study to identify drivers of ESBL-E colonisation in this setting.

Materials/methods: Malawian adults with planned antimicrobial therapy were recruited on admission to Queen Elizabeth Central Hospital, Blantyre, Malawi, along with antimicrobial-unexposed hospital and community controls. ESBL-E carriage was defined at enrolment and 1, 4, 12 and 24 weeks with ESBL-selective stool culture. Isolates underwent short-read whole-genome sequencing as high-resolution typing. Multivariable logistic regression was used to identify associations with ESBL-E carriage at baseline and Markov models used to identify associations with ESBL-E acquisition/loss.

Results: 425 adults were recruited. 42% (95%CI 38-47%) of participants carried an ESBL-E at baseline, rising to 78% (95%CI 71-84%) in antimicrobial-exposed inpatients by day 7. Rainy season (aOR 2.2 [95%CI 1.4-3.4]), use of unprotected water source (aOR 3.0 [95%CI 1.1-8.8]), household crowding (aOR 1.2 [95%CI 1.0-1.4] per adult) and recent hospital admission (aOR 5.9 [95%CI 1.8-27.0]) were independently associated with colonisation. Longitudinal models showed that hospitalisation drives net acquisition of ESBL-E by increasing turnover (aHR for loss 10.0 [95%CI 1.2-52.3] and acquisition 27.8 [95%CI 3.6-143.1]) and antimicrobials act to prolong carriage by reducing loss (aHR 0.16 for loss [95%CI 0.05-0.58]), with a post-antibiotic effect (half-life 44 days [95%CI 15-98]) whereby antimicrobials act to prolong ESBL-E carriage long after they have been excreted. Whole-genome sequencing showed a dynamic process with rapid turnover of bacteria and mobile genetic elements.

Conclusions: In Malawian adults, ESBL-E colonisation is common, and environmental and person to person transmission routes may both play a role. Rapid turnover at the genomic scale suggests frequent exposure. Hospitalization and antimicrobial exposure act synergistically to produce rapid increase in and prolonged carriage of ESBL-E, driven in part by a prolonged post-antibiotic effect. The mechanism of this effect is unknown but warrants study as a potential therapeutic target.

Abstract 8501

Development of a combination antibiogram for empiric treatment of Pseudomonas aeruginosa in the intensive care unit

Brandon Dionne*1,2, Sanjat Kanjilal2, Karrine Brade3

1Northeastern University, Boston, United States, 2Brigham and Women’s Hospital, Boston, United States, 3Boston Medical Center, Boston, United States

Background: The 2016 IDSA/ATS treatment guidelines for hospital-acquired or ventilator-associated pneumonia (HAP/VAP) endorse empiric double coverage for high-risk patients. An antipseudomonal β-lactam plus either a fluoroquinolone (FQ) or aminoglycoside (AG) are suggested, along with the recommendation that selection is guided by local resistance data. Therefore, the primary objective of this study was to develop a combination antibiogram to determine the most active empiric coverage for the intensive care unit (ICU) population.

Materials/methods: The first isolates of Pseudomonas aeruginosa from adult (>18 years) patients collected between 1/1/2017-12/31/2018 at two tertiary care medical centers were included. Isolates were analyzed if they were the first collected per patient per year and excluded if the patient was not in the ICU at the time of collection. Susceptibilities to amikacin (AMK), cefepime (FEP), ciprofloxacin (CIP), gentamicin (GEN), levofloxacin (LVX), meropenem (MEM), and piperacillin/tazobactam (TZP) were assessed by either disk diffusion or Vitek 2 per 2018 CLSI criteria. A combination antibiogram was then developed by including isolates that were non-susceptible to the β-lactam but susceptible to either the FQ or AG.

Results: In total there were 345 isolates included in the analysis; however, not all isolates were tested against each antibiotic. Culture sources included: 255 (73.9%) respiratory isolates, 46 (13.3%) urinary isolates, 8 (2.3%) bloodstream isolates, and 36 (10.4%) isolates from other sources. FEP was the most active β-lactam monotherapy agent (Table 1). Susceptibilities to non-β-lactams were: AMK, 96.7%; GEN, 87.8%; CIP, 74.8%; LVX, 71.8%. Isolates were 6% (95% CI; 2.7%-9.3%) more susceptible to the combination of FEP + AMK than FEP + LVX.

<td>TZP</td>
<td>84.0%</td>
<td>98.0%</td>
<td>95.5%</td>
<td>91.4%</td>
<td>90.6%</td>
</tr>
</tbody>
</table>

Conclusions: AGs provide greater additional activity than FQs. In ICU patients with suspected pseudomonal infection, TZP combined with AMK would offer the most active empiric coverage while MEM plus LVX offers the least.

Abstract 8504

Non-steroidal anti-inflammatory drug administration impairs antibiotic treatment of orthopaedic device-related infection in a rat model

Fintan Moriarty*, Geoff Richards¹, Keith Thompson¹

¹AO Research Institute Davos, Davos, Switzerland

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are a mainstay of perioperative pain management in orthopaedic trauma surgery, although due to their anti-inflammatory properties, NSAIDs may also negatively impact on host immune responses. This could have negative consequences for their use in the context of orthopaedic device related infection (ODRI). The aim of this study was to determine the impact of NSAIDs on antibiotic therapy of ODRI in a rat model.

Materials/methods: A polyetheretherketone (PEEK) screw was inserted in the proximal tibia of 48 skeletally mature (24-week old) female Wistar rats: 12 control animals received a sterile screw, of which 6 also received NSAID therapy (carprofen, 5 mg/kg s.c. once daily); 36 animals received a S. epidermidis-inoculated screw, of which 18 also received NSAID therapy. Antibiotic therapy (cefazolin: 30 mg/kg; s.c., b.i.d. plus rifampin: 25 mg/kg; s.c., b.i.d.) was administered from day 7-21 in 9 animals from each group (i.e. +/- NSAID treatment) receiving S. epidermidis-inoculated screws. Bone changes were monitored using in vivo microCT scanning, performed postoperatively and at 3, 6, 9, 14, 20 and 28 days (euthanasia). Quantitative bacteriology of the implant, bone and overlying soft tissue was also performed to assess infection status.

Results: All animals receiving S. epidermidis-inoculated screws without antibiotics were confirmed as infected at euthanasia. Quantitative microbiology showed no difference in bacterial load control versus NSAID-treated animals (CTL = 53’686 CFU + 68’094; NSAID = 45’617 CFU + 36’057). However, NSAID administration dramatically impaired antibiotic efficacy, with 7/8 animals remaining infected versus 2/9 control animals.

Pronounced osteolysis was observed in infected control animals, which peaked at day 9. Reparative processes (periosteal proliferation and mineralization) in the vicinity of the screw was observed at day 14 and continued until day 28. NSAID treatment markedly prevented S. epidermidis-induced osteolysis but also markedly impaired reparative processes. Antibiotic treatment did not affect the bone changes in control or NSAID-treated animals.

Conclusions: NSAID administration dramatically affected the response of bone tissue to infection, reducing osteolysis but also dramatically reducing antibiotic efficacy. Given these observed negative effects, further investigations should be conducted to determine the underlying pathophysiological mechanism.

Prevalence of resistance-associated mutations for ciprofloxacin in Neisseria gonorrhoeae and azithromycin and moxifloxacin in Mycoplasma genitalium

Roel Nijhuis*1, Rutger Duinsbergen1, Peggy Godschalk1
1Meander Medical Center, Amersfoort, Netherlands

Background: STI causing bacteria Neisseria gonorrhoeae (NG) and Mycoplasma genitalium (MG) are both listed on the CDC’s list of Antibiotic resistance threat in the US. For NG, ciprofloxacin has no longer been recommended for treatment as of 2007 because of increasing resistance. Resistance of MG to first-choice antibiotic azithromycin is high across the globe. Resistance to the alternative antibiotic moxifloxacin has already been reported. Because these bacteria are commonly diagnosed using PCR only, phenotypical detection of antibiotic resistance is hardly ever feasible for NG and impossible for MG. In this study, we determined the prevalence of resistance to abovementioned antibiotics for respectively NG and MG using molecular methods.

Materials/methods: All specimens received for routine STI diagnostics from December 2018 – May 2019 were tested for NG and MG and positive specimens were subsequently tested for the presence of resistance associated mutations (RAM). A prototype of the NG-FQres qPCR assay (NYtor B.V.) was used to detect ciprofloxacin RAM in NG. To detect RAM in MG, the RealAccurate® TVMgres PCR assay (Pathfinder) and a prototype of the MG-FQres qPCR assay (NYtor B.V.) was used for detection of azithromycin and moxifloxacin resistance respectively.

Results: From a total of 2644 specimens, 41 (1.6%) and 106 (4.0%) tested positive for NG and MG respectively. Thirty-three NG positives could be tested for ciprofloxacin RAM, of which 7 tested positive. In addition, 55 previously collected NG positive specimens were tested, of which 11 contained ciprofloxacin RAM. In total, 18 out of 88 (20.5%) contained ciprofloxacin RAM. For MG, 106 and 86 could be tested for azithromycin and moxifloxacin RAM respectively. Forty-three (40.6%) tested positive for azithromycin RAM, whereas 7 (8.1%) for moxifloxacin RAM.

Conclusions: Although treatment of NG with ciprofloxacin is not recommended, the use of ciprofloxacin might again be an option when testing individual patients for RAM since almost 80% is susceptible. This study shows that the prevalence of azithromycin RAM in MG is alarmingly high, indicating that azithromycin should not be used as first-choice treatment without prior susceptibility testing. Moxifloxacin is still an option, but the prevalence of the respective RAM should be monitored.

Abstract 8506

Excessive antibiotic use and costs in hospitalised adults with chronic heart failure

Olga Zorya1, Svetlana Rachina*1, Andrey Bobylev2, Girindu Hewathanthirige1

1PFUR, Moscow, Russian Federation, 2Smolensk State Medical University, Smolensk, Russian Federation

Background: Clinical presentation of chronic heart failure (CHF) can be easily confused with the signs and symptoms of lower respiratory tract infections such as pneumonia. Therefore patients with CHF worsening have a high probability of antibiotics (AB) overprescribing even if clinical suspicion for pneumonia is low. Our study aimed to evaluate the rate of inappropriate AB prescription and calculate direct costs due to excessive antibacterial therapy in hospitalized patients with CHF.

Materials/methods: Hospitalized adults with previously diagnosed decompensated CHF and suspected community-acquired or hospital-acquired pneumonia were included into a prospective two-centered observational study. Diagnosis of pneumonia was confirmed/excluded by multispiral computed tomography (MSCT) or chest radiography (evaluated independently by two radiologists) along with standard methods and procedures. Patients with any systemic infections were excluded. Unnecessary AB use and direct costs related to antibacterial therapy were calculated.

Results: Overall 140 patients, median age 77 (67; 82) years old, were enrolled, 56.5% were female. Diagnosis of pneumonia was excluded in 52 (37%) cases. Of them, 49 (94.2%) patients received systemic AB. The median duration of antibacterial therapy was 8 (7;11) days. Ceftriaxone, azithromycin and cefotaxime were the most commonly prescribed AB. The median direct cost associated with excessive antibacterial therapy was 101,34 (47,7; 141,1) Euro per patient.

Conclusions: Difficulties in verification of pneumonia among patients with CHF lead to high rate of unnecessary AB use and inappropriate expenditures. More reliable algorithm to differentiate pneumonia and CHF worsening is required to prevent potential adverse outcomes of AB overprescription.

Abstract 8507

**Impact of intra-partum azithromycin on carriage of group A Streptococcus in Gambia: an ad hoc analysis of a double-blind randomised trial**

Isatou Jagne*1, Abdoulaye Bojang1, Edrisa Jallow1, Elina Senghore1, Bully Camara1, Claire Oluwalana1, Saikou Y. Bah1,2, Alexander Keeley2, Claire Turner1, Abdul Karim Sesay1, Umberto D’alessandro1, Christian Bottomley3, Thushan I. De Silva1,2, Anna Roca1

1MRCG at LSHTM, Fajara, Gambia, 2The Florey Institute, University of Sheffield, Sheffield, United Kingdom, 3LSHTM, London, United Kingdom

**Background:** Group A Streptococcus (GAS) is an important cause of both maternal and neonatal sepsis. Asymptomatic bacterial colonization is considered a necessary step towards sepsis.

**Materials/methods:** We performed an adhoc analysis of a phase-III, double-blind, placebo-controlled randomized-trial (ratio 1:1) conducted in The Gambia to determine the impact of one oral dose (2g) of intra-partum azithromycin on maternal and neonatal GAS carriage. Biological samples (nasopharyngeal swabs, breast milk and vaginal swabs) were collected at different time points during the 4 weeks following the intervention. All samples were processed using conventional microbiology techniques. Statistical analysis was done using STATA 14. Whole Genome Sequencing (WGS) of GAS isolates was performed using the illumina Miseq platform. De novo assembly (SPAdes), gene annotation (prokka), core genome determination (roary), maximum likelihood phylogenetic tree construction (RAxML) and antimicrobial resistance gene analysis (abricate) were used to analyse sequence data.

**Results:** We randomized 829 mothers who delivered 843 babies. Among women who received azithromycin, there was lower GAS prevalence of post-intervention carriage in breast milk (2.40% vs 0.27%, Prevalence Ratio (PR)=0.11, 95% CI 0.01 -0.87, p=0.021) and in the nasopharynx (1.87% vs 0.27%, PR=0.14, 95% CI 0.02-1.16, p=0.069), but not in the vaginal tract (2.13% vs 1.87%, PR=0.88, 95% CI 0.32-2.39, p=1.000). Among neonates whose mothers had received azithromycin, there was also lower prevalence of GAS carriage in the nasopharynx (2.20% vs 0.56%, PR=0.26, 95% CI 0.06-1.21, p=0.107). Prevalence of carriage of GAS azithromycin resistant was low and similar in participants from both arms, except for a higher prevalence in the vaginal tract post-intervention among women from the azithromycin arm (1.88% vs 0.27%, PR=7.04, 95% CI 0.87-56.92, p=0.038). WGS revealed all azithromycin-resistant vaginal tract isolates from the azithromycin arm to be Group A carbohydrate-expressing Streptococcus dysgalactiae harbouring macrolide resistant genes msr(D) and mef(A). Other isolates were confirmed as GAS as expected, with low prevalence of genotypic macrolide resistance.

**Conclusions:** Oral intra-partum oral azithromycin reduced prevalence of GAS carriage among Gambian mothers and neonates. The prevalence of carriage in the maternal vaginal tract was not affected by the intervention due to azithromycin-resistant Streptococcus dysgalactiae isolates expressing Group A Lancefield antigens.

Antimicrobial stewardship teams in candidaemia management: advise or take care of the patient?

Ana Alemán Alemán1, Noemi Gómez-Manero1, María Fernández Regueras1, María Ángeles Mantecón1, Luis Buzón Martín2, Miguel Ángel Morán-Rodríguez4, Carolina Navarro San Francisco*2

1Hospital Universitaria de Burgos, Internal Medicine, Burgos, Spain, 2Hospital Universitaria de Burgos, Infectious Diseases Unit. Internal Medicine Department., Burgos, Spain, 4Hospital Universitaria de Burgos, Microbiology, Burgos, Spain, 4University Hospital of Araba, Infectious Diseases. Internal Medicine., Vitoria-Gasteiz, Spain

Background: It is known that the intervention of antimicrobial stewardship teams with infectious diseases specialist (AST-ID) improves compliance with the bundle of diagnostic and therapeutic measures in candidemia. The difficulty lies in establishing what type of intervention is the most efficient.

Materials/methods: Data regarding the management and evolution of candidaemia of a tertiary hospital without solid organ and hematopoietic transplantation, with 680 beds, from January 2015 to June 2019 have been collected. AST-ID interventions were making a non-impositive recommendation to the responsible physician or taking direct charge of the patient’s management. Adherence to standard recommendations and outcomes were evaluated. Categorical variables were compared with the chi-square test.

Results: A total of 110 episodes of candidaemia were evaluated in non-neutropenic patients. Of these 43 were women (39.1%) and 67 men (60.9%). 92 episodes were nosocomial (83.6%). They were managed without the help of AST-ID 47 (42.7%) episodes, in 24 (21.8%) AST-ID give non-impositive recommendations and in 39 (35.5%) episodes AST-ID took direct charge of patient management.

The 90-days mortality related to candidiaemia in the AST-ID management group was 10.3 %, while in the AST-ID recommendation group it was 20.8 % (p = 0.28).

Conclusions: The comprehensive management of patients with candidaemia by an AST-ID improves adherence to the diagnostic measures included in the candidaemia bundle, which prolongs the average stay. The directed treatments are correct to a greater extent and as a consequence related mortality decrease. We suggest that episodes of candidaemia should be managed by AST-ID in the centers where it is available, in order to provide patients the best standard of care. Future guidelines will probably address this issue.

Abstract 8514

Direct detection of intact Klebsiella pneumoniae carbapenemase (KPC) enzymes from bacterial isolates using liquid chromatography coupled with high-resolution Orbitrap mass spectrometry

William Mcgee*, Matthew Faron2, Jason Neil1, Scott Kronewitter1, Blake Buchan2,3, Jim Stephenson1, Nathan Ledeboer2,3

1Thermo Fisher Scientific, Cambridge, United States, 2Medical College of Wisconsin, Milwaukee, United States, 3Wisconsin Diagnostic Laboratories, Milwaukee, United States

Background: Carbapenem resistance in bacteria is an urgent concern. Infections by these organisms have limited therapeutic options, increased mortality rates, and can spread quickly through a hospital environment. Rapid detection of these resistance mechanisms is essential to improve patient management and prevent hospital transmission. Klebsiella pneumoniae carbapenemases [KPCs] are endemic in the United States and are found globally. Herein, we present a method for direct from colony detection of intact KPC using mass spectrometry.

Materials/methods: Clinical isolates were evaluated for the presence or absence of KPC genes using either whole genome sequencing or polymerase chain reaction (PCR). Intact cells from clinical isolates were mechanically lysed and centrifuged. The protein-containing supernatant was extracted and transferred to a short solid phase extraction (SPE) column, from which proteins are eluted, ionized via electrospray ionization (ESI), and introduced to the mass spectrometer (MS). KPC variants were detected via dissociation of intact protein ions via tandem mass spectrometry (MS/MS), forming diagnostic fragment ions representative of the presence of the target enzymes.

Results: Protein fragment ions produced from KPC variants possess specific characteristics, such as mass-to-charge ratios (m/z) and correct charge states, thereby providing the opportunity to correctly identify the intact proteins. These fragments are individually informative, but collectively produce sequence information corresponding specifically to KPC variants. Additionally, MS alone is not always capable of detecting specific proteins in a complex mixture, yet MS/MS performs this task well. To date, more than 30 species of Enterobacteriales as well as Pseudomonas aeruginosa have been evaluated to detect KPC-2, KPC-3, KPC-4 and KPC-5. Our evaluations have shown zero false positives with near 100% sensitivity of KPC detection.

Conclusions: These data describe a method for direct and rapid detection of KPC enzymes using liquid chromatography, electrospray ionization, and tandem mass spectrometry. It does not require time-consuming protein digestion or lysate purification steps, yet provides accurate results and could be extended to detection of other carbapenemases to improve turnaround time of resistance detection.

Using point prevalence methodology to evaluate antimicrobial prescribing in the UK’s largest renal dialysis centre
Aneeka Chavda*, Anan Ghazy1, Laura Whitney1, Mark Gilchrist1, Alison H. Holmes1,2
1Imperial College Healthcare NHS Trust, London, United Kingdom, 2Imperial College London, London, United Kingdom

Background: The outpatient haemodialysis population are amongst the most vulnerable to infections and have a higher risk of colonisation with multi-drug resistant organisms (MDRO)1. A rise in antibiotic use and increased hospital contact within this group are key factors for accelerating the acquisition of MDRO. Antibiotic prescribing and stewardship practices in this setting are under-researched in comparison to in-patient prescribing. Here we present point prevalence antibiotic prescribing data from the largest single haemodialysis service in the UK serving 1400 patients.

Materials/methods: This is a prospective observational study across eight satellite hospital outpatient haemodialysis units which are affiliated with a large tertiary academic institution. Data were collected over 3 months from October to December 2019 by a member of the Infectious Diseases Pharmacy team. All adult patients receiving intermittent haemodialysis the day prior to data collection were included. Baseline demographic and antibiotic prescribing data were collected for by review of prescription charts and medical records. Each antibiotic regimen prescribed was reviewed independently by a Consultant microbiologist and an Infectious Diseases Pharmacist to determine appropriateness of the prescription.

Results: At the time of this abstract 405 patients had been reviewed from 6 of the 8 haemodialysis centres. 4% of patients were identified as being on antibiotics at the time of data collection. 25% of patients had a documented antibiotic allergy of which 66% did not specify the nature of the allergy. 45% of the antibiotic prescriptions had a documented indication and 72% had a review date specified on the medication chart. The most commonly prescribed antibiotics were vancomycin and meropenem. The appropriateness of antibiotics prescribed will be reported once independent review is complete.

Conclusions: Interim results show that despite low prevalence of antibiotic prescribing there is significant exposure to broad spectrum antibiotics within this cohort. Of concern is poor documentation of indication and antibiotic allergies. Gaining an understanding of antimicrobial prescribing patterns in this setting will inform the development of an outpatient haemodialysis antibiotic stewardship framework, focusing on interventions to minimise unnecessary exposure to antimicrobials, curtailing the risk of MDRO acquisition and improving patient outcomes.

Multidisciplinary interventions to reduce nosocomial transmission of influenza

Ben Warne*, Mark Reacher², Maria Zambon³, Hamid Jalal¹

Background: Seasonal influenza is an under-recognised cause of nosocomial infection. During the 2016-17 winter, 112/315 (36%) adult inpatients with confirmed influenza at Cambridge University Hospitals (CUH) acquired their infection in hospital. Subsequent genomic and epidemiological investigations confirmed extensive patient-to-patient transmission. However, the impact of clinical and infection control practices in reducing influenza transmission are poorly understood. The aim of this study is to describe a range of interventions over three winters and their impact on clinical practice, hospital-acquired infection and mortality.

Materials/methods: CUH is a 1100-bed teaching hospital with high staff uptake of influenza vaccination. Data were derived from electronic records for all patients with PCR-confirmed influenza attending CUH from August 2016-April 2017 (n=348) and compared to cohorts from August 2017-May 2018 (n=763) and August 2018-April 2019 (n=823). Four key interventions were introduced prior to the 2017/18 winter: 1) improved isolation procedures, with dedicated side room capacity for suspected respiratory virus cases; 2) increased frequency of laboratory testing; 3) changes in antiviral prescribing and wider oseltamivir availability; 4) comprehensive staff education for emergency and acute medicine specialties. Additionally, point-of-care influenza testing (Cepheid GeneXpert) was available in the Emergency Department during the 2018/19 winter.

Results: Isolation of adult patients on admission rose from 48% of influenza cases in 2016-17 to 93% in 2018-19. Over the same period, the median time from admission to swabbing fell from 9 hours to 2 hours, while the delay from admission to first antiviral dose fell from 45 hours to 7 hours. The proportion of influenza infections acquired in hospital fell from 36% in 2016-17 to 17% in 2018-19. Adult inpatient mortality fell from 9.7% to 3.6%.

Conclusions: Influenza is an important cause of morbidity and mortality in secondary care. Better use of existing resources and the utilisation of rapid diagnostics have led to considerable improvement in patient management and are associated with a reduction in hospital-acquired infection and inpatient mortality. Although focused on a single centre, these findings are likely applicable in many secondary care settings. Responding to this challenge requires interdisciplinary engagement, utilising a range of approaches to better understand, manage and prevent transmission.

Half of prescribed antibiotics are not needed: a pharmacist-led antimicrobial stewardship intervention and clinical outcomes in a referral hospital in Ethiopia

Makeda Semret*1, Gebremedhin Beeedemariam Gebretekle2, Cedric Yansouni1, Michael Libman1, Workie Abebe Taye2, Tinsae Alemayehu1, Wondewossen Amogne Degu2, Atalay Mulu2, Damen Haile Mariam2

1McGill University Health Centre, Montréal, Canada, 2Addis Ababa University, Addis Ababa, Ethiopia

Background: Intense antibiotic consumption in Low- and Middle-Income Countries (LMICs) is fueled by critical gaps in laboratory infrastructure and entrenched syndromic management of infectious syndromes. Few data inform the achievability and impact of antimicrobial stewardship interventions, particularly in Sub-Saharan Africa. Our goal was to demonstrate the feasibility of a pharmacist-led laboratory-supported intervention at Tikur Anbessa Specialized Hospital in Addis Ababa, Ethiopia, and report on antimicrobial use and clinical outcomes

Materials/methods: This was a single-center prospective quasi-experimental study conducted in two phases: (i) intervention phase (November 2017 to August 2018), during which we implemented weekly audit and immediate feedback sessions on antibiotic prescriptions of hospitalized patients, and (ii) post-intervention (September 2018 to January 2019) during which we audited prescriptions but provided no feedback to treating teams. The AMS team consisted of 4 clinical pharmacists and one ID specialist. Our primary outcome was antimicrobial utilization (measured as days of therapy (DOT) per 1000 patient-days and duration of antibiotic treatment courses); secondary outcomes were length of hospital stay and in-hospital all-cause mortality

Results: We collected data on 1,111 individual patients (707 during the intervention and 404 in the post-intervention periods). Ceftriaxone, vancomycin, cefepime and meropenem were the most commonly prescribed antibiotics; 96% of the recommendations made by the AMS team were accepted. The AMS team recommended to discontinue antibiotic therapy in 54% of cases during the intervention period. Once the intervention ceased, total antimicrobial use increased by 51.6% and mean duration of treatment by 4.1 days/patient. Mean LOS stay and crude mortality also increased significantly post-intervention (LOS: 19.8 vs 24.1 days in hospital death 6.9% vs 14.7%). These differences remained significant after adjusting for potential confounders.

Conclusions: An AMS intervention focused on duration of antibiotic treatment was feasible and had good acceptability in our setting. Cessation of audit-feedback activities was associated with immediate and sustained increases in antibiotic consumption reflecting a rapid return to baseline prescribing practices, and worse clinical outcomes (increased length of stay and in-hospital mortality). Pharmacist-led audit-feedback activities can effectively reduce antimicrobial consumption and result in better-quality care, but require organizational leadership for sustainable benefits.

Detection of respiratory Mycoplasmataceae during prolonged mechanical ventilation

Erik Clarke¹, Ebbing Lautenbach¹, Emily Reese⁵, Magda Wernovsky¹, Pam Tolomeo¹, Brendan Kelly*¹

¹University of Pennsylvania, Philadelphia, United States

Abstract third-party references: Centers for Disease Control and Prevention (CDC), National Institute for Allergy and Infectious Diseases

Background: Mycoplasma pneumoniae is a common cause of community-acquired lower respiratory tract infection (LRTI), but the role of Mycoplasmataceae in ventilator-associated LRTI is not well understood. Recent investigations of the lung microbiome during critical illness and mechanical ventilation have identified the persistence of bacteria of the family Mycoplasmataceae, including Mycoplasma and Ureaplasma species, in the lower respiratory tract. We sought to characterize the prevalence and persistence of Mycoplasmataceae in the lower respiratory tract, as well as host and respiratory microbiome features associated with Mycoplasmataceae detection, in patients dependent on mechanical ventilatory support.

Materials/methods: We enrolled 83 subjects at the time of admission to an academic long-term acute care hospital (LTACH) for ventilator weaning, performed longitudinal sampling of endotracheal aspirates, followed by 16S rRNA gene sequencing (Illumina HiSeq), and bacterial community profiling (QIIME2). Statistical analysis was performed with R and Stan; mixed effects models were fit to relate the abundance of respiratory Mycoplasmataceae to host and other respiratory microbiome features.

Results: Of the 83 subjects enrolled, 66 had Mycoplasma species detected in the lower respiratory tract on consecutive days, and 9 had Ureaplasma species detected in the lower respiratory tract on consecutive days. Overall both Mycoplasma and Ureaplasma were observed with high proportional abundance but low absolute read counts; no significant differences were observed between genera. However, individual subjects demonstrated high absolute abundance, confirmed by quantitative 16S qPCR. The abundance of lower respiratory Mycoplasmataceae was significantly associated with younger age and lower serum white blood cell count; an association was observed with the diagnosis of hematologic malignancy, but this did not reach statistical significance.

Conclusions: We identified a high prevalence of lower respiratory Mycoplasmataceae during mechanical ventilation and long-term acute care. In general, Mycoplasma and Ureaplasma species were detected with high relative but low absolute abundance, but in some cases high absolute abundance was observed.

Abstract 8521

Nation-wide audit with feedback of antibiotic stewardship in Norwegian hospitals: a low cost initiative with many opportunities

Per Espen Akselsen*, Marion Neteland1, June Utnes Høgland, Brita Skodvin1, Stig Harthug1

1Haukeland University Hospital, Bergen, Norway, 2Regional Centre for Infection Control, University Hospital of North Norway, Tromsø, Norway

Background: In January 2016, The Norwegian Ministry of Health and Care Services launched their Action Plan against Antimicrobial Resistance. For hospitals, antibiotic stewardship programs (ASP) became mandatory, and an explicit target of 30% reduction in the combined use of five groups of broad-spectrum antibiotics by the end of 2020 was set. KAS’ mandate is to support rational use of antibiotics, and we decided to offer voluntary audits to all hospital trusts. We also wanted to find out whether audit with feedback is a useful method to assess ASP in hospitals.

Materials/methods: KAS developed an interview guide with 40 questions, covering seven focus areas closely linked to the ASP as described in the action plan. We conducted the audits as single-day visits, relevant documents were collected beforehand. In each hospital, we interviewed the medical director individually and conducted group interviews with other hospital leaders, the ASP-team, junior and senior doctors and nurses, respectively. Findings and points of advice were summed up in a final report.

Results: All 22 hospital trusts and private hospitals in Norway were audited from October 2017 to April 2019. The four northernmost hospital trusts were audited (mandatorily) by the Northern Regional Health Authority (NRHA) by a comparable method, the remaining 18 by KAS. The total estimated workload for two auditors combined was 7 days (6-10) for each visit. Final reports were sent to the hospital management and published on KAS’ website 33 days (median) after the visit. Main findings were: a) lack of specific targets at clinic and unit level, b) recognized stewardship measures such as audits of antibiotic use and mandatory reevaluation within 48-72 hours were only sporadically implemented, and c) nurses were only to a limited extent involved in antibiotic stewardship. NRHA’s findings were similar: lack of leadership accountability and quality improvement methodology in clinical units, potentially leading to risk of unnecessarily broad-spectrum treatment.

Conclusions: A complete, nationwide audit provide unique and comprehensive insight in antibiotic stewardship in hospitals and is feasible with a reasonable use of resources. The feedback with analyses identifies targets for further improvement of antibiotic use in hospitals.

Dron, Centre Hospitalier Universitaire de Tourcoing, Paris, France, 10Department of Infectious Diseases, Hôpital St Louis, Paris, France

**Background:** High incidence of sexually transmitted infections has been reported among MSM using PrEP for HIV prevention. PEP with doxycycline has shown to reduce the incidence of syphilis and chlamydia infections among MSM in the ANRS IPERGAY trial, but not of GC [Molina et al, Lancet ID, 2018]. Few strains of GC were available for the assessment of phenotypic resistance. We wished to assess the clonality and impact of doxycycline PEP on tetracycline resistance among GC strains using molecular tests.

**Materials/methods:** Within the ANRS IPERGAY PrEP trial, MSM were enrolled in a prospective randomized (1:1) open-label sub-study of PEP with doxycycline [200 mg within 24h after sex] or no PEP. All subjects were tested for STIs at baseline, and every two months including real-time PCR assays for GC detection at 3 sites (urine, throat and anus). GC-positives samples by NAATs were analyzed for the molecular detection of tetracycline resistance mediated by acquisition of the *tet* (*M*) determinant or/and mutations in S10 protein. Clonality targeting the two alleles *porB* and *tbpB* (NG-MAST) was investigated by nested PCR

**Results:** From July 2015 to June 2016, 232 subjects were enrolled in the study. Among them, 42 patients had 70 GC-positive samples [2 urines, 32 anus and 36 throats] available for further testing. The overall rate of GC resistance to tetracyclines was 82.9% [64.3% at low level and 18.6% at high level]. Five GC infections were diagnosed at baseline, 4 were resistant to tetracyclines. Thirty-eight patients acquired a GC infection during the study. Tetracycline resistance was observed in 17/19 patients (89.5%) in the PEP arm and 14/19 patients (73.7%) in the no PEP arm (p=0.41). Fifteen NG-MAST profiles were characterized; the most frequent were ST 5624 (21%), ST 5441 (12.5%) and ST 5793 (12.5%). By comparison, these STs were found in 3.1%, 9.7% and 2.6%, respectively, in France over the same period.

**Conclusions:** Tetracycline resistance among GC strains in MSM was high, with or without doxycycline PEP. Additional studies with a larger sample size are needed to confirm these findings and assess the clonality of gonococcal strains circulating within this population.

**Presenter email address:** beatrice.bercot@aphp.fr
Chlorhexidine resistance of bacterial flora of HCWs’ hands: is there any impact related to the routine use for hand hygiene?

Icaro Boszczowski¹,², William Kazumassa⁳, Marcia Maria Baraldi⁴, Amanda Luiz Pires Maciel¹, Cristiane Schmitt¹, Ana Paula Marchi², Sânia Santos⁴, Maria Eduarda Rufino Zani¹, Nicole Soares De Souza¹, Letícia Muniz De Souza³, Silvia Figueiredo Costa⁶

¹Hospital Alemão Oswaldo Cruz, São Paulo, Brazil, ²Hospital das Clínicas FMUSP, São Paulo, Brazil, ³University Center São Camilo, São Paulo, Brazil, ⁴Institute of Tropical Medicine of São Paulo, São Paulo, Brazil, ⁵University Center São Camilo, Sao Paulo, Brazil, ⁶Faculdade de Medicina da USP - FMUSP, São Paulo, Brazil

Background: Although guidelines recommend the use of chlorhexidine gluconate (CHG) for hand hygiene (HH), the impact of the routine use on antimicrobial resistance is not clear. We aimed to analyze the impact on the CHG susceptibility among isolates obtained from hands of healthcare workers (HCW) during its routine use for HH.

Materials/methods: Crossover study at a tertiary care hospital in São Paulo, Brazil from April 2016 to April 2018. In two units (intervention) we established routine use of CHG for HH and at other two units (control) regular soap was provided. At intervals varying from 4 to 10 months we swapped the units. Before each swap, we put HCW’s hands inside a sterile bag containing a solution of phosphate-buffered saline, Tween 80 and sodium thiosulfate and inoculated on Brain Heart Infusion. Next, it was plated on MacConkey and Mannitol agar. MALDI TOF was used for identification. Agar dilution was performed for Staphylococcus spp. and Gram-negative bacilli (GNB). All Staphylococcus spp. with MIC ≥ 8 and GNB with MIC ≥64 were tested for inhibition of efflux pump. If a decrease of two dilutions occurred, we searched the genes qacA/B and cepA among Staphylococcus spp. and GNB respectively, by polymerase chain reaction.

Results: We obtained 262 samples from HCW’s hands yielding 428 isolates, Acinetobacter spp. (8%), Enterobacter spp. (8%), Klebsiella spp. (4%), Pseudomonas spp. (3%), Stenotrophomonas spp. (5%), Staphylococcus spp. (58%) and others (14%). Staphylococcus spp. were less frequent in the intervention (43% X 61%, OR 0.61, CI 0.48-0.81, p=0.029). Among Staphylococcus spp. and GNB, the proportion of chlorhexidine resistance (RCHG) was 12% and 14%, respectively. All resistant isolates recovered susceptibility with pump-efflux inhibitor. For Staphylococcus spp. pump inhibited, 53% had gene qacA/B. Four Klebsiella spp. had cepA amplified. There was a non-significant increase in Staphylococcus spp. RCHG in the intervention group (4% to 6%, p=0.9).

Conclusions: We did not find significant difference in RCHG during routine use of CHG for HH, although we observed a trend in resistance increase. Although genes qacA/B and cepA may play a role, further investigation is needed to clarify other reasons of increased MIC to CHG.

Abstract 8526

Screening of risk groups detects only a minority of patients with carbapenemase-producing Gram-negative bacilli
Alex Wagemakers*, Laura Cadenau1, Rosa Van Mansfeld1

1Amsterdam UMC, Department of Medical Microbiology and Infection Prevention, location VUmc, Amsterdam, Netherlands

Background: Patients admitted to Dutch hospitals with certain risk factors [e.g. stay at foreign hospital] are isolated and screened for resistant micro-organisms. In our tertiary care hospital, risk factor surveys are used which should be completed at or within one month before hospital admission. We investigated the yield of carbapenemase producing Gram negative bacilli [GNB] identified in admitted patients by this targeted screening.

Materials/methods: We retrospectively analysed carbapenemase producing GNB from our laboratory information management system [GLIMS] from January 2014 to July 2019. After excluding 10 Acinetobacter baumanii isolates associated with an outbreak, 65 isolates were included for analysis, including only the first isolate per species per patient. Electronic patient files [if available] were checked for risk factors recorded in the survey.

Results: Sixty-five carbapenemase producing GNB isolates from 53 individual patients were detected, mostly Klebsiella pneumoniae [n=28], Escherichia coli [n=12] and Pseudomonas aeruginosa [n=10]. A minority of isolates were detected in screening cultures of patients with risk factors for colonization [n=20] or in cultures performed for contact tracing [n=3]. Six isolates were found in patients suspected of colonization with another species of carbapenemase producing GNB, either in follow-up cultures for known colonization [n=4] or during large-scale outbreak screening for A. baumanii [n=2]. Most isolates however seemed entirely unexpected: 23 were first identified in clinical cultures and 13 were found in routine weekly screening cultures on the ICU and haematology wards. Twenty-seven of these unpredicted isolates were collected after introduction of an electronic patient file, enabling analysis of the screening survey. While screening questionnaires were not completed in 14 cases, 11 of the remaining 13 isolates were cultured from patients who had negative answers on all screening questions in the survey.

Conclusions: Most patients with carbapenemase producing GNB isolated in our hospital were missed with our current screening policy. Imperfect adherence to completing risk screening surveys plays a role, although many unexpected isolates were cultured from patients with none of the specific risk factors. A more targeted screening policy is needed to avoid admission of colonized patients without proper infection prevention measures.

Can HLA type I and II alleles presence be associated with the clinical spectrum of chikungunya virus infection
José Fernando Arias Correal1, Juan Camilo Rueda Sanchez1,2, Ana Maria Santos3, Jose Ignacio Angarita1, Eugenia Lucia Saldarriaga1, Daniel Augusto Martin Arsanios1, Viviana Reyes1,3, Diana Marcela Padilla Ortiz1,2, Santiago Bernal Macias1,3, Sofia Margarita Arias Correal1, Nathalia Muñoz4, Ingris Peláez Ballestas4, Mario H. Cardiel5, John Dario Londoño1,3

1Universidad de La Sabana, Grupo de Espondiloartropatías, Rheumatology Department, Chía, Colombia, 2Universidad de La Sabana, Student from the Biosciences Programme, Faculty of Medicine and Engineering, Chía, Colombia, 3Central Military Hospital, Rheumatology Department, Bogotá, Colombia, 4General Hospital of Mexico, Rheumatology Unit, Ciudad de México, Mexico, 5Centro de investigación clínica de Morelia, Morelia, Mexico

Background: Virulence factors, as well as host immune response, play an important role in disease susceptibility via the Human Leukocyte Antigen (HLA). There are no known studies associating the presence of HLA class I and II alleles with the chikungunya virus (CHIKV) infection in Latin America. We aim to identify which HLA alleles are present in patients with the CHIKV infection when compared to healthy controls, as well as their association with the clinical spectrum of the disease.

Materials/methods: We carried out a cross-sectional analysis nested in a community cohort based on the COPCORD study related on our population. We included patients 18 years and older with serological confirmation of CHIKV infection. We performed HLA typing of HLA-A, HLA-B and HLA-DRB1 alleles. We used two-by-two tables to establish associations between allele presence and clinical characteristics.

Results: Data from 65 patients with confirmed CHIKV infection were analysed for HLA typing. Most patients were mestizo females. CHIKV infection was associated with the presence of HLA-A*68 (p=0.005; OR: 8.90, CI: 1.88-42.13), HLA-B*35 (p=0.03; OR: 2.02, CI: 1.06–3.86), HLA-DRB*01 (p=0.001; OR: 5.70, CI: 1.95–16.59), HLA-DRB1*04 (p=<0.001; OR: 7.37, CI: 3.33-16.30) and HLA-DRB1*13 (p=0.004; OR: 3.75, CI: 1.50-9.39) compared to healthy subjects. A statistically significant relationship was found between the presence of rash in the face or the abdomen and the presence of HLA-B*35 and HLA-DRB1*04.

Conclusions: Our study demonstrated that in our cohort, HLA type I and type II alleles are associated with CHIKV infection, and specifically an HLA type II allele with dermatological symptoms. The results suggest, that further research and of set a path for future investigation on genes outside the HLA system to help elucidate the pathophysiology of the CHIKV infection as well as its interaction with its host.

Emergence of plasmid-mediated AmpC genes in Enterobacter cloacae complex strains from a sepsis outbreak in a neonatal intensive care unit

Enrique Hernandez Alonso*, Veronique Faraut-Derouin1, Marine Evevrin1, Millie Villet2, Mariana Bilan1, Pierre Jatteau2, Daniele De Luca2, Florence Doucet-Populaire1,2, Nadège Bourgeois-Nicolaos1,2

1University Paris-Saclay, Institute for Integrative Biology of the Cell (I2BC) UMR 9198, CNRS, CEA, Gif-sur-Yvette, France, 2Hôpital Antoine-Béclère Ap-Hp, Service de Bacteriologie-Hygiène, Clamart, France

Abstract third-party references: Institut of Integrative Biology of the cell CNRS, CEA, Paris-Saclay University, Gif-sur-Yvette, France, AP-HP-Université Paris-Saclay, Service de Bacteriologie-Hygiène, Hôpital Antoine-Béclère, Clamart, France

Background: The dissemination of plasmid-mediated ampC genes [pAmpC] conferring resistance to third-generation cephalosporins has been widely reported around the world making this a public health problem. pAmpC enzymes are most often found in nosocomial Escherichia coli and Klebsiella pneumoniae strains and there are few published reports regarding occurrence of these enzymes in other genera. In this study we described the prevalence of pAmpC encoding genes in Enterobacter cloacae complex (ECC) isolates collected from a sepsis outbreak in a neonatal intensive care unit (NICU).

Materials/methods: Among 60 non-related ECC strains, 25 cefotaxime resistant isolates were obtained from the outbreak in NICU. The isolates were identified by MALDI-TOF and antimicrobial susceptibility was performed by disk diffusion according to Antibiogram Committee of the Microbiology French Society (CA-SFM, 2018). PCR and sequencing were employed to detect pAmpC genes (ACT, MIR and CMH) and whole genome sequences (WGS). The clonal relatedness of pAmpC-positive isolates was evaluated by enterobacterial repetitive intergenic consensus (ERIC)-PCR method.

Results: In total 25 Isolates of ECC were positive for presence of pAmpC genes among those $\text{bla}_{\text{ACT-like}}$ (19/25) was the most prevalent gene followed by $\text{bla}_{\text{MIR-like}}$ (5/25) and $\text{bla}_{\text{CMH-like}}$ (1/25). All strains were susceptible to carbapenems. (ERIC)-PCR analysis showed clonal relationship between $\text{bla}_{\text{ACT-like}}$ isolates and non-clonal relationship between $\text{bla}_{\text{MIR-like}}$ isolates. Two new alleles $\text{bla}_{\text{MIR-like}}$ and $\text{bla}_{\text{CMH-like}}$ were identified by WGS. The amino acid sequences showed 89% identity between $\text{bla}_{\text{MIR-like}}$ and $\text{bla}_{\text{MIR-14}}$ with 14 amino acid changes. $\text{bla}_{\text{CMH-like}}$ show 2 amino acid changes with the other 5 alleles reported in GenBank.

Conclusions: Plasmid-mediated $\text{bla}_{\text{ACT-like}}$ ampC genes was highly prevalent in this study. A two novel alleles plasmid-mediated AmpC [MIR/CMH] in E. cloacae complex were identified. The highly prevalence found in this work is worrisome due to their possible plasmidial location that could be disseminated and favored the selection of multiresistant strains.

First national survey on colistin resistance among \textit{Escherichia coli} in Belgium

Olivier Denis\textsuperscript{1}, Pierre Bogaerts\textsuperscript{1}, Catherine Berhin\textsuperscript{1}, Martin Hoebeke\textsuperscript{1}, Wassifa Bouchahrouf\textsuperscript{1}, Youri Glupczynski\textsuperscript{1}, Te-Din Huang\textsuperscript{1}

\textsuperscript{1}National Reference Center for Antibiotic-resistant Gram-negative bacilli, CHU UCL Namur - Site Godinne, Yvoir, Belgium

**Background:** Since the emergence of carbapenemase-producing \textit{Enterobacteriaceae}, colistin is considered as a antibiotic of last resort. We conducted a national survey to determine: 1) the presence of \textit{Escherichia coli} colistin-resistant (COL-R) mediated by the transferable resistant determinants MCR; 2) the characteristics of patients infected or colonized by \textit{mcr}\textsuperscript{-positive} \textit{E. coli}.

**Materials/methods:** All hospital-based and community-serving laboratories were invited to refer non duplicate colistin-resistant \textit{E. coli} collected from clinical specimens (fecal specimens excluded) to the National Reference Center (NRC) between May and October 2019. Colistin susceptibility was tested by automated system or by broth microdilution available in local laboratories. Putative COL-R isolates were sent to the NRC with a case structured report with clinical data. At the NRC, colistin susceptibility was verified using broth microdilution method and confirmed COL-R strains were further tested by multiplex PCR targeting plasmid-mediated colistin-resistance genes \textit{mcr-1}\textsuperscript{1} to \textit{mcr-5}\textsuperscript{1} and by disk diffusion method for their susceptibility profile to other antimicrobials. Reference strains \textit{E. coli} ATCC25922 and \textit{E. coli} NCTC 13846 were included in each run for susceptibility testing and PCR as quality control.

**Results:** Of the 107 isolates (1 to 14 isolates per laboratory) from 25 hospital-based and 3 community-serving laboratories collected by the NRC during the 6-month study period, 86 \textit{E. coli} isolates (80%) were confirmed COL-R by broth microdilution. Among COL-R isolates, 32 (37%) strains isolated from 17 laboratories (including 3 community-serving) were tested positive for \textit{mcr-1} by PCR. All \textit{mcr}\textsuperscript{-positive} strains were susceptible to carbapenems and six were resistant to third-generation cephalosporins conferred by an ESBL phenotype. All but two isolates were isolated from urines mainly from hospitalized patients (n=18). Twelve isolates were isolated from outpatients and twenty-five strains were considered as clinically significant.

**Conclusions:** Our survey data confirm the common circulation of \textit{mcr}-positive \textit{E. coli} causing mainly urinary tract infections both in hospitalized and ambulant patients, although most of the strains remain susceptible to the majority of antimicrobials. The high proportion (20%) of false COL-R isolates also highlights the difficulty to achieve correct determination of colistin resistance by Belgian routine laboratories.

Abstract 8535

**An outbreak of hypervirulent and multidrug-resistant clone (ST2096) *Klebsiella pneumoniae* silently transmitting in a Saudi Arabia western region hospital: a clinical and molecular surveillance study**

Sharif Hala1,2,3,4, Antony Chakkiat1,5, Mohammed Alshehri2,3,4, Asim Alsaedi1,2,3, Abdulhakeem Althaqafi2,3,4, Ghadeer Alahmadi4, Mai Kaaki4, Meshari Alazmi6, Baraa T. Alhaj Hussein2,3,4, Muhammad Yaseen4, Raeece Ghazali1, Hosam Zowawi2,3,4,7,8, Abdulfattah Alamri2,3,4, Arnab Pain1,9,10

1King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, 2King Abdullah International Medical Research Center, Jeddah, Saudi Arabia, 3King Saud University, Riyadh, Saudi Arabia, 4Ngha, Jeddah, Saudi Arabia, 5Red Sea King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, 6University of Hail, Hail, Saudi Arabia, 7WHO Collaborating Centre for Infection Prevention and Control, and GCC Center for Infection Control, Riyadh, Saudi Arabia, 8The University of Queensland, Q Centre for Clinical Research, Queensland, Australia, 9Global Institution for Collaborative Research and Education (Gi-CoRE), Hokkaido University, N20 W10 Kita-ku, Sapporo, Japan, 10Nuffield Division of Clinical Laboratory Sciences (NDCLS), Oxford, United Kingdom

**Abstract third-party references:** King Abdullah University of Science and Technology

**Background:** The global nosocomial dissemination of high-risk multi-drug resistant (MDR) *Klebsiella pneumoniae* strains has been a growing threat in health-care facilities. Epidemiological studies are infrequently combined with pathogen genomics and clinical observations of an outbreak to suggest changes in policy and procedures of infection control. In this study, we employed Whole-genome sequencing (WGS) phylodynamic data, the influence of clinical practice, and infection control methods to understand the infection course, transmission map, and the clinical gaps aiding the successful transmission of a potentially lethal MDR and hypervirulent clone ST2096.

**Materials/methods:** We collected 235 MDR *Klebsiella pneumoniae* isolates from 220 patients of King Abdulaziz medical city within the Ministry of National Guard - health affairs (MNGHA) hospital (Jeddah, Saudi Arabia) between 2014-2018. All the isolates were sequenced at high genome-coverage using the Illumina technology. The clinical metadata of the identified outbreak cases were collected, and the isolates were tested for antibiotic resistance phenotypic using broth microdilution (BMD). We analyzed the sequencing data to identify the antibiotic resistance profile, virulence factors, the clonal relationships between *K. pneumoniae* isolates, and transmission patterns.

**Results:** We identified an ongoing clonal transmission of 99 hypervirulent MDR ST2096 *K. pneumoniae* strain of the cc14, followed by the global high-risk clone ST14 of the same clonal group. ST2096 silently transmitted within the hospital and was found to be associated with high mortality (58.6%). The transmission of ST2096 predominated over other sequence types until the end of our collection period in March 2018. We identified the outbreak index case arriving at the hospital in December 2016. The index case carried a hypervirulent and highly resistant *K. pneumoniae* ST2096 isolate, which had been transferred between several wards for treatments and clinical-related tests.

**Conclusions:** The benefits of combined deep and active WGS surveillance, transmission model, and applications of infection control are needed to avoid clinical outbreaks and the dissemination of fatal infections. This study identified *K. pneumoniae* ST2096 strain as an emerging MDR and extensively-drug resistant (XDR), hypervirulent, and vastly communicable clone that constitute a considerable danger to patients.
"Beanbag" tree of indirect transmission events

Pharmacokinetic, efficacy and safety of micafungin administered at high doses to neonates suffering from invasive candidiasis: results from a phase II study

Cinzia Auriti*, Bianca Maria Goffredo, Iliana Bersani, Fiammetta Piersigilli, Alessandra Santisi, Sara Cairoli, Andrea Dotta, Pietro Bagolan

1 Ospedale Pediatrico Bambino Gesù, Department of Medical and Surgical Neonatology, Rome, Italy, 2 Ospedale Pediatrico Bambino Gesù, Laboratory of Specialistic Pediatrics, Rome, Italy, 3 Ospedale pediatrico Bambino Gesù, Department of Medical and Surgical Neonatology, Roma, Italy, 4 Ospedale Pediatrico Bambino Gesù, Laboratory of Specialistic Pediatrics, Rome, Italy

Background: The few available studies on pharmacokinetic and on the appropriate dosage in neonates limit the possibility of recommending micafungin as drug of first choice in the therapy of neonatal invasive candidiasis. We aimed to study the pharmacokinetic profile of micafungin administered at high dose to neonates suffering from invasive candidiasis and to evaluate the proportion of success, of failure and the safety of this therapy.

Materials/methods: During a Phase 2 Study plasma, CSF levels, efficacy and safety of micafungin, administered at a dose of 8 mg/kg/day for a mean of 16.7 days, at a concentration of 2 mg/ml, to 53 neonates suffering from systemic candidiasis and candida meningitis were studied. Micafungin plasma and CSF levels were measured by HPLC on blood and CSF capillary samples, picked up by microtube with EDTA.

Results: Fifty-three patients were enrolled in study, 37 with a proven candidiasis. Three patients had Candida meningitis. In 31/37 (83.8%) patients with proven candidiasis we observed the mycological eradication. The AUC₂₄ was higher than 166 h * mg /L in 46/52 (88.5%) patients, compared with the 75h * mg /L -139 h * mg /L range, effective in adults exposed to 100 mg /day. CSF concentrations were between 1.3 and 1.80 mg /L. Five/53 (9.4%) patients died without relation with the use of micafungin. The most frequent side effect was the transient increase in gamma glutamyl transferases (11/53, 2.8%).

Conclusions: Micafungin at high doses is effective and safe in the treatment of neonatal candidiasis.

Abstract 8539

**How does blood volume cultured in Europe comply with guidelines? Results of a 125-centre ESGBIES/CTCB survey**

Brigitte Lamy*, Adeline Morisot, Erick Sanchez, Laurent Bailly, Raymond Ruimy, Christian Pradier, Stéphanie Albarède, Jean-Louis Galinier

1CHU Nice, Nice, France; 2CTCB, Toulouse, France

**Background:** Poor volume of blood cultured affects the performance of the microbial diagnosis of sepsis. This ESGBIES survey assessed the real-life total volume of blood cultured at the European level, identified factors for poor volume and quantified gap to guidelines.

**Materials/methods:** European volunteer participants extracted from routine the data related to 50 successive clinical episodes for which blood cultures (BC) were collected from adult patients. Data included the number of samplings over a 24-h period, the number of bottles per sampling, the volume of blood per bottle (estimated from the difference between mean empty bottle weight and post sampling bottle weight, taking account of blood density, 1.055), laboratory characteristics, method characteristics. For each center, key-performance indicators for ordering, sampling and clinical impact were determined, which corresponded to rates of: i) episodes with ≥4 bottles, ii) bottles with volume of blood >5 ml, iii) episodes with minimal or compliant volume of blood during a 24 h sampling period [20-80 ml], respectively. Student t-test and \( \chi^2 \) were used for comparison between groups as appropriate.

**Results:** 125 laboratories from 16 countries participated, totaling 5,313 episodes and 20,323 bottles. Compliance with guidelines was poor: 0.9% of the centres had >80% of the bottles with >5 ml of blood; 42.6% and 5.2% of the centres had >80% episodes with >4 bottles collected and >20 ml of blood cultured, respectively. Total blood volume <30 ml per 24 h was more frequent in: Southern than Northern and Eastern countries \( (p<10^{-4}) \), hospitals than clinics \( (p<10^{-4}) \), centres without protocolized preanalytics \( (p<10^{-4}) \) or specific training \( (p<0.03) \), emergency room than other wards \( (p<10^{-4}) \), or when only one BC set was drawn \( (p<10^{-4}) \). Interestingly, centres with advanced BC instrument that monitors blood volume performed better \( 49.1\% \) and 59.1% series >20 ml with bactec-FX® and Virtuo® instruments vs 41.2% and 42.4% with Bactec and BactAlert 3D systems, respectively, \( p<10^{-4} \). Neither elderly \( (p=0.43) \) nor ISO15189 accreditation \( (p=0.68) \) impacted blood volume >30 ml, although laboratory accreditation positively influenced volume in the subgroup France \( (p=0.03) \).

**Conclusions:** This study provides for the first time an overview and determinants of bloodstream infection diagnosis quality in Europe. Regular external quality assessment should improve diagnostic quality.

**Presenter email address:** brigitte.lamy@yahoo.fr
Changing profile of invasive disease-causing Staphylococcus aureus in Australia

Sarah Baines*, Stefano Giulieri1,2, Anders Gonçalves Da Silva1, Natasha Holmes2, Geoffrey Coombs1, Stanley Pang3, Timothy P. Stinear1, Benjamin Peter Howden1,2

1University of Melbourne, Parkville, Australia, 2Austin Hospital, Heidelberg, Australia, 3Murdoch University, Murdoch, Australia

Background: Staphylococcus aureus is a significant human pathogen. However, the population responsible for invasive disease is not panmictic but rather composed of mixtures of genetically distinct lineages that undergo temporal fluctuations in prevalence. These populations often display different clinically relevant characteristics, subsequently shifts in lineage prevalence can drastically alter the phenotypic/genotypic profile of the population, with downstream implications for disease management and prevention. Here we present work exploring an invasive S. aureus population, using combined genomic and phenotypic data, modelling the impact that changes in population composition have had on clinically relevant bacterial features, including antimicrobial resistance, virulence, and geographic movement.

Materials/methods: Collection included S. aureus bacteraemia (SAB) isolates from two large multicentre cohort studies; a subset of the Australian and New Zealand Cooperative in Staphylococcal Sepsis study (n=526, 2007-2008) and the Vancomycin Efficacy in Staphylococcal Sepsis in Australasia study (n=221, 2011-2012), supplemented with the sequence data for MRSA identified in the 2015 Australian Staphylococcal Sepsis Outcome Program (n=387). This collection was subjected to phenotypic and genomic profiling of antimicrobial resistance and virulence characteristics, and detailed phylogeographic modelling.

Results: The S. aureus population responsible for invasive disease in Australia demonstrated extensive genetic diversity. However, the proportion of different lineages has markedly changed over the time-frame sampled, reflecting a complex clonal replacement event denoted by the rapid decrease of the predominant MRSA lineage (ST239) and replacement by multiple MRSA (ST22, ST45, ST93) and MSSA (ST30, ST8) lineages. This has coincided with a population-level decrease in carriage of resistance genes, increase in phenotypic antimicrobial susceptibility (including vancomycin), and increased carriage of virulence genes; characteristics which align with the lineages most altered in prevalence. Phylogeographic modelling identified that the replacing lineages demonstrated a higher frequency of interstate movement, suggesting that the new population may have potentially enhanced geographic mobility.

Conclusions: This works highlights that invasive S. aureus populations are diverse and fluid, and regular surveillance is required to capture changes in population composition. However, this needs to be complemented with detailed profiling of the lineages involved to understand the implications of these changes on the management and prevention of invasive staphylococcal disease.

Abstract 8545

**Epidemiology, complications, and outcomes of vertebral diskitis/osteomyelitis among patients with *Staphylococcus aureus* bacteraemia**

Hassan Ishaq1, Rommel Ramesh*,1, Larry Baddour1, M. Rizwan Sohail1, Bharath Raj Varatharaj Palraj1

1Mayo Clinic, Rochester, United States

**Background:** *Staphylococcus aureus* bacteremia (SAB) is associated with significant morbidity, mortality, and a high risk of hematogenous seeding at distant sites. The aim of the current investigation is to evaluate the epidemiology of vertebral osteomyelitis among patients with SAB, and to describe management, interventions and associated outcomes.

**Materials/methods:** We retrospectively reviewed all adults admitted to Mayo Clinic in Rochester MN with SAB between July 2006 and December 2017. Cases of SAB were identified using Advanced Cohort Explorer (ACE) based on diagnostic codes and microbiology data that included positive culture results. Vertebral osteomyelitis cases were defined based on diagnostic imaging criteria. Modified Duke criteria were used to define infective endocarditis (IE) cases. We reviewed the index hospitalization and assessed outcomes at 3-month follow up.

**Results:** During the study period, 1324 patients were hospitalized at our institution with SAB. Median age was 62 years. Of them, 104 (8%) had vertebral diskitis/osteomyelitis. Most patients presented with fever, back pain and malaise. An epidural abscess was identified on imaging in 15%. Seventeen (16.3%) patients had concomitant IE. The median duration of bacteremia was 5 days and 36% of isolates were methicillin resistant (MRSA). Eighty-three patients underwent surgical intervention. For methicillin susceptible (MSSA) isolated, the primary antibiotic therapy was either cefazolin in 62% and semisynthetic penicillin in 21.6%. For MRSA cases, the most commonly administered antibiotic was vancomycin in 83.2%; daptomycin was used in 12%. Overall, the median duration of antibiotic regimen was 42 days. Twenty-one patients died due to SAB-related complications. Post-discharge follow up data were available in 102 of the patients. During the 3-month follow up period, 4 (3.8%) patients suffered SAB relapse.

**Conclusions:** Vertebral diskitis/osteomyelitis was diagnosed in only 8% of our SAB cohort. Despite prolonged, parenteral antibiotic therapy and a large majority of patients undergoing surgical intervention for attempted cure, 21% of them died secondary to SAB-related complications. Vertebral diskitis/osteomyelitis remains a formidable complication of SAB and evaluation of potential interventions to improve outcomes is warranted.

**Epidemiology of bloody diarrhoea in Georgia and haemolytic-uraemic syndrome associated with it**

Mikheil Atskvereli*1, Kvariani Gvantsa1, Natali Shulaia1

1David Tvildiani Medical University, Tbilisi, Georgia

**Background:** According to WHO there are about 1.7 Billion cases of diarrhea annually, 760000 children under 5 years die from complications or irrelevant treatment. One of the feared conditions is a bloody diarrhea, caused by different pathogens like Salmonella, Shigella and others including Shiga toxin-producing *Escherichia coli* (STEC), which also causes Hemolytic Uremic Syndrome (HUS). HUS is characterized by symptom triad: thrombotic microangiopathy, thrombocytopenia, and acute kidney injury. In USA HUS is found in 6% of diarrheas caused by STEC 0157:H7. But other strains have their role too. Lethal outcome is registered in about 5% of cases.

**Materials/methods:** Study report: We present you the results of a study made by Georgian doctors, based on 760 clinical cases of bloody diarrhea between years 2005 and 2016. The goals were the following: 1) Studying epidemiological features of bloody diarrhea and HUS in Georgia and revealing possible disease outbreaks. 2) Raising awareness among individuals under risk and evaluate level of knowledge among medical personnel 3) Provide practical recommendations for avoiding this disease and unwanted complications. The research was conducted in two steps: I. Retrospective study; II. Prospective study. The Data collected from recordings of different Georgian hospitals were registered in electronic data base. Incidence, prevalence, relative risk confidence interval and p-value were calculated. Analysis of identified pathogens were held.

**Results:** 760 registered cases. 14.7% (112 cases) complicated with HUS. 51% of cases (387 cases) in women. First registered outbreak was in 2009 – 25 patients complicated with HUS (12 children; 2 deaths). *E. coli* 0104:H4 was identified during this outbreak, same strain that caused epidemic of Hus-complicated bacterial infections in Europe 2011. Pathogenic strains of *E. coli* 0126, 0104:H4, 0119, 0128, 033 and 045 were found.

**Conclusions:** Incidence rises in warm months of the year. Most cases of HUS are in children between 1-4 and almost none found in children under 1 year. High mortality is registered during outbreaks, especially in cases complicated with HUS. Chances are high after consuming non-cleaned vegetables, certain types of ice-cream and animal contacts. Studies must be held for identifying outbreak sources.

**Abstract 8551**

**Evaluation of the new BL-RED electrochemical test for the detection of 3GC-resistant Enterobacteriaceae directly from positive blood cultures**

Clarisse Durand¹, Agathe Boudet*¹, Jean Philippe Lavigne¹, Alix Pantel¹

¹CHU Nimes, Nîmes, France

**Background:** Bloodstream infections (BI) are expensive healthcare and the mortality rate is high. The rapid identification of the pathogen as well as the rapid antimicrobial susceptibility testing (AST) is decisive to clinical management and to avoid an excessive exposure to broad-spectrum treatment.

The aim of the present study was to evaluate the performance of a new electrochemical test, BL-RED™ (β-lactamase rapid electrochemical detection, AirDiag), in the rapid detection of third generation cephalosporin-resistant (3GC-R) Enterobacteriaceae from positive blood cultures (PBC).

**Materials/methods:** One hundred and fifty isolates with various β-lactamase content previously characterized was selected. This panel consisted of isolates: 3GC-susceptible (n = 50), Extended Spectrum β-Lactamase (ESBL) producers (n = 41), chromosomal- (n = 31) or plasmid-mediated (n = 10) AmpC producers, extended-spectrum OXY (n = 3) and carbapenemase (n = 30, including 12 ESBL and 3 AmpC) producers.

Approximately 100 CFU of each isolate were inoculated into sterile blood culture bottles and incubated in a BACTEC™ FX (BD) automated system. The BL-RED™ test was performed as soon as the bottle was positive, according to the manufacturer’s recommendations. The results were compared with those obtained by conventional technique (AST by disc diffusion method following EUCAST recommendations).

**Results:** The sensitivity and specificity of the BL-RED™ assay in the detection of class A (ESBL, KPC, OXY) β-lactamase-producing Enterobacteriaceae were respectively 87.5% (5 CTX-M and 1 SHV producers not detected) and 100%.

The overall sensitivity and specificity of BL-RED™ in the detection of 3GC-resistance were 46.7% and 100% (VPN 54.2%, VPP 100%). The assay failed to detect AmpC-overproducing isolates (sensitivity 2.4%) or metalloenzymes-producing isolates (0%).

**Conclusions:** The BL-RED™ assay was easy to use and efficient for the early detection of most ESBL-producing Enterobacteriaceae, one hour after the positivity of the blood culture, allowing rapid adequacy of antimicrobial therapy and improved prognosis. However, the test did not reliably detect all 3GC-R isolates and a high level of vigilance is required with overproduced AmpC Enterobacteriaceae.

Abstract 8555

**Inflammatory response of murine macrophages and alveolar epithelial cells following exposure to Aspergillus fumigatus spores**

Fany Agostini*, Marie Delles†, Tanguy Déméautis†, Gilles Devouassoux‡, Azzak Bentaher†, Jean Menotti‡,‡

†Claude Bernard University Lyon 1, EA7426 PI3 Team Inflammation and Immunity of the Respiratory Epithelium, Oullins, France, ‡Hospices Civils De Lyon - Hcl, Croix-Rousse Hospital - Department of Respiratory Medicine, Lyon, France, ‡Hospices Civils De Lyon - Hcl, Croix-Rousse Hospital - IAI - Department of Parasitology and Medical Mycology, Lyon, France

**Background:** Exposure to *Aspergillus* spores is associated with symptoms of airway tract inflammation in people living in damp dwellings or in exposed professionals, that can lead to severe diseases such as allergic bronchopulmonary aspergillosis or chronic pulmonary aspergillosis. To better understand the setting of inflammation processes, our aim was to study the pulmonary inflammation induced by the exposure to *Aspergillus fumigatus* spores in cell culture systems using murine alveolar epithelial cells and macrophages.

**Materials/methods:** RAW 264.7 mouse macrophages and MLE-15 mouse alveolar epithelial cells were cultured in DMEM and RPMI 1640 media, respectively, supplemented with fetal calf serum and 1% penicillin-streptomycin, at 37°C and 5% CO₂. Cells were seeded in 12-well culture plates. Confluent wells were treated with *Aspergillus fumigatus* spores at a multiplicity of infection of 3 and incubated for 4 h. A lactate dehydrogenase cytotoxicity test was performed on both cell lines. RNA extraction was performed with the All-in-One DNA/RNA/Protein Miniprep kit (BioBasic). Reverse transcription was performed with the Superscript IV Reverse Transcriptase kit (Invitrogen). Gene expression of defined cytokines was quantified with TaqMan Gene Expression Assays (ThermoFisher). Real-time reverse transcription PCR results were expressed using the $2^{-\Delta\Delta C_t}$ method. The TATAbox Binding Protein gene was used as endogenous control.

**Results:** Lactate dehydrogenase test showed no cytotoxicity for the 4-h exposure to *A. fumigatus* spores of both cell lines. After 4-h exposure of RAW 264.7 cells to *A. fumigatus* spores, significant inductions of IL-1β [P<0.0001], TNF-α [P=0.015], CCL-2 [P=0.0027] and CXCL-2 [P<0.0001] gene expression were observed, with 57, 5, 8 and 68-fold inductions, respectively. After a 4-h exposure of MLE-15 cells to *A. fumigatus* spores, gene expression of GM-CSF, CXCL-1 and CXCL-2 was markedly low compared to that of RAW cells (4, 3 and 4-fold inductions, respectively).

**Conclusions:** Unlike MLE-15 alveolar epithelial cells, RAW 264.7 macrophages exhibited a strong induction of defined proinflammatory cytokine gene expression following the exposure to *A. fumigatus* spores. The strongest inductions concerned the gene expression of IL-1β and CXCL-2, key cytokines in inflammatory processes involved in leukocyte recruitment and activation.

Evaluation of obesity as a risk factor for drug-resistant Enterobacteriaceae among hospitalised adults

Navaneeth Narayanan*1,2, Saira Chaudhry1, David Vinarov1, Thomas Bucek3, Liya Johnson1, Cheryl Mathew1, Tiffany Lin1, Luigi Brunetti1

1Rutgers University, Ernest Mario School of Pharmacy, Piscataway, United States, 2Rutgers University, Robert Wood Johnson Medical School, New Brunswick, United States, 3Rutgers University, Piscataway, United States

Background: Gram-negative (GN) antibiotic resistance is a global concern that requires a better understanding of contributing risk factors. These concerns are heightened in patients with obesity as antibiotics may be inadequately dosed, leading to suboptimal systemic exposure, antibiotic failure, and potential emergence of antibiotic resistance. The objective of our study was to determine if obesity is associated with presence of multidrug-resistant organisms (MDRO) among Enterobacteriaceae.

Materials/methods: We conducted a multicenter, retrospective cohort study of adult hospitalized patients with at least one specimen sampled for bacterial culture yielding an Enterobacteriaceae from November 2016 to May 2017. Study groups were stratified by obesity status based on body mass index (BMI): BMI<30 kg/m² (non-obese) and ≥30 kg/m² (obese). Analysis of covariates included basic demographics, history of prior antibiotic therapy, presence of immunosuppression, transfer from healthcare facility, sampling specimen from a critical care unit, and comorbidities. The primary outcome was the presence of GN MDRO on culture defined as presumptive extended-spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae [ceftriaxone resistance] or carbapenem-resistant Enterobacteriaceae [CRE]. A multivariable logistic regression model was fit to estimate the adjusted odds ratio while controlling for potential confounders.

Results: The final analytic sample consisted of 366 patient patients, 238 non-obese and 128 obese patients. There were no significant differences between study groups expect for higher median creatinine clearance (71.9 versus 48.2 mL/minute, p<0.001) and higher proportion of history of cancer (18 versus 9.7%, p=0.022) in obese patients. The most common GN species identified was E. coli (64.2%). There was a higher proportion of GN MDRO in obese versus non-obese patients (18.8 versus 11.3%, p=0.051). In the multivariable logistic regression analysis, obesity was independently associated with GN MDRO after controlling for confounders (adjusted odds ratio, 1.92; 95% CI 1.03-3.60).

Conclusions: Among adult hospitalized patients, obesity was independently associated with GN MDRO (presumptive ESBL or CRE). Obesity may be a significant risk factor for antibiotic resistance. We hypothesize this may be partly mediated due to inadequate antibiotic dosing and systemic exposure. Further studies are needed to investigate the causal pathway to elucidate effective interventions to reduce the emergence of drug resistance.

Abstract 8559

Characterising outer membrane permeability for β-lactam antibiotics in Acinetobacter baumannii strain HUMC1

Yinzhi Lang1, Xun Tao1, Jieqiang Zhou1, Nirav Shah1, Dhruvitkumar Sutaria1, Alaa Ropy1, Bartolome Moya23, Yuanjuan Jiao1, Arnold Louie4, George Drusano4, Herbert Schweizer5, Robert A. Bonomo6, Richard E Lee7, Jürgen Bulitta1

1University of Florida, Department of Pharmacotherapy and Translational Research, Orlando, United States, 2Fundació Institut d’Investigació Sanitària Illes Balears - Hospital Universitari Son Espases, Palma, Spain, 3Fundació Institut d’Investigació Sanitària Illes Balears – IdISBa, Hospital Universitari Son Espases, Palma, Spain, 4University of Florida, Institute for Therapeutic Innovation, Orlando, United States, 5University of Florida, College of Medicine, Gainesville, United States, 6CASE Western Reserve University, Cleveland VAMC, Cleveland, United States, 7St Jude Children’s Research Hospital, Memphis, United States

Background: The outer-membrane (OM) poses unique challenges for antibiotic penetration. While Acinetobacter baumannii (AB) is believed to be poorly penetrable, there is a dearth of OM permeability data on clinically relevant β-lactam antibiotics. This study characterized the OM permeability of six clinically-relevant β-lactams in multidrug-resistant MDR-AB via LC-MS/MS.

Materials/methods: Clinical AB isolate HUMC1 was grown to 10^7 CFU/mL in broth and washed four times in PBS (containing 1.14 mM Mg^{2+} and Ca^{2+}). Half of these bacteria were lysed to evaluate the periplasmic β-lactamase activity; the other half was concentrated by 10-fold and served as intact bacteria to characterize OM permeability. One separate intact bacteria suspension was incubated in PBS for 120 min. During that incubation, bacteria-free supernatant samples were obtained at 3, 15, 30, 60 and 120 min to assess the time-dependent β-lactamase activity in extracellular space. The time-course of extracellular β-lactam concentrations was determined over up to 120 min in control, lysed and intact bacteria via LC-MS/MS (LLOQ: 0.03 mg/L for each β-lactam).

Results: For lysed bacteria, β-lactams were freely exposed to β-lactamases. Therefore, the hydrolysis was rapid for all drugs. For imipenem, meropenem, sulbactam, carumonam and cefepime, extracellular β-lactamase activity caused minimal hydrolysis. When the OM remained intact, drugs had to penetrate the OM before being hydrolyzed in periplasm. Therefore, the slope of concentration decline (intact bacteria profile) indicated the rate of OM permeability (Figure). Extracellular β-lactamase significantly hydrolyzed ceftazidime; this caused the extracellular concentrations in the cell-free PBS control to decline. We simulated the concentration decline of ceftazidime in this control, and the profiles overlapped with the observed profiles in intact bacteria indicating very slow penetration of ceftazidime.

Conclusions: OM permeability was rapid (>200 nm/s) for imipenem, intermediate for meropenem, sulbactam and cefepime (approximately 20 nm/s), slow for carumonam (3 nm/s), and very slow for ceftazidime (<1 nm/s). Our assay successfully accounted for the extracellular β-lactamase activity. This novel assay therefore extended the scope of strains for OM permeability studies. Future studies in a large collection of strains with different OM porin patterns are warranted.

Performances of a new random access system for hepatitis B and C viral load quantification

Juliette Besombes¹, Charlotte Pronier*, Anne Maillard¹, Gisele Lagathu¹, Pauline Comacle¹, Claire Grolhier¹, Vincent Thibault²

¹CHU Rennes, Virology, Rennes, France, ²CHU Rennes, Virology - IRSSET INSERM U1085, Rennes, France

Background: Viral load (VL) monitoring for hepatitis B and C is essential to evaluate disease progression and treatment response. Automated, random-access and rapid systems are becoming standard to provide reliable VL to clinicians. The aim of this study was to evaluate the performances of the recently launched NeuMoDx for HBV-DNA and HCV-RNA quantification.

Materials/methods: 373 HBV-VL and 373 HCV-VL routinely quantified on the Beckman-Veris Dx system were either retrospectively (frozen samples; n=178 HBV, n=249 HCV), or in parallel (fresh primary tubes; n=103 HBV, n=124 HCV) tested using NeuMoDx specific reagents. Linearity range of these assays was assessed on serial dilution of high tittered plasmas containing different HBV genotypes (A-E, n=10) and HCV genotypes (1a, 1b, 2-5, n=12).

Results: Overall test failure, corresponding mostly to internal control amplification failure was 2.3% and was not influenced by the matrix type, frozen plasma or plasma from primary tube. For HBV-VL, the overall Kappa qualitative agreement was 74%, with 27 (12.6%) discrepancies [Veris Positive/NeuMoDx negative]; discrepant sample VL ranged from 1.1 to 2.6 log IU/mL. Correlation between both HBV assays on 72 quantified samples by both methods was excellent (r=0.963) with a mean bias [NeuMoDx-Veris] of 0.21 log IU/mL. For HCV-VL, the overall qualitative agreement reached 94%, with 9 (2.8%) discrepancies. Among those, 8 HCV-VL were detected positive [HCV-VL from 17 to 71 IU/mL] on NeuMoDx while negative on Veris. The r-correlation factor between both HCV assays on 106 samples was 0.960 with a mean bias [-0.14 log IU/mL] [NeuMoDx-Veris]. Serial dilutions confirmed the claimed linear ranges for HBV and HCV whatever the tested genotypes. On NeuMoDx, the mean turnaround time was 72' [55-101] for HBV and 96' [78-133] for HCV and depended on the number of loaded samples on the system.

Conclusions: These first results obtained on the NeuMoDx confirmed the overall good functionality of this system based on microfluidic with short turnaround time, simple training, full traceability and easy handling. Preliminary results on HBV- and HCV-VL look promising and should be challenged with further comparisons with other systems.

Is periodic screening of donor faeces with temporary quarantine storage effective in preventing transmission of multidrug-resistant organism during faecal microbiota transplantation?

Karuna Vendrik*1,2, Elisabeth Terveer1, Sam Nooij1, Eline Boeije-Koppenol1, Ingrid Sanders1, Josbert Keller1,2, Emilie Van Lingen1, Eric Berssenbrugge1, H.W. Verspaget1, Ed J. Kuijper1,2, Joffrey Van Prehn1

1 Leiden University Medical Center (LUMC), Leiden, Netherlands, 2 National Institute for Public Health and Environment, Bilthoven, Netherlands, 3 HMC Antoniushove, Leidschendam, Netherlands

Abstract third-party references: On behalf of the Netherlands Donor Feces Bank (NDFB) study-group

Background: The FDA recently issued a warning after transfer of faeces containing an extended-spectrum beta-lactamase (ESBL)-producing Escherichia coli by faecal microbiota transplantation (FMT), which led to bacteraemia in two immunocompromised patients. This prompted our national donor feces bank to re-evaluate the donor screening protocol, which includes periodic multi-drug resistant organisms (MDRO) screening of donors with additional screening after foreign visits. Faecal suspensions are stored in quarantine during a three months period, until re-screening results are available.

Materials/methods: A retrospective cohort study was performed. Data from January 2016 until October 2019 of (potential) NDFB faeces donors on previously performed tests for MDRO were analysed. Furthermore, the presence of MDRO was assessed in faecal suspensions that were approved for patient treatment between January 2017 and April 2019 using a selective broth enrichment media with subsequent subculturing on selective solid media. All MDRO isolates that had been detected in donor faeces were subjected to Whole Genome Sequencing using the Illumina NovaSeq6000 platform with subsequent core-genome MultiLocus Sequence Typing (cgMLST).

Results: Six out of 16 active donors (38%) were MDRO-positive at some point during their donor activities, with a median duration of donor activity of 268 days. This included 10 MDRO-positive samples among 96 tested faeces samples (10.4%). Seventy-one percent of the detected MDROs was an ESBL-producing E. coli. Among results of all initial screenings, 7 of 66 potential donors (11%) were MDRO-positive. Importantly, no MDRO were detected in 170 faecal suspensions that were approved for patient treatment with the current screening protocol. Furthermore, cgMLST of all detected MDRO isolates revealed that two donors carried an identical MDRO isolate in their faeces.

Conclusions: Healthy donors have a relatively high risk to become colonised with a MDRO at some point during their donor activities. This study shows that our current screening protocol is effective in preventing the presence of MDRO in approved faecal suspensions.

Hospital outbreak of carbapenem-resistant Enterobacteriaceae associated with an OXA-48 plasmid hosted mainly by Escherichia coli ST399

Alice Ledda1, Rohini Manuel2*, Holly Ciesielczuk1, Heather Dolphin1, Deborah Barry1, James Summerville1, David Wareham4, Benny P. Cherian3, John Paul1, Caryn Rosmarin2, Martina Cummins3

1Imperial College London, London, United Kingdom, 2Public Health England, London, United Kingdom, 3Barts Health NHS Trust, London, United Kingdom, 4Queen Mary University of London, London, United Kingdom

Background: A hospital ward outbreak of carbapenem-resistant Enterobacteriaceae was detected by routine surveillance. Despite robust infection prevention and control interventions, the outbreak continued for 18 months.

Materials/methods: A ward outbreak epidemic alert was triggered when carbapenem-resistant Enterobacteriaceae samples were recurrently found upon screening in a hospital ward. Bacterial isolation and whole genome sequencing were performed to ascertain all known resistance genes carried, MLST type and strain background, plasmid backbone and type of plasmid/plasmids carried and associated virulence factors present. Fifty-five isolates were cultured from 48 patients during ten consecutive months from May 2016 to February 2017. All clinical isolates showing carbapenem-resistant were archived and investigated.

Results: Whole genome sequencing and subsequent analysis revealed a conserved promiscuous OXA-48 carrying plasmid as the defining factor within this outbreak. Four different species of Enterobacteriaceae were involved in the outbreak. E. coli ST399 accounted for more than half of the isolates. Comparative genomics of publicly available E. coli ST399 sequence data showed that outbreak isolates formed a specific clade. The OXA-48 plasmid identified in the outbreak differed from other known plasmids by a few homologous recombination events. We estimate an upper bound to the plasmid conjugation rate to be rconj0.13 conjugation events per lineage per year.

Conclusions: Our analysis suggests co-adaptation between the plasmid and its main bacterial host to be a main driver of the outbreak. This supports roles for both plasmid conjugation and clonal expansion in the evolution of the outbreak. A specific E. coli ST has not previously been reported as the majority host in a plasmid-borne outbreak of carbapenem resistance.

Polyclonal antibody anti-CR3-RP Ab inhibits biofilm of *Candida albicans* and decreases an expression of the genes related to biofilm-formation and cell surface hydrophobicity

Jaroslava Dekkerova*, Helena Bujdáková†, Samuel Kendra†

Comenius University in Bratislava, Faculty of Natural Sciences, Bratislava, Slovakia

**Background:** Treatment of biofilm formed by *Candida* sp. is very often problematic due to increasing resistance to antifungals (ATF). Thus, it is of importance to focus a research on alternative ways of treatment. One of the alternative approaches in anti-fungal therapy could be through using surface antigens or antibodies directed against them. Presented research was aimed at an impact of polyclonal antibody (Ab) anti-CR3-RP to biofilm of *C. albicans* resistant to common ATF and possible role of this Ab in regulation of biofilm-associated genes and cell surface hydrophobicity.

**Materials/methods:** The XTT reduction assay was used to measure viability of biofilm in the presence of fluconazole (FLC) and anti-CR3-RP Ab [added at the adherence phase and the 24-h pre-formed biofilm]. Quantitative real-time PCR was used to determine changes in the *ALS1, ALS3, ALS9, BCR1*, and *CSH1* gene expression in biofilms formed w/wo Ab. Changes in hydrophobic properties of biofilm was estimated by N-octane assay and calculated in percentage of hydrophobic cells after treatment w/wo Ab.

**Results:** The anti CR3-RP Ab was able to inhibit biofilm of *C. albicans* SC5314 and the FLC-resistant *C. albicans* CCY29-3-164 strain when added to the adherence phase [decrease of metabolic activity of SC5314 and CCY29-3-164 in 70% and 35%, respectively]. Moreover, Ab also demonstrated activity against the 24-h pre-formed biofilms [decrease of metabolic activity in 30% for both strains], which compared favorably to levels of inhibition achieved by treatment with FLC. Real-time PCR showed a decrease of relative expression of the biofilm-associated genes [2x for *ALS1*, 4x for *ALS9*, 3x for *BCR1*, and 2x for *CSH1*] in both biofilms of *C. albicans* formed in the presence of Ab. In addition, changes in the cell surface hydrophobicity of yeasts was observed after 1h-treatment with Ab. N-octane assay proved a decrease of hydrophobicity in 40% for SC5314 and 15% for CCY29-3-164.

**Conclusions:** Our results point to a high potential of anti-CR3-RP Ab in eradication of resistant *Candida* biofilms and its role in regulation of genes associated with biofilm development.

This work was supported by project VEGA 1/0537/19 and the Slovak Research and Development Agency under the contract No.APVV-15-0347.

Tolerance of prolonged oral tedizolid (TDZ) antibiotic therapy for peri-prosthetic joint infections (PJIs): results of a pilot multi-centre French study

Eric Senneville*, Aurélien Dinh3, Tristan Ferry4, Olivier Robineau5,6

1 Lille University/Gustave Dron Hospital Tourcoing, Tourcoing, France, 2 Lille Université/Hôpital Gustave Dron Tourcoing, Hôpital Gustave Dron Tourcoing, Tourcoing, France, 3 104 Boulevard Raymond Poincaré, Garches, France, 4 Hospital La Croix-Rousse - HCL, Lyon, France, 5 Hôpital Gustave Dron, Tourcoing, France, 6 Lille Université/ Hôpital Gustave Dron, Tourcoing, France

Background: Linezolid (LZD) has proven efficacy in patients treated for PJIs but prolonged therapy is limited notably by bone marrow and neuro-toxicity. TDZ is an oxazolidinone close to LZD which exhibits a higher intrinsic antibacterial activity and a better toxicity profile than LZD. Data on the clinical and biological tolerance of oral TZD prolonged therapy in patients treated for PJIs are lacking.

Materials/methods: We conducted a prospective pilot study in 3 national referent centres for bone and joint infections in France (Lille-Tourcoing, Paris and Lyon) from August 2018 to August 2019. All patients were operated and the decision to use TZD was taken in the setting of multidisciplinary meetings and given the off-label use of TDZ, and informed written consent was obtained in every patient. The planned duration of TZD treatment had to be at least 6 but not more than 12 weeks.

Results: Thirty-four patients (18/16 M/F) of mean age 73.5 ± 10.1 years were included. ASA score was 2 in 18 (53%) cases and a previous revision for infection was noted in 11 patients (32%). Surgical interventions consisted in retention of the infected implants and one/two stage-replacements in 12 (35%) and 18/4 (53/12%) patients, respectively. Microbiology was dominated by Staphylococcus spp. (n=22, including 10 S. aureus) and Enterococcus spp. (n=8). The mean duration of TZD therapy in 30 patients (88%) who completed the planned therapy was 61±19 days [42-88]. TZD was associated to another antibiotic in 19 patients (56%), including rifampicin in 17 cases (50%). At least one adverse event likely related to TZD was recorded in 15 patients (44%). Four patients (12%) had to prematurely stop TZD therapy for failure (n=3) and anaemia (n=1 related to haemorrhagic erosive gastritis). Haemoglobin at baseline and at the end of TZD therapy was 10.5±1.6 and 11.5±1.7 g/dL, respectively. No cases of thrombocytopenia, leucopenia, neurotoxicity or drug-drug interaction were recorded during TZD therapy.

Conclusions: The results of the present pilot study show a favorable toxicity profile of TZD, allowing prolonged treatment in patients treated for PJIs. Larger size clinical studies are warranted to confirm these preliminary results.

Presenter email address: senneric@numericable.fr
Investigating the effect of wastewater treatment systems on antimicrobial resistance and virulence factors
Claire Bertelli¹, Sophie Courtois², Marta Rosikiewicz¹, Trestan Pillonel¹, Sabrina Berlendis¹, Sebastien Aebi¹, Belen Galofre¹, Gertjan Medema⁴, Jean-Francois Loret², Gilbert Greub¹

¹Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, ²SUEZ, Le Pecq, France, ³Aigues de Barcelona, Barcelona, Spain, ⁴KWR Watercycle Research Institute, Nieuwegein, Netherlands

Background: Water pollution by antibiotics may contribute to the spread of antimicrobial resistances (AMRs) worldwide and hence poses a serious threat to global public health. Sewage often collects strongly contaminated water with potentially resistant bacteria, and must hence be managed adequately to remove chemicals and favour the growth of non-pathogenic bacteria. Engineered chemical and physical treatments impact the structure of microbial communities in water treatment plants, hence affecting the pool of antimicrobial resistance genes (ARGs) and virulence factors (VF). The present study aimed at investigating the effect of secondary and tertiary treatments on the microbial communities and their resistance and mobility genes in waste water treatment plants (WWTP).

Materials/methods: Twenty-six water samples were collected along the industrial processes of WWTP, including biological secondary and tertiary treatment, in France, Spain, and in The Netherlands. The V3-V4 region of the 16S rRNA was sequenced with 300 bp-read using a MiSeq for microbiota profiling. Taxonomical assignment of reads was performed with an in-house bioinformatic pipeline using QIIME (Caporaso, 2010) and EzBioCloud database (Yoon, 2017). Shotgun metagenomics was performed on a subset of 13 samples. Assembled metagenomics and raw reads were used to identify ARGs, VF genes and MGEs, using homology searches with proteins of the CARD database (Jia, 2017), VF databases and plasmid databases, respectively.

Results: The biological treatments changed the composition of microbial communities that are dominated by well-known faecal bacteria belonging to Proteobacteria, Firmicutes, and Bacteroidetes in raw waste water. In the four WWTP sampled, sewage secondary treatment successfully decreased ARGs from all classes, including the most prevalent multidrug efflux pumps. However, the three different tertiary treatments implemented in the industrial processes showed divergent effect on the resistome. VFs exhibiting the biggest decrease in relative abundance after treatment were biofilm regulators such as bfmR, motility proteins and catalases.

Conclusions: Understanding the occurrence of AMR in waste water systems and defining the performances of treatment strategies is key to introduce effective intervention measures to reduce the selection for AMR and virulence in the environment.

Presenter email address: claire.bertelli@gmail.com
Comparing ethanol lock therapy versus vancomycin lock on a salvation strategy for totally implantable vascular access device infections due to coagulase-negative staphylococci (the ETHALOCK study): a prospective randomised clinical trial

Clement Theis*1, Magali Vidal1, Natacha Mrozek1, Delphine Martineau1, Bruno Pereira1, Olivier Lesens1

1CHU Clermont-Ferrand, Clermont-Ferrand, France

Background: effectiveness of ethanol lock therapy (ELT) in central line associated bloodstream infections (CLABSI) has been previously suggested on retrospective studies. A recent prospective study found that ELT did not prevent treatment failure. However data are small and none of these studies focus on totally implantable venous access device (TIVAD). Thus far the 2009 IDSA guidelines on managing intravascular catheter related infections have not positioned this strategy.

Materials/methods: a 2-arms, randomized, double-blinded, multicentre trial was set to compare the efficacy of ELT versus vancomycin lock in TIVAD infections due to coagulase negative staphylococci (CoNS), either or not associated with bacteremia. Patients were randomly assigned (1:1) to receive either ELT (ethanol 40% + enoxaparin) or vancomycin lock, for 10 days in both arms. Lock therapy was renewed every day, dwelling in the lumen for 24 hours. A systemic antibiotic course was given in case of bacteremia. The primary outcome, assessed after a 12 weeks follow up, was treatment success defined as clinical and biological cure, or non-attributable death or catheter removal. Secondary outcome was ELT tolerance and complications. All-cause mortality at 14 weeks and the TIVAD removal rate and its cause were also assessed. This trial is registered with Clinicaltrials.gov, number NCT02411331.

Results: 62 patients with TIVAD infection have been included between 2015 and 2019. 19 of them were complicated with bacteremia. Cure rate was 54.84% (17/31) in vancomycin lock group and 61.29% (19/31) in ELT group (p=0.61). There was no difference between infections complicated with bacteremia (cure rate was 50% in vancomycin group [5/10] and 77.78% in ELT group [7/9], p=0.35) and infections without bacteremia (cure rate was 57.14% in vancomycin group [12/21] and 54.55% in ELT group [12/22], p=0.86). Adverse effects happened equally in both group.

Conclusions: ELT is not an efficient solution to treat TIVAD infections due to CoNS, complicated or not with bacteremia. Catheter salvage strategy should be considered only in patients with poor health condition or precious catheter.

Abstract 8577

Chorioamnionitis: time for changes in management?
Beatriz Crespo Estrada*1, Isabel Gutierrez Gonzalez1, Clara Alegría1, Noelia Hernandez1, Beatriz Reyes1

1Hospital, Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: Chorioamnionitis is one of the most important risk factors associated with early-onset neonatal sepsis (EOS). However, the exposed infants with confirmed EOS is low and empirical therapy represents the first cause of antibiotic use in newborns.

Since September 2018, a new protocol was established in the neonatology unit in our hospital, whereby children > 35 weeks don’t receive antibiotic treatment while they remained asymptomatic and without alterations on the analytic parameters.

Our purpose was the description of the microbiological diagnosis of chorioamnionitis and the therapeutic management of neonates, after this protocol was established.

Materials/methods: Between October 2017 - September 2019, 204 placental samples from women with clinical suspected chorioamnionitis (>35 weeks of gestation) were collected, plated in thioglycolate broth, blood agar, MacConkey agar, chocolate agar, and selective media for S. agalactiae, Neisseria gonorrhoeae, Gardnerella vaginalis and Candida spp. and incubated at 37°C 24 or 48 hours for anaerobios.

Since December 2018, Anyplex™ II STI-7 Detection (Seegene) was performed to molecular detection of sexual microorganisms transmission.

Women and children data were collected.

Results: In 76 samples some microorganism was found (17 polymicrobial). Gram negative bacilli (n=38), Enterococcus (n=16), S. agalactiae (n=12) were the most common microorganisms found in cultures.

Ureaplasma spp was the most frequently detected by PCR method (n=24).

Before protocol establishment, all infants exposed to suspected clinical maternal chorioamnionitis (n=149) received antibiotics, following the current recommendations of the American Academy of Pediatrics (AAP) and the CDC; however, in 64% of the placental samples no microorganisms were isolated. Only 3.3% (n=5) of the infants developed some symptom and one positive blood culture (Enterococcus faecalis) was detected.

Following new protocol, only 27% (n=43) of children were treated (presence of symptoms or abnormal laboratory results) and no cases of positive blood culture occurred. The antibiotic use decreased in 73% ([149/149 (100%) vs 43/158 (27%)].

Conclusions: Clinical maternal chorioamnionitis diagnosis, based in non specific criteria lead to unnecessary treatment in newborns.

According to these data, the combination of microbiological, analitical and clinical criteria with and expectant attitude results in a decrease in costs and toxic effects of antibiotic therapy, without an increase of EOS.

Abstract 8578

**Directly detecting imipenemase (IMP) carbapenemase with high-resolution Orbitrap mass spectrometry**

William Mcgee\(^1\), Scott Kronewitter\(^1\), Marjaana Viirtola\(^2\), Arvind Verma\(^2\), Jason Neil\(^2\), David Sarracino\(^3\), Mark Hutchins\(^3\), Soniya Gurung\(^3\), Jim Stephenson*\(^4\)

\(^1\)Thermo Fisher Scientific, Cambridge, United States, \(^2\)Thermo Fisher Scientific, Vantaa, Finland, \(^3\)Thermo Fisher Scientific, Basingstoke, United Kingdom

**Background:** Carbapenemase-producing organisms (CPOs) are becoming a serious global public health threat as a consequence not only of rapid propagation of successful clones, but also of horizontal gene transfer of resistance genes. Additionally, CPOs are frequently associated with high morbidity and mortality rates.

Imipenem-type metallo-β-lactamase (IMP) producing organisms contain carbapenemase enzymes that confer antibiotic resistance to almost all antibiotics with the exception of a select few of last-resort. These precious antibiotics are intentionally seldom-administered with the intent of preventing microbe exposure leading to developed novel resistances to our last line of defense. Imipenem, a noted last-resort antibiotic due to its unusually high potency and effectiveness against a broad spectrum of microbes, is catalytically metabolized by what are typically difficult-to-treat IMP-producing bacteria.

Herein, we present an approach for directly detecting IMP from cultures using short LC gradient methods that leverage tandem mass spectrometry (MS/MS).

**Materials/methods:** Single bacterial colonies on agar were harvested, mechanically lysed, centrifuged, and lysates were extracted. The proteins in the lysate were bound to RP-4H monolithic solid phase extraction columns and chromatographically eluted with subsequent ionization and transfer to a mass spectrometer for analysis. Using MS/MS, ions with mass-to-charge ratios \(m/z\) corresponding to intact IMP were dissociated such that diagnostic fragment ions were detected and used to confirm the presence of the protein.

**Results:** To date, multiple species of both Enterobacteriales and *Pseudomonas aeruginosa* that had been previously determined to harbor IMP genes using whole genome sequencing were evaluated. MS/MS of IMP isolates resulted in production of informative fragments, having specific \(m/z\) and charge states. The combination of these fragments provided sufficient information to determine the presence of IMP in 10 of 10 isolates. Furthermore, non-carbapenemase-producing isolates showed negative results from the assay.

**Conclusions:** Directly detecting IMP on short gradients facilitates clinical adoption. This approach involves the direct measurement of the active carbapenemase, making it extremely selective due to the sequence-specific molecular weight of the proteins. Although this shows great promise for the strains we have evaluated, IMP often has low expression levels and the limit of detection has yet to be systematically evaluated in clinical samples.

Abstract 8580

**Ultimate survival of Serratia marcescens in chlorhexidine**

Alberto Delgado-Iribarren*1, Raquel Barquero Jiménez2

1Alcorcón, Madrid, Spain

**Background:** Chlorhexidine is an antiseptic widely used. In December 2014 there was an outbreak of *Serratia marcescens* (*Sm*) associated with 2% aqueous solution of Chlorhexidine (asC, Bohmclor ®) in Spain. In our hospital we isolate the strain in three presentations of 2% asC i36 and i37 batches and in 0, 5% asC i35 batch, that were prepared in October 2014. We have studied the survival of these strains until September 2018, and also of different strains of clinical isolates.

**Materials/methods:** Colony counts of Sm outbreak strain of the contaminated stock bottles were performed at monthly intervals. Experimental inoculation of 10 ml of chlorhexidine with different concentrations of isolates of other bacteria from clinical sources, (gram positives, gram negatives and yeasts). Colony counts were done at the time of inoculation and 7 days later. We also inoculated 1-10 ml of SmOS 0,5 McFarland solution in bottle stock solution of 250 ml with colony counts performed at monthly intervals.

**Results:** Sm was isolated in three presentations of asC i36 during 6 months but in the i37 batch it remained viable until july 2018 (44 months); in 0, 5% asC i35 batch was negative in the first month. We found no growth in experimental inoculation of 10 ml of chlorhexidine with different concentrations of all isolates from clinical sources at the time of inoculation up to 7 days. The experimental contamination of the stock bottles of 250 ml of chlorhexidine obtained positive cultures with high colony counts. Surprisingly the 5 ml and 10 ml inoculations only survived for 3 months and the inoculation of only 1 ml remained viable 12 months.

**Conclusions:** Sm may survive in 2% asC for prolonged periods. We describe a survival of 44 months what has never been described to date. We have more questions than answers to explain what are the factors on this extreme survival depends. *Serratia marcescens* may survive in 2% asC for prolonged periods. We describe a survival of 44 months what has never been described to date. We have more questions than answers to explain what are the factors on this extreme survival depends

Abstract 8587

**Rickettsiosis in southern Tunisia: serodiagnosis, epidemiology and severe cases**

Gargouri Olfa\(^1\), Nour Ben Ayed\(^1\), Amel Chtourou\(^1\), Basma Mnif\(^1\), Sonda Mezghani\(^1\), Faouzia Rhimi\(^1\), Hela Karray-Hakim\(^1\), Adnene Hammami\(^*\)

\(^1\)Laboratory of Microbiology, Habib Bourguiba University-Hospital, Sfax, Tunisia

**Background:** Rickettsioses are emerging infectious diseases caused by obligate intracellular bacteria belonging to the genus *Rickettsia* and are transmitted by arthropods. Although classified as neglected diseases, they continue to cause severe illnesses and death worldwide. Our aim was to determine the seroprevalence of *Rickettsia* in our region and describe epidemiological and clinical characteristics of patients.

**Materials/methods:** All *Rickettsia* serodiagnosis carried out in the laboratory of Microbiology, Habib Bourguiba University-Hospital, Sfax (Tunisia) between January 2016 and August 2019 were included. Serum samples were tested for the presence of antibodies against *R. Typhi* and *R. conorii* by micro immunofluorescence assay. The positivity criteria were: IgG ≥ 1:128 and IgM ≥ 1:64, seroconversion or significant elevation of IgG (x4) between two sera.

**Results:** During the study period, 2424 serology were performed. Forty-Eight rickettsial infection cases were retained. Rickettsial diseases occurred in patients 4 to 86 years of age. A recrudescence of rickettsioses was observed during the autumn season (52%). 58% of the patients had IgG titer ≥ 1:128 and IgM titer ≥ 1:64. Seroconversion was observed in 17% of cases and a significant elevation of IgG between two sera was noted in 25%. Tests were positive for spotted fever group in 70.8%, typhus group in 12.5% and a cross reaction between the two groups was noted in 16.7%. Clinically, fever was noted in 71% of cases; fever was associated to cutaneous rash in 58.4%. Pneumonia was observed in 8.3% of cases. Other clinical symptoms have been observed such as uveitis and Confusion. Two cases of severe rickettsiosis have required ICU admission of two young adults. Biological abnormalities such as cytolysis, renal failure and thrombocytopenia have been noted. One of the patients had convulsions and myocarditis, but he improved with doxycycline. The other patient had fatal outcome due to an aggravation of a dilated cardiomyopathy.

**Conclusions:** In Tunisia, Mediterranean Spotted Fever caused by *Rickettsia conorii* is the most common rickettsiosis. Rickettsial diseases can be presented with variable but serious clinical forms. Serology is of great benefit especially in the presence of a clinical polymorphism.

Abstract 8588

Diagnostic impact of molecular detection of enteropathogenic bacteria compared to stool culture

Salud Rodríguez-Pallarés*, Ana Ruiz-Castillo, Paula Panes-Ortega, Federico Arroyo Navarro, Fatima Galan-Sanchez, Manuel Rodriguez-Iglesias

1 Hospital Universitario Puerta del Mar, Cádiz, Spain

Background: Gastroenteritis is a common disorder usually caused by infection and characterized by the acute onset of diarrhea. Molecular diagnosis using syndromic panels allows the detection of multiple pathogens that cause this process. Our goal is to evaluate the diagnostic performance of a commercial molecular method compared to conventional techniques in the detection of bacterial pathogens.

Materials/methods: Seven-hundred and thirty-nine stool samples with a Bristol score equal to or greater than 5 were processed, 352 samples (47.6%) from community health centers and 387 (52.4%) from hospital, both emergencies and hospitalization. Samples were transferred to Cary-Blair medium and processed using usual culture media for the detection of enteropathogenic bacteria. DNA extraction was performed from the liquid transport medium (Microlab Starlet, Hamilton). A syndromic panel of bacteria was used for real-time PCR amplification (Allplex GI Bacteria I / II Assay, Seegene) following the manufacturer’s instructions.

Results: The molecular method allowed to detect enteropathogens in 234 samples (31.7%), while conventional culture could only recover 59 (8.0%). In 38 samples, more than one pathogen was detected by the syndromic panel. The pathogens detected, in order of frequency, were 69 Aeromonas spp. (9.3%), 62 Campylobacter spp. (8.4%), 54 Escherichia coli with enteropathogenic potential (EPEC, EAEC, EIEC, ETEC, STEC and O157) (7.3%), 47 Clostridiodes difficile toxin B (6.4%), 10 Salmonella spp. (1.4%), 7 Yersinia enterocolitica (0.9%), and 4 Vibrio spp. (0.5%).

Conclusions: The highest diagnostic performance of the molecular method compared to the culture occurred in the detection of E. coli (54 vs 0). The detection in Campylobacter was almost doubled (62 vs 36), however the range and median of the Ct in the samples with positive culture (23.0-38.6 and 27.5) was lower than the samples with negative Campylobacter culture (26.4-43.8 and 35.4), which shows the highest sensitivity of the molecular method. The molecular detection performance of Aeromonas spp. with respect to culture is also very relevant (69 vs 16), although it should be noted that the median Ct of the positive samples is high (42.3) and of uncertain clinical significance.

Hospital physicians’ perspective on antibiotic prescribing and antimicrobial resistance: a qualitative study

Ingrid Christensen*1, Jon Birger Haug1, Jørgen Vildershøj Bjørnholt2, Dag Berild2, Brita Skodvin3, Lars-Petter Jelsness-Jørgensen*4

1Østfold Health Trust, Sarpsborg, Norway, 2Oslo University Hospital, Oslo, Norway, 3Haukeland University Hospital, Bergen Health Trust, Bergen, Norway, 4Faculty of Health and Social Studies, Østfold University College, Fredrikstad, Norway

Background: Antimicrobial resistance (AMR) is a growing threat to global health. To develop targeted antibiotic stewardship interventions, it is crucial to understand health care workers’ and, in particular, prescribing physicians’ behaviour. To our knowledge, there have been few studies exploring physicians’ attitudes and beliefs towards AMR from countries with low antibiotic resistance rates. This qualitative study aimed to investigate physicians’ views on AMR as well as factors affecting their prescribing behaviour.

Materials/methods: After giving their informed consent, 14 physicians with varied clinical experience and affiliation and a high antibiotic prescribing activity were recruited at the Østfold Hospital Trust, a 380-bed secondary care centre in Norway. Aided by an interview guide, semi-structured interviews were held and audio-taped, then transcribed verbatim and analyzed using thematic analysis. Interviewing was continued until no new themes were identified.

Results: Regarding AMR, three main themes emerged; «A knife at the throat», «Fear of losing control» and «Ethical responsibility». AMR was unanimously perceived as a real threat. Although the situation in Norway was felt to be under control, many found the subject of AMR generally to be under-debated. Most respondents feared not only for the safety of future patients but also drew lines to their own personal life. Increased ethical dilemmas were anticipated from a frequent wish to «do everything» for the patient versus an escalating AMR.

Regarding antibiotic prescription practices, three themes emerged: «Cover one’s back», «In the clinical squeeze» and «Supporting tools». There was a willingness among physicians to fight AMR and prescribe restrictively, and infectious disease consultants were used for support. However, barriers to rational prescribing was a «just in case» prescribing attitude, high patient turn-over versus lack of resources, fear of colleague or patient disapproval, and a partly suboptimal microbiology sampling.

Conclusions: The study identified factors of importance to further develop targeted interventions against AMR. In particular, some structural barriers were identified which may prove modifiable. A great foundation for improvement was found in our hospital physicians’ awareness of AMR and a readiness to optimize their prescription habits.

An intervention bundle to improve compliance with clinical guidelines for \textit{Clostridioides difficile} infection: a quasi-experimental study

Julia Orügüen Sabater\textsuperscript{1*}, Mario Agreda\textsuperscript{1}, Mario Fernandez Ruiz\textsuperscript{1}, Laura Corbella Vazquez\textsuperscript{1}, Tamara Ruiz Merlo\textsuperscript{1}, Patricia Parra\textsuperscript{1}, Ma Angeles Orellana Miguel\textsuperscript{1}, Jennifer Villa\textsuperscript{1}, Francisco Lopez-Medrano\textsuperscript{1}, Isabel Rodriguez Goncer\textsuperscript{1}, María Ruiz-Ruigómez\textsuperscript{1}, Rafael San Juan Garrido\textsuperscript{1}, Manolo Lizasoain\textsuperscript{1}, Jose M. Aguado Garcia\textsuperscript{1}

\textsuperscript{1}University Hospital 12 de Octubre, Madrid, Spain, \textsuperscript{2}Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain

\textbf{Background:} Although \textit{Clostridioides difficile} is a common cause of health care–associated infection, the compliance with clinical practice guidelines is poor.

\textbf{Materials/methods:} The aim of our interventional study was to evaluate the impact of a bundle of measures for patients with a first episode of \textit{C. difficile} infection (CDI): provision of talks and workshops, antimicrobial stewardship and optimization of treatment. Patients diagnosed with a first episode of CDI at our institution from February to December 2017 \{“intervention group”\} were prospectively included and compared with a retrospective cohort of patients diagnosed during a previous 12-month period \{2015\} in which no systematic intervention had been implemented \{“non-intervention group”\}. Specific anti-CDI treatment was considered appropriate if it adhered to current clinical practice guidelines, and was used at optimal doses and duration, without duplication or combination with unnecessary drugs.

\textbf{Results:} Overall, 172 and 231 first episodes of CDI were included in the intervention and non-intervention group, respectively. Anti-CDI treatment was appropriate in more episodes within the intervention group \{75.6\% [130/172] vs. 64.5\% [149/231]; \textit{P}-value=0.023\}. The improvement in compliance with guidelines was mainly at the expense of reducing overuse for non-severe episodes \{8.0\% [10/125] vs. 23.4\% [40/172]; \textit{P}-value<0.001\} and reducing underuse for severe episodes \{27.7\% [10/36] vs. 36.6\% [15/41]; \textit{P}-value = 0.5\}. The intervention led to an increase in the use of oral vancomycin \{50.6\% [87/172] vs. 34.5\% [79/231]; \textit{P}-value<0.001\} and fidaxomicin \{3.5\% [6/172] vs. 0\% [0/231]; \textit{P}-value<0.001\} and a decrease in the use of oral metronidazole \{36\% [62/172] vs. 54.5\% [126/231]; \textit{P}-value=0.0014\} and intravenous metronidazole \{7.6\% [13/172] vs. 23.8\% [55/231]; \textit{P}-value=0.005\}. The number of patients who received systemic antibiotics concomitantly with the anti-CDI treatment was reduced in the intervention group \{19.2\% [33/172] vs. 26.8\% [62/231]; \textit{P}-value=0.08\}. The rate of recurrent CDI episodes was numerically lower in the intervention group, without statistical significance \{12.2\% [21/172] vs. 14.7\% [34/231]; \textit{P}-value=0.56\}, with a lower proportion of patients experiencing more than one relapse \{5 vs. 11 patients; \textit{P}-value=0.55\}.

\textbf{Conclusions:} A bundle of evidence-based measures for patients diagnosed with a first episode of CDI provided a better compliance with clinical practice guidelines and might reduce the rate of relapses.

Performance and comparison of the rapid Vivalytic STI multiplex assay for the detection of sexually-transmitted infections (STI) in specimens from male patients attending an STI dermatologist practice

Gerald Felician Lang*1

1Praxis Dr. Lang, Vienna, Austria

Background: Point of care Multiplex STI assays enable timely results for immediate patient treatment and prevent spreading of sexually transmitted infections. The Vivalytic STI Multiplex assay from Bosch is a fully automated cartridge-based-system that processes specimens from nucleic acid extraction to results analysis. It detects 10 pathogens simultaneously, including Neisseria gonorrhoeae (NG), Mycoplasma genitalium (MG), Ureaplasma urealyticum (UU), Chlamydia trachomatis (CT), Trichomonas vaginalis (TV), Haemophilus ducreyi (HD), Mycoplasma hominis (MH), Treponema pallidum (TP), Herpes simplex virus I (HSV1) and Herpes simplex virus II (HSV2).

The objectives of this non-interventional study are to: 1) Analyse the performance of Vivalytic STI Multiplex assay from specimens collected with dry FL00Swabs®. 2) Detect the yield of different collection sites. 3) Compare Vivalytic STI Multiplex assay to Cepheid Xpert(R) CT/NG assay for CT and NG detection.

Materials/methods: This study contains clinical specimens: urethral (US), anal (AS) and pharyngeal swabs (PS) collected from primarily MSM patients attending an STI dermatologist practice. US collection with FL00Swabs® 551C, AS and PS collection with FL00Swabs® 552C, elution in 1 ml tube of eNAT™ medium code 606C (COPAN) and addition of 300µl of eNAT™ specimens to each cartridge. Duplicate specimens are collected from same patients and tested with both, the Vivalytic STI Multiplex and the Xpert(R) CT/NG according to manufacturer’s methods.

Results: In the 112 clinical specimens, 78 negatives and 34 positives were detected with the Vivalytic assay. A single pathogen was detected in 22 specimens (1CT, 2MH, 9UU, 2MG, 2NG, and 2TP), 2 pathogens in 7 specimens (1UU+NG, 1UU+MH, 2UU+MG, 1TP+HSV2, 1UU+HSV2, and 1CT+UU) 3 pathogens in 5 specimens (1CT+MH+UU, 1MH+UU+TP, 1MH+UU+MG, 1CT+MG+UU, and 1MH+UU+MG). Eighty-seven samples were tested with both, the Vivalytic STI Multiplex and the Xpert(R) CT/NG with generally matching results.

Conclusions: The generated data demonstrates that the Vivalytic assay detected a substantial number of mixed infections. A rapid point-of-care multiplex test may support on-site diagnosis resulting in immediate patient treatment and antibiotic stewardship. Vivalytic STI Multiplex performed well compared to Cepheid Xpert(R) CT/NG assay for CT and NG detection.

Abstract 8593

What constitutes a healthy faecal microbiome?
Suparna Mitra1,2, Anthony Buckley1, Ines B. Moura1, Duncan Ewin1, William Spittal1, Emma Clark1, Karen Bentley1, Jane Freeman*2, Mark H. Wilcox1,2

1University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom, 2Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Disruption of gastrointestinal microbiota by antimicrobials leads to dysbiosis, resulting in opportunistic colonisation by potential pathogens such as Clostridium difficile and multi-drug resistant organisms (MDRO). Understanding the relative risk of antibiotic predisposition to such colonisation to facilitate the optimal development of novel therapeutic strategies (including microbiota disruption preventatives and restoratives) is of major importance. We have previously established a successful, clinically reflective in vitro gut model of CDI, which can be used to investigate the relative risk of pathogen colonisation following antimicrobial challenge.

Materials/methods: Two gut models (fed with faecal slurry, n=4 healthy donors) were run simultaneously; one model was supplemented with standard gut model media, the other with mucin and extra bile acids. The microbial populations reached 'steady-state', and were monitored for a further 5 weeks. Models were challenged with both low [week 6] and high dose [week 7] Clostridium difficile spores and carbapenem-resistant Enterobacteriaceae to assess the efficacy of colonisation resistance provided by the microbiota.

Sequential faecal samples from the same healthy donors (n=4) on 5 occasions were compared with gut model samples using bacterial taxonomic analysis and metagenomic profiling. Multiple tools/databases were used to quality control and annotate 16S (Cutadapt, QIIME, SILVA) and shotgun sequencing (DIAMOND, NCBI-nr) data. MEGAN and R were used for annotation and graphics.

Results: Longitudinal sampling demonstrated limited intra-donor bacterial variation, in contrast to inter-donor variation [Figure]. Microbial populations within our gut models were stable throughout; these contributed to colonisation resistance upon exposure of pathogens [i.e. prevention of growth/expansion]. The most dominant families (Ruminococcaceae, Lachnospiraceae and Bacteroidaceae) were similar between the two models. We identified a core set of bacteria at the genera and family level, associated with colonisation resistance upon pathogen exposure. There were 24 detected families common among donors and models and 4-5 different families unique to each set.

Conclusions: Longitudinal microbiome characterisation has enabled identification of a 'core microbiota' common to the different sample types. We found close microbial similarities between gut models and healthy faecal samples, and demonstrated robustness of model microbiota populations over time. This will provide important baseline data when defining microbial alterations during dysbiosis.

Abstract 8602

**Vertical transmission of the gene blaKPC-3 in clinical isolates of carbapenemase resistant *Klebsiella pneumoniae***

Catarina Ferreira*1, Jaqueline Rocha1, Santosh Bikkarolla1, Karolin Frykholm2, Saga Pohjanen1, Margarida Brito3, Catarina Lameiras3, Olga C. Nunes4, Fredrik Westerlund2, Célia M. Manaia1

1Universidade Católica Portuguesa, CBQF - Centro de Biotecnologia e Química Fina – Laboratório Associado, Escola Superior de Biotecnologia, Porto, Portugal, 2Division of Chemical Biology, Department of Biology and Biological Engineering, Chalmers University of Technology, Gothenburg, Sweden, 3Serviço de Microbiologia IPPO-FG, Porto, Portugal, 4LEPABE - Laboratory for Process Engineering, Environment, Biotechnology and Energy, Faculty of Engineering, University of Porto, Porto, Portugal

**Background:** Carbapenem-resistant *Klebsiella pneumoniae* are major threats in healthcare facilities. The propagation of carbapenem resistance determinants can occur through vertical transmission, with the genetic elements being transmitted during host cell division, or by horizontal transmission, with the same genetic element being transferred among distinct bacterial hosts. This work aimed to track carbapenem resistance transmission by *K. pneumoniae* isolates obtained from hospitalized patients.

**Materials/methods:** A set of 40 clinical isolates of *K. pneumoniae* isolates recovered over a period of two years were screened for carbapenem resistance. This procedure resulted in the identification of five isolates from two patients, which were characterized based on conjugation assays, resistance phenotype and genotype, capacity to form biofilm, whole genome sequencing, and plasmid characterization by pulsed field gel electrophoresis and optical DNA mapping.

**Results:** The five isolates harboured the blaKPC-3 gene, were multidrug-resistant and belonged to multilocus sequence type ST147. The blaKPC-3 gene was integrated in conjugative plasmids with 140 kbp, in three isolates, or 55 kbp, in two isolates, belonging to the replicon types FIA/FIIk or N/FIIk, respectively. Although the five isolates belonged to ST147, they could be divided into two groups harbouring a distinct blaKPC-3 plasmid suggesting the blaKPC-3 gene was being spread via bacterial transmission. All isolates harboured the virulence determinants, type 3 fimbriae encoding *mrk* operon (*mrk*ABCDFHIJ), which can be involved in mucous adherence, tissue colonization and biofilm formation, and the *wzi* gene involved in capsule attachment to the host cell surface. The *mrk* operon could be responsible for the classification of the isolates as weak to moderate biofilm producers. In addition, only isolates with 55 kbp plasmid harboured the virulence genes: *fyu*A, a gene involved in ferric *yersiniabactin* uptake, *irp2* and the cluster *gbr*AEPQSTUX both involved in production of *yersiniabactin*, which is essential for disease establishment.

**Conclusions:** Although all isolates harboured the same gene variant and belonged to the same MLST group, carbapenem resistance in this healthcare facility was transmitted vertically and not through horizontal gene transfer.

Determining the mode of transmission of antibiotic resistance in healthcare facilities is essential to promote its control and using polyphasic approaches may be essential.

**Bloodstream infections caused by Enterococcus spp.: incidence, clinical features, and outcomes**

Tommaso Lupia¹, Luca Scaglione¹, Antonio Curtoni¹, Rossana Cavallo¹, Francesco G. De Rosa¹, Silvia Corcione*¹

¹University of Turin, Turin, Italy

**Background:** Enterococcus faecalis and faecium have become increasingly important pathogens, especially in Healthcare-associated infections. We aimed to evaluate the clinical features, outcomes and the risk factors for mortality in Enterococcal Bloodstream infections (E-BSI).

**Materials/methods:** All subjects with a positive blood culture for *E. faecalis* or *E. faecium* between 2015-2016 were enrolled. E-BSI were defined as community acquired (CA-BSI), healthcare-associated (HCA-BSI) or hospital acquired (HA-BSI). Antibiotic therapy for Enterococcus spp. was defined as appropriate if the following criteria were met: first administration of an active antibiotic, second the administration of combination therapy (at least two drugs, with the exception of Daptomycin), third ≥15 days of treatment. The 21”and 28” day mortality was investigated.

**Results:** We reported 201 episodes of E-BSI. Infection rate was 2.4/1000 days of hospital admission. E. faecalis represented 52.1% of E-BSI: *E. faecalis* (and *E. faecium*) had resulted resistant to ampicillin in 3.1% (*E. faecium*, 22.2%), to gentamicin in 16.2% (47.3%) and to vancomycin in 2.2% (23.3%). Most were HA-BSI (78,1%). Patients' characteristics were reported in Table 1. Only 52 patients (25.8%) received an appropriate therapy. No differences with statistical significance, between the appropriate vs not-appropriate therapy group, except for infectious endocarditis which was more frequent in the first group (p= 0.003); although only 59% of patients underwent echocardiography. At the univariate analysis mortality is associated with resistance to Vancomycin (p=0.042), Sepsis (p=0.003) and Septic shock (p=0.007), confirmed by the multivariate analysis. During the hospitalization death rate was 26%. Median survival time was 65 days from blood positivity. 75.3% survived for 21 days and the survivability curve at day 28th of follow up, showed no difference between appropriate vs not-appropriate therapy.

**Conclusions:** Enterococcus confirms to be an HA and HCA infection. The advanced age, prevalent comorbidities, high invasiveness and medicalization suggest that the infection occurs in frail patients. A quarter of subjects received an appropriate therapy: reasons were premature stopping, monotherapies, or inactive drug on Enterococcus spp. Nevertheless, the antibiotic therapy was not associated with lower mortality, probably because of this frail population it tended for a poor outcome even though an appropriate treatment. Furthermore, E-BSI intracardiac sources were not ever well deepened.

Abstract 8607

Weekly surveillance of bacterial, viral and parasitic infections involving private and public medical analysis laboratories through 317833 diagnostic tests in the Provence-Alpes-Côte-d’Azur region, 2014-2019

Philippe Colson1, Jean Dominique Poveda2, Sabine Trombert Paolantoni3, Audrey Giraud-Gatineau1, Stephanie Haim-Boukobza4, Laura Verdurme2, Jean-Marc Rolain1, Hervé Chaudet1

1IHU Méditerranée Infection, Marseille, France, 2LBM, CERBA, Saint-Ouen-l’Aumône, France

Background: Infection surveillance is essential to optimize their clinical and diagnostic management and to better understand their epidemiology. A network (PACASurvE) for weekly surveillance of infections and analyzes of laboratories of medical biology (LBM) was created in 2013 in Provence-Alpes-Côte-d’Azur (PACA). In particular, it analyzes data from CERBA, a specialized LBM. We present here the analysis of the data of this laboratory for the period 2014-2019.

Materials/methods: The study covers the period 11/2014-07/2019 (57 months). The weekly data consisting in the numbers of tests and positive diagnoses (pos.) were collected from the CERBA LBM, which carries out specialized medical biology analyzes transmitted by private and public LBMs of PACA region. The data was analyzed using Excel and R softwares.

Results: 110 different diagnostic tests for bacterial [n= 50], viral [58] or parasitic [2] infections were monitored, corresponding to respiratory infections [n= 39 tests] or neurological infections [24], gastrointestinal infections [9], hepatitis [7], tropical [6] or sexually transmitted [14] infections, or rash [7]. Of the 317833 tests performed, 29,362 (9.2%) were found to be pos. (on average: 1301 tests and 120 positive tests involving 196,888 patients [mean age= 42±21 years, 64% female]. A diagnosis was found for 22694 patients from 386 LBM located majoritarily in Bouches-du-Rhône (9,899 [44%]) and Var (23%). The most frequent tests targeted Chlamydia trachomatis [n = 3946], HPV [1647], hepatitis B [HBsAg] [1243] and C [1016], anti-HEV IgM [917], detection of Clostridium difficile [533], or Bordetella pertussis [475] by PCR. Changes were observed, for example between 2016 and 2017 and between 2017 and 2018 for the number of anti-HEV IgM tested (+17% and +18%, respectively) and of pos. (+7% and +27%, respectively), and between 2015 and 2017 for the proportion of C. difficile tests found pos. (+212%).

Conclusions: Collection within the PACASurvE network of tests and diagnoses of bacterial, viral and parasitic infections constitutes a unique database for monitoring and studying the epidemiology of infections at the regional level.

Abstract 8608

Rise in Campylobacter jejuni antimicrobial resistance in Split-Dalmatia County, Croatia: 2013 - 2018

Merica Carev1, Anita Novak2, Marija Tonkic2

1Public Health Institute of Split and Dalmatia County, University of Split School of Medicine, Department of Clinical Microbiology, Split, Croatia; 2University Clinical Centre Split, Department of Clinical Microbiology, Split, Croatia

Abstract third-party references: University Clinical Hospital Centre Split, EFWISG, Public Health Institute of Split and Dalmatia County, University of Split School of Medicine

Background: Tracking changes in antibiotic resistance among human Campylobacter jejuni isolates through ongoing surveillance data could provide valuable clinical and public health information.

Here, we aimed to compare the resistance rates of C. jejuni to antibiotics in the largest Croatian county of Split - Dalmatia (SDC) between 2013 and 2018.

Materials/methods: In a population-based laboratory surveillance program for campylobacteriosis in SDC from the 1st January to the 31st December 2018, C. jejuni were collected from stool samples of all the patients hospitalized with gastroenteritis (n = 55) and symptomatic outpatients (n = 289). Antimicrobial susceptibility testing of all 331 C. jejuni isolates was done by disc diffusion method according to EUCAST guidelines. Resistance rates detected in SDC in 2018 were compared with the results obtained in SDC in 2013.

Results: Approximately 79% (260) of the C. jejuni isolates were resistant to ciprofloxacin (CipR), whereas 36% (119) of isolates were resistant to tetracycline (TcR); of the latter, 117 C. jejuni isolates were also co-resistant to ciprofloxacin (TcR/CipR) - in a total 35%. Although two MDR resistant C. jejuni were also detected, resistance to erythromycin and gentamicin was infrequent (≤ 0.6%). However, the prevalence of ciprofloxacin resistant C. jejuni (p < 0,001) and TcR/CipR co-resistant C. jejuni (p < 0,01) increased sharply after 2013.

Conclusions: A high prevalence of CipR resistant and TcR/CipR co-resistant C. jejuni strains were detected in patients in SDC, Croatia, in 2018, as well as significant increases of resistance and co-resistance during the five-year period 2013 - 2018. These results suggest that therapeutic options in campylobacteriosis are very limited and warrant further studies of campylobacter resistance mechanisms and epidemiology.

Abstract 8610

High-throughput bacterial phenotyping to characterise antimicrobial resistance mechanisms

Ben Warne1*, Josefin Bartholdson Scott1, Sally Forrest1, Mailis Maes1, Sushmita Sridhar1, M. Estee Török1, Gordon Dougan1

1University of Cambridge, Department of Medicine, Cambridge, United Kingdom

Background: Current approaches to studying antimicrobial resistance (AMR) are constrained by limitations in traditional bacterial phenotyping methods. Recent advances in high-content imaging (HCI) enable detailed morphological studies of individual bacteria that cannot be captured using existing approaches. Using the Opera Phenix (PerkinElmer) we have developed a HCI platform to study thousands of bacteria growing under specific conditions in 96-well plates. We illustrate the potential of this approach using Klebsiella pneumoniae, a major reservoir of AMR, as an exemplar.

Materials/methods: Bacterial cultures were incubated for 2 hours before staining with fluorescent dyes and imaging using the Opera Phenix. Image analysis was performed in Harmony. Over 60 morphological features were measured per bacterium. This platform was used to study how antimicrobials affect the morphology of Klebsiella pneumoniae, Escherichia coli, Salmonella Typhimurium and Staphylococcus aureus. A collection of 150 Klebsiella pneumoniae isolates, representing species diversity, was assessed in the presence of ciprofloxacin at the minimum inhibitory concentration of each isolate. RNAseq was conducted on five K. pneumoniae isolates in the presence of antimicrobials in parallel with HCI.

Results: Distinct, quantifiable phenotypic changes were observed in the presence of each antimicrobial class (Figure 1). These changes were similar among the Gram-negative isolates. Comparable phenotypic changes were observed across the K. pneumoniae species in response to ciprofloxacin. Each antimicrobial class induced distinct patterns of differential gene expression. Despite extensive morphological changes, there was minimal effect on transcription in response to cefuroxime, meropenem and colistin. Ciprofloxacin induced extensive changes, up-regulating genes that likely contribute to AMR: efflux pumps; plasmid-mediated resistance (qnr, bla, cat); polymerases that induce mutagenesis (umuC/D); and genes associated with plasmid replication.

Conclusions: HCI is a powerful tool to study phenotypic changes at the level of individual bacteria. This enables rapid assessment of large microbial collections in standardised conditions and has a range of potential applications, including accurate phenotyping of resistance and evaluation of novel agents. We have identified multiple pathways that are upregulated under antimicrobial pressure which may promote AMR. Further work is required to determine whether these morphological and transcriptomic changes are reproducible across the diversity of K. pneumoniae and other species.

Abstract 8616

**Comparison of six simple methods for ribosomal DNA extraction directly from nail sample suspected to onychomycosis for PCR-based assay**

Marjan Motamedi*1,2, Mojgan Mahmoudi1, Somayeh Yazdanpanah1

1Department of Medical Parasitology and Mycology, School of Medicine, Shiraz University of Medical Sciences, Shiraz, Iran

**Background:** Since extraction DNA directly from the nail sample suspected to onychomycosis reduces diagnosis time and is a primary and crucial step which has a principal effect on PCR results, in the current study six simple methods for extraction DNA directly from nail were applied and compared by evaluating the presence, appearance and intensity of PCR products visualized on agarose gels and amplified from DNA extracted by each of the methods.

**Materials/methods:** After preparing pooled sample from nails with onychomycosis, total DNA was extracted using six different methods, including mechanical grinding, boiling, glass bead, conical bullet, potassium hydroxide and the use of a commercial kit. In order to DNA purification except for the commercial kit method, a conventional phenol chloroform DNA purification protocol was used. To evaluate the efficacy of each method, the internal transcribed spacer (ITS) region gene was chosen as representative markers for ribosomal DNA.

**Results:** Among the six DNA extraction methods, the boiling method was the most cost effective, followed by the glass bead and conical bullet. All three methods produced high intensity bands on agarose gels and were characterized by no or minimal smear formation; however, boiling was less expensive.

**Conclusions:** Boiling was the most suitable methods regarding its amplicon quality, easiness, quickness and cost effectiveness.

IgM antibody to pneumococcal serotype 3 polysaccharide activates the classical pathway

Stephen I. Pelton¹, Rotem Lapidot*¹, Michelle Lee²

¹Boston University School of Medicine, Boston, United States, ²Boston Medical Center, Boston, United States

Abstract third-party references: funded in part by an investigator initiated grant from Pfizer, inc.

**Background:** Serotype 3 Streptococcus pneumoniae (SP3) is a virulent pathogen across the age spectrum. In US, SP3 now accounts for ~65% of vaccine type invasive pneumococcal disease (IPD) in individuals 65 years of age and older. Characteristically, SP3 uses multiple strategies to evade host defense including displaying a mucoid capsule that enable resistance to phagocytosis and binding Factor H to limit surface C3 binding.

**Materials/methods:** We evaluated complement deposition to the surface of SP3 by flow cytometry. Strains were isolated from Massachusetts' children from nasopharynx, blood, and lung. We compared surface binding of normal human complement in the absence and presence of anti-type 3 polysaccharide immune rabbit sera (provided by Dr. Rick Malley, Boston Childrens Hospital) and anti-type 3 polysaccharide IgM monoclonal antibody (provided by Dr. Moon Nahm, WHO Pneumococcal Reference Lab, UAB). Once flow analysis of our 80 isolates is completed (40 invasive and 40 nasopharyngeal colonizers) we will compare complement binding on serotype 3 strains grouped by site of disease versus colonization and by phenotypic appearance (mucoid vs. non-mucoid).

**Results:** Preliminary results demonstrate that IgM monoclonal antibody activates complement binding through the classical pathway as demonstrated by an increase in C4 deposition on the surface of serotype 3 strains for all 20 strains tested to date. Deposition of C4 occurs in a dose related manner.

**Conclusions:** Our data suggest IgM to capsular polysaccharide may play an important role in host defense against serotype 3. Epidemiologic data suggests the introduction of PCV13 into NIP schedule has had limited, if any, impact on colonization and invasive disease due to serotype 3 pneumococci. Understanding the role of IgM and IgG anti-capsular antibody for serotype 3 is necessary to develop new strategies for prevention of SP3 disease.

**Fig 1.** IgM binding to SP3.
Red: in presence of 0.1% IgM
Blue: in presence of 3% IgM;
Orange: in presence of 5% IgM

**Fig 2.** C4 binding to same SP3 in figure 1, detected with anti C4 PE.
Red: in presence of 0.1% IgM
Blue: in presence of 3% IgM;
Orange: in presence of 5% IgM

Characterisation of the unique contributions of bedaquiline and rifabutin against actively-growing and nutrient-starved populations of *Mycobacterium abscessus*

Jin Lee¹, Nicole Ammerman*¹, Eric Nuermberger¹

¹Johns Hopkins University, Baltimore, United States

**Background:** Bedaquiline and rifabutin have each shown promise for use in the treatment of *Mycobacterium abscessus* lung disease. Previous studies in our lab suggested that bedaquiline and rifabutin exert *in vitro* bactericidal activity against nutrient-starved and actively-growing populations of *M. abscessus*, respectively, and we hypothesized that combining these drugs would result in enhanced bactericidal activity across culture conditions. The objective of this study was to evaluate the specific activity of bedaquiline and rifabutin alone and in combination against actively-growing, nutrient-starved, and intracellular *M. abscessus* populations.

**Materials/methods:** Time-activity curves of bedaquiline and rifabutin against *M. abscessus* subsp.* abscessus* strain ATCC 19977 were determined in the following culture conditions: actively-growing [cation-adjusted Mueller-Hinton or Middlebrook 7H9 broth]; nutrient-starved in phosphate-buffered saline for 7 or 14 days; and intracellular infection in THP-1 cells. All activity was measured by determining bacterial colony forming units before and after drug exposures. Minimum bactericidal activity (MBC) was defined as the lowest concentration that killed 99% of the bacteria.

**Results:** For bedaquiline, limited to no bactericidal activity was observed against actively growing *M. abscessus*, while potent killing was observed against nutrient-starved bacteria. The addition of rifabutin at 1, 2, or 4 µg/mL did not increase bedaquiline killing against actively growing cultures but did increase the killing against nutrient-starved bacteria by 4-, 16, and 32-fold, respectively. For rifabutin, concentration-dependent bactericidal activity was observed against actively-growing bacteria, but activity decreased with increased time of nutrient starvation such that the MBC was ≥64 µg/mL after 14 days of nutrient starvation. The addition of bedaquiline did not impact rifabutin activity against actively-growing bacteria, but did increase the killing against nutrient-starved *M. abscessus*; the MBC against bacteria nutrient-starved for 14 days decreased to 1 and 0.25 µg/mL in the presence of 0.03 or 0.125 µg/mL bedaquiline, respectively. Bedaquiline added bactericidal activity to rifabutin against intracellular *M. abscessus* only after the fifth day of drug exposure.

**Conclusions:** Exposure of nutrient-starved bacteria to both drugs significantly decreased the MBC of each drug, suggesting synergistic killing against non-replicating bacteria. These data support the *in vivo* evaluation of bedaquiline-rifabutin combinations against *M. abscessus* infection.

**Presenter email address:** nicole.ammerman@gmail.com
Abstract 8620

**Clostridioides difficile infection incidence and consumption of selected antibiotics: EU/EEA countries 2008—2018**

Pete Kinross*1, Liselotte Diaz Högberg1, Sarah Tschudin-Sutter2, Klaus Weist3, Carl Suetens4

1European Centre for Disease Prevention and Control, [ECDC], Solna, Sweden, 2University Hospital Basel, University Basel, Basel, Switzerland

Abstract third-party references: on behalf of ECDC HAI-Net C. difficile infection and ESAC-Net participants

**Background:** In the 2011-2012 and 2016-2017 European Centre for Disease Prevention and Control (ECDC) point prevalence surveys in European Union/European Economic Area (EU/EEA) acute care hospitals (ACHs), the proportion of healthcare-associated infections that were *Clostridioides* (*Clostridium*) difficile infection (CDI) was 3.6% and 4.9%, respectively. In the 2018 ESCMID guidance to prevent CDI in ACHs, the recommendation with the strongest quality of evidence is ‘restriction of antibiotic agents/classes’. This study describes current CDI incidence in EU/EEA ACHs and EU/EEA trends in consumption of selected antibiotics relevant to CDI.

**Materials/methods:** Since January 2016, ECDC coordinates CDI incidence surveillance in ACHs in EU/EEA countries. The ECDC CDI protocol minimum data requirement includes collection, by ACH staff, of the number of hospitalised patients who match the current ESCMID CDI case definition and aggregate denominators.

National-level antimicrobial consumption data in EU/EEA countries are available from the European Surveillance of Antimicrobial Consumption Network (ESAC-Net) as WHO Defined Daily Doses (DDDs)/1,000 inhabitants/day. Joinpoint regression (v4.7.0.0) assessed annual changes in EU/EEA-level population-weighted means.

**Results:** As of 20 November 2019, 23 EU/EEA countries had reported CDI data from 2016-2018, with >47,000 CDI cases for >150 million patient-days from 1,806 ACHs. In 2016-2018, the mean hospital-level incidence was higher in tertiary hospitals [3.87 cases/10,000 patient-days] than in secondary or primary hospitals [3.49 and 2.41 cases/10,000 patient-days, respectively]. In 2016-2017, the crude annual national-level CDI incidence ranged from 2.4 to 7.5 cases/10,000 patient-days.

Twenty-eight EU/EEA countries reported antimicrobial consumption data for 2008—2018. Annual consumption and multi-year trends differed between countries for both total and hospital sector consumption of fluoroquinolones [Anatomical Therapeutic Chemical code J01MA], clindamycin [J01FF01], third-generation cephalosporins [J01DD] and amoxicillin-clavulanic acid [J01CR02]. For example, whilst during 2008-2018, EU/EEA-level hospital sector fluoroquinolone consumption decreased by 3.6% (95%CI: 1.6%-5.5%), in 2018, the range of national-level consumption rates was 0.04-0.36 DDDs/1,000 inhabitants/day.

**Conclusions:** CDI is common in all types of ACHs in EU/EEA countries. The range of national consumption of the selected antibiotics suggests that further reductions are achievable. All ACHs should consider integrated surveillance of CDI and consumption of key antimicrobials, to enable locally-targeted CDI prevention.

Implementation of model-based therapeutic drug monitoring of vancomycin

Romain Garreau1, Mathilde France1, Laura Chatel1, Dimitri Leclercq1, Nicolas Montmartin1, Laurent Bourguignon1, Nicolas Montmartin1, Sylvain Goutelle*1

1University Hospitals of Lyon, Lyon, France

Abstract 8622

Background: Vancomycin therapeutic drug monitoring (TDM) based on the area-under the concentration-time curve (AUC) and pharmacokinetic (PK) modelling may improve attainment of target exposure and safety (Neely et al. Antimicrob. Agents Chemother 2018;62). The objective of this study was to report our experience with model-based TDM of vancomycin.

Materials/methods: This was a retrospective analysis of data collected in our center from 2015 to 2019 in patients who underwent routine vancomycin TDM on at least two occasions. Bayesian analysis was performed using BestDose™ software to estimate pharmacokinetic parameters and AUC based on measured concentrations in each patient. We compared the proportion of patients achieving concentration and AUC targets before and after TDM by using the Fisher exact test for paired data.

Results: Data from 82 patients (35 women and 47 men) were available. Initial values (mean ± SD) of age, body weight and creatinine clearance were as follows: 79 ± 13 years, 67 ± 16 kg and 61 ml/min ± 29 ml/min. Vancomycin was administered by intermittent infusion in 64 patients and by continuous IV in 18 patients. The median (min-max) number of TDM occasions was 3 (2-17). Vancomycin dosage was modified in 76% and 63% of patients on the first and second TDM occasion, respectively. Vancomycin model-based TDM results are shown in Table 1.

Comparison versus first TDM *p<0.05; **p<0.01

Conclusions: AUC and model-based TDM of vancomycin is feasible in routine practice. While a controlled study is necessary to confirm our findings, they show that this intervention was associated with frequent dose adjustment, a lower proportion of underexposure and a higher proportion of therapeutic exposure to vancomycin over therapy.

Evaluation of the performance of a commercial rapid diagnostic test for cystic echinococcosis in a clinical setting

Ambra Vola*, Annalisa De Silvestri², Mara Mariconti³, Raffaella Lissandrino³, Marcello Maestri⁴, Antonella D’addiego⁴, Enrico Brunetti³, Tommaso Manciulli²

¹IRCCS San Matteo Hospital Foundation, Unit of Infectious Diseases, Pavia, Italy, ²IRCCS San Matteo Hospital Foundation, Clinical Epidemiology and Biometric Unit, Pavia, Italy, ³University of Pavia, Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, Pavia, Italy, ⁴IRCCS San Matteo Hospital Foundation, Unit of General Surgery, Pavia, Italy, ⁵University of Pavia, PhD School of Experimental Medicine, Pavia, Italy

Background: Cystic echinococcosis (CE) is a cosmopolitan zoonosis caused by the tapeworm Echinococcus granulosus. It causes the formation of cysts prevalently in the abdomen of humans. Abdominal CE is usually diagnosed by ultrasound (US) with serology playing a complementary role. In recent years, Rapid Diagnostic Tests (RDTs) have become part of the routine serological diagnosis in many laboratories. We present our retrospective evaluation of the performance of a commercially available RDT.

Materials/methods: We retrospectively enrolled samples from patients seen at a single tertiary care center for CE. Patients were referred as having a suspect CE lesion or were known CE patients seen from September 2017 to July 2019. All patients were tested with two tests: VIRAPID HYDATIDOSIS RDT (Vircell, Spain) and ELISA RIDASCREEN ECHINOCOCCUS IgG (R-Biopharm, Germany). We collected data relating to the final diagnosis (CE vs non-CE) and CE stage according to the WHO-Informal Working Group classification. Sensitivity and specificity were then calculated for all tests. Differences in test performances were assessed using the Wilcoxon Rank test.

Results: We included 246 samples in our evaluation. Of these, 174 (70.7%) belonged to patients with CE cysts or to residual lesions from surgical treatment. Fifty-one patients (29.3%) had active or transitional cysts (CE1-CE3). Seventy-two sera (29.3%) came from patients who had non-parasitic lesions. The overall sensitivity and specificity were 47% and 89.6% for the ELISA, 65.2% and 81.8% for the RDT. If only active lesions were considered, sensitivity increased to 84% and 78% respectively. The RDT proved more sensitive in detecting active cysts (p=0.017). Combining the two tests gave a sensitivity of 45% and 48% (including or excluding active cases).

Conclusions: Our evaluation of the diagnostic performance of the tests showed lower sensitivity and specificity values compared to findings from other research groups. This could be explained by differences in cohort composition, as well as by the inclusion of sera specimens from all anatomic locations, something which is known to influence serological results. The overall performance of the tests confirms that serology still plays a complementary role in the diagnosis of CE.

Abstract 8627

A rapid method for direct detection of intact OXA-48-like carbapenemases using liquid chromatography and high-resolution Orbitrap mass spectrometry

William Mcgee*, Scott Kronewitter1, Arvind Verma1, Marjaana Viirtola2, Jason Neil1, Jim Stephenson1

1Thermo Fisher Scientific, Cambridge, United States, 2Thermo Fisher Scientific, Vantaa, Finland

Background: Carbapenem resistance in Gram negative bacteria is a continuously growing global threat. Although significant efforts have been made to mitigate the spread of carbapenemase-producing organisms (CPoS), there is a dire need to maximize detection of these bacteria. Among other carbapenemases produced in Enterobacterales, the OXA-48-like family of carbapenemases present challenges for some routine susceptibility testing due to low-level carbapenemase activity. In an effort to increase detection fidelity, we have shifted from phenotypic and molecular techniques to develop a method that focuses specifically on the intact proteins. Herein we present a method combining liquid chromatography (LC) and mass spectrometry (MS) for direct and rapid detection of intact OXA-48-like carbapenemases.

Materials/methods: Clinical isolates of Enterobacteriales have been evaluated for the presence of OXA-48-like carbapenemases using combinations of whole genome sequencing (WGS) or polymerase chain reaction (PCR), phenotypic susceptibility testing, and a novel mass spectrometric assay. In an automated sample preparation, bacterial cells are mechanically lysed, centrifuged, and protein-containing supernatant is transferred to a solid phase extraction (SPE) column. Proteins are eluted from the column, ionized via electrospray ionization (ESI), and introduced to the MS. Clinically-relevant variants within the OXA-48-like family are evaluated. Carbapenemase-non-producing isolates are evaluated for comparison.

Results: Tandem mass spectrometry (MS/MS) is used to dissociate intact OXA-48-like carbapenemases, which allows protein-specific fragment ions to be identified for the utmost confidence in identification. Several species of Enterobacteriales have been evaluated. Combining LC with MS/MS has been found to have a dramatic impact on overall sensitivity. To date, over 20 OXA-48-like-producing isolates, most of which having low-MICs to ertapenem, have had carbapenemases detected, including OXA-48, OXA-162, OXA-181, OXA-232 and OXA-244, while carbapenemase-non-producing isolates have all produced negative results.

Conclusions: The use of LC-MS is an effective method for identifying the intact mass of carbapenemases; however, with the added implementation of MS/MS fragmentation, we are able to enhance our sensitivity with extremely high confidence for identification. As phenotypic evaluations of this carbapenemase go so easily undetected, it is critical to establish a sensitive method of direct detection of OXA-48-like carbapenemases.

Abstract 8628

The impact of Zika virus epidemic on maternal mental health in Brazil
Tamila Araujo1, Tania De Araujo1, Darci Neves2, Silvia Ferrite2, Leticia Marques2, Iracema Lua1, Guilherme Werneck*3

1Universidade Estadual de Feira de Santana, Feira de Santana, Brazil, 2Federal University of Bahia, Salvador, Brazil, 3State University of Rio de Janeiro, Rio de Janeiro, Brazil

Abstract third-party references: Supported by CNPq and FAPESB

Background: The Zika virus epidemic in Brazil started in 2015, with one of the main consequences being the Zika virus congenital syndrome, which not only compromises the child’s development but may also have an impact on family life, especially maternal mental health. This study aimed to estimate the prevalence of depression among mothers of babies born during the Zika virus epidemic in Salvador, Bahia, Brazil.

Materials/methods: A cross-sectional study with baseline data from the cohort study “Effects of Zika virus-associated congenital neurological manifestations on child development: a prospective cohort study in the context of Primary Care in Salvador-BA-Brazil.” The sample consisted of women living in Salvador whose children were born during the Zika virus epidemic in Brazil, 2015-2016 (N=264: 154 mothers of children with the syndrome and 110 mothers of typical children). Depression was assessed by the PHQ-9 scale.

Results: Mothers of children with congenital Zika virus syndrome were predominantly young (<28 years, 53.9%), black race (90.7%), with partner (59.7%), high school (48.7%), income lower than one minimum wage (55.2%), and without paid work (83.8%). Among mothers of children not affected, predominated those older than 28 years (51.8%), black race (90.6%), with a partner (61.8%), high school (57.3%), and income higher than the minimum wage (52.7%). The proportion of mothers without paid activity was lower than among affected mothers but still high (70.9%). The depression prevalence among mothers of babies with the syndrome was 39.0% versus 25.0% among mothers of babies without the syndrome [53% higher in affected mothers, prevalence ratio: 1.53; 95%CI:1.05-2.23].

Conclusions: The study revealed more vulnerable characteristics for the mothers of children with the Zika syndrome: they were younger and with lower income. They also had a higher percentage of exclusion from the labor market [13% higher]. The depression prevalence was high in both groups but increased substantially among mothers of children with the syndrome. The study highlights the need to broaden the focus of epidemic attention to groups whose impacts of the epidemic are less visible, such as the mental health of affected mothers. Strategies related to health promotion in this group are needed.

**Lactobacillus iners in vaginal microbial community**

Kornelija Trajkova¹, Katerina Popovska Jankovic², Biljana Curcic³, Ognen Petrovski⁴, Aleksandar Dimovski⁵, Milena Petrovska⁶

¹Adzibadem Sistina Hospital, Department of Gynecology, Skopje, Macedonia, ²Macedonian Academy of Sciences and Arts, Ss Cyril and Methodius University, Faculty of Pharmacy, Department of Medical Sciences, Research Center for Genetic Engineering and Biothecnology "Georgi D. Efremov", Skopje, Macedonia, ³Aszibadem Sistina Hospital, Department of Microbiology, Skopje, Macedonia, ⁴Ss Cyril and Methodius University, Faculty of Pharmacy, Skopje, Macedonia, ⁵Macedonian Academy of Sciences and Arts, Department of Medical Sciences, Research Center for Genetic Engineering and Biothecnology "Georgi D. Efremov", Skopje, Macedonia, ⁶Ss Cyril and Methodius University, Faculty of Medicine, Skopje, Institute of Pharmacology, Skopje, Macedonia

**Background:** The role of *Lactobacillus iners* in maintaining a healthy vagina environment is unclear weather it is detected in normal conditions, as well as in vaginal dysbiosis and bacterial vaginosis (BV).

**Materials/methods:** The vaginal swabs of 93 females in reproductive age were examined by classical microbiological protocols and by molecular methods of 16S rRNA DNA sequence analysis for identification of different *Lactobacillus* spp., as well as *Gardnerella vaginalis*, *Ureaplasma urealiticum* and *Mycoplasma hominis*. Three groups were analysed according the Nugent score: negative for BV (0-3) (n=51); intermediate for BV (4-6) (n=23) and indicative for BV (7-10) (n=19).

**Results:** A total of 22 different lactobacilli were identified, predominantly *Lactobacillus iners* (as a single strain in 39 of total 93 females and once in combination with other lactobacilli), *L. crispatus* and *L. casei* (in combination together and with other lactobacilli, in 26, 33 and 30 cases, respectively). No statistically significant association was observed between *L. iners* and BV as well as intermediate BV (Pearson Chi-square: 2.500, p = 0.11 3846). *L. iners* was the most frequent in subjects with vaginal pH>4.5 as a single strain, as well as together with other bacteria (*G. vaginalis*, *U. urealiticum*, *M. hominis*). *L. crispatus*, *L. casei* and other 19 lactobacilli were almost always in combination of 2, 3, 4, 5 and 7 lactobacilli and less frequent in vaginal pH>4.5 and other bacteria.

**Lactobacillus iners** in females with other detected or isolated bacteria

**Conclusions:** Further studies of the pathogenicity factors, lactic acids and H₂O₂ production are needed to explain the role of *L. iners* as the most frequently detected lactobacillus in healthy and disturbed vaginal niche as well as its interaction with other bacteria.

Abstract 8630

**Evaluation of an immunochromatographic assay for rapid identification of PBP2a-positive *Staphylococcus aureus***

Rocio Sainz Rodriguez*1, Miriam Valverde Troya1, Maria Gasca Santiyan1

1Málaga, Spain

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) is a significant pathogen causing both health-care-associated and community-acquired infection. Rapid and accurate detection of this pathogen is crucial for the use of appropriate antimicrobial therapy and the control of nosocomial spread. The molecular tests have been proposed, providing results in less than two hours; however, cost, equipment requirements and the need for specific technical expertise and training have limited widespread routine use.

**Objective:** Evaluate the PBP2a Culture Colony Test™ (Alere®) a rapid immunochromatographic qualitative assay for the detection of penicillin binding protein 2a (PBP2a) direct from *S. aureus* culture.

**Materials/methods:** A total of 107 *S. aureus* strains were assayed for methicillin resistance: Vitek2® (bioMérieux), CHROMagar® MRSA II (BD Becton Dickinson), disk diffusion in agar for cefoxitin 30 μg and immunochromatography PBP2a SA Culture Colony Test (AlereTM). The results of conventional tests were compared with the “gold standard” real time PCR SmartCycler (Cepheid®) with RealCycler SAMAPV kit.

**Results:** A total of 107 *S. aureus* strains were isolated from clinical samples: blood 72,82% (78), abscess 3,73% (4), biopsy 0,93% (1), respiratory 3,73% (4), wound exudates 5,60% (6) and nasal swab 1 3,08% (1 4). 57 (53,27%) were MRSA and 50 (46,73%) MSSA. Panton-Valentine leukocidin (PVL) gene is detected in 2,80% of MRSA strains (2 abscess, 1 biopsy). The concordance between the results obtained using immunochromatographic tests and using molecular techniques was 100%, with a Cohen’s kappa coefficient of 1 (p<0.001).

**Conclusions:** An assay for quickly differentiating between MRSA and MSSA was highly sensitive, highly specific, and inexpensive in actual hospital use and led to rapid prescription of appropriate antistaphylococcal therapy 24–48 hours after culture specimens were collected.

**Abstract 8631**

**Antimicrobial resistance of Escherichia coli strains isolated from frugivorous (Eidolon hervum) and insectivorous (Nycteris hispidia) bats in Southeast Nigeria, with detection of CTX-M-15-producing isolates**

Lynda O. Obodoechi¹, Isabel Carvalho²,³, Chenouf Nadia Safia², John Nwanta¹, Chah Foinkfu Kennedy⁴, Carmen Torres*²

¹University of Nigeria, Nsukka, Nsukka, Nigeria, ²University of La Rioja, Logroño, Spain, ³University of Trás-os-Montes and Alto Douro, Vila Real, Portugal, ⁴University Of Nigeria Nsukka, Nsukka, Nigeria

**Background:** Antimicrobial resistance (AMR) is one of the greatest global public health challenges, and extended-spectrum beta-lactamases (ESBL) is one of the most relevant mechanisms. The role of food-producing and companion animals as reservoirs of AMR is well documented. However, the role of wildlife in the ecology of antimicrobial resistant and pathogenic bacteria is poorly understood. Analysis of the antimicrobial resistance genes (ARGs) together with molecular typing of *E. coli* strains from bats will contribute with useful data to predict potential risks associated with *E. coli* strains in these animals. This study was conducted to determine the antimicrobial resistance pheno/genotypes and to carry out the molecular typing of *E. coli* isolates from frugivorous (*Eidolon hervum*) and insectivorous (*Nycteris hispidia*) bats in Nigeria.

**Materials/methods:** Thirty-five lactose fermenting bacterial isolates obtained from liver (n=16), intestine (n=11) and spleen (n=8) of frugivorous (n=15) and insectivorous (n=20) apparently health bats in two locations in Southeast Nigeria were identified as *E. coli* isolates by Maldi-TOF. Susceptibility of the *E. coli* isolates to antimicrobial agents was tested by the disk diffusion method (EUCAST). PCR assays were performed to detect the presence of ARGs and phylogenetic-groups. Multiplex PCR/sequencing as well as multilocus sequence typing were performed on cefotaxime (CTX)-resistant strains to identify the ESBL gene type and sequence type (ST), respectively.

**Results:** Resistance to at least one of the antimicrobial agents tested was observed in 25 isolates (71.4%). Eight (22.9%) of the strains showed multidrug resistant (MDR) phenotype [resistant to three or more classes of antimicrobials]. Two strains were resistant to CTX which harbored the *bla*\(_{CTX-M-15}\) gene type and belonged to lineages ST10184 and ST2178. TetA was detected in all tetracycline-resistant strains (100%) while *intI* (n=8) and *bla\(_{TEM}\) (n=7) were also found in some of the strains. The *E. coli* strains were ascribed to four phylogenetic groups: A=4, B1=21, B2=8 and D=2.

**Conclusions:** Bats in Nigeria can be considered as environmental reservoirs and possible sources of MDR, including ESBL-producing *E. coli* strains belonging to virulence-associated phylogenetic groups. Therefore, due consideration should be given to wildlife in AMR risk assessment framework in Nigeria.

Abstract 8634

Fast and reliable detection of group B Streptococcus during antepartum screening: evaluation of the PCR-based Simplexa GBS Direct assay in comparison to routine culture after Lim Broth enrichment and from ESwabs without enrichment.

Teresa Alcaro1, Salvatore Nisticò1, Manuela Colosimo1, Giuseppina Panduri1, Giuseppe Caruso1, Marco De Fazio1, Alessandra Surace1, Daniela Talarico1, Pasquale Minchella*1

1Italy, Microbiology and Virology - AO Pugliese Ciaccio Catanzaro, Catanzaro, Italy

Background: Group B Streptococcus (GBS) remains the most common cause of neonatal sepsis and meningitis in many countries, mainly due to its vertical transmission from mothers to newborns at the time of delivery. Antepartum testing of vaginal/rectal colonization by GBS at week 35-37 of gestation from broth-enriched culture represents a valuable tool for the clinical management of pregnant women screening candidates for intrapartum antibiotic prophylaxis (IAP). The aim of this study is to evaluate the performance of a fast PCR-based assay compared to culture (gold standard), as an efficient alternative for GBS colonization antepartum screening, after Lim Broth enrichment (validated samples) as well as directly from ESwabs without enrichment (non-validated samples).

Materials/methods: Sixty-nine vaginal/rectal specimens collected antepartum with ESwabs (Copan) were enriched overnight in Lim Broth (bioMérieux), followed by a 48h incubation on chromogenic medium (bioMérieux). All of the enriched samples were tested in parallel with the Simplexa GBS Direct assay (DiaSorin Molecular). The same samples were also tested with the Simplexa system but from the primary ESwabs. Discordant samples were resolved with the Xpert GBS Assay (Cepheid) with a modified off label protocol from the Lim enriched specimens [1]. Sensitivity/specificity were defined after discrepancy resolution.

Results: Sixteen out of 69 (23.2%) samples were positive with Simplexa after enrichment, with a concordance to culture of 94.2%. Four of those were positive with Simplexa but negative by culture, of which two were confirmed positive by Xpert GBS (Ct-values: 34.6-41.5). Sensitivity/specificity of Simplexa were 100% / 96.2%, respectively. When the same 69 ESwabs were tested without enrichment, Simplexa showed a 95.7% concordance with culture, and a sensitivity/specificity of 85.7% / 98.2%, respectively.

Conclusions: This study shows excellent performance of the Simplexa assay after Lim Broth enrichment, and promising results directly from ESwabs. This fast and sensitive approach may represent a significant advantage for improving patient management by reducing the turnaround time by 24-48h. Moreover, its ease of use and simplified workflow would provide another valuable advantage, especially for 24/7 laboratories.

Background: During the European project SpARK, which aims to characterize and study the transmission of Klebsiella in humans, animals and environment, we isolated and sequenced 37 Klebsiella strains collected in the province of Pavia (Italy) from Jul-2017 to Sept-2018. We found 4 strains belonging to Ko3 phylogroup of K. oxytoca complex. One strain of Ko3, strain SG271, was previously isolated.

This work aimed to describe Ko3 phylogroup and to compare it to the Klebsiella oxytoca complex through a genomic comparative analysis.

Materials/methods: Phylogenetic analyses were performed based on 3814 genes of the core genome, gyrA gene, rpoB gene, 16s rRNA and bla-OXY gene. Two genome similarity indexes were evaluated: Average Nucleotide Identity (ANI), and in silico DNA-DNA Hybridization (isDDH). Biochemical-metabolic characteristics of the Ko3 were analysed with API20E and Biolog. The peptide mass fingerprinting was obtained through MALDI-TOF. One genome was also sequenced with Oxford Nanopore. Genome annotation was performed by Prokka. Plasmids, resistance and virulence factors were searched through the tool ABRicate. Clusters of Orthologous Groups of proteins (COGs) were identified by COGnitor.

Results: The phylogenomic analysis of core genome shows that the Ko3 isolates formed a well-defined cluster with SG271. The well-defined clustering of Ko3 strains was supported also by phylogenetic analysis of the gyrA, rpoB and blaOXY loci. The ANI nucleotide identity between Ko3 and the type strains of other K. oxytoca phylogroups was below 96%. The isDDH relatedness ranged 36.3–44.1%. Ko3 phylogroup shared the metabolic profile with Ko8, but they differed by Ko8 unique ability to utilize 3-O-methyl-glucose. Protein fingerprinting of Ko3 obtained with MALDI-TOF displayed two characteristic peaks. All these analyses guarantee a new species that we named K. spallanzanii.

Conclusions: The size of K. spallanzanii genome sequenced with a hybrid approach based on Illumina and Oxford Nanopore was 6280958 bp, thus large for a member of the Klebsiella genus. This genome had a GC content of 53.4%, low compared to its close relatives, with 6035 putative protein predicted. No known resistance and virulence factors were found. Plasmid analysis and COG analysis are currently ongoing.

Abstract 8636

**Efficacy of a screening and prophylaxis protocol to prevent infections in patients treated with anti-CD20/CD52 for multiple sclerosis**

Antonio Riccardo Buonomo¹, Emanuela Zappulo¹, Riccardo Scotto¹, Luca Bruno¹, Biagio Pinchera⁎¹, Ivan Gentile¹

¹Section of Infectious Diseases, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy

**Background:** Monoclonal antibodies (MAbs) have changed the efficacy of multiple sclerosis (MS) treatments. Infective complications have been observed in patients on MAbs targeting lymphoid cells surface antigens, namely anti-CD52 (alemtuzumab, ALM) and anti-CD20 agents (ocrelizumab [OCR] and rituximab [RTX]). Despite these emerging data, there is no standardized consensus regarding pre-treatment testing, vaccinations, patient education before and during therapy or infection monitoring strategies.

**Materials/methods:** We conducted a retrospective/prospective real-life study to evaluate the efficacy of a program of screening and prophylaxis for infective adverse events (IAE) in patients affected by MS-related disorders treated with MAbs directed against CD20/52 antigens.

All patients referring to the Centre of Neurodegenerative Diseases of Naples, University of Naples "Federico II", who started ALM (Lemtrada®), OCR (Octrevus®) or RTX (Mabthera®, off-label use) from 1 November 2015 to 30 June 2019 were recruited. From the 1st of February 2018 all patients were evaluated by an infectious disease specialist (IDs) before infusion to rule out active infection and underwent a complete serological screening for viral infections. Moreover, they started a prolonged anti-HSV prophylaxis and add to the recommended schedule an anti-Listeria/JJP prophylaxis with Cotrimoxazole. Therefore, we retrospectively evaluated IAE incidence before the introduction of the above-mentioned protocol and then prospectively to evaluate the effect on IAE incidence of this intervention.

**Results:** We enrolled 256 patients, 101 retrospectively (pre-intervention group, PREG) and 155 prospectively (post-intervention group, POST).

No statistically significative differences emerged between the two groups in terms of age, sex and clinical characteristics of the neurological disease. Conversely, in PREG group most of the patients were treated with alemtuzumab (57.4% vs 20.6%, p<0.001) and the follow-up period was longer than in POST group (732 vs 215 days, p<0.001). In PREG 34 patients experienced one or more infective adverse events (IAE) while in POST 20 patients received diagnosis of infection. Our screening and prophylaxis protocol resulted associated with a reduction in IAE incidence at univariate (p<0.001) and multivariate analysis (p=0.003) (Figure 1).

**Conclusions:** In patients affected by MS treated with anti CD20/CD52, a standardized protocol of screening and prophylaxis for IAE resulted effective and safe in reducing such events.

**Abstract 8638**

**Childhood brucellosis: characteristics and outcomes in a sample from an endemic country**

Renad Nahhas1, Zain Nemer1, Walaa Alzahrani1, Zahra Askar1, Abrar Thabit*1

1King Abdulaziz University, Pharmacy Practice Department, Faculty of Pharmacy, Jeddah, Saudi Arabia

**Background:** Brucellosis is a zoonotic infectious disease caused by *Brucella* spp. that affects multiple body systems and may lead to several complications. Saudi Arabia is one of the countries where brucellosis is endemic. Studies on childhood brucellosis are limited. Therefore, the objective of this study was to describe characteristics and outcomes of pediatric patients infected with brucellosis in an endemic country.

**Materials/methods:** This was a retrospective descriptive study in a Saudi tertiary academic medical center. Pediatric patients aged < 18 years with confirmed brucellosis (via culture, serology, or both) who received antibiotic therapy were included. Descriptive statistics including mean ± standard deviation and percentages were used. Outcomes of different antibiotic treatment regimens were described in terms of clinical cure, mortality, and hospital length of stay of admitted patients.

**Results:** A total of 16 pediatric patients met the inclusion criteria. Mean age of patients was 9.1 years, they were mostly males (62.5%), and about half were hospitalized (56.3%). Only five patients (31.3%) had their parents reporting the consumption of a dairy product as a potential risk factor for brucellosis. Serologically, both baseline median antibody titer for *Brucella melitensis* and *B. abortus* were 1 280. Only half (50%) complained of arthralgia and were febrile at presentation. All but two cases were uncomplicated brucellosis. The two complicated brucellosis were a case of neurobrucellosis and brucella orchitis. While white blood cells elevation was not significant (mean=6.7 cells/mm$^3$), both C-reactive protein and erythrocyte sedimentation rate were elevated at baseline (28.1 and 28.8, respectively). Regimens administered varied considerably, but about half of the patients received at least three antibiotics (Table); however, all but one patient (93.8%) experienced clinical cure and none died.

**Conclusions:** Brucellosis is an endemic zoonotic disease that can infect both adults and children. This study describes the characteristics of brucellosis reported in children infected in an endemic country and provides an evidence of the positive prognosis associated with appropriate antibiotic therapy active against *Brucella* spp.

Abstract 8642

Development of a methodology for reverse transcription and amplification of small RNA amounts in serum for whole genome sequencing of hepatitis A virus

Paula Bardon¹, Silvana Teresa Tapia², Laura Mora¹, Eduardo Martínez², Encarnacion Clavijo*¹

¹Hospital Universitaria Virgen de la Victoria, Málaga, Spain, ²University of Malaga, Málaga, Spain

Background: Whole genome sequencing has become a very useful tool that complements classical techniques in molecular studies. However, the main obstacle to further molecular analyzes is the small number of molecules after nucleic acids extraction, especially when microorganism load in the host is low. New techniques allow to extract and / or to work with amounts of nucleic acids of the order of picograms, undetectable by most routine quantification techniques. This fact calls into question many of the negative results obtained by previous techniques and opens up new ways of applying molecular biology to epidemiological studies. Objective: To develop a methodology capable of detecting viral sequences in low quantity, for subsequent sequencing and molecular characterization.

Materials/methods: RNA was extracted from 10 serum samples of positive HAV patients using Speedtools RNA Virus Extraction Kit (Biotools B&M Labs S.A.). The RNA obtained could not be quantified by spectrophotometric, fluorometric or electrophoretic methods for subsequent sequencing. cDNA was synthesized by reverse transcription of RNA with SMARTER-Seq Stranded Kit (Takara Bio). For this purpose, 7 µl of extraction product were taken with a contribution of between 10pg and 10ng of total starting RNA, regardless of the quality or RIN (RNA integrity number) obtained in the Bioanalyzer. In order to transcript both rRNA and ncRNA, “random” approach was used. The kit is also capable of eliminating cDNA of human origin, derived from the rRNA that could be synthetized by capture with selective probes. Subsequently, cDNA libraries were loaded into a mid-output NextSeq 550 (Illumina) run.

Results: Following this methodology, we were able to detect the small amount of RNA present in the studied samples. Sequencing generated between 8 and 26 million readings per sample, with a length of 2x150bp. These readings were filtered and analyzed by comparison in database for molecular characterization.

Conclusions: The new tools, such as SMARTER-Seq Stranded Kit (TakaraBio), are capable of working with quantities of undetectable nucleic acids by conventional methods. This kit allows the integrated elimination of cDNA derived from rRNA, abundantly present after cDNA synthesis, from total RNA entries. This provides an extremely sensitive workflow and highly reproducible data.

Abstract 8643

**Descriptive study of Lyme disease suspected patients with discordant serological tests: negative enzyme immunoassay and positive immunoblot**

Yves Hansmann*1, Caroline Sauton1, Nicolas Lefebvre1, Daniel Christmann1, Emilie Talagrand-Reboul1, Pierre Boyer1, Benoit Jaulhac1

1Strasbourg, France

**Background:** Diagnosis of disseminated Lyme borreliosis is based on clinical and serological criteria. The guidelines recommend a two-step approach for serological tests: first enzyme immunoassay (EIA) and in case of positivity, confirmation by immunoblot. This approach is very controversial, especially about the EIA sensitivity.

As part of a reference center for Lyme borreliosis, we are led to see patients whose diagnosis is difficult to establish. In some cases, with serological discordance, we are led to control serological test in our reference center and sometimes request an immunoblot test regardless of the result of the EIA.

**Materials/methods:** We performed a retrospective observational study by analyzing the medical records of patients with negative EIA and positive immunoblot. The objective is to evaluate in this specific population if the diagnosis of Lyme borreliosis would have been missed in front of a negative EIA.

**Results:** Between 2013 and 2017, 3102 patients had EIA test. Among them, 1233 had a positive or doubtful test and 1869 a negative test. Among the patients with negative test, 216 had an immunoblot performed at the request of the clinician, of whom 38 had a positive or doubtful result. Of these patients, 37 were subjected to descriptive analysis. The M/W sex ratio was 1.05 and the mean age 48 years. Six patients had a history of confirmed erythema migrans and 9 patients of possible erythema migrans. Articular symptoms were present for 27 patients [including 2 patients with mono/oligo arthritis of large joints compatible with the diagnostic criteria, the others presenting with polyarticular damage without objective inflammatory signs], neurological symptoms for 22 patients [headache, root pain]. No cardiac conduction disorders and no atrophic acrodermatitis have been reported. None of the patients had a lumbar or joint puncture. In total, no patient met the confirmed borreliosis criteria, and 12 patients met the possible borreliosis criteria defined by French guidelines.

**Conclusions:** The proportion of patients with negative EIA and positive immunoblot is low and none of these patients presented a clinical picture suggestive of Lyme borreliosis. These results confirm the achievement of serology in two steps proposed in the majority of guidelines.

Abstract 8644

Prominent role of oprD mutations in carbapenem-resistant Pseudomonas aeruginosa strains in a previous context of VIM-1 outbreaks

Hanane Raqioui1, Anna Bertoncelli1, Annarita Mazzariol*1

1University of Verona, Department of Diagnostics and Public Health, Verona, Italy

Background: Pseudomonas aeruginosa is a common opportunistic pathogen and a major cause of infection in hospitalized patients. P. aeruginosa had an extraordinary capacity for developing resistance by the selection of mutations in its chromosomal genes. The aim of this study was to characterize 53 P. aeruginosa strains isolated from purulent specimen to identify the molecular mechanisms responsible for their resistance to carbapenems and epidemiology changes in a clinical context with history of VIM-1 discovery and outbreaks.

Materials/methods: Antimicrobial susceptibility was tested by broth micro-dilution. Molecular characterization of the most frequent carbapenemase genes (blaKPC, blaIMP, blaVIM, blaNDM, and blaGES) and oprD gene presence/absence was investigated by PCR and sequencing. Efflux pumps involvement was investigated by phenotypic test using antimicrobial susceptibilities test in presence of CCCP.

Results: The molecular characterization revealed that only 4 of 53 strains harbor carbapenemases: 3 strains with blaVIM-1 and one strain with blaGES-5.

Efflux pumps involvement in the carbapenems resistance by phenotypic test was very low (3 strains).

We have characterized all our strains for oprD gene. 30% of strains have no amplification of oprD gene, suggesting a deletion of this. Sequences of oprD amplicons of the other strains reveal the presence of different mutations other than IS insertion or deletion that can be responsible of carbapenem resistance.

Sequence analysis revealed the presence of different mutations inside the oprD gene and all of them result in a reading shift that bring a premature stop codon.

Conclusions: Molecular analysis revealed that OprD mutations or deletion plays a very important role in carbapenem resistance of P. aeruginosa isolated in our hospitals.

The number of oprD mutations registered let us to think to be in presence of hyper mutable strains.

Carbapenemase producing strains is a minority in the strains isolated now days: just 3 VIM-1 and one GES-5. Also efflux seems not plays a prominent role (3 strains).

The mechanism of carbapenem resistance in P. aeruginosa clinical isolates in our clinical context is completely changed.

Abstract 8645

**Characteristics and management of skin and soft tissue infections caused by Panton-Valentine leukocidin-producing Staphylococcus aureus (PVL-SA): a retrospective study of 99 cases**

Ady Assaf*, Caroline Loiez†, Marie Charlotte Chopin‡, Sophie Panaget‡, Aurelie Dozier‡, Emmanuel Faure‡, Karine Faure‡, Fanny Vuotto‡

1University Hospital of Lille, Infectious Diseases Department, Lille, France; 2University Hospital of Lille, Microbiology Department, Lille, France; 3University Hospital of Lille, Infectious Diseases Department, Lille, France

**Background:** Staphylococcus aureus (SA) is a major human pathogen with multiple virulence factors such as the Panton-Valentine leukocidin (PVL). PVL-SA cause recurrent skin and soft tissue infections (SSTI) and necrotizing pneumonia, in healthy young people with a high risk of human-to-human transmission. The study aims were to describe the clinical characteristics, evaluate the diagnosis delay and optimize the care pathway of patients with PVL-SA SSTI.

**Materials/methods:** Descriptive analysis of a retrospective study of patients with a PVL-SA SSTI followed by the Infectious Diseases Department between March 2009 and March 2019. Patients over 15 years and 3 months with a bacteriological specimen of a PVL-SA positive skin lesion were included. In our center, the search for PVL is performed systematically in case of SSTI positive to Staphylococcus aureus. Patients with PVL were reported to the Department of Infectious Diseases for specific consultation.

**Results:** 99 patients were included, 52% were men and the median age was 29. 88% had no comorbidity, 16% practiced a profession at risk of PVL-SA and 20% practiced a risky hobby, 32% traveled outside Europe in the year, a contagion was found in 16%. 43% had a previous history of SSTI. The median of diagnostic delay was 6 days, the median of consultation delay was 9 days. PVL-SA resistant to meticillin was present in 28%. 77% of patients had a single skin abscess. 45% of the cutaneous lesions were on the lower limbs, 29% on the trunk and 21% at the axillary level. 91% received surgical treatment. Postoperative antibiotic therapy was amoxicillin/clavulanic acid in 57%, 3% just received an antitoxicnic antibiotic. During the consultation, 56% had active infection. Linezolid was prescribed for 55% of patients. 93% had cutaneous decontamination, 60% of patients were recovered, 20% were lost to follow-up and 20% recidivated.

**Conclusions:** PVL-SA cause recurrent SSTI in healthy young people, a collaboration between surgeon, bacteriologist and infectious disease specialist is necessary for a quick diagnosis and to set up specific therapeutics in order to avoid relapse.

In vivo and in vitro synergistic activity of colistin combining with meropenem and sulbactam against multidrug-resistant and pandrug-resistant Acinetobacter baumannii clinical isolates

Canan Kulah*, Eldan Subasi, Aydan Atalar

1Zonguldak Bulent Ecevit University Faculty of Medicine, Zonguldak, Turkey, 2Zonguldak Bulent Ecevit University, Zonguldak, Turkey

Background: Multidrug-resistance (MDR) and pandrug-resistance (PDR) in Acinetobacter infections is an increasing health concern. Colistin has been reported to be frequently used clinically in these infections, single or combined with other antimicrobials. There is no report regarding the potential synergistic effects of colistin combining with meropenem or sulbactam. In this study, we investigated the synergistic activity of colistin combining with meropenem and sulbactam against MDR and PDR Acinetobacter baumannii clinical isolates both by in vitro and in vivo methods.

Materials/methods: The antibacterial activity of colistin, meropenem and sulbactam against sensitive (n=3), MDR (n=3) and PDR A. baumannii clinical isolates (n=3) was investigated. The A. baumannii ATCC 19606 was also included. Minimum inhibitory concentrations (MICs) of antimicrobial agents were determined by reference broth microdilution method. The synergistic activity of colistin with meropenem and sulbactam was evaluated by checkerboard method. Interactions between the selected antibiotics were determined by calculating the fractional inhibitory concentration (ΣFIC) index. Galleria mellonella was used as an experimental model for in vivo activity testing. The larvae were infected with 10^8 CFU / ml bacteria, the antimicrobials were injected and incubated at 37 °C and observed for 120 hours for death.

Results: Both combinations, colistin meropenem and colistin sulbactam had additive effect on PDR isolates (with ΣFIC = 0.51–1.48) while additive effect or synergism on MDR isolates (with ΣFIC = 0.04–0.53). No interactions by both combinations were reported on sensitive isolates and reference strain. The larvae infected by PDR isolates and treated with colistin, meropenem or sulbactam alone or colistin meropenem combination were all dead; while 80% were dead in the colistin sulbactam combination group. In the larvae group infected by MDR isolates, death rates were as follows; treated with colistin 50%, with meropenem 90%, with sulbactam 90% and with colistin+meropenem combination 30%.

Conclusions: Our results indicate that colistin with combination to both sulbactam and meropenem has enhanced activity and may be promising for life threatening MDR and PDR Acinetobacter infections. This study is also remarkable to be the first for evaluating colistin combinations on clinical isolates by both in vitro and in vivo methods.

Abstract 8654

**Comparison of the performances of three commercial real-time PCR kits with an in-house real-time PCR assay for the diagnosis of invasive aspergillosis**

Clémentine Dulac¹, Alexane Bourguignon¹, Loïc Mollier-Pierret¹, Damien Dupont¹, Damien Wallon¹, Martine Rabodonirina¹, Florence Persat¹, Jean Menotti*¹

¹Hospices Civils De Lyon - Hcl, Croix-Rousse Hospital - IAI - Department of Parasitology and Medical Mycology, Lyon, France, ²Claude Bernard University Lyon 1, Lyon Neuroscience Research Center, Bron, France, ³Claude Bernard University Lyon 1, International Center for Infectiology Research, Lyon, France, ⁴Claude Bernard University Lyon 1, EA7426 PI3 Team Inflammation and Immunity of the Respiratory Epithelium, Oullins, France

**Background:** Early diagnosis of invasive aspergillosis is crucial for better prognosis. Yet, conventional mycological techniques have low sensitivity and galactomannan antigen detection is subjected to false negative and false positive reactions. Real-time PCR assays are required not to yield cross reaction with other fungi genus such as *Penicillium* and to reach low limits of detection of *Aspergillus* DNA to be of clinical utility. Our aim was to assess the performances of three commercial real-time PCR kits compared with the performances of an in-house real-time PCR assay.

**Materials/methods:** The MycoGENIE® Aspergillus fumigatus (MycoGENIEAf) and Aspergillus spp. (MycoGENIEAspp) Real-Time PCR Kits and the Fungiplex Aspergillus PCR Kit were compared to an in-house real-time PCR assay targeting *Aspergillus fumigatus* 28S rRNA gene (28SqPCR). A standard curve was generated for the four assays with serial dilutions of *A. fumigatus* DNA. The four assays were also tested on 4 pg/µl DNA from 10 species of *Aspergillus* and *Penicillium*.

**Results:** The lower limit of detection of all four assays was 10 spores/ml of *A. fumigatus*. The serial dilutions of *A. fumigatus* DNA yielded mean threshold cycles (Ct) 0.14, 1.79 and 3.35 higher for MycoGENIEAspp, MycoGENIEAf and Fungiplex, respectively, than for 28SqPCR. 28SqPCR and MycoGENIEAf detected only *A. fumigatus* DNA. MycoGENIEAspp detected 4 pg/µl DNA of all species of *Aspergillus*, but with Ct values ranging from 21.11 for *A. terreus* to 40.76 for *A. nidulans* and 43.49 for *A. ustus*; meanwhile Ct values were 29.68 for *P. purpurogenum* and 24.34 for *P. chrysogenum*. Fungiplex detected 4 pg/µl DNA of all species of *Aspergillus* with Ct values ranging from 25.64 for *A. niger* to 30.15 for *A. ustus*; *P. purpurogenum* was not detected and Ct value was 38.49 for *P. chrysogenum*.

**Conclusions:** Although the lower limit of detection of all four assays was 10 spores/ml, MycoGENIEAf and Fungiplex yielded higher mean Ct values than 28SqPCR. MycoGENIEAspp yielded Ct values quite as low as those obtained with 28SqPCR. However, the weak detection of some *Aspergillus* species combined with the sensitive detection of non-clinically relevant *Penicillium* species makes its results difficult to interpret.

Abstract 8656

Diagnostic accuracy of synovial cell count at reimplantation in periprosthetic knee infection undergoing two stage procedure

Tiziana Ascione1, Pasquale Pagliano2, Massimo Mariconda3, Andrea Baldini4, Giovanni Balato5

1D. Cotugno Hospital, Via G. Quagliariello 54, Naples, Italy, 2University of Salerno, Department of Infectious Diseases, Fisciano, Italy, 3Clinic of Orthopaedic Surgery, Napoli, Italy, 4Department of Orthopaedic surgery, Florence, Italy

Background: Time to reimplantation in patients with prosthetic joint infection (PJI) undergoing 2-stage exchange can be difficult to establish. Clinical signs disappearance, negative microbiology at reimplantation, and serum biomarkers (ESR, CRP) normalization do not identify accurately patients at risk of recurrence. Despite synovial fluid analysis (WBC count and neutrophils percentage) represents an effective tool to diagnose PJI, only cut-off value adopted at the time of PJI diagnosis has been standardised. Aim of this study was to evaluate the accuracy of synovial WBC and neutrophil percentage before definitive reimplantation in patients with periprosthetic knee infections undergoing 2-stage exchange.

Materials/methods: Seventy-two synovial fluid aspirates from patients undergoing the second step of 2-stage procedure after clinical findings disappearance, negative microbiology at reimplantation, and serum biomarkers (ESR, CRP) normalization were evaluate in a case-control study (1:3 ratio). Synovial WBC count and relative neutrophil percentage from patients who developed PJI recurrence (18 cases, Group A) were matched with those obtained from a comparable group of patients reporting definitive cure (54 cases, Group B). The diagnostic performance of these tests was assessed by receiver operating characteristic (ROC) curve analysis. The sensitivity and specificity (and 95% CIs) were calculated for each of the cut-off values and the area under the curve (AUC) was calculated.

Results: Median synovial fluid leukocyte and neutrophil percentage were significantly higher in patients with recurrence of periprosthetic infection than in those reporting infection eradication [WBC (cells/µL), 2001 (804-2776); Vs. 400 (80-1200), p<0.001; % Neutrophil count, 64% (22-90) Vs. 39% (11-78), p<0.001]. In predicting PJI recurrence, synovial WBC count >1068/µL had 94% sensitivity and 97.3% specificity, instead, Neutrophils percentage >50% had 78% sensitivity and 81% specificity. Diagnostic accuracy was higher for WBC (AUC 0.99, 95% CI 0.96-1.0) than for PMN percentage (AUC 0.76, 95% CI: 0.60-0.91).

Conclusions: On the basis of our investigations, a cut-off value at reimplantation of synovial WBC count >1068/mL was useful to predict recurrence of infection in patients with periprosthetic knee infections undergoing 2-stage exchange procedure. Adopting these cut-off values, synovial fluid cell count is a diagnostic test useful to establish the optimal timing for reimplantation with elevated diagnostic accuracy.

Identification of a clinically relevant anal HPV infection in HIV-positive men having sex with men: data from Czech anal cancer screening programme

Jana Nemcova*, Katerina Cerna

Faculty Hospital in Pilsen, Faculty of Medicine in Pilsen, Pilsen, Czech Republic

Background: The prevalence of anal high-risk HPV (hrHPV) infection is very high in HIV positive men having sex with men (HIV+MSM). A long-term anal HPV infection together with impaired immunity in this population increases the risk for the development of an HPV-induced anal carcinoma (AC), with its incidence up to 131/100000. Therefore, screening for curable (pre) malignant anal lesions is justified in HIV+MSM to reduce morbidity and mortality connected to the invasive stadium of AC. Because of an analogy of AC and cervical cancer, the same screening approach, based on the detection of clinically relevant hrHPV infection might be useful. The aim of our study is to identify a clinically relevant HPV infection in anal samples using HPV genotyping, mRNA hrHPV detection, and methylation analysis of cellular genes while correlated to the anal cytology results.

Materials/methods: HPV genotyping, hrHPV mRNA expression, and methylation analysis were performed in anal smears taken from 171 Czech HIV+MSM. Results were correlated to the anal cytology findings.

Results: 117 anal smears (68 %) tested positive for at least one hrHPV type, 44 (26 %) tested negative, and 10 samples were not analyzable. There was no significant difference in the ratio of normal/abnormal cytology findings between hrHPV positive and negative groups. Transcriptional activity of hrHPV was proven in 48 %, and methylation in 31 % of hrHPV DNA positive smears. The most significant difference in the prevalence of abnormal cytology was between the group of transcriptionally active hrHPV positive smears with methylation (85 %) and a group of hrHPV positive patients without detected transcriptional activity and without methylation (24 %), p = 0.0002.

Conclusions: HPV genotyping seems not to be a sufficient tool in defining clinically relevant hrHPV infection in anal cancer screening HIV+MSM cohort. Both follow-up procedures, that is a detection of transcriptional activity and methylation analysis are better for distinguishing patients with abnormal cellular changes related to the viral oncological process.

Presenter email address: jana.nemcova@biopricka.cz
Are carbapenems a choice in OXA-163 carbapenemase-producing Enterobacterales infections? Clinical outcomes of 29 OXA-163 infections in a general hospital in Argentina

Martin Jaume, Marco Flor Montero, María Paz Amaya, Alicia Sisto, Lorena Abusamra, Laura Errecaide, Fernando Pasteran*, Liliana Guelfand, María Rolón

1Hospital Fernández, Ciudad de Buenos Aires, Argentina, 2National Reference Laboratory on Antimicrobial Resistance. INE-ANLIS Dr. Carlos Malbran, Ciudad de Buenos Aires, Argentina

Background: The emergence of carbapenemase-producing Enterobacterales represents a global health problem. OXA-163 is a variant of OXA-48 betalactamase, with limited in-vitro hydrolytic effect on carbapenems (CBP). Clinical data about patients with infections due to OXA-163-producing Enterobacterales is limited to a few case reports in Argentina and Egypt.

Materials/methods: Retrospective descriptive study of infections due to OXA-163-producing Enterobacterales between 2012-2018 in a single center in Argentina. Epidemiological, clinical and microbiological data was recalled. Pathogen identification and antimicrobial susceptibility testing were performed using conventional and automated methods (PHOENIX BD®, MALDI-TOF-MS®). The presence of OXA-163 was confirmed by immunochromatographic lateral flow assay (K-SeT RESIST-3 O.O.K, Britania) and PCR/DNA sequencing.

Results: 29 patients OXA-163-producing Enterobacterales were identified, 6 were excluded from the clinical analysis due to lack of data. Of the remaining 23 patients, 70% were adult men, median age 63 (IQR 46-67) and 1.1% were male neonates. Ninety-one % had previous antibiotic use, 70% were admitted to the ICU and 65% had a surgery within 90 days prior to the OXA-163 infection. Median hospital stay before infection was 15 days [RIC9-38]. Distribution of infections was: 43% urinary, 17% intra-abdominal and 18% primary bacteremia. The most frequent isolate was K. pneumoniae (66%). Figure 1 shows the antibiotic susceptibility profile. ESBL coproduction was detected in 45% strains, KPC-type carbapenemase in 2.5% and NDM-type carbapenemase in 2.5%. Only 44% of the initial empirical therapy was considered appropriate. Definitive treatment included CBP in 78% with monotherapy administered in 67% of the infections. Median duration of adjusted treatment was 11 days (IQR 7-19) and clinical resolution at day 7 occurred in 83% of the cases. The 30 day overall mortality was 17%.

Conclusions: Infections due to OXA-163-producing Enterobacterales are associated with high mortality. Although OXA-163 is classified as a carbapenemase, in this study we found that CBP susceptibility is usually preserved in OXA-163-producing Enterobacterales and CBP monotherapy may be considered as an effective treatment option.

Antibiotic resistance in anaerobic infections in a hospital in Tenerife
Beatriz Crespo Estrada*, Isabel Gutiérrez González

1Hospital, Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: During last decade the importance of anaerobic bacteria infections has increased; especially due to the high number of patients with several comorbidities. Moreover, antimicrobial resistance has also experiment an increment and empiric antibiotic therapy is becoming a challenge.

Our objective was to determinate the incidence and antibiotic susceptibility of anaerobic bacteria.

Materials/methods: Between January 2014-September 2019, 284 isolates (1 for patient) were collected from: blood (18.66%), abscesses (15.84%), peritoneal fluids (35.91%), other sterile fluids (5.63%), skin and soft tissues (10.21%) and others (13.75%); plated on BD Schaedler-KV, SNVS, BEE and incubated 48h at 37ºC in anaerobic atmosphere. Antimicrobial susceptibility was tested by broth microdilution method, with the ATB tm ANA (bioMérieux).

Results: Bacteroides spp was the most frequent anaerobic bacteria detected, in 84.15% of the cases (48.53% B.fragilis); Prevotella in 7.39%, Fusobacterium in 4.57% and 3.89% for gram positive cocci.

Fusobacterium susceptibility to amoxicillin-clavulanate was 84.71%, 23.07% to penicillin, 92.30% to metronidazole and cefoxitin, 91% to clindamycin and 92.30% to penicillin. No resistant isolates to imipenem were detected.

Prevotella showed 90.47% susceptibility to amoxicillin-clavulanate, 90.47% to imipenem and cefoxitin, 28.57% to penicillin, 95.35% to clindamycin and 95.35% for piperacillin-tazobactam.

All gram positive-cocci isolates were susceptible to cefoxitin, 77.77% to amoxicillin-clavulanate, 88.98% to imipenem, 55.55% to penicillin and metronidazole; and 88.88% for clindamycin and piperacillin-tazobactam.

The following table describes susceptibility distribution in Bacteroides

<table>

</tr>
</tbody>
</table>

Conclusions: Antimicrobial susceptibility to anaerobic bacteria has persistently decreased among last years, especially in Bacteroides group, with remarkable changes in susceptibility patterns.

According to our data, although metronidazol and imipenem could still be considered as the elected drugs in anaerobic infections, gradually increases in resistance have been observed in Bacteroides.

These statistics should indicate that individualized susceptibility of each isolate for a correct treatment choice is becoming essential nowadays.

Delayed diagnosis and increase mortality in native vs prosthetic/device-related coagulase-negative staphylococci infective endocarditis

Lourdes M. Prunonosa1, Nuria Vallejo2, Raquel Núñez Aragón2, María Dolores Duesada1, Ainhoa Vivero Larraza1, Elisabet Berastegui1, Cinta Llibre1, Nieves Sopena2, Esteban Reynaga Sosa1, Borja Ruiz1, Adrián Steinherr Zazo1, Luis Delgado1, Cristian Munoz1, Gemma Lladós1, María Luisa Pedro-Botet1

1Hospital Universitari Germans Trias i Pujol, Badalona, Spain, 2Universitat Autònoma de Barcelona, Barcelona, Spain, 3Institut Germans Trias i Pujol, Badalona, Spain, 4Universitat Autònoma de Barcelona, Bellaterra, Spain

Background: Coagulase-negative staphylococci (CoNS) are able to produce biofilm and to affect to prosthetic valve and cardiac devices. To the contrary native valve CoNS infective endocarditis (IE) is seldom described. The increase in the last decade of invasive intravascular techniques in elderly and frail patients may have increased CoNS infections. The aim of this study was to compare native CoNS IE with prosthetic/device-related IE.

Materials/methods: Prospective observational study of patients diagnosed with IE from January 2003 - January 2019 was performed in a tertiary reference center in Badalona (Barcelona), Spain. 475 IE, 177 (37.3%) staphylococcal infections, and 79 (44.6%) by CoNS were registered in the study period. Patients were classified into 2 groups: Group 1: native IE, Group 2: prosthetic/device-related IE.

Results: Among the 79 CoNS IE, group 1 included 22 patients (27.8%), and group 2, 57 patients (72.2%). Group 2 included 25 (73.5%) patients with biological prosthetic valve, 8 (23.5%) patients with mechanical prosthetic valve and 1 (2.9%) patient with mitral valve repair. No significant differences were found in according to age, gender, nosocomial acquisition, hemodialysis, liver cirrhosis and reinfection. However patients from group 1 had significantly a higher Charlson Index (4.5 vs 2.9, p 0.005), a longer diagnosis delay (8.9 vs 3.8 days, p 0.039), more renal chronic failure (7 (37.8%) vs 6 (10.5%), p 0.022), higher aortic IE (15 (68.2%) vs 19 (33.9%), p 0.006), more valvaral insufficiency at the diagnosis or evolution (19 (86.4%) vs 27 (51.9%), p <0.01), more complications (20 (90.9%) vs 35 (61.4%), p 0.013), cardiac failure (19 (91.8%) vs 15 (31.2%), p<0.01), greater surgical indication (19 (86.4%) vs 33 (60%), p 0.032) and a higher mortality (15 (68.2%) vs 25 (43.9%), p 0.053).

Conclusions: CoNS native valve endocarditis is not an infrequent infectious complication that affects comorbid and frail patients. The clinical suspicion is poor and that may lead the high rate of complications seen in the study.

**IntFinder: a freely-available user-friendly web tool for detection of class 1 integrons in next-generation sequencing data using k-mer alignment**

Karen Adriana Loaiza Conza*, David Ortega-Paredes*, Markus Hans Kristofer Johansson1, Alfred Ferrer Florensa2, Ole Lund2, Valeria Bortolaia1

1Technical University of Denmark, National Food Institute, Kongens Lyngby, Denmark, 2Universidad Central del Ecuador, Unidad de Investigación de Enfermedades Transmitidas por Alimentos y Resistencias a los Antibióticos, Quito, Ecuador

**Abstract third-party references:** UNIETAR, SENECYT, DTU Food

**Background:** Class 1 integrons are the most frequent genetic platforms capable to capture and express antibiotic resistance genes embedded within gene cassettes. These genetic elements are involved in the acquisition shuffling and dissemination of multi-resistance among clinically important bacteria. Despite its importance, few bioinformatics tools for integron detection have been developed to aid the understanding of antimicrobial resistance dynamics, but they are intended for users with effective programming knowledge. Filling a gap, we aimed at creating an open-access bioinformatics tool to enable detection of class 1 integrons in NGS data by users without any programming skills.

**Materials/methods:** From the whole list of integrons with attributed integron (In) numbers available in INTEGRALL (http://integrall.bio.ua.pt/), we curated 1,356 accessions to create a Class 1 integron database. We used Nucleotide BLAST 2.8.1+ to detect genes that defined the integron conserved regions 5’ (intI1) and 3’ (qacEΔ1, sul1, and orf5). We wrote a script using k-mer alignment (KMA) to match an input sequence with a database entry according to a user-defined similarity threshold. We tested IntFinder by analyzing 2,097 plasmids from NCBI refseq, and we compared the results with those obtained by existing tools such as Integron Finder and Integron Visualization and Identification Pipeline (I-VIP) run using default parameters.

**Results:** IntFinder integrates a python script and a database of 1,331 integrons in fasta format. At 90%, 95%, and 100% similarity, IntFinder detected integrons in 390, 359, and 243 plasmids encompassing 134, 129, and 97 different In numbers, respectively. Integron Finder and I-VIP detected integrons not detected by IntFinder in 139 and 72 plasmids, respectively. This was due to strict inclusion criteria for IntFinder database which encompasses exclusively class 1 integrons with an assigned In number. The three tools categorized integrons differently and only IntFinder follows the standard In nomenclature.

**Conclusions:** IntFinder is a bioinformatics tool to enhance capacity to detect class 1 integrons with assigned In numbers in NGS data in settings with limited bioinformatics expertise. IntFinder is freely available at https://cge.cbs.dtu.dk/services/IntFinder-1.0/, and it can be used online by non-bioinformaticians or it can be downloaded to be used in the command line.

**Presenter email address:** s181423@student.dtu.dk
Genotypic investigation of Leishmania spp. in dog population of northern Greece

Androniki Papoutsi, Georgios Chatzisimeonidis, Nikolaos Vastarouchas, Anestis Karamitos, Nikolaos Zoumpoulidis, Urania Giannakou, Eleni Andreadou, Theodoros Lialiaris

Dept. of Biomedical Sciences, International Hellenic University, School of Health Sciences, Thessaloniki, Sindos, Greece; Small animal veterinary clinic "Karamitros Anestis", Thessaloniki, Greece; Democritus University of Thrace, School of Health Sciences, Alexandroupolis, Greece

Background: The incidence of leishmaniasis in Greece has been increasing in recent years and Leishmania infantum seems to be the main cause of the cutaneous (CL) and visceral (VL) form of the disease, although sporadic cases of CL due to L. tropica have also been reported. In addition, it is well known that a large proportion of endemic dogs are infected even if they remain asymptomatic or seronegative. Serological techniques detect most of the symptomatic and a proportion (up to 50%) of asymptomatic dogs. In view of the above and the fact of the close relationship between canine morbidity and the increasing human incidence of the disease in endemic areas, genotypic investigation of leishmaniasis in dogs is crucial.

Materials/methods: Sixty-two whole blood and serum samples collected from dogs (32 male and 30 female, 8 months to 11 years old) were subjected in the study. The vast majority of the dog population exhibited mild to very severe clinical form of VL (n=46) while 16 dogs were asymptomatic. PCR for the internal-transcribed-spacer-1 (ITS1) region of rRNA gene was applied to all extracted DNA samples. RFLP (with HaeIII) and Sequencing analysis was performed to all positive amplicons for Leishmania species identification and confirmation. The sequences obtained were compared for their homology to known sequences in the GenBank database (http://www.ncbi.nlm.nih.gov/BLAST). Serological detection of IgG Leishmania antibodies was performed by an indirect Elisa kit.

Results: Among 62 tested samples, 20 (32.2%) were PCR positive and confirmed at the genus level by comparison with the deposited Genebank sequences with the BLAST tool. PCR, RFLP analysis, revealed the L. infantum electrophoretic pattern for all positive samples. Seventeen PCR-positive samples were symptomatic while 3 were non-symptomatic. IgG antibodies were not detected in 4 of the PCR positive samples, which points to cases of recent early-stage infection.

Conclusions: Our findings confirm the prevalence of L. infantum in our country. However, low rates of Leishmania DNA detection in blood are probably correlated with the duration of parasitemia. Furthermore, the genotypic investigation of Leishmania at the species level with additional genetic loci (eg kDNA) appears to be essential for conducting safer conclusions.

Abstract 8667

**Performances of a new random access system for human immunodeficiency virus RNA quantification**

Anne Maillard¹, Charlotte Pronier*,² Gisele Lagathu³, Pauline Comacle¹, Claire Grolhier¹, Vincent Thibault²

¹CHU Rennes, Virology, Rennes, France, ²CHU Rennes, Virology - IRSET INSERM U1085, Rennes, France

**Background:** Human immunodeficiency virus (HIV) RNA quantification is a key marker at diagnosis and to monitor treatment of this infection. Automated, standardized and rapid systems are essential tools to provide fast and reliable viral load (VL) quantification to clinicians. The aim of this study was to evaluate the performances of the recently launched NeuMoDx for HIV-RNA quantification with a peculiar focus on HIV diversity.

**Materials/methods:** 103 HIV positive frozen plasmas previously quantified for HIV-VL using Veris Dx (Beckman) were selected to represent a wide range of VL (from 1.55 to 6.74 log copies/mL) and genetic strain diversity (B subtype n=34 (33%), non B n=69 (67%): CRF02_AG n=21, non-typable n=8, A-like n=5, C n=4 and 31 other rare subtypes). Twenty-seven fresh blood samples tested with Veris were analyzed in parallel on NeuMoDx.

**Results:** Overall, only one (0.8%) test failure occurred on a frozen plasma sample and corresponded to internal control amplification failure. One sample was not properly processed due to insufficient volume. Quantification was obtained on NeuMoDx for 98 samples and 3 low VL samples (1.64, 1.66, 2.62 log cop./mL) of different subtypes (CRF02_AG, non-B not typable and B, respectively), were not detected. VL obtained on both system were well correlated (r=0.92) with a mean bias of -0.35 log cop./mL (NeuMoDx-Veris). Quantification differences were more important toward the lower linearity range. Seven samples presented more than 1 log copies/mL differences between the two techniques and all but one belonged to subtype B. Among the 27 fresh analyzed samples on primary tubes, 12 had low HIV-VL below Veris quantification level (35 cop./mL) and 5 (42%) were quantified with NeuMoDx with VL ranging from 0.48 to 2 log cop./mL. Among the 15 remaining negative samples as classified with Veris, one was quantified at 1.2 log cop./mL with NeuMoDx.

**Conclusions:** These first results obtained on the NeuMoDx confirmed the overall good functionality of the system based on microfluidic with short turnaround time, simple training, full traceability and easy handling. These preliminary data did not highlight any major issue on this double target challenging assay. Further evaluations are ongoing to confirm this pilot study.

**Presenter email address:** charlotte.pronier@chu-rennes.fr
Background: Gastric cancer has been associated with Epstein-Barr Virus (EBVaGC) in 10% of all gastric cancers and is characterized by a distinct molecular profile. Recently it has been shown that in EBVaGC there are no TP53 mutations, nevertheless it may be observed accumulation of wildtype p53 in these tumors. In this study we aimed to analyze the potential role of mdm2 protein, the major p53 negative regulator, as the explanation for the p53 dysregulation in EBVaGC.

Materials/methods: We used tumor samples collected from formalin-fixed paraffin-embedded (FFPE) tissue blocks collected from IPO-Porto patients with EBV-positive (EBVaGC, n=12) and EBV-negative (EBVnGC, n=28) gastric cancers. MDM2 mRNA expression levels was assessed by two-step real-time PCR and protein expression was analyzed in tissues by immunohistochemistry (IHC).

Results: IHC demonstrated that mdm2 is present in 5/12 EBVaGC and 10/27 EBVnGC, with 80% of EBVaGC showing expression in the majority of cells, compared with 20% in EBVnGC (p=0.089). A significative difference was found when compared high mdm2 expression in EBVaGC and EBVnGC diffuse histological subtype (p=0.048). Regarding the MDM2 mRNA levels, a significative increased expression was observed in EBVaGC, when compared with EBVnGC intestinal type (p=0.034) and a trend when compared to EBVnGC indeterminate type (p=0.057).

Conclusions: Our study shows that mdm2 may be an important marker for EBVaGC, which is reflected in the higher accumulation in tissue. Furthermore, this is probably explained by the increased transcriptional activity, enhanced by some viral protein or miRNA which may contribute for the dysregulation in the p53-mdm2 balance in these cancers.

Neurologic complications in Chagas disease: results from a systematic review of published literature

Luciana Lepore1,2, Maria Letizia Giancola1,2, Davide Checchi1,2, Federica Caldara1,2, Tommaso Ascoli Bartoli1,2, Alessandra D'abramo1,2, Laura Scorzolini1,2, Giuseppe Ippolito1,2, Karl Philipp Puchner2,4, Emanuele Nicastri1,2

1National Institute for Infectious Disease “L. Spallanzani”, IRCCS, Rome, Italy, 2Chagas Chronic Morbidity and Disability Working Group of the Chagas Coalition, Barcelona, Spain, 3Clinical Infectious Disease, Tor Vergata University, Rome, Rome, Italy, 4German Leprosy and TB Relief Association, Wuerzburg, Germany

Background: Chagas Disease (CD) is a parasitic infection caused by Trypanosoma cruzi, endemic in Latin America with an increasing impact on public health also in non-endemic countries. Although the cardiac and gastrointestinal involvement have been widely explored, little knowledge on neurologic manifestations of CD has been achieved. Here we present the first results of our systematic review on the neurologic involvement of CD.

Materials/methods: We conducted a systematic review of the literature from January 1, 2000 to October 4, 2019 using the PubMed and Embase databases. Relevant studies were investigating using the following string of MeSH terms: ((Chagas disease OR American trypanosomiasis) AND (neurolog* OR transplant OR brain OR complications OR central nervous system OR meningoencephalitis OR neuro chagas OR chagoma OR stroke OR HIV OR AIDS OR immunosuppression OR reactivation)). Only articles in English, Spanish and Portuguese were included in the analysis elaborated by four reviewers. Both human and animal studies were included. Studies on the peripheral nervous system were excluded.

Results: A total number of 3844 papers (2581 from PubMed, 1263 from Embase) were reviewed; 341 records were included and subsequently divided into category as showed in Figure 1. The analysis of the scientific production over the years showed a growing linear trend (+13.53%). Overall, studies on the central nervous involvement represented the dominant part (271/341, 79.5%) and included studies on ischemic stroke (91/271, 33.6%) and on typical neurologic findings in CD, meningoencephalitis, animal studies and studies on pathogenesis of cerebral involvement of CD (180/271, 66.4%). The most frequent topics of included studies were related to infectious and tropical diseases/internal medicine 172/341 (50.4%), neurology 105/341 (30.8%), cardiology 43/341 (12.6%).

Conclusions: The increasing body literature on the neurologic involvement of CD demonstrates the need of the scientific community to better define this multiform clinical entity. Although less common than the gastrointestinal and cardiac involvements, it can represent an emergency, especially in the context of acute CD or during CD reactivation in immunosuppression. The interest in this topic of different medical disciplines underlines the need for a multidisciplinary management of CD patients.

**High-frequency of Specific Polysaccharide Antibody Deficiency (SPAD) in adults with unexplained recurrent and/or severe bacterial infections: the SPIDAC French Study**

1 CHRU Lille, Lille, France, 2 Clinique La Louvière, Lille, France, 3 Clinique Tessier, Valenciennes, France, 4 CH Roubaix, Roubaix, France, 5 CH Montreuil / mer, Montreuil sur mer, France, 6 CH Tourcoing, Tourcoing, France, 7 CH Armentières, Armentières, France, 8 CH Denain, Denain, France, 9 CH Boulogne, Boulogne sur mer, France, 10 CH Seclin, Seclin, France, 11 CH Dunkerque, Dunkerque, France, 12 GH Cochin Broca Hotel Dieu, Paris, France

**Background:** Antibody deficiencies are the most frequent primary immunodeficiencies (PIDs) in adults and are mainly revealed by recurrent and/or severe bacterial infections. The objective of this study is to evaluate a systematic research strategy of PIDs in adults with unexplained bacterial infections.

**Materials/methods:** A prospective study was conducting in 15 centers in North of France (NCT02972281). Main inclusion criteria were recurrent benign upper and lower respiratory tract infections [group 1], severe upper and lower respiratory tract infections requiring hospitalization [group 2], and/or invasive infections documented with encapsulated bacteria [group 3]. Main exclusion criteria were all local [including tobacco use] and general associated conditions which could explain infections. If no PID diagnosis was made, response to polysaccharide antigens was assessed after PPV23, as previously published.

**Results:** From March 2015 to September 2019, 106 patients were included [34 males, mean age 42 years], and full data were available in 88 at the time of the present analysis. Thirty-four PIDs were diagnosed, giving an estimated frequency between 31.1% [n=34/106] to 37.5% [n=34/88]. Specific Polysaccharide Antibody Deficiency (SPAD) was the most frequent diagnosis by far [n=30/34, 88%], and was made in 13, 7 and 8 patients from groups 1 to 3, respectively. According to infectious history, SPAD patients were on surveillance [N=25] or treated with preventive antibiotics [N=4] or with immunoglobulins replacement therapy[N=6], the latter being dramatically efficient in all cases.

**Conclusions:** This study highlight the high prevalence of SPAD among adults with unexplained recurrent and/or severe bacterial infections. SPAD should be screened in those patients.

Allergic bronchopulmonary aspergillosis (ABPA) complicating chronic obstructive pulmonary disease (COPD) without asthma: responses to antifungal therapy
Sunil Aggarwal*1, Chris Kosmidis1

1Wythenshawe Hospital, Wythenshawe, United Kingdom

Background: Allergic bronchopulmonary aspergillosis (ABPA) is traditionally associated with asthma and cystic fibrosis. Aspergillus hypersensitivity and ABPA is present in 8-18% and 1-3% (respectively) with chronic obstructive pulmonary disease (COPD); however little is known about the significance of ABPA complicating COPD (ABPA-COPD). Case studies have demonstrated good responses to oral corticosteroids; however, it is not known whether antifungal therapy is beneficial in ABPA-COPD.

Materials/methods: We extracted clinical data from patients with a COPD and ABPA diagnosis at the National Aspergillosis Centre, Manchester University NHS foundation trust, UK. ABPA was diagnosed as having: ABPA symptoms, Total IgE (TlGE) >1,000kU/L, raised Aspergillus specific-IgE, and radiology consistent with ABPA. Exclusion criteria: asthma or cystic fibrosis history, other forms of pulmonary aspergillosis, lung function not consistent with COPD, age <40 years, no COPD predisposing factor.

Relevant medical history, symptoms, sputum culture, Aspergillus serology, radiology and response to antifungal therapy was extracted.

Results: Fifteen patients were included. Five were male. Median age 70 (56-81). Average MRC dyspnea scale and % predicted FEV1 was 2.93 and 66.4% respectively. Average TlGE was 4,562kU/L (1,193 - 32,615).

Eight of 15 patients were treated with Itraconazole. Two stopped within 1 month because of adverse events (AEs). Four stopped at 1-7 months because of AEs. 75% reported no improvement in symptoms. One of 8 patients reported a significant improvement (MRC dyspnoea scale increased from 4 to 2).

Patients who received >1 month of Itraconazole had an average TlGE of 2,375kU/L. In 80%, TlGE dropped to <1,000kU/L within 1 year. Two patients had TlGE available within 3 months of Itraconazole commencement, all had a TlGE decline >25% within 3 months.

4 of 15 patients received Amphotericin B nebulisers (AmpB), all stopped within three weeks because of AEs, one patient reported symptom improvement.

Conclusions: This is the first study to describe ABPA-COPD treatment with antifungal therapy. Oral Itraconazole gives a good serological response. However Itraconazole and AmpB may not be practical because the majority report no symptomatic improvement and experience AEs. Improvements reported could be explained by concomitant corticosteroids. High AEs could be explained by patient factors associated with COPD [elderly, co-morbidities].

**Abstract 8680**

**Activity of ceftolozane-tazobactam and combinatorial regimens against a contemporary collection of carbapenem-resistant Pseudomonas aeruginosa**

Cody Black*, James Shurko1, Chang-Jui Chen1, David Burgess2, Gerard Gawrys3, Grace Lee1

1UT Austin & UT Health San Antonio, San Antonio, United States, 2University of Kentucky, Lexington, United States, 3Methodist Healthcare System, San Antonio, United States

**Background:** Pseudomonas aeruginosa remains an important cause of hospital-acquired infections, globally. P. aeruginosa strains have become multidrug resistant (MDR) through multiple mechanisms and are increasingly resistant to carbapenems and other beta-lactams. The purpose of this study was to evaluate the in vitro activity of newer agents such as ceftolozane-tazobactam (CT), meropenem–vaborbactam (MV) and other relevant comparators and combinations against a contemporary collection of carbapenem-resistant *P. aeruginosa* clinical isolates.

**Materials/methods:** Antimicrobial susceptibilities were determined for 46 carbapenem-resistant *P. aeruginosa* strains from unique patients within 2 medical centers (University of Kentucky, Lexington KY and Methodist Healthcare System, San Antonio, TX). Minimal inhibitory concentrations (MICs) were interpreted according to the Clinical and Laboratory Standards Institute (CLSI) breakpoints. Isolates testing non-susceptible to at least one agent in ≥ 3 antimicrobial classes were defined as MDR and isolates testing non-susceptible to at least one agent in ≥ 5 antimicrobial classes were defined as extensively drug resistant (XDR). Synergy testing was performed on 10 meropenem-resistant XDR isolates. Combinatorial effects of meropenem+tobramycin and MV+tobramycin were evaluated using synergy tests and interpreted based on calculations of the fractional inhibitory concentration index (FICI).

**Results:** Of the 46 meropenem-resistant strains, 89% were classified as MDR and 39% were classified as XDR. All (100%) isolates were resistant to piperacillin-tazobactam, 80% to ciprofloxacin, 70% to amikacin, 80% to tobramycin, and 20% to cefepime. CT demonstrated 100% in vitro activity against both MDR and XDR isolates while all isolates were resistant to MV. Of the isolates evaluated for synergy testing, one demonstrated synergy between meropenem+tobramycin (FICI<0.5); however, all remained non-susceptible. None of the isolates demonstrated synergy with MV+tobramycin; however, additivity resulted in MV susceptibility (MIC < 8 ug/mL) in 25% of isolates.

**Conclusions:** CT demonstrated *in vitro* effectiveness against both MDR and XDR carbapenem-resistant *P. aeruginosa* strains, while MV had poor activity as both monotherapy and in combination with tobramycin against these isolates. These data provide insight into the potential value and pitfalls of these therapies as either empiric or targeted treatment of MDR *P. aeruginosa* infections.

Keep the attention high on Putative Invasive Pulmonary Aspergillosis (PIPA) in medical wards and intensive care units: a four-year retrospective analysis

Keep the attention high on Putative Invasive Pulmonary Aspergillosis (PIPA) in medical wards and intensive care units: a four-year retrospective analysis

Tommaso Lupia1, Stefania Raviolo1, Alice Trentalange1, Antonio Curtoni1, Rossana Cavallo1, Francesco G. De Rosa1, Silvia Corcione*1

1University of Turin, Turin, Italy

Background: Invasive pulmonary aspergillosis (IPA) outside the haematological ward, bears a troublesome diagnosis. We aimed to describe features of aspergillosis, through the criteria of “Putative Invasive Pulmonary Aspergillosis” (PIPA), introduced by Blot and colleagues in the Intensive Care Unit (ICU) and extending them into Medical Wards (MW)

Materials/methods: All patients with an Aspergillus spp. positive culture on low airways samples (BAL or BA) from 2012 to 2016 were retrospectively included in the study. Subjects with previous history of haematological diseases or IPA were excluded. The study population was divided into three groups (e.g. Proven diagnosis, Diagnosis of PIPA and Aspergillus spp. respiratory tract colonization).

Results: 78/80.9570 (0.09%) of admitted, fulfilled entry criteria. Overall Aspergillus spp. positivity on respiratory samples was 0.97/ every 1000 hospital admissions (4.94/1000/HA in the ICUs and 0.28/1000/HA in MWs, Figure 1). 52/78 (66,6%) had a diagnosis of PIPA: 69.2% of them in the ICU. The remaining (33.4%) were defined as colonized. Antifungal therapy was appropriate in 88.5% of subjects with PIPA and 37.5% of colonized (p<0.0001), confirmed comparing deads vs alives (p=0.001). In the univariate analysis patients with PIPA in the ICUs had more frequently COPD (p=0.018), sepsis or septic shock (p<0.0001), acute kidney injury (AKI, p=0.010), needed more surgery (p<0.0001), mechanic ventilation (MV, p<0.0001), vasopressors (p<0.0001), hemodialysis (p<0.0001), blood (p<0.0001) or platelets (p=0.043) transfusions. PIPA in MW had more often a history of smoke (p=0.0025), interstitial lung disease (p=0.035) and inhaled steroid therapy (p=0.008). Overall mortality within 21 days was 50%; 54.2% in ICU, 36.8% in MW (p=0.622). Factors associated to death in univariate analysis were: length of hospitalization (p=0.006), influenza (p=0.048), radiological pneumonia (p=0.042), liver transplant (p=0.048), AKI (p<0.0001), ARDS (p=0.019), sepsis and septic shock (p<0.0001).

Conclusions: We reported a lower incidence of PIPA in MWs compared to previous published data by Russo et al and Falcone et al. Furthermore, putative aspergillosis in ICUs had higher disease severity and needed more organ support than MWs cases: cases of PIPA in ICU and MW are emerging, despite that, trends are difficult to demonstrate given the problematic diagnosis.

Salivary microbiota profiling for discrimination between individuals in forensic science
Valentin Scherz*1, Sebastien Aeby1, Laurent Falquet2, Franco Taroni3, Claire Bertelli1, Gilbert Greub1

1Lausanne University Hospital and Lausanne University, Institute of Microbiologie, Lausanne, Switzerland, 2University of Fribourg, Department of Biology & Swiss Institute of Bioinformatics, Fribourg, Switzerland, 3University of Lausanne, School of Criminal Justice, Lausanne, Switzerland

Background: Many applications of forensic sciences require distinguishing individuals. Standard Short Tandem Repeat (STR) profiling can fail due to mixture or degradation of host-DNA, or in presence of monozygotic twins that are indistinguishable. Salivary microbiota represents an interesting alternative since bacterial DNA is protected by its circular conformation and robust cellular walls. Microbiota profiles could be used as a fingerprint for personal identification since it varies between individuals and remains stable over time. 16S rRNA metagenomics is affordable, actionable on low-DNA templates and compatible with legislation preventing sequencing of suspects’ DNA. In this longitudinal prospective study, we evaluate the ability of 16S rRNA metagenomics to discriminate individuals, including monozygotic twins, from salivary samples.

Materials/methods: Thirty pairs of healthy twins, confirmed monozygotic by STR profiling, are included with visits at recruitment and after 1, 12 and 13 months. A health questionnaire is submitted at each visit. Spit saliva is collected in 50ml tubes and DNA is extracted with the Nucleospin Soil kit [Macherey-Nagel]. Samples are attributed randomly to sequencing runs to prevent systematic batch effects. 16S rRNA libraries are prepared according to the V3V4 Illumina protocol and sequenced on MiSeq. Positive controls (ATCC-2002) and negative controls (extraction and PCR reagents) are included for each batch. Reads are processed into Amplicon Sequence Variants (ASVs) with DADA2 and classified by RDP against the EzBioCloud database.

Results: Inclusion and one-month follow-up samples were obtained from 30 pairs of volunteers, for which library preparation and sequencing are ongoing (21/120 sequenced, one pair from the same individual due to randomization). Read processing into ASVs increases the distance between unrelated samples compared to conventional Operational Taxonomic Units (OTUs) clustering (Figure). Once sampling and sequencing completed, we will compare intra versus inter-individual microbiota variation. A statistical model will be developed to express the support for the hypothesis that two samples belong to the same individual. A sub-study on a subset of samples will assess that these observations remain valid when sampling dry saliva on surfaces, a targeted case scenario for forensic applications.

Conclusions: Preliminary results on a limited number of samples confirm the “idiosyncrasy” of the saliva microbiota.

Abstract 8685

**Enterobacter spp. infections: epidemiology and risk factors for resistance to third generation cephalosporins**

Mariana Garcia*1

1San José, Hospital Rafael Angel Calderon Guardia, San José, Costa Rica

**Background:** Third generation cephalosporin-resistant (TGC-R) *Enterobacteriacea* constitute WHO level 1 priority due to alarming increase in incidence. Suboptimal treatment translates to high mortality and costs. Epidemiological data from Central America is scarce.

**Materials/methods:** Observational, retrospective cohort study of patients with *Enterobacter* spp. infection in a tertiary care teaching hospital in San Jose, Costa Rica from 2014-2017. Only one episode per patient was recorded. Phenotypic analysis of the antibiogram (VITEK® 2, BioMérieux) was used to detect resistance to TGC. Clinical data collected and analyzed using T-test and Chi2 or Fisher’s when appropriate. ORs were calculated by multivariate logistic regression for binary outcomes; HRs for death using Cox regression.

**Results:** 1,842 samples were analyzed, with increasing incidence over time. *E. cloacae* represented 73% of samples. Isolates corresponded to respiratory samples (n=608, 33%), urine (n=497, 27%), surgical wound (n=387, 21%), peritoneal fluid (n=166, 9%), bloodstream (n=129, 7%), perianal abscess (n=18, 1%), CSF (n=13, 0.7%), bone (n=13, 0.7%) and pleural fluid (n=11, 0.6%). Male sex (60%) predominated. *Enterobacter* spp. infections were mainly of nosocomial origin (79%) with a strong positive correlation between hospital days and time to a positive culture. (rs=0.623, p<0.00001). Resistance to TGC increased from 25% in 2014 to 33.5% in 2017. Coinfection was noted in 38% of samples, most frequent *P. aeruginosa* (21%), *E. coli* (19%) and *K. pneumoniae* 18%. Patients diagnosed with respiratory (OR 2.6, CI 1.60-4.28, p=0.0001) and intraabdominal infections (OR 3.9, CI 2.63-5.76, p=0.0001) were more likely to develop resistance. Overall mortality was 32%, highest in males (69%) (p=0.0001) and the elderly. Hospital-acquired strains carry double mortality (OR 2.1, p=0.00001, CI 1.46-3.14). Resistant isolates denote higher risk of death (45%) than susceptible counterparts (27%) (OR 2.24, p=0.004, 1.70-2.95) HR for death were malignancy (HR 2, p=0.0001, 1.43-2.89) and renal disease (3.2, p=0.0001, 2.5-6.7).

**Conclusions:** *Enterobacter* spp. infections are predominantly nosocomial with mortality being highest in elderly men. Admission for intraabdominal and respiratory tract infections confer a higher risk for resistant strains. Renal disease triplicates the risk of death and solid malignancy doubles it. Antimicrobial stewardship, infection control and limiting indwelling catheters are critical measures to improve outcomes.

Abstract 8686

Osteomyelitis in sickle cell adults: descriptive study in a high-income country
Conan Pierre-Louis*, Olivier Steichen1, Aline Santin1, Claude Bachmeyer1, Pauline M Bappe1, Francois Lionnet1, Sarah Mattioni1

1Service de Médecine Interne - Centre de la Drépanocytose, Hôpital Tenon (AP-HP), Paris, France

Background: Sickle cell disease (SCD) mainly affects populations from sub-Saharan Africa and the Indian sub-continent. Osteomyelitis (OM) is one of the main infectious complications in SCD patients, with an estimated prevalence of between 12 and 18% in low-income countries, adults and children combined. There are few data on OM in SCD adults in high-income countries.

Materials/methods: This monocentric observational study included all patients followed in a reference centre who had at least one OM with microbiological documentation in adulthood. The objective was to characterize the clinical and microbiological profile of this complication.

Results: Seventeen patients were included (15/17 (88%) SS genotype, median age at diagnosis of OM 23 years, 7/17 (41%) women, 15/17 (88%) sub-Saharan origin), corresponding to a prevalence in our centre of 1.2% (17/1464). In 16/17 (94%) of the cases, the infection had started while the patients were in a high-income country. The most frequent locations were the lower limbs (9/17, 54%) with multifocal forms in 8/17 (40%) of cases. Microbiological documentation was obtained by bone sampling (5/17, 29%) or blood cultures (7/17, 42%). The most common germs found were non-typhi Salmonella (6/17, 35%) and Staphylococcus spp. (5/17, 29% including methicillin-sensitive Staphylococcus aureus (4/5) and Staphylococcus epidermidis (1/5)). Other rarer pathogens were also detected (Clostridium difficile, Pantoea agglomerans or Propionebacterium acnes).

Antibiotic therapy was systematic, with a median duration of 90 days, and 9/17 (75%) of patients required surgical debridement (sequestrectomy or drainage of Brodie’s abscess). At the last follow-up visit, 3 patients had relapsed or had persistent OM despite appropriate medical and surgical treatment.

Conclusions: The epidemiology of OM in SCD differs between low- and high-income countries: non-typhi Salmonella in Europe and the USA and Staphylococcus aureus in sub-Saharan Africa and the Middle East. Susceptibility factors in SCD patients include immunosuppression and bone or periosteal infarctions that are the bedrock of infection. Our study finds a lower prevalence and over-representation of Salmonella compared to low-income countries. The supposed entry point is digestive translocation, via parietal micro-infections. The evolution is generally favourable without relapse, even in the absence of surgical management.

Abstract 8687

X-ray induced changes in substrate specificity of OXA-48

Marianlaura Dabos1, Michele Mondini2, Eric Deutsch2, Thierry Naas1,3

1Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 2Institut Gustave Roussy, Villejuif, France, 3Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: X-ray irradiation is widely used in diagnostic and therapeutic. To our knowledge, the effect of X-ray exposure was never evaluated on carbapenemase-producing Enterobacteriaceae (CPE). OXA-48, one of the most prevalent carbapenemase hydrolyzes penicillins and carbapenems, but not expanded-spectrum cephalosporins (ESC). Here we evaluated the effect of X-ray exposure on OXA-48 producing Enterobacteriaceae, in respect to ESC resistance selection.

Materials/methods: K. pneumoniae 14003, E. coli 109B1 and S. marcescens Sm1 were used in the study. The three isolates harbored a plasmidic blaOXA-48 gene. The bacteria were exposed to different doses of X-ray and plated on ceftazidime (4 X MICs) containing plates and on TSA plates in order to count the surviving bacteria. All the analyses were done in duplicate. Disc diffusion antibiograms and MIC determinations were used to assess phenotypical changes. Whole genome sequencing (WGS) was performed using an Illumina Miseq platform. Mutated blaOXA-48 genes were cloned and expressed in E. coli TOP10. OXA-48 mutants were purified and their kinetic parameters determined and compared with those of OXA-48. Structural analysis was also performed.

Results: In the three species the phenotypical changes were the same, an increase in the susceptibility for all the β-lactams except for ceftazidime, which showed a reduction in the susceptibility. The sequence analysis revealed mutations in OXA-48. In K. pneumoniae 14003 study 11 mutants were recovered, 10 of them with the mutation W157L and one with W157R. In E. coli 109B1 8 mutations were observed, W157R, L158P, W157R-L158F, G160C, G160D, G160S, P68S and L139R-A141V. While in S. marcescens Sm1 two mutations were observed F156S and W157R. Interestingly, almost all the mutations were located in the Ω loop of OXA-48. All the pTOPO(blaOXA-48-mutated) E. coli TOP10 presented increased MIC values for ceftazidime and reduced for imipenem. The kinetic parameters confirmed these results.

Conclusions: X-ray irradiation produced ceftazidime resistant mutants with decreased susceptibility for all the other β-lactams. W157, that is frequently mutated in OXA-48, correspond to an amino-acid that stabilizes the KCX motif that is important for the activity of the enzyme.

Human transcriptomic response to vaccination with recombinant VSV expressing Ebola virus glycoprotein

Francesco Santoro¹, Alessia Donato¹, Sara Sorgi¹, Alice Gerlini², Angela Huttner², Claire-Anne Siegrist³,⁵, Donata Medaglini¹, Gianni Pozzi³

¹University of Siena, Department of Medical Biotechnologies, Siena, Italy, ²Microbiotec srl, Siena, Italy, ³University of Geneva, World Health Organization Collaborating Centre for Vaccine Immunology, Geneva, Switzerland, ⁴Geneva University Hospitals, Infectious Diseases Service, Geneva, Switzerland, ⁵University of Geneva, Department of Pathology and Immunology, Geneva, Switzerland

Background: rVSV-ZEBOV is a live-attenuated recombinant vesicular stomatitis virus vaccine expressing Zaire Ebolavirus glycoprotein G and is the first vaccine licensed against Ebolavirus disease. Here we studied the blood transcriptomic response upon administration of a single dose of vaccine.

Materials/methods: Whole blood RNA from 64 healthy volunteers, 51 vaccinated either with $10^7$ or $5 \times 10^7$ PFU of rVSV-ZEBOV and 13 injected with placebo, collected at different time points after vaccination, was analysed by targeted transcriptome sequencing. At each time point, differentially expressed genes (DEGs) were identified with edgeR, ranked by FDR, and used to find biological signatures assessing the activation of 346 blood transcription modules.

Results: Between baseline and day 1 after vaccination, 5,469 DEGs were detected. This number decreased over time: at day 28 no DEGs were detected. Functional analysis identified 145 different modules affected by vaccination. Innate immunity pathways were activated from day 1 to day 14. At days 2 and 3, neutrophil modules were downregulated and complement-related modules upregulated. T-cell and cell-cycle associated modules were upregulated at days 7 and 14, while at day 28 no modules remained activated. Correlation analysis of module activation with ZEBOV glycoprotein-specific antibody titres identified seven significant directly correlated modules at day 14 after vaccination, including two related to B cell activation.

Conclusions: Vaccination with rVSV-ZEBOV produced a significant modulation of gene expression over time. This live viral vector induced a strong and durable modulation of genes associated with innate response, with upregulation of T cell- and cell-cycle-associated genes at days 7 and 14. The activation of seven blood transcription modules at day 14 after vaccination could be correlated with the magnitude of antibody response against Ebola glycoprotein at day 28.

Trimethoprim-sulfamethoxazole as de-escalation agent in bloodstream infections due to Enterobacter spp, Serratia marcescens and Citrobacter freundii

Adrian Sousa*1, María Teresa Pérez-Rodríguez1, Milagros Suárez1, Patricia Diéguez1, Olalla Lima1, Andrea Cabaleiro1, Anton Otero1, Francisco Vasallo Vidal1, Rebeca Longueira1, Andrés Nodar1, Manuel Crespo1

1Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Enterobacter spp. Serratia marcescens and Citrobacter freundii (ESC group) are associated with higher antibiotic resistance rates because they are able to produce high levels of AmpC betalactamases in the presence of beta-lactams and select resistant mutants. Trimethoprim-sulfamethoxazole (TMP-SMZ) could be a useful option to de-escalate the empirical antibiotic treatment but there is little evidence of its efficacy and safety in the treatment of infections by this type of microorganisms. The aim of our study was to analyse the efficacy and safety profile of TMP-SMZ as de-escalation agent in bloodstream infections due to ESC-group microorganisms.

Materials/methods: this study included all patients over 18 years of age with ESC-group bacteraemia, collected and evaluated prospectively and consecutively in the University Hospital of Vigo between January 1, 2015 and December 31, 2017. They were classified in two groups: TMP-SMZ de-escalation group and no-switch group. We excluded patients with inadequate empirical treatment. De-escalation was defined as change empirical treatment to TMP-SMZ within 96 hours after index blood cultures were performed. Propensity score was calculated using a multivariable logistic regression model in which the dependent variable was a binary indicator of de-escalation strategy. The primary and secondary outcomes was 30-day all-cause mortality and 90-day recurrence of infection.

Results: During the study period we included 63 patients who met eligibility criteria (37 in TMP-SMZ group and 26 in no-switch group. Characteristics of both groups patients are shown in Table 1. Overexpression of AmpC betalactamase was present in 20 (32%) of ESC group isolates. Most frequent source of infection was urinary (39%), followed by intraabdominal (27%) and respiratory (16%). Betalactam+betalactam inhibitor was the first choice as empirical treatment (34%), followed by carbapenem (25%) and 3rd G cephalosporin (23%). In multivariate analysis adjusted by propensity score only septic shock (OR 4.22 [95% CI 1.55-23.35]) and urinary source (OR 0.36 [95% CI 0.18-0.74]) were associated with 30-day mortality.

Conclusions: TMP-SMZ could be a safe and effective option to de-escalate empirical antibiotic treatment in patients with ESC-group bloodstream infections.

Abstract 8694

Performance of EUCAST’s rapid antibiotic susceptibility testing on sterile body fluids in blood culture bottles
Stefan Zimmermann*1, Jasmin Kaur Jasuja1, Irene Burckhardt1

1University Hospital Heidelberg, Department of Infectious Diseases, Heidelberg, Germany

Background: A shortened time to report is crucial for patients with symptoms of septicemia, but also patients with severe infections, e.g. joint infections or peritonitis, might benefit from RAST results. It was proven that inoculation of sterile body fluid in blood culture bottle (BC) is beneficial. EUCAST’S RAST has been evaluated for positive BCs and was further evaluated for its applicability on sterile body fluids in BCs to reduce time to report when using total lab automation (TLA). The objective of this study was to test the applicability of RAST on blood cultures and sterile body fluids in blood culture bottles and to evaluate its performance.

Materials/methods: Positive blood culture bottles (BACTEC™ Aerobic, BACTEC™ Anaerobic, BACTEC™ PED) inoculated with sterile body fluid from patients (e.g. joint fluid, ascites, etc.) were sub-cultured on standard agars and Mueller-Hinton agar. On latter, six antibiotic discs were added (cefoxitin, ampicillin, vancomycin, piperacillin/tazobactam, meropenem, ciprofloxacin). Subculture and streaking were done on a TLA. Subcultures were imaged after 6h and 23h. RAST plates were imaged and MALDI-TOF MS was performed after 6h and inhibition zones were measured using the TLA software and interpreted due to EUCAST RAST. MIC values were determined using VITEK2 panels for all isolates.

Results: In the time period of November 2018 to August 2019 Staphylococcus aureus (n=143), Enterococcus spp (n=72) and Escherichia coli (n=33) were the most frequent detected pathogens. Comparison of RAST and MIC results showed 5.6% of major errors for Enterococcus spp. in Ampicillin and 3.9% in Vancomycin. 7.7% of minor errors were found for E. coli. Very major errors were not found for any pathogen. 3 and 18 samples were found within area of technical uncertainty (ATU) in gram-positive cocci and E. coli, respectively. Category agreement between MIC values and RAST was 94.6%.

Conclusions: Applicability and performance of RAST from positive blood cultures became a routine method in our lab, but also use of sterile body fluid in blood culture bottle is promising and patients may benefit from the more rapid AST results. Further investigation of ATU is necessary and more EUCAST breakpoint, e.g. for koagulase-negative staphylococci are needed.

Abstract 8697

Treatment outcome and clinical characteristics of patients with community-acquired pneumonia treated in an infectious disease intensive care unit

Marta Popović1, Rafaela Novak1, Marko Kutlesa1,2, Marija Santini1,2, Bruno Baršić1,2, Vladimir Krajnović2

1School of Medicine, University of Zagreb, Zagreb, Croatia; 2University Hospital for Infectious Diseases Dr. Fran Mihaljevic, Zagreb, Croatia

Background: Patients admitted to an intensive care unit with a primary diagnosis of community-acquired pneumonia (CAP) have a high in-hospital mortality rate and often demand complex treatment. This study aimed to evaluate the clinical and epidemiological characteristics of patients with severe CAP, as well as to compare treatment outcomes in an infectious disease intensive care unit (IDICU) with the literature data on the outcome of patients with severe CAP in non-IDICUs.

Materials/methods: This research is a retrospective analysis of data collected on 305 patients treated in an IDICU with a primary diagnosis of CAP in the period between January 2016 and December 2018 in an 18 bed IDICU of University Hospital for Infectious Diseases in Zagreb, Croatia.

Results: The research included 305 patients (67% male) with CAP, with a median age of 63 years (IQR 50-71), median Charlson Comorbidity Index of 3 (IQR 2-5) and a median APACHE II score of 16 (IQR 13-22). The average length of hospital stay was 14 days. The most frequent infectious agents were the influenza virus and Streptococcus pneumoniae. CAP was complicated with sepsis in 15% of the cases. Almost 50% of the patients developed multiple organ failure (MOF). Around two thirds of the treated CAP patients required some method of intensive medicine life support, most commonly mechanical ventilation (67%), hemodialysis (34%) and VV ECMO (18%). The most common complications were ARDS, pleural effusion and pneumothorax. At discharge only 14% of the patients were completely independent, 30% had reduced functional ability and 27% of the discharged patients were completely dependent and immobile. The specific in-hospital mortality rate for CAP was 28%.

Conclusions: Patients treated for CAP in an IDICU have numerous comorbidities and severe forms of this disease regularly requiring ICU life support. The in-hospital mortality of CAP in IDICU was lower than the CAP mortality of patients with similar APACHE II score in non-IDICUs (32-55%) as stated in the literature. This could indicate that treatment outcome could depend on patient characteristics but also on the type of ICU.

Background: The use of polymyxins such as colistin has increased in Colombia due to the KPC dissemination in the country. Consequently, resistance to colistin is increasingly reported among KPC-producers. Resistance to polymyxin has been attributed to mobile colistin resistance (mcr) genes and chromosomal mutations. Among these mutations, the inactivation of the mgrB gene by the integration of an insertion sequence (IS) or its complete deletion is the most common mechanisms of polymyxin resistance in clinical isolates of Klebsiella pneumoniae (Kpn). Herein, we describe the mechanism of resistance to polymyxins in clinical isolates of carbapenem-resistant Kpn (CR-Kpn) from Colombia.

Materials/methods: Twenty-four CR-Kpn isolates resistant to polymyxin B (PMB) recovered in clinical institutions from six Colombian cities between 2009 and 2019 were analyzed. The minimum inhibitory concentration (MIC) for PMB was confirmed by broth macrodilution, and the presence of carbapenemases by qPCR. Illumina whole-genome sequencing (WGS) was performed to identify changes in the genes encoding for PhoP/PhoQ, PrmA/PrmB and MgrB associated with resistance to polymyxins.

Results: According to both EUCAST and CLSI 2019 breakpoints for colistin (resistance at MIC >2 mg/L, and ≥4 mg/L, respectively), polymyxin resistance was found among all studied isolates, with PMB MIC ranging from 4 to ≥16 mg/L. Most isolates (18/24) carried blaKPC-3 and belonged to ST258 (17/24); 6 isolates were KPC-2 producers and 1 carried blaNDM-1. Most of isolates carried a truncated mgrB gene, the common mutation was insertion at nucleotide position 74, explaining the PMB resistance; amino acid substitutions in the PmrA/PmrB system were found in 6/24 isolates; additional substitutions in PhoP/PhoQ or mcr genes were not identified. Table 1 summarizes the results obtained by WGS.

Conclusions: We found a clonal dissemination of polymyxin and carbapenem-resistant Kpn ST258 harboring blaKPC-3 in the last 10 years in Colombia. The main resistance mechanism identified was the insertional inactivation of the mgrB gene. Active surveillance is warranted to contain the dissemination of Kpn isolates with dual polymyxin and carbapenem resistance associated with very few therapeutic options left for treatment.

Table 1. Molecular characterization of polymyxins and carbapenem-resistant Kpn isolates.

Abstract 8701

Molecular epidemiology of carbapenem-resistant *Klebsiella pneumoniae* isolates in France 2018

Mabel Budia¹², Remy Bonnin¹, Laurent Dortet¹, Thierry Naas¹²

¹Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, ²Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France

**Background:** *Klebsiella pneumoniae* is an important pathogen responsible of nosocomial infections. Carbapenem resistance in *K. pneumoniae* is mainly associated with acquired carbapenem-hydrolyzing β-lactamases. These β-lactamases can be serine-β-lactamases like Ambler class A enzymes (KPC) and class D oxacillinases (OXA-48) or class B Metallo-β-lactamases (NDM, IMP, and VIM). According to the latest results of the French National Reference Center in last years, the most prevalent carbapenemase was OXA-48. The aim of our study is to obtain epidemiological data on carbapenem-resistant *K. pneumoniae* clinical isolates recovered in France in 2018.

**Materials/methods:** We performed genetic characterization of carbapenem-resistant *K. pneumoniae* strains by analysing WGS of 689 clinical isolates collected from different regions of France. Isolates were processed via Illumina (Next500, 2X150-bp) and Illumina reads de novo assemblies were performed using CLC Genomics Workbench v12. Antibiotic resistance gene determination, Multi-locus sequence typing, plasmid analysis and phylogenetic studies were done using software available at the Center for genomic epidemiology. Plasmids were extracted using Kieser method for the most prevalent STs.

**Results:** The most prevalent carbapenemase was OXA-48 (58% of presence in the isolates) follow by NDM-1 (16% of presence in the isolates) and OXA-48 like (9% of presence in the isolates). 150 different STs were observed with the ST 307 being the most prevalent one (106 isolates), followed by ST 147 (64 isolates), ST 11 (56 isolates) and ST 405 (40 isolates) and ST 101 (26 isolates). All the isolates belonging to the ST 405 were OXA-48 producers, and all possessed the prototypical IncL plasmid. These isolates came from all over the country, suggesting the dissemination of a high risk clone. For the other STs, the prevalence of the different carbapenemases was variable. For ST307, 69% produced OXA-48-like and 23% NDM-like, ST147 expressed mostly NDM (61%).

**Conclusions:** In our study the most prevalent carbapenemase was OXA-48. The isolates belonging to the ST 405 were all OXA-48 producers, what indicate a strong relation between the ST 405 and the presence of blaOXA-48 gene. On the other hand, the carbapenem-resistant *K. pneumoniae* belonging to ST 147 harbored in most case a NDM-like gene.

Abstract 8702

Aspergillosis complicating severe influenza in intensive care unit patients: a retrospective case-control study

Caitlin Visek*, Hannah Nam1, Michael G. Ison1

1Northwestern University Feinberg School of Medicine, Chicago, United States

Background: Invasive pulmonary aspergillosis (IPA) has been recognized as a complication of influenza infection even in immunocompetent patients. We aimed to understand the incidence of IPA among critically ill patients with influenza infection over multiple seasons.

Materials/methods: A retrospective case-control study was conducted in a single center in Chicago. Data was collected over 9 seasons (March 2009-March 2018) from adult patients admitted to the ICU at a large urban tertiary care center with influenza. Patients were included if they had a positive influenza PCR test, were ≥ 18 years, were admitted to the ICU, and developed IPA. IPA was defined per both the EORTC/MSG criteria as well as the revised AspICU criteria. A random cohort of 114 influenza positive patients admitted to the ICU who did not develop IPA were also identified for comparison. Descriptive statistics were calculated. In univariable analysis, we compared categorical variables by Fisher’s exact test and Chi-square test and continuous variables by Student’s t-test where appropriate.

Results: A total of 345 patients with influenza were admitted to the ICU over the study period. The overall rate of IPA in the study population was low at 1.7% (6/345). Factors associated with development of IPA in those with severe influenza pneumonia were hematological malignancy (p=0.03), history of hematopoietic stem cell transplant (p=0.00), non-transplant related immunosuppression (p=0.00), and history of solid organ malignancy (p=0.01). There was no significant difference in outcomes such as overall length of stay, need for mechanical ventilation or renal replacement therapy, and death. Other coinfections were common with incidences of 46.7% [bacterial], 11.7% [viral], and 13.3% [non-aspergillosis fungi].

Conclusions: The incidence of IPA was significantly lower (1.7%) in our study over 9 influenza seasons than has been reported in similar studies. Malignancy and immunosuppression were risk factors strongly associated with the development of IPA. IPA did not significantly predict morbidity and mortality among critically ill influenza patients.

Abstract 8703

The Global Point Prevalence Survey of Antimicrobial Consumption and Resistance (Global-PPS): results of antimicrobial prescribing at Ghana’s National Referral Centre

Mariyam Mirfenderesky¹**, Joyce Mahungu², Asiwome Aggor³, Ann Versporten⁴, Ines Pauwels⁴, Herman Goossens⁴, Daniel Ankrah³

¹North Middlesex University Hospital, Medical Microbiology, London, United Kingdom, ²North Middlesex University Hospital, Pharmacy Department, London, United Kingdom, ³Korle Bu Teaching Hospital, Korlebu, Ghana, ⁴University of Antwerp, Antwerpen, Belgium

Abstract third-party references: Common Wealth Association for Antimicrobial Stewardship, Tropical Health Education Trust, Commonwealth Pharmacy Association, biomerieux

Background: The Korle Bu Teaching Hospital is a 2000 bedded tertiary hospital in Accra, and Ghana’s national referral centre. In February 2019 a health partnership was formed with a UK institution in order to build professional capacity, and develop antimicrobial stewardship and infection prevention and control programmes. The first comprehensive surveillance of antimicrobial use at the institution was undertaken to establish a baseline, and identify required stewardship interventions.

Materials/methods: A standardized method for surveillance of antimicrobial use in hospitals [www.global-pps.com] was conducted over three days by 15 pharmacy professionals in June 2019. The survey included all inpatients receiving an antimicrobial at 8am on the day of the PPS. Data included details on antimicrobial agents, reasons and indications for treatment and a set of quality indicators.

Results: 988 patients were admitted to 69 wards. Antimicrobial prevalence was 53%, which varied between ward type [46% in adult medical, 57% in adult surgical, 69% in paediatric medical, 50% in paediatric surgical and 48% in neonatal units]. Out of all antimicrobials prescribed, 41.2% were for community acquired infections and 14.9% for health-care associated infections. The main indications for prescribing were prophylaxis for obstetric and gynaecological reasons [20.2%], sepsis [9.5%] and pneumonia [9.2%].

Systemic antibiotics accounted for 83.5%, of which amoxicillin with beta-lactam inhibitor [17.5%], metronidazole [11.8%] and ceftriaxone [11.5%] were most often prescribed. Surgical prophylaxis accounted for 33.0% of all antimicrobial use of which amoxicillin with beta-lactam inhibitor [33.3%], cefuroxime [19.9%] and metronidazole [18.0%] were most often prescribed; and overall 78% were prescribed >1 day. Guidelines were missing in 25% of antibiotic prescriptions. Guideline compliance was 89%. Stop/review dates were completed in 33.4% with a documented reason recorded in 53% of prescriptions.

Conclusions: The Global-PPS is an important tool used to establish baseline prescribing, and identify areas for improvement. Moving forward, interventions to decrease the duration of surgical prophylaxis, with a focus on obstetrics and gynaecology, guideline revision and development, and tools to improve quality indicators are identified as initial targets to improve antimicrobial prescribing at this institution.

Changing seroprevalence of viral diseases among young adults in a tertiary care educational university hospital? Experience with 1993 cases

Meltem Isikgöz Tasbakan¹, Deniz Akyol*¹, Aysin Zeytinoglu¹, Husnu Pullukcu¹

¹Ege University Medical Faculty Hospital, Izmir, Turkey

Background: The risk of vaccine-preventable and other transmissible infections for health-care workers and also for medical students is high due to direct contact with patients. Thus, screening and immunization policies of medical students should be performed regularly in order to assess their immunity and serostatus against relevant viral diseases. Herein, we aimed to evaluate the serologic test results of medical students retrospectively in a tertiary-care educational university hospital.

Materials/methods: The study included students who were attending medical school between 2008-2019. Serologic test results concerning hepatitis (A, B and C), measles, mumps, rubella, varicella-zoster and HIV were reviewed retrospectively from medical records of students including all preclinical and clinical semesters. Anti-HAV IgG, HBsAg, anti-HBcIgG, anti-HBs, anti-HCV, measles IgG, mumps IgG, rubella IgG, varicella-zoster IgG and anti-HIV were studied by ELISA method.

Results: There were a total of 1993 students (mean age 22.20 ± 2.43 years and 51.48% female). Virus-specific immunity rates were: rubella 96.15% in 1223 students, varicella-zoster 90.42% in 595 students, mumps 82% in 750 students, measles 72.95% in 880 students, anti-HBs 92.32% (vaccinated) in 1654 students, anti-HCV 0.20% in 1480 students, hepatitis A 30.8% in 1662 students and anti-HIV 0.09% in 1024 students.

Conclusions: Our results indicate that approximately two-third of the medical students were seronegative for hepatitis A and seropositivity rates for mumps and measles were not satisfactory especially for Turkey considering endemicity. Therefore, medical students in a health care set up should undergo vaccination against hepatitis A, B, mumps and measles after prevaccination immunity screening.

Detection of hepatitis B virus reactivation and near complete sequencing of the viral genome by high-throughput sequencing in a kidney transplant

Maelia Etoundi1, Sarah Aherfi1, Anne Motte1, Valérie Moal2, Philippe Colson*1

1IHU Méditerranée Infection, Marseille, France, 2Conception hospital, Aix-Marseille univ., Marseille, France

Abstract 8712

**Background:** Hepatitis B virus (HBV) serology indicating past resolved infection is often associated with HBV DNA persistence as covalently closed circular DNA in hepatocyte nuclei. This allows viral reactivation in case of severe immunosuppression. Renal transplant recipients constitute a group at high risk of such HBV reactivation. Next-generation sequencing is gradually emerging in routine clinical diagnosis. Here, we describe the obtention of a near complete HBV genome using this technology directly from the plasma of a renal transplant presenting HBV reactivation.

**Materials/methods:** HBV serology was performed with Abbott Architect assays, Abbott Diagnostics, Chicago, IL, USA. HBV viral load was performed with the Veris DxN Beckman-Coulter Diagnostics assay, Brea, CA, USA. Next-generation sequencing used Illumina technology on MiSeq with the paired-end protocol (Nextera XT protocol, Illumina Inc, San Diego, CA, USA).

**Results:** HBV reactivation was diagnosed in a 73-year-old male patient from Madagascar, in France since 1975. He received a kidney transplant in August 2016 and was subsequently treated with azathioprine/prednisone/ciclosporin A/thymoglobulin. Pre-transplant serology showed HBsAg-negativity/anti-HBs-negativity/anti-HBc-positivity, indicating past resolved infection. In February 2019, during routine post-transplant follow-up, HBV serology showed HBsAg-positivity/anti-HBs-negativity/anti-HBc-positivity. Viral load was 42480000 IU/mL. The patient was clinically asymptomatic, without liver cytolysis. Quasi-complete genome sequencing was performed directly from the plasma DNA extract by next-generation sequencing. The genome obtained has a size of 3182 nucleotides and mean coverage (± standard deviation) is 753±269 reads/nucleotide position (min-max: 155-1200). Mean nucleotide diversity is 0.4±2.1% (0.0-45.8). Viral genotype is D2. HBsAg amino acid substitutions P120Q/L (10% of the quasispecies), P142L (40%), R122K (59%), and G145R (100%) described as altering HBsAg antigenicity and associated with immune escape, and a drug resistance-associated substitution in reverse transcriptase (I169L) were observed. The patient was treated with Entecavir 0.15 mg/day.

**Conclusions:** This case demonstrates the importance of systematic monitoring of HBV reactivation in renal transplant patients with a serologic profile indicating past resolved hepatitis B, and the value of next-generation sequencing in routine diagnosis to characterize more comprehensively the viruses involved in these reactivations.

Perioperative administration of cefepime-daptomycin combination during prosthetic joint replacement is associated with high bone and synovial concentrations

Eric Senneville1, Olivier Robineau2, Benoit Brunschweiler3, Yves Herpe4, Beltrand Eric5, Antoine Grillon6, Cédric Joseph3, Blondiaux Nicolas6, François Jehl7

1Lille Université, Gustave Dron Hospital, Tourcoing, France, 2Lille Université, Tourcoing, France, 3CHU Amiens, Amiens, France, 4Hôpital Gustave Dron Tourcoing, Tourcoing, France, 5CHU Strasbourg, Strasbourg, France, 6Gustave Dron Hospital, Tourcoing, France, 7Strasbourg, Medical microbiology laboratory, Strasbourg, France

Background: It is recommended to start the administration of broad-spectrum antibiotics during prosthesis replacement for periprosthetic joint infection (PJI) peroperatively and to continue the treatment until the samples culture results are available. However, data demonstrating that antibiotics are present in the surgical site at concentrations exceeding the MICs of usual bacteria at the moment the new prosthesis is inserted are lacking.

Materials/methods: We conducted a prospective pilot study in two national referent centres for bone and joint infections in France (Lille-Tourcoing and Amiens) between January and August 2017. Patients with PJI operated with one or two-stage replacement during which cefepime-daptomycin combination (2d q8h and 10mg/kg, respectively) administered intravenously as peroperative empirical antibiotic treatment were included, provided they had given an informed written consent. Bone and synovial biopsies were taken just before the insertion of the new prosthesis and were frozen before grouped shipment to a central laboratory for determination of the tissue concentrations of each antibiotic. Serum concentrations of each antibiotic were also assessed at the same time.

Results: Eighteen patients of mean age 67.83 ±12.4 years with PJIs (7 total hip and 11 total knee prosthesis) were included. Surgical interventions consisted in one/two-stage-replacement in 11/7 cases. Microbiology was dominated by Staphylococcus spp. (n=9, including 8 coagulase negative staphylococci) and Gram negative rods (n=6, including 2 E. coli and 2 E. aerogenes). Cultures were sterile in 4 cases. The mean delay between the end of the intravenous administration of cefepime and daptomycin and intraoperative sampling was, respectively 37.7±16.6 and 34.5±16.9 mn. Blood and synovial/bone concentration values were respectively, 39.6±25.9 mg/L and 14.4±15.5, 13.7±18.5 mcg/g of tissue for cefepime and 96.2±33.5 mg/L and 15.5±6.5, 12.5±16.5 mcg/g for daptomycin. Median MIC of cefepime for Gram negative rods was 1mg/L and that of daptomycin for Gram positive cocci was 0.38mg/L.

Conclusions: The present study suggests that cefepime-daptomycin combination administered peroperatively during one or two-stage replacement in patients with PJIs is associated with surgical site, including bone, concentrations well above the MICs of usual pathogens.

Antimicrobial susceptibility testing by MALDI-TOF MS of lipids determines true MICs in six hours
Matthew Sorensen1, Erik Nilsson1, Francesca Gardner1, Salma Ramadan1, David Goodlett2, Robert Ernst*2
1Pataigin, Seattle, United States, 2University of Maryland, Baltimore, United States

Background: Accelerating antimicrobial susceptibility testing [AST] is recognized as needed for improved infectious disease outcomes. Regardless, any AST test's results must be useful to clinicians. In particular, there is no good substitute for minimum inhibitory concentration (MIC), which is often critical to infectious disease diagnosis and treatment.

We have developed a rapid AST test that determines true MICs via MALDI-TOF MS of deuterium-labeled membrane lipids. This highly sensitive measurement of growth allows accelerated determination of MICs.

Materials/methods: Broth dilution AST was performed on Gram-negative and -positive bacterial species, including ESKAPE pathogens, using both custom and standard [Sensititre, ThermoFisher] microdilution plates, with growth media containing up to 10% deuterium oxide (D2O). After six hours, incorporation of deuterium to membrane lipids was measured by MALDI-TOF MS in negative ion mode using norharmane matrix.

Results: Lipids from the initial inoculum have hydrogen with the natural isotopic distribution. However, bacteria growing in D2O-containing media produce lipids enriched in deuterium, which exhibit a mass shift detected by MALDI-TOF MS, allowing growth to be sensitively determined.

As shown in Figure 1, Escherichia coli YD626 was transfected with the mcr-1 plasmid, conferring colistin resistance. Transfected and WT YD626 isolates were grown in microdilution plates, and MALDI spectra collected, as described above. For each concentration, growth was estimated as the ratio of deuterium-labeled to -unlabeled peaks. As expected, mcr-1 conferred colistin resistance to YD626: growth was detected at 2.0 µg/ml with mcr-1, four times higher than without mcr-1. Additional bacterial species have been successfully evaluated against various antimicrobials covering most of the major antimicrobial classes.

Conclusions: We have demonstrated a new, rapid AST that can use existing AST microtiter plates and media. Our novel method thus accelerates AST testing, while retaining proven methods and materials. AST by MALDI-TOF MS detection of deuterium incorporation into lipids during growth therefore promises fast, practical, and credible AST.

Figure 1: Deuterium incorporated into lipids during growth shows that colistin-resistant E. coli has an MIC four time higher than colistin-susceptible E. coli.

Abstract third-party references: Scientific Council for Complex Bone and Joint Infections Referral Centers

Background: The French registry for complex bone and joint infections (BJI) was created in 2012 in order to facilitate a homogeneous management of patients presented for multidisciplinary advice in referral centers for BJI, to monitor their activity and to produce epidemiological data. We aimed here to present the genesis and characteristics of this national registry and provide the analysis of its data quality.

Materials/methods: A centralized online secured database gathering the electronic case report forms (eCRF) was filled for every patient presented in multidisciplinary meetings (MM) among the 24 French referral centers. Metrics of this registry were described from 2012 to 2016. Data quality was assessed by comparing essential items from the registry with a controlled dataset extracted from medical charts of a random sample of patients from each center. Internal completeness and consistency were calculated.

Results: From 2012 to 2016, 30,607 presentations in MM were recorded corresponding to 17,748 individual patients, [mean age: 62.1 years, 61.8 % males]. BJI was considered as complex for 63% of cases, and 44% had prosthetic joint infections. The controlled dataset, available for 19 centers, included 283 patients. Global consistency and completeness were estimated at 88.2% and 88.9% respectively considering missing items in the eCRFs as negative results.

Conclusions: This national registry is one of the largest prospective databases on BJI and its acceptable data quality parameters allow further use for epidemiological purposes.

Abstract 8722

**Cabotegravir and bictegravir placental transfers in ex vivo human cotyledon perfusion**

Lucile Pencolé*, Minh-Patrick Le², Florian Bouchet Crivat³, Dominique Duro³, Gilles Peytavin³, Laurent Mandelbrot¹

¹Hôpital Louis Mourier, APHP, Colombes, France, ²Hôpital Bichat, APHP, Paris, France, ³Hopital Bichat, APHP, Paris, France

**Background:** Data on placental transfer is lacking for the most recent HIV integrase inhibitors (INI), bictegravir and cabotegravir. They will inevitably be used in the coming years by pregnant women on antiretroviral therapy, thereby potentially exposing fetuses in utero, without safety data. Our objective was to determine the placental transfer of bictegravir and cabotegravir in the ex vivo human cotyledon perfusion model.

**Materials/methods:** Maternal-to-fetal transfer across the term human placenta was investigated using the open-circuit ex-vivo dually perfused cotyledon model. Cabotegravir or bictegravir was added to a maternal perfusate containing 2 g/liter of human albumin and antipyrine, a marker to validate the cotyledon’s viability. INI tested concentrations were chosen close to post-dose plasma C24h. INI maternal and fetal concentrations were determined using UPLC-MS/MS (LOQ < 5 ng/mL). Median (IQR25-75%) of values are presented.

**Results:** 5 experiments were validated for cabotegravir and 6 for bictegravir. Results are presented in the Table. After 90 min of perfusion, the maternal-to-fetal ratio was 5% (interquartile range, IQR : 5-16) for cabotegravir and 7% (IQR : 6-9.5) for bictegravir. The median cotyledon accumulation index was 4% (IQR : 3-5) for cabotegravir and 4% (IQR : 3-5) for bictegravir.

**Conclusions:** Placental transfer of both cabotegravir and bictegravir was similar and low. This may limit the potential for fetal toxicities, but also be a limit to their usefulness at the time of labor and delivery to reduce the risk of vertical HIV transmission. The safety and efficacy of these new INI in pregnancy require more investigation.

Abstract 8726

**Clostridioides difficile infection in haematological patients: a 14-year experience**

Silvia Noemi Vazquez Cuesta, Agustín Estévez Prieto, Silvia Monsalvo, Laura Villar Gomara, Luis Alcalá, Mercedes Marín, Patricia Muñoz, Emilio Bouza, Elena Reigadas Ramirez

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases, Madrid, Spain, 2Hospital General Universitario Gregorio Marañón, Hematology, Madrid, Spain

**Background:** The hematological population is particularly susceptible to Clostridioides difficile infection (CDI), however little is known about specific risk factors and markers of recurrence and poor evolution. Our objective was precisely to assess the epidemiological, clinical characteristics, and outcome of CDI in hematological patients during a 14 year period in a large teaching hospital.

**Materials/methods:** From January 2006 to September 2019 (ongoing study), all episodes of CDI patients aged > 2 years with hematological disease were prospectively collected in a database (cases). For clinical assessment, all cases were reviewed and 140 controls (hematological patients with C. difficile-negative diarrhea) were randomly selected. Epidemiological and clinical data were collected by reviewing hospital medical records.

**Results:** During the study period, the number of CDI episodes in hematological patients was 162. Patients' median age was 56.0 and 53.7% were male. The most common hematological disease was acute myeloid leukemia (30.9%), followed by Non-Hodgkin lymphoma (25.9%) and acute lymphoid leukemia (9.3%). When compared to controls, independent risk factors for CDI were previous antibiotics (94.4% vs 69.9%; p<0.001) and proton pump inhibitors (PPIs) (60.7% vs 39.3%; p=0.007). Cases had a higher comorbidity index (3.0 (IQR 2-6) vs 2.0 (IQR 2-2); p<0.001), more days of diarrhea (3 [IQR 0.5-7] vs 2 [IQR 1-4]), more abdominal pain (39.1% vs 21.6% p=0.004) and more abdominal distension (11.8% vs 0.0%; p<0.001). Severe CDI accounted for 10.5% and severe complicated CDI for 13.6% of the episodes. Recurrence rate was 14.2% and treatment failure 4.0%. Independent risk factors for R-CDI were female sex (p=0.019) and chemotherapy (p=0.020). Overall 30-day mortality was 5.5% and mortality attributable to CDI was 1.2%.

**Conclusions:** Despite the high susceptibility of hematological patients, the majority of CDI episodes were non severe and mortality due to CDI was low. Independent risk factors for CDI in this population were antibiotics and PPIs and risk factors for R-CDI were female sex and chemotherapy. Diarrhea due to CDI lasted longer, caused more pain and abdominal distension than diarrhea due to other causes in the hematologic population. Mortality rates were similar to those of the hematological population without CDI.

Abstract 8729

Differences in clinical characteristics and prognosis of patients with AmpC-producing Enterobacteriaceae versus Escherichia coli bloodstream infection

Adrian Sousa*, María Teresa Pérez-Rodríguez, Milagros Suárez, Patricia Diéguez, Olalla Lima, Andrea Cabaleiro, Anton Ótero, Francisco Vasallo Vidal, Rebeca Longueira, Ana López-Domínguez, Andrés Nodar, Manuel Crespo

1Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Enterobacter spp, Serratia marcescens and Citrobacter freundii (ESC group) present common characteristics that differentiate them from other Enterobacteriaceae: they are able to produce high levels of AmpC betalactamases in the presence of beta-lactams, trend to select resistant mutants, difficulties in antibiotic treatment and greater morbidity and mortality. The aim of our study was to analyze and compare the clinical, epidemiological and prognostic characteristics of bacteremias produced by ESC group vs. those produced by Escherichia coli.

Materials/methods: This study included all patients over 18 years of age with GNB bacteremia, collected and evaluated prospectively and consecutively in the University Hospital of Vigo between January 1, 2015 and December 31, 2017. They were classified in two groups: Escherichia coli vs ESC bloodstream infections group. The primary outcome was 30-day all-cause mortality.

Results: During the study period we included 287 patients who met eligibility criteria (224 in E.coli group and 63 in ESC group: 37 Enterobacter spp, 16 Serratia marcescens and 10 Citrobacter freundii). Characteristics of both groups patients are shown in Table 1. Overexpression of AmpC betalactamase was present in 20 (32%) of ESC group isolates. Most frequent source of infection was urinary (49%), followed by intraabdominal (25%) and respiratory (10%). Betalactam+betalactam inhibitor was the first choice as empirical treatment (34%), followed by carbapenem (25%) and 3rd G cephalosporin (23%). Inadequate empirical treatment was higher in ESC group [44% vs 22%; p=0.03]. All-cause 30-day mortality was significantly higher in ESC group. In multivariate analysis only septic shock [OR 6.02 [95% CI 1.55-23.35]], Charlson Index>2 [OR 2.50 [95% CI 1.31-4.79]] and urinary source [OR 0.36 [95% CI 0.18-0.74]] were associated with 30-day mortality.

Conclusions: Bloodstream infections due to ESC group affected patients with more comorbidities, cause longer hospital stays, more inadequate empirical treatments and are associated with greater mortality. The only 30-day mortality associated factors were septic shock, higher Charlson Index and a urinary source of infection.

Epidemic *Clostridioides difficile* isolates are significantly more lethal and persist at higher rates than non-epidemic isolates in hamsters following vancomycin treatment

Mark Pulse*, John Vitucci, William Weiss, Jerry Simecka

1UNT Health Science Center, College of Pharmacy, Fort Worth, United States

**Background:** Previous reports have suggested that epidemic *Clostridioides difficile* ribotypes are hypervirulent and that their characteristics can dramatically impact clinical disease. Some evidence has shown that epidemic ribotypes have a higher rate of sporulation than non-epidemic isolates, which is thought play a role in the persistence of *C. difficile* in recurrent infections. Support for this association has largely been investigated *in vitro*, but not *in vivo*. Therefore, studies were conducted in a hamster model of *C. difficile* infection to evaluate the virulence of 13 epidemic and non-epidemic isolates as well as their abilities to persist following vancomycin treatment in the model.

**Materials/methods:** Median lethal dose (LD$_{50}$) studies involved orally infecting male Golden Syrian hamsters with 6 epidemic or 7 non-epidemic isolates in a titer range of 800 to 30,000 spores per isolate, and persistent infection studies involved orally infecting hamsters with ~4.7 log$_{10}$ spores of 2 vancomycin-sensitive epidemic or non-epidemic isolates. Clindamycin (10 mg/kg) was SC administered 24 hours after infection, and for persistent infection studies, vancomycin (20 mg/kg) was orally administered once daily for 5 days starting 18 hours after dosing clindamycin. Feces were daily collected from sterile cages to determine CFU/spore and toxin titers, and survival census was recorded up to 11 days post-infection.

**Results:** Mean LD$_{50}$ values in the hamster CDI model were 3.56 and 3.97 log$_{10}$ spores for epidemic and non-epidemic isolates, respectively, and these values were determined to be significantly different by the extra sum-of-squares F test ($p \leq 0.05$). Mean toxin titers associated with feces collected from epidemic infected hamsters had up to 2-4 times more Toxin A and B within 4 days of infection as compared to hamsters infected with non-epidemic isolates. Epidemic isolates also had increased persistence in hamsters with 3 times more spores remaining in their feces at the end of vancomycin treatment as compared to non-epidemic infected hamsters.

**Conclusions:** These results suggest that epidemic *C. difficile* isolates can persist in the gastrointestinal tract at a higher rate than non-epidemic isolates following treatment, which can lead to higher rates of severe recurrent infections in at risk patients.

Abstract 8731

**Genetic antimicrobial resistance determinants found in Escherichia coli and other environmental microorganisms isolated from raw vegetables expended in Ibarra, Ecuador**

Alejandra Plasencia1, Alejandra Pinto1, Santiago Salazar1, Valeria Olmedo1, Pedro Barba*1

1Universidad Tecnica del Norte “UTN”, Ibarra, Ecuador

**Background:** Antimicrobial resistance has a great concern worldwide. The dynamic of arise and spread of resistance genes must be identified in environmental bacteria to understand its possible implication in clinic.

**Materials/methods:** Six vegetables products were sampled by triplicate in three popular markets in Ibarra – Ecuador (tomato, coriander, parsley, lettuce, celery and pepper). All samples were filtered and cultivated on 3 μg/mL ceftriaxone supplemented MacConkey agar. *Escherichia coli* type- and nontype-colonies were picked out. ESBL doble disc synergy test were performed in all recovered isolates. Specie identity was achieved by MALDI-TOF. *bla_CTX,* *bla_SHV,* *bla_TEM,* *bla_KPC,* *bla_NDM* and *mcr-1* resistance genes variants were identified by PCR and sanger sequencing.

**Results:** 54 vegetables samples were included in the study, 9 of each class. Third generation cephalosporin (3GC) resistant bacteria were observed in 36/54 samples (67%). 54 isolates were recovered. *Acinetobacter calcoaceticus* and *E. coli* were the mayor species identified (23/54 and 20/54 isolates, respectively). *Achromobacter spanius, Rahnella aquatilis* and various species of *Pseudomonas* genera also were found. ESBL phenotypic production was identified in 29 isolates (14/29 isolates were *E. coli*). 6/29 and 4/29 ESBL isolates were *Rahnella aquatilis* and *Achromobacter spanius*, respectively. Ten isolates show the presence of ESBL genes [seven *E. coli* isolates]. The mayor ESBL variant found was *bla_CTX-M-55* [four isolates], following of *bla_CTX-M-65* [two isolates] and *bla_CTX-M-8* [two isolates]. Two isolates showed co-presence of *bla_CTX-M-55* and *bla_CTX-M-65*. Three *Achromobacter spanius* isolates and two *Rahnella aquatilis* showed *bla_KPC*. Two non-*E. coli* isolates also presented *bla_NDM* and *bla_MCR* variants. Two *E. coli* isolates showed the presence of *mcr-1.1*. This variant was also found in *Acinetobacter calcoaceticus* (4 isolates) and *Achromobacter spanius* (3 isolates), and *mcr-1.3* variant was found in *Rahnella aquatilis* (two isolates).

**Conclusions:** This study prove the presence of 3GC resistant microorganism in vegetables spending in Ibarra. *bla_CTX-M-55* and *bla_CTX-M-65* was the mayor ESBL genes found proving the success of this variants in the environment. The presence of *bla_CTX-M-55* and *mcr-1* resistance genes in environmental species alerts us to the importance of environmental resistome study to best antimicrobial resistant dynamics understanding and its implication in the clinic.

Abstract 8739

**Bacteriological profile of urinary tract infection in a rural area in Uganda**

Félix Carrasco*1,2,3, Juan Cuadros2,4, David Roca3, Miguel Górgolas5,6, Ramón Pérez Tanoira5,6

1Hospital Príncipe de Asturias, Alcalá de Henares, Spain, 2Facultad de Medicina, Alcalá de Henares, Spain, 3Fundación El Alto, Vinarós, Spain, 4Hospital Príncipe de Asturias, Madrid, Spain, 5Autonomous University of Madrid, Madrid, Spain, 6Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

**Background:** Urinary tract infections (UTIs) are a frequent cause of infection that are usually managed with broad-spectrum empirical treatments favoring the emergence of antimicrobial resistance. This problem is accentuated in rural areas in developing countries with low accessibility to medicines and lack of a microbiological diagnosis. The aim of this study was to investigate the etiology and antimicrobial susceptibility in UTIs in a rural hospital in northern Uganda.

**Materials/methods:** Prospective study conducted at the Saint Joseph Kitgum hospital (Uganda) between April-June 2019, which includes 139 patients with suspected UTI and who presented leukocyturia. Urine samples were cultured quantitatively according to accepted laboratory procedures. All microorganisms isolated in Uganda were subsequently identified in Spain by MALDI-TOF mass spectrometry. In the field, antibiotic susceptibility was determined for all isolates using the Kirby–Bauer disk diffusion method, according to EUCAST guidelines, and these results were confirmed in Spain using the Becton Dickinson Phoenix M50 device.

**Results:** A total of 102 microorganisms were isolated, of which 94 showed more than $1 \times 10^5$ colony forming units/ml. Two organisms were isolated in three patients. The microorganisms identified were: *Staphilococcus* spp (n=34), *Escherichia coli* (n=28), *Klebsiella pneumoniae* (n=2), *Enterobacter cloacae* (n=2), *Enterococcus* spp (n=21) [ *E. faecalis* (16), *E. faecium* (4), *E. hirae* (1)], *Streptococcus* spp (n=6), *Pseudoglutamicibacter cumminsi* (n=2), *Acinetobacter baumanii* (n=2), *A. junii* (n=1), *Corynebacterium amycolatum* (n=1), *C. coyleae* (n=2) and *Pseudomonas putida* (n=1). High resistance to amoxicillin (66.2%) and ciprofloxacin (44.6%) was found. Nitrofurantoin (9.6%) and Imipenem (2.2%) were the antibiotics with lowest resistance. In 19 of the gram-negative bacteria, high resistance to third generation cephalosporins was found. The resistances obtained in Uganda and Spain have similar values (deviation between 2 and 6%) except in the case of ciprofloxacin (30%).

**Conclusions:** Because of the increased development of resistance, new strategies are needed for the treatment of UTI in rural areas of developing countries. Bacteriological cultures make antibiotic treatment for UTI more specifically and thus more effectively. We found significant levels of antibiotic resistance for the First line of treatment of Uganda (amoxicillin and ciprofloxacin). It is recommended to start using antibiotics such as nitrofurantoin.

Leptospirosis in hospitalised patients in Ambatondrazaka, Madagascar: incident cases and exposure factors

Marine Nadal*,1,2, Vaomalala Raharimanga3, Angela Rahaniraharinivoh1, Niry Rabenindrina4, Zely Anvelo Randriamanantany4, Laurence Randrianasolo5, Eric Cardina1e, Jean-Michel Heraud5, Claudia Filippone6, Cesare Marino7, Pascale Bourhy8, Ines Vigan-Womas4, Hélène Guis5,6, Laurence Baril5

1CHU Tenon, APHP, Paris, France, 2Institut Pasteur de Madagascar, Antananarivo, Madagascar, 3Centre Hospitalier Régional de Référence d’Ambatondrazaka, Ambatondrazaka, Madagascar, 4Unité d’Immunologie des Maladies Infectieuses, Institut Pasteur de Madagascar, Antananarivo, Madagascar, 5Unité d’Épidémiologie et de Recherche Clinique (EPI-RC), Institut Pasteur de Madagascar, Antananarivo, Madagascar, 6CIRAD, UMR ASTRE, Univ Montpellier, Montpellier, France, 7Unité de Virologie, Institut Pasteur de Madagascar, Antananarivo, Madagascar, 8CNR Leptospirose, Unité de Biologie des Spirochètes, Institut Pasteur Paris, Paris, France

Abstract third-party references: Institut Pasteur de Madagascar, Direction Internationale de l’Institut Pasteur, INTERREG FEDER TROI, Fondation Pierre Ledoux Jeunesse Internationale, DP One Health Indian Ocean

Background: Leptospirosis is considered a major public health problem in the Indian Ocean Islands. However, in Madagascar, human seroprevalence studies are contradictory and only 3 confirmed human cases have been reported in the literature.

Materials/methods: The main objective of the study was to identify incident cases of leptospirosis among febrile patients over 5 years old hospitalized in the Centre Hospitalier Régional de Référence d’Ambatondrazaka, in Madagascar. Polymerase chain reaction (PCR) on blood and urine were performed at inclusion time as well as IgM- and IgG ELISA, which was repeated 7 to 14 days later. The secondary objective was to identify exposition factors through a matched nested case-control study. Exposition factors were collected through a detailed paper questionnaire.

Results: Between the 25.01.2018 and the 15.03.2019, 323 patients were enrolled in the study. Among them 26 were confirmed cases (based on PCR) and 53 were probable cases (presence of IgM antibodies). Cases (confirmed and probable) presented more consciousness disorders (38% / 25%, p = 0.01) but less fatigue (91% / 98%, p = 0.01) and less clinical signs of hepatic impairment (13% / 23%, p = 0.048). Overall 46% had had prior antibiotherapy and 7% of them died during the study. Rainy season (OR = 1.8; 95% CI = [1.05-3.01]) and farming (OR = 1.99; 95% CI = [1.33-1.48]) were positively associated with leptospirosis, whereas exposition to cattle (OR = 0.4; IC 95% = [0.24-0.69]) and a higher level of education (OR = 0.58; 95% CI = [0.36-0.96]) were negatively associated with it.

Conclusions: We show for the first time the heavy burden of leptospirosis in Madagascar. The awaited results on circulating strains (currently being identified) should help improve knowledge on animal reservoirs and will enable, if necessary, to reassess performances of diagnostic tests used in Madagascar in order to develop better control strategies for the disease.

**Rapid MALDI-TOF MS-based method for vancomycin-resistant *Enterococcus faecium* detection**

Ana Candela*, Lidia Quiroga, Manuel Arroyo, Emilia Cercenado, Gema Méndez, Mercedes Marín, Patricia Muñoz, Luis Mancera Pascual, Belen Rodriguez-Sanchez, Gema Méndez, Mercedes Marín, Patricia Muñoz, Luis Mancera Pascual, Belen Rodriguez-Sanchez.

1Hospital General Universitario Gregorio Marañón, Clinical Microbiology and Infectious Diseases Department, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3Clover Bioanalytical Software, Urbanización los Vergeles, Spain, 4CIBER de Enfermedades Respiratorias (CIBERES CB06/06/0058), Madrid, Spain, 5Complutense University of Madrid, Medicine Department, School of Medicine, Madrid, Spain

**Abstract third-party references**: European Union’s Horizon 2020 research and innovation programme under grant agreement No 868365

**Background**: *Enterococcus faecium* is increasingly becoming a nosocomial threat due to its ability to rapidly spread and cause outbreaks in hospital settings. Recently, q vancomycin resistance on *E. faecium* has been on the rise and that is the reason why *E. faecium* is included in the ESKAPE group for highly resistant microorganisms. The main objective of this study was to develop a MALDI-TOF MS based method of analysis of *E. faecium* clinical strains that could differentiate vancomycin-resistant (VRE) from vancomycin-susceptible (VSE) Enterococci.

**Materials/methods**: A total of 140 strains were included in this study (82 susceptible, 27 vanA strains and 31 vanB strains, all confirmed by molecular methods) and cultured overnight in Columbia agar.

In order to assay the reproducibility of the MALDI-TOF-based method, each isolate was analyzed in duplicates and each spot was read twice. This approach was performed during 3 consecutive days, yielding a total of 12 spectra in the range of 3.000 to 10.000 Da.

Protein spectra were analyzed by Clover Bacterial Analysis software (Clover Biosoft, Spain). All spectra were preprocessed by a pipeline of a) baseline subtraction using Top-Hat filter, b) smoothing via Savitzky-Golay filter, c) peak alignment and d) TIC normalization. Finally, 30 PLS-DA (Partial Least Squares Discriminant Analysis) was applied to discriminate the different groups of isolates.

**Results**: The implementation of PLS-DA to protein spectra allowed the correct classification of 75/82 susceptible and 27/31 vanB *E. faecium* isolates. The total accuracy of the assay was 91.15% (Figure 1). Besides, *E. faecium* vanA isolates could be correctly differentiated from *E. faecium* vanB isolates in 93.1% of the cases.

**Conclusions**: The developed method has shown its ability to correctly differentiate above 90% of the *E. faecium* vanB isolates from the VSE analyzed. A PLS-DA-based algorithm for the discrimination of *E. faecium* vanB vs. VRE isolates is proposed as a first step, followed by vanA vs vanB discrimination. Although further studies are needed in order to demonstrate its usefulness in a clinical setting, MALDI-TOF could be a promising way for rapid detection of VRE in laboratory routine detection of resistance mechanisms.

**Presenter email address**: ana.acg93@hotmail.com
A case of cystic hydatid disease acquired in Ireland
Conor Grant*,1, Caroline Conlon1, Catherine Fleming2, Helen Tuite1, Eoin Slattery1
1Galway University Hospital, Galway, Ireland

Background: Cystic hydatid disease is caused by the cestode Echinococcus granulosus. Humans are infected by ingesting eggs released in the faeces of infected dogs. The liver or lungs are most frequently affected. Treatment depends on the WHO stage as determined on ultrasonography. A ‘watch and wait’ approach is recommended for late-stage, calcified cysts. Hydatid disease is not thought to be endemic in Ireland.

Case Report: In January 2019, an 86 year old female presented to Galway University Hospital with a three-day history of right upper quadrant pain and vomiting. She was a sheep farmer and had never travelled outside Ireland.

Two years previously, a CT scan had identified an 11.6x9.2x11.4cm cystic lesion in the right lobe of the liver with a calcified rim consistent with a hydatid cyst. Given the patient’s frailty, and following the WHO guidelines, a ‘watch and wait’ management approach had been adopted.

On admission she was stable and apyretic. Laboratory investigations revealed a neutrophilia, normal eosinophil count and elevated C-reactive protein. A CT scan demonstrated a ruptured hydatid cyst and right sided pleural effusion.

The patient was reviewed by the Infectious Diseases team. Albendazole 400mg, orally, twice daily was commenced initially and then Praziquantel added. She was deemed unfit for surgical intervention. Over the following weeks the pleural effusion increased in size and the patient clinically deteriorated. The input of Palliative Care was sought and the patient died 6 weeks following admission. Hydatid serology sent early in the admission was negative.

Conclusions: We describe the first reported case of cystic hydatid disease acquired in Ireland. The two previously reported Irish cases had travelled to areas of high prevalence. The late disease stage suggests a previously unrecognised endemicity of E. granulosus, rather than recent spread to the island.

Hydatid serology was negative, despite characteristic radiological findings. However, hydatid serology is known to be poorly sensitive, especially in late disease.

At diagnosis, in light of her WHO stage, surgical management was not pursued. Our patient then presented with a ruptured cyst - a described complication. More research is necessary to determine the limits of the ‘watch and wait’ approach.

Risk factor for nosocomial and surgical site infection after cardiac surgery

María Teresa Pérez-Rodríguez*, Bruno Vilas1, Adrian Sousa1, Julio César Lugo1, Miguel Pereira1, André Nodar1, Rebeca Longueira1, Víctor Del Campo1, Juan José Legarra1, Manuel Crespo1

1Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Infection in patients after cardiac surgery is one of the most severe complications. In 2005 Fowler et al elaborated a score to identify patients with higher risk for major infections. In the last years, bilateral internal mammary artery (BIMA) has been associated with enhanced overall long-term outcome, compared with single internal mammary artery. However, BIMA has also related to a higher risk of surgical site infection. The aim of the study was analyzed the impact of BIMA in the outcome of infection after cardiac surgery.

Materials/methods: Adult patients undergoing cardiac surgery between February 1st and December 31st 2018 were prospectively included. Clinical characteristics of patients, hospital stay before surgery, type of intervention (urgent/elective, revascularization/valve surgery), time on-pump were gathered. The incidence of any kind of infection was collected. Differences between patients with and without infection were analyzed.

Results: Ninety-three patients were identified, 14 (15%) suffered a nosocomial infection: 7 respiratory infection, 6 surgical site infection and 1 urinary tract infection.

Fowler index >= 14 was associated in multivariable analysis with nosocomial infection (OR = 6.8, 95% IC 2.0-23.5, p = 0.002). After studying the different variables included in Fowler index, we found that only arteriopathy (OR = 7.3, 95% CI 1.6-32.4, p = 0.009) and chronic lung diseases (OR = 4.1, 95% IC 1.2-14.8, p = 0.028) were related to a higher risk of infection.

For surgical site infection, Fowler index >= 14 was not associated with higher risk of infection, not in univariable analysis, neither in multivariable analysis. The only factor related to surgical site infection was BIMA (OR = 11.7, 95% IC 1.3-105.4, p = 0.028)

Conclusions: Risk factors for surgical site infection after cardiac surgery were different from those associated with nosocomial infection. BIMA was the most important risk factor for sternal wound infection. In these patients, all preventive infection measures should be implemented in order to reduce the incidence of infection.

**Infectious complications after chimeric antigen receptor modified T cells in adolescent and young adult relapse/refractory B cell precursor acute lymphoblastic leukaemia: report of the French experience**

Florence Rabian*1, Nicolas Boissel2, Matthieu Lafaurie1, Jerome Larghero2, Isabelle Madelaine1, Elie Azoulay2, Jean-Michel Molina2, Blandine Denis2

1Hôpital Saint Louis, Paris, France, 2Hôpital Saint Louis, Paris, France

**Background:** Chimeric antigen receptor T cells (CAR-T) is a promising therapy for patients with relapse/refractory (R/R) B cell precursor acute lymphoblastic leukemia (BCP-ALL). However, this population is at high risk of infectious complications (IC) due to preexisting immunosuppression and CAR-T therapy itself (cytokine released syndrome (CRS), prolonged hypogammaglobulinemia).

**Materials/methods:** Patients treated with Tisagenlecleucel for R/R BCP-ALL in the Adolescent Young Adult Unit (AYA) of Saint-Louis Hospital from July 2018 to July 2019 were included. Data on IC were retrospectively collected. The aim was to describe IC in this population.

**Results:** 21 patients were included (7 women (33.3%), 14 men (66.7%)). Median age was 22 y.o. (18-29). 20 patients received CAR-T for BCP-ALL relapse (median 2nd relapse (1-6)) and one patient for primary refractory disease. 13 patients had a previous history of bone marrow transplantation (61.9%).

6 (28.6%) patients were bridged with immunotherapy. All patients received anti-pneumocystis, antiviral and antifungal prophylaxis. Lymphocytes count was <200/mm3 at D0 for all. 14 patients (66.7%) received G-CSF. Median time until aplasia recovery was 13 days (0; NR). 13 patients (61.9%) developed fever. Median grade of CRS was 2 (1-5). 8 patients (38%) had to be transferred to intensive care unit. 4 patients underwent neurotoxicity (median grade 3 (2-4)). 6 patients received tocilizumab and steroids, 3 of them received siltuximab. Median follow up was 6.2 months.

29 IC were documented. 16 early IC (D0-D30) in 9 patients: 9 bacterial (including 2 clostridium difficile colitis), 1 fungal (aspergillosis), 6 viral (3 CMV reactivation, 1 rotavirus, 1 HHV-6-B and 1 parainfluenzae). 13 late IC (>D30) were diagnosed in 10 patients: 8 bacterial (including bacteriemia to providencia stuartii, pseudomonas aeruginosa, serratia marcescens, enterobacter cloacae, E.Coli), 2 fungal (alternaria, mucor) and 3 viral.

95.2% patients were alive at D30 (1 toxic death); 6 patients died after D30 but not from IC alone (28.6%).

**Conclusions:** BCP-ALL patients receiving CAR-T cells are at high risk of IC. They developed viral reactivation, bacteriemia and invasive fungal infections. Prospective record of these IC is necessary to better understand their incidence and the correlation between CRS and infection.

Abstract 8754

Epidemiology and risk factors for *Clostridioides difficile* at a referral cancer centre in Mexico: a case-control study

Frida Rivera*,1, Daniel De-La-Rosa-Martinez1, Eloisa Rivas-Pichon1, Bertha Garcia-Pineda1, Patricia Cornejo1, Diana Vilar1

1Instituto Nacional De Cancerologia, Ciudad de México, Mexico

Abstract third-party references: Instituto Nacional de Cancerologia

Background: *Clostridioides difficile* infection (CDI) is the most common cause of nosocomial diarrhea. Community onset healthcare facility-associated (CO-HCFA) and community-associated (CA) CDI has increased. Patients with cancer have a higher risk of CDI. We investigated clinical characteristics, and outcomes in patients with CDI at a cancer referral center in Mexico.

Materials/methods: We included patients with cancer and diarrhea between January 2015 and December 2018. Medical records were retrospectively reviewed. Demographics, clinical characteristics, laboratory, outcomes, and 30 day-mortality were recorded. Cancer diagnosis-matched participants were randomly selected as controls. Logistic regression analysis was conducted.

Results: One-hundred and forty-eight CDI cases were reported: 72 (49%), 68 (46%) and 8 (5%) for healthcare facility-onset (HO), CO-HCFA, and CA-CDI, respectively. Seventy-seven (52%) were women; median age 49 years (QR 31.25-61.0). Seventy (47%) patients had a solid neoplasm and 78 (53%) a hematologic malignancy (OR, 0.95; 95% CI, 0.6-1.5; p=0.82). The most frequent symptoms at diagnosis were: abdominal pain 93 (63%), fever 72 (49%), and ≥ 4 diarrheal evacuations (40%). Relapse was observed in 12 patients (8%). Incidence rate of CDI was 0.49 X 1000 patient-days. During the study period an increase on CO-HCFA and CA-CDI was observed (Figure 1). Overall 30-day mortality was 16%; 8 patients with CDI and NAP027 died (4.05%). Risk factors associated with CDI were: the use of previous antibiotics (OR, 3.42; 95% CI, 1.95-6.02; p=<0.001), and proton pump inhibitors (PPI) (OR, 2.16; 95% CI, 1.27-3.70; p=0.005), abdominal pain (OR 2.19; 95% CI, 1.30-3.68; p=0.003), and ≥ 4 episodes of diarrhea/24 h (OR 2.17; 95% CI, 1.27-3.68; p=0.004). According to antibiotic type, quinolones (OR, 2.62; 95% CI, 1.14-6.02; p=0.023) and cephalosporins (OR, 2.19; 95% CI, 1.13-4.28; p=0.21) were related to CDI.

Conclusions: In this cohort the rate of CDI was lower compared to other series. Risk factors were similar to those previously reported in non-cancer patients. The number of CDI increased by almost three times, from 2015 to 2018. The associated mortality was similar to that reported in non-cancer patients.

Abstract 8756

Zika, dengue and chikungunya viruses seroprevalence among adolescents in Brazil
Tainara Melo¹, Marcus Vinicius Dantas Junior¹, Vania Almeida², Thiago Silva², Tauanne Nascimento¹, Luis Porto², Katia Bloch¹, Guilherme Werneck*¹, Gerusa Gibson¹

¹Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, ²State University of Rio de Janeiro, Rio de Janeiro, Brazil

Background: The recent emergence of Zika (ZIKV) and chikungunya (CHIKV) viruses in highly endemic dengue virus (DENV) contexts has posed major challenges for surveillance services in Brazil, particularly due to the overlap of symptoms associated with limited laboratory support. The objective was to describe the serological profile of dengue, Zika and chikungunya infections among adolescents and the association with previous history of dengue infection and yellow fever vaccination.

Materials/methods: Cross-sectional study conducted among adolescents from the Study of Cardiovascular Risk Factors in Adolescents (ERICA), recruited in 2014 and reassessed in 2018. Serum samples were tested for anti-DENV IgG, anti-DENV IgM, anti-ZIKV IgG and anti-CHIKV IgG using a commercial ELISA kit (Euroimmun, Germany).

Results: Seroprevalence in 2018 was 83.4% for dengue, 49.3% for Zika and 15.2% for chikungunya, not varying with age and race. Dengue and Zika seropositivity were more frequently found among young females, while chikungunya seropositivity were more frequent among males. The most frequent serological profiles were adolescents who tested positive for dengue and Zika simultaneously and negative for chikungunya [35.5%], as well as adolescents who tested positive only for dengue [34.1%]. Additionally, 11.5% tested negative and 10.6% tested positive for the three arboviruses. When combined with previous diagnostic reports by these arboviruses, the tests indicated an asymptomatic or oligosymptomatic frequency of 83.1% for dengue, 13.1% for chikungunya, and 45.1% for Zika. Among those who reported anti-yellow fever vaccination, 49% tested positive for Zika, while in the group that reported not being vaccinated, 58% tested positive for this same arbovirus (p=0.351). Dengue seroprevalence in 2014 was 75.7% [IgG], no IgM seropositivity was detected. Previous seropositivity for Dengue [2014] was associated with Zika seroprevalence in 2018 (p=0.011) but not with Chikungunya (p=0.677).

Conclusions: The findings suggest a wide and “silent” circulation of dengue, Zika and Chikungunya viruses, evidenced by the expressive frequency of participants with positive serology without previous diagnosis of acute disease. Associations between previous dengue fever infection and present Zika might indicate cross-reactivity between serological tests. There is a need for studies that seek to better characterize the infection profile of these arboviruses through more accurate diagnostic tests.

Dysbiosis in a triplet with an autism spectrum disorder: a case study

Sabine Hazan*1, Jordan Daniels2, Andreas Papoutsis2

1Ventura Clinical Trials, Ventura, United States, 2ProgenaBiome, Ventura, United States

Background: We present a case of triplets, one diagnosed with an Autism Spectrum Disorder (ASD). While patients with ASD are characterized by deficits in language and social interaction, these are often accompanied by gastrointestinal (GI) symptoms. Approximately half of children with ASD have GI problems as well, and there appears to be a positive correlation in severity of GI symptoms and autistic severity. Trials of vancomycin and fecal microbiota transplant (FMT) have shown that altering the microbiome of the gut has success in improving both GI and ASD symptoms. The purpose of this study was to compare the microbiome of an autistic child with that of the child’s biological siblings and mother, in the hopes of elucidating perturbations possibly associated with ASD.

Materials/methods: Next-generation sequencing was performed on fecal samples from a mother and her 3 siblings, two healthy and one with ASD (Sibling #3). Following stool collection, DNA was then extracted, quantitated, and normalized for downstream library fabrication utilizing shotgun methodology. Prepared and indexed libraries were subsequently pooled and sequenced on the Illumina NextSeq 550 System. Metagenomic readout data was analyzed for relative abundances of defined bacteria and overall microbiome diversity as measured by Shannon index.

Results: The ASD patient (Sibling #3) was found to possess lower Bifidobacteria and Prevotella to the patient’s healthy mother, and overall lower biodiversity as measured by the Shannon Index. Additionally, healthy Sibling #1 was found to have greater bacterial diversity than the mother, more Prevotella and Bifidobacter than Sibling #2.

Conclusions: Our findings demonstrate the role of dysbiosis in ASD, and the utility of microbiome sequencing in order to draw conclusions regarding etiology and potential treatment modalities. Sequencing of the microbiome also presents potential insights in determining the optimal donor for a patient. As highlighted in Figure 1, Sibling #1 has greater microbial diversity and more Bifidobacterium than the mother, and more Prevotella than Sibling #2 and Sibling #3.

Figure 1. Comparative diversity of the gut microbiome of a patient with ASD (Sibling #3) and the patient’s biological siblings and mother.

Correlation between vaginal microbiota diversity and human papilloma virus induced cervical carcinogenesis in population of Santander, Colombia

Laura Melissa Torrado García*1, Bladimiro Rincon-Orozco2, Ruth Aralí Martinez Vega1, Nathalia Jones-Cifuentes1

1Universidad Industrial de Santander - UIS, Universidad Industrial de Santander, Bucaramanga, Colombia, 2Universidad Industrial De Santander, Universidad Industrial de Santander, Bucaramanga, Colombia

Background: Specific composition of vaginal microbiota could predispose of coinfection with Human Papillomavirus (HPV) showing higher risk to progress to dysplasia, therefore require closer follow-up protocols and/or early intervention treatment. Objective: To determine the differences of the vaginal microbiota diversity among women with normal cytology HPV +/-, cervical dysplasia, and cervical cancer.

Materials/methods: Six groups of patients were evaluated according to HPV status and dysplasia degree, the groups were Normal cytology and negative HPV (n = 6), Normal cytology and positive HPV (n = 4), CIN I (n = 6), CIN II (n = 4), CIN III (n = 5), and cervical cancer (n = 3). DNA extraction was performed on samples obtained by cervical brushing. DNA library preparations from V3 and V4 regions of 16S rRNA gene, were performed by using the Nextera XT index kit following ILLUMINA protocols, sequencing of amplicons were carried out in a MiSeq sequencer. The data analysis was fulfil using the MG-RAST on-line server. For taxonomic, phylogenetic and statistical analysis the MEGAN Community, STATA and R software were used.

Results: Three Community State Type (CST) were identified within the samples as follows: normal cytology and negative HPV samples were dominated by CST I composed mainly of *Lactobacillus crispatus* (4/6; 66.6%), normal cytology and positive HPV samples (3/4; 75%), CIN I (3/6; 50%), CIN II (4/4; 100%) and CIN III (3/5; 60%) presented a predominance of CST IV which was characterized by having an abundance of anaerobic microorganisms such as *Prevotella*, *Gardnerella*, *Megasphaera* and others, but only *Megasphaera* presented statistically significant differences (p <0.01) with respect to samples without HPV infection. The CST III depicted an abundance of *Lactobacillus iners*, showed dominance in Cancer samples (2/3; 66.6%) and to a lesser extent in CIN III (2/5; 40%).

Conclusions: HPV infection is related with an increase of microbial richness and diversity present in the vagina. The composition of the vaginal microbiota could play a principal role in the persistent of HPV infection and development of premalignant cervical lesions and cancer progression.

Human milk oligosaccharides exhibit biofilm inhibition and eradication activity against biofilms formed by yeast isolated from cystic fibrosis patients

Sylwia Jarzynka*, Aneta Bialkowska1, Barbara Garczewska3, Ewa Augustynowicz Kopeć3, Gabriela Olędzka1

1Medical University of Warsaw, Poland, Department of Medical Biology, Warszawa, Poland, 2Medical University of Warsaw, Poland, Students Research Group “Agar”, Warszawa, Poland, 3Hospital, National Institute of Tuberculosis and Lung Diseases in Warsaw, Poland, Warsaw, Poland

Abstract third-party references: I submit the abstract on behalf of Sylwia Jarzynka.

Background: Recent years statistically significant increase in the incidence of infections and colonizations caused by Candida species are observed from cystic fibrosis patients. Yeast produce virulence factors, which enable to infect host organism. Ability to form biofilm structure is one of them. Biofilm production is associated with decrease of treatment effectiveness and enhance of antifungal resistance. Research are currently performed to find compounds, which may affect directly on inhibition and eradication of fungal biofilm. Compounds which may become effective are human milk oligosaccharides (HMOs). The aim of this study was evaluation of potential anti-biofilm properties of oligosaccharides isolated from human milk.

Materials/methods: Human milk was obtained from five healthy donors. Milk samples were pooled, next in the skimming milk proteins were precipitated. The oligosaccharides fraction had been cleaned and lyophilized. 25 Candida strains (C. albicans, C. glabrata) were isolated from sputum culture of adult patients suffered from cystic fibrosis. Spectrophotometric method and quantitative method based on multiple dilution were performed for biofilm formation and determine influence of oligosaccharides on biofilm. Measurement of optical density was carried out after staining by crystal violet using microtiter plate. Quantitative method indicated decrease of colony forming unit per mL in dose dependent manner of oligosaccharides.

Results: Differential level of biofilm production was observed in Candida species (p<0.0001). Partial capacity to inhibition was demonstrated by using oligosaccharides isolated from human milk at optimal concentration 20 mg/mL, which was determined as minimal biofilm inhibitory concentration – MBIC (p<0.05). Static influence of oligosaccharides was observed on eradication biofilm produced by Candida strains (p<0.005). The lack of effect of lactose contained in breast milk on the antimicrobial activity of oligosaccharides tested in the experiment was determined.

Conclusions: Human milk oligosaccharides may be natural, easily absorbed potential compounds that inhibit fungal biofilm, enhance the effect of antifungal drugs, or be used in the prophylaxis of fungal infections as oral or inhaled preparations.

Abstract 8764

Genomic characterisation and pathogenicity determination of the classical, hypermucoviscous and hypervirulent Klebsiella pneumoniae isolates in Mexico

Ulises Garza-Ramos*,1, Jonathan Rodríguez-Santiago2, Alan Sagal-Prado2, Jesus Silva-Sanchez2

1Instituto Nacional de Salud Pública, Instituto Nacional de Salud Pública, Cuernavaca, Morelos, Mexico, 2Instituto Nacional de Salud Pública, Instituto Nacional de Salud Pública, Cuernavaca, Mexico

Abstract third-party references: Instituto Nacional de Salud Publica

Background: K. pneumoniae is one of the main pathogens causing hospital-(HAI) and community-(CAI) acquired infections. It is highly resistant to antibiotics and its pathogenicity has increased, which is classified as classical (cKpn) and hypervirulent (hvKpn) K. pneumoniae.

Materials/methods: The species was identified by VITEK and by PCR-multiplex. The hypermucovisosity was determined by string test, virulence factors by PCR, production of extended spectrum ß-lactamases (ESBL) by Kirby-Bauer, carbapenemases by CarbaNP, resistance to colistin by Polymixin-NP. Its pathogenicity was determined in murine model, serum resistance and neutrophil phagocytosis. The genomes were sequenced by Illumina, and phylogenetic analyses were performed and virulome and resistome were determined.

Results: A total of 91.5% of the isolates corresponded to K. pneumoniae, 4.3% to K. quasipneumoniae and 4% to K. variicola. According to the string test and virulence factors it was determined that 91.8% are cKpn, 6.1% [24/392] were classified as hypermucoviscous [hmwKpn] [not hvKpn] and 2% hvKpn. The 3.0% were identified in cKpn with resistant to colistin, which 100% were producers of ESBL, of which 54.5% were also producers of NDM-1 and KPC-2. Both cKpn and hvKpn were sensitive to pathogenicity tests. However, the K. pneumoniae isolates were K1 [1] and K2 [6] and K. quasipneumoniae K1 [1] also showed the hypermucoviscous phenotype and showed resistance to pathogenicity tests. The genomes of the cKpn and hvKpn strains contain a larger number of genes of resistance to antibiotics [resistome] and a smaller number of virulence factors [viruloma]. The virulome of hvKpn is greater and with a smaller resistome, however, 50% of the isolates were producers of ESBL, observing an increase in their resistome. The hvKpn with serotype K1, corresponded to colibactin-producer K. pneumoniae ST23, which genotoxin has been associated with cancer of colon.

Conclusions: The colistin-resistant cKpn are producers of ESBL and / or carbapenemases, being pathogens difficult to treat in HAI. An increase in antibiotic resistance was observed in hvKpn strains, isolated from CAI, however, it was also identified in IAAS. The hvKpn K1 [ST23] is a public health problem in Asian countries and this study describes this clone for the first time in Mexico.

Presenter email address: ulises.garza@insp.mx
Impact of imipenem MIC in the outcome of patients with OXA-48 carbapenem-resistant Klebsiella pneumoniae bacteraemia

María Teresa Pérez-Rodríguez*, Olalla Lima1, Francisco Vasallo Vidal1, Adrián Sousa1, Antonio Pérez-Landeiro1, Patricia Diéguez1, Milagros Suárez1, Rebeca Longueira1, Ana López-Domínguez1, Andrés Nodar1, Manuel Crespo1

1 Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Carbapenem-resistant Enterobacteriaceae are a concerning emerging pathogen around the world. Combination of carbapenem and other active drug is one of the main options in the treatment. Most of the studies are carried out with meropenem, and information about the useful of imipenem is scarce. The objective of the study was analyzed the impact of imipenem MIC in outcome of patients with OXA-48-positive carbapenem-resistant Klebsiella pneumoniae bacteraemia.

Materials/methods: Retrospective study of adult patients with bacteremia due to OXA-48-positive carbapenem-resistant Klebsiella pneumoniae between December 2015 and January 2018. Epidemiologic characteristics, comorbidities, source and severity of infection and clinical outcome were collected. Due to meropenem-MIC was ≥8 µg/ml in all the strains, 1g/6 h in extended perfusion of imipenem was the carbapenem used in treatment. We classified the patients among those which strains has an imipenem-MIC ≤4µg/ml and those with >4µg/ml; comparator were patients treated with ceftazidime-avibactam.

Results: A total of 91 patients with OXA-48-positive carbapenem-resistant K. pneumoniae were identified, 72 were treated with imipenem or ceftazidime-avibactam (28 patients received imipenem ≤4µg/ml, 21 imipenem >4µg/ml and 21 ceftazidime-avibactam). Comorbidity index was high and was similar among the three groups (Charlson index >3; imipenem ≤4µg/ml, 61% vs. imipenem >4µg/ml, 57% vs. ceftazidime-avibactam, 48%, p=0.655), however those on ceftazidime-avibactam and imipenem >4µg/ml groups had less frequently dementia (dementia; imipenem ≤4µg/ml, 29% vs. imipenem >4µg/ml, 4% vs. ceftazidime-avibactam, 5%, p=0.016).

Among patients treated with imipenem ≤4µg/ml, urinary source was the most common (imipenem ≤4µg/ml, 61% vs. imipenem >4µg/ml, 30% vs. ceftazidime-avibactam, 19%, p=0.008). Catheter was the most common source on imipenem >4µg/ml and ceftazidime groups (imipenem ≤4µg/ml, 21% vs. imipenem >4µg/ml, 35% vs. ceftazidime-avibactam, 43%, p=0.265). Combination therapy was used only in patients who received imipenem treatment (imipenem ≤4µg/ml, 82% vs. imipenem >4µg/ml, 91% vs. ceftazidime-avibactam, 0%, p <0.001).

Clinical cure was lower in patients with imipenem-MIC >4µg/ml (imipenem ≤4µg/ml, 75% vs. imipenem >4µg/ml, 61% vs. ceftazidime-avibactam, 95%, p=0.027) and 14-day mortality was lower in patients that received ceftazidime-avibactam (imipenem ≤4µg/ml, 25% vs. imipenem >4µg/ml, 35% vs. ceftazidime-avibactam, 5%, p=0.052)

Conclusions: Imipenem-MIC >4µg/ml was related with a lower clinical cure in patients with OXA-48 carbapenem-resistant bloodstream infection. However, mortality was lower among patients treated with ceftazidime-avibactam regardless of imipenem-MIC of the strains.

Abstract 8767

Outcome of a screening programme for the prevention of neonatal invasive early-onset Group B Streptococcus infection in a maternity unit of the University Hospital “Dr Dragisa Misovic” (Belgrade, Serbia)

Milan Lacković¹, Miloš Gostimirović²*, Sladana Mihajlovic³

¹Belgrade, Hospital for gynecology and obstetrics “Dr Dragisa Misovic”, Belgrade, Serbia, ²Belgrade, Institute of pharmacology, clinical pharmacology and toxicology, Belgrade, Serbia

Background: Group B Streptococcus (GBS) emerged as the leading cause of newborn infection worldwide. In order to reduce burden of GBS disease of a newborn, during 2017 Serbia developed the First National Guideline for the Prevention of perinatal GBS disease. Recommendations from this Guideline suggest antenatal screening for GBS colonization and intrapartum antimicrobial prophylaxis (IAP) to colonized women or applying IAP to all women with certain obstetric risk factors during labor. The aim of this study was to investigate impact of a screening test for GBS in all pregnant women from 35 - 38 gestational weeks, its influence on reducing GBS EOS (early-onset sepsis) among newborns and to compare results before and after bringing recommendations from Guideline into clinical work.

Materials/methods: We conducted an observational, analytic, single-center study at Obstetrics Department of University Hospital “Dr Dragisa Misovic” (Belgrade, Serbia). The screening test for GBS was vaginal rectal swab.

Results: During the period of 2017-2018 in this study were retrospectively included more than 4200 mothers and newborns. Among 2200 newborns, before the implementation of screening test, 4 (2 ‰,) had GBS EOS and 13 (6 ‰) had suspected GBS EOS due to elevated CRP. However, after the GBS screening implementation, no confirmed neonatal GBS EOS was found (0/2157) and 3‰ (7/2157) infants had suspected GBS EOS. Vaginal GBS colonization was found at the 9th month of pregnancy in 22.15% mothers so IAP was administered to all of those women. The antibiotic of choice was Penicillin G (5 million IU + 3 million/4h, iv). Alternative antibiotic was Clindamycin (900 mg/8h, iv). Before the implementation of Guideline all neonates at risk required complete blood count and blood culture followed by a 48-hour period of observation with a standardized physical examination. However, after implementation of Guideline only standardized physical examination was performed.

Conclusions: Identifying high-risk neonates susceptible for development of an early-onset sepsis is a challenge. The ambiguity of clinical presentation can easily be overlooked and result in delayed treatment. In Serbia, universal systematic antibiotic therapy is recommended in all GBS positive mothers which significantly decrease the incidence of an early neonatal GBS infection.

Abstract 8769

The impact of rapid identification of blood culture pathogens by MALDI-TOF MS and their direct antibiotic susceptibilities on antimicrobial stewardship at a large district general hospital, United Kingdom

Nadia Malik*1, Hala Kandil2

1West Hertfordshire Hospital NHS Trust, London, United Kingdom, 2West Hertfordshire Hospital NHS Trust, Watford General Hospital, London, United Kingdom

Background: Matrix Assisted Laser Depolarisation/Ionisation and Time of Flight (MALDI-TOF) identification coupled with direct sensitivities of Blood culture (BC) isolates have revolutionised the management of sepsis.

The aim of this study is to evaluate the usefulness of MALDI-TOF identification and direct susceptibilities on positive blood culture isolates and whether it improves antimicrobial stewardship

Materials/methods: All positive BC were prospectively reviewed on a daily basis over a period of six weeks. Demographics, clinical data and turnaround times of identification of BC pathogens and their sensitivities were collected. The impact of the rapid identification and availability of direct antibiotic susceptibility on antibiotic stewardship and clinical management of these patients were analysed.

Discrepancies between direct and final susceptibilities by phoenix and the impact on patient management were also analysed.

We excluded blood cultures that were not thought to be clinically significant. We also excluded those patients who died before their BC flagged positive, or those that had more than one blood culture for the same infection episode

Results: We included a total of 100 significant blood cultures. Gram negative organisms were isolated in 54%. Urosepsis was identified as the source of infection in 33%, followed by intra-abdominal sepsis in 16%.

Same day MALDI-TOF identification was available in only 5 cases, and the next day for 56 cases. 34/56 could potentially have been identified on the same day and in 50% of these cases this would have impacted on patient management. This could either be due to failure of the organism to grow or delayed subculture.

Direct sensitivities, when available in timely manner, impacted on the advice given in 70% of the cases. Antibiotic susceptibility by phoenix was compared with the direct sensitivity and showed discrepancy in 22% and resulted in change of antibiotic management in 53%.

Conclusions: Rapid identification of BC pathogens has substantial impact on patient management. Further evaluation is needed to ensure processing of positive BC is streamlined to allow earlier identification of isolates. Microbiologists need to be aware of the possibility of discrepancy in susceptibilities while advising on antibiotic management

**Developing a molecular toolbox for *Staphylococcus haemolyticus*: mimicry-by-methylation**
Hermoine Jean Venter¹, Jorunn Pauline Cavanagh¹, Christopher D. Johnston²

¹UiT The Arctic University of Norway, Tromsø, Norway, ²Fred Hutchinson Cancer Research Center, Seattle, United States

**Background:** *Staphylococcus haemolyticus* is common among normal skin flora, yet it is also increasingly common as the cause of nosocomial infections. Knowledge of the causative links between virulent phenotypes and the responsible genes of *S. haemolyticus* in the hospital environment is lacking, as are the molecular tools required to characterize suspected virulence genes. Active restriction modification (RM) systems makes genetic modification challenging in staphylococci. RM systems recognise specific DNA methylation patterns which allow them to detect and destroy incoming foreign DNA.

**Materials/methods:** We are developing a set of molecular tools which circumvent these systems in *S. haemolyticus*. Ten *S. haemolyticus* isolates were selected for Single Molecule Real-Time (SMRT) genome sequencing and methylome analysis. We identified the recognition sequences which undergo methylation in these genomes, as well as the genes responsible for the RM systems associated with these methylation patterns.

**Results:** One of the recognition sequences (GAGG) and its associated methylase gene, a fusion m5C-m6A methylase, was found in 4 of the 10 genomes sequenced. A BLAST search revealed that this methylase gene is also present in 25% of the *S. haemolyticus* genomes in our collection.

**Conclusions:** Expressing this fusion methylase in *E.coli* has allowed us to develop a mimicry-by-methylation tool which increases transformation efficiency in *S. haemolyticus* strains bearing this RM system.

Optimising antimicrobial stewardship: an evaluation of temocillin in the treatment of Gram-negative bacteraemia

Laura Cottom*1, Linda Bagrade1, Raje Dhillon1, Jenna Gillies1, Brian Jones1

1Glasgow Royal Infirmary, Department of Medical Microbiology, Glasgow, United Kingdom

Background: The spread of multi-drug resistant Gram-negative bacteria continues to be an emerging threat to public health worldwide. Gram-negative septicaemia remains an important therapeutic challenge, associated with significant morbidity and mortality. In Scotland alone, a total of 4,738 cases of E.coli bacteraemia were reported for 2018 (rate of 87.3 per 100,000 population). Over the last decade there has been a growing awareness that improvements to stewardship and robust surveillance is needed. Empirical management guidelines should always be interpreted alongside individual patient findings and be guided by local epidemiology and resistance rates.

Temocillin (6-α-methoxy-ticarcillin) is an attractive carbapenem ‘sparing’ agent for the treatment of Enterobacterales bloodstream infections (BSI), being resistant to most extended-spectrum β-lactamases and AmpC enzymes. The aim of this study was to evaluate the utility of temocillin in the treatment of BSI and assess clinical outcome.

Materials/methods: A retrospective analysis was performed over 6 months (September to February 2019). Data was analysed from five large university teaching hospitals within Greater Glasgow and Clyde, the largest NHS organisation in the UK serving a population of 1.2 million. Only cases were the patient had been actively treated were included for analysis. The source of infection and management was reviewed for each case. The 30-day, 90-day and all-cause mortality rate were determined for the study population.

Results: A total of 468 patients were identified, of these 42% received temocillin as primary targeted treatment (first month; September 2018 n=86). In 56% of cases the patient had a urinary tract source. 34% of cases were related to an intra-abdominal infection. E.coli was the most common pathogen isolated (56%). Less than 3% of all isolates tested temocillin resistant; 8% tested piperacillin-tazobactam (tazocin) resistant and 10% tested gentamicin resistant in vitro (either on disc diffusion testing or Vitek AST testing). When comparing 30-day mortality, no statistically significant difference in mortality was found using Chi-Square calculation when comparing temocillin as primary therapy.

Conclusions: Our study provides a valuable evaluation of the utility of temocillin in the management of BSI and supports the importance of effective surveillance to promote stewardship and the judicious use of antimicrobial agents.

Abstract 8772

Genomic epidemiology of paediatric invasive Group A Streptococcus infections in British Columbia, Canada
Inna Sekirov*1, Walter Demczuk2, Irene Martin1, Samara David3, Monika Naus3, Jocelyn Srigley4, Linda Hoang1

1University of British Columbia, BC Center for Disease Control Public Health Laboratory, Vancouver, Canada, 2Public Health Agency of Canada, National Microbiology Laboratory, Winnipeg, Canada, 3University of British Columbia, BC Center for Disease Control, Vancouver, Canada, 4University of British Columbia, BC Children’s and Women’s Hospital, Vancouver, Canada

Background: Group A Streptococcus can cause invasive infections (iGAS) with significant morbidity and mortality. In recent years there has been a rise of iGAS incidence in Canada overall, as well as in the province of British Columbia (BC). iGAS of emm1 type was overrepresented in BC children, notably rising between 2015 and 2017. iGAS cases of emm1 type were more likely to have a severe presentation than other emm types. Whole genome sequencing (WGS) was used to evaluate the relatedness and potential transmission dynamics of pediatric emm1 iGAS isolates, with a focus on cases admitted to the BC Children’s Hospital.

Materials/methods: All iGAS isolates in BC are sent to the National Microbiology Laboratory (NML) for typing. A subset of pediatric emm1 cases diagnosed between 2010 and 2017 was identified for WGS (n=23), along with a selection of contemporaneous adult emm1 iGAS cases for “background” comparison (n=29). All isolates were sequenced using MiSeq Illumina technology. Sequences were analyzed for phylogenetic relatedness using SNVPhyl pipeline with the oldest strain in the dataset as a reference strain. A total of 70 sites were used to construct the phylogeny, using 86.2% of the core genome. Strains were analyzed for the presence of antimicrobial resistance (AMR) genes using an AMR detection pipeline (RGI and StarAMR tools), with results compared to those of phenotypic AMR testing.

Results: BC iGAS emm1 isolates were a heterogeneous population. No significant clustering of pediatric emm1 iGAS isolates was observed. Several small clusters (2-4 isolates) of 0 to 3 single nucleotide variants (SNVs) apart were seen. Some of these clustered in space and time and in one case represented a known epidemiologically linked pair. Others, despite close phylogenetic relatedness, were isolated in different BC regions, months to years apart. Only 3 strains carried AMR genes (ermB and tetM). There was phenotypic confirmation of erythromycin resistance but phenotypic tetracycline resistance testing was not done.

Conclusions: Despite over-representation of emm1 type among pediatric iGAS cases in BC there was no evidence of a unique emergent pediatric strain in circulation. WGS could be used to confirm strain relatedness of epidemiologically linked cases.

Abstract 8773

Implementation of a full-length HIV-1 NGS assay into clinical diagnostics

Judith Heaney*, R. Bridget Ferns1, Matthew Byott1, Paul Grant1,2, Ana Garcia2, Stuart Kirk1, Clare Booth1, Jade Raffle1, Maria Paraskevopoulou1, Tabitha Mahungu2, Zisis Kozlakidis1, Dan Frampton2, Deenan Pillay2, Eleni Nastouli1

1University College London Hospitals NHS Foundation Trust, Advanced Pathogen Diagnostic Unit, London, United Kingdom, 2University College London, Department of Infection, Division of Infection and Immunity, London, United Kingdom, 3Health Services Laboratories, London, United Kingdom, 4University College London Hospitals NHS Foundation Trust, London, United Kingdom, 5Royal Free London NHS Foundation Trust, London, United Kingdom, 6World Health Organisation, International Agency for Research on Cancer (IARC), Lyon, France, 7University College London, Division of Infection and Immunity, London, United Kingdom, 8University College London, Institute for Child Health, London, United Kingdom

Background: New anti-retroviral treatment regimens targeting previously un-sequenced regions of HIV-1 have necessitated the development of whole genome next generation sequencing (NGS) strategies. These allow in-depth analysis of HIV-1 viral genomes and quasispecies in a rapid, yet cost effective manner. While Sanger sequencing remains the gold standard for HIV-1 drug resistance testing for treatment-naïve patients and for monitoring drug resistance mutations following anti-retroviral treatment (ART), it is limited by the non-detection of resistance-associated mutations (RAMs) with prevalence below 20%. The high coverage and depth of sequencing achievable with NGS allows for the detection of minor variants (MVs) at very low level. However, larger datasets are required to evaluate the use of MVs as a predictor for virological failure.

Materials/methods: Almost full-length HIV-1 amplification was achieved using a four RT-PCR method spanning ~600 – ~9000 nucleotides of the viral genome (HXB2). For NGS, 10µl of pooled amplicon was utilized with the Nextera® FLEX library preparation kit and sequencing performed on a MiSeq using the V2 reagent kit with 500 cycles. Analysis was with an in-house de novo assembly pipeline using an Iterative VirusAssembler (IVA). Drug resistance and virus tropism predictions (20% and 5% frequency) were made using the Stanford database (https://hivdb.stanford.edu/) and Geno2Pheno web service (http://coreceptor.geno2pheno.org/) respectively and compared with the Sanger sequencing data.

Results: At 20% frequency, almost complete concordance was observed between Sanger and NGS RAM predictions of both clinical samples (100) and multiple external quality assurance (EQA) schemes. Good coverage of all HIV-1 major subtypes was observed with a median read depth of ~1000 at viral loads as low as 1000 copies/ml. As expected, additional RAMs were predicted at 5% minor variant threshold.

Conclusions: It is now becoming cost effective and practical to introduce HIV-1 NGS into clinical service. Further, new and emerging ART treatments target regions of the viral genome often not included with current targeted sequencing approaches, highlighting the advantage of incorporating NGS in diagnostic practice. However, the critical question remains: “what is the clinical significance of additional read depth achieved with HIV-1 NGS and can the results generated predict treatment outcomes and guide patient management?”

**Should we change our diagnostic strategy for the detection of verotoxigenic *Escherichia coli* infection?**

Soledad Illescas*1,2, Sergio Sánchez3, Victoria Carmona2, José Martínez-Alarcon1, María Dolors Vidal2,4

1Hospital General Universitario de Ciudad Real, Ciudad Real, Spain, 2Área de Microbiología, Facultad de Medicina, UCLM, Ciudad Real, Spain, 3Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain, 4Grupo Emas. Centro Regional de Investigaciones Biomédicas (CRIB), Albacete, Spain

**Background:** Shiga toxin-producing *Escherichia coli* (STEC) have emerged within foodborne pathogens in developed countries. STEC can cause bloody diarrhoea and the life-threatening haemolytic-uremic syndrome. In Spain, STEC infection is a notifiable disease since 2015, but the notification rate seems to be still very low. Since 2013 we have included in our Microbiology Service a new protocol to analyze specifically for STEC in suspected cases. The aims of this study are: (i) to determine the role of STEC as etiological agents of bacterial gastroenteritis in two cross-sectional sampling in 2016, and (ii) to assess if our internal protocol established since 2013 can detect STEC cases that are not specifically requested.

**Materials/methods:** (i) To know role of STEC as etiological agents of gastroenteritis, 223 faecal cultures from July and December 2016 were analyzed by streak culture in MacConkey agar and subsequent molecular detection of the *stx1* and *stx2* genes. (ii) Between 2013 and October 2019, 394 faecal cultures on MacConkey agar originating from suspected cases or specific requests for STEC were sent to the National Center for Microbiology for the detection of the main diarrhoeagenic pathotypes of *E. coli* by molecular testing of their respective virulence genes.

**Results:** The relative importance of STEC infection was low (1/223; 0.4%), since only one sample was *stx*-positive (*stx1*). From suspected cases, 14% (52/394) were positive for any diarrhoeagenic pathotype, with STEC being present in 21% of positives (Figure 1). Half of the isolates belonged to the enterohaemorrhagic serotype O157:H7. Only 9% of positive cases for STEC had been expressly requested by the clinicians.

**Conclusions:** STEC is not a common cause of gastroenteritis in our area. From suspected samples, other pathotypes have been detected more frequently than STEC. Since 2013, almost 90% of the positive cases have been detected due to our protocol, thus increasing the total number of STEC that should be notified.

**Figure 1.** Diarrhoeagenic pathotypes of *E. coli* detected among STEC suspected cases of gastroenteritis [aEPEC: atypical enteropathogenic *E. coli*, EAEC: enteraggregative *E. coli*, EIEC: enteroinvasive *E. coli*, Others include mixed infections such as aEPEC with EAEC or enterotoxigenic *E. coli*].

Abstract 8783

Contribution of vaginal culture to predict early-onset neonatal infection in case of preterm premature rupture of membrane before 34 weeks’ gestation

Imane Ben M. Barek, Kankoe Sallah, Luce Landraud, Marion Schneider, Camille Couffignal, Luc Desfrère, Laurent Mandelbrot

1Hopital Louis Mourier, APHP, Colombes, France, 2Hopital Bichat, APHP, Paris, France

Background: Preterm Premature Rupture of Membrane (PPROM) is a major cause of morbidity and mortality for the mother and neonate. The vaginal microbial profile in PPROM is poorly known, particularly regarding the risk of early-onset neonatal infection (EONI), which is of importance for antibiotic prophylaxis. Our objective was to determine clinical and microbiological risk factors for EONI in case of PPROM before 34 weeks’ gestation (WG).

Materials/methods: A single center, retrospective cohort study. Patients with PPROM before 34 WG from 2008 to 2016 were categorized according to outcome in 2 groups, with or without EONI. The primary outcome was to determine if a positive endocervical culture was associated with EONI. Secondary outcomes were the association between EONI and vaginal dysbiosis (lack of lactobacilli), between EONI and histopathological chorioamnionitis and the correlation between pathogens including Group B Streptococci (GBS) and E. Coli in maternal vaginal swabs and in neonates with EONI.

Results: 268 patients were included, 39 in the EONI group and 229 in the non-EONI. The prevalence of EONI in our population of PPROM before 34 WG was 14.5 %. The endocervical culture was positive for 16.9% at admission and 24.8% at delivery, with no difference between the groups. The presence of lactobacilli was higher in the non-EONI than in the EONI group at time of rupture (74.4% vs 52.94; p=0.01) and at time of delivery (41.57% vs 10.71%; p<0.001), whereas clinical chorioamnionitis was more frequent in the EONI than in the non-EONI group (94.7% vs 38.8%, p<0.001). After adjustment, a vaginal flora rich in lactobacilli before delivery tended to be protective against EONI (OR=0.21, 95% CI 0.04, 1.02, p=0.03), while clinical chorioamnionitis was significantly higher in EONI (OR=5.22, 95% CI 1.5, 18.19, p<0.01). We found no statistically significant concordance between the maternal microbiological samples and the neonatal samples.

Conclusions: The presence of lactobacilli in the vagina was protective for neonatal infection in PPROM, but the presence of pathogenic bacteria at admission and at delivery was not predictive of EONI in this study. Clinical evidence of intra-uterine infection had the strongest association with EONI.

A Monte Carlo simulation modelling meropenem bolus to prolonged infusion dosing and expected suppression of resistance in *Pseudomonas aeruginosa*

Sarah Moore*1, Michael Kays2, Christian Cheatham3

1Norton Hospital, Louisville, United States, 2Purdue University, Indianapolis, United States, 3Franciscan Health Indianapolis, Indianapolis, United States

**Background:** Previous in vitro data indicates a meropenem trough concentration of 6.2 times the minimum inhibitory concentration (x MIC) could suppress resistance development in *Pseudomonas aeruginosa*. The same effect was seen at a trough 1.7 x MIC when meropenem was used in combination with tobramycin.

**Materials/methods:** This Monte Carlo simulation in 5000 patients utilized pharmacokinetic profiles from 49 patients, studied in 3 cohorts: non-obese patients (<120 kg), obese non-critically ill patients (≥120 kg) and obese critically ill patients (≥120 kg). Bolus doses ranged from 250-1000 mg paired with infusion doses ranging from 500-1500 mg. Boluses were modeled over 5, 15 and 30 minutes and bolus plus infusion time totaled 3 hours. All doses were modeled on 8-hour intervals. Outcomes included probability of target attainment (PTA) trough concentrations 6.2 x MIC and 1.7 x MIC at both first dose (FD) and steady state (SS).

**Results:** In the three cohorts, all doses in achieved >90% PTA trough 1.7x MIC at both FD and SS for MICs of 0.25 mg/L or lower. In the <120 kg and ≥120 kg non-critically ill groups, >90% PTA trough 6.2 x MIC was achieved at both FD and SS at an MIC 0.25 mg/L for all doses with the exception of 500mg/500mg. In the ≥120kg critically-ill group, >90% PTA trough 6.2 x MIC was achieved at 0.125 mg/L consistently with only certain doses achieving the same target for higher MICs. PTA 6.2 x MIC=2mg/L was consistently <90% in all three cohorts, but PTA >90% was achievable for 1.7 x MIC=2mg/L in the non-obese and obese non-critically ill patients with a 500/1500 mg dose at SS.

**Conclusions:** Given global concerns over multi-drug resistant *P. aeruginosa*, exploring strategies that may suppress resistance development could prove useful. Additional data is needed to determine if meropenem BPI is a safe and effective treatment modality.

**Background:** Linezolid is an oxazolidinones antibiotic, indicated for treatment of infections caused by multidrug-resistant gram-positive organisms. Resistance to linezolid is unusual, but it is being observed an increase in the number of cases of linezolid-resistant Staphylococcus spp. worldwide. The most common linezolid resistance mechanism is consequence of a single mutation G2576T in 23S ribosomal ribonucleic acid (rRNA).

**Materials/methods:** Between March-May/2019, linezolid-resistant coagulase-negative Staphylococcus spp. (CoNS) isolated from blood cultures in a microbiology lab that perform 8,000 blood cultures/month from 33 private hospitals, in Sao Paulo, Brazil, were selected. The species were identified by mass spectrometry using Vitek MS (Biomerieux, France) and resistance to linezolid, based on minimal inhibitory concentration (MIC), was detected by Vitek2 (Biomerieux, France) and confirmed by diffusion-gradient method E-test (Biomerieux, France), using European Committee on Antimicrobial Susceptibility Testing (EUCAST) criteria. All isolates were submitted to Pulsed Field Gel Electrophoresis (PFGE) for clonality analysis and polymerase chain reaction (PCR) for 23S rRNA to detect G2576T mutation were performed. PFGE’s clonal pattern was defined as >=95.0% of similarity.

**Results:** Ten *Staphylococcus epidermidis* and seven *Staphylococcus capitis* linezolid-resistant isolates were identified on blood cultures from patients of six hospitals (linezolid MIC range: 1 2-64mg/L *S. epidermidis* and 1 2-48mg/L *S. capitis*). Among *S. epidermidis*, G2576T mutation was detected by PCR in six isolates (60.0%), whereas it was detected in all *S. capitis* isolates (Figure). One clone was found among *S. epidermidis*, involving seven isolates from a same hospital (clone A), as well as three *S. capitis* isolates from the same hospital and one from another hospital that belonged to the same clone named clone B (Figure).

**Conclusions:** Despite its low frequency, resistance to linezolid is being observed in CoNS isolates. We have observed that most *S. epidermidis* had G2576T mutation not detected by PCR, suggesting that other mechanisms might be the reason for linezolid resistance. The clonal pattern detected by PFGE involving *S. epidermidis* and *S. capitis* isolates from the same hospital suggest a common source of infection and the possibility of a resistance mechanism transmission between species.

**Figure.** PFGE clonality analysis and characteristics of samples. Up: *Staphylococcus epidermidis*. Down: *Staphylococcus capitis*.

Rapid detection of *Mycobacterium abscessus* complex and associated antibiotic resistance directly in cystic fibrosis samples

Amanda Bordin, Chris Coulter, Julia Clark, Sushil Pandey, Scott Bell, Claire Wainwright, Graeme Robert Nimmo, Amy Jennison, Melanie Syrmis, Carolyn Pardo, Hazel Hackett, David Whiley

The University of Queensland, University of Queensland Centre for Clinical Research, Herston, Australia, Pathology Queensland, Queensland Mycobacterium Reference Laboratory, Herston, Australia, Queensland Children’s Hospital, Infection Management and Prevention Service, South Brisbane, Australia, The University of Queensland, Faculty of Medicine, Herston, Australia, The Prince Charles Hospital, Department of Thoracic Medicine, Chermside, Australia, QIMR Berghofer Medical Research Institute, Herston, Australia, Queensland Children’s Hospital, Respiratory and Sleep Medicine, South Brisbane, Australia, Pathology Queensland, Central Laboratory, Herston, Australia, Queensland Health, Forensic and Scientific Services, Coopers Plains, Australia

**Background:** *Mycobacterium abscessus*, a bacterium closely related to the causative agent of tuberculosis, is of growing clinical concern. While *M. abscessus* can be found in the environment, it can cause life-threatening infections in certain susceptible populations. For example, chronic respiratory *M. abscessus* infections in people with Cystic Fibrosis (CF) are associated with more severe respiratory symptoms and accelerated declines in lung function.

Despite disappointing success rates due to extreme antimicrobial resistance (AMR), current best therapy involves intensive and long courses of multiple antimicrobials. A key laboratory process is to generate macrolide and amikacin AMR profiles, as treatment guidelines differ for *M. abscessus* infections that demonstrate acquired AMR against these antibiotics. Current methods for detection of *M. abscessus* and AMR are dependent on culture, which have limitations including long turnaround times, a tendency to be overgrown by other bacteria, and a limited capacity to detect infections with mixed resistance. As these limitations can impede effective and timely treatment, rapid culture-independent methods for *M. abscessus* detection and AMR characterisation are needed.

**Materials/methods:** We developed PCR-based methods for *M. abscessus* detection and characterisation of key macrolide and amikacin acquired resistance mechanisms. These PCR methods were applied to clinical respiratory samples (over 900 CF samples to date). PCR results were compared to gold-standard bacterial culture methods.

**Results:** Compared to culture, the *M. abscessus* detection assay’s sensitivity was 83.8% and specificity was 97.8%. Direct AMR characterisation results were concordant for most samples where both culture and PCR results were available. Discordant results were due to samples where PCR detected a mix of resistant and susceptible strains, whereas the cultured organism was susceptible-only. PCR results were generated the day after sample receipt, compared to the 2-3 weeks generally required for culture.

**Conclusions:** Molecular methods can detect most *M. abscessus* infections in CF and characterise associated AMR, and have the potential as an adjunct to culture to rapidly inform treatment. Notably, >80% of positive patients could have clinically-informative macrolide and amikacin AMR information within hours by PCR compared to weeks by culture. Potential implications of the mixed AMR samples remain to be explored, and investigations are ongoing.

Abstract 8794

Prevalence and outcome of Clostridioides difficile infection in a multi-centre study in Southern Brazil
Adriane Maestri1, Sonia Raboni1, Hugo Manuel Paz Morales1, Leonardo Ferrari1, Felipe Tuon1,2, Alexandre Losso1, Camila Marcon1, Keite Nogueira*1,3
1Complexo Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil, 2Laboratory of Emerging Infectious Diseases (LEID), Pontifícia Universidade do Paraná, Curitiba, Brazil, 3Departamento de Patologia Básica, Universidade Federal do Paraná, Curitiba, Brazil

Abstract third-party references: Fundação Araucária-PR / SESA-PR / CNPq / MS-Decit

Background: Clostridioides difficile is the main cause of antimicrobial associate diarrhea and a frequent health-care associate infection. C. difficile infection (CDI) is related to high mortality, severe cases and recurrent infection. In Brazil few data are available about epidemiology and recurrence of CDI. The aims of this study were to identify the prevalence, clinical characteristics and outcomes of CDI in eight Brazilian Hospitals.

Materials/methods: This was a multicenter prospective cohort which included inpatients presenting diarrhea, older than 18 years, that had used antimicrobials in the last 90 days. The stools samples and clinical baseline dates were obtained by assistance staff. The follow-up clinical data (60 days) and outcome were obtained from medical records. Stools samples was tested using enzymatic immunoassay (EIA) to glutamate dehydrogenase antigen (GDH) and A/B toxins. Positive GDH samples were also evaluated by real time polymerase chain reaction (qPCR) for the presence of genes coding for toxin B (tcdB), binary toxin (cdt), and C. difficile hypervirulent strain marker (tcdC deletion). A case of CDI was defined with a positive test for toxin-producing C. difficile in stool by EIA or qPCR.

Results: During the study, were included 351 patients. Among of them, 62 (17.7%) were defined as CDI. The EIA was GDH and toxin negative for 266 patients, GDH and toxin positives tests for 26 and discordant (GDH positive and toxin negative) for 59 patients. The gene tcdB (toxin B) was detected in 26 samples with toxin positive results and in 36 samples with toxin negative result in EIA. PCR have also detected cdt (binary toxin) genes in ten samples and tcdC deletion (hipervirulent strain trial) in two samples. All patients with CDI have received antimicrobial therapy. Among of them, 52 have presented primary cure and 10 have died with diarrhea symptoms. The outcome was not evaluated in four patients. Among of others, 38 have had general cure and 10 have recurrence of CDI.

Conclusions: C. difficile infection is prevalent in Brazilians hospitals and related to high mortality and recurrence of infection. Detection of tcdC gene deletion warns to risk of hypertoxigenic strains circulation.

Abstract 8796

**Genetic diversity of invasive, non-invasive and colonising Group B Streptococcus isolates in Southern Brazil**

Otto Henrique May-Fuerschutte¹, Eduardo Venancio Alves², Ana Paula Vilela², Fernando Hartmann Barazetti³, Jussara Kasuko Palmeiro⁴, Mara Cristina Scheffer*¹, Maria Luiza Bazzo³

¹Federal University of Santa Catarina Florianópolis Campus Trindade, Federal University Hospital, Florianópolis, Brazil, ²Federal University of Santa Catarina Florianópolis Campus Trindade, Programa de Pós Graduação em Farmácia, Florianópolis, Brazil, ³Federal University of Santa Catarina Florianópolis Campus Trindade, Curso de Graduação em Biologia, Florianópolis, Brazil, ⁴Federal University of Santa Catarina Florianópolis Campus Trindade, Departamento de Análises Clínicas, Florianópolis, Brazil

**Background:** Group B Streptococcus (GBS) remains an important cause of invasive infectious disease. It has increasing among nonpregnant patients, such as young adults with underlying medical conditions, and elderly individuals, due to their ability to persist in different host site. We characterize capsular typing, resistance profile, and genetic relatedness of GBS isolated from outpatient and inpatient in a Brazilian academic care hospital (HU-UFSC).

**Materials/methods:** Three-hundred forty-seven GBS strains were collected between 2015 and 2017. AST was performed using disk-diffusion. PCR was used to detect MLSB resistance genes, capsular types, and hypervirulent GBS adhesion (HvgA). MLVA was carried out to discriminate strains. Isolates with similarity of 60% were considered to belong to the same cluster.

**Results:** GBS isolates were classified as invasive (I), noninvasive (NI), or colonizing (C) strains recovered from neonates, nonpregnant, and pregnant patients. Resistance to erythromycin and clindamycin was 23% and 15.6%, respectively. The *erm*(TR) and *mef*(A/E) genes were widely detected in our GBS isolates (n = 45 and n = 44). The *erm*(B) gene was also detected in some isolates (n = 18). The *erm*(TR) and *mef*(A/E) further *erm*(B) and *mef*(A/B) co-production genes were found. These isolates with MLSB coding genes showed a great diversity of MLSB phenotypic profiles among them: iMLSB, cMLSB and susceptible isolates. We found serotypes Ia (42.4%), V (23.9%), II (12.9%), III (7.5%), Ib (4%), IV (2.3%), and IX (1.4%). HvgA gene was detected only in 16 isolates. Forty-two MLVA types (MTs) were identified considering all the isolates and this result yielded Gaston and Hunter’s diversity indices of 0.879. The most frequent MTs was MT12 (25.4%), MT18 (14.4%), MT4 (12.4%), MT26 (11.8%), MT6 (6.6%), and MT40 (3.2%). The other 36 MLVA types represented 26.2% of the isolates.

**Conclusions:** Isolates sharing the same MT were groups into different serotypes and MLSB resistance determinants. This could be related to the occurrence of capsular and resistance genes switching by genome rearrangement or horizontal transfer genes. These findings revealed a substantial genetic diversity among I, NI, and C GBS strains.

1ICBA, Belgrano, Argentina

**Background:** Surgical site infection (SSI) after median sternotomy is an uncommon complication of cardiovascular surgery. Although infrequent PSM is one of the most serious and feared with a high mortality rate (14-47%) and cost of treatment. Most cases appear after 2nd week following surgery, but a small group can occur in the first 7 days, representing a diagnostic challenge.

**Materials/methods:** To describe PSM´s clinical characteristics, microbiology, medical and surgical management and outcome in a single reference cardiovascular center, an observational, descriptive study was carried out between 6/1988 and 12/2018. All consecutive cases of PSM were prospectively collected in a database and were evaluated and treated by the same surgical and infectious diseases team.

**Results:** A total of 191 PSM cases were registered out of 11,533 surgeries performed (incidence rate: 1.65%); 41/191 (21.46%) were in the first week (early-onset). Mean age: 68 (SD + 16.5); 31 men (75.6%). BMI: 27.35 (SD: + 4.96). DBT 16 (39%), chronic renal failure 5 (12.2%). Previous cardiac surgery 6 (14.64%). Type of surgery: CABG: 19 (46.34%), valve replacement 8 (19.5%), combined 10 (24.4%), heart transplant 2 (4.3%). Clinical presentation: fever: 148 (78%); wound discharge: 25 (61%), erythema 6 (14.6%), sternal instability 9 (21%) and sepsis: 18 (44%). Microbiology: GPC 18 (44%; S. aureus 55.5%), GNB 18 (44%). Blood cultures: 27 positive (65.8%); subxiphoid samples: 33/35 (94.28%). Surgery: 33 underwent open debridement and primary closure. In-hospital mortality: 8 (19.5%).

**Conclusions:** Early onset PSM is an unusual but complex and frequently subtle disease that requires a high index of suspicion to be identified. The clinical manifestations are nonspecific and difficult to interpret because of the proximity of cardiac surgery. Fever being the most frequent symptom, many times is interpreted as of non-infectious origin. It demands combined medical and surgical approach in order to decrease the mortality. Wound [subxiphoid] aspiration is an extremely easy way to perform rapid diagnosis, yielding high microbiology performance. Immediate debridement, drainage and primary closure could be an interesting approach offering short time of hospitalization and a similar mortality to that observed with other strategies.

Abstract 8803

**The emerging non-conventional invasive aspergillosis: 5-year experience**

Marina Machado¹*, Maricela Valerio Minero¹, María Olmedo Samperio¹,², Ana Alvarez-Uria¹,², Elena Reigadas Ramirez¹,², Jesus Guinea Ortega¹,², Antonio Vena¹, Roberto Alonso¹, Almudena Burillo¹, Emilio Bouza Santiago¹,²,³, Patricia Muñoz¹,²,³

¹Gregorio Marañón Hospital, Clinical Microbiology and Infectious Diseases, Madrid, Spain, ²Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, ³CIBERES, Madrid, Spain

**Background:** Invasive aspergillosis (IA) is a recognized cause of morbi-mortality in patients with "classic" immunosuppression (IS) (onco-hematologic or SOT). However, recently, attention has shifted towards new populations at risk. Objective: to describe our large IA series and their main underlying conditions.

**Materials/methods:** Prospective registry of IA cases validated by a multidisciplinary collaboration group (COMIC) in a tertiary centre, according to local and international guidelines. Study period: Oct-2014 and July-2019. A pre-established protocol was fulfilled including demographics, clinical, radiological and microbiological characteristics, antifungal therapy and outcome.

**Results:** During the study period, IA was diagnosed in 93 patients, 81.7% male (7 proven/75 probable/11 possible) in the following wards: medical 52.7%, Haematology 30.1%, ICU 10.8% and surgical 6.5%. Regarding underlying conditions, 41.9% had classic IS – CIS – 32/39 haematological and 7/39 SOT) and 53.8% had non-classic IS – NCIS – (solid organ cancer 18/50, advanced liver disease 16/50, COPD 8/50, advanced HIV 4/50, autoimmune diseases 1/50 and other IS 3/50). 4 patients (4.3%) had no recognized IS.

Differences between NCIS and CIS were: use of corticosteroids (63% vs. 25.6%; p<0.001), neutropenia (3.7% vs. 64.1%; p<0.001), acute liver failure (25.9% vs. 0%; p=0.001), influenza virus infection (18.5% vs. 2.6%; p=0.019), antifungal prophylaxis (1.9% vs. 48.7%; p<0.001) and Charlson comorbidity index [4 (IQR 3-7) vs. 2 (IQR 2-3); p<0.001]. There was no difference in age – 64 (IQR 53-71) vs. 64.5 (IQR 53.5-78) p=0.28. Regarding IA clinical presentation, NCIS had presented with less fever than CIS (51.9% vs. 82.1%; p=0.001) and more Aspergillus fumigatus infection (74.1% vs. 43.6%; p=0.001). The differences between NCIS and CIS in sensitivity of serum galactomannan (GM) were 59.5% vs. 52.2% (p=0.15) in GM-BAL. No significant differences were found in needed ICU admission or septic-shock. Regarding the outcome, no differences in overall mortality (51.9% vs. 53.8%; p=0.85) or IA-related mortality (40.7% vs. 28.2%; p=0.21) were observed.

**Conclusions:** Non-classic immunosuppression is responsible for more than half of IA cases in a recent large series. The prompt recognition of new risk factors is essential for improving the outcome of this severe condition.

Abstract 8804

**Exposure to maternal antiretroviral therapy in utero frequently differs between twins**

Margaux Louchet, Hélène Didelot, Gilles Peytavin, Minh-Patrick Le, Agnès Bourgeois-Moine, Lionel Carbillon, Dominique Luton, Isabelle Matheron, Luc Rigonnot, Laurent Mandelbrot

1Hopital Louis Mourier, APHP Colombes, France; 2Hopital Bichat, APHP, Paris, France; 3Hôpital Jean Verdier, APBP, Colombes, France; 4Hopital de Villeneuve St Georges, Villeneuve St Georges, France; 5Centre Hospitalier du Sud Francilien, Corbeil, France; 6Hopital Louis Mourier, APHP, Colombes, France

**Background:** Placental passage of drugs in twins is poorly understood, and unknown regarding antiretroviral (ARV) therapy. In the event of large differences in the exposure of 2 twins to the same maternal treatment, this could have a clinical impact in terms of prevention of perinatal transmission or adverse effects. Our objective was to describe the frequency of transplacental passage differences between antiretrovirals between twins.

**Materials/methods:** We conducted a retrospective, multicenter study. Samples were taken simultaneously for the 2 fetuses by venipuncture of the umbilical cords after delivery. We considered that a difference in concentrations of more than 50% between twins was a substantial difference (ratios below 0.67 or above 1.50).

**Results:** We analyzed 29 pairs of twins for which the concentration of at least one ARV was available for a twin pair. There were 27 dichorionic and 2 monochorionic diamniotic pregnancies. Cord blood concentrations differed by more than 50% for at least one ARV between the 2 twins in 9 twin pairs, 8 dichorionic and 1 monochorionic diamniotic. Discordant concentrations were observed for several nucleoside reverse transcriptase inhibitors (tenofovir, emtricitabine, lamivudine, zidovudine) and protease inhibitors (atazanavir, lopinavir, saquinavir); within individual twin pairs placental transfer was discordant for one or more ARVs, but identical for others.

**Conclusions:** Concentrations differed in nearly one third of twin pairs. This may be due to both interindividual genetic variability of placental transporters between dizygotic twins and to physiological differences between twins.

Linking the resistome to the microbiome: a culture-free method links plasmid, virus, and antimicrobial resistance genes to their hosts in complex microbial populations

Ivan Liachko*1;1;1
1Phase Genomics, Seattle, United States

Background: The rapid spread of antibiotic resistance is a global health threat. A range of environments have been identified as reservoirs of the antibiotic resistance genes (ARGs) found in pathogens, but we lack understanding of the origins of these ARGs and their spread from environment to clinic. This is partly due to an inability to identify the bacterial hosts of ARGs and the mobile genetic elements that mediate horizontal gene transfer due to the loss of intra-cellular contiguity upon DNA extraction.

Materials/methods: In two recent studies we describe the application of proximity-ligation (Hi-C) methods for the determination of the in situ host range of numerous ARGs, viruses, plasmids, and integrons within complex microbiome samples. This method forms physical junctions between sequences present within the same cell prior to DNA extraction. Subsequent sequencing generates a dataset that robustly connects mobile elements to their hosts and can accurately assemble de novo genomes directly from mixed communities without culturing.

Results: Our application of this technology to highly complex wastewater and rumen samples yielded hundreds of novel ARG-, virus-, and plasmid-host interactions, as well as over a thousand new microbial genomes. In the case of wastewater sample analysis, we assembled >1000 genome clusters and identified >300 ARG-host affiliations from a single sample. In a study analyzing a rumen sample, we used SMRT long read technology as well as Hi-C to detect 188 novel viruses and their host associations. We will also describe other published and upcoming projects applying this technology.

Conclusions: These studies highlight the power of the proximity-ligation approach to deconvolving microbiome samples and foreshadow the development of rapid culture-free strategies for tracking and managing the spread of antimicrobial resistance.

Accuracy of chikungunya case definition in patients with arbovirus illness seeking care in an urban emergency department in Rio de Janeiro, Brazil

Hury Hellen De Paula1, Cristiane Lamas*1,2,3, José Moreira2, Renato Santana De Aguiar4, Sergian Cardozo1

1Unigranrio - Campus I Duque de Caxias, Duque de Caxias, Brazil, 2INI - Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, 3Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil, 4Federal University of Minas Gerais, Belo Horizonte, Brazil

Abstract third-party references: Supported by Faperj.

Background: Chikungunya (CHIKV), dengue and zika share similar clinical features, which makes a clinical diagnosis complex in regions where the three arboviruses co-circulate. We evaluated the accuracy of the World Health Organization’s (WHO) CHIKV case definition against the gold standard of laboratory diagnosis, in individuals with suspicion of arboviral illness seeking care in an urban emergency department (ED) in Rio de Janeiro, Brazil, from January to June 2018.

Materials/methods: A cross-sectional study was conducted enrolling consecutive patients with arbovirus illness without an evident focus of infection. CHIKV RT-PCR and CHIKV IgM serology were performed. Odds ratio (OR) was used as the association measure to identify the clinical features related to CHIKV against the laboratory diagnosis of CHIKV [i.e., defined as either a positive RT-PCR or IgM]. Stepwise logistic regression was done with forwarding selection to identify the best CHIKV prediction model, with a significance level of 5%. The diagnostic accuracy of the WHO CHIKV case definition was evaluated.

Results: A total of 172 subjects were included. The prevalence of CHIKV infection was 110/172 (64%) and 62/172 (36%) had other febrile illnesses. Participants had a mean age of 39 ±15.5 years, females predominated (52.3%), and 65% presented within three days after onset of illness. Among CHIKV-infected patients, 92/172 (53.5%) were positive by RT-PCR and 10.5% only by IgM. CHIKV patients presented much earlier after onset of symptoms (2 vs. 3.5, p= 0.007) and reported most frequently arthritis (61.8% vs. 33.9%, p <0.0001), arthralgia (96.4% vs. 79%, p <0.0001), and conjunctivitis (35.5% vs. 16.1%, p = 0.007) compared to CHIKV-negative subjects, respectively. After adjustments for other clinical predictors, arthritis/arthralgia [aOR: 6 (95%CI 1.8-19.7)] and the presence of conjunctivitis [aOR: 2.3 (95%CI 1.5-2.5)] were positively associated with CHIKV. The sensitivity, specificity, and accuracy of the CHIKV case definition was 85.45% (95% CI 77.46% to 91.45%), 38.71% (95% CI, 26.60% to 51.93%) and 68.6% (61.10% to 75.45%) respectively.

Conclusions: Arthritis/arthralgia and conjunctivitis were positively associated with CHIKV. The current definition for CHIKV had a lower accuracy, in our setting, where other arboviruses co-circulate

Abstract 8813

Antimicrobial susceptibility testing directly from positive blood culture with the Reveal Rapid AST System: clinical results for Gram-negative pathogens

Robert Tibbetts¹, Sheeja George², Paul Rhodes³, Pragya Singh³, Linoj Samuel*¹

¹Henry Ford Health System, Detroit, United States, ²Specific Diagnostics, Mountain View, United States

Background: Obtaining phenotypic antimicrobial susceptibility test (AST) results directly from positive blood culture is of increasing importance with the evolution and spread of drug-resistant blood stream infection. Here we report the first clinical results of the Specific Diagnostics Reveal Rapid AST system on Gram negative patient samples.

Materials/methods: Remnant material from positive clinical monomicrobial Gram negative blood cultures was diluted 1:1000 in Pluronic water and inoculated into MicroScan (Beckman Coulter) dried antibiotic plates, sealed with Specific’s sensor sheet, and placed in the Reveal instrument where it was rocked and incubated at 37°C. Sensor changes above each well were optically monitored to detect the volatile emissions that are a sign of population growth, thereby ascertaining which antimicrobial-containing wells were growing and thus MIC. MIC was compared to that of VITEK2® (bioMérieux) performed after isolate growth. Essential Agreement (EA) was defined as the Reveal and VITEK2 MIC being within one two-fold dilution, while Categorical Agreement was defined as exact agreement in results interpreted according to CLSI clinical breakpoints. The assay determined MIC for all 25 Gram negative antimicrobial agents present on the MicroScan Gram negative plate. The few disagreements between Reveal and VITEK2 will be adjudicated by broth microdilution (BMD) at the end of the study. Experiments were performed in duplicate, with QC strains used to verify Reveal system performance.

Results: Clinical samples with 28 distinct strains tested in duplicate were assayed directly from positive blood cultures, with a total of 74S bug-drug combinations tested, with 16.4% of the assays resistant as assessed by VITEK2 results interpreted with CLSI breakpoints. Using VITEK2 as the reference, Reveal results yielded EA of 97.36% and CA of 95.03%, with no very major errors (VME) for this sample set. discords with VITEK2 will be adjudicated by BMD at the end of the study. Average time to result was 5.7 hours across this highly resistant set of clinical Gram-negative samples.

Conclusions: In this first study with clinical samples, the Reveal Rapid AST system showed excellent agreement in MIC determination compared to VITEK2, providing a preliminary indication of same-shift AST utility in a clinical setting.

**Abstract 8814**

**Evaluation of a urinalysis predictive model and the performance of direct-from-urine susceptibility testing**

Chris Doern*1, Shannon Hedrick2, Lani Matthews3, Alexandra Bryson1, Keighly Bradbrook2, Christopher Jay2, Nickale Taylor1, Adam Sima1, Melissa Jamerson2

1Virginia Commonwealth University Health, Richmond, United States, 2Virginia Commonwealth University, Richmond, United States, 3VCU School of Medicine, Richmond, United States

**Background:** Antimicrobial susceptibility testing (AST) for urinary tract infection (UTI) has an approximately 48 hour turnaround time and as a result, often plays little role in guiding therapeutic decision making. In this study, we investigate an AST method which inoculates disk diffusion (DD) testing directly from urine specimens. Only 30% of urinalysis-positive specimens yield significant growth, thus, performing Direct-AST (D-AST) for all urinalysis positive specimens is a waste of resources for ~70% of specimens. To better predict which patients would benefit from D-AST, we developed a predictive urinalysis model designed to optimize urinalysis specificity.

**Materials/methods:** Specimen inclusion criteria were the following: urinalysis positive and clean catch specimens collected in the Emergency Department. D-AST of cefazolin (CZ), nitrofurantoin (FUR), trimethoprim-sulfamethoxazole (SXT), and ciprofloxacin (CIP) were inoculated to Mueller Hinton (MH) and a MacConkey (MAC) agar on the day of collection. Results were compared to standard of care (SOC) DD. In total, there were 69 evaluable specimens for CZ and NITRO, 39 for CIP, and 42 for SXT.

**Results:** CZ testing yielded an overall categorical agreement (CA) of 95.7% and 98.6% on MH and MAC agars, respectively. FUR testing yielded an overall CA of 95.6% and 92.8% on MH and MAC agars, respectively. SXT testing yielded an overall CA of 95.2% for both MH and MAC agars. CIP testing yielded an overall CA of 97.4% for both MH and MAC agars.

Using this approach, we determined that 78.6% of nitrate positive patients had UTI. Of the nitrate negative patients, 70.0% with >50 WBC’s and numerous bacteria visualized, had UTI. Thus D-AST will only be applied to specimens meeting these criteria.

**Conclusions:** Overall categorical agreement for all antibiotics and all media was >90%. Direct AST yielded VME’s for CZ and FUR. However, in the CZ VME event, zone sizes for the D-AST and the SOC differed by 2 mm (16 mm vs. 14 mm, respectively). Thus, adopting a zone size cutoff of 16 mm would have eliminated the CZ VME. The FUR VMEs both occurred on MAC and thus, adopting the MH agar for direct AST would have eliminated all VMEs.

**Abstract 8818**

**Improved specie identification of *Staphylococcus argenteus* with MALDI-TOF MS using an extended MSP library**

Unn Tjörnstrand\(^1\), Hanan Seid\(^1\), Ann-Cathrine Petersson\(^1\), Bo Nilson*\(^1,2\)

\(^1\)Region Skåne, Clinical Microbiology Lund, Lund, Sweden, \(^2\)Lund University, Division of Medical Microbiology, Department of Laboratory Medicine Lund, Lund, Sweden

**Background:** *Staphylococcus argenteus* was up to recently known as a divergent *Staphylococcus aureus* clonal lineage. It was recognized as a novel species in 2015 and is a member of the *S. aureus* complex. Of importance is that methicillin-resistance strains are described for both species. As *S. aureus* and *S. argenteus* are closely related and share many characteristics, it is difficult to distinguish the two species with routine diagnostics.

Specie identification of bacteria with Matrix Assisted Laser Desorption/Ionisation Time of Flight (MALDI-TOF) mass spectrometry (MS), is a common method in routine diagnostics. However, current MALDI-TOF MS system (Bruker MALDI Biotyper with the MBT 8468 MSP library 2019) cannot accurately differentiate the two species.

The aim of this study was to evaluate if it is possible to improve the MALDI-TOF MS method for the identification of *S. argenteus* by creating a new MALDI-TOF mass spectral profile (MSP) library from local strains of *S. argenteus* and *S. aureus*.

**Materials/methods:** Clinical strains were selected and determined to species level by *nuc* gene sequencing (Sanger methodology) as either *S. argenteus* or *S. aureus*. Then the strains were analyzed with MALDI-TOF MS and new Mass Spectra Profiles (MSP) were created. All of the strains were divided into two groups. One group of strains was used to create a new MSP library and the second group of strains was used to test and validate the new library.

**Results:** Using *nuc* sequencing 16 *S. argenteus* strains and 20 *S. aureus* strains were determined to the specie level and were included in the study. When the *S. argenteus* strains were analysed with the MALDI Biotyper and the MBT 8468 MSP library then 43% of the *S. argenteus* strains could not be identified accurately. When the new MSP library were added all *S. argenteus* strains could be identified correctly with MALDI Biotyper. Specie specific mass spectra differences could also be identified.

**Conclusions:** By expanding the existing MALDI Biotyper library with a custom made library of MSPs from local strains, we were able to improve the identification accuracy and the ability to distinguish *Staphylococcus argenteus* from *Staphylococcus aureus*.

Abstract 8820

**Fc-mediated Fcγ receptor engagement of CD377, a novel antiviral Fc-conjugate, translates into potent antibody-dependent cellular phagocytosis and antibody-dependent cellular cytotoxicity activity**

Simon Döhrmann*, Rajvir Grewal†, Elizabeth Abelovski†, Tom Brady†, Wanlong Jiang†, Zhi-Yong Chen†, Allen Borchardt†, Jason N. Cole†, Leslie W. Tari†

1Cidara Therapeutics, San Diego, United States

**Background:** Cidara's AVCs (antiviral Fc-conjugates) are novel, immunotherapeutic conjugates of potent, antiviral agents with the Fc domain of human IgG1. CD377 is an AVC development candidate for the prevention and treatment of seasonal and pandemic influenza that has demonstrated potent, broad-spectrum activity and efficacy in multiple influenza challenge mouse models. Herein, we characterize Fc-mediated interaction of CD377 with Fcγ receptors and the function of CD377 in antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP) against influenza.

**Materials/methods:** CD377 interaction with multiple Fcγ receptors (human and murine) was determined by ELISA. For ADCC and ADCP experiments, MDCK cells were infected with varying multiplicity of infection (MOI) for 18-24 h and treated with CD377 ranging from 0.1 – 1000 nM. ADCC and ADCP was determined according to manufacturer’s instructions.

**Results:** CD377 binding affinity to human Fcγ receptors (I, IIa, IIIa) was comparable to unconjugated Fc (hIgG1 Fc), demonstrating that the conjugation chemistry did not interfere with Fc-mediated effector functions of the antiviral Fc-conjugate, CD377. Additionally, the Fcγ receptor binding profiles of CD377 are comparable to those observed for a full-length human IgG1 antibody.

Immune cells, such as NK cells and macrophages, are crucial mediators of host defense against influenza infection. A hallmark of macrophage function in immunity is phagocytosis of antibody-opsonized infected cells. CD377 mediated MOI- and dose-dependent ADCP via FcγRIIa engagement (Figure). NK cells have been demonstrated to be important in immune defense against influenza infection by inducing apoptosis of infected cells through the release of perforin/granzymes. CD377 induced robust ADC via FcγRIIIa engagement with MOI- and dose-dependency against multiple seasonal and pandemic influenza A/H1N1, influenza A/H3N2, and influenza B strains.

**Conclusions:** CD377 triggers potent, broad-spectrum induction of ADCP and ADCC, thereby contributing to immune defense against multiple seasonal and pandemic influenza A and B strains. This potent induction of Fc-mediated effector function of CD377 in combination with potent efficacy in lethal mouse models of influenza infection support further development of CD377 for the prevention and treatment of influenza infection.

**Presenter email address:** sdoehrman@cidara.com
CD377, a novel antiviral Fc-conjugate, demonstrates potent broad-spectrum activity in multiple in vitro assays against influenza A and B

Simon Döhrmann*1, Amanda Almaguer1, Nicholas Dedeic1, Tom Brady1, Wanlong Jiang1, Zhi-Yong Chen1, Allen Borchart1, Jason N. Cole1, Jeffrey Locke1, Leslie W. Tari1

1Cidara Therapeutics, San Diego, United States

Background: AVCs (antiviral Fc-conjugates) are novel, long-acting immunotherapeutic conjugates of potent antivirals and the Fc domain of human IgG1.

CD377 is an AVC development candidate for the prevention and treatment of seasonal and pandemic influenza, comprising a novel neuraminidase inhibitor (NI) conjugated to IgG1 Fc, designed to provide broad-spectrum coverage of influenza A and B, including drug-resistant strains. CD377 has demonstrated efficacy in multiple lethal influenza mouse models. Herein, we characterize the activity of CD377 in multiple in vitro assays against influenza A and B strains including clinically relevant baloxavir- and NI-resistant mutants.

Materials/methods: CD377 was tested alongside oseltamivir, zanamivir, or baloxavir at concentrations ranging from 0.01 nM to 10,000 nM. Neuraminidase inhibition (NAI) activity was determined using a commercial NA-Fluor kit. Cytopathic effect (CPE) was determined against influenza A after 3 days and B strains after 5 days in MDCK SIAT1 cells. Activity in plaque reduction assay (PRA) was determined in MDCK cells after 48–72 h depending on virus strain tested.

Results: CD377 demonstrated potent NAI activity in a low nM range (IC50 0.01 – 23.55 nM) against influenza A/H1N1, influenza A/H3N2, and influenza B strains. The activity of CD377 did not shift against variants that confer resistance/reduced susceptibility to oseltamivir (H275Y, E119V), to oseltamivir and zanamivir (R292K), or to baloxavir (I38T/L/M) in NAI.

In the cell-based assays, CD377 demonstrated up to 100-fold increased potency than oseltamivir or zanamivir against influenza A and B wild-type strains. Notably, CD377 activity did not shift against H1N1 H275Y or H3N2 R292K mutants. The activity of CD377 in PRA or CPE was on par with or greater than that of baloxavir.

Conclusions: CD377 demonstrated potent, broad-spectrum antiviral activity in vitro against multiple seasonal and pandemic H1N1 and H3N2, and B strains. While CD377 shares a mechanism with approved NIs, its potency in cell-based assays was superior to oseltamivir or zanamivir, and comparable to or greater than baloxavir. This potent antiviral activity of CD377 in multiple in vitro assays, combined with efficacy in lethal mouse models of influenza infection support further development of CD377 for prevention and treatment of influenza infection.

Abstract 8833

**Optimising the microbiological diagnosis of prosthetic joint infection: a 5-year evaluation**
Laura Cottom*1, Pauline Wright2

1Glasgow Royal Infirmary, Department of Microbiology, Glasgow, United Kingdom, 2Queen Elizabeth University Hospital, Department of Microbiology, Glasgow, United Kingdom

**Background:** Arthroplasty is an effective surgical intervention that improves quality of life. In Scotland over the last decade the number of primary knee and hip arthroplasties have almost doubled, with 15,091 cases being performed in 2018. Periprosthetic infection albeit rare, remains a major complication that continues to pose a diagnostic and therapeutic challenge.

The aim was to evaluate the impact of our interventions (restructuring of workflow, microbiological processing and integration into our electronic management order comm system) over the last 5 years and assess if through effective diagnostic stewardship in a routine laboratory an improvement in the microbiological diagnosis of PJI could be achieved and sustained.

**Materials/methods:** A retrospective analysis was performed over 5 years; 4-month time periods May-August, 2015 [pre-intervention] to 2019. Data was analysed from two large university teaching hospitals within Greater Glasgow & Clyde, the largest NHS organisation in the UK. Only cases where a PJI diagnosis [knee or hip arthroplasty] had been confirmed according to either the clinical practice guidelines by the Infectious Diseases Society of America or on clinical judgement were included for analysis. The number of intra-operative samples, the culture positive rate and time to positivity [growth of a significant organism] and the causative organism[s] isolated were assessed for each case.

**Results:** A total of 177 patients were identified over the post-intervention study period [2016 to 2019]. Following interventions the mean number of intra-operative specimens sent per case increased and was found to be sustained at 6 [2017-2019] compared to 4 in 2015. A statistical significant increase in the positive culture rate [significant pathogen being cultured] was also demonstrated [Chi-square test: P value < 0.0001].

**Conclusions:** PJI remains an important complication of arthroplasty. Through effective diagnostic stewardship and development of an integrated standardised laboratory strategy for processing orthopaedic specimens, a significant and sustained improvement in the microbiological diagnosis and management of PJI was achieved.

**Background:** AVCs (antiviral Fc-conjugates) are novel, long-acting immunotherapeutic conjugates of potent antivirals and the Fc domain of human IgG1. CD377, an AVC development candidate for the prevention and treatment of influenza A and B, comprises a novel neuraminidase inhibitor conjugated to IgG1 Fc. CD377 has demonstrated potent, broad-spectrum activity against influenza at levels greater than current influenza antivirals and efficacy in multiple influenza challenge models. Herein we characterize the activity of CD377 on viral lung burden and host immune responses in a lethal mouse model of influenza infection.

**Materials/methods:** BALB/c mice were challenged intranasally with $3 \times 10^2$ PFU (3 x LD95) of mouse-adapted influenza A/ Puerto Rico/8/1934 (H1N1). Treatment was started 2 h post-challenge with either CD377 as a single subcutaneous dose (0.1 – 3 mg/kg) or oral oseltamivir (5 or 50 mg/kg BID x 4 days). At day 4 post-infection, lungs were harvested; cytokine levels were determined via ELISA and viral burden was determined by plaque assay.

**Results:** CD377 demonstrated a dose-dependent reduction in viral lung burden resulting in 1.06 log at 0.1 mg/kg, 2.12 log at 0.3 mg/kg, 3.17 log at 1 mg/kg, and 3.63 log at 3 mg/kg compared with PBS control titers of $5.1 \times 10^7$ PFU/g (Figure). Oseltamivir demonstrated minimal effects on reduction of viral lung burden with 0.8 and 0.78 log reductions at the humanized dose (5 mg/kg) and 50 mg/kg, respectively. Minimal difference in lung burden was observed between negative controls, PBS and hIgG1 Fc of 0.47 log. The dose-dependent reduction of viral burden by CD377 correlated with a dose-dependent reduction of multiple cytokines TNF-α, IL-6, MCP-1, MIP-1α, and KC, which at the 3 mg/kg dose approached levels observed in uninfected control mice (Figure). Oseltamivir showed a lesser effect on cytokine reduction compared to CD377.

**Conclusions:** CD377 demonstrated a superior profile compared to oseltamivir in controlling infection and inflammation in a lethal H1N1 influenza model. CD377 mediated protection via multi-log reduction in viral lung burden correlating with reduction in pro-inflammatory cytokines. These results underscore the novel mechanism of action of AVCs and support further development of CD377 for prevention and treatment of influenza infection.

**Figure:** CD377 reduces viral burden and cytokine MCP-1 with dose-dependency. CD377 efficacy in a lethal mouse model of influenza A/PR/8/1934 (H1N1) reduces (A) viral burden and (B) MCP-1 levels in the lung in dose-dependency on day 4 post-infection.

Abstract 8845

Analysis of early outcomes in the STRIVE Trial of rezafungin once-weekly treatment of candidaemia and invasive candidiasis

George Thompson¹, Jose Vazquez*, Paloma Merino-Amador¹, Anita Das⁴, Rolando Viani⁴, Taylor Sandison⁴, Peter George Pappas⁵

¹University of California Davis Medical Center, Davis, United States, ²Augusta University, Augusta, United States, ³University Hospital Clinico San Carlos, Madrid, Spain, ⁴Cidara Therapeutics, San Diego, United States, ⁵University of Alabama at Birmingham, Birmingham, United States

Background: Front-loading of antimicrobials (ie, achieving and maintaining high drug exposure early in therapy) has been shown to be a pharmacometric determinant of efficacy. Rezafungin is a novel echinocandin that demonstrates a long half-life and front-loaded plasma exposures. The Phase 2 STRIVE trial [NCT02234862] evaluated the safety and efficacy of rezafungin once weekly (QWk) compared with once daily (QD) caspofungin in the treatment of candidaemia and/or IC. Secondary efficacy endpoints were evaluated to assess treatment response throughout the course of therapy, including at Day 5, by which point patients had either received one dose of QWk rezafungin or 5 doses of QD caspofungin.

Materials/methods: Adults (≥18 y) with systemic signs and mycological confirmation of candidemia and/or IC were randomized to receive rezafungin 400 mg QWk, rezafungin 400 mg on Week 1 followed by 200 mg (400 mg/200 mg) QWk, or caspofungin 70 mg on Day 1 followed by 50 mg OD for ≥14 days. Overall response (resolution of clinical signs of infection + mycological eradication) at Day 5 and time to negative blood culture were determined for rezafungin (pooled), as both groups received 400 mg in Week 1 versus caspofungin.

Results: At Day 5, the rate of overall success was 62.3% (76/122) for rezafungin and 55.7% (34/61) for caspofungin [Table]. Rates of mycological cure at Day 5 were 69.7% and 62.3%, respectively. Rezafungin-treated patients demonstrated a shorter time to negative blood culture (median: 19.5 hours versus 22.8 hours for caspofungin, log-rank p=0.02) [Figure]. While small differences favoring rezafungin were noted initially, the probability of a negative blood culture reached its maximum difference about 24 hours after the first dose.

Conclusions: Early efficacy of rezafungin was demonstrated based on outcomes of overall success, mycological success and time to negative blood culture. These findings support front-loaded plasma exposure as a pharmacometric determinant of efficacy and the development of rezafungin for treatment of candidaemia and IC.

Abstract 8857

Epidemiological profile, mortality and causes of death in the first year of newly HIV-diagnosed patients of a national referral centre in Costa Rica from January 2015 to December 2017

Mary Yesenia Brenes Madrigal*, Manuel Antonio Villalobos Zúñiga

1Hospital San Juan de Dios, Caja Costarricense del Seguro Social, San José, Costa Rica

Background: The HIV epidemic continues to be a serious health threat despite the efforts made by the healthcare providers. In Costa Rica, there are still large HIV-related epidemiological gaps and also lacks representative and quality local data to support strategic interventions.

Materials/methods: A retrospective, observational and descriptive study was conducted. Late presentation, follow-up after diagnosis and survival curves were also analyzed.

Results: The population of newly diagnosed HIV patients was mostly male [9 to 1 male: female ratio], young adults, under 29 years of age, Costa Rican, single, residing in the province of San José and with incomplete schooling. In the majority of patients, 87.6% ART was started (461) and the mostly used combination was TDF, xTC and EFV for 61.7% (325). 26.7% of the patients had advanced disease at presentation and 44.0% with late diagnosis. Mortality in the first year after the diagnosis was 7.5%. The main identifiable cause of death was CNS toxoplasmosis opposite of what is reported worldwide literature which describes tuberculosis. Regarding mortality, several protective factors were identified: < 40 years (RR 0.25 IC95% 0.15-0.42), viral load < 100 000 copies / ml (RR 0.2, IC95% 0.1-0.4) and ART (RR 0.2 IC95% 0.1-0.3). And as for its risk factors: incomplete high school or lesser educational status (RR 2.7 IC95%: 1.5 - 4.7), late diagnosis (RR 5.6 IC95% 2.8-11.4) and advanced disease (RR 5, 1 IC95% 2.9-9.0). The patients were not linked to proper healthcare, and important delay in each point of the process that goes from the diagnosis to the beginning of the ART was detected.

Conclusions: There are important differences in survival among newly diagnosed patients. In this national referral center in Costa Rica, 26.7 % of new HIV patients were diagnosed with advanced disease and 44 % with late presentation. Mortality in the first year after HIV diagnosis was 7.5 %, and it was significantly influenced by age, schooling, presence of ART, viral load and CD4 count. The main cause of death identified was CNS toxoplasmosis.

**Macrolide-resistant *Mycoplasma pneumoniae* detection**

Stanley Wai Ming Leung*

1Hong Kong Adventist Hospital, Clinical Laboratory and Pathology, Hong Kong, Hong Kong

**Background:** Mycoplasma pneumoniae is a major cause of community-acquired pneumonia, especially in infants and children. Macrolides have been recommended for the treatment of Mycoplasma pneumoniae infections because of their low MIC and high safety profile. However, macrolide-resistant *M. pneumoniae* (MRMP) has become increasingly prevalent worldwide, especially in Asia. MRMP infections have been associated with alternative therapy and higher chance of complications. The increasing trend of the resistant strain highlights the need for a timely diagnosis of MRMP for the clinical management and infection control of patients.

**Materials/methods:** The aim of the study was to determine the prevalence of MRMP in Hong Kong. Nasopharyngeal swabs (flocculated swabs from Copan, Italy) were collected in viral medium. Sputum and bronchial lavage samples with a standard collection procedure were obtained from patients for the period of February, 2019 to October, 2019 from Hong Kong Adventist Hospitals. In total, 7,160 patient samples were received during this period for PCR testing using Filmarray respiratory panel. Wherein, there were 428 (6.0%) positive cases of *M. pneumoniae*. These positive cases were tested for macrolide resistant genotype at 23S rRNA position A2063G by simple-probe real-time PCR coupled to melting curve analysis in Rotorgene Q platform.

**Results:** The macrolide resistance genotyping was successfully carried out on all 428 positive *M. pneumoniae* samples. Simple-probe real-time PCR coupled to melting curve analysis identified 18 cases (4.2%) as having the MRMP genotype by detecting the A2063G transition.

**Conclusions:** Mycoplasma pneumoniae is a common cause of respiratory tract infection in Hong Kong. Targeted antibiotic therapy is required for the patients with serious symptoms. Macrolides, fluoroquinolones and tetracyclines are treatment options for *M. pneumoniae* patients, but only macrolides have been approved for use in young children. In our study, patients with the A2063G mutation, detected by conventional PCR coupled to melting curve analysis, are more likely required a change of therapy from macrolides to fluoroquinolones or tetracyclines. This was consistent with our records which showed that these patients had changed their antibiotic regimen. In conclusion, a rapid diagnosis of *M. pneumoniae* and macrolide resistant strain would definitely help the clinicians for antibiotic selection.

Abstract 8862

Depicting the pathogenicity and genomics traits of hypermucoviscous Enterobacteriaceae clinical isolates

Nadia Rodriguez Medina*, Ulises Garza-Ramos1, Humberto Valdovinos-Torres1

1Instituto Nacional de Salud Publica, Instituto Nacional de Salud Publica, Cuernavaca, Mexico

Background: Hypervirulent K. pneumoniae displays a distinctive phenotype named hypermucoviscosity. Two plasmid-borne regulators rmpA and rmpA2 are involved in the HMV phenotype acting in the cps locus. An increasing population of K. pneumoniae, K. variicola and K. quasipneumoniae isolates displaying the hypermucoviscous phenotype without rmpA and rmpA2 genes associated have been reported worldwide. Some forms of immunodeficiency such as diabetes represents a greater risk for infections with classical and hypervirulent K. pneumoniae strains.

Materials/methods: In this project were included a collection of K. variicola (1), K. pneumoniae (5), K. quasipneumoniae (1), K. oxytoca (1) and E. coli (1) with hypermucoviscous phenotype; without rmpA and rmpA2 genes associated. We performed antimicrobial susceptibility test, plasmid profile, chemical plasmid curing, serum resistant killing assay and resistance to phagocytosis. Male Balb/c mice healthy and diabetic mice of 7 weeks old were inoculated with 10^7 to 10^8 CFU. Survival curve and LD50 were determined. The complete genomes were determined and Roary, Artemis and ACT were used for comparative genomics.

Results: K. variicola 8917 was successfully curated; we observed that the hypermucoviscous phenotype is lost when the plasmid is segregated. K. variicola 8917 inoculated in the healthy mice was able to induce 100% mortality at higher doses (10^8) in contrast with its cured variant Δ8917 showed a decrease in virulence and mortality. We did not observe changes when diabetic mice were inoculated with K. variicola 8917; however, diabetic mice die faster (18h) at higher doses (10^9). K. pneumoniae 3478 showed resistance to serum and E. coli 10270 was resistant to phagocytosis. The pan genome of hypermucoviscous strains was composed for 17,667 genes, a core-genome of 344 genes and the variable genome of 5100 genes. These strains possessed classical virulence factors and 50% of the strains were multidrug resistant.

Conclusions: In general, the pathogenicity was heterogeneous among the hypermucoviscous isolates. K. variicola decreases its pathogenicity when the phenotype is absent in cured strain. The diabetic mice showed greater susceptibility during the infection caused by hypermucoviscous isolates. The hypermucoviscous phenotype has expanded to various bacterial genus.

Abstract 8863

Rapid, non-invasive detection of Legionella and resolution of species diversity in clinical infections using the Karius test, a microbial cell-free DNA sequencing test for pathogen detection

Asim Ahmed*, Sudeb Dalai¹, David Hong², Lily Blair¹, Martin Lindner¹, Desiree Hollemon¹, Sivan Bercovici¹, Timothy Blauwkamp¹, Mickey Kertesz¹, Ann Macintyre¹

¹Karius, Redwood City, United States, ²Formerly at Karius, Redwood City, United States

Background: Legionella species can cause lower respiratory tract infection or a systemic febrile illness (“Pontiac fever”). Infections can occur sporadically or in the context of outbreaks associated with environmental sources. Legionella is difficult to culture and urine antigen testing only detects Legionella pneumophila serogroup 1 which is thought to cause most clinical infections. However, many additional Legionella species can cause disease and are undetected by urine antigen testing.

Materials/methods: Karius Test (Redwood City, CA) results from the prior two years were reviewed for detections of Legionella. The Karius Test is a CLIA-certified/CAP-accredited next generation sequencing (NGS) plasma test that detects microbial cell free DNA (mcfDNA). After mcfDNA is extracted and NGS performed, human sequences are removed and remaining sequences are aligned to a curated pathogen database of >1000 organisms. Organisms present above a statistical threshold are reported. The time to result reporting is 24 hours (on average) from sample receipt.

Results: The Karius Test detected Legionella in 29 patient samples including 25 adults (86%) and four children. Twenty-one patients (72%) were immunocompromised; 23 patients (79%) had a pulmonary focus with a presumptive lower respiratory tract infection. Thirteen samples were positive for Legionella pneumophila (45%), four samples were positive for Legionella bozemaniae (14%), two samples each were positive for Legionella anisa (7%), Legionella cincinnatiensis (7%), Legionella micdadei (7%), Legionella sainthelensi (7%), and one sample each was positive for Legionella feeleii (3.5%) and Legionella brunensis (3.5%). To our knowledge this is the first reported detection of Legionella brunensis as a cause of human infection. The majority (75%) of infections in immunocompetent individuals were caused by Legionella pneumophila whereas Legionella identified in immunocompromised individuals were more commonly non-pneumophila species (67%).

Conclusions: The Karius Test detected a broad diversity of Legionella species causing infections, most of which were non-pneumophila species undetectable by the urine antigen test. Plasma mcfDNA NGS offers a rapid, non-invasive means of detecting a broad diversity of known and potentially novel Legionella species. Accurate species-level identification of Legionella also has important public health implications given the pathogen’s association with environmental outbreaks.

Abstract 8864

**Species distribution and antifungal susceptibility of Candida spp. causing candidaemia in China: an update from the CHIF-NET study**

Meng Xiao*1, Sharon Chen2, Fanrong Kong2, Yingchun Xu1

1Peking Union Medical College Hospital, Beijing, China, 2Centre for Infectious Diseases and Microbiology Laboratory Services, Institute of Clinical Pathology and Medical Research, New South Wales Health Pathology, Westmead Hospital, Westmead, Australia

**Background:** Candidemia is the most common, serious fungal infection, and antifungal resistance has become a notable challenge. Here we report the most recent surveillance results (1 August, 2014 to 31 July, 2017) of candidemia from the China Hospital Invasive Fungal Surveillance Net (CHIF-NET) study.

**Materials/methods:** The study encompassed 77 hospitals across China over three years. Species identification of causative Candida spp. was by mass spectrometry supplemented by DNA sequencing. Antifungal susceptibility was determined using the Clinical and Laboratory Standards Institute broth microdilution method.

**Results:** A total of 4,010 isolates were collected from candidemia patients. Although C. albicans remained the most common species, non-albicans Candida species accounted for over two-thirds of isolates – predominated by C. parapsilosis complex (27.1%), C. tropicalis (18.7%) and C. glabrata complex (12.0%). Most C. albicans and C. parapsilosis complex isolates were susceptible to all antifungal agents (resistance rate <5%). However, there was a consistent decrease in voriconazole susceptibility to C. glabrata sensu stricto over the three years (the non-wild-type phenotype rose from <20% to ~50%). In addition, the fluconazole resistance rate in C. tropicalis tripled from <10% in 2009-2010 to >30% in 2016-2017. Moreover, amongst less common Candida species, over one-third of C. pelliculosa isolates were co-resistant to fluconazole and 5-flucytocine, and >56% of C. haemulonii isolates were multidrug resistance.

**Conclusions:** Non-albicans Candida species has become predominant cause of candidemia in China, and azole resistance is notable amongst C. tropicalis and C. glabrata. In addition, co-resistance and multi-drug resistance has emerged in less common Candida species.

**Presenter email address:** cjtxiaomeng@aliyun.com

1Victorian Infectious Diseases Services, Parkville, Australia, 2Menzies School of Health Research, Tiwi, Australia, 3National Centre for Infectious Diseases (NCID), Singapore, Singapore, 4Institute of Infectious Diseases and Epidemiology, Tan Tock Seng Hospital, Singapore, Singapore, 5Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 6Rabin medical center, Beilinson, Petah Tikva, Israel, 7Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, 8Australasian Kidney Trials Network (AKTN), Woolloongabba, Australia, 9Monash University, Box Hill, Australia, 10Royal Perth Hospital, Perth, Australia, 11Fiona Stanley Hospital, Murdoch, Australia, 12PathWest Laboratory Medicine WA, Nedlands, Australia, 13Antimicrobial Resistance and Infectious Diseases Research Laboratory, School of Veterinary and Life Sciences, Murdoch University, Murdoch, Australia, 14NSW Health Pathology, Westmead, Australia, 15Faculty of Medicine and Health, The University of Sydney, Sydney, Australia, 16NSW Health Pathology, Liverpool, Australia, 17Victorian Infectious Diseases Reference Laboratory Epidemiology Unit, Royal Melbourne Hospital, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, 18Centre for Epidemiology and Biostatistics, The University of Melbourne, Melbourne, Australia, 19Department of Infectious Diseases, John Hunter Hospital, Newcastle, Australia

**Background:** The CAMERA2 trial compared the combination of a β-lactam with standard antibiotic therapy vs standard therapy alone for MRSA bacteremia. Acute kidney injury (AKI) occurred more commonly in the combination (23%) compared to the standard therapy (6%) group. This study aims to identify patient and treatment factors associated with the development of AKI in the CAMERA2 cohort.

**Materials/methods:** Two definitions of AKI were used: 1) modified RIFLE (1.5-fold increase in the serum creatinine days 1-7 or new renal replacement from days 1-90; as specified in the trial protocol), and, 2) modified KDIGO (modified RIFLE OR ≥26.5µmol/L increase from baseline creatinine to day 2). Patients were excluded if they were randomized in error; were on dialysis at randomization; or had no baseline or follow-up creatinine or 90-day follow-up. Variables associated with AKI on univariate analysis (P<0.10) or clinically relevant to the development of AKI (age, sex, baseline creatinine) were included in multivariable models.

**Results:** Of the 356 patients enrolled, 87 were excluded from the analysis [54 chronic dialysis, 22 insufficient creatinine measurements, four randomized in error, seven loss to follow-up]. Overall, AKI occurred in 43/269 [16.0%] or 65/269 [24.0%] patients using the modified RIFLE or modified KDIGO criteria respectively.

On univariate analysis, development of modified RIFLE AKI was associated with lower age [mean age difference -7.4 years [-1.5, -13.4] for AKI] and lower baseline creatinine [difference -35.1 [-14.0, -56.3] for AKI]. Development of modified KDIGO AKI was associated with lower age [-5.2 years [-0.1, -10.3]].

On multivariate analysis, allocation to combination therapy was the only predictor of AKI for modified RIFLE [aOR 4.4, 95% CI 2.0-9.7] and modified KDIGO [aOR 2.4 [1.4-4.2]] criteria. Within the combination group, the receipt of flu(cloxacillin) only [n=106] verses cefazolin only [n=25] was not statistically significantly associated with AKI [modified RIFLE [aOR 6.4 [0.73, 55.5]] or modified KDIGO [aOR 2.1 [0.58, 7.3]]].

**Conclusions:** Combination therapy with a β-lactam was independently associated with AKI using RIFLE and more recent KDIGO definitions. A direct comparison between flu(cloxacillin) and cefazolin was limited by the small sample size but point estimates suggest AKI is more likely with flu(cloxacillin).

Abstract 8871

Prevalence of latent tuberculosis in the adult population of the National Institute of Respiratory Diseases in the period 2016-2019 through an interferon-gamma release assays

Eduardo Becerril Vargas1, Mario Mujica Sánchez1, Mariela Segura Del Pilar*, Luis Armado Narváez Díaz1, José Arturo Martínez Orozco1, Angel Sanchez Tinajero1, Andrea Delgado Cueva1, Isabel Anahí Gallardo Reyes1, Elia Flores Perez1

1 National Institute of Respiratory Diseases, 1 National Institute of Respiratory Diseases, Mexico City, Mexico

Background: Tuberculosis (TB) is one of the most relevant causes of disease and mortality around the world, mainly in Africa and Asia. TB is currently the ninth cause of death worldwide, and the main cause by an infectious disease, outgrowing mortality by HIV related infections. By 2008, it was estimated that 30% of the world population has a latent (LTBI) or active (ATBI) infection. The treatment of LTBI infection is one of the best strategic elements towards eradicating TB. In Mexico, studies on LTBI prevalence have reported estimations that range from 35 to 76% positivity with IGRAs, but with no nation-wide representativeness, so the magnitude of the national problem remains unknown. It’s important to perform a study to assess the magnitude of the problem. The objective was to determine the prevalence of latent tuberculosis infection in the adult population with an IGRAs.

Materials/methods: A retrospective study including adult patients attended at the INER and had an IGRAs. The results were obtained using descriptive statistics; percentages, means ± SD. It was used chi2, to compare characteristics the patients with IGRAs positive, negative and indeterminate. The prevalence of TB was obtained from the ratio of the total tests conducted against the total of positive tests.

Results: 507 patients were included. The average age was 51 years ± 16.45. The prevalence of latent tuberculosis was 23% (116/461). The prevalence increased in patients with more than 60 years. We observed a higher prevalence in women, contact with tuberculosis and health workers, 34% and 32% respectively. We found a low prevalence in patients with HIV, 15% similar to what’s found in patients with DM2. 46 patients had an undetermined IGRA result. The factors associated with an indeterminate result were immunosuppressants, HIV infection and hypoalbuminemia.

Conclusions: The prevalence of tuberculosis in population treated at the INER was similar to the estimated by the WHO.

Abstract 8872

**Airborne antibiotic-resistant *Staphylococcus epidermidis* in inpatient wards linked to deep surgical site infections**

Anders Johansson1*, Micael Widerstrom1, Tor Monsen1, Anders Rhod Larsen2, Marc Stegger2

1Umeå University, Clinical Microbiology, Umeå, Sweden, 2Statens Serum Institut, Copenhagen, Denmark

**Background:** Hospital-associated multiple antibiotic resistant *Staphylococcus epidermidis* (MRSE) strains remain important causes of healthcare-associated infections (HAI) despite significant improvement in infection prevention and control measures to stop contact transmission. Here, we investigate the prevalence of MRSE and other microorganisms in the air in a hospital, and compare MRSE in air with MRSE causing deep surgical site infections (SSI) or blood stream infections (BSI).

**Materials/methods:** The setting was a tertiary care University hospital in Northern Sweden serving 900 000 inhabitants. From April 3 to May 9 2017, microorganism in the air were sampled by 14 cm settle blood agar plates in the acute orthopedics ward, the cardiothoracic critical care unit, the general ICU, the neonatal ICU, and in three operation theatre suites. Eight agar plates were placed for 8 h twice a week at each site. Microbiological work included incubation, colony forming unit (cfu) counts, MALDI-TOF, and antimicrobial susceptibility tests. Airborne MRSE resistant to cefoxitin + ≥3 more antimicrobials, and MRSE judged with high clinical certainty as causes of BSI or deep SSI associated with surgical implants 2015-2017 were genome sequenced using illumina technology.

**Results:** Coagulase-negative staphylococci and *Micrococcus* spp. were commonly airborne at all seven sampling sites. Median total microbial surface deposition ranged 534-2790 cfu/m²/h. Additional microorganisms identified included multiple species of fungi, *Bacillus* spp. *Enterococcus* spp., and *Streptomyces* spp. One *Staphylococcus aureus* cfu was identified at the neonatal ICU, but not at other sampling sites. Air loads of MRSE were highly variable among sites and sampling dates (0-9.2 cfu/m²/h), suggesting that airborne skin scales from certain individuals carrying MRSE contributed to variation. There were no airborne MRSE in the operation theater suits or in the neonatal ICU. Whole-genome analyses of relationships among MRSE from air (n=133) and MRSE from BSI or deep SSI (n=27) illustrated very close relationships (Figure 1).

**Conclusions:** These data suggest that airborne MRSE with potential to cause HAI are present in inpatient wards, but not in operation theatre suits. Future work should investigate the potential role of a transmission route from airborne skin scales to the nasal epithelium by inhalation.

Activity of imipenem-relebactam against a genetically diverse collection of carbapenemase-producing and non-producing carbapenem-resistant Enterobacteriaceae

Chang-Jui Chen*1, Wonhee So1, Steven Dallas1, Nathan Wiederhold1, Raymond Benavides2, Gerard Gawrys3, Kelly Reveles1, James Shurko1, Grace Lee1

1UT Austin & UT Health San Antonio, San Antonio, United States, 2UT Health San Antonio, San Antonio, United States, 3Methodist Healthcare System, San Antonio, United States

Background: Carbapenem-resistant Enterobacteriaceae (CRE) poses a significant global public health threat. Resistance among CRE is particularly complex, owing to numerous possible resistance mechanisms, including the production of carbapenemases, porin mutations, efflux pumps, and extended-spectrum beta-lactamases (ESBLs). Imipenem-relebactam (IMI-REL) is a novel β-lactam/β-lactamase inhibitor combination for the treatment of Gram-negative infections. In this study we evaluated the in vitro activity of IMI-REL against a contemporary collection of CRE isolates that have been genotypically characterized.

Materials/methods: We compared the in vitro activities of 20 antimicrobial agents by broth microdilution, including IMI-REL, against 97 CRE clinical isolates that were recovered from unique patients at 2 medical centers in South Texas. MICs were interpreted based on Clinical and Laboratory Standards Institute breakpoints; interpretive criteria for imipenem (IMI) were applied to IMI-REL. Molecular characteristics and resistance mechanisms were analyzed using whole-genome sequences.

Results: CRE isolates represented 9 unique species: Klebsiella pneumoniae (n=50), Enterobacter cloacae (n=29), Klebsiella aerogenes (n=5), Escherichia coli (n=3), Morganella morgani (n=2), Serratia marcescens (n=3), Citrobacter freundii (n=3), Klebsiella oxytoca (n=1), and Hafnia alvei (n=1). Interestingly, only 64% of isolates harbored carbapenemases [KPC-2 (41), KPC-3 (14), and OXA-48 like enzymes (7)]. Among K. pneumoniae, isolates belonged to ST258, ST307, ST678, ST25, ST1500, and ST273. The addition of relebactam restored in vitro IMI susceptibility to 98% of CRE isolates harboring KPC and/or ESBL/CMY as well as 40% of those harboring OXA-48 like enzymes. Notably, IMI-REL had 100% activity against 3 polymyxin-resistant KPC-producing Klebsiella isolates that harbored the plasmid-mediated mcr-1 gene. Among K. pneumoniae isolates, 58% [all ST258 strains] contained mutations in ompK35 and/or 44% in ompK36. The in vitro activity of IMI-REL was not impacted by ST, KPC type, nor whether they harbored mutations in ompK35 and/or ompK36. IMI-REL had no activity against all 3 S. marcescens isolates that contained SME-3 with 1 co-harboring KPC-2.

Conclusions: This study highlights the diversity of resistance mechanisms underlying CRE in South Texas with almost 40% not harboring a carbapenemase. IMI-REL was highly effective against CRE including isolates producing carbapenemases with porin mutations, as well as all those that were also polymyxin-resistant.

Background: Community-acquired pneumonia (CAP) is among the most common causes of mortality in patients admitted in intensive care unit (ICU). *Streptococcus pneumoniae* remains one of the most common causative pathogens in severe CAP. However, multidrug-resistant bacteria, respiratory viruses and polymicrobial infections are frequently underestimated. We aimed to provide new trends in microbial etiology of severe CAP in ICU.

Materials/methods: Adults admitted for severe CAP to the ICU of the Nîmes University Hospital (France) were studied retrospectively during a 12-month period. Microbiological testing methods included conventional cultures from different respiratory samples (e.g. sputum, protected distal bronchial samples and bronchoalveolar lavage); urinary antigen testing for detection of *S. pneumoniae* and *Legionella pneumophila*; multiplex real-time polymerase chain reaction (PCR) (Seegene Allplex™ Respiratory panel, Eurobio-Ingen, France) performed on all respiratory samples for detection of 21 pathogens, including 16 viruses and 5 atypical bacteria; and multiplex real-time PCR (R-DiaLeg™, Diagenode, Belgium) targeting all *Legionella* species performed on respiratory samples.

Results: A total of 128 patients (median age: 67 years; 62.2% male) were enrolled. Microbial etiology was determined in 74 patients (57.8%). Respiratory viruses were the most frequently isolated pathogen group (37 of 74 patients; 50%), of which Influenza A virus in 13 patients (17.6%), Rhinovirus (RhV) in 10 (13.5%) and Influenza B virus in 5 (6.8%). The most commonly identified bacterial pathogens were: *S. pneumoniae* in 12 patients (16.2%), the so-called PES (*Pseudomonas aeruginosa*, extended-spectrum ß-lactamase Enterobacteriaceae, and methicillin-resistant *Staphylococcus aureus*) pathogens in 11 patients (12.9%), *Legionella* species in 6 (8.1%) including *L. pneumophila* in 4 (5.4%) and non *L. pneumophila* in 2 (2.7%), *Haemophilus influenzae* in 3 (4.1%) and *Moraxella catarrhalis* in 3 (4.1%). Two or more pathogens were present in 14 patients (18.9%) (most commonly RhV together with a bacteria).

Conclusions: Respiratory viruses have become the most frequent organisms isolated in ICU patients admitted for severe CAP, with Influenza viruses as leading pathogens, exceeding *S. pneumoniae*. Viral infections are prone to severe bacterial super-infections. Among severe bacterial CAP, PES pathogens occur in many cases. These new trends should be considered for the management of severe CAP in ICU.

Background: SAB carries severe complications. Evidence shows that consultation with infectious diseases specialists (IDs) is associated with better outcomes. However, divergent practices among IDs may obscure these benefits. We evaluated the consistency of practice in the management of SAB among IDs across 5 LA countries.

Materials/methods: We applied an anonymous on-line survey to IDs from Chile, Peru, Brazil, Colombia, and Argentina. The survey consisted of 14 questions related to diagnosis (n=4), management (n=5) and demographic information (n=5), and was distributed by e-mail and text messages between 06/20/19 to 11/20/19.

Results: We collected 741 responses (Argentina=267, Chile=124, Colombia=70, Brazil=200, and Peru=80), 86% and 14% corresponded to adult and pediatric IDs, respectively; 29% of respondents worked at teaching institutions. Working in a non-teaching hospital and having >10 years of practice were significantly associated with higher probability of drawing follow-up blood cultures solely when patients remained febrile/unstable (OR, [95%CI] = 1.7 [1.07-2.67]; 2.1 [1.44-3.09], respectively). Seventy-nine percent of the sample reported to perform an echocardiogram always/almost always. Pediatrics IDs choose to perform a transthoracic echocardiogram more frequently than adult IDs (65% vs 10%, P<0.01). Conversely, transesophageal echocardiogram was more frequently preferred by adult IDs (28% vs. 9%, P<0.01)

Cefazolin/cephalothin and oxacillin/cloxacillin were the first-line therapy for methicillin-susceptible SAB in 51% and 47% of cases, respectively. Daptomycin (monotherapy or combination) was the preferred option to treat persistent methicillin-resistant SAB (62%). Most IDs (72%) treat uncomplicated SAB for a minimum of 14 days; subjects with >10 years of practice were more likely to prescribe shorter (7 days) courses of therapy (OR =3.25, [2.01-5.26]). Thirty-one percent of IDs would consider 1/2 positive blood cultures with S. aureus a contamination and would not prescribe treatment, with significant differences by country [Argentina 21%, Chile 22%, Colombia 36% Brazil 37%, Peru 61%; P<0.01]. Years of experience and type of hospital were not associated with the preference of not treating at all.

Conclusions: We found great variation in the management of SAB among IDs in LA, with notable differences between countries, type of specialists, practice type, and years of experience. Adherence to guidelines should be reinforced to improve SAB outcomes.

Abstract 8882

**Resistance and virulence determinants of faecal Salmonella spp. isolated from slaughter animals in Benin**

Victorien Dougnon*, Esther Deguenon², Lamine Baba-Moussa²

¹University of Abomey-Calavi, Calavi, Benin, ²University of Abomey-Calavi, Calavi, Benin

**Background:** *Salmonella* spp. are one of the leading foodborne pathogens worldwide naturally found in the intestines of many animals. People that are in direct contact with the infected animals or their cages may become ill. The aim of this study was to determine the prevalence, antibiogram and virulence genes associated with *Salmonella* serovars from fecal samples of animals intended for consumption in Southern Benin.

**Materials/methods:** The collection of animal faeces, namely poultry, sheep and pigs for the search for Salmonella was conducted in the cities of Allada, Abomey-Calavi, Cotonou, Porto- Novo, Adjara and Cocotomey characterized by the strong presence of breeders and large markets. The bacteriological analysis was conducted according to the current AFNOR standard (NF U: 47–100). Kirby Bauer techniques were used to perform the susceptibility testing. The isolates were tested for different virulent genes using PCR with five sets of specific primer pairs. The genes of virulence that were targeted for amplification by PCR were invA, spvR, spvC, fimA and stn.

**Results:** Out of a total of 406 samples, 2.46% were positive. The isolates identified were multidrug-resistant *Salmonella* spp. to penicillins, first generation cephalosporins and some aminoglycosides. All *Salmonella* isolates produced invA gene of 284 bp, fimA of 85 bp and stn of 260 bp. The spvC gene (571 bp) was present in 10% of the isolates whereas the spvR gene (310 bp) was found in 20% of the isolates. The control strain possessed all the tested genes. The invA gene implies that strains are able to invade epithelial cells. The fimA and stn genes present in all isolates show that they are capable of causing gastrointestinal illness in humans. The presence of spvC and spvR genes suggests the possibility of these strains to produce toxins.

**Conclusions:** The presence of multidrug resistant *Salmonella* spp. in the faeces of animals is of major concern and the presence of virulence genes confirms the possible pathogenicity of these strains. The present study is therefore of paramount importance in the surveillance of salmonellosis.

Abstract 8884

**A new approach of antibiotic stewardship in geriatric facilities**

Rocco Collarino¹,², Cédric De Villelonge¹, Xavier Lescure¹, Virginie Fossey-Diaz², Laurène Deconinck³, Laetitia Vaillant³

¹Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France, ²Bretonneau Hospital (AP-HP), Paris, France, ³Bichat-Claude Bernard Hospital, Paris, France

**Background:** Antibiotics are frequently prescribed and often inappropriately used in geriatric facilities; antimicrobial resistance is a real challenge. We evaluate the impact and acceptability of an antimicrobial stewardship with on-site visits in a geriatric hospital.

**Materials/methods:** In a 200 beds Parisian geriatric hospital grouping acute medicine, long-term, psychogeriatrics and palliative cares, collaboration has been set up with clinical infectious and infection control experts since 2016. Bi-monthly on-site visits, in addition to phone calls (available every day), were implemented. Clinical, biological and microbiological data was collected for every infectious medical advice. A satisfaction questionnaire was administered to geriatricians.

**Results:** From December 2016 to November 2019, 291 advices including 213 initial advices (IAs) and 78 follow-ups were collected. Among the IAs, 12% had known multidrug-resistant bacteria (MDRB) colonization. IAs concerned pulmonary infections (33%), urinary tract infections (26%) bacteremia (17%), and abdominal infections (7%). For 63 patients, antibiotic wasn’t initially prescribed (lack of bacterial infection arguments, need of more explorations) but was introduced for 9 (14%) patients after IA. In contrary, a total of 11 treatments (7%) have been stopped. During the 3 years IAs numbers decreased but proportion of antibiotic modification increased from 38% in 2017 (34/90), 40% in 2018 (23/57) to 51% in 2019 (26/51). Modifications mainly concerned the drug change (68% in 2017, 61% in 2018, 58% in 2019). Dose or length modifications were less frequent (5% in 2017, 15% in 2018, 12% in 2019). Drug changes concerned replacement of third-generation cephalosporins by amoxicillin (10%), “new drug” prescription (as dalbavancin) or other different modifications. Among the 3 initial prescriptions of carbapenem, 2 have been secondarily changed by antibiostewardship. Site visits seemed more personalized than phone calls for 26 (87%) of 30 geriatricians and 24 (80%) were very satisfied with this organization. The intervention of the stewardship team was mainly requested for therapeutic opinions and complex situations.

**Conclusions:** This new strategy of antibiotic counseling with on-site visits by infection control experts enabled to reduce antibiotic prescription and to perform antibiotic escalation. Antibiotic stewardship in geriatric hospital could reduce pressure of MDRB selection and inappopriate prescriptions and is well accepted by geriatricians.

**Presenter email address:** rocco.collarino@aphp.fr
Inter- and intraspecies spread of mcr-1 between twenty-nine distinct Enterobacteriaceae isolates from one patient

Hao Xu*, Beiwen Zheng1, Yonghong Xiao1

1Zhejiang University, Hangzhou, China

**Background:** Colistin is one of the most critically important last-resort antibiotics that used to treat infections caused by multidrug-resistant bacteria. Colistin resistance is a growing global threat in the field of antimicrobial resistance. After the initial report in 2015, the transmissible colistin resistance gene, mcr-1, was first discovered in China then spread worldwide. Significantly, mcr-1 has been found in different plasmid types, such as IncI2, IncHI2, and IncX4, which also containing other antimicrobial resistance determinants such as extended-spectrum β-lactamases simultaneously. These transferable plasmids likely facilitate the inter- and intraspecies spread of mcr-1 gene among Enterobacteriaceae.

**Materials/methods:** Here, we describe a unique case of sequential isolation from one patient with three species of MCR-1-producing producers, and characterize the inter- and intraspecies dissemination of mcr-1 gene via Illumina and PacBio sequencing, and plasmid analysis.

**Results:** Here we report the unexpected isolation of 29 distinct MCR-1 producing Enterobacteriaceae isolates from a single patient over 30 months. The phylogenetic tree analysis revealed within-host evolution of 19 Escherichia coli and 9 Klebsiella aerogenes isolates, respectively. Plasmid analysis demonstrated that mcr-1 gene was carried by transferrable 66 kb IncI2 plasmids and 94 kb pO111 plasmids. We present evidence that inter- and intraspecies spread of mcr-1 gene among Enterobacteriaceae isolates from the same patient.

**Conclusions:** So far, reports on inter- and intraspecies spread of antimicrobial resistance genes in a single patient are rare. Isolation of various MCR-1-producers from the same patient has never been described thus far. In this study, we report the first known sequential isolation of twenty-nine distinct MCR-1-producing Enterobacteriaceae isolates from multiple specimens obtained from the same patient. The MCR-1-producing isolates in this patient may due to exposure to other colonized/infection patients, since MCR-1-producers was identified from isolates in this hospital early in 2014. The fact that 29 isolates possessed mcr-1 in one patient is of particular concern as it indicates that MCR-1-producers can colonizations or infections within a single patient over several years. Importantly, this case reinforces the idea of inter- and intraspecies dissemination of the mcr-1 gene in clinical Enterobacteriaceae isolates through horizontal gene transfer during human infection.

Abstract 8889

Probiotics for recurrent *Clostridioides difficile* infection: a systematic review and meta-analysis
Sydney George*, Neal Irfan1,3, Dominik Mertz1,2

1McMaster University, Hamilton, Canada, 2Hamilton Health Sciences, Hamilton, Canada, 3McMaster University, Department of Medicine, Hamilton, Canada

**Background:** Around a quarter of patients initially treated for *Clostridium difficile* infection (CDI) will develop a recurrence of CDI – contributing to increased healthcare costs, prolonged use of antibiotics [and associated risks], and an increase in morbidity and mortality. The disturbance of the gastrointestinal microbiota due to antibiotic treatment of recurrent CDI, has garnered attention around the role of probiotics as a potential treatment option in an attempt to restore microbial balance. The objective of this study is to assess the efficacy of the use of probiotics in conjunction with standard of care, in the prevention of CDI recurrence through a systematic literature review.

**Materials/methods:** The Cochrane Central Register of Controlled Trials, MEDLINE, EMBASE, grey-literature sources, references of included studies from systematic reviews on similar topics, consultation with field experts and trial registries were searched from inception to September 2019, with no limit on language or publication date. Selection criteria involved both randomized control trials (RCT) and non-randomised observational studies reporting recurrent CDI incidence, and including patients who were receiving probiotics of any strain, dose or method of ingestion, with at least one CDI occurrence. Two authors independently screened articles, extracted data and assessed risk of bias. GRADE guidelines were used to rate confidence in effect estimates per outcome.

**Results:** 8 studies including 696 participants met the eligibility criteria. 5 RCTs were pooled in the meta-analysis, resulting in probiotics reducing the incidence of recurrent CDI by 43% (pooled relative risk, 0.57 [95% CI, 0.35 – 0.93]) in comparison to placebo. Moreover, lactobacilli strains reduced recurrent CDI by 60% (pooled relative risk, 0.40[95% CI, 0.10 – 1.51]) in comparison to *Saccharomyces boulardii* strain which only reduced CDI recurrence by 35% (pooled relative risk, 0.65 [95%CI, 0.41-1.05]) among randomised studies. There were no significant findings in regards to adverse events between groups. According to the findings reported in the observational studies analyzed, probiotics may confer beneficial results in CDI recurrence prevention.

**Conclusions:** Moderate quality of evidence suggests probiotics may result in a small reduction in recurrent CDI patients with at least one CDI occurrence.

Evaluating the performance of a host-protein signature for distinguishing between bacterial and viral disease in adults with Lower Respiratory Tract Infection (LRTI): results from the OBSERVER clinical study

Meital Paz1, Michal Stein1, Einat Moscoviz2, Salim Halabi3, Shachaf Shiber1, Shirly Yanai2, Ynon Lishtzinsky4, Dani Kirshner5, Yasmin Maor6, Tanya Gottlieb1, Eitan Simon1, Yael Israeli1, Noa Avni1, Gali Kronenfeld1, Naama Sitry1, Mor Smith1, Alona Boukin1, Alona Angel1, Yali Orr1, Niv Mastboim1, Tahi Ilan-Ber2, Rotem Gidron Budovsky1, Eran Eden1, Liran Shani1

1MeMed Diagnostics, Tirat Carmel, Israel, 2Carmel medical center, Haifa, Israel, 3Rabin medical center, Petach Tikva, Israel, 4Ram-bam Health Care Campus, Haifa, Israel, 5Wolfson Medical Center, Holon, Israel

Background: Failure to distinguish between bacterial and viral infection in LRTI patients is a major healthcare problem contributing to antibiotic misuse and antimicrobial resistance. A novel assay that integrates blood levels of three immune-proteins TRAIL/IP-10/CRP was developed to assist in differentiating bacterial from viral disease. The assay exhibited high performance in previous blinded pediatric validation studies. We evaluated the assay’s diagnostic performance and potential clinical utility in adult patients, focusing on patients suspected for LRTI.

Materials/methods: OBSERVER (NCT03011515) is an EU Horizon 2020 funded study (grant No. 684589), the first to validate the signature in adult LRTI patients. For every participant recruited at the emergency departments of three hospitals in Israel, we collected medical history, physical examination, routine lab, imaging and respiratory multiplex PCR data. The assay outcomes are bacterial, viral or equivocal. Reference standard outcome of bacterial, viral, indeterminate or non-infectious, was assigned by expert panel majority adjudication. Indeterminates were excluded from the analysis.

Results: We included 492 in this analysis. Age ranged from 18 to 98 years (mean 54.6). Clinical syndromes included: 29% pneumonia, 27% URTI, 17% acute bronchitis, 6% asthma or COPD exacerbation and 13% unspecified LRTI or viral infection.

The assay demonstrated high diagnostic performance for distinguishing bacterial from viral disease (Figure 1).

In this cohort, antibiotics were prescribed to 105/195 patients with viral reference outcomes, indicating an overuse rate of 54%. Of these, 78 yielded viral index test outcomes, supporting the potential of the assay to reduce overuse by 74%.

Conclusions: The TRAIL/IP-10/CRP assay demonstrated high diagnostic performance and potential utility for differentiating between bacterial and viral disease in adult patients presenting to the emergency department with suspicion of LRTI. Use of this new assay can help to close the gap between guidelines antibiotic prescription recommendations and reported prescribing rates and improve adherence to the guidelines.

Abstract 8892

Octenidine: new insights in the detailed killing mechanism on Gram-negative bacteria at a cellular and molecular level

Nermina Malanovic*, Ayse Oen¹, Georg Pabst¹, Karl Lohner¹

¹University of Graz, Graz, Austria

Background: Octenidine (OCT) is a well-tolerated antiseptic molecule, which is widely used for wound management, skin- & mucous membrane antisepsis and infection control. Its antimicrobial spectrum covers (multi-drug resistant) bacteria, fungi and enveloped viruses. However, the detailed molecular mechanism has not been elucidated so far. The objective of our study was to investigate the mode of action of OCT’s potent effect on Gram-negative bacteria by using Escherichia coli as model organism as well as corresponding membrane model systems.

Materials/methods: Effects of OCT on cellular morphology were observed by electron microscopy, changes affecting membrane integrity [surface charge, fluidity, permeabilization and depolarization] by zeta potential, fluorescence microscopy and spectroscopy, while specific interactions of OCT with membrane phospholipids were addressed using differential scanning calorimetry, X-ray scattering and fluorescence techniques.

Results: OCT neutralizes the surface charge of E. coli leading to disruption of the outer membrane and dramatic loss of cell wall at higher concentrations. In turn OCT penetrates through the periplasmic space reaching the inner membrane. Membrane model systems composed of bacterial inner membrane phospholipids showed that OCT inserts into the hydrophobic fatty acyl chain region of the bilayer inducing complete lipid disorder. The loss of membrane integrity is also reflected in in vitro experiments as demonstrated by membrane depolarization and changes in membrane fluidity of E. coli and eventual disruption as shown by electron microscopy.

Conclusions: Insertion of OCT into the outer and inner membrane of E. coli results in a chaotic lipid arrangement that leads to rapid disruption of the cell envelope. Note that this kind of action demands a defined number of OCT molecules per cell to induce cell death. Thus, when used in very low concentrations, not all bacteria will be covered with sufficient numbers of OCT molecules, which can be misinterpreted as tolerance or adaption. We propose that this very rapid and unspecific mode of action based on purely physical interactions is on one hand the basis of the very broad antimicrobial profile and on the other hand makes it unlikely that resistance towards this molecule will occur.

Abstract 8893

**Risk factors for amputation in diabetic foot infections**

Tuna Demirdal1*, Pinar Sen1

1Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Infectious Diseases and Clinical Microbiology, Izmir, Turkey

**Background:** Lower extremity amputation is an important cause of morbidity and mortality in patients with diabetic foot infection (DFI). We aimed to determine the risk factors for lower extremity amputation in DFI.

**Materials/methods:** Data of patients who were hospitalized for DFI between 2010 and 2019 were recorded retrospectively from the hospital records. The clinical data of patients who did and who did not undergo amputation were statistically analyzed.

**Results:** Data were collected for 401 patients including 280 (69.8%) men. The mean age was 59.6±11.1 (29-81) years. Thirteen (3.2%) of the patients were type 1 diabetes and mean duration of diabetes was 14.1±9.2 years. The causes of the DFI were as follows; ischemic ulcer (33.7%), trauma (13.5%), neuropathic ulcer (11.5%), venous ulcer (10.5%) burn injury (2.7%) and idiopathic (25.4%). Of these patients, 47.4% had right foot wound, 43.6% had left foot wound and 9% had bilateral foot wounds. Treatment modalities included medical treatment (146, 36.4%), debridement/drainage (88, 21.9%), minor amputation (71, 17.7%) and major amputation (96, 23.9%).

Male sex (p=0.047), ischemic wound (p=0.024), forefoot wound (p<0.001), osteomyelitis (p=0.005), peripheral arterial disease (p=0.001), low hemoglobin levels (p=0.002), high leukocyte levels (p<0.001), high platelet levels (p=0.021), high glucose levels (p=0.016), high erythrocyte sedimentation rate levels (p=0.005), high C-reactive protein levels (p<0.001) and high procalcitonin levels (p=0.039) were found to be significant factors in amputated patients. Among these factors, forefoot infections (OR:3.347, 95% CI:1.408-7.956; p=0.006) and peripheral arterial disease (OR:4.99, 95% CI: 1.225-20.324; p=0.025) were independent risk factors in predicting amputation in DFI (Figure).

Mean duration of follow-up was 23.7±22.9 months; 146 (46.8%) patients completely recovered, 63 (%20.2) patients developed a chronic foot ulcer and 103 (%33) patients required re-operation. The overall mortality rate was found 3%.

**Conclusions:** Early recognition of need for amputation is also crucial in terms of limiting amputation level and decreasing mortality. We conclude that these clinical parameters are simple, broadly available and cost-effective promising parameters in predicting amputation in DFI.

Abstract 8895

**Diversity of colistin resistance mechanisms in carbapenemase-producing Klebsiella pneumoniae isolated in Bulgaria from 2013 to 2018**

Krasisma Ivanova*, Ivan Ivanov1, Stefana Sabtcheva2, Veselin Dobrinov1, Martyn Nedyalkov1, Elina Dobreva1, Rumiyan Hristova1, Todor Kantardjiev1

1National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria, 2National Oncology Center - USHATO, Sofia, Bulgaria

Abstract third-party references: Partially supported by The Bulgarian National Science Fund under Grant No KП-06-М23/6

**Background:** Colistin-based antimicrobial regimes have been used successfully for the treatment of carbapenemase-producing *Klebsiella pneumoniae* (CPKP) infections, but mutational and plasmid-mediated colistin resistance (CR) has been reported, compromising even the combinatorial therapeutic regimes. We report molecular mechanisms in colistin-resistant clinical isolates detected among CPKP referred to the National Reference Laboratory for AMR in Bulgaria between 2013 and 2018.

**Materials/methods:** A collection of 322 non-duplicate CPKP with PCR-confirmed carbapenemases was screened for CR by the BMD method according to EUCAST. Carbapenemase genes, ESBL, pAmpC, plasmid aminoglycoside and quinolone resistance determinants were studied by PCR and sequencing. Genotyping by MLVA8, MLST and PBRT was conducted. PCR detection of mcr genes 1 to 8, sequencing of the entire mgrB, phoPQ, pmrAB and crrB and qRT-PCR for the expression levels of pmrCDH, phoP and crrC were performed for studying mechanisms of colistin resistance.

**Results:** Forty colistin resistant CPKP strains were confirmed. Of these, 23 (57%) were XDR, 9 (22%) were PDR and 8 were MDR. The *bla*NDM-1 was detected in 33 strains (from eight hospitals) associated with incA/C plasmids and *bla*CTX-M-15 all belonging to ST11, whereas seven strains were KPC-2 producers distributed in ST15 and ST258. ArmA contributing to the PDR phenotype was detected in eleven ST11 strains from four hospitals, all co-producing *bla*NDM-1 and *bla*CTX-M-3/15. The qnrB2 and *aac(6’)Ib-cr* genes were found in 15 and 9 strains respectively. While *mcr* genes were absent, various alterations or complete lack of *mgrB* were responsible for CR in 80% of the isolates. Most of the novel missense substitutions found in *mgrB*, *pmrB* and *phoP* as well as an indel in *mgrB* were predictably deleterious. A common expression pattern was observed, consistent with a significant upregulation of the L-Ara4-N operon apparently through increased *phoPQ* and *pmrAB* activation and mediated by *pmrD*.

**Conclusions:** Colistin was registered in Bulgaria in 2014 but its use in hospitals was effectively initiated in 2015. This study shows that CR-CPKP has been introduced prior to colistin use. Noteworthy, CR has been associated mostly with MDR/XDR CPKP and the PDR strains seem to emerge in 2017 following the apparent acquisition of the *armA* gene.

Abstract 8897

Fosfomycin susceptibility testing by different methods in multidrug-resistant urinary Klebsiella pneumoniae isolates

Zeycan Semerci 1, Arzu Ilki* 1

1 Marmara University Medical Faculty, Department of Microbiology, Istanbul, Turkey

Background: The emergence of multidrug-resistant (MDR) gram negative bacilli creates a challenge in the treatment of urinary tract infections. Fosfomycin has regained attention because of its in vitro activity against extended-spectrum beta lactamase (ESBL) positive Klebsiella pneumoniae isolates. Rapid and accurate antibiotic susceptibility testing (AST) for fosfomycin is necessary for clinical microbiology laboratories. For this reason, we aimed to determine the susceptibility of fosfomycin by using gradient test, disk diffusion and VITEK2 AST system (BioMerieux, France) and compare with the results of agar dilution as reference method.

Materials/methods: A total of 251 ESBL-positive Klebsiella pneumoniae strains isolated from urine specimens were collected from May 2018 to 2019 in Marmara University Hospital Clinical Microbiology Laboratory, Istanbul. Minimum inhibitory concentrations (MICs) of fosfomycin were determined by the agar dilution method in accordance with EUCAST guidelines. The MIC of fosfomycin was determined by supplementation with 25 mg/L glucose-6 phosphate and fosfomycin in a concentration of 0.25-1024 µg/mL. AST were performed using VITEK2 system, by Gradient test (Liofilchem, Italy) and disk diffusion. Results were evaluated in comparison with agar dilution method according to EUCAST criteria.

Results: Of these ESBL positive K. pneumoniae isolates (n:251), 20 (8%) were also carbapenemase (CP) positive. Fosfomycin susceptibility was 81.8% in ESBL positive and 70% in carbapenemase positive isolates. MIC90 was determined as 8/256 µg/mL. The categorical agreement was 90%, 88.4% and 83.5% in gradient test, disk diffusion and VITEK2 system respectively when compared with agar dilution (Table 1).

<table>
<thead>
<tr>

</tr>
<tr>
<td>Disk diffusion</td>
<td>20/223 90.0%</td>
<td>223/251 (68.9%)</td>
</tr>
<tr>
<td>Automated AST (VITEK2)</td>
<td>19/223 86.1%</td>
<td>223/251 (68.9%)</td>
</tr>
</tbody>
</table>

Conclusions: Fosfomycin has a high activity (>80%) against ESBL positive K. pneumoniae. Therefore determination of fosfomycin susceptibility is important for the laboratories to lead the treatment options particularly for the MDR isolates. Rapid and automated method (VITEK2 AST) results for fosfomycin is relatively low whereas gradient test results were acceptable with high in categorical agreement. Agar dilution still seems to be the gold standard as suggested by the guidelines.

Abstract 8909

**Amikacin resistance mechanisms in Mycobacterium abscessus**

Maria Søndermølle*, Ghalia Sbaa1, Emmanuel Lecorche1, Hanaa Benmansour1, Faiza Mougari1, Emmanuelle Cambau1

1French National Reference Centre for Mycobacteria, AP-HP Hopital Lariboisiere, University of Paris, Inserm IAME UMR1137, Paris, France

**Background:** Mycobacterium abscessus (mAB) is a multidrug-resistant nontuberculous mycobacteria (NTM) causing chronic respiratory and iatrogenic health-acquired infections. Clarithromycin and amikacin (AMK) are the drugs of choice although inducible clarithromycin resistance is present in strains of the subspecies *bolleti* and in most strains of *subsp. abscessus* (*erm41* sequevar t28). Contrarily, *subsp. massiliense* and *subsp. abscessus* *erm41* sequevar c28 are intrinsically clarithromycin susceptible. Therefore, AMK became the first therapeutic choice for all mAB whatever the subspecies. Recently, liposomal AMK was approved for NTM treatment. Since AMK resistance emerged due to its increased usage, we investigated mAB clinical isolates for AMK mechanisms of resistance. Several genetic mutations have been observed in *in vitro* mutants but only one mutation (*rrs* a1 408g) have been observed in clinical isolates so far.

**Materials/methods:** From all mAB clinical isolates received in our reference laboratory from November 2012 until June 2018, isolates yielding AMK MIC≥64 mg/L by Sensititre RAPMYCO (ThermoFisher) were considered resistant. PCR sequencing of *hsp65, erm41, rrl* and *rrs* was performed together with the GenoType® NTM-DR for subspecies assignment and clarithromycin and AMK genotypic resistance. All resistant isolates were re-tested for AMK MIC by broth microdilution CLSI reference method.

**Results:** 42 AMK resistant isolates were investigated from 29 patients (17 men, 12 women, median age 24 years, range 7-77). The isolates distributed as five *subsp. massiliense*, six *subsp. bolletii*, four *subsp. abscessus* *erm41* sequevar c28 and 27 *subsp. abscessus* t28. Morphotypes were primarily rough (26, 62%). The *rrs* mutation a1 408g was found in 26 strains, all showing MIC≥8,192 mg/L, but four strains with MIC>8,192 µg/mL did not show this mutation. Seven strains had MICs ranging from 64 to 512 mg/L, which could indicate enzymatic mechanism. Finally, five strains had MIC<64 mg/L and no *rrs* mutation, indicating they were probably wild type. The 17 strains with no *rrs* mutations are undergoing whole genome sequence analysis.

**Conclusions:** mAB isolates with a1408g *rrs* mutation are AMK resistant at a high level precluding their use, whereas isolates without this mutation should be studied further in order to know if high AMK concentrations achieved locally can overcome resistance.

Abstract 8915

Bacterial iron-uptake pathways: gates for the transport of antibiotics
Quentin Parraud¹, Sabatier Laurence², Gaëtan Mislin¹, Isabelle Schalk*¹

¹Strasbourg University, ESBS UMR7242, Strasbourg, France, ²Strasbourg University, Institut Pluridisciplinaire Hubert Curien, Strasbourg, France

Background: Vectorization of bactericide compounds by siderophores (iron chelators produced by bacteria) is a promising Trojan horse strategy able to considerably increase the efficacy of drugs by overcoming the impermeability of the bacterial wall, especially that of Gram-negative bacteria. In such a Trojan horse strategy, the idea is that each time a bacterium internalizes a ferric ion, a molecule of drug is transported as well.

Iron is a cofactor of many redox-dependent enzymes and thus essential for growth and virulence. During infection, an important aspect of the innate immune system is to limit iron availability to invading microbes, a strategy called nutritional immunity. To overcome this problem of iron accessibility, bacteria had to develop diverse and efficient iron uptake processes. Pseudomonas aeruginosa is able to express in order to get access to iron several strategies: a ferrous iron uptake pathway, two haem uptake pathways and several iron acquisition pathways involving siderophores.

Materials/methods: Using proteomic and molecular biology approaches, we have investigated how P. aeruginosa adapts the expression of its iron acquisition pathways depending on its environment and in the absence or presence of siderophore-antibiotic conjugates and catechol compounds present in the host like (L-DOPA, dopamine and norepinephrine, siderophore often having catechol groups to chelate iron).

Results: We have shown that the catechol type siderophore-antibiotic conjugates were clearly more efficient in inducing the expression of their corresponding transporters than other siderophore-antibiotic conjugates because of their very high affinity for iron. In parallel, a significant repression of the expression of the other iron uptake pathways were as well observed, indicating clearly that bacteria opt for the use of the catechol siderophores to get access to iron when such compounds are present in their environment.

Conclusions: The data also point out that catechol siderophores are the most promising siderophores for antibiotic vectorization. This study indicated as well that catecholamines (L-DOPA, dopamine and norepinephrine) are able to transport iron into bacteria and may affect bacterial growth during infection.

Different expression of CD26 and CD66 receptors on PBMCs from MERS Coronavirus infected patients

Abdulkarim Alhetheel*1, Ahmed Albarrag1, Zahid Shakoor1, Ali Somily1, Muhammed Bakhrebah2, Majed Nassar2, Ziad A. Memish3, Ayed Asiri3

1King Saud University, Riyadh, Saudi Arabia, 2King Abdulaziz City for Science and Technology (KACST), Riyadh, Saudi Arabia, 3Prince Mohammed Bin Abdulaziz Hospital, Riyadh, Saudi Arabia

Abstract third-party references: King Abdulaziz City for Science and Technology

Background: Middle East respiratory syndrome-coronavirus (MERS-CoV) is a novel emerged virus which often cause severe lower respiratory infection leading to pneumonia, renal failure and death especially in patients with co-morbidity. Recent in-vitro reports demonstrated that the MERS-CoV utilizes CD26 (dipeptidyl peptidase-4) and/or CD66 (carcinoembryonic antigen-related cell adhesion molecule 5) receptors for cell infection and blocking these receptors with specific antibodies could prevent the infection. Considering the role of peripheral blood mononuclear cells (PBMCs) in clearing pathogens, we aimed in this study to assess the susceptibility of these cells to MERS-CoV infection by measuring the expression levels of CD26 and CD66 receptors on cell surface.

Materials/methods: In this study we evaluated the expression level of CD26 and CD66 receptors on peripheral blood mononuclear cells (PBMCs) including CD4+T cells, CD8+T cells, and on monocytes from MERS-CoV patients (n=20) and healthy controls (n=20) using flow cytometry.

Results: We found that there was a significant increase in the expression level of CD66 receptor on CD4+T cells (mean MFI= 404.9 ± 34, P< 0.03), CD8+T cells (mean MFI= 534.6 ± 52.6, P< 0.03), and on monocytes (mean MFI= 346 ± 18.9, P< 0.004) from MERS-CoV patients compared with those of healthy controls (CD4+T cells; mean MFI= 325 ± 19.7, CD8+T cells; mean MFI= 392.4 ± 37.7, monocytes; mean MFI= 266.8 ± 20.6). There was a significant increase in the expression level of CD26 receptor on monocytes from MERS-CoV patients [mean MFI= 862.8 ± 116.4, P< 0.04] compared with those of healthy controls [mean MFI= 610.2 ± 67.6]. There were no statistical significant difference between the expression level of CD26 on CD4+ T cells [mean MFI= 896 ± 122], and CD8+ T cells [mean MFI= 1134 ± 122.6] from MERS-CoV patients and those of the healthy controls [CD4+T cells; mean MFI= 819.4 ± 106, CD8+T cells; mean MFI= 902 ± 144.4].

Conclusions: The increased expression levels of CD66 receptor on PBMCs and CD26 receptor on monocytes from MERS-CoV patients highlights the importance of investigating the role of these receptors during the course of MERS-CoV infection.

Impact of selective digestive and oropharyngeal decontamination on the gut microbiome and resistome in intensive care patients

Basil Britto Xavier1, Sascha Patz2, Nienke Leonie Plantinga2, Bastiaan Wittekamp2, Christine Lammens3, Daniel Huson2, Marc J.M. Bonten3, Herman Goossens1, Philippe Jorens4, Surbhi Malhotra-Kumar1

1Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, University of Antwerp, Wilrijk, Belgium, 2University of Tübingen, Department of Bioinformatics, Tübingen, Germany, 3UMC Utrecht, Department of Medical Microbiology and Epidemiology of Infectious Diseases, Julius Center for Health Sciences & Primary Care, Utrecht, Netherlands, 4Antwerp University Hospital, Department of Intensive Care Medicine and Clinical Pharmacology, Edegem, Belgium

Background: Selective decontamination of the digestive tract (SDD) and of the oropharynx (SOD) are prophylactic interventions to reduce mortality and infectious complications in intensive care unit (ICU) patients. These involve daily administration of topical antibiotics (amphotericin B, tobramycin and colistin) during their ICU stay. Here we aimed to compare the gut resistome and microbiome of patients receiving SDD, SOD or standard care.

Materials/methods: A cluster randomised controlled study was conducted in the ICU of the University Hospital Antwerp [UZA], Belgium from 2014–2016. In total, 200 rectal swabs were collected from patients (P) (n=75) receiving standard care (n=58; P=20), SOD (n=86; P=32) and SDD (n=56; P=23). Metagenomic DNA was isolated (FastDNA, MP Biomedicals), libraries were generated (Nextera XT), followed by shotgun-sequencing (2 x 100 bp, HiSeq2500, Illumina) targeting ≈80 million reads/sample. Non-human reads were mapped against the NCBI-nr database. MEGAN Ultimate 6 was used for taxonomic classification to compare normalised samples. Relative abundances of antibiotic resistance genes were calculated by mapping reads against the CARD database using DIAMOND in blastx mode with 97% identity.

Results: Of the 200 samples, 171 (P=74) passed the sequence quality cutoff and underwent further analysis [Figure 1A]. Microbial diversity [Shannon-Weaver diversity index: SID] in patients receiving SDD [2.0 ± 1.05; 7 genera] was reduced compared to those receiving standard care [2.2 ± 0.63; 9 genera] (p=0.42). In contrast, the SID in patients receiving SOD was very similar to those receiving standard care [2.4 ± 0.82; 11 genera] (p=0.38). Dominant microbial genera after treatment were Bacteroides and Alistipes (standard care), Clostridium (SDD), and Bacteroides and Enterococcus (SOD). Enterobacteriaceae were reduced during both SDD and SOD. Relative abundance of beta-lactamases was lower during SDD and SOD, while aminoglycoside and macroline resistance genes (aph(2’)-Ia, ermB and ermC) were more abundant during SDD. No significant changes were observed in the relative abundance of tetracycline resistance genes [tet] across all three treatment groups [Figure 1B].

Conclusions: Our data indicate that, among the three treatments studied, SDD led to a higher decrease in microbial diversity and to an increased relative abundance of both aminoglycoside- and macroline-resistance genes.

Abstract 8931

**Actinomycosis: a case series of 10 patients from an infectious diseases department**

João Paulo Caldas¹, Rita Filipe¹, João Nuak¹, Carmela Piñeiro¹, Candida Abreu¹, Nuno Rocha Pereira*¹, André Silva-Pinto¹, António Sarmento¹

¹Centro Hospitalar Universitário de São João, Porto, Portugal

**Background:** Actinomycosis is a rare chronic disease caused by *Actinomyces* species. These are anaerobic Gram-positive commensal bacteria of the human mouth, digestive and genital tracts, with low virulence, making it difficult to distinguish between colonization and infection. We reviewed the cases of actinomycosis treated in our Infectious Diseases Department.

**Materials/methods:** Retrospective study of actinomycosis cases treated in an Infectious Diseases Department of a Portuguese tertiary care hospital in the last 5 years. Data were collected from individual medical records. *Actinomyces* were identified using MALDI-TOF technology, PCR techniques or histopathological examinations.

**Results:** Ten cases were identified: 4 cervicofacial, 2 pulmonary, 2 cutaneous and single cases of gastrointestinal and genitourinary actinomycosis. Five of them were women and age ranged between 19-70 years. Median time of follow-up was 9 months (IQR 6). Except in one case, several risk factors for active disease were identified (the most common: poor oral hygiene in 4 cases, active cancer in 3 and chronic pulmonary disease in 2). Diagnosis was made combining clinical data (presence of symptoms and/or active inflammation in biopsies) with identification of *Actinomyces* by histopathological examinations (in 5 cases, 3 of them complemented by PCR techniques) or culture of samples (5 cases). *Actinomyces* species identification was made in 7 cases: *A. radingae* and *A. naeslundii* accounted for 2 cases each and *A. odontolyticus*, *A. europaeus* and *A. neuii* for one case each. Most of them underwent an initial regimen of intravenous penicillin or ampicillin followed by chronic oral therapy (mainly amoxicillin; due to gastrointestinal intolerance one patient underwent maintenance therapy with clindamycin and doxycycline). Median time of completed oral treatment was 9 months (IQR 8). Source control was performed in 6 cases. Five patients were considered cured (given symptoms resolution and/or imaging improvement), one patient died of pharynx cancer, one was lost on follow-up and three are still on treatment but significantly improved.

**Conclusions:** Our case series describes the diagnostic and treatment approach of a rare disease. In fact, there are few cases reported and a lack of clinical trials regarding treatment options. Physicians must be acquainted with typical actinomycosis presentations to overcome this problem.

Vaginal carriage of *Enterobacter cloacae* and *Klebsiella pneumoniae* among pregnant women in Bukavu, Democratic Republic of Congo: prevalence, risk factors and adverse pregnancy outcomes

Karen De Keyser*1, Guy Mulinganya2, Serge Balole2, Jerina Boelens1, Daniel De Vos1, Annelies De Vulder1, Erick Hendwa1, Richard Kambale1, Freddy Kampara2, Innocent Mubalama1, Jules Mongane2, Isia Nianci4, Serge Zigabe4, Steven Callens1, Mario Vaneechoutte1, Piet Cools1

1Ghent University, Ghent, Belgium, 2Université Catholique de Bukavu, Bukavu, Democratic Republic of Congo, 3Queen Astrid Military Hospital, Brussels, Belgium, 4Université Catholique de Bukavu, Bukavu, Democratic Republic of Congo

**Background:** In sub-Saharan Africa, three percent of newborns die within the first month of life. Neonatal sepsis (NS) causes one fourth of these deaths and is caused by maternal vaginal bacteria that are transmitted to the fetus/newborn just before/during birth. In Bukavu, DRC, we previously showed that the major pathogens causing NS are *Enterobacter cloacae* (EC) and *Klebsiella pneumoniae* (KP). In the current study, we aimed to assess the prevalence of vaginal carriage of EC and KP, and to identify associated risk factors and adverse pregnancy outcomes.

**Materials/methods:** We followed 553 women from Bukavu, DRC during pregnancy and delivery and quantified EC and KP in a subset of 330 cervicovaginal lavages (CVLs) (taken in first trimester) using newly developed and validated in-house quantitative PCR assays. All women and newborns were subjected to an extended clinical examination, all women to a gynecological examination. Vaginal infections including bacterial vaginosis were diagnosed by Gram-stain and wet mount of vaginal smears. Questionnaires were used to ask about sociodemographics, reproductive health history, sexual behavior, vaginal hygiene practices, vaginal signs and symptoms. Different multivariate logistic regression models were built for both EC and KP to identify risk factors and adverse pregnancy outcomes.

**Results:** The prevalence of EC and KP carriage was 42.4% [95% CI, 37.2 - 47.8%] and 12.1% [95% CI, 9.0 - 17.8%], respectively. The concentration of EC was low for all EC-positive women (< 2.5log^3 EC/ml CVL), while KP concentrations ranged from 3.63log^2 to 6.25log^6 KP/ml CVL. Carriage of EC was significantly and independently associated with a previous premature delivery [aOR 13.43], previous dysuria [aOR 6.26], and borderline with anal intercourse [aOR 6.85, p=0.054]. KP carriage was independently and significantly associated with a disturbed vaginal microbiome [aOR 3.01], maternal tachycardia [aOR 4.14], previous abortion [aOR 2.04], C-section [aOR 3.43] and polypnea/apnea of the newborn [aOR 8.49].

**Conclusions:** We found EC carriage to be highly prevalent, but at low concentrations; KP carriage was relatively low, at moderate concentrations. Both EC and KP were independently associated with [a history of] adverse pregnancy outcomes.

Home-based care of low-risk febrile neutropenia in children: an implementation study in a tertiary paediatric hospital

Gabrielle Haeusler*, Ben Teh, Franz Babl, Lisa Orme, Francoise Mechinaud, Penelope Bryant, Bob Phillips, Richard De Abreu Lourenco, Monica Slavin, Karin Thursky

1Peter MacCallum Cancer Centre, Department of Infectious Diseases, Melbourne, Australia, 2Royal Children’s Hospital, Emergency Department, Melbourne, Australia, 3Royal Children’s Hospital, Children Cancer Centre, Melbourne, Australia, 4Hopital Robert Debré, Unité d’hématologie immunologie pédiatrique, Paris, France, 5Royal Children’s Hospital, Department of Infectious Diseases, Melbourne, Australia, 6University of York, Centre for reviews and dissemination, York, United Kingdom, 7University Technology Sydney, Centre for Health Economics Research and Evaluation, Sydney, Australia

Background: Home-based management of low-risk febrile neutropenia (FN) is safe, improves quality of life and reduces healthcare expenditure. A formal low-risk paediatric program has not been implemented in Australia. We aimed to describe the implementation process and evaluate the clinical impact on length of stay (LOS) and patient safety.

Materials/methods: This prospective study incorporated three phases: implementation, intervention and evaluation. A low-risk FN implementation toolkit was developed and included a care-pathway, patient information, home-based assessment and educational resources. The program had executive-level endorsement, a multidisciplinary steering committee, and a dedicated nurse specialist. All children with cancer and low-risk FN were eligible to be transferred to home-based after an overnight period of observation for intravenous antibiotics with a nurse visiting daily. Low-risk patients were identified using a locally-validated decision rule and suitability for home-based care using disease-, chemotherapy and patient-level criteria. Plan-Do-Study-Act methodology was used to evaluate clinical impact and safety pre- and post-implementation and key barriers were identified.

Results: Over 18 months, 336 children with FN were screened: 130 (39%) were low-risk, of which 63 were transferred to home-based care. Compared to pre-implementation there was a significant reduction in in-hospital median LOS (4.6 to 1.5 days, p<0.001) and 291 in-hospital bed days were saved. Eight (13%) patients needed readmission and there were no adverse outcomes. A key barrier was timely screening of all patients, and program improvements, including utilising the electronic medical record for patient identification, have been implemented.

Conclusions: This program significantly reduces in-hospital LOS for children with low-risk FN. Ongoing evaluation, including formal economic and quality of life impact assessments, will inform sustainability and identify areas for improvement. The paediatric low-risk FN toolkit is available online (www.cancerandinfections.org) and, together with these outcomes, will support national scale up.

Abstract 8939

Risk factors for mortality in bloodstream infections in cancer patients
Aslihan Ulu1, Suheyla Komur1, Ferit Kuscu1, Ayse Seza Inal*,1, Behice Kurtaran1, Yesim Tasova1
1Çukurova Üniversitesi Tip Fakültesi, Adana, Turkey

Background: Blood stream infections (BSI) are related to increased morbidity and mortality in cancer patients. Our aim is to determine the risk factors of mortality in cancer patients,

Materials/methods: Single center retrospective cohort study was performed in Haematology and Oncology Units in Çukurova University Medical School Hospital from January 2015 to December 2017. Patients with first episode of bacteremia were enrolled to the study. Patients of whom multiple microorganisms yielded in the blood culture were excluded. BSI diagnosis was performed according to CDC criteria. Demographic characteristics, infection data and risk factors were recorded prospectively by infection control committee. Multidrug resistance (MDR) was defined for gram positive and negative bacteria according to an international expert proposal for interim standard definitions for acquired resistance by Magiorakos AP, et. al.

Results: 220 bacteremia patients were enrolled to the study according to inclusion and exclusion criteria. Of the patients 122 were male (55.5%), mean age was 48.4 16.3 years. 53.6% of the patients was primary bacteremia (20.9%, n=46, catheter related vs. 32.7%, n=72, non catheter related). Most common secondary bacteremia source was pneumonia (37.3%, n=82). In hospital mortality rate was 51.8% (n=114). Most common pathogen was Acinetobacter baumannii. Of the isolated 202 bacteria 62.7% (n=138) was MDR. Significant risk factors for mortality were peripheral venous catheter (p=0.006, OR=0.192; CI:0.054-0.684), urinary catheter (p<0.001, OR=3.021; CI:1.724-5.292), haematologic cancer (p=0.004, OR=0.424; CI:0.237-0.760), MDR (p=0.002, OR=2.690; CI:1.456-4.970), diagnosis (p=0.001), isolated microorganism (p<0.001), length of stay (p=0.002) in univariate analysis. MDR (2.26; CI:1.375-3.714), secondary bacteremia (1.975;CI:1.321-2.952) and length of stay (0.975;CI:0.964-0.987) was significant risk factors in cox regression model. MDR was also associated with decreased survival (log rank: 0.006, figure 1).

Conclusions: Longer stay in the hospital, secondary bacteremia and MDR was found as risk factors of mortality. MDR was also also associated with decreased survival. Besides increased infection control practices, broader spectrum antibiotics can be thought for empirical treatment of cancer patients with bacteremia symptoms.

CIBER en Epidemiología y Salud Pública (CIBERESP), Madrid, Spain. ²Servicio de Microbiología. Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación Sanitaria (IRYCY). Madrid, Spain. ³Servicio de Microbiología. Hospital Universitario Ramón y Cajal and Instituto Ramón y Cajal de Investigación Sanitaria (IRYCY). Red Española de Investigación en Patologia Infecciosa (REIPI), Madrid, Spain

Abstract third-party references: Abbott Molecular

**Background:** Nowadays, HIV-1, HBV and HCV viral load testing is the backbone for monitoring antiviral treatments. The objective of the current study was to evaluate the analytical performance for the molecular quantification of HIV-1, HBV, and HCV using the new Abbott Alinity m system and to determine the correlation with the molecular methods used routinely in our laboratory.

**Materials/methods:** A total of 153 HIV-1, 195 HBV, and 190 HCV leftover plasma and serum samples with known viral loads were re-analyzed with the Alinity m system. Previous clinical routine testing had been performed with Siemens kPCR (HIV-1) and Roche cobas 6800 (HCV, HBV). Samples were collected between July 2017 and April 2019 and selected according to their viral loads in order to represent the entire quantification ranges of the assays. In case of insufficient sample volume, a dilution protocol following the manufacturer’s instructions was applied.

**Results:** Alinity m assays showed a high linear correlation when compared to the respective routine methods: R² was 0.93 for HIV (kPCR compared to Alinity m), 0.96 for HBV and 0.92 for HCV (both: cobas 6800 compared to Alinity m). Slope and intercept point were 0.94/0.29 (HIV-1), 0.93/0.45 (HBV), and 0.87/0.64 (HCV). The mean biases between Alinity m and the routine methods were low: Alinity m minus routine method was 0.10 log cp/ml (HIV-1), 0.17 log IU/ml (HBV), and -0.01 log IU/ml (HCV). Sixteen out of 153 HIV-1 samples (10.4%), fifteen out of 195 HBV samples (7.7%) and twenty-one out of 190 HCV samples (11.1%) showed a difference >0.5 log.<1.0 log and one out of 153 HIV-1 samples (0.7%), five out of 195 HBV samples (2.6%) and nine out of 190 HCV samples (4.7%) showed a difference >1.0 log. Alinity m yielded higher viral load values in 59%, 80% and 60% of the cases, respectively. No differences in HBV and HCV quantification were observed between serum and plasma samples.

**Conclusions:** The Alinity m system showed a high concordance in HIV-1, HBV and HCV molecular quantification compared to the routine methods used in our laboratory and in many other laboratories.

Abstract 8944

Antibiotic resistance patterns of *Staphylococcus aureus* isolated in blood cultures in primary care

Sonia Thibaut*, Thomas Coeffic1, David Boutoille2, Gabriel Birgand1, Jocelyne Caillon2, Primo Network1

1Cpias Pays de la Loire, Nantes, France, 2CHU de Nantes, Nantes, France

**Background:** Patient care methods have significantly changed over time, due to decreased length of stay in hospital so the epidemiology of bacterial infections has evolved. The *Staphylococcus aureus* (*S.aureus*) resistance to antibiotics was especially monitored in hospitals whereas that has few been documented in the community. The objective of this study was to evaluate MRSA rate isolated in blood cultures in primary cares and describe the different resistant patterns of these *S.aureus* strains.

**Materials/methods:** From 1st January 2015 to 31st December 2018, antibiograms of *S. aureus* isolated from blood culture were collected in a large network of laboratories across France. Administrative and microbiological data were downloaded by laboratories on an e-platform dedicated to the surveillance. Strains isolated from patients living at home or nursing home residents were included in the analysis. Hospitalised patients and screening samples were excluded. Statistical analyses were performed using Student test or variance analysis as appropriate.

**Results:** The total number of 504 *S.aureus* antibiograms included varied from 90 in 2015 (147 laboratories) to 171 in 2018 (742 laboratories across 11 French regions). The proportion of MRSA strains was 11% (n=90) in 2015, 16% (n=86) in 2016, 11% (n=157) in 2017 and 10% (n=171) in 2018 (non significative, NS). MRSA strains was isolated from patients living at home in 88% of cases every year. Among this MSSA strains, 4% were resistant to fluoroquinolones in 2015 to 3% in 2018 (NS). The proportion of MSSA resistant to erythromycin varied from 12% in 2015 to 18% in 2018. Among this MRSA isolates, 90% were resistant to fluoroquinolones in 2015 to 65% in 2018 (NS). The proportion of MRSA resistant to erythromycin varied from 30% in 2015 to 11% in 2018 (NS).

**Conclusions:** *Staphylococcus aureus* bacteraemia is an important cause of morbidity and mortality. Suboptimal treatments are associated with poor patient outcomes. In order to optimize the treatment, the resistance patterns of the circulating *S.aureus* in the community must be studied. This study suggests that MRSA strains isolated from blood culture were more susceptible to fluoroquinolones and erythromycin over time.

Abstract 8947

National reporting of severe *Clostridioides difficile* infections in Germany between 2014 and 2018
Nicole Schmidt*1, Annicka Reuss1, Doris Altmann1, Michaela Diercke1, Tim Eckmanns1

1Robert Koch-Institut, Berlin, Germany

Background: *Clostridioides difficile* infection (CDI) is responsible for 15–25% cases of antibiotic-associated diarrhoea and accounts for 10% of all healthcare-associated infections in Germany. Since the early 2000s, there has been a marked increase in the incidence and severity of CDI and several major outbreaks. In response, Germany introduced mandatory reporting of severe CDI (sCDI) in 2007. We analysed the criteria that triggered reporting sCDI and the trend in sCDI reporting over a five-year period.

Materials/methods: sCDIs are defined according to the four-criteria definition from the European Centre for Disease Prevention and Control’s surveillance protocol. We analysed data that were continuously reported for all regions from 2014 to 2018, thus focusing solely on this three reporting criteria: i) Admission to an intensive care unit for treatment of CDI or its complications (ICU), ii) Surgery (colectomy) for toxic megacolon, perforation or refractory colitis (Surgery), iii) Death within 30 days after diagnosis if CDI is either a primary or contributing cause (Death). Each sCDI case could be reported due to one or more criteria. We counted sCDI criterion separately and calculated the percentage of each criterion among the sum of all three sCDI criteria together.

Results: The reported sum of the three sCDI criteria was 1,239 in 2014 and was consistent at 1,811, 1,803 and 1,757 between 2015, 2016 and 2017 respectively, and decreased to 1,507 in 2018. Reported “ICU” data were relatively stable between 35% and 39% during 2014 and 2018, and similarly for “Surgery”, which remained fairly stable at around 7%. Reported “Death” data ranged between 53% and 59% during the observed period.

Conclusions: Reporting of the three sCDI criteria (“ICU”, “Surgery” and “Death”) in Germany increased initially and then reached a plateau. A decrease was then observed from 2017 to 2018 and a possible further decrease suggested from preliminary data until October 2019. This may be in line with data from the US and Europe, which suggest the incidence of CDI may have peaked in recent years and is leveling off or slightly declining.

Abstract 8950

The Global Point Prevalence Survey of Antimicrobial Consumption and Resistance (Global-PPS): an opportunity to lead global stewardship actions in Belgian hospitals?

Xavier Holemans*1；2, Celine Marie-Louise V. Van Wetter1；2,3, Ann Versporten4；5, Olivier Tassin2；3, Ines Pauwels4, Herman Goossens4, Manfredi Ventura2；6

1Grand Hôpital De Charleroi - Notre Dame, Infectious Diseases, Charleroi, Belgium, 2Grand Hôpital De Charleroi Saint-Joseph, Antimicrobial Stewardship Committee, Charleroi, Belgium, 3Grand Hôpital De Charleroi Saint-Joseph, Clinical Pharmacy, Gilly, Belgium, 4Federal Public Service Health, Food Chain Safety and Environment, Belgian Antibiotic Policy Coordination Committee (BAPCOC), Brussels, Belgium, 5University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious Diseases Institute, Antwerpen, Belgium, 6Grand Hôpital De Charleroi Saint-Joseph, Medical Director, Charleroi, Belgium

Background: The 'Grand Hôpital de Charleroi' with 1154 beds capacity had set new antibiotic stewardship priorities in 2008, but several structural challenges hampered major improvements in appropriate antimicrobial prescribing. Using the standardized Global-PPS [www.global-pps.com], we aimed to improve the quality of antimicrobial prescribing guided by quality indicators and goals to be reached by 2019, as defined by the Belgian Antibiotic Coordination Committee (BAPCOC) (table).

Materials/methods: Based on the first hospital-wide Global-PPS, conducted in March 2015, we initiated stewardship interventions, consisting of dedicated education of surgeons and anesthetists to antibiotic prophylaxis, systematic review of antibiotics during systematic infectious diseases physician and clinical pharmacist rounds, point analyses and feedback, and standardization of antibiotic delivery rules. The impact of these interventions was assessed by a follow-up PPS conducted in October-November 2017.

Results: Out of 862 and 763 admitted patients, 29.6% and 26.3% were on antibiotics in 2015 and 2017 respectively [see table for details by activity medicine, surgery and intensive care units (ICU)]. Most quality indicators improved in 2017 as compared to 2015 (in green, table) but the BAPCOC target “indication antibiotic therapy noted in the patient chart in >90% of cases” was reached only for ICU.

Conclusions: This PPS gave us an opportunity to lead a global action which reinforced global awareness amongst physicians and staff. Results highlighted indicators not provided by other databases such as reason in notes and guideline compliance. It helped us to measure results of actions and to show favourable trends. As the BAPCOC goals have not yet been reached, a third follow-up Global-PPS is ongoing to further measure results of ongoing actions.

Re-evaluating and refining predictors of bacterial infection in children with cancer and febrile neutropenia

Gabrielle Haeusler1, Karin Thursky1, Monica Slavin1, Franz Babl2, Richard De Abreu Lourenco1, Francoise Mechinaud4, Bob Phillips5

1Peter MacCallum Cancer Centre, Infectious Diseases, Melbourne, Australia, 2Royal Children's Hospital, Emergency Department, Melbourne, Australia, 3University Technology Sydney, Centre for Health Economics Research and Evaluation, Sydney, Australia, 4Hôpital Robert Debré, Unité d’hématologie immunologie pédiatrique, Paris, France, 5University of York, Centre for reviews and dissemination, York, United Kingdom

Background: Seventeen paediatric febrile neutropenia (FN) clinical decision rules (CDRs) that risk stratify children with cancer and FN for infection have been derived. Collectively they include 29 different variables with 15 common across >1 CDR. Validation studies show reduced performance in external settings. Our objectives were to evaluate the association between variables common across FN CDRs to predict bacterial infection and refine existing CDRs using these data.

Materials/methods: Prospectively collected data from the multisite (n=8) Australian-PICNIC study which enrolled 858 FN episodes in children with cancer were used. Variables common across >1 CDR were analysed. Disease/chemotherapy were excluded given treatment changes over time. For recalibration, rules not including chemotherapy or disease factors and with variables common across >1 CDR were considered. Recalibration included re-evaluation of beta-coefficients (logistic model) or recursive-partition analysis (tree-based models).

Results: Ten variables were able to be analysed. On univariate analysis, location, temperature, hypotension, rigors, severely unwell and decreasing platelets, white cell count (WCC), absolute neutrophil count (ANC) and absolute monocyte count (AMC) were significantly associated with bacterial infection. The multivariable model included temperature, platelets and severely unwell, with an AUC 0.67, sensitivity of 93% and specificity of 23% (threshold 15%).

Five rules were recalibrated: three use monocyte count and temperature (Klaassen, Baorto, Rackoff) one used haemoglobin, platelets, rigors and requirement for in-patient care (SPOG-bacteraemia) and one used chemotherapy intensity, haemoglobin, platelets and WCC (SPOG-AE). The optimal AMC cut-off was 0.015 cells/mm3 (originally 0.1 or 0.15) and temperature 39.5°C. The SPOG-bacteraemia and SPOG-AE recalibration set three factors at ‘1’ and dropped haemoglobin as uninformative. Across all rules, recalibration increased the low-risk yield but reduced sensitivity (least in SPOG-AE rule).

Conclusions: Degree of marrow suppression (low platelets), features of inflammation (height of temperature) and clinical judgement (severely unwell) have been consistently shown to predict infection in children with FN. Exclusion of disease factors and recalibration of existing CDRs is a novel way to improve diagnostic performance and maintain relevance over time.

Abstract third-party references: On behalf of the NAMAP study group

Background: Amoxicillin is recommended by European guidelines as first-line treatment in streptococci or enterococci infective endocarditis (IE) (45% of monomicrobial IE). Regimen is linearly adapted to the weight but other potentially interesting co-variates such as renal function are neglected. Objectives were to identify which co-variates influenced pharmacokinetics (PK) of amoxicillin in IE treatment in order to develop a simple tool based on identified co-variates for individual adaptation.

Materials/methods: Patients treated with amoxicillin administered by continuous infusion for an IE at Nantes University Hospital between January 2013 and May 2019 were included retrospectively via the Nantes endocarditis cohort. Dialyzed patients were excluded from the study. The population PK analysis was performed using Pmetrics package for R (NPAG algorithm). Influence of weight, ideal weight, height, body mass index, body surface area, glomerular filtration rate adapted to the body surface area and calculated by the CKD-EPI method (GFR in mL/min) and serum protein level on amoxicillin PK were tested. A nomogram was then developed to determine the daily dosage to achieve a steady-state concentration between 20 mg/L (free fraction above 4CMI, 100 % of time for an MIC ≤ 4 mg/L) and 80 mg/L.

Results: One hundred and sixty patients were included. Seventy-nine percent were male and the median age was 72. Streptococci were identified in 124 cases and Enterococcus faecalis in 36 cases. The initial median dosage of amoxicillin was 12 g/day (from 2 g to 20 g/day). Median GFR was 78.77mL/min (from 12.68 to 136.07 mL/min). Population pharmacokinetic analysis was performed on 540 amoxicillin plasma concentrations. A two-compartment model best described amoxicillin PK and the GFR covariate significantly improved the model when included to the elimination constant Ke. To achieve a steady state concentration between 20 mg/L and 80 mg/L with a probability of 0.9, the daily dose should be from 0.0001 x GFR^2 + 0.06 1.3 x GFR + 1.157 (g/day) to -0.0004 x GFR^2 + 0.2073 x GFR + 0.6325 (g/day), respectively.

Conclusions: This work allowed the development of personalized medicine tool which can help to increase achievement of the PK-PD targets in IE treated by amoxicillin.

Presenter email address: antoine.rambaud@chu-nantes.fr
Background: Several commercial multiplex PCR systems for respiratory pathogens have become available. They demonstrate high accuracy but data on clinical significance of test results is scarce. Especially significance of multiplex respiratory bacterial pathogen PCR is unclear.

Materials/methods: We analyzed burden of detected respiratory pathogens estimated with the length of parental work absenteeism in a prospective study with pediatric ED patients during one epidemiological year in Oulu, Finland. We obtained nasal swabs of 737 children for the detection of 16 viral and seven bacterial pathogens. The parents filled out symptom diaries throughout the study. Follow up data and viral PCR results were available for total of 505 children, bacterial data was available for 244 children.

Results: The most common detected viruses were Rhinovirus (n=156, 31 %), followed by Adenovirus (n=48, 9.5 %), Metapneumovirus (n=47, 9.3 %) and RSV (n=38, 7.5 %). Streptococcus pneumoniae PCR was positive for 118 children (48 % of the tested), Haemophilus influenzae was positive for 51 (23 %) and Mycoplasma pneumoniae for 2 (0.8 %) children. We did not find any cases of Legionella pneumophila, Chlamydia pneumoniae, Bordetella pertussis or Bordetella parapertussis. Mean length of parental work absenteeism was 4.7 days (SD 14.2). We did not find significant differences between the viruses nor between negative and any positive virus PCR results. Positive Streptococcus pneumoniae PCR was associated with longer absenteeism (2.3 days for PCR negative vs. 4.1 days for PCR positive children, 95 % CI for difference -3.1 - -0.46, p = 0.009). Positive pneumococcal PCR was also associated with longer absenteeism when present at the same time with rhinovirus (1.9 days vs. 3.5 days, 95 % CI -3.1 - -0.31, p = 0.046), adenovirus (1.6 days vs. 4.5 days, 95 % CI -4.9 - -0.98, p = 0.007) and RSV (0.28 days vs. 4.0 days, 95 % CI -6.8 - -0.65, p = 0.023). We did not find significant changes associated to Haemophilus influenzae PCR.

Conclusions: Positive Streptococcus pneumoniae PCR is associated with longer parental work absenteeism independently of simultaneous viral PCR findings in children. PCR testing could have clinical significance when predicting burden of the disease.

Background: Mortality from S. aureus bacteraemia remains high. However, the dynamics and risk factors leading either directly or indirectly to death are largely unknown.

Materials/methods: From January 2013 until April 2015, we performed a prospective observational cohort study of consecutive hospitalised adult patients with S. aureus bacteraemia at 17 European centres (United Kingdom, Spain, Germany) and assessed predictors of mortality. The treating physicians categorised mortality as either directly S. aureus-attributable or not directly attributable.

Results: Median age of 985 included patients was 65 years (IQR 51-75) and 63.2% (623) were male. Death at 30 days and 90 days occurred in 17.3% (170) and 28.4% (270), respectively. S. aureus-attributable mortality accounted for 50% (85) of deaths at 30 days and for 36% (99) at 90 days. The focus-stratified ratio between attributable and non-attributable mortality ranged from 3.5 (15.4% vs. 4.4%) and 1.3 (19.1% vs. 14.6%) for endocarditis to 0 (0% vs. 8.6%) and 0 (0% vs. 22.9%) for surgical wound infections [see Figure]. Higher age and SOFA-Score were independently associated with both attributable and non-attributable 30-day and 90-day mortality in multivariable analysis. Only the attributable mortality was increased in female patients [adjusted hazard ratio (aHR) 1.68, 95% confidence interval (CI) 1.09-2.60, for 30-day- and aHR 1.51, 95% CI 1.01-2.28, for 90-day mortality] and in patients with persistent bacteraemia [aHR 2.81, 95% CI 1.82-4.33, for 30-day- and aHR 2.55, 95% CI 1.71-3.8, for 90-day mortality] but not the non-attributable mortality. Attributable mortality decreased after focus removal [aHR 0.41, 95% CI 0.21-0.81, for 30-day and aHR 0.44, 95% CI 0.25-0.79, for 90-day mortality] but not the non-attributable mortality. In contrast, higher Charlson score was associated with non-attributable mortality [aHR 1.13, 95% CI 1.06-1.21, for 30-day and aHR 1.12, 95% CI 1.05-1.19, for 90-day mortality] but not with attributable mortality.

Conclusions: Death after S. aureus bacteraemia is often perceived as not directly attributed to S. aureus. Future interventions to improve outcome should not only focus on direct but also indirect and late effects of S. aureus bacteraemia.
Abstracts 2020

**Figure:** Differentiation between *S. aureus* attributable and non-attributable mortality from a cumulative incidence analysis of competing events; stratified according main infectious focus

Late spot evaluation reveals enhanced phage lytic activity

Dace Rezevska*1, Karlis Racenis1,2, Juta Kroica1

1Riga Stradins University, Riga, Latvia, 2Pauls Stradiņš Clinical University Hospital, Riga, Latvia, 3Pauls Stradins Clinical University Hospital, Nephrology centre, Riga, Latvia

Background: The wide use of antimicrobials has resulted in an increase of antimicrobial resistance. Accordingly, this public health concern makes it imperative to find novel therapeutic agents. Lytic bacteriophages specifically infect and kill bacterial hosts, even drug-resistant strains, thus allowing to consider phages as medical products. For this purpose, it is crucial to examine lytic activity of bacteriophage cocktails and their antimicrobial effect over various conditions. To assess phage cocktail efficacy, spot test should be applied.

Materials/methods: 49 Staphylococcus aureus strains acquired from peritoneal dialysis and hemodialysis patients, one S.aureus reference strain ATCC 4336 and seven commercial bacteriophage cocktails containing S.aureus phages – six produced by Eliava BioPreparations, Ltd. [Staphylococcal, Pyo, Ses, Fersisi, Enko, Intesti] and one by Microgen, Ltd. [Pyobacteriophage] were used. To detect phage titer plaque assay was performed. A spot test was implemented to detect the lytic ability of phages. The results of spot tests were evaluated following overnight incubation for 18h and 144h. A positive lytic effect was characterized as confluent, partial lysis or individual plaques, while a negative effect as no lysis.

Results: All seven commercial bacteriophage cocktails displayed steady improvement in lytic activity over time. Increase of confluent lysis at 144h vs 18h for Staphylococcal, Pyo, Fersisi, Enko and Pyobacteriophage cocktails was observed, respectively for more than 2 \(n=2 \rightarrow 4\), 3.3 \(n=3 \rightarrow 10\), 3 \(n=1 \rightarrow 3\), 1.8 \(n=5 \rightarrow 9\) and 2 \(n=3 \rightarrow 6\) times. Result of Intesti phage cocktail after 18h showed no confluent lysis in any of the strains, conversely after 144h 4 strains displayed confluent lysis.

Conclusions: The obtained data indicate that later reading of spot test results shows improved interaction between bacteriophage cocktails and S.aureus strains, i.e. lytic activity. Thus, our study suggests that bacteriophages might need more time than 18h to lyse the bacterial host and to overcome bacterial resistance. Variations of optimal lysis time could be explained by bacteriophage viral nature. Furthermore, difference among phage cocktail lytic activity could be clarified because of each cocktail different content of various S.aureus viral phagotypes and their titer differences.

Impact of time to central venous catheter removal on the mortality of adults with non-severe catheter-related candidaemia

Caroline Agnelli Bento1,2, Maricela Valerio Minero2,3, Marina Machado2,3, Jesus Guinea Ortega3,4,5, Antonio Vena2, Emilio Bouza2,3,4, Patricia Muñoz2,3,4

1Universidade Federal de São Paulo, Department of Infectious Diseases, São Paulo, Brazil; 2Hospital General Universitario Gregorio Marañón, Department of Clinical Microbiology and Infectious Diseases, Madrid, Spain; 3Universidad Complutense de Madrid, Department of Medicine, Madrid, Spain; 4CIBER Madrid, CIBERES, Madrid, Spain; 5Hospital, Gregorio Marañón Hospital, Madrid, Spain

Background: Catheter-related candidemia (CRC) comprises a significant part of Candida spp. bloodstream infections. Management requires adequate antifungal treatment and effective source control. Central venous catheter (CVC) removal is often delayed due to the severity of candidemia, with prompt source control being usually performed in patients with an already lower risk of death. Thus, the impact of time to CVC-removal on survival of candidemic patients remains controversial. We sought to analyze the effect of early CVC-removal on the mortality rates of adults with non-severe CRC.

Materials/methods: Retrospective cohort including all cases of CRC in adults diagnosed from 2010-2018 in a tertiary university hospital. CRC was confirmed if semi-quantitative roll-plate culture of the CVC tip yielded $\geq 15$ CFU of the same Candida species in bloodstream. Non-severe cases were defined as those with a Pitt-score $\leq 1$. Early CVC-removal occurred within 48 hours from index candidemia. Primary outcome was mortality at 14 and 30 days. Secondary outcomes included complications (ocular candidiasis, thrombophlebitis, endocarditis, and dissemination), and hospital length of stay (HLOS).

Results: Overall, 154 patients with confirmed CRC were included and 99/154 (64.3%) presented a Pitt-score $\leq 1$. Early CVC-removal was performed in 54/99 (54.5%) and late removal in 45/99 (45.6%). Baseline characteristics are described in Table 1. Median time to CVC-removal in each group was 1 (0-2) vs. 4 (3-32) days, $p<0.001$. Patients whose CVC was removed earlier had lower mortality rates at 14 days [1 (1.9%) vs. 8 (17.8%), $p=0.01$] and at 30 days [8 (14.8%) vs. 15 (33.3%), $p=0.03$]. There were more complications among patients with late CVC-removal [11 (24.4%) vs. 8 (14.8%), $p=0.31$]. No difference in the median HLOS was observed between groups among survivors [27.5 (6-164) vs. 23 (7-130) days, $p=0.36$]. In the multivariate analysis, early CVC-removal was an independent protective factor from 30-day mortality [OR 0.3, CI95% (0.107-0.856), $p=0.024$], whereas age [OR 1.02, CI95% (0.986-1.068), $p=0.2$] and solid tumor [OR 1.18, CI95% (0.433-3.263), $p=0.738$] were not predictors.

Conclusions: Early CVC removal is associated with a better prognosis among adults with non-severe CVC-related candidemia. Thus, clinically eligible patients with presumed CRC should have the CVC ideally removed within 48 hours.

Table 1. Baseline characteristics of adult patients with CVC-related candidaemia according to the timing of CVC removal.

Abstract 8966

Drug-resistant Neisseria gonorrhoeae and Mycoplasma genitalium identified in the private healthcare sector in South Africa

Liteboho Maduna1, Remco Peters2, Chanel Kingsburgh3, Kathy-Anne Strydom4, Marleen Kock5

1University of Pretoria, Pretoria, South Africa, 2University of Pretoria/Maastricht University, Pretoria, South Africa, 3Ampath National Reference laboratory, Pretoria, South Africa, 4Ampath National Reference laboratory/University of Pretoria, Pretoria, South Africa, 5University of Pretoria/NHLS, Pretoria, South Africa

Background: Neisseria gonorrhoeae and Mycoplasma genitalium are two of the causative pathogens of the male urethritis and vaginal discharge syndromes. Diagnostics tests are not routinely performed as these syndromes are managed using a syndromic approach, which means limited data are available in South Africa on these pathogens. Most available data are linked to the public healthcare sector [serving >80% of the population]. This study was designed to determine the antimicrobial resistance (AMR) of N. gonorrhoeae isolates and M. genitalium strains in the private healthcare sector.

Materials/methods: Neisseria gonorrhoeae isolates and positive M. genitalium DNA samples were collected from a private sector diagnostic laboratory from August 2018 to June 2019. The AMR profiles of the N. gonorrhoeae isolates were determined following EUCAST guidelines. Macrolide resistance of M. genitalium was screened for using a validated real-time PCR assay coupled with melting curve analysis targeting the 23S rRNA gene, and confirmed using Sanger sequencing. The quinolone resistance determining regions (QRDR) of gyrA and topoisomerase of macrolide resistant strains were determined by Sanger sequencing.

Results: Twenty-one N. gonorrhoeae isolates were collected and all were found to be susceptible to azithromycin, cephalosporins and spectinomycin. High rates of resistance to tetracycline (19/21; 90%), penicillin (18/21; 86%) and ciprofloxacin (13/21; 62%) were observed. Twenty-seven M. genitalium positive DNA samples were collected. The screening PCR assay detected five mutations (5/27), which was confirmed by the sequence data as follows: three strains (3/27) harboured an A-to-G transition at position 2071 and in two strains (2/27) an A-to-G transition at position 2072 (M. genitalium numbering). Two macrolide resistant strains harboured mutations in the QRDR, which included a mutation linked to moxifloxacin and sidafloxacin treatment failure.

Conclusions: The prescribing behaviour of doctors as well as the availability of antibiotics in the private healthcare sector differ significantly from that in the public healthcare sector where resistance patterns are different. This study highlights the importance of the introduction of STI diagnostics and enhanced surveillance systems to monitor and track the emergence of drug resistant N. gonorrhoeae and M. genitalium strains in the private healthcare sector.

Antibiotic resistance profile of ESKAPE pathogens in Limpopo, South Africa: A two-year retrospective analysis

Molebogeng Ruth Lekalakala*1
1Pathology Department, University of Limpopo, South Africa, National Health Laboratory Services, Polokwane, South Africa

Background: The acronym ESKAPE encompasses two Gram positive and four Gram negative pathogens ([Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa and Enterobacter species] which are the leading cause of nosocomial infections worldwide. These pathogens are amongst the twelve multidrug resistant organisms listed by World Health Organization (WHO) for which new antibiotics are urgently needed. This study describes the antibiotic resistance analysis of the ESKAPE pathogens in Limpopo province, South Africa.

Materials/methods: Retrospective data containing routine antimicrobial susceptibility test (AST) results for the ESKAPE pathogens isolated between January 2017 and December 2018 were sourced from the National Health Laboratory Services data warehouse (CDW) and the local laboratory information system (LIS). TrakCare. Vitek 2 machine was used for identification of these pathogens and susceptibility results were ascertained from minimum inhibitory concentrations and interpreted using Clinical and Laboratory Standards Institute guidelines. The analysis aimed at also detecting the district with most of these pathogens.

Results: 23,397 ESKAPE pathogens were eligible for analysis. Klebsiella pneumoniae was most frequently isolated (n = 7,547, 32%), followed by Staphylococcus aureus (n = 6,352, 27%), the least was Enterococcus faecium (n = 999, 4.2%). A reduction in rates of extended spectrum beta-lactamase (ESBL) production in K. pneumoniae was observed (49% in 2017 and 44% in 2018) however the carbapenem resistance among K. pneumoniae and Enterobacter spp. was <1%. High rates of multi-drug resistance were observed in A. baumannii (n = 1,943, 8.3%) with 52% resistance to carbapenems and <1% resistance to colistin. Capricon district had most of these ESKAPE pathogens (n = 14,305, 61%).

Conclusions: This study describes the magnitude of antimicrobial resistance in the rural Limpopo province of South Africa. These findings attest to the global spread of multidrug resistant ESKAPE pathogens and the risk of outbreaks even in the most rural hospitals. This also signal the need for enhancement of antimicrobial stewardship and infection control measures this two provincial tertiary hospital.

Abstract 8971

**Multi-centre study performance results of ETEST delafloxacin for antimicrobial susceptibility testing against Gram-positive organisms and Pseudomonas aeruginosa**

Claire Anglade*1, Thomas Armstrong2, Carey ANN Burnham3, Hardy Dwight4, Mandy Wootton5, Gilles Zambardi6, Veronique Sauvonnet6

1bioMérieux - Campus De L’étoile, Marcy-l’Étoile, France, 2bioMerieux, Saint Louis, United States, 3Washington University, Saint Louis, United States, 4University of Rochester Medical Center, Rochester, United States, 5University Hospital of Wales, Cardiff, United Kingdom, 6bioMérieux, La Balme les Grottes, France

**Background:** Delafloxacin (DFX), BAXDELA brand name, is a fluoroquinolone antibacterial indicated for the treatment of adults with the following infections caused by designated susceptible bacteria: Acute Bacterial Skin and Skin Structure Infections (ABSSSI) and Community-Acquired Bacterial Pneumonia (CABP). This study evaluated the performance of ETEST® DFX, a new gradient diffusion strip (FDA cleared but not yet CE marked) for determining antimicrobial susceptibility of Gram-positive organisms and *Pseudomonas aeruginosa* as compared to CLSI M07 broth microdilution reference method (BMD).

**Materials/methods:** A population of 625 isolates including 287 *Staphylococcus aureus* (methicillin-resistant and methicillin-susceptible isolates), 46 *Staphylococcus haemolyticus*, 32 *Staphylococcus lugdunensis*, 127 *Enterococcus faecalis* and 133 *Pseudomonas aeruginosa* were tested at 4 clinical trial sites, including one internal laboratory using ETEST® DFX and BMD. Results were analyzed in terms of essential (EA), category (CA) agreements, minor (mE), major (ME) and very major (VME) error rates using FDA breakpoints in Table 1.

### Table 1:

Abstract 8975

**Role of epitopes of four immunogenic Group B streptococci (GBS) proteins and their derivatives in differentiation between pregnant GBS carriers and non-carriers**

Anna Dobrut¹, Anna Malska-Wozniak¹, Ewa Brzozowska², Sabina Gorska², Andrzej Gamian², Monika Brzychczy-Wloch*¹

¹Jagiellonian University Medical College, Krakow, Poland, ²Institute of Immunology and Experimental Therapy, Wroclaw, Poland

**Abstract third-party references:** Supported by the National Centre for Research and Development [grant no. TANGO2/340018/NCBR/2017]

**Background:** Group B Streptococci (GBS) are opportunistic pathogens, which can cause life-threatening infections in newborns. Currently, screening of pregnant women for GBS carriage is based on time-consuming culture methods. Therefore, the aim of this study was to determine the ability of chosen core epitopes of the immunoreactive GBS proteins and their derivatives to detect GBS carriers in immunoenzyme assay using antibodies present in pregnant women’s blood.

**Materials/methods:** The epitopes (n=12) of four immunoreactive GBS proteins: enolase, elongation factor Tu, inosine 5’-monophosphate dehydrogenase and molecular chaperone GroEL were detected by PEPSCAN, synthesized and conjugated with BSA protein. Phenotypic diagnosis of GBS carriage was conducted according to CDC guidelines. Patients (n=50) were monitored over the three trimesters of gestation. Serum samples were examined by ELISA assay in 96-well plates coated with the single epitopes conjugated with BSA protein and representative for four immunoreactive GBS proteins. Core epitopes and their derivatives were examined both individually and in combinations. Both IgG and IgM class antibodies were studied. This study was supported by the National Centre for Research and Development [grant no. TANGO2/340018/NCBR/2017].

**Results:** Among the 50 patients examined, 10 were colonized with GBS in the vagina or rectum. High immunoreactivity of the investigated epitopes in the presence of GBS-positive serum (mean absorbance value=1.6 nm) was discovered, whereas weak immunoreactivity (mean absorbance value=0.13) was observed in the presence of samples from non-carriers. Absorbance for IgM antibodies was noticeably higher for serum samples originating from patients with fresh carriage. Moreover, seroconversion for IgG was observed. The derivatives of epitopes demonstrated reactivity at least as high as core epitopes. These results allowed determining the cut-off point of absorbance equal to 0.2 nm, according to which patients could be qualified as GBS-carriers or GBS-non carriers.

**Conclusions:** In our study, we showed that epitopes of enolase, elongation factor Tu, inosine 5’-monophosphate dehydrogenase and molecular chaperone GroEL of GBS demonstrated high immunoreactivity and specificity; therefore, they can be considered as good markers in immunodiagnostic assay for detection of GBS carriage in pregnant women.

**Presenter email address:** mbrzych@cm-uj.krakow.pl
**Abstract 8976**

**Dipstick urinalysis: an alternative screening test for urine cultures to rule out negatives?**

Furkan Doganci¹, Mertcan Karaoglan¹, Batuhan Erdir², Sanem Aslan², Omer Ozel³, Arzu Ilki*⁴

¹Marmara University Medical Faculty, Istanbul, Turkey, ²Marmara University Medical Faculty, Istanbul, Turkey, ³Marmara University Faculty of Medicine, Istanbul, Turkey, ⁴Marmara University Medical Faculty, Department of Microbiology, Istanbul, Turkey

**Background:** Urine samples account an important part of the clinical microbiology laboratories. However the culture process is time consuming and a large proportion is reported as negative. To reduce unnecessary culture process, easy and rapid resulting screen tests are needed.. The aim of the research is to assess the validity of dipstick test as screening method in comparison with urine culture and flow cytometry.

**Materials/methods:** The urine specimens submitted to Marmara University Hospital Clinical Microbiology Laboratory were simultaneously screened with flow cytometry (Sysmex UF 1000i, Japan), and dipstick test (Mediatape UC-9A). In addition to these methods urine cultures were performed. Dipstick nitrite (NT) and leukocyte esterase (LE) tests results were compared with urine culture and flow cytometry. The collected data were analyzed in SPSS 20.0.

**Results:** A total of 555 urine specimens were enrolled in our study. Of these 49.5% were from children and 50.5% from adult patients. Urine cultures were reported as negative in 49% (n=272), mixed growth in 38.7% (n=215), and positive in 12.8% (n=68). Dipstick leukocyte esterase test resulted negative in 95.6% of these culture negatives and in 94.2% of UF1000i negatives. Nitrite test was determined negative of culture negatives and of UF1000i negatives as 98.2% 98.9% respectively. Of 98.3% urine culture negatives both dipstick nitrite+leukocyte esterase were analyzed as negative. When leukocyte esterase+nitrite test were evaluated together, the negative predictive value was 98.3% and positive predictive value 47%. The specificity of dipstick leukocyte esterase, nitrite and leukocyte esterase + nitrite were determined as 98.2%, 85.6%, 98.3% respectively.

**Conclusions:** Dipstick leukocyte esterase+nitrite test with >98% negative predictive value (NPV) can be an acceptable alternative test to detect negative cultures rapidly for clinical microbiology laboratories. However it should be noted that microbiology laboratories should be aware of samples from neutropenic and pediatric patients as screening systems can give false-negative results.

Abstract 8979

Lichtheimia corymbifera cutaneous infection

Oihana Sabalza,1, Noelia Lozano Rodríguez,1, Marta Garrido Jareño1, Rabab Chouman Arcas2, Eva M. González-Barberá1, José Miguel Sahuquillo-Arce1, Javier Peman García1, Jose Luis López-Hontangas1

1Hospital Universitario y Politécnico de La Fe, València, Spain, 2Carrer de l’Hospital, Vinaròs, Spain

Background: Mucorales is the most studied order of zygomycete fungi. They are ubiquitous, fast-growing molds (soil, water, food, surgical material) and play a major role in carbon cycle. Rhizopus is the most common genera associated to infection in humans and the 80% of mucormycosis cases are related to 4 genera of this order (Rhizopus, Rhizomucor, Mucor or Lichteimia, also called Absidia). Although rare, the incidence of infection caused by these filamentous fungi is increasing. It is the third cause of invasive fungal infection, after candidiasis and aspergillosis and most cases are reported in immunocompromised hosts with hematological malignancies, diabetes mellitus, transplantation. Trauma, burn, bite are the main risk for local infection in immunocompetent patients.

Materials/methods: Retrospective study of microbiological isolates of mucorales from January 2010 to October 2019 from Hospital La Fe, Valencia, Spain. We used mass spectrometry (MALDI-TOF) or microscopical analysis to identify molds, after 4-5 days of incubation on Sabouraud plates at 30 ºC.

Results: A total of 45 isolates from skin samples (34 skin exudates and 11 biopsies, 3 from the soft palate) were reported, 30 (66.6 %) male and 15 (33.3%) female with a median age of 47 years. The samples grew of Rhizopus (13), Mucor (22), Syncephalastrum racemosum (2) and Lichteimia corymbifera. Lichteimia corymbifera was isolated in 8 samples. Five of eight isolates had clinical relevance, 6 patients were older than 50 years (6 males, 3 females) and all of them presented risk factors such as burns (3), trauma (2), diabetes mellitus (1), chronic kidney disease (1) and leukemia (1). Surgical treatment was needed in 5 of 8 patients together with bi-antifungal therapy. Thirty-day survival rate was 5/8, similar to 1-year survival rate.

Conclusions: Local cutaneous infection is the main reported mucoral infection in our hospital, although rhinocerebral and pulmonary zygomycosis by Lichteimia corymbifera seems to be more frequently described in literature.

In our hospital, Lichteimia corymbifera in an opportunistic pathogen secondary to local injury and no systemic disease was reported. Therefore, it should be borne in mind when dealing with burn and immunocompromised patients.

Radical surgery combined with antifungal therapy, according to in vitro susceptibility, should be initiated soon for improving the survival prognosis.

Abstract 8981

**A genomic snapshot of antimicrobial resistance in Campylobacter fetus**

Birgitta Duim*1,2, Aldert Zomer1,2, Torey Looft3, Arjen J. Timmerman1,2, Jaap A. Wagenaar1,2, Linda Van Der Graaf-Van Bloois1,2

1Utrecht University, Faculty of Veterinary Medicine, Utrecht, Netherlands, 2WHO/OIE Campylobacter reference laboratory, Utrecht, Netherlands, 3USDA, National Animal Disease Center, Ames, IA, United States

**Background:** The increase in antimicrobial resistance (AMR) in *Campylobacter* is a worldwide public-health concern. *Campylobacter fetus* is primarily associated with fertility problems in sheep and cattle but can also cause severe infections in humans and requires antimicrobial treatment. It is unknown how AMR in *C. fetus* is developing. By using whole genome analysis, we determined the resistance gene content of different *C. fetus* lineages, the location of resistance genes (on the chromosome or mobile elements), and the presence of resistance genes over time in *C. fetus* isolates from different hosts. The aim is to investigate the emergence of resistance in *C. fetus* from the pre-antimicrobial era until now.

**Materials/methods:** *C. fetus* isolates obtained between 1942 - 2019 from animals (n=102) and humans (n=31) were Illumina sequenced and assembled using SPAdes. *C. fetus* genomes from public databases (n=161) were included and plasmid contigs of all genomes were predicted using RFPlasmid (github.com/aldertzomer/RFPlasmid). The Harvest suite was used for reconstruction of single-nucleotide polymorphism (SNP) based phylogeny, and BEAST for time-resolved evolutionary tracking of the genomes. Resistance genes were identified using ResFinder, and *gyrA* genes were aligned to reference resistance genes in *Campylobacter*.

**Results:** The SNP phylogeny divided 294 *C. fetus* isolates in 11 MLST lineages, of which ST20 and ST6 were overrepresented with human isolates. Forty human and 33 animal isolates carried resistance genes, of which 19% were associated with plasmids carrying tetracycline (*tetO*) and aminoglycoside resistance genes (*ant(6)-Ib, aph(3’)-III*), first detected in 1999. *GyrA* mutations were present in 55 isolates, first detected in 1962. If all these mutations confer resistance to fluoroquinolones, and the mechanism of the intrinsic resistance to nalidixic acid with absence of resistance to ciprofloxacin in wild-type *C. fetus* is currently being studied.

**Conclusions:** The overall SNP diversity in *C. fetus* after 70 years was extremely low. Chromosomal mutations in *gyrA* appeared in the 60ths in ovine isolates. Two lineages were associated with humans, carrying most of the plasmid associated tetracycline and aminoglycoside resistance genes that most likely, given their gene homology, are shared with other *Campylobacter* species.

Abstract 8984

**Early-onset prosthetic valve endocarditis: features in a contemporary cohort**

Rafael Garrido1,2, Giovanna Ianini Barbosa1, Marcelo Correia1, Leonardo Ribeiro-Da-Silva1, Luiz Henrique Lemos1, Bruno Zappa1, Clara Weksler1, Wilma Golebovski1, Cristiane Lamas1,2,3

1Instituto Nacional de Cardiologia, Rio de Janeiro, Brazil, 2INI - Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, 3Unigranrio Barra da Tijuca, Rio de Janeiro, Brazil

**Abstract third-party references:** Supported by Faperj, Rio de Janeiro, Brazil.

**Background:** Early onset prosthetic valve endocarditis (EO-PVE) is an infrequent complication with incidence ranging from 1 to 6%. It occurs up to 12 months after valve implantation and is a healthcare-associated infection due to contamination of the prosthesis during surgery or in the early postoperative period. Mortality ranges from 15 to 80%.

**Materials/methods:** This is an analysis of a prospectively implemented cohort of adult patients with definite IE from January 2006 to September 2019. Comparison between IE affecting valve prosthesis inserted for less than 1 year (EOPVE) and the remaining cohort was done using Jamovi 1.0.7 software. The ICE CRFs were used to collect data.

**Results:** EOPVE accounted for 25/359 (7%) of IE; males were less often affected compared to the cohort (48.0% vs 65.2%, p=0.09), but there was no difference in age. Episodes were more often acute (84.0% vs 50.9%, p=0.006). Patients with EOPVE more often had COPD (16.0% vs 4.9%, p=0.028), coronary artery disease (24.0% vs 8.5%, p=0.014), atrial fibrillation (30.4% vs 12.7%, p=0.021), heart failure, HF (56% vs 34.8%, p=0.037) and CABG in the past (12.5% vs 2.7%, p=0.046). In EOPVE significantly less often there was aortic or mitral regurgitation (20.7% vs 42.7% and 28.0% vs 49.3%, respectively), but more often paravalvular abscess (27.5% vs 18.9%, p=0.033) and conduction disturbances (18.2% vs 6.8%, p=0.082). No differences were seen regarding clinical features or frequency of blood culture positivity, but acute renal failure was more often seen in EOPVE (47.8% vs 26.1%, p=0.028). EOPVE was less frequently associated with *S. aureus* (0 vs 12.3%, p NS) and to viridans group streptococci (8% vs 27.8%, p=0.031) but more frequently with coagulase-negative staphylococci, CNS (24% vs 6.2%, p=0.002), and to non-HACEK Gram negatives, GN (16% vs 4.4%, p=0.038). Surgery was less often indicated for EOPVE (72 vs 89.9%, p=0.009). In-hospital mortality was similar (28% vs 25.7%).

**Conclusions:** Patients with EOPVE had hospital associated etiology (GN and CNS), less often had surgery indicated, possibly due to technical difficulties, or refusal, and despite its severity, had similar mortality compared to the other cases of IE.

Antimicrobial susceptibility of Streptococcus dysgalactiae subspecies equisimilis isolates recovered from invasive infections in Portugal

Ana Carolina Castro¹, José Melo-Cristino¹, Mário Ramirez¹, Marcos Daniel Pinho*¹
¹Faculdade de Medicina da Universidade de Lisboa, Instituto de Microbiologia, Instituto de Medicina Molecular, Lisbon, Portugal

Abstract third-party references: On behalf of the Portuguese Group for the Study of Streptococcal Infections

Background: Invasive infections by beta-hemolytic Streptococcus dysgalactiae subspecies equisimilis (SDE) are increasingly reported worldwide together with significant antimicrobial resistance. We determined the genomic background and antimicrobial susceptibility of SDE isolates recovered from invasive infections in Portugal to evaluate the genetic traits responsible for resistance and to identify the associated lineages.

Materials/methods: A total of 316 SDE isolates were recovered from invasive infections in Portuguese hospitals from 2011 to 2017. Antimicrobial susceptibility to 12 antimicrobial agents was evaluated by disk diffusion according to CLSI guidelines. Genomic sequences (Illumina) were obtained for all isolates. Antimicrobial resistance genes and multilocus sequence typing (MLST) information were extracted and clonal complexes (CCs) were defined by goeBURST at the single-locus-variant level.

Results: Resistance was found to erythromycin (30%, n=95), tetracycline (16%, n=51), clindamycin (8%, n=26), levofloxacin (4%, n=12), streptomycin (3%, n=9) and gentamicin (0.3%, n=1). Overall, 133 (42%) of SDE isolates were resistant to at least one antimicrobial agent and 17 (5%) to three or more. Erythromycin resistance was associated with CC17 (p<0.001), the most frequent CC identified (32% of all isolates). CC17 included 56% (n=53) of erythromycin resistant isolates, mostly expressing an inducible MLSₐ resistance phenotype conferred by ermA (n=50) or ermB (n=3) genes. Resistance to tetracycline decreased from 39% to 7% (p=0.01) over the study period and was associated with CC15 (p<0.001), which included 43% (n=22) of all tetracycline resistant isolates carrying either tetM alone or in combination with tetL (n=2). Different amino acid substitutions were present in levofloxacin resistant isolates, the most common being S81F in GyrA and S79F in ParC, mostly among CC17 isolates (n=8/12). The genes ant6-la, aph(3’)-III and satA4 were detected in combination in 6/9 of streptomycin resistant isolates, while the single gentamycin resistant isolate carried the aac(6’)-le-aph(2’)-la gene. Resistance to aminoglycosides had a polyclonal background.

Conclusions: A high resistance to multiple antimicrobials was observed among invasive SDE from Portugal. Resistance was found among multiple lineages indicating it emerged in various successful lineages, despite the high prevalence of some clones. Further analysis of the genomic information will allow the identification of the MGEs associated with resistance.

Abstract 8987

**Plant-based biomolecules against antibiotic-resistant microbes in skin infections and diseases**

1Department of Clinical Microbiology, IIS-Fundación Jiménez Díaz, Madrid, Spain, 2Universidad Autónoma de Madrid, Madrid, Spain, 3Department of Otorhinolaryngology-Head and Neck Surgery, Helsinki University Hospital, University of Helsinki, Helsinki, Finland, 4VTT Technical Research Centre of Finland Ltd, Espoo, Finland, 5Department of Infectious diseases, IIS-Fundación Jiménez Díaz, Madrid, Spain

**Background:** Staphylococcus aureus is the most common cause of surgical site infections which are among the most common hospital acquired infections. Treatment of *S. aureus* is challenging due to the emergence of multi-drug resistant strains such as methicillin-resistant *S. aureus* (MRSA). New antistaphylococcal compounds provide a promising therapeutic strategy. We have evaluated the antimicrobial activity of different polyphenolic compounds extracted from three different nordic berries on development of biofilm and as treatment of mature biofilm caused by three different strains of MRSA.

**Materials/methods:** Three MRSA strains were used: SAP 231 (a clone from USA 400), MRSA 1 (a wild type strain extracted from a wound exudate), and MRSA 2 (a wild type strain extracted from a paronychia). Biofilm development was induced in 96-well plates for 24h using $10^6$-colony-forming-units inoculums in tryptic-soy broth (TSB) supplemented with 0.5% glucose with or without berry extracts. In second test bacterial biofilm of each strain was grown in the same setting 24h and thereafter the anti-biofilm effect of the berry extracts was tested by treating the mature biofilm with TSB supplemented with 0.5% glucose with or without berry extracts for 24h. Effect of the berry extract on both the biofilm development and the mature biofilm was evaluated by adding TSB with 10% of alamarBlue® and by measuring the fluorescence at 560/590 nm (ex/em). The statistical data were analyzed by the nonparametric Wilcoxon test with a level of statistical significance of $p<0.05$.

**Results:** The results obtained are shown in Figure 1:
Figure 1. Results of biofilm viability in the prevention and treatment of MRSA biofilm using different berry extracts. CSSE1: cloudberry side stream extract 1. CSSE2: cloudberry side stream extract 2. RBHE: raspberry press cake, hydrothermal extract. BCCE1: Bilberry cell culture extract 1. CSSE3: cloudberry side stream extract 3. BCCE2: Bilberry cell culture extract 2.*: p-value<0.05, **: p-value<0.01, ***: p-value<0.001 for Wilcoxon test.

Conclusions: Berry extracts showed an inhibitory effect both on the biofilm development and on mature biofilm of three different strains of MRSA. Major advantages in local treatment are high level of antimicrobial compound in infection focus and limited systemic side effects.

**Abstract 8989**

**Virulence factor prediction: comparison of databases and their use for *Staphylococcus aureus* genomes analysis**

Trestan Pillonel*1, Claire Bertelli1, Florian Tagini1, Jacques Schrenzel2, Gilbert Greub1

1University Hospital Center and University of Lausanne, Lausanne, Switzerland, 2Geneva University Hospitals, Geneva, Switzerland

**Background:** Virulence can be defined as the ability of a microbe to induce disease. Variations of bacterial virulence are attributed to i) the presence/absence of virulence factors (VFs) encoded on mobile genetic elements (MGE) or the chromosome, but also ii) mutations in VFs modifying the protein activity, as well as iii) changes in the expression of these VFs. Reference databases can be used to identify and annotate known VFs in bacterial genomes. This work aimed at investigating and comparing the content of existing public databases for the annotation of bacterial VFs.

**Materials/methods:** Amino acid sequences and annotations of VFs were retrieved from five different sources: 1) the Pathosystems Resource Integration Center (PATRIC), 2) Victors, 3) Swiss-Prot, 4) the Virulence Factor Database (VFDB) and 5) the pathogen-host interaction database (PHI-base). Comparisons were made by clustering VFs at 90% sequence identity. The conservation of VFs was investigated for complete genomes of *Staphylococcus aureus*.

**Results:** Comparative analyses revealed that VFs from the five databases are highly heterogeneous. Out of over 1,200 non-redundant VFs, only 74 were found in all 5 databases and 240 in 4 out of 5 databases. Out of 252 *S. aureus* VFs, only 2 are listed in all five databases (the alpha-hemolysin and the staphylococcal protein A), and more than 75% are conserved in most *S. aureus* genomes. The annotation of most VFs is supported by a single reference to scientific literature in Victors (98%), PATRIC (94%) and PHI-base (92%), whereas more than 50% of Swissprot entries have more than one reference.

**Conclusions:** These results highlight the lack of consistency in VF databases and limited support for the annotation of many virulence factors. It reflects the difficulty of databases curation in the context of a loose definition of virulence. This limits the predictive value of VF identification in terms of disease outcome and clinical usefulness for patient management. The construction of a database containing curated clinically-relevant VFs, comparative data and a defined ontology is essential to overcome current limitations and allow target VF analysis in the routine of diagnostic laboratories.

Abstract 8990

Severe community-acquired pneumonia in the Czech Republic
Hynek Bartos*1,2, Olga Dzupova1

1 Charles University in Prague Third Faculty of Medicine, Prague, Czech Republic, 2 Ústí nad Labem, Masaryk’s hospital, Ústí nad Labem, Czech Republic

Background: The aim of the study is to describe patients with severe community-acquired pneumonia (CAP) in the Czech Republic and to test the reliability of the scoring systems on the same group. A similar study has not been published in the Czech Republic yet.

Materials/methods: The prospective observational study launched on 1.9.2017 includes adults with severe CAP treated in three Czech ICU.

Results: By 31.5.2019, 74 patients, 21 women and 53 men, aged 20-87 with median age of 62.5 years were enrolled. The underlying chronic disease was present in 53 (71.6%) patients, most frequently chronic lung disease in 26 (35.1%) and diabetes in 20 (27%) persons, smokers were 36 (48.6%). The main symptoms were cough and dyspnea in 64 (86.5%) persons and pathological auscultation findings in 64 (86.5%). Eight (10.8%) patients had initial hypotension and 51 (68.9%) patients had low oxygen saturation. The most common pathogens were Streptococcus pneumoniae in 22 (29.7%) and influenza viruses in 16 (21.6%) patients, in 23 (31.1%) the etiology was not proved. Third-generation cephalosporins in 37 (50%) and aminopenicillins in 20 (27%) patients was the most commonly used empiric treatment. This treatment was evaluated as effective in 60 (80%) patients. Mechanical ventilation was necessary in 46 (62.2%) patients, vasopressors in 40 (54.1%) and renal replacement therapy in 10 (13.5%) patients. Forty-seven (63.5%) patients were discharged, 17 (23%) were transferred to long-term care facilities and 10 (13.5%) patients died. Seven established and three newly created pneumonia scoring systems were evaluated at admission. SMART-COP (AUC 0.707) and CURB-65 (AUC 0.700) showed the best predictive value of the need for intensive care (mechanical ventilation or vasopressors).

Conclusions: The results of the study confirmed that patients with severe CAP often have underlying chronic disease and S. pneumoniae and influenza viruses are the main pathogens. Although the initial antibiotic treatment was effective in most patients and all methods of intensive care were provided, the outcome was unsatisfactory in more than a third of patients. The established scoring systems SMART-COP and CURB-65 demonstrated the best sensitivity and specificity in intensive care needs predictions.

The study was supported by grant IGA-KZ-2017-1-9

Abstract 8992

Unexpected detection of clinical isolates of Proteus mirabilis producing OXA-48 but susceptible to carbapenems and piperacillin-tazobactam

María José Artacho1,2*, Rosa Pedraza Merino1,2, Manuel Causse1,2, Montserrat Muñoz De La Rosa3,4, Elena Perez-Nadales5, Cristina Pitart6,5, Marta Hernández García6,7, Jordi Vila Estape3,4,5, Rafael Canton Moreno6,5, María Del Pilar Egea1,2, Luis Martínez-Martínez1,2,8

1 Reina Sofia University Hospital, Córdoba, Spain, 2 Maimonides Institute of Biomedical Research of Cordoba, Córdoba, Spain, 3 Barcelona Clinical and Provincial Hospital, Barcelona, Spain, 4 University of Barcelona, Barcelona, Spain, 5 Institute of Global Health of Barcelona, Barcelona, Spain, 6 Ramón y Cajal University Hospital, Madrid, Spain, 7 Ramón y Cajal Institute for Health Research, Madrid, Spain, 8 University of Cordoba, Córdoba, Spain

Background: Detecting enterobacteria producing OXA-48 is challenging as they can be carbapenem-susceptible or even present carbapenem MICs below the EUCAST screening-cutoff for carbapenemase detection. During routine work in our laboratory, we occasionally found Proteus mirabilis (Pm) isolates susceptible to ertapenem/meropenem and producing OXA-48. We have retrospectively and prospectively studied a set of Pm clinical isolates to evaluate how frequently these organisms are detected.

Materials/methods: All Pm from blood cultures or with an ESBL-phenotype from any other clinical sample obtained from May-2017 to May-2019, and all Pm from any clinical sample from May-2019 to July-2019 were considered (one isolate per patient). Pm were identified by MALDI-Tof (Bruker). The following tests were performed in all isolates: modified carbapenem inhibition method (mCIM), beta-carba (Beta-C; BioRad) and immunochromatography (IC; both OXA K-Set and NG-Test CARBA; NG Bio-tech). When any of the test was positive, a PCR with specific primers for OXA-48 and amplicon sequencing was done, and susceptibility testing was performed by broth microdilution (Sensititre DKMGN panels, Thermo Fisher) and a temocillin disc (30 mcg).

Results: One hundred and seven Pm (diagnostic samples: 91, rectal swabs: 16) were collected. Thirty (28%) isolates were positive with the two IC tests (diagnostic samples: 23, rectal swabs: 7); in all of them, the presence of blaOXA-48 was confirmed. Among these 30 isolates, two (6.7%) were negative with mCIM, and another two (6.7%) different isolates were negative with Beta-C. None of the isolates negative by IC were positive by either mCIM or Beta-C. In 26/30 (86.7%) isolates with OXA-48, MICs (mg/L) of ertapenem, meropenem and piperacillin-tazobactam were <=0.125, <=0.125 and <=1/4, respectively, and the inhibition-zone of the temocillin disc was >11 mm. For the remaining 4 isolates, ertapenem, meropenem and piperacillin-tazobactam MICs and inhibition-zones of temocillin were <=0.125-1, <=0.25-0.25, and <=1/4-8/4 mg/L and 6-25 mm, respectively.

Conclusions: A relevant unexpected proportion of Pm isolates from both diagnostic and surveillance clinical samples in our center harbored blaOXA-48 gene, but are highly susceptible to ertapenem, meropenem, piperacillin-tazobactam and temocillin. Additional strategies are needed to identify these organisms to avoid a hidden reservoir of OXA-48.

Abstract 8993

Carbapenem resistance mechanisms uncovered by nanopore sequencing in wastewater canalisations from Ghana
José Francisco Delgado Blas*1, Elena Marin Rodriguez1,2, Cecilia Valenzuela1,2, Carlos Serna Bernaldo1,2, Natalia Montero1,2, Courage Saba3, Bruno Gonzalez-Zorn1,2
1UCM Faculty of Veterinary Medicine, Madrid, Spain, 2Center for Veterinary Health Surveillance (VISAVET) U.C.M., Madrid, Spain, 3University for Development Studies, Tamale, Ghana

Background: Wastewater plays a critical role in antimicrobial resistance dissemination, especially in developing countries where health control measures are scarce. Carbapenems are last resort antibiotics, which are used in hospitals to treat infections caused by multi-drug resistant bacteria. The main goal of this study was to determine the mechanisms responsible of carbapenem-resistant bacteria from wastewater canalisations around three hospitals and one wastewater treatment plant (WWTP) located in the region of Tamale (Ghana).

Materials/methods: In 2017, samples were obtained from the canalisations before and after the centers and from their main drains. Isolates resistant to carbapenems were selected in MacConkey agar plates supplemented with imipenem. Bacterial species were identified by MALDI-TOF. Minimum Inhibitory Concentrations MICs to the most clinically relevant carbapenems were accomplished according to the EUCAST guidelines. Eight selected isolates belonging to different bacterial species were sequenced by Nanopore WGS, and the subsequent analysis were performed by Porechop, Unicycler, Bandage and Abricate.

Results: A total of 18 isolates showed high MIC values to carbapenems. Most of the isolates (n=15) belonged to different species of the genus Pseudomonas and were generally recovered from all canalisations around the hospitals, whereas the other isolates (n=3) were identified as one Escherichia coli and 2 Citrobacter freundii. All Pseudomonas isolates harbored the carbapenemase gene bla_VIM-5 and a novel variant of the beta-lactamase bla_CAR in the case of P stutzeri, integrated in the chromosome and flanked by mobilizable structures. P. guariconensis isolates shared an unidentified plasmid encoding the carbapenemase gene bla_DIM-1. Enterobacteriaceae isolates presented several carbapenemase genes distributed in different plasmids, including bla_NDM-1, blaCTX-M-15 and blaOXA-48. Further analysis will uncover the total structure of these resistance genes and the mobile elements involved in their dissemination.

Conclusions: This study revealed the high presence of diverse beta-lactam and carbapenem resistance genes, some of them described for the first time, which were broadly disseminated in different Pseudomonas species. Furthermore, some Enterobacteriaceae isolates carried an alarming plethora of carbapenem resistance genes. However, the dissemination of these Enterobacteriaceae and their resistance determinants was remarkably lower compared to the Pseudomonas isolates, which were circulating in all wastewater canalisations of Tamale.

Modelling pathogen transmission in intensive care units by integrating screening and antibiogram data

Thi Mui Pham*1, Mirjam Kretzschmar1,2, Xavier Bertrand3, Martin Bootsma1,4

1UMC Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2National Institute for Public Health and Environment (RIVM), Bilthoven, Netherlands, 3Centre Hospitalier Régional et Universitaire de Besançon, Besançon, France, 4Utrecht University, Mathematical Institute, Utrecht, Netherlands

Abstract third-party references: COMBACTE-MAGNET Consortium

Background: Hospital-acquired infections remain a major cause of morbidity and mortality worldwide, particularly in immunocompromised patients. Understanding the transmission dynamics of multi-drug resistant bacteria in intensive-care units (ICUs) is essential for designing and tailoring successful infection control strategies. Previous approaches have concentrated on infectious disease outbreaks. Far less has been done for endemic hospital frameworks. The challenge remains in distinguishing frequently imported cases from outside and acquisitions within the ward. Our aim is to tackle this problem by integrating only data routinely collected in ICUs, such as screening and antimicrobial susceptibility testing and to investigate the added value of antibiograms for recovering the transmission trees in nosocomial non-outbreak settings.

Materials/methods: We use stochastic SI models where ICU patients from an open study population either belong to the susceptible or colonized compartment. A susceptible patient may become colonized at a certain transmission rate. Two acquisition routes are considered. The endogenous route is independent of other patients and may be due to e.g. an overgrowth of the pathogen caused by antibiotic selection pressure. Cross-transmission is usually due to temporarily contaminated hands of health-care workers. We aim to extend a Bayesian data-augmented Markov Chain Monte Carlo method allowing for unobserved cases, as well as including information on antibiograms. By comparing the antibiograms involved in potential transmission pairs, we can confirm or rule out person-to-person transmissions. We conduct both simulation studies and use data on Pseudomonas aeruginosa from two ICUs of the University hospital of Besançon (UHB, France). The parameters and relative contributions of the transmission routes will be determined and compared to the results of the model without information on antibiograms.

Results: Endogenous route and cross-transmission account for a similar proportion of transmissions of Pseudomonas aeruginosa in the two ICUs of UHB, i.e. 55 (crI: 41-69%) and 45% (crI: 28-58%) respectively. Adding antibiogram data is expected to significantly reduce the uncertainty in the estimates.

Conclusions: Integrating antibiograms with routine surveillance data represents a promising approach to improve the understanding of transmission dynamics of pathogens in ICUs. The developed methods pave the way to further integrate genetic sequences with epidemiological data in nosocomial settings.

Abstract 9001

Micro-elimination of hepatitis C in HIV co-infected persons in Slovenia: analysis of HCV infection in a national HIV cohort

Jasna Cernosa*, Janez Tomažič1,2, Tomaž Vovko1, Blaz Pecavar1, Gabriele Turel1, Manja Kordiš1, Maja Pleško1, Barbara Ulčar1, Jelka Melič1, Mario Poljak3, Jeffrey Lazarus4, Mojca Maticic1,2

1Ljubljana, Clinic for Infectious Diseases and Febrile Illnesses, University Medical Centre, Ljubljana, Slovenia, 2Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, 3Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, 4Barcelona Institute for Global Health (ISGlobal), Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Globally, the prevalence of hepatitis C virus (HCV) infection in HIV-positive persons has been estimated at 6.3%, with approximately 2.3 million being co-infected. In Slovenia, the management of all HIV-infected persons has been organized systematically for over three decades and centralised at one medical centre, which has performed regular HCV screening since the mid-1990s. With the advent of direct acting antivirals (DAAs), a national “test-and-treat” strategy for HCV elimination in this sub-population was prepared. The aim of this study was to evaluate the strategy at the national level.

Materials/methods: All HIV-infected persons in Slovenia who tested anti-HCV positive were identified in the national HIV cohort, managed at the Clinic for Infectious Diseases, University Medical Centre Ljubljana, and included in the study retrospectively. Active infection was defined with HCV RNA positivity. Demographic, virological, and clinical data on HCV infection were extracted from patients’ medical records.

Results: Of all 668 HIV-infected persons, 45 (6.7%) were HCV co-infected and 84% of them were male. The average age at HIV and HCV diagnosis was 33.64 ± 8.7 and 36.18 ± 9.69, respectively. 20/43 (46%) were men who have sex with men, and 9/43 (21%) were injecting drug users. At first presentation, 34/45 (76%) were asymptomatic, 7/45 (16%) had AIDS, and 4/45 (9%) had acute HIV syndrome. 24/45 (53%) acquired HCV infection after being HIV diagnosed, 16/45 (36%) were found to be HIV/HCV co-infected at first presentation, and 5/45 (11%) were managed for HCV before being diagnosed HIV-positive. 15/45 (33%) presented acute HCV infection. HCV genotype 1 was predominant (22/44; 50%), followed by genotypes 4 (11/44; 25%), 3 (8/44, 18%), 2 (1/44; 2%) and 1+4 (1/44, 2%), respectively. 4/45 (9%) spontaneously cleared HCV, one died before HCV treatment, and 35/35 of treated (100%) were cured; 4 of them (11%) got reinfected. 6/45 are currently scheduled to receive DAAs, 3 with re-infection.

Conclusions: This study demonstrated that in Slovenia, the micro-elimination of HCV in HIV patients was achieved. Regular HCV screening needs to continue at high risk of infection or re-infection.

Efficacy of teicoplanin-loaded targeted nanoparticles in a Staphylococcus aureus thigh infection model

Baris Ata Borsa1, Mehmet Ersoy Aldag2, Isik Ikbal Baris3, Mert Sudagidan4, Ibrahim Cagatay Acuner5, Veli Cengiz Ozalp6

1Linköping University, Department of Physics, Chemistry and Biology, Linköping, Sweden, 2Corlu State Hospital, Medical Microbiology Laboratory, Tekirdag, Turkey, 3Cakmak Erdem Hospital, Pathology Laboratory, Istanbul, Turkey, 4Konya Food and Agriculture University, Kit-Argem Research Center, Konya, Turkey, 5Yeditepe University, Medical Faculty, Department of Medical Microbiology, Istanbul, Turkey

Background: Targeted therapy may be one of the most important developments in medical sciences in near future. Also, if antibiotics can be targeted, that may be the best way of preventing side effects, slowing down the antimicrobial resistance by lowering the unnecessary exposure in long-term. We used short oligonucleotide chains called aptamers that have ability to specifically attach to different molecules and/or cells including Staphylococcus aureus. The aim of our study was to determine in-vivo efficacy of teicoplanin-loaded aptamer-targeted nanoparticles on mice thigh infection model.

Materials/methods: For the purpose of targeting, teicoplanin was loaded in mesoporous silica nanoparticles and the pores were blocked using specific aptamers in order to prevent the release of teicoplanin in the absence of S. aureus. To analyze the efficacy of these nanoparticles, mice thigh infection model was used. 16 female immuno-competent BALB/c mice were divided into 4 groups as non-infected/PBS treated, infected/teicoplanin treated (40 mg/kg), infected/targeted-teicoplanin treated (40 mg/kg teicoplanin), infected/PBS treated. Thigh infection induced by injecting 3x10^5 CFU S. aureus ATCC 29213 on both thighs. Single dose intraperitoneal treatment was administered 2 hours after the initial infection and mice were sacrificed at the end of 24 hours and thigh muscles were removed for bacteriologic and histopathologic analysis (H&E).

Results: Teicoplanin and targeted-teicoplanin was able to reduce the number of bacteria on thigh muscles for 79% and %44 respectively. Inflammation scores were also found correlated with bacteriologic response in histopathological examination of the muscle tissue. These results indicated that the targeting antibiotics using nanoparticles may be an effective way on the treatment of infectious diseases.

Conclusions: Targeted treatment of infectious diseases may be a great hope to win the battle against bacterial infections and one of the most important healthcare problems of today, antimicrobial resistance, in long-term. Our results showed that teicoplanin is active when capsulated inside nanoparticles in a way that will never be released in the absence of a specific pathogen. We believe that this approach may be translated into clinic with more detailed investigations of the efficacy of different loading doses, specificity and toxicity.

Evaluation of potential implication of the wastewater microbiome in fungal pathogens spreading using next-generation sequencing technology

Hanane Yousfi*, Morin Loïc², Goubet Anne³, Palmier Karima⁴, Labadi Karine⁴, Lemainque Arnaud⁴, Pernelle Jean-Jacques⁴, Sghir Abdelghani²

¹Génomique métabolique, Genoscope, Institut de Biologie François Jacob, CEA, CNRS, Université d’Evry, Université Paris-Saclay, Evry, France, ²Institute Of Biology Intégrative De La Cellule, Université d’Evry Paris Saclay, Orsay Cedex, France, ³University of Paris-Saclay, INRAE, PROSE, Antony, France

Background: Fungi are considered to be among the main causes of infectious diseases, especially, for immunocompromised patients. Pathogenic fungal species are ubiquitous in the environment with important diversity within wastewater treatment plants (WWTPs). They may constitute a serious threat to human health, since it is showed that fungi are not completely removed by conventional WWTPs processes. In addition, antifungal resistance and emergence of life-threatening fungal species, not previously well identified, characterized or not yet cultivated, make patients treatment very complex. Therefore, it is important to manage and control the source of pathogens contamination, to reduce fungal infections incidence.

Materials/methods: Twenty-three wastewater sludge samples were collected from the Seine-Morée WWTP, started de novo without external sludge inoculation, for 236 consecutive days. Metagenomic DNA was extracted according to Nucleo spin soil DNA kit. The eukaryotic diversity was investigated by PCR amplification of the V9 region of the 18S rRNA gene. The resulting PCR fragments were sequenced on Illumina MiSeq platform at Genoscope. Sequence reads affiliation was performed by blast using SILVA 132 18S database. BIOM files (abundance + taxonomy) were constructed and imported in R (version 3.5.2) for statistical analysis.

Results: A total of 74,432 high-quality sequence reads [345 OTUs] were obtained for the twenty-three samples. These sequences are affiliated with nine different fungal phyla among which a not yet cultivated Cryptomycota phylum was the most predominant making up to 76 % of the total fungal population. Among the potential human fungal genera-containing pathogen species, we counted 45, totaling 8035 reads. Candida and Pichia were the two most important genera reported for Ascomycota phylum, while Lichtheimia and Rhizopus were observed for Mucoromycota phylum. These genera represent the most persistent potential fungal pathogens within the WWTP microbiome, over the 236-sampling days.

Conclusions: The overall results of this study highlight that treated wastewater and sludge represent a potential source of pathogenic fungi. Hence, it is important to consider human fungal pathogens during safety evaluation for any agricultural or recreational water use.

Presenter email address: hanane.yousf@gmail.com
Background: Extra-pulmonary tuberculosis (EPTB) infection is an increasing problem in the Philippine setting. Local programs have been formulated to tackle this entity, however, there is limited domestic literature as to the profile and characteristics of these patients. The aim of this study is to determine the prevalence, distribution and pattern of EPTB according to their demographical data and collect data that may later be used in the treatment and observation of such cases.

Materials/methods: The medical records of patients diagnosed to have EPTB in Makati Medical Center from January 2016 to December 2018 were reviewed. Demographics, clinical profile, site of EPTB, comorbidities, drug susceptibility and testing data were collected.

Results: Pulmonary Tuberculosis had 4,361 (93.6%) cases while 296 (6.3%) were extra-pulmonary. Male to female ratio was 1.3 (p=0.512). Mean age of genders was 36.5 for male and 32.9 for female with difference of 1.4 (p=0.8395). Most common sites seen in the lymphatics (35%), GI (19%), bones and joints (12.35%). Most common presenting sign or symptom was a palpable mass (42%), then pain (21%), fever and respiratory symptoms (11%). HIV infection (21%), Hypertension (12%) and previous tuberculosis treatment (9.4%) were frequent findings in the history.

Conclusions: The proportion of EPTB was 6.3% compared to 1% in the last surveillance report in 2013. No significant correlation was found as to differences in gender, age groups and comorbidities. Most common sites of EPTB were found in the lymphatics followed by GI and pleural forms presenting as palpable masses, diarrhea, vomiting, cough and shortness of breath.

Abstract 9007

**Title:** Anti-biofilm activity of bacteriophage $\phi$WL-3 conjuncted with ciprofloxacin, fosfomycin, gentamicin, meropenem or ceftriaxone against a ciprofloxacin-ceftriaxone-resistant *Escherichia coli* clinical isolate

Lei Wang1, Tamta Tkhillashvili2, Beatriz Bernal Andrés1, Andrej Trampuz1, Mercedes Gonzalez Moreno1

1Charité – Universitätsmedizin Berlin, Centrum für Muskuloskeletale Chirurgie, Berlin, Germany

**Background:** *Escherichia coli* is among the most common cause of Gram-negative prosthetic joint infections (PJIs) and ciprofloxacin is the first-line recommended antibiotic for anti-biofilm therapy. Due to emergence of fluoroquinolone resistance, the management of *E. coli* PJIs becomes more challenging with an increased rate of treatment failure. Here, we investigated the efficacy of a newly isolated bacteriophage $\phi$WL-3 as a therapeutic agent in combination with ciprofloxacin, fosfomycin, gentamicin, meropenem or ceftriaxone against the biofilm of a ciprofloxacin/ceftriaxone resistant *E. coli* strain.

**Materials/methods:** Bacteriophage $\phi$WL-3 was isolated from hospital sewage targeting a ciprofloxacin/ceftriaxone resistant *E. coli* clinical strain obtained from a patient diagnosed with PJI. Twenty-four-hour old biofilm formed on porous glass beads were exposed to antibiotics alone or combined with bacteriophage $\phi$WL-3 [10^8 PFU/mL] simultaneously for 24h or in a staggered manner (first bacteriophage for 4h followed by antibiotic for 24h). Recovering bacteria after treatment were detected by measuring growth-related heat production at 37°C for 48h by isothermal microcalorimetry. The minimum biofilm bactericidal concentration (MBBC) was defined as the lowest concentration of antibiotic that strongly reduced biofilm cells viability and led to the absence of heat flow production.

**Results:** All tested antibiotics presented high MBBC values (ranging from 32 to $>1024$ µg/mL) when tested alone against biofilm [Table 1]. A simultaneous administration of $\phi$WL-3 and antibiotics showed an improved antibiofilm activity for fosfomycin, gentamicin or meropenem, but not for ciprofloxacin and ceftriaxone. However, the highest antibiofilm efficacy was observed after staggered exposure, where the MBBC of ciprofloxacin could also be decreased from $>1024$ to 4 µg/mL. In contrast, ceftriaxone showed no improved activity in either case.

**Conclusions:** The co-administration of bacteriophage with antibiotics improved considerable the antibiotic efficacy against biofilm, especially after staggered exposure. Our data suggest the use of bacteriophages could restore the susceptibility of biofilms to antibiotics, as seen in our case with ciprofloxacin. These results have implications for optimal combined treatment approaches.

Continuous infusion versus intermittent antipseudomonal β-lactam antibiotics for acute pulmonary exacerbations of cystic fibrosis: effect on the respiratory microbiome

Katherine Langan*1,2, Jocelyn Choo1, Geraint Rogers3, Dominic Keating4,6, Robert Stirling4, John Wilson4, Allen C. Cheng1,2, Christina Chang1,2, Tom Kotsimbos4,5, Anton Peleg1,2

1Department of Infectious Diseases, Monash University, Melbourne, Australia, 2Department of Infectious Diseases, The Alfred, Melbourne, Australia, 3South Australia Health and Medical Research Institute (SAHMRI), Adelaide, Australia, 4Cystic Fibrosis Service, The Alfred, Melbourne, Australia, 5Department of Medicine, Monash University, Melbourne, Australia

Abstract third-party references: Monash University, Alfred Health

Background: Acute pulmonary exacerbations (PEx) of cystic fibrosis (CF) in patients infected with Pseudomonas aeruginosa are treated with intravenous anti-pseudomonal β-lactam and aminoglycoside therapy. In vitro and modelling data suggest that administration of β-lactams by a continuous infusion (CI) can increase bacterial killing when compared to standard intermittent (SI) administration but the impact on the respiratory microbiome in CF has not previously been described. Whether this differs between different antipseudomonal β-lactams is also unknown.

Materials/methods: We performed a prospective, randomized, cross-over study comparing SI versus CI intravenous antipseudomonal β-lactam therapy (cefepime, ceftazidime, piperacillin-tazobactam, ticarcillin-clavulanate or meropenem) in combination with tobramycin for treatment of PEx in adult patients with P. aeruginosa. Spontaneously expectorated sputa at Day 0, 3 and 7 (CI: n = 22, SI: n = 18) had quantitative bacterial load (Real time PCR 16S rRNA gene), quantitative pseudomonal load (Real time PCR oprL gene) and microbiome (V1 to V3 hypervariable region 16S rRNA gene metagenomic sequencing) analysis performed.

Results: There were no significant differences in either total bacterial (P = 0.697) or pseudomonal load (P = 0.989) between the SI and CI groups at day 7. The microbiota composition also did not differ significantly between the groups (PERMANOVA P = 0.178, square root ECV= 4.22, 9922 permutations). However, significant reduction in mean total bacterial (P = 0.004) and pseudomonal (P = 0.03) loads were observed for the CI ceftazidime group but there was no significant difference in the SI ceftazidime group. For meropenem, no significant differences were observed in either group. There were significant differences in the microbiome composition at Day 7 between ceftazidime and meropenem for both SI (t 2.17, P = 0.002, 1813 permutations) and CI (t 1.63, P = 0.06, 6642 permutations) groups. At day 7, those treated with ceftazidime, had more Streptococcus and Prevotella in their sputa than those treated with meropenem. In contrast, those treated with meropenem, had more Pseudomonas.

Conclusions: CI intravenous anti-pseudomonal β-lactam therapy has similar clinical efficacy and impact on the microbiome when compared to SI treatment but there were differences within antibiotic subgroups.

Abstract 9009

**Community-Acquired Bacteraemia (CAB) in senior adults: risk factors, outcomes and correlation with frailty**
Shadia Ahmed*, Daniel Kehlenbeck1, Sarah Yaseen1, Gauhiyabanu Saiyad1, Jane Minton1

1St James’s University Hospital, Leeds, United Kingdom

**Background:** Increasing life expectancy has led to an increase in the very-elderly (≥85 years) population. The characteristics of community-acquired bacteraemia (CAB) in this population are not well studied. Our objectives were to describe the characteristics of CAB in the very-elderly population and to determine which risk factors are associated with poor outcomes.

**Materials/methods:** A prospective, observation single-centre case-control study was carried out in a tertiary university hospital in Leeds, United Kingdom. Cases were patients aged ≥85 years presenting with signs and symptoms of infection and a bacteraemia within 48 hours of admission to hospital. A control group of patients aged between 65-84 were matched on a 1:1 basis by gender. Informed consent was obtained from all patients or (where the patient lacked capacity) a nominated consultee. Data on clinical characteristics including assessment of frailty, microbiological characteristics and outcomes were collected.

**Results:** Seventy-four patients were recruited between Nov 2018-July 2019, 37 patients were in the case group (aged ≥85) and 37 in the control group (aged 65-84). Fever was reported in 10.8% and 13.5% patients in the control and case groups respectively. At presentation, 37.8% of cases presented with an altered mental state compared to 29.7% of controls. In the case group 48.6% had CAB due to a UTI compared to 24.3% in the control group. Median CRP was 77 (IQR 44-202) and 142 (IQR 59-251) respectively. Median Rockwood frailty score was 6 (IQR 4-6) in cases versus 3 (IQR 3-5) in controls. Median qSOF score was 2 in both groups (IQR 1-2). Mortality at 28 days was 0% in the control group and the case group and 10.8%. At 90 days, mortality was 5.4% & 21.6% respectively (p 0.041).

Several challenges were encountered during the study. These included difficulties in gaining informed consent and the inability to recruit patients who died soon after admission to hospital.

**Conclusions:** Very-elderly patients were more likely to have bacteraemia due to UTIs, were frailer and had a higher mortality at 90 days. We also found that recruitment of this group is challenging and this needs to be considered during the study design stage.

Abstract 9015

Biofilm killing activity of bacteriophage $\phi$WL-3 against antibiotic-resistant Escherichia coli clinical isolate

Lei Wang\textsuperscript{1}, Tamta Tkhiaishvili\textsuperscript{1}, Beatriz Bernal Andrés\textsuperscript{1}, Andrej Trampuz\textsuperscript{1}, Mercedes Gonzalez Moreno\textsuperscript{1}

\textsuperscript{1}Charité – Universitätsmedizin Berlin, Centrum für Muskuloskeletale Chirurgie, Berlin, Germany

**Background:** The treatment of implant-associated infections caused by *Escherichia coli* has become more challenging due to the increase of antibiotic resistance. The use of bacteriophages as bactericidal agents has been revalued as a promising alternative approach in the treatment of bacterial infections. The implementation of therapies using bacteriophages requires not only optimal dosage but also an optimal time of antimicrobial exposure. In our study, the time-killing kinetic of bacteriophage $\phi$WL-3 was investigated on *E. coli* biofilms.

**Materials/methods:** $\phi$WL-3 was isolated from hospital sewage targeting a ciprofloxacin/ceftriaxone-resistant *E. coli* clinical strain. The antimicrobial activity against *E. coli* ATCC-25922 and the clinical strain was investigated by microcalorimetry. Twenty-four-hour old biofilms were formed on porous glass beads and exposed to $\phi$WL3 at $10^8$ PFU/mL for 24h. Samples were collected at times 0h, 4h, 8h, 12h and 24h of incubation for determination of bacterial concentration. Addition of ciprofloxacin [4 µg/mL] at 4h of bacteriophage pre-treatment was also analyzed. Viable bacteria on the beads were detected by colony-counting after plating of sonication fluids. Bactericidal effect was defined as a $\geq$3-log$_{10}$ CFU/mL reduction (99.9% kill) compared to concentration at time zero.

**Results:** Microcalorimetry analysis showed that $10^6$ PFU/mL $\phi$WL3 completely lysed $10^7$ CFU/mL of *E. coli* clinical isolate, whereas a higher titer ($10^8$ CFU/mL) was necessary to completely lyse *E. coli* ATCC-25922. Time-killing kinetic of $\phi$WL3 revealed a rapid decrease of bacteria cell viability within the first 4h of incubation at 37 °C against the clinical strain, with an approximately 2-log$_{10}$ CFU/mL reduction. No cell reduction was observed for *E. coli* ATCC-25922 within 24h. The addition of ciprofloxacin after 4h pre-treated with bacteriophages lead to a complete biofilm eradication (Figure 1).

**Conclusions:** Our results suggest a notable dependency between the bacteriophage and the bacterial strain involved on its isolation in terms of treatment efficacy. The possible impact of host specificity for the therapeutic use of bacteriophages should be further investigated. Nevertheless, bacteriophage/antibiotic combinatorial treatment seems to provide a more broad therapeutic potential, including antibiotic-resistant strains.

**Figure 1.** Effect of bacteriophage $\phi$WL3 and/or ciprofloxacin on viability of *E. coli* ATCC-25922 and clinical strain biofilms at different time points.

Abstract 9016

**Urinary tract infection and fungaemia due to Saprochaete capitata in a patient with acute myeloid leukaemia**

Asuman Birinci*1, Tugba Avan1, Esra Tanyel1, Demet Gur Vural1, Kemal Bilgin1, Yeliz Tanriverdi Cayci1

1Ondokuz Mayis University, Department of Medical Microbiology Faculty of Medicine, Samsun, Turkey, 2Ondokuz Mayis University, Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Samsun, Turkey

**Background:** *Saprochaete capitata* is a non-fermentative, non-capsular, urease-negative yeast-like fungi. It is found in the skin, respiratory tract and gastrointestinal tract microflora of healthy people as well as animal and vegetal all environmental sources. *S.capitata* infection is rarely seen and often reported from immunocompromised patients. *S.capitata* is considered to be intrinsically resistant to echinocandins; combination of voriconazole and amphotericin B is recommended for treatment.

**Materials/methods:** In this study, a case of urinary tract infection and fungemia associated with *S. capitata* in a 58-year-old female patient who developed acute myeloid leukemia during the treatment of metastatic ovarian carcinoma is presented. Antibiotic treatment and prophylactic posaconazole was initiated to the patient due to the presence of fever. Caspofungin was added to the treatment of the patient due to the continuation of fever. Urine and blood samples from patient were sent to the microbiology laboratory. Yeast growth was detected in the patient’s urine and blood cultures. Dry and cream-colored yeast colonies were growth on SDA agar medium after 24 hours. In the gram stained preparations, *S. capitata*’s artrospores and annelloconidis were seen. The Vitek MS (Biomerieux / France) was used to identify the isolate. Antifungal susceptibility of the isolate was studied by microdilution method (SensititreYeastOne, ThermoScientific, UK)

**Results:** The fungi was identified as *S. capitata* by Vitek MS. MIC values for amphotericin B, fluconazole, voriconazole, caspofungin, fluconosine, posaconazole and itraconazole were determined as 0.5µg/ml, 4µg/ml, 0.06µg/ml, 8µg/ml, ≤0.06µg/ml, 0.25 µg/ml, 0.12µg/ml, respectively.

**Conclusions:** In our case, fungemia and urinary tract infections developed under the treatment of caspofungin and the MIC value was determined as 8 µg / ml. This has shown us that echinocandins are not an effective treatment for *S.capitata* infections as they are in other studies. In neutropenic patients, it should be considered that the causative agent is *S.capitata*, especially if continuing fever despite echinocandin treatment.

Abstract 9017

**Impact of hand hygiene intervention on hand washing ability of school-aged children**

Samreen Khan*, Hiba Ashraf, Sundus Iftikhar, Naila Baig Ansari

1The Indus Hospital, Karachi, Pakistan

**Background:** To assess the current knowledge related to hand washing and efficiency of intervention on hand washing techniques amongst school children.

**Materials/methods:** A randomized control trial was conducted amongst class II students of a private school in Korangi, Karachi. Pre-intervention assessment including baseline knowledge and observed practices of hand washing in comparison with World Health Organization (WHO) standard hand washing techniques was done. This was followed by education and demonstration of proper hand washing steps by principal investigator utilizing visual aids. Participants were then randomized into two group: Group A (education only group) and Group B (education along with glow gel application group). First post-intervention assessment was conducted on same day where both groups were observed for the hand washing steps and scored for hand washing technique. In addition, participants of group B were shown germs under Ultraviolet (UV) light. School was revisited after 1 week later and participants were reassessed for their hand washing technique along with cleanliness grade after applying glow gel and observing under UV light. Data was entered and analyzed using SPSS version 21.0.

**Results:** No significant differences were found in median hand washing scores pre-intervention between both the groups (Group A vs B: 4 vs 5, p-value=0.659), while significant improvement in median hand washing scores was seen post intervention in group B as compared to group A (7 vs 6, p-value=0.011). However, no significant differences were seen in median hand washing scores at follow-up between both the groups (Group A vs B: 9 vs 8.5, p-value=0.715) but a significant improvement was observed in both the groups in the hand washing practices from baseline (p-value=0.000). On the contrary, no significant differences were found in median cleanliness grade between both the groups (Median for both the groups was 5, p-value=0.695).

**Conclusions:** Hand washing education utilizing various aids is an effective method to improve children’s hand washing capability. This short term intervention was effective even in absence of glow gel, but no cleanliness of hands was observed in both the groups.

Abstract 9020

The impact of antimicrobial stewardship for outpatient parenteral antimicrobial therapy

Ainhoa Vivero Larraza*, Nieves Sopena†, Montserrat Bonet‡, Elena De Felipe‡, Lourdes Mateu Prunonosa‡, Esteban Reynaga Sosa‡, Helena Manjón Navarro‡, Jordi Joseph Vilaplana‡, Amalia Arguedas Hernandez‡, Gloria Bonet†

†Germans Trias i Pujol Hospital, Badalona, Spain

Background: The outpatient parenteral antimicrobial treatment (OPAT) provides patients the opportunity to complete treatment safely and effectively, while avoiding complications due to prolonged hospitalization. Despite the benefits, risks with drug-related and central venous catheter (CVC)-related complications exist. For these reasons, advising antimicrobial stewardship is a crucial factor in optimizing clinical outcomes and combatting antimicrobial resistance. The Infectious Diseases Society of America recommends that all patients should have Infectious disease (ID) expert review prior to initiation of OPAT.

Materials/methods: Our objective was to evaluate whether a consultation of infectious diseases (ID) physician prior to discharge for OPAT improves the adequacy of the prescription of antibiotics in the OPAT.

It was a prospective analysis of the patients visited by ID physician prior to the discharge to the OPAT. The study was performed from May 2016 to June 2017 at Germans Trias i Pujol Hospital, a 600-bed teaching hospital.

Results: Of 341 patients included during the study period, 141 patients (41.3%) maintained the same antimicrobial treatment as in Hospital, 100 patients (29.3%) changed choice of IV antimicrobial (optimization or de-escalation) and 90 patients were discharged with either oral treatment (84 patients, 24.6%) or without antibiotic treatment in 6 cases (1.8%).

Among the 90 patients without OPAT criteria, there was no related return due to therapeutic failure. The median age of this group was 70.1 years (SE 15.9 years) and 68.9 % were man. The mean Charlson Index was 2.5 (SE 1.8). The most common diagnosis was urinary infection (45.7%), followed by respiratory infection (33.3%) and intra-abdominal infection (9 %). Among them 6.7% of the infection agents were mutirresistant.

Conclusions: In our study, ID physician enabled the optimization or de-escalation (29%) of antimicrobial therapy, the early implementation of sequential oral therapy, and helped to reduce treatment duration.

90 patients (26%) of potential OPAT’s cases were avoided through ID intervention, probably reducing the risk of healthcare-associated complications.

Avoiding OPAT when there are other treatment alternatives reduce OPAT overuse, is cost saving and improve the quality and safety of the OPAT service.

Abstract 9021

**Acinetobacter baumannii-complex related osteomyelitis**

Priscila Oliveira*, Eduardo Saconi1, Vladimir Carvalho1, Jorge Silva1, Ana L. Munhoz1

1University of São Paulo, Sao Paulo, Brazil

**Abstract third-party references:** University of Sao Paulo

**Background:** *Acinetobacter baumannii* complex (ABC) is an increasingly important cause of osteomyelitis, particularly in cases related to traumatic etiology.

**Materials/methods:** Observational retrospective study of cases of microbiologically confirmed ABC osteomyelitis between 2007 and 2015. Susceptibility profile of isolates was assessed, as well as the following: sex; age; length of hospital stay; Charlson’s index; physical status classification according to American Society of Anaesthesiologists (ASA) score; presence of comorbidities or immunosuppression; history of illicit drug use, active smoking or alcohol abuse; osteomyelitis classification; need for soft tissue repair and use of negative pressure therapy. Antimicrobial drugs for treatment and their duration were observed, as well as report of adverse events. Outcomes were evaluated after 12 months follow up.

**Results:** A total of 171 patients with ABC osteomyelitis were treated. Mean age was 43.2 years (7-88), most of them were male (78.4%). Charlson’s index was between 0 and 2 in 92.4% of patients and comorbidities were identified in 33.9%. Immunosuppressive conditions were identified in 18.7%. Active smoking and alcohol abuse was present in 6.4% and 5.8%. ASA Score was II in 51.5%. Most cases were diagnosed as post-traumatic osteomyelitis (64.9%) and inferior limbs were responsible for 62% of affected topography. Soft tissue repair was required in 32.5% and use of negative pressure in 25.1%. Acute osteomyelitis was identified in 52.6% of cases. Co-infection occurred in 72.5%, being *S. aureus* (19.4%) and *P. aeruginosa* (17.7%) the most frequent agents. Overall susceptibility was 61.4% to amikacin, 58.5% to gentamicin, 43.3% to ampicillin-sulbactam, 15.8% to cefepime, 14.6% to ciprofloxacin and 33.3% to meropenem. Colistin (19.9%), ampicillin-sulbactam (18.7%) and tygecil (18.1%) were the most frequently used drugs, mean treatment length was 72.6 days. Average hospitalization time was 77.9 days. Adverse events occurred in 21.6% of patients and change of antimicrobial drug due to them was required in 3.5% of cases. After 12 months of the end of treatment, remission was achieved in 53.8%.

**Conclusions:** Most cases of ABC osteomyelitis were post-traumatic and affected lower limbs. Co-infection was present in most patients and susceptibility rate was below 60% for most antimicrobials, including carbapenems.

Abstract 9028

Medical software approach for French ILI sentinel surveillance
Laetitia Vaillant*, Romain Pons1, Titouan Launay1, Damien Simon2, Catherine Goupillon2, Corentin Hervé1, Victoire Roussel1, Clément Turbelin1, Thierry Blanchon1

1Institute Pierre Louis Epidemiology And Public Health, Sorbonne University, Paris, France, 2AMEDULO, Paris, France, 3A10 Technology, Sceaux, France

Background: Electronic medical record (EMR) have been widely adopted by primary care physicians. This huge data source could be used for providing data to sentinel surveillance system. In 2014, an experimental project has been settled with a medical software editor and the French sentinel network for epidemiologic surveillance based on GPs reporting, to develop an exchange plug-in enabling to detect patient who potentially met the criteria of cases definition, and to export automatically some information. Aims were to evaluate the impact of this system on GP's participation and on the quality of data collected comparing with traditional ways of reporting, and to validate it through the influenza-like illness (ILI) surveillance.

Materials/methods: Case identification was based on 4 different medical coding classifications. We collected numbers and data of GP’s reports associated to a count of different cases and a number of monitored days during the ILI season. We calculated activity defined as the monitored period covered by a report. Data quality was evaluated by the completeness of ILI cases (age, sex, vaccine, treatment or hospitalization). Finally, we studied incidence of ILI. We compared three groups of GPs: 2 traditional surveillance processes (website, desktop software) and the exchange plug-in.

Results: We investigated, between 01/10/2018 and 14/04/2019, 379 GPs aged 51 on average, with 19 years of seniority in medical practice and enrolled in the surveillance network from 11 years on average. At overall, 14,653 reports were done, and 9,624 ILI cases reported by 215 GPs using exchange plug-in, 175 GPs using the desktop software and 183 using the website. Reports were more frequent (every 2.9 days vs 4.4 and 5.1), activity (24.8 weeks vs 21.0 and 15.8) and average reported cases (76.0 vs 73.4 and 53.5) were higher with the exchange plug-in. Completeness was higher for exchange plug-in users only for age and sex. Incidence characteristics were the same between the 3 groups.

Conclusions: GPs using the exchange plug-in reported more cases and more frequently than traditional surveillance process. This new approach provided a validated and efficient framework within the traditional ILI surveillance.

Abstract 9029

The impact of war on cutaneous leishmaniasis disease transmission and its control in Syria

Richard Allan*, 1, Ghada Muhjazig2

1The MENTOR Initiative, The MENTOR Initiative, Haywards Heath, United Kingdom, 2WHO, WHO EMRO, Cairo, Egypt

Background: Cutaneous leishmaniasis (CL) - “Aleppo Boil” - is transmitted by sandflies and has devastating, and sometimes fatal, outcomes. CL is synonymous with northern Syria, where, since the outbreak of war in 2011, there has been a dramatic evolution of CL transmission. This has paralleled the destruction of cities, towns and health services, mass population displacement, and emergency disease control efforts.

Materials/methods: Data on the scale and timing of urban destruction, population displacement and emergency prevention and case management control efforts across northern Syria, were compared against newly published data (12th Dec 2019) on number of CL cases for the period 2011-end 2018, extracted, cleaned and merged from three different surveillance systems: the Ministry of Health (MoH) routine surveillance system, the MoH/WHO sentinel-syndromic Early Warning Alert and Response System (EWARS), and surveillance data collected by the international NGO The Mentor Initiative. The impacts of war and control efforts on the evolution of disease were analyzed, and seasonality of transmission, access, reporting completeness, and other factors were accounted for.

Results: The analysis of the different data sets indicates that rapid rise in CL cases correlated closely with timing and scales of urban destruction and population displacement, and scale of sandfly prevention and case management activities. Cases peaked in 2015, decreased in 2016, remained stable in 2017, and increased overall again in 2018 and 2019, whilst targeted control efforts showed significant reductions in accessible areas. The data also indicates that mass population displacement from historically identified epidemiological hot spots of disease, such as Aleppo, were responsible for the spread of CL in some governorates, which previously did not experience CL at notable levels, prior to the war.

Conclusions: War in Syria has created the perfect conditions for the exponential increase of sandfly populations and their epidemic transmission of CL. In addition, mass population displacement from affected areas has caused a significant and rapid geographic expansion of CL, threatening populations inside Syria, and some countries hosting Syrian refugee populations. However, large scale control efforts have proven effective at reducing and controlling transmission, where security allows access.

Abstract 9034

Association of carbapenemase-producers in hospital effluents with carbapenemase-producer’s infection incidence and sewages heavy metals concentrations: results from the Canalis project

Laura Romero-Oraá*, Jaime Borrego-Jiménez1, Fatima Galan-Sanchez1, Rocío Tejero-García1, Maria Dolores Rojo Martin1, María Eugenia Rodríguez-Mateos1, Antonio Pérez-Pérez1, Vicente Merino Bohórquez1, Lorena Lopez-Cerero2

1University Hospital Virgen Macarena, Sevilla, Spain, 2University Hospital Virgen de las Nieves, Granada, Spain, 3University Hospital Puerta del Mar, Cádiz, Spain, 4University Hospital Reina Sofia, Córdoba, Spain

Background: Hospitals effluents could play a role in the generation and spread of carbapenemases-producing Gramnegatives (CPB). In these effluents, the presence of CPB from patients is combined with the selective pressure of spilled antibiotics and heavy metals. Carbapenemase genes have been found along with metals efflux pumps. Our study investigates the prevalence of CPB from hospitals effluents regarding to CPB incidence rate, antibiotics consumption and heavy metals discharge.

Materials/methods: Sewage were monthly collected from 4 hospitals [HA, HB, HC and HD] in the South of Spain during a 12-month period. Unconcentrated wastewaters were quantitatively inoculated on chromogenic selective media and analyzed to detect heavy metals [Zn, Cu, Hg, Pb, Co, Cr and Al] by inductively coupled plasma mass spectrometry. Counting, identification by Maldi TOF and detection of carbapenemase by lateral immunochromatography and PCR of each different colony was performed. CPB bacterial counts were related (Spearman correlation) with CPB infection incidence density/1000 occupied bed, antibiotics [ertapenem, meropenem, piperacillin/tazobactam, ciprofloxacin and levofloxacin] as DDD per 1000 patient day, and heavy metals concentrations.

Results: CPB mean was 3,15 log CFU/ml in the period of study [maximum mean at HB 4,5 log CFU/ml, p<0,05]. KPC producers were more frequently detected in 3 hospitals [HA, HB and HD] and VIM producers were more frequent in HC during the study period. CPB count was found negatively correlated with consumption of ciprofloxacin (r=-0,45, p=0,002), levofloxacin (r=-0,47, p=0,001) piperacillin/tazobactam (r=-0,61, p<0,001) and meropenem (r=-0,512, p<0,001) and HB had the lowest DDD for these antibiotics (p<0,001). On the contrary, CPB discharge was found moderately correlated with Cu (r=0,381, p=0,014), Hg (r=0,373, p=0,016), Co (r=0,474, p=0,002) and Al (r=0,302, p=0,058) sewages concentrations, showing HB the highest Hg (p=0,026) and Al (p<0,001) values. Likewise, the correlation was positive with the CPB incidence density (r=0,330, p=0,027), with a mean of 0,138 and HB had the highest (p<0,001).

Conclusions: 1) Different CPB count were found in the 4 hospital effluents studied; 2) in our area, higher CPB count in these effluents are directly related with heavy metal contents of sewages along with incidence of infected cases, but inversely related with antibiotic consumption.

Background: Tegumentary leishmaniasis (TL), a frequent and heterogeneous dermatological infection in travellers, can spread from the skin to oral mucosa. Clinical presentation impacts therapeutic management.

Materials/methods: From 2006 through 2019, the LeishMan consortium collected precise demographic and clinical data on 464 episodes of TL in 459 patients.

Results: Episodes were acquired in 47 countries. Compared to lesions acquired in the Old World (279 episodes), lesions acquired in the New World (185 episodes) were more frequently ulcerative (75% v 47%), less frequently papulonodular (5% v 25%), larger (3 v 2 cm), more frequently on the limbs (61% v 47%) and less frequently on the face (17% v 38%). Mucosal involvement was unexpectedly less frequent in New World than in Old World infections (2.7% v 5%). Compared to patients with only skin lesions, patients with mucosal lesions were older (58 v 30 years), more frequently immunosuppressed (37% v 3.5%), with skin lesions more frequently on the head (64% v 29%), but with similar rates of lymphangitis (15.5% v 15%). Identification of infecting Leishmania species in 122 patients delineated 3 typical forms. Children infected with L. major in Africa had rapidly evolving multiple lesions of the limbs; 40-70 year-old tourists infected with L. infantum in Southern Europe had a slowly evolving facial lesion and mucosal involvement in 22% of cases; young adults infected in Latin America with the L. braziliensis complex had a rapidly evolving ulcer of the lower limbs with lymphangitis and mucosal involvement in 35% and 6% of cases, respectively.

Conclusions: Analysis of TL acquired in 4 continents delineates well-demarcated clinical forms. Infections with L. infantum acquired in Europe display higher rates of mucosal involvement than infections with L. braziliensis acquired in Latin America, especially in immunosuppressed patients. The relatively low rate of mucosal involvement supports the use of local therapy in most patients regardless of the continent of infection. Based on the topography and numbers of lesions, most patients can be treated locally.

Abstract 9036

**Cost analysis of a Point-of-Care diagnostic test for detecting influenza A/B and respiratory syncytial virus in the ER setting in Norway**

Janne Charlotte Mewes¹, Anne Voermans¹, Tove Ofstad²*, Thorbjørn Halvorsen¹, Katalin Ersek³, Lotte Steuten⁴;⁵

¹Panaxea bv, Amsterdam, Netherlands, ²Roche Diagnostics Norge AS, Oslo, Norway, ³Roche Diagnostics, Subregion North-West, Almere, Netherlands, ⁴Office of Health Economics, London, United Kingdom, ⁵City University, London, United Kingdom

**Background:** New point-of-care (POC) tests for influenza A/B and RSV are available with a turnaround time (TAT) of approximately 20 minutes and excellent accuracy, enabling physicians at the emergency room (ER) to quickly identify the need for isolating patients. As a POC test has additional costs, the objective was to evaluate the difference in costs of care associated with using a POC test analysed directly at the ER (POC ER) versus a PCR lab batch test.

**Materials/methods:** A previously developed health economic model was adapted to the Norwegian ER setting, comparing the isolation and test costs of using a POC ER versus a lab batch test over a time horizon of one year from the healthcare perspective. Patients were ≥18 years presenting with unspecified lower respiratory symptoms. The main outcome of the analysis was the total isolation and test costs per patient tested. For patients tested with a POC ER test the result was available before admission to the ward allowing basing the decision on isolation on the test’s result, leading to no unnecessary isolation and to late isolation of 1.7% (influenza A), 4.8% (influenza B), and 3.0% (RSV) of patients. Results of the lab batch test were available with an average delay of 1.5 days, leaving the decision on isolation to the physician’s opinion upon admission to the ward. Of the patients isolated, 50% was isolated unnecessarily and 15% of the patients with influenza A/B or RSV were missed and isolated late.

**Results:** For influenza A/B the average isolation and test costs per patient tested were expected to be €1,597 for the POC ER and €3,289 for the lab batch test, leading to incremental costs of -€1,692, indicating cost-savings of 51.4%. For RSV the average isolation and test costs per patient tested were expected to be €601 for the POC ER and €1,219 for the lab batch test, leading to incremental costs of -€618, indicating cost-savings of 50.7%.

**Conclusions:** Using a POC ER test is expected to result in considerable cost-savings from a healthcare perspective by preventing unnecessary and late isolation, which outweigh the additional test costs by far.

Abstract 9039

Evaluation of hepatitis B vaccine efficacy and factors affecting its response in patients receiving anti-tumour necrosis factors

Gülay Okay*, Elmas Biberci Keskin1, Yasemin Akkoyunlu1

1Bezmialem Vakıf University, Istanbul, Turkey

Background: Anti-TNF agents are widely used in chronic inflammatory diseases (CIDs) and have potent immunosuppressive effects. However, the response rate of patients to hepatitis B virus (HBV) vaccination receiving anti-TNF agents is quite low. We aimed to assess the efficiency of HBV vaccination in CID patients receiving anti-TNF agents as well as in healthy controls. We also evaluated the impact of different factors on the efficacy of HBV vaccination.

Materials/methods: Patients with CIDs (inflammatory bowel disease [IBD], rheumatological diseases, and psoriasis) receiving anti-TNF agents and healthy controls vaccinated for HBV were included in the study. An adequate immune response and an effective immune response to HBV were defined as >10 and > 100 mIU/mL, respectively. Binary logistic regression analysis was performed to investigate the risk factors affecting non-response rate of vaccine.

Results: Among 274 participants, 187 were CID patients and 87 were healthy controls. The mean age of the patients with CID (43.9 ± 11.7 years) was significantly higher than that of the healthy controls [31.4±7 years] (P=0.000). Percentage of male participants (59.9%) in patients with CID was significantly higher than that of the healthy controls (42.5%) (P=0.007). Adequate immune response was 60.8% and 94.3% in patients with CID and healthy controls (P=0.000), respectively, whereas effective immune response was 38.2% and 75.9 (P=0.000), respectively. In logistic regression analysis, male gender (OR, 0.408; 95% CI, 0.201-0.830; P=0.013), use of infliximab (OR, 2.694; 95% CI, 1.203-6.035; P=0.016) and sertoluzimab (OR, 3.307; 95% CI, 1.287-8.498; P=0.013), vaccination after anti-TNF treatment (OR, 0.224; 95% CI, 0.083-0.602; P=0.003) were identified as risk factors of non-response to HBV vaccine.

Conclusions: Non-response rate to HBV vaccine is significantly higher in CID patients compared to that in healthy controls. In CID patients, the rates of adequate and effective immune response as well as median level of anti-HB titers were significantly lower than those in healthy controls. Non-response rates were higher in IBD group than those in psoriasis and rheumatological diseases. Infliximab and sertoluzimab usage, male gender, and vaccination after anti-TNF treatment were risk factors of non-response. Therefore, HBV vaccination should be given to CID patients before initiation of anti-TNF treatment and awareness should be spread on this subject.

Abstract 9040

**Comparison of diagnostic performance of two Aspergillus antigen ELISAs**

Kathrin Hoffmann*, Viola Borchardt-Lohölter1, Philip Rosenstock1, Karl Dichtl2, Ulrich Seybold3, Steffen Ormanns4, Heidi Horns5, Johannes Wagener2

1EUROIMMUN Medizinische Labordiagnostika AG, Institute for Experimental Immunology, Lübeck, Germany, 2Medizinische Fakultät, LMU München, Max von Pettenkofer-Institut für Hygiene und Medizinische Mikrobiologie, München, Germany, 3Medizinische Klinik und Poliklinik IV, Klinikum der Universität, LMU München, Sektion Klinische Infektiologie, München, Germany, 4Medizinische Fakultät, LMU München, Pathologisches Institut der Ludwig-Maximilians-Universität, München, Germany, 5Klinikum der Universität, LMU München, Medizinische Klinik und Poliklinik III, München, Germany

**Background:** Aspergillus spp. are ubiquitous and opportunistic pathogenic fungi. Inhalation of their spores can cause life-threatening invasive aspergillosis (IA) in immunocompromised patients. Current diagnostic guidelines recommend serial screening for Aspergillus antigen in serum or bronchoalveolar lavage fluid samples from patients at risk of IA. Only few enzyme-linked immunosorbent assays (ELISAs) based on monoclonal antibodies with high specificity for Aspergillus antigens are commercially available. We assessed the serodiagnostic performance of the novel Aspergillus-specific galactomannoprotein (GP) ELISA (EUROIMMUN) by comparing it to the Platelia Aspergillus galactomannan (GM) ELISA (Bio-Rad).

**Materials/methods:** Diagnostic performance of the two ELISAs was assessed by analysing serum samples from 43 patients with IA and 77 without IA. The agreement between manual versus automated processing of the GP ELISA using the EUROIMMUN Analyzer I was evaluated in sera from 16 patients with IA and eight fungus-spiked pooled sera.

**Results:** The GM ELISA identified 24 true positive and 77 true negative samples, whereas the GP ELISA identified 27 true positive and 74 true negative samples. The two assays had a positive and negative agreement of 90% and 88%, respectively. The overall agreement between the ELISAs was substantial (Cohen’s $\kappa = 0.65$). Nine IA patients were correctly identified with the GP ELISA but missed by the GM ELISA. The GP ELISA classified two IA patients as negative for Aspergillus antigen, which were identified by the GM ELISA. Manual and automated processing of GP ELISAs agreed almost perfectly (Cohen’s $\kappa = 0.91$, one discrepant sample was close to cut-off).

**Conclusions:** The GM ELISA correctly identified more patients without IA, whereas the GP ELISA correctly identified more patients with IA. Although each test identified cases that were not detected by the competitor, their performance in the serodiagnosis of IA was comparable. Overall, the assays are similarly suitable for screening of patients at risk for IA. However, serial testing and use of further diagnostic tools are recommended by standard guidelines. Furthermore, our results demonstrated that the GP ELISA can be reliably processed on fully automated systems, thus providing high-throughput analysis for monitoring patients at risk of IA.

Abstract 9045

**Unusual mechanisms of resistance to ceftazidime-avibactam in Klebsiella pneumoniae**

Evelyn Patricia Sanchez Espinoza1, Lauro Perdigao Neto1,3,4, Marina Farrel Córtes4, Tatiana Orsi1, Roberta Cristina Ruedas Martins1, Esther Lira1, Icaro Boszczowski2, Claudia Maria Dantas De Maio Carrilho1, Thais Guimaraes1, Anna Sara Levin1,2, Silvia Figueiredo Costa1,2

1University of Sao Paulo, Sao Paulo, Brazil, 2Clinical Hospital, Sao Paulo, Brazil

**Background:** The emergence of carbapenem resistant Enterobacteriales (CRE) has urged the development of new drugs. Cef-tazidime-avibactam (caz-avi) is used for its treatment but resistance has surfaced. The most prevalent resistant mechanism is the mutation of blaKPC-3 gene. The aim of this study is describe the mechanisms of resistance of Klebsiella pneumoniae (KP) to caz-avi in patients not previously exposed to the drug.

**Materials/methods:** Twenty seven multi-drug resistant KP collected at the University of São Paulo Bacteriology Laboratory from 2013 to 2016 corresponding to colonization or health-care associated infection patients were analyzed. One isolate per patient was included.

Susceptibility was performed by Broth microdilution (BMIC), efflux pump performance was evaluated with Carbonyl Cyanide 3-Chlorophenylhydrazone (CCCP). Typing, resistome and comparative genomic was assessed by Whole genome sequencing (WGS).

**Results:** The isolates belong to eleven different lineages; the most frequent ST was 11 (n=9). All isolates were susceptible to caz-avi but one. None of the twenty-seven isolates harbored KPC-3, seventy percent of the isolates harbored KPC-2 but none had mutations.

The resistant isolate was obtained from a corporal fluid, its BMIC was evaluated and corroborated by different persons. Additionally, its MIC was not altered when CCCP was added, other efflux pump inhibitors should also be tested. When analyzed by WGS no previously described resistance mechanisms were found. However, unknown mutations in efflux pumps [acrR and ramR, CRP, emrB, emrR, marR, marA, msbA, patA ] and membrane porines [ompK36 and ompK37] genes were identified. A comparative genomic analysis was performed with a clonal susceptible KP aiming to find genes involved in the resistance mechanism. Thirteen genes including two involved in response to antibiotic were present only in the resistant isolate (Figure 1). This KP is been analyzed to clarify the resistance mechanism.

**Conclusions:** This work highlights the importance of caz-avi emerging resistance even without previous exposure to the drug. Therefore, caution in prescription of the new antibiotics for CRE is strongly recommended. Other mechanisms as efflux pumps and porine modification should be profoundly evaluated in order to elucidate ceftazidime-avibactam resistance.

Abstract 9046

**Using whole genome sequencing to assess *M. leprae* transmission in French overseas Territories**

Emmanuel Lecorche*1,2,3, Baron Violaine4, Mohand-Oussaid Dalila5, Avanzi Charlotte6, Klement Elise7, Faïza Mougari1,2, Hanaa Benmansour1,2,3, Vincent P. Jarlier1, Emmanuelle Cambau1,2,3

1 Centre National de Référence des Mycobactéries et de la Résistance des Mycobactéries aux Antituberculeux, Paris, France, 2 Hospital Lariboisiere, Service de Microbiologie, APHP, Paris, France, 3 Infection, Antimicrobials, Modelling, Evolution (IAME), UMR1137 INSERM, Université Paris Diderot, Université Paris Nord, Paris, France, 4 Service de Santé Publique - DASS NC, Noumea, New Caledonia, 5 Centre Hospitalier de Mayotte, Mamoudzou, Mayotte, 6 Global Health Institute, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, 7 Service de médecine interne et maladies infectieuses du Centre hospitalier territorial de Nouvelle-Calédonie, Noumea, New Caledonia

**Background:** Our National reference center for mycobacteria diagnosed 154 cases of leprosy (multibacillary forms) from 2001 to 2019 in French Overseas territories. Most of them were diagnosed in New-Caledonia (NC) and Mayotte (MY), two islands in the Pacific and Indian Ocean, respectively. Importantly, over the last 10 years, new cases of pediatrics leprosy were diagnosed showing the persistence of leprosy transmission. Here we applied whole genome sequencing (WGS), in order to investigate *Mycobacterium leprae* transmission dynamic.

**Materials/methods:** Since *M. leprae* does not grow in vitro, *M. leprae* DNA was extracted directly from positive skin biopsies using DNA Microbiome kit (QIAamp, Qiagen) in order to eliminate DNA from human cells and skin microbiota. WGS data were produced by Illumina sequencing technology. Sequencing data were solved using Bionumerics (Applied Maths) and mapped on the reference genome *M. leprae* TN (NCBI Reference Sequence: NC_002677.1). Datasets were composed by 8 genomes from NC, 6 genomes from Mayotte and 2 laboratory strains (Thai53 and Hairaku).

**Results:** The mean coverage of sequenced genomes was 116X. The comparison of the 16 genomes to the reference genomic sequence of *M. leprae* TN generated 412 single nucleotides polymorphisms (SNP). Genome analysis of NC *M. leprae* strains showed a cluster of 6 strains from the 3K subtype, with only 10 SNP differences. The other NC genomes belonged to subtypes 1C and 4N. Interestingly, all the genomes from MY, belonged to subtype 1D but differed by 15 to 50 SNP.

**Conclusions:** WGS is an interesting tool to differentiate *M. leprae* strains can be used for molecular epidemiology analysis of cases occurring in isolated islands. In the two studied islands, transmission seemed to have occurred differently, strains being nearly identical in NC whereas showing more diversity in MY.

In vivo virulence of different clones of OXA-48-producing Klebsiella pneumoniae in Galleria mellonella infection model

Alvaro Leal1,2, Lorena Forcelledo Espina2, Azucena Rodriguez-Guardado1,3, Fernando Vazquez1,2, M. Rosario Rodicio1,4, Javier Fernández*1,2

1Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, 2Hospital Universitario Central de Asturias, Oviedo, Spain, 3Hospital of Cabueñes, Gijón, Spain, 4University of Oviedo Campus del Cristo, Oviedo, Spain

Abstract third-party references: This work was supported by project FIS PI17/00728 (Fondo de Investigación Sanitaria, Instituto de Salud Carlos III, Ministerio de Economía y Competitividad, Spain, cofunded by the European Regional Development Fund of the European Union).

Background: Infections by carbapenemase-producing Klebsiella pneumoniae represent an increasing threat to human health. Despite its significance, only a few studies have evaluated the “in vivo” virulence of these bacteria. Recently, “in vivo” non-mammalian animal models of infection have been developed for virulence studies. The Galleria mellonella larvae model has been tested with different bacterial and fungal pathogens, showing a good correlation with models in mammals. The objective of this study was to compare the virulence of different clones of OXA-48-producing K. pneumoniae in the G. mellonella model.

Materials/methods: Five isolates of OXA-48-producing K. pneumoniae previously characterized at the molecular level and belonging to different clones (ST15, ST104, ST147, ST326 and ST405) were evaluated. Two solutions of each of the clones were prepared in PBS at 10⁷ colony forming units (CFU)/mL and 10⁵ CFU/mL. 10 µL of each solution were injected in the hemocoele of larvae (40 larvae per strain; 10⁵ CFU and 10³ CFU per larvae). Then, they were incubated at 37ºC for ten days and survival data were recorded daily. A non-manipulated control group (temperature control), another one inoculated with PBS and a third one with heat-killed bacteria were also evaluated. Tests were performed in duplicate and independently. Survival data were interpreted with the GraphPad Prism 6 program using Kaplan-Meyer curves and performing statistical analysis by the Log-rank test (Mantel-Cox) with a significance level p<0.05.

Results: Kaplan-Meyer curves are shown in Figure 1. Virulence of OXA-48-producing K. pneumoniae strains was low to moderate. As expected, virulence was significant higher for the 10⁵ CFU/larvae inoculum, being also the virulence differences between analyzed strains more marked. Virulence of ST405 was statistically significant higher with respect to the other clones (p=0.045), while virulence of ST147 and ST104 was statistically significant lower (p=0.0016 and p=0.049, respectively).

Conclusions: Statistically significant differences were found in the virulence of representative strains of five high-risk international clones of K. pneumoniae involved in carbapenemase spread. Further studies are required to validate these experiments and to analyze the correlation between the virulence found, the virulence gene content of the strains and the clinical outcomes of patients infected by them.
Abstracts 2020

Figure 1. (A) Mortality curves of different clones of Klebsiella pneumoniae, generating by inoculating $10^5$ UFC/larvae (●), $10^6$ UFC/larvae (▲) and PBS (■). (B) Comparison of virulence between the different clones using the $10^5$ UFC/larvae inoculum.

Trends in antimicrobial resistance in Gram-negative pathogens among haematological patients: results of multi-centre study

Galina Klyasova*, Anna Korobova1, Svetlana Khrulnova1, Anastasia Fedorova Mironova1, Irina Frolova1, Kristina Tandilova1, Antonina Vetokhina2, Irina Molchanova3, Olga Kutsevalova4

1National Research Center for Hematology, Moscow, Russian Federation, 2Regional hospital of Irkutsk, Irkut, Russian Federation, 3Regional hospital of Chelyabinsk, Chelyabinsk, Russian Federation, 4Rostov-on-Don research center for oncology, Rostov-on-Don, Russian Federation

Background: The goal was to evaluate the trends in antimicrobial resistance among gram-negative pathogens from blood culture in haematological patients during various periods.

Materials/methods: Gram-negative rods isolated from blood culture in 11 hospitals from 9 cities in Russia in 2002-2018 were studied. Susceptibility was determined by the broth microdilution method [CLSI 2018, EUCAST 2018 for colistin]. Extended-spectrum beta-lactamases (ESBL) production was confirmed by phenotypic tests. PCRs were performed for detection of blaCTX-M genes, groups of blaCTX-M, blaNDM-1, blaOXA-48, blaVIM, blaIM, blaOXA-23, blaOXA-24/40, blaOXA-58.

Results: A total of 2338 gram-negative isolates were evaluated, of those 1180 were isolated in 2003-2010 and 1158 in 2011-2018. There were no differences in distribution of pathogens in these periods. The rate of Escherichia coli was 35% vs 34.5%, Klebsiella pneumoniae 17.1% vs 25.2%, Pseudomonas aeruginosa 15.9% vs 16%, Enterobacter cloacae complex 7.2% vs 6.2%, Stenotrophomonas maltophilia 4.7% vs 3.5%, Acinetobacter baumannii 4.6% vs 4.3%, Aeromonas spp. 0.4% vs 0.3%, other Enterobacteriales 6.5% vs 5.8%, other non-fermentative gram-negative rods 8.6% vs 4.5%, accordingly. Differences were revealed in antimicrobial resistance for K.pneumoniae and A.baumannii [Table]. In K.pneumoniae the rate of carbapenemase producing strains rose from 2% to 27.1% (p<0.001), carbapenem and colistin non-susceptible isolates from 5.9% to 21.9%, 1.5% to 12.3%, accordingly (p<0.001). The prevalent carbapenemase genes in K.pneumoniae were blaOXA-48. There was increase in detection of carbapenemase genes in A.baumannii from 37% to 94% (p<0.001), carbapenem non-susceptible strains from 66.7% to 94% (p<0.001). A. baumannii harboring blaOXA-23 and blaOXA-48 rose from 18.5% to 42% (p<0.01), from 11.1% to 48% (p<0.001). Susceptibility to colistin in A. baumannii was stable during the study. The rate of carbapenem non-susceptibility and carbapenemase-producers in P.aeruginosa was not change. The predominant carbapenemase genes in P.aeruginosa were blaOXA-48 (97% vs 100%). The level of trimethoprim-sulfamethoxazole resistance in S.maltophilia slightly increased from 8.9% (2003-2010) to 12.5% (2011-2018).

Conclusions: The distribution of gram-negative pathogens causing blood stream infections in haematological patients did not change in contrast to determinants of resistance which increased in K.pneumoniae and A.baumannii.

Prevalence of human papilloma virus 16, 18 and other high-risk genotypes in Baku, Azerbaijan

Alakbarova Gumral*1, Agarza Agayev1, Lala Veliyeva1, Afsana Mammadova1, Vidadi Narimanov1, Ramin Bayramli1, Valeh Huseynov1

1Thalassemia Center, Baku, Azerbaijan

Background: Cervical cancer is one of the most common female malignancies. Human papillomavirus (HPV) is thought to be the primary cause of cervical intraepithelial neoplasia and cervical cancer. The aim of this study was to determine HPV type distribution in women with and without cervical neoplasia from Azerbaijan and to estimate the potential future impact of an HPV 16/18 and other high risk genotypes.

Materials/methods: A total 172 cervical swab samples were included in the study. All samples sent to Clinical Microbiology Laboratory of Thalassemia Center, Baku, Azerbaijan between October 2018 - November 2019. In our study, HPV types 16, 18 and other high-risk genotypes (31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68) were differentiated. HPV genotype determination was performed by multiplex real-time PCR method (Rotor-Gene Q, Qiagen, California, USA) using HPV Genotypes 1 4 Real-TM Quant (Sacace, Como, Italy) kit.

Results: HPV positivity was detected in 57 (33.1%) of 172 cervical specimens. Single HPV genotypes were detected in 16 (28%), two different HPV genotypes in 16 (28%) and multiple HPV genotypes in 5 (8.9%) specimens. HPV type 16 was found in 11 (19.6%), HPV type 18 was found in 14 (25%) and high risk groups were found in 38 (67.8%) of HPV positive samples.

Conclusions: The prevalence of HPV type 18 in our region was higher than HPV type 16. The detection of HPV types in the diagnosis of genital HPV infections is important for epidemiological studies. The 33.1% positivity rate for our region suggests that screening programs in our country should be expanded especially for the early diagnosis of oncogenic HPV types. Cytology results of our patients will be discussed in poster presentation.

Impact assessment of the results of BIOFIRE FILMARRAY pneumonia panel plus for the detection of pathogenic bacteria and individualised therapeutic targeting

Cristina Gómez-Camarasa, Violeta García-Casas, Maria Eugenia Yuste Ossorio, Natalia Chueca Porcuna

Hospital Universitario Clínico San Cecilio, Granada, Spain

Background: The etiological diagnosis of bacterial pneumonia is based on the identification of causal pathogens by cultures, which require prolonged incubation periods and have limited sensitivity. The BIOFIRE® Filmarray® Pneumonia Panel plus enables rapid and accurate automated testing for 27 bacteria and viruses that cause pneumonia directly from patient samples and can improve diagnostic accuracy to guide antibiotic treatments. In this study, we hypothesise that improved detection of pathogens by BIOFIRE® Filmarray® can improve culture-based diagnosis and cause changes for therapeutic management.

Materials/methods: From April 2019 - Nov 2019 we enrolled 20 adult patients admitted to the Medical ICU with acute respiratory failure within 24 h of intubation for mechanical ventilation. We performed BIOFIRE® Filmarray® Pneumonia Panel plus to determine pathogen identification in lower respiratory tract samples, and assessed individualized antimicrobial stewardship.

Results: 20/22 patients could perform culture. 14/20 patients (60%) presented significant bacterial counts cultures. BIOFIRE® Filmarray® Pneumonia Panel plus detected a pathogen in 20% of the culture-negative patients, and most of them had been exposed to broad-spectrum empiric therapy. When Filmarray reported > 10^7 copies / ml, concordance with a significant count (>10^6) was 85%. Filmarray® had an overall 59% impact on the antibiotic adequation. For patients without treatment or with incorrect treatment, Filmarray® result always guided a change in therapy. For FILMARRAY® negative samples, change/deescalation in antimicrobial treatment were made only in 49% of the cases. On the other hand, in patients with adequate broad-spectrum empirical treatment, the filmarray results were followed only in 43% of cases.

Conclusions: FILMARRAY® Pneumonia Panel plus allows a faster and enhanced detection of pathogenic bacteria; FILMARRAY® offers a substantial opportunity for individualized therapeutic targeting and antimicrobial stewardship in ICU patients with mechanical ventilation pneumonia.

Abstract 9061

**The rational of antibiotic failure in Helicobacter pylori**

Sobhan Ghafourian1, Elham Aboualigalehdari*1, Behzad Badakhsh1

1ilam university of medical sciences, Ilam, Iran

**Background:** Antibiotic failures in *Helicobacter pylori* and the novel mechanism of bacterial resistance against antibiotic lead us to investigate the causes of antibiotic failure in patients with *H. pylori* in Ilam, Iran.

**Materials/methods:** 120 *H. pylori* isolates were collected from Mostafa Khomeini Hospital, Ilam, Iran and Rasoul-e-Akram Hospital, Tehran, Iran. Afterward, *H. pylori* were identified by phenotyping methods and *urea* gene was subjected to confirm isolates as *H. pylori*. Initially, antibiotic susceptibility testing was performed by disc diffusion for metronidazole and clarithromycin. *rdxA* gene also evaluated to confirm the resistance strains. Bacteria were cultured in stationary phase and mixed 1 milliliter from 24 hours incubated suspension bacteria and lyse solution. Then, they were vortex for 10 seconds and kept on 10 minutes in room temperature. Then, 200 macro liter of Lysis enzyme solution added and incubated in 37 °C with 200 rpm. Finally, solutions were cultured in Luria-Bertani media and grown colonies were considered as persister cells. For confirmation of persistence those susceptible isolates were subjected for MIC with both metronidazole and clarithromycin and 5 folds greater than MIC were cultured and evaluated their growth. If bacteria were positive in culture it was considered as peresistant. After DNA extraction PCR was performed with specific primers.

**Results:** Our results demonstrated that among 120 *H. pylori* isolates, 35 % (n=42) were sensitive, 16.6 % (n=20) were intermediate and finally 48.4% (n=58) of isolates showed resistance to metronidazole. Clarithromycin resistance was observed in 21.6 % (n=26) isolates. Overall, 35% (n=42) of isolates showed susceptibility to both metronidazole and clarithromycin [figure 1]. This 42 isolates were chosen to evaluate as persister cells.

The persister assay analysis demonstrated that 38.1% (n=16) that were antibiotic susceptible *H. pylori* were persister cells. The confirmation was performed by MIC for both antibiotics.

**Conclusions:** This study demonstrates that, there were Metronidazole and clarithromycin resistant isolates among 120 mentioned collection, which can be one of the most important reasons to fail of treatment. In addition, among Metronidazole and Clarithromycin sensitive isolates the persister cells were observed that can be the novel cause of failure to treatment and recurrent of infectious.

Abstract 9062

National survey of Neisseria gonorrhoeae isolates by whole genome sequencing in France in 2018

Aymeric Braille$^{1,2}$, Mary Mainardis$^{1,2}$, Manel Merimèche$^{1,3}$, Thibaut Poncin$^4$, Nathalie Schnepf$^4$, Hervé Jacquier$^{1,2}$, Cécile Bébéar$^1$, Jean-Michel Molina$^6$, Florence Lot$^4$, Ndeindo Ndeikoundam$^4$, Beatrice Bercot$^{*1,2}$

1 National Reference Center for Bacterial STI, Associated expert laboratory for gonococci, Paris, France, 2 Paris University, IAME / APHP, St Louis Hospital, Department of Infectious Agents, Paris, France, 3 Picpus Institute, AP-HP Bioinformatics Platform, Paris, France, 4 French national public health agency, Santé Publique France, Saint-Maurice, France, 6 St Louis Hospital, Infectiology Department, Paris, France

Background: According to WHO estimates, there are 106 million new cases of gonorrhea each year. Epidemiological surveillance of Neisseria gonorrhoeae (NG) has become a major issue, due to both the increasing number of cases and the emergence of multidrug-resistant clinical isolates. This study reports a national survey by using combination of clinical data and whole genome sequencing for investigating GC isolates infections in France.

Materials/methods: From 1 September to 31 December 2018, 127 laboratories in metropolitan France and French overseas islands were asked to collect strains obtained in NG culture associated with anonymous clinical data. Isolates of NG were sent to the Associated Laboratory of the National Reference Center for bacterial STI and 7 antibiotics MICs were determined by Etests (Biomerieux). Molecular determinants of resistance and genotyping were obtained by Whole Genome Sequencing (WGS), Illumina technology (Nextseq, Illumina, San Diego, CA). Data analysis was performed by the in silico genome study (NG-MAST, NG-MLST and NG-STAR).

Results: Clinical information from 223 NG-infected patients reported a predominance of men (161; 72.2%). The age ranged from 15 to 75 years old (mean: 30 years), 5.8% were HIV-infected, 18.4% were coinfected by Chlamydia trachomatis or Treponema pallidum. From the 158 cultivated NG isolates, 110 (69.6%) were isolated from genital sites and 44 (27.8%) from extragenital sites: anus (43; 97.7%) and throat (1; 2.3%). NG isolates were resistant to tetracycline, ciprofloxacin, azithromycin in 62.2%, 61.4%, and 7.6% of cases, respectively and all were susceptible to ceftriaxone and cefixime. Only 3 NG isolates had a ceftriaxone or cefixime MIC >0.032 mg/L. The NG isolates were largely distributed into 42 different MLST Sequence Types with minor clusterisations, ST1583 (n=20; 12.7%) and ST9263 (n=18; 11.4%) being more prevalent.

Conclusions: This survey showed no resistance to the first-line antimicrobial treatment. The combination of clinical data with phenotypic study and high throughput WGS of strains provides important data for monitoring circulating strains on a national scale. Observation of a larger collection of strains would be of interest for our 2019 survey.

Abstract 9063

In vitro evaluation of single or combined bacteriophages targeting different Staphylococcus aureus clinical isolates

Javier Orcastegui Delso*, Fabian Kunisch1, Andrej Trampuz1, Mercedes Gonzalez Moreno1

1Charité – Universitätsmedizin Berlin, Berlin, Germany

Background: The decreasing effectiveness of classic antibiotic therapies due to an increased diffusion of multidrug-resistant bacterial strains and to the occurrence of biofilm-associated infections requires investigations with alternative therapies. Among such therapies, the use of bacteriophages is a promising treatment strategy. In this work, we analyzed the performance of three bacteriophages as monotherapeutic agents or as a phage cocktail against different Staphylococcus aureus (SA) isolates.

Materials/methods: Three SA-targeting bacteriophages (ϕM, ϕE and ϕT) isolated from human saliva, MRSA ATCC-43300 and two clinical isolates, SA1 and SA2, were used for this study. The susceptibility of each bacterial strain to the bacteriophages was determined by broth-microdilution assay. Moreover, the ability of each bacteriophage or a combination of all three as a cocktail to prevent biofilm formation on glass porous beads and to eradicate pre-established 24h-old biofilms was investigated by isothermal microcalorimetry.

Results: MRSA ATCC-43300 was susceptible to all three bacteriophages with MIC values of $10^5$ PFU/mL for ϕM and $10^6$ PFU/ml for ϕE and ϕT, whereas SA1 was susceptible to ϕM and ϕE (MIC $10^7$ PFU/ml) and SA2 to ϕE (MIC $10^7$ PFU/ml). The phage cocktail showed the highest activity in preventing biofilm formation against MRSA ATCC-43300 and SA1, but had an analogous activity than ϕE alone against SA2. Biofilm treatment revealed high efficacy of ϕM against MRSA ATCC-43300 with more than 90% reduction of the heat-flow production compared to the growth control. Overall, our results presented a variable antibiofilm efficacy of bacteriophages depending on the strain tested (Figure 1).

Conclusions: The cocktail was found to be superior to the individual phages in preventing biofilm formation against those bacterial strains susceptible to at least two of the three bacteriophages within the cocktail. However, compared to individual phages, the cocktail did not always have an improved antibiofilm activity against tested strains. Further studies including more clinical strains and phages with broader host range should be investigated to design phage cocktails with optimized antibiofilm activity.

Figure 1. Microcalorimetry analysis of the antibiofilm activity of bacteriophages ϕM, ϕE, ϕT and the cocktail ϕM/E/T against MRSA ATCC-43300 and two S. aureus clinical isolates. GC, growth control.

Abstract 9066

Evaluation of PrimeStore molecular transport medium for long-term preservation of mycobacterial RNA at ambient temperature and subsequent detection of Mycobacterium tuberculosis Ag85B

Siphiwe Matukane¹, Bernard Fourie*¹

¹University of Pretoria, Pretoria, South Africa

Background: In this study, we have investigated the potential of PrimeStore Molecular Transport Medium (PS-MTM) to release and preserve Mycobacterium tuberculosis RNA from raw sputum without requiring cold chain steps. The hypothesis is that the procedure would have utility in clinical trials of anti-TB drugs or in patient treatment monitoring as a surrogate marker of antibiotic effect. Working with RNA is challenging, however. It is highly labile and prone to rapid decay. After isolation, RNA must immediately be stored at -80°C, or must be converted into cDNA for longer storage. We show in this study that raw sputum samples transferred into PrimeStore Molecular Transport Medium (PS-MTM) resulted in the release and preservation of mRNA from cells without the need for freezing at ultra-low temperature.

Materials/methods: Forty auramine smear-positive sputum specimens (scanty, 1+, 2+ and 3+) were collected in PS-MTM and kept for up to 90 days at ambient temperature. RNA extractions were performed using an miRNeasy Mini Kit (QIAGEN®). The resultant RNA was quantified using a NanoDrop Spectrophotometer (Thermo Fisher Scientific). The ratio of absorbance at 260 and 280 nm (i.e. the A260/A280 ratio) was used to determine purity of RNA. Optimisation of the real-time PCR assay was achieved by using Mycobacterium tuberculosis Ag85B primers and TaqMan probes on the QuantStudio 5 real-time PCR system.

Results: Extracted RNA (host and mycobacterial) was detected in all samples in our study, with an average ratio of 1.67 recorded for A260/A280 despite long-term storage at ambient temperature. Real time PCR was positive for the viable M. tuberculosis in the patient sputum consistent with diagnosis of active disease during laboratory diagnosis of the patients. The PCR assay was able to detect both the mycobacterial DNA (IS6110) and the mycobacterial mRNA (Ag85B).

Conclusions: PS-MTM was able to preserve RNA, including the smaller mycobacterial mRNAs, for longer than three months when stored at room temperature without the use of a cold chain protocol.

Antimicrobial resistant and enteropathogenic bacteria in 'filth flies': a cross-sectional study from Nigeria
Francis Chinedu Onwugamba*1, Alexander Mellmann1,2, Nwaugo Victor Oluohaegbulam3, Frieder Schaumburg1

1University Hospital Münster, Institute of Medical Microbiology, Münster, Germany, 2University Hospital Münster, Institute for Hygiene, Münster, Germany, 3Abia State University, Uturu, Nigeria

Background: ‘Filth flies’ breed in garbage, animal and human faeces and can be colonized with numerous bacterial species. The aim of this work was to study the intestinal colonization of ‘filth flies’ with Extended-spectrum beta-lactamase producing Enterobacterales (ESBL-E), Staphylococcus aureus, Campylobacter sp., Salmonella sp., Shigella sp. and Yersinia enterocolitica in Nigeria.

Materials/methods: Flies (n=2000) were sampled from 109 urban, semi-urban and rural sites in Southern Nigeria. Sequencing of the cytochrome oxidase gene was used for species identification of flies. After enrichment in BHI-broth, homogenized flies were screened for the targeted pathogens. Bacterial species identification was done using MALD-TOF and antibiotic susceptibility testing was done with Vitek 2 automated system. Isolates were screened for resistance genes and enterotoxins. Genotyping included E. coli phylogrouping, spa-typing multilocus sequence typing (MLST) and whole genome sequencing.

Results: Of a randomly selected subset of flies, Musca domestica (44.8%, 179/400) was predominant followed by Chrysomya putoria (21.6%, 85/400) and Musca sorbens (18.8%, 75/400). Flies were colonized with S. aureus (13.8%, 275/2000) and ESBL-E (0.8%, 16/2000). No other enteropathogenic bacteria were detected. S. aureus were positive for chp (100%, 275/275) and scn (97%, 267/275) but negative for sak. All S. aureus belonged to MLST sequence type ST15 and spa types t674, t1980, t5305 and t6313. The staphylococcal enterotoxin SEI was most common (26%, 70/275), followed by the SEA (12%, n=32/275). Other enterotoxins were not detected (SEB, SEC, SED, SEE, SEF, SEG and SEH). Four S. aureus were methicillin resistant (mecA positive). The ESBL E. coli (n=15) belonged to phylogroup D (n=2), B2 (n=1), ST10 (n=5), ST617 (n=2), and singular occurrences of other STs.

Conclusions: ‘Filth flies’ can carry antimicrobial resistant bacteria in Nigeria while enteric bacteria were rarely detected. Enterotoxin-positive S. aureus might be the main reason for food poisoning by ‘filth flies’ in the study area.

Direct sequencing from clinical samples in the diagnostic microbiology laboratory without capital expenditure or specialised bioinformatic training is possible using nanopore technology

Adela Alcolea Medina1, Caoimhe Nicfhogartaigh1, Jonathan Lambourne1, Robert Serafino-Wani1, Mark Wilks1,2

1Royal London Hospital, Barts Health NHS trust, London, United Kingdom, 2Queen Mary University London, London, United Kingdom

Abstract third-party references: Barts and the London Charity

Background: The use of ‘next generation sequencing’ for the direct detection of microbes in clinical specimens has been advocated for several years. Its implementation in diagnostic laboratories has been hampered by high capital cost and the need for bioinformatic expertise to interpret results. Nanopore sequencing requires no capital cost, and is suitable for low volume use without the need for batching. The introduction of dedicated software has made reliable results much easier to achieve without formal training. We assessed the feasibility of nanopore sequencing using the MinION (Oxford Nanopore) to sequence clinical samples from which no results of clinical significance had been obtained after routine analysis but where infection still suspected.

Materials/methods: Samples were referred by infection specialists from patients with diagnosis or management uncertainty following standard culture and molecular testing (16S PCR). After initial depletion of human DNA with saponin/nuclease method, DNA was extracted, and libraries prepared using the Rapid PCR Barcoding Kit. After two hours of sequencing, the results were analysed using WIMP, software provided by ONT. Infection specialists were informed, and action taken based on the result recorded.

Results: Ten specimens were tested. The turnaround time was 10 hours and all organisms detected with routine diagnostic tests were detected by MinION. Additional organisms were detected in all samples tested. A plausible cause of infection was found in 6 clinical samples which had not been detected by standard methods were culture and 16S negative, and the result impacted patient management (see table).

Conclusions: MinION sequencing detected clinically plausible microorganisms not detected by routine methods in a variety of samples and results helped inform clinical management. MinION sequencing is suitable for use as a routine method for supporting diagnosis of infection where the results of conventional methods are considered inadequate or incomplete.

Presenter email address: adelaalcolea@gmail.com
Background: Metallo-\(\beta\)-lactamase-producing \textit{Pseudomonas} spp. are important agents of healthcare-related infections in Brazil. The presence of carbapenemases makes treatment with beta-lactams unfeasible and is often an indicator of multiresistance. The most common metallo-\(\beta\)-lactamase (MBL) in \textit{Pseudomonas} spp. in Brazil is SPM, however we observed an increase in the detection of MBL VIM in the last years.

Materials/methods: During the period from January 1, 2015, to January 30, 2019, as part of the Bacterial Resistance monitoring Network of ANVISA-Brazil, the Laboratório de Pesquisa em Infecção Hospitalar (LAPIH/IOC) received 35 MBL-producing \textit{P. aeruginosa} \(n=33\) and \textit{P. putida} \(n=2\), positive for \textit{bla}\textsubscript{VIM-like} gene by PCR. The \textit{bla}\textsubscript{VIM} was sequenced using the ABI Prism 3700 DNA Sequencer. The evaluation of carbapenemase activity was performed by CARBA NP, Blue Carba and mCIM/eCIM. The antimicrobial susceptibility was evaluated by disk diffusion method and broth microdilution test according the BrCAST. Molecular typing was performed using PFGE and MLST.

Results: The allelic variant found among the isolates were \textit{bla}\textsubscript{VIM-2} \(n=34\) and \textit{bla}\textsubscript{VIM-24} \(n=1\). All of them presented activity of MBL by CARBA NP, 94.2\% by mCIM/eCIM, but the Blue Carba identified them as serino-carbapenemase. All isolates were considered multiresistant. The most common resistance was to imipenem and meropenem \(100\\%\), followed doripenem \(93.3\%\), amikacin \(93.3\%\), cefepime \(86.6\%\), ciprofloxacin \(86.6\%\), levofloxacin \(86.6\%\), ceftazidime \(80\%\), gentamycin \(73.3\%\), piperacillin/tazobactam \(66.6\%\), and Aztreonam \(33.3\%\). The lowest non-susceptibility rate was for Aztreonam \(33.3\%\). All VIM producers showed susceptibility to polymyxin \(MICs 0.25\text{-}1\ mg/L\) and resistant to ceftolozane-tazobactam \(256\ mg/L\), 85.7\% resistant to cefazidime-avibactam \(1.5\text{-}256\ mg/L\). PFGE analyses of \textit{P. aeruginosa} revealed 15 different pulsotypes with the predominance of a clone \(n=16\) corresponding to ST2559. Other ST found including ST1015, ST111, ST233 and ST381. Both of VIM-2-producing \textit{P. putida} isolates belonging to the same clone.

Conclusions: The results suggest the dissemination of \textit{bla}\textsubscript{VIM-2} and the first description of \textit{bla}\textsubscript{VIM-24} in Brazil. Blue Carba did not show good results for VIM detection. Although SPM is most common MBL in Brazil, our study indicate an increase in the detection of \textit{bla}\textsubscript{VIM-2} in \textit{Pseudomonas} spp. suggesting a change in the epidemiological profile in Brazil.

Presenter email address: ivsoncass@gmail.com
**Who should we test for arboviral infection? Rational diagnostic testing in an era of increased global prevalence**

Rebecca Ryan*,1, Iain Milligan1, Sarah Logan1, Eleni Nastouli2,3, Anna Checkley1, Tommy Rampling1

1Hospital For Tropical Diseases, University College London Hospital, London, United Kingdom, 2University College Hospital, Department of Clinical Virology, London, United Kingdom, 3University College London, Department of Population, Policy and Practice, Institute of Child Health, London, United Kingdom

**Background:** Approximately 3000 returning travellers attend the Hospital for Tropical Diseases (HTD) emergency walk-in clinic each year. In our practice as elsewhere, there is substantial overlap in clinical presentation of arboviral infections, defined here as dengue, Zika and chikungunya. We reviewed our investigation of suspected arboviral infection, focusing on clinical and laboratory predictors of a positive diagnosis.

**Materials/methods:** Data for patients presenting between September 2015 and March 2019 were extracted from a prospective clinical database, combined with laboratory data and analysed in R. A 'positive' arboviral result was defined as a positive PCR or documented seroconversion to dengue, Zika or chikungunya. A negative result was defined as PCR and all serological tests negative. An indeterminate result was defined as a single positive serological result without demonstrated seroconversion. Clinical features and laboratory parameters associated with positive and negative tests were compared where clinical data were available.

**Results:** 10,595 patients attended the HTD walk-in clinic between September 2015 and March 2019. Of these, 2318 patients were investigated for arboviral infection. 168 tested positive (116 dengue, 40 Zika, 2 chikungunya), 1548 were negative, and 602 were indeterminate, so excluded from further analysis. Presenting symptoms were documented for 136 arboviral positive and 1382 negative patients.

Reports of fever, headache, rash and arthralgia/myalgia were all significantly higher in those with a positive result (chi-squared comparisons p < 0.05). Presence of a rash had the largest discordance [64% vs. 29%, p < 0.0001] and was the strongest individual positive and negative predictor of a positive arboviral test [PPV 0.18 [95% CI 0.14-0.21], NPV 0.95 [95% CI 0.94-0.96]]. Rash plus headache had a positive predictive value of 0.23 [95% CI 0.18-0.29].

**Conclusions:** It is difficult to clinically distinguish arboviral infections from other common presentations, and only a small proportion of tests yielded a positive result. Diagnostic testing should focus on patient groups with a higher prior probability of infection.

The limitations of a retrospective dataset are being addressed by collection of a contemporary prospective dataset. An in-depth analysis of these data and a diagnostic algorithm to optimise arbovirus testing of returning travellers will be presented.

**Presenter email address:** rebecca.ryan6@nhs.net
Implementing a scalable bioinformatics infrastructure to enable national clinical pathogen genomics services

Matthew Bull1, Amy Gaskin*, Joel Southgate2, Anna Price2, Thomas R. Connor1,2

1University Hospital of Wales, Pathogen Genomics Unit, Public Health Wales, Cardiff, United Kingdom, 2Cardiff University, School of Biosciences, Cardiff, United Kingdom

Background: In 2017 the Welsh Government launched the Genomics for Precision Medicine Strategy, including over £8M of investment to date to develop new clinical genomics services to enable better, more personalised and more precise medical care. A key component of this strategy has been the development of clinical Pathogen Genomics services, all of which are underpinned by microbial bioinformatics. This presentation will introduce the bioinformatics infrastructure which over the last 18 months has underpinned the development of clinical genomics services focused on HIV, Influenza, Clostridioides difficile and Mycobacteria tuberculosis and non-tuberculosis Mycobacteria.

Materials/methods: We have used a combination of software containers and the nextflow workflow engine running on top of virtualized cloud computing resources in order to build our systems. Combining bioinformatics software and enterprise IT, our bioinformatics infrastructure provides a single software framework operating on top of an integrated, redundant, computational infrastructure that enables the processing of genomic sequence samples from a range of pathogens, sequenced using both Illumina and Nanopore sequencing technologies.

Results: The provision of a core, modular, automated infrastructure has enabled the processing of over 150,000 individual jobs from over 8,000 patient samples in the last 18 months. This infrastructure has underpinned the development of four clinical services, including two that have achieved ISO 15189 accreditation. By moving to genomics approaches, and combining this with automated, easily managed bioinformatics/software systems, we have been able to decrease assay costs, improve turnaround times, and increase test resolution – supported with only a small bioinformatics team.

Conclusions: In order to implement services based upon next generation sequencing, the bioinformatics elements are critical. Here we introduce the service that we have built in Wales, which now underpins a set of national services across multiple pathogen types. This work provides a template for others who are also seeking to develop services based on next generation sequencing in their own clinical laboratory.

Random forest and multilevel multivariable analyses to assess risks for colonisation with multidrug-resistant Gram-negatives in 27 long-term care facilities in high endemic settings

Anna Maria Azzini¹, Giuliana Lo Cascio²*, Giorgia Be³, Ilaria Coledan¹, Lorenza Lambertenghi¹, Nicola Duccio Salerno¹, Laura Naso¹, Alda Bazaj³, Massimo Miranda³, Anna Gorska¹, Francesca Russo⁴, Giuseppina Napoletano⁴, Fulvia Mazzaferri¹, Giuseppe Cornaglia³, Ercole Concia¹, Evelina Tacconelli¹

¹University of Verona, Department of Diagnostic and Public Health - Infectious Disease Unit, Verona, Italy, ²Azienda Ospedaliera Universitaria Verona, Microbiology, Verona, Italy, ³University of Verona, Department of Diagnostic and Public Health - Microbiology Unit, Verona, Italy, ⁴Regione Veneto, Direzione Prevenzione, Sicurezza Alimentare, Veterinaria, Venezia, Italy

Background: Residency in long-term care facilities (LTCFs) increases the likelihood of colonization with multidrug-resistant Gram-negative bacteria (GNB). Knowledge of individual level risk factors is mainly limited to small cohort or prevalence studies applying conventional statistical analysis. We prospectively assessed the prevalence rate and risk factors for colonization by extended-spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-Ent) and carbapenemase-producing gram-negative bacteria (CP-GNB) in a large cohort of LTCFs in high endemic setting.

Materials/methods: A point prevalence survey (PPS) with rectal screening (RS) was conducted in 27 LTCFs in north Italy in high endemic setting for ESBL-Ent in a 12-month period. Epidemiological and clinical variables including presence of medical devices and percutaneous endoscopic gastrostomy (PEG) on the PPS day, history of hospitalization and surgery within one year of study inclusion, and antibiotics within three months were collected. The presence of ESBL-Ent and CP-GNB was assessed using a selective culture on chromogenic medium and PCR. Risk analysis was performed using Random Forest (RF) and multilevel multivariate logistic regression model with a random component at local unit was used to account for the underlying structure of the sampling procedure. Association with colonization was considered for a p value < 0.05.

Results: In the study period 1933 RSs in 2890 residents were performed. The prevalence rates were: 51% (95CI: 49%-53%) for ESBL-Ent and 3.5% (95CI: 3%-4.5%) for CP-GNB. Carbapenemase-producing Enterobacteriaceae were 8% of total isolated Enterobacteriaceae. KPC was the most frequent carbapenemase (80% - CI95: 69%-88%) detected followed by MBL (19%; 95CI:11%-30%) and OXA-48 (6%; 95CI:2%-14.5%). Previous hospitalization (OR1.4), the presence of urinary cather (OR1.8), PEG (OR7.2), bedsores (OR1.5), and peripheral venous cather (OR1.6) were independently associated (p<0.05) with ESBL colonization at multivariate analysis and RF. At the analysis of feature fluoroquinolones usage ranked high in predicting colonization.

Conclusions: The prevalence rate of colonization by ESBL- and CP-GNB among LTCF residents in high setting for antimicrobial resistance reflects the rate in local hospitals. Intervention to reduce the colonization rates in these settings must be linked to referred hospitals and include antibiotic stewardship targeting quinolones and infection control measures for the management of devices.

Metabolomic comparison of biofilm matrix of six species of Candida

Ignacio Antonio Sigona-Giangreco1,2, Marta Garcia-Hita1, Victor Garcia Bustos2,3, Alba Ruiz*1,2, Elías Cortes-Acosta2, Javier Peman2,4, Emilia Canton2, Eulogio Valentin2,4

1Microbiology department, Hospital Universitari i Politècnic La Fe., Valencia, Spain, 2Severe Infection Research Group, Health Research Institute La Fe., Valencia, Spain, 3Internal Medicine department, Hospital Universitari i Politècnic La Fe, Valencia, Spain, 4Microbiology and Ecology department. Universitat de València, Burjassot, Spain

Abstract 9091

**Background:** Nowadays there is an enormous effort to develop new diagnostic and therapeutic strategies to identified and eliminate biofilms. Candida spp. is the most relevant forming-biofilm. The metabolomic studies are important to understand the growth process and the components immersed in their development of resistance to antibiotics.

**Materials/methods:** Eleven Candida isolates were selected from clinical samples: 2 Candida albicans (blood culture), 1 Candida auris (blood culture), 2 Candida glabrata (blood culture and pleural fluid), 2 Candida krusei (ascitic liquid and intrabdominal catheter), 2 Candida parapsilosis (Intraabdominal catheter) and 2 Candida tropicalis (blood culture and gallbladder catheter). Furthermore 7 reference strains were studied: C. albicans ATCC® 90028, C. parapsilosis ATCC® 22019, C. krusei ATCC 6258®, C. tropicalis ATCC® 750, C. glabrata ATCC® 90030, C. auris VPCI 479/P13 and C. auris KCTC® 1 7809 were used as control strain. Biofilms were processed using Matrix-Assisted Laser Desorption/Ionization-Time of Flight mass spectrometry (MALDI-ToF MS) and Gas Chromatography quadrupole Time of Flight mass spectrometry (GC-QToF) obtaining metabolomic information. Data was analyzed using NTSYSpc version 2.0 and veni's diagram using the Venny free software tool, (CNB-CSIC).

**Results:** A total of 353 molecules were identified using (MALDI-ToF MS) and (GC-QToF): 70.8% (257) proteins, 8.21% (29) peptides and amino acids; 5.66% (20) carbohydrates, 3.68% (13) lipids and 9.62 (34) other molecules. Metabolomic analysis of the 3 C. albicans strains, share 6 proteins with metabolic functions, not found in other species. C. krusei had only 2 distinctive molecules one protein and one nucleotide. C. glabrata presented 1 protein, 1 organic acid and 1 fatty acid. A different result was obtained with C. tropicalis, which had 20 different proteins present exclusively in their biofilm matrix, many of these proteins have metabolic and structural function. C. parapsilosis and C. auris share molecules with the other species, but no distinctive molecules were found.

**Conclusions:** Matrix biofilm of each Candida species tested had distinctive metabolomic profiles. Proteomic profiles are species-specific and could be useful to elaborate immunoassay as a diagnostic test and new treatment strategies.

Abstract 9093

Characterisation of a new class 1 integron carrying \textit{blaVIM-1} and \textit{blaGES-7} in extensively and pandrug-resistant \textit{Pseudomonas aeruginosa} ST155 isolates from patients with ventilator-associated pneumonia

Marta Hernandez*1, Laura Alvarez-Montes2, David Abad2, Catalina Díaz Ríos2, Ana Arribi3, Alain Ocampo-Sosa2

1Agricultural Technological Institute of Castilla and Leon (ITACYL), Valladolid, Spain, 2IDIVAL, Santander, Spain, 3Hospital Clínico San Carlos, Madrid, Spain

**Background:** \textit{Pseudomonas aeruginosa} is one of the major pathogens isolated in ventilator-associated pneumonia (VAP). The aim of this study was to characterise seven \textit{P. aeruginosa} isolates co-producing \textit{VIM-1} and \textit{GES-7} recovered from patients suffering from VAP in an intensive care unit (ICU) at a Spanish hospital.

**Materials/methods:** Seven carbapenem-resistant \textit{P. aeruginosa} isolates recovered from respiratory-tract samples of seven patients who developed a VAP while hospitalized in an ICU were analysed in this study. Isolates were identified by Vitek-2 system and species confirmation was performed by MALDI-TOF (Vitek-MS). Antimicrobial susceptibility test (AST) was performed by broth microdilution using the following antibiotics: aztreonam, piperacillin-tazobactam, ticarcillin-clavulanate, ceftazidime, cefepime, imipenem, meropenem, gentamicin, tobramycin, amikacin, netilmicin, ciprofloxacin, levofloxacin, colistin, polymixin B and fosfomycin. EUCAST breakpoints were applied. The strains were subjected to whole-genome sequencing (WGS) on an Illumina MiSeq platform in order to analyse their resistome and virulome.

**Results:** AST results demonstrated that 2 isolates were extensively drug-resistant (only susceptible to colistin, MICs between 1-2 mg/L) and 5 isolates were pandrug-resistant (non-susceptible to all agents in all antimicrobial classes) according to Magiorakos el al. criteria [2012]. WGS analysis revealed a pangenome of 6764 genes, comprising 6252 core and 512 accessory genes. Between 69 and 376 SNPs differences were found among the isolates. All isolates belonged to the “high-risk” international clone ST155 and harboured 52 antibiotic resistance (AR) genes, including the metallo-\(\beta\)-lactamase gene \textit{bla}_{\text{VIM-1}}, two copies of \textit{bla}_{\text{GES-7}}, \textit{aac(3)-I}, \textit{aac(6')-Ib4}, \textit{aph(3’)-XV}, \textit{ant(3’’)-Ia}, \textit{catB3} and \textit{su1}, which were located in a new class 1 integron (Figure). Other AR determinants such as the beta-lactamase gene \textit{bla}_{\text{OX A-396}} and the \textit{catB7}, \textit{crpP} and \textit{fosA} genes, conferring resistance to chloramphenicol, ciprofloxacin and fosfomycin, respectively, were also identified. Two-hundred and nineteen virulence genes were identified by using VFDB (>97% identity, >60% coverage). All strains contained \textit{exoS} gene, suggesting an invasive phenotype. No plasmid replicons were documented.

**Conclusions:** It is alarming the occurrence of extensively-and pandrug-resistant \textit{P. aeruginosa} of the “high-risk” international clone ST155 co-producing VIM-2 and GES-7 among VAP patients in our hospital, which drastically reduces the antimicrobial therapy options to treat common infections in ICUs such as VAP.

Streptococcus agalactiae in adults in England and Wales 2014-2015, large scale recombination and capsular shifting

Uzma Basit Khan*, Elita Jauneikaite1, Robert Andrews3, Victoria Chalker4, Brad Spiller3

1Cardiff University, Division of Infection and Immunity, School of Medicine, Cardiff, United Kingdom, 2Cardiff University, Department of Infectious Disease Epidemiology, School of Public Health, London, United Kingdom, 3Cardiff University, Systems Immunity University Research Institute and Division of Infection and Immunity, School of Medicine, Cardiff, United Kingdom, 4Public Health England, National Infection Service, London, United Kingdom

Background: Recombination is a key contributor to bacterial clonal diversity and can lead to capsule switching in Streptococcus agalactiae (GBS). This impacts vaccine development through shifting virulence determinant association to altered capsular loci outside vaccine coverage.

Materials/methods: Genomic analysis of 183 invasive and 11 non-invasive isolates determined capsular type, MLST, presence of virulence factors, antimicrobial resistance genes, phylogeny and genetic recombination. Phylogenetic relationships between the most prevalent clonal clades were also compared to presence of antimicrobial resistance genes and age/gender groups.

Results: GBS serotypes III (26.8%), Ia (26.2%) and V (14.9%) were most common in adults, but differed in gender/age distributions. Most isolates (n=185) grouped to 5 clonal complexes: CC1, CC8, CC17, CC19 and CC23 with common associations between specific serotypes and virulence genes. Serotype V/αlP3, serotype II and III/bca+cbo and serotype Ia/bibA predominantly clustered in CC1, CC8 and CC23, respectively, whereas serotype III/rib clustered in CC17 and CC19. All isolates carried at least one pilus island; mostly PI-1+PI-2a, but PI-1+PI-2b exclusively co-located to CC17 isolates. Large recombination events mediating capsular switching from CC1-serotype V to serotype Ib (n=2), II (n=2) and VI (n=2) were found, and CC19-serotype III to serotype V (n=8), CC23-serotype Ia to serotype V (n=2) and a hypervirulent CC17 (hvgA positive) serotype III to serotype IV (n=1).

Conclusions: This is the first extensive genomic investigation of GBS isolates from adults in England and Wales. The main serotype isolates from adults were split between serotypes III, Ia and V. A significant number of mismatches between expected clonal clades corresponding to capsular serotype were found [17/195 isolates]. This is particularly concerning with the emergence of the rare case of hypervirulent hvgA virulence factor present in a strain with serotype IV capsular determinants. This highlights the need for improved and continuing surveillance to inform vaccine development as escape mutations emerge.

Abstract 9098

**In vitro anti-biofilm and immunomodulatory effects of functionalised magnetite nanoparticles**

Alina Maria Holban*1,2, Alexandru Mihai Grumezescu2, Hamzah Basil1, Carmen Iordache1, Lia-Mara Ditu1, Manastireanu Denisa3, Bianca Ghita1, Bogdan Vasile2, Veronica Lazar1, Ecaterina Andronescu2

1University of Bucharest, București, Romania, 2Politehnica University of Bucharest, București, Romania, 3University of Bucharest, Bucharest, Romania

**Background:** Nanoparticles are currently investigated to increase the specificity and efficiency of antimicrobials by allowing the use of lower amounts of drugs, the stabilization of volatile or less stable compounds and modulation of microbial behaviours. This study aimed to obtain, characterize and investigate the antibiofilm effect of magnetite nanoparticles (NPs) functionalized with various essential oils (EOs) (i.e. obtained from Eugenia caryophyllata, Cinnamomum verum) and antibiotics (i.e. ceftriaxone, cefuroxime, cefotaxime) and to evaluate their ability to interfere with the production of cytokines in vitro.

**Materials/methods:** Functional NPs were obtained by co-precipitation and physico-chemically characterized by TEM, SEM, IR and XRD. Gram positive, Staphylococcus aureus and Gram negative, Pseudomonas aeruginosa clinical and laboratory strains were utilized in this study. The antimicrobial effect was analyzed by qualitative (agar diffusion method) and quantitative (minimum inhibitory concentration, MIC) assays. Biofilm formation and attachment were analyzed by microdilution crystal violet method, while the production of inflammatory interleukins was evaluated by enzyme linked immunosorbent assay (ELISA), using HeLa cells.

**Results:** The study revealed that the functionalized magnetite NPs present different minimum inhibitory concentrations (MICs) ranging from 0.01 mg/mL (S. aureus) to 0.5 mg/mL (P. aeruginosa) in planktonic cultures while biofilm formation is inhibited by concentration higher than 0.05 mg/mL in all strains. Subinhibitory concentrations of the obtained aqueous NPs dispersions significantly inhibited microbial attachment and biofilm formation in vitro, including clinical antimicrobial resistant strains, the effect being maintained for at least 3 days. ELISA results demonstrated that the EOs functionalized nanoparticles have the ability to promote the production of proinflammatory cytokines, especially interferon gamma (IFNγ) and interleukin 1 (IL1) in stimulated cells, suggesting they could be useful in immunomodulation.

**Conclusions:** The obtained magnetite NPs proved a great ability to stabilize and potentate the antimicrobial effects of EOs and antibiotics. These materials showed an enhanced efficiency in biofilm inhibition and also stimulated the release of inflammatory cytokines, which could significantly impact on the progression of the infectious process.

Abstract 9104

Secretion of TNFα by human macrophages is dependent of the sequence type of clinical Legionella pneumophila isolates

Johann Guillemot*1, Christophe Ginevra1, Patricia Doublet2, Annelise Chapalain1, Sophie Jarraud1

1Claude Bernard University Lyon 1, CIRI, Centre International de Recherche en Infectiologie, Inserm U1111, UCBL1, CNRS UMR5308, ENS Lyon, Villeurbanne, France

Background: Legionnaires' Disease (LD) is mainly caused by Legionella pneumophila serogroup 1 (Lp1), an environmental bacterium that could infect alveolar macrophages in human lungs. The clinical frequencies of the different sequence type (ST) from Lp1 are not correlated to the environmental representation, suggesting that some strains are more able to induce a lung infection. Several risk factors for LD have been identified, including anti-TNFα therapy. TNFα is a major cytokine that regulates the inflammatory process. In this study, we have evaluated the ability of various clinical isolates to modulate TNFα secretion from macrophage to better understand the impact of strain variability in LD inflammatory response.

Materials/methods: We challenged the human macrophage-like cell line U937 with a cohort of 108 Lp1 clinical strains belonging to 40 STs for TNFα secretion and intracellular multiplication capability. Lactate dehydrogenase (LDH) and caspase-3 assays were used to evaluate necrosis and apoptosis, respectively. We have established a double-staining technique to detect simultaneously L. pneumophila and TNFα on the single-cell level by flow cytometry.

Results: Lp1 isolates induce differential TNFα secretion from macrophages. The number of colony-forming units indicated that this differential TNFα secretion is not associated with a differential growth of Lp1 isolates in macrophages. Interestingly, we observed that ST1 isolates induced significantly more TNFα secretion than the others STs meaningfully involved in LD, such as ST20, ST23, ST40, ST47 and ST146. Since it has been recently suggested that TNFα was mainly produced by uninfected cells rather than by infected macrophages, we evaluated these populations by flow cytometry. Surprisingly, we observed that both infected and uninfected macrophages produce TNFα during infection with all Lp1 isolates. Finally, we showed that macrophages infected by ST1 strains display a significant increase of LDH release and caspase-3 activation compared to macrophages infected by other strains whereas treatment of macrophages with antibody against TNFα reversed these effects.

Conclusions: TNFα secretion by human macrophages is dependent of the ST of Legionella isolates. The observation that ST1 strains induce a more efficient host immune response could explain the high prevalence of these strains for immunocompromised patients.

Abstract 9106

Characterisation of mcr-5 action suggests a unified mechanism for polymyxin resistance
Youjun Feng*

1Zhejiang University School of Medicine, Hangzhou, China

Abstract third-party references: This work was supported by National Natural Science Foundation of China (31830001, 31570027, and 81772142, Y.F.; 81772233, Z.Z.) and National Key R&D Program of China (2017YFD0500202, Y.F.).

Background: A growing number of mobile colistin resistance (MCR) proteins is threatening the renewed interest of colistin as a “last-resort” defense against carbapenem-resistant pathogens.

Materials/methods: Whole-genome sequencing was used to elucidate a mcr-5-harboring plasmid, phylogenetic tree was applied to give its evolutionary place, and integrated biochemical assays were conducted to address its enzymatic action.

Results: Here, the comparative genomics of a large plasmid harboring mcr-5 from Aeromonas hydrophila and the structural/functional perspectives of MCR-5 action are reported. Whole genome sequencing has identified the loss of certain parts of the Tn3-type transposon typically associated with mcr-5, providing a clue toward its mobilization. Phylogeny of MCR-5 suggests that it is distinct from the MCR-1/2 sub-lineage, but might share a common ancestor of MCR-3/4. Domain-swapping analysis of MCR-5 elucidates that its two structural motifs (transmembrane domain and catalytic domain) are incompatible with its counterparts in MCR-1/2. Like the rest of the MCR family, MCR-5 exhibits a series of conservative features, including zinc-dependent active sites, phosphatidylethanolamine-binding cavity, and the mechanism of enzymatic action. In vitro and in vivo evidence that MCR-5 catalyzes the addition of phospho-ethanolamine to the suggestive 4′-phosphate of lipid A moieties is integrated, and results in the consequent polymyxin resistance. In addition, MCR-5 alleviates the colistin-induced formation of reactive oxygen species in E. coli.

Conclusions: Taken together, the finding suggests that a growing body of MCR family resistance enzymes are functionally unified.

Background: Carbapenemase-producing Enterobacterales (CPE) have been listed as a critical priority problem by the WHO. The Spanish study CARBA-ES-19 aims to provide data on the current situation of the most important CPE (Klebsiella pneumoniae and Escherichia coli) in Spain.

Materials/methods: From February 2019 to May 2019, 72 hospitals representing all 50 Spanish provinces collected the first ten non-duplicate K. pneumoniae or E. coli using the screening cutoff for CPE recommended by EUCAST. Carbapenemase characterization was performed by phenotypic methods and confirmed by PCR. Participating hospitals also registered the number of infections caused by K. pneumoniae and E. coli and the number of admissions/patients-day to calculate the prevalence and incidence rates of CPE.

Results: 408 CPE (382 K. pneumoniae and 26 E. coli) were collected. The carbapenemases detected in K. pneumoniae were OXA-48-like (268; 70.2%), KPC (76; 19.9%), VIM (29; 76.9%), NDM (14; 37%), and IMP (1; 0.3%). In E. coli were OXA-48-like (20; 76.9%), VIM (4; 15.4%), KPC (2; 7.7%) and NDM (1; 3.9%). Six K. pneumoniae and one E. coli isolates produced two types of carbapenemases. The overall prevalences of carbapenemase-producing K. pneumoniae and E. coli were 2.6% (range, 0 to 19.2%) and 0.05% (range, 0 to 0.4%), respectively. The overall incidence rate and incidence density rate of CPE were 0.04% (range, 0 to 0.7%) and 0.08% (range, 0 to 1.02%), respectively. At least one case of CPE was identified at 63 (87.5%) hospitals, which were located in 46 of the 50 (92%) Spanish provinces. OXA-48 was the most widely distributed carbapenemase in 41 provinces, followed by VIM in 18, KPC in 14, NDM in 7 and IMP in one. Of the 408 CPE, 220 (53.9%) were collected from urine and 53 (13%) from blood samples. Prevalences of carbapenemase-producing K. pneumoniae and E. coli from urine were 1.4% and 0.02%, respectively; and from blood were 5.9% and 0.02%, respectively.

Conclusions: We found a wide geographic distribution of CPE with > 90% of the Spanish provinces affected, but also a great geographic variability in the incidence of CPE and in the carbapenemases types.

Abstract 9109

Conservation in p24 capsid protein regions in HIV-1 groups M, O, P and N
Paloma Troyano Hernández¹, Roberto Reinosa², África Holguín³

¹Hospital Ramón y Cajal - IRYCIS-CIBERESP-RITIP, Laboratorio de Epidemiología Molecular del VIH, Servicio de Microbiología y Parasitología, Madrid, Spain

Background: HIV p24 capsid protein has an essential structural and functional role in the viral cycle. This highly conserved protein is considered genetically fragile, as changes in its sequence reduce viral fitness. P24 is an interesting target for the design of vaccines, diagnostic tests and new antiretroviral drugs against HIV. This study analyzes, for the first time, the conservation of each p24 secondary structure regions in HIV-1 M, O, P and N groups.

Materials/methods: All p24 sequences ascribed to the 4 HIV-1 groups were downloaded from the US Los Alamos-HIV-Sequence-Database, including subtypes, sub-subtypes and CRF from group M with >3 available sequences. Using a bioinformatics tool developed in our laboratory, we inferred consensus sequences for each group and a consensus consensus for HIV-1 at amino acid level. Then, we analyzed residue conservation in each region of the N-terminal (ß strand, Cyp-A loop and α-helixes 1-7) and C-terminal Domains (Inter-Domain Region [IDR] and α-helixes 8-11 including the Major Homology Region [MHR]), as described in RCSB Protein Data Bank.

Results: We downloaded all 38,827 available p24 sequences of 99 variants of group M (8 subtypes, 7 sub-subtypes and 84 CRF), 104 of group O, 4 of P and 11 of N. Although the overall structure of p24 was highly conserved, conservation of certain regions differed within groups and type of structure. Figure 1 describes the different level of conservation of p24 regions in each group (A) and median conservation for each region (B) within HIV-1. The most conserved regions were α-helixes 1, 2 and 5, followed by α-helixes 11, 7, 8 and MHR and α-helixes 4, 3, 9, 10 and the IDR. The less conserved were ß strand, α-helix 6 and Cyp-A loop (90-93%). Previous studies based in group M stated that α-helixes were the most fragile regions; we observed intermediate or low conservation of some helixes when considering all variants. Discrepancies were reduced when analyzing only group M sequences.

Conclusions: Since p24 genetic variability can impact on new diagnostic and therapeutic methods based on this protein, conservation studies must always consider all circulating HIV-1 variants worldwide for correct analysis.

Abstract 9112

Presence of carbapenem- and colistin-resistant Gram-negative bacteria in illegally imported foods to Europe
David Rodriguez-Lazaro1, Lorena Casado1, Jorge Santamaria1, Ernestina Pantilie1, R. Hortensia Rodriguez-Pollan2, Marta Hernández1, Isabel Fernández-Natal3*

1University of Burgos, Burgos, Spain, 2Complejo Asistencial Universitario de León, León, Spain, ITACyL Instituto Tecnológico Agrario de Castilla y León, Valladolid, Spain

Background: The emergence of antimicrobial resistant (AMR) bacteria in food-producing animals has provoked a great concern in the presence of AMR bacteria in associated foodstuff. Likewise, enforced mobility of people has become a major issue in the recent years. A strong intra-European transmigration has become a matter for mobility systems due to million of employees living or working outside their home countries. However, little information is available on the rate of AMR bacteria importation via contaminated illegal food, consequently, defining a neglected route of transmission.

Materials/methods: A total of 170 animal-originated foods (meat and dairy samples) recalled from travellers’ luggage at the International Bilbao airport (Spain) were taken and analysed for the presence of carbapenem- and colistin- enterobacteriaceae. Samples of 25 g were 1:10 diluted in buffered peptone water and incubated at 37°C for 24 hours, and streaked on selective agar media for testing carbapenem (Brilliance CRE, Oxoid) and colistin (CHROMID Colistin R, bioMerieux) resistance. Colonies grown in the respective media were identified using MALDI TOF Biotyper (Bruker Daltonics) and an antimicrobial sensitivity test was performed using MICROSCAN (Beckman Coulter). Further confirmation of the nature of the resistance mechanisms was performed using specific PCRs, and a set of the isolates were submitted to Whole Genome Sequencing.

Results: Fourteen (8.2%), eight (4.7%) and four (2.4%) food samples contained isolates tested resistant to colistin, carbapenems and resistance to the two families of antibiotics, respectively. In addition, 2 extra food samples possessed isolates with intermediate resistance two carbapenems which were also resistant to colistin. Most of the isolates belong to the order Enterobacterales, mainly to the families Enterobacteriaceae, Hafniaceae, Yersiniaceae and Morganellaceae, and to the order Xanthomonadales.

Conclusions: This study shows the presence of enterotoxigenic carbapenem- and colistin- resistant Gram negative in foods illegally entering the EU, and highlights illegal importation of food as route of AMR spread. Several of the bacterial species with resistant to one or both antibiotic families are known nosocomial agents [eg. Stenotrophomonas maltophilia, Hafnia or Serratia]. Consequently Uncontrolled entry of food stuffs into the EU can be a relevant neglected route of AMR dissemination.

Abstract 9114

**Therapeutic response of meropenem and azithromycin in the treatment of extensively drug-resistant (XDR) typhoid fever in a lower-middle income country**

Sonia Qureshi*, Farah Naz1, Abdullah Naveed1, Tahir Yousafzai2

1Aga Khan University Hospital, Karachi, Pakistan

**Background:** *Salmonella Typhi* is one of the leading causes of bacterial illnesses in Pakistan. With the emergence of extensively drug resistant (XDR) *Salmonella Typhi*, treatment options are limited. Here we report the clinical manifestations and the response to treatment with meropenem and azithromycin either alone or in combination for the treatment of patients with XDR Typhoid during an outbreak setting in Pakistan.

**Materials/methods:** We reviewed the records of culture confirmed XDR typhoid patients – both inpatient and outpatient - who visited Aga Khan University Hospital (AKUH), Karachi and Aga Khan Secondary Care Hospital, Hyderabad during April 2017 to June 2018. Frequency of clinical symptoms at presentation, relapse of disease, unplanned treatment extension and complications developed while on antimicrobials was recorded. Means with standard deviation were calculated for duration of treatment, time to defervescence, and cost of treatment.

**Results:** Records of 60 culture confirmed XDR typhoid patients admitted at the AKU hospitals were reviewed. Most, (n=33; 55%) were male. Mean age of the cases was 9.63 ± 1.22 years. About three quarter (n=45) of the patients were treated as inpatient. Fever and vomiting were the most common (n=47; 78% each) symptoms at the time of presentation. Oral azithromycin alone (n=20; 33%), intravenous meropenem alone (n=10; 17%), or a combination of azithromycin and meropenem (n=30; 50%) were the options used for treatment. Average [95% confidence interval] time to defervescence was 7.5(5.7-9.3), 5.3(2.6-8.0), and 7.0(5.6-8.4) days for each treatment option respectively whereas there were 2, 1 and 2 treatment failures in each treatment option respectively. There was no significant difference in time to defervescence (p=0.330) across the groups. Cost of treatment per day for azithromycin was US$0.14 whereas it was US$42.95 for meropenem.

**Conclusions:** Azithromycin, meropenem alone or in combination are the only treatment options for XDR Typhoid. Time to defervescence and treatment failure were similar across groups. Clinical trials are needed for more robust evidence.

**Presenter email address:** sonia.qureshi@aku.edu
Levonadifloxacin (WCK 771), a recently approved benzoquinolizine fluoroquinolone exhibits potent in vitro activity against methicillin- and quinolone-resistant Staphylococcus aureus: a report from Indian tertiary care hospital

Yamuna Devi Bakthavatchalam¹, Abirami Shankar¹, Harthi R.², Veeraraghavan Balaji*¹

¹Christian Medical College, Vellore, India

Background: Staphylococcus aureus is a clinically challenging pathogen due to its virulence and multiplicity of antibiotic resistance mechanisms. Levonadifloxacin (WCK 771) is a broad-spectrum benzoquinolizine fluoroquinolone with well-differentiated mechanism of action (primary target - DNA gyrase) driven potent activity against methicillin resistant/quinolone-resistant S. aureus (MRSA/QRSA). Levonadifloxacin and its prodrug alalevonadifloxacin (WCK 2349) have recently received regulatory approval in India for the indication of acute bacterial skin and skin structure infections (ABSSSIs) with concurrent bacteremia and diabetic foot infections. As levonadifloxacin would be available soon for clinical use in India, the present study was undertaken to evaluate the in-vitro activity of levonadifloxacin against recent S. aureus isolates collected from a large tertiary care hospital located in South India.

Materials/methods: Recent (2018-2019) non duplicate S. aureus (n= 662) cultures were isolated from the pus, respiratory specimens and blood collected from various units of Christian Medical College and Hospital, Vellore. Species identification and MRSA characterization were undertaken employing MALDI-TOF and cefoxitin disks, respectively. The minimum inhibitory concentrations [MIC] of levonadifloxacin and comparator drugs viz., levofloxacin, vancomycin, teicoplanin, linezolid, erythromycin, clindamycin and co-trimazole were determined using CLSI recommended broth micro-dilution method (BMD). Mutations in the quinolone resistance determining region (QRDR) were identified using whole genome sequencing.

Results: Among 662 isolates, methicillin susceptible (MSSA) and MRSA were 49% (n= 325) and 51% (n=337), respectively. Levonadifloxacin inhibited 96.4% and 99.4% of all tested isolates at 0.5 mg/L and 1 mg/L, respectively. Levonadifloxacin retained potent activity against QRSA and MRSA isolates (MIC90 of 0.5 mg/L) with 16 times lower MICs than levofloxacin. The genomic analysis of QRDR regions in 17 QRSA (levonadifloxacin MIC: 0.25 - 2 mg/L) revealed double mutations, gyrA S84L, parC S80F (n = 8); and gyrA S84L, parC S80Y (n = 9). All the isolates were susceptible to vancomycin and linezolid.

Conclusions: In conjunction with several clinically relevant favourable features such as bactericidal action, class-leading lung concentrations, freedom from monitoring safety parameters and oral option, the potent activity against contemporary MDR S. aureus isolates revealed in this study supports levonadifloxacin’s clinical use for serious MRSA infections as potentially a new standard of care.

Abstract 9116

Four-year experience of carbapenem-resistant Acinetobacter baumannii in a Spanish tertiary hospital: the threat still exists?

Manuel Belda1, Carme Salvador1, Nuria Tormo*, María Martínez-Serrano1, Marta Moreno1, Begoña Fuster1, Daniel Alberto González1, Irene Tur1, Concepción Gimeno Cardona1

1Consorci Hospital General Universitari de València, València, Spain

Background: In the era of the difficult-to-treat Enterobacterales infections, other multidrug-resistant bacteria, such as Acinetobacter baumannii, seem to have disappeared; but A. baumannii is a pathogen with high morbidity and mortality in some settings, especially in the intensive care unit (ICU). The aim of the study is to describe the epidemiological, demographic and molecular characteristics of carbapenem resistant A. baumannii clinical (CRAB) isolates in a 500-bed Spanish tertiary hospital in the last 4 years.

Materials/methods: We performed a retrospective study of all clinical samples with an isolate of A. baumannii between January 2016 and October 2019. The microorganisms were identified by MALDI-TOF mass spectrometry (Bruker®) and the antimicrobial sensitivity was obtained by MicroScan WalkAway (Beckman Coulter®). The characterization of carbapenemases was evaluated in 53 CRAB isolates by using the Eazyplex® SuperBug Complete A (Amplex) according to manufacturer’s instructions, which detects KPC, NDM, OXA-48, VIM, OXA-23, OXA-40 and OXA-58.

Results: 492 (83%) out of 595 A. baumannii isolates from 228 patients (67% men – 33% women) were CRAB, with a median age of 69 years old (15-98). 20% of the total were found in 2016, 34% in 2017, 39% in 2018 and 7% in 2019. The more frequent CRAB isolates were from respiratory tract infections (37%), urinary infections (23.4%) and bacteremia (18.6%). There were also 2 CRAB isolates in the cerebrospinal fluid. Half (52%) of the infected patients were previously colonized. The distribution by type of carbapenemase was: 15.2% OXA-23, 68.6% OXA-40 and 16.2% co-production OXA-23 and OXA-40. By hospitalization wards, the number of CRAB isolates was significantly higher in the intensive care unit (43.3%) followed by internal medicine and the emergency ward with 11.5% and 11%, respectively.

Conclusions: 1) CRAB isolates in our setting still be a problem, mostly affecting men aged >65 years; however in 2019 there is a decrease. 2) CRAB in ICU is significantly higher than other hospital wards, probably associated with the use of invasive devices and prolonged stays. 3) The most frequent CRAB isolates corresponded to respiratory tract infections. 4) Interestingly, a high percentage of carbapenemase OXA-40 is observed in CRAB isolates and no NDM carrier has been found.

Presenter email address: nuriatormo@hotmail.com
Cotrimoxazole in bone and joint infections is the “old” antibiotic still relevant
Matthieu Bardou1, Piseth Seng*, Andreas Stein1
1Centre de Référence des Infections Ostéo-Articulaires [CRIOA] Sud-Méditerranée, AP-HM, Marseille, France

Background: Cotrimoxazole (trimethoprim-sulfamethoxazole) has shown an effectiveness in the management of staphylococcal infections of osteosynthesis devices and joint prostheses. In recent years, an increase in resistance of Gram-negative bacteria has been reported worldwide. Furthermore, bone and joint infections may be often polymicrobial. In this study, we studied the effectiveness of high oral doses of cotrimoxazole on a broad spectrum of microorganisms.

Materials/methods: We included in a single-center, a retrospective study of 129 patients who started curative treatment during hospitalization with a high-dose cotrimoxazole orally alone or combined with another anti-infective agent from January 1, 2013 and who stopped treatment before the December 31, 2017 for any documented osteoarticular infection with or without equipment of the limbs or spine. We evaluated the efficacy defined as the absence of relapse at one year after discontinuation of antibiotic therapy. We also assessed tolerability and treatment-related adverse events.

Results: Of these 129 patients, 31.8% (41) had an adverse effect on treatment requiring early or late cessation and 21.7% (28) were lost before the end of one year of follow-up. Sixty cases were fully treated and the overall efficacy of treatment was 60.0% (36 of 60 patients). The polymicrobial infection rate was 61.7% (37/60). 55.6% of patients were cured (15 of 27 patients) in Staphylococcus aureus infections, 58.8% (10/17) in coagulase-negative staphylococcus infections and 60.5% (26/43) in enterobacteria infections.

Conclusions: The results of the present study confirm that oral high-dose cotrimoxazole can be an interesting alternative for the oral treatment of osteoarticular infections. Its effectiveness is now proven not only for multi-resistant staphylococcal infections but also for GNB and polymicrobial infections. We suggest that cotrimoxazole can be used in complex polymicrobial or multiresistant Gram-negative infections with devices and may have an interest in the management of open fractures. “Old” cotrimoxazole remains an interesting weapon, not only for staphylococcus, but also for gram-negative bacteria and polymicrobial bone and joint infections. Nevertheless, treatment with cotrimoxazole is frequently complicated by adverse effects and needs to be carefully monitored.

Screening and characterisation of multidrug-resistant Enterobacteriaceae in healthy companion animals in close contact with humans

Juliana Menezes*1, Adriana Belas1, Inês Cunha E Silva1, Pedro Pinto Silva1, Maria Constança Pomba1

1University of Lisbon, Faculty of Veterinary Medicine, Lisboa, Portugal

Background: The role of companion animals as potential sources and reservoirs of antimicrobial resistant bacteria represent growing concerns worldwide. The aim of this study was to evaluate the presence of extended-spectrum β-lactamases (ESBL) and Carbapenemase-producing Enterobacteriaceae or Acinetobacter spp. as well as Methicillin-Resistant Staphylococcus aureus (MRSA) bacteria faecal carriage in healthy companion animals (CAs) in close contact with humans.

Materials/methods: Between January 2016 and October 2019, 79 healthy companion animals (54 dogs and 25 cats) living in close contact with humans in 54 households, were enrolled in this study. The pet owners were informed of the procedures and conducted the fecal sample collection from their companion animals with sterile gloves, containers and plastic bags. Informed consent was obtained. Fecal samples were inoculated on MacConkey agar plates containing 1.5µg/mL cefotaxime, 1.0 µg/mL meropenem, CHROMagar Acinetobacter, CHROMID® OXA-48 plates and Oxoid™ Brilliance™ MRSA (Thermo Fisher Scientific). Beta-lactam genes were screened by PCR and sequencing. The species identification was performed PCR. Susceptibility tests were performed by microdilution with MicroScan® Neg MIC Panel Type 44 (Siemens, Sacramento, CA, US), and results interpreted according to EUCAST.

Results: Third-generation cephalosporin-resistant Enterobacteriaceae were detected in 9.3% of the dogs (n=5/54) and in 4% of the cats (n=1/25). In dogs, among these 3CG-resistant Enterobacteriaceae: i) one Escherichia coli was positive for the blaCTX-M-15 gene, with resistance to fluoroquinolones, sulfamethoxazole/trimethoprim, penicillins and aminoglycosides; ii) other carried a blaCMY-2 gene, with the corresponding phenotype of resistance; iii) other multidrug-resistant E. coli harbored the blaCTX-M-79 + blaCMY-2 genes; iv) an E. coli harbored the blaCMY-2 + blaTEM-32 genes; v) one multidrug-resistant Klebsiella pneumoniae was simultaneously positive for the blaCTX-M-15 + blaTEM-1 + blaSHV-110 genes. Among cats, only one 3CG-resistant Enterobacteriaceae harbored the blaCTX-M-15 + blaCMY-2 genes. In both groups of CAs neither carbapenemase-resistant Enterobacteriaceae/Acinetobacter spp. nor MRSA were detected.

Conclusions: The isolation of multidrug-resistant Enterobacteriaceae in healthy companion animals is an emerging problem and dissemination of resistant bacteria through fecal contamination of the environment should not be neglected and is a concern towards animal and human health.

Abstract 9123

Impact of non-use of levofloxacin prophylaxis during neutropaenia on reduction of resistance among Gram-negatives causing bloodstream infection in haematopoietic stem cell transplantation patients: very successful preliminary data

Thais Guimaraes*1, Fernanda Spadao1, Livia Caroline1, Marina Nascimento1, Vanderson Rocha1, Silvia Figueiredo Costa1

1Hospital das Clínicas - FMUSP, Instituto Central, São Paulo, Brazil

Background: Universal prophylaxis with quinolones is a strategy used by several centers to reduce the febrile episodes and bloodstream infections (BSI) during the period of neutropenia in hematopoietic stem cell transplantation (HSCT) patients. This strategy can lead to selection of resistant bacteria and it has been associated with increase of resistance among gram-negative bacilli (GNB) all over the world. So we evaluate the impact of non-use of universal levofloxacin prophylaxis during neutropenia on the reduction of antibiotic-resistance in GNB causing BSI in HSCT patients.

Materials/methods: Quasi-experimental study of before (2016-2018) and after (2019) to assess the density of incidence (DI) of BSI using two denominators: patients-day and neutropenia-day; the profile and susceptibility of microorganisms causing BSI in HSCT patients at HC-FMUSP, Brazil. We compared DI of BSI related to central venous catheter (CVC-BSI) from January 2016 to June of 2019 as well as mucosal barrier injury (MBL-BSI) from 2018 to 2019. In December 2018, we stopped the levofloxacin prophylaxis during the neutropenia period in our Bone Marrow Transplantation Unit. Statistical analysis was performed using Epi-Info version 7 from CDC.

Results: A total of 297 HSCT were performed during the study-period. The CVC-BSI DI in 2016, 2017, 2018 and 2019, were respectively: 4.6; 1.4; 0.6 and 6.3 BSI/1000 patients-day. In 2018 and 2019, MBL-BSI DI was 13.8 and 26.4 BSI/1000 neutropenia-day. The profile of microorganisms causing BSI in 2017-2018 and 2019 were respectively 11/22 (50%) and 20/35 (57.1%) of GNB, being 6/11 (54.5%) and 0/20 carbapenem-resistant (p=0.005). In 2019, only 2/20 (10%) GNB causing BSI was ESBL-producing and all others were susceptible to third generation cephalosporin. Regarding mortality, only one death occurred due to MBL-BSI caused by K. pneumoniae ESBL producer.

Conclusions: Although, the suspension of the use of quinolones as prophylaxis lead to an increase of MBL-BSI as expected, our data showed a significant reduction of resistance among GNB causing BSI with only one death. Nowadays we are able to handle fast progressing BSI using third generation cephalosporin. Thus, non-use of levofloxacin prophylaxis during neutropenia had important impact on reducing resistance among GNB and appears to be a safe strategy.

Abstract 9125

**Nosocomial influenza**

Erik Rothman*1, Blenda Bottiger2, Ulf Karlsson1

1Skånes universitetssjukhus Lund, Infection Control, Lund, Sweden, 2Skånes universitetssjukhus Lund, Department of Microbiology, Lund, Sweden

**Background:** Nosocomial influenza is associated with substantial morbidity and a mortality of 9-16% in partly historic reports. Hospital outbreaks are not uncommon but are likely substantially under-reported. The proportion of nosocomial infections among patients hospitalized for influenza in a few studies has varied from 4-20%. This may be explained by regional differences in transmission rate but may also depend upon diverse properties of dominating influenza strains during different seasons. We performed a retrospective study of hospitalized influenza patients during five seasons to determine mortality in patients with nosocomial infections, and also to investigate if influenza subtypes correlated with the proportion of nosocomial infections and hospital outbreaks.

**Materials/methods:** Influenza-PCR positive adult patients (>18 years), hospitalized in Skåne County, Sweden, during 2013-2018, were evaluated retrospectively. Medical records were examined to identify nosocomial infections, 30-day mortality, and influenza subtypes. Nosocomial infection was defined as an influenza-PCR positive hospitalized patient who had developed symptoms indicative of influenza ≥ 3 days after hospital admission, and who had no prior signs of infectious respiratory disease and/or unexplained fever. Influenza subtypes were available from the Medical Microbiology Department, Skane University Hospital.

**Results:** Out of 3466 hospitalized influenza patients, 358 (10%) were nosocomial infections. The proportion of nosocomial infections varied between seasons (3-22%). In total, 236 (15%) of H3N2, 34 (5%) of H1N1, and 87 (7%) of influenza B infections were nosocomial (p < 0.0001). A total of 60 clusters were identified. Clustered cases were more common for H3N2 (72%) than for H1N1 (38%) and influenza B (36%). Mortality in nosocomial influenza was 8%, did not differ between subtypes, and was similar to hospitalized non-nosocomial influenza cases. Mortality in H3N2 nosocomial infection was associated with higher age (87 years) as compared to influenza B (76 years) and H1N1 (67 years).

**Conclusions:** In our evaluation over 5 influenza seasons, influenza H3N2 cases were responsible for a majority of nosocomial infections, often as a part of clustering. Elderly hospitalized patients may be specifically vulnerable to nosocomial influenza H3N2 infection. Mortality in nosocomial influenza was lower than previously reported and similar to non-nosocomial influenza.

A home humidifier responsible for Legionnaires’ disease: input of WGS for genomic investigation in a ST1 case

Jeanne Couturier1,2, Christophe Ginevra3,4, Gil Dhenin5, Sarah Jolivet5, Didier Nesa1, Latifatou Boukari6, Murielle Maison7, Sandra Lapoussin8, Béatrice Salauze9, Sophie Jarraud3,4, Frédéric Barbut1,2,5, Ghislaine Descours*3,4

1Laboratoire de Microbiologie de l’environnement, GHUEP, Hôpital Saint-Antoine, Paris, France, 2Université Paris Descartes, UMR-S1139, Sorbonne Paris Cité, Paris, France, 3Hospices Civils de Lyon, Groupement Hospitalier Nord, Institut des Agents Infectieux, Centre National de Référence des Légionelles, Lyon, France, 4Centre International de Recherche en Infectiologie, Équipe Pathogénèse des Légionelles, Lyon, France, 5Unité d’Hygiène et de lutte contre les infections nosocomiales, Hôpital Saint-Antoine, Paris, France, 6SSR Médecine interne et polyvalente, Hôpital Rothschild, Lyon, France, 7Équipe Opérationnelle d’Hygiène, Hôpital Rothschild, Paris, France

Background: The L. pneumophila ST1 clone has been shown to colonize hospital water networks worldwide and to be often implicated in nosocomial Legionnaires’ disease (LD) cases. Here, we evaluated the contribution of Whole Genome Sequencing (WGS) for resolving investigation of a 60-year-old woman ST1 LD case after a 14-day hospitalization for a pulmonary pre-transplant evaluation.

Materials/methods: To investigate this case, sputum was cultured and the potential sources of exposure, i.e. hot water from shower and washbasin of the 2 rooms attended by the patient, were cultured according to NF T90-431 standard. The history revealed the use of a home humidifier filled with tap water from her home, which she had kept over her hospitalization period; the patient claimed that she had not used hospital tap water in this humidifier while hospitalized. The tank water that had not been thrown at the time of LD diagnosis was cultured.

Results: The sputum grew L. pneumophila serogroup 1 (Lp1). The 4 hospital water samples tested negative for L. pneumophila (< 10 CFU/L), as all samples that had been tested coincidentally at the time of the onset of symptoms and for 2 years on the building water network (hot water outlet and return, and points of use). The water of the humidifier tank grew Lp1 (300 CFU/L). The clinical and environmental strains were analysed by Sequence-Based Typing; both were ST1 strains. We could not formally conclude on the source of infection as ST1 strains are widespread and account for 10% of LD cases. The strains analysis was thus complemented by WGS, the mapping of sequence reads and phylogenetic analyses being performed as described by David et al. (CID, 2017). They showed a same common ancestor, with no SNP.

Conclusions: We report a health-care associated ST1 LD case related to use of a domestic humidifier filled with patient’s home water before hospitalization. Such sources have been rarely described so far (n=4), and the increasing use of aerosolizing devices would require special attention when investigating LD cases. Combined with medical history and epidemiological data, WGS was determinant to resolve the investigation.

Abstract 9131

Carbapenemase-producing *Klebsiella pneumoniae* belonging to sequence type 23 is a predictor of poor outcome in haematological patients

Kristina Tandilova1, Galina Klyasova1, Svetlana Khrulnova1, Parovichnikova Elena1, Sergey Kravchenko1, Elena Gribanova1, Evgeniy Zvonkov1, Gennadiy Galstyan1, Valeriy Savchenko1

1National Research Center for Hematology, Moscow, Russian Federation

**Background:** The aim of this study was to compare bloodstream infections (BSI) caused by carbapenemase-producing *K. pneumoniae* belonging to sequence types [ST] 23 and ST395 in haematological patients.

**Materials/methods:** Prospective study (2014-2019) included haematological patients with BSIs caused by carbapenemase-producing *K. pneumoniae*. Carbapenemase genes (*bla*OXA-48*,* *bla*KPC*, *bla*VIM*, *bla*NDM and *bla*IMP) and virulence genes (*iucA*, *rm-pA*, *rmpA2*) were tested by PCR. Multiplex PCR was performed to detect K1,K2,K5,K20,K54 and K57 serotype-specific alleles. Multilocus sequence typing (MLST) was performed according to the protocol described in Institut Pasteur MLST on a website ([http://bigsdb.pasteur.fr/klebsiella/primers_used.html](http://bigsdb.pasteur.fr/klebsiella/primers_used.html)).

**Results:** During the study period 39 patients had BSI caused by carbapenemase-producing *K. pneumoniae*, of them 14 (36%) of isolates belonged to ST23 (*K. pneumoniae*-ST23), 13 (33%)–to ST395 (*K. pneumoniae*-ST395), 4 (10%)–to ST377, 3 (8%)–to ST512 and each one to ST13, ST11, ST874. The majority of isolates harbored *bla*OXA-48* (90%), followed by *bla*OXA-48+, *bla*NDM and *bla*KPC (5% each). Outcome of infections caused by *K. pneumoniae* belonging to the predominant STs such as ST23 (n=14) and ST395 (n=13) was evaluated, all isolates (n=27) harbored *bla*OXA-48. There were no differences in age (48 vs 56 years), underlying disease and phase of therapy, neutropenia and its duration. Infections caused by *K. pneumoniae*-ST23 and *K. pneumoniae*-ST395 were presented as BSI (57% vs 77%), BSI+pneumonia (29% vs 23%), BSI+pneumonia+meningitis (1.4% vs 0%). Capsular type K57 was detected in all *K. pneumoniae*-ST23 compared to *K. pneumoniae*-ST395 (100% vs 0%, p<0.0001), whereas capsular type K2 was associated with *K. pneumoniae*-ST395 (38% vs 0%, p<0.01). Virulence genes were detected more often among *K. pneumoniae*-ST23 (93% vs 46%, p=0.01). Septic shock, vasopressor administration and higher Pitt bacteremia score were statistically significantly associated with BSIs caused by carbapenemase-producing *K. pneumoniae*-ST23 (p<0.05). Overall 30-day survival was lower (p=0.04) among patients with infections caused by *K. pneumoniae*-ST23 compared to *K. pneumoniae*-ST395 (61.5% vs 21%), especially in presence of virulence genes (67% vs 15%) (figure a,b).

**Conclusions:** *K. pneumoniae*-ST23 was associated with capsular type K57 and virulence genes. Septic shock, vasopressor administration and higher Pitt bacteremia score were significantly associated with BSIs caused by *K. pneumoniae*-ST23. The main predictor of poor outcome in patients with BSI caused by carbapenemase-producing *K. pneumoniae* was affiliation to ST23.

Abstract 9132

Aminoglycoside resistance mechanisms in invasive Klebsiella pneumoniae and Escherichia coli: a threat of rmtC mediated resistance

Iffet Uzun*, Tugce Celik¹, Burak Aksu¹, Nurver Ulger Toprak¹, M.Ufuk Hasdemir¹

¹Marmara University School of Medicine, Istanbul, Turkey

Background: Aminoglycosides (Ags) are often used in combination with other antibiotics and provide a valuable therapeutic option for treating multidrug resistant bacterial infections. Aminoglycoside resistance (AgR) due to 16S ribosomal methyltransferases (RMTs) seems to emerge as real threat that limit the use of these antibiotics for salvage therapy. In this study, we aimed to investigate genetic determinants of RMTs together with aminoglycoside modification enzymes (AgMEs) in invasive Klebsiella pneumoniae and Escherichia coli.

Materials/methods: Fifty K. pneumoniae and 49 E. coli, isolated throughout the year 2016 and exhibited resistance to at least amikacin or gentamicin in routine susceptibility testing (VITEK® 2 Compact, BioMérieux, France) were included in the study. Amikacin, gentamicin, tobramycin, and netilmicin MICs of the isolates were determined by standard broth microdilution method (BMD) in the study isolates. Genetic determinants of RMTs [armA, rmtA, rmtB, rmtC, rmtD, rmtE, rmtF, rmtG, npmA] and AgMEs [aac(3)-II, aac(3)-I, aac(6’)-Ib, ant(2’’)-I] were investigated by PCR.

Results: Twelve of 50 (24%) K. pneumoniae isolates exhibited high level resistance (>256 mg/L) to all Ags tested in BMD. High level aminoglycoside resistance was not detected in any of the E. coli isolates. rmtC was the most common (13/50) RMT gene followed by armA (2/50) in K. pneumoniae (Table 1). aac(3)-II was found together with aac(6’)-Ib in 64% of K. pneumoniae and 32.7% of E. coli isolates.

Conclusions: rmtC encoded high level aminoglycoside resistance seems to be a threat in K. pneumoniae in our hospital, especially considering high risk of multidrug resistance in such isolates.

Abstract 9133

**Risk factors for epilepsy and cysticercosis in Abidjan, Ivory Coast: a case-control study**

Man Koumba Soumahoro¹, Jihen Melki¹,², Yves-Landry Kangah¹, Abel Christain Tanoh¹, Narcisse Tano¹, Mariam Diomandé¹, Mamadou Camara¹, Major Ngouan⁴, Thérèse Sonan⁵, Berthe Assi³, Ronan Jambou⁶

¹Institut Pasteur de Côte d'Ivoire, Epidemiology Unit, Abidjan, Côte d'Ivoire, ²Institut Pasteur de Côte d'Ivoire, Parasitology Unit, Abidjan, Côte d'Ivoire, ³Cocody University Hospital, Neurology Unit, Abidjan, Côte d'Ivoire, ⁴General Hospital Adjame, Neurology Unit, Abidjan, Côte d'Ivoire, ⁵Yopougon University Hospital, Neurology unit, Abidjan, Côte d'Ivoire, ⁶Institut Pasteur, Global Health Department, Abidjan, Côte d'Ivoire

**Background:** Cysticercosis is due to the larva of the *Taenia solium* human tape worm. Seizures are the main clinical symptoms of the disease, and WHO considers this disease as one of the main causes of epilepsy in tropical countries. The aim of this study was to analyze the association between cysticercosis and epilepsy in Abidjan.

**Materials/methods:** A case control study was conducted including patients suffering from epilepsy and attending the neurology clinic of the three main hospitals of the town, and age-matched patients attending dispensaries of the same area, without neurological symptoms. Data related to socio-cultural and nutritional habits were collected as well information on the household and its environmental context. All the patients were blood sampled and cysticercosis specific serology was done using Tsang et al methods. Variable comparisons were conducted using Mac Nemar, Student or Wilcoxon matched tests when relevant. Conditional logistic regression model was built.

**Results:** Overall, 226 epileptics and 226 age-matched non-epileptic patients were included. Epileptics were more often males (69% vs. 55%; p=0.001), without professional occupation (21% vs. 9%; p=0.005). Presence of pigs in the surrounding was more frequent for epileptics (5% vs. 1%; p=0.019), as well as a poorer environmental setting of the household with open air defecation (5% vs. 0%, p=0.001) and no facilities for waste water elimination (39% vs. 28%, p=0.020). However, no significant difference was found between the two groups for cysticercosis positive serology (8.41% vs. 4.42%, p=0.13). Multicomponent analysis confirmed that factors related to epilepsy were the gender, the family status, the professional employment and the area of residence.

**Conclusions:** This study didn't support association of epilepsy and cysticercosis in the urban setting of Abidjan. The main factors associated with the disease in comparison with the control group are related to the way of life of the epileptic which could be either related to risk factors for other infectious diseases (toxoplasmosis, schistosomiasis etc) or to a social exclusion of these patients.

**Presenter email address:** smkoumba@yahoo.fr
Abstract 9134

Laboratory diagnosis and circulation of respiratory syncytial virus (A and B subgroups) and influenza virus A (H1 and H3 subtypes) and B in a three-winter season (2016-17 to 2018-19) hospital-based survey in northern Italy

Maria Cristina Arcangeletti1, Clara Maccari*1, Flora De Conto1, Francesca Ferraglia2, Federica Pinardi2, Paolo Montagna2, Carlo Chezzi1, Adriana Calderaro1

1University of Parma, Department of Medicine and Surgery, Parma, Italy, 2University Hospital of Parma, Unit of Clinical Virology, Parma, Italy

Background: Respiratory syncytial virus (RSV), Influenza A (IAV) and B (IBV) virus are among the leading causes of viral upper and lower respiratory infections and a significant cause of hospitalization and even death in ‘at-risk’ individuals, such as children and older adults.

We analysed a three-winter seasonal circulation of RSV (A and B subgroups), IAV (H1 and H3 subtypes) and IBV in the population with influenza-like illness (ILI) attending to the University Hospital of Parma, Italy.

Materials/methods: Respiratory samples (n=2066), collected in three winter seasons (December 2016-March 2019) from 1875 patients with ILI, were analyzed by conventional and molecular methods for viral detection and subtyping at the Virology Unit of the University Hospital of Parma, Italy.

Results: Among the 810 RSV and/or IV positive samples, 22.8% were RSV A, 34.9% RSV B, 34.8% IAV and 7.4% IBV. As to RSV subgroups, RSV A prevailed in 2016/2017, and was reversed by RSV B in the last two seasons. RSV was identified in children ranged from 1 month to 1 year and in elderly (>50 years). Concerning IV, all the epidemic seasons were characterized by the prevalence of IAV; IAV-H3 dominated in 2016/17, while all samples resulted positive for IAV-H1 in 2017/2018; finally, both subtypes co-circulated in the 2018/19. As regards IBV circulation, a significant increase of IBV was detected only in the 2017/2018, vs a negligible number of cases in the 2016/2017 and no cases in the 2018/2019 winter seasons. Both IAV and IBV infections were most prevalent among children ranged from 1 to 6 years and ≥ 50 year-old adults.

Conclusions: This study represents a useful tool for the surveillance of viral infectious agent circulation and variability, as the considered population is mostly represented by hospitalized pediatric and elderly patients who more often can develop adverse events upon RSV or IV infection.

Remarkably, RSV A responsible for the most severe clinical pictures in infants was reversed by RSV B in the two last winter seasons, possibly related to new genetic variants.

Also of interest, IBV peaked only in 2017/18, according to the European Centre for Disease Prevention and Control data.

Modulation of toll-like receptors and interferons signalling pathways by sub lethal dose of scopolamine gives protection from Japanese encephalitis virus infection in embryonated chick model

Arghyadeep Bhattacharjee*, Manish Saha

1Peerless Hospital, Kolkata, India, 2R.G. Kar Medical College and Hospital, Kolkata, India

Background: Japanese encephalitis (JE) has become a global health concern due to specific antiviral therapy and thus demands new potential strategies to combat the disease. Toll like receptors and Interferon mediated intracellular signalling plays a pivotal role in the initiation of innate immune response via induction of interferons (IFNs) controlling the viral replication and subsequent severity of the infection. The study was conducted to evaluate the effect of Scopolamine, an active component of *Atropa Belladonna* plant in controlling JE virus infection in chick embryo, which is already an established model for study of host pathogen interactions and screening of antiviral agents.

Materials/methods: In our study twelve day old embryos were pre-treated with Scopolamine to investigate whether it can give protection from JE virus infection and subsequent pathogenicity. Total RNA from Chorioallantoic membrane (CAM), Brain and Amniotic fluid were extracted and the viral load was determined. Semi quantitative RT-PCR for gene expression analysis was carried out. Histological analysis of Brain and CAM tissues were performed to determine the extent of pathogenicity and morphological changes. All the experiments were replicated thrice and data's were represented as mean ±SD. One way and Two way analysis of variance, t-test were applied for the analysis of differences among different test groups. For correlation study Pearson’s correlation was used.

Results: There was significant decrease in the viral loads in the Brain, CAM and Amniotic fluid of the embryo in Scopolamine pre-treated groups compared to the infection groups. There were significant changes for IFNs and IRFs both in CAM and brain tissue among the four groups. Nevertheless, Scopolamine pre-treated group also showed significant up-regulation of IFN-α and TLR3, TLR7, TLR8 mRNA. The histological changes showed significant reduction of necrosis, inflammation and other co-morbid pathology in the Scopolamine pre-treated groups.

Conclusions: Scopolamine exerts the antiviral effect by influencing the TLR signalling pathway which is one of the contributing factors in the immune-pathogenicity of JE virus infection. The present study may pave the way in the development of targeted immunotherapy through targeting specific molecules of TLR, IFN and other signaling pathways in future against JE by altering the innate immune signalling.

**The profile of virulence gene exoS, exoT, exoU and exoY from gene encoding effector protein type III secretion system of *Pseudomonas aeruginosa* in clinical isolates in Sanglah Hospital Bali**

Wayan Agus Gede Manik Saputra*, Ni Made Mertaniasih, Ni Nengah Dwi Fatmawati

1RS Bali Mandara, Bali Provincial Health Office, Denpasar, Indonesia, 2Airlangga University, University of Airlangga, Surabaya, Indonesia, 3Udayana University Campus Sudirman, Udayana University, Denpasar, Indonesia

**Background:** *Pseudomonas aeruginosa* is one of the Gram-negative rods bacteria that causes opportunistic and nosocomial infections. Type III secretion system (TTSS) is main virulence factor of *P. aeruginosa*. There are four effector proteins TTSS *P. aeruginosa* they are ExoS and ExoT possessed GAP and ADPRT activities, ExoU as potent cytotoxin exhibits phospholipase A, activity and ExoY is a adenylil cyclase that elevates cAMP eukaryote cells. This study was aimed to know the distribution and proportion virulence genes exoS, exoT, exoU dan exoY of gene encoding effector protein TTSS *P. aeruginosa* from clinical isolates in Sanglah general hospital 2015.

**Materials/methods:** *Pseudomonas aeruginosa* isolates were obtained from clinical specimens were then grouped into blood, sputum, urine and pus specimens which had been identified phenotypically by Vitek2 Compact system (bioMérieux, Inc., Marcy-l’Etoile - France), and then continued by genotipic detection by PCR method. The characterization of genes encoding effector proteins TTSS *P. aeruginosa* were performed by dupleks PCR (dPCR) method that separated into two dPCR consisted of dPCR to genes exoS paired with exoT and dPCR to genes exoU paired with exoY.

**Results:** In total 124 *P. aeruginosa* isolates from blood, sputum, urine and pus specimens known the proportion of each genes exoS, exoT, exoU and exoY were 92,7%, 97,5%, 58,1% and 92,7%, respectively. The isolates genotypically exoS+/exoT+/exoU+/exoY+ accounted for 55,65% dan 57,26%, respectively.

**Conclusions:** The distribution and proportion virulence genes exoS, exoT, exoU and exoY of gene encoding effector protein TTSS *P. aeruginosa* were independent to various kind of specimens (blood, sputum, urine and pus). There were no significant differences between distribution and proportion of each virulence genes to each kind of specimens.

The probability of infection caused by carbapenemase-producing Enterobacterales (CPE) in haematological patients with rectal carriage of CPE

Kristina Tandilova*1, Galina Klyasova1, Svetlana Khrulnova1, Parovichnikova Elena1, Sergey Kravchenko1, Elena Gribanova1, Evgeniy Zvonkov1, Gennadiy Galstyan1, Valeriy Savchenko1

1National Research Center for Hematology, Moscow, Russian Federation

Abstract 9141

**Background:** The aim of this study was to evaluate the probability of CPE-infection in haematological patients colonized by CPE.

**Materials/methods:** Prospective study (2015-2018) included haematological patients with colonization of gut by CPE. Genes of carbapenemases \( \text{bla}_{\text{OXA-48}}, \text{bla}_{\text{KPC}}, \text{bla}_{\text{VIM}}, \text{bla}_{\text{NDM}} \) and \( \text{bla}_{\text{IMP}} \) were detected by real-time PCR.

**Results:** During the study period 76 patients were included (39 male, 37 female; median age 42 years). The majority of patients had acute leukemia 34 (45%) and non-Hodgkin lymphoma 23 (30%). 52 (68%) received chemotherapy, 15 (20%) underwent hematopoietic stem cell transplantation [12 – allogeneic, 3 – autologous]. 46 (60%) patients were transferred from another hospital, median time from admission to our center till the first isolation of CPE from gut was 40 days, excluding 17 (22%) patients who were colonized by CPE at admission. Overall 81 CPE were isolated from gut in 76 patients: \( \text{K.pneumoniae} \) – 68 (84%), \( \text{E.coli} \) – 5 (6%), \( \text{E.cloacae} \) – 4 (5%), \( \text{C.freundii} \) – 2 (2%), \( \text{S.marcescens} \) – 1 (1%), \( \text{M.morganii} \) – 1 (1%). Isolates harboring \( \text{bla}_{\text{OXA-48}} \) predominated – 64 (79%), followed by \( \text{bla}_{\text{NDM}} \) – 10 (12%), \( \text{bla}_{\text{OXA-48}+\text{bla}_{\text{NDM}}} \) – 6 (7%), \( \text{bla}_{\text{KPC}} \) – 1 (1%). The probability of CPE-infection was 56% (figure a). Risk factors for CPE-infection were as follows (\( p<0.05 \)): presence of central line, admission to intensive care unit (ICU), appearance of CPE-colonization in ICU, CPE-colonization of more than 1 site, parenteral nutrition.

**Conclusions:** The probability of CPE-infection among CPE-rectal carriers was 56%. The most common pathogen was \( \text{K.pneumoniae} \) harboring \( \text{bla}_{\text{OXA-48}} \). The probability of CPE-infection was significantly higher in patients who had more than 1 site of CPE-colonization and among ICU-patients.

Abstracts 2020

Abstract 9145

**Impact of influenza Point-of-Care testing in the emergency department on clinical care of adult patients at three hospitals in Lanarkshire, Scotland: an observational study**

Antonia Ho\(^1,2\), Patrick Anstey\(^2\), Heather Black\(^1\), Erin Kerr\(^3\), Jamie Mcallister\(^2\), Christopher Mullen\(^1\), Matthew Tate\(^*4\), David Cromie\(^5\), Ian McCormick\(^6\), Sarah Whitehead\(^6\)

\(^1\)University of Glasgow, MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom, \(^2\)University Hospital Monklands, Infectious Diseases Unit, Airdrie, United Kingdom, \(^3\)University Hospital Hairmyres, Department of Medicine, East Kilbride, United Kingdom, \(^4\)University Hospital Wishaw, Department of Respiratory Medicine, Wishaw, United Kingdom, \(^5\)NHS Lanarkshire, Department of Public Health, Cumbernauld, United Kingdom, \(^6\)University Hospital Monklands, Microbiology Department, Airdrie, United Kingdom

**Background:** Rapid influenza molecular tests with similar sensitivities to laboratory-based polymerase chain reaction (PCR) are gradually being introduced at the front door of UK hospitals. We examined the impact of influenza point-of-care testing (POCT) on patient journey and management during the influenza season across three adult acute hospitals in Lanarkshire, Scotland.

**Materials/methods:** Cobas Liat influenza A/B POCTs were instituted in the emergency department (ED) at University Hospitals Hairmyres, Monklands and Wishaw between December 2018 and March 2019. Patients tested for influenza on presentation during this period were compared to those tested by real-time reverse transcriptase PCR between December 2017 and March 2018 (pre-POCT). Outcomes of interest included patient time in the acute assessment areas (including ED, medical assessment unit and ambulatory care unit), hospitalisation rate, antiviral and antibiotic utilisation, time to antivirals, and length of stay.

**Results:** In total, 733 and 1202 patients were included in the 2017/18 (pre-POCT) and 2018/19 (POCT) seasons, respectively. A higher proportion of the pre-POCT cohort were influenza PCR positive (38.9 vs. 34.2%, p=0.04). The POCT group had a lower rate of hospital admission (76.3 vs 90.9%, p<0.001) and spent less time in the acute assessment areas (3.7 vs. 5.3 hours, p=0.001).

POCT was associated with significantly shorter time to influenza result (median turnaround time 3.0 vs. 24.6 hours, p<0.001). Similar proportions of influenza PCR positive patients were prescribed antivirals among the pre-POCT and POCT groups (80.6 vs. 80.1%), but substantially fewer influenza-negative patients in the POCT cohort received antivirals (1.3% vs. 35.2%, p<0.001). Median time to the first dose of antivirals was shorter in the POCT group (5.2 vs. 15.3 hours, p<0.001). A lower proportion of patients in the POCT cohort received antibiotics (68.5 vs. 86.3%, p<0.001). Furthermore, the median length of hospital stay was shorter in the POCT group (5 vs. 6 days, p<0.001).

**Conclusions:** Notwithstanding the limitations of a before-and-after study, influenza POCT was associated with shorter time in acute assessment areas, timelier influenza diagnosis, more rapid and prudent antiviral prescribing, in addition to lower rates of hospitalisation, antibiotic use, and shorter length of stay.

Bacteriophage therapy in orthopaedic and cardiovascular surgery: first clinical experience with difficult-to-treat infections

Paula Morovic*1, Tamta Tkhilaishvili1, Donara Margaryan1, Svetlana Karbysheva1, Andrej Trampuz1

1Charité - Universitätsmedizin Berlin, Berlin, Germany

Abstract third-party references: Suppported by: PRO - IMPLANT Foundation

Background: Antibiotics have limited activity in the treatment of multidrug-resistant or chronic biofilm-associated infections, in particular when implants cannot be removed. Lytic bacteriophages can rapidly and selectively kill bacteria, and can be combined with antibiotics. However, clinical experience in patients with surgical infections is limited. We investigated the outcome and safety of local application of bacteriophages in addition to antimicrobial therapy.

Materials/methods: Patients with complex orthopedic and cardiovascular infections were included, in whom standard surgical treatment was not feasible or impossible. Before inclusion, patient informed consent was obtained and the treatment was performed in agreement with the Article 37 of the Declaration of Helsinki. Bacteriophages were provided by ELIAVA Institute in Tbilisi, Georgia, after performing susceptibility testing of the isolated pathogen. Bacteriophages were applied during surgery in the surgical site and continued through percutaneous drains placed during surgery three times per day for the following 5-14 days. Patients were followed-up on regular clinical visits at 3, 6 and 12 months.

Results: We included 6 patients (2 female and 4 male). Median age was 57 years, range 36-80 years. 3 patients had left ventricular assist device (LVAD) infection, 1 cardiovascular implantable electronic device (CIED) infection, 1 periprosthetic joint infection (PJ) and 1 chronic posttraumatic osteomyelitis. The infection was polymicrobial in 3 patients (including gram-negative rods and staphylococci), Pseudomonas aeruginosa was isolated in 2 cases and Staphylococcus aureus in 1 patient. 5 patients underwent surgical revision with retention of the implant (if present), one patient with LVAD infection was treated conservatively. At follow-up of 12 month, 5 patients were without signs or symptoms of infection, whereas in one patient with LVAD infection, a relapse was observed with emergence of phage-resistant Pseudomonas aeruginosa. In this patient, no surgical revision was performed.

Conclusions: Bacteriophage therapy may represent a valid additional approach, when standard antimicrobial and surgical treatment is not possible or feasible, including in difficult-to-treat infections. In our case series, 5 of 6 patients were infection free after 1 year. Further studies need to address the optimal bacteriophage administration route, concentration, duration of treatment and combination with antimicrobials.

Abstract 9159

**Surveillance for control of antifungal resistance in Candida bloodstream infections fails to inform antifungal stewardship in European countries**

Liliana Galia¹, Astrid Callegari*², Elena Carrara¹, Nithya Babu Rajendran³, Monica Compri¹, Evelina Tacconelli¹³

¹University of Verona, Verona, Italy, ²University of Bologna, Bologna, Italy, ³University of Tuebingen, Tuebingen, Germany

**Abstract third-party references:** This research project receives support from the Innovative Medicines Initiative Joint Undertaking under grant agreement n° 115737 resources of which are composed of financial contribution from the European Union Seventh Framework Programme (FP7/2007-2013) and EFPIA companies in kind contribution.

**Background:** Resistance monitoring among *Candida* isolates represents a new challenge for epidemiological surveillance due to the increasing resistance trends, especially among non-*albicans* strains. COMBACTE-Magnet EPI-Net’s surveillance network rose to this challenge by performing the first systematic assessment of resistance rates in *Candida* blood-isolates in Europe, in order to provide barrier-free access to existing data.

**Materials/methods:** The protocol was developed following the guidance already in place for antimicrobial resistance surveillance among bacteria (SUSPIRE-protocol). Surveillance systems and studies reporting data on *Candida* blood-isolates were searched through Google engine and Pub-Med from January-2005 to August-2019. Data reported from 28 EU and 4 EFTA countries with no language restriction were considered. To increase representativeness, only multicentre studies with at least 12-months consecutive surveillance were included. Final assessment of existing surveillance included: surveillance systems’ characteristics, reporting modalities and study quality.

**Results:** Out of 53 retrieved national surveillance, 14 reported on *Candida* isolates but only Austria, Italy, Norway, Spain and UK included resistance data. Azole resistance in *C.albicans*, was the most frequently reported, while data on *C. glabrata, C.parapsilosis*, echinocandin and amphotericin B-resistance was reported in 4 surveillance only. The average isolates tested per-year varied between 19 and 454.

Among 318 publications, 26 studies from 13 countries were included. More than a half was supported by private companies. The most tested antifungal agents were fluconazole (96%), voriconazole (77%), amphotericin B (73%), and caspofungin (50%). The most reported *Candida* species were *C.albicans* (96%), *C.parapsilosis* (98%), and *C.glabrata* (85%). Multi-drug-resistant *Candida* was reported in 3 studies only. No data on *Candida auris* resistance were reported. Broth microdilution, S.YeastOne and E-test were used in 10, 5 and 2 studies, respectively. CLSI reference was used in 16 studies (62%).

Detailed description of microbiological methods was not available for 83% of surveillance systems and 35% of the included publications.

**Conclusions:** Anti-fungal resistance surveillance among *Candida* blood-isolates is fragmented and heterogeneous. Scarce reporting of microbiological methods and inclusion of low number of samples hinder the validity and representativeness of the data, delaying the application of a translational approach to the threat of antifungal resistance and the identification of relevant target for antifungal stewardship.

Assessment of de-escalation of empirical antimicrobial therapy in medical wards with high rates of multidrug-resistant bacteria: a multi-centre prospective cohort study

Garyfallia Poulakou*, Vasiliki Rapti1, Konstantinos Leontis1, Athanasios Kakasis1, Stamatina Pagoni1, Ioannis Tsimbos1, Katerina Masgala1, Liana Sybardi1, Nikolaos Alexiou1, Vasileios Apostolopoulos1, Charalampos Giannopoulos1, Christo Trokati1, Apostolos Prionas1, Michael Samarkos1, Sotiros Tsiodras2, Nikolaos Alexiou5, Vasileios Apostolopoulos5, Charalampos Giannopoulos5, Kostoula Arvaniti6, Christina Trakatelli7, Apostolos Prionas8, Michael Samarkos9, Sotirios Tsiodras3, Helen Giamarellou10

1Third Department of Medicine, School of Medicine, National and Kapodistrian University of Athens, Sotiria General Hospital, Athens, Greece, 2Third Department of Medicine, General Hospital of Athens “G.Gennimatas”, Athens, Greece, 3Fourth Department of Medicine, School of Medicine, National and Kapodistrian University of Athens, Attikon University Hospital, Athens, Greece, 41st Department of Medicine, Konstantopoulio General Hospital of Athens, Athens, Greece, 5First Department of Medicine, Thriasio General Hospital of Elefsina, Athens, Greece, 6Critical Care Department, Papageorgiou General Hospital of Thessaloniki, Thessaloniki, Greece, 7Third Department of Medicine, Aristotle University, Papageorgiou General Hospital of Thessaloniki, Thessaloniki, Greece, 8School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, 9First Department of Medicine, School of Medicine, National and Kapodistrian University of Athens, General Hospital of Athens “LAIKO”, Athens, Greece, 101st Internal Medicine & Infectious Diseases Clinic, Hygeia General Hospital, Athens, Athens, Greece

Background: De-escalation of empirical antimicrobial treatment has been considered a key component of antimicrobial stewardship programs. However, this strategy has not been adequately evaluated in settings with increased prevalence of multidrug-resistant (MDR) bacteria. The aim of this study was to identify frequency, associated factors and safety of de-escalation in Greek medical wards (MW), with recognized MDR prevalence.

Materials/methods: Prospective observational study conducted in six centers during a 6-month period in 2017-2018, analyzing the first septic episode of patients with microbiologically documented infections including sepsis or septic shock. Patient characteristics including admission diagnosis, illness severity, empirical antibiotic regimen, culture results, length of hospital stay (LOS), and 28-day mortality were recorded. Antibiotic de-escalation was defined as change to narrower spectrum antibiotics or discontinuation of part of the initial antibiotic regimen on the basis of culture results.

Results: A total of 142 patients were enrolled, male 78 (54.9%); Charlson comorbidity index (CCI) mean 4.97 (SD 2.48); SOFA score mean 2.88 (SD 2.26). Escherichia coli was the most frequent pathogen (49.2%), followed by Klebsiella pneumoniae (17.6%), Pseudomonas aeruginosa (7%) and Proteus mirabilis (4.9%). Urinary tract, abdominal sources and the lung were the most frequent sites of infection (66.9%, 5.6% and 6.3% respectively); primary bacteraemia was 6.3%. Overall 46.4% of infections were bacteraemic, 56.3% of patients had sepsis and 12.6% septic shock. De-escalation (DE) was applied in 72/142 patients (50.7%) and 9/29 (31%) in difficult to treat pathogens (p=0.08). Carbapenem de-escalation was achieved in 11/20 patients (55.5%). 28-day crude mortality was 23.9% for the whole cohort and 8.3% for de-escalated patients (p=0.01). There was no significant difference in age, diagnosis, admission CCI and SOFA scores and total antibiotic duration between DE and non-DE.

Conclusions: Antimicrobial de-escalation was applied in 50.7% of patients with sepsis or septic shock in medical wards with prevalence of MDR pathogens, including those with difficult to treat bacteria and was associated with favorable clinical outcomes. Although no causality can be demonstrated, careful clinical selection of patients can result in reduction of unnecessary antibiotic use without compromising safety.

The bacterial gut microbiota during controlled human infection with Necator americanus larvae

Quinten Ducarmon, Marie-Astrid Hoogerwerf, Jacqueline Janse, Anoe Geelen, Jan Pieter Koopman, Romy D. Zwittink*, Jelle Goeman, Ed J. Kuijper, Meta Roestenberg

Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Hookworms are soil-transmitted helminths which use immune-evasive strategies to persist in the human duodenum where they are responsible for anemia and protein loss. Despite mass drug administration, hookworm is still responsible for a high burden of disease globally, underscoring the need for an effective vaccine. A controlled human hookworm infection (CHHI) model was developed to aid vaccine development. Apart from their pathogenic role, hookworms are increasingly investigated for attenuating autoimmune disease, as they induce immunoregulation. Currently, little is known about the bacterial-helminth relationship during helminth infection. The current study explored temporal changes in the gut microbiota in response to human infection with Necator americanus in a CHHI model with healthy volunteers.

Materials/methods: Twenty-four healthy volunteers were included in a randomized CHHI, of which 20 completed the study. Volunteers were exposed to cumulative doses of 50, 100 and 150 larvae. The 150 larvae group received first infection at trial week 0, the 100 group at trial week 2 and the 50 larvae group at trial week 4. Fecal samples were collected for bacterial microbiota profiling at weeks 0 (baseline), 4, 8, 14 and 20 of the trial.

Results: All volunteers developed patent infection. Heavy gastrointestinal (GI) complaints were observed in 11 volunteers and were not associated with the larval dose. No differences in microbiota richness, diversity and stability were observed between the three study groups, nor were significant differences in abundance of individual bacterial taxa found. Overall, bacterial richness increased from week 8 to week 20 (p=0.017) of the trial. Volunteers with heavy GI had transient instability of the microbiota during the first eight weeks (p=0.047) and a rapid recovery at week 20 (p=0.004). Additionally, eosinophil count significantly correlated with microbiota stability (Jaccard, r=-0.26, p=0.02). Barnesiella, amongst other taxa, was found to be more abundant in the heavy complaints group throughout the study (p<0.05).

Conclusions: We found a remarkable stability of the gut microbiota in response to N. americanus infection over the twenty-week study period, although transient instability was observed in individuals with heavy GI complaints. This instability correlated with eosinophil counts, suggesting a relationship between microbiota and eosinophilic enteritis.

Presenter email address: r.d.zwittink@lumc.nl
Julieanne Kubes1, Jesse Jacob*2

1Emory Healthcare, Atlanta, United States; 2Emory University, Atlanta, United States

Background: Influenza vaccination is recommended for all patients aged >6 months, and hospitalization provides an opportunity for vaccination in patients with limited access to care. We sought to assess the cascade of care in administering influenza vaccinations.

Materials/methods: In a 500-bed US hospital, nurses complete a screening tool for influenza vaccination embedded in the electronic medical record as part of the admissions process for adults. The tool assesses 1) if patients are eligible for vaccine (have not received influenza vaccination during the current season), 2) if any medical contraindication or egg/latex allergy exist, and 3) if the patient refuses the vaccination. If the patient does not refuse, influenza vaccine is automatically ordered with the next morning's medications. Between 10/1/2018 and 3/30/2019, we calculated frequency of tool completion, the responses to each step in the tool, frequency of vaccine administration and the pooled influenza vaccination rate/100 eligible encounters. Differences in vaccination rate were calculated by each nursing unit, by 3 nursing unit types [intensive care unit (ICU), ward, mother/baby] and by individual nurse completing the tool. Only the first completed tool per encounter was included.

Results: Among 13,437 unique patient admissions by 779 nurses, 12,936 (96%) had the tool completed. Most (55%) patients did not have prior influenza vaccination, and few patients had allergies (latex: 1.2%, eggs: 1.2%) or medical contraindications (0.7%). Of the 6,597 eligible patients without allergy/contraindication, 4,654 (71%) declined the vaccine. Only 1,943 (14%) of screened encounters had an order for influenza vaccine, but only 1,169 (61%) of those with orders had an influenza vaccine administered (Figure 1). The highest rates of vaccination/100 eligible patients were in the ICU (20), followed by wards (17) and mother/baby units (12). By individual nursing unit, the median vaccination rate/100 eligible encounters was 9.3 [range: 2.1-25.5]. Nurses varied in vaccination rate/100 eligible encounters varied widely [median: 5.4; range: 0-100].

Conclusions: During the 2018-2019 influenza season, nearly half of adult patients were not vaccinated before hospitalization, and <10% of those eligible for influenza vaccination received the vaccine. Scripting nursing interactions or other standardization efforts may improve influenza vaccination rates among inpatients.

Presenter email address: jtjacob@emory.edu
Background: In countries with high endemicity for carbapenem-resistant Enterobacteriaceae (CRE) colonization of long-term care facilities (LTCFs) residents play an essential role in the spread between community and healthcare facilities. Rapid identification of colonized patients are therefore essential for a prompt start of infection control measures. Aim of the study was to compare specificity and sensitivity rapid molecular tests in detecting CRE on rectal swab in LTCFs residents in a high endemic country.

Materials/methods: A point prevalence survey (PPS) with rectal screening (RS) was conducted in 27 LTCFs in north Italy in high endemic setting for ESBL-Ent in a 12-month period. Rectal swabs were inoculated onto ChromID ESBL agar (bioMerieux, Marcy l’Etoile, France) with an Ertrapenem disk (10ug) and on McKonkey agar with a Meropenem disk (10ug). Resistance to carbapenems were confirmed with immunocromatographic Lateral flow assay Carba5 (NG Biotech). Rapid molecular test were done using the CRE ELITe MGB kits (Elitech Group, Italy) with the ELITe InGenius RT (Real Time PCR) which detect KPC, NDM, VIM, IMP, and OXA-48 like families, performing a complete run of 12 samples in 2h and 30 min. Sensitivity, specificity and negative and positive predictive value were calculated according to standard methods.

Results: Overall, we screened 1947 residents. CRE were identified in (70/1947) 3.5% of cultures and in (124/1947) 6.37% of molecular tests with a concordance of 96%. CRE ELITe MGB identified 50 positive residents not identified from conventional cultures (50/124, 40%). The carbapenem resistant genes were classified with the real time PCR as KPC in 55% of the positive samples; the remaining were NDM/VIM/IMP. Sensitivity and specificity of the molecular test were 94% and 97% respectively, with a NPV of 99.7%.

Conclusions: Molecular tests identify 40% more CRKP colonized residents in LTCFs than conventional cultures. Moreover, molecular methods could give a rapid evidence of the type of carbapenemas produced. Cost-effectiveness studies are needed to define the role of rapid tests linked to infection control measures in containing the spread of CR-KPC outside the hospital in high endemic countries.

Abstract 9182

**Surveillance of Mycobacterium leprae in Analamanga region of Madagascar**

Dauphin Randriarimanana*, Malalaniaina Andrinarison, Tahirinamandanto Rasamoelina, Petra Angelot Rakotomalala, Avanzi Charlotte, Lala Soavina Ramarozatovo, Bertrand Cauchoix, Jean-Luc Berland, Fahafahantsoa Rapelanoro Rabelo

1Centre d’Infectiologie Charles Mérieux, Antananarivo, Madagascar, 2University Hospital Joseph Raseta Befelatanana, Antananarivo, Antananarivo, Madagascar, 3Colorado State University, Colorado, United States, 4Fondation Raoul Follereau Madagascar, Antananarivo, Madagascar, 5Fondation Mérieux, Lyon, France

**Background:** Leprosy still remains a major problem of public health in Madagascar with over 1500 reported new cases per year in these last years. The Centre d’Infectiologie Charles Mérieux (CICM), named by the Ministry of the Public Health as the National Reference Laboratory for the surveillance of resistance to anti-leprosy therapy, ensures the diagnosis and study of resistance of leprosy cases reported by the Programme National de Lutte contre la Lèpre (PNLL) from the region of Analamanga, Bongolava and Itsy. The lack of reliable diagnostic tools especially for the early stage and differential of the disease is of major concern. We report here the first results stemmed from PCR RLEP, recently added to the diagnosis algorithm.

**Materials/methods:** Patients have been recruited by dermatologists from the University Hospital of Befelatanana and during scheduled mass consultations in other parts of the island. Skin biopsies have been sampled as well as some earwax. Microscopic diagnosis after Ziehl-Neelsen staining and PCR targeting the repeated sequences of M. leprae genome were performed.

**Results:** Since August 2012, 124 skin biopsy and earwax have been analyzed by microscopy and PCR RLEP. One hundred and fourteen (92%) patients were clinically classified as multibacillary (MB), and 10 (8%) were classified paucibacillary (PB). From skin biopsies, 103 specimen were positive with either smear microscopy or PCR RLEP. Among MB, 64 (56%) were smear microscopy positive versus 98 (86%) were PCR RLEP positive. Among the 10 PB patients, three were PCR positive but none were smear positive. Twenty-one (17%) specimen remain negative for both methods: 14 among MB patients and 7 among PB ones.

**Conclusions:** The PCR RLEP correlates with clinical presentations and allows confirming more cases than smear microscopy. As bacteriology drives the polychemotherapy regimen of leprosy patients, these results questions the role of PCR RLEP in patient classification. More data on clinical outcome will give evidence about.

Abstract 9183

Travel-related meningitis: results from a thirteen-year retrospective study
Conan Pierre-Louis*, France Charton1, Luc Labarbe1, Mathieu Cabon1, Marie Gominet1, Dinaherisoa Andriamanantena1, Cécile Ficko2

1Infectious and tropical diseases, military teaching hospital Bégin, Saint-Mandé, France, 2Respiratory diseases department, military teaching hospital Saint-Anne, Toulon, France

Background: Meningitis is a rare but potentially severe cause of morbidity in travelers. Few data are available on microbiological data in this setting. The aim was to describe the etiologies of meningitis in travelers and compare them to meningitis in non-travelers.

Materials/methods: This monocentric observational study included all consecutive patients hospitalized for meningitis between January 1, 2002 and December 31, 2015. Meningitis was classified as bacterial (culture or PCR positive in the cerebrospinal fluid (CSF)), viral (PCR positive in CSF), or probably viral (favourable outcome without antibiotic therapy within 7 days of diagnosis) or without etiology. A patient was considered as a traveler if he had left metropolitan France within a month before the onset of symptoms.

Results: Two hundred and ninety-six patients were included, including 47 travelers [median age 31 years [26-37], 23 (48.9%) women]. The main destinations were sub-Saharan Africa [n=11, 23.4%], Maghreb [n=10, 21.3%] and Europe [n=6, 12.8%]. For 7 patients [14.9%], symptoms had started during the stay but none had been repatriated. Thirty-five [74.5%] had viral meningitis [22 documented and 13 probable], 11 [23.4%] had meningitis of undetermined etiology and 1 [2.1%] had bacterial meningitis. Microbiology showed a clear predominance of Enterovirus [n=15, 31.9%] and Herpesviridae [HSV 2, 3 cases and VZV, 2 cases]. One [2.1%] patient had meningitis due to mumps virus. The only bacterial meningitis was due to Mycoplasma pneumoniae in a young man returning from Ivory Coast. Only 2 [4.3%] meningitis were due to a non-cosmopolitan etiology: dengue fever in a patient returning from Malaysia and Toscana virus after a stay in Italy.

When comparing with the non-travelers group, the two populations were no different in age and sex (p=0.69 and 0.57 respectively). The proportions of bacterial (p=0.14, OR 0.21 [0.04-1.18]), documented viral (p=0.59, OR=1.19 [0.64-2.2]), probably viral (p=0.59, OR=1.3 [0.65-2.6]) and undetermined (p=0.97, OR=0.95 [0.46-1.96]) meningitis were not different.

Conclusions: The diagnostic approach to meningitis in traveler should focus on cosmopolitan etiologies. Tropical causes must be mentioned in second intention, especially in case of an evocative epidemiological context.

Abstract 9185

**Etiology of viral and bacterial gastroenteritis in a third-level hospital in Spain in relation to age**

Eduardo León¹, Maria Gasca Santiyan¹, Begoña Palop*¹

¹Hospital Regional Universitario, Málaga, Spain

**Background:** Acute gastroenteritis (AGE) is one of the most common infectious diseases. Viral pathogens cause most of these cases. However, bacteria, parasites, and fungus can also cause AGE. The aim of this study was to establish the prevalence of different enteropathogens in our hospital in relation to age.

**Materials/methods:** This study was conducted from January 2018 to August 2019. We studied stool samples received from patients with suspected gastroenteritis. The identification of bacterial species was carried by mass spectrometry MALDI-TOF (Bruker Daltonics®) and the study of Rotavirus and Adenovirus by detection of antigens by immunochromatographic methods (MonlabTest®), as well as for Norovirus (CerTest Biotec®) in all those samples in which it was requested. In addition, the study of parasites was carried out by the concentration technique (VircellMiniSystem - Total-Fix®). Only one sample per patient was considered.

**Results:** 6274 samples were processed as coproculture, of which 356 (5.67%) were positive. The study of viral antigens of Adenovirus and Rotavirus was carried out in 1549 samples, while that of Norovirus was carried out in 388. Finally, the study of parasites was carried out on 4447 samples and the one most frequently observed was *Giardia lamblia* on 41 occasions (0.92%). The results are observed in the next table.

**Conclusions:** The age group with the highest number of positives was the one formed by 5-years-old children. The most frequently isolated bacterial enteropathogen was *Campylobacter* spp. followed by *Salmonella* spp. Rotavirus was the main viral etiologic agent, but regarding the samples in which the virus study was requested, Norovirus was the most prevalent. It is likely that the presence of Norovirus and the other gastrointestinal viruses is underdiagnosed because their studies are not usually included in the diagnosis.

Abstract 9194

Validation of a semi-automated surveillance of surgical site infections: improving exhaustiveness, representativeness and efficiency

Rui Malheiro*, Nuno Rocha Pereira, Raquel Duro, Claudia Pereira, Carlos Alves, Sofia Correia

1ACES Grande Porto VI - Porto Oriental, Porto, Portugal, 2Centro Hospitalar Universitário S. João, Porto, Portugal, 3EPIUnit – Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal

Background: Traditionally, Surgical Site Infections (SSIs) surveillance implies manually review of patient charts, which is labour intensive, time-consuming and prone to error. Its representativeness is frequently unknown, though local data is used in the Healthcare-Associated Infections Surveillance Network (HAI-Net). We aimed to assess the exhaustiveness of SSIs surveillance in a tertiary care teaching hospital in Porto, Portugal, and to address whether a semi-automated model, using electronic health records’ data to select patients with high-risk of SSI for subsequent manual review, was valid and could improve efficiency.

Materials/methods: Colorectal surgeries performed between January 2016, and December 2018, were selected. For each hospitalization, post-surgical antibiotic use, positive cultures, C-reactive protein (CRP>50; CRP>100mg/dL), leukocyte counts (>11.000/mm³), body temperature (>38°C), surgical re-intervention, post-discharge visit to the emergency room and hospital readmission were retrieved. Representativeness was evaluated by comparing characteristics of the procedures registered in the HAI-Net with the non-included ones. Within HAI-Net procedures, the validity of each variable (or combination of variables) was tested using as the gold-standard the presence of a SSI registered in the current surveillance system. The proportion of medical records flagged by each criterion for manual review was estimated, as a measure of efficiency.

Results: Out of 1330 colorectal procedures, 743 (56%) were registered in HAI-Net (SSI risk: 10.6%). Non-included procedures were more likely to be emergent interventions and presented higher proportions of antibiotic use and other proxies of infection. CRP presented the highest sensitivity (92%; 95%CI 84%-97%) followed by antibiotic use (89%; 95%CI 79%-95%). However, the latter showed a higher positive predictive value (22%, or 23% if considering antibiotic use or positive culture). Antibiotic use flagged fewer procedures for manual review (47.7%) than any other criteria.

Conclusions: Current surveillance is neither exhaustive nor representative: it systematically misses procedures with high risk of infection. Thus, reported incidence is likely underestimated. Antibiotic use seems to be a good criterion to select procedures for manual review. Rather than just saving time, by demanding merely half of procedures to be manually reviewed, it may also improve the exhaustiveness and representativeness of surveillance. Nevertheless, all criteria need to be validated prospectively before their application.

Abstract 9200

Risk factors for carbapenem-resistant Enterobacteriaceae infections among rectal carriers in carbapenemase co-circulation setting: data from SPACE-CP study

Patricio Favier*1, Enrique Serio1, Jessica Maresca1, Fidel Pinilla Huayta1, Claudia Muñoz Soto1, Diego Torres1, Carla Raffo1, Johanna Perez1, María Inés Gallino1, Liliana Kumar4, Carlos Blanco5, Alejandra Marcela Macchi1, Sebastián Nuñez6

1Hospital de Trauma y Emergencias Dr. Federico Abete, Sección Infectología, Pablo Nogués, Argentina, 2Hospital de Trauma y Emergencias Dr. Federico Abete, Laboratorio de Microbiología, Pablo Nogués, Argentina, 3Hospital de Trauma y Emergencias Dr. Federico Abete, Laboratorio de Genética y Biología Molecular, Pablo Nogués, Argentina, 4Hospital de Trauma y Emergencias Dr. Federico Abete, Servicio de Terapia Intensiva, Pablo Nogués, Argentina, 5Municipalidad de Malvinas Argentinas, Secretaría de Salud, Pablo Nogués, Argentina, 6Sanatorio Güemes, Buenos Aires, Argentina

Background: Scoring systems to predict carbapenem-resistant Enterobacteriaceae (CRE) infections are useful to select adequate therapy. Those models were created in CRE-bla_KPC environments. Thus, designing strategies to evaluate other classes of CRE (e.g. CRE-bla_NDM) is crucial because their treatment varies. Our aim was to detect risk factors for CRE infections among CRE-bla_KPC or CRE-bla_NDM rectal carriers. Secondary outcome was to assess exclusive factors for each CRE.

Materials/methods: Retrospective study among CRE-bla_KPC and CRE-bla_NDM rectal carriers from a tertiary hospital of Buenos Aires Province (Argentina) from July 2016 to July 2019. We compared patient with and without CRE infections to identify general and specific risk factors for developing them. Extra-rectal sites were studied according to physicians’ criteria. Rectal swabs cultures were performed in transferred patients from other center, admitted to critic areas or shared room with CRE-colonized. Molecular techniques were used to detect CRE genes. Possible associated factors in univariate analysis were included in the logistic regression model. Statistics measurements were executed by R-Studio 3.0.

Results: 320 carriers (48.6% CRE-bla_KPC, 28.6% CRE-bla_NDM and 21.6% both) were included. 58.7% were male, the median age was 66 years (IQR 21). 11.2% developed a CRE infection (7% bacteremic, 4.2% non-bacteremic). Adjusted model showed that at least one extra-rectal colonized site (aOR 3.0 [IC95% 1.1-7.9] p=0.03) was the only linked factor to any kind of CRE infection. Surprisingly, surveillance swab cultures did not predict episodes by the same resistance mechanism: CRE-bla_KPC (OR 1 [0.44-2.37] p=0.9) and CRE-bla_NDM (OR 2.1 [95% CI 0.6-6.8] p=0.2). Also, this tendency was observed taking into account at least one extra-rectal colonized site for CRE-bla_KPC (OR 1.9 [0.5-6.9] p=0.4) and CRE-bla_NDM (OR 4.5 [0.9-22.8] p=0.1) infections. Finally, no distinctive factors were evident concerning sex, age, previous antibiotic use, surgical procedures, length of stay and prior comorbidities.

Conclusions: Extra-rectal colonization was a marked risk factor for any CRE infection in our colonized population. Conversely, no specific factors for predicting each class of event were detected. These findings highlight the ubiquitous conditions for the acquisition of both CRE and the inability to predict each one in context of co-circulation.

Travel patterns and knowledge of risk of infections during international travels in solid organ transplantation

Pilar Martín-Dávila*, Francesca Norman, Jesus Fortun Abete, Tamara Ruiz Merlo, Mario Fernandez Ruiz, Jose M. Aguado Garcia, María Carmen Farinas, Claudia González Rico, Beatriz Mahillo, Patricia Parra, Rogelio López-Vélez

1Hospital Ramon y Cajal, Infectious Diseases, Madrid, Spain, 2Hospital Ramon y Cajal (Madrid), Madrid, Spain, 3Hospital 12 de Octubre, Madrid, Spain, 4Hospital 12 De Octubre, Madrid, Spain, 5Hospital Marques de Valdecilla, Santander, Spain, 6Hospital Marques de Valdecilla, Santander, Spain, 7Organización Nacional de Trasplantes, Madrid, Spain, 8Hospital Ramon y Cajal, Colmenar Viejo, Spain

Abstract third-party references: The work was supported by Plan Nacional de I+D+i 2013-2016 and Instituto de Salud Carlos III, Subdirección General de Redes y Centros de Investigación Cooperativa, Ministerio de Ciencia, Innovación y Universidades, Spanish Network for Research in Infectious Diseases (REIPI RD16) - co-financed by European Development Regional Fund “A way to achieve Europe”, Operative program Intelligent Growth 2014-2020

Background: International travel (IT) after SOT may pose a risk of medical complications and infection acquisition that could be prevented with adequate information and advice prior to the trip as well as updating vaccinations if necessary.

Materials/methods: Prospective, multicenter survey performed in 3 Spanish hospitals during Nov.18 to Nov.19. Survey was anonymous and voluntary for SOT recipients. Questionnaire has two parts: 1ª) for all SOT recipients with questions aimed at assessing the level of knowledge of vaccination status, ways of transmission and prevention measures for transmissible travel-related infection. In addition, patterns of pre-SOT travels were explored (destinations and frequency). 2º) For those who had travel after SOT, questions regarding destinations, frequency, medical encounter, adherence to recommendations and complications during the trip were considered. Changes in travel patterns before and after SOT were analyzed.

Results: 258 SOT recipients participated in the survey (163 kidney, 35 cardiac, 48 liver, 12 combined organs). Median time from tx to survey: 10 m (1 - 520). 193 (74.8%) were transplanted > 6 months. Age (median): 57 yrs-o (19-84). 29 (11.2%) were foreign-born (82.7% from high-risk countries).

| Unknown vaccination status (infection; %) | HAV 35.3%; HBV 25.6%; measles [29%], chicken-pox [26%], meningococcal (40.7) |
| % recipients known way of transmission (T) and prevention measures (P) | HIV (T 91%, P 88%), syphilis (T 81%, P 75%), HAV (T 46%, P 40%), HBV (T 57%, P 53%), malaria (T 46.9%, P 35%), TB (T 38.7%, P 34.8%) |
| Pre-SOT IT | IT 50% (129 pts). 38% to high-risk areas. |
| Main destination: Europe [42%] |
| Post-SOT IT (SOT > 6 months) | IT 15% (39 pts). Reasons IT: 68.9% tourism, 14.9% business, 12.6% VFR, 3.4% others. |
| Main destination: Europe [67%] |
| 60% medical advice (<50% follow) |
| Travel-complications: 7.7% (2 bacterial infections, 1 cardiac) |

Conclusions: Low level of knowledge about vaccination status and prevention measures of travel-transmissible infections has been detected in SOT patients. Medical education should be implement. Patients continue travelling after SOT. Frequency and destinations of IT are modified, avoiding countries at risk of infection or with difficult access to health. Complications were infrequent. Medical advice by ID/Travel medicine specialists is recommended, especially for high-risk trips.

Abstract third-party references: This work is funded by the Netherlands ZonMw grant number 547001005 within the 3rd JPI ARM framework, co-fund grant no 681055 for the consortium EMerGE-Net.

Background: The impact of patient movements inside the hospital on pathogen spread is not well studied. The aim of this study is to analyze patient movement patterns between hospital wards to assess if movement patterns differ between patients at high or low risk of colonization. Next, we aim to quantify the impact of intra-hospital patient movement patterns on pathogen spread using agent-based simulations.

Materials/methods: We analyzed patient electronic medical record data from five hospitals and stratified patients into low-risk and high-risk groups based on specific ICD-10 codes. Movement patterns were extracted and visualized as networks, and network centrality measures were calculated. Next, we simulated the spread of a pathogen inside one hospital, using an agent-based model – where agents represent patients and inter-ward patient movements were modelled.

Results: Risk stratification of patients according to ICD-10 codes revealed that length of stay, patient age, and mean number of movements per admission were higher in the group we defined as high-risk. Movement networks in all hospitals displayed a high variability among wards concerning their network centrality and connectedness with a few highly connected wards and many weakly connected peripheral wards. Simulating the spread of a pathogen in such a network of wards showed positive correlation between ward prevalence and network centrality measures.

Conclusions: This study highlights the importance of inter-ward patient movements and their possible impact on pathogen spread. Targeting interventions to wards of higher (weighted) degree during an outbreak may help to control the spread of pathogens. Moreover, when colonization status of patients coming from different wards is unknown, a ranking system based on ward centralities may be used as a potential intervention to mitigate pathogen spread.

Early experience with percutaneous vegetation suction (Penumbra) versus valve replacement surgery for right-sided infective endocarditis in people who inject drugs

Michael Veve*, Yasir Akhtar¹, Peter Mckeown², Morgan Morelli³, Mahmoud Shorman³

¹University of Tennessee, Knoxville, United States, ²Tennova Healthcare, Knoxville, United States, ³University of Tennessee Medical Center, Knoxville, United States

Background: Infective endocarditis (IE) carries significant morbidity and mortality. IE valve replacement surgery can be life-saving, but remains controversial in people who inject drugs (PWID) due to perceived risks of re-infection due to recidivism. Percutaneous vacuum suction (PVS) can effectively remove valve vegetations without valve replacement, but data surrounding this technique are limited. The objective of this study was to describe early experience with PVS (Penumbra) in PWID compared to valve replacement surgery in right-sided IE.

Materials/methods: Retrospective cohort study performed at two medical centers in the southeast United States and included hospitalized PWID with definitive right-sided IE who received PVS or valve replacement from 1/14-8/19. Patient characteristics and outcomes were described and compared.

Results: 58 patients were included: 38 PVS, 20 valve replacement surgery. Baseline patient demographics were similar between groups; 44 (76%) of patients were women, and the median (IQR) age was 31 (27-40) years. Twenty-six (45%) patients presented with septic shock on admission, and 53 (91%) had noted septic pulmonary emboli. Fifty-one (88%) patients had a previous history of IE in which they received long-term antibiotic therapy prior to intervention. Sixty organisms were identified from 57 patients; the most common organisms were 26 (43%) methicillin-resistant Staphylococcus aureus, 18 (30%) methicillin-sensitive Staphylococcus aureus, 5 (8%) Pseudomonas aeruginosa, 3 (5%) Serratia marcescens, and 8 (13%) other organisms. Patients who received PVS had a shorter median (IQR) duration of therapy (13 [6-30] days vs. 18 [13-35] days, P=0.04), and 4 (7%) patients died in the hospital compared to none who received valve replacement surgery (P=0.3). There were no differences between PVS and valve replacement surgery regarding 30-day readmission (13% vs. 15%, P=1.0), 12-month readmission (47% vs. 55%, P=0.8), 30-day mortality (15% vs. 0%, P=0.08), and 12-month mortality (24% vs. 15%, P=0.5). PVS patients less commonly had repeat embolic events in the preceding year when compared to valve replacement surgery (11% vs. 40%, P=0.02). Among patients who received PVS, 19 (31%) required blood transfusions post-procedure.

Conclusions: PVS was associated with similar outcomes as valve replacement surgery. Additional data are needed to support PVS in improving outcomes for PWID.

**Abstract 9208**

**Improved taxon identification from similarity searches using Taxonomic Vote**

Neris Garcia-Gonzalez*1,2, Fernando Gonzalez-Candelas1,2

1University of Valencia, Institute for Integrative Systems Biology, I2SysBia, Paterna, Spain, 2FISABIO, Genomic and Health, Valencia, Spain

**Background:** Despite its limitations, the most popular method to identify the source taxon of a nucleotide sequence relies on obtaining the best hit in a BLAST search. Usually, this corresponds to the source organism or its closest relative present in the database. However, in certain situations the first hit can be misleading, even an artifact, because BLAST does not identify orthologous sequences nor close evolutionary relatives but only sequences sharing segments of high similarity that may arise through additional processes to shared inheritance or phylogenetic history. We propose an alternative method, denoted Taxonomic Vote (TV), to gain insight about the overall taxonomy of a sample and that of the sequences obtained from it.

**Materials/methods:** TV is based on the results obtained by BLAST+ or any similarity search program yielding scored results against predefined databases. At first, a BLAST+ search is made for each query sequence/contig/read. The first 500 hits for each query are considered but only those with a score not lower than 90% of the best-hit score are included in subsequent analyses. With these, the TV algorithm performs a vote (counting the number of occurrences of each taxon) in each taxonomic level and estimates at what level a robust taxonomic identification has been produced. This results in different TV classes dependent on how well a gene is identified at each taxon level.

**Results:** TV allows obtaining the most probable taxonomy for each query and evaluating how many queries in a sample are well identified. Also, it gives information about the taxonomy of the sample for each taxonomic level, contributing to create a very approximate idea of the closest relative organism to that in the sample of interest. We have applied this method to characterize unknown cultures and to ascertain contaminant sequences in HTS data.

**Conclusions:** Although TV was developed to evaluate the taxonomic content of a sample, it can be applied to many other situations, such as the identification of contamination in high-throughput sequencing studies, characterizing horizontal gene transfer events, or identifying the taxonomic contents of metagenomic samples. The method will be available in a publicly accessible repository.

Abstract 9209

The emergence of new STs of blaNDM-positive hypervirulent Klebsiella pneumoniae isolates in an oncology hospital, Russia

Polina Starkova, Irina Lazareva, Vladimir Ageevets, Julia V. Sopova, Vladimir Gostev, Irina Tsvetkova, Marina Lebedeva, Sergey Sidorenko

1National Research Institute of Information Technologies, Mechanics and Optics, Saint Petersburg, Russian Federation, 2Pediatric Research and Clinical Center for Infectious Diseases, Saint Petersburg, Russian Federation, 3Saint Petersburg University, Saint Petersburg, Russian Federation, 4North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation, 5Clinical Research and Practical Center of Specialized Types of Medical Care (Oncologic), Saint Petersburg, Russian Federation

Abstract third-party references: The Russian Science Foundation (grant number 18-75-10117) supported this work.

Background: The confluence between two Klebsiella pneumonia (Kp) pathotypes - "hypervirulent" (hvKp) and carbapenem-resistant (CR) classical (cKp), due to acquisition of virulence genes by cKp is a huge healthcare worldwide concern. Most outbreaks of hvKp and CR infections are reported from Asia and caused by K1 capsular type belonging to clonal complex 23. The simplest, although not very reliable, method for screening for hypervirulence is hypermucoviscosity detection by the string test. Highly sensitive and specific hvKp biomarkers were proposed by Russo in 2018. In the current study we report emergence hypermucoviscous (hm) CRKp isolates in an oncology hospital in St. Petersburg, Russia.

Materials/methods: Sixteen string-test positive CRKp isolates recovered in an oncology hospital from 2017 to 2018 were subjected to whole-genome sequencing on the Illumina platform and assembled de novo by SPAdes (BioProject PRJNA522420). Genomes were screened with Kleborate. The virulence of selected isolates was assessed in a mouse lethality assay. LD_{50} values were determined using the Reed and Muench method. The uniqueness of results observed for hvKp ST395 K2 bla_{NDM} was confirmed with Standalone BLAST based on analysis of 7245 Kp genomes from the ftp NCBI server.

Results: HmCRKp isolates belonged to two STs: ST395 \( (n=9) \) and ST147 \( (n=7) \). Four groups of HmCRKp isolates were distinguished based on the presence of hvKp biomarkers and LD_{50} values (Table). Highly virulent representative isolate ST395/K2 harboring bla_{NDM} was recovered from a deceased patient. According to our knowledge, this is the first report about hvKp ST395/K2.

Conclusions: In this study we observed two new clones long-term circulating in St. Petersburg oncology hospital – ST147/K20 and ST395/K2 harboring bla_{NDM} and hvKp biomarkers, simultaneously. ST395/K2 bla_{NDM} – positive Kp isolates belongs to dangerous highly virulent previously unregistered clone.

Pharmacodynamics of common antibiotics against uropathogenic *Escherichia coli* revealed significant antibiotic tolerance and persistence of intracellular bacteria

Ivana Kerkez*1, Marta Putrins1, Paul Tulkens3, Tanel Tenson2, Françoise Van Bambeke1

1University of Tartu, Institute of Technology, Tartu, Estonia, 2University of Tartu, Tartu, Estonia, 3UCLouvain, Brussels, Belgium

**Abstract third-party references:** University of Tartu, Institute of Technology

**Background:** Urinary tract infections (UTIs) are a severe public health problem with high rate of recurrent infections. The major causative agent of UTIs is uropathogenic *Escherichia coli* (UPEC). Many studies revealed ability of UPEC to invade bladder epithelial cells as well as macrophages. Internalization leads to increased formation of persisters and better protection of pathogen from immune system and antibiotics. The aims of this study were to establish an in vitro model of infection of macrophages with UPEC and to compare pharmacodynamic properties of commonly-prescribed antibiotics against intra- and extracellular bacteria. Fluorescent marker protein Timer was used to gain better insight into physiological heterogeneity of bacteria surviving the antibiotic treatment.

**Materials/methods:** Mouse macrophage cell-line J774 was infected with opsonized and fluorescently labelled CFT073 strain. Non-phagocyted bacteria were eliminated by short incubation with gentamicin. Infected cells were exposed to a range of clinically relevant concentrations of antibiotics for 24h and analysed by CFU plating, flow cytometry and/or confocal microscopy. For measuring extracellular activity, the bacteria were exposed to the same concentrations of antibiotics in medium.

**Results:** A MOI of 50 was used to infect permissive J774 cells. An extracellular concentration of gentamicin equivalent to 3x its MIC was needed to prevent extracellular growth and macrophage killing within 24hours. Flow-cytometry and microscopy analysis of intracellular bacteria revealed that while cell division is restricted bacteria remain metabolically active. Extracellular and intracellular E<sub>max</sub> for used antibiotics are shown in the Figure Panel A. Extracellularly Sulfamethoxazole and Trimethoprim had bacteriostatic effect, while all other antibiotics were bactericidal. Intracellularly, the activity of all tested antibiotics was reduced in comparison with their activity in broth. Our fluorescent reporter-protein showed that a subpopulation of intracellular bacteria was metabolically active even in the presence of high level of host-cell permeable antibiotics [Figure Panel B].

**Conclusions:** All antibiotics failed to eradicate intracellular UPEC completely, even when bactericidal in broth. Among the drugs tested, fluoroquinolones are the most effective, killing almost 99.9% of intracellular bacteria.

Panel A – E<sub>max</sub> for used antibiotics against extra- and intracellular bacteria. Panel B – fluorescence microscopy image of infected macrophages after 24h ciprofloxacin 100xMIC treatment

Abstract 9219

Outcomes of people who inject drugs with infectious endocarditis and valve replacement surgery

Michael Veve1*, Grace Cooksey2, Mahmoud Shorman2

1University of Tennessee, Knoxville, United States, 2University of Tennessee Medical Center, Knoxville, United States

Background: Infective endocarditis (IE) is a common disease state observed in people who inject drugs (PWID). Valve replacement surgery (VRS) is often necessary for disease management and improved patient outcomes; however, active injection drug use may deter surgical intervention due to risk of reinfection. The objective of this study was to compare the outcomes of PWID who received VRS to those who did not receive VRS.

Materials/methods: Retrospective cohort performed at a large academic medical center in the southeast United States that included hospitalized PWID with definitive IE who received VRS and those who did not receive VRS (no-VRS) from 1/14-10/18. The primary outcome of interest was all-cause 12-month mortality; secondary outcomes included short-term mortality and readmission. Patient characteristics and outcomes were described and compared.

Results: 178 patients were included: 41 (23%) VRS, 137 (77%) no VRS. Patient demographics were similar between groups, except patients who received VRS were more likely to present in septic shock (73% vs. 35%, \(P<0.001\)); 103 (58%) patients were women and the median (IQR) age was 33 (27-45) years. Native-valve IE was most common in VRS and no-VRS groups (91% vs. 93%, \(P=1.0\)), and the most frequent IE types were left-sided (54% vs. 24%, \(P=0.001\)), right-sided (32% vs. 64%, \(P=0.001\)), both left and right-sided (15% vs. 6%, \(P=0.1\)), and unknown (0% vs. 5%, \(P=0.4\)). 216 organisms were identified from 176 patients; the most commonly identified organisms were 37% methicillin-resistant Staphylococcus aureus, 25% methicillin-sensitive S. aureus, 9% streptococci, 9% enterococci, 5% P. aeruginosa, 1% Candida spp., 23% other organisms. Patients who received VRS had no significant differences in in-hospital (0% vs. 8%, \(P=0.07\)) and all-cause 12-month mortality (15% vs. 12%, \(P=0.6\)), as well as all-cause 12-month readmission (54% vs. 53%, \(P=1.0\)) when compared to no-VRS patients, respectively. However, patients who received VRS were less likely to have an infection-related readmission within 90 days compared to no-VRS patients (26% vs. 72%, \(P<0.001\)). In multivariable regression, left-side IE was the only variable associated with all-cause 12-month mortality (Table 1).

Conclusions: VRS did not have a mortality benefit in PWID, but was associated with fewer short-term infection-related readmissions.

**Table 1: Variables associated with all-cause, 12-month mortality**

Abstract 9221

An audit of cadaveric liver and kidney organ transport fluid microbiology cultures in a tertiary referral centre

Rackesh Patel*1, Miruna David1

1Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

Background: UK national guidance mandates routine microbiological testing of solid organ transport fluid (OTF) at recipient abdominal transplant centres despite limited evidence in the literature of the impact of this practice. Infections are a source of morbidity and mortality in transplant patients and transport fluid represents a potential vector for the transmission of infection.

This retrospective audit aims to establish adherence to routine culturing of all liver and kidney graft OTFs in a tertiary referral centre, an epidemiological surveillance of positive results and 12-month follow-up of these patients.

Materials/methods: Recipients receiving liver and kidney grafts from deceased donors between 1st September 2017 and 1st September 2018 were identified. Transport fluid samples were processed in standard laboratory manner. The hospital’s electronic clinical records were used to track outcomes at 12 months post-transplantation.

Results: Of 368 transplants carried out, 351 OTF samples were received and 62 (18%) were culture-positive. Of these, coagulase-negative Staphylococci accounted for 21 isolates, Enterobacteriaceae accounted for 19 isolates each, Staphylococcus aureus for 7 (1 of which was Panton-Valentine Leukocidin-producing MRSA), Pseudomonas spp. for 3, Lactobacillus spp. for 3 and Enterococcus spp. for 2 (1 of which was vancomycin-resistant) with varying other micro-organisms in the rest.

There were 9 (15%) cases of fungal growth in OTFs – all Candida spp.; out of these, 4 received targeted antifungal therapy. In 13 cases (31% of OTFs) culture-positive isolates were specifically treated (9 bacterial).

Overall 12-month mortality was 6.8%; 10% of culture-positive OTFs died within 12 months compared with 6.5% of culture-negative OTFs. 24% of deaths at 12 months occurred in culture-positive OTFs despite making up 18% of OTFs received.

Conclusions: In our centre, rates of culture-positive OTF samples were lower compared to rates reported by other transplant centres. The spectrum of microorganisms isolated predominantly represents those of gastrointestinal or skin flora. Their presence may indicate that sterility was compromised during the harvesting procedure. Candida spp. were isolated in a significant proportion of culture-positive OTFs; in these cases recipients typically would require targeted treatment. UK-based OTF contamination data is scarce and further research is needed to elucidate the relationship with nosocomial infection.

Tackling resistance to carbapenem and colistin in clinical isolates of *Acinetobacter baumannii*

Rushiil Ravichandran¹, Diana Machado*², Miguel Viveiros², Carsten Kroeger¹, Marta Sofia Martins¹

¹Trinity College Dublin, Dublin, Ireland, ²Global Health and Tropical Medicine (GHTM), Lisboa, Portugal

Abstract third-party references: Supported partially by Trinity College Dublin and the Master program in Infection Control Management.

**Background:** Resistance to antibiotics is a serious threat in the 21st century. The healthcare sector is being severely affected by the presence of resistant bacteria and their associated nosocomial infections. *Acinetobacter baumannii* has been classified as a critical pathogen by the WHO and rightly so due to its notorious presence in the hospital and health centres. *A. baumannii* resistance to even last resort antibiotics, such as carbapenems and colistin establishes the need for new treatment strategies.

**Materials/methods:** In this study, we analysed a collection of 29 *A. baumannii* clinical isolates from different countries (Ireland, Germany and Portugal). The antibiotic resistance profile of these isolates was determined against 24 different antibiotics and isolates resistant to doripenem or colistin selected. Synergistic combinations of antibiotics with efflux pump inhibitors were performed. The efflux pump inhibitors comprised the phenothiazines: Thioridazine, Chlorpromazine, Promazine, Trifluoperazine, and the proton motive force disrupters: 1-{1-Napthylmethyl}piperazine and Carbonyl cyanide m-chlorophenyl hydrazine (CCCP). These tests were conducted by checkerboard assays and synergies assessed with fractional inhibitory concentration index analysis. The ability of the isolates to produce biofilms was evaluated by the crystal violet method. Isolates showing strong biofilm forming capabilities were selected for treatment with the most active synergistic combinations.

**Results:** All clinical isolates tested were MDR with 11 showing resistance to carbapenems (meropenem, imipenem and doripenem) and 3 to colistin. Thioridazine and trifluoperazine had a higher antibacterial activity (MIC from 50 to 400 mg/L). When synergistic combinations of doripenem and the efflux inhibitors were tested against resistant isolates these not affected. We speculate that this could be due to the presence of other factors that contribute to resistance, namely the presence of carbapenemase enzymes. However, thioridazine and CCCP proved very effective against colistin-resistant isolates of *A. baumannii* (FIC 0.206 – 0.46), demonstrating the important role that efflux has in colistin resistance. In colistin-resistant isolates, synergistic combinations of colistin and thioridazine or CCCP showed good biofilm disruption capabilities (biofilm reduction of 2-3 log).

**Conclusions:** The use of combination therapy could provide new ways to treat multidrug resistant *Acinetobacter baumannii*, namely in isolates that present resistance to colistin.

Abstract 9224

Genomic surveillance at the regional scale: antimicrobial-resistant Klebsiella pneumoniae ST11 isolates in the Valencian community, Spain

Neris Garcia-Gonzalez*1,2, Fernando Gonzalez-Candelas1,2

1University of Valencia, Institute for Integrative Systems Biology, I2SysBia, Paterna, Spain, 2FISABIO, Genomic and Health, Valencia, Spain

Abstract third-party references: Red de Vigilancia de Resistencias a Antimicrobianos de la Comunitat Valenciana

Background: Antimicrobial resistance (AMR) is a major threat to public health and a serious concern worldwide. Klebsiella pneumoniae is one of the main agents causing nosocomial infections, especially in intensive care and neonatal units. In the Valencian Community (Spain, population 5.5 million), similarly to other regions around the world, there has been an emergence of multidrug-resistant (MDR) strains of K. pneumoniae, mainly due to clonal complexes ST11 and ST307. In order to study the molecular epidemiology and the evolution of these clones in the Valencian Community (VC), we have collected more than 800 ESBL producing K. pneumoniae isolates from 8 different hospitals across the VC from 2014 until 2019.

Materials/methods: Next-generation sequencing was performed with Illumina NextSeq (2x150 paired-ends) using Nextera libraries. The resulting reads were analysed using ARIBA and SRST2 to obtain the ST of each sample and we used ST11 isolates for further analyses. Cleaned reads were mapped using Bowtie2. Variant calling and consensus alignment were made with samtools and vcftools. A maximum likelihood tree was constructed using IQTREE. Dated phylogenies and short-term phyldynamics and evolutionary parameters were estimated with BEAST.

Results: We have obtained complete genome sequences of 136 K. pneumoniae ST11 isolates. Most isolates fall into 4 well-supported clades with strong but not perfect association to a single hospital in 3 of them. Genetic diversity was very low within clades, indicating a recent common ancestry (colonization from a single clone). We inferred the time of the common ancestor for two clades [May-2012 and January-2008, for clades A and D, respectively]. Clade A corresponds to a community outbreak with many cases associated to hospitalization, whereas clade D is associated to a possible transmission of pOXA-48. Transmissions between hospitals of ST11 were frequent but our results also point to at least two independent introductions of this ST in the CV.

Conclusions: These analyses reinforce the idea that genomic surveillance studies are necessary to control and eliminate the transmission of resistance to antibiotics within and between hospitals since they provide essential information about the within and between hospitals dynamics of the most serious variants of this and other microorganisms.

Abstract 9225

Comparison of a new MALDI-TOF MS platform, Autof MS1000, with Bruker Biotyper for mucoid bacterial strains identification
Qi Zhang*, Yuan Youhua2, Qiong Ma3, Yi Li3
1 Henan Provincial People's Hospital, Department of clinical microbiology, Zhengzhou, China, 2Henan Provincial People's Hospital, Department of clinical microbiology, Zhengzhou, China, 3 Henan Provincial People's Hospital, Department of clinical microbiology, Zhengzhou, China

Background: Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) is widely used in clinical microbiology species identification for its fast speed and high accuracy. However, some mucoid bacterial strains often got unsatisfied identification due to the rich of mucous strands. The Autof ms1000 system (Auto Experimental Instrument Co. Ltd., China) was recently developed for microbial identification. We aimed to compare its performance on clinical mucoid bacterial strains with that of Bruker Biotyper (Bruker Daltonics GmbH, Germany).

Materials/methods: A total of 76 mucoid bacterial strains (including 52 Klebsiella pneumoniae and 24 Pseudomonas aeruginosa strains) were collected from a tertiary hospital in China from June to October 2019. The specimens were inoculated in 5% sheep blood agar, and then incubated for 18–24 hours at 35°C. For both Autof ms1000 and Bruker Biotyper, a single bacterial colony from the agar was smeared onto the target plate directly, and some other single colonies were washed with deionized water and then smeared onto the target plate. The matrix solution was α-cyano-4-hydroxycinnamic acid, and the peptide profile was acquired and analyzed by using their software respectively. All the strains were confirmed by 16S rDNA sequencing.

Results: For the method without pretreatment, the accuracy of Autof ms1000 at both the species and genus levels were higher than Bruker Biotyper (90.8% vs. 56.6%, P<0.05 for species level, and 92.1% vs. 67.1%, P<0.05 for genus level, respectively). For the method with deionized water, Autof ms1000 and Bruker Biotyper presented excellent performance (98.7% vs. 92.1%, P>0.05 for species level, and 100.0% vs. 96.1%, P>0.05 for genus level, respectively).

Conclusions: Autof ms1000 presented a higher accuracy in identification of clinical mucoid bacterial strains than Bruker Biotyper, and washing strains with deionized water was suggested in MALDI-TOF MS identification.

Do we re-admit after outpatient artemether-lumefantrine? Evaluating the safety and efficacy of an ambulatory guideline for the treatment of uncomplicated Plasmodium falciparum malaria in a busy district general hospital in east London, UK

William Niven1, Joanna Quinn1, Neil Studd1, Justin Healy1, Jibril Abukar1, Aileen Boyd1, Kate Woods*1

1Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: In 2018 there were 1683 imported cases of malaria to the United Kingdom, 82% were Plasmodium falciparum. Current UK Malaria treatment guidelines (2016) advocate admission for all patients with P. falciparum. Evidence on the safety of ambulating patients with uncomplicated P. falciparum in non-endemic countries since the widespread introduction of artesunate combination therapy (ACT) is lacking. 50-60 patients present to Homerton University Hospital (HUH), London, with P. falciparum annually. Approximately 80% are uncomplicated and ACT is first line treatment. We designed and implemented an ambulatory pathway for the management of adult patients with P. falciparum, with post-implementation monitoring of safety and efficacy.

Materials/methods: In September 2017 Infectious diseases, ambulatory and emergency care specialists retrospectively reviewed 52 cases of malaria presenting to HUH in the previous year. An ambulatory guideline with strict inclusion and exclusion criteria was developed and introduced in November 2018. Monthly data was collected prospectively on all adult patients (>16 years) who presented to HUH with P. falciparum: including demographics, parasitaemia, guideline compliance, and follow up data. Preliminary analysis for 1st December 2018 – 31 October 2019 given here.

Results: 32 adult patients were treated for P. falciparum at HUH during the study period. All patients acquired P. falciparum in Sub-Saharan Africa, 63% in Nigeria. Average age was 45 years. Median parasitaemia at presentation was 1.1% (IQR 0.2 – 2.2%). 24/32 cases had initial parasitaemias of <2%. 21 patients were admitted, 11 patients were ambulated (35%). Day 2 parasitaemia results were available for 23/32 patients – 22/23 patients’ parasitaemia decreased; 1 admitted patient’s parasitaemia increased (1.1% to 2.2%) but this was after a delay in administering ACT. No ambulated patients clinically deteriorated on treatment or required subsequent admission. All ambulated patients attended for follow up blood films, clinical review and completed treatment. No patients were lost to follow up. Following the introduction of the ambulatory malaria pathway there was a significant reduction in number of bed days for malaria patients from 121 (2016/17) to 46 (p=0.04).

Conclusions: Ambulatory treatment of uncomplicated P. falciparum malaria with ACT is safe, effective and cost-saving in our patient population, but requires adherence to a clear management pathway.

Abstract 9231

Sharing of MLVA clusters of Listeria monocytogenes among bovine and human invasive clinical isolates

Ilena Drigo*,1, Elena Mazzolini1, Cosetta Bacchini1, Antonio Barberio1, Lisa Barco1, Monia Cocchi1, Laura D’este1, Michela Favretti1, Tolinda Gallo1, Antolla Gattuso3, Antonia Anna Lettini1, Eliana Schiavon1, Alexander Tavella1, Fabrizio Agnoletti1

1Istituto Zooprofilattico Sperimentale delle Venezie, Legnaro, Italy, 2Asui Ud Dipartimento di Prevenzione - Ambulatorio Malattie Sessualmente Trasmissibili (MST), Udine, Italy, 3Istituto Superiore di Sanità, Roma, Italy

Background: The scope of this work is to explore whether domestic bovines host Listeria monocytogenes (Lm) of pathogenic potential for humans.

Materials/methods: Sampling of bovine milk and faeces was carried out from 2018 and 2019 in Triveneto region. Lm strains collected in the same study area from 2015 and belonging to the IZSVe collection were also included. All strains were characterized by MLVA and serotyping; carriage of hlyA, actA, inlA, prfA and plcA genes was investigated by PCR. MIC of 13 antimicrobials (Table 1) was determined by broth microdilution. Results were compared with ones obtained from humans Lm (HLm).

Results: From 612 farms 11 Lm were isolated (9 from faeces/gut and 2 from milk samples). Overall, 53 HLm and 11 bovine Lm (BLm) were characterized. 58.5% of HLm were serotype 1/2a, 24.5% 4b, 13.2% 1/2b and 3.8% 1/2c. 63.6% of BLm were serotype 4b, 18.2% serotype 1/2a and 0.9% 1/2b.

Minimum spanning tree analysis showed 2/36 MLVA profiles shared between humans and bovines. All strains resulted positive for the studied virulence genes. MIC distribution is reported in table 1.

Conclusions: The role of bovine as possible reservoir of Lm affecting human needs to be assessed. In this study we observed a low percentage of bovines colonized by Lm, however, most of BLm are strictly correlated to HLm by MLVA. HLm and BLm showed comparable MIC distribution for all antimicrobials with the exception of sulfamethoxazole-trimethoprim. Differently from the HLm, all BLm showed sulfamethoxazole-trimethoprim MICs >ECOFF.

Table 1. MIC distribution of HLm and BLm. Vertical bars indicate the epidemiological cut-off of the antibiotic

Abstract 9232

Imported dengue fever in French travellers: a multi-centre retrospective study
Conan Pierre-Louis*1, Cécile Ficko1, Alice Perignon2, Christophe Rapp1, Eric Caumes2

1Infectious and tropical diseases, military teaching hospital Bégin, Saint-Mandé, France, 2Infectious and tropical diseases, Hôpital de la Pitié-Salpêtrière, APHP, Paris, France

Background: Dengue fever is the most extensively spread arthropod-borne viral disease in the world. Viremic travelers play a key role in the globalization of infection in disease-naive countries that house Aedes.

Materials/methods: Multicenter retrospective descriptive study from 2008 to 2015 of all laboratory-proven cases of dengue fever in 2 university-affiliated hospitals.

Results: Two hundred and seventy-four patients were included (median age 34 years [IQR 24-47] - 141 males). The majority were white Europeans (220, 80.3%) who stayed in Southeast Asia (117, 42.7%), Latin America and the Caribbean (94, 34.3%). Mean reason for travel was tourism (203, 74.1%). DF trends in Paris mirrored the global activity of dengue fever with two peaks in 2010 and 2013. New or atypical areas of transmission were highlighted (Madeira and sub-Saharan Africa). Digestive signs accounted for 49.4 % of patients. Two patients (0.73%) had a severe dengue fever without lethal cases. NS1 antigen testing showed a 80.2 % sensitivity in our series and allowed a quick diagnosis. 70.1 % of patients were viremic during the activity period of Aedes and likely to cause autochthonous secondary cases.

Conclusions: Travelers are epidemiological sentinels. Analysis of imported cases provides information about viral circulation in endemic areas. Practitioners must consider dengue fever in travelers with suggestive signs and must be aware of mosquito bite prevention measures for viremic patients.

Graphene oxide sheets affect expression of biofilm formation key genes in Escherichia coli
Claudia Vuotto*, Lucia Pappalardo1, Gianfranco Donelli1, Iolanda Francolini2
1 Fondazione Santa Lucia IRCCS, Microbial Biofilm Laboratory, Rome, Italy, 2 Sapienza University of Rome, Dept. Chemistry, Rome, Italy

Background: Graphene-based nanomaterials are constituted by single layers of carbon atoms with unique mechanical properties, large surface area, chemical stability, and superior electric and thermal conductivities. Among them, graphene oxide (GO) has the greatest potential for application in the biomedical field. GO is under investigation for infection control even if its antimicrobial and mostly anti-biofilm activity is still under debate, and very little is known.

Materials/methods: GO sheets, thoroughly characterized by Fourier transform infrared spectroscopy, X-ray Photoelectron Spectroscopy, Raman Spectroscopy, and Atomic Force Microscopy, were used at different concentrations (from 0.01 to 1 mg/mL) to evaluate their ability to inhibit planktonic and biofilm growth of Escherichia coli CFT073 by cell count, biofilm production assay, field emission scanning electron microscopy and RT-qPCR. The expression level of 9 genes involved in fimbriae production (fimA, fimH, csgA), oxidative stress (soxR, oxyR, dps) and iron homeostasis (tonB, iscR) was evaluated.

Results: Different concentrations of low-defects, 2-3 layers GO sheets, with specific physico-chemical properties, were put in contact with E. coli cells in planktonic and biofilm mode of growth. GO sheets did not cause substantial inhibition and damage of planktonic cells at 0.01 and 0.1 mg/mL of GO while 1 mg/mL significantly reduced cell viability after 3 h (p<0.01). On the contrary, a significantly reduction of adhesiveness of E. coli onto glass after 20h incubation time, as well as an almost total disappearance of adhesive fibers, were detected at 0.1 and 1 mg/mL of GO. RT-PCR revealed, after GO exposure, that the most significant reduction in genes expression concerned those involved in curli expression (csgA), and in iron availability (tonB, iscR), while an increase in the expression of dps, an alternative iron-storage protein important for the defense against hydrogen peroxide, was detected.

Conclusions: We hypothesize that the analysed GO, due to its definite physico-chemical properties, negatively interferes, in a concentration-dependent manner, on the biofilm-forming abilities by affecting curli production and pathways related to iron metabolism.

Our findings provide new insight on the possible mechanism behind GO anti-biofilm activity against E. coli and could contribute to the development of novel anti-biofilm compounds or surface coatings.

A study to determine the frequency of QT interval prolongation in people treated with bedaquiline for drug-resistant tuberculosis

Sharon Isralls*, James Millard2, Kathy Baisley1,3, Eric Ngam4, Joyce Der1, Alison Grant1,3

1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom, 3Africa Health Research Institute, Durban, South Africa, 4University of KwaZulu-Natal, Durban, South Africa

Background: Bedaquiline (BDQ) is a recent addition to the drug-resistant tuberculosis (DR-TB) armamentarium. In the licensing trials, excess mortality was observed in the BDQ treatment arm, which whilst not clearly related to QTc prolongation, resulted in a black-box warning of the risk of arrhythmias and sudden death associated with BDQ therapy. The aim of this study was to determine the incidence of QTc prolongation and cardiac events in patients receiving BDQ DR-TB therapy under routine conditions.

Materials/methods: This was a retrospective cohort study of routinely collected data at a DR-TB hospital in KwaZulu Natal, South Africa, from September 2017 to February 2019. Medical records, including ECG data, were transcribed using a digital collection tool. The QT interval was corrected for heart rate using the Fridericia formula (QTcF). The primary outcome, a prolonged QTcF, was defined as QTcF >500ms, QTcF change >60ms from baseline, or both.

Results: A consecutive sample of 419 medical records was reviewed. Patients had a median age of 36 years (29-44), 278/419 (66.4%) were male and 311/419 (74.2%) were HIV positive. 418/419 patients (99.8%) were receiving concomitant levofloxacin and clofazamine. The observed retention rate was 84.0% over 26 weeks of BDQ therapy. The mean QTcF was 406.0ms at baseline increasing to 433.3ms by week 12 and 437.5ms at week 24. 19/419 patients (4.5%) had a QTcF >500ms and 62/419 patients (14.8%) had a QTcF change >60ms. There were no arrhythmias or deaths attributable to arrhythmias. QTcF >500ms was more common in older patients [OR 3.61, 95%CI [0.81-18.0] for age>50 vs. age<=30] and females compared to males [OR 2.36, 95%CI [0.84-6.72]]. The QTcF declined after prolongation without clinical sequelae, whether drugs were interrupted (QTcF change -45.4ms, n=11) or not (QTcF change -26.8ms, n=10).

Conclusions: BDQ prolonged the QTcF but no arrhythmias or related deaths were observed. Management of QTcF prolongation with or without an interruption to BDQ therapy did not affect the outcome in patients, although the small sample and inconsistent ECG frequency limit these inferences.

Clinical characteristics and treatment of 255 patients hospitalised with bacterial cellulitis
Ljiljana Lukic*1, Monika Mudrović1, Maša Pulijiz2, Ivan Pulijiz1,2

1University hospital for infectious diseases 'Dr Fran Mihaljevic', Zagreb, Croatia, 2School of Medicine, University of Zagreb, Zagreb, Croatia

Background: Acute bacterial cellulitis (BC) is one of the most common skin and soft tissue infections. It places a substantial burden on the hospital system. This study assessed the clinical characteristics and treatment of BC in one healthcare center.

Materials/methods: We retrospectively analyzed data of 255 patients with BC hospitalized at one university hospital center in Zagreb in 2018. The diagnosis of BC was based on clinical and laboratory features.

Results: In 2018, 4.6% of all hospitalizations in our center were due to BC. The mortality rate was 2.7% (7 patients). More than half of the patients were female (54.9%) and the majority (74.1%) were older than 65 (median 65.5 years, IQR 20.0). At admission, the majority of patients (83.1%) were febrile (median 38.4°C, IQR 1.2) while 29.8% appeared unwell. The most common localization was the lower extremity (83.9%). Nearly all patients (93.3%) had at least one risk factor. This was the first documented episode of BC for 52.2% of the patients. Chronic ulcers were the most common entry site of infection (35.3%), while 11.8% of patients had no determinable entry site. Blood cultures were obtained in all patients at admission, with 4.7% being positive. At admission, C-reactive protein was elevated in 98.8% patients (mean 141.7 mg/L, IQR 132.6). Leukocytosis was present in 70.2% patients (mean 13.5x10^9 cells x mm³, IQR 6.0). The mean duration of fever after initiation of parenteral antibiotic was 3.1 days. In 35.3% of patients antibiotic therapy was changed. Complications arose in 23.1% of patients. Cefazolin was the most common antibiotic initiated at admission (45.1%), while 27.1% patients received combination antimicrobial therapy. The mean duration of parenteral treatment was 10.4 days (IQR 4.0). Cefazolin was associated with the shortest hospital stay (mean 9.6 days, IQR 4.0).

Conclusions: We observed a discrepancy between the relatively short time to defervescence and the relatively long duration of parenteral therapy and hospitalization. There is a potential space for shortening the length of parenteral therapy. However, the relatively high complication rate and comorbidities should be taken into mind.

Cat scratch disease in children and adults: what a difference?
Cécile Le Brun*, Adrien Lemaignen1, Adeline Pastuszka1, Philippe Lanotte1, Laurent Mereghetti1, Zoha Maakaroun Vermesse1

1CHRU de Tours, Tours, France

Background: Cat-scratch disease (CSD) is a zoonotic infection caused by Bartonella henselae. The typical manifestations of CSD include regional lymphadenitis and fever. However, CSD can have a wide variety of clinical manifestations that can lead to incorrect diagnoses and prolonged hospital stays. Is the presentation of the disease different in children and adults?

Materials/methods: This retrospective monocentric study was performed between January 1, 2010 and December 31, 2018. Patients (children and adults) with positive PCR for Bartonella henselae were included. For each patient, epidemiological context, clinical picture, histological analyses and treatment were investigated.

Results: 78 patients with catch-scratch disease (CSD) were diagnosed by PCR at the CHRU de TOURS in 2010-2018, the group consisted of 43 children and 35 adults, median age 20.37 years (9.62 in children group and 34.83 in adults). 72 (92.3%) had an isolated localization. Axillary and inguinal lymph nodes were affected the most often, in respectively 30 and 21 patients. Fever is present in 36 patients (54%), whereas sweats and an impairment of the general state were found only in 7 and 9 patients respectively. The mean time from symptom onset was 22.3 days. Inflammatory syndrome with moderate level of CRP was found in 24 (48%) patients. 55 of 57 patients had contact with cats when the question was asked. From 36 cases with histological examination, 19 (52.8%) had classical CSD features of suppurative granulomatous lymphadenitis. Surgical drainage occurred in 32 patients and 51 received antibiotics. 11 patients had complications with hepatosplenic localization, meningoencephalitis, endocarditis and glomerulonephritis. Two differences in course of disease in children and adults were found: a larger inflammatory syndrome (p 0.05) and more complications in adults (p 0.01).

Conclusions: Bartonella henselae is a common pathogen in children but also in adults in whom serious complications may occur more frequently.

Hepatitis C reflex testing in Spain in 2019: a story of success

Federico Garcia Garcia*1, Antonio Aguillera2, José Luis Calleja Panero3, Jose María Eiros4, Antonio Javier Blasco Bravo5, Pablo Lazaro5, Francisco Javier Garcia-Samaniego Rey6, Javier Crespo7

1Hospital Universitario San Cecilio. Instituto de Investigación Biosanitaria IBS, Granada, Granada, Spain, 2Complejo Hospitalario Universitario de Santiago. Xerencia de Xestion Integrada de Santiago de Compostela, Santiago de Compostela, Spain, 3Hospital Universitario Puerta de Hierro. Majadohonda. Universidad Autónoma de Madrid, Madrid, Spain, 4Hospital Universitario Rio Hortega, Valladolid, Spain, 5Investigador independiente en Servicios de Salud, Madrid, Spain, 6Hospital Universitario La Paz. IDiPAZ. CIBERehd, Madrid, Spain, 7Hospital Universitario Marqués de Valdecilla. IDIVAL. Facultad de Medicina, Universidad de Cantabria, Santander, Spain

Background: In 2017 we conducted a survey across hospital diagnostic laboratories, finding that only 31% of them were providing reflex testing (HCV antibodies and HCV RNA on the same sample). As a consequence, Spanish Societies of ID & Clin Microbiology [GEHEP-SEIMC], Hepatology [AEEH, SEPD] and the Viral Hepatitis Elimination Alliance (AEHVE) signed a position document with recommendations on reflex testing. Training and dissemination activities to promote reflex testing implementation in Spanish hospitals were also developed. In 2019, we have evaluated reflex testing implementation in Spain.

Materials/methods: Cross-sectional study with data collection through a survey addressed to hospitals of the Hospitals National Catalogue with the following inclusion criteria: 1) general hospital (monographic, e.g., psychiatric hospitals are excluded), 2) with at least 200 beds, and 3) public, or teaching hospital if private. A questionnaire with the variables of interest, designed by a scientific committee composed of hepatologists and microbiologists, was sent to the selected hospitals. The fieldwork was carried out in September and October 2019.

Results: In 2019, 161 hospitals were surveyed, and 129 (80,1%) responded, vs 90/160 (56,3%) who responded in 2017 (p<0,001). Reflex testing is now implemented in 89% of Spanish hospitals (115/129), in 2017 only 31% (28/90; p<0,001) performed reflex testing. The number of hospitals that implemented alert systems to communicate HCV active chronic infection rose from 68,9% (2017) to 86,0% (2019) (p=0,002). Access to dried blood spot (DBS) and/or point of care testing in 2019 in Spain was: 10,9% for antibody testing from DBS; 15,5% for RNA testing from DBS; 36,4% for point of care (POC) RNA testing; 0,85% for antibody POC testing. Overall, 43,4% of Spanish hospitals has access to at least one of DBS/POC testing strategies.

Conclusions: In Spain, the proportion of hospitals that perform reflex testing for chronic HCV infection has significantly increased to 89% in 2019. Recommendations, training and dissemination measures performed since 2017 may be responsible for this increase. However, in 2019 new screening strategies such as DBS and POC testing are poorly implemented in Spanish hospitals.

**Easy technique for ultra-fast identification of positive blood cultures with MALDI-TOF MS**

Florian Bressant¹, Marie-Rose Messy¹, Hector Rodriguez-Villalobos¹, Alexia Verroken*¹

¹Cliniques universitaires Saint-Luc, Brussels, Belgium

**Background:** Bacteremia is associated with high rates of morbidity and mortality. International guidelines recommend instauration of empirical broad-spectrum antibiotics to be tailored upon availability of microbiological results from positive blood cultures (BC). Multiple MALDI-TOF MS methods directly performed on positive BC have been developed aiming at a time reduction to identification yet some are laborious, require various reagents and are costly. In this study we evaluate an ultra-fast (UF) identification approach requiring limited hands-on time, no specific reagents and based on a 1-hour broth incubation of positive BC followed by MALDI-TOF MS identification.

**Materials/methods:** This study was performed at the microbiology laboratory of the Cliniques universitaires Saint-Luc over a 1-month period on all routine positive BC. Briefly 5 drops of each positive bottle (Bactec culture vials, Becton Dickinson®) were inoculated in a 1ml Tryptic Soja Broth (TSB) followed by a 1-hour incubation at 35°C. Subsequently, TSB was centrifuged (2 minutes, 13000RPM) and the pellet was spotted twice on a target with 1µl formic acid and 1µl matrix for MALDI-TOF MS identification. Results were compared with routine identification based on subculture MALDI-TOF MS. Testing was performed once a day.

**Results:** 206 positive BC comprising 91 aerobic, 79 anaerobic and 36 pediatric bottles were tested. 198 positive BC were monomicrobial and 8 were polymicrobial. Routine MALDI-TOF MS identified 119 Gram-positive cocci, 83 Gram-negative bacilli, 4 Gram-negative cocci, 3 Gram-positive bacilli and 5 Yeast. Considering monomicrobial bottles, UF MALDI-TOF MS led to 125/198 (63.1%) concordant results and 31/198 (15.6%) discordant results compared to routine identification as well as 42/198 (21.2%) no results. Sub-analysis of all UF MALDI-TOF MS results with a minimum score of 1.7 (112/198) improved concordance to 93.8% (105/112). 7 identifications remained discordant with routine testing and consisted in *Staphylococcus* coagulase-negative identifications suggesting contamination during testing. Among the 8 polymicrobial BC, UF MALDI-TOF MS identified 1 of the 2 strains in 6 bottles and no strains in 2 bottles.

**Conclusions:** The UF MALDI-TOF MS identification approach shows good performances with a cut-off score ≥1.7 and could replace costly and hands-on time requiring approaches for direct MALDI-TOF MS identification.

Abstract 9245

Designing a feasible, locally-appropriate socioeconomic intervention for TB-affected households in Nepal: a mixed-methods study

Kritika Dixit1, Bhola Rai1, Tara Prasad Aryal1, Suman Chandra Gurung1,2, Raghu Dhital1, Maxine Caws1,2, Tom Wingfield2,3,4

1Birat Nepal Medical Trust, Kathmandu, Nepal, 2Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 3Karolinska Institutet, Stockholm, Sweden, 4Royal Liverpool and Broadgreen University Hospital, Liverpool, United Kingdom

Abstract third-party references: Wellcome Trust, UK, Academy of Medical Sciences, UK

Background: Tuberculosis (TB), the leading single infectious diseases killer globally, is driven by poverty. Having TB worsens impoverishment due to lost income and out-of-pocket costs which frequently become “catastrophic”, leading patients to abandon treatment or even die. WHO’s 2015 End TB Strategy recommends eliminating catastrophic costs through provision of socioeconomic support for TB-affected people. We conducted a mixed-methods study to identify the socioeconomic barriers and facilitators to accessing TB diagnosis and care, and inform design and implementation of a socioeconomic support intervention for TB-affected households in Nepal.

Materials/methods: The study consisted of two integrated, complementary projects. Project 1 was a quantitative, prospective case-control study of 221 people on TB treatment and 112 randomly-selected TB-unaffected controls; and Project 2 consisted of qualitative focus group discussions with 56 key stakeholders including people with TB, community representatives, and National TB Program staff and volunteers. Existing and potential socioeconomic interventions in Nepal and the findings from Projects 1 and 2 were then discussed with the key stakeholders at a two-day national, multi-sectoral workshop in Kathmandu, which culminated with the participants selecting the most promising intervention design for further trial evaluation.

Results: The workshop elicited that Nepal has existing social protection coverage but this is limited to free basic health care and cash-transfers or allowances for chronic diseases, disability, old- or young-age, or the extremely poor. The existing socioeconomic support for TB-affected households is restricted to counseling for treatment adherence and insufficient cash-transfers for food and nutritional support for people with drug-resistant-TB (DS-TB) only. Participants shortlisted two potential socioeconomic interventions [Table 1]. In a subsequent vote on these interventions, the majority of participants chose an intervention that included community-based psychosocial counselling during household visits and an integrated, enhanced cash transfer program, which provided additional payments to high-risk patients (e.g. extremely poor, HIV-TB coinfection, MDR-TB, Table 1).

Conclusions: This mixed methods research was the first of its kind in Nepal to evaluate barriers to TB care and involve local stakeholders to design a locally-appropriate socioeconomic intervention package to address these barriers. The chosen intervention is now being refined for trial evaluation.

Abstract 9246

Detection of linezolid-resistant enterococci carrying optrA and/or poxtA in raw-frozen dog foods commercialised in the EU: trend or threat?

Liliana Finisterra¹, Carla Novais¹, Barbara Duarte¹, Luisa Maria Vieira Peixe¹, Ana Raquel Freitas*¹

¹ Faculdade de Farmácia do Porto, UCIBIO-Requimte, Porto, Portugal

Abstract third-party references: The work was supported by UID/MULTI/04378/2019 with funding from FCT/MCTES through national funds.

Background: Raw-food-based diets have grown popularity recently as a healthier choice. Increasing controversy regarding their safety is installed, with limited scientific evidences showing their role as vehicles for transmission of antibiotic-resistant bacteria. Dogs have been described as reservoirs of clinically-relevant ampicillin-resistant (AmpR) Enterococcus faecium (Efm), but strains origin remains unknown. We aimed to characterize enterococci obtained from processed [dry/wet] and non-processed [raw-frozen] foods of main brands commercialized in Portugal.

Materials/methods: Forty-six samples [wet-n=22/dry-n=15/raw-frozen-n=9 foods; 24-international brands] from supermarkets/stores-n=8 and veterinary clinics-n=1 were included (September-November 2019). Raw-frozen samples were mainly constituted of salmon, chicken, turkey, calf, deer or duck, being a mixture of different meat types (muscle/viscera), fruits and vegetables. Samples [25g] were pre-enriched (37ºC/16-18h) in Buffered-Pettone-Water (ISO6887-2), enriched without/with different antibiotics (BHI-broth+Amp-16µg/mL or vancomycin-6µg/mL or chloramphenicol-16µg/mL) and plated in Slanetz-Bartley-agar without/with the same antibiotics. Different morphotypes/plate were saved and antibiotic susceptibility studied [13 antibiotics-disk-diffusion; linezolid-microdilution; Amp-Etest; EUCAST/CLSI]. Identification of species (sodA), search of optrA/poxtA (linezolid-resistance) and ptsD (clinically-relevant Efm marker) genes was done by PCR. MLST (pubmlst.org) was done in representatives and WGS is ongoing.

Results: Enterococcus (n=163) were identified in 19/46 (41%) (8/15-dry, 2/22-wet, 9/9-raw) of samples and identified as Efm (n=91), E. faecalis (Efs, n=59) or other species (n=13). Eighty-four were deeply studied. All 9 raw-frozen meat samples [Efm+Efs; n=30 each] carried Multi-Drug-Resistant (MDR) enterococci [n=20-Efm+22-Efs] including to ampicillin/ciprofloxacin/erythromycin/tetracycline/streptomycin/chloramphenicol-100% each, linezolid-78%, and gentamicin/quinupristin-dalfopristin-67% each. Linezolid-resistance (MIC=8-16mg/L) was detected in MDR enterococci carrying optrA+poxtA [5-Efs+3-Efm], only optrA [3-Efs, one ST40; 1-Efm] or only poxtA [2-Efm], corresponding to 78% of raw-frozen and 15% of all samples. MDR-AmpR-Efm (MIC=8->256 mg/L; n=18, one ST80) were identified in all raw-frozen samples and some carried optrA-n=1, poxtA-n=2 and/or ptsD-n=9. AmpR-linezolid-resistant-Efm were limited to one raw-frozen brand. In contrast, only one MDR-Efm (erythromycin/tetracycline/gentamicin) was detected in a wet sample.

Conclusions: Our study demonstrates that raw-frozen-foods for dogs carry MDR enterococci including to last-resource molecules for the treatment of human infections (linezolid). The close contact of pets with humans and the commercialization of the studied brands in different EU countries pose an international Public Health risk if transmission of such strains occurs between dogs and humans.

Evidence for diminishing returns in supplementary immunisation activities: a spatio-temporal analysis of oral polio vaccination

Megan Auzenbergs1, Kathleen O’Reilly*

1London School of Hygiene & Tropical Medicine, Centre for Mathematical Modelling of Infectious Diseases, London, United Kingdom

Abstract third-party references: Centre for Mathematical Modelling of Infectious Disease, London School of Hygiene and Tropical Medicine

Background: The dramatic reduction in poliovirus incidence over the past decade has been driven by both routine immunisation (RI) and supplemental immunisation activities (SIAs). Whilst SIAs have been proven beneficial, the actual effectiveness of activities remains largely unknown and non-polio-endemic countries with under-immunised children remain at risk of circulating vaccine derived poliovirus outbreaks (cVDPVs).

Materials/methods: Multiple data sources are integrated within a Bayesian spatial-temporal analysis and implemented in the BUGS language in R: (1) Demographic and Health Surveys (DHS), (2) Multiple Indicator Cluster Surveys (MICS), and (3) Polio Information System (POLIS) data. Spatiotemporal analyses identify the spatially varying probability of being protected from poliomyelitis and using modelling, we aim to test hypotheses that SIA effectiveness depends on: time, SIA activities, RI, and remoteness.

Results: Combining vaccination history from DHS and MICS with POLIS data shows that substantial subnational spatial variation of immunity exists within countries and OPV dose-histories vary by data source. Our per-dose SIA mechanistic model highlights that in some contexts, SIAs alone can be as effective as RI, but often diminishing returns are exhibited, such that the effectiveness of the first SIA is high, but this effectiveness plateaus with subsequent activities. Furthermore, SIA effectiveness can be used to estimate SIA coverage.

Conclusions: Combining data from DHS, MICS and POLIS gives our analysis more power than previous approaches and shows that substantial spatial variation of immunity exists within countries. This is the first time, to our knowledge, that polio SIA effectiveness has been estimated from multiple data sources. This research will be used to improve polio programming within the Global Polio Eradication Initiative.

**Abstract 9249**

**Rickettsioses: a series of 80 cases**

Fatma Larbi, Maissa Ben Azaiez*, Jihene Chelli, Sondes Arfa, Olfa Berriche, Mohamed Habib Sfar

1CHU Taher Sfar, Internal Medicine and Endocrinology Department, Mahdia, Tunisia

**Background:** Rickettsioses are zoonotic diseases. They are common in Tunisia. Their main presentation is spotted fever. The diagnosis is based on a cluster of epidemiological and serological arguments. The aim of this study is to determine the epidemiological, clinical, biological, therapeutic, and evolutionary characteristics of rickettsioses in Mahdia’s region.

**Materials/methods:** This is a descriptive retrospective study of patients hospitalized at Taher Sfar Mahdia Hospital (2010-2016) for febrile syndrome due to rickettsioses which was diagnosed in the presence of epidemiological, clinical and/or serological arguments.

**Results:** Our study includes eighty patients with an average age of 31 years (19 days to 80 years) and with a sex ratio = 0.9. The physical examination showed fever, rash, and black spot in 97.5%, 51.3%, and 8.7% of cases respectively. Retinitis was objectively in the fundus in two cases. The biological abnormalities were: thrombocytopenia (42.5%), leukocytosis (16.3%), leukopenia (12.5%) and hepatic cytolysis (60%). The serology of rickettsioses detected anti-*Rickettsia conorii* antibodies (68.6%) and anti-*Rickettsia typhi* antibodies (31.3%). An antimicrobial therapy was prescribed in 75% of cases: doxycycline (55%), clarithromycin (23%) and fluoroquinolone (21.7%). The average duration of antimicrobial therapy was 9.7 days (2 to 21 days). The evolution was favorable for all our patients.

**Conclusions:** Our study shows that rickettsioses are a common cause of hospitalization either in children and adults. They are often underestimated because of the lack of specificity of the clinical presentation and the rapid means of diagnosis.

**Presenter email address:** maissa.benazaiez@hotmail.com
Population-level antimicrobial consumption is associated with cultural factors in 37 high-income countries: a global ecological analysis

Chris Kenyon*

1 Institute of Tropical Medicine, Antwerp, Antwerp, Belgium

Background: Previous studies evaluating the cultural and structural factors underpinning the large variations in the consumption of antibiotics between high-income countries have reached different conclusions as to whether corruption and cultural factors such as the degree of uncertainty avoidance (UA) and performance-orientation versus cooperation-orientation (POCO) play a role. These studies have been limited to Europe and we therefore aimed to expand this analysis to all high-income countries with available data.

Materials/methods: Using antimicrobial consumption data from the IQVIA MIDAS database, linear regression models were constructed with country-level cephalosporin, fluoroquinolone and macrolide consumption (standard doses/1000 population/year) as the outcome variables and country-specific scores of UA and POCO (obtained from the Hofstede Index), GDP/capita, world region and markers of effective governance (Control of Corruption and Regulatory Quality extracted from World Bank data) as the explanatory variables. All data, excluding the Hofstede Indices, used country-level averages for the years 2013 to 2015.

Results: Complete data was available for 37 countries from 4 world regions. Consumption of cephalosporins, macrolides and fluoroquinolones were all associated with POCO and UA but not the markers of effective governance (Table 1). In the case of macrolide consumption, the association with UA narrowly missed statistical significance. Repeat analyses limited to Europe - the region with the greatest number of countries in the dataset - as well as analyses excluding the world region dummy variables revealed very similar findings.

Conclusions: Previous studies have found that doctors in uncertainty-tolerant countries are more likely send their patients away with a comforting talk, without any prescription. When advocating not to prescribe antibiotics, one of the arguments used, is that this will reduce the emergence of antimicrobial resistance which is would be good for the whole population. Populations that are more orientated towards cooperation tend to show more concern for other members of society and may thus be more receptive to this message than performance-oriented societies. More thought should be given to construct stewardship campaigns that are tailored to the local extent of UA and POCO.

Presenter email address: ckenyon@itg.be
Long-read sequencing for the diagnosis and characterisation of pathogens in severe pneumonia: the role of simulation and standards in clinical metagenomics pipeline development

Meera Chand¹², Natalie Groves¹, Gregory Amos³, Victoria Chalker¹

¹Public Health England, London, United Kingdom, ²Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, ³NIBSC, South Mimms, United Kingdom

Background: Clinical use of metagenomics for severe pneumonia is now feasible due to improved enrichment methods and the real-time analysis potential of nanopore sequencing. Analysis remains challenging due to low biomass samples, similarity between pathogens and commensals, and clinical importance of relative abundance in interpretation. In preparation for a clinical study, we developed and validated a respiratory microbiome DNA standard and clinical pipeline for diagnosis and characterisation of respiratory pathogens.

Materials/methods: To test demultiplexers (n=4), we combined reads from samples sequenced on single-sample flowcells. We developed a quantified DNA standard containing respiratory pathogens and commensals, including species identified as closely related by MASH distance, and sequenced this repeatedly (SQK-RPB004, R9.4 flowcells, Oxford Nanopore Technologies). Data were used to train a nanopore-specific read simulator, generating labelled reads from each genome in the standard. These were combined and downsampled, and subjected to different long-read correctors (n=3), classifiers incorporating in-house post-processing (n=4), and metagenomic and species-specific assemblers (n=4). We used the results to develop an optimised pipeline for real-time species identification during sequencing and a more stringent, deferred pipeline for pathogen characterisation.

Results: Optimised demultiplexing assigned 94.6% of reads correctly. Remaining reads were unassigned with only 0.01% misassigned. The pipeline preserves relative abundance with a mean difference from true relative abundance of 0.59% per species (range 0.09-1.8%). Metagenomic assembly had more mismatches than species-specific assembly, and had misassemblies between highly related species (e.g. Neisseria), but was sufficient for classification of contigs to confirm species. Assembly using species-binned reads was of high quality (99.93% of the genome, LG50 = 1.67, 1.55 mismatches and 2.92 indels per 100 kbp on average across 6 species). Comparison of simulation and sequencing data shows species-specific assemblies following classification are comparable at equivalent quantities, but reveals biases due to wet-laboratory processes.

Conclusions: Nanopore-based sequencing has potential for clinical diagnosis and characterisation of respiratory pathogens. Simulation reveals substantial biases introduced during wet-laboratory and analysis processes. Both simulation and a site-specific microbiome standard were needed to develop a high-fidelity pipeline and are recommended as part of validation of future clinical metagenomic pipelines.

Failure to complete treatment for latent tuberculosis infection in Portugal, 2013-2017: geographic, socio-demographic and medical associated factors

Alexis Sentís Fuster1,2,3*, Paula Vasconcelos2, Rita Sá Machado1, Joan Caylà4, Mònica Guixens2, Vasco Ricoca Peixoto1, Raquel Duarte1, Isabel Carvalho1, Carlos Carvalho1

1Directorate-General of Health, Lisbon, Portugal, 2ISGlobal, Barcelona, Spain, 3Pompeu Fabra University (UPF), Barcelona, Spain, 4Foundation of Tuberculosis Research Unit of Barcelona, Barcelona, Spain

Background: There is conflicting evidence about factors associated with failure to complete treatment (FCT) for latent tuberculosis infection (LTBI). We aim to identify the geographic, socio-demographic and medical factors associated with FCT in Portugal, highlighting the two main metropolitan areas of Porto and Lisbon.

Materials/methods: We performed a retrospective cohort study including LTBI patients that started treatment in Portugal between 2013 and 2017. We calculated adjusted odds-ratios (aOR) and 95% confidence intervals (95%CI) using multivariable logistic regression to identify geographic, socio-demographic and medical factors associated with FCT.

Results: Data on completion of treatment were available for 15,478 of 17,144 patients (90.3%). Of those, 2,132 (13.8%) failed to complete treatment. Factors associated with FCT were being older than 15 years (aOR: 1.65 [95%CI=1.34-2.05] for those aged 16 to 29), being born abroad (aOR: 2.04 [95%CI=1.19-3.50] for Asia, aOR: 1.57 [95%CI=1.24-1.98] for Africa), having a chronic disease (aOR: 1.29 [95%CI=1.04-1.60]), alcohol abuse (aOR: 2.24 [95%CI=1.73-2.90]), and being intravenous drug user (aOR: 1.68 [95%CI=1.05-2.68]). Three-month course treatment with isoniazid plus rifampicin was associated with decreased FCT when compared to 6- or 9-month courses of isoniazid-only (aOR: 0.59 [95%CI=0.45-0.77]). In Lisbon metropolitan area, being born in Africa, and in Porto metropolitan area, alcohol abusing and being intravenous drug user were distinctive factors associated with FCT.

Conclusions: Socio-demographic and medical factors associated with FCT may vary by geographical area and should be taken into account when planning interventions to improve LTBI treatment outcomes. This study reinforces that shorter course treatment for LTBI might reduce FCT.

Improving country-level antimicrobial prescribing with the implementation of a uniform and standardised surveillance method: the Global-PPS Chilean experience, year 2015 and 2017

Camila Carvajal1*, Ann Versporten2, Alvaro Rojas1, Marcela Cifuentes1, Francisco Silva1, Herman Goossens2, Jaime Labarca1

1Pontificia Universidad Católica de Chile, Department of Infectious Diseases, School of Medicine, Santiago, Chile, 2University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious Diseases Institute, Antwerpen, Belgium, 3Hospital Clínico Universidad De Chile, Infection control and prevention unit, Recoleta, Chile, 4Hospital Clínico Universidad De Chile, Laboratory of Medical Microbiology, Recoleta, Chile

Background: A standardized method for surveillance of antimicrobial use (AMU) [www.global-pps.com] was performed in Chile in 2015 and 2017. We aimed to compare antimicrobial prescribing indicators from both audits, and analyzed their contribution for improving AMU.

Materials/methods: The Global-PPS included 12 and 27 chilean hospitals respectively. Hospitals were guided by a central local team, which provided continuous assistance for conducting the survey. The survey included all inpatients receiving an antimicrobial at 8am on the day it was conducted. Data included antimicrobial agents used, source of infections treated, and quality indicators of AMU. Local data was reported to each participating center through local meetings and written documents including guidance to improve their AMU.

Results: PPS included 3043 patients (2504 adults) in 2015 and 6809 patients (5540 adults) in 2017. Overall antimicrobial prevalence was 35.6% and 42.2%, respectively. Increase in antimicrobial prevalence was significantly explained by an increased AMU in hemato-oncology wards, both in adults (17.5 to 49.6%) and pediatrics (20.8 to 27.1%). Top 3 sources of infection, both in 2015 and 2017, were pneumonia, skin and soft tissue infections and intrabdominal infections. Missing guidelines decreased, from 2015 to 2017, in medical wards (34.1% to 25.5%), surgical wards (30.0 to 26.3%), and intensive care wards (21.8% to 20.5%). For both periods, top three most prescribed systemic antibiotics were ceftriaxone (mean 18.3%), metronidazole (mean 10.9%) and cefazolin mainly prescribed for surgical prophylaxis (mean 8.7%). Guidelines compliant prescriptions increased, from 2015 to 2017, in medical wards (62.2 to 77.9%), surgical wards (52.1 to 64.8%), and intensive care wards (54.3 to 67.6%). Prolonged surgical prophylaxis decreased from 63% to 44%. However, reason and stop/review date written in notes did not improve (84.0% versus 84.2%) and (38.5% versus 36.7%) in 2015 and 2017, respectively

Conclusions: Global PPS contributed to further develop collaborative networks with voluntary participation, which have obtained significant information regarding AMU, in a local and national perspective. An improvement of antimicrobial prescribing was observed, which we attributed to the provided guidance to each hospital, pointing out potential useful local interventions. Continued efforts are needed to further improve the quality of prescribing.

Abstract 9260

The dissemination and reservoirs of ESBL-producing Escherichia coli in intensive care unit
Liu Baomo*1, Chao Zhuo1, Yingyi Guo1

1The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: ESBL-EC is an important pathogen for blood infection. For tracking the dissemination and reservoirs of ESBL-producing Escherichia coli (ESBL-EC) in hospital, it need an understanding of the epidemiology of ESBL-EC in hospital-related environments and patient carriage.

Materials/methods: We collected samples from patients and surroundings once a week in an ICU for three months in 2019. Except for gathering rectal swabs and oral swabs from inpatients, the environmental samples were collected as follows. Sterilized swabs were dipped by fresh TSB and wiped the surface of bed units. After incubating the swabs in a tube with TSB at 37 degree for 24 hours, the culture were inoculated on Chromagar plates for screening ESBL-producing Escherichia coli. The positive culture and the original information of strains were recorded.

Results: A total of 122 ESBL-producing Escherichia coli isolates were collected in 12 weeks. About a half were carried by patients, of which most were isolated from rectal swabs. Even though some patients undergone powerful antibiotic treatment, gut-colonized ESBL-EC of these patients could co-colonized with CRKP or CRAB rather than being erased. Patients acted as reservoirs as well as "comfortable medium" for the dissemination of carbapenem-resistance genes. Another half of isolates were from surroundings of bed units. About 70% ESBL-EC were isolated from water sinks. There was a patient who carried ESBL-EC at the second week and lost it for 9 weeks. But we isolated ESBL-EC for 2 months from water sinks and bed curtains of this patient's bed unit. At 11th week, ESBL-EC reappeared in this patient rectal swabs. Further STs of these ESBL-EC needed to be detected for exploring the dissemination routes.

Conclusions: Patient carriage and water sinks are two major reservoirs for ESBL-EC in ICU. A better view of ESBL-EC colonization in ICU could help us take measures to control the related infection. Under rough antibiotic stresses, ESBL-EC could maintained in guts and might evolve into carbapenem-resistance bacteria.

**Abstract 9263**

**Interferon gamma release assay and tuberculin skin test agreement in latent tuberculosis infection diagnosis among healthcare workers at a tertiary Hospital in western Saudi Arabia**

**Fayssal Farahat**, John Ossenkopp, Mohammed Abdalaziz, Majid Alshamrani, Asim Alsaedi

**1** King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Jeddah, Saudi Arabia, **2** King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia

**Background:** Diagnosis and treatment for Latent TBI is an essential component of TB elimination. Two tests are available, TST and IGRA. Data on diagnostic performance and agreement between these tests are limited. This study aimed to assess the agreement of IGRA test with the traditional TST in diagnosing latent TBI among Health Care Workers.

**Materials/methods:** Retrospective review of medical records of HCWs was conducted at King Abdulaziz Medical City, Jeddah, Saudi Arabia from June 2018 to September 2019. Records were included when both IGRA-TB and TST were performed simultaneously or within a month for purpose of preemployment or periodic screening. The cut-off for TST was 10mm.

**Results:** A total of 746 healthcare workers had simultaneous IGRA-TB and TST results. Most of them were females (68.7%). Saudi represented 46.3%, followed by Filipinos (25.9%) then Malaysians (13.9%). Half of the HCWs were non-clinical staff (50.2%). Nurses, physicians and allied health professionals represented 22.5%, 21.4% and 5.9%, respectively. Dual positive results were identified in 24.9%, positive IGRA-TB in 31.6% and positive TST in 36.3%. Among females, 26.9% had dual positive results compared to 21.1% among males (p=0.09). Dual positive results were the highest among Filipinos (48.2%), Malaysians (40.8%), then Saudi (5.4%) (p=0.001). Based on job categories, high prevalence of dual positive results was observed among non-clinical staff (39.2%) and nurses (36.8%) compared to allied health (12.9%), and physicians (6.3%) (p=0.001). Mean ±SD age of HCWs with dual positive test was higher (38.5 ±8.9) than those with either test positive (34.4 ±9.1) or dual negative result (29.4 ±6.0) (p=0.001). There was good overall agreement between IGRA-TB and TST (82.6%, kappa 0.61, p=0.001). Lower agreement was observed in the low incidence groups [Saudi, physicians/allied health and young age], kappa= 0.32, 0.43, 0.43, respectively.

**Conclusions:** This study revealed relatively high burden of latent TB infection among healthcare workers in King Abdulaziz Medical City, Saudi Arabia. Most of the cases were from southeast Asia. Choice of a screening test depends on TB burden, test cost and population to be tested. Longitudinal study is required to determine diagnostic performance of dual positive compared to either test positive.

Abstract 9269

**Infectious disease specialist intervention in the neonatal intensive care unit: a safe approach to reduce antibiotic exposure in neonates**

Jakob Armann*, Barbara Seipolt¹, Mario Rüdiger¹, Reinhard Berner¹

¹Dresden, University Children's Hospital, Dresden, Germany

**Background:** Neonatal sepsis is a major cause of neonatal mortality and morbidity. Prompt initiation of antibiotics in newborns with clinical suspicion of sepsis improves outcome but leads to an overuse of antibiotics in a population vulnerable for long term adverse effects of these medications.

Studies on adults have shown that including infectious disease specialist (IDS) in the care of patients improves the appropriateness of antibiotic prescription, decreases antibiotic consumption and improves outcome in patients with severe infection. However, for patients on neonatal intensive care units this data is missing so far. In 2018 we established a weekly proactive audit of antibiotic use on our 12-bed neonatal intensive care unit as joint interdisciplinary rounds between an IDS and the neonatologist taking care of the patients.

**Materials/methods:** Patient-related therapy adjustments were systematically documented; antibiotic use before and after audit as well as ABS strategies (de-escalation, duration of treatment, dose and administration optimization) were analyzed as well as antibiotic use in infants weighing less than 1500g [Data from the German Neonatal Infection Surveillance Network (NeoKISS; "Krankenhaus-Infektions-Surveillance-System) and outcome data (mortality, BPD- and IVH-rate) in the 12 months prior/post the establishment of the interdisciplinary rounds.

**Results:** Weekly interdisciplinary rounds were established in March 2018. In the following 12 months joint rounds were performed on 404 patients. 86 (21%) of those patients were diagnosed with an infection and 90 (22%) received antibiotics at the time of the interdisciplinary rounds. 79 interventions regarding antibiotic use were made. This led to a reduction in antibiotic use in infants weighing <1500g by 26% with a particular high reduction in the use of broad-spectrum antibiotics (3rd Generation Cephalosporines by 60%, Carbapenems by 40% and Glycopeptides by 50%). There was no significant change in mortality, BPD- or IVH rate prior/post intervention.

**Conclusions:** Infectious disease specialist intervention can safely improve the appropriateness of antibiotic prescription and decreases antibiotic consumption in the neonatal period and can therefore help to reduce long term adverse effects of antibiotic overuse in this age group.

Turn around time and performances of blood cultures with regard to hospital organisation

Gauthier Pean De Ponfilly*, Hanaa Benmansour1, Emmanuel Lecorche1, Fatima Mougar1, Anne-Lise Munier2, Sabrina Temim1, Herve Jacquier1, Emmanuelle Cambau1

1AP-HP Lariboisiere University Hospital, Microbiology Laboratory, Department of Infectious Agents, Paris, France, 2AP-HP Lariboisiere University Hospital, Department of Infectious Diseases, Paris, France

Background: Bloodstream infections (BSI) are associated with a high mortality, particularly if first-line antimicrobial therapy is inadequate. Blood culture (BC) efficiency is critical for BSI diagnosis but the results are usually available long after the treatment has started because of delayed BC positivity.

Materials/methods: Our hospital is a 850-bed university hospital with about 1,000 patients yearly hospitalized with BSI. We measured the positivity rate, the time to incubation and to positivity, and the number of BSI episodes diagnosed during two periods with different organization for BC incubation. During the first period [2015-2016], the organization was classical with the BC bottles incubated in BACT/Alert incubators in the bacteriology lab but this lab being closed during nights (from 18.30 pm to 7:30 am). During the second period [2017-2018], the incubators were replaced by Bact/ALERT VIRTUO enabling to implement one incubator in the emergency lab opened 24/7 since it does not require specialized technicians to introduce the BC bottles. A second incubator was still present in the lab for the bottles incubated during the day.

Results: Whereas the number of BC processed during the period 2 was similar to those of period 1 (30,974 and 30,821, respectively), the number of positive BC was higher during period 2 (3,293 vs. 2,757) as well as the positive BSI episodes (1,192 and 1,003). The increase was especially significant for patients from the emergency rooms (100,000 visits per year) for which 333 BSI episodes vs. 229 were diagnosed. The median time to incubation was significantly shorter during period 2 (1.52 h vs. 6.88h). These changes were observed whatever the bottle [aerobic or anaerobic] and for BC sampled during night or day. For BSI due to Gram-negative bacilli, we observed a median decrease in time to positivity of 6 hours leading to a total of 13 hours between sampling and positivity.

Conclusions: Operational changes like incubating 24/7 in an easy of use and efficient BC automate can reduce not only the time to positivity but lead also to an increase in BC positivity and of the number of the sepsis episodes microbiologically diagnosed as BSI.

Abstract 9280

Chitosan-coated magnetite nanoparticles as a biocompatible nystatin carrier: physicochemical characterisation and in vitro fungicidal determination

Somayeh Yazdanpanah*, Kamiar Zomorodian1, Hamed Veisi1, Hojat Veisi2

1Shiraz university of medical sciences, Shiraz, Iran, 2Payame noor University, Tehran, Iran

Background: Nystatin (Nyst) is a tetraene diene polyene antibiotic with low solubility in water, which is broadly used in antifungal treatments. In this study, super-paramagnetic iron oxide nanoparticles (SPIONs) were synthesized via a chemical co-precipitation procedure and its antifungal activities against pathogenic yeasts were determined.

Materials/methods: The nanoparticles were coated with chitosan (CS) as a biocompatible and stabilizing agent. Then, Fe3O4/CS/Nyst nanocomposite was prepared by immobilizing Nyst on CS based on chemical interactions. Fe3O4/CS/Nyst nanocomposite was characterized by X-ray diffractometry (XRD), Fourier-transform infrared spectrophotometry (FT-IR), vibrating sample magnetometry (VSM), transmission electron microscopy (TEM), field emission scanning electron microscopy (FESEM), and energy-dispersive X-ray spectroscopy (EDX). Antifungal activity of the nanostructure was tested against yeast microorganisms including Candida species by broth microdilution method according to the Clinical Laboratory Standard Institute (CLSI). The cytotoxicity of Fe3O4/CS/Nyst on human cell lines was determined by MTT assay.

Results: The FTIR analysis revealed the binding of CS on the surface of Fe3O4 NPs and also the loading of Nyst on the nanostructure. The nystatin drug loading was measured by Uv-Vis showing a 22% loading capacity on the nanostructure. TEM revealed Fe304/CS/Nyst nanocomposites in monodispersed spherical shape with a mean diameter of ~10-20 nm. Synthesized nanostructures exhibited good activity against representative microorganisms of public concern.

Conclusions: The formulated nystatin-loaded modified chitosan-magnetic nanoparticles showed a good encapsulation and loading efficiency coupled with magnetic responsivity. This Fe304/CS might be used in targeted therapy of mucosal infections such as esophageal candidiasis by using an external magnetic field.

Abstract 9281

**Increase of carbapenemase-producing Enterobacteriaceae in a Portuguese hospital from 2016 to 2019**

Rui Filipe Ramos Figueiredo¹, Paula Gama¹, Carlos Cortes*¹

¹Centro Hospitalar Médio Tejo E.P.E, Tomar, Portugal

**Background:** Carbapenemase-producing Enterobacteriaceae (CPE), specially *K. pneumoniae* (CP-Kp), is an increasing health threat globally. The aim of this study was to perform a molecular and epidemiological survey of CPE isolates and their susceptibility to colistin in a Portuguese Hospital.

**Materials/methods:** CP-Kp isolates (n = 118) were collected from biological samples from patients admitted to Hospital Centre of Médio Tejo, Portugal, between January 2016 and September 2019. Antimicrobial susceptibilities were determined by automatic Vitek2-BioMérieux and colistin MICs confirmed by broth microdilution. Both GeneXpert (Cepheid) and NG-Test CARBA 5 immunochromatographic assay (NG Biotech, Guipry, France) were used to screen for CPE.

**Results:** Of the patients 55% were male; 35.8% with age between 81-90 years. Clinically significant CPE isolates were most frequently cultured from urine (69.2 %), blood cultures (13.3%), respiratory tract (4.2%). Total number of CPE in this study were 120 strains. The annual number of CPE strains increased from one (0.8%) in 2016 to 53 (44.2%) in 2019. The most frequent carbapenemases were KPC [n = 113; 94.2%] followed by OXA-48-like [n = 7; 5.8%]. One strain of *A. baumannii* and other of *E. aerogenes* also produced KPC-carbapenemase during the time analysed. All CPE strains were resistant to quinolones, aminoglycosides and beta-lactams tested. There was an increase of nitrofurantoin efficacy in CPE strains [n = 83] [0% in 2016 to 18.9% [n = 40; yr 2019]] from urine. Susceptibility to fosfomycin in urine CPE strains [n = 83] oscillated from 51.7% [n = 29; yr 2016] to 77.5% [n = 40; yr 2019]. Colistin resistance increased from 0% in 2016 to 13.2% in 2019.

**Conclusions:** CP-Kp are still rare in this region, however results showed a gradually increasing over time, and appearance in other Enterobacteria. Also, a decrease of susceptibility to colistin is relevant, one of the last resort antimicrobial agent. Most frequent clinically significant isolations are from urine. Distressingly, some patients are colonized by CP-Kp, which is known to survive for long periods in the hospital environment and nursing homes. Real-time surveillance using screening methods, rapid response and coordinated outbreak investigation are crucial in controlling the spread of CP-Kp.

Multi-omics approaches to understand the regulation of biofilm formation in high biofilm-forming clinical isolate of Candida parapsilosis

Sulman Shafeeq*, Bengt Sennblad2, Manfred Grabherr2, Ute Römling1

1Karolinska Institutet, Department of Microbiology, Tumor and Cell Biology, Stockholm, Sweden, 2Uppsala University, Department of cell and molecular biology, National Bioinformatics Infrastructure Sweden, Science for Life Laboratory, Uppsala, Sweden

Background: Biofilm formation of Candida parapsilosis on central venous catheters puts patients at increased risk to develop bloodstream infection with C. parapsilosis. An important, if not the major, virulence factor of C. parapsilosis is its ability to form biofilms. Interestingly, the major biofilm regulator BCR1 does not affect biofilm formation of high, spider-like, biofilm forming clinical strains indicating a novel regulatory mode. This study was set up to investigate regulation of biofilm formation of high, spider like, biofilm forming strains.

Materials/methods: The genomes of 5 C. parapsilosis clinical isolates with high (3 isolates) and no (2 isolates) biofilm forming abilities from bloodstream infection were whole-genome sequenced using PacBio technology. In liquid phase, high biofilm forming strains show yeast cell aggregation, which we consider an early biofilm forming stage. Total RNA isolated from early biofilm cultures was subjected to RNA sequencing performed by Illumina HiSeq 2500 with 2 x 125 reads. Protein isolated was subjected to whole proteomic analysis performed by LC-MS. Construction of deletion mutants and complementation was performed by using the SAT1 flipping strategy. Crystal violet staining was used to assess biofilm formation on a polystyrene surface. The cell morphology was assessed by light microscopy, confocal laser scanning microscopy, TEM and SEM.

Results: We have previously categorized clinical strains of C. parapsilosis from bloodstream infection into no, low, and high biofilm formers. Here, we performed whole genome-, RNA- sequencing and proteomic analysis of 5 selected isolates with no- and high biofilm forming ability to understand the regulation of biofilm formation in clinical isolates of C. parapsilosis. Transcriptome comparison between high and no biofilm formers revealed altered expression of 94 genes with expression of selected genes to be confirmed by qRT-PCR. Integration of proteomic data with transcriptomic data resulted in 36 differently regulated genes. Deletion of candidate genes affecting biofilm formation in high biofilm forming strains is in progress.

Conclusions: This study demonstrates that a multi-omics approach between no and high biofilm forming strains is a successful strategy to identify candidate genes involved in regulation of biofilm formation in the clonal species C. parapsilosis.

Abstract 9287

Integrating genome-wide association study with bulk and single-cell RNA sequencing reveals a role for LY86 in the anti-Candida host response

Vinod Kumar*1,2, Dylan H. De Vries1, Vasiliki Matzaraki2, Olivier B. Bakker3, Harm Brugge3, Harm-Jan Westra1, Mihai Gheorghe Netea2, Lude Franke3, Monique G.P Van Der Wijst1

1University of Groningen, University Medical Center Groningen, Groningen, Netherlands, 2Radboud University Medical Center, Department of Internal Medicine and Radboud Center for Infectious Diseases, Nijmegen, Netherlands, 1University of Groningen, University Medical Center Groningen, Groningen, Netherlands

Background: Candida bloodstream infection, i.e. candidemia, is the most frequently encountered life-threatening fungal infection worldwide, with mortality rates up to almost 50%. In the majority of candidemia cases, Candida albicans is responsible. Worryingly, a global increase in the number of patients who are susceptible to infection (e.g. immunocompromised patients), has led to a rise in the incidence of candidemia in the last few decades. Therefore, a better understanding of the anti-Candida host response is essential to overcome this poor prognosis and to lower disease incidence. However, small patient group sizes have limited our ability to gain such understanding.

Materials/methods: Here, we conducted a systems genetic study using candidemia genome-wide association data, bulk and single-cell transcriptomic analyses of immune cells stimulated with Candida albicans. We performed differential expression analysis upon Candida stimulation in single-cell expression data to reveal the important cell types involved in the host response against Candida. We performed the integration of candidemia genome-wide SNP data from a large patient cohort with Candida-response expression QTLs identified in peripheral blood mononuclear cells from 150 samples. We carried out gene knockdown experiments and migration assays in monocytes to reveal the function of candidemia risk genes.

Results: Gene expression analysis in single-cell data upon stimulation confirmed the known major role of monocytes, but more interestingly, also uncovered an unprecedented role for NK cells. Moreover, combining the power of bulk RNA-seq with the high resolution of single-cell RNA-seq data led to the identification of 27 Candida-response QTLs and revealed the cell types potentially involved herein. Integration of these response QTLs with a GWAS on candidemia susceptibility prioritized LY86 as a risk gene for candidemia. By performing knockdown experiments of LY86 and cell migration assays we describe a novel mechanism through which this gene affects the immune response against Candida infection.

Conclusions: Altogether, our integrative systems genetics approach identifies previously unknown mechanisms underlying the immune response to Candida infection. We expect that such an approach can be generalized to other infectious diseases for which small patient group sizes have restricted our ability to unravel the disease mechanism in more detail.

Abstract 9288

Descriptive analysis of patients with influenza virus admitted to intensive care unit from 2010 to 2019

Montserrat Vallverdú1,2, Sulamita Carvalho Brugger*1,2, Mar Miralbés1,2, Silvia Iglesias1,2, Begoña Balsera1,2, Jesús Caballero1,2

1University Hospital Arnau de Vilanova, Lleida, Spain, 2Institut de Recerca Biomèdica de Lleida Fundació Dr. Pifarré, Lleida, Spain

Background: Influenza is a major public health concern, especially in critically ill patients. This work aims to describe the characteristics of patients with influenza virus admitted to ICU.

Materials/methods: Retrospective descriptive study includes patients diagnosed with influenza between 2010 and 2019 admitted to ICU in a reference hospital for a population of 450000 inhabitants. The diagnosis was obtained by nasopharyngeal smear, sputum or bronchotracheal aspirate. Epidemiological variables, risk factors, severity at admission, treatments administered, life support measures and mortality were collected.

Results: A total of 89 patients were included (mean 9.8/year). Average age 60.5 years old (16-86), 63% male. Mean APACHE-II score was 19.1, and SOFA 6.3. 28 patients (31.4%) had received vaccine. It was identified influenza A H1N1 in 49 patients (55%), seasonal influenza A in 28 (31.4%), B in 11 (12.3%) and in 1 it was not typified. Comorbidities were present in many of them: COPD 33 (37%), hematological diseases 11 (12.3%), obesity 13 (14.6%), pregnancy 5 (5.6%), chronic renal failure 6 (6.7%), immunosuppression 10 (11.2%), asthma 6 (6.7%), diabetes 15 (16.8%), HIV 1 (1.1%), and 20 patients (22.4%) had no comorbidities. In 62 cases (69.6%) the radiology was positive. 43 patients (48.3%) needed vasoactive drug infusion, and 9 (10%) continuous renal replacement. 84 patients (94.4%) needed mechanical ventilation (MV), from which 66 (74.2%) received non-invasive MV (NIMV), 29 (32.6%) invasive, and 32 (35.9%) both. In 33 (37%) there was a failure of NIMV support, needing orotracheal intubation. 8 patients (9%) needed prone position. 77 (86.5%) were treated with oseltamivir, during an average of 6.5 days [mean 5.5 days between symptoms started and first dose]. 76 patients (85.4%) received empiric antibiotherapy, coexisting respiratory bacterial infection in 28 (31.5%). The length of stay in ICU was 11.26 days. 22 patients (24.7%) died, 20 of them (91%) in ICU. For them, the median APACHE-II was 24 points, SOFA 8.25, and the time between symptoms started and treatment was 5.9 days.

Conclusions: Most patients presented influenza A H1N1 and MV. The subgroup of patients who died had a higher incidence of immunosuppression, severity and more time between symptoms and treatment.

Abstract 9290

Delayed treatment response in healthcare-associated infections by OXA-48 carbapenemase-producing Enterobacteriaceae

Marwa Amer¹, Omneya Helmy*², Hadir El-Mahallawy³, Magdy Amin²

¹Cairo University, National Cancer Institute, Cairo, Egypt; ²Cairo University, Faculty of Pharmacy, Department of Microbiology and Immunology, Cairo, Egypt; ³Cairo University, National Cancer Institute, Department of Clinical Pathology, Cairo, Egypt

Background: Carbapenem-resistant Enterobacteriaceae (CRE) are important causes of health-care associated infections and present a great challenge to clinicians. We set out to investigate the impact of carbapenemase-producing Enterobacteriaceae infections on the response to treatment in pediatric cancer patients receiving chemotherapy at National Cancer Institute, Cairo University.

Materials/methods: During a six month period extending from June to December 2017, 151 febrile episodes among 129 neutropenic pediatric cancer patients were included in the study; their clinical characteristics and the response to treatment were investigated. Blood cultures from febrile patients were performed; isolates were identified and their antibiotic susceptibility profile determined by Vitek-2. Enterobacteriaceae isolates were further tested by multiplex PCR for the presence of carbapenem-resistance genes: bla\textsubscript{OXA-48}, bla\textsubscript{KPC}, bla\textsubscript{NDM} and bla\textsubscript{VIM}.

Results: Eighty-five Enterobacteriaceae, carbapenem-resistance, isolates were recovered from blood cultures and they included: Escherichia coli (n=45/85, 53%) and Klebsiella pneumoniae (n=40/85, 47%). Carbapenem-resistance genes were detected in 41.2% (n=35/85) of the tested isolates, as follows: bla\textsubscript{OXA-48} (n=33/85, 38.8%), bla\textsubscript{KPC} (n=4/85, 4.7%) and bla\textsubscript{NDM} (n=3/85, 3.5%); the concomitant presence of bla\textsubscript{OXA-48} with either bla\textsubscript{KPC} or bla\textsubscript{NDM} was detected in (n=4/85, 4.7%) and (n=1/85, 1.17%), respectively; bla\textsubscript{VIM} was not detected in any of the tested isolates. A percentage of 85.7% (n=30/35) of PCR positive patients and 30% (n=15/50) of PCR negative patients had fever till day 10 of the episode; a significant difference was observed in the response to antimicrobial therapy in febrile patients harboring carbapenem-resistance genes and those missing them, (p=0.009). Colistin was added in the treatment of 34% of the febrile episodes (n=51/151); it was significantly more used in bla\textsubscript{OXA-48} PCR positive patients (n=23/35, 65.7%) compared to PCR negative patients (n=6/50, 12%), p <0.001.

Conclusions: The presence of bla\textsubscript{OXA-48} was associated with delayed response to antimicrobial therapy and the need for colistin addition in high risk patients.

Abstract 9291

**Antibiotic stewardship: assessment of education and awareness tools for improving citizen involvement**

Felix Grimaud*1,2,3, Xavier Lescure4,5, Josselin Le Bel5,6, Yazdan Yazdanpanah4,5

1 Hospital Center Intercommunal De Créteil, Créteil, France, 2 Département de médecine générale, Faculté de Médecine Paris Descartes, Paris, France, 3 APHP, Hôpital Bichat, Service de maladies infectieuses et tropicales, Paris, France, 4 APHP, Hôpital Bichat, Service de maladies infectieuses et tropicales, Paris, France, 5 Université de Paris, IAME, INSERM, Paris, Paris, France, 6 Département de médecine générale, Université Paris Diderot, Sorbonne Paris Cité, Paris, France

**Background:** The development of bacterial resistance to antibiotics could become one of the leading causes of death in the world by 2050 if nothing changed. The consumption of antibiotics in France is high and stable over 10 years despite the continuous awareness of prescribers. The objective was to evaluate information materials to aware users to the issue of bacterial resistance and the correct use of antibiotics by focusing messages around the main role of the gut microbiota.

**Materials/methods:** Quantitative, cross-sectional, descriptive study conducted in France from February 2018 to February 2019, involving users by paper questionnaire, email or social network. Creation of fact sheets explaining the bacterial resistance and its consequences, the pivotal role of the gut microbiota, the concept of “One Health”, and the principles for better use of antibiotics. We included users over the age of 15, speaking French and answering the questionnaire before and after reading fact sheets. Comparison of knowledge using a score obtained before and after information.

**Results:** Five hundred and sixty-nine users were included between November 2018 and February 2019, 83% of whom were female and 32% of the participants consumed an antibiotic at least once a year. Overall success rate before information was 65.0%, up to 93% for gut microbiota questions. The overall median score increased from 15/22 [IQR [12-17]] before information to 18/22 [16-19] after information (p <0.001). The average percentage of correct responses for bacterial resistance increased from 56.9% before information to 65.9% after information (p <0.001). The major gain in knowledge was about 30% for questions about antibiotic indications.

**Conclusions:** Information on the bacterial resistance and the good use of antibiotics makes it possible to aware the users. Users’ knowledge of the microbiota can help raise awareness of the ecological impact of antibiotics and participate largely to improve antibiotics use especially in the community.

Abstract 9292

Microbiome changes among patients who transitioned from *Clostridioides difficile* negative to *C. difficile* positive using systematic screening tests

L. Silvia Munoz-Price*,1, Samantha Atkinson1, Amy Pan1, Kim Mai1, Vy Lam2

1Medical College of Wisconsin, Milwaukee, United States, 2Pita Analytics, Washington DC, United States

Abstract third-party references: Medical College of Wisconsin Cancer Center

**Background:** Colonization with toxigenic *Clostridioides difficile* (*Cdiff*) is necessary for *Cdiff* infection to occur. Here we aimed to understand the microbiome disruptions associated with transitioning from *Cdiff-* to *Cdiff+* [N2P] in patients who underwent systematic *Cdiff* screening tests.

**Materials/methods:** Five high-incidence *Cdiff* inpatient units in Milwaukee, WI performed screening upon admission and weekly thereafter using nucleic-acid-amplification tests (NAAT; Xpert*®* *C. difficile*, Cepheid, CA). Available stool samples underwent 16S rDNA sequencing. Non-metric multidimensional scaling (NDMS) plots were constructed based on non-parametric comparison testing analysis (ADONIS) of Bray-Curtis distance matrices. Twenty-four samples also underwent shotgun metagenomics sequencing. Reads were filtered for quality, assembled, and individual samples were mapped back to contigs. Taxonomic and protein identity were assigned with Kaiju and COGs, PFAM, and InterproScan, respectively. Anvi’o was used for visualization and downstream analyses. Linear mixed models were used to investigate the association between groups and relative abundance of individual species over time. Data was fitted using arcsine square-root or logit transformation.

**Results:** A total of 606 stool samples from 120 patients underwent 16S rDNA sequencing [N2P n=44; Negative-control [always *C. difficile* (-)] n=47; Positive-control [always *C. difficile* (+)] n=19]. N2P patients were on average 60 years old, 50% male, 91% had hematology-oncology diagnoses, 31% had bone marrow transplants, and 64% were exposed to antibiotics. These demographics and exposure variables were not statistically different when compared to Negative-controls or Positive-controls. Diversity indexes and the number of OTUs were no different between *Cdiff-* and *Cdiff*+ samples belonging to N2P or between *Cdiff-* samples within N2P and Negative-controls. NDMS showed similar distribution of *Cdiff-* and *Cdiff*+ samples belonging to N2P patients (Fig1A); however, overtime abundance of *Clostridioides*, *Lachnoclostridium*, and *Coprococcus* increased while *Blautia* abundance decreased. Negative-controls and Positive-controls showed differences in two NDMS quadrants (Fig1B); Positive-controls in the right-lower quadrant had lower *Bacteroides* and higher *Clostridioides* than Negative-controls. Analysis of metagenomic data (Fig1C) showed that N2P compared to Negative-controls had increasing levels of *Coprobacter* and *Desulfovibrio* and decreasing levels of *Ruminococcus*, *Coprococcus*, *Blautia*, and *Bacteroides*.

**Conclusions:** N2P patients had similar demographics, drug-exposures, underlying comorbidities, diversity indexes, and number of OTUs compared to controls. However, compared to controls, abundance differences in specific taxa were observed.

**Presenter email address:** smunozprice@mcw.edu
Morphogenesis and pathogenesis regulation of *Candida albicans* by probiotic bacterium: *Pediococcus acidilactici*

Zahra Zare Shahrabadi¹, Kamiar Zamorodian², Keyvan Pakshir², Sassan Rezaie¹

¹Tehran University of Medical Sciences, Tehran, Iran, ²Shiraz University of Medical Sciences, Shiraz, Iran

**Background:** Oral candidiasis is a frequent form of candidiasis, caused by *Candida* species in particular, *Candida albicans*, which normally reside on mucosal surfaces. The transition of *C. albicans*, from yeast to hyphae allows the attachment to oral epithelial cells, followed by biofilm formation, invasion and tissue damage. Hence, the effect of *Pediococcus acidilactici* on growth, biofilm and germ tube formation of *C. albicans* were investigated in vitro as well as in vivo.

**Materials/methods:** Inhibitory activity of *P. acidilactici* on *Candida* species growth was determined by the broth microdilution method and inhibition of *C. albicans* biofilm formation was measured using XTT assay. Also, expression of seven genes as Agglutinin-like protein 1 (ALS1,3), hyphal cell-wall protein (HWP1), secreted aspartyl proteinase (SAP4,6), Enhanced filamentous growth 1 (EFG1) and Enhanced activated protein 1 (EAP1) were analyzed by RT-PCR with different concentrations of *P. acidilactici*. The experimental activity of the probiotic bacterium was assessed in an animal model by culture and histopathological methods in three groups of mice including those treated with probiotics, fluconazole and distilled water as the control.

**Results:** *P. acidilactici* inhibited the growth of Candida species at concentrations of 8-512 µg/mL. This probiotic bacterium inhibited the biofilm and germ tube formation in a dose-dependent manner. RT-PCR analysis showed a reduction in gene expression following the treatment with this bacterium. The *P. acidilactici* significantly reduced the CFUs in mice receiving this probiotic treatment compared to the control group. Histopathological analyses showed that Candida colonization was diminished in mice following the administration of probiotic.

**Conclusions:** Our data provide new insight into the biotherapeutic effects of *P. acidilactici* by inhibition of *Candida* species growth, germination, and biofilm formation. Also, the obtained data suggest that this bacterium can reduce Candida colonization and fungal burden on mucosal surfaces and relieve signs and symptoms of oral candidiasis. Further studies are still needed to clarifying the effects of the secreted biosurfactant and byproducts of this bacterium on adhesion, morphogenesis and pathogenesis of *Candida* yeasts.

Evaluation of the EasyScreen ESBL/CPO kit for the detection of β-lactam resistance genes

Camille Gonzalez*1, Saoussen Oueslati1, Delphine Girlich1, Laurent Dortet1, Thierry Naas1,2

1Université Paris Sud XI Faculty of Medicine, Le Kremlin-Bicêtre, France, 2Bicètre Hospital AP-HP, Le Kremlin-Bicêtre, France

Background: Antibiotic resistance has become a major international concern for public health, especially with the spread of the carbapenemases producing Enterobacteriaceae (CPE). Thus development of efficient and reliable detection tests is essential to prevent spread of these deadly bacteria in hospital settings and to assist clinicians with appropriate antibiotic therapies. Here we have evaluated the performance of the novel molecular diagnostic test, the EasyScreen™ ESBL/CPO for β-lactam resistance genes detection.

Materials/methods: EasyScreen™ ESBL/CPO [Genetic Signatures] is a rapid in vitro nucleic acid amplification assay for the qualitative detection of 15 β-lactamase (including carbapenemase) genes and the colistin encoding mcr-1 gene. The assay is based on real time PCR technology, fluorescent probes, and 3base™ technology. More than 300 bacterial isolates [Enterobacterales, Pseudomonas aeruginosa, Acinetobacter baumannii] were isolated from agar culture. One colony was suspended in extraction buffer, which lyses and converts the nucleic acids into a 3base DNA form [all cytosine bases are converted as thymine bases]. The bacterial DNA is then added to the 6 PCR tubes, with primers for three targets plus one internal control. The targeted genes are blaKPC, blaVIM, blaIMP, blaNDM, blaIMI, blaSme, blaOXA-48, blaGES, blaSHV, blaTEM, blaCTX, blaDHA, blaCMY, blaOXA-23, blaOXA-51, and mcr-1.

Results: EasyScreen™ ESBL/CPO is able to detect the major carbapenemases [NDM, VIM, IMP, KPC, OXA-48, IMI, Sme] and their variants in Enterobacteriaceae and in Pseudomonas aeruginosa with nearly a sensitivity of 100% but also some plasmid-encoded cephalosporinases and their variants [CMY, DHA]. However, the detection of the chromosomally-encoded CMY and DHA, where less efficiently detected and some OXA-23 and OXA-51 variants were not detected. Finally, EasyScreen™ ESBL/CPO was not able to distinguish between penicillinase and ESBL variants of TEM and SHV, and similarly between GES-ESBLs and GES carbapenemases.

Conclusions: Our data showed that EasyScreen™ ESBL/CPO is an efficient and rapid (<3h from colony to result) detection test for the most frequently encountered penicillinases [including ESBLs], carbapenemases, cephalosporinases and mcr-1 in Enterobacteriaceae, P. aeruginosa, and A. baumannii. EasyScreen™ detection Kit is compatible with most existing automated nucleic acid extraction and real-time PCR instruments and can be fully automated.

The polymorphism rs2305619 of Pentraxin 3 is associated with susceptibility of non-HIV-related cryptococcosis in a Chinese Han population

Weili Zhang*, Quanfeng Liao1, Ya Liu1, Siying Wu1, Mei Kang1

1West China Hospital of Sichuan University, Chengdu, China

Background: To conduct association analysis between the polymorphism rs2305619 of Pentraxin 3 (PTX3) and the susceptibility to non-HIV-related cryptococcosis, which may provide molecular evidence for early risk prediction of disease, individualized treatment, and prognosis monitoring.

Materials/methods: Using SNaPshot SNP typing technique, PTX3 rs2305619 was typed on 97 non-HIV-related cryptococcosis patients and 120 healthy controls. The results were analyzed by SHEsis software.

Results: PTX3 rs2305619 polymorphism was associated with the risk of cryptococcal infection. Compared with the healthy controls, the proportion of rs2305619 A/A homozygotes increased in the non-HIV-related cryptococcosis patients (OR 2.076, 95% CI: 1.026–4.203, P=0.040). In the non-HIV-related cryptococcosis without immunocompromised underlying diseases group, this increase was more obvious (OR 2.708, 95% CI: 1.217–6.027, P=0.015). While, the proportion of G/G homozygotes in non-HIV-related cryptococcosis patients reduced (OR 0.539, 95% CI: 0.311–0.936, P=0.028). In the non-HIV-related cryptococcosis without immunocompromised underlying diseases group, this reduction was more obvious (OR 0.331, 95% CI: 0.160–0.683, P=0.003).

Conclusions: The rs2305619 polymorphism of PTX3 was associated with susceptibility to non-HIV-associated cryptococcosis. The rs2305619 A/A genotype increased the risk of cryptococcal infection, while the G/G genotype reduced the risk of cryptococcal infection.

Abstract 9311

Genomic characterisation of clinical Enterococcus faecium from Tunisia: remarkable identity with ampicillin-resistant strains obtained from animals/meat in the same area

Ana Raquel Freitas*, Houyem Elghaieb, Carla Novais, Barbara Duarte, Mohamed Salah Abbassi, Luisa Maria Vieira Peixe

1 Faculdade de Farmácia do Porto, UCIBIO-Requimte, Porto, Portugal, 2Université de Tunis El Manar, Tunis, Tunisia

Abstract third-party references: The work was supported by UID/MULTI/04378/2019 with funding from FCT/MCTES through national funds.

Background: MDR-Enterococcus faecium (Efm) infections continue to increase worldwide, including in Tunisia where genetic characterisation of clinical enterococci remains scarce. We aimed to characterize Efm causing human infections in healthcare institutions from Tunisia and to position them within the worldwide Efm epidemiology by genome comparison with those available in public and personal databases.

Materials/methods: Efm isolates (n=29; August-2011 -March-2016) from two private clinics (Tunis-north) and one regional hospital (Gafsa-southwest) were analysed. Species were identified by PCR. Antibiotic susceptibility testing (disk-diffusion: 13-antibiotics; E-test:ampicillin) was performed [EUCAST, 2019] and transfer of vancomycin-vanA and ampicillin-pbp5 resistance done by conjugation (1:1-donor:recipient-EfmGE1). Clonality was established by SmaI-PFGE. WGS-Illumina was done for representative Efm (n=10) that were analysed through CGE [MLST/ResFinder/PlasmidFinder/CSIphylogeny] and in house databases of virulence factors (n=41 VF). They were compared with strains from non-clinical sources in Tunisia [our collection/PMID:31243458] as well as other regions [GenBank public genomes].

Results: Clinical Efm (48% MDR) were resistant to erythromycin-55%, ciprofloxacin-48%, high-level-aminoglycosides-45%, ampicillin-41% (AmpR); quinupristin-dalfopristin-38%; tetracycline-28%; glycopeptides-14%. Three ICU-patients from one of the clinics (2016) were infected with the same bloodstream vancomycin-resistant-vanA-MDR (glycopeptides/ampicillin/ciprofloxacin/erythromycin/tetracycline/gentamicin/streptomycin) ST80 clone, which was enriched in relevant virulence markers (ptsD/orf1481/IS16/complete-acm/scm/espA/4-pili-gene-clusters). vanA-Tn1546 was located on a conjugative pRUM-like plasmid. These Efm were compared with GenBank ST80-Efm available genomes and infection-derived Efm from Australia/2012 and Malaysia/2011 (vanA) were the closest (262-271 -SNPs) ones. Among Tunisian AmpR-Efm (n=12), two clinical strains were closely related to a non-clinical AmpR-Efm from bovine-meat (ST18/3-SNPs) and two cow-milk/bovine-meat (ST17/0-29-SNPs) from Tunisia, all with similar MICAmp (128->256 mg/L) and VF (ptsD/orf1481/IS16/complete-acm/scm/espA/4-pili-gene-clusters; hyl in ST17). The pbp5 gene was transferred by the VanA-AmpR-ST80-Efm and AmpR-ST17-Efm. Clinical/bovine-meat ST18-AmpR-Efm and ST203-AmpR-Efm [2014-2016] from Tunisia differed in 15-20 SNPs and 86-SNPs from French [2000-2009] and U.S.-AmpR-VRE-linezolid-resistant [2014] clinical strains, respectively.

Conclusions: Clinical-MDR-Efm clones causing human infection in Tunisia can be closely related to clinical-Efm of other continents. Identical AmpR-MDR-Efm strains carrying markers associated with an increased risk of human infection (high-level-AmpR + relevant-VF) were found in clinical and animal sources from Tunisia or other countries, emphasizing the global/continuous transmission of relevant Efm across different hosts/settings and the urgent need of One Health measures to contain their spread.

Abstract 9313

**Echinocandin resistance in emerging multidrug-resistant yeast *Candida auris* and investigation into the mechanism of resistance**

Dipti Sharma*1, Raees Ahmed Paul1, Shivaparakash M. Rudramurthy1, Saikat Paul1, Hariprasath Prakash1, Sanjay Bhattacharya2, Arunaloke Chakrabarti1

1Post Graduate Institute of Medical Education & Research, Chandigarh, India, 2Tata Medical Center, Kolkata, India

**Background:** *Candida auris* is a rapidly emerging multidrug resistant yeast of worldwide importance. Resistance to echinocandins, the drug of choice for treatment of *Candida* infection is of concern. The present study was conducted to determine the burden and mechanism of echinocandin resistance in *C. auris* isolates.

**Materials/methods:** Antifungal susceptibility testing of *C. auris* (n=144) were performed by CLSI broth microdilution technique against echinocandins (caspofungin, anidulafungin and micafungin). Sequencing of the FKS gene was carried out for isolates with high echinocandin minimum inhibitory concentration (MIC). Expression levels of putative chitin synthase genes (*CHS1* and *CHS2*) and β-1,3-glucan synthase (*BGS*) were determined after sub optimal drug treatment. The results were correlated with quantity of cell wall chitin content using flowcytometry. Growth kinetics of resistant mutants and wild type (WT) isolates and impact of chitin binding dye, calcofluor white (CFW) on their growth was also analysed.

**Results:** Seven (4.86%) isolates had MIC above the tentative clinical breakpoint of ≥2 mg/L for caspofungin. Four isolates had intermediate MIC of 1 mg/L for capofungin. FKS sequence of two isolates carried a novel mutation, F635Y. Three isolates carried previously reported mutation S639F, while two isolates demonstrated no target site mutation. *CHS1* transcript levels were not different in resistant isolates with WT FKS gene (6.52±2.04) and in those with intermediate MIC (7.93±1.18), but significantly different from resistant isolates with a mutation in FKS gene (2.90±0.97). There was no significant difference in *BGS* expression levels in resistant isolates with and without mutation (1.49± 0.31 and 2.74±0.37 respectively). However, increased expression of *BGS* in isolates with intermediate caspofungin MICs (8.34±2.20) was noticed. Flowcytometric analysis showed significant difference in the chitin content of mutant and WT resistant isolates. Growth of resistant isolates with mutation in FKS gene was more strongly inhibited by higher concentrations of CFW compared to wild type isolates. Growth kinetic behaviour was similar for all isolates.

**Conclusions:** Although, mutations in FKS1 gene is most commonly reported mechanism of echinocandin resistance, other yet unknown mechanisms could account for resistance. Resistant mutants were more susceptible to CFW and growth kinetics suggests no fitness cost associated with echinocandin resistance-conferring mutations.

Abstract 9314

**Successful reduction of urinary catheter days and inadequate catheterisation after introduction of a prevention bundle**

Michela Cipriani*, Matthias Schlegel¹, Marianne Schwark-Bähler², Philipp Patrick Kohler¹, Werner Albrich¹

¹Cantonal Hospital of St. Gallen, St. Gallen, Switzerland, ²Hospital of Rorschach, Rorschach, Switzerland

**Background:** Catheter-associated urinary infections (CAUTIs) are frequent and one of the most preventable nosocomial infections. We assessed the effectiveness of an intervention bundle to reduce urinary catheter-days and to prevent catheter-related infectious and non-infectious complications.

**Materials/methods:** This before-after study was carried out in a regional 62-bed hospital in Switzerland with a prevention bundle consisting of three evidence-based measures: training session emphasizing adequate indications for catheterization and appropriate antibiotic therapy, catheter insertion only according to defined criteria with daily re-evaluation, and training of personnel for safe insertion and handling of bladder catheters. We prospectively included all patients with preexisting or newly placed urinary catheters (in place for ≥24 hours). Catheter episodes per number of discharged patients, catheter-days per bed days, catheter dwell time, indications for catheterization, as well as infectious (CAUTIs) and non-infectious complications were compared between the 2-month period before and the 4-month period after a 5-week implementation phase.

**Results:** A total of 193 catheter episodes were included: 101 among 510 discharged patients before and 92 among 894 discharges after intervention (p<0.001). Overall, there was a significant reduction of catheter days during the post-intervention period (1898/10,000 hospital bed days vs. 1269/10,000 hospital bed days, p<0.001). Catheter dwell time increased from 5.8 to 7.4 days (p=0.16). Among placed catheters, there was a trend towards reduction of incorrect indications before and after intervention (11/101 vs. 5/92, p=0.17). Incorrect indications were catheterization for incontinence (5% vs. 0%, p=0.03) and for urinary tract infection (3% vs. 3%, p=0.9). The most frequent correct indications for catheterization were urinary retention (41% vs. 46%, p=0.6), followed by urine-monitoring (35% vs. 39%, p=0.7) and surgery (15% vs. 18%, p=0.6). The overall rate of CAUTIs was low both before (3/101, 3%) and after intervention (2/92, 2%) (p=0.9). Most of them (4/5) were related to preexisting urinary catheters. Only one patient in the post-intervention period experienced a non-infectious complication (bleeding).

**Conclusions:** This intervention bundle brought a significant reduction of catheter days, probably due to a reduction of insertions due to incorrect indications. The low baseline-infection rate prevented us from showing a reduction in CAUTI-incidence.

Abstract 9317

**AST for fastidious bacteria: a reliable automation to standardise the EUCAST disk diffusion test**

Michela Paolucci*1, Carla Lacchini1, Nicole Schepis1, Laura Navarria1

1 COPAN WASP S.r.l, Brescia, Italy

**Background:** Fastidious bacteria antimicrobial resistance (AMR) is a growing threat to public health. EUCAST implemented a disk diffusion based antimicrobial susceptibility test (AST) using Mueller Hinton + 5% mechanically defibrinated horse blood + 20 mg/L β-NAD (MH-F) agar plates.

Copan established and validated an automated workflow starting from MH-F streaking, antibiotic disks dispensing, CO₂ incubation and AST plates digitalization to facilitate results analysis on the screen.

The aim of this study was to compare the automated workflow, from sample preparation to digital measurement of the inhibition zone diameters (IZD) on the Copan WASP® and WASPLab®, to the reference manual preparation method.

**Materials/methods:** In this study an assessment of the automated system reproducibility was performed. Quality control strains (QCs), proposed by EUCAST, of *S.pneumoniae* ATCC 49619, *H.influenzae* ATCC 49766 and *C.jejuni* ATCC 33560, processed in triplicate for 5 days, were tested with both the automated and manual methods against most of the antimicrobials specified in the EUCAST protocol. In addition, 14 clinical strains, representative of species requiring MH-F for disk diffusion, were analysed in triplicate by both methods. All the disks IZD were read by two operators with both manual calliper and the digital measuring tool.

**Results:** In the QC strains tested, a total of 8700 IZD were measured: for all the strain/drug combinations, the mean diameter of the inhibition zone was within the EUCAST QC range for both workflows. During the 5 days testing, the average difference between IZD obtained with the manual and the automated workflows for each combination strain/drug, showed to be less than 1 mm. In the clinical strains tested, a total of 5280 inhibition zones were measured and a 97.9% categorical agreement was obtained with 0.4% of Very Major Error, 1.5% of Major Error and 0.2% of Minor Errors.

**Conclusions:** Together with previously validated protocols for aerobic bacteria, the present study demonstrates that WASP® and WASPLab® automation are offering a reliable strategy to properly perform, manage and standardize disk diffusion test for fastidious organisms.

**Presenter email address:** michela.paolucci@copangroup.com
Abstract 9320

**Screening the antifungal activities of monoterpenes and their isomers against Candida species**

Kamiar Zomorodian*, Aida Iraji¹, Somayeh Yazdanpanah¹

¹Shiraz University of Medical Sciences, Shiraz, Iran

**Background:** Increasing occurrence of non-albicans Candida species with intrinsic or acquired resistance to antifungals as well as the emergence of multidrug Candida species coupled with the limited antifungal agents challenges the treatment of candidiasis. Consequently, a class of secondary metabolites of plants exhibiting decent antifungal activity. Therefore, this study aimed to evaluate the antifungal potential of various monoterpenes including Carvone, Limonene, Pinene, Menthone, Menthol, Camphor, Thujone, Citronellol, and Piperitone against standard and clinical isolates of Candida.

**Materials/methods:** Minimum inhibitory concentration (MIC) of compounds were determined, using broth Microdilution method based on M27-A3 protocol documented by clinical laboratory standard institute (CLSI).

**Results:** Amongst the tested monoterpenes, oxygenated terpenoids showed strong antifungal activity. Specifically, alcoholic terpenoids such as (±)-Citronellol possess more efficacy than the corresponding ketonic ones with MIC, ranging from 0.03 to 2.00 µl/ml. Among the examined yeasts, C. tropicalis was the most susceptible species to (±)-Citronellol. Moreover, the examined monoterpenes successfully inhibited the growth of fluconazole-resistant Candida species. Moreover, statistical analysis showed no statistically significant difference between the (+) and (−) isomers, except for (±) α-Pinenene and (±) Menthone (P value < 0.05).

**Conclusions:** Considering the significant antifungal activity of the examined monoterpenes, they could be used in controlling or treating candidiasis. Pleasant taste and odor of these monoterpenes in addition to their safety and GRAS grades makes them appropriate additive or preservative compounds in food and cosmetics products. Furthermore, these data might help researchers to predict EOs antifungal activities, after determining its constituents.

Abstract 9321

Exploring barriers to penicillin allergy de-labelling in a UK teaching hospital

Christopher Jones*,1, Sue Wade1, Emily Marshall1, Carys Jones1, Finbarr Canney1, Rajeka Lazarus1

1Bristol Royal Infirmary, University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom

Background: Penicillin allergy is commonly reported by patients but the prevalence of type 1 hypersensitivity is low. An inappropriate penicillin allergy label is associated with adverse outcomes. This survey aimed to explore the barriers to penicillin allergy de-labelling.

Materials/methods: During World Antibiotic Awareness Week 2019, healthcare workers at an English teaching hospital were invited to participate in an anonymous electronic survey. Respondents were asked knowledge-based questions about the prevalence of penicillin allergy and its association with adverse outcomes. Respondents were asked to identify barriers to penicillin allergy de-labelling experienced within their practice.

Results: In total there were 105 respondents: 55 (52.4%) doctors, 20 (19.1%) pharmacists, 18 (17.1%) nurses, and 12 (11.4%) other healthcare workers. Duration of professional experience was evenly distributed – 0-2 years (21; 20%), 2-5 years (17; 16.2%), 5-10 years (35; 33.3%), and >10 years (32; 30.5%). Overall, 47 (44.8%) correctly identified the prevalence of reported penicillin allergy and 65 (61.9%) identified the prevalence of true IgE-mediated (type 1) allergy to penicillin. Pharmacists and respondents with >5 years’ experience were more likely to give a correct answer. Only 20 (19.1%) correctly identified all the complications associated with penicillin allergy. The majority of respondents (78.4%) felt that avoiding penicillin is harmful in patients with a history of intolerance (not allergy) to penicillin. The most commonly reported barriers to removing an inappropriate penicillin allergy label were unreliable history, fear of harm, and uncertainty in assessing risk (both clinician and patient uncertainty). Doctors and pharmacists were more likely to report barriers related to acquiring an allergy history, risk assessment, and time constraints. Nurses were more likely to report lack of training, knowledge, and experience.

Conclusions: The low prevalence of type 1 allergy to penicillin was well recognised. Although the majority felt that avoiding penicillin is harmful in patients with a history of intolerance to penicillin, understanding of the complications related to penicillin allergy was poor. Future initiatives to remove an inappropriate penicillin allergy label should be supported by educational activities for both healthcare staff and patients. A concerted system-wide approach to penicillin allergy de-labelling across primary and secondary care is required.

Abstract 9323

Impact of out-of-hours results and infection specialist intervention on the time to the first appropriate antimicrobial therapy in patients with Gram-negative bacteraemia: the South London CLAHRC cohort experience

Cristina Suarez*1, Elia Vitale1, Eva Galiza1, Shrey Mathur1, Bakshika Jeyarathnam1, Simon Goldenberg1, Jonathan Edgeworth3, Timothy David Planche1;4

1St George’s, University of London, Institute for Infection and Immunity, London, United Kingdom, 2King’s College Hospital, Department of Infection Sciences, London, United Kingdom, 3King’s College London, Centre for Clinical Infection and Diagnostics Research, London, United Kingdom, 4St George’s NHS Foundation Trust, Medical Microbiology, London, United Kingdom

Abstract third-party references: NIHR South London CLAHRC

Background: It is urgent to identify interventions in the bacteraemia pathway to reduce the time to the first appropriate antimicrobial treatment (TFAAT). In the UK, the infection specialist (IS) manages patients with Gram-negative bacteraemia (GNB), prompted by positive blood culture (BC) results during working hours (DWH). Out-of-hours (OOH) results are acted on the following day. IS intervention (ISI) improves outcome of infections. We evaluated the impact of OOH results and ISI on the TFAAT of patients with GNB.

Materials/methods: Ambispective cohort of GNB episodes from three hospitals (October 2014-December 2015). Data: clinical-microbiological-epidemiological information; date-time for laboratory results (Gram/identification/susceptibility testing), ISI and treatments. TFAAT: time (hours) from BC sampling to first appropriate antimicrobial therapy (according to in vitro susceptibility). BC positivity time (BCPT): time in the day when BC bottles flagged positive [DWH [08:01-18:00], OOH [18:01-08:00]]. TFISI: time (hours) to first ISI from first result. Methods: Cox regression: best predictive model for TFAAT (event) that included IS intervention/OOH. Episodes in adults off appropriate antimicrobial at the BCPT were included. Quantitative variables are expressed as median (p25, p75), regression outputs as HR [95% CI].

Results: 366 of 800 episodes recorded [181/366 [49%] DWH] had available clinical-microbiological-outcome data; 278 had treatment data. Among 73/278 [26%] episodes off appropriate antimicrobial treatment at BCPT, the DWH group compared to the OOH had shorter TFAAT [42 [24,45] vs 57 [35,97]], p=0.019) and TFISI [3 [1,18] vs 11 [7,17], p<0.01]; there was strong correlation between TFAAT and the time from BC sampling to Gram stain [DWH r=0.7 vs OOH r=0.559]; there was no correlation between TFAAT and ISI/TFISI. In the final model [adjusted by TFISI, comorbidity and severity] both antimicrobial resistance [28 [2,390], p=0.013] and a non-urinary source [24 [1,441], p=0.033] significantly increased the TFAAT; the association with TFISI was not significant.

Conclusions: Antimicrobial resistance and a non-urinary source were associated with TFAAT delays in GNB. There may be subgroups of patients where the OOH results delayed the TFAAT although this association was not identified in the final overall model. This information will help to optimise workflows and resources to improve the management of patients with GNB.

Complete genome sequencing and identification of *Mycobacterium chimaera* by MALDI-TOF MS: a modified approach to discriminate *Mycobacterium chimaera* and *Mycobacterium intracellulare*

Jessica Bagnarino¹, Vincenzina Monzillo¹, Daniela Barbarini¹, Antonio Piralla¹*, Arash Ghodousi², Enrico Tortoli², Piero Marone¹

¹Microbiology and Virology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, ²IRCCS San Raffaele Scientific Institute, Milano, Italy

**Background:** *Mycobacterium chimaera* is an opportunistic biofilm-forming pathogen intrinsically resistant to numerous classes of antibiotics. Since 2004, several outbreaks were observed worldwide due to the contamination of water tanks of heater-cooler units (HCUs) used during open-heart surgery. The invasive infections caused by *M. chimaera* are characterized by a mortality rate of about 50%. Until now, only 18 cases of invasive *M. chimaera* infections have been reported in Italy with 7 deaths and 55 contaminated HCUs (http://www.trovanorme.salute.gov.it/norme/renderNormsanPdf?anno=2019&cod-Leg=67585&parte=1%20&serie=null).

**Materials/methods:** From January 2016 to July 2019, all water samples collected from the HCUs were processed according to ECDC guidelines (https://www.ecdc.europa.eu/en/publications-data/eu-protocol-case-detection-laboratory-diagnosis-and-environmental-testing). Five *M. chimaera* strains isolated from clinical samples and collected in the period 2015-2019 were included in the study. Identification was performed using DNA probes (GenoType NTM-DR). Whole Genome Sequencing (WGS) was performed using Illumina NextSeq platform. Identification of *M. chimaera* strains was also using MALDI-TOF MS with standard protocols. A modified algorithm (Panada AB et al., JMM 2017; 66:670-7) based on the analysis of specific peaks was used in order to discriminate *M. chimaera* from *M. intracellulare*. Twenty *M. intracellulare* strains were used as control for the algorithm evaluation using at least 8 replicates.

**Results:** Twenty-eight out of 40 (70.0%) water samples were positive for *M. chimaera* and in 20 of them, WGS was performed. Of note, 12/20 (60.0%) *M. chimaera* strains belonged to subgroup 1.1 (with <10 single nucleotide polymorphism), which also includes 1 of 5 clinical sample identified in 2015. Logarithmic ratio (log(IQ)) between the sum of the intensity of selected peaks for *M. chimaera* (n=3) and *M. intracellulare* (n=3) spectra were used for discrimination analysis. The median log(IQ) observed was 0.37 (range 0.28-0.51). Among intra-samples variability, the mean of coefficient of variation was 20.4% (SD 9.9%) evaluated in 8 replicates for each sample.

**Conclusions:** Most of the strains isolated from HCUs belonged to subgroup 1.1 also reported as the same clone responsible for outbreaks globally occurred. Moreover, the logarithmic approach applied to MALDI-TOF MS demonstrate a valid and powerful tool to discriminate *M. chimaera* and *M. intracellulare*.

Abstract 9329

**Accuracy of sepsityper methodology for identifying microorganisms directly from positive blood culture bottles using MALDI-TOF MS**

Rebecca Gorton*1, Rachel White1, Catherine Baker1, Robin Smith1,2

1Health Services Laboratories (HSL), London, United Kingdom, 2Royal Free Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom

**Background:** Processing of positive blood cultures traditionally involves subculture and agar growth to obtain organism identification. Sepsityper, a sample preparation method, enables MALDI identification directly from a positive blood culture bottle. Although our laboratory has utilized the direct Sepsityper method for some time, it has been considered a provisional identification tool and MALDI of agar growth has always been performed to provide definitive identification. This analysis evaluated accuracy of direct Sepsityper identification compared with growth MALDI identification, with a view to increasing clinical confidence in the Sepsityper ID and reducing unnecessary repeat MALDI processing.

**Materials/methods:** Results from 1263 positive blood culture bottles which had undergone both direct Sepsityper and growth MALDI methods were analyzed.

**Results:**

112/1263 (8.87%) gave no peaks / no ID with Sepsityper.

205/1263 (16.2%) yielded mixed growth on agar. Sepsityper correctly identified at least one of the organisms present in 195/205 (95.1%), but it only detected all organisms present in 2/205 bottles.

946/1263 (74.9%) gave an ID with Sepsityper and yielded a pure growth of a single organism.

<tr>
<td>12/946</td>
<td>Sepsityper ID accurate to genus level</td>
</tr>
<tr>
<td>5/946</td>
<td>Sepsityper ID erroneous</td>
</tr>
</tbody>
</table>

For most commons organisms, the ID given by direct Sepsityper was unchanged on growth MALDI ID. This included all E coli, Enterococcus faecalis, Klebsiella spp, Micrococcus spp, Proteus mirabilis, Pseudomonas aeruginosa, Staphylococcus aureus, Staphylococcus epidermidis.

The 5 erroneous Sepsityper IDs were unusual organisms to found in blood cultures: Pantoea, Peptoniphilus, Prevotella, Weissella, Cutibacterium.

Sepsityper IDs accurate to genus level included 9 very closely-related organisms.

**Conclusions:** Sepsityper accurately identified 98.2% of positive blood cultures containing a single organism. Any bottle with a common organism ID on Sepsityper and yielding pure agar growth did not require repeat MALDI ID from agar growth. In this analysis, this accounted for at least 560/1263 (44.34%) positive cultures analyzed.

All Sepsityper results giving an uncommon organism ID, genus level ID or no ID, plus any mixed growth on subculture required confirmatory growth MALDI.

Abstract 9330

Clinical class 1 integron patterns and relative antibiotic resistance gene carriage in urban compartments
Marcos Quintela-Bujan1, Mohamed Abouelnaga2, Jesus L. Romalde3, Mariano Gomez Lopez4, Ben Allen5, Dominic Frigon6, David Graham5

1Newcastle university, Newcastle, United Kingdom, 2Suez Canal University, Ismailia, Egypt, 3Universidad de Santiago de Compostela, Santiago de Compostela, Spain, 4Labaqua, Santiago de Compostela, Spain, 5Newcastle University, Newcastle, United Kingdom, 6McGraw-Hill University, Montreal, Canada

Background: The presence and versatility of gene transfer mechanisms in bacteria have shown antibiotic resistance genes (ARGs) do not respect phylogenetic, geographical or ecological borders, causing the use of antibiotics on one place, such as households, to impact the wider resistome, such as medical systems and the wider environment. Therefore, studying bacterial traits behind acquisition, expression, and spread of ARGs may be more important than studying ARGs themselves.

Materials/methods: Here we combined targeted sequencing of the clinical class 1 integron gene-cassette (clintI1) and qPCR to determine the i) relative abundance, ii) dynamics and iii) ARG-cassette diversity across a urban network in Spain, which includes two main hospitals [HP], community wastewater sources [only] [CM], and the wastewater treatment plant [WWTP] influent [INF], WWTP effluent [EFF], and recycled activated sludge [RAS] as well as water column and sediments upstream [RU and SRU] and downstream [RD and SRD] of the WWTP discharge point (Figure 1).

Results: Results show that clintI1 was much more abundant than other integrons in all urban wastewater compartments despite wide variations in their normalized abundances. Subsequent clintI1 gene-cassette sequencing showed much higher ARG diversity in hospital waste cassettes and much lower diversity in RAS and downstream river sediment cassettes [Figure 1]. clintI1 gene-cassettes were dominated by ARGs coding from aminoglycoside, β-lactam, and carbapenem inactivating enzymes, especially from hospital wastewaters samples [Figure 1]. These show that clintI1 may be an important evolutionary factor in increasing antimicrobial resistance in wastewater bacteria. However, the carriage of clintI1 varies widely across wastewater network compartments; greatest in hospital wastewaters and a lowest in RAS.

Conclusions: Overall, the higher abundance of clintI1 in hospital wastewater confirm that may be useful for assessing "risk" in wastewater releases, suggesting our data that the carriage of ARGs in the clintI1 correlates with antibiotic use. Furthermore, clintI1 has been identified as a key driver in the dissemination of emerging clinical ARGs from hospital wastes into the environment.

Figure 1: Clinical class 1 integron patterns across a wastewater network: i) Relative abundance [clintI1 per 1000 bacteria], ii) dynamics [relative abundance of empty-clintI1], and iii) ARG-cassette diversity (richness).

**Bacterial growth in antiseptics, disinfectants and soaps in a tertiary care hospital, Ouagadougou, Burkina Faso**

Palpougni Lompo*, Marjan Peeters†, Nadia Esther Ouédraogo*, Hervé Kafando*, Anne-Sophie Heroes‡, Saydou Yameogo*, Halidou Tinto*, Lassana Sangaré†, Jan Jacobs‡,§

1Nanoro Department, Clinical Research Unit of Nanoro, Nanoro Department, Burkina Faso, 2Katholieke Universiteit Leuven, Leuven, Belgium, 3Institute of Tropical Medicine Antwerp, Antwerp, Belgium, 4Université AUBE Nouvelle/Bobo Dioulasso, Bobo-Dioulasso, Burkina Faso, §Hospital Center Universitaire Yalgado Ouédraogo, Ouagadougou, Burkina Faso

**Background:** To assess the hospital environment as a reservoir of antimicrobial resistance (AMR), we sampled in-use soaps, disinfectants and antiseptics in a tertiary care hospital in Burkina Faso.

**Materials/methods:** In August-September 2019, liquid samples (6ml) were collected from in-use disinfectants and antiseptics in different hospital wards. Dispensers and bar soaps were swabbed with NRSII Transwabs (MedicalWire). 100 µl of each sample was inoculated in triplicate on Tryptic Soy Agar (TSA)+0.7%Lecithin (Difco) and MacConkey agar (Oxoid). Quantitative count was done from the TSA after 24 hours of incubation. Identification was done from Gram-negative colonies with Phoenix M50 equipment (Becton Dickinson).

**Results:** Out of 171 samples collected, 68 showed growth with Gram-negative bacteria (39.8%). Nine samples included growth of Enterobacteriaceae (including *Klebsiella pneumoniae* (n = 2) and *Enterobacter cloacae* (n = 5), of which all except one (460 CFU/ml), showed confluent growth, indicating heavy contamination. From most of the grown samples, two or more different bacterial species were isolated (40/68, 58.8%). Among a total of 133 isolates, the key organisms were *Shewanella putrefaciens* (n = 22, 16.5%), *Pseudomonas aeruginosa* (n = 14, 10.5%) and *Sphingomonas paucimobilis* (n = 13, 9.8%). Soaps were most frequently contaminated (45/75, 60%), followed by disinfectants (7/23, 30.4%), as shown in the table below. EB = Enterobacteriaceae, NF = Non-fermentative organism, Other species = *Moraxella* (n = 2), *Chromobacterium violaceum* (n = 2), *Pasteurella multocida* (n = 1), *Suttonella indologenes* (n = 1), *Aeromonas* sp. (n = 1).

**Conclusions:** Assessment of in-use antiseptics, disinfectants and soaps in different hospital wards in a tertiary care hospital in Burkina Faso showed high contamination rates, including the presence of possible pathogens. Further research will include AMR testing and molecular typing to compare these environmental with clinical isolates.

Abstract 9334

The first blood-stage controlled human malaria infection model in Europe for Plasmodium vivax vaccine efficacy testing

Angela Minassian*1, Yrene Themistocleous1, Sarah Silk1, Jordan Barrett1, Carolyn Nielsen1, Doris Quinkert1, Ian Poulton1, Fernando Ramos Lopez1, Celia Mitton1, Thomas Rawlinson1, Nick Edwards1, Katherine Ellis1, Megan Baker1, Raquel Lopez Ramon1, Jeessun Cho1, Susanne Hodgson1, Florian Bach2, Wiebke Nahrendorf2, Alison Lawrie1, Philip Spence3, Andrew Blagborough3, Iona Taylor3, Fay Nugent1, Kimberly Johnson1, Alison Kemp4, Julian Rayner4, Wanlapa Ro5, Jetsumon Prachumsri5, Sumi Biswas6, Simon Draper6

1University of Oxford, Jenner Institute, Oxford, United Kingdom, 2University of Edinburgh, School of Biological Sciences, Edinburgh, United Kingdom, 3Imperial College of Science, Technology and Medicine, Infection and Immunity Section, London, United Kingdom, 4University of Cambridge, Wellcome Sanger Institute, Cambridge, United Kingdom, 5Mahidol University, Bangkok, Mahidol Vivax Research Unit, Bangkok, Thailand

Background: Plasmodium vivax has been viewed for many decades as a "benign" parasite. However, current estimates suggest it accounts for 7.5 million malaria cases each year, among 2.5 billion people living at risk of infection, with a significant burden of morbidity and mortality. Unfortunately, efforts to control the parasite lag far behind those for its cousin, P. falciparum, largely because of critical bottlenecks in vaccine development. A key problem is limited access to P. vivax parasite inocula for use in a controlled human malaria infection (CHMI) model to provide an early indication of vaccine efficacy. To date, only groups in the Americas have performed sporozoite challenges in human volunteers and the only blood-stage challenges have been performed in Australia.

Materials/methods: In 2018/19, we undertook the first proof-of-concept studies in Europe of P. vivax CHMI (ClinicalTrials.gov Identifiers: NCT03377296 and NCT03797989), demonstrating we could safely infect two healthy UK adult volunteers with P. vivax by the bite of infected mosquitoes produced and transported from southern Thailand. We obtained 250mL of blood from the volunteers at threshold parasitaemia/clinical criteria, and generated a viable, sterile GMP-like bank of cryopreserved P. vivax-infected erythrocytes. We then tested the safety and feasibility of blood-stage infection at three dilutions of the inoculum in six malaria-naïve UK volunteers. This blood bank has since been utilised in a pilot safety and efficacy trial of the high priority blood-stage vaccine candidate P. vivax Duffy Binding Protein [ChAd63-MVA PvDBP_RII], in Oxford, September 2019 (N=5; NCT04009096).

Results: Infectivity of the blood bank was robust, with even the lowest 1:20 dilution resulting in blood-stage infection. All volunteers were diagnosed within 1-2-16 days of infection. Symptoms were mainly mild-moderate, compatible with clinical malaria, and all volunteers were safely managed as outpatients, completing a course of antimalarials. The pilot efficacy trial was successfully completed and data will be presented.

Conclusions: This human challenge model provides a key platform for progression of P. vivax malaria vaccine candidates to Phase Ila efficacy testing. The model has since been taken forward to a head-to-head comparison of two leading blood-stage P. vivax vaccine candidates, with challenge planned for April 2020.

Abstract 9337

Surgical site infections in orthopaedic surgery: a retrospective analysis of the risks associated with multi-drug resistant bacteria isolation

Margherita De Masi*1, Laura Campogiani1, Elisabetta Teti1, Vincenzo Malagnino1, Ludovica Ferrari2, Novella Cesta1, Arianna Di Marcantonio1, Pasquale Farsetti1, Umberto Tarantino1, Massimo Andreoni1, Loredana Sarmati1

1Università degli Studi di Roma “Tor Vergata”, Infectious Disease Unit, Department of Systems Medicine, Roma, Italy, 2Università degli Studi di Roma “Tor Vergata”, Department of Orthopaedic Surgery, Roma, Italy, 3Università degli Studi di Roma “Tor Vergata”, Department of Orthopaedics and Traumatology, Roma, Italy

Background: Surgical Site Infections (SSI) are a frequent complication of orthopaedic surgeries, that negatively impact on both morbidity and mortality of patients, causing prolonged hospitalizations and an increase of healthcare-associated costs.

Materials/methods: We conducted a retrospective monocentric study at Tor Vergata Hospital, Rome, between 2016 and 2018. Patients admitted to the Orthopaedic ward for at least 48 hours who underwent surgery were enrolled if they presented clinical signs of SSI and had at least one microbiological isolate collected intra-operatively or from the surgical wound. Clinical and microbiological data were analysed, together with data on duration of hospitalizations and infection impact on functional outcome up to 6 months after the diagnosis. Statistical analysis was performed using Pearson’s chi-square test for categorial variables and univariate and multivariate logistic regression.

Results: Among 2269 patients who underwent orthopaedic surgery, 83 (3.6%) developed a SSI: 40/83 (48%) patients developed osteomyelitis or prosthetic joint infection (PJI), 43/83 (52%) had a superficial or deep infection, without bone and joint involvement. Compared with the latter, PJI and osteomyelitis were more frequently associated with methicillin-resistant Staphylococcus aureus (MRSA) [7% (3/43) Vs 32.5% (13/40); p=0.003] and there was an increased trend of multidrug resistant (MDR) Gram-negative bacteria (GNB) isolation [18.5%(8/43) Vs 35%(14/40); p=0.09]. At univariate analysis, increased age [OR 1.04 (CI95% 1 - 1.07); p=0.013], cardiovascular comorbidities [OR 5.34 (CI 95%1.39-20.5); p=0.015], long-term care facility stay [OR 4.9 (CI95% 1.54-15.5); p=0.007] and longer hospital stay [OR 1.01 (CI95% 1-1.02); p=0.017] were associated with MRSA isolation, while at multivariate analysis only longer hospitalization showed a significant association [OR 1.01 (CI95% 1-1.02); p=0.039]. MDR-GNB isolation was associated with longer hospitalization, urinary and intravascular catheters use at univariate analysis, and only with longer hospitalization at multivariate analysis [OR 1.78 (CI95% 1.22-2.5); p=0.002]. More often patients with PJI and osteomyelitis had worse functional outcome compared to patients without bone involvements [16/40 (40%) Vs 4/43 (9%); p=0.001].

Conclusions: In our population MRSA and MDR-GNB often were associated with the development of PJIs and osteomyelitis. Screening measures and prevention strategies might be implemented accounting for patient specific risk factors, improving both short and long-term outcomes in orthopaedic patients.

Abstract 9339

**VIM-producing Pseudomonas aeruginosa isolated in Southern Tunisia, 2012-2018**  
Yosr Jellouli1, Nour Ben Ayed1, Basma Mnif1, Adnene Hammami1

1Laboratory of Microbiology, Habib Bourguiba University-Hospital, Sfax, Tunisia

**Background:** *Pseudomonas aeruginosa* (*P. aeruginosa*) is one of the major opportunistic pathogens implicated in serious nosocomial infections. The emergence of multidrug-resistant strains of *P. aeruginosa* is of global concern. A high number of carbapenemases were reported in *P. aeruginosa* isolates, they include mainly class B enzymes (metallo-β-lactamases).

The aim of this study was to determine the spread of VIM-producing *P. aeruginosa* in a Tunisian hospital between 2012-2018.

**Materials/methods:** Clinical isolates of ceftazidim and imipenem resistant *P. aeruginosa* obtained from patients hospitalized at a University Hospital in Sfax-Tunisia between 2012 and 2018 were included. Specific primers were used in PCR based assays to amplify metallo-β-lactamases encoding genes: *bla*VIM. O-serotyping was determined by slide agglutination test using O-specific anti-sera.

**Results:** During the study period, 504 non-repetitive strains of CAZ/IPM-R *P. aeruginosa* were isolated. 49% of these isolates were from patients hospitalized in Intensive Care Unit. CAZ/IPM-R *P. aeruginosa* was isolated mainly from respiratory samples (31%), pus (24%) and blood cultures (15.3%). The study focused on 352 strains that were conserved. PCR showed that 27.3% of isolates (96/352) harbored *bla*VIM gene. The frequency of acquiring this metallo-β-lactamases had increased since 2016 but this result is not statistically significant. PCR sequencing of the amplified fragments obtained from representative isolates revealed *bla*VIM-2. The serotype 012 (56.3%) and the serotype 011 (34.4%) were the most frequently identified in the VIM-producing isolates.

**Conclusions:** During the last years, *bla*VIM-2 became the most often reported acquired MBL genes in *P. aeruginosa* worldwide. In our hospital, the spread of VIM-2-producing *P. aeruginosa* clinical isolates is alarming and poses challenges for the treatment of hospital infections due to this species. Antimicrobial selection pressure could allow silent spread of these genes. A continued surveillance and a study of the epidemiological link between these strains should be adopted to limit their further dissemination.

**Presenter email address:** adnene.hammami@rms.tn
It takes two to tango: antimicrobial resistance and virulence contribute to the success of particular *Acinetobacter baumannii* clones

Filipa Grosso*1, Liliana Silva2, Carla Rodrigues3, Magdalena Ksiezarek1, Helena Ramos4, Luisa Maria Vieira Peixe1

1Porto, UCIBIO/REQUIMTE. Faculdade de Farmácia da Universidade do Porto, Porto, Portugal, 2UCIBIO/REQUIMTE. Laboratório de Microbiologia, Faculdade de Farmácia, Universidade do Porto, ESALD. Instituto Politécnico de Castelo Branco, Castelo Branco, Porto, Portugal, 3Biodiversity and Epidemiology of Bacterial Pathogens, Institut Pasteur, Paris, France, 4HGSA. Hospital Geral de Santa António, Porto, Portugal

**Background:** In our country, carbapenem-resistant *Ab* was associated with ST98, ST103, ST208 and, more recently ST218 (Oxford-scheme), with a dominant clone being usually associated with a particular period. These clonal shifts were primarily explained by an increased antimicrobial resistance (AMR) profile. In this study we aimed to explore genomic and biochemical differences among these clones that could further explain the *Ab* diversity and evolution that occurred in our hospitals in the last two decades.

**Materials/methods:** A total of 112 carbapenemase-producing-Ab isolates [ST98/OXA-40, ST103/OXA-58, ST208/OXA-23, ST218/OXA-23] were included. Isolates were initially characterized using FT-IR-ATR/PCA analysis. Representatives of different FTIR-ATR/MLST-clusters were randomly selected for WGS (n=12). WGS was performed with Illumina HiSeq (2x150bp), assembly with SPAdes 3.9.0, and annotation with Geneious R10. AMR genes and SNP analysis were determined by ResFinder and CSIPhylogeny tools-Center for Genomic and Epidemiology. SNP tree was visualized using iTOL. Virulence genes were identified with VFanalyzer tool-Virulence Factors Database.

**Results:** *Ab* clones evolution-ST103 (2001-2004), ST98 (2002-2006), ST208 (2006-2010) and ST218 (2010-2015) was consistently accompanied by an increase in AMR genes content: of note, transition to carbapenemases conferring higher carbapenem MICs, increasing number of aminoglycoside resistance genes (ST218-armA). Virulence factors enrichment was also observed: siderophores, adhesins, biofilm-associated factors, quorum-sensing and cytotoxic enzymes. Visual inspection of the phylogenetic tree was congruent with MLST. Overall, analyzed isolates presented 2-19300 SNPs. Within clusters, a smaller variation was observed within ST208 (2-5-SNPs), and larger within ST218 (9-131-SNPs). Among clones, a larger difference was observed between ST103 and ST218 (819300 SNPs), being lower between ST208 and ST218 (F1600 SNPs). FTIR-ATR clustering was congruent with MLST but, contrarily to SNP analysis, a higher relatedness was observed between ST98 and ST103, explained by the surface sugar composition extracted by WGS, associating both ST98 and ST103 capsules with fucosamine, ST208-capsule with pseudaminic acid and ST218-capsule with legionaminic acid that better resembles the siaic-acid from mammalian cells.

**Conclusions:** In this study, WGS together with FTIR-ATR-biochemical information allowed to describe the carbapenem-resistant *Ab* dynamics that occurred in our country, and also worldwide. This evolution was essentially promoted by consecutive virulence and AMR gene pool enlargement, together with pathogen-host adaptation.

**Presenter email address:** fgrosso@ff.up.pt
Abstract 9342

**Sepsis diagnosis: have we solved the riddle yet?**

Anusha Rohit1*, Akshay Dangari1, Mala Prasad4, Angel Jenifer1, Sureshkumar Dorairajan1, Collins Boahen2, Vinod Kumar2

1Hospital, The Madras Medical Mission, Chennai, India, 2University, Radboud University, Nijmegen, Netherlands

**Background:** Sepsis is a complex condition that has severely impacted mortality rates of patients in many countries. Diagnosis is equally complex and dependent on many factors for each test, especially in culture negative cases. We present data from an observational study of blood cultures received from 1139 patients suspected with sepsis over one year for factors which impact sepsis diagnosis such as volume of blood, contamination rates, site of draw, and biomarkers. The impact of these factors on positivity, relation with mortality and length of hospital stay was also studied.

**Materials/methods:** The Department of Microbiology received 2158 blood cultures from 1139 patients in 2018. Data such as time to positivity, volume of blood, site of draw, rate of contamination, immune markers like procalcitonin (PCT), WBC (white blood cell) count, polymorphonuclear leukocyte count, C reactive protein, lactate dehydrogenase, length of stay and mortality was collected from all 1139 patients. All data was analysed by programming language R.

**Results:** Of the 2158 cultures analysed, the blood cultures were positive in 383 bottles (17.8%). Gram-negative organisms were most commonly isolated in 61.7% cases and Gram-positive organisms in 33.1% (P < 0.01). We found a trend of association (P = 0.193) between adequate volume and higher rate of culture positivity (19.6% cases) compared to inadequate volume (16.5% cases).

We found a trend of association between positivity of the culture and the sites of blood drawn (P = 0.078). Samples were positive when cultures were drawn from the neck line in 50.8% cases, peripheral-arm in 23.6% cases and leg in 18.2% cases, 7.4% site not mentioned.

Culture positivity significantly correlated with increase in PCT (P=0.03). Similar results were seen with other biomarkers as well, albeit with less significance. Interestingly, in majority of the culture negative cases (ranged from 75% to 87%) we observed the higher levels of different biomarkers, particularly CRP and lactate dehydrogenase (Figure 1).

**Conclusions:** Our observational study in a large sepsis cohort highlights the importance of adequate blood volume and combination of biomarkers such as PCT, CRP, lactate dehydrogenase and polymorphonuclear leukocyte counts in improving the diagnosis of sepsis.

Abstract 9345

**What does the space-time dynamics of arboviral diseases epidemic in Curaçao tell us? Unravelling potential factors of disease persistence and spread**

Maria F. Vincenti-Gonzalez,*1 Yaskara Halabi2, Izzy Gerstenbluth2, Ashley Duits3, Alexander W. Friedrich1, María E. Grillet4, Adriana Tami2

1University Medical Center Groningen, Medical Microbiology and Infection Prevention department, Groningen, Netherlands, 2GGD, Epidemiology & Research Unit, Willemstad, Curacao, 3Red Cross Blood Bank Foundation, Willemstad, Curacao, 4Central University of Venezuela, Instituto de Ecología y Zoología Tropical. Laboratorio de Biología de Vectores y Parásitos, Caracas, Venezuela

**Background:** In the last 5 years, the Americas and Curaçao have witnessed major arbovirus epidemics. Dengue, chikungunya and Zika viruses are all transmitted by *Aedes aegypti* and currently co-circulate in Curacao island. To understand the behavior of these diseases and design tailored interventions for prevention and outbreak response, we characterized the spatiotemporal dynamics of the three arboviruses between 2014-2016 in Curacao. Additionally, we unraveled potential associated factors of disease dynamics through spatial analysis and fitting generalized linear models (GLM).

**Materials/methods:** Laboratory confirmed cases of dengue, chikungunya, and Zika obtained from the Ministry of Health in Curaçao were used for analysis. The spatial and temporal patterns of dengue occurrence were examined at Geozone level over a period of 3 years. Clusters of dengue, chikungunya and Zika cases and incidence in space and time were detected using Anselin’s Local Moran I. We quantified the persistence of these viruses as the maximum number of consecutive weeks reporting cases per Geozone. Finally, a GLM was applied to evaluate if the case spatial distribution depends on socio-demographic and climatic factors.

**Results:** From 2014 to 2016, nearly 5000 cases of dengue, chikungunya and Zika were reported. Significant space and space-time clusters (P<0.05) were primarily concentrated in urban areas and in smaller but densely populated areas, all situated around the central-east part of the island. Dengue, chikungunya and Zika persistence was greater in the same hotspot areas. Preliminary results show that number of households per Geozone, unemployment rate and non-active economic status were good predictors for arboviral diseases occurrence (AIC: 1026.1; P<0.001). Further analysis will be conducted using climatic data extracted from remote sensed data.

**Conclusions:** Our findings contribute to a better understanding of the spatial dynamics of arboviral diseases in Curaçao high-lighting the role of densely populated urban centers and crowded conditions in maintaining persistent dengue transmission and as sources of disease spread. An integrated approach of dengue prevention and control can inform targeted control measures maximizing the allocation of resources to high risk areas.

**Abstract 9346**

**Evolutionary insights of multidrug-resistant hypervirulent ST23 *Klebsiella pneumoniae* predominantly driven by ICEKp**

Chaitra Shankar*, Jobin John Jacob*, Kartthick Vasudevan*, Manigandan Venkatesan*, Shalini Anandan*, Veeraraghavan Balaji*

1Christian Medical College and Hospital, Vellore, India

**Background:** The emergence and global expansion of multidrug resistant (MDR) hypervirulent *Klebsiella pneumoniae* (hvKp) has been a cause of serious concern. Recently there are reports of MDR clones acquiring virulence plasmid and hvKp acquiring resistance. Despite this, the prevalence and evolution of hvKp at the national level is poorly understood in India. In this study we investigate the events that led to the evolution of two ST23 hypervirulent MDR Kp isolated from bacteremic patients by comparative genomics.

**Materials/methods:** Two MDR hypervirulent Kp isolates were subjected to whole genome sequencing and hybrid genome assembly using Ion Torrent and MinIon platforms. Genomes were analysed to determine the resistance and virulence genes and plasmids. The timed evolution of ST23 *K. pneumoniae* from India was estimated using Bayesian phylogenetic method BEAST v.1.10 with *K. pneumoniae* NTUH-K2044 as reference.

**Results:** The hybrid genome of both the isolates belonged to ST23 with K1 capsule type and O1v2 O antigen type. Both study isolates harboured seven putative distinct plasmids replicons in common namely IncA/C, IncFIB (pQil), IncFIB, IncX, ColRNAI, Col440II along with the virulence plasmid. Virulence plasmids of isolates were characterised by the presence of chloramphenicol resistance gene (*catA1*), possibly inserted through IS110 transposase. Both the study isolates were found to carry yersiniabactin locus ybt9 located in ICEKp3. Multiple MDR plasmids harbouring resistance genes encoding for β-lactamases, aminoglycoside modifying enzymes, fluoroquinolone resistance, sulfonamide resistance, trimethoprim resistance, and rifampicin resistance were present. Phylogenetic analysis based on Core genome SNPs showed the Indian MDR hvKp isolates formed a monophyletic cluster with reference strain. Two clades were formed and Indian isolates grouped with two oldest strains M109, NCTC9494; and NTUH-K2044. These were estimated to be evolved around 1872. Two MDR hvKp isolates along with another susceptible Indian isolate dated back 1959. Both genomes were submitted to NCBI with accession numbers CP035905-CP035912 and CP036190-CP036198.

**Conclusions:** Carbapenem resistant ST23 *K. pneumoniae* incidence is extremely challenging for infection control. Presence of *catA1* on virulence plasmid indicates the potential of other resistance genes being carried by virulence plasmid. Phylogenetic analysis shows that Indian MDR hvKp have evolved from susceptible global hvKp isolates.

**Fig. 1a:** Circular representation of chromosome of *K. pneumoniae* isolates BA4656 and BA35918 genome displayed using CG View server with reference genomes SGH10 and NTUH-2044. KV154505 is the reference used for ICEKp3. SGH10 and NTUH-2044 have ICEKp10 and ICEKp1 respectively. **Fig. 1b:** Comparison of virulence plasmid of hv K. pneumoniae isolates BA4656 and BA35918 with virulence plasmids from *K. pneumoniae* strains SGH10, NTUH-K2044, AP6555 and E225. The plasmid carried virulence genes including *mpa*, *mpal*, *pvi* and *psc* gene clusters along with heavy metal resistance encoding *lce* and *pco* gene clusters. *catA1*, coding for chloramphenicol resistance with IS110 was inserted in plasmids of BA4656 and BA35918.
Abstract 9350

A prolonged measles outbreak in a vaccine refusing community, Austria, 2019
Lukasz Henszel1,2, Daniela Schmid2, Andrea Grisold3, Heidemarie Holzmann4

1European Programme for Intervention Epidemiology Training (EPIET), European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden, 2The Austrian Agency for Health and Food Safety, Vienna, Austria, 3Medical University of Graz, Graz, Austria, 4Medical University of Vienna, Vienna, Austria

Background: In Austria, the population measles immunity is estimated to be below 95%. By 21 January 2019, Public Health authorities of two neighboring provinces reported 10 confirmed measles cases, which exceeded the expected number. The AGES conducted an investigation to identify further cases, assess vaccination status and recommend prevention measures.

Materials/methods: Probable cases were residents of province A or B, with clinical presentation of measles after 1 January 2019, and linked to a confirmed case with positive RNA virus detection. Descriptive epidemiology was performed. We collected data on age, rash onset, certificate-based vaccination status and reason for being unvaccinated by telephone interview. Contact history was used to identify chains of transmission.

Results: By 11 March 2019, we identified 47 cases (41 confirmed), 40 (85.1%) were unvaccinated. We identified transmission chains in two provinces, affecting communities with different attitudes towards vaccination. In province A, 35 cases with a median age of 7 years (IQR: 1-11) occurred between 09 January-20 February, belonging to one transmission chain with four case generations. In province B, between 10 January-01 March, we identified 12 cases belonging to five further, unlinked chains of transmission, each of which subsided after two generation (5 primary, 7 second generation cases, median age: 22 years, IQR: 11-35). Of the 31 vaccine-eligible cases of province A, 25 were unvaccinated, of which 13 were vaccine refusers. Of the 12 province B cases, none of the 11 unvaccinated had a vaccination-refusing attitude. Ring vaccination was hardly accepted in province A, where a prolonged measles outbreak occurred, in comparison to province B, where short-lived transmission chains were identified.

Conclusions: A prolonged measles outbreak in a vaccination-refusing community, compared to five short-lived transmission chains, concurrently occurring in the neighboring province, illustrates how vaccine refusal hampers control of transmission. We recommend information campaigns by the national health authority to increase knowledge and vaccine confidence in the Austrian vaccine-hesitant population-groups.

Abstract 9351

BCR1-independent biofilm formation of outbreak related Candida parapsilosis isolates from nosocomial bloodstream infections

Sulman Shafeeq*, Srisuda Pannanusorn, Joachim Morschhäuser, Ute Römling

1 Karolinska Institute, Department of Microbiology, Tumor and Cell Biology, Stockholm, Sweden, 2 Thammasat University, Department of Biotechnology, Faculty of Science and Technology, Bangkok, Thailand, 3 University of Würzburg, Institute for Molecular Infection Biology, Würzburg, Germany

Background: Candida parapsilosis is notable for its ability to form biofilms on medical devices and to be frequently associated with nosocomial outbreaks. A nosocomial outbreak of C. parapsilosis was reported from a hospital in Southern Sweden in 2006. Four patients admitted to the haematological ward had acquired bloodstream infections, associated with intravascular catheters, with the same strain of C. parapsilosis within a month.

Materials/methods: Crystal violet staining and the metabolic XTT assay were used to assess biofilm formation. The cell morphology was assessed by light and confocal laser scanning microscopy. The genome of a C. parapsilosis outbreak isolate, SMI828 [high spider like biofilm former] and in independent bloodstream isolate SMI416, which did not form biofilms, were whole-genome sequenced using PacBio technology. In the liquid phase, the high biofilm forming strain showed yeast cell aggregation, which we consider an early biofilm forming stage. RNA isolated was subjected to RNA sequencing performed by Illumina HiSeq 2500 with 2 x 125 reads. Construction of deletion mutants and complementation was performed by using the SAT1 flipping strategy.

Results: Robust high levels of biofilm formation with a complex biofilm structure consisting of macrocolonies with spider-like appearance composed of aggregated yeast cells and pseudohyphae was characteristic for all eight C. parapsilosis isolates from the outbreak on three different surfaces: silicone, thermanox and polystyrene. Taking SMI828 as an example, biofilm formation was independent of the biofilm regulator Bcr1. Whole genome sequencing of outbreak isolates indicated the presence of a chromosomal translocation compared to the reference strain CDC317. Transcriptome comparison of the outbreak isolate with no biofilm formers revealed altered expression of multiple genes and expression of selected genes was confirmed by qRT-PCR.

Conclusions: Our results indicate that BCR1 independent high biofilm formation is a characteristic feature of the isolates involved in a nosocomial outbreak of catheter related bloodstream infection with a biofilm-specific gene expression pattern. This finding has implications for the development of treatment strategies targeting attachment and biofilm formation.

Abstract 9353

Rapid identification of *Candida auris* from direct blood culture positive samples by MALDI-TOF MS from patients with *candidaemia* in a tertiary care hospital

Roungmei S. K. Marak*1, Seema Yadav1, Ajaikumar Dixit1

1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Rae Bareli Road, Lucknow, India

**Abstract third-party references:** Roungmei S K Marak

**Background:** *Candida auris* is a recently described agent of fungemia that poses a serious global health threat. *C. auris* is known to cause outbreaks in healthcare settings and notable for its antifungal resistance; often multidrug-resistant. *C. auris* is difficult to identify; polymerase chain reaction, DNA sequencing and MALDI-TOF MS can correctly identify it. Therefore, it is important to rapidly identify *C. auris* in a hospitalized patient and the healthcare facilities can take special precautions to prevent its spread. The study used of MALDI-TOF-MS as a rapid method of identification of *Candida auris* directly from positive blood cultures and analysed the associated risk factors.

**Materials/methods:** To identify the *Candida auris* from direct positive blood cultures by MALDI-TOF MS. A prospective study was conducted from February 2017 to June 2019 by taking 8 ml of positive blood cultures. After multiple washings and treating with triton X -100, it was directly subjected to the MALDI-TOF MS assay. The clinical data of candidemia cases due to *C. auris* infection were determined for significant associated risk factors.

**Results:** Of the 167 candidemia cases reported during the study, 31 (18.85%) were due to *C. auris*; being the 3rd most common species after *C. tropicalis* and *C. parapsilosis*. The age ranged from 4-day old neonate to 80 years old and there was female preponderance (*n* =18). MALDI-TOF MS was able to rapidly identify all *Candida auris* species on the same day when the blood culture was flagged positive thereby shortening the time for species identification by MALDI-TOF MS from culture. The underlying risk factors significantly associated with *C. auris* candidemia were diabetes mellitus, underlying respiratory illness, gastrointestinal surgery, prior antifungal exposure. Mortality was seen in 51.61%. All isolates were resistant to fluconazole (MIC ≥ 64µ/ml).

**Conclusions:** MALDI-TOF MS is a useful tool for rapid identification of *Candida auris* directly from positive blood culture. Identification of *C. auris* in a hospitalized patients can help the healthcare facilities in infection control measures and precautions to prevent its spread in the healthcare center.

Abstract 9355

**Adaptation and validation of a quantitative vanA/vanB PCR on a high-throughput PCR system**

Anna Both*,1, Laura Berneking1, Benjamin Berinson1, Holger Rohde1, Marc Lutgehetmann1

1University Medical Center Hamburg-Eppendorf, Institute of Medical Microbiology, Virology and Hygiene, Hamburg, Germany

**Abstract third-party references:** Consumables were provided by Roche Diagnostics

**Background:** Vancomycin resistant enterococci (VRE) are one of the leading causes of intensive care-related blood stream infections in Europe, with high mortality rates (20-50%). It is of paramount importance to determine risk factors for transmission and infection in VRE carriers. The bacterial load in enteral colonization may be associated with a higher probability of transmission and might play a role in facilitating infection. We established a quantitative vanA/vanB real time PCR assay on the open mode of the automated PCR system Cobas6800 (VRE-LDT) for screening and quantification directly from rectal swabs.

**Materials/methods:** We used a published vanA/vanB real time PCR assay (Fang et al. 2008), introduced 5’ acetylation to primer ends and optimized concentrations for the cobas PCR master. Limits of detection (LOD), (2 fold dilutions of strains ATCC 51299 (vanB) and SX6010 (vanA), n=20 repetitions per dilution) of the assay were determined using spiked modified Amies-Media. Inclusivity of the assay was tested on 50 vanB-positive strains and 27 vanA-positive strains (5x10^6 CFU/mL). Linear range was determined by dilution series (1:10). For clinical validation, we tested 176 rectal swabs (eSwab, Copan), which were positive with VRE by culture after broth enrichment.

**Results:** All isolates (n=77) from inclusivity testing were detected. LOD was 102 CFU/mL for vanA and 141 CFU/mL for vanB, while linear range determined in Amies-media went down to 650 CFU/mL for vanA (R²=0.998) and to 1100 CFU/mL for vanB (R²=0.998). Clinical validation: 153/176 enrichment culture positive samples (1 vanA, 171 vanB, 4 vanA/vanB) were detected by the VRE-LDT (22 invalid due to insufficient volume in swab, one false negative). Quantification in rectal swabs revealed a median VRE load of 4.6x10⁵ CFU/mL (range: 5x10⁷–<1.41 CFU/mL) in clinical specimens.

**Conclusions:** The newly validated quantitative VRE-LDT is a useful and sensitive tool for the detection and quantification of the vanA/vanB resistance determinant directly from rectal swabs. Sample volume requirements may be a concern in routine practice.

The new assay could be employed in investigating the role of VRE burden in transmission and infection establishment.

Abstract 9360

**Sepsis caused by Salmonella Paratyphi B variant producing a blaOXA-48 in a traveller patient**

Alizee Balandraud¹, Linda Hadjadj¹, Gregory Dubourg¹, Jean-Marc Rolain¹, Sophie Baron*¹

¹IHU, Marseille, France

**Background:** Whole genome sequencing is taking an increasingly important place in clinical microbiology. We describe here the case of a blaOXA-48 producing *Salmonella enterica* serovar paratyphi B variant Java sepsis in a traveler that was identified through sequencing. The patient, 27 year-old with no medical history consults for prolonged hyperthermia after visiting Australia, Hong Kong, Singapore, Uruguay, and United States. Blood culture turned positive for a *Salmonella enterica* OMA+ Vi+ producing an OXA-48. We used WGS to precisely identify the variant of this atypical isolate and to describe the environment of this blaOXA-48 gene.

**Materials/methods:** We performed a WGS using both MiSeq and MinION technologies. Assembly and annotation were performed using Spades and Arg-annot respectively. Identification of the species was done by rMLST ([https://pubmlst.org/rmlst/](https://pubmlst.org/rmlst/)) and DNA/DNA hybridization. The presence of the blaOXA-48 gene was confirmed using Abricate and we described in genomic environment.

**Results:** The genome of this isolate was assembled into a unique chromosome of 4.77 Mb length and 52.3 GC%. Interestingly the strain was identified as a *Salmonella enterica* serovar paratyphi B variant Java, corresponding to a ST86. Whereas the Vi agglutination test was positive, we did not find this toxin in the genome of this species that is not known to carry it in literature. We are currently confirming the test to better understand this discrepancy. The strain carried 3 plasmids, including a small Col156 plasmid of 7,999 bp carrying a blaOXA-48 gene. It also carries resistance a qnrB19 gene conferring resistance to fluoroquinolones but remain susceptible to ceftriaxone. We are currently comparing our genome with the other *S. paratyphi* B to try to identify the origin of the isolate and to know if this carbapenemase have already been found in a genome.

**Conclusions:** We describe the case of a sepsis caused by a *Salmonella* paratyphi B variant Java producing an OXA-48 carbapenemase. After a treatment by ceftriaxone IV during 10 days, the patient cured. This variant is known in literature to be multi-drug resistant but to our knowledge, this is the first description of a major Salmonella producing OXA-48.

Abstract 9361

**Sub-standard and falsified antibiotics: a systematic review**

Guillermo Zabala*, Konnie Bellingham1,2,3, Vayouly Vihamaly1,2,3, Phonepasith Boupha1,2,3, Kem Boutsamay1,2,3, Paul Newton1,2,3,4, Celine Cailliet1,2,5

1Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane, Laos, 2Infectious Diseases Data Observatory, Oxford, United Kingdom, 3Worldwide Antimalarial Resistance Network, Oxford, United Kingdom, 4University of Oxford, Oxford, United Kingdom, 5Worldwide Antimalarial Resistance Network, Vientiane, Laos

**Abstract third-party references:** Worldwide Antimalarial Resistance Network (WWARN), Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMWRU), Infectious Diseases Data Observatory (IDDO)

**Background:** Antimicrobial Resistance (AMR) is one of the greatest threats faced by humanity. Substandard and Falsified (SF) antibiotics are hypothesized to be a neglected contributing factor in the spread of AMR. Previous studies have estimated the global prevalence of SF medicines between 10 and 28%. The World Health Organization (WHO) reported an estimated modelled case fatality rate in the treatment of childhood pneumonia of 8,000 to 18,000 per 1% prevalence of SF antibiotics. The aim of this study is to review the global prevalence and distribution of SF antibiotics and the quality of the available evidence.

**Materials/methods:** We searched PubMed, Embase, Google and Google Scholar for publications studying antibiotic quality. Results were entered into the Infectious Diseases Data Observatory online medicines database. Publications reporting on the prevalence of SF antibiotics were considered for quantitative analysis. Those which had prevalence as a primary endpoint were assessed using the 26 items from the Medicines Quality Assessment Reporting Guidelines (MEDQUARG).

**Results:** From the 6,955 screened entries, 560 were relevant to antibiotic quality. Ninety-one (16.2%) were prevalence surveys that qualified for quantitative analysis. Publication years ranged from 1992 to 2019. The total number of antibiotic samples was 11,767. The median number of samples per survey was 46 (18-133). The median prevalence of poor-quality antibiotics was 20% (7.4-39%) but with important caveats for generalizability. Amoxicillin, ampicillin, tetracycline and ciprofloxacin were the most commonly surveyed antibiotics. No data were found for carbapenems, piperacillin, vancomycin and other antibiotics in the WHO “Reserve” group. MEDQUARG scores were assigned to 71 (78%) qualifying prevalence surveys. The median score was 11 (7-14) out of 26.

**Conclusions:** Our review raises concerns that SF antibiotics are widely spread with an alarming prevalence in Low-and-Middle-Income Countries (LMIC). The quality of the evidence is poor, and most studies are of small size, making aggregation of data and interpretation difficult. Urgent research is needed to assess the epidemiology and impact of SF antibiotics on human health and AMR.

Study of brain-derived neurotrophic factor gene expression in brain tissue of rat infected to acute and chronic toxoplasmosis: a study in animal model

Mohammad Fallah1, Mohammad Matini2, Amirhossein Maghsood2, Mohammadreza Arabestani3, Mehdi Shahbazi2

1University, Hamadan University of Medical Sciences, Hamadan, Iran, 2Hamadan University of Medical Sciences, Hamadan, Iran, 3University, Hamadan University of Medical Sciences School of Medicine, Department Microbiology, Hamadan, Iran

Background: Brain-derived neurotrophic factor is a protein encoded by a gene called BDNF. This protein promotes the development of the peripheral and central nervous system. Many evidence suggests that BDNF plays important roles in memory, learning, behavioral disorder, energy intake and energy metabolism. In some studies, infection with Toxoplasma has been shown to alter the level of BDNF in the brain.

The aim of this study was to determine the effect of acute and chronic infections of the dominant strain of Toxoplasma in Iran on the expression of BDNF gene expression in rat brain tissue.

Materials/methods: Sixty adult male Wistar albino rats (230-300 g) were allocated in to the six groups. Three groups inoculated by 200000 tachyzoite of T. gondii RH strain and three groups were controls without inoculation. After two, five and ten weeks, groups 1, 2 and 3 and their controls' brain removed.

In brief, total RNA from the brain was extracted using RNAX_Plus Cinnagen kit according to the manufacturer's instructions and then synthesized by cDNA synthesis kits (Fermentas Co). In the next step, primers designed for BDNF gene, as well as beta-actin gene, were used as a housekeeping gene for control and comparison in real time PCR reaction with cyber green fluorescence color

Results: Acute T. gondii infection can reduce the expression of T. gondii genes by 7.54 fold compared to the control group, which is significant statistically. There was no significant difference in the expression of the gene in the five week and ten week chronic infection groups compared to the control group.

Conclusions: The results of this study showed that acute infection with RH T. gondii can reduce the amount of BDNF expression in the rat brain, while chronic toxoplasmosis infection has no significant effect on BDNF gene expression. By performing microscopic examination and injection of brain suspension into mice, it was determined that the T. gondii RH strain was not able to produce cysts.

Key words: BDNF, gene expression, acute toxoplasmosis, chronic toxoplasmosis

Abstract 9364

Patient perceptions of antimicrobial resistance: are we getting the right messages across?
Jean Claude Doukrou Calsina1, Timothy David Planche1,2, Cristina Suarez1*

1St George’s, University of London, Institute for Infection and Immunity, London, United Kingdom, 2St George’s NHS Foundation Trust, Medical Microbiology, London, United Kingdom

Background: Patient perceptions of antimicrobial resistance (AMR) and its potential physical and psychological consequenc- es are extremely important in an era of increasing resistance. Patients colonised/infected with resistant Gram-negative organ- isms (rGNO) are at increased risk of death and prolonged hospital stay, require isolation in side rooms (SR), among others. There are no guidelines about how the issues around AMR should be discussed with patients. We aimed to assess the un- derstanding of inpatients about AMR, explore the quality of information given by the healthcare professionals (HCP) and the emotional impact associated with colonisation/infection by rGNO.

Materials/methods: Patients. Consecutive adult inpatients with colonisation/infection by rGNO (October 2017 - January 2018), identified using routine surveillance systems. For each case, a control of similar age on the same ward was selected.

Methods Semi-structured interview: combination of closed and open questions in five categories (knowledge of AMR, quality of information received from healthcare professionals (HCP), psychological impact, information preferences, open comments-feedback). The infection control advice had already been given routinely as per national and local recommendations, that did not change during the study period. Analysis: Descriptive analyses.

Results: 11 patients with rGNO and 15 controls were interviewed. The rGNO group were more likely to answer they had knowl- edge about AMR (83% vs 57%); only 6% showed a ‘good’ level of understanding. In the rGNO group, 58% of interviewees report- ed not been informed by HCP about AMR/rGNO; 58 % said they did not know they had rGNO; 27% recalled being told they needed to be in a SR but no-one recalled being told details about the isolation characteristics or expected duration. 56% of interviewees reported they would react negatively if told they were colonised with a resistant bacteria. Diagnostic disclosure preferences were: by a doctor (80%), in a private room (58%), be accompanied by relatives/friends (46%), be offered the choice to disclose to family/friends (23%).

Conclusions: An important proportion of patients with rGNO had sub-optimal understanding of antimicrobial resistance and its consequences, were not aware of their status and disclosed negative associated emotions. Communication to patients with rGNO can be improved.

"Tell me and I forget, involve me and I learn": citizen science for mosquito management in a Dutch Caribbean island

Maria F. Vincenti-Gonzalez*, Daan De Kort, Daan Haarsma, Rutger Haan, Quinten Van Der Leest, Boudewijn Sagel, Ashley Duits, Elwin Schoop, Meredith Kelie, Yaskara Halabi, Marieta Braks, Lanionel Tromp, Alexander W. Friedrich, María E. Grillet, Adriana Tami

1University Medical Center Groningen, Medical Microbiology and Infection Prevention Department, Groningen, Netherlands, 2University of Groningen, Groningen, Netherlands, 3Red Cross Blood Bank Foundation Curaçao, Willemstad, Curacao, 4GGD, Willemstad, Curacao, 5GGD, Epidemiology & Research Unit, Willemstad, Curacao, 6Rijksinstituut voor Volksgezondheid en Milieu (RIVM), Group Wildlife and Vector-borne zoonoses, Bilthoven, Netherlands, 7Central University of Venezuela, Instituto de Zoología y Ecología Tropical, Laboratorio de Biología de Vectores y Parásitos, Caracas, Venezuela

Background: Mosquito-borne diseases (MBD) such as dengue, chikungunya and Zika are expanding worldwide, becoming an increasing threat to public health. The three responsible viruses have been transmitted by yellow fever mosquito *Aedes aegypti* in Curaçao. There is need to improve the methods for surveillance and control of both mosquito and MBD. Monitoring of adult mosquitoes has proven more accurate to determine high-risk transmission areas than larva/pupa. Engaging citizens in surveillance and control efforts of MBD has been effective in the past, since scientific information is collected while MBD education and prevention objectives are achieved. Therefore, we aimed to determine the effectiveness of an economic do-it-yourself Sticky Gravid Ovitrap (SGO) as a new surveillance method for adult mosquitoes within a citizen science framework.

Materials/methods: A total of 104 households were recruited and two kind of ovitraps were deployed per household, for comparison purposes, a commercial ovitrap (BG-GAT) was paired to the SGO. Each household was visited once weekly to collect trapped mosquitoes for analysis. Additionally, a mosquito breeding site assessment was carried out. and vector immatures indices were calculated. Lastly, we applied a KAP questionnaire regarding mosquito and MBD prevention.

Results: The SGO trap index (number of traps positive for mosquitoes) varied between 4% to 20%, compared to 56-72% for BG-GAT traps. BG-GAT traps were 5.25 times more likely to trap mosquitoes than the SGO traps. However, to be able to quantify mosquito relative density, the deployment of 3 traps per house would be necessary. No significant association was found between *Aedes* immature stages indices and *Aedes* adult mosquito data (W=0.110, p>0.05). The majority of individuals interviewed were willing to participate on mosquito surveillance (86%), 90% of them reported that having a trap at home was not a nuisance while 70% would make use of an app for surveillance of mosquito and suitable breeding sites.

Conclusions: This potential adult mosquito surveillance method continues to be evaluated. Classic immature indices seem not to be related to adult mosquito population and therefore only loosely to disease risk. Citizen engagement could be a critical step to perform the integrated management of *Aedes aegypti* in Curacao.

Hybrid genome based approach for investigation of molecular basis of international high risk clone ST357

Pseudomonas aeruginosa circulating in India

Agila Kumari Pragasam1*, Jobin John Jacob1, Karthick Vasudevan1, Vignesh Narasiman1, Shalini Anandan1, Veeraraghavan Balaji1

1Christian Medical College, Vellore, India

Background: Pseudomonas aeruginosa is a common nosocomial pathogen causing opportunistic infections. Carbapenem resistant P. aeruginosa have been frequently isolated from several hospitals worldwide and are denominated as high-risk clones (HRC). In India, international HRC ST357 seemed endemic, however there is a lack of whole genome-based studies. We performed whole genome sequencing (WGS) and hybrid genome assembly approach for improved genomic analysis.

Materials/methods: A total of 9 carbapenem resistant P. aeruginosa belonging to ST357 isolated from blood and respiratory tract infections were chosen. WGS was done by both short read (Ion-Torrent) and long read (Oxford Nanopore Technology-Minion) technologies. An in house developed de-novo hybrid assembly based approach was employed to combine short and long reads to achieve more accurate genomic information. The genomes have been deposited in the GenBank under the accession no’s: CP032569, CP033432, CP034368, CP034434-36, CP034409, CP034369, CP033439. Genomes were analyzed for antimicrobial resistance, virulence/pathogenicity, mobile genetic elements and phylogenetic evolution.

Results: De novo hybrid assembly of P. aeruginosa genomes using short and long read has yielded a complete circular chromosome of all the study isolates. Extra chromosomal elements such as plasmids were not observed. In the molecular phylogeny, ST357 being the only HRC belonging to Group 2 cluster, whereas the previously well-characterized international HRCs ST244, ST111, ST664, ST125, ST233 and ST235 were found within the large Group 1 cluster (Figure-1). Isolates harbored AMR genes against 10 classes of anti-pseudomonalas with >15 AMR genes present in each genomes. blaNDM was present in five of the isolates (2 blood and 3 respiratory), with three of the respiratory isolates harboring two copies of blaNDM-1 and one with blaNDM-1+blaNDM-11. Seven different extra chromosomal regions integrated into the genomes were observed in seven isolates. Presence of novel MDR-transposon Tn6649 and five novel integrons In1615-16, and In1622-24 carrying AMR genes have also been found.

Conclusions: Hybrid genome assembly based approach provides a complete and closed chromosomal genome sequence for a GC-rich challenging organism like P. aeruginosa. HRC ST357 harbors multiple drug resistant markers, favoring its survival in the hospital environment, thereby causing nosocomial spread. This approach can be employed for future genomic analysis of P. aeruginosa.

Figure 1: Maximum likelihood phylogenetic tree of 700 P. aeruginosa genomes derived using SNIPPY. Bolded branches (Red) indicates this study isolates

Multidrug-resistant *Klebsiella pneumoniae* ST231: the new endemic super bug of India?

Chaitra Shankar*, Jobin John Jacob1, Karthick Vasudevan1, Baby S. Abirami1, Shalini Anandan1, Veeraraghavan Balaji1

1Christian Medical College and Hospital, Vellore, India

**Background:** Among the carbapenem resistant *K. pneumoniae* (Kp), ST258 is the KPC epidemic clone prevalent in Europe and America while in India, endemic to NDM and OXA48-like carbapenemases, there is lack of data on prevailing genotypes. Previous study from our centre showed that Kp belonging to ST231 was the predominant genotype among susceptible, carbapenem resistant and colistin resistant isolates from various centres across India. Hence in the present study, two ST231 Kp were characterised by whole genome sequencing (WGS).

**Materials/methods:** A total of 37 ST231 isolates were obtained from six Indian centres. Two representative isolates were subjected to WGS using Ion Torrent and MinIon platforms and hybrid assemblies were generated. Antimicrobial resistance genes, virulence characters and plasmids were studied. Phylogenetic tree was constructed using core genome SNPs along with global ST231 Kp isolates.

**Results:** Both the isolates were extensively drug resistant (XDR); one being susceptible to colistin while the other being resistant. Colistin resistance was chromosomally mediated. Both hybrid genomes belonged to K51 and O1v2. Yersiniabactin locus ybt14 was carried on chromosomal ICEKp5. None of the ST231 Kp studied was hypervirulent. Interestingly, IncL/M plasmid known to carry *bla*OXA-48 like was absent. Chromosomal integration of two copies of *bla*CTX-M-15 in both isolates was associated with ISEc9 transposase. Chromosomal virulence genes encoding for iron uptake and biofilm formation were also present.

**Table 1:** Results of hybrid genomes of two ST231 *K. pneumoniae*

**Conclusions:** ST231 is the predominant genotype circulating among carbapenem and colistin resistant *K. pneumoniae* in India. They are predominantly-blaoxa-232 carriers harboured on ColKP3 plasmid and are responsible for increase in OXA48-like carbapenemases in India. This genotype has the potential of thriving in hospital environments and poses the threat of acquiring virulence plasmid. Containment of this genotype is of utmost importance in order to prevent it from emerging as hypervirulent XDR *K. pneumoniae*.

**Presenter email address:** chaitra.strings@gmail.com
Abstract: Current multiple sclerosis (MS) treatments consist of immunomodulatory agents, immunosuppressants or selective immunosuppressants and could impact on immune system. These disease-modifying therapies (DMTs) may result in high risk of opportunistic infections including TB, mainly related to the reactivation of latent TB infection (LTBI). Approximately two billion people worldwide are infected with Mycobacterium tuberculosis and about one in 10 will develop tuberculosis (TB) at some point of their lives.

Materials/methods: At the Neuroinfectious Unit of Policlinico Umberto I (Rome), a TB screening by QuantiFERON®-TB Gold In-Tube (QFT-GIT) for MS patients candidate for DMTs was carried out. Following screening, LTBI diagnosis was based on medical history, physical examination, and exclusion of active TB disease by chest X-ray (if necessary, sputum smear microscopy, sputum culture and Mycobacterium tuberculosis PCR testing). Before started DMTs, each patient diagnosed with LTBI was undergone to TB prophylaxis with isoniazid plus rifampin for three months.

Results: One hundred and nine MS patients (56 females, 53 males) with a median age [interquartile range (IQR)] of 48.5 (39.7-55.2), median years of disease (IQR) of 9 (3-17.7) and median Expanded Disability Status Scale (IQR) of 4 (2-6), were enrolled. The 5.5% (6/109) of the patients enrolled was from Romania, the 0.9% (1/109) from Argentina, the 0.9% from Asia (1/109) and the 92.6% (101/109) from Italy. At baseline, the 7.3% (8/109, two from Romania and six from Italy) of MS patients showed QFT-GIT positivity. Active TB was excluded and DMTs was started at least one month after TB prophylaxis. To date, four patients are at six months of ocrelizumab (anti-CD20 monoclonal antibody) treatment, two patients at seven months of teriflunomide (oral DMT immunomodulator) treatment, one patient at five months of dimethyl fumarate (oral DMT immunomodulator) treatment. No TB reactivation was observed.

Conclusions: The TB screening in MS patients candidate to DMTs must be considered standard care as part of disease management. The use of two active molecules on TB allowed an earlier starting of DMTs avoiding a possible TB reactivation. Furthermore, LTBI management in MS patients could contribute to reduce the transmission, morbidity, and mortality of active disease in global population.

Abstract 9377

Discontinuation of antimicrobial therapy during fever of unknown origin in adult neutropenic patients according to ECIL-4 criteria: RELAPS, a descriptive cohort study

Raphael Paret*1, Amandine Lebourgeois1, Pierre Peterlin1, Thomas Gastinne1, Rose Anne LaVergne1, Florent Morio1, Deschanvres Colin1, Raphael Lecomte1, Steven Legouill2, David Boutoille1, Benjamin Gaborit1

1Hôtel-Dieu University Hospital, Infectious Diseases Department, Nantes, France, 2Hôtel-Dieu University Hospital, Hematology department, Nantes, France, 3Hôtel-Dieu University Hospital, Parasitology and mycology laboratory, Nantes, France

Background: In neutropenic patients with fever of unknown origin [FUO], discontinuation of antibiotics recommended according to ECIL-4 criteria, 2011. However, data concerning the risk of febrile recurrence are limited. The objective of our study was to analyse risk factors and morbidity-mortality of febrile recurrences after antibiotics discontinuation in this population.

Materials/methods: We prospectively enrolled all neutropenic patients with FUO admitted to a French teaching hospital between February 2018 and September 2019 for which a discontinuation of antibiotics, according to ECIL-4 criteria, has been achieved. Medical records were reviewed retrospectively: underlying disease, duration of aplasia, recurrence rate, bacterial documentation, severity to assess risk factors for febrile recurrence. Risk factors of recurrence were compared using Cox regression analysis.

Results: A total of 86 patients corresponded to 92 cases were enrolled. Underlying diseases were mainly acute leukemias (58%; 50/86) and lymphomas (8%; 7/86). Neutropenia was due to allograft (47%; 44/92), autograft (9%; 8/92) and induction (35%; 32/92). Recurrence fever was observed in 57% of cases (52/92) and a bacterial documentation was obtained for 52% (27/52) of them. 67% (n=18/27) of documented recurrence fever were not covered by first line empirical antibiotic therapy (9 Enterococcus spp, 4 Staphylococcus spp, 3 anaerobes, 2 BLSE and one candidemia). On average 7 [0;25] days of antibiotics were spared for each neutropenic episode. No sepsis shock or sepsis-related mortality was reported due to antibiotic discontinuation. Median time of aplasia was significantly lower in the no recurrence subgroup compared to the recurrence subgroup (16 days vs 21 days respectively, p<0.001). On multivariable analysis, risk factors identified for fever recurrence were the presence of colitis [hazard ratio [HR] 3.1; 95 IC [1.3-7.6]; p=0.015], mucositis [HR 3.2; 95 IC 1.7-6.2; p<0.001] and lymphoma as underlying disease [HR 3.7 [1.6-9.0]; p<0.01]. The initial duration of antibiotic therapy did not influence the risk of recurrence [HR 1.0 [0.9-1.1]; p=0.5].

Conclusions: Discontinuation of antibiotic therapy during neutropenia did not appear to induce a higher morbidity-mortality rate. Febrile recurrences were correlated with a longer duration of neutropenia, the presence of colitis, or mucositis and lymphoma.

Incidence, risk factors and outcome determinants of healthcare-associated blood stream infection at a neonatal intensive care unit in North India

Karnika Saigal1*, Adheeti K Achuthan1, Arnab Ghosh1, Mamta Jajoo1

1Delhi, Chacha Nehru Bal Chikitsalya, Delhi, India

Background: Bloodstream infection (BSI) is one of the most common causes of nosocomial infection in neonatal intensive care units (NICU). In low-middle income countries, laboratory confirmed BSI (LCBI) rates are two to three times higher than those of high-income countries, which makes HA surveillance in the intensive care unit (ICU) essential for infection control. Aim of the present was to.

Materials/methods: Active surveillance to determine the incidence, risk factors, outcome determinants and antibiotic pre-scription practices of LCBI s (as per CDC) in a level 2 NICU was carried out over a period of 4 years from 2016-2019. A pre-designed questionnaire containing risk factors associated with LCBI s was filled under supervision of nursing staff involved in multifaceted infection prevention plan.

Results: Over the study period 65 episodes of LCBI were identified. Cumulative incidence of LCBI was 2.71 neonates per 1000 patient days with incidence density of 3.4, 3.17, 1.21 and 3.05 for the year 2016, 2017, 2018 and 2019 respectively. Incidence of LCBI in neonates with weight less than 750 gm was 24.02 per 1000 patient days. Independent risk factors for LCBI were: preterm neonates, extremely low birth weight neonates (p<0.01), duration of NICU stay more than 14 days, premature rupture of membrane in mothers, neonate born through meconium-stained amniotic fluid, endotracheal intubation, prior hospitalization and surgical intervention after the birth. Major pathogens causing LCBI were Candida species (43.1%), Acinetobacter baumannii (29.2%), Klebsiella pneumoniae (21.5%) and Escherichia coli (6.2%). LCBI was associated with a mortality rate of 21.54% (14 out of 65). LCBI due to MDR GNB resulted in dose dispensed of 200 per 1000 patient days for Colistin and 450 per 1000 patient days for Meropenem.

Conclusions: The results of our study can be used to identify high-risk neonates for LCBI in resource-constrained settings and highlights the need for strengthening risk-targeted surveillance for LCBI in neonatal ICUs. The results of the present study can be used to design and implement an antibiotic stewardship policy and introduce interventions to reduce LCBI.

Background: Identification and antibiotic susceptibility testing of microorganisms isolated from blood cultures (BC) are crucial for early and effective treatment of patients with blood stream infections (BSI). Karolinska University Laboratory (KUL) handles more than 100,000 referrals for blood culturing every year. Approximately 98% originate from four of the largest tertiary care hospitals in the region: Karolinska University Hospital in Solna and Huddinge, Danderyd Hospital, and South Hospital. Previously we reported negative effects of long transport time on time to detection of microorganisms from BC, emphasizing the need to place BC systems units closer to patients.

Materials/methods: During 2017 a collaboration between Clinical Microbiology, Laboratories for community care and pre-analyses and Clinical Chemistry-KUL 24/7 was initiated, aiming at shortening turn-around-times (TAT). We hypothesized that by placing a semi-automated blood culture system (Bact/ALERT VirtuO/Myla, BioMérieux) at hospital laboratories with 24-h service, time from sampling to incubation would significantly shorten. Positive BC bottles are transported to Clinical Microbiology for further analyses, and we hypothesized shorter TAT from sampling to preliminary microscopy-based results.

Results: In 2018 relocation of BC systems were initiated, with deployment in each of the four hospitals in intervals. In September 2019 a total of 10 units had been deployed at 24/7 laboratories. Statistical analyses based on a total of 49,096 BC bottles show, as expected, an improvement with on average 90% (from 5.7 h to 0.6 h median time) in TAT for sampling to incubation, compared to 50,031 BC bottles from the same time period a year prior to relocation. Analyses of 5,976 positive bottles within the cohort show an improvement of 8.7 h (27%) in median time to preliminary results (compared to 5,996 the year before). Further, we observed a positive effect in distribution of positive bottles over a 24-h period, with a larger portion of positive bottles determined positive during regular opening hours for Clinical Microbiology.

Conclusions: The relocation of blood culture units to laboratories with 24/7 service have significantly improved TAT for blood cultures in Clinical Microbiology, without any adjustment in laboratory opening hours. Further improvements could be possible with further optimization of transports and work-flows.

Abstract 9384

Development of attenuated bovine herpesvirus 4 as a safe, inexpensive, single-dose vaccine to control Streptococcus suis infection in domestic pigs

Katie Sealey*

1Plymouth University, Plymouth, United Kingdom

Background: Streptococcus suis is a worldwide pathogen of pigs, causing meningitis and septicaemia. S. suis represents a major problem for the swine industry. There are currently no commercial vaccines that are protective against all 35 S. suis serotypes. Consequently, antibiotic usage is extremely high in pig farming, which has contributed to antimicrobial resistance (AMR) in both pig and human isolates. S. suis is also a rapidly emerging zoonotic pathogen.

A vaccine against S. suis would significantly reduce antibiotic use in the swine industry, thereby helping control AMR. Bovine herpesvirus 4 (BoHV-4) is a new vaccine vector platform capable of inducing high levels of immunity in livestock species, potentially representing an effective and inexpensive means of control.

Materials/methods: Previously identified protective antigens from S. suis, Sly and 38kDa, were cloned into the BovH-4 vector followed by genetic characterization. Restriction enzyme digestion followed by electrophoresis showed maintenance of genome integrity. PCR using primers flanking the site of insertion of the S. suis genes within the BoHV-4 genome combined with Sanger sequencing showed preservation of S. suis gene sequence.

Results: Following this extensive in vitro characterization, vaccine vectors were reconstituted in bovine cells and vectors were shown to express Sly and 38kDa antigens by western blot. Virus stocks have been prepared and will shortly be tested for immunogenicity and efficacy in rodents and pigs. Additional novel S. suis antigens have been identified using the Reverse Vaccinology pipeline Vaxign. Novel B cell epitopes in both known and novel immunogenic antigens were identified using BepiPred, ABCPred and BCEPred. Conservation of epitopes across species was identified using MEGAX software. These novel second generation epitopes will be inserted into the BoHV-4 for immunological and efficacy testing.

Conclusions: BoHV-4 is a new vector platform suitable for targeting important bacterial pathogens such as S. suis in livestock. Identification of immunogenic peptides by reverse vaccinology approaches is a potentially promising approach to identify additional antigens from these bacteria that may be targeted to interrupt AMR acquisition in livestock species.

CRISPR typing of *Salmonella enterica* serovar Typhimurium from clinical and non-clinical sources reveals the possible transmission from environment to humans

Jobin John Jacob*, Karthick Vasudevan1, Manigandan Venkatesan2, Shalini Anandan1, Veeraraghavan Balaji1

1Christian Medical College, Vellore, India

**Background:** *Salmonella Typhimurium* is one of the most common serotypes identified among Non-Typhoidal *Salmonella* (NTS). Traditional serotyping based on the phenotypic variation of O- and H-antigen is the gold-standard for the identification and classification of *Salmonella* isolates. Global evolution of distinct genotypes of *S. Typhimurium* led to frequent discrepancies when identified by conventional methods. High resolution molecular techniques such as Multi Locus Sequence Typing (MLST) & Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) typing can be alternative for classical methods. This study is an attempt to characterize *S. Typhimurium* clinical isolates using MLST and CRISPR typing and compare with non-clinical isolates to identify the potential transmission from environment to humans.

**Materials/methods:** *S. Typhimurium* clinical isolates (*n=50*) were identified and classified based on conventional serotyping (Kauffmann–White scheme) and biochemical tests. MLST and CRISPR typing were performed to accurately identify the NTS serovars and to identify the genetic relationships among clinical and non-clinical *S. Typhimurium* in India. Serotypes and subtypes were assigned based on MLST and CRISPR typing and compared with the phenotypic results. The phylogenetic relationship between isolates from different sources was demonstrated in MLST based Maximum Likelihood (ML) phylogenetic tree.

**Results:** Among *S. Typhimurium* ST36 (50%) found to be the predominant sequence type followed by ST19 (42%) and ST31 3 (8%). CRISPR types of all the clinical isolates were distributed according to the STs and no clonal distribution was observed within STs. Although CRISPR types on non-clinical isolates revealed subtypes within ST19 and ST36, similar clones were present in both study sources. MLST based phylogenetic tree revealed the relationships among strains from different sources and potential transmission from environmental to humans.

**Conclusions:** Mismatches occurred in serovar designation between MLST/CRISPR database and serotyping due to the misinterpretation of the antigenic structures. Presence of similar CRISPR types in clinical and non-clinical sources revealed potential transmission from environmental to humans. CRISPR Subtyping is a powerful tool to track the *Salmonella* transmission between humans, animals and plants (One Health Concept).

Abstract 9389

An optimised strategy for linkage to care of patients newly diagnosed of active hepatitis C infection

Ana Fuentes*, Fernando García García, Elena Ruiz, Francisca Sousa, Federico García García

1Hospital Universitario Clínico San Cecilio, Granada, Spain

Background: Spain is on-track for hepatitis C elimination and is expected to reach WHO elimination goals by 2024. However, special efforts must be made to avoid diagnostic burn-out and to find all patients that may be diagnosed, treated and cured. We have been actively working on reflex testing (HCV antibody and, when positive, viremia detection on the same sample) in the last years. We have also found from previous evaluations that in addition to reflex testing, active communication strategies for effective linkage to care are also necessary. Here we present a novel communication strategy that has increased the number of patients that have access to treatment and cure.

Materials/methods: we have performed a pilot, prospective study in which all patients diagnosed in our laboratory of chronic hepatitis C active infection, were candidates for a direct medical appointment at our hospital for treatment evaluation. We have analyzed: a) number of patients that have attended the medical appointment, b) time since diagnosis to medical appointment, c) number of patients that have started treatment, and d) time since diagnosis to treatment initiation.

Results: during the study period (January-September 2019), 33 patients have been diagnosed of chronic active infection in our laboratory. Mean age was 59, and 67% were male. Mean core antigen levels were 3184 fmol/L [1112.04-6154.41], and genotype distribution was as follows: 21.2% 1a, 42.4% 1b, 9.1% 2, 6.1% 3, and 9.1% 3a (12.1% without assigned genotype). Mean fibrosis score was 8.3 kpa. As of the end of September, 94% of the patients have attended their medical appointment. After treatment evaluation, three patients were not eligible (over 95 years of age, multiple comorbidities). Time since diagnosis to medical appointment was 13 days [7.5-19] for the pre-summer period, and 25.5 days for the summer period [20.5-37.25]. All patients that started treatment were on the first appointment. Treatment was started with Sofosbuvir/Velpatasvir 12 weeks [n=6], or Glecaprevir/Pibrentasvir B/12 weeks [n=15].

Conclusions: direct medical appointment strategies have shown a great success on linkage to care and hepatitis C treatment initiation. In addition, a reduction on time since diagnosis to treatment has also been achieved.

Abstract 9390

**Update on Candida auris in Russia**

Natalia Barantsevich*, Olga Orlova1, Larisa Ivanova1, Irina Churkina1, Yuri Belsky1, Shkoda Andrey2, Antonina Vetokhina3, Elena Barantsevich1

1Almazov National Medical Research Centre, Saint Petersburg, Russian Federation, 2Vorahobov’s City Clinical Hospital № 67, Moscow, Russian Federation

**Background:** Candida auris is currently considered one of the top threats in public health as it is capable to cause outbreaks in hospitals and tends to survive for a long time in hospital environment. The aim of the present study was surveillance of C. auris infections in Russia and evaluation of the pathogenicity of strains with different morphology of colonies.

**Materials/methods:** C. auris was isolated from patients samples with Sabouraud dextrose agar (Oxoid, UK) and chromogenic agar (Liofilchem, Italy). The identification was performed with MALDI-TOF mass spectrometry (Bruker Daltonics, USA). Study of isolates included sequencing of ITS and D1-D2 regions as well as ERG11 gene (ABI 3130, USA). Susceptibility to antifungal preparations was assayed with Sensititre panels (Thermo Fisher Scientific, USA). Pathogenicity of C. auris strains, isolated from patients, was studied in a murine model without previous immunosuppression.

**Results:** 97 strains of C. auris were isolated in 3 regions of Russia. All studied strains clustered with isolates of Indo-Pakistan origin, demonstrated K143R mutation in ERG11 gene, typical to South Asian clade, and had high level resistance to fluconazole. Susceptibility to amphotericin B and other azoles was variable. Most isolates were susceptible to echinocandins.

Experimental studies of 2 types of C. auris strains that differed in the size of colonies in murine model showed low pathogenicity of both. During 5-weeks of observation all mice demonstrated no signs of systemic infection. The fungus was isolated from blood vessel and renal tissue in 2 (12.5%) mice at the end of follow up period.

**Conclusions:**

1. C. auris strains, belonging to South Asian clade, are being isolated from patients in different regions of Russia.
2. C. auris strains demonstrate high level resistance to fluconazole and variable resistance to amphotericin B and other azoles. Most strains are susceptible to echinocandins.
3. C. auris showed low pathogenicity in murine model without immunosuppression, though was able to persist in blood vessel and renal tissue of few mice.

The concordances of genotypic and phenotypic drug susceptibility testing of Mycobacterium tuberculosis isolates from MDR TB patients

Ciobanu Nelly,1 Sofia Alexandru2, Alexandru Codreanu3, Nadejda Turcan3, Ecaterina Noroc3, Valentina Vilc3, Anna Donica3, Elena Chesov4, Dumitru Chesov5, Valeriu Crudu6

1Institute of Phthisiopneumology “Chiril Draganiuc”, Chisinau, Moldova, 2Institute of Phthisiopneumology “Chiril Draganiuc”, Chisinau, Moldova, 3Institute of Phthisiopneumology “Chiril Draganiuc”, Chisinau, Moldova, 4State University of Medicine and Pharmacy “Nicolae Testemitanu”, Chisinau, Moldova, 5State University of Medicine and Pharmacy “Nicolae Testemitanu”, Chisinau, Moldova, 6State University of Medicine and Pharmacy “Nicolae Testemitanu”, Institute of Phthisiopneumology “Chiril Draganiuc”, Chisinau, Moldova

Background: Antimicrobial resistance is one of the most important threats of global tuberculosis control. Rapid and accurate detection of resistance to either Rifampicin or Isoniazid is crucial for selection of treatment regimens. Genotypic drug susceptibility testing (gDST) and phenotypic drug susceptibility testing (pDST) results must be considered collectively to reach a final interpretation of drug resistance.

Aim: to evaluate the concordances of the pattern of mutations of gDST and the level of drug resistance for RMP and INH of the isolates from MDRTB patients for rapid and reliable correction of treatment schemes.

Materials/methods: In study were included 6952 patients with new and previously treated pulmonary TB, examined during 2014-2018 years. From these 57.1% were positive by microscopy, 66.2% by GeneXpert and 69.98% by culture method. The pDST results of 4865 M.tb strains of MGIT960 method, were correlated with the gDST results of MTBDRplusv.2. The mutation types in the rpoB gene, and the presence of inhA mutation in the same M.tb isolates was correlated correspondingly with the different level of MIC for Rifampicin and Isoniazid of individual strains, assessed by MGIT 960.

Results: From 157 M.tb isolates with presence of inhA mutations only (INH low resistance), in 31% of cases these strains were susceptible on higher MIC demonstrated by pDST. From 114 M.tb isolates with genotypic RIF resistance without S531 and H526 mutations, and/or without wild genes, the pDST demonstrated that 28.8% of these strains were susceptible on higher MIC.

Discussion: The patients with low-level genotypic resistance should have additionally information about the level of phenotypic resistance. For reliable DST results, phenotypic and genotypic methods should be used in parallel, to be phased in without loss of existing solid culture and DST capacity.

Conclusions: pDST is still required, for corrective of rapid gDST results, in special from smear-negative specimens for detect XDR-TB. Different levels of phenotypic resistance could take into account in the procedures used by pDST of M.tuberculosis.

Abstract 9395

Global spread of poultry-associated *Campylobacter jejuni* genotypes to the Peruvian Amazon

Ben Pascoe*1, Margaret Kosek2, Samuel K. Sheppard1

1University of Bath, The Milner Centre for Evolution, Bath, United Kingdom, 2Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

**Background:** *Campylobacter* is the leading bacterial cause of gastroenteritis worldwide and incidence is high in low- to middle-income countries. Disease epidemiology is different to that of the developed world, where infection is mostly associated with consumption of contaminated meat products. Infection is endemic among young children and asymptomatic carriage is thought to be common. Widespread malnutrition encourages asymptomatic colonization and is associated with deficits in early childhood growth, leading to poor cognitive and physical development.

**Materials/methods:** In this study, we sequence and characterize an archived collection of *Campylobacter jejuni* isolates (n=62) from children enrolled in the Peruvian cohort of the MAL-ED study.

**Results:** In combination with disease severity scores determined from detailed symptom records, we identify the genotypes involved in disease. Epidemiological differences in disease presentation were reflected in the genomes, specifically by the absence of common global disease lineages, including the host generalist ST21 and ST45 clonal complexes. Despite this, our Peruvian collection was more diverse than a representative global collection of genomes and many local disease cases were attributed to rare STs, not commonly isolated from other countries or reservoir sources. Phylogenetic analysis could not discriminate symptomatic and asymptomatic isolates, suggesting that asymptomatic carriage is not restricted to specific ecological groups or clonal complexes. Using probabilistic source attribution methods, we identify chicken as the primary source of infection in 78.4% of the isolates, which is significantly higher than previous attribution studies in developed countries.

**Conclusions:** A better understanding of the genotypes underlying differences in disease epidemiology will support work to improve infant health globally and guide intervention strategies.

**Presenter email address:** b.pascoe@bath.ac.uk
Burden of influenza C in a paediatric population with severe respiratory disease
Anita Wong¹, Alexandra Presbitero¹, Kanti Pabbaraju¹, Kevin Fonseca¹,², Nathan Zelyas¹,³, Byron Berenger*¹,⁴

¹Alberta Public Health Laboratory (ProvLab), Alberta Precision Laboratories, Calgary, Canada, ²Department of Microbiology, Immunology and Infectious Diseases, University of Calgary, Calgary, Canada, ³Department of Laboratory Medicine and Pathology, University of Alberta, Edmonton, Canada, ⁴Department of Pathology and Laboratory Medicine, University of Calgary, Calgary, Canada

Background: Compared to other respiratory viruses, there are fewer studies on influenza C (FluC) even though it causes a similar spectrum of disease. FluC is more prevalent in children than adults and has high rates of co-infection with other respiratory viruses. Our goal was to determine the burden of FluC and its co-infection rate in hospitalized pediatric patients tested in the Canadian province of Alberta (pop: 4.4 million, <10 year old pop: 0.55 million).

Materials/methods: We included hospitalized patients ≤10 years old tested with the Luminex NxTAG Respiratory Pathogen Panel (RPP) from July 2, 2018-April 22, 2019. Specimens from the same patient received within 30 days of the first were excluded. We included specimens collected from the lower respiratory tract (auger suction, bronchoalveolar lavages, bronchial washes, and endotracheal tube aspirates) and all specimens from intensive care patients. We screened all available specimens for FluC using an in-house RT-PCR (Pabbaraju et al. 2013 doi:101111/irv.12099) and lineages were determined by sequencing the hemagglutinin esterase gene.

Results: Of 598 specimens (from 334 males and 264 females), 1.5% (n=9) were positive for FluC from either Kanagawa or Sao Paulo lineages. Peak incidence was in January (n=3) and March (n=3). Of the 9 cases, 5 patients (55.6%) had a co-infection including RSV A/B (n=2), RSV B and enterovirus/rhinovirus (n=1), parainfluenza-3 (n=1), and human metapneumovirus (n=1). In our cohort, the incidence of FluC was higher than the following RPP targets: influenza B (n=0), parainfluenza-1 (n=3), coronavirus 229E (n=2), coronavirus NL63 (n=5), coronavirus HKU1 (n=1), M. pneumoniae (n=4) and C. pneumoniae (n=0).

Conclusions: The burden of FluC in a pediatric population with lower respiratory disease and/or admitted to the intensive care unit is greater than some other commonly tested pathogens. This study suggests that the role of FluC, both as a single or co-infecting agent, is under-appreciated and contributes to the burden of pediatric respiratory infections in hospitalized cases. For this reason, inclusion of FluC should be considered in the design of future multiplex assays.

**KpnBR: Brazilian genomic database for monitoring resistance and virulence of *Klebsiella pneumoniae***

Louise Cerdeira*1, Bruna Fuga1, Ana Judith Quaresma2, Rafael Nakamura2, Danny Fuentes1, Larissa Rodrigues1, Fernanda Esposito1, Brenda Cardoso1, Carlos Emilio Levy5, Eliana Carolina Vespero5, Resineide Ribas6, André Pitondo3, Nilton Lincopan1

1Universidade de São Paulo, São Paulo, Brazil, 2Instituto Evandro Chagas, Belém, Brazil, 3Universidade de Ribeirão Preto, Ribeirão Preto, Brazil, 4Hospital de Clínicos / Universidade Estadual de Campinas, Campinas, Brazil, 5Universidade Estadual de Londrina, Londrina, Brazil, 6Universidade Federal de Uberlândia, Uberlândia, Brazil

**Abstract third-party references:** CNPq, Bill and Melinda Gates

**Background:** The emergence and dissemination of critical-priority multidrug-resistant (MDR) *Klebsiella pneumoniae* (*Kp*) is a One Health issue worldwide. On the other hand, convergence of virulence and resistance, and identification of highly virulent or hypervirulent *K. pneumoniae* (*hvKp*) lineages is a worrying topic of public health interest. In Brazil, KPC-2-producing *K. pneumoniae* has acquired an endemic status, whereas highly virulent and hvKp strains have emerged. In this context, this work aims to create a cured and integrated genomic database, named *Klebsiella pneumoniae* Brazilian Resistance and Virulence Database (KpnBR), for surveillance and monitoring dynamic of critical-priority *K. pneumoniae*, with identification of high-risk resistant and/or virulent clones, mapping outbreaks and hotspots.

**Materials/methods:** KpnBR web database contains a metadata file, based on reports from an automated bioinformatic pipeline called PIPA, which includes all genomic background of *K. pneumoniae* strains (i.e., resistome, virulome, MLST, etc). Currently, KpnBR hosts genomic data from 113 *Kp* genomes obtained from this study, and 80 further *Kp* genomes obtained from the freely and publicly available NCBI database.

**Results:** KpnBR database (http://app.kpnbr.com.br) shows a worrying landscape of *K. pneumoniae* in Brazil, where, in the last 15 years, dissemination of KPC-2 producers has been associated with the pandemic CC258, identified in environmental and clinical settings. CTX-M-15-positive *Kp* ST340 is now found in human, food-producing and companion animals, highlighting a One Health problem. In addition, polymyxin-resistant strains are increasing. Finally, convergence of resistance and virulence has enhanced, whereas highly virulent (ST307, ST340, ST11) and hvKP (ST23/K1) *Kp* lineages have begun to be identified at the human-animal interface.

**Conclusions:** The KpnBR can contribute to the development of strategies for prevention, genomic surveillance, diagnosis and treatment of *K. pneumoniae* infections in Brazil with high endemicity of carbapenem-resistant.

**Presenter email address:** lcerdeira@usp.br
Longitudinal microbiome analysis defines expected and aberrant antibiotic effects on the human respiratory microbiome

Erik Clarke¹, Ebbing Lautenbach¹, Emily Reesey¹, Magda Wernovsky¹, Pam Tolomeo¹, Brendan Kelly*¹

¹University of Pennsylvania, Philadelphia, United States

Abstract third-party references: National Institute for Allergy and Infectious Diseases, Centers for Disease Control and Prevention

Background: Antibiotics are defined by their spectra of activity. But the observed impact of an antibiotic on a complex microbial community depends not only on microbial killing, but also on community membership at time of antibiotic initiation, inter-taxa interactions, and neighboring environmental communities that may contribute to microbial succession. We sought to define expected and aberrant effects of commonly used antibiotics on the human respiratory tract microbiome by longitudinal sampling of patients admitted to a long-term acute-care hospital (LTACH) with ventilator-dependent respiratory failure.

Materials/methods: From 83 subjects enrolled at the time of their admission to an academic LTACH, we obtained 1691 endotracheal aspirate specimens. We performed 16S rRNA sequencing (Illumina HiSeq), sequence error correction and binning (QIIME2 and DADA2), and applied a phylogenetic transform to account for compositionality. Statistical analysis was performed with R and Stan; mixed effects models were fit to evaluate aggregate and subject-level antibiotic effects.

Results: We observed 10834 amplicon sequence variants, with 8586 associated phylogenetic balances, across all specimens. We evaluated the variance of phylogenetic balance, which captures the degree to which clades co-vary, to identify exclusionary dynamics associated with antibiotic exposure. Antibiotic exposure significantly reduced balance variance; the greatest balance variances were observed in the pre-antibiotic and post-antibiotic periods. Significant differences in exclusionary dynamics were observed across antibiotics (cefepime, meropenem, piperacillin-tazobactam, and intravenous vancomycin) and subjects.

Conclusions: Longitudinal microbiome analysis reveals features that discriminate differential antibiotic impacts on the respiratory tract microbiome, as well as subject-level differences in post-antibiotic succession.

How partnership network and HPV type interaction shape the distribution of HPV infection before and after vaccine introduction

Mélanie Bonneault*1, Chiara Poletto2, Maxime Flauder1, Margarita Pons-Salort1, Didier Guillemot1, Elisabeth Delarocque-Astagneau1, Anne Thiébaut1, Lulla Opatowski1

1Institut Pasteur Paris, Université de Versailles–Saint-Quentin-en-Yvelines, Inserm, UMR 1181, Paris, France, 2Inserm & Sorbonne Université, iPLESP, Paris, France, 3Imperial College London, London, United Kingdom

Background: Human papillomaviruses (HPV) are common sexually transmitted infections, characterized by a large diversity of genotypes. HPV prevalence usually peaks at ages 20-24 years, a characteristic that most compartmental mathematical models fail at reproducing. Current vaccination protecting against a subgroup of genotypes, it is key to better understand whether and how genotypes interact to anticipate the impact of vaccination. Here we use a novel realistic agent–based-model of HPV transmission over a heterosexual partnership network in France and assess the impact of assumptions regarding HPV vaccine (V) and non-vaccine (NV) genotypes interaction on HPV epidemiology after vaccination.

Materials/methods: Gender-specific data regarding sexual behaviour in France were used to model a dynamic partnership network with heterogeneous and age-specific sexual activity. Transmission rates and natural immunity parameters were calibrated to match HPV genotype prevalence by age. Ecological interactions between genotypes (competitive, neutral, or synergistic), mechanisms (altering the infection duration or the acquisition probability) and context of interaction (between groups of genotypes or between genotypes) were tested in a series on hypothetical scenarios to investigate their effect on the dynamics post vaccine introduction.

Results: Please copy and paste the corresponding text here In our simulations, infection had reached >70% of the population by the age of 29 years. An important part of infected people (61%) were co-infected by at least two types, a phenomenon observed in individuals with both high and low sexual activity. In all investigated scenarios, vaccine introduction modified NV genotypes prevalence, except for two cases: (i) no interaction and (ii) interactions independent from vaccine inclusion. The pre/post vaccine prevalence ratios of NV ranged 0.92–0.82 in synergistic interactions scenarios and ranged 1.08–1.14 in competitive scenarios. Interestingly, predicted post-vaccination variations of V and NV were stronger for individuals with fewer partners () compared with others.

Conclusions: The proposed agent-based model reproduces realistic patterns of HPV infection and age-distributions. Our simulations results suggest that better knowledge of genotype interactions is key to anticipate accurately the impact of existing and future anti-HPV vaccines targeting a subgroup of genotypes.

**Molecular surveillance of mcr gene in gut microbiome of healthy individuals, acute diarrhoea and inflammatory bowel diseases patients from India**

Sayantan Banerjee*, Tarosi Senapati1, Jyoti Verma2, Anbu Mani2, Arti Kapil3, Bhabatosh Das2

1All India Institute Of Medical Sciences, New Delhi, Infectious Diseases, New Delhi, India, 2Translational Health Science And Technology Institute, CHME, Faridabad, India, 3AIIMS Hospital, Department of Microbiology, New Delhi, India

**Abstract third-party references:** All India Institute of Medical Sciences, New Delhi, India, Center for Human Microbial Ecology, Translational Health Science and Technology Institute, Faridabad, Haryana, India

**Background:** The aim of this study was to assess the prevalence of mcr (Mobilized Colistin Resistance) gene in gut microbiota of healthy and diseased individuals from different parts of India. The limitation of detecting colistin resistance in unculturable and fastidious microbes in the human gut microbiota can be overcome by culture-independent approach wherein the metagenomic DNA representing the DNA of culturable and nonculturable microbes can be targeted by PCR screening followed by confirmation.

**Materials/methods:** Faecal samples from healthy and diseased subjects (n=484) and hen’s eggs ready for human consumption (n=104) from different parts of India were subjected to screening by mcr 1-5 multiplex PCR. Samples screened positive were further confirmed by nested PCR, restriction enzyme digestion and sequencing. Whole genome sequencing of colistin resistance bacterial isolates (Klebsiella pneumoniae, Vibrio cholerae, Pseudomonas aeruginosa, Campylobacter jejuni) were conducted to explore the resistance genes and mobile genetic elements that carry the resistance genes.

**Results:** A total of 24 out of 484 (4.9 %) faecal samples were positive for mcr-1, which included 2% samples of inflammatory bowel disease patients (1 out of 48), 4.3% acute diarrhoea patients (15 out of 350) and 21% healthy subjects (8 out of 38) living in Leh, the northernmost union territory of India amidst The Himalayas. The present finding of a high prevalence of mcr-1 in healthy subjects from Leh, who have no history of prescribed colistin intake is quite perplexing. Among the 104 screened hen’s eggs meant for human consumption, 15 were culture positive for bacteria and 1 carried the mcr-1 mobile genetic. This study depicts the current scenario of the presence of mobile colistin resistance gene mcr-1 in Indian population, highlighting the potential risk of emergence of polymyxin resistance.

**Conclusions:** Till now, to the best of our knowledge this is the first study in India relating the prevalence of mcr-1 gene in the gut metagenome of healthy and diseased individuals with due consideration of dietary habits and other environmental factors, which may potentially contribute to the emergence and spread of mcr-1 harbouring human associated microbiota.

ABSTRACT BOOK – 30th ECCMID 2020

Abstract 9412

A critical appraisal of the new antibiotic prescription chart using HAPPI [Hospital Antibiotic Prudent Prescribing Indicators] in a large UK district hospital

Alice Liu*

1Gloucestershire Hospitals Nhs Foundation Trust, Cheltenham General Hospital, Cheltenham, United Kingdom

Background: A point prevalence audit was conducted respectively in October 2018 and January 2019 at a large UK district hospital to assess the appropriateness of antibiotic use according to the requirements of Public Health England and NHS Improvement 2018/19.

Materials/methods: Ten antibiotic prescriptions were reviewed per ward according to the following three care elements:

1. Appropriate choice of antibiotic[s]
2. Antibiotic review within 24 - 72 hours?
3. Length of course of antibiotic documented on the prescription chart?

Results: A total of 654 antibiotic prescriptions were reviewed in the study and the breakdown is shown below.

<table>
<thead>
<tr>
<th>Month/Year</th>
<th>Oct-18 (N=328)</th>
<th>Jan-19 (N=326)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Appropriate antibiotic choice</td>
<td>90%</td>
<td>90%</td>
</tr>
<tr>
<td>Antibiotic review within 72 hours (%)</td>
<td>43%</td>
<td>39% ↓</td>
</tr>
<tr>
<td>Stopped date specified on the antibiotic prescription chart</td>
<td>17%</td>
<td>28% ↑</td>
</tr>
</tbody>
</table>

Both audits found 90% of compliance with appropriate antibiotic choice which demonstrated that clinicians were aware of the hospital antimicrobial guidelines. There was an improvement in the length of antibiotic course being specified in the 2nd audit after a strong advocate of prudent use of antibiotic among hospital staff through the social media in November 2018. However, hesitation has been illuminated in the antibiotic review within 72 hours by the clinicians; which may indicate that a rapid diagnostic test analysis and a simplified procedure for microbiologist consultation are necessary.

Conclusions: Antibiotic review is a crucial part of antimicrobial stewardship to combat bacterial resistance and hospital acquired infections. It requires multi-disciplinary approach from an operational level to clinical directorate level to achieve success. Lack of antibiotic review could be due to operational system failure [design of the prescription chart], lack of motivation/engagement by senior clinicians and microbiologists, and insufficient training/advocate of antimicrobial stewardship among junior doctors, pharmacy and nursing staff. Suggestion includes constant surveillance of antibiotic prescriptions, a set-up of an “e-referral” procedure for easier access of microbiologist’s advice, regular feedback of the antibiotic usage to the relevant stakeholders/directorates to enhance their engagement in antimicrobial stewardship, and a widespread message of the harm of antibiotic abuse and bacterial resistance to patients and the community.

Abstract 9413

**Adequate exposure time of cold atmospheric pressure plasma on *Staphylococcus aureus* biofilms**

Foad Fahmide*1, Parastoo Ehsani1, Seyed Mohammad Atyabi1

1Pasteur Iran Institute, Tehran, Iran

**Background:** *Staphylococcus aureus* biofilms play a significant part in pathogenicity and result in persistent infections in tissue, external and indwelling devices. Considering escalation in Antibiotic Resistance, one of the influential technologies is the Cold atmospheric plasma (CAP). It had found a diverse advantage in the food industry and the health care system. Consequently, exploration of the effects of bacterial biofilms affected by CAP is essential for the annihilation of pathogenic biofilms.

**Materials/methods:** The two-day-old biofilms of *Staphylococcus aureus* (ATCC 6538) were established in (96-well plate) in tetrad using the TSBG medium. They were exposed to the (Helium) CAP exposure for 0 to 360 s. Following CAP treatment the plates were sonicated to resuspend biofilms in the aquatic estate for further analysis. Features of the CAP affected biofilms including the overall structure and viability of bacteria were investigated. Biomass of the biofilms estimated by Crystal violet (CV) staining and the comprehensive construction of biofilms were measured by Optical Density (OD). Number of culturable colonies and cell viability of CAP treated biofilms evaluated by Colony-forming-unit (CFU) and MTT assay respectively.

**Results:** In the first 60 s the OD increasing showed that the CAP treated biofilms became stiffer compared with the non-treated control wells. Between 30 s to 60 s of CAP exposure, the CFU and MTT records increased, subsequently with more exposure up to 360 s all three CV, CFU and MTT amounts decreased.

**Conclusions:** We have indicated that the short CAP exposure (≥60s) could increase the firmness of biofilm thus shelters interior bacteria from antibacterial factors. The mentioned rigidity results in pseudo-CFU count. This is an unexpected effect of CAP in preserving the biofilm structure. The CFU and MTT increase until 60 s, though by lasting the CAP exposure time, the biofilm structure breaks down. Afterward, More CAP exposure to the biofilms reduces the CFU, MTT, and the OD of solubilized CV. For that reason, adequate CAP exposure time must be considered for absolute destroying the biofilms beside kill entirely its containing bacteria, moreover prevention of wrong results.

Abstract 9415

Prevalence of genes encoding 16S rRNA methyltransferase in carbapenemase-producing Serratia spp. in south Brazil

Larissa Bail*1, Carmen Antonia Sanches Ito1, Lavinia Arend1, Keite Nogueira2, Felipe Tuon1

1Pontifical Catholic University of Paraná, Curitiba Campus, Curitiba, Brazil, 2Federal University of Parana, Curitiba, Brazil

Background: Serratia spp. are members of Enterobacterales Order and have been emerged as an opportunistic pathogen associated mainly with nosocomial infections. These species are intrinsically resistant to many antibiotics and the treatment of infections caused by Serratia spp is a challenge, mainly in carbapenemase producers. Since aminoglycosides are an option to these strains, the aim of this study is to evaluate the distribution of genes encoding 16S rRNA methyltransferases in carbapenemase-producing Serratia spp. with high-level aminoglycoside resistance from various clinical specimens in South of Brazil.

Materials/methods: One hundred and fifteen carbapenemase-producing Serratia spp., being 114 blaKPC and 1 blaNDM, isolated on 94 patients from clinical specimens (colonization or infection) during January 2014 and December 2017 were evaluated for aminoglycoside high-level resistance according to Rapid Aminoglycoside NP Test. Serratia spp. were identified by the MAL-DI-TOF method and all samples positive on Rapid Aminoglycoside NP Test were investigated for the presence of 10 different 16S rRNA methyltransferases by two multiplex PCR and confirmed by single PCR.

Results: Serratia marcescens was the only species identified in 115 isolates and 15 samples were positive on Rapid Aminoglycoside NP Test, indicating high-level aminoglycoside resistance. Of them, five (4.3%) samples were positive on multiplex PCR for genes encoding 16S rRNA methyltransferases and confirmed by single PCR, being 3 rmtD and 2 rmtB, all in Serratia marcescens KPC-producers. This seems to be the first report of co-production blaKPC and rmtD in Serratia marcescens.

Conclusions: This study showed a prevalence of 4.3% of genes encoding 16S rRNA methyltransferases in Serratia marcescens. These results emphasize the need to survey aminoglycosides high-level resistance when this bacteria is found in clinical specimens. Therefore, plazomicin, a novel broad-spectrum aminoglycoside inactive by methylases but active against aminoglycoside-modifying enzymes, could be an option for carbapenemase-producing Serratia spp in 95.7% of the cases.

Presenter email address: larabail1504@hotmail.com
Factors contributing to the duration of hospitalisation of patients with bacterial cellulitis
Monika Mudrović¹, Ljiljana Lukić², Maša Puljiz², Ivan Puljiz¹²

¹University Hospital for Infectious Diseases Dr. Fran Mihaljevic, Zagreb, Croatia; ²School of Medicine, University of Zagreb, Zagreb, Croatia

Background: Bacterial cellulitis (BC) presents a therapeutic challenge. The optimal choice of antimicrobial agent and duration of treatment for BC continue to be heavily debated. Our aim was to analyze risk factors and treatment regimens associated with a prolonged hospital stay.

Materials/methods: We conducted a retrospective analysis of data from our cohort of 255 patients admitted to our university hospital from January 1st 2018 to December 31st 2018 with BC as the primary diagnosis. Statistical evaluation was done using Student’s t-test and ANOVA where applicable.

Results: The mean duration of hospital stay for all patients was 11.2 days. The factors we found to be associated with a prolonged hospital stay were acute kidney injury at admission; cardiac decompensation at admission; the clinical observation that the patient appears unwell at admission; a history of cardiovascular disease; as well as chronic venous insufficiency. Age >65 years was also associated with a significantly longer hospital stay, as was identification of pathogens in a skin swab. Patients with no determinable gateway for infection had a significantly shorter hospital stay. We observed no significant difference in the duration of hospitalization for patients with other comorbidities; neither was there any relation of CRP levels at admission or highest documented axillary temperature to length of hospital stay.

Cefazolin was the most commonly used antibiotic in our sample (45.1% patients) and was associated with the shortest hospital stay, significantly shorter than cloxacillin or clindamycin (the second and third most commonly used monotherapy agents). Patients treated with monotherapy had a significantly shorter hospital stay than those initially treated with multiple antibiotics.

Conclusions: The most significantly prolonged hospital stay was observed in patients with a toxic appearance and end organ damage at admission. Based on our data, cefazolin was the antibiotic associated with the shortest hospital stay. Patients receiving combined antimicrobial therapy were observed to have a prolonged clinical course, but this can likely be attributed to these patients having a more complex presentation.

Abstract 9420

Evaluation of salivary protein rTiSP14.6 as a marker of exposure to the bite of the insect Triatoma infestans, vector of Trypanosoma cruzi

Ana Maria Moreno¹, Ines Martin², Emilia Garcia³, Javier Nieto³, Maria Flores-Chavez*¹

¹Fundación Mundo Sano / Centro Nacional de Microbiología, Madrid, Spain, ²Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Maryland, United States, ³Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain

Abstract third-party references: Supported by Fundación Mundo Sano and Instituto de Salud Carlos III

Background: The Triatoma infestans insect is the main vector that transmits the Trypanosoma cruzi protozoan, the causative agent of Chagas disease (CD). In Latin America, this vector has been controlled thanks to insecticides, but its monitoring is essential to identify new infestations. As the population at-risk of exposure can develop an immune response against the salivary gland proteins of this insect, it is postulated that the detection of antibodies against these proteins could be an epidemiological marker of infestation and exposure. Therefore, in this work we have evaluated the potential of the highly immunogenic recombinant protein rTiSP14.6, a 14.6 kDa salivary protein of T. infestans, as an epidemiological marker of exposure to the vector bite.

Materials/methods: 1191 samples of sera were analyzed. 1081 out of them were from the Latin American population, 29 were from individuals born in Spain, children of Latin American or non-Latin American mothers who had made a stay in endemic area for T. cruzi, and 81 samples were from to individuals without risk of exposure to T. infestans. All samples were previously characterized by serological detection of anti-T. cruzi antibodies using ELISAs (conventional and recombinant) and indirect immunofluorescence assays. Of these, 178 were from individuals with a positive diagnosis for CD. The detection of antibodies against the rTiSP14.6 protein was performed using the ELISA technique.

Results: Out of the 178 positive samples for T. cruzi infection, 9 showed antibodies against the recombinant salivary protein of T. infestans. On the other hand, 81 samples from the population with a negative diagnosis for CD presented high levels of antibodies against the rTiSP14.6 protein, 79 out of them had lived in endemic areas. It was mostly detected in the Bolivian population (p=0,032).

Conclusions: Although no correlation was observed between the detection of anti-salivary protein rTiSP14.6 and T. cruzi infection, its detection in a non-infected population from endemic area corroborates its potential utility as an epidemiological marker of exposure.

Abstract 9421

First use of Fourier-transform infrared spectroscopy in Romania for investigating Klebsiella pneumoniae strains isolated from a possible cluster

Daniela Talapan*1,2, Andreea-Mihaela Sandu1, Brindusa-Elena Lixandru3, Doina-Viorica Iovanesco1, Adrian Streinu-Cercel1,2, Daniela Pîţigoi1,2, Alexandru Rafila1,2

1National Institute of Infectious Diseases-Prof. Dr. Matei Balş, Bucureşti, Romania, 2Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania, 3Cantacuzino National Institute of Research, Bucureşti, Romania

Background: Strain typing is commonly used in infection control for epidemiological investigation. Gold standard methods are DNA-based techniques, as PFGE and WGS. New Fourier-transform infrared (FTIR) spectroscopy method relies on carbohydrate composition of bacteria and has been used in last years in veterinary and food microbiology; lately there have been studies on its usefulness in clinical microbiology for rapid analysis of outbreaks.

Materials/methods: There were analyzed 19 isolates of Klebsiella pneumoniae with similar antibiotype (OXA-48-type producers) isolated in a 6 months period for identifying a possible epidemiological link between strains. These were isolated from 10 patients admitted in the same hospital ward (n=17) and from environmental samples (n=2). The strains were identified by MALDI TOF Biotyper (Bruker Daltonik GmbH) and analyzed using PFGE at the National Reference Laboratory. IR Biotyper (Bruker Daltonik GmbH) was used to identify the clusters and to compare with PFGE results. Analyzing all 19 strains three times on different days assessed the reproducibility of the technique.

Results: Cluster analysis was used to determine clonal similarities between strains. Our results show that FTIR spectroscopy adequately clustered 14 isolates as possible cluster, while three isolates were misclassified probably based on their biological variations. All 17 isolates showed the same pulsotype. Furthermore, 5 isolates were ruled out from the main cluster according to FTIR spectroscopy as it was by PFGE showing high discriminatory power. Results are visualized as dendrogram.

Conclusions: FTIR spectroscopy proves to be a fast and reliable tool in assessing a possible outbreak. Besides its sensibility to bacterial growth and environmental conditions, this technique could be easy implemented in clinical microbiology laboratory to help monitor infection control measures.

Presenter email address: dtalapan@gmail.com
Molecular and epidemiological characterisation of an outbreak of Candida auris in a Spanish hospital

Elías Cortes-Acosta1, Ignacio Antonio Sigona-Giangreco1,2, Alba Ruiz*1,2, Asunta Martínez-Martínez1,3, Eulogio Valentin1,3, Javier Peman1,2

1Severe Infection Research Group, Health Research Institute La Fe., Valencia, Spain, 2Microbiology department, Hospital Universitari i Politècnic La Fe., Valencia, Spain, 3Microbiology and ecology department. Universitat de Valencia, Burjassot, Spain

Background: Candida auris is an emerging multi-drug resistant yeast. Currently, it is considered a global threat due to its high-level environmental resistance and transmissibility. C. auris outbreak in La Fe Hospital (Valencia, Spain) began in 2016 and till now, it has become the largest one worldwide.

Materials/methods: A total of 111 C. auris strains 100 Spain, and other countries (2 Colombia, 1 Korea, 2 Brazil, 2 Oman, 2 Japan and 2 from Venezuela) and 8 reference strains: Candida albicans CS5314, Candida haemulonii ATCC® CBS123?1, Candida psedohaemulonii ATCC® CBS12370, Candida doubushaemulonii ATCC® CBS7798, Candida tropicalis BIOC10, Candida lipolytica ATCC® 340, Candida parapsilosis ATCC® 22019 and Candida krusei ATCC® 564 were analyzed.

RAPD (Random Amplified Polymorphic DNA): PCR-RAPD reactions were made using a Ready-To-Go RAPD Analysis Beads® (Amersham Biosciences Corporation, Piscataway, NJ, EE. UU.) kit. Oligonucleotides selected for assay were M2 (5'-CTTGATTGCC-3') and P4 (5'-AAGAGCCCGT-3'). Nuclease free water was used as a negative control. All reactions were done in duplicate and different days. PCR products were analyzed using electrophoresis on agarose gel 2. RAPD profiles were analyzed with Bionumerics® v. 7.6 (Applied Maths®) constructing an UPGMA dendrogram.

Results: All Spanish isolates were clustered in 4 clades (A to D). 40 Isolates included in clade A with 75% of similarity. Clade B grouped 8 isolates with 80% of similarity. Clades C included 24 isolates and cluster D 8, both with 80 and 85% of similarity, respectively.

Conclusions: C. auris isolates from the Spanish outbreak are clonal. Nevertheless, there seems to be a relationship with the isolates from Oman.

The RAPD technique allows preliminary characterization of isolates in epidemic situation; however, these results must be confirmed with a robust tools such as PFGE or WSG.

Multi-resistant *Escherichia coli* in long-distance migratory birds: how graylag geese (*Anser anser*) and pink-footed geese (*Anser brachyrhynchus*) can act as vectors for antimicrobial resistance

Hans Kristian Mjelde*, Håvard Kallbekken, Thongpan Leangpichart, Henning Sørum, Carlos Das Neves, Marianne Sunde

1Norwegian University of Life Sciences NMBU, Institute for food safety and infection biology, Oslo, Norway, 2Norwegian Veterinary Institute, Oslo, Norway

Abstract third-party references: Norwegian University of Life Sciences (NMBU)

**Background:** Migratory birds carries resistant *E. coli* strains over large distances. The continuous increase in geese populations poses a threat concerning global antimicrobial resistance. Recent studies show antimicrobial resistance patterns in wildlife, carrying resistance genes against drugs listed on the "WHO's List of Essential Medicines". Close contact interactions between wildlife and human populations pose a threat for the global health situation, where wildlife habitat are exposed to spillage from wastewater runoff with antibiotic residues and resistant coliform bacteria.

**Materials/methods:** During autumn 2015 and 2019, 201 cloaca samples were collected from Graylag- and Pink-footed geese landing close to farm areas in the middle of Norway. These samples were screened and isolated for resistant *E. coli*. All isolates were tested using disc diffusion and minimum inhibitory concentration methods (EUCAST). DNA was extracted and analyzed using whole genome sequencing.

**Results:** 39 of the samples from 2015 (35%) showed a prevalence for antimicrobial resistance for one or more drugs, whereas 26 of the samples from 2019 (29%) showed more or less the same patterns. In total, there were multiple isolates resistant against colistin, tetracycline, nalidixic acid, ampicillin, ciprofloxacin, trimethoprim and sulfamethoxazole. Several of these isolates had multi-resistant patterns. ST-469 was the predominant sequence type (23%), and ST-1126 come second place (17%) where all ST-1126 strains were carrying the tet(A) gene. Most interesting is the ST-744 clonal complex (11%), all carrying the gyrA and parC mutations, along with several resistance genes. This sequence type is closely related to human clonal complexes. Finally, one complex (3%), ST-2165, carried the qnrS1 gene for quinolone resistance.

**Conclusions:** Around one third of the *E. coli* samples were resistant against one or more antibiotic drugs, indicating that migrating birds can act as vectors for resistant bacteria. Genomic analysis indicates both horizontal and vertical transmission of resistance genes closely related to human isolates. To figure out the zoonotic capability of *E. coli* found in migratory birds, further testing of human and livestock populations living closely to wildlife should be performed.

**Presenter email address:** hkmjelde@gmail.com
Study on Bartonella related to small mammals in the Canary Islands, Spain

Estefanía Abreu Yanes1, Aaron Martin-Alonso2, Natalia Martín Carrillo*, Katherine García Livia2, Elena Mercedes Izquierdo Rodríguez2, Néstor Abreu Acosta1, Jordi Miquel3, Carlos Feliu3, Pilar Foronda Rodríguez2

1Nertalab S.L., Santa Cruz de La Laguna, Spain, 2Universidad de La Laguna, La Laguna, Spain, 3Universitat de Barcelona, Barcelona, Spain

Abstract third-party references: Funded by ProID2017010092 Project (Comunidad Autónoma de Canarias, FEDER 2014-2020), Funded by Fundación CajaCanarias 2015BIO20

Background: Bartonella genus is comprised of several species of zoonotic relevance, some of them considered emerging nowadays. Rodents are reservoirs for some of these Bartonella species, and their associated vectors contribute to the maintenance and dissemination of the pathogen. The aim of the present study was to analyze Bartonella species along the Canary Islands (Spain) in rodent and their ectoparasites, and its possible repercussion to public health.

Materials/methods: A total of 304 small mammals, including black rats (Rattus rattus) and mice (Mus musculus domesticus) were captured in Tenerife, La Palma, El Hierro and Lanzarote (Canary Islands, Spain) in both urban and rural areas, as well as 264 fleas collected from them. Molecular analyses were carried out based on the gltA gene, to detect and identify Bartonella species.

Results: The overall prevalence of Bartonella organisms in rodents was 13.5%, whereas the prevalence in fleas was 17.4%. Zoonotic Bartonella elizabethae, Bartonella tribocorum and Bartonella rochalimae were identified in rodents and fleas in all the islands analyzed. About 16.5% of Bartonella-positive rodents were captured in intradomiciliary or peridomesticary settings of urban areas, which supposes a potential risk of acquiring Bartonella for the population. Besides, at least three flea species were identified as carriers of Bartonella in our study.

Conclusions: Our results indicate that rodents species and fleas act as reservoirs and vectors, respectively, in this archipelago, and the prevalence and distribution of the pathogen along the islands including urban areas, show the need to establish a routine procedure of diagnosis of bartonellosis in public healthcare, as Bartonella species may be the causative agents of human infections of unknown origin in the Canary Islands (Funded by Fundación CajaCanarias 2015BIO20 and ProID2017010092 Project [Comunidad Autónoma de Canarias, FEDER 2014-2020]).

Diagnostics and treatment of invasive aspergillosis in B-cell lymphoma patients after cytostatic chemotherapy and autologous stem cell transplantation

Julia Chudinovskikh1, Tatiana Semiglazova1, Marina Popova1, Olga Shadrivova1, Ekaterina Frolova1, Tatyana Bogomolova1, Svetlana Ignatyeva2, Ilya Zyuzgin1, Larisa Filatova1, Julia Oleinik1, Nikolai Klimko*3

1N.N. Petrov National Medical Research Centre of Oncology, Ministry of Health of Russian Federation, St. Petersburg, Russian Federation, 2Raisa Garbacheva Memorial Research Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of St.Petersburg, Ministry of Health of Russian Federation, St. Petersburg, Russian Federation, 3I.I. Mechnikov North-Western State Medical University, Saint-Petersburg, Russian Federation, St. Petersburg, Russian Federation

**Background:** Invasive aspergillosis (IA) in B-cell lymphoma patients after cytostatic chemotherapy (CCT) and autologous stem cell transplantation (ASCT) is not studied enough today.

**Materials/methods:** The prospective study included 813 B-cell lymphoma patients: Hodgkin lymphoma (HL) – 363, 16-65 years (median – 33), and non-Hodgkin lymphoma (NHL) – 450, 19-74 years (median – 50). For the IA diagnosis criteria EO-RTS/MSG 2008 were used.

**Results:** Frequency of IA in patients with B-cell lymphoma was 4.98% (HL – 5.6%, NHL – 4.5%, p=0.49), in patients with relapse of NHL - 10.25%, after ASCT – 2.85% (HL – 2.35%, NHL – 3.33%, p≥0.05). The main etiology agents were Aspergillus fumigatus (41%), A.niger (39%), and A.flavus (14%). Risk factors for IA were: relapse of lymphoma (p=0.005), B-symptoms (p=0.035) and radiation therapy in anamnesis (p=0.041), profound neutropenia (p=0.000), concurrent lung (p=0.007) and renal pathology (p=0.03). Clinical symptoms of IA were nonspecific: fever 68%, cough 48%, dyspnea 32.5%. Chest CT scan sings of IA were: focal changes 63.5%, infiltrates 58.7% and “ground-glass opacity” 23%. Galactomannan test was positive in BAL fluid and serum in 83.6% cases. The presence of septate mycelium in BAL was observed at microscopy in 15.5% patients. Aspergillus spp. culture was obtained in 34.7% of patients with B-cell lymphoma (HL – 20.4%, NHL – 46.3%, p=0.004). “Probable” IA was diagnosed in 92.9%, “proven” – in 7.1% of cases. The main antifungal drug was voriconazole – 79%. In patients with IA the 12-weeks overall survival (OS) was 84.9% (HL – 88.1%, NHL – 82.1%). The use of bronchoscopy and voriconazole improved 12-weeks OS (88.1% vs 64.7%, p=0.011; 92.6% vs 71.1%, p=0.004, accordingly). IA did not influence on 2- and 4-year OS, 1-,2-,3- year progressive-free survival (PFS) and 1-,2-,5- year relapse-free survival (RFS) in patients with induction chemotherapy. IA did not influence on 2-year OS, 1-,2-year PFS and 1-,2-year RFS in patients with relapsed or refractory B-cell lymphoma (p>0.05).

**Conclusions:** Frequency of IA in patients with B-cell lymphoma was 4.98%. Early diagnosis with bronchoscopy and adequate therapy with voriconazole of IA allowed to conduct cytostatic chemotherapy. IA did not influence on OS, PFS and RFS in B-cell lymphoma patients with induction and anti-relapse chemotherapy.

Abstract 9428

Meningitis due to Toscana virus: analysis of clinical and laboratory features of the cases observed in the period 2008-2018 at the Careggi University Hospital, Florence, Italy

Michele Spinicci*1,2, Pietro Sponga1, Giampaolo Corti1,2, Marco Pozzi1, Baldovino Sponga1, Lorenzo Zammarchi1,2, Alessandro Bartolini1,2

1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, 2AOU Careggi, Infectious and Tropical Diseases Unit, Florence, Italy, 3Statistician, Belluno, Italy

Background: Toscana virus (TOSV) is an emerging arbovirus which is estimated to cause more than half cases of aseptic meningitis during the summer season in Central Italy. Moreover, increasing number of cases have been reported in other Mediterranean countries. However, the current knowledge of clinical and laboratory features of TOSV relies on few available data from limited cases series.

Materials/methods: We retrospectively collected data from medical records of all patients diagnosed with TOSV meningitis (TOSVm), admitted at the Infectious and Tropical Diseases Unit, Careggi Hospital, Florence, Italy, during the lapse 2008-2018. As control group, we collected data of patients diagnosed with aseptic meningitis in the same period, wherein TOSVm was excluded by serological and/or molecular testing. Cases of meningitis due to bacterial (Listeria monocytogenes, M. tuberculosis) and herpetic etiologies were excluded from further analysis.

Results: A total of 104 and 222 cases of aseptic meningitis were included in TOSVm and control group, respectively. Sex distribution, median age and Charlson comorbidity index were comparable between the two groups. As for clinical presentation, presence of nausea/vomiting (67/104, 64% vs 95/222, 43%, p<0.001) and stiff neck (48/104, 46% vs 73/222, 33%, p=0.021) were significantly more frequent in TOSVm group at univariate analysis. Moreover, TOSVm patients had slightly lower white blood cells (7140 vs 7970 /μL, p=0.014) and platelets count (179000 vs 220000 /μL, p=0.001), and higher values of cerebrospinal fluid (CSF) mean leukocyte (511 vs 155 cells/μL, p<0.001), protein (1.22 vs 0.81 mg/dL, p<0.001) and lactate (32 vs 22 mg/dL), with a lower CSF/blood glucose ratio (49% vs 58%, p<0.001). Multivariate analysis by stepwise-forward regression produced a model which includes CSF lactate concentration, plasmatic platelets count and presence of nausea/vomiting, with highest correlation for TOSVm diagnosis.

Conclusions: To the best of our knowledge, we reported data of the largest TOSVm cohort available to date. The study evidenced some clinical and laboratory peculiarities observed in TOSVm patients, with respect to a control group of aseptic meningitis. Our findings may contribute to better define the clinical picture of TOSVm, in order to drive the diagnostic work-up of aseptic meningitis.

Abstract 9429

Diabetic foot osteomyelitis: an epidemiological retrospective analysis in a Portuguese university hospital

Ana Cipriano*, Diogo Guerra1, Miguel Abreu1, André Carvalho1, Maria Ernestina Matos Dias Reis1

1Centro Hospitalar Universitario do Porto, Porto, Portugal

Background: Osteomyelitis is one of the expressions of diabetic foot infection, often requiring hospitalization and amputation. We aimed to evaluate the microbiological profile and clinical characteristics of patients admitted with Diabetic foot osteomyelitis in our hospital, and to analyze the antimicrobial therapy strategy to establish future local guidelines for empirical treatment.

Materials/methods: Retrospective analysis of adult patients admitted in our center, with Diabetic foot osteomyelitis, from 2015 to 2016. Microbiology results, antibiotic susceptibility profiles and medical records were reviewed.

Results: Of the 103 processes analyzed, 61 patients were admitted with clinical and radiologic criteria of osteomyelitis, and 45 (73.8%) fulfilled the diagnosis of Diabetic foot osteomyelitis. 73.3% were male, with a median age of 64 years. In 82.2% of the infections forefoot was affected. Osteomyelitis was present in 46.7% of neuropathic foot and in 53.3% of neuroischaemic foot. At the diagnosis, 8.9% patients had fever and 57.8% had received previously antibiotic.

Concerning to microbiology, bone biopsy was performed in 37.8%, and soft tissue biopsy in 24.4%. Infections had microbiologically identification in 77.6%. 51.1% were polymicrobial, Staphylococcus aureus (47.2%) was the most identified microorganism (58.8% were MSSA), followed by Enterobacteriaceae (51.4%), Enterococcus spp. (25%) and Pseudomonas aeruginosa (14.3%). There were no fungal or anaerobes isolated. Carbapenem and piperacillin-tazobactam were used as part of empirical therapy in 39%, Teicoplanin in 32%, and Vancomycin in 9.8%. Oral antibiotics covered isolated agents in 71.4% of the cases. Besides antibiotic therapy, 55.6% needed minor amputation.

Conclusions: This study, allowed us to determine the local epidemiology of diabetic foot osteomyelitis. Most of the infections were polymicrobial, becoming a treatment challenge. Although most of patients admitted had neuroischaemical foot infections, and a smaller number neuropathic, was not possible to evaluate if there were pathogens differences between them. Since, 71.4% of microorganisms were covered by oral antibiotics, we hypothesize that an early diagnosis and a previous antimicrobial management optimization could diminish hospital admissions and amputations. We highlight the importance of a multidisciplinary management of this pathology and concluded that further studies are needed to establish local empirical treatment guidelines.

Abstract 9430

**Blocking mycobacterial efflux pumps might potentiate efficacy of antimycobacterial drugs in vitro**

Mike M. Ruth*1, Lian Pennings1, Jodje Schildkraut1, Valerie Koeken1, Heiman Wertheim1, Jakko Van Ingen1

1Radboud University Medical Center, Nijmegen, Netherlands

**Background:** *Mycobacteria,* especially *Mycobacterium avium* complex (MAC), are highly drug-resistant and cause difficult-to-treat infections. Efflux pumps of varying specificity and mechanism contribute greatly to their drug-resistance. Inhibition of efflux pumps to potentiate antimycobacterial drugs is an emerging field of interest. Here, we investigate the effect of thioridazine as a non-specific efflux pump inhibitor alone and together with antimycobacterial drugs, as well as drug outflow over time under influence of thioridazine.

**Materials/methods:** Minimum inhibitory concentration (MIC) of thioridazine was determined per CLSI guidelines for *M. avium* ATCC700898. Synergism between thioridazine and drugs recommended in the treatment of MAC was determined by checkerboard titration using the fractional inhibitory concentration index (FICI). Time-kill assays (TKs) were performed with thioridazine alone and in combination with drugs showing low FICIs. Here, we incubated the bacteria in bottles and quantified colony forming units at pre-determined time points. For single-drug assays, we used a two-fold serial dilution range starting at 32x MIC and ending at 0.25x MIC. For multi-drug assays, we screened concentrations from 2x MIC to 0.5x MIC for the partner drugs alone and in combination. The effect of thioridazine on *M. avium*-infected human macrophages was assessed by incubating *M. avium*-infected macrophages together with thioridazine for a maximum of 6 days, quantifying *M. avium* bacterial load on day 0 and 6 as well as assessing macrophage viability based on morphology. An efflux assay was performed with MAC pre-incubated with ethidium bromide, with and without thioridazine, assessing outflux using increasing fluorescence over one hour in a LightCycler 480.

**Results:** The MIC of thioridazine against *M. avium* was 16 µg/mL. We found lowest FICIs between thioridazine and rifampicin or clarithromycin (FICI = 0.5). In TKs, thioridazine achieved >2 log kill at concentrations > 2x MIC (figure a). Synergy in TKs was observed together with clarithromycin, but not rifampicin (figure b, c). In human macrophages, thioridazine alone could lower the bacterial burden and was synergistic with clarithromycin (figure d). Thioridazine inhibited the efflux of ethidium bromide (figure e).

**Conclusions:** Efflux pump inhibition is a potent tool for increasing antimycobacterial efficacy, but thioridazine shows little efficacy against *M. avium* within macrophages.

Abstract 9433

Superior discriminatory capacity of qSOFA over SIRS criteria for predicting mortality and extensiveness of organ failure in sepsis

Sonja Adamovic1*, Dunja Becejac1, Sonja Mitic1, Maja Drljača1, Anita Vukelic1, Dajana Lendak1,2

1University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, 2Clinical Center of Vojvodina, Novi Sad, Serbia

Background: The new sepsis definition (Sepsis-3) raised the debate about usefulness, sensitivity and specificity of newly introduced quick Sequential Organ Failure Score (qSOFA) and previously used Systemic Inflammatory Response Syndrome (SIRS) score. We aimed to compare discriminatory capacity of the qSOFA vs SIRS criteria measured on admission for predicting lethal outcome and extensiveness of organ failure in patients with sepsis (defined by Sepsis-3 definition).

Materials/methods: 407 consecutive septic patients were included. qSOFA and SIRS scores on admission were available. For predicting in-hospital mortality, the area under the receiver operating curve (AUC ROC) was constructed. Organ failure was measured by SOFA score. Spearman’s correlation was used for correlation of qSOFA and SIRS scores with extensiveness of organ failure.

Results: For predicting in-hospital mortality, AUC for qSOFA (0.681, 95%CI 0.633-0.726, p<0.001) was greater than SIRS (0.542, 95%CI 0.492-0.591, p=0.167), which was not predictive. In-hospital mortality of patients with qSOFA 0, 1, 2 and 3 points was: 7.6%, 28.9%, 41.2% and 57.9% (p<0.001). Mortality of patients with SIRS 0, 1, 2, 3 and 4 points was: 28.0%, 24.3%, 30.0%, 28.9% and 45.0% (p=0.400). Sensitivity and specificity for different thresholds for qSOFA and SIRS are given in Table 1. Finally, qSOFA correlated better with organ failure (SOFA score) extensiveness (p<0.001, r=0.352) than SIRS score (p=0.011, r=0.126).

<td>0.96</td>
</tr>
</tbody>
</table>

Conclusions: In patients with sepsis, qSOFA score on admission had greater accuracy for predicting lethal outcome than SIRS, and correlated better with organ dysfunction (SOFA) score. Still, concerns about the low sensitivity of qSOFA≥2 criterion, as well as low specificity of SIRS≥2, seem to be grounded.

Abstract 9434

Retrospective analysis of antibacterial resistance among uropathogen *Escherichia coli* in a veterinary teaching hospital (Italy, 2014-2019)

Patrizia Nebbia*1, Alessandro Bellato1, Anna-Rita Attili2, Maria Cristina Stella1, Francesca Canavesi1, Patrizia Robino1

1University of Turin, Department of veterinary Sciences, Grugliasco (Turin), Italy, 2University of Camerino, school of biosciences, Camerino, Italy

**Background:** Urinary tract infections (UTIs) often require long follow-up periods and repeated antimicrobial therapies that can lead to the onset of antimicrobial-resistance. *Escherichia coli* is the most frequent bacterium involved in uncomplicated UTIs in pet animals in which treatment is sometimes threatened by the steady increase in the number of strains bearing concurrent resistance to various antimicrobial agents. The study aimed to report the variation of antibacterial resistance of urinary pathogen *E. coli* (UPEC) isolated from pets in a veterinary teaching hospital, North Italy (Turin) during a 5-and-a-half-year period (2014-2019).

**Materials/methods:** This retrospective study was carried out on *E. coli* strains (n= 219) collected from dogs (n=139) and cats (n=80) with UTI. Each strain was tested to 18 antibiotics belonging to 8 categories: aminoglycosides, carbapenems, folate pathway inhibitors, not-extended spectrum cephalosporins: 1st and 2nd generation, extended spectrum cephalosporins: 3rd and 4th generation, penicillins, penicillins + β-lactamase inhibitors, quinolones, following Kirby-Bauer method and interpreted according to the EUCAST guidelines. Isolates were classified as MDR (multidrug-resistant), XDR (MDR susceptible to only one or two antibiotic categories) and PDR (resistant to all agents tested). Data were analyzed using χ2 test, Pearson’s correlation among years and variance-weighted least-square regression models with STATA 15.1, choosing a significance level of α=0.05.

**Results:** Out of 219 UPEC, 114 (52.05%) of them were MDR, of which 37 were XDR and 1 was PDR. Increasing resistance among years was seen for 4 out of 8 classes of antimicrobial agents. An overall increase in MDR proportion (coeff. = 0.074; 95CI 0.038-0.110), and in the number of concurrent resistances (coeff. = 0.297; 95CI 0.126-0.467) were assessed. A significative difference in the baseline level of resistances and the rising of them was observed between dogs and cats.

**Conclusions:** Approximately half of isolated strains were MDR (52.05%), but they came all from clinically ill patients, which might suggest that the prevalence in the general pet population is lower. Nevertheless the upward trend of antimicrobial resistance of UPEC to various antibiotics, the rise in the amount of concurrent resistances and the presence of XDRs and a PDR strain, poses serious public health issues.

Detection of pathogenic Vibrio species in estuary water samples in southwest Spain

Teresa Trujillo-Soto*, Jesus Ruiz-Cayuso, Inmaculada Guerrero Lozano, Fatima Galan-Sanchez, Sokratis Papaspyrou, Manuel Rodriguez-Iglesias

1Puerta del Mar Univ Hosp, Cadiz, Spain, 2Distrito Sanitario Bahía de Cádiz/La Janda, Cadiz, Spain, 3University of Cadiz, Cadiz, Spain

Background: Vibrio spp are aquatic bacteria that are ubiquitous in warm estuarine and coastal waters with low to moderate salinity. Several species of Vibrio are pathogens that can cause potentially serious infections such as septicemia, gastroenteritis, wound infections and otitis. In Europe Vibrio infections are not reportable (with cholera exception) and, consequently, accurate estimates of Vibrio spp are not available. The sea surface temperature of estuaries has increased as a result of climate change and Vibrio is considered the most reliable biomarker of climate change. Our objective has been to measure the presence of Vibrio with pathogenic potential in an area with high risk, due to low salinity and high temperature suitable for the appearance of infectious outbreaks.

Materials/methods: Water samples were collected in 6 estuarine points (Guadalquivir river outfall, SW Spain) with a biweekly frequency between July and September 2019. Parameters, such as temperature, pH and salinity were measured, and 500 ml of water was filtered (10 μm, 2.0 µm and 0.45 µm membrane filters (Millipore). Filters were inoculated in alkaline peptone water 2% NaCl and plated to TCBS agar (Becton Dickinson) and ChromID Vibrio agar (BioMerieux). Identification were done by MALDI-TOF MS (Bruker Daltonics). V. parahaemolyticus were screened for the presence of tdh and trh virulence genes by PCR.

Results: Ten species were isolated. V. alginolyticus was the most predominant (14) followed by V. harveyi (9), V. parahaemolyticus (8), V. fluvialis (7), V. natriegens (7), V. navarrensis (3), V. albensis (2), V. vulnificus (1), V. diazotrophicus (1) and V. furnissii (1). Detection of tdh and trh genes was negative for all V. parahaemolyticus isolates. The species with the highest pathogenic potential were related to the points of lowest salinity and highest temperature. Median water temperature was 26.3 ºC (range = 25.3-29.1º C).

Conclusions: Several species of Vibrio with high human pathogenic potential have been isolated in coastal waters but is important to highlight the isolation of V. vulnificus, V. parahaemolyticus and V. navarrensis strains. Although the pathogenic potential of V. alginolyticus is low, its high presence in seawater samples justifies the increasingly frequent isolation in clinical samples.

Comparison of different nucleic acid extraction methods for viral metagenomic analysis

Marina Sabatier1,2,3, Antonin Ball1,2,3, Grégory Destras1,2,3, Florence Morfin1,2, Bruno Lina1,2,3, Vincent Navratil4, Laurence Josset1,2,3

1Université de Lyon, Virologie et Pathologie Humaine (Virpath) - CIRI– INSERM U1111, Lyon, France, 2Hospices Civils De Lyon - Hcl, Laboratoire de Virologie – Institut des Agents Infectieux, Lyon, France, 3Hospital La Croix-Rousse - HCL, Centre National de Référence des Virus Respiratoires, Lyon, France, 4Université de Lyon, Pôle Rhône-Alpes de Bioinformatique - PRABI, Lyon, France

Background: In recent years, the development of viral metagenomics next-generation sequencing (mNGS) approaches have contributed to improve the characterization of the human virome. However, differences in mNGS protocols may impact virome characterization. In particular, the impact of viral nucleic extraction techniques on downstream analyses remains unknown. The objective of this study was to compare the performances of 3 different methods of extraction for respiratory virome characterization.

Materials/methods: Two respiratory samples from hospitalized patients with respiratory infections were selected: 1 nasopharyngeal aspirate positive for RSV, 1 bronchoalveolar lavage positive for HSV. One mock sample comprising 5 viral strains combined in equimolar ratio was also used. Nucleic acids were extracted in triplicate using one of the following methods: the manual QIAamp Viral RNA Mini Kit extraction (Qiagen) and two automated extraction platforms (MagNA Pure, Roche and EMag, Biomérieux). A single mNGS workflow was used for characterization of DNA and RNA respiratory viruses. Performances of the methods were compared in term of sensitivity, cross-sample contamination and reagents contamination (kitome).

Results: MagNA Pure and EMag yielded higher viral reads (0.22% to 0.23% viral reads) than QIAamp (0.04% viral reads). Higher relative abundance of RNA viruses was observed in the mock sample using QIAamp, compared to the other methods. Cross-sample contamination, evaluated using negative template controls (NTC) between each sample, were higher using MagNA Pure representing up to 37% of the reads in the NTC. Finally, QIAamp was associated with higher reads mapping to bacteriophages, including Siphoviridae/Microviridae/Podoviridae/Myoviridae families that likely belong to the kitome.

Conclusions: Although the potential of mNGS technology is very promising, several factors such as cross-sample contamination and kitome contamination can lead to misinterpretation. Our results highlighted the importance of nucleic acid extraction, which has an impact on number of viral reads, cross-sample contamination and kitome contamination by NGS analysis. Here, the automated platform EMag seems to be the best extraction platform for the respiratory virome characterization.

Abstract 9441

Phased-primer library preparation improves 16S rRNA metagenomics sequencing quality with limited impact on output
Valentin Scherz*, Sebastien Aeby¹, Gilbert Greub¹, Claire Bertelli¹

¹ Institute of Microbiology, University Hospital Center and University of Lausanne, Lausanne, Switzerland

Background: Widely used for amplicon-based metagenomics, Illumina sequencing quality is affected by sequence conservation of the 16S rRNA. The strong bias towards sequencing the same nucleotide in all clusters at each cycle reduces the contrast from signals emitted by colored fluorescent dideoxynucleotides. Thus, Illumina recommends spiking libraries with up to 30% of PhiX to increase sequence diversity, at the expense of reducing the exploitable throughput. Alternatively, Qiagen recently released QIAseq “phased-primers” kits introduce 0-11 nucleotides between adapters and primers to randomly shift sequences. In the present study, we compared standard Illumina library preparation with QIAseq for V3V4 16S rRNA metagenomics.

Materials/methods: Two negative extraction controls, three ATCC-2002 mock-community, 15 respiratory, and 12 fecal samples were prepared with both QIAseq and Illumina V3V4 protocols. Libraries were sequenced on Illumina Miseq. Reads were processed into Amplicon Sequence Variants (ASVs) by a pipeline based on DADA2 [Callahan 2016]. Sequences were rarefied at 20,000 for alpha and beta-diversity analyses. Moreover, V3V4 amplicons extracted from reference genomes of the ATCC-2002 bacteria by in silico PCR were compared to raw sequences and ASV with Qiime2 q2-quality-control plugin [Bolyen 2019].

Results: The average phred sequencing quality score was significantly better with QIAseq (35.4 vs 32.9, p<0.001), allowing more reads to pass filters in DADA2 pipeline (79.9% vs 67.8%, p<0.001). Despite these differences, Shannon alpha-diversity remained highly correlated (Pearson R = 0.98, p<0.001) and Bray-Curtis beta-diversity distance low between pairs of samples (mean = 0.15, sd = 0.21). Surprisingly, more sequences without mismatch, but also more sequences with more than 3 mismatches were found in ATCC-2002 raw reads prepared with Illumina compared to QIAseq (Figure). Noteworthy, similar error profiles were found for both preparations after read error correction by DADA2.

Conclusions: Phased-primers significantly improved sequencing quality and reduced sequencing errors for amplicon-based metagenomics. However, the effect on generated ASVs is minimal thanks to the effective error-correction provided by DADA2. Cost-efficiency analysis must consider the higher proportion of reads passing filters that would allow to sequence more samples in the same run.

Tuberculosis (TB) and cancer: why a previous TB infection may not alert us in a near future

Miguel Pedromingo Kus*,1,2, Jose Manuel Barragan Casas3, Ana Cristina Antoli Royo1, Teresa Meiras Arriaga1

1Hospital Nuestra Señora de Sansoles, Ávila, Spain, 2Complutense University of Madrid, Madrid, Spain

Background: it is believed that chronic inflammation during TBC may lead to cancer development. Although its pathogenesis is imperfectly known, several reports implicate TBC as a risk factor for cancer, especially in lung disease.

Co-existence of tuberculosis and cancer has been stated, particularly pulmonary tuberculosis being a risk factor for developing lung cancer. Fibrotic scars frequently found next to lung cancer development would explain this finding.

However, the nature of the relationship between pulmonary or non-pulmonary scarring and cancer remains uncertain and results are inconsistent.

Materials/methods: we conducted a computed retrospective review from microbiologically documented tuberculosis infections occurred over the past 13 years in Ávila, Spain (2006-2018). Our objective was to describe their localization and cancer relationship over time.

Results: 162 tuberculosis patients were finally included. Tuberculous lymphadenitis was found in 12 cases (12/162, 7.4%). We also found 6 miliary cases (3.7%), 5 tuberculous peritonitis (3.1%), 3 osteoarticular TBC (1.8%), 4 genitourinary TBC (2.5%), 2 cerebral forms (1.2%) and 1 case of hepatic and neonate TBC (0.6% each).

29 patients (29/162, 17.9%) had cancer; of them, 10 patients were diagnosed with cancer before TBC (34.5%), and 19 were newly diagnosed with cancer after TBC diagnosis (65.5%). The latter (all men but a woman with non-Hodgkin lymphoma) were divided into different categories according to organ involvement: 6 hematological (6/19, 31.6%), 5 colorectal (26.3%), 3 pulmonary (15.8%), and 1 cerebral, choanalcarcinoma, gastric, tongue and bladder cases (5.3% each).

TBC involvement for those who developed cancer after TBC diagnosis was variable: 8 pulmonary, 4 miliar, 3 genitourinary, 2 peritoneal, 1 lymphadenitis and 1 osteoarticular.

Finally, from the 10 previous-to-TBC cancer diagnosed patients, 7 developed pulmonary tuberculosis (70%), and 1 genitourinary, cerebral or lymphadenitis (10% each). Tumors site was principally digestive, prostatic, endometrial (2/10 each, 20%), and skin, lung, testicles and bladder (10% each).

Conclusions: our data do not show any apparent increase in cancer development amongst patients previously diagnosed with TBC. Moreover, there is no evidence that any tumor predisposes to suffering from TBC.

The link between tuberculous scarring and promotion of cancer needs to be deeply studied.

Abstract 9444

Investigation of colistin resistance mechanisms in Klebsiella pneumoniae strains
Baris Ata Borsa*1, Goktug Karabiyik2, Iskender Karalti3, Bilge Guvenc-Tuna4, Ibrahim Cagatay Acuner5

1Linköping University, Department of Physics, Chemistry and Biology, Linköping, Sweden, 2Koc University, Department of Cellular and Molecular Medicine, Istanbul, Turkey, 3Yeditepe University, Department of Nutrition and Dietetics, Istanbul, Turkey, 4Yeditepe University, Medical Faculty, Department of Biophysics, Istanbul, Turkey, 5Yeditepe University, Medical Faculty, Department of Medical Microbiology, Istanbul, Turkey

Background: Increasing rate of infections caused by multiple drug resistant Gram-negatives has led to resuscitation of colistin. As a result, colistin resistance, mainly among Klebsiella pneumoniae strains has also been increased. The aim of this study was to investigate molecular mechanisms behind colistin resistance.

Materials/methods: Colistin-resistant 9 K. pneumoniae strains isolated from clinical samples of different patients were involved in this study. To identify the mechanisms of resistance, expression levels of pmrA, pmrB, pmrD, and pmrK genes were measured with or without pre-exposure to colistin. Also, presence of mcr-1 gene was investigated by real-time PCR as well as rapid cassette test.

Results: As a result of the study, significantly increased expression levels of the pmrD and pmrK genes were observed in the experiments with or without previous colistin exposure both. Statistically significant increase in expression level of pmrB gene could only be detected in previous colistin exposure group which also showed increased the expressions of pmrD and pmrK genes compared with unexposed group. However, after colistin exposure, we have also detected an unexpected reversal of increased expression of pmrA gene. Relative median increase rates were found 3.4-fold for pmrA (p<0.05), 1.3-fold for pmrB (p=0.89), 5.8-fold for pmrD (p<0.01), and 17.6-fold for pmrK (p<0.01) without previous colistin exposure. When we have exposed bacteria to sub-inhibitory doses of colistin previously, we observed that the up regulation of pmrB, pmrD and pmrK genes were increased to 1.6-fold (p<0.05), 15.9-fold (p<0.01), and 70-fold (p<0.01) respectively. Unexpectedly, median expression levels of pmrA gene were found decreased with the previous colistin exposure. None of the 9 tested strains were positive for mcr-1 gene by both methods used.

Figure 1. Mean 2-ΔΔCq values for pmrA, pmrB, pmrD, and pmrK genes.

Conclusions: Colistin resistance is a growing problem in the treatment of infections caused by multiple drug resistant bacteria. We believe that more detailed data related to colistin resistance mechanisms and how the resistance spread among bacteria is crucial to prevent these infections as well as to control overuse of colistin.

**Abstract 9445**

**Culture-dependent analysis of the bacterial profile of breast milk samples from women with diagnosis of subacute lactational mastitis**

Mayli Lung1,2, Alicia García Señán*,1, Yolanda Roca1, Maria Carmen López1, Encarnación López Gimeno1, M.Belén Viñado1

1Vall d’Hebron University Hospital, Barcelona, Spain, 2Universitat Autònoma de Barcelona, Bellaterra, Spain, 3Institut Català de la Salut, Barcelona, Spain

**Background:** Lactational mastitis is a common and under-diagnosed condition that affects approximately one third of breastfeeding women. Subacute forms due to their nonspecific clinical manifestations are difficult to diagnose. In mastitis, techniques culture-independent have revealed a loss of bacterial diversity and predominance of some genera in milk samples. If an infectious etiology is suspected, bacterial culture of breast milk may be indicated. The aim was to describe, by culture, potential pathogens in breast milk samples from diagnosed women with subacute lactational mastitis and its antimicrobial susceptibility.

**Materials/methods:** Retrospective, descriptive study including 1493 cultures of maternal milk [663 patients], from 43 Primary Care Centers of the city of Barcelona, during June 2014-June 2018.

Quantitative cultures (10µL) were carried out. Based on some related articles and guidelines a bacterial count \(>10^3\)CFU/mL was considered. According to growth characteristics, cultures were classified into three categories: probably related to infectious process \(>10^3\)CFU/mL and \(\leq 3\) morphotypes), microbiota without clinical significance \(<10^3\)CFU/ml -except for *Staphylococcus aureus*-, or \(>10^3\)CFU/mL and \(>3\) morphotypes), and those with growth of microorganisms considered as contaminants. Identification and antimicrobial testing was only carried out on the first culture category isolations.

**Results:** Bacterial growth was observed in 90% (1346) of total cultures. 57.9% (774) were in the first culture category and 32.4% (222) and 9.7% (67) in the two remaining, respectively. Out of 1047 microorganisms identified, the most prevalent were coagulasa-negative staphylococci (CoNS) (49.2%, 515), followed by *S.aureus* (14.9%, 156), *Streptococcus* spp. (16.2%, 170) and *Cutibacterium* spp. (9.2%, 96). Antimicrobial resistance extract in *Staphylococcus* spp. is shown in the table:

<table>
<thead>
<tr>
<th>Microorganisms</th>
<th>Meticilline (%)</th>
<th>Clindamycin (%)</th>
<th>Quinolones (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoNS</td>
<td>43.1</td>
<td>44.9</td>
<td>28.1</td>
</tr>
<tr>
<td>S.aureus</td>
<td>5.4</td>
<td>9.2</td>
<td>12.1</td>
</tr>
</tbody>
</table>

**Conclusions:** *Staphylococcus* spp. and *Streptococcus* spp. were the most frequently isolated. There is an upward trend in the resistance of first line antibiotics used in primary care. Coincidence of the breast milk bacterioma core with the genera commonly involved in subacute mastitis added to the lack of rigorous cut-off point, makes difficult the culture interpretation. Clinical-microbiological correlation studies are necessary to support the indication and interpretation of maternal milk cultures.

**Presenter email address:** alicia.garcia@vhebron.net
Abstract 9448

Inappropriate use of interferon gamma release assays in a UK teaching hospital

Rowena Mills*, Rohit Bazaz1, James Wingfield Digby1

1Manchester University NHS Foundation Trust, National Aspergillosis Centre and Infectious Diseases Department, Wythenshawe Hospital, Manchester, United Kingdom

Background: It is estimated that between a quarter and a third of the world’s population has latent tuberculosis (LTBI). Interferon gamma release assays (IGRA) can be used to help diagnose LTBI. The UK National Institute for Health and Care Excellence (NICE) have published guidelines for the use of IGRAs during LTBI screening.

We had concerns that IGRAs were being used inappropriately in our institution, particularly during the assessment of patients for active TB, a practice which is not recommended by NICE or WHO. Inappropriate use of IGRAs has the potential to lead to unnecessary investigations and anti-tuberculosis therapy. Our aim was to determine the appropriateness of IGRA testing against the NICE Guidelines.

Materials/methods: Data were collected for all patients who had an IGRA between January and April 2018 at Manchester University NHS Foundation Trust and compared to the NICE guidelines.

Results: In total 202 patients had an IGRA, with a mean age of 48. IGRAs were sent outside of guideline recommendations in 90 cases (45%). Of these, 59 were done for immunosuppressive medication for which there is negligible or no increased risk of active TB. These included rituximab, azathioprine, ciclosporin, methotrexate, hydroxychloroquine and sulfasalazine. A further 28 were sent inappropriately during the work up of possible active TB.

112 tests were deemed appropriate, including 97 for immunosuppressive medication which increase the risk of active TB, 8 for close TB contact, 4 for conditions causing immunosuppression, 2 for NHS employees from high incident settings and 1 for a research case.

IGRAs were positive in 12 cases (5.9%), 5 of which were sent inappropriately. Of these 5, 1 attended TB clinic and completed LTBI treatment, 2 had alternative diagnoses, sarcoid and active TB. It was noted that 2 positives who were tested appropriately were previously treated for LTBI.

Conclusions: Nearly half of IGRAs were deemed inappropriate. Incorrect use of IGRAs on this scale, especially in areas with higher background rates of LTBI, could have significant cost implications with regard to test cost, unnecessary clinic appointments and anti-tuberculosis therapy. Further education on the indications for IGRAs is required to reduce inappropriate testing.

Incidence, risk factors and clinical impact of invasive pulmonary aspergillosis in patients hospitalised with influenza infection

Valeria Bellelli*, Guido Siccardi1, Luigi Celani1, Paolo Vassalini1, Elena Congeduti2, Cristian Borrazzo1, Mario Venditti1, Gabriella D’ettorre1

1Sapienza University of Rome, Roma, Italy, 2Electrical Engineering Mathematics and Computer Science, TU Delft, Delft, Netherlands

Background: Invasive Pulmonary Aspergillosis (IPA) typically occurs in immunocompromised subject. Recently, cases of IPA in immunocompetent patients have been reported associated with severe influenza virus infection.

Materials/methods: We performed a retrospective observational study in a large italian hospital during the past flu season (January–April 2019) to evaluate incidence, risk factors and clinical impact of IPA in patients with a diagnosis of influenza. We included patients with influenza confirmed by PCR on respiratory samples. For the diagnosis of IPA, we adopted the modified AspICU algorithm. We also developed a risk predictive model for IPA through machine learning techniques (decision trees), to try to identify IPA high risk patients who would benefit from antifungal prophylaxis.

Results: We enrolled 77 patients with flu, 5 of them have developed IPA. Associated risk factors were: smoking (p=0.011), COPD (p<0.001), lymphocytopenia (p<0.001) and corticosteroids (p<0.001). Clinical course of patients with IPA was more severe in terms of needs of hemodialysis (p=0.003), ECMO support (p=0.012), orotracheal intubation (p<0.001), ICU admission (p<0.001). The mortality rate was higher in IPA group (100%) compared to patients without Aspergillus coinfection (8%) (p<0.001). The predictive model has highlighted two variables as decisive in risk assessment: lymphocytes<340/µl and methylprednisolone>0.65 mg/kg/day.

Conclusions: IPA represents a frequent complication in hospitalized patients with influenza infection. Our data revealed smoking, COPD, steroid treatment and lymphocytopenia at the diagnosis of influenza as risk factors for development of IPA in patients hospitalized with influenza virus infection. Due to extremely severe prognosis, antifungal prophylaxis in IPA high risk patients should be considered and its effectiveness should be studied on larger population. Furthermore, in our study, the methodology for the prediction of IPA risk using machine learning techniques, seemed to provide interesting insights about relevant IPA associated factors. Nonetheless these findings needed to be confirmed and validated on larger cohorts.

**Dengue fever in returning travellers: a retrospective study in London, UK**

Amedine Duret*, Ivo Suchett-Kaye1, Sayyed Adnan Aali1, Padmasayee Papineni1

1Ealing Hospital, London, United Kingdom

**Background:** Dengue fever is common worldwide, however clinicians in Europe may rarely manage it. We present a case series of acute dengue from Ealing Hospital in West London, which serves an ethnically diverse population with a large proportion of migrants from the Indian sub-continent.

**Materials/methods:** Patients were identified from the laboratory information management system (Winpath®) and clinical data obtained from electronic patient records from 01/05/2014-25/11/2019.

Cases of acute dengue fever were defined as: virus IgM immunoassay positive, or viral RNA detected using polymerase chain reaction (PCR).

**Results:** Over the study period, 126 blood samples were sent. 23 patients had acute dengue: 4 (17%) PCR positive, 10 (43%) IgM positive, and 9 (39%) both PCR and IgM positive.

Most (17) patients presented in winter and autumn months, reflecting an increase in cases associated with the rainy season in Asia. The median age was 32 (IQR 28-44). Most had travelled to South Asia (11, 47%), particularly India, followed by South-East Asia (8, 35%).

All patients presented with fever. Other common symptoms were arthralgia/myalgia (8, 35%), headache/retro-orbital pain (5, 22%), and rash (4, 17%).

At presentation, thrombocytopenia (15, 65%), leucopenia (22, 96%) and transaminitis (5, 22%) were often already present, but they tended to develop further during the course of the illness. During admission 21 (95%) developed thrombocytopenia, 21 (95%) developed leucopenia, and 13 (59%) developed transaminitis. One 18-year-old patient had severe dengue with liver involvement and plasma leakage and died of haemophagocytic lymphohistocytosis.

**Conclusions:** Most patients in our analysis had travelled to India, reflecting the local epidemiology of our population who were visiting friends and relatives. This highlights the need to improve pre-travel bite avoidance advice to this group.

The classical biochemical picture of thrombocytopenia, leukenopaenia and transaminitis may not be seen at presentation. Therefore, clinicians must have a high index of suspicion and recognise the need for close monitoring. Most returning travellers have a mild clinical course but a small proportion develop severe complications that necessitates intensive care support.

Abstract 9452

KPC-producing and colistin-resistant Klebsiella pneumoniae ST258 persistence during wastewater treatment plant processes

Ilda Czobor*1, Irina Gheorghe2,3, Laura Ioana Popa1, Marius Surlea1, Simona Paraschiv1, Dan Otelea1, Luminita Marutescu1,3, Marcela Popa1, Sajjad Mohsin3, Mariana Carmen Chifiriuc1,3
1University of Bucharest, Research Institute of the University of Bucharest, Bucharest, Romania, 2University of Bucharest, Research Institute of the University of Bucharest, Bucureşti, Romania, 3University of Bucharest, Faculty of Biology, Microbiology Dept., Bucureşti, Romania, 4National Institute of Infectious Diseases-Prof. Dr. Matei Balş, Genetics Dept., Bucureşti, Romania, 5National Institute of Infectious Diseases-Prof. Dr. Matei Balş, Genetics Dept., Bucharest, Romania

Background: Carbapenem resistance (CR) in wastewaters and surface waters represents an important issue, as resistance strains could disseminate via agriculture to humans and animals and ultimately cause difficult-to-treat infections. Here we investigated the CR and ESBL producing strains within and near a wastewater treatment plant (WWTP) from South Romania.

Materials/methods: Wastewater samples were collected in April 2019 from influent, residual sludge, effluent, as well as upstream and downstream of the WWTP, filtered through 0.45 µm pore filters, inoculated on selective chromogenic agar plates (ChromID ESBL, CARBA). CR and ESBL counts were estimated from several volumes and/or dilutions. Six colonies were randomly selected from each phenotype/sample identified by MALDI-TOF-Ms and analyzed for antibiotic susceptibility patterns. Strains with similar antibiotic resistance (AR) profiles from each sampling point were subjected to whole genome sequencing (WGS).

Results: Quantification of target colonies from chromogenic media is summarized in table 1

<table>
<thead>
<tr>
<th>Sample</th>
<th>ESBL KESC</th>

<td>7.25E+01</td>
<td>3 CR (ST258)</td>
</tr>
</tbody>
</table>

45 Klebsiella pneumoniae (21 ESBL and 24 CR) were selected from each sampling point, all expressing multidrug resistance profile, with 12 CR strains being resistant also to colistin. WGS data revealed that all selected CR strains are ST258 KPC-2 producing K. pneumoniae and have an IS26Kpn insertion in mgrB gene. AR genes to several other classes of antibiotics are present. Core genome comparison analyses (Ridom SeqSphere) suggests they represent the same clone. ESBL strains belonged to different STs (table 1) and mainly harbored blaCTX-M-15 and various blaSHV alleles.

Conclusions: Here we report the presence of a K. pneumoniae ST258 KPC-producing and colistin resistant clone in all sampling points (including downstream of the WWTP) but upstream point, highlighting that this successful clone could survive in the WWTP and evade in surface waters.

Abstract 9455

**Consumption of antibiotics effective against multi-resistant Gram-positive pathogens: data of German hospitals from 2015-2018**

Birgitta Schweickert*, Marcel Feig1, Marc Schneider1, Karin Gruenschn1, Willrich Niklas1, Michael Behnke5, Luis Alberto Pena Diaz2, Petra Gastmeier1, Doreen Richter1, Hans-Peter Blank1, Hartwig Wehrmeyer1, Tim Eckmanns1, Muna Abu Sin1

1Robert Koch-Institut, Department for nosocomial infections and surveillance of antimicrobial resistance and antimicrobial consumption, Berlin, Germany, 2Charité University Medicine Berlin Campus Benjamin Franklin, Institute for Hygiene and environmental medicine, Berlin, Germany

**Background:** In the light of constantly decreasing rates of methicillin-resistant *Staphylococcus aureus* and a steep increase of vancomycin-resistant *Enterococcus faecium* in blood culture isolates over the last years, the consumption of antibiotics used for the treatment of multiresistant grampositive pathogens should be assessed. Hospital consumption data from 2015-2018 derived from the German Antibiotic Consumption Surveillance (AVS)-system have been analyzed.

**Materials/methods:** The calculation of antibiotic consumption values is based on the ATC (Anatomical Therapeutic Chemical) /DDD (Defined Daily Dose) method of WHO (ATC/DDD-version 2019). Target value is the antibiotic consumption density (CD) expressed in DDD per 100 patient days (PD). The CDs of vancomycin, linezolid, daptomycin, tigecycline, ceftobiprole mediocaril and ceftaroline fosamil are presented as medians with interquartile range. The analysis relies on data submissions of general acute care hospitals from 2015 to 2018 and is confined to hospitals, which consistently provided data for the whole time period (n=90). Data have been analyzed for the whole hospital and differentiated according to hospital size (≤800/>800 beds).

**Results:** The data reveal that the median CDs of total antibiotic consumption and of the selected antibiotic substances are higher in hospitals >800 beds than in hospitals ≤800 beds and partly show an opposite course over time for both size categories (Table 1). This also applies for the proportional use in relation to total consumption. The median CDs of vancomycin slightly increased from 2015 to 2018 in hospitals >800 but showed a decline in hospitals ≤800 beds. The use of linezolid increased in hospitals of both size categories with a more pronounced rise in hospitals ≤800 beds. Daptomycin is used in less than 50% of the hospitals ≤800 beds in 2015/16 but the median CDs reveal a rise over time for hospitals of both size categories. The consumption of tigecycline shows a relatively constant course. Fifth generation cephalosporins were only used sporadically in <10 hospitals.

**Conclusions:** Descriptive analysis of routine surveillance data shows an increase of the consumption of linezolid and daptomycin, albeit at a low level. The analysis of an association with the changing epidemiology of MRSA and VRE requires further investigation.

Application of a user-friendly, end-to-end metagenomics platform for rapid pathogen identification in children with osteoarticular infections

Rita Stinnett1, Nanda Ramchandar2,3, Heng Xie1, Steven Flygare1, Toni Schwarz1, Kate Broadbent1, Amy Davis1, Lauge Farnaes2,3, Robert Schlaberg*1,4

1IDbyDNA, Salt Lake City, United States, 2Rady Children’s Hospital - San Diego, San Diego, United States, 3University of California San Diego, La Jolla, United States, 4The University of Utah, Salt Lake City, United States

Background: Osteoarticular infections may cause substantial morbidity in children. Rapid, accurate and comprehensive pathogen detection is critical in directing antimicrobial therapy and prevention of long-term sequelae. In adults, metagenomic sequencing has been demonstrated to increase the diagnostic yield compared to standard care testing, and there is growing interest in implementing metagenomic testing in the routine diagnostic workup. However, complexities of metagenomic data analysis pose barriers for adoption. We present a metagenomic shotgun RNA and DNA assay built on a user-friendly software platform that supports all steps from sample to report. We used this assay for rapid pathogen identification in hospitalized children with osteoarticular infections.

Materials/Methods: Children hospitalized with a diagnosis of osteomyelitis and/or septic arthritis were enrolled in an IRB-approved study. Operative samples (swabs and synovial fluid) were analyzed by shotgun metagenomic RNA and DNA sequencing with the Explify platform. This platform provides easy-to-use metagenomic analysis including quality control (QC) and quality filtering of sequencing data, identification of a customizable set of pathogens using curated databases, reproducible result interpretation, result review, and report generation.

Results: A total of 31 samples from 21 children were analyzed by metagenomic sequencing (2 samples were available for 10 patients). For use in this study, interpretive criteria were defined for >700 relevant bacteria and fungi that have been implicated in the pathogenesis of osteoarticular infections based on published data. Metagenomic sequencing detected a putative pathogen in 14 of 21 (67%) patients. Putative pathogens detected included Staphylococcus aureus, Kingella kingae, and Enterobacter cloacae. Predominant detections in this study were consistent with the known etiology of pediatric osteoarticular infections and were corroborated by standard of care testing.

Conclusions: Analysis of metagenomic sequencing data with the Explify platform provided rapid pathogen identification (<1 hour from data availability to result). The use of evidence-based interpretive criteria maximized the diagnostic yield while limiting detection of non-pathogenic microorganisms that often complicate interpretation of metagenomic sequencing results. The Explify platform provides user-friendly access to comprehensive application-specific QC, pathogen detection, and identification of antimicrobial resistance markers.

Abstract 9459

In vitro activity of novel β-lactam and β-lactam enhancer combination, cefepime-zidebactam (WCK5222) against Gram-negative clinical isolates with high-level carbapenem resistance rate: report from a large tertiary care centre in India

Saranya Vijayakumar1, Baby S. Abirami1, Veeraraghavan Balaji*1

1Christian Medical College, Vellore, India

Background: Antimicrobial agents currently available for clinical use show limited activity against multi-drug resistant (MDR) Enterobacterales and Pseudomonas aeruginosa, emphasizing the urgent need for MDR Gram-negatives active novel agents. WCK5222 (FEP-ZID) is a combination of cefepime and a PBP2 binding β-lactam enhancer antibiotic, zidebactam. FEP-ZID is being developed for the treatment of infections caused by MDR/XDR Gram negatives including Enterobacterales and P. aeruginosa. In this study, we evaluated the in-vitro activity of cefepime-zidebactam against contemporary clinical isolates of E. coli, K. Pneumoniae and P. aeruginosa collected from a large tertiary care center in India.

Materials/methods: A total of 528 nosocomial clinical isolates comprised of E. coli (n=155), K. pneumoniae (n=232) and P. aeruginosa (n=141), collected from January 2017 to August 2019 at Christian Medical College, Vellore, India were included in this study. The isolates included those expressing class A ESBLs, AmpC, Class B and D carbapenemases. Susceptibility testing was performed against cefepime-zidebactam (1:1) and comparator antibiotics by CLSI recommended broth microdilution method.

Results: Meropenem non-susceptibility was observed in 52% of Enterobacterales (E.coli & K.pneumoniae) and 63% P. aeruginosa isolates. FEP-ZID demonstrated potent activity against E.coli with MIC50/90 of 0.12/0.25 mg/L and K. pneumoniae MIC50/90 with 0.25/2.0 mg/L. All tested P. aeruginosa isolates were inhibited at FEP-ZID MIC of ≤16 mg/L. Ceftazidime-avibactam, imipenem-relebactam, ceftolozane-tazobactam showed limited activity with MIC90 of >16 mg/L against all three pathogens group.

Conclusions: While β-lactam and β-lactamase inhibitors, ceftazidime-avibactam, imipenem-relebactam and ceftolozane-tazobactam suffer from important spectrum gaps, β-lactam and β-lactam enhancer, FEP-ZID exhibits potent and comprehensive activity against MDR Gram negatives irrespective of the associated resistance mechanisms. The present in-vitro study findings further support the clinical development of cefepime-zidebactam for the treatment of MDR Gram-negative infections.

Direct detection of *Escherichia coli* in clinical samples by an ultrasensitive fluorescent copper nanoparticles-aptasensor

Yuling Xiao*, 1, Peng Zhang2, LI Wang1, Zhenzhen Wang1, Jia Geng1,2

1Westchina Hospital, Sichuan university, Chengdu, China, 2State Key Laboratory of Biotherapy, Sichuan University, Chengdu, China

**Background:** *Escherichia coli* (*E. coli*) is a particularly significant pathogen and has always been a serious threat to human health. Conventional culture-based detection methods are quite time-consuming and other quick detection methods are usually based on complex pre-treatments. Therefore, the development of a convenient, rapid and cheap strategy will be very desirable and practical for the direct detection of *E. coli* in clinical samples.

**Materials/methods:** We designed a capture probe complex that contained specific *E. coli*-aptamer and partly hybridized signal trigger sequence, which had the ability of binding to viable *E. coli* directly. The trigger sequences would be liberated when the capture probe complexes bound to *E. coli*, and reacted with three hairpins successively to initiate the triple strand migration reaction, producing numerous hairpin-A-B-C complexes with scaffolds of copper nanoparticles ([CuNPs]), thus providing significantly enhanced fluorescent signals (shown in Fig. 1). Sensitivity, specificity, reproducibility and linear correlation of the nanoparticles-aptasensor were tested and verified. In order to evaluate the clinical application of this strategy, *E. coli* at the concentrations from 10 to 10⁵ CFU/mL in various clinical samples including blood, urine, cerebrospinal fluid, pleural effusion, and ascites were detected.

**Results:** The strategy achieved an ultrasensitive detection limit of live *E. coli* down to 10 CFU/mL with a linear range from 10 to 10⁵ CFU/mL, and no significant fluorescence intensity increase was observed upon the addition of other clinical pathogenic bacteria except for *E. coli*. The linear range between the fluorescence intensity and viable *E. coli* concentration was from 10 to 10⁴ CFU/mL in different clinical samples.

**Conclusions:** In this study, we provide a novel DNA extraction-free, label-free and enzyme-free strategy for direct detection of viable *E. coli* in clinical samples by an ultrasensitive fluorescent copper nanoparticles-aptasensor, which shows an ultrasensitive detection limit and a high specificity, as well as a low cost.

![Fig. 1 Schematic illustration of the DNA extraction-free, label-free and enzyme-free direct detection of viable *E. coli* based on a novel ultrasensitive fluorescent copper nanoparticles-aptasensor.](image)

Abstract 9463

Evaluation of on-site polymerase chain reaction technology for cerebrospinal fluid samples at Cork University Hospital versus referral to reference laboratories in suspected cases of meningitis or encephalitis

Rachel Barry¹, Catherine Dempsey¹, Louise Barry¹, Carmel Hooton¹, Claire Reynolds¹, Molly Cremin¹, Susanna Felsenstein¹, Dan Corcoran¹

¹Cork University Hospital, Cork, Ireland

Background: Currently, cerebrospinal fluid (CSF) samples from Cork University Hospital, that require molecular diagnostics for viral/bacterial pathogens, are sent to the National Virus Reference Laboratory and the Irish Meningitis and Sepsis Reference Laboratory. This introduces a significant delay for a critical result (turn-around time [TAT] 72hrs - 7 days). Temporary funding from The Strategy for the Control of Antimicrobial Resistance Ireland (SARI), a health service initiative, was sought to facilitate on-site testing using FilmArray® polymerase chain reaction technology, with a predicted TAT of 2 hours for a result.

Materials/methods: Our aims were to perform in-house validation of FilmArray® technology for CSF samples, versus referral to reference laboratories (n=100); secondly, to perform a clinical audit evaluating differences in length of stay and antimicrobial prescribing, based on rapid acquisition of a result; and finally, to provide a cost analysis of our findings.

Any CSF with abnormally high white cell count was tested on the FilmArray®. Samples were simultaneously sent to reference laboratories to correlate results and allow comparison of TAT. Clinical audit was facilitated through communication with the attending clinical team, data collection sheets, and medical chart reviews.

Results: Preliminary results (n=44/100) have shown a TAT of 8 hours (FilmArray®) versus 6 days (reference laboratories). In cases of enterovirus meningitis, length of stay was reduced by 2.4 days. Unnecessary antimicrobials were stopped in 48% of cases. In 2 cases an unexpected pathogen was isolated and essential antimicrobials were started. Total savings, including cost of bed days and early cessation of antimicrobials, amounted to €71,387 (deducting €150/cost of test).

Conclusions: On-site rapid molecular testing for CSF is cost-effective, reduces length of stay, and improves antimicrobial stewardship practices.

Abstract 9467

**Carbapenem-resistant Enterobacteriaceae infections: more could be worst?**

Stella De Gregorio*, Valeria Tudanca, Silvia Repetto, Lucía Paravano, Carlos Rodríguez, Marcela Nastro, Daniel Ricardo Stecher, Carlos Vay, Angela Famiglietti, Monica Foccoli

1Hospital de Clínicas “José de San Martín”, Buenos Aires, Argentina, 2Hospital de Clínicas “José de San Martín”, Buenos Aires, Argentina

**Background:** Carbapenem-resistant Enterobacteriaceae (CRE) infections have worldwide spread during the last years. CRE dissemination was attributed to clonal spread (bla\_KPC gene) and less commonly by horizontal gene transference. The last one could be responsible for isolation several CRE in the same sample. Our aim was to compare infected patients with polymicrobial isolates by several CRE (CRE-S) and patients with polymicrobial isolates being only one of them CRE (CRE-M).

**Materials/methods:** A retrospective, case-control descriptive study was conducted at a teaching Hospital. Period: 2010-2017.

Adult inpatients with CRE infections were included and divided in two groups.

We compared epidemiological, demographic, clinical and microbiological characteristics of patients in Group A: polymicrobial isolates with CRE-S and Group B: polymicrobial isolates with CRE-M.

Identification was done by MALDI-TOF MS Bruker Daltonics, Germany, Biotyper 3.1 and susceptibility test by Phoenix100 system BD.

The presence of KPC-carbapenemase was confirmed phenotypically and genotypically

**Results:** Group A: 16 patients/17 episodes and Group B: 41 patients/episodes.

No differences statistically significant were found between age, sex, co-morbidities, Charlson Score, length of stay (days), antibiotics previously and mortality.

Surgical site infections episodes of CRE-S were the only statistically significant variable

\(p: 0,005\) OR 1,8 IC 1,26-2,5

Abstract 9469

Integrons & antibiotic resistance: do integrons provide 'adaptation on demand'?  
Celia Souque*1, Jose Escudero2, Craig Maclean1

1University of Oxford, Oxford, United Kingdom, 2Departamento de Sanidad Animal, Madrid, Spain

Background: Mobile integrons are widespread and clinically relevant drivers of antibiotic resistance, present in some settings in up to 60% of Gram-negative clinical isolates. Acting as genetic platforms, they allow bacteria to capture, express and re-order mobile antibiotic resistance gene cassettes, whose expression levels depend on their distance from the promoter, located at the start of the integron. Cassettes can be integrated and excised by the integrase enzyme, produced by the bacteria in time of stress. It has been hypothesized that integrons allow bacteria to adapt quickly to changing antibiotic pressures by reshuffling the cassette order, and therefore their resistance levels, such that integrons provide ‘adaptation on demand’.

Materials/methods: To test this ‘adaptation on demand’ hypothesis we used experimental evolution to test the impact of the integron integrase on evolvability. Specifically, we constructed a mobile integron carrying three resistance cassettes and either a functional or dysfunctional integrase. Using Pseudomonas aeruginosa, we tested the impact of the integrase on the bacteria ability to adapt to increasing doses of antibiotics when the relevant resistance cassette is located at the end of the array and can be brought forward by integrase activity, in the case of two different cassettes and their corresponding antibiotics (gentamicin and piperacillin). In the end starting and evolved populations were sequenced by Next Generation Sequencing to identify any integron rearrangements.

Results: When compared against the non-functional integrase control population, we saw an increase in evolvability against gentamicin but a decrease in survival against piperacillin. We identified extensive cassettes rearrangements as well as cassette duplications in nearly all the surviving populations with a functional integrase in the gentamicin experiment. While the frequency of rearrangements was much lower in the piperacillin populations, we observed unexpected integron-mediated inversions in the plasmid backbone.

Conclusions: These results highlight the key impact of antibiotics and cassette characteristics on the potential integrase benefits and provide novel insights in the mechanisms controlling cassettes and integrase prevalence. We showed integrase activity is not limited to cassette shuffling or cassette acquisition, but may also promote cassette duplication and off-target recombinations, with far-reaching effects on plasmid maintenance and evolution.

De novo hybrid genome assembly and genome analysis of polymyxin- and carbapenem-resistant clinical isolate *Klebsiella pneumoniae*

Margarita Zubasheva*, Dmitrij Shcherbinin¹, Gleb Speshilov¹,², Vladimir Zhukhovitsky³

¹Gamaleya Research Center for Epidemiology and Microbiology, Moscow, Russian Federation, ²BioSpark Limited Liability Company, Troitsk, Russian Federation

Abstract third-party references: 1 Gamaleya Research Center for Epidemiology and Microbiology, Gamaleya street, 18, Moscow, 123098, Russian Federation. 2 BioSpark Limited Liability Company, Moscow, Troitsk, Promyshlennaya street, 2b, build. 61-62, 108841, Russian Federation

**Background:** *Klebsiella pneumoniae* is the bacteria with special clinical and epidemiological significance due to the ability to form acquired multiple resistance. Polymyxins are currently the last resort for the treatment of infections caused by gram-negative multidrug-resistant *K. pneumoniae*, especially carbapenem resistant.

**Materials/methods:** Carbapenem- and polymyxin (32 mg/ml) resistant *K. pneumoniae* 20467 was analyzed by whole genome sequencing. Library preparation and sequencing were performed by BioSpark Limited Liability Company (Moscow, Troitsk). The DNA sequencing was performed using an Illumina NovaSeq 6000 platform (USA) and an Oxford Nanopore MinION sequencer (UK) according to manufacturer’s instructions. The Unicycler pipeline v0.4.8 was used for the hybrid assembly *de novo* of the Nanopore and the Illumina reads. The quality of genome assembly was estimated by using Quast server. The sequence annotation and additional gene prediction was performed by the RASTtk server. The Comprehensive Antibiotic Resistance Database and RASTtk server were used for identification of antibiotic-resistance genes. The sequences of the allelic variants of the resistant genes were taken from the Pasteur Institute database (https://bigsdb.pasteur.fr/).

**Results:** The *de novo* assembled genome of *K. pneumoniae* 20467 consists of a circular chromosome of length 5,365,937 bp with the average GC content of 56,6%, and of four circular plasmids of sizes 127,792 bp, 63,589 bp, 8,351 bp and 4,897 bp, and approximate multiplicities of 1.76x, 1.86x, 5.5x and 3.57x, respectively. The chromosome contained 108 RNA-genes (23 rRNA genes, 85 tRNA genes). A total of 5,304 predicted protein-coding genes were identified. Genes, involved in multidrug resistance, were found: 4 fluoroquinolone resistance genes (*gyrA_20, gyrB_1, parC_10 and parE_1*), 4 genes resistant to beta-lactamase [carbapenems] (*blaSHV_110, blaCTX_M_CTX-M-15, blaOXA_OXA-1, blaOXA_OXA-48*); 2 genes of resistance to aminoglycoside (*aac3 Ia c2 and aac6P lb b-cr*); one gene for resistance to fosfomycin (*fosA*). In the polymyxin resistance genes *phoP, pmrA, pmrB, arnA, arnB, arnC, arnD, eptA, arnF, arnT* no mutations were found. In polymyxin resistance gene *phoQ* P75T mutation was found [conservative in all 140 allelic variants of the *phoQ* P75 gene]. The mutation C39Y in the gene *mgrB* founded earlier by PCR was confirmed.

**Conclusions:** It is known that a functional defect in *mgrB* leads to resistance to polymyxins.

**Abstract 9477**

**Do we need to screen the colibactin genomic island (CGI) for diagnosis of colorectal cancer? Paradigm of Klebsiella pneumoniae**

Mariem Ben Khedher1, Sami Khabthani1, Raymond Ruimy2, Jean-Marc Rolain1, Seydina M. Diene*1

1Aix-Marseille University, MEPHI, IRD, APHM, IHU-Mediterranee Infection, Marseille, France, 2Centre Hospitalier Universitaire de Nice, Laboratoire de bactériologie, Nice, France

**Background:** Colibactin is a bacterial genotoxin encoding by polyketide synthase (pks) genomic island in Enterobacteriaceae. This bacterial toxin induces cell cycle arrest, DNA double-strand breaks, senescence and DNA interstrand cross-links in infected eukaryotic cells and thus, as reported colibactin-producing Escherichia coli was associated with colorectal cancer in human. This bacterium has been reported as the main colibactin-producer despite that colibactin has been identified in other bacterial species. However, prevalence, origin, and structural genetic organization of the colibactin genomic island (CGI) among Enterobacteriaceae are unknown.

**Materials/methods:** Here, we aim to analyze 29’934 genomes of different bacterial genera with clinical interest including Klebsiella (n= 6’412), Escherichia (n= 18’000), Citrobacter (n= 287), Shigella (n= 2’000), Enterobacter (n= 800), Salmonella (n= 9’000), Proteus (n= 190), Serratia (n= 600), Yersinia (n= 700), and Morganella (n= 65) to investigate CGI in these genomes.

**Results:** As preliminary results, among the 6’412 analyzed genomes of K. pneumoniae, CGI was detected 187 genomes (2.92%). This latter with 55’140-bp of size exhibited highly conserved structure in this bacterial species. Interestingly, annotation of this CGI reveals the presence of transposable elements in both sides of the CGI, suggesting therefore a possible transfer to other bacteria. Analysis of available metadata of CGI-positive K. pneumoniae genomes (n=107 isolates), reveals that all were exclusively isolated from human and from different clinical samples including broncho-alveolar lavages, blood, liver abscess, respiratory tract secretion, sputum, wound, and urine. 36% of these KP isolates were reported in USA and 25% reported in China and Thailand. Thanks to our preliminary results, the prevalence of CGI (2.92%) in sequenced K. pneumoniae genomes appears not negligible and highlights therefore the importance to explore the presence of this CGI in genomes of Enterobacteriaceae with clinical interest. Since the CGI is located on transposable element, genome analysis of Enterobacteriaceae species will bring new insights on the potential transmission mechanism of the CGI in bacteria associated with colorectal cancer.

**Conclusions:** Expected findings of this study will highlight the needness to set up molecular diagnostic tools, such as specific CGI-qPCR that could be applied directly from rectal swab samples to diagnosis colorectal cancer.

Co-aggregation of uropathogenic Klebsiella oxytoca with Klebsiella pneumoniae and probiotic Escherichia coli on the cell line

Adeliia Giliazeva*1,2, Jonas Noack2, Ayslu Mardanova1

1Kazan Federal University, Institute of Fundamental Medicine and Biology, Kazan, Russian Federation, 2Brandenburg University of Technology Cottbus-Senftenberg, Institute of Biotechnology, Senftenberg, Germany

Background: Polymicrobial infections account for up to 25% bacterial infections, especially in urological department. However, there is not enough data of interbacterial communication among uropathogenic bacteria. Oral bacteria form mixed bacterial aggregates that involve lectin-like adhesins and polysaccharide-containing receptors. Besides sugars, arginine prevents interbacterial coaggregation. During this study mixed adhesion of uropathogenic bacteria was performed.

Materials/methods: For infection GFP-labeled urine isolate Klebsiella oxytoca and td-Tomato-expressing K. pneumoniae, Enterobacter cloacae, Escherichia coli and probiotic E. coli Nissle (EcN) as a negative control were used. E. coli strains were grown for 48 h at 37 °C without shaking, while the rest strains were grown with shaking at 37 °C until OD600 0.5. Bacteria were treated with lactose (0.1 M), mannose (0.1 M) and arginine (0.05 M) for 30 min. Then 5 x 10^6 of each bacteria/well were added to bladder carcinoma cells 5637 in different combinations and plates were incubated for 2 h. Cell nuclei were stained with DAPI. Plates were analyzed with multicolor fluorescence detection system VideoScan (Aklides®). The measurement results were evaluated in software MaxiSlider and MaxiSliderAddon.

Results: During infection K. oxytoca formed coaggregates with K. pneumoniae and EcN, while coaggregation with the other bacteria was not significant. While mixed with K. pneumoniae, adhesion rate of K. oxytoca is increased compared to single K. oxytoca infection [2050±820 versus 513±123 bac/mm²]; presence of EcN caused more relevant increase of adhesion of K. oxytoca [6639±1790]. Mannose decreased EcN adherence to 46 % and in mixed infection decreased adhesion of K. oxytoca [3024±1802], but had no effect on the adherence of single Klebsiella. Lactose and arginine did not prevent the formation of coaggregates. In mixed infection 40-63 % of overall adhered K. oxytoca were coaggregated with K. pneumoniae, while the ratio of EcN-associated K. oxytoca was 56-88 %.

Conclusions: Adhesion rate of K. oxytoca is increased in model polymicrobial infection. This may indicate bacterial synergy in host colonization and their reinforcement of virulent properties of each other during infection.

Klebsiella oxytoca (green) in coaggregation with K. pneumoniae (red, A) and probiotic Escherichia coli Nissle (red, B) on the urothelial cells 5637.

Longitudinal assessment of liver fibrosis rates using non-invasive APRI and Fib-4 scores in HIV, HBV and HIV-HBV co-infected patients

Diana Gabriela Iacob*, Monica Lumințița Luminos1, Benea Otilia2, Ana Maria Tudor2, Simona Alexandra Iacob2, Cristina Olariu3, Mihaela Raus2, Loredana Benea3, Cristina Marin3, Simona Maria Ruta4

1University Emergency Hospital, Bucharest, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania, 2“Prof. dr. Matei Bals” National Institute of Infectious Diseases, Bucharest, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania, 3“Prof. dr. Matei Bals” National Institute of Infectious Diseases, Bucharest, Romania, 4“Stefan S. Nicolau” Institute of Virology, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania

Background: Liver disease is a major cause of mortality in patients infected with human immunodeficiency virus (HIV) and/or hepatitis B viral infection (HBV). Given the large Romanian cohort of HIV and HIV-HBV patients infected in early infancy, the current study analysed the progression and risk factors for liver fibrosis in HIV, HIV-HBV and HBV infected patients under long-term antiviral treatment.

Materials/methods: We performed a 6-year retrospective observational study at “Prof. dr. Matei Bals” National Institute of Infectious Diseases on 310 treated patients (113 HIV, 103 HBV and 104 HIV-HBV coinfected patients) with median ages of 49, 42 and 37 years (69% of HIV and HIV-HBV patients treated>10 years at enrolment). The rate of liver fibrosis was estimated at 4 time-points (at 6, 2-, 1- year prior and current data) using APRI and Fib-4 non-invasive scores. APRI scores <0.5 and Fib-4 values <1.45 were used to rule out fibrosis and APRI ≥1.5 and Fib-4 ≥3.25 indicated advanced fibrosis. Data was analysed using generalized estimating equations, nonparametrical Kruskal-Wallis and Pearson correlations.

Results: Over time most patients displayed normal transaminases (≥88% for each group) and advanced liver fibrosis was detected in coinfected patients only (0.05%, 5/104).

APRI and Fib-4 scores were discordant between groups, with consistently higher APRI scores in HIV-HBV-infected patients versus higher Fib-4 scores in HBV mono-infected patients as confirmed using non-parametrical Kruskal Wallis tests.

In all models Fib-4 and APRI scores were associated with plasma HIV RNA (B=1.056, p<0.001 and B=3.716, p<0.001 respectively) and HIV-HBV co-infection (B=-0.416, p<0.001 and B=-0.699, P=0.012).

Interestingly, at the last assessment cholesterol was significantly associated with both APRI and Fib-4 scores (p=0.002 and 0.001 respectively), in addition to HIV RNA, HBV DNA and treatment adherence.

Conclusions: We observed a low rate of liver fibrosis across groups over a 6-year period. Nevertheless, few HIV-HBV co-infected patients progressed to advanced liver fibrosis despite treatment.

It is probable that over time dyslipidemia plays an important role in the progression of liver disease in HIV and HIV-HBV co-infected patients, yet further data are still needed to confirm this effect.

Knowing local cumulative antibiogram: does it matter?

Sara Carvalho1, João Paulo Caldas2, Raquel Duro2, Carlos Alves2, Nuno Rocha Pereira*1,2

1Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal, 2Centro Hospitalar Universitário São João, Porto, Portugal

Abstracts 2020

Background: Antimicrobial resistance is a serious and growing threat to global health, with consequences in patient’s outcomes and with broad social and economic impact. Responsible use of antibiotics is a crucial instrument to tackle this threat.Cumulative antibiograms are tools that aim to improve knowledge about local antimicrobial resistance epidemiology and by doing so improve antibiotics use. Our aim was to evaluate the impact in antimicrobial appropriateness of a consistent use of cumulative antibiogram in antimicrobial prescription moments. As a secondary objective we assessed the impact in antibiotic therapy spectrum.

Materials/methods: The study was conducted in a public teaching hospital in 2019, with physicians working in Internal Medicine, Intensive Medicine, Infectious Diseases and General Surgery departments that agreed to participate and respond to the survey. Four case vignettes were assigned to each doctor, with selected amounts of information. The vignettes were constructed by two infectious diseases physicians using real patient data and numbered as Cases 1 to 4. There were two moments in the study: first, the physicians answered the vignettes; second, they were given the cumulative antibiogram and the same vignettes, and were asked to rethink their answers. Appropriateness was evaluated by comparing the answers with the actual susceptibility test. Statistical analysis was performed with IBM® SPSS® statistics, 25th.

Results: Seventy-one surveys were answered. Thirty eight percent of physicians commonly used the cumulative antibiogram to help their decision. Without consulting the cumulative antibiogram, appropriateness was low, ranging from 32.4% to 38.6%, with exception of vignette 3 with 72.9% appropriate therapies. After antibiogram use appropriateness rose to 47.1% - 71.8% (figure 1). Improvement in antimicrobial appropriateness was observed in all professional groups but it was only statistically significant in residents. There were excessive and unnecessary switches in antibiotic spectrum in Cases 1 to 3, 26.3%, 11.5% and 22.4% respectively.

Conclusions: An improvement in appropriateness with the use of cumulative antibiogram was seen. However, a risk of unnecessary broader-spectrum exists and warrants caution when introducing new tools, with careful evaluation of potential impact in antimicrobial use.

Characterisation of the host lipidome in Enterovirus-infected cells: implications on pathogenesis and potential antiviral strategies

Jasper Chan*1, Bingpeng Yan1, Zijiao Zou1, Hin Chu1, Jessica Tsang1, Shuofeng Yuan1, Cyril Yip1, Richard Kao1, Kong-Hung Sze1, Susanna K. P. Lau1, Kwok-Yung Yuen1

1The University of Hong Kong, Hong Kong, Hong Kong

Background: Enterovirus A71 (EV-A71) and coxsackievirus A16 (CV-A16) are the most common causes of hand, foot, and mouth disease. Severe EV-A71 and CV-A16 infections may be associated with life-threatening complications. However, the pathogenic mechanisms underlying these severe clinical and pathological features remain incompletely understood. Lipids are known to play critical roles in multiple stages of the virus replication cycle. The specific lipid profile induced upon virus infection is required for optimal virus replication. The perturbations in the host cell lipidomic profiles upon enterovirus infection have not been fully characterized.

Materials/methods: Clinical isolates of EV-A71 and CV-A16 obtained from patients with hand, foot, and mouth disease were used in this study. Ultra-high performance liquid chromatography–electrospray ionization–quadrupole–time of flight-mass spectrometry (UPLC-ESI-Q-TOF-MS)-based lipidomics was performed to characterize the change in host lipidome upon EV-A71 and CV-A16 infections in human rhabdomyosarcoma (RD) cells (ATCC, CCL-136). MetaboAnalyst 3.0 (http://www.metaboanalyst.ca) and SIMCA-P V12.0 (Umetrics, Umeå, Sweden) were used for univariate and multivariate analysis, respectively. The host lipidomes were characterized and the in vitro antiviral effects of selected lipids which were significantly perturbed in EV-A71 and CV-A16 infection were evaluated. All experiments involving live EV-A71 and CV-A16 followed the approved standard operating procedures of the biosafety level 2 facility at the Department of Microbiology, The University of Hong Kong.

Results: A total of 47 lipids within 11 lipid classes in the categories of phospholipids, glycerolipids, fatty acyls, and sphingolipids were significantly perturbed after EV-A71 and CV-A16 infection. Among them, 4 polyunsaturated fatty acids (PUFAs), namely, arachidonic acid (AA), docosahexaenoic acid (DHA), docosapentaenoic acid (DPA), and eicosapentaenoic acid (EPA), were consistently upregulated (P<0.05) upon EV-A71 and CV-A16 infection. Importantly, exogenously supplying three of these four PUFAs, including AA, DHA, and EPA, in cell cultures significantly (P<0.001 to <0.05) reduced EV-A71 and CV-A16 replication.

Conclusions: Taken together, our results suggested that enteroviruses might specifically modulate the host lipid pathways for optimal virus replication. Excessive exogenous addition of lipids that disrupted this delicate homeostatic state could prevent efficient viral replication. Precise manipulation of the host lipid profile might be a potential host-targeting antiviral strategy for enterovirus infection.

Abstract 9503

Application of a comprehensive, user-friendly metagenomic sequencing platform for rapid pathogen identification in a paediatric population with meningitis and encephalitis

Rita Stinnett1, Nanda Ramchandar2,3, Kate Broadbent1, Toni Schwarz1, Steven Flygare1, Heng Xie1, Jennifer Foley2, Amy Davis1, Lauge Farnaes1,2, Robert Schlaberg*1;4

1IDbyDNA, Salt Lake City, United States, 2Rady Children’s Hospital - San Diego, San Diego, United States, 3University of California San Diego, La Jolla, United States, 4The University of Utah, Salt Lake City, United States

Background: Central nervous system (CNS) infections often present with nonspecific symptoms, resulting in a broad differential diagnosis including infectious and non-infectious etiologies. Rapid and accurate diagnosis is essential. In adults, metagenomic sequencing has been demonstrated to provide increased diagnostic yield compared to standard of care testing. There is growing interest in implementing metagenomic testing in routine diagnostic workup. However, complexities of metagenomic data analysis pose barriers for adoption. We present a metagenomic shotgun RNA and DNA assay built on a user-friendly software platform that supports all steps from sample to report. We used this assay for rapid pathogen identification in children hospitalized with a putative CNS infection.

Materials/methods: Children hospitalized with suspected meningitis or encephalitis were enrolled under an IRB-approved multi-center clinical study. Residual cerebrospinal fluid (CSF) was analyzed by shotgun metagenomic RNA and DNA sequencing and the Explify platform. The Explify platform provides easy-to-use metagenomic analysis, including quality control (QC), sequence quality filtering, identification of a customizable pathogen set using curated databases, reproducible result interpretation, result review, and report generation. Results were compared to standard laboratory testing.

Results: At the time of this analysis, a total of 51 samples from 51 enrolled children were analyzed by metagenomic sequencing. For use in this study, interpretive criteria were defined for >1800 relevant bacteria, viruses, parasites and fungi that are implicated in the pathogenesis of CNS infection based on published data. Metagenomic sequencing detected a putative pathogen in CSF samples from 12 of 51 (24%) patients. Putative pathogens detected included Streptococcus pneumoniae, Streptococcus agalactiae, Neisseria meningitidis, Haemophilus influenzae, herpes simplex virus and enteroviruses (Coxsackievirus B, Echovirus). Predominant detections in this study were consistent with known etiology of pediatric CNS infections and were corroborated by standard of care testing.

Conclusions: Analysis of metagenomic sequencing data with the Explify platform provided rapid (<72 hours from sample processing to result) and accurate pathogen identification. The use of evidence-based reporting criteria maximized diagnostic yield and expedited result interpretation. The Explify platform provides user-friendly access to comprehensive application-specific QC and pathogen detection, and identification of antimicrobial resistance markers.

Abstract 9504

**Epidemiology of previous antibiotic treatment in a community setting infectious diseases consultation office**

Jacques Choucair*

1Université Saint Joseph - Campus des Sciences Médicales CSM, Bayrut, Lebanon

**Background:** Bacterial resistance is nowadays a growing problem of public health in hospitals and community. Antibiotic dispensation is over the counter in most of the developing countries. This study aims to evaluate the antibiotic treatment in the 3 months period before an Infectious Diseases consult in a community setting in a developing country.

**Materials/methods:** This is a prospective cohort study that took place in the community setting of the IDs consultation offices in a developing country from October 1st 2017 until January 1st 2018. Every consultation with previous antibiotic treatment for the same reason of the consult is included with the following features: age, gender, molecule, dose, duration of therapy, presence of fever, indication of treatment, bacteriologic result of cultures if done and the identity of the prescriptor. The data were collected on excel and served for statistics.

**Results:** 70 patients were evaluated with 68 eligible included in the study accounting 95 courses of antibiotics. The sex ratio F/M is 5/2 with a mean age of 43.7 years (18 – 82). The used molecules are cephalosporins in 17 episodes, macrolides [4], amoxicillin [5], amoxicillin-clavulanate [20], quinolones [34] and 11 miscellaneous. Fever is present in only 19 / 95 cases counting 4 / 19 true indications, 5 uncertain and 10 without indication for antibiotic treatment.

Nevertheless, antibiotics were prescribed even though the patients were non febrile in 76 cases (80%) including 7 / 76 true indications only. Besides, 35 courses of treatment were either with a wrong dosage or duration of therapy and were taken OTC by the patients themselves in 11 cases or prescribed by the pharmacist in one case or the physician in 23 cases. Cultures were performed in only 9 cases and were positive in 5.

Finally, the prescriptors were physicians in 49/95 episodes, pharmacists in 16/95 episodes and the patients themselves in 30/95 of the cases.

**Conclusions:** We clearly need more public health awareness for the misuses of the antibiotics, a proper and urgent education for physicians along with a law regulating the dispensation of antibiotics by the pharmacists.

**Presenter email address:** jacqueschoucair@hotmail.com
Background: Neonatal sepsis refers to an infection involving bloodstream in newborn infants less than 28 days old. It continues to remain a leading cause of morbidity and mortality among infants, especially in middle and lower-income countries. Signs and symptoms of neonatal sepsis can range from nonspecific or vague symptoms to hemodynamic collapse, i.e. septic shock.

Materials/methods: The retrospective study included 133 medical charts of Neonatal ICU during Dec/2016 to Jun/2017 period. We chose some symptoms, which are important for diagnosing neonatal sepsis and separated them in 3 groups: commonly-associated (≥50% cases), frequently-associated (25 to 50%) and occasionally-associated (<50%) with sepsis. Hyperthermia (>38.5°C), respiratory distress and tachycardia are in the first group; lethargy, poor feeding, bradycardia, jaundice and hepatomegaly are part of the second group; and, finally, the third group is consisted of hypothermia, seizures, abdominal distension and diarrhea.

Results: Five patients of 133 had sepsis and two of them had septic shock. The number of patients who had high temperature (>38.5°C) was six and there was no data about hypothermia cases. Of 133 neonates 105 (78.9%) had respiratory distress. CBC showed that 78 of newborns (58.6%) had high levels of WBC (>12,000) and 15 (11.3%) of them had left shift of leukocytes. Overall, 105 neonates were poor fed. Hepatomegaly and jaundice were found in 59 (44.4%) and 12 (9%) newborns, respectively. Abdominal distension was also among common symptoms [51.9%, n=69], with one (0.7%) case of diarrhea. Symptoms such as lethargy (6%, n=8), seizures (8.3%, n=11) and bradycardia (0.7%, n=1) were rarely reported.

Conclusions: In contrast to adult patients, the diagnostic criteria for neonatal sepsis are not perspicuous, therefore we assume that evaluation of these symptoms can be beneficial for early detection and prophylaxis of complications. Combined laboratory and clinical examinations can provide reduction of misdiagnosis.

Paris-Sud, Paris, France; 20Nantes University Hospital, Department of Infectious Diseases and CIC 1413, INSERM, Nantes, France

Background: Cefotaxime (CTX) is widely recommended to treat central nervous system (CNS) bacterial infections, especially bacterial meningitis. The recommended dosage varies depending on the guidelines. To date, limited data exist about cerebrospinal fluid (CSF) diffusion of cefotaxime in adults treated for CNS infections. The aim of the study was to describe the CSF diffusion of cefotaxime in patients treated for CNS infection with high-dose cefotaxime as recommended by French guidelines.

Materials/methods: We report pharmacological data from the DIFCEFO study (CSF diffusion of high-dose cefotaxime in CNS infections), a multicenter, observational, retrospective study. Adult patients who received high-dose cefotaxime as recommended by French Guidelines (defined as 200–300 mg/kg/day without upper limit, whether or not dexamethasone is coadministered) for CNS infections between January 2012 and October 2019 for whom cefotaxime was measured in CSF were included. Concomitant plasma dosages were also collected. Medical charts were retrospectively reviewed.

Results: Seventy four patients were included in the study, 54 with meningitis, 17 with brain abscess and 3 undocumented. Median age was 60 years (range: 24-88) and median glomerular filtration rate measured by CKD-EPI was 106 mL/min/1.73 m 2 (range: 8-189 mL/min/1.73 m 2). Forty six percent of patients received dexamethasone. Most isolated pathogens were Streptococcus pneumoniae (n=29), Escherichia coli (n=10) and Staphylococci (n=7). The median daily dosage of cefotaxime was 14 g (Q1:12; Q3:18) corresponding to a median of 204 mg/kg [Q1:164; Q3:247], 60% in continuous infusion. One hundred and twenty three CSF concentrations were measured (43 lumbar punctures and 75 external ventricular derivations and 5 undocumented). Median CSF cefotaxime concentration was 6.4 mg/L [Q1:3.3 mg/L; Q3:12.5 mg/L] and median CSF/plasma ratio was 23% [Q1:8.7%; Q3:32%]. In the subgroup of pneumococcal meningitis, median CSF cefotaxime concentration was 10.25 mg/L [Q1:5 mg/L; Q3:19.5 mg/L] and 100% of concentrations (n=42) were above the upper bound of the EUCAST MIC breakpoint for CTX-susceptible Streptococcus pneumoniae [MIC 0.5 mg/L].

Conclusions: Pharmacological data presented here demonstrate the good diffusion of cefotaxime in adults treated for CNS infection as recommended by French guidelines. Otherwise, concentrations measured in patients with pneumococcal meningitis were all above the targeted EUCAST MIC breakpoint.

Presenter email address: matthieu.gregoire@chu-nantes.fr
Parenteral colistin therapy induces rapid selection of colistin-resistant bacteria in human gut: first report from India

Sayantan Banerjee*, Jyoti Verma1, Tarosi Senapatii, Anbu Manim1, Manish Soneja1, Ashutosh Biswas1, Naveet Wig1, Bhabatosh Bas2, Arti Kapil1

1All India Institute Of Medical Sciences, New Delhi, India, 2Translational Health Science And Technology Institute, Faridabad, India

Abstract third-party references: Center for Human Microbial Ecology, THSTI, Faridabad, Haryana

Background: Unregulated use of broad-spectrum antimicrobials owing to lack of stewardship and regulations, over-the-counter availability of antibiotics including colistin pediatric syrup and indiscriminate usage of polymyxins in animal husbandry and poultry farming, set the stage for selection of colistin resistant bacteria in India.

Materials/methods: A case-control study of fecal carriage of colistin resistant Enterobacteriaceae (colRE), and its genetic characterization was conducted. Patients in medical ICU and wards receiving parenteral colistin for at least five days were recruited as cases and an equal number of their healthy consenting adult family members, without any history of antibiotic intake in last 3 months served as controls. Stool samples were subjected to molecular screening and culture. Colistin resistance was confirmed by microbroth dilution. Metagenomic DNA extracted from stool samples and bacterial DNA extracted from colRE isolates were subjected to screening by mcr 1-5 multiplex PCR and confirmed by nested PCR, restriction digestion and sequencing.

Results: Seventeen out of 34 cases were culture positive for colRE in their stool, compared to 4 out of 34 controls (p<0.001). Half of the patients (8 out of 17) developed colRE carriage within first week of parenteral colistin therapy. None of the colRE isolates were positive for mcr gene. Out of 68 stool metagenomic DNA screened, 6 samples from the controls were positive for mcr1 gene, confirmed by nested PCR and sequencing. However, no colRE were isolated from the stool of those 6 subjects. Nonvegetarian dietary habit, particularly, consumption of chicken was found to be predominant (5 out of 6) among those detected positive for mcr1 gene, but this was statistically insignificant considering the entire study population (p= 0.101). One representative colistin resistant Klebsiella pneumoniae isolate was subjected to whole genome sequencing to analyse possible mechanism(s). mcr gene was not detected. Mutations were detected in arrT and AraC transcription-regulator proximal to the phoP and phoQ genes.

Conclusions: Our study showed rapid selection of colRE in the gut of unsuspecting patients receiving parenteral colistin. Though molecular presence of mcr gene in the gut of healthy Indian adults was detected, yet the colRE culture isolates were all negative for mcr.

Abstract 9509

Clinical predictors of peripheral vascular graft infection by *Staphylococcus aureus*

Laura Maria Castelo Corral1*, Lucia Ramos1, Alicia Alonso Álvarez1, Ana Padín-Trigo1, María Rodríguez Mayo2, Fernanda Peña-Rodriguez2, Cristina Suárez González1, Cristina Sierra Freire1, Milvia García López1, Efrén Sánchez Vidal1, Enrique Míguez Rey1, Dolores Sousa1

1Hospital Universitario A Coruña, Infectious Diseases Unit, A Coruña, Spain, 2Hospital Universitario A Coruña, Microbiology Department, A Coruña, Spain, 3Hospital Universitario A Coruña, Vascular Surgery Department, A Coruña, Spain

**Background:** Peripheral vascular graft infection (PVGI) is a predominantly staphylococcal disease. However, data in the literature about these types of infections are scarce. The objective of the study was to describe the clinical characteristics of PVGI by *Staphylococcus aureus* (SA-PVGI).

**Materials/methods:** An observational study of a prospective hospital-based cohort of adult patients with VGI. All patients admitted to hospital between 2009 and 2019 were included if they had a confirmed infrainguinal infection. The SA-PVGI cases were compared with all others (0-PVGI).

**Results:** Eighty-four cases of PVGI were included, of which 34 (40.5%) were SA-PVGI (17 methicillin-resistant isolates). In the 0-PVGI group, a microbiological diagnosis was reached in 42 cases and the most frequently isolated microorganisms were: *Enterobacteriaceae* (19), coagulase-negative staphylococci (15), *Enterococcus* sp. (8), *Pseudomonas* sp. (8), *Streptococcus* sp. (5), *Bacteroides* sp. (5) and *Propionibacterium* sp. (5). The infection was polymicrobial in 42.9% of 0-PVGI and 38.2% of SA-PVGI. *Enterobacteriaceae* were the most frequent microorganisms in polymicrobial SA-PVGI (8 of 13 cases). There were no significant differences between groups regarding the age, the comorbidity and the type of graft. No disparities in the infection management or in the in-hospital mortality rate were observed. The main differences in clinical features and outcomes are shown in Table 1. In addition, a statistically significant association was observed between graft thrombosis and the isolation of coagulase-negative staphylococci (p 0.019) and *Propionibacterium* sp. (p 0.045).

Abstract 9511

Adenovirus types associated with severe respiratory diseases in intensive care unit-admitted patients during the 2017-2019 period

Antonio Piralla1, Federica Novazzi1, Federica Giardina1, Alice Fratini1, Giulia Salve1, Sandro Pregnolato1, Fausto Baldanti1,3, Francesco Mojoli2,3

1Fondazione I.R.C.C.S. Policlinico San Matteo, Molecular Virology Unit, Microbiology and Virology Department, Pavia, Italy, 2Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Anaesthesia and Intensive Care, Pavia, Italy, 3The University of Pavia, Department of Clinical, Surgical, Diagnostic and Paediatric Sciences, Pavia, Italy

Background: Acute lower respiratory tract infections are caused by different viruses, including human adenoviruses (HAdVs). However, life threatening adenovirus infections, e.g. viral pneumonia and ARDS were reported and associated with a few adenovirus types, but appear to be rare. Aims of present study were to: i) determine the frequency of respiratory infections HAdV-associated in ICU-patients and ii) elucidate the impact of different HAdV genotype as cause of severe respiratory infections.

Materials/methods: Respiratory samples collected from ICU patients and tested for the presence of HAdV using a quantitative real-time PCR at the Molecular Virology Unit, Microbiology and Virology Department, of Fondazione IRCCS Policlinico San Matteo in Pavia (Italy) between 1st January 2017 and 30th October 2019 were included in this study.

Results: HAdV DNA was detected in respiratory samples from 9 (3.5%) of 260 patients hospitalized in ICU. The median age of positive patients was 55 years [24-78 years] with a median time of ICU stay of 22.5 days [range 5-80 days]. In almost all [8/9] patients HAdV was detected in bronchoalveolar lavages with viral load ranging from 2.7x10^2 to 6.7x10^7 DNA copies/ml. According to the phylogenetic analysis of the hexon gene sequences, the most prevalent HAdV types detected in patients with viral pneumonia were E4 (n=3), D37 (n=2), D56 (n=2), B3 (n=1) and B55 (n=1). Co-infections were observed in only 2/9 (22.2%), one with influenza A/H3N2 and one with H. influenzae. Almost all patients had a comorbidities and two out of 9 patients had ARDS at the ICU admission. The median value of PaO2/FiO2 ratio was 166 mmHg [range 61-310] and one patient required extracorporeal membrane oxygenation for 32 days.

Conclusions: Adenovirus respiratory infection may cause severe disease requiring ICU admission and mechanical ventilation, mostly in patients with underlying conditions. Unexpected HAdV types were observed in patients with severe infections. Monitoring respiratory viruses involved in severe infections, will improves the orientation of therapeutic and preventive measures, avoids unnecessary use of antibiotics, and helps control hospital infection.

Clonality and genetic determinants of resistance in paired isolates of Klebsiella pneumoniae with divergent polymyxin B phenotypes

Suely Sampaio, Rozane De Lima B. Carvalho, Marcelo Mimica, Cely Barreto Da Silva, Aline Valerio Lima, Keila De Oliveira Lima, Darlan Augusto Da Costa Rocha, Jorge Luiz Mello-Sampaio

1Faculdade de Medicina da Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil, 2Universidade de São Paulo, School of Medicine, São Paulo, Brazil

Abstract third-party references: Faculdade de Medicina da Santa Casa de Misericórdia de São Paulo

Background: Infections caused by carbapenem and polymyxin B (PolB) resistant Klebsiella are a priority in terms of infection control worldwide. In this study we aimed at characterizing the molecular determinants of polymyxin resistance and clonal relationship in K. pneumoniae with divergent susceptibility phenotypes recovered from the same patients.

Materials/methods: A total of 25 pairs of isolates obtained from clinical samples collected at different dates (January 2015 to May 2017) from patients treated at Santa Casa de Misericórdia Central Hospital of São Paulo - Brazil were analyzed. Species identification was achieved by MALDI-ToF-MS and multiplex PCR as described by Fonseca et al. Presence of mcr-1 and integrity of mgrB were evaluated as described respectively by Liu et al. and Cannatelli et al. Mutations in pmrA, pmrB, phoP and phoQ were evaluated by full gene sequencing. PFGE was performed as described by Ribot et al., using XbaI. Polymyxin B (PolB) susceptibility was determined by broth microdilution as recommended by EUCAST using the interpretative criteria recommended for colistin.

Results: All isolates were positive for blaSHV-1 and were identified as K. pneumoniae. None of them were positive for mcr-1. Truncation of mgrB was observed in 5/21 PolB resistant isolates. No mutations were observed in the pmrA or phoQ. The R256G substitution in PmrB was observed in 5/21 PolB resistant isolates. This finding contrasts with a previous publication by Yi-Hsiang et al. The T157X and F204L substitutions were detected in isolates with a PolB MIC of 32 mg/L but were not present in isolates from the same clone with an MIC ≤ 0.5 mg/L; consequently these substitutions may be implicated in PolB resistance. Concerning PhoP, all sequenced isolates, both susceptible and resistant ones, had the L26Q substitution. This finding contrasts with a previous publication by Yi-Hsiang et al. Concerning clonality, 10 patients were infected by two different clones when evaluating isolates detected one week to 11 months apart.

Conclusions: Mutations R256G in PmrB and L26Q in PhoP do not confer PolB resistance. T157X and F204L substitutions in PmrB are implicated with PolB resistance.

Abstract 9514

**Diversity and antimicrobial susceptibility of Gram-negative bacteria from Sparus aurata from aquaculture**

Vanessa Salgueiro*1,2, Vera Manageiro1,2, Narcisa Bandarra3, Eugénia Ferreira1,2, Manuela Caniça1,2

1National Reference Laboratory of Antibiotic Resistances and Healthcare Associated Infections, Department of Infectious Diseases, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal, 2Centre for the Studies of Animal Science, Institute of Agrarian and Agri-Food Sciences and Technologies, University of Porto, Porto, Portugal, 3Division of Aquaculture and Upgrading, Portuguese Institute for the Sea and Atmosphere, IPMA, Lisbon, Portugal

**Background:** In aquaculture, a higher density of fish in a specific area is usually related with an increase in stress conditions, which leads to a greater tendency for infectious diseases and a higher antibiotic consumption. This study aimed to characterize antibiotic resistance (AR) in bacteria and understand bacterial diversity in *Sparus aurata* (sea bream) collected from aquaculture.

**Materials/methods:** During the years of 2018 and 2019 we collected samples of *Sparus aurata* (n=12) from fish farms and market. All samples were homogenized and further diluted (each dilution plated in selective media). Colonies with different morphology were selected and DNA extracted. Strains were identified by MALDI-TOF and amplification of the 16S rRNA gene. Antimicrobial susceptibility was assessed by disc diffusion and MIC methods for 20 antibiotics from 9 classes. The investigation of clinically important AR-encoding genes was performed by PCR-amplification. The whole-genome-sequencing from an *Enterobacter cloacae* strain was also performed.

**Results:** A total of 157 Gram negative strains from *Sparus aurata* were isolated. *Aeromonadaceae, Enterobacteriaceae, Hafniaceae, Shewanellaceae, Comomonadaceae, Erwiniaaceae, Erysipelotrichaceae, Moraxellaceae, Pseudomonadaceae* and *Yersiniaceae* families were identified. Decreased susceptibilities to β-lactam, phenicols, tetracyclines, quinolones, and trimethoprim/sulfamethoxazole antibiotics were found. The qnrB-19 gene, associated to diminished susceptibility to quinolones, was detected in two *Enterobacteriaceae*, one *Escherichia coli* (with disc diffusion of ciprofloxacin=21mm and flumequine MIC=16mg/L) and one *Leclercia adecarboxylata* (with disc diffusion of ciprofloxacin=24mm and flumequine MIC=4mg/L). Genomic analysis of Enterobacter cloacae from ST190 lineage, allowed to identify β-lactam (*blaACT-7*) and phosphomycin (*fosA*) resistance genes, integrase genes, iroN virulence factor, plasmids (col, IncFIB, IncFII) and phages.

**Conclusions:** We highlight the diversity of Gram-negative bacterial species from aquaculture samples. Some of these species and AR genes identified have already been detected in the human reservoirs. Thus, bacteria found in aquaculture might have the ability to acquire several AR-encoding genes and act as a reservoir of AR, which need to be monitored.

Direct detection of Mycobacterium tuberculosis complex in clinical specimens from patients in Norway by two different polymerase chain reaction tests

Irena Szpinda*, Jagdip Kaur, Mari Elisabeth Hagbe, Siv Heidi Hamsund, Oda Wold, Tone Tonjum

Oslo University Hospital, Oslo, Norway

Background: Mycobacterium tuberculosis (Mt) is the causative agent of tuberculosis (TB). Our aim was to compare the use of two different assays for DNA amplification with the polymerase chain reaction (PCR) for detection of the Mt complex directly in human clinical specimens in Norway.

Materials/methods: Five hundred and fifteen clinical samples, including 370 airway samples and 145 extrapulmonary samples, were processed by culture (BACTEC MGIT, BD), direct microscopy and PCR. The PCR assays employed for qualitative detection of DNA from Mt complex cells in clinical specimens were the Roche COBAS® TaqMan® MTB real-time PCR test targeting the 16S rRNA gene and the Cepheid Xpert® MTB / RIF Ultra test targeting the gene encoding RNA polymerase B (rpoB).

Results: Among the 515 specimens, 71 were culture positive for Mt and 21 were culture positive for non-typable mycobacteria (NTM). Compared to culture, the COBAS® TaqMan® MTB test had a sensitivity of only 76% in Mt positive specimens, while the sensitivity of the Xpert® MTB / RIF Ultra test for Mt positivity was 100% in both airway specimens and extrapulmonary samples. No false positive reactions were detected with either test. However, COBAS® TaqMan® MTB was inconclusive (yielded “Invalid” result) in 9 out of the 21 cases that were NTM culture positive (42.8%), while Xpert® MTB / RIF Ultra yielded a negative result in all the 21 NTM positive samples. The COBAS® TaqMan® MTB test detected only 10 out of the 15 cases with multidrug-resistant (MDR) TB. In all the 15 MDR-TB cases, Xpert® MTB / RIF Ultra detected Mt positivity and the mutations encoding rifampicin resistance.

Conclusions: The Xpert® MTB / RIF Ultra test demonstrated much higher sensitivity and specificity in detecting Mt compared to culture than the COBAS® TaqMan® MTB test. The data imply that 24% of patients with TB will not be detected by COBAS® TaqMan® MTB, while many patients who do not have TB will appear to potentially be Mt positive by this test. The rapid procedure, more automation, semi-quantitation and concomitant detection of rifampicin resistance makes the Xpert® MTB / RIF Ultra test a valuable tool in mycobacterial diagnostics.

Rapid identification of bacteria directly from positive blood cultures by a modified method using a Serum Separator Tube (SST) and MALDI-TOF MS

Octavio Carretero1, Gonzalo Rivas1, Cristina Loras2, Ma Angeles Orellana Miguel1,3

1University Hospital 12 de Octubre, Madrid, Spain, 2Hospital Universitario de Getafe, Getafe, Spain, 3University Hospital 12 de Octubre, Madrid, Spain

Background: To evaluate a modified and simplified method, based on serum separator tube (SST), in the identification of bacteria directly from positive blood cultures (BC).

Materials/methods: Positives BC with no more than one hour since the positive signal were included. MALDI-TOF after 24 hours of incubation was considered the Gold Standard. The modified method is based on the use of 8 mL SST Gel. Briefly, 4 mL of blood are transferred to SST; centrifuged at 3000 rpm/10 minutes and discarded the supernatant. 1 μL inoculation loop is impregnated in the pellet and inoculated into the MALDI-TOF plate. 1 μL of 100% formic acid and 0.5 μL of matrix were added. To estimate the bacterial load, the microorganisms were counted in three fields of GRAM stain. Samples were assigned to 3 groups. 1: less than 50 microorganisms/field (MOF), 2: 51-100 MOF and 3: more than 100 MOF.

Results: We analyzed 253 positive BC of 195 patients. 156 (61.7%) Gram + and 97 (38.3%) Gram –. 68.8% (174/253) were correctly identified at the species level and 79.1% (200/253) at the genus level. Of the 174 BC identified at the species level, 66.1% (115/174) were with a score ≥1.70, 25.8% (45/174) with 1.31-1.69 and 8.1% (14/174) with 1.00-1.30. Total mean: 1.81±0.32. In Gram –, 92 (94.9%) were correctly identified both at the species and genus level. 88% (81/92) with a score ≥1.70, 10.9% (10/92) with 1.31-1.69 and 1.1% (1/92) with 1.00-1.30. Total mean: 1.95 ± 0.234. In Gram +, 82 (52.6%) and 108 (69.2%) were correctly identified at the species and genus level respectively. Of those, 41.5% (34/82) were with a score ≥1.70, 42.7% (35/82) with 1.31-1.69 and 15.9% (13/82) with 1.00-1.30. Total mean: 1.66 ± 0.342. The relation between bacterial loads, correct identification and mean score is represented in table 1.

Conclusions: This method allows us to obtain the etiological agent of bacteremia in less than half hour from a positive BC with a simple technical process.

Characteristics of vascular graft infection: a prospective single-centre cohort study

Donara Margaryan1*, Tamta Tkhiashvili1, Novella Cesta1, Margherita De Masi1, Andrej Trampuz1

1Charité - Universitätsmedizin Berlin, Berlin, Germany

**Background:** The optimal management of vascular graft infections (VGI) is unknown. We evaluated the clinical, microbiological, radiological and treatment characteristics of VGI.

**Materials/methods:** Consecutive patients with VGI treated at our institution between 01/2017 and 10/2019 were prospectively included. VGI was defined by presence of ≥1 criterion: sinus tract or exposed graft; purulence at surgical site; positive culture of intraoperative tissue/sonication fluid; positive blood culture without other infectious focus; inflammation in perigraft histopathology; perigraft abscess seen at preoperative CT/MRI or PET-CT.

**Results:** 33 patients were included, median age 67 (34-87) years. Reasons for primary graft implantation were aneurism (n=15), aortic dissection (n=10), aortic isthmus stenosis (n=5) and other (n=3). Median time from primary graft implantation to diagnosis of VGI was 6 (0-316) months; 31 were aortic and 2 were peripheral grafts. Importantly, 13 patients (39%) had simultaneously other intravascular devices such as prosthetic heart valves, pacemaker, cardiac resynchronization therapy (CRT) or implantable cardioverter defibrillator (ICD). Clinical manifestations included fever in 17 (51%) and surgical site infection signs in 4 patients (16%). MRI or PET/CT showed perigraft abscesses in 13 patients (39%), perigraft fluid in 2 patient (6%) and nonspecific signs in 9 (27%). 3 patients had simultaneous endocarditis/endoplastitis. VGIs were monomicrobial in 18 patients (54%), polymicrobial in 9 (27%) and culture negative in 6 (18%). Most frequent pathogens were Candida species (n=8), gram-negative bacilli (n=8), coagulase-negative staphylococci (n=7) and S. aureus (n=5). The pathogen was isolated from blood in 24 (72%) and from intraoperative samples in 14 patients (42%). Graft exchange was performed in 15, debridement & graft retention in 10 and no surgery in 7 patients. The median duration of antimicrobial therapy was 11.7 weeks. 20 patients (60%) received biofilm-active antibiotics, 11 long-term suppression. The most frequent postoperative complication was mediastinitis (8 patients), one patient died during hospital stay.

**Conclusions:** VGI was mostly diagnosed by positive blood cultures (72%) and MRI or PET/CT imaging (48%). Staphylococci, Candida and gram-negative bacilli were the predominant pathogens. The infected vascular graft was retained in about one third of patients and about every fourth VGI was complicated by mediastinitis.

Abstract 9525

**Early diagnosis in sepsis: T2 bacteria magnetic resonance assay versus blood culture**

Petkova Salz Elizabet1, Jaime Esteban Moreno1, Ricardo Fernández Roblas1, Ignacio Gadea Gironés1, Macias Valcayo Alicia3, Nerea Carrasco Antón1*

1Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

**Background:** Sepsis is an entity with high morbidity and mortality in which response time is absolutely decisive. The application of the new molecular techniques in the microbiological diagnosis implies a faster identification of the pathogens. The goal of this study is to describe the performance of the magnetic resonance-based T2Bacteria Panel assay (T2BPA) for rapid detection of pathogens in whole blood samples of patients with diagnosis of sepsis in an every-day clinical setting.

**Materials/methods:** We performed a prospective observational study from May to November 2019. Patients admitted to the adult Emergency Department with an initial diagnosis of sepsis (SOFA ≥ 2) were included if a blood culture (BC) and T2BPA had been performed. First we analyzed the agreement between both tests, including the whole population and again after excluding subjects with infections from pathogens not included in T2BPA. Then we evaluated the diagnostic properties of the tests using an ad-hoc microbiological-clinical combined criteria as gold standard. These criteria include microbiological results from other samples yielding the same pathogen to assess true infection, along with clinical decision to treat when other samples were negative.

**Results:** Forty-five patients were included (mean age = 68.5 years). T2BPA and BC were positive in 37.7% and 40% of the cases, respectively. In 33.3% of cases, BC detected bacteria not included in the T2BPA. *E. coli* was the most frequent isolated bacteria (24.4%) by T2BPA, followed by *K. pneumoniae* (11.1%). The percentage agreement between both tests was 73.3%, with a Cohen’s kappa = 0.53 (moderate agreement) considering the whole population. After excluding subjects with infections from pathogens not detected from T2BPA, the percentage agreement increased to 84.6% with a good kappa agreement (0.71). The accuracy of the tests in the whole sample was 96% and 87% for T2BPA and BC, respectively (Table).

<table>
<thead>
<tr>
<th>Test</th>
<th>Sensitivity</th>
<th>Specificity</th>
<th>PPV</th>
<th>PPN</th>
<th>Accuracy</th>

<td>0.89</td>
<td>0.85</td>
<td>0.87</td>
</tr>
</tbody>
</table>

**Conclusions:** The T2BPA has shown a moderate-to-good agreement with current standard (BC) for pathogen detection in a real-world sepsis scenario. Furthermore, this faster technique yielded a higher diagnostic accuracy using a clinical-microbiological criteria as gold standard.

Abstract 9527

Microbiota modifications in travellers to tropical and subtropical areas

Carla Franch Serrano1, David Antón Carmen Jiménez2, Laura Prieto-Pérez1, Martín Casapia4, Manuel Linares5, Juan Cuadros6, Pamela Carolina Köster2, Begoña Bailo2, Miguel Górgolas3, Jose Manuel Ramos Rincón7, Alfonso Cabello3, Ramon Perez Tanoira*3

1Universidad Autónoma de Madrid, Madrid, Spain, 2Parasitology Reference and Research Laboratory, National Centre of Microbiology, Health Institute Carlos III, Majadahonda, Spain, 3Department of Infectious Diseases, IIS-Fundación Jiménez Díaz, Madrid, Spain, 4Hospital Regional de Loreto “Felipe Santiago Ariola Iglesias”, Iquitos, Peru, 5Fundación IO, Madrid, Spain, 6Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain, 7Hospital General Universitario de Alicante and Universidad Miguel Hernández, Alicante, Spain

**Background:** Microbiota may be modified due to changes in diet, environmental factors and the use of antibiotics. These alterations can lead to colonization by multi-resistant enterobacteria (MRE), meticillin-resistant Staphylococcus aureus (MRSA) and/or enteroparasites, and this fact besides may pose a risk of transmission between health workers and patients.

The objective of this study was to determine an eventual colonization by MRE, MRSA and intestinal protozoa in previously uninfected travellers to tropical or subtropical areas. In addition, the burden of colonization by these microorganisms in health-workers and inpatients was measured.

**Materials/methods:** A prospective study in the Regional Hospital of Loreto (Iquitos, Peru) and the Notre Dame de la Santé Hospital (Dschang, Cameroon) was performed. Different chromogenic agars for the detection of carbapenemases-producing enterobacteria (CPE), Extended-spectrum beta-lactamases (ESBL) and MRSA were used. A stool sample and a nasal exudate were taken in every patient; in the case of travellers, the sample collection was carried out before and after travelling.

Pathogenic protists were also detected by qPCR (Giardia duodenalis, Entamoeba histolytica/dispar), ssu-PCR (Cryptosporidium, Blastocystis) and ITS-PCR (Enterocytozoon bieneusi).

**Results:** Four travellers (27%) acquired ESBL, two CPE (13%) and one SAMR (11%). One of the cooperant aid workers acquired Entamoeba histolytica in Peru; and another one acquired Giardia duodenalis in Cameroon. Additionally, two aid workers travelled to Cameroon with Blastocystis spp or Entamoeba dispar.

Considering local population, in Cameroon 9p had ESBL (60%), 2p CPE (13%), 7p MRSA (26%), 2p Giardia duodenalis, 4p Blastocystis spp, 1p Entamoeba dispar. In Peru 2p were colonized by ESBL (22%), 3p CPE (33%) and 16p MRSA (26%). No enteroparasite DNA was detected in any subject in Peru.

Matching inpatient information with travelling aid workers, Cameroon was found to have a higher proportion of ESBL acquisition (61%) compared to Peru (25%) (p=0.027), as well as a higher ratio of gastrointestinal parasites (36%) compared to Peru (5%) (p=0.017).

**Conclusions:** Subtropical populations show a high prevalence of EMR colonization. Travelling to these areas increases the risk for EMR and enteroparasites acquisition, with a possible subsequent dissemination in the country of origin.

Abstract 9529

Identification of methicillin resistance in Staphylococcus spp. of dogs with pyoderma

Luciana Guimarães¹, Isabella Silva¹, Milena Antunes¹, Carolina Fonseca¹, Camilla Pesset¹, Izabel Teixeira¹, Ana Luiza Santos¹, Bruno Penna*¹

¹UFF - Biomedical Institute, Universidade Federal Fluminense, Niterói, Brazil

Abstract third-party references: Bill & Melinda Gates Foundation, CNPq, FAPERJ, CAPES

Background: Staphylococcus sp. is a comensal bacteria from skin and other sites microbiome of asymptomatic animals. They can also be associated with skin infections (pyodermitis and otitis). S. pseudintermedius and S. schleiferi are among the main causes of skin and otitis bacterial infections. The potential of zoonotic transmission of canine bacteria has been demonstrated elsewhere. Since there is an increasing number of infections caused by multidrug-resistant bacteria in dogs, chief among them Methicillin resistant S. pseudintermedius, there is a great need for studies new studies. Thus, the present study aimed to determine tehddiversity of Staphylococcus sp. isolated from dogs with topical bacterial infections and the presence of methicillin resistance among them.

Materials/methods: Samples of 100 animals with dermatopathies (pyoderma and otitis) were collected with sterile swabs. Species identification was performed by mass spectrophotometry (MALDI-TOF) and methicillin resistance was evaluated with the detection of meca gene. In order to assess possible risk factors a questionnaire with epidemiological information was performed with the dog’s owners.

Results: A total of 270 colony forming units were obtained, being 57% S. pseudintermedius; 26% S. schleiferi; 4% S. haemolyticus; 2% S. intermedius; 2% S. sciuri; 2% S. epidermidis; 2% S. hominis; 2% S. simulans; 1% S. aureus; 1% S. sropheyticus; 1% S. warneri and 1% S. delphini. Among the samples 35% were methicillin resistance, where the highest percents were 40% Staphylococcus pseudintermedius and 15% to Staphylococcus schleiferi. Importantly, among these animals 52% of them sleep in their guardians’ beds and 90% have chronic pyoderma processes.

Conclusions: The present study shows high rates to methicillin resistance, showing the importance of antimicrobial susceptibility testing to diagnosis and treatment. Avoiding empirical choises and reinforce zoonotic and anthropozoonotic potencial of those samples.

Deciphering resistome and virulome of Gram-negative bacteria isolated from farmed fish and molluscs
Vera Manageiro1,2, Tânia Rosadp2,3, Vanessa Salgueiro1,4,2, Narcisa Bandarra4, Elsa Dias2,3, Eugénia Ferreira2,3, Manuela Caniça1,2

1National Reference Laboratory of Antibiotic Resistances and Healthcare Associated Infections, Department of Infectious Diseases, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal, 2Centre for the Studies of Animal Science, Institute of Agrarian and Agri-Food Sciences and Technologies, University of Porto, Porto, Portugal, 3Laboratory of Biology and Ecotoxicology, Department of Environmental Health, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal, 4Division of Aquaculture and Upgrading, Portuguese Institute for the Sea and Atmosphere, IPMA, Lisbon, Portugal

Background: The use of antibiotics in aquaculture has resulted in the emergence of reservoirs of antibiotic resistant bacteria in farmed fish and other animals, as well as in the aquatic environment. The aim of this study was to analyse the whole genome sequence (WGS) and resistome of a selection of isolates collected from different bacterial and animal species combination that reported non-susceptibility to at least one of the tested antibiotics, including 20 antimicrobial agents from 9 classes (β-lactams, aminoglycosides, folate pathway antagonists, fusidic acid, glycopeptides, mupirocin acid, phenicols, quinolones, and tetracyclines).

Materials/methods: In this study, 50 Gram negative isolates [including 21 Enterobacteriaceae, 11 Hafniaceae, 8 Aeromonadaceae, 3 Vibriaceae, 2 Shewanellaceae, 2 Pseudomonadaceae, 1 Morganellaceae, 1 Yersiniaceae, and 1 Rhodospirillaceae] were analysed. These strains were collected among samples of Sparus aurata (from an aquaculture tank and from a market), and Mytilus galloprovincialis (from a market). WGS was performed on a MiSeq Illumina platform. INNUca was used for quality control of reads, de novo assembly and contigs quality assessment. Prokka and ABRicate were used for genome annotation and screening for antibiotic resistance and/or virulence factors-encoding genes, respectively. Freeware web-based resources [e.g., PathogenFinder, ResFinder, CARD, VirulenceFinder, PlasmidFinder, PHAST].

Results: Results obtained allowed the identification of not only antibiotic resistance genes, but also virulence factors, efflux pumps and phages. We highlight the presence of the qnrB19 gene, which confers resistance to quinolones, in a Leclercia adecarboxylata strain [from a skin sample of S.aurata, from an aquaculture tank] and in an Escherichia coli [from an intestine sample, from S.aurata obtained in a market]. Furthermore, we detected a mcr-9 gene in an Enterobacter cloacae [from a muscle sample of S.aurata, from an aquaculture tank], co-producing β-lactam (blaACT-1 2-type) and phosphomycin [fosA2-type] resistance genes. MCR-9-encoding gene was firstly described in USA, in a clinical Salmonella Typhimurium isolate, which demonstrates the high transmission potential of this colistin resistance determinant.

Conclusions: In conclusion, this work highlights the resistance mechanisms that are being promoted in aquaculture environments, thereby allowing antibiotic resistance to develop and spread via food fish and the environment, resulting in significant human health threats.

**Abstract 9533**

**Endocarditis management and OPAT in the POET era**

Goldblatt Jennifer*, Shoshana Burke1, Gabriele Pollara1, Stephen Morris-Jones1, Sarah Logan1, James Hatcher1

1University College Hospital, London, United Kingdom

**Background:** The use of at least six weeks of intravenous antimicrobial therapy in the treatment of infective endocarditis (IE) has been challenged by the POET study, which reported non-inferiority of completing courses with oral therapy, following at least 10 days intravenous therapy (IVT). Outpatient Parenteral Antimicrobial Therapy (OPAT) services, including our own, already facilitate the discharge of IE patients. Adopting partial oral antimicrobial therapy for endocarditis could improve patient experience, reduce IVT-related morbidity and be cost-effective. We considered whether the POET study is applicable to patients referred to our OPAT service and if adopting its protocols could significantly reduce costs.

**Materials/methods:** Records of all patients managed by our OPAT service between January 2015 and March 2019 were reviewed. We established: (1) The number of OPAT patients fulfilling the POET study eligibility criteria (modified to accept echocardiogram confirmation performed outside of the 48 hours prior to randomisation/inclusion). (2) The number of days of OPAT which could have been replaced with monitored oral therapy (taking the first possible time for an oral switch to be hospital discharge) and (3) The comparative costs of providing OPAT care vs monitored oral therapy. Costs considered included medications, therapeutic drug monitoring, supporting IVT administration and review appointments.

**Results:** Our OPAT cohort consisted of 25 patients treated for 26 separate episodes of IE. 5/26 (19%) of episodes fulfilled POET study inclusion criteria. Switching to monitored oral antibiotics would have replaced 141 days of OPAT, median of 31 days per patient (range 18-33) and saved £1,500 per episode.

**Conclusions:** In our OPAT cohort, the POET study would have been directly applicable to a sizable minority (19%) of patients. The predicted cost savings per patient are derived from a reduction in the costs of supporting IVT administration. The stringency of inclusion criteria of the POET study led to the exclusion of a number of patients who were clinically very likely to have endocarditis, were stable and able to tolerate oral medications. Exploring whether an oral switch could safely be made in this group would be an interesting area for future study.

Ability of antibiotic-loaded bone cement to prevent bacterial adhesion, biofilm formation and selection of resistance

Alessandro Bidossi*, Marta Bottagisio¹, Elena De Vecchi²

¹IRCCS Orthopedic Institute Galeazzi, Milano, Italy

Background: Antibiotic-loaded bone cement (ALBC) has a number of different uses in primary and revision total joint arthroplasty. Despite the release of antibiotics from ALBC, over time bacteria may adhere to the surface, grow in biofilms, and develop infections.

Materials/methods: In this study, we evaluated a commercially available calcium-sulphate/hydroxyapatite ALBC loaded with gentamicin, vancomycin or without antibiotics to evaluate the ability of clinically relevant strains of S. aureus, S. epidermidis and P. aeruginosa to adhere and form biofilm. Furthermore, the capability of the tested antibiotics to select for antibiotic resistance was also evaluated to confirm the safe use of the product. In order to standardize the experimental conditions, loaded or unloaded ALBC discs were produced. Microbial adhesion ability was evaluated in the first hours of contact with the discs surface and measured by colony counting, while biofilm formation was assessed after 48 hours of incubation and analyzed by confocal laser microscopy. The ability to select for microbial resistance was evaluated by serial cultures on agar plates containing gentamicin- or vancomycin-enriched discs.

Results: Vancomycin loaded cement totally impaired Staphylococcal adhesion even of those isolates showing reduced susceptibility to glycopeptides, while gentamicin resistant strain still displayed a residual adherence on gentimicin-loaded cement. In contrast, gentamicin resistant P. aeruginosa was unable to attach to gentamicin-loaded cement. Similarly, biofilm formation by all staphylococci was drastically impaired on ALBC with significantly higher mortality rates on the residual sessile cells of all the isolates, made exception for the gentamicin resistant. In none of the clinical strains was observed any stable or transient adaptation to the two antibiotics.

Conclusions: Though biofilm formation or microbial adhesion were not totally prevented for some of the clinical strains, our in vitro results indicate that the tested calcium-sulphate/hydroxyapatite bone cement is a reliable strategy for the prevention or the treatment of orthopedic infections.

Abstract 9537

Spinal implant-associated infections: results from a four-year prospective cohort study
Donara Margaryan*, Nora Renz, Peter Vajkoczy, Andrej Trampuz

1Charité - Universitätsmedizin Berlin, Berlin, Germany

Background: Spinal implant-associated infections (SIAI) are severe complications after spine instrumentation. We evaluated the clinical, laboratory, microbiological and radiological characteristics and treatment approaches in patients with SIAI.

Materials/methods: Consecutive patients with SIAI treated between 2015 and 2019 were prospectively included. SIAI was defined by: (i) significant microbial growth from intraoperative tissue or sonication fluid, (ii) intraoperative purulence, secondary wound dehiscence or implant on view, (iii) radiographic evidence of infection and fever, increasing back pain or neurologic impairment, (iv) peri-implant inflammation in histopathology.

Results: A total of 252 patients were included, 154 patients had early-onset infection and 98 patients had late-onset infection. The median age was 67 [8-90] years, 133 [53%] were females. The most common reason for spinal stabilization was degeneration in 144 patients [57%] followed by tumor metastasis in 43 [17%]. 96 patients [38%] had one or more previous spine surgeries. The site of spinal instrumentation was lumbar/sacral in 115 [46%], thoracic in 86 [34%] and cervical in 51 patients [20%]. The median number of fused segments was 3 [1–16]. Clinical manifestations included wound healing disturbance in 143 patients [57%], increasing back pain in 93 [37%], implant on view in 14 [5%], neurologic impairment in 59 patients [23%] and fever in 38 [15%]. Serum CRP was elevated in 193 patients [76%]. Most infections were postsurgical [n=247], 3 were hematogenous and 2 contiguous. Imaging showed epidural, intraspinal, paravertebral or subcutaneous abscess in 63 patients [25%], implant loosening in 38 cases [15%] and implant failure in 16 [6%]. 41/63 abscesses were present in early-onset infections and 30/38 implant loosening were observed in late-onset infections. Monomicrobial infection was observed in 148 [59%], polymicrobial in 69 [27%] and culture-negative in 33 patients [13%]. Predominant pathogens were coagulase-negative staphylococci [n=94], S. aureus [n=52] and gram-negative rods [n=45]. Surgery included debridement and implant retention in 157 patients [62%], partial implant exchange in 38 [15%] and complete exchange in 44 [17%].

Conclusions: Wound healing disturbance was the most common manifestation in early-onset SIAI whereas late-onset SIAI manifested with increasing back pain. Abscesses were found in 25 % of SIAI. The predominant pathogens were staphylococci.

Abstract 9538

**Genetic diversity of the Plasmodium vivax circumsporozoite protein in isolates from Brazilian Amazon rainforest and Rio de Janeiro Atlantic Forest**

Natalia Oliveira¹, Rebecca Fernandes¹, Lidiane Cury², Aline Lavigne², Anielle Pina³, Daiana Perce², Marcos Catanho², Patricia Brasil³, Claudio Tadeu Daniel Ribeiro², Maria De Fatima Ferreira Da Cruz*²

¹Fundacao Oswaldo Cruz, Instituto Oswaldo Cruz, Rio De Janeiro, Brazil, ²Fundação Oswaldo Cruz, Instituto Oswaldo Cruz, Rio De Janeiro, Brazil, ³Fundacao Oswaldo Cruz, Instituto Nacional de Infectologia, Rio De Janeiro, Brazil

**Abstract third-party references:** Supported by FAPERJ, CNPq, CAPES, DECIT and SVS/MS

**Background:** *Plasmodium vivax* is the most widespread human malaria parasite outside Africa and is the predominant parasite in the Americas. Increasing reports of *P. vivax* severity disease together with the emergence of drug-resistant strains, underscore the urgency of the development of vaccines against vivax malaria. Circumsporozoite protein is a major preerythrocyte vaccine target in *Plasmodium* species. The knowledge about their genetic diversity and population structure could help to predict the vaccine efficacy and the origin and spread of novel parasite variants.

**Materials/methods:** We investigated *pvcsp* polymorphisms in 210 isolates from endemic Brazilian Amazon (BA) and non-endemic Rio de Janeiro Atlantic Forest (AF), where the *pvcsp* diversity remains unknown, as well in imported cases from 9 non-Brazilian countries. The region flanking *pvcsp* was amplified by PCR and sequenced. The polymorphisms were analysed using NovoSNP and BioEdit software and the DnaSP and MEGA4 programs.

**Results:** The *pvcsp* sequences revealed 48 polymorphic sites: 46 affecting the central region (CR) and two affecting the C-terminal region of the encoded protein. All isolates corresponded to VK210 variant, but 25 VK210 sub-types generating 13 allotypes in repeat motif, associated with length polymorphism in nonapeptides repeats units, were disclosure. The nonapeptides allotypes ([GDRADGQPA / type 1] and [GDRAGQPA / type 2] consisting of 7 to 19 and 1 to 14 repeats, respectively, were presented in all samples. Type 10 was found in 71% of samples and type 3 in 17%. The other nine allotypes were unique from this study and appeared in low frequency and all but one of them (type 13) were detected in more than one locality. The window analysis showed a quite similar pattern of nucleotide diversity between BA and AF (x=0.052).

**Conclusions:** Our data suggest that CR was, in part, under purifying selection due to the high number of synonymous polymorphisms contributing by the fixation of the VK210. On the other hand, the CR repeat units 19 and 20 has been accumulating non-synonymous SNPs probably by an immune-modulated balance selection.

Monitoring mosquito populations and detection of West Nile virus and Usutu virus in mosquito pools collected in Attica regional units, Greece, 2017-2018

Eleni Patsoula*, Stavroula Beleri1, Georgios Balatsos2, Vasilios Karras2, Nikolaos Tegos1, Fani Sereti3, Dimitrios Papachristos2, Antonios Michaelakis3

1Department of Public Health Policy, Laboratory for Surveillance of Infectious Diseases, School of Public Health, University of West Attica, Athens, Greece, 2Laboratory of Agricultural Entomology, Department of Entomology and Agricultural Zoology, Benaki Phytopathological Institute, Kifissia, Attica, Athens, Greece, 3Department of Public Health Policy, Laboratory for Surveillance of Infectious Diseases, School of Public Health, University of West Attica, Athens, Greece

Background: WNV is an emerging vector-borne pathogen in Europe. WNV human cases in Greece are transmitted by Culex pipiens mosquitoes. In this study we present data on mosquito surveillance activities and detection of WNV and Usutu viruses in three Regional Units (R.U.) of the Region of Attica (East Attika, South Sector and West Sector of Athens), for the period of June 2017 to December 2018.

Materials/methods: Collection of adult mosquitoes was performed by BG-Sentinel traps (CO2, Lure), in 8 fixed sampling sites, in urban and rural locations on a weekly basis. Mosquitoes were morphologically identified to species level and only female Culex pipiens were pooled (2-200 adults). RNA extraction was performed by an automated extraction system and samples were analyzed by Real-Time PCR protocols specific for WNV and Usutu. Positive samples were subjected to conventional PCR for verification.

Results: A total of 56,654 adult mosquitoes were collected, with larger variety and number of species in the East Attica R.U. (n = 37,810), followed by West Athens R.U. (n = 9,928) and South Athens R.U. (n = 8,916). In total, 384 mosquito pools were analyzed and 46 positive samples were recorded (11.9%). 30/267 positive mosquito pools for WNV were isolated from the East Attica R.U., 8/47 in West Athens R.U. and 8/99 in South Athens R.U. All samples but one was negative for Usutu virus, however with a high Cycle threshold/(Ct) and low viral load. Conventional PCR for both pathogens verified our findings.

Conclusions: Results of this study highlight WNV circulation among mosquitoes in the Attica region in the absence of human cases during 2017 and in WNV re-emergence during 2018 and the risk for Usutu virus introduction in the country. Mosquito surveillance actions are of major importance in order to design and apply Integrated vector management programs and public health interventions.

Abstract 9542

Outcome of infections caused by carbapenemase-producing Enterobacterales in patients with haematological disorders

Kristina Tandilova1*, Galina Klyasova1, Svetlana Khrulnova1, Parovichnikova Elena1, Sergey Kravchenko1, Elena Gribanova1, Evgeniy Zvonkov1, Gennadiy Galstyan1, Valeriy Savchenko1

1National Research Center for Hematology, Moscow, Russian Federation

Background: The aim of this study was to evaluate outcome according to the type of infection and regimen of antimicrobial therapy in haematological patients with infections caused by carbapenemase-producing Enterobacterales (CPE).

Materials/methods: Prospective study (2014–2019) included haematological patients with CPE-infection. Genes of carbapenemases bla_{OXA-48}, bla_{KPC}, bla_{VIM}, bla_{NDM}, and bla_{IMP} were detected by real-time PCR. The outcome was evaluated at 30 days from the first episode of infection caused by CPE.

Results: A total of 58 patients with CPE-infections were included in the study (32 male, 26 female; median age 46.5 years). The prevalent underlying disease was acute leukemia (48%) and non-Hodgkin lymphoma (28%); 35 (60%) patients received chemotherapy; 14 (24%) of patients underwent hematopoietic stem cell transplantation (HSCT), 12/14 (86%) had allogeneic HSCT.

CPE-infections were attributable to blood stream infection (BSI) (n = 24; 41%), BSI + pneumonia (n = 16; 28%), pneumonia (n = 12; 20%), urinary tract infection (n = 5; 9%), cellulitis (n = 1; 2%). The majority of CPE-infections were caused by K. pneumoniae (96%), followed by S.marcescens (2%) and E.coli (2%). The majority of clinical isolates harbored bla_{OXA-48} (88%), followed by bla_{NDM} (5%), bla_{OXA-48+NDM} (3%), bla_{IMP} (3%). Overall 30-day survival was 53% (Figure a). Patients with BSI+pneumonia caused by CPE had statistically significantly lower survival compared to patients with pneumonia only (25% vs 83%, p=0.004) (Figure b).

Outcome according to the regimen of antimicrobial therapy was evaluated. Overall 30-day survival in patients treated with ceftazidime/avibactam-containing regimen was higher in comparison to patients treated with other antibiotics (67% vs 50%, p>0.05) (figure c).

Conclusions: In patients with CPE-infection most common type of infection was BSI (n = 40; 69%) caused by K.pneumoniae (96%) harboring bla_{OXA-48} gene (88%). Survival rate was 53%. Patients with BSI+pneumonia caused by CPE had significantly worse outcome in comparison to patients with pneumonia. Patients treated with ceftazidime/avibactam-containing regimen had slightly higher rates of survival.

Abstract third-party references: Hospitals participating in "WHOnet Greece AMR Surveillance Network"

Background: Longitudinal studies on the evolving antimicrobial resistance patterns of bloodstream isolates is crucial for assessing the progression and magnitude of the problem and evaluating the implemented interventions for its management. The aim of our study was to evaluate and compare trends in carbapenem non-susceptibility of three key Gram-negative bloodstream pathogens; Klebsiella pneumoniae, Acinetobacter baumannii and Pseudomonas aeruginosa between two 8-year periods; 2002-2009 and 2010-2017, before and during the gradual implementation of a national action plan to combat infections from these carbapenem resistant organisms.

Materials/methods: Routine susceptibility data of bloodstream isolates from 27 tertiary Greek hospitals participating in the WHONET-Greece AMR surveillance network from 2002 to 2017 was used. Dummy-variable regression was used to compare the trends of the two periods.

Results: During the first period, a significant \((p<0.01)\) increasing temporal trend was observed in the non-susceptibility of K. pneumoniae and A. baumannii bloodstream isolates to carbapenems, ranging from 0.7% to 32.6% and 16.3% to 59.3% in wards, and from 33.6% to 70.2% and 31.5% to 85.3% in ICUs respectively.

A significant \((p<0.01)\) increasing temporal trend was also observed in the second period in carbapenem non-susceptibility of K. pneumoniae and A. baumannii, which ranged from 45% to 55% and 79.7% to 94.4% in wards and from 80.8% to 86.9% and 95.3% to 98.1% in ICUs respectively. During both periods, P. aeruginosa nonsusceptibility to meropenem remained stable in wards \([2002-2009: 28.7%-28.6%; 2010-2017: 38.7%-39.7%]\), with a decreasing trend observed in ICUs \([2002-2009: 64.5%-59%; 2010-2017: 61%-50%]\). By comparing the trend slopes between the two periods, we found that for K. pneumoniae isolates, the slope decreased by 71.7% in wards \((p<0.001)\) and 79.7% in ICUs \((p=0.003)\), while for A. baumannii isolates the slope decreased by 77.8% and 94.1% in wards and in ICUs respectively \((p<0.001)\).

Conclusions: Non susceptibility of bloodstream K. pneumoniae and A. baumannii isolates to carbapenems was found to display an intertemporal increasing trend. However, the observed decrease in its slope as well as the decreasing trend in carbapenem resistance of P. aeruginosa might be regarded as consistent with the launch of the national campaign for AMR focusing both to infection control and antibiotic stewardship practices.

Non-human primate injuries in returning travellers: implications for pre- and post-travel management

Tommy Rampling*, Sneha Baljekar1, Max Brodermann1, Michael Brown1, Nicky Longley1

1Hospital For Tropical Diseases, London, United Kingdom

Abstract 9548

Non-human primate injuries in returning travellers: implications for pre- and post-travel management

Tommy Rampling*, Sneha Baljekar1, Max Brodermann1, Michael Brown1, Nicky Longley1

1Hospital For Tropical Diseases, London, United Kingdom

Background: Non-human primates (NHPs) carry a range of zoonotic pathogens that pose risks to humans. Whilst significant human infections following NHP bites, or other injuries are rare, the consequences can be very high, especially for rabies and simian Herpes B virus infections.

The literature around NHP injury is limited. We aim to characterise the frequency and nature of NHP injury in a central London clinic for returning travellers, and identify areas to improve standards of care.

Materials/methods: We conducted a database search of records from September 2015 to March 2019 using selected keywords to identify attendances to the Hospital for Tropical Diseases (HTD) walk in service, where NHP injury was a component of the presenting complaint. NHP injury was confirmed by case note review, and data collected on country, type and anatomical site of injury, pre- and post-exposure management.

Results: 128 cases of confirmed NHP injury were identified in 11001 attending returned travellers episodes. The most common countries of injury were Indonesia (44/128, 35%), Thailand (37/128, 29%), India (10/128, 8%) other South Asian countries (14/128, 11%) (Figure 1). Bites were the most commonly reported injury (88/128, 69%), followed by scratch (38/128, 30%).

Rabies vaccine status at presentation was more reliably documented than tetanus (50% vs 24%), as was post-exposure rabies management (84% vs 24%). Of those with documentation, 16/60 were fully vaccinated. The remaining 44/60 reported partial, or no vaccination. In-country rabies management was documented in 101 patients. 77/101 (76%) patients received some form of post-exposure prophylaxis (PEP), including 12 receiving rabies immunoglobulin prior to HTD presentation. In HTD clinic, rabies PEP was administered to 90/120 patients. Consideration of Herpes B prophylaxis was rarely documented, and administered to 4 patients.

Conclusions: This data represents one of the largest returning traveller NHP injury datasets. Emphasis on prevention and management of potential NHP injuries in the pre-travel consultation is paramount, particularly for travellers to select regions, including South and South East Asia. Inconsistencies in documentation and management plans present opportunities to further protocolise the management of NHP injuries using clinical proformas and local guidelines.

Strategies for the above will be presented.

Adaptation to host of a *Staphylococcus schleiferii* responsible of an elbow prosthetic infection

Alessandro Bidossi, Marta Bottagisio, Elena De Vecchi

IRCCS Orthopedic Institute Galeazzi, Milan, Italy

**Background:** Prosthetic joint infections represent a devastating complication in orthopaedic surgery with heavy cost for patients in terms of life quality and for the health system because of prolonged hospitalization. These infections are considered as the typical biofilm-related infections. Coagulase negative staphylococci are the most frequently pathogens. *Staphylococcus schleiferii* was described in 1988 as a zoontic agent but in the last years it has been associated to severe infections such as endocarditis or, less frequently, prosthetic joint infections. In this study we investigated the ability of an *S. schleiferii* isolated from elbow prosthetic infection to modulate biofilm production during antibiotic treatment.

**Materials/methods:** The strain was isolated from periprosthetic tissues collected before (isolate 1) and after (isolate 2) a 5 months period of antibiotic treatment of a 66 years old male with a chronic HCV related liver disease, rheumatoid arthritis and diabetes. Biochemical identification and susceptibility testing were performed on a Vitek2 Compact (bioMerieux). MIC were further confirmed by broth microdilution test according to EUCAST procedure. To confirm strain identity, the whole genomes of the 2 isolates were compared by means of nanopore sequencing approach. Moreover, biofilm production and interference on biofilm formation by gentamicin, oxacillin, rifampicin and vancomycin at from ½ X to 8 X MIC concentrations were also evaluated.

**Results:** Both isolates were susceptible to gentamicin, oxacillin, rifampicin and vancomycin, without significant changes in MIC values. Sequencing confirmed that the 2 isolates belonged to the same strain. Significant differences were observed in biofilm production, with isolate 2 producing higher amount of biomass than isolate 1. When biofilm was put in contact with increasing gentamicin and vancomycin concentrations, isolate 2 showed a greater biomass than isolate 1.

**Conclusions:** Results of this study evidence the capability of an *S. schleiferii* strain responsible of a prosthetic joint infection to adapt to antibiotic therapy, by increasing biofilm production. The tested antibiotics exhibited a different ability to modulate biofilm production in the 2 isolates. It may be hypothesized that the ability to adapt to changed environmental conditions might be related to infection persistence.

Abstract 9558

**Comparative effectiveness of stewardship interventions in reducing *Clostridioides difficile* infection incidence**

Kevin Brown*1,2, Kevin L. Schwartz1,2, Bradley J. Langford1, Christina Diong3, Gary Garber1, Nick Daneman1

1Public Health Ontario, Toronto, Canada, 2The Dalla Lana School of Public Health, Toronto, Canada, 3Institute for Clinical Evaluative Sciences, Toronto, Canada

**Background:** Antibiotic utilization in nursing homes is highly variable across jurisdictions in North America and Europe. The objective of this study was to quantify the comparative benefit of antibiotic stewardship strategies targeting prescribing dimensions of antibiotic initiation, duration, or selection, using real-world data on antibiotic prescribing and *C. difficile* infection risk.

**Materials/methods:** We conducted a cohort study of residents of over 600 Ontario nursing homes in the 2014 to 2017 period. We simulated antibiotic course exposures for the population corresponding to each of 4 intervention targets: (1) reducing a percentage of antibiotic initiations, (2) changing a percentage of long antibiotic courses (8-14 days) to short courses (5 days), (3) substituting a percentage of high-risk antibiotic courses for medium or low risk courses often used for the same indication, and (4) the combination of all three of these interventions. We previously developed a Poisson regression model of antibiotic-associated *C. difficile* infection risk, which estimated nursing home resident specific risk as a function of antimicrobial agent and duration of exposure. This model was used to project *C. difficile* infection incidence across Ontario as a function of intervention coverage.

**Results:** The baseline population included almost all nursing home residents in Ontario between 2012 and 2017 corresponding to 212,314 unique patients. The prevalence of antibiotic use in the prior 90 days was 27.0% in the baseline cohort. We identified 2,432 cases of *C. difficile* infection, for an incidence of 1.68 per 100,000 resident-days. Interventions targeting initiation were the most effective [incidence rate ratio (IRR)=0.973 per 10% increase in coverage, 95%CI: 0.962-0.986], followed by interventions targeting high risk antibiotic prescribing [IRR=0.986 per 10% increase in coverage, 95%CI: 0.975-0.998]; interventions targeting reductions in duration were the least effective [IRR=0.997 per 10% increase in coverage, 95%CI: 0.985-1.009]. The combined intervention that decreased all 3 target prescribing behaviors led to a 4.2% reduction in *C. difficile* infection incidence (IRR=0.958 per 10% increase in coverage, 95%CI: 0.946-0.970).

**Conclusions:** Strategies targeting reductions in antibiotic initiation have substantially larger impacts than strategies targeting antibiotic substitution or duration when it comes to *C. difficile* infection risk in nursing homes.

**Presenter email address:** kevin.brown@phe.gov.uk
Abstract 9563

**Antimicrobial stewardship and perioperative antimicrobial prophylaxis: results of an educational intervention**

Francesco Vladimiro Segala*1, Rita Murri12, Eleonora Taddei1, Francesca Giovannenze1, Pierluigi Del Vecchio1, Emanuela Birocchi1, Francesco Taccai1, Roberto Cauda12, Massimo Fantoni12

1Catholic University of the Sacred Heart, Rome, Italy, 2Agostino Gemelli University Polyclinic, Roma, Italy

**Background:** Worldwide, perioperative antimicrobial prophylaxis (PAP) represents a major indication of antibiotic consumption. Aim of this study is to investigate inappropriateness in PAP prescription and assessing the role of an Antimicrobial Stewardship (AS) intervention in a University Hospital performing more than 40,000 surgical procedures per year.

**Materials/methods:** PAP inappropriateness was defined according to the ASHP guidelines2 and divided in four main categories: indication, duration, timing and prescribed molecule (type). In the procedures lasting longer than 4 hours, we underlined whether an adjunctive dose of antibiotic was administered or not (repeat). Between 2013 and 2019 we conducted a continuous AS intervention over 11 departments of specialised and general surgery, based on active participation of the prescribers (both surgeons and anaesthesiologists) in drafting and reviewing the local PAP guidelines. Here, we report the results of the PAP appropriateness before (baseline, April 2013) and at the end (April 2019) of the AS educational intervention.

**Results:** We collected a total of 708 PAP prescribed to 698 patients (mean age 55.6±17.7 y). The overall prevalence of PAP inappropriateness dropped, from 62.9% (n=258/410) at baseline to 32.2% (n=96/298) at post-intervention (figure 1). A significant improvement (p<0.001) between pre- and post-intervention was also detected for each category: indication (from 41.2% to 4.0%), type (from 41.2% to 16.1%), timing (from 7.6 to 2.0%), duration (from 29.5% to 15.1%). In 2019, three departments have been identified as the main drivers of the remaining SP inappropriateness.

**Conclusions:** Though results cannot be generalized to all hospital populations, participative AS interventions may be highly effective in improving PAP appropriateness rates. Once identified the main causes of PAP inappropriateness, tailored AS interventions for each department may be beneficial. Further studies are needed to evaluate specific outcomes as incidence of surgical site infections and antimicrobial resistance.

Table 1: the table reports the total number of inappropriate PAP cases observed for each category.

**Figure 1:** the table reports the total number of inappropriate PAP cases observed for each category.

Abstract 9564

**Economic evaluations of malaria interventions: a systematic review**

Anna Klicpera*1,2, Aduragbemi Banke-Thomas2

1Social Medical Center East - Donauspital, Wien, Austria, 2London School of Economics and Political Science, London, United Kingdom

**Background:** Although malaria is declining in parts of the world, it still claimed around 500,000 lives in 2016 and in some areas the burden of malaria has even increased. At the same time, there is a huge gap in funding of malaria interventions. Decisions on investment of scarce resources need to be based on evidence of relative costs and consequences of interventions.

**Aim:** The aim of this review is to assess the cost-effectiveness of different interventions to diagnose, treat and control malaria and to identify the interventions that provide good value for money in different settings.

**Materials/methods:** A systematic review of economic evaluations of malaria interventions that were published between 2011 and 2017 was conducted. Within a narrative synthesis the costs and effectiveness or benefit estimates were compared across different interventions, regions and types of analyses. All reported outcome measures were inflated to 2016 US$ for standardization and selected results were presented adjusted for purchasing power parity.

**Results:** 62 studies were included in this review. Rapid diagnostic testing, artemisinin combination therapies, seasonal malaria chemoprophylaxis, intermittent preventive treatment in pregnancy, insecticide-treated nets and larviciding were found to be cost-effective. Treatment with artemisinin-naphthoquine, intermittent screening and treatment in pregnancy and mass screening and treatment were not cost-effective. Indoor residual spraying and vaccination could be valuable interventions in specific settings. Lack of standardization in methodology and reporting of economic evaluations limited comparability and usefulness of included studies.

**Conclusions:** Many cost-effective interventions exist to diagnose, treat and prevent malaria. It is important to tailor malaria control policies to the local context, depending on malaria endemicity, resistance against drugs and insecticides, accessibility and coverage levels of implemented interventions.

Abstract 9565

Severe respiratory diphtheria caused by *Corynebacterium ulcerans*: lessons learned from a rare emerging infection

Raqib Huq*1,2, Robert Shortern1, Avinash Jha1, Arun Cardozo1, Irfan Chaudry1, Leila White1, Alison Muir1, Gayatri Amirthalingam3, Meera Chand3, Pauline Jumaa1

1Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom, 2Health Education England, Northwest Deanery, Manchester, United Kingdom, 3National Infection Service, Public Health England, London, United Kingdom

Abstract third-party references: Public Health England, Lancashire Teaching Hospitals NHS Foundation Trust

Background: *Corynebacterium ulcerans* is a zoonotic, aerobic, Gram positive bacillus which can produce diphtheria toxin and cause diphtheria. We present a case of severe respiratory diphtheria caused by a toxigenic strain of *C. ulcerans*, highlighting learning points from the case.

Materials/methods: A 76 year-old lady was admitted to hospital with difficulty breathing and swallowing following one week of sore throat and cough. She developed rapidly progressive stridor and required emergency intubation with fiberoptic laryngoscopy, which showed upper airway oedema and copious mucopurulent secretions in the nasal cavity. She was transferred to the intensive care unit (ICU), and treated with empirical broad spectrum antimicrobials for sepsis of unknown source. On day 3 of admission, *C. ulcerans* was isolated from oropharyngeal tissue collected during intubation. Following advice from Public Health England (PHE) the patient was treated with diphtheria antitoxin and the antimicrobial treatment was changed to benzylpenicillin and clarithromycin; the pharyngeal and laryngeal oedema improved. Toxigenicity of the *C. ulcerans* strain was confirmed by the PHE reference laboratory. On day 11 she developed a ventilator-associated pneumonia. She was treated for this and extubated after three weeks' admission. Contact tracing for community and healthcare contacts identified no community contacts and 39 healthcare worker contacts who had failed to wear appropriate personal protective equipment (PPE) during intubation and while the patient was ventilated on ICU. Two microbiology laboratory staff who had manipulated the *C. ulcerans* were also identified as potential contacts. All healthcare worker contacts were screened for *C. ulcerans* carriage and given prophylactic antimicrobials. They were excluded from work pending the screening results in line with PHE guidance. No healthcare worker carriers were identified. The patient had a companion dog, which was found to be negative for *C. ulcerans*.

Results: n/a

Conclusions: This case adds to the current knowledge of *C. ulcerans* as an emerging pathogen with public health implications. Learning points include: the need for improved compliance with routine infection prevention and control procedures for respiratory protection; logistics of supply and administration of diphtheria antitoxin in the UK; poor awareness of *C. ulcerans* as a cause of diphtheria among laboratory staff.

Abstract 9566

**Cytomegalovirus reactivation in allogeneic stem cell transplant recipients: frequency, time to reactivation and dynamic of viraemia in different types of donors and in repeated episodes**

Marcia Garnica*1,2, Sylvia Dalcolmo1, Bianca Gaio1, Isabela Alves1, Marcia Rejane Valetim2, Angelo Maiolino1

1Universidade Federal do Rio de Janeiro, Brazil, 2Complexo Hospitalar de Niterói, Brazil

**Background:** Cytomegalovirus (CMV) remains leading to high morbidity and mortality in allogeneic stem cell transplant (Allo-SCT). High immunosuppression increases the risk of reactivation and allows repeated reactivation episodes. However, immunosuppression varies in accordance to donor types. In this study, we compared CMV reactivation in different Allo-SCT: Related (RD), unrelated (URD), and haploidentical (Haplo) donor SCT and analyzed the dynamic of repeated CMV episodes.

**Materials/methods:** Prospective cohorts of Allo SCT (from 2013 to 2019). Patients were screened by CMV quantitative PCR (Taqman Sistem – artus CMV Qiagen) in plasma. The screening started on the first week after SCT, repeated once a week until D+100, and after D+100 if immunosuppression was maintained. Repeated episode was defined if at least two negative CMV CRP results were obtained after the first episode. The following variables were analyzed: time after SCT to reactivation, initial viral load, highest viral load within the event, duration of viremia, and response to treatment.

**Results:** There were 123 Allo-SCT performed. Median age was 47 years (ranging 1 to 70), and acute leukemia represented 63%. RD, URD, and Haplo were 72 (58%), 30 (24%), and 21 (17%), respectively. The median duration of follow-up was 251 days. CMV reactivation was documented in 84 (68%), with a median number of 2 (1 – 9) episodes per patient. RD, URD, and Haplo had similar frequencies of reactivation (64%, 70%, and 81%; p=0.33). URD-SCT had earlier reactivation than others (median D+6, versus D+37 and D+ 21 in RD and Haplo, p<0.001). A total of 192 CMV reactivation episodes were analyzed: 100 in RD, 55 in URD, and 37 in Haplo. Haplo-SCT reached the highest viral loads (median of 1070 copies/mL vs., 373 and 163 copies/mL in RD and URD-SCT; p=0.036). First CMV reactivation episode reached higher viral load (median 1897 vs. 143 copies/mL; p<0.001) and longer viremia (median 28 vs. 14 day; <0.001), compared with repeated ones.

**Conclusions:** Reactivation of CMV occurred with different dynamics by SCT donor type and in the first or repeated episode. Treatment and preventive strategies should be adapted, considering these different scenarios.

Abstract 9571

**Trichomonadine association with Pneumocystis jirovecii: a retrospective study**

Sara Mille¹, Dominique Toubas², Frédérique Foudrinier¹, Depaquit Jerôme¹,³, Antoine Huguenin*¹,³

¹Centre Hospitalier Universitaire Reims, Laboratoire de Parasitologie-Mycologie, Reims, France, ²UFR Pharmacie, EA7506 Biosapect, Reims, France, ³Faculty of Medicine and Pharmacy, EA7510, Reims, France

**Background:** Pneumocystis pneumonia (PCP) is a serious condition caused by *Pneumocystis jirovecii* in immunocompromised patients. Human trichomonesis, caused by trichomonadines, is mainly represented by sexually transmitted infections, caused by *Trichomonas vaginalis*. However, the presence of trichomonadine has been described several times at the pleuropulmonary level and an association with PCP has recently been demonstrated. We thus studied the prevalence of detection and the diversity of trichomonadine species as well as the risk factors favoring the unusual presence of the parasite at the pulmonary level from the respiratory samples of patients with detection of PCR-positive *Pneumocystis jirovecii* DNA.

**Materials/methods:** Our retrospective study, over a period of 12 years in Reims, northern France included 349 patients with positive *Pneumocystis jirovecii* real-time PCR. The presence of trichomonadines on respiratory samples was screened using primers targeting rRNA. Positive samples were sequenced to allow species identification.

**Results:** At first, it allowed us to describe the local epidemiology of PCP. Our local analysis verifies the data from the literature. In a second step, the trichomonadine research by PCR has shown that the detection of the parasite at the pulmonary level is not anecdotal (12%) and that it is more frequently present in patients with HIV (p < 0.0001) and hypoxemic (p < 0.026). The species identified are not limited to *Trichomonas tenax*, commensal of the oral cavity, since we found in particular a new species associated with empyemas: *Tetratrichomonas empyemagena*. Our results also demonstrate a correlation between trichomonadins and the presence of numerous *Pneumocystis jirovecii* cysts on direct examination (p = 0.0008).

**Conclusions:** The pathogenic potential of trichomonadines, however, remains unclear and further studies are needed.

Abstract 9575

**Clinical and financial impact of an empiric antibiotic prescribing policy: single department experience**

Luis Melo1, Mariana Barosa1, Ricardo Marques*1, José Delgado Alves1

1Hospital Prof Doutor Fernando Fonseca, Amadora, Portugal

**Background:** The development of local suited protocols is a useful tool to help improving the judicious use of antibiotics, which is primordial to face the challenge of antibiotic resistance. This study aims to evaluate the clinical outcomes of mortality, clinical and microbiologic failure of a single department Empiric Antibiotic Prescribing Policy (EAPP) and to assess the financial impact resulting from its application.

**Materials/methods:** An EAPP was developed for the most prevalent infections considering clinical practice guidelines and local microbiology data. Clinical data of 159 consecutive empiric antibiotics prescriptions after the application of the EAPP, from March 1st to July 31st 2019 was collected and analyzed prospectively. A control group constituted by 234 empiric antibiotic therapy prescriptions in patients admitted in the same department, over the same period of time in 2018 was analyzed retrospectively.

**Results:** Compliance with the EAPP reached 86.2%. The use of broad-spectrum antibiotics as Piperacillin/Tazobactam and Carbapenems was reduced from 25.2% in the control group to 4.4% after the EAPP (p<0.001). No significant change in mortality occurred between the two groups. The median length of antibiotic use was reduced from 7 (±2.8) to 5 (±1.5) days (p<0.001) and the duration of hospitalization from a median of 8 [IQR 5-18] to 7 [IQR 4-10] days (p<0.001). Oral therapy was increased to 52.2% from 21.4% in the control group (p<0.001). Although EAPP advocated the use of narrower spectrum schemes, clinical failure was reduced from 19.7% to 10.1% (p=0.013). There was a reduction in the percentage of multiresistant bacteria isolated (34.3% vs 26.4%), although this was statistically non-significant. The total expense with antibiotics of the department decreased from €11917 (€53.90 per patient) to €6543 (€27.50 per patient).

**Conclusions:** The antibiotic schemes from the EAPP and duration of therapy proposed for each condition proved to be effective and safe. The authors believe that the clear definition of failure criteria helped reducing the wide spectrum antibiotic prescriptions by preventing early escalation in cases which proved to evolve favorably with the EAPP recommended option. We believe the EAPP is a valuable tool to curb inadequate antibiotic use and therefore reduce induction of resistance.

Abstract 9588

Carbapenemase-producing *Pseudomonas aeruginosa* in south Brazil
Carmen Antonia Sanches Ito1, Larissa Bail*1, Lavinia Arend1, Marcelo Pilonetto1, Guilherme Becker1, Keite Nogueira2, Felipe Tuon1

1Pontifical Catholic University of Paraná, Curitiba Campus, Curitiba, Brazil, 2Federal University of Parana, Curitiba, Brazil

**Background:** Carbapenem-resistant *Pseudomonas aeruginosa* (CRPA) is an important pathogen of hospital infection associated with increased morbidity and mortality rates. The resistance in *P. aeruginosa* to carbapenems is up to 70% in some Brazilian hospitals. Different mechanisms may contribute to carbapenem resistance in *P. aeruginosa*. Although, the carbapenemases production, mainly the metallo-β-lactamases (MBLs), is the most important because its hydrolyzes almost all clinically-available β-lactams antibiotics and are often carried on transferable structures as plasmids. This study aims to report the prevalence of carbapenemases types in CRPA collected in different hospitals in the South of Brazil.

**Materials/methods:** The study included 557 clinical unique strains of CRPA from inpatients by different hospitals on Paraná (225) and Santa Catarina (332) states located in the South of Brazil, collected between January 2011 and October 2017. The *blaSPM*, *blaIMP*, *blaVIM*, *blaGIM*, *blaNDM*, and *blaKPC* carbapenemases genes were assessed by multiplex real-time PCR (qPCR) following previously reported conditions.

**Results:** The strains were isolated from bronchoalveolar lavage (50), tracheal aspirate (130), blood (90), sputum (20), cerebrospinal fluid (7), ascitic fluid (1), pleural fluid (1), peritoneal fluid (5), synovial fluid (1) and urine (252). A hundred ninety (32.9%) out of the 557 CRPA isolates recovered from clinical specimens were carbapenemase producers. The *blaSPM* gene was found in 131 (22.7%) isolates, followed by *blaKPC* in 33 (5.7%), *blaIMP* in 15 (2.6%) and *blaVIM* in 11 (1.9%).

**Conclusions:** In Brazil, SPM remains the predominant carbapenemase in *Pseudomonas aeruginosa*. However, other carbapenemases have emerged including KPC which has exceeded the IMP and VIM types in this study.

Listeriosis in Ávila, Spain: a real warn amongst immunocompromised hosts

Miguel Pedromingo Kus*, Teresa Meiras Arriaga, Amparo San Pedro Garrido, Óscar Fraile Santos, Nuria Iglesias Nuñez, Rafael Sanchez Arroyo, Jose Manuel Barragan Casas, Ana Cristina Antoli Royo

1Hospital Nuestra Señora de Sonsoles, Ávila, Spain

Background: Listeriosis is an uncommon but potentially serious foodborne infection caused by Listeria monocytogenes. It generally affects elderly people, pregnant women and immunosuppressed hosts, and is an increasingly life-threatening disease, crossing the intestinal barrier, the placenta and the blood-brain barrier producing gastroenteritis, maternal-fetal infections and meningoencephalitis. It is most commonly diagnosed from a positive culture of a sterile site. The treatment of choice includes the use of intravenous ampicillin alone or in combination with gentamicin.

Materials/methods: a marked increase in reported cases of listeriosis during 2019 in Spain motivated a retrospective survey in our Institution (Hospital Nuestra Señora de Sonsoles, Ávila, Spain). We retrospectively describe the epidemiological patterns and trends of this serious infection among patients diagnosed in our province, Ávila, Spain, from 2002 through 2019.

Results: overall, 31 cases were identified; the majority of them were admitted to the Internal Medicine Department (15/31, 48.4%) and were from rural settings (18/31, 58.1%).

Blood stream infection was found in 26/31 patients – 83.9%.

The most common clinical syndromes in these patients were primary bacteremia (13/31, 42%) and meningitis or meningoencephalitis (9/31, 29%); the latter, all with signs of romboencephalitis, mononeuritis or cranial nerve palsy. Surprisingly, we did not find any perinatal, nor neonatal cases in our records. Other clinical presentations were as follows: bacteremic pneumonia (3/31, 9.7%), bacterial peritonitis (2/31, 6.5%), and 1 case of complicated diverticulitis, spondylodiscitis, arthritis and abdominal abscess (1/31, 3.3% each).

In general, 17 patients deceased (54.8%), and listeriosis related mortality accounted for a 38.7% of the patients (12/31), the rest being related to concomitant illnesses (5 patients, 16.1%, all with different kinds of cancer).

Most of the 31 cases involved immunocompromised patients (27/31, 87%), mostly due to malignancies (18/31, 58.1%), and overlapping in some cases with chronic liver disease (5/31,16.13%), chronic renal failure (7/31, 22.6%), or diabetes mellitus (9/31, 29%).

Only 1 patient was not treated. He deceased from non-Hodgkin lymphoma complications. All the rest received specific antibiotics.

Conclusions: our study shows a higher trend regarding the epidemiology of listerial infections. Immunosuppressed patients are at the highest risk of developing listerial serious infections and death, especially those with malignancies.

Abstract 9593

Genomic epidemiology of NDM-producing Enterobacteriaceae in Portuguese hospitals

Vera Manageiro*, Eugénia Ferreira, Manuela Caniça

1National Reference Laboratory of Antibiotic Resistances and Healthcare Associated Infections, Department of Infectious Diseases, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal

Abstract third-party references: National NDM-study group

Background: New Delhi metallo-β-lactamase (NDM)-producing Enterobacteriaceae were rarely identified in Portugal, with the first case reported during an NDM-1-producing Providencia stuartii outbreak, in 2014/2015. The aim of this study was to analyze the whole genome sequence (WGS) and resistome of NDM-producing Enterobacteriaceae strains referred to the Laboratory of Antibiotic Resistances and Healthcare Associated Infections, at National Institute of Health Dr Ricardo Jorge from 2016 onwards.

Materials/methods: WGS was performed on a MiSeq Illumina platform. INNUca was used for quality control of reads, de novo assembly and contigs quality assessment. Prokka and ABRicate were used for genome annotation and screening for antimicrobial resistance and/or virulence genes, respectively. Phylogenetic inference was performed with chewBBACA pipeline, using the core genome MultiLocus Sequence Typing (cgMLST) schema. The evolutionary relationship was accessed by Minimum spanning trees (MST) using the PHYLOViZ.

Results: During the study period, 28 Enterobacteriaceae isolates (11 Klebsiella pneumonia, 6 Providencia stuartii, 6 Escherichia coli, 3 Enterobacter cloacae, 1 Klebsiella oxytoca and 1 Proteus mirabilis) collected in eleven different Portuguese hospitals, were included in the study. From those, 23 were NDM-1 producers while 5 were NDM-5-producing E. coli. The results obtained demonstrated the diversity of genetic structures associated with blaNDM-type gene, including: (i) host bacterial specie; (ii) plasmid types and associated mobile genetic elements; and (iii) blaNDM variants.

Conclusions: In conclusion, the emergence and spread of NDM-producing Enterobacteriaceae in Portugal has been driven by multiple mechanisms. Indeed, genomic and epidemiological data can yield a useful map of an outbreak and facilitate the control of nosocomial transmission.

Abstract 9594

First description of GES-20-producing Pseudomonas aeruginosa in Brazil
Aline Valerio Lima1, Darlan Augusto Da Costa Rocha1, Keila De Oliveira Lima1, Suely Sampaio2, Jorge Luiz Mello-Sampaio*1,3
1Universidade de São Paulo, School of Pharmacy, São Paulo, Brazil, 2Faculdade de Medicina da Santa Casa de São Paulo, São Paulo, Brazil, 3Fleury Medicine and Health, Microbiology Section, São Paulo, Brazil

Abstract third-party references: Fundação de Amparo à Pesquisa do Estado de São Paulo, Fleury Medicine and Health

Background: Pseudomonas aeruginosa is a major agent of healthcare-related infections worldwide. Empirical treatment of serious infections caused by this species usually includes carbapenems. Carbapenemase production is the most efficient resistance mechanism and molecular detection can aid in faster antimicrobial therapy adjustment. Consequently it is important to know the local molecular epidemiology.

Materials/methods: Eleven carbapenem-resistant nosocomial P. aeruginosa isolates able to hydrolyze imipenem in spectrophotometric assay but negative for known carbapenemase genes had the full genome sequence determined. Isolates were collected from private hospitals located at the city of São Paulo, Brazil. Genomic DNA extraction was performed using the Illustra Bacteria Genomic Prep Mini Spin Kit before libraries were prepared using the Nextera XT DNA Library Preparation kit. DNA sequencing was performed using the MiSeq reagent kit v3 150 cycles. De novo assembling was performed using the Geneious software. Resistance genes were detected using CARD/RGI. MLST type was determined analyzing the contigs at the PubMLST homepage. Imipenem and meropenem MICs were determined according to the EUCAST guidelines.

Results: Four isolates belonged to ST277, three belonged to ST1560 and one of each belonged to ST224, ST309 and ST313. A single isolate had a new MLST pattern designated ST3187. The isolate pertaining to ST309, had the GES-20 carbapenemase and the GES-19 ESBL. All other isolates were negative for known carbapenemase genes, but had three different types of OXA-50 variants with similarities varying 98.85 to 99.62%. These isolates had imipenem MICs ranging from 8 to 32 mg/L. The isolate expressing GES-20 was recovered from the urinary tract of a patient with nephrolithiasis in July 2013. The blaGES-20 gene was found to be located in a class 1 integron flanked upstream by the blaGES-19 ESBL and downstream by the aacA4 aminoglycoside resistance gene [Figure]. The integron is identical to the In724 described in Mexico, except that qacH gene is absent. The isolate expressing GES-20 had imipenem MIC > 32 mg/L and meropenem MIC > 128 mg/L.

Conclusion: This is the first description of GES-20 from Brazil. Our preliminary findings concerning OXA-50 variants indicate that these variants may be implicated in imipenem resistance in P. aeruginosa.

Abstract 9595

**Evolution of awareness and knowledge of congenital cytomegalovirus infection among healthcare providers in France between 2011 and 2018**

Thanina Fellah\(^1\), Jeanne Sibiude\(^1\), Christelle Vauloup-Fellous\(^2\), Anne-Gaëlle Cordier\(^1\), Liliane Grangeot-Keros\(^2\), Alexandra Benachi\(^3\), Laurent Mandelbrot\(^1\), Sébastien Guitton\(^1\), Olivier Picone*\(^1\)

\(^1\)Hopital Louis Mourier, APHP, Colombes, France, \(^2\)Paul Brousse, APHP, Villejuif, France, \(^3\)Antoine Beclere, Clamart, France

**Background:** Cytomegalovirus (CMV) is the first cause of congenital viral infection, concerning 1% of newborns, of whom 10% have major symptoms. Antenatal and postnatal treatments, although promising, are still under evaluation. The importance of hygiene counselling to prevent CMV infection is established and should be systematic. Our objective was to evaluate health care providers’ awareness of CMV maternal and congenital infection in France.

**Materials/methods:** A questionnaire was sent in 2018 by e-mail to obstetricians, pediatricians, midwives and laboratory physicians, members of medical or midwives’ associations. We evaluated their knowledge concerning CMV epidemiology, transmission, symptoms in adults, newborns and long-term effects. Scoring was based on 30 points. We then compared the results to a previous study of our group published in 2012.

**Results:** The questionnaire was completed by 597 respondents. Most of them (91%) were unaware of the precise transmission route of CMV. One third (33%) was wrongly convinced that in utero therapy for congenital CMV infection was standard of care in France at the time of the study. Recommendations of HAS (Haute Autorité de Santé) and CNGOF (Collège National des Gynécologues et Obstétriciens Français) were known by less than half of the respondents. However the majority of the respondents correctly answered more than one half of the questions. The better their knowledge of CMV, the better was the hygiene advice given to patients. Between 2011 and 2018 we note an improvement in knowledge for the doctors and the midwives concerning the routes of transmission, symptoms in adults and the long-term effects of CMV infection.

**Conclusions:** This study shows an improvement in knowledge among healthcare providers, but there are still gaps. To bridge these gaps, health care providers should improve their knowledge about congenital CMV by various means: medical reviews, continuing medical education, meetings, conferences, the internet. Moreover, better knowledge will allow for better information for pregnant women as recommended by HCSP and CNGOF in France.

**Presenter email address:** olivier.picone@aphp.fr
Abstract 9596

**eHealth-based antimicrobial stewardship programme focused on individual prescriptions assessment: sustainability at 4 years**

Carlos Palos¹, Luís França¹, Paulo Rodrigues¹, Raquel Tavares¹, Ana Rita Silva¹

¹Hospital Beatriz Ângelo, Infection Control and Antibiotics Committee, Loures, Portugal

**Background:** Assessment of individual antibiotic prescriptions are a pillar of Antimicrobial Stewardship Programs as 30 to 50% of all worldwide antibiotic prescriptions are inappropriate and are the main drive for antibiotic resistance, a Public Health problem. eHealth is a major tool for ASP activities. Authors present the results of the first four years of an eHealth-based innovative solution that includes new order forms, automated pop-ups and emails, whenever antibiotics are conditioned or are in disagreement with local recommendations, allowing analysis and interventions directed to the physicians in charge of the patients. In this way, both back-to-end [audit and feedback] and front-to-end [conditioning] strategies are adopted, being complemented by education, awareness and feedback information about consumption.

**Materials/methods:** For the purpose of this work, evaluation of ASP activities are based on antibiotic consumption of relevant antibiotics as defined by ECDC/EFSA and EMA, expressed as Defined Daily Doses (DDD), obtained from the Pharmacy and administrative software. No other information, such as patient outcome, length of stay, bacterial resistance pattern or economic evaluation, is considered.

**Results:** Since full implementation of ASP activities (January 2015), relevant variations are as follows: Ertapenem -66%; Ceftriaxone -55%; Ciprofloxacin -57%; Meropenem -52%; Levofloxacin -49%; Colistin +250%. Reductions were most accentuated in the first year of interventions, were in the desired direction and have been maintained throughout the time. Some observed variations are the result of local bacteria incidence or the implementation of new therapeutic strategies.

**Conclusions:** Implementation of an eHealth-based ASP for assessment of individual prescriptions had a huge impact on the profile of antibiotic prescription, which is maintained after 4 years of full activity. Long-term sustainability of ASP is a challenge requiring combination of factors where a combination of eHealth, real-time continuous conditioning and audit and feedback of individual prescriptions, as well awareness and education are essential.

Abstract 9599

**The burden of chronic pulmonary aspergillosis on the respiratory service at a district general hospital**

Firas Maghrabi*, Ruth Cade, Chris Kosmidis, Ram Sundar, David W. Denning

1University of Manchester, National Aspergillosis Centre, Manchester, United Kingdom, 2Royal Albert Edward Infirmary, Wigan, United Kingdom

**Background:** Wigan is a town located 17 miles North West of The City of Manchester with a population just over 325,000. It was known as major mill town and coal mining district and is covered by Wigan Infirmary, a district general hospital (DGH) with 513 beds.

A recent report from the National Aspergillosis Centre (NAC) based in Manchester, UK; highlighted Wigan as the home of the highest number of referrals with Chronic Pulmonary Aspergillosis (CPA) with 63 patients of 522 (12%) under active follow up. This was a significantly higher case burden than expected for a DGH that warranted further investigation.

**Materials/methods:** A retrospective analysis of electronic case-notes of all patients admitted to Wigan Infirmary with a diagnosis of CPA or invasive pulmonary aspergillosis (IPA) within a six-year period from January 2013 to December 2018. We also reviewed the case-notes of all the outpatients diagnosed with CPA and referred to the NAC during this period.

**Results:** Patients were diagnosed with CPA and classified according to the ESCMID guidelines. 41 patients were admitted during this period, 37 with CPA and 4 with IPA. 78 were diagnosed with CPA as outpatients and received treatment at the NAC.

Overall, 63% had COPD, 85% had a smoking history of >10 pack years. 68% of patients had been treated with inhaled steroids. 87% of patients lived in postcodes in the most deprived 50% of areas for health and disability according to the 2015 English Indices of Deprivation, with 24% of patients living in the most deprived areas.

Mortality was high, 21% of inpatients died before they could be referred to the NAC. 43% of outpatients with CPA died by the time of the analysis.

**Conclusions:** The burden of pulmonary aspergillosis is higher than expected in the Wigan area with an estimated prevalence of 35/100,000 population, compared with the estimated national burden of 5.7/100,000. The reasons for the raised burden are unclear, but probably health deprivation, a high prevalence of chronic lung disease and smoking related morbidity and mortality are factors. Further comparative studies from similar populations are required to understand the burden of CPA further.

**Presenter email address:** firas.maghrabi@doctors.org.uk
Abstract 9600

A systematic evaluation of the anti-plasmodial activity of low molecular weight heparin against human malaria parasite Plasmodium falciparum

Muqdad Hmoud*, Paul Horrocks

1Keele University, Newcastle under Lyme, United Kingdom

Background: Despite the global effort to decrease mortality and morbidity, malaria still causes 435,000 deaths and more than 200 million infection cases according to World Health Organization report 2018. Plasmodium falciparum is the most lethal malaria parasite among other malaria spp, and account the majority of malaria death cases. Antimalarial drug resistance has emerged in many affected areas, representing the hallmark malaria treatment delay and failure. Pfalciparum drug resistance has been reported to all known antimalarial therapies. There is high demand to develop a new approach to face antimalarial drug challenge. Heparin has shown anti-plasmodial activity by inhibiting Pfalciparum growth via blocking merozoite invasion into erythrocyte. This activity seems to be mediated by interfering with major merozoite surface (MSPs), resulting in merozoite failure to invade the erythrocyte and establish a new life cycle. Heparin has been used clinically to treat patients with malaria infection, but due to its highly anticoagulation activity, heparin has been halted to be used as an adjunct therapy. Whilst heparin and other heparin mimetics their growth inhibition activity has been evaluated, a systematic exploration of this activity of range of Low Molecular Weight Heparins (LMWHs) has not. In this study, a systematic side by side comparison of the in vitro growth inhibition of commercial LMWHs are explored. In addition, exploration of using LMWHs as adjunct therapy has been evaluated.

Materials/methods: Growth inhibition and invasion blocking activity of LMWHs are determined using standard growth inhibition assay by Flow cytometry using two distinct parasite clones. The invasion blocking activity of LMWHs is determined by light microscopy. All experiments were done as technical triplicate in three biological repeats (n=9). All anti-plasmodial activity of LMWHs has been compared with unfractionated heparin.

Results: LMWHs showing anti-plasmodial activity by blocking merozoite invasion to the erythrocyte in two Pfalciparum clones. This activity is correlated with the molecular weight and chain length of LMWHs

Abstract 9601

Unexpected low antibiotic resistance of *Klebsiella* spp. isolated from children’s faeces, water samples, soil and animals from Andean rural homes in Cajamarca, Peru

Maribel Riveros Ramirez1, Maria Pinedo Bardales*2,3, Raymi Alosilla4, Maria Luisa Medina Pizzali2, Daniel Mäusezahl6, Theresa Ochoa Woodell7, Stella Hartinger8

1Universidad Peruana Cayetano Heredia, Institute of Tropical Medicine Alexander von Humboldt, San Martín de Porres, Peru, 2National University of Piura, Piura, Peru, 3Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru, 4Universidad Peruana Cayetano Heredia, Institute of Tropical Medicine Alexander von Humboldt, San Martín de Porres, Peru, 5Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru, 6Swiss Tropical And Public Health Institute, Institute, Basel, Switzerland, 7Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru, 8Universidad Peruana Cayetano Heredia, San Martín de Porres, Peru

**Background:** The dissemination of multidrug-resistant strains (MDR) with a potential to express resistance to multiple drugs represents a threat of dissemination in the community. Reports of MDR strains in livestock populations, the environment and the community demonstrate that the transmission and persistence of these bacteria also occur outside the clinical setting. This study aimed to identify *Klebsiella* spp in feces of children under six years and samples of water, soil and animals from wells, and establish their level of antimicrobial resistance.

**Materials/methods:** The study was located in the provinces of San Marcos and Cajabamba in Cajamarca, with altitudes between 2,200 and 3,900 m above sea level. Samples of children's feces (stored in Cary Blair), water, soil and animals (rectal swabs) were collected from households (n=40) in rural areas. The water samples were analyzed for thermotolerant (fecal) coliforms using the membrane-filtration method and the soil samples were enriched with LB Broth. *Klebsiella* spp isolates were obtained after seeding water samples positive for enterobacteria and identified using chromogenic and conventional media following standard methods. The antibiotic resistance pattern of *Klebsiella* was determined against 14 antibiotics by disk-diffusion method according to the guidelines of the Clinical and Laboratory Standards Institute.

**Results:** Of 200 samples, 253 coliforms were isolated and 11% (28/253) were identified as *Klebsiella* spp, 67.86% (n=19) *K. pneumoniae* and 32.14% (n=9) *K. oxytoca*. The isolates only displaying unexpected lower levels of resistance high levels of resistance to all tested antibiotics. Only 5 (17.86%) were no susceptible to ciprofloxacin [3 resistant and 2 intermediate], of these only 2 isolates showed intermediate resistance levels to nalidixic acid, while suggests the presence of transferable mechanisms of quinolone resistance unable to confer resistance to nalidixic acid. Finally 3 isolates in, addition to ampicillin resistance, displaying at time resistance to cotrimoxazol and tetracycline, and other 2 showed resistance to cefoxitin and amoxicillin plus clavulanic acid. No isolate showed resistance to the remaining tested antibiotics.

**Conclusions:** There is evidence of low antibiotic resistance of *Klebsiella* spp isolated from children, water, soil and animals in Cajamarca, Peru.

Big data analysis of all bacterial genomes establishes a triple whammy of carbapenemases, ICEs and multiple clinically-relevant bacteria

João Francisco Tomaz Santos Botelho*, Joana Vanessa Cordeiro Melro Mourão, Adam Roberts, Luisa Maria Vieira Peixe

1Universidade do Porto, Faculdade de Farmácia, UCIBIO/REQUIMTE, Laboratório de Microbiologia, Porto, Portugal, 2University of Coimbra, Center for Neuroscience and Cell Biology, Contanhede, Portugal, 3University of Coimbra, Institute for Interdisciplinary Research, Coimbra, Portugal, 4Liverpool School of Tropical Medicine, Department of Tropical Disease Biology, Liverpool, United Kingdom, 5Liverpool School of Tropical Medicine, Centre for Drugs and Diagnostics, Liverpool, United Kingdom

Background: Carbapenemases inactivate most β-lactam antibiotics, including carbapenems, and have been frequently reported among Enterobacteriaceae, Acinetobacter spp. and Pseudomonas spp. Traditionally, the horizontal gene transfer of carbapenemase-encoding genes (CEGs) has been linked to plasmids. However, given that integrative and conjugative elements (ICEs) are possibly the most abundant conjugative elements among prokaryotes, we conducted an in-silico analysis to ascertain the likely role of ICEs in the spread of CEGs among all available bacterial genomes.

Materials/methods: All RefSeq bacterial genomes available in NCBI were downloaded (n=107,887) and blasted against a local database of 688 carbapenemases using diamond v0.9.25. The CEG-bearing genomes were annotated with prokka v1.14.0, and the GenBank files were used as input to mine ICEs on the standalone version of ICEfinder. Hits corresponding to putative plasmids were excluded from the following analyses. The translated coding sequences of extracted ICEs were analyzed on the standalone CONJscan module of MacSyFinder v1.0.5 to predict MPF families. To identify the multi-locus sequence type of each CEG-bearing ICE, we used mlst v2.16.1. Associated mobile genetic elements were annotated using GalileoTM AMR. Among the ICEs, we also search for antibiotic resistance genes [amrfinder v3.2.3], bacteriocins, ribosomally synthesized and posttranslationaly modified peptides [Bagel4], restriction-modification systems [REBASE], and CRISPR arrays as well as their associated [Cas] proteins [CRISPRCasFinder].

Results: We detected 7457 CEGs, of which 118 were located within putative ICEs among several clinically-relevant bacterial species [including Klebsiella pneumoniae, Escherichia coli, Citrobacter freundii, Enterobacter hormaechei and Pseudomonas aeruginosa]. We also identified a Bacillus subtilis strain with an NDM-1-encoding ICE. Most CEGs detected within ICEs belong to the KPC, IMP, and NDM families and different mechanisms were likely responsible for the acquisition of these genes. The majority of CEG-bearing ICEs belong to the MPF2, MPF6, and MPF6 classes and often encode additional adaptive traits such as resistance to other antibiotics [e.g., aminoglycosides and fluoroquinolones], restriction-modification systems and bacteriocin production.

Conclusions: This study provides a snapshot of the different CEGs associated with ICEs among all bacterial genomes and sheds light on the underappreciated contribution of ICEs to the spread of carbapenem resistance globally.

Oral empiric antibiotic treatment given in an ambulatory setting for febrile neutropenic patients with a solid tumour, predicted at low-risk for serious complication

Angela Loizidou*1, Aspasia Georgala1, Jean Klastersky1, Mickael Aoun1

1Institut Jules Bordet, Brussels, Belgium

Background: Evaluation of the safety and feasibility to discharge patients with febrile neutropenia assessed by MASCC score, as low risk patients, after a preliminary evaluation in the emergency room.

Materials/methods: Prospective study in a single oncology hospital, in all adults with febrile neutropenia (FN) induced by chemotherapy and/or molecularly targeted therapy for solid tumors. Patients assessed as low risk, eligible for oral antibiotic, such as moxifloxacin, were discharged from the emergency room, after a clinical exam, consideration of psycho-social environmental criteria, initial laboratory and microbiological tests, chest X-ray and a first dose of antibiotics. A follow up at consultation, reassessed the patients in order to readjust the treatment, if needed. The primary objective was the resolution of febrile neutropenia without serious complications.

Results: Out of 160 episodes of febrile neutropenia at low risk for complications [Intention To Treat:ITT] presented in the emergency room, between October 2008 and July 2014, 118 were included [modified Intention To Treat: mITT] in the study. They did not have any severe complications, but 5.08% needed admission. The rate of successful response to the empirical treatment was 87.29%, while the risk to develop adverse events was 7.6% and further infections was 6.78%.

Conclusions: The study shows that the immediate discharge and the oral empiric antibiotics in an outpatient treatment, in febrile neutropenic episodes, was feasible and safe for carefully selected patients.

Abstract 9614

Prevalence and susceptibility profile of Corynebacterium glucuronolyticum in semen cultures

Ainara Rodríguez Achaerandio*, Eva Insagurbe Saez Camara, Angel Palomares Casado, Sandra Guerra Merino, Ainhoa Fernández De Romarategui Gómez, Ruth Salazar Calleja, Andrés Canut

1Microbiology Service, University Hospital of Alava. OSI ARABA, Vitoria-Gasteiz (Alava), Spain, 2Medical Analysis Service, University Hospital of Alava. OSI ARABA, Vitoria-Gasteiz (Alava), Spain, 3Ginecology Service, University Hospital of Alava. OSI ARABA, Vitoria-Gasteiz (Alava), Spain

Background: Corynebacterium glucuronolyticum (CG) is a rare species isolated from male patients with genitourinary tract infections, probably being part of the normal male genitourinary microbiota that is only recently being acknowledged as a potential pathogen, most often implicated in cases of urethritis and prostatitis in men. Thus, different research groups have contributed by highlighting its important role in non-gonococcal urethritis in men, in chronic bacterial prostatitis (CBP); in the pathogenesis of persistent cystitis in males without predisposing factors and its adverse influence on various laboratory parameters of semen. The aim of this study is to analyze the prevalence and antimicrobial susceptibility of CG in semen cultures in Alava, (North of Spain, Basque Country) over the last 2 years.

Materials/methods: Between 2017 and 2018 semen specimens were inoculated on Columbia Blood Agar supplemented with colistin and nalidixic acid and PVX chocolate agar (bioMerieux®, France) and incubated at 37 °C aerobically under 5% CO₂ atmosphere. A significant growth (>1 × 10⁴ CFU/mL), as a pure culture, on blood-containing media of an organism producing, tiny, white-yellow, non-hemolytic colonies of about 1.5 mm of diameter-sized, that grew better after 48 h. The colonies were catalase positive, identified as CG by MALDI-TOF® (Bruker Daltonics, Germany). Agar disk diffusion test performed according to the EUCAST guidelines.

Results: 40 of total of 1177 screened semen specimens, a total of 3.39% patients aged between 20 to 73 (mean age 45.1) had CG as a single isolate in significant quantities. 57.14% showed resistance to ciprofloxacin, 15.38% tetracycline, 10.53% gentamicin, 72% erythromycin, and 82.35% to clindamycin but all isolates were susceptible to penicillin, vancomycin, linezolid and rifampicin. Individuals with CG isolates, 25% have a diagnosis of infertility, 7.5% hematospermia, 15% prostatitis and different diagnosis 57.5%.

Conclusions: All C. glucuronolyticum strains are susceptible to penicillin, vancomycin, linezolid and rifampicin but quinolones, tetracycline, macrolides and lincosamides must be tested because of trend towards resistance. Although C. glucuronolyticum is not frequently isolated in clinical genitourinary samples, its potential pathogenicity has been demonstrated; we suggest therefore to consider the organism in the differential diagnostics of bacterial diseases of the urinary tract.

Abstract 9621

**Evaluation of the antifungal stewardship programme at St George's Hospital, London 2018-19**

Angela Natalee Rusdiah1, Ting Yee Yau2, Clare Logan1,2, Tihana Bicanic1,2

1St George’s University of London, London, United Kingdom, 2St George’s Hospital, London, United Kingdom

**Background:** Antifungal stewardship (AFS) has risen to prominence with outbreaks of multi-drug resistant Candida auris and national incentives in England. St George’s introduced AFS in 2010, demonstrating reduction of inappropriate prescribing without compromising clinical outcomes and resistance rates in a published evaluation from 2010-16.

**Materials/methods:** From October 2018-November 2019, adult inpatients receiving treatment with Amphotericin B, echinocandins or azoles [except oral prophylaxis] were reviewed in a weekly ward round by an Infectious diseases consultant and Antimicrobial Pharmacist. Patient demographics, antifungal drug and duration, invasive fungal infection (IFI) risk factors and final EORTC diagnostic classification, use of biomarkers, stewardship advice, length of hospital stay and inpatient mortality were prospectively recorded.

**Results:** 109 patients (55%M) median age 58 had a total of 179 antifungal courses reviewed. Common IFI risk factors were broad-spectrum antibiotic exposure (78%), central line (38%), haemato-oncological disease (28%), critical care (19%), abdominal surgery (16%) TPN (16%).

Prescriptions reviewed were echinocandins in 26%, Ambisome® and IV fluconazole IV (19% each). Rationale for prescribing was targeted in 35%, empiric in 25%, pre-emptive in 10% and prophylaxis in 29% of episodes. 160 recommendations were made, commonly further investigations (30%), antifungal switch or de-escalation (27%) and duration of therapy (14%).

Of those receiving targeted antifungals, 73% ultimately had proven/probable/possible IFI. Implementation of on-site weekly beta-D-glucan testing in May 2019, midway through this evaluation, reduced median laboratory turnaround-time to 9d (overall for 2018-19) compared to 12d for 2010-16. Inappropriate antifungal prescribing decreased: the proportion of patients receiving empiric or pre-emptive antifungal therapy who ultimately had no IFI on EORTC criteria was 52% for 2018-19: significantly reduced compared to two periods 2010-16 and 2016-18 when 75% of patients had no IFI (p=0.038, chi square test).

Median[IQR] length of stay was longer for patients with proven/probable/possible IFI: 37(25-53) v 27 (15-48) days in those with no IFI (p=0.4). Overall in-hospital mortality was 22%, compared to 28% in 2010-16 (further subgroup analyses and statistical comparisons of LOS, mortality and antifungal treatment duration by prescribing indication will be presented).

**Conclusions:** Recent implementation of in-house BDG biomarker testing has resulted in further reductions in inappropriate antifungal prescribing without compromising on clinical outcomes.

Neutrophilia is associated with lung tissue damage in pulmonary tuberculosis

Mayla Gabryele Miranda De Melo*, 1, Adriana Rezende Moreira 1, Caio Da Silva Monteiro 1, Carolyne Lalucha 1, Anna Karla Almeida Silveira 1, Tatiana Dutra 1, Elisangela Costa Da Silva 2, Afrânio Kritski 1

1 Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, 2 Darcy Ribeiro State University of Northern of Rio de Janeiro, Rio de Janeiro, Brazil

Background: Tuberculosis remains a major cause of morbimortality in low-middle income countries such as Brazil. Regardless of anti-tuberculous treatment (ATT), in some patients the infection is countered at the expense of great tissue destruction and pulmonary sequelae. Despite its chronic evolution, the role of neutrophils is crucial in the immune response against Mycobacterium tuberculosis. These cells become strong producers of proteinases, reactive oxygen species and extracellular traps (NETs), which are related to tissue damage and bacteria growth in different infections. This study aimed at understanding the possible mechanisms of tissue damage in TB and underlying biomarkers of poor prognosis during ATT.

Materials/methods: The study enrolled a cohort of 325 presumed pulmonary TB cases in Rio de Janeiro, Brasil. Chest radiographs (CXR), blood count, results of inflammatory markers (C-reactive protein - CRP, erythrocyte sedimentation rate - ESR, ferritin and albumin), smear microscopy (AFB) and sputum culture were obtained before (T0) and after 60 (T60) and 180 (T180) days of treatment. Subjects were classified as TB or RS (respiratory symptomatic) based of AFB or sputum culture. The groups were compared using univariate analysis performed in GraphPad Prism v6.0.

Results: TB patients showed higher counts of neutrophils (figure 1-A) and platelets, and lower lymphocytes when compared with RS patients (p ≤ 0.001). CRP, ESR and ferritin levels were higher in TB patients, while albumin was lower, when compared to RS. TB patients with neutrophilia had higher mycobacteria load and number of cavitations (figure 1-B), and bilateral disease (figure 1-C). Additionally, TB patients with neutrophilia showed more persistence of positive culture after 60 and 180 days of ATT (figure 1-D). 69.8% of TB patients with neutrophilia on T0 did not show improvement on radiological images after 180 days of treatment.

Conclusions: Our results suggest that a neutrophil-mediated hyperinflammatory response aggravate lung tissue damage and may contribute to poor prognosis and treatment failure. The identification of this inflammatory profile may enable early intervention with adjuvant therapies aimed at controlling tissue damage.

Abstract 9626

**Structural study of new KatG mutations selected on isoniazid-resistant strains of *Mycobacterium tuberculosis* in vivo**

Andra-Cristina Bostanaru*1, Mihai Mares2

1 "Ion Ionescu de la Brad" University, Laboratory of Antimicrobial Chemotherapy, Iasi, Romania; 2 "Ion Ionescu de la Brad" University, Laboratory of Antimicrobial Chemotherapy, Iasi, Romania

**Background:** In the course of this study, we identified new mutations in the KatG, the role of which has never been characterized before. For these mutations, structural and biochemical studies have been undertaken to establish their contribution in resistance to isoniazid (INH).

**Materials/methods:** katG genes coding for the wild-type protein and six new mutants A162E, D189G, H270R, Q461P, G494D and F658V have been included in this study. Expression and purification of KatG in *Escherichia coli* was carried out by cloning the katG genes in the pET30 expression vector. The crystal structure of the *M. tuberculosis* KatG protein (Zhao X., code-PDB 2CCA) was used to model the position and the consequences of the new mutations in the KatG.

**Results:** The KatG protein contains a covalently bound heme surrounded by a proximal and a distal pocket. Of all the mutations studied, H270R, which was identified in a clinical strain of high level of INH resistance (INH-R), appears to be of great interest since H270 is part of the proximal pocket and is covalently linked to the heme. Thus, H270R causes loss of the covalent bond linking the heme and, consequently, of the catalytic activity of KatG. The mutation A162E, linked to a high level of INH-R, is located in a alpha-helix situated close to the distal pocket and creates steric hindrance in this region. Two others mutations (F658, Q461P), found in strains showing a low level of INH-R, are located in alpha-helices positioned far from the heme. F658V leads to steric hindrance, while Q461P likely contributes to the destabilization of the alpha-helix secondary structure. Finally, D189G and G494D, conferring low and high-level of INH-R, respectively, modify the pattern of ionic interactions in regions located far from the heme pocket, and their role in the KatG protein is less obvious.

**Conclusions:** These results shed light on the importance of KatG mutations other than S315T in resistance to INH and will be integrated in a global strategy involving molecular modeling and biochemical studies to increase our ability to predict resistance to INH, a goal particularly important to improve the treatment of tuberculosis patients.

Abstract 9627

**Clinical profile and associated comorbidities to predict outcomes in patients with scrub typhus with acute kidney injury: a study from Central India**

Deepak Jeswani*,1 Deepti Jeswani1
1Criticare Hospital & research Institute, Nagpur, India

**Background:** Scrub typhus is an acute febrile illness caused by Orientia tsutsugamushi. Scrub typhus is a challenging clinical problem which contributes to the burden of acquired Acute Kidney Injury (AKI).

**Materials/methods:** The medical records of last four years (2016-19) were analysed for the key clinical, laboratory and in hospital stay parameters. Scrub typhus infection was diagnosed by ELISA technique.

**Results:** 39 patients were analysed (male 22, female 17). The distribution of the was as follow, in year 2019 (n=14), 2018 (n=6), 2017 (n=7), 2016 (n=12). 28 patients were referred from outside a radius of 30 km and nine were from the close vicinity. 12 cases presented with both overlapping paroxysm of fever and shaking chills with sweating. Four patients were both hypertensive and diabetic. The mean age was 51 years, no of days of admission was 9.1 days, no of days of ICU stay was 4.4, the mean platelet values were 91,000/mcl, with all the patients having thrombocytopenia. The mean TLC count was 11159/mcl. 14 patients were 60 years and above. The mean serum urea was 97 (mg/dl) and mean serum creatinine was 2.5 (mg/dl). The details are described in the table. There was one mortality due to multi-organ dysfunction, severe thrombocytopenia, stress cardiomyopathy and respiratory failure. 33 (85%) patients responded to doxycycline 200 mg/day in two divided dose.

**Conclusions:** Our study highlights the association of scrub typhus with AKI as the complication. The early addressal of thrombocytopenia and multi-organ failure is important to improve the outcomes with associated AKI. The timely diagnosis of scrub typhus with varied clinical manifestations is important to have minimal clinical impact of the AKI.

Abstract 9629

A point prevalence study of carbapenemase-producing Enterobacteriaceae colonisation of drains in a tertiary care hospital

Sara Woods*, Nuala O Connell†, Lorraine Power‡

†The Mater Misericordiae University Hospital, Dublin, Ireland, ‡University Hospital Limerick, Limerick, Ireland

Background: Carbapenemase Producing Enterobacterales (CPE) are an increasing problem worldwide. There is mounting evidence for the role of the environment as a source of potential cross transmission in the hospital setting. In our centre there has been an outbreak of CPE, predominantly Klebsiella pneumonia carbapenemase (KPC), with an increase in numbers in recent years. In this study we sought to quantify the number of clinical wash-hand basins (WHB) colonised with CPE.

Materials/methods: Over a fourteen month period environmental testing of the drains of WHB and showers was carried out in a tertiary referral hospital. Superficial and/or deep swabs were taken from the drains, inoculated on to selective chromogenic agar(s) and incubated aerobically at 37°C overnight. Isolates were identified by MALDI-TOF. Enterobacterales were then tested for CPE enzymes/encoding genes by molecular analysis (Cepheid Xpert’s Carba-R assay). A number of CPE detected isolates were sent for confirmation to the National CPE Reference Laboratory, Galway.

Results: In fourteen months (March 2018-April 2019), 214 swabs were taken from 94 hospital drains in 13 wards. Twenty-one percent (20/94) of drains had CPE detected. Eight out of twenty-nine (28%) CPE positive drains remained positive on repeat testing. All these isolates had KPC, one had KPC and Verona integron-encoded metallo-β-lactamases (VIM) and another KPC and IMP-type CPE.

Conclusions: We demonstrated that there is a reservoir of CPE in the hospital drains. This represents a possible source of ongoing cross transmission within these wards. In April 2019, we consulted with a UK based consultant microbiologist, chair of the healthcare infection society working party on water, to advise on solutions which are currently being implemented.

**Comparison of the Panther Fusion MRSA assay with conventional culture for patient swabs in Amies transport medium with charcoal**

Nick Otten¹, Rogier Jansen¹, David Kwa¹, Thijs Van De Laar*²

¹OLVG Lab BV, Amsterdam, Netherlands

**Background:** Screening and pre-emptive isolation of patients at increased risk for infection with methicillin-resistant Staphylococcus aureus (MRSA) are important elements of the Dutch search and destroy policy to prevent MRSA transmission in the healthcare setting. Since MRSA screening with conventional culture can take up to 3 days, molecular tests with a shorter turnaround time (TAT) are often used to lift ‘unnecessary’ barrier precautions for MRSA-negative patients.

**Materials/Methods:** Nasal, pharyngeal and rectal swabs were collected in charcoal containing Amies transport medium (ATM). MRSA screening was performed using (i) direct conventional culture on ChromID MRSA agar (18-24 hours at 35-37°C), (ii) conventional culture on ChromID MRSA agar after overnight enrichment using a desferal® containing Columbia broth, (iii) Panther Fusion® MRSA PCR assay on direct patient material, and (iv) Panther Fusion® MRSA PCR assay after overnight enrichment in a desferal® containing Columbia broth.

**Results:** MRSA PCR screening results were available for 1107 patient materials before and after enrichment. In total, we identified 68 true MRSA+ patient materials from 34 different patients using conventional culture with enrichment as the gold standard. After enrichment, discrepant MRSA screening results were observed in 24/1107 (2.2%) patient materials (16 were PCR+/Culture-; 8 were PCR-/Culture+), resulting in a sensitivity of 88.2% and specificity of 98.4% of the MRSA PCR. Without enrichment, the yield of the MRSA PCR dropped almost 3-fold to a sensitivity of 35.2% with a specificity of 99.7%. None of the true MRSA+ patient materials initially missed by PCR (hence before enrichment) were detected by direct conventional culture. Charcoal containing ATM did not result in invalid MRSA PCR test results (<0.5%).

**Conclusions:** In our low-prevalence MRSA setting, the Panther Fusion® MRSA assay, if applied after enrichment, has a very high predictive negative value even when charcoal containing ATM is used, and therefore could be applied to shorten pre-emptive isolation of patients at high-risk for MRSA infection. With further reduction of the TAT using direct PCR without enrichment, the yield of the MRSA PCR significantly dropped compared to conventional culture with enrichment but not compared to direct conventional culture.

Abstract 9632

Measuring and mapping the burden of antimicrobial resistance in enteric infections

Christiane Dolecek*1, Annie Browne2, Bahar Kashef2, Emmanuelle Kumaran3, Catrin Moore4, Puja Rao3, Gisela Robles-Aguilar2, Susannah Dunachie1, Michael Chipeta2, Stephen Baker4, Alan Lopez5, Nicholas Day6, Simon I. Hay7

1Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, 2Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, University of Oxford, Oxford, United Kingdom, 3Institute for Health Metrics and Evaluation, University of Washington, Seattle, United States, 4Department of Medicine, University of Cambridge, Cambridge, United Kingdom, 5Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, 6Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Background: Antimicrobial resistance (AMR) is a threat to global health. The GRAM project aims to synthesize global AMR data, produce maps of the distribution of AMR and incorporate the burden attributable to AMR into the Global Burden of Disease (GBD) study estimates.

Salmonella Typhi and Paratyphi cause an estimated 14 million cases of enteric (typhoid) fever and 135,000 deaths; whilst Shigella infections cause an estimated 220,000 deaths and 264 million episodes of shigellosis per year. Both diseases are transmitted faeco-orally.

Materials/methods: We performed two systematic reviews of worldwide studies published between 1990 and 2018, reporting the prevalence of AMR in a) Salmonella Typhi and Paratyphi A (blood culture) and b) Shigella (stool culture). MDR (resistance against ampicillin, chloramphenicol and co-trimoxazole) and fluoroquinolone non-susceptibility (FQNS) were assessed. We performed random effects meta-analyses, stratified by GBD region and 5-year time period. Heterogeneity was assessed using the I² statistics. A descriptive analysis of ceftriaxone and azithromycin resistance was conducted.

We evaluated global antibiotic sales data (IQVIA, WHO) and data on antibiotic use from household surveys to produce estimates on global antibiotic consumption as covariate for the geospatial model to predict resistance.

Results: We extracted data from 384 articles, comprising 94,616 S. Typhi and 29,731 S. Paratyphi A isolates. With the exception of MDR S. Typhi in South Asia, which declined between 1990 and 2018, resistance trends worsened for all regions. For Shigella, we extracted data from 521 studies, comprising 123,202 isolates. High prevalence of FQNS Shigella was identified in North Africa and the Middle East and Southern Sub-Saharan Africa.

Data gaps were notable throughout our study. These not only pertained to AMR surveillance data [especially in Africa and the Middle East], but also antibiotics sale data. Incomplete reporting of antimicrobial susceptibility testing and lack of quality control were identified.

Conclusions: We aim to use geospatial modelling techniques to produce granular maps of the prevalence of AMR S. Typhi and Paratyphi and AMR Shigella. It is essential that targeted public health interventions, which include improvements in water quality and sanitation, the deployment of vaccination and an informed choice of treatment are implemented.

The potential impact of molecular rapid identification of pneumonia by The BIOFIRE FILMARRAY pneumonia panel on antimicrobial stewardship and patient management at a large district general hospital, United Kingdom

Hala Kandil*, Rachel Hilson¹, Valerie Page¹

¹West Hertfordshire Hospital NHS Trust, London, United Kingdom

Background: Pneumonia remains a worldwide health problem with a high rate of morbidity and mortality. Microbiological diagnosis of pneumonia is fundamental to ensure appropriate antibiotic therapy, which is a big challenge for conventional microbiological methods. The development of molecular diagnostics for pneumonia has been a major advance in the microbiological diagnosis of respiratory pathogens in recent years. The aim of this study is to explore the potential impact BioFire® FilmArray® Pneumonia Panel (PnP) with or without procalcitonin on antimicrobial stewardship.

Materials/methods: Total of 55 Respiratory samples collected from critically ill patients admitted to intensive care unit (ICU) at West Hertfordshire hospitals NHS trust, with radiologically confirmed new onset, pneumonia were taken for standard culture and sensitivity and molecular diagnosis using the PnP. Serum procalcitonin levels were measured. A microbiologist and intensivist reviewed antimicrobial prescriptions, inflammatory markers, procalcitonin results and daily SOFA data to determine: 1) Changes in antimicrobial prescription 2) Missed opportunities to change antimicrobial prescriptions. Further 60 patients from ICU, respiratory wards and outpatient clinics were also included in this study and data are under review.

Results: Data on 30 patients were included, 21 men, age range 26 to 86 (mean 60.9), APACHE score range 7 to 38 (mean 17). PnP resulted in the additional detection of 13 bacteria not cultured using standard technique. Antibiotics were stopped or de-escalated in eight and missed in seven patients. Earlier detection of resistance in two occasions by PnP. Serum procalcitonin levels were measured. A microbiologist and intensivist reviewed antimicrobial prescriptions, inflammatory markers, procalcitonin results and daily SOFA data to determine: 1) Changes in antimicrobial prescription 2) Missed opportunities to change antimicrobial prescriptions. Further 60 patients from ICU, respiratory wards and outpatient clinics were also included in this study and data are under review.

Conclusions: The results of this exploratory project suggest that pneumonia panel and appropriate procalcitonin results provide valuable information, with potential for better antimicrobial stewardship, specifically shorter courses.

Abstract 9634

14-year evolution of antimicrobial consumption in a Belgian tertiary hospital based on the BeH-SAC surveillance
Franky Buyle*, Steven Callens¹, Annemie Somers¹, Sabrina Commeyne¹, Dirk Vogelaers¹

¹Ghent University Hospital, Ghent, Belgium

Background: Surveillance of antimicrobial consumption is one of the key elements of an antimicrobial stewardship program. All Belgian hospitals have access to an interactive platform where the “Belgian Hospitals – Surveillance of Antimicrobial Consumption” (BeH-SAC) can be consulted. This tool consists of both numerator (consumed units per drug in defined daily doses [DDDs]) and denominator data (patient days and admissions). Feedback reports per hospital are provided with benchmarking and stratification.

In this study we describe and evaluate the 14-year evolution of antimicrobial consumption in the Ghent University Hospital based on BeH-SAC.

Materials/methods: Data from 2003 until 2017 were extracted for the Ghent University Hospital including a benchmark of all Belgian tertiary hospitals (=7) expressed in DDD/1000 patient days. Units with psychiatric beds and day clinics were excluded.

Results: The antibiotic (J01) consumption in 2017 was 646.8 DDDs/1,000 patient days, which is an increase of 3.6% compared to 2003 (624.3 DDDs/1,000 patient days). Also the median antibiotic (J01) consumption for the 7 tertiary hospitals increased with 11.6% (560.2 DDDs/1,000 patient days in 2003 versus 625.6 DDDs/1,000 patient days in 2017).

In 2017 amoxicillin in combination with a beta-lactamase inhibitor [J01CR02], flucloxacillin [J01CF05] and cefazoline [J01DB04] were the most frequently used products. For these three products the consumption increased comparing 2003 with 2017 for amoxicillin in combination with a beta-lactamase inhibitor with 67.9%, for flucloxacillin with 66.2% and for cefazolin with 51.8%.

The benchmark with the 7 university hospitals shows a moderate consumption in the Ghent University hospital of piperacillin-tazobactam [J01CR05] (41.5 DDDs/1,000 patient days in the Ghent University hospital versus median consumption of 51.3 DDDs/1,000 patient days) and meropenem [J01DH02] (23.4 DDDs/1,000 patient days in the Ghent University hospital versus median consumption of 34.3 DDDs/1,000 patient days).

Conclusions: Although BeH-SAC provides data which can be used for benchmarking and for assessing interventions further improvement is necessary with focus on detailed data per diagnose and a shorter delay. Furthermore data should be provided on the level of medical discipline and not aggregated for surgical or medical wards.

**Abstract 9635**

**Characterisation of extended-spectrum β-lactamases by mass spectrometric analysis**

Saeyoung Lee*, Won Suk Yang¹, Hanseul Suh¹, Heejung Jang¹, Yoonha Park¹, Seohyun Hwang¹, Je-Hyun Baek¹

¹Seegene Medical Foundation, R&D Center for Clinical Mass Spectrometry, Seoul, South Korea

**Background:** According to the recent report of WHO (World Health Organization), the emergence and infection of antibiotic resistant or antibiotic multidrug-resistant bacteria causes serious problems worldwide. In order to solve these problems, the development of new antibiotics is inevitable, but the emergence of antibiotic resistant bacteria is so fast that it is incomparable with the development of new antibiotics. Therefore, it is necessary to develop a rapid and accurate diagnosis of antibiotic resistant bacteria. Recently, mass spectrometry has enabled rapid and accurate identification of microorganisms. Mass spectrometric studies of antibiotic resistant proteins must be accompanied by a more accurate and reliable diagnosis of antibiotic resistant microorganisms. Here, we characterized the ESBL proteins that are directly involved in antibiotic resistance through mass spectrometry.

**Materials/methods:** We constructed standard bacterial cells harboring β-lactamase genes such as CTX-M. A target protein from the standard strains was purified and well-characterized by the high resolution mass spectrometry (e.g. Thermo Q Exactive HF-X). A peptide mapping and top-down mass analysis was performed by nanoflow LC-MS/MS system. We also developed methods to detect the target protein from clinical strains on the different MS platforms (Bruker MALDI-TOF and Agilent 6545XT Q-TOF).

**Results:** We identified CTX-M proteins from standard strains transforming the CTX-M gene, one of the ESBL classes related to β-lactam antibiotic resistance. In addition, CTX-M protein was confirmed by mass spectrometry from clinical strains, previously identified as ESBL. CTX-M proteins were mapped with 143 peptides (90.38% coverage). Interestingly, the N-terminal region was not observed in all cases (standard and clinical strains). Sequence coverage of the truncated CTX-M proteoform was 100% when considering sequences without the N-terminal region. Accurate mass and identification upon the proteoform was confirmed by Top-down mass analysis (<10ppm & E = 2.36E-25).

**Conclusions:** We have developed methods for the detection of antibiotic resistance proteins using various methods of mass spectrometry. In this study, we demonstrated a truncated proteoform through mass spectrometry, which has β-lactamase activity and consistently expressed in clinical strains. We expect that direct detection of the proteoform is a good target for rapid monitoring of CTX-M series.

Abstract 9638

**Misidentification of *Staphylococcus argenteus* by MALDI-TOF MS**

Hin Fung Tsang*1, Stanley Wai Ming Leung1, Sze Chuen Cesar Wong2

1Hong Kong Adventist Hospital, Hong Kong, Hong Kong, 2The Hong Kong Polytechnic University, Hong Kong, Hong Kong

**Background:** *Staphylococcus argenteus* belongs to *Staphylococcus aureus* clonal complex (CC) 75 lineage. Infections caused by *S. argenteus* are underestimated because *S. argenteus* is often misidentified as *S. aureus* using standard identification test.

*S. argenteus* usually have the same virulence factors and antibiotics resistance genes as *S. aureus*. However, *S. argenteus* lacks staphyloxanthin, a carotenoid pigments protect against oxidative stress and impair neutrophil killing. Although the majority of *S. argenteus* are negative for the genes encoding Panton-Valentine-Leucocidin (PVL), studies showed that some strains can acquire PVL.

Cultivation followed by species identification of 100 *S. aureus* isolates from unselected patients in Hong Kong Adventist Hospital in 2019 by Vitek MALDI-TOF MS (bioMerieux, Marcy l’Etoile, France) and Bruker Biotyper MALDI-TOF MS (Bruker Daltonics, Bremen, Germany) showed that 2% of isolates identified by Vitek MALDI-TOF MS with confidence value of 99.9% using IVD knowledgebase version 3.2 were actually *S. argenteus*.

**Materials/methods:** A total of 100 *S. aureus* isolates from unselected patients in Hong Kong Adventist Hospital obtained in 2019 were studied. The types of specimens from which the isolates obtained included abscesses, blood, body fluids, urine, high vaginal swab and pus. Analysis of the isolates was performed by two Matrix Assisted Light Desorption/Ionization Time of Flight Mass Spectrometry (MALDI-TOF MS) platforms (Bruker Daltonics, Bremen, Germany; bioMerieux, Marcy l’Etoile, France). *Escherichia coli* strains ATCC® 8739 and MB11464 were used as calibration standards in Vitek MALDI-TOF MS and Bruker Biotyper MALDI-TOF MS respectively.

**Results:** In this study, 2 out of 100 (2%) *S. aureus* isolates identified by Vitek MALDI-TOF MS (bioMerieux, Marcy l’Etoile, France) with confidence value of 99.9% using IVD knowledgebase version 3.2 were identified as *S. argenteus* by Bruker Biotyper MALDI-TOF MS (Bruker Daltonics, Bremen, Germany) with score values > 2.0. Species-level identification was confirmed by sequencing.

**Conclusions:** Vitek MALDI-TOF MS (bioMerieux, Marcy l’Etoile, France) cannot distinguish *S. argenteus* from *S. aureus* whereas Bruker Biotyper MALDI-TOF MS (Bruker Daltonics, Bremen, Germany) can accurately identify *S. argenteus* at species-level.

Systematic blood culture testing identifies a large proportion of patients in whom antibiotics could be safely discontinued: hospital-associated infections in a tertiary care hospital in Ethiopia

Makeda Semret*1, Workeabeba Abebe Taye2, Ling Yuan Kong3, Tinsae Alemayehu1, Temesgen Beyene2, Michael Libman1, Wondwossen Amogne Degu2, Øystein Johansen2, Gebremedhin Beedefemariam Gebretekel2, Daniel Seifu4, Cedric Yansouni1

1McGill University Health Centre, Montréal, Canada, 2Addis Ababa University, Addis Ababa, Ethiopia, 3Jewish General Hospital, Montréal, Canada, 4Addis Ababa, Ethiopia, 5Vestfold Hospital Trust, Tønsberg, Norway

Background: Hospital Associated Infections (HAI) and Antimicrobial Resistance (AMR) have emerged as major threats for Low-Resource Settings (LRS). Interventions to decrease rates of HAI and AMR depend on diagnostic bacteriology capacity, which is lacking throughout Africa. We recently implemented a laboratory strengthening intervention in Ethiopia’s largest referral hospital, with systematic blood culture testing of patients with suspected HAI. Prior to this study, fewer than 1% of patients with suspected infection had microbiologic testing. Our goal was to characterize clinical outcomes and AMR patterns associated with HAI and blood stream infections (BSI), and assess antimicrobial usage.

Materials/methods: This was a single-center correlational study of patients hospitalized at Tikur Anbessa Specialized Hospital (TASH) October 2017 - October 2018. HAI suspects had blood culture testing using an automated platform. Results were reported to clinicians, without additional interventions. We collected clinical and antimicrobial usage data. Primary outcomes were proportion of patients with blood stream infections (BSI), resistance patterns, and 14-day status. We also assessed days of therapy (DOT) pre- and post-blood culture testing.

Results: We enrolled 978 patients; 777 had blood culture testing. Of these, 237 (30%) had a BSI. Enterobacteriaceae were isolated in 49% of the cases; 90% of these were broadly resistant to cephalosporins; 42% of Klebsiella sp and 12% of E. coli were also resistant to carbapenems. Mortality at 14-days was 31% and 21% in those with and without BSI, respectively. Other predictors of death were malignancy and exposure to >4 antibiotics prior to blood culture testing. Pre-testing, DOT was 10 days vs 2 days in those with and without BSI, respectively. After blood culture testing, DOT were comparable between the 2 groups (median 20 vs 18 days, respectively).

Conclusions: BSI are frequent and fatal among patients with suspected HAI in Ethiopia, despite heavy empiric antibiotic therapy. Pan-resistant blood isolates are alarmingly common. This study provides evidence that investing in systematic blood culture testing in LRS identifies a large proportion of patients in whom antibiotics could be safely discontinued - but also shows that adequate training and stewardship are necessary to achieve substantial reductions in antibiotic consumption and better outcomes.

Clinical evolution of yellow fever patients in the 2017-2018 outbreaks in Minas Gerais, Brazil: preliminary analysis of risk factors for death

Carolina Rodrigues*1, Wanessa Clemente1, Camila Bonis2, Paulo Mourão1

1Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, 2Centro Universitário de Belo Horizonte, Belo Horizonte, Brazil

Background: Yellow fever (YF) is a viral disease, caused by a flavivirus, which is transmitted to humans by arthropod bites. There are two cycles of the disease, wild and urban, with different vectors.

YF has a variable clinical spectrum that usually consists of a biphasic clinical condition, with a first phase of acute febrile illness, followed by evolution to spontaneous cure or to a second phase, characterized by jaundice and hemorrhagic symptoms, that correspond to severe forms.

Despite being an immune preventable disease, wild outbreaks of YF are frequent in Brazil, as occurred in 2017 and 2018 in the State of Minas Gerais, with 1,582 reported cases and 260 suspected deaths from the disease. Most cases were attended at a secondary hospital in Belo Horizonte city, reference for the care of patients with suspected AF.

This study aims to describe the evolution of these patients, with emphasis on their clinical and demographic aspects.

Materials/methods: Retrospective analysis of medical record data from 256 patients diagnosed with AF admitted in the Hospital from January 2018 to March 2019. Only patients over 18 years, with positive serology or viral isolation were included.

Results: To date, data from 94 patients have been reviewed. The median time between the onset of symptoms and the date of hospitalization was 4 days (4 in the deaths group x 3 among survivors, without statistical significance). The mortality rate was 22.3% [21/94], reaching 46.6% among patients requiring ICU hospitalization. INR correlated with death (median 2.57x1.02, p<0.01). Elevation of transaminases also increased the risk of death, with a median TGO at admission of 1,454UI/L [8,134x765, p<0.01], and a median TGP of 1,319UI/L [4,253x793; p<0.01]. The same association was observed for total bilirubin levels, with admission median of 6.8x0.9mg/dL (p<0.01). The clinical variables correlated with death were dialysis, bleeding and encephalopathy, all with p<0.01.

Conclusions: The findings of this study corroborate some risk factors for death already described in the literature, such as increased transaminases and INR. However, to date, no study has shown the association of death with increased bilirubin, which is considered a "benign" marker.

Outbreak of mixed cases of gastrointestinal and cutaneous anthrax in the rural village of northern Luzon, Philippines, March 2017

Karen Lonogan*1, Alethea De Guzman2, Vikki Carr De Los Reyes2, Nemia Sucaldito2, Ferchito Avelino3

1FETP Philippines, Department of Health, Manila, Philippines, 2Department of Health, Epidemiology Bureau, Manila, Philippines, 3Department of Health, Epidemiology Bureau, Manila, Philippines

Background: On March 21, 2017, FETP team was sent to Cayapa Village, Abra due to increasing cases of foodborne illness. Epidemiologic investigation was conducted to verify the diagnosis, establish existence of outbreak, identify risk factors, and recommend control and prevention measures.

Materials/methods: We conducted a 1:3 case-control study for cutaneous and 1:2 case-control study for gastrointestinal anthrax. A suspect case was a previously well resident of Cayapa Village who developed the following from February 27 - March 14, 2017:

- Cutaneous anthrax: skin lesion (papular, vesicular or depressed black eschar)
- Gastrointestinal anthrax: abdominal pain or diarrhea and any of the following: vomiting, fever, difficulty swallowing, and lymphadenopathy.

Confirmed case was a suspect case positive for Bacillus anthracis on bacterial culture or rt-PCR test. A control was well resident negative for Bacillus anthracis. We collected serum specimens and soil samples for laboratory confirmation. We conducted environmental survey and key informant interview. We used Stata ver.13 to analyze data.

Results: Thirty-eight suspect cases were identified. Majority (21, 55%) were males. Age ranged from 6-85 years (Median: 26). For gastrointestinal anthrax, clinical manifestations were abdominal pain (26, 90%), fever (16, 55%), and diarrhea (14, 48%). One (3%) had lymphadenopathy. For cutaneous anthrax, aside from eschar, clinical manifestations were fever (57%), headache, body malaise, and abdominal pain (36% each). All had history of consuming and handling by-product of dead water buffalo. All 11 serum specimens and five soil samples were negative for Bacillus anthracis. After multivariate analysis, eating uncooked meat of dead animal (Adj.OR=6.95% CI: 1.7-18.4) was a risk factor for gastrointestinal anthrax while handling raw meat of dead animal (Adj.OR=7.4, 95% CI: 6.1-902.5) and eating uncooked meat of dead animal (Adj.OR=16, 95% CI: 1.3-185.2) were risk factors for cutaneous anthrax.

Conclusions: The epidemic curve indicates a point source outbreak. We found valid statistical and temporal association of eating and handling by-product of dead water buffalo and anthrax infection. The clinical manifestations were all consistent with Bacillus anthracis as evidence by presentation of eschar including lymphadenopathy observed from a case. Hence, we conducted massive information education campaign of properly handling and disposal of animal carcasses in the community.

Abstract 9681

Levels of evidence supporting European and American community-acquired pneumonia guidelines

João Artur Ferreira Freitas Coimbra¹, Sofia Tejada Magraner², Laura Campogiani³, Jordi Rello⁴

¹Centro Hospitalar Universitário do Porto, Porto, Portugal, ²Vall d’Hebron Institut of Research (VHIR), Barcelona, Spain, ³Clinical Infectious Diseases, Department of System Medicine, Tor Vergata University, Rome, Italy, ⁴Vall d’Hebron Institut of Research (VHIR), Barcelona, Spain

Background: Optimal clinical decisions should be supported by clinical practice guidelines (CPG) based on evidence generated from randomized clinical trials (RCT).

Materials/methods: We evaluated the class and level of evidence (LOE) supporting international community-acquired pneumonia (CAP) guidelines and their variation over time. 2019 Infectious Diseases Society America/American Thoracic Society (IDSA/ATS) and 2011 European Respiratory Society/European Society Clinical Microbiology Infectious Diseases (ERS/ESCMID) CPG and immediate predecessors (2007 and 2005) were evaluated. Number of recommendations and distribution as LOE A (supported by multiple RCT or a single, large RCT), B (supported by data from a single RCT or observational studies) and C (expert opinion, case studies or standard of care) were identified.

Results: Overall, recommendations for diagnosis, management and prevention were graded as strong in 51.4%, 62.9% and 23.5% in spite that they were supported by LOE A in 5.7%, 11.1% and 52.9%, respectively. In 2019 ATS/IDSA guidelines (39 recommendations), 7.7% (n=3) recommendations were classified as LOE A, 30.8% (n=12) as LOE B, and 61.5% (24%) as LOE C. Across 2011 ERS/ESCMID guidelines (68 recommendations), 21.2% (n=14) recommendations were classified as LOE A, 4.6% (n=3) as LOE B, and 74.2% (n=49) as LOE C. When comparing with prior versions, the proportion of recommendations that were LOE A did not significantly increase in ERS/ESCMID (21.2% vs 20%) and decreased in ATS/IDSA (7.7% vs 32.0%).

Conclusions: In conclusion, large randomized trials or network meta-analysis including comparison of regimens to identify high probability of best cure and mortality are an unmet clinical need.

**The penicillin allergy delabelling program: a prospective multicentre interventional study**

Kyra Chua1, Sara Vogrin2, Susan E. Bury1, Abby Douglas3, Natasha Holmes1, Elizabeth Phillips4,5, Jason Trubiano*1,3,6

1Austin Hospital, Heidelberg, Australia, 2University of Melbourne, St Vincent’s Hospital, Fitzroy, Australia, 3Peter MacCallum Cancer Centre, Melbourne, Australia, 4Vanderbilt University Medical Center, Nashville, United States, 5Murdoch University, Murdoch, Australia, 6University of Melbourne, Department of Medicine [Austin Health], Heidelberg, Australia

**Background:** Penicillin allergies are associated with inferior patient and antimicrobial stewardship outcomes. We implemented a whole-of-hospital program at two Australian centres to assess the efficacy and safety of inpatient delabelling for low-risk penicillin allergies.

**Materials/methods:** Patients ≥ 18 years reporting an antibiotic allergy were prospectively assessed and those with a low-risk penicillin allergy offered a single-dose oral penicillin provocation or direct label removal based on history (direct delabelling), as appropriate. The primary endpoint was the proportion of low-risk penicillin allergy patients delabelled. Key secondary endpoints were antibiotic utilization pre (index admission) and post-delabelling (index admission/90-days). Propensity score analysis using inverse probability of treatment weighting was used.

**Results:** Between 21 January and 31 August 2019 we prospectively assessed 1,791 patients reporting 2,315 antibiotic allergies; 1,225 patients reported ≥ 1 penicillin allergies – 29% (355/1,225) overall were delabelled. 64% (355/558) with a low-risk penicillin allergy were delabelled – 161 based on history and 194 via oral provocation. 97% (194/200) of patients were negative on oral penicillin provocation. In the delabelled patients (n=355), antibiotic usage pre and post-testing is demonstrated in Figure 1. In the delabelled patients (n=355) we observed an increase in narrow spectrum penicillin usage (aOR 10.51 [95% CI [5.39, 20.48]], improved appropriate antibiotic prescribing (aOR 2.13 [1.45, 3.13]) and a reduction in restricted antibiotic usage (aOR 0.30 [0.27, 0.54]). In the propensity score analysis there was an increase in narrow spectrum penicillins (OR 10.89 [5.09, 23.31]), beta-lactam/beta-lactamase inhibitors (OR 6.68 [3.94, 11.35]) and a reduction in restricted antibiotic use (OR 0.52 [0.36, 0.74]) and inappropriate prescriptions (RRR 0.43 [0.26, 0.72]) in the delabelled compared with the non-delabelled cohort. There was no difference in total antibiotic usage between the cohorts. There was no difference in mortality or length-of-stay.

**Conclusions:** This multicentre whole-of-hospital health services intervention resulted in significant impacts on both utilization of preferred antibiotics therapies and appropriate prescribing. Direct oral provocation in this large inpatient cohort, with multiple comorbidities, was safe and effective.

**Figure 1:** Antibiotic utilization in the delabelled cohort

Paediatric meningoencephalitis due to entero- and human parechoviruses in Cork, Ireland - epidemiology and neurodevelopmental follow-up by parental report

Carol Stephens\(^1\), Rachel Barry\(^*\), Louise Gibson\(^1\), Cilian De Gascun\(^2\), Susanna Felsenstein\(^3\)

\(^1\)Cork University Hospital, Cork, Ireland, \(^2\)UCD National Virus Reference Laboratory, Dublin, Ireland, \(^3\)Alder Hey Children's Hospital - Liverpool, Liverpool, United Kingdom

**Background:** Epidemiological data on paediatric infections caused by human Parechovirus (hPEV); and the impact of both entero- and parechoviral meningoencephalitis (EVME; hPEVME) on neurodevelopmental outcome remains subject to intensive research. hPEV in particular is emerging as a neurotropic pathogen, with the potential for neurological sequelae, especially prior to myelination being complete. Our goal was to 1) describe distribution of circulating picornaviruses causing paediatric morbidity at a large center in Ireland and 2) initiate prospective neurodevelopmental assessment of children who had experienced EVME or hPEVME in infancy.

**Materials/methods:** All samples submitted for virology work-up from children aged 0-16 years by University Hospital Cork between 01/2014 and 12/2018 were included for analysis of circulating picornaviruses (n=199). Where possible, serotyping was performed. In those with picornaviral meningoencephalitis, clinical presentations, laboratory findings and imaging were reviewed. Between October and December 2019, parents of children with infantile meningoencephalitis were asked to complete an age-matched ASQ3 questionnaire.

**Results:** CSF analysis identified 86 children with meningoencephalitis, n=63 EV\(^+\); n=23 hPEV\(^+\). 68 (80%) were aged ≤3 months at time of illness. hPEVME patients were significantly younger (P<0.05). 9/10 hPEV serotyped were type3. 38/86 (44%) submitted an ASQ3, 29/38 had been ≤3 months at the time of illness, 35/38 ≤2 years. Based on ASQ3 data, 2/10 hPEV\(^+\) and 6/27 EV\(^+\) children warranted observation, 1/10 and 3/27 developmental follow-up, respectively. Parental concern was expressed in 4/10 hPEV\(^+\) and 14/27 EV\(^+\) children. Neither age at diagnosis, WBC\(_{\text{max}}\) in CSF or virus identified were associated with ASQ3 score or parental concern.

**Conclusions:** In this cohort currently undergoing prospective assessment, available data indicates that approximately 10% of patients who experienced EVME or hPEVME in infancy require observation and/or physician-directed follow-up later in childhood. Clinical parameters available during the acute illness did not predict later expressed parental concerns. Parental concern exceeded level of concern identified by ASQ3 questionnaire. Detailed prospective patient assessment will identify if this is the result of parental perception, or if sensitivity of parental assessment outperforms ASQ3 in identifying subtle neurocognitive sequelae of viral meningoencephalitis in infancy.

**Figure 1. Cases of paediatric enteroviral (EV) and parechoviral (hPEV) meningoencephalitis over time**

**BacteriaGame, a serious game to revise knowledge in medical Bacteriology**
Nicolas Pineros¹, Etienne Carbonnelle¹, Vicent Berry¹, Mathilde Lescat*²

¹Université Sorbonne Paris Nord, Villetaneuse, France, ²Avicenne Hospital (AP-HP), Bobigny, France

**Background:** For a long time, the educational game has been developed in order to encourage the motivation and interaction of students. In medical studies, few students attend the course of Bacteriology and we observe thereafter, real gaps in the knowledge of students in this discipline. We thus just created an educational game “BacteriaGame” born from the collaboration within our University Paris 13 between our laboratory of the medical school and the “Ludomaker”, a laboratory of educational games.

**Materials/methods:** The game lasts approximately 20 minutes and can be used by maximum 8 players. Briefly, it is an association game between 20 main bacteria and their characteristics (bacterial family, direct examination, commensal site, pathogenicity, type of community or nosocomial infection, type of diagnosis and antibiotic treatment). Players must associate these characteristics with the bacteria that they have drawn at the start of the game and whose identification they keep hidden. The other players have to guess these bacteria thanks to the characteristics which are visible on the table. Bonus questions add to the difficulty and the possibility of earning points.

**Results:** We tested this game during teaching in the 3rd year of medicine. The students formed 8 groups of 6 students and were able, after a brief explanation, to play it independently thanks to the rules available. The teacher was present and could intervene between the different game tables and an evaluation of the game was then carried out by the students [score between 1 and 4]. This evaluation was found to be very positive with 72% of the participants who gave scores 3 and 4.

**Conclusions:** We want to extend the use of this game which has shown great success with students and at national congresses to other levels of students [resident in medicine and pharmacy]. In this context we plan to study in the next weeks the impact of the use of this game on the learning outcomes of students at different levels by assessments before and after use.

Abstract third-party references: Supported by SCYNEXIS, Inc.

Background: Candida infections resistant to currently available antifungals are an emerging global threat. Ibrexafungerp is an investigational broad-spectrum glucan synthase inhibitor antifungal with activity against Candida and Aspergillus species, including azole- and echinocandin-resistant strains. A Phase 3 open-label, single-arm study of oral ibrexafungerp (FURI) [Clinicaltrials.gov NCT03059992] is ongoing for the treatment of patients (≥18 years) with fungal diseases who are intolerant of or refractory to standard antifungal therapies.

Materials/methods: An independent Data Review Committee (DRC) provided an assessment of treatment response for 41 patients who completed therapy by October 2019. Patients were enrolled in 22 centers from 6 countries. Patients were eligible for enrollment if they had proven or probable, invasive or severe mucocutaneous candidiasis and documented evidence of failure of, intolerance to, or toxicity related to a currently approved standard-of-care antifungal treatment or could not receive approved oral antifungal options (e.g., susceptibility of the organism) and a continued IV antifungal therapy was undesirable or unfeasible.

Results: The 41 patients assessed had the following infection types: intra-abdominal abscesses, oropharyngeal candidiasis, esophageal candidiasis, candidemia, and others. The DRC adjudicated 23 patients (56%) as achieving complete or partial response, 11 patients (27%) maintaining stable disease, 6 patients (15%) with progression of disease and one case was considered indeterminate. The efficacy of oral ibrexafungerp by pathogen was as follows:

<table>

1 patient outcome indeterminate, 1 patient’s organism not identified

Ibrexafungerp was well-tolerated with the most common treatment-related adverse events being of gastrointestinal origin. No deaths due to progressive fungal disease were reported.

Conclusions: Preliminary analysis of these 41 cases indicate that oral ibrexafungerp provides a favorable therapeutic response in the majority of patients with difficult to treat Candida spp. infections, including those caused by non-albicans Candida species.

Abstract 9730

Clinical effectiveness of individualized, c-reactive-protein-guided durations and fixed, seven-day durations of antibiotic therapy compared to 14-Day Durations for Gram-Negative Bacteremia: A Multicenter, Non-inferiority Point-of-Care-Randomized Clinical Trial

Elodie Von Bach1, Werner Albrich2, Anne-Sophie Brunel3, Virginie Prendki1, Shawna Mccallin1, Clémence Cuvelier1, Domenica Flury2, Angèle Gayet-Ageron1, Philipp Patrick Kohler3, Eva Lemmenmeier3, Stephan J. Harbarth1, Laurent Kaiser4, Pierre-Yves Bochud2, Angela Huttner*1

1Geneva University Hospitals, Geneva, Switzerland, 2St. Gallen Cantonal Hospital, St. Gallen, Switzerland, 3Lausanne University Hospital, Lausanne, Switzerland

Background: Gram-negative bacteremia is frequent and results in substantial antibiotic use. We compared individualized, C-reactive-protein-(CRP) guided antibiotic durations and fixed 7-day courses to fixed 14-day courses.

Materials/methods: This multicenter non-inferiority trial randomized adults 1:1:1 on day 5 (±1) of effective antibiotic therapy for fermenting, gram-negative bacteremia to a total duration that was (1) CRP-guided [antibiotic(s) discontinued when CRP decreased by ≥75% from peak, beginning on day 5], (2) 7 days, or (3) 14 days; patients were followed thereafter for 90 days. Patients who were febrile on day 5, severely immunosuppressed, or had recurrent or complicated infection (e.g., abscess) were not eligible for inclusion. Patients, investigators and ward physicians were blinded to allocation until antibiotic discontinuation. Non-investigators were additionally blinded to the CRP algorithm used for antibiotic discontinuation. The primary outcome was incidence of clinical failure by day 30, requiring either relapse (recent bacteremia), local suppurative complication, distal complication, restarting of gram-negative-directed antibiotic therapy due to clinical worsening suspected to be due to the initial organism, or death due to any cause through day 30; the non-inferiority margin was 10%. Secondary outcomes included incidence of Clostridioides difficile infection.

Results: Among 504 patients randomized (median age 79 years [IQR 68-86], female sex 306/503 [61%]), 493 (98%) day-30 follow-up. The urinary tract (348/503, 69%) and Escherichia coli (373/503, 74%) were the most common infection site and etiology, respectively. Median duration in the CRP arm was 7 days (IQR 6-10). Clinical failure occurred by day 30 in 4/164 (2.4%), 11/166 (6.6%), and 9/163 (5.5%) in the CRP, 7-day and 14-day arms, respectively (difference -3.1% [95%CI -7.3, 1.1], P=.126, for CRP- versus 14-day arm; and 1.1% [95%CI -4.1, 6.3], P=.426, for 7 versus 14-day arm). By day 90, failure occurred in 10/143 (7.0%), 16/151 (10.6%) and 16/153 (10.5%), respectively. Clostridioides difficile infection occurred in 0/49 (0%) of patients receiving <7 days of antibiotics, 5/245 (1%) receiving 7-10 days, and 8/201 (4%) receiving >10 days.

Conclusions: In adults with uncomplicated gram-negative bacteremia, individualized/CRP-guided and fixed 7-day durations were non-inferior to 14-day durations of antibiotic therapy. C-reactive-protein-guided durations are antibiotic sparing and safe.

Abstract 9734

A randomised trial of two 2-dose influenza vaccination strategies for patients following autologous haematopoietic stem cell transplantation

Benjamin Teh\(^1\,\,^2\), Vivian Leung\(^3\), Francesca Mordant\(^3\), Sheena Sullivan\(^3\), Trish Joyce\(^1\), Simon Harrison\(^1\,\,^2\), Ian Barr\(^1\), Kanta Subbarao\(^3\), Monica Slavin\(^1\,\,^2\), Leon Worth\(^1\,\,^2\)

\(^1\)Peter MacCallum Cancer Centre, Melbourne, Australia, \(^2\)University of Melbourne, Parkville, Australia, \(^3\)World Health Organization Collaborating Centre for Reference and Research on Influenza, Doherty Institute for Infection and Immunity, Parkville, Australia

**Background:** Recommendations for dose, type and timing of seasonal influenza vaccination of patients following autologous haematopoietic stem cell transplantation (autoHSCT) are inconsistent in clinical guidelines. We sought to evaluate seroprotection and seroconversion rates associated with two 2-dose schedules.

**Materials/methods:** A randomised single-blind control trial of two influenza vaccination strategies was conducted at a quaternary cancer centre during the Southern Hemisphere 2019 influenza season (ACTRN12619000617167P). AutoHSCT patients in their first year post-transplant were randomised 1:1 to trivalent (TIV) high dose (HD) followed by quadrivalent standard dose (SD) vaccine 4 weeks later (HD-SD arm) or two SD vaccines 4 weeks apart (SD-SD arm). Haemagglutination inhibition (HI) assay for TIV strains was performed at baseline, 1 and 2 months post-first dose. Patients were prompted weekly to report influenza-like-illness (ILI), which also triggered testing. Evaluable outcomes were seroprotection (HI titre ≥40) and seroconversion (4-fold titre rise) rates, unadjusted geometric mean titres (GMT) and GMT ratios at 1 and 2 months following initial vaccination. Outcomes in each arm were compared utilising chi-square or Fisher’s exact test with \(p<0.05\) considered statistically significant.

**Results:** Sixty-eight patients were enrolled (34 per arm) with median age of 61.5 years, majority male (68%) and myeloma the most common transplant indication (68%). Median time from autoHSCT to first vaccine dose was 2.0 (95% CI 0.9-10.5) months in HD-SD arm compared to 4.3 months (95% CI 0.92-11.8) in the SD-SD arm (\(p=0.06\)). For HD-SD and SD-SD arms, percentage of patients achieving seroprotection was 78.8% and 79.4% for H1N1, 87.9% and 91.2% for H3N2 and 81.8% and 94.1% for influenza-B/Yamagata respectively (all \(p>0.05\)). Seroconversion rates, GMT and GMT ratios were not significantly different between arms across influenza strains or time periods except for a higher GMT ratio 1 month following HD compared to SD vaccination (5.96 vs. 3.61, \(p=0.047\)). There was no difference in the number of patient-reported episodes of ILI or laboratory proven influenza between arms.

**Conclusions:** High seroprotection rates against all influenza strains can be achieved early post-autoHSCT with two-dose vaccine schedules. Although post-vaccination GMTs were comparable, the HD-SD arm showed greater gains in titres as reflected by higher GMT ratio.

Diabetic status and the risk of tuberculosis: a nationwide population-based study

Yoo Jung Eun*1

1Healthcare System Gangnam Center, Seoul National University Hospital, Seoul, South Korea

Background: Tuberculosis (TB) infections continue to be a concern worldwide and it remains deadly communicable disease. Diabetic mellitus (DM) appears to be a risk factor for lower respiratory infections including TB and to have a profound adverse impact on TB treatment outcome. To evaluate the association between DM duration and the incidence of TB in general population.

Materials/methods: We identified 6,312,283 subjects who are free of TB until one year after the day of their health examination (2009) and were followed up until December 31, 2018 using the database of the Korean National Health Insurance Service. Cox proportional hazard regression was used to assess adjusted hazard ratios (aHR) of DM status for TB with adjustment for potential confounders.

Results: A total of 30,917 individuals were diagnosed with TB during follow-up period. An increased risk of TB incidence was observed in DM subjects compared to non-DM subjects (aHR 1.49, 95% confidence interval [CI] 1.45-1.53). While subjects with impaired fasting glucose showed a decreased risk of TB incidence (aHR 0.96, 95% CI 0.93-0.98), the risk of TB incidence was increased with as the duration of DM increased (aHR 1.32, 95% CI 1.25-1.40 in the new-onset DM; aHR 1.46, 95% CI 1.39-1.53 in the DM with duration < 5 years; aHR 1.54, 95% CI 1.48-1.60 in the DM with duration ≥ 5 years). Among non-DM subjects, a U-shaped association was noted between fasting glucose concentrations and the risk of TB.

Conclusions: DM status was an independent predictor for developing TB with a dose-response relationship. In non-DM subjects, there was a U-shaped association between fasting glucose concentrations and TB risk, suggestive of protective role of BMI on TB in non-DM subjects.

Abstract 9739

**Siderophores of environmental *Pseudomonas* for application against human opportunistic pathogens**

Vera Vollenweider*, Karoline Rehm², Laurent Bigler², Rolf Kümmerli¹

¹University of Zurich, Department of Quantitative Biomedicine, Zürich, Switzerland, ²University of Zurich, Department of Chemistry, Zürich, Switzerland

**Background:** Alternative approaches targeting multi-drug resistant pathogens are urgently needed. For successful pathogenesis, bacteria rely on virulence factors to directly target the host or to exploit their nutrients. Iron-scavenging siderophores fulfil both tasks and are indispensable for bacterial proliferation, which makes them excellent antimicrobial targets. Once the siderophore has bound iron, bacteria require a specific receptor for ferric-siderophore uptake. Here, we exploit this strategy by screening for siderophores of non-pathogenic environmental bacteria that cannot be used by opportunistic pathogens and thereby induce iron starvation and growth arrest in the pathogens. We focussed on pyoverdines, produced by fluorescent *Pseudomonas* bacteria, which are a class of siderophores with strong affinity for iron.

**Materials/methods:** In a first step, we screened 340 supernatants of environmental pseudomonads, containing pyoverdine, for their activity against 12 human opportunistic pathogens. To rule out any non-pyoverdine related pathogen inhibition we repeated the assay in iron-replete conditions. For the top candidates, inhibiting the growth of all pathogens, we established the minimal inhibitory (MIC) and half maximal inhibitory concentrations (IC₅₀) for each pathogen. We then crudely purified the candidate pyoverdines and subjected them to liquid chromatography–high resolution mass spectrometry (LC-HRMS) to determine their mass, relative abundance in the supernatant, and to elucidate their chemical structure.

**Results:** We identified seven pyoverdine candidates that strongly inhibited the growth of all pathogens exclusively under iron-deplete conditions, suggesting that the pyoverdines are indeed responsible for the observed growth inhibition. We further show that the crudely purified pyoverdines act in a concentration-dependent manner against the different pathogens. Our chemical analyses reveal that five out of seven top-candidate pyoverdines differ in their chemical structure. Currently, we are about to validate the antibacterial activity of these pyoverdines in vivo in our host model system *Galleria mellonella* and to test for their level of cytotoxicity against mammalian cells.

**Conclusions:** We establish a novel approach, based on the induction of iron starvation, to combat bacterial opportunistic pathogens, including members of the ESKAPE pathogens that increasingly become resistant to antibiotics.

Phage cocktails in the treatment of bacteriophage insensitive mutants
Prasanth Manohar1, Ramesh Nachimuthu2, Sebastian Leptihn1

1Zhejiang University, Zhejiang University-University of Edinburgh, Haining, China, 2Vellore Institute of Technology, SBST, Vellore, India

Background: The rising prevalence of antibiotic resistance in bacteria is an important health obstacle, given that about 2.25 million people sickened each year by antibiotic-resistant infections. If it continues, the world is heading towards a post-antibiotic era, in which alternative therapeutics such as phage therapy should be considered. Though bacteriophages are effective antibacterial agents, there is a possibility that the bacteria could develop resistant mutants against the infecting lytic phage. This study aims to eliminate the bacteriophage insensitive mutants using phage cocktails.

Materials/methods: For this study, Enterotoxigenic E. coli (ETEC) were collected from the diagnostic centre in Chennai, Tamil Nadu. The water samples were collected from sewage treatment plants in Karur district. The bacteriophages were isolated using phage enrichment method. Spot test and double agar overlay method were used to test the phage activity. Bacteriophage insensitive mutants (BIMs) were isolated and selected using challenge tests. The bacteriophages were characterized; absorption time, latency period, burst size, morphological analysis, and genomic analysis. Phage cocktail was prepared using characterized phages to eliminate BIMs. In vivo studies were performed using Galleria mellonella and the larvae were infected with $10^6$ CFU/mL bacteria and treated with $10^4$ PFU/mL phages.

Results: A bacteriophage EP1 was isolated against E. coli ETEC311. The host-range analysis showed that the phage was infecting 4/8 ETEC tested. Out of 4 ETEC isolates [ETEC311/235/315/326], BIMs was observed in 3 ETEC [235/315/326] isolates. In this regard, another bacteriophage EP2 was isolated to infect BIMs. Importantly, 2/3 BIM isolates [235A/315A] were eliminated using the phage EP2 but one BIM isolate [326A] was still resistant. In vivo studies showed that when treated with EP1, ETEC311 (no BIMs) infected larvae obtained 100% larval survival within 48hrs but ETEC235/315 (BIMs) infected was not. When infected with ETEC235/315 (BIMs) and treated with phage cocktail [EP1 and EP2], 100% survival was observed within 72hrs. No significant survival was observed in untreated and ETEC326 infected groups.

Conclusions: This study can be used as a strategy in the preparation of phage cocktails to combat BIMs. In future, studies on evolution of phage resistance can be used to guide therapeutic phage preparations.

Abstract 9756

**Routine molecular point-of-care testing for influenza in hospitalised adults improves patient management and outcomes: results of a multicentre, randomised controlled trial (FluPOC)**

Tristan Clark*1,2,3, Kate Rhian Beard1,2, Nathan Brendish1,2,3, Stephen Poole1,2,3, Cathleen Chan2, Nick Cortes4, Ahalya Malachira2, Samuel Mills2, Sean Ewings5

1University of Southampton, Clinical and Experimental Sciences, Southampton, United Kingdom, 2University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, 3University Hospital Southampton Foundation NHS Trust, NIHR Southampton Biomedical Research Centre, Southampton, United Kingdom, 4Hampshire Hospitals NHS Trust, Winchester, United Kingdom, 5University of Southampton, Primary Care and Population Sciences, Southampton, United Kingdom

**Background:** Influenza infections often remain undiagnosed in patients admitted to hospital due to lack of routine testing. When tested for, the diagnosis of influenza is delayed due to the long turnaround times of laboratory PCR, leading to inappropriate and late antiviral and isolation facility use. Molecular point-of-care tests (mPOCT) for influenza can deliver results in under 1 hour but high quality evidence for impact on clinical management and outcome is lacking.

**Materials/methods:** In this pragmatic, multicentre, randomised controlled trial we enrolled adults admitted to hospital with acute respiratory illness (ARI) during influenza season. Patients were randomised (1:1) to receive mPOCT for influenza or routine clinical care. The primary outcome was the proportion of influenza-infected patients who received antivirals. Secondary outcomes included; detection of influenza, time to antivirals, isolation facility use and clinical outcome measures.

**Results:** Between December 2017 and May 2019, 613 patients were enrolled (307 assigned to mPOCT and 306 to routine care) and all were analysed. 100/307 (33%) patients in the mPOCT group and 102/306 (33%) patients in the control group were influenza-infected. The median (IQR) turnaround time for results was 1.2 (1.1 to 1.4) hours in the mPOCT group and 23 (16 to 29) hours in the control group (p<0.0001). 100/100 (100%) influenza-infected patients were diagnosed in the mPOCT group but only 60/102 (59%) were diagnosed in the control group, p<0.0001. 99/100 (99%) influenza-infected patients received antiviral treatment in the mPOCT group versus 63/102 (62%) in the control group, relative risk 1.6 (95%CI 1.4 to 1.9); p<0.0001. Median (IQR) time to antivirals was 1·0 (0 to 2.0) hour in the mPOCT group versus 6·0 (0 to 12.0) hours in the control group (p=0.0039). 70/100 (70%) of influenza-infected patients in the mPOCT group were correctly nursed in single room accommodation versus 39/102 (38%) in the control group, p<0.0001. In the mPOCT group there were fewer adverse events and median Hospital Recovery Scale score was lower versus the control group (p=0.045).

**Conclusions:** Routine mPOCT for influenza was associated with enhanced detection of influenza, improvements in appropriate and timely antiviral and isolation facility use and better clinical outcome.

**Funding:** NIHR

Decreased sensitivity of rapid influenza diagnostic test among vaccinated adults in influenza season 2018-19

Raija Auvinen*, Niina Ikonen1, Raisa Loginov2, Anu Haveri2, Satu Kurkela2, Hanna M. Nohynek3, Ritva Syrjänen2, Jukka Ollgren2, Esa Ruokokoski2, Kirsi Skogberg4

1Inflammation Center and Internal Medicine and Rehabilitation, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, 2Finnish Institute for Health and Welfare, Helsinki, Finland, 3Virology and Immunology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland, 4Inflammation Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Abstract third-party references: Funding: Innovative Medicines Initiative 2 Joint Undertaking under grant agreement No 777363. DRIVE collaboration receives support from the European Union’s Horizon 2020 research and innovation programme and EFPIA.

Background: The sensitivity of rapid influenza diagnostic tests (RIDTs) detecting viral antigens has proved low to moderate compared to RT-PCR tests. Their accuracy depends on the type of respiratory specimen, factors related to sampling such as transport medium and swab, time from symptom onset to sampling and patient age. We wanted to investigate whether prior influenza vaccination affects their sensitivity.

Materials/methods: During influenza season 2018-19 a prospective test-negative design (TND) influenza vaccine effectiveness (IVE) study was conducted at HUS Jorvi Hospital as a part of international DRIVE collaboration. Adult inpatients fulfilling severe acute respiratory infection (SARI)-criteria were recruited and swabbed for influenza. According to local sampling strategy, respiratory samples were first tested by RIDT and negative results were tested by RT-PCR in HUSLAB clinical laboratory. Positive RIDT and RT-PCR results were confirmed and influenza subtype was determined by real-time RT-PCR at the Finnish Institute for Health and Welfare (THL). Those tested positive at THL were considered laboratory-confirmed influenza (LCI) cases.

Results: Of the 69 LCI SARI cases that were tested for influenza with both RIDT and RT-PCR, 21 (30.4%) tested positive, 46 (66.7%) negative and 2 (2.9%) unclear with RIDT. The overall sensitivity of the RIDTs in detecting influenza was only 31.3%. Prior influenza vaccination during the current influenza season seemed to be associated with decreased sensitivity of the antigen test (OR = 0.374, 95% CI 0.124, 1.068, P = 0.066). Among those vaccinated over 14 days before sampling, 28 (77.8%) had false-negative RIDT results compared to 17 (56.7%) of the non-vaccinated. Patient age, influenza A subtype or genetic clade did not have a significant effect on the sensitivity of the RIDT.

Conclusions: Our data suggests an association between prior influenza vaccination and decreased sensitivity of RIDT. False-negative RIDT results and consequent underdetection of influenza cases may lead to insufficient use of infection-control measures and antiviral treatments and unnecessary use of antibiotics. Additionally, IVE may be overestimated due to false-negative influenza test results among vaccinated population. Thus, caution is warranted when interpreting negative RIDT results especially in areas with high influenza vaccination coverage.

**Impact of the introduction of EUCAST's concept of the "Area of Technical Uncertainty"**

Eveline Van Honacker*1, Stien Vandendriessche2, Liselotte Coorevits3, Bruno Verhasselt45, Jerina Boelens36

1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium, 1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium, 1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium, 1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium, 1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium, 1Ghent University Hospital, Department of Medical Microbiology, Ghent, Belgium

**Background:** On the first of January 2019 the European Committee on Antimicrobial Susceptibility Testing, EUCAST, introduced the concept of "area of technical uncertainty" (ATU). One year later, the impact of the implementation of this new approach in the laboratory of our 1062-beds tertiary care teaching hospital was studied. The aim was to report on the incidence of ATU test results in a selection of common bacterial species and the subsequent impact on antimicrobial resistance categorisation.

**Materials/methods:** A retrospective analysis of clinical samples collected from February 2019 till November 2019 was performed. Susceptibility to amoxicillin-clavulanic acid and piperacillin-tazobactam in Enterobacterales (Escherichia spp., Klebsiella spp., Proteus spp.), piperacillin-tazobactam in Pseudomonas spp. and amoxicillin-clavulanic acid and cefturoxime in Haemophilus influenzae was studied. Primary antibiotic susceptibility testing was performed using disk diffusion with paper disks [Bio-Rad, France] and the ADAGIO 93400 automated system [Bio-Rad, France] for reading and interpretation. In case of inhibition zone in the ATU, strains were retested using gradient minimal inhibitory concentration method [E-test, BioMérieux, France].

**Results:** Overall, 14168 isolate-antibiotic combinations were tested in 7924 isolates, resulting in 1206 (8.5%) disk zone diameters in the ATU region.

For amoxicillin-clavulanic acid we observed a category change from S to R in 12% of the ATUs in Escherichia spp., 2/58 in Klebsiella spp. and 2/37 in Proteus spp. For piperacillin-tazobactam a category change from I to R was found in 28% of Escherichia spp., 15% of Klebsiella spp. and 4/5 of Proteus spp.. A category change from S to R occurred in 36% of Pseudomonas spp.. In Haemophilus influenzae the category changes for both amoxicillin-clavulanic acid (S to R) and cefturoxime (S or I to R) were less than 5%.

**Conclusions:** Additional testing due to ATU led to clinically relevant antibiotic susceptibility changes, in particular for piperacillin-tazobactam: very major errors (S to R) were observed in >25% of Pseudomonas spp., Proteus spp. and Escherichia spp..

We conclude that ATU testing has a substantial impact on the interpretation of antimicrobial resistance.

Abstract 9810

**Antibiotic resistance prediction by analysis of whole genome sequence data using ARESdb**

Ines Ferreira*1,2, Stephan Beisken1, Lukas Lueftinger1, Thomas Weinmaier1, Matthias Klein3, Johannes Bacher3, Robin Patel4, Arndt Von Haeseler2, Andreas Posch1

1 Ares Genetics GmbH, Wien, Austria, 2 Center for Integrative Bioinformatics Vienna, Max Perutz Laboratories, University of Vienna and Medical University of Vienna, Vienna, Austria, 3 Curetis GmbH, Holzgerlingen, Germany, 4 Mayo Clinic, Rochester, United States

**Abstract third-party references:** Ares Genetics GmbH

**Background:** Whole genome sequencing (WGS) is now routinely performed in clinical microbiology laboratories to assess isolate relatedness. With appropriately developed analytics, the same data can be used for prediction of antimicrobial susceptibility.

**Materials/methods:** We assessed WGS data for antibiotic susceptibility testing (AST) prediction using ARESdb compared to broth microdilution phenotypic susceptibility testing on clinical isolates from a multicenter clinical trial of the Unyvero LRT Application (Curetis). For the trial, more than 2,000 patient samples were collected from ICUs across nine hospitals and tested for LRT infection. The isolate subset used in this study included 566 clinical isolates originating from 455 LRTI culture-positive patient samples. Isolates were sequenced using the Illumina Nextera XT protocol and FASTQ-files with raw reads uploaded to the ARESdb cloud platform (ares-genetics.cloud, released for research use in 2020). The platform combines Ares Genetics’ proprietary database ARESdb, with state-of-the-art bioinformatics tools and curated public data. Binary AST classification models were trained using a k-mer-based approach on approximately 10,000 de novo genome assemblies per species-compound pair dependent on availability of AST data for 21 antibiotics. Intermediate and susceptible dose-dependent phenotypes were treated as susceptible.

**Results:** WGS-predicted susceptibility showed 89% categorical agreement with phenotypic susceptibility across a total of 129 species-compound pairs analyzed. Categorical agreement exceeded 90% in 78 and reached 100% in 32 species-compound pairs (Table).

**Conclusions:** Results of this study add to the growing body of literature showing that, with improvement of analytics, WGS data could be used to predict antimicrobial susceptibility. With continuous expansion and availability of sequenced isolates and reference AST data, together with an improved understanding of AMR, predictive AST could be incorporated into clinical practice.

Abstract 9814

**Vancomycin loading doses in the emergency department: a Bayesian approach**

Karan Raja1*, Ashita Debnath2, Caroline Bezzubik2, Brandon Chen1, Mark Attalla1, Ruben Patel1, Soo Kang1, Mitesh Patel1, Mona Philips1

1Clara Maass Medical Center, Belleville, United States, 2Ernest Mario School of Pharmacy, Piscataway, United States

**Background:** Appropriate vancomycin dosing is imperative in the first 24 – 48 hours of critical illness to ensure adequate drug concentration and effectiveness while avoiding adverse events. Recent data confirm the ratio of area-under-the-curve to minimum inhibitory concentration (AUC/MIC) predicts efficacy. Vancomycin loading doses theoretically achieve earlier effective concentrations. Bayesian dosing programs utilize population kinetics to estimate patient-specific AUCs and dosing strategies. There is an opportunity to employ Bayesian dosing tools to identify optimal loading doses for critically ill patients. This study sought to compare current loading dosing practice with Bayesian dosing tool recommendations.

**Materials/methods:** The electronic medical record was queried to identify all adult patients given a single vancomycin dose for sepsis treatment in the ED during a one-month period. Patients with a BMI over 30 were excluded as these patients fell outside of the Bayesian dosing software limits. Patients with antibiotic indications not requiring a loading dose were also excluded. Bayesian dosing software was used to extrapolate troughs and AUC24 achieved with the actual dose administered and to calculate a population-based, single loading dose and its associated troughs and AUC24. The primary outcomes evaluated were the dose, anticipated AUC, and trough difference between actual and Bayesian calculated loading doses. Continuous data were analyzed using student’s t-test.

**Results:** Of 121 patients, 43 met inclusion criteria. A loading dose was not indicated in 38 patients and 40 patients had a BMI >30. The Bayesian-calculated loading dose was 119% greater than the actual dose given, with an associated 217% greater modeled AUC24. The AUCs achieved for actual and Bayesian-calculated loading doses were 204.6 mcg*h/mL and 424 mcg*h/mL, respectively \( p<0.05 \). The average actual dose administered was 15.5 mg/kg (1,006 mg) while the average recommended dose from the Bayesian model was 33.1 mg/kg (2,180 mg). The extrapolated troughs for actual and Bayesian-calculated loading doses were 4.3 mcg/mL and 9.1 mcg/mL, respectively \( p<0.05 \).

**Conclusions:** This study demonstrates current dosing strategies in our ED likely achieve sub-therapeutic vancomycin AUC24. The results support application of Bayesian dosing tools for calculating loading doses to increase the likelihood of achieving target AUCs rapidly and potentially decrease clinical failures.

Increased enterococcal abundance and low microbial diversity are early predictive markers of a microbiota primed for development of Clostridioides difficile infection

Matilda Berkell*1, Mohamed Mysara2, Basil Britto Xavier1, Cornelis H. Van Werkhoven3, Pieter Monsieurs2, Christine Lammens1, Annie Ducher4, Maria J.G.T. Vehreschild5,6,7, Herman Goossens1, Jean De Gunzburg4, Marc J.M. Bonten2, Surbhi Malhotra-Kumar1

1University of Antwerp, Antwerpen, Belgium, 2SCK•CEN, Belgian Nuclear Research Centre, Mol, Belgium, 3UMC Utrecht, Utrecht, Netherlands, 4Da Volterra, Paris, France, 5Universität zu Köln, Köln, Germany, 6Deutsches Zentrum für Infektionsforschung (DZIF) e. V., Braunschweig, Germany, 7University Hospital Frankfurt, Frankfurt am Main, Germany

Background: Clostridioides difficile infection (CDI) is the most common form of infectious antibiotic-associated diarrhoea (AAD) causing considerable morbidity and mortality in acute-care facilities. Identification of early markers predictive of CDI in hospitalized patients could substantially contribute to decreasing the CDI burden.

Materials/methods: In this European, prospective, longitudinal cohort-study including 1,007 patients aged ≥50 years receiving broad-spectrum antibiotic treatment with penicillins + beta-lactamase inhibitors, other beta-lactam antibiotics, or fluoroquinolones during hospital stay, we characterized faecal samples using high-resolution, single-nucleotide 16S rRNA gene profiling before (D1, n = 945) and after antibiotic treatment (D6, n = 737). CDI was defined according to the ESCMID diagnostic guidelines.

Results: C. difficile carriage was observed in 51/945 (5.4%, D1) and 50/737 (6.8%, D6) patients. Among patients who developed diarrhoea within 90 days, those with CDI (n=14) exhibited significantly lower diversity (p≤0.016) and a distinctly different microbial composition at D1 compared to those with non-C. difficile AAD (n=64) and no diarrhoea (n=669, 198 lost to follow-up, Figure). At D1, the microbiota was enriched for Enterococcus spp. in patients who later developed CDI, for Clostridiales Incertae Sedis XI, Blautia and Ruminococcus spp. in patients developing non-C. difficile AAD, and for Blautia luti, Porphyromonas, Prevotella, and Bifidobacterium spp. in non-diarrheic patients. Antibiotic treatment reduced microbial diversity and induced class-specific dysbiosis; beta-lactam treatment specifically increased enterococcal abundance, and fluoroquinolone treatment depleted Prevotella spp.

Conclusions: Our findings of a distinct, low-diversity CDI-associated microbiota can be exploited for enriching high-risk patients in prospective clinical trials and for the development of predictive, microbiota-based diagnostics for clinical management of patients at high risk of CDI.

Figure. Characterization of microbial diversity in baseline (D1) samples. CDI patients [blue] display significantly lower alpha diversity in terms of Shannon (A) and Chao1 indices (B), compared to AAD [light blue], and ND patients [green] at D1. Cladogram demonstrating significantly higher abundances of Actinobacteria, Alphaproteobacteria and Enterococcus spp. in the gut microbiota of CDI patients at baseline (D1) compared to AAD and ND patients (C). AAD: patients with antibiotic-associated diarrhoea. CDI: patients with confirmed C. difficile infection. ND: non-diarrheic patients. *: p<0.05. **: p<0.01. ***:p<0.001.

Phenotypic and genotypic characterisation of BLNAR and BLPACR strains of *Haemophilus influenzae*: a rare finding of presence of ESBLs and highly resistant ftsI mutations in Australian isolates.

Syeda Naqvi*,1; Hemalatha Varadhan1, Rodney Givney1

1 John Hunter Hospital, NSW Health Pathology, Hunter, Newcastle, Australia

**Background:** *Haemophilus influenzae* is responsible for respiratory tract and severe invasive infections such as meningitis and sepsis. The purpose of this study was to characterise the dual mechanism of β-lactam resistance among *H. influenzae* isolates from Australia.

**Materials/methods:** 100 *H. influenzae* isolates which were resistant to both ampicillin and amoxicillin-clavulanate on initial disk diffusion were collected from 2017 to 2019 and phenotypically classified as pBLNAR and pBLPACR based on nitrocefin hydrolysis. Disk diffusion results were verified with gold standard broth microdilution (BMD using EUCAST) and also by CLSI disk diffusion standards to look for concordance. Whole genome sequencing was performed on 44 of these isolates to study *ftsI* and *bla* genes using Illumina MiSeq platform. The Nullarbor pipeline v2.0.20180910 was used to perform de novo assembly using SKESA v2.2. Point mutations associated with resistance (in particular in the transpeptidase domain of penicillin-binding protein 3 encoded by *ftsI* gene) were investigated using the Resistance Gene identifier (RGI) implemented in The Comprehensive Antibiotic Resistance Database (CARD).

**Results:** Among the pBLNAR strains, 25.5% isolates had ampicillin MIC of 1mg/L at the borderline of susceptible range, and 4.6% had a low MIC of 0.5mg/L, making them Low BLNAR [L-BLNAR] strains. Conversely, 100% pBLPACR strains had a very high MIC (8mg/L). Both BLNAR and BLPACR, had a very similar pattern of amoxicillin-clavulanate MIC, higher if *ftsI* gene mutations were of Ubukata group III or Skaare nomenclature group III and III like (D350 N, S357N, S385T and L389F), which have not been previously reported in Australian isolates (Figure 1). Furthermore, we were able to detect three different types of ESBLs in our isolates, which are not previously reported in *H.influenzae*.

**Conclusions:** EUCAST standardized disk diffusion showed better correlation with genotype than CLSI methods. Detecting of *ftsI* mutations and ESBLs in *H.influenzae* may have critical management and infection control implications. WGS is a promising modality to understand β-lactam resistance mechanisms in depth in *H. influenzae*.

**Figure 1:** *ftsI* mutations in our study isolates based on Skaare et al. nomenclature.

Abstract 9828

Intact EfrEF operons seem essential for chlorhexidine tolerance among Enterococcus faecalis from different hosts and genetic backgrounds

Ana Paula Pereira*,1, Barbara Duarte1, Patricia Antunes1,2, Luisa Maria Vieira Peixe1, Ana Raquel Freitas1, Carla Novais1

1UCIBIO/REQUIMTE. Departamento de Ciências Biológicas, Faculdade de Farmácia da Universidade do Porto, Porto, Portugal, 2Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal

Background: Chlorhexidine (CHX) is used in the hospital, community and food-animal production settings (hand-hygiene, skin-antisepsis, oral-care and patient-washing; 1200-40000mg/L). Its activity against Enterococcus faecalis-Efs, a major nosocomial pathogen, has been scarcely explored in strains from diverse epidemiological and genetic backgrounds. The EfrEF operon [coding for a heterodimeric ABC transporter] and its transcriptional regulator ChlR were demonstrated to have an important role in CHX tolerance in the Efs-V583 reference strain, by deletion and complementation experiments (doi:10.1128/AAC.00267-18). However, no studies exploring ChlR-EfrEF in diverse Efs strains are available. Here, we evaluated CHX activity and the occurrence and variability of the ChlR-EfrEF operon among Efs from different origins and clonal lineages.

Materials/methods: Efs isolates (n=55; 1999-2018; 4 countries; 46 STs; multidrug-resistant: 31%), recovered from humans [hospitalized-patients-infection, n=12; hospital/healthy-humans/long-term-care-patients surveillance, n=18], food [raw-poultry-carcass, n=7; ready-to-eat-salads, n=2], food-animal-production-settings [piggery, n=8; aquaculture, n=3; aviary, n=1], aquatic-environment [hospital-sewage, n=3; river-water, n=1] were included. CHX-Minimum-Inhibitory-Concentration (MIC\textsubscript{CHX}) was determined by broth-microdilution (range:1 -32mg/L; ISO20776-1:2006;37ºC/24h) in log-phase strains followed by CHX-Minimum-Bactericidal-Concentration (MBC\textsubscript{CHX}) (NCCLS:1999; 37ºC/48h). The ChlR-EfrEF operon was searched by PCR followed by sequencing, using the Efs-V583 (GenBank accession no:AE016830.1) as reference strain. Occurrence of truncated proteins within the ChlR-EfrEF operon was evaluated by the DNA translate tool of ExPASy SIB Bioinformatics Resource Portal (https://web.expasy.org/translate/).

Results: MIC\textsubscript{CHX} ranged between ≤1-8mg/L (modes of 4mg/L; 69% of Efs) and MBC\textsubscript{CHX} ≤1≥32mg/L (modes of 4mg/L/33% and 8mg/L/35% of Efs). Efs associated with infection (n=12) or other sources (n=43) showed the same MIC\textsubscript{CHX}=8mg/L but different MBC\textsubscript{CHX} (8 vs ≥32mg/L, respectively). Vancomycin-resistant Efs [3-clinical/ST2/ST6/ST159; 1-hospital-surveillance/ST6] showed similar MIC\textsubscript{CHX} and MBC\textsubscript{CHX} values (4-8mg/L). Differences among MIC\textsubscript{CHX}/MBC\textsubscript{CHX} were not detected among MDR/non-MDR strains (8≥32mg/L). The ChlR-EfrEF operon was present in all Efs studied, but those with MIC\textsubscript{CHX}≤1mg/L showed EfrE (n=2; aquaculture/healthy-human; both ST40) or EfrF (n=1; piggery-manure/St1200) truncated.

Conclusions: CHX presented good activity against MDR-Efs from different sources and clonal lineages. The variability of ChlR-EfrEF operons among diverse Efs strains was here demonstrated for the first time. In accordance with the studies performed with Efs-V583, our data also show the importance of an intact ChlR+EfrE+EfrF operon for chlorhexidine tolerance in different strains.

Colistin resistance detection: an easy test for routine laboratories

Deniz Guneser*1, Kübra Özgüler2, Turgut Bozan1, Aysegul Karahasan1

1Marmara Üniversitesi Pendik Edf. Ve Arş. Hastanesi, Medical Microbiology Department, Istanbul, Turkey, 2Marmara University Faculty of Medicine, Medical Microbiology Department, Istanbul, Turkey

Background: Colistin, as an old antibiotic, became last crucial therapy option due to increasing rates of multidrug resistant (MDR) gram negative bacteria. Yet a rapid and user-friendly susceptibility testing remains to be needed for clinical microbiology laboratories.

Aim: In this study, we compared the accuracy of colistin disk broth elution test (CBDE) to that of broth microdilution (BMD) which is the gold standard, in clinical isolates.

Materials/methods: We included MDR Klebsiella pneumoniae [n: 33] and Acinetobacter baumannii [n: 46] strains in our study. Blood isolates consisted 40.5% of strains. BMD was performed as recommended by EUCAST [colistin sulfate powder, Sigma-Aldrich, USA; cation adjusted Mueller Hinton Broth, Becton Dickinson, USA; 96 well polystyrene plates, TPP, Switzerland]. CBDE was performed with cation-adjusted Mueller-Hinton broth [Sigma-Aldrich], 3 tubes per isolate; to which 1, and 2 colistin 10-µg disks (Oxoid, UK) were added, generating final concentrations in the glass tubes of 0 (growth control), 2, and 4 µg/ml, respectively (CLSI M100, 30th ed.; 2020). All experiments were accomplished in duplicates. We interpreted categorical agreement discrepancies as very major error (false susceptibility by CBDE) and major error (false resistance by CBDE). Other antimicrobials were studied by disk diffusion method and VITEK 2 system (bioMérieux, France), then interpreted as recommended by EUCAST.

Results: As seen in Table, very major error was detected in any of the isolates. However, in 9 A. baumannii and in 2 K. pneumoniae isolates major error was detected.

Conclusions: Colistin is one of the very limited drug options in patients infected with MDR bacteria. In a recent past there was no reliable laboratory test except BMD for colistin susceptibility. However, BMD is costly and time consuming. In January 2020, CLSI suggested to implement CBDE test for colistin testing. There are very limited number of publications regarding this issue. We may conclude that, CBDE is an easy to perform and cheap test, but if an isolate was found to be resistant by CBDE, the result should be confirmed by BMD.

Declining antibiotic use in Infants and falling asthma Incidence in children: New findings from population and prospective cohort studies suggest a causal link mediated through the gut bacterial community.

David Patrick*1,2, Hind Sbihi, Darlene Dai1, Abdullah Al Mamun1, Drona Rasali1, Caren Rose1, Fawziah Marra2, Rozlyn Boutin2, Charisse Petersen1, Leah Stiensma4, Geoff Winsor2, Anita Kozysrykij1, Meghan Azad2, Allan Becker7, Piush Mandhane6, Theo Moraes5, Malcolm Sears9, Padmaja Subbarao8, Brett Finlay2, Stuart Turvey2

1British Columbia Centre for Disease Control, Vancouver, Canada, 2University of British Columbia, Vancouver, Canada, 3University of British Columbia, Vancouver, Canada, 4Pepperdine University, Malibu, United States, 5Simon Fraser University, Burnaby, Canada, 6University of Alberta, Edmonton, Canada, 7University of Manitoba, Winnipeg, Canada, 8University of Toronto, Toronto, Canada, 9McMaster University, Hamilton, Canada

Abstract third-party references: Major Funding: British Columbia Ministry of Health, Pharmaceutical Services Branch; Canadian Institutes of Health Research; Allergy, Genes and Environment (AllerGen) Network of Centres of Excellence; Genome Canada. On behalf of the CHILD Cohort Study Investigators

Background: Asthma incidence among children is falling in some countries. Observational studies have linked infant antibiotic use with asthma risk. We hypothesized that falling asthma incidence is linked to reduced antibiotic prescribing at population level, that the same association can be demonstrated in individual children followed over time, and that this is mediated through changes in the gut bacterial community.

Materials/methods: Using administrative data from British Columbia, Canada (population=4·7 Million) we determined the association between antibiotic prescribing (age<1yr) and asthma incidence (ages 1-4yr) at the population level and applied Poisson regression to assess how antibiotic use would predict asthma rates at fine geographic scale. The CHILD prospective birth cohort (n=2644) examined the association at the individual level, with adjustment for key covariates. A mechanistic investigation (n=917) within CHILD used 16S rRNA gene sequencing to assess gut microbiota. Structural equation modeling was applied to explore direct and indirect causal pathways.

Results: Between 2000-14, asthma incidence (ages 1-4y) fell from 27 to 20 per 1000 and was associated with declining antibiotic use in infancy from 1254 to 489 prescriptions per 1000 (Rho=0·88, p<0·0001). Across local health areas, asthma incidence increased 24% with each 10% increase in antibiotic prescribing (IRR=1·24; 95%CI: 1·2-1·3; p<0·0001). In the CHILD cohort, after excluding children who received antibiotics for respiratory symptoms and adjusting for other key covariates, asthma was associated with infant antibiotic use (aOR=2·15; 95%CI: 1·37-3·39; p=0·00093) with a significant dose-response (p=0·00082). Increasing α-diversity of the gut microbiota at age 1yr was associated with a lower risk of asthma at age 5yr (interquartile aOR=0·68; 95%CI: 0·46-0·99; p=0·046). Some taxa that exhibited significant differences in their relative abundance between antibiotic-treated and asthma-diagnosed children compared with controls have previously been demonstrated to have immunomodulatory activity. Structural equation modeling provided evidence that the gut microbiota was a probable mediator between antibiotics and asthma (p=0·027).

Conclusions: Our findings suggest that a significant reversal in the asthma epidemic may be an unexpected dividend of community antibiotic stewardship efforts acting through preservation of the infant gut microbial community.

The approach to HCV treatment in patients with haematologic malignancies: an ESGVH-ESGICH cross-sectional survey

Laura Ambra Nicolini, Andrea Lombardi, Matteo Bassetti, Malgorzata Karolina Mikulska

1 Ospedale Policlinico San Martino-IRCCS, Infectious Diseases, Genova, Italy, 2 IRCCS Ca’ Granda Ospedale Maggiore Policlinico Foundation, Infectious Diseases, Milano, Italy, 3 University of Genoa, Department of Health Sciences, Genova, Italy

Abstract third-party references: ESCMID study group for viral hepatitis (ESGVH), ESCMID study group for infections in compromised hosts (ESGICH)

Background: Evidence on safety and efficacy of direct acting agents (DAAs) against hepatitis C virus (HCV) in patients with haematological malignancies (HM) is low. This study aims at evaluating the current prescribing practice of HCV treatment in this setting.

Materials/methods: DAAs prescribers were invited to participate in a cross-sectional survey endorsed by two ESCMID study groups and they provided answers on their prescription choices in 12 clinical situations featuring patients with HM, stem cell donors and recipients.

Results: Between November 2019-January 2020, 33 specialists from 16 countries responded to the survey. All but one were Infectious Diseases specialists, median age was 41 (IQR 33-57) years, 41% were females (n=14), 40% (n=13) have worked as specialist for more than 10 years. Most of them (n=29) report having treated <20 patients with HM in the last year. All but one colleagues have access to pan-genotypic DAAs. The regimens currently used in naïve hematological patients are: sofosbuvir/velpatasvir (84.6%, n=22), sofosbuvir/velpatasvir/voxilaprevir (15%, n=4), glecaprevir/pibrentasvir (53.9%, n=14), grazoprevir/elbasvir (23%, n=6), sofosbuvir/ledipasvir (11.5%, n=3). The 96% (n=26) usually administer DAAs as first-line option in case of indolent lymphoma, while 52% (n=14) and 58% (n=15), respectively, consider co-administration of DAAs and chemotherapy for aggressive lymphoma or chronic lymphocytic leukaemia/multiple myeloma requiring immediate chemotherapy. Main perceived risks for treatment during chemotherapy are drug-drug interactions (56%, n=10) and paucity of evidence in this setting (39%, n=7). All but two specialists do not exclude HCV-infected stem cell donors, but 31% (n=8) harvest stem cells from HCV donors only after sustained virological response, while 38% (n=10) and 12% (n=3) once HCV-RNA is undetectable or HCV treatment is ended, respectively. Regarding transplant candidates, the 35% (n=9) schedule HCV treatment following transplantation and 64% (n=17) start HCV treatment before transplant. For stem cells transplant recipients, main reasons to postpone DAAs are ongoing severe bacterial infection (35%, n=9), opportunistic infection (31%, n=8), relapse of HM (27%, n=7), graft-versus-host disease (27%, n=7).

Conclusions: DAAs prescribers consult few patients with HM, they agree on the need for DAAs treatment but the timing is widely variable. Data on optimal timing and safety of DAAs are urgently needed.

Pharmacokinetics study of cefiderocol in intensive care unit patients
Benoit Llopis*, Alexandre Bleibtreu², Pierre Jacquet³, Agathe Selves⁴, Benjamin Rohaut³, Helga Junot⁵, Charles-Edouard Luigt³, Noël Zahr¹

¹AP-HP Pitié-Salpêtrière Hospital, Department of Pharmacology and CIC-1421, Paris, France, ²AP-HP Hôpital Pitié-Salpêtrière, Service des maladies infectieuses et médecine tropicale, Paris, France, ³Department of Neurology, Neuro-ICU Brain & Spine Institute [ICM], Picnic-Lab AP-HP Sorbonne University, Pitié-Salpêtrière Hospital, Paris, France, ⁴Réanimation Chirurgicale et Polyvalente, AP-HP Sorbonne University, Pitié-Salpêtrière Hospital, Paris, France, ⁵Pharmacy Department, AP-HP Sorbonne University, Pitié-Salpêtrière Hospital, Paris, France, ⁶Médecine Intensive Réanimation Institut de Cardiologie Groupe Hospitalier Pitié-Salpêtrière, Assistance Publique – Hôpitaux de Paris Sorbonne Universités, UPME Université Paris O6 INSERM, UMRS_1166-ICAN Institute of Cardiometabolism and Nutrition, Paris, France

Background: Cefiderocol is a novel parenteral siderophore cephalosporine that shows potent efficacy against various Gram negative bacteria, including carbapenem-resistant strains, in vitro and in preclinical models of infection. Pharmacokinetics parameters of cefiderocol in patients are currently limited in the literature. The aim of this study was to characterize the pharmacokinetics of cefiderocol after multiple administrations in patients hospitalized in intensive care unit (ICU).

Materials/methods: Patients hospitalized in ICU, and treated with 3-hour intravenous infusions of cefiderocol were included in the study. For each patient, nine successive blood samples were collected at steady state: one sample prior to the start of the infusion for a residual concentration (C0), four samples at 30min, 1h, 2h and 3h during infusion and four samples at 15min, 1h, 2h and 3h after the end of the infusion. Cefiderocol plasma concentration was measured using an ultra-performance liquid chromatography system coupled with mass tandem spectrometry (UPLC-MS/MS), developed and validated in our laboratory. The pharmacokinetic parameters were performed using WinNonLin software.

Results: Seven patients were included in the study. They were treated for P. aeruginosa, A. xylosidans, K. pneumoniae or A. baumannii infection only susceptible to cefiderocol. Ventilated associated pneumonia was the most frequent infectious site [n=6]. The median age was 53 years old [23-73], patients were mostly women [4/7]. Patients were treated with a 2g TID regimen. The mean C0, Cmax, AUC0-8h, t1/2 and Vd were 42.1 ± 20.1 mg/L [21.5-76.3], 77.1 ± 12.9 mg/L [55.8-95.5], 448 ± 155 h.mg/L [306-682], 13 ± 11.3 h [3.3-30.8], and 26.7 ± 9.4 L [18.1-42.3], respectively. The coefficient of variation of C0, Cmax and AUC0-8h were 47.7%, 16.8% and 34.6%, respectively. One patient with renal hyperfiltration was treated with 2g QID regimen. For the QID regimen C0, Cmax, AUC0-6h, t1/2 and Vd were 18.5 mg/L, 75.6 mg/L, 228 h.mg/L, 1.4 h and 15.6 L, respectively.

Conclusions: This is the first prospective pharmacokinetic study of cefiderocol in intensive care unit patients. Our results suggest that there is significant inter-individual pharmacokinetic variability in this patient population; this argue to consider cefiderocol a candidate for therapeutic drug monitoring.

Abstract 9864

Dose and duration of antibiotic treatment in children with community-acquired pneumonia in UK/Ireland: results from the randomised, double-blinded, non-inferiority factorial CAP-IT trial

Julia A. Bielicki1,2, Wolfgang Stöhr1, Mark Lyttle1, Damian Roland1, Nishdha Naufal2, Kate Sturgeon2, David Dunn2, Diana Gibb2, Mike Sharland1

1St George’s University of London, London, United Kingdom, 2MRC Clinical Trials Unit at University College London, London, United Kingdom, 3University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom, 4University of Leicester, Leicester, United Kingdom

Abstract third-party references: On behalf of CAP-IT and PERUKI

Background: Amoxicillin is recommended for oral treatment of childhood community-acquired pneumonia (CAP). CAP-IT (ISRCTN76888927) investigated the effect of amoxicillin dose and duration on efficacy, safety and antimicrobial resistance.

Materials/methods: Children clinically diagnosed with uncomplicated CAP and planned for discharge from hospital or emergency departments were concurrently randomized (1:1 ratio) to 35-50 mg/kg or 70-90 mg/kg total daily dose and shorter (3d active, then 4d placebo) or longer (7d active) durations. The primary endpoint was clinically-indicated systemic non-trial antibiotic treatment for respiratory tract infection (RTI) during four weeks of follow-up as adjudicated by a blinded review committee. Adverse events and severity/duration of parent-reported symptoms and pneumococcal resistance were secondary endpoints. We tested, using time-to-event methods, the non-inferiority of lower dose to higher dose and shorter to longer duration (8% non-inferiority margin) for re-treatment.

Results: 824 children from 29 hospitals were randomized (February 2017 - April 2019). Ten never started any trial medication and were excluded. Median (IQR) age was 2.5 years (1.6-3.7); 52% male; 591/814 (73%) were discharged from ED; 223 (27%) from ward; 242 (30%) were on beta-lactam antibiotics at enrolment (100% <48h; 76% <24h). At presentation, 441 (54%) were febrile, 578 (71%) had tachycardia, 528 (65%) tachypnea. 767 (94%) children completed trial treatment. The primary endpoint was ascertained for 789 (97%) children. It occurred in 51/410 (12.6%) children receiving lower dose versus 49/404 (12.2%) higher dose (difference 0.4% [90%CI -3.7, 4.0]) and 51/413 (12.5%) shorter duration versus 49/401 (12.5%) longer duration (difference 0.1% [90%CI -3.8, 3.9]), both meeting non-inferiority criteria. Time to resolution of symptoms differed by randomization arm only for cough (median 2 days more with shorter duration, p=0.040) and sleep disturbance (p=0.026). There was a higher prevalence (p=0.005) of rash at day 8 in the longer treatment arm (9.3%) than the shorter treatment arm (4.1%), but mainly of slight severity.

Conclusions: In children with CAP discharged from hospital, the effectiveness of 3-day amoxicillin treatment was similar to 7-day treatment; 35-50 mg/kg/d was also non-inferior to 70-90 mg/kg/d. Analyses of antimicrobial resistance data are ongoing.

Abstract 9866

**Surprisingly low levels of measles immunity in persons with HIV: a seroprevalence survey in a United States HIV clinic**

Lindsey Rearigh*1, Sara Bares1, Susan Swindells1, Harlan Sayles1, Jennifer O’neill1, Maureen Kubat1

1University of Nebraska Medical Center, Omaha, United States

**Abstract third-party references:** Research Support Fund grant - Nebraska Medicine and the University of Nebraska Medical Center

**Background:** Measles outbreaks have become increasingly common due to deteriorating vaccination rates, fluctuating herd immunity, and varying antibody decline. Limited knowledge exists regarding prevalence and risk factors associated with measles seronegativity among persons with HIV (PWH).

**Materials/methods:** This was a cross-sectional study conducted at an academic HIV clinic in Omaha, Nebraska. All PWH presenting to the clinic from November 2019 through January 2020 were invited to enroll. Participants were screened for the presence of measles IgG antibody. Demographic and clinical information was obtained through electronic medical record review. T-tests, chi-square tests, and Fisher’s-exact tests were used to compare characteristics. Simple and multivariable logistic regressions were performed to identify risk factors for measles seronegativity.

**Results:** 351 participants were enrolled with a seronegativity rate of 29.7%. Mean age was 48 years (range 20 to 74), 77% were male and 53% Caucasian. Mean CD4 nadir was 334 cells/mm3 (range 1 to 1675). At the time of testing, 86% and 87% of the seronegative and seropositive participants had an HIV RNA <50 copies/mL, respectively. Younger age was significantly associated with measles seronegativity (p=0.003). Birth year before 1957 was associated with seropositivity (p=0.016), but 6% of seronegative participants were born before 1957. All other risk factors evaluated, including written documentation of adequate vaccination, were not associated with seronegativity.

**Conclusions:** Our study demonstrates a measles seronegativity rate that is remarkably higher than the rate reported in the general population (5%), and, more importantly, is significantly higher than the rate needed to maintain herd immunity (5-7%). With higher than expected seronegativity and absence of notable risk factors aside from age, our findings support expanded measles immunity screening and consideration of revaccination for PWH who are at risk of measles exposure.

**Characteristics Associated with Measles Seronegativity in PLWH**

A hospital outbreak of linezolid-resistant and vancomycin-resistant ST80 Enterococcus faecium harbouring an optrA-encoding conjugative plasmid investigated using whole-genome sequencing

Sarah Egan*1, Suzanne Corcoran1, Helene Mcdermott2, Milly Fitzpatrick1, Andrea Hoyne1, Olwyn Mccormack2, Brian O’connell2, Grainne Brennan3, David C. Coleman1

1Dublin Dental University Hospital, Dublin, Ireland, 2Bon Secours Hospital Dublin, Dublin, Ireland, 3St. James’s Hospital, Dublin, Ireland

Abstract third-party references: Dublin Dental University Hospital, Trinity College Dublin

Background: Ireland had the highest rates of vancomycin-resistant Enterococcus faecium (VREfm) bloodstream infections in Europe between 2006-2018. Linezolid-resistance (LR) following acquisition of the resistance genes optrA, poxtA and variants of the cfr gene have been reported with increasing frequency worldwide. Recently, Ireland was also found to have the highest prevalence (22.7%) of gene-encoded linezolid resistance in E. faecium and E. faecalis isolates from hospitalised patients reported to date. Resistance was predominantly encoded on conjugative plasmids in diverse enterococcal lineages.

Materials/methods: Between 22nd October and the 1st November 2019, 34 VREfm were recovered from patient screening swabs (n=14) and environmental sites (n=20) on two wards and radiology of an Irish hospital. All isolates were screened for LR genes by PCR and underwent Illumina MiSeq whole-genome sequencing. Isolate relatedness was assessed using E. faecium core-genome MLST (BioNumerics). MinION sequencing (Oxford Nanopore) and hybrid assembly were used to resolve an optrA-encoding plasmid (pM19/0995). Isolate MiSeq reads were mapped against pM19/0995 and the percentage depth and breadth of coverage was calculated using BedTools coverage.

Results: Thirty-two VREfm belonged to ST80, while two were single-locus variants of ST80. Seventeen LR-VREfm harboured optrA, whereas the remaining 17 linezolid-susceptible (LS) VREfm lacked LR genes. A closely related cluster of 23 isolates involving nine patients denoting an outbreak (17 LR-VREfm [6 patients] and six LS-VREfm [three patients]) was revealed with an average pairwise allelic difference of 2 [range 0-10]. A majority (16/17) of LR-VREfm harboured a 58,684 bp conjugative optrA-encoding plasmid (pM19/0995). Five of the 17 samples that yielded optrA-positive ST80 isolates also yielded optrA-negative isolates. In three cases, the optrA-negative isolates were genetically indistinguishable from optrA-positive samples from the same sample apart from the absence of pM19/0995. In the remaining two samples, the optrA-negative isolates had different genetic backgrounds from optrA-positive isolates from the same sample, indicating a mixed population. These findings indicated the spread of a single optrA-positive VREfm clone, following plasmid acquisition.

Conclusions: This demonstrates the transmissible nature of linezolid-resistance in VREfm. Acquisition of optrA by VREfm on a conjugative plasmid is of concern to public health as it reduces treatment options for infected patients.

Abstract third-party references: Funding for this research was provided by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA

**Background:** Invasive aspergillosis (IA) is a life-threatening disease with limited treatment options and is associated with delays ineffective treatment and significant early mortality. Posaconazole has been recommended as primary treatment, but novel [intravenous and oral] formulations of the broad-spectrum azole posaconazole are now also available.

**Materials/methods:** A randomised, prospective, phase 3, double-blind, double-dummy study compared posaconazole (1:1 randomisation) given for ≤12 weeks in the primary treatment of IA. More than 90 study sites in 23 countries enrolled subjects from 2013 through 2019 (ClinicalTrials.gov, NCT01782131; EudraCT, 2011-003938-14). Enrolled subjects were ≥13 years, weighed >40 to ≤150 kg and met criteria for proven, probable or possible disease per modified 2008 EORTC/MSG criteria. Those with chronic, relapse/recurrent or refractory IA were excluded. At randomisation, subjects were stratified by underlying disease risk [high risk: allogeneic stem cell transplant, liver transplant, relapsed AML]. Fungal disease classification and response outcomes were assessed by an independent adjudication committee (AC). Safety was monitored by an independent data monitoring committee. The primary endpoint was all-cause mortality through day 42 in the intent-to-treat population (ITT), with a 10% noninferiority margin.

**Results:** 575 randomly assigned subjects received ≥1 dose of study drug (ITT). The mortality rate through day 42 was 15.3% (44/288) in the posaconazole arm and 20.6% (59/287) in the voriconazole arm (95% CI: –11.5, 1.0). Of the 575 ITT subjects, 331 were AC-classified as having proven or probable infection [full analysis set [FAS] cohort]. Global clinical response rates in the FAS were similar between treatment groups: 45.4% and 45.0% at week 6 and 42.9% and 45.6% at week 12 for posaconazole and voriconazole, respectively. All subjects (ITT) were evaluated for safety. Reported drug-related adverse event (DRAE) rates in ITT subjects were 29.9% for posaconazole and 40.0% for voriconazole (95% CI: –12.9, –2.4). No deaths from DRAE occurred in posaconazole subjects versus three deaths from DRAE in voriconazole subjects.

**Conclusions:** Posaconazole was noninferior to voriconazole for the primary treatment of IA. Posaconazole [IV/tablet] was well tolerated with fewer DRAE. These findings support the use of posaconazole as primary antifungal therapy for IA.

Efficacy and Safety of Posaconazole versus Voriconazole for the Treatment of Invasive Aspergillosis
Fosfomycin vs meropenem or ceftriaxone for bacteremia urinary tract infections caused by multidrug-resistant Escherichia coli: a randomised trial (FOREST)

1Hospital Universitario Virgen Macarena, Seville, Spain, 2Hospital Virgen de la Arrixaca, Murcia, Spain, 3Hospital General Universitario de Alicante, Alicante, Spain, 4Hospital Universitari Vall d’Hebrón, Barcelona, Spain, 5Hospital de Cruces, Bilbao, Spain, 6Hospital Ramon Y Cajal, Madrid, Spain, 7Hospital Mutua de Terrassa, Barcelona, Spain, 8Hospital Universitario Reina Sofia, Córdoba, Spain, 9Hospital del Mar, Barcelona, Spain, 10Hospital San Espases, Palma de Mallorca, Spain, 11Hospital Marina Baixa, La Vila Joiosa, Alicante, Spain, 12Hospital Universitari de Bellvitge, Barcelona, Spain, 13Hospital Arnau de Vilanova, Lleida, Spain, 14Hospital Universitario Virgen del Rocío, Seville, Spain, 15Hospital Raya Villanueva, Zaragoza, Spain, 16Hospital General de Burgos, Burgos, Spain, 17Hospital Marqués de Valdecilla, Santander, Spain, 18Hospital 12 de Octubre, Madrid, Spain, 19Hospital Doctor Negrín, Las Palmas de Gran Canarias, Spain, 20Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain., 21Hospital Santa Creu i Sant Pau, Barcelona, Spain, 22Hospital Regional de Málaga, Málaga, Spain

Abstract third-party references: On behalf of REIPI/GEIRAS/FOREST group

Background: The objective of this study was to demonstrate the non-inferiority of fosfomycin in bacteremia urinary tract infections (BUTI) due to multi-drug resistant E. coli (MDREC).

Materials/methods: A multicenter, open, randomised controlled trial in patients with BUTI due to MDREC comparing (1:1) intravenous fosfomycin (4 g/6h) vs. meropenem (1 g/8h) or ceftriaxone 1 g/24h if susceptible as targeted treatment was performed. Switch to oral drugs was allowed after 5 days. Randomisation was stratified by appropriate empirical therapy and cephalosporin-resistance. Endpoints were: primary, clinical and microbiological cure (CMC) at test-of-cure (TOC) in the modified intention-to-treat (mITT) population; secondary, clinical cure (CC) and microbiological cure (MC) in the clinically and microbiologically evaluable populations (CEP, CMP), respectively, 30-day mortality, recurrences and adverse events (AE). The calculated sample size for a non-inferiority margin of 7% was 198 patients. The study was funded by Instituto de Salud Carlos III; Registration: NCT02142751.

Results: 161 patients from 16 sites could be randomized; 143 formed the mITT population; 70 received fosfomycin and 73 the comparator (42 meropenem, 31 ceftriaxone). Both groups were similar in baseline features: median age, 70 years; male, 49%; Charlson index ≥3, 31%; urinary catheter, 30%; community-acquired infection, 50%; sepsis/shock, 26%; inappropriate empirical treatment, 26%. The endpoints are shown in the Table. More patients in the fosfomycin group did not reach CMC for reasons other than failure (12 [17.1%] vs. 4 [5.4%]; p=0.01). Six patients treated with fosfomycin and 1 with comparator suffered a heart failure [probable or definitive]. Two patients treated with fosfomycin developed a skin rash.

Conclusions: Even if the calculated sample size would be achieved, it is improbable that fosfomycin could demonstrate to be non-inferior to carbapenem or ceftriaxone for CMC; however, more patients in the fosfomycin arm did not reach CMC for reasons other than clinical and microbiological failure. In fact, failure, clinical or microbiological cure rates were similar in both arms in the appropriate populations. Withdrawn of patients because of AE was more frequent with fosfomycin, which must be interpreted considering the open design, but caution is needed in patients at risk of heart failure. Recurrences were more frequent with fosfomycin.

Abstract 9879

**Safety, tolerability and clinical outcomes of RSV infection challenge in older adult volunteers**

Pete Dayananda*1, Stephanie Ascough1, Zoe Gardener1, Emma Bergstrom1, Seng Kuong Ung1, Mohini Kalyan1, Veda Avadhan1, Satwik Kar1, Suzanna Paterson1, Malcolm Begg2, Edith Hessel2, Peter Openshaw3, Christopher Chiu1

1Imperial College London, Department of Infectious Disease, London, United Kingdom, 2GlaxoSmithKline, Medicines Research Centre, Stevenage, United Kingdom, 3Imperial College London, National Heart and Lung Institute, London, United Kingdom

**Background:** Respiratory syncytial virus (RSV) causes bronchiolitis in infants and is increasingly recognised as a cause of severe disease in the elderly. Current understanding of human immunity against RSV infection is incomplete and neither specific treatments nor effective vaccines are yet available. Controlled human RSV infection studies of healthy adult volunteers enable detailed longitudinal analysis of immune responses but studies in higher-risk volunteers have not previously been performed. To extend the applicability of the model to those at higher risk, we now report the development, safety and clinical outcomes of a human infection challenge study in older adults.

**Materials/methods:** We contacted and screened 381 prospective participants using health and protocol-defined inclusion/exclusion criteria. Twelve healthy adult volunteers aged 60-75 were inoculated intranasally with 10^4 PFU RSV Memphis-37, quarantined for 10 days and followed up for 6 months. All volunteers completed self-reported symptom diaries; viral load was measured daily by qPCR of nasal lavage and antibodies were quantified in serum and respiratory secretions.

**Results:** Of 381 participants contacted, 251 replied and 155 were excluded following pre-screening questions. Ninety-six participants were eligible for full screening; 24 attended and 12 were excluded based on safety-screening results. Following inoculation, 9 of 12 participants developed PCR-confirmed RSV infection. Reported symptoms were mild/moderate with no clinical/self-reported systemic symptoms, hence no trial ‘pausing/stopping’ rules were met. None of the volunteers developed fever (≥38°C) or had a National Early Warning Score (NEWS) >3, which would trigger clinical review.

On average, symptoms started on Day 4 post-inoculation and peaked at Day 7. The symptoms were primarily upper respiratory tract in nature and resolved by Day 10 post-inoculation. Up to Day 28, no participants reported unexpected adverse events or symptom recurrence.

**Conclusions:** We show that experimental infection with RSV in selected older adults has an acceptable safety profile with good attack rate and symptom distribution. We anticipate that efficacy testing of new therapeutic and vaccine candidates in this more clinically relevant age group will decrease the lead time from discovery to clinical practice and enable better understanding of age-related immunological changes and protective immunity against RSV in healthy older adults.

Different impact of modification of voriconazole therapy following therapeutic drug monitoring (TDM) on the prevention of hepatotoxicity and visual symptoms: Japanese multicenter study

Takashi Ueda1, Yoshio Takesue*1, Yukihiro Hamada1, Kazuhiko Nakajima1, Keiko Fukunaga1, Taiga Miyazaki2, Nana Nakada-Motokawa2, Miki Nagao2, Hideki Kawamura3, Akari Shigemi2, Fumiya Ebihara2, Kazuhiro Ikegame3, Toshimi Kimura2, Yoshitsugu Miyazaki7

1Hyogo College of Medicine, Department of Infection Control and Prevention, Nishinomiya, Japan, 2Tokyo Women’s Medical University Hospital, Department of Pharmacy, Tokyo, Japan, 3Hyogo College of Medicine, Department of hematology, Nishinomiya, Japan, 4Nagasaki University Hospital, Department of Respiratory Medicine, Nagasaki, Japan, 5Kyoto University Hospital, Department of Infection Control and Prevention, Kyoto, Japan, 6Kagoshima University Hospital, Department of Infection Control and Prevention, Division of Medical and Environmental Safety, Kagoshim, Japan, 7National Institute of Infectious Diseases, Department of Chemotherapy and Mycoses, Tokyo, Japan

Background: The pooled risk for hepatotoxicity was 13.6% and that for visual symptoms was 15.7% in patients underwent voriconazole therapy. We retrospectively evaluated the impact of antifungal stewardship on the modification of voriconazole treatment based on TDM, and the occurrence of adverse effects.

Materials/methods: Patients were reviewed at 5 institutions. Target trough concentration (Cmin) was defined as 1–5 µg/mL. Hepatotoxicity was defined as AST/ALT above three times normal/baseline.

Results: 401 patients were included. Loading dose was performed in 46.9%. Median maintenance dose was 3.8 mg/kg twice daily [interquartile range (IQR) 3.2–4.1]. Median day of TDM was 6 [IQR 5–7]. Modification was conducted in 103 of 108 patients with high initial Cmin (discontinuation 32; dose reduction 71) and in 23 of 44 patients with low initial Cmin (discontinuation 4; dose increase 19). Subsequent Cmin achieved target range in 77.9% of patients with dose reduction and 88.0% of patients with dose increase. Hepatotoxicity and visual symptoms occurred in 6.0% and 9.5%, respectively. Median day of the occurrence of adverse effect was 10 days [IQR 8–19] in hepatotoxicity and 4 days [IQR 2–7] in visual symptoms. Although higher initial Cmin tended to cause visual symptoms [area under the curve (AUC) 0.603, p=0.050, odds ratio (OR) 3.59], there was no significant correlation between hepatotoxicity and initial Cmin (AUC 0.562, p=0.292, OR 1.67), which mean the effect of dose modification based on initial Cmin. In contrast, significant correlation with Cmin at the occurrence of adverse effect was demonstrated in hepatotoxicity [AUC 0.725, p<0.001, OR 5.20] and visual symptoms [AUC 0.684, p<0.001, OR 5.89]. Cut-off Cmin to discriminate the occurrence of adverse effects was 3.5 µg/mL in hepatotoxicity and 4.2 µg/mL in visual symptoms. In patients without immediate discontinuation, 14 of 15 patients with hepatotoxicity and 27 of 30 patients with visual symptoms completed voriconazole therapy.

Conclusions: Low incidence of hepatotoxicity was demonstrated with the modification of voriconazole therapy. Because of early occurrence, significant impact on the prevention of visual symptoms was not obtained. A lot of patients with hepatotoxicity and visual symptoms completed voriconazole therapy with antifungal stewardship.

Abstract 9896

**Validation of an isothermal amplification platform for microbial identification and antimicrobial resistance detection in blood: a prospective study**

Harish Mallapura Maheshwarappa1, Prasadini Guru2, Snehali Majumder2, Vishakha Mangale1, Reddy Sailaja Mundre1, Nima Lawrence3, Albein Sigamani2, Sudeshna Adak2

1Department of Critical care medicine, Mazumdar Shaw medical center, Narayana Hrudayalaya, Bengaluru, India, 2Narayana Hrudayalaya Hospital, Mazumdar Shaw medical center, Narayana Hrudayalaya, Bengaluru, India, 3Omix Research & Diagnostics Laboratories Pvt Ltd, Bangalore Bioinnovation Centre, Bangalore, India

**Background:** Blood stream infections (BSI) and the associated complications remain a leading cause of morbidity and mortality in the hospital Intensive care unit setup. Nucleic acid amplification technique (NAAT) based identification of pathogens in BSI has revolutionized molecular diagnostics in comparison to traditional clinical microbiology practice of blood culture for pathogen detection. Main aim of the study was to evaluate an in-house developed lyophilized OmiX RapID Pathogen test based on isothermal amplification technology for the detection of top six BSI causing bacteria along with two major antimicrobial resistance (AMR) markers of Carbapenem and compare with to traditional blood culture-based detection and to establish concordance between the tests.

**Materials/methods:** 143 subjects admitted to Medical Intensive Care Unit (MICU) at Mazumdar Shaw Medical Center, A unit of Narayana Hrudayalaya, Bangalore, with either suspected or proven BSI, of either gender, of age >=18 years were enrolled for the study. Pathogen DNA was extracted from 200 µl blood culture sample using OmiX pReP method and amplified at isothermal conditions of 65°C and analyzed at real time using OmiX READ software.

**Results:** Among the processed 143 samples, 54 were true negative, 83 were true positive, 3 were false negative and 2 were false positive as analyzed by OmiX READ software. 91.3% of Gram-negative bacteria and 75% of Gram-positive bacteria were detected in true positive cases. With specificity of 100% and sensitivity of 95.69%, the OmiX RapID Pathogen detection kit could identify correct pathogens, even polymicrobial infection, along with the AMR markers in 4 hours of time.

**Conclusions:** We successfully demonstrated that OmiX RapID Pathogen test detects pathogens with 96.5% concordance in comparison to traditional blood culture. Henceforth, OmiX RapID Pathogen test can be used for diagnostic purpose in bacterial BSI. The study would help further to develop the OmiX pathogen DNA extraction and detection in whole blood independent of traditional culture techniques.

Therapeutic drug monitoring of antibiotics in intensive care patients treated with extracorporeal membrane oxygenation (ECMO): an observational single-center study

Dennis Kühn*1, Carlos Metz1, Frederik Seiler1, Holger Wehrfritz2, Mohammad Alqudrah1, Andre Becker1, Robert Bals1, Mathias Hoffmann1, Ulrich Hübner1, Jürgen Geisel1, Philipp Lepper1, Sören Leif Becker1

1Saarland University Hospital, Homburg, Germany

**Background:** Effective antimicrobial treatment is key to reduce the high mortality of bacterial sepsis in patients on intensive care units (ICUs). Dose adjustments are often necessary to account for pathophysiological changes or renal replacement therapy. Extracorporeal membrane oxygenation (ECMO) is increasingly being used for the treatment of respiratory and/or cardiac failure. However, it remains unclear whether dose adjustments are necessary to avoid subtherapeutic drug levels in septic patients on ECMO support. To evaluate and comparatively assess the mean serum concentrations of continuously applied antibiotics in intensive care patients being treated with and without ECMO.

**Materials/methods:** Between November 2018 and December 2019, we prospectively enrolled patients on a pneumological intensive care unit in southwest Germany who received antibiotic treatment with piperacillin/tazobactam, ceftazidime, meropenem, or linezolid. All antibiotics were applied using continuous infusion, and therapeutic drug monitoring of serum concentrations (expressed as mg/L) was carried out using high-performance liquid chromatography. Target concentrations were defined as 4-fold above the minimal inhibitory concentration (MIC) of susceptible bacterial isolates, according to EUCAST breakpoints.

**Results:** The final cohort comprised 105 ICU patients, of whom 30 were treated with ECMO. ECMO patients were significantly younger (mean age: 47.73 vs. 61.15 years; p=0.001), required haemodialysis more frequently (53.3% vs. 32.0%; p=0.048) and had an elevated ICU mortality (60% vs. 22.7%; p=0.0005). In the ECMO group, mean antibiotic serum concentrations were significantly lower for piperacillin (42.2 vs. 72.5; p=0.004), high-dose meropenem (6g/d) (22.0 vs. 41.5; p=0.022) and linezolid (8.2 vs. 12.6; p=0.005). We found high rates of insufficient antibiotic serum concentrations among ECMO patients, which did not reach the pre-specified MIC target (piperacillin: 48.4% vs. 13.0% in non-ECMO; linezolid: 34.8% vs. 15.0% in non-ECMO; meropenem standard-dose (3g/d) 6.1% vs. 3.1% in non-ECMO), whereas no such difference was observed for ceftazidime and meropenem in high-dose.

**Conclusions:** ECMO treatment was associated with significantly reduced serum concentrations of piperacillin, linezolid and, to a lesser extent, meropenem. Future studies are needed to assess the pharmacokinetic characteristics of antibiotics in ICU patients on ECMO support.

Abstract 9898

Prospetive validation in children with adenovirus detection of a TRAIL/IP-10/CRP host-proteinassay for guiding antibiotic treatment decisions

Liat Etshtein1, Alberto Argentiero2, Cihan Papan3,4, Tanya Gottlieb1, Eran Barash1, Niv Mastboim1, Liran Shani1, Einaiv Simon1, EinnatMoscovitz1, Tahlil Ilan-Ber1, Roy Navon1, Asi Cohen1, Meital Paz2, Olga Boico5, Ellen Bamberger6, Kfir Oved7, Eran Eden7, EdoardoFarinelli7, Ilaria Testa7, Maria Bruna Pastiacci7, Daniele Mezzetti7, Katia Perruccio7, Marian Porwoll8, Ummayah Hakimi7, AmSimon7, Johannes Liese6, Markus Knuf9, Michaeld Stein10, Renata Yacobov7, Sven Schneider7, Susanna Esposito12, Tobias Tennenbaum11

Background: Adenovirus infection can trigger bacterial-like immune responses leading to misdiagnosis and unwarranted antibiotic prescription. Previous studies showed that a host-protein assay comprising TNF-related apoptosis induced ligand (TRAIL), interferon gamma induced protein-10 (IP-10) and C-reactive protein (CRP) accurately differentiates between bacterial and viral infections. Here we examine the potential of the signature to reduce antibiotic misuse among adenovirus positive children.

Materials/methods: Children aged > 90 days with fever without source or respiratory tract infection were recruited in a prospective study at pediatric emergency departments [ED] in Germany and Italy [AutoPilot-Dx; grant #701088; NCT03052088]. Infection etiology was adjudicated by unanimous decision of three independent experts based on clinical, laboratory, radiological and follow-up data. Viruses were detected using multiplex PCR on nasopharyngeal swabs. The host-protein assay [ImmunoXpert™, MeMed] gives three possible outcomes: viral, bacterial or equivocal; equivocal is a valid result that does not provide clear-cut etiology determination.

Results: 628 out of 732 children (mean age 3.5 years, 41.9% female) with unanimous adjudication were assigned viral etiology. Of these, 78 (12.4%) had PCR detection of adenovirus [Panel A], with predominantly upper respiratory tract clinical syndromes [Panel B]. Twenty-three out of 78 adenovirus positive children were given antibiotics, representing overuse of 29.5%. Adoption of the host-protein assay would lead potentially to only 8 out of 78 adenovirus positive children being given unwarranted antibiotics [Panel C]; hence, a 3-fold reduction in antibiotic overuse (p-value < 0.01).

Conclusions: This study shows the potential of timely host-protein assay results in aiding the determination of infection etiology and reducing unwarranted antibiotics among adenovirus positive children.

Effect of CMV replication on relapse and survival in pediatric AML
Jörn-Sven Kühl¹, Sebastian Voigt*²
¹Universitätsklinikum Leipzig, Leipzig, Germany, ²Robert Koch Institute, Berlin, Germany

Background: Several studies have indicated better survival after stem cell transplantation (SCT) for acute leukemias, especially acute myeloid leukemia (AML), in case of cytomegalovirus (CMV) reactivation. Here, we investigated if CMV reactivation had an impact on survival after SCT for AML or acute lymphoid leukemia (ALL) in children.

Materials/methods: 177 pediatric allogeneic stem cell transplant recipients from our institution who received myeloablative conditioning were included. Transplant indications included AML, T-ALL and B-precursor ALL. CMV reactivation was correlated with relapse, mortality as well as acute graft-versus-host disease (GVHD) and was analyzed by Fisher’s Exact test or Chi-Square test (if n>100).

Results: From 177 patients included, 42 were transplanted for AML (24 %), 22 for T-ALL (12 %), and 113 for B-precursor ALL (64 %). Mortality and relapse rates (27-37% and 18-26%, respectively), CMV reactivation rates (21-36%) as well as numbers of negative CMV serology status (19-32%) of donor and recipient were comparable between different acute leukemias. When patients were analyzed altogether, CMV reactivation had no effect on relapse rates or mortality. However, a tendency towards fewer relapses after CMV reactivation was observed in AML patients (no relapse (0%) with CMV reactivation vs. 11 relapse cases (33%) without CMV reactivation; p=0.083). In those 128 leukemia patients capable of reactivating CMV, CMV reactivation had a protective effect on relapse rates in AML (no relapse (0%) with CMV reactivation vs. 11 relapse cases (44%) without CMV reactivation; p=0.017). Different effects of CMV on relapse rates and mortality in AML versus B-precursor ALL were noticed in 79 patients who did not reactivate CMV or who did reactivate CMV post SCT. In 17 AML patients, there were no relapses (0%) and 2 deaths (12%) in contrast to 17 relapse cases (27%) and 24 deaths (39%) in 62 children with B-precursor ALL (p=0.017 and p=0.044, resp.).

Conclusions: Latently CMV infected AML patients without documented CMV reactivation after SCT have a significant worse prognosis compared with all other AML patients. The protective effect of CMV reactivation in AML does not appear to be GVH-related.

Abstract 9907

**In vivo efficacy of NP339 against Invasive Pulmonary Aspergillosis (IPA)**

Daniel Smith*1, Laura Katvars1, Deborah O’neil1

1 NovaBiotics Ltd, Bridge of Don, United Kingdom

**Background:** NP339 is a novel, cationic, synthetic antifungal peptide with anti-mould and anti-yeast activity demonstrated *in vitro*. NP339 is highly differentiated from existing antifungal drug classes with a membrane-targeting, rapidly fungicidal mechanism of action. NP339 is being developed for intravenous and also inhaled administration as an intervention for invasive pulmonary aspergillosis (IPA). Here we demonstrate the *in vivo* efficacy of nebulised NP339 in a murine model of IPA.

**Materials/methods:** Immunosuppressed, male CD1 mice were infected via intranasal administration of *A. fumigatus* conidia. NP339 was nebulised as a monotherapy (*n*=8 mice/treatment group). Lung burden of *A. fumigatus* was assessed by plating of homogenates at clinical end point. A second model investigated the combination of NP339 & AmB. Survival and serum Galactomannan index (GMI) was assessed for up to 96h. *In vitro* interactions of NP339 and AmB were determined in parallel by broth microdilution checkerboards vs. four *A. fumigatus* strains. Metabolic activity was assessed at 24h by way of resazurin and FICIs were determined and annotated (Burkhart *et al* 2006).

**Results:** Nebulised NP339 monotherapy elicited a reduction in lung burden relative to vehicle control in a murine model of IPA. In subsequent experiments, all untreated mice and those given single treatments (NP339 or AmB only) succumbed to infection and were euthanised before the end of the study. In contrast, 25% of animals survived to 96h in the groups given both nebulised NP339 & IV AmB. Serum GM levels and mouse weight at day 3 also tracked with these findings. *In vitro* combinations of NP339 and AmB were additive against *A. fumigatus* with no negative drug interactions observed.

**Conclusions:** This initial study demonstrates the *in vivo* efficacy of nebulised NP339. Combining NP339 with a parenterally administered antifungal led to survival of test subjects in a well-established murine model of IPA. This data supports the future development of NP339 as a component of a dual therapy for IPA. Although there is potential to apply nebulised NP339 (to directly address lung tissue burden) in combination with other antifungal agents (to target disseminated infection), NP339 will be developed for administration by both routes for optimal outcomes.

Abstract 9911

**Global distribution of the known mobile colistin resistance: mcr genes across different microbiomes**

Qiang Lin*, Basil Britto Xavier¹, Blaise Alako², Alex Mitchell², Sahaya Rajakani¹, Robert Finn², Guy Cochrane², Surbhi Malhotra-Kumar¹

¹University of Antwerp, Laboratory of Medical Microbiology, Vaccine & Infectious Disease Institute, Antwerp, Belgium, ²Wellcome Genome Campus, European Molecular Biology Laboratory, European Bioinformatics Institute, Cambridge, United Kingdom

**Background:** Colistin is one of the last-line antibiotics for treatment of carbapenem-resistant Enterobacteriales, and its increasing use has led to the emergence of resistance in these and other Gram-negative pathogens. The extensive discovery of mobilised colistin resistance (mcr-1 to mcr-9), across pathobionts and plasmid types, highlights their transmissibility, posing a potential threat to human and animal health. We screened metagenomes from different sources and continents to gauge the prevalence and distribution of known mcr genes.

**Materials/methods:** For this global surveillance 11522 publicly available metagenomic assembly data (2008-2019), from ENA and other public databases, covering 32 different types of microbiomes across six continents, were screened using tblastn [Fig. 1a]. The full-length protein sequences of all known mcr genes (mcr-1 to mcr-9), were queried on ≥ 98% identity and 100% coverage. Exact sequence hits were extracted along with associated metadata including geographic, temporal and other information. This geographic distribution of mcr genes represented by latitude and longitude (regions) was visualized using the R (v.3.6) package “ggplot”.

**Results:** In total, 113 mcr gene hits (mcr-1, mcr-3, mcr-4, mcr-8 and mcr-9) were from 51 samples across 7 different microbiomes, and distributed in 23 regions across six countries and four continents [Fig.1b]. Over 70 % (n=83) of the mcr genes were detected in human gut metagenomes. Mcr-9 was most prevalent overall (n=79), in terms of highest temporal prevalence in metagenomes from the human gut (n=73), bioreactors (n=2), food (n=2) and fermentation (n=1) [Fig. 1c]. Mcr-3 (n=18) as the second most prevalent gene was found only in wastewater and freshwater metagenomes. Mcr-1 was frequently present but only in human gut metagenomes (n=12). Mcr-9 distributed most widely in 8 regions across North America, Europe, Asia and Africa, and mcr-1 and mcr-3 distributed in 3 regions across Europe, Asia and North America [Fig. 1b]. Mcr-4 and mcr-8 were only detected in one region of North America and Asia, respectively.

**Conclusions:** Our results show that the recently discovered mcr-9 is the most widely distributed mcr variant geographically and temporally. Importantly, we identified human gut metagenomes as the primary reservoir of these easily transmissible colistin resistance genes.

Abstract 9916

**Legionella pneumophila urinary antigen testing during an outbreak: Read it or not**

Jos Van Acker*, Elke Vanlaere1, Charlotte Verfaillie1, Anne-Marie Van Den Abeele1, Filip Triest2, Naïma Hammami3, Fedoua Echahidi4

1 Algemeen Ziekenhuis St-Lucas, Laboratory of Clinical Microbiology, Gent, Belgium
2 Algemeen Ziekenhuis St-Lucas, Department of Respiratory Diseases, Gent, Belgium
3 Flemish Government, Agentschap ZORG & Gezondheid, Gent, Belgium
4 UZ Brussel, Laboratory of Microbiology, Jette, Belgium

**Background:** Legionnaires’ disease (LD) is a severe form of pneumonia, mostly caused by *Legionella pneumophila* (L.pn) serogroup 1. A qualitative L.pn urinary antigen test (LUAT) based on lateral flow immuno-chromatography is commonly used in clinical laboratories for the rapid diagnosis of LD. The antigen test can be read visually, or in conjunction with an automatic reader. However, not much is known about the real life benefit of such a reader for objective LUAT interpretation. During May and June 2019 an outbreak of L.pn serogroup 1, eventually linked to a cooling tower, caused 32 cases of LD around an industrial zone in Ghent, Belgium. We demonstrate the diagnostic impact of the systematic use of an automatic LUAT reader during this outbreak.

**Materials/methods:** In our secondary care hospital lab, urine samples of possible LD cases are analyzed with LUAT (Abbott BinaxNOW™ Legionella Urinary Antigen Card used with DIGIVAL™ reader) and lower respiratory samples, when available, with real-time PCR (BioGX Mycoplasma pneumoniae, Legionella pneumophila and Chlamydia pneumoniae open system reagents for BD MAX™) following manufacturer instructions. Positive respiratory samples are sent to the national reference lab (NRC UZ Brussels) for confirmatory testing by culture and PCR for L.pn and Legionella spp.

**Results:** During the outbreak our lab performed a total of 319 LUAT and 81 PCR. Twenty out of 32 LD cases (62.5%) linked to this outbreak were diagnosed in our lab. All these cases were LUAT positive. Noteworthy, seven of them (35%) were visually negative, but positive with the reader. A lower respiratory sample was available for 13 cases (65%), of which 3 were only reader positive on the urine sample. All 13 samples were PCR positive and confirmed at the NRC. No false positive LUAT results were seen.

**Conclusions:** During a LD outbreak, the use of an automatic reader increased the diagnostic sensitivity of LUAT considerably without loss of specificity.

DAV132 protects intestinal microbiota of patients treated with quinolones. A European phase II randomized controlled trial

Annie Ducher1, Maria J.G.T. Vehreschild2, Thomas Louie3, Oliver A. Cornely4, Celine Feger1, Aaron Dane6, Marina Varastet1, Jean De Gunzburg1, Antoine Andremon1,7, France Mentre7, Mark H. Wilcox8

1Paris, Da Volterra, Paris, France, 2Frankfurt, University Hospital, Frankfurt, Germany, 3Calgary, Cumming School of Medicine, University of Calgary, Calgary, Canada, 4Cologne, Clinical Trials Centre Cologne, Germany, 5Cologne, University of Cologne, Cologne, Germany, 6Macclesfield, Danestat, Macclesfield, United Kingdom, 7Paris, INSERM U1137, IAME, Paris, France, 8Teaching Hospital & University of Leeds, Leeds, United Kingdom

Background: Antibiotic treatments elicit intestinal microbiota dysbiosis with short and long-term deleterious effects. A colon-targeted adsorbent, DAV132, prevents dysbiosis in healthy volunteers and so may protect antibiotic-treated patients.

Materials/methods: An open label, randomized clinical trial targeted hospitalized patients treated with oral/iv fluoroquinolones (FQ) for lower respiratory or urinary infections or febrile neutropenia prophylaxis. Patients were randomised 1:1 to receive DAV132 (7.5g tid orally), or not, during FQ treatment. Central laboratories evaluated plasma concentrations of FQ after 4d by LC-MS/MS, free faecal FQ concentrations, αβ diversity of the intestinal microbiota (16S rRNA gene profiling) at D1, D4, D6, End-of-FQ, 10 days after End-of-FQ, and 30 days after End-of-FQ. Resistance to colonisation by C. difficile (Cd) was assessed ex-vivo [suppression of Cd proliferation]. The primary endpoint [proportion of adverse events (AE) related to DAV132 and/or FQ] was adjudicated by blinded independent experts.

Results: 260 hospitalized patients at 24 sites (median age 71, ≥1 chronic comorbidity: 96%) were treated for 7.5d on average (79% iv) with levofloxacin (43%), ciprofloxacin (40%) or moxifloxacin (17%). Compared with the No-DAV132 arm, faecal FQ levels in DAV132-treated patients were reduced by more than 98.8%, whilst plasma levels did not change significantly. During FQ treatment, significant differences in all metrics of intestinal microbiota diversity were observed between the two arms, such as changes from D1 of the Shannon index at End-of-FQ (Δmean ± SEM at End-of-FQ: 0.56 ±0.17, p.003). The proportion of patients with DAV132- and/or FQ-related AEs did not differ significantly between arms ([4.8 vs. 10.8%, difference of proportions: 4.0%; 95% CI [-4.7; 12.6]]. No Cd infection occurred. Ex-vivo resistance to colonisation by Cd was markedly reduced in stool samples of patients receiving FQ only, but was maintained in those co-administered DAV132 (p=0.0003). Faecal carriage of vancomycin-resistant enterococci (VRE) was reduced in DAV132 treated patients (p=0.01).

Conclusions: DAV132 was well tolerated in elderly hospitalized patients with comorbidities. It neither altered antibiotic plasma concentrations nor elicited changes in concomitant drugs regimens. Intestinal microbiota diversity was protected and resistance to colonization by Cd was preserved. DAV132 is a promising, novel product to prevent antibiotic-induced intestinal dysbiosis.

Abstract third-party references: Wojciech Swidzinski, Senior Field Applications Specialist EMEA, Luminex Corporation

Background: Reliable, simple and fast detection of SARS-CoV-2 seems to be a key element in the worldwide public health and individual patient management of the ongoing global COVID-19 outbreak. New ubiquitous walk-away PCR platforms with an open channel for lab developed tests (LDT) could increase diagnostic capacity, especially if set up in close cooperation with (and quality controlled by) a national reference lab. As the ARIES platform (Luminex) was already implemented in 4 labs of the Bilulu vzw group across Flanders, Belgium, we investigated transferring the design of the reference lab method of the University Hospitals of Leuven to this efficient platform, targeting the SARS-CoV-2 E-gene and ORFab region.

Materials/methods: As an initial design, EvaGreen dye was used to test the two primer sets separately with a positive RNA extract from SARS-CoV-2 provided by the national reference lab, on the ARIES system. RNA extract or a negative control were added directly into the ARIES PCR tube, together with primer mix and EvaGreen dye while nuclease free water was added to the sample chamber. Additionally, a patient sample, positive for HCoV-HKU1 (NxTAG Respiratory Pathogen Panel, Magpix, Luminex), was tested for possible cross-reactivity. Luminex SYNCT software was used to interpret PCR results and melting curves.

Results: Both targets, E-gene (ct value 16) and ORFab region (ct value 19.9) were detected for the RNA extract from SARS-CoV-2.

Conclusions: A first proof of concept implementing a consensus molecular SARS-CoV-2 screening on the ARIES instrument was successful. With a hands-on-time of 10 minutes, a turn-around-time of 2 hours and 5 minutes at a cost less than 30 EUR, this assay can be a simple and feasible 24/7 solution for many labs. Inter-laboratory testing and close cooperation with a national reference lab could support a safe and high quality expansion of testing capacity.

Background: The recent description of sequential inflammatory stages characterizing early tuberculosis (TB) disease and reports of disease caused by differentially culturable M. tuberculosis have significantly complicated the diagnostic landscape. These detection gaps threaten global TB elimination goals.

Materials/methods: During early development of a new ultrasensitive molecular TB assay, we tested consecutive anonymized respiratory samples submitted to the microbiology laboratory for routine non-TB testing from patients admitted to a safety net hospital in Boston, and consecutive anonymized control samples from a community hospital. We subsequently performed a longitudinal study to determine clinical associations and outcomes.

Results: 18/146 (12.6%) anonymized specimens tested positive for M. tuberculosis DNA (TB-DNA), compared to 1/50 (2%) controls (p=0.03). The prospective study included 101 patients [median age 59, 63% male, 70% US-born]; 16/101 (15.8%) tested TB-DNA positive, with a clear bimodal age distribution. Whereas older TB-DNA positive subjects [n=12, mean age 62] had various infectious and non-infectious clinical syndromes commonly encountered in hospitalized patients, 3/4 young TB-DNA positive patients [mean age 22] presented with acute chest syndrome [3/16 vs. 0/85; p=0.003]. TB-DNA positive individuals were more likely to have been tested for M. tuberculosis infection prior to study inclusion [p=0.03], to be TST or IGRA-negative [p<0.001], and to have anemia [p=0.002] a known laboratory marker of TB disease. During a median 1,819 days [interquartile range 1,658–1,842] of follow up, 6/16 (38%) TB-DNA positive patients died a median 390 days [5–694] after hospital discharge, compared to 21/85 (25%) of those TB-DNA negative that died after a median 26 days [14–102] after discharge (p=0.30). Most TB-DNA positive patients died from septicemia [67% vs 14%, p=0.02].

Conclusions: We unexpectedly detected M. tuberculosis DNA in a presumably low TB risk population. In addition to unmasking novel clinical associations, our findings suggest a paucibacillary and inflammatory form of TB disease that is currently clinically unsuspected and undetectable with existing tools. These results require further investigation given the potential implications for patient outcomes and public health.

Abstract 9930

Seven versus 14 days of antibiotic treatment for male urinary tract infection (PROSTASHORT): a randomized study

Matthieu Lafaurie*, Lelia Escaut1, Louis Bernard1, Caroline Gatey2, Antoine Froissart2, Anne Bourgarit3, Vanina Meyssonni4er, Amelie Chabrol5, Sylvie Chevret1, Jean-Michel Molina6, Agnes Lefort10

1Hospital Saint-Louis AP-HP, Paris, France, 2Kremlin Bicetre hospital, Bicetre, France, 3Tours hospital, Tours, France, 4Clamart hospital, Clamart, France, 5CHIC, Creteil, France, 6Hospital Jean-Verdier, Bondy, France, 7La croix saint simon, Paris, France, 8Hospital sud francilien, Corbeil, France, 9Hospital Saint-Louis AP-HP, Paris, France, 10Beaujon hospital, Clichy, France

Background: Despite a paucity of data on the optimal antibiotic duration for male urinary tract infections (UTI), current guidelines recommend antimicrobials for at least 14 days. Shorter duration may expose patients to recurrence whereas longer duration may lead to more side effects, C. difficile infections and increased antimicrobial resistance.

Materials/methods: Multicenter, non-inferiority (10% margin), double blind, randomized placebo-controlled trial comparing a short (7 days) versus a standard (14 days) treatment duration for febrile adult male UTI. After a 3-day initial treatment consisting in ofloxacin (400 mg/d), cefotaxime (3g/d) or ceftriaxone (1g/d), patients were assigned to receive oral ofloxacin, 200 mg bid, for 4 days and placebo for 7 days (short treatment arm) or oral ofloxacin 200 mg bid for 11 days (standard treatment arm). Male adults with febrile UTI defined by fever, at least one sign of UTI and urinary culture yielding a single pathogen, susceptible to quinolones and 3rd generation cephalosporin and normal ultrasound findings were randomized at day 3 if fever had resolved (T<38°C). Randomization was stratified on center, age and urological history. Main non-inclusion criteria were: septic shock, nosocomially acquired UTI, UTI in the past year, current urinary catheter.

The primary endpoint was resolution of fever and sterile urine up to 4 weeks after the end of treatment. Secondary outcomes included the acquisition of intestinal carriage of resistant gram-negative bacilli, the incidence of drug related adverse events and the recurrence of UTI during 12 weeks.

Results: 240 patients were included between March, 2015 and April, 2019, 115 and 125 in the short and standard duration arms, respectively. Median age was 60.4 years; 72 (30%) patients had a history of urological abnormalities.

Final results of intention-to-treat and per protocol analyses will be presented at the ECCMID meeting.

Conclusions: The results of this first multicenter, double blinded randomized trial comparing 7 days versus 14 days for the treatment of febrile male UTI should allow to better define the optimal duration of antibiotic treatment in this population.

Are healthcare workers more worried but less prepared for novel COVID-19 as compared to non-healthcare personnel? Online Questionnaire based comparison of knowledge, attitude and practices during the current outbreak

Mehvash Haider*1, Mridu Dudeja1

1Hamdard Institute of Medical Sciences and Research, New Delhi, India

Background: World Health Organization has declared the current Coronavirus outbreak a Public Health Emergency of International Concern. To date, epidemiological data on attitude, practices and mental health issues of health professionals and the general public of the current outbreak is not available. Dissemination of the right information is necessary to understand the risks and initiate containment interventions. This study aimed to quantify the present knowledge, prevalent attitude and planned practices to counter the current COVID-19 outbreak and study differences in these parameters between healthcare (HCP) and non-healthcare personnel (nHCP).

Materials/methods: An anonymous online questionnaire-based cross-sectional survey was conducted among a section of the adult population consisting of both HCPs and nHCP. The questionnaire included 11 questions to assess knowledge in MCQ format, 6 questions to assess attitude on a 5 point Likert scale and 9 questions to assess practices on a 3 point Likert scale. The survey was circulated among peer groups and on social media platforms.

Results: There were a total of 470 respondents between 2nd to 11th Feb 2020 (342 HCP, 128 nHCP). Average score of the knowledge section was 76.5% (HPC 78%, nHPC 72%). For assessment of attitude, 5-point Likert Scale responses were converted into a weighted score by assigning graded points for each response. As per this weighted score, 92% HCP & 91% nHCP would avoid overseas travel, 55% HCP & 53% nHCP preferred to avoid public transport, 81% HCP and 88% nHCP agreed covering their cough would decrease the risk of transmission of COVID-19. 34% HCP and 53% nHCP admitted having never worn masks in public spaces. 20% HCP and 33.6% nHCP had never avoided public transport during previous outbreaks. 77% HCP & 70.3% nHCP were distressed about the current outbreak but only 25% HCP and 15% nHCP thought they might get infected.

Conclusions: Our survey found a low level of knowledge among both HCP and nHCP with HCP performing slightly better than nHCP. The recommended attitude and best practice scores were similar among both groups. The stress levels about the epidemic are higher among HCP. Wider dissemination of correct information is urgently needed.

**Background:** COVID-19 epidemic originated in December 2019 in Wuhan, China; as of 16/02/2020, the virus spread in 25 countries, including France. The proportion of severe cases was high in the first reports; extremely few cases under the age of 18 have been reported. First works estimated the basic reproduction number to be 2.2-3.6.

On 7/2, a COVID-19 case was confirmed in the UK in a British male who had traveled in Singapore and had then stayed in a French ski resort while being symptomatic. We investigated to identify potential secondary cases and interrupt transmission.

**Materials/methods:** A case for this cluster was a patient either symptomatic or asymptomatic with a sample positive for SARS-CoV-2, and an epidemiological link with the index case or a confirmed case linked to the index case.

**Results:** From 25 to 28/01, the index case, while symptomatic, stayed in a chalet in the French Alps with 12 other British adults and 3 children. Of those, five tested positive for SARS-CoV-2 in France (4 adults and a 9-year-old child). Moreover, 6 additional close contacts who had left the chalet in the meantime tested positive for SARS-CoV-2 (5 in the UK, 1 in Spain). On 14/02, one additional case was diagnosed; he had stayed in the chalet after the index case had left, suggesting tertiary transmission. Five of the 6 positive patients diagnosed in France had transitory mild fever at the end of January; at the time of the diagnosis, they had no fever, and mild symptoms (cough and/or running nose); one case had no symptoms. All other close contacts of the secondary cases who developed symptoms tested negative (including those linked to the infected child, who attended three schools and one ski class while symptomatic). The first negative sample from the cases was obtained 5 to 7 days after the first positive sample.

**Conclusions:** Our investigations indicated that one single individual spread SARS-CoV-2 in 11 others. In contrast, the infected child, despite very close interactions with a large number of contacts, did not transmit the infection. Mild cases are probably more frequent than initially suspected.

Abstract 9943

**Novel Formulations of Polymyxin B to Mitigate Polymyxin-Induced Nephrotoxicity in Rats**

Saransh Chaudhary*, Manu Chaudhary, Dilip Roy, Kuntal Ganguly, Anmol Aggarwal

*Venus Medicine Research Centre VMRC, Baddi, India

**Background:** Despite its crucial role in treating life-threatening gram-negative infections, the clinical utilization of polymyxin B is limited due to the risk of acute kidney injury (AKI). In this study, we assessed four novel formulations of polymyxin B (VRP034_F21-24) with regard to their ability to reduce polymyxin-induced nephrotoxicity.

**Materials/methods:** Healthy male SD rats were treated with either standard polymyxin B [control] or one of the four formulations [treatment] at a dose of 25 mg/kg/day [human equivalent dose: 4mg/kg/day] in 4 divided doses for 2 days via subcutaneous injection (n=6 for each group). Serum samples were collected at baseline and on day 3 for analysis of serum biomarkers - KIM-1 [kidney injury molecule], cystatin-C, creatinine and urea. Necropsy was done on day 3 for gross observation and kidney was collected for histopathological evaluation. Data were compared with basal values and statistical analysis was performed to evaluate nephrotoxicity associated with each formulation.

**Results:** In the control group, a significant increase in all four serum biomarkers was observed on day 3 as compared to basal values [urea: 311% (p<0.001); creatinine: 700% (p<0.001); KIM-1: 180% (p<0.001); cystatin-C: 66% (p<0.01)]. In addition, clinical manifestations like pallor of the ears and pads with redness, muscular incoordination and respiratory distress, eventually leading to complete flaccidity of skeletal muscle with dyspnea, were noted in the control group. As a result, 50% animals died after the 8th dose before scheduled necropsy. On the contrary, animals treated with novel formulations did not show any significant increase across all four serum biomarkers on day 3 (p>0.05), except for KIM-1 in formulation VRP034_F24 that increased by 19% (p<0.01). Also, none of the animals died in the treatment groups. Histopathology of the kidney (Fig-1) confirmed necrotic changes in tissues with congestion and vacuolization in the control group, whereas, only minor tubular damage was noted in two (VRP034_F21, F24) of the four formulations tested and no appreciable damage was detected in the other two groups (VRP034_F22-23).

**Conclusions:** Novel formulations of polymyxin B [VRP034 F22-23] significantly mitigated the risk of AKI and can provide a safer alternative in treating resistant gram-negative infections.

**Figure 1:** Representative histopathological images of kidneys from rats in control and treatment groups:
- (VRP034_F21) - Kidney showing normal organization of glomeruli, mild tubular damage with vacuolization.
- (VRP034_F22) - Showing normal glomerular and tubular histology. The tubules were largely intact without the presence of any mononuclear infiltrates in the interstitium and blood vessels were also unremarkable. (VRP034_F23) - Showing normal glomerular and tubular histology. The tubules were largely intact without the presence of any mononuclear infiltrates in the interstitium and blood vessels were also unremarkable. (VRP034_F24) - Showing normal organization of glomeruli, mild tubular damage with vacuolization. (Control) - Showing necrotic changes in kidney tissues with congestion and vacuolization.

Comparison of in-house and commercial RT-PCR assays for the diagnosis of 2019-novel Coronavirus (SARS-CoV-2) infection

Valeria Micheli*, Alessandra Lombardi1, Alessandro Mancon1, Alberto Rizzo1, Maria Rita Gismondo1

1ASST Fatebenefratelli Sacco - L. Sacco University Hospital, Laboratory of Clinical Microbiology, Virology and Bioemergencies, Milan, Italy

**Background:** in December 2019 an outbreak of pneumonia of unknown cause spread from Wuhan (Hubei) to China: it rapidly became a global concern due to the risk of worldwide diffusion. The etiologic agent has been promptly identified as a novel coronavirus, recently named SARS-CoV-2, closely related to SARS-CoV (about 79% sequence identity). L. Sacco University Hospital in Milan is one of the two Italian reference centers for bioemergencies diagnosis and treatment.

**Materials/methods:** between February 10th and 14th 2020 a total of 10 nasopharyngeal swabs, collected from COVID-19 (2019 novel coronavirus disease) suspected patients, were assayed using different in-house and commercial kits, based on the market availability. Viral RNA was extracted by NucliSENS® easyMag® (bioMérieux) eluting 500 µL of sample in 50 µL. The following assays were used according to manufacturers’ instructions: Novel Coronavirus (2019-nCoV) Real Time Multiplex RT-PCR Kit (targets: E gene, N gene, RdRP gene), Liferiver; TaqMan™ 2019 nCoV Assay Kit v1 (targets: N gene, Orf-1ab gene, S gene), Applied Biosystem; Allplex™ 2019-nCoV Assay (targets: E gene, N gene, RdRP gene), Seegene Inc; in-house protocol from Hong Kong University [targets: N gene, Orf-1b gene], available at WHO website [01/23/2020]. The 7500 RT-PCR System (Applied Biosystem) was used for all but Seegene assay, running on CFX96 (BioRad). Viral RNA extracted from frozen cell-culture supernatant, obtained from a SARS-CoV diagnosed patient at L. Sacco University Hospital in 2003, was included as positive control due to the high sequence identity.

**Results:** All samples resulted negative for SARS-CoV-2 with any assays. Viral RNA from SARS-CoV showed a positive signal in RT-PCR for the following gene targets: two out of three genes for Liferiver assay (E and N); E gene for Seegene assay; both N and Orf1b genes with Hong Kong protocol, whereas none of the three targets was detected by Applied Biosystem assay.

**Conclusions:** in-house Hong Kong protocol was able to detect SARS-CoV RNA for both gene targets. All commercial assays provided a good specificity for SARS-CoV-2: SARS-CoV RNA showed amplification profile negative for RdRP gene, or a pattern of positive results for E and/or N genes classified as negative according to manufactures’ interpretation.

Abstract 9961

Unprecedented rates of azole-resistant *Aspergillus fumigatus* identified in the environment of Mekong Delta of Vietnam, with marked variability by ecological niche.

Tra My Nu Duong1,2, Thi Phuong Nguyen1, Thu Anh Nguyen3, Greg Fox1,3, Guy Marks3, Sharon Chen1, Vanessa Barrs1, Catriona Halliday1, Tania C. Sorrell1, Jeremy Day*2, Justin Beardsley1,2

1University of Sydney, Marie Bashir Institute, Sydney, Australia, 2Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam, 3Woolcock Institute Vietnam, Ha Noi, Vietnam

Abstract third-party references: Woolcock Institute for Medical Research Vietnam, National Lung Hospital, Ha Noi, Vietnam, Oxford University Clinical Research Unit, Vietnam, University of Sydney

**Background:** Rising rates of azole-resistance in environmental *Aspergillus fumigatus*, driven by agricultural azole use, are a major public health threat. Since the leading risk factor for aspergillosis is prior TB infection, this threat is greatest in high-TB low-income settings, which lack the capacity to diagnoseazole-resistance or to provide alternative treatments.

Globally, environmental resistance rates of 10-15% have been reported, 33% in high-azole-use niches, though Southeast Asian data are lacking. Vietnam has high TB-incidence, intensive farming, unregulated agri-chemical use, and limited fungal diagnostic capacity; together making azole-resistance both likely and clinically important. Therefore, we conducted an environmental sampling study.

**Materials/methods:** We collected samples in a rural province of Vietnam, from 150 locations distributed across the principal environmental niches (see table). We measured *A. fumigatus* susceptibility with EUCAST methodology, and concentration of agricultural azoles at all sample sites. We investigated the relationship between niche, azole contamination, and *A. fumigatus* resistance rates using logistic regression.

**Results:** Of 529 *Aspergillus* spp. isolates, 192 were *A. fumigatus* complex and 61 *A. fumigatus sensu stricto*. Of the 116 *A. fumigatus* complex tested to date, 60% were resistant to itraconazole (ITZ-R) (71% posaconazole (PSZ-R), 44% voriconazole (VRZ-R)), varying by niche (see table). ITZ-R rate in *A. fumigatus sensu stricto* was 85%. We detected azoles in 26/142 sites (see table). Compared to National Park, odds ratios for ITZ-R *A. fumigatus* were 0.56 (p=0.46) for shrimp farm, 1.73 (p=0.37) for rice farm, 3.92 (p=0.02) for rural residential, and 10.32 (p=0.001) for urban residential. Our models did not show a significant relationship between azole contamination and resistance, but the lowest rate of resistance was in the National Park, where no azoles were detected.

**Conclusions:** We found unprecedented levels of azole resistance, and have shown that rates vary by ecological niche. These alarming rates of resistance undermine the local validity of existing empiric azole therapy guidelines.

Abstract 9962

Metagenomic Next-Generation Sequencing to Evaluate Changes in the Gastrointestinal Microbiome and Resistome of Patients with Varying Carbapenem-Resistant Enterobacterales Colonization Status

Patricia Simner*1, Yehudit Bergman1, Brian Fanelli2, Huai L1, Nur Hasan2, Pranita Tamma1

1Johns Hopkins University School of Medicine, Baltimore, United States, 2CosmosID Inc, Rockville, United States

Background: The purpose of this study was to identify changes in the intestinal microbiome and resistome that promote a favorable environment for carbapenem-resistant Enterobacterales (CRE) colonization and/or progression to infection among high-risk patients (i.e., ICU, oncology, solid and bone marrow transplant recipients).

Materials/methods: We screened >4,000 patients for intestinal colonization at admission and weekly thereafter for CRE by culturing >10,000 rectal swabs. The following goups were included: (a) patients with longitudinal samples who never acquired CRE, (b) patients CRE positive at admission who remained positive, (c) patients initially CRE negative who became CRE positive and did not progress to infection, and (d) patients initially CRE negative who became CRE positive and progressed to CRE infection. Long-read metagenomic next-generation sequencing (mNGS) using the Oxford Nanopore sequencing platforms of sequential swabs was performed on 133 swabs from 55 patients to assess diversity in the microbiome and resistome of patients. The CosmosID bioinformatics pipeline was applied to analyze data and perform comparative analyses (alpha-diversity; Shannon diversity).

Results: We found that the bacterial taxa diversity among samples for most patients is already disrupted at admission for high-risk patients and predominated by pathobionts (e.g. Enterococcus spp, Enterobacterales) (Figure 1A-D). The diversity of the resistome is higher relative to the microbiome among these patients (F.1A&B). Both the microbiome and resistome can shift considerably within a patient. Using Patient 2 as an example, the diversity index varied from 0.9 to 3.9 among 9 swabs. Upon deeper investigation, the differences in diversity for this specific patient align temporally with three separate admissions. The observed changes in diversity are possibly associated with separate microbiome disruption events accompanying those admissions (1C). However, upon progression to infection, the CRE dominated the microbiota prior to infection (CRE K. pneumoniae on Admission 2; 1C).

Conclusions: The microbiota of high-risk patients are disrupted at admission reducing colonization resistance and leading to an increased likelihood of CRE acquisition. An inverse relationship between the intestinal microbiome diversity and the resistome was observed and CRE dominated the microbiota prior to progressing to infection. As a next step, we will link clinical metadata to the mNGS results.

Abstract 9964

Phase IIa dose escalation treatment of *Clostridioides difficile*-associated diarrhea with MGB-BP-3, a novel first in class DNA minor groove binding antibiotic

Thomas Louie*1, Allison Morgan2, Oscar Larios1, Miroslav Ravic3

1University of Calgary, Calgary, Canada; 2MGB biopharma, Bellshill, United Kingdom; 3MGB Biopharma, Bellshill, United Kingdom

Background: MGB-BP-3 is a synthetic polyamide related to Distamycin A, which selectively binds to the minor groove of microbial DNA, is highly active against gram positive pathogens, has been found to be bactericidal vs *C. difficile* and associated with lower sporulation in-vitro as compared to vancomycin. In the Hamster model of *C. difficile* infection, MGB has been shown to protect against death and prolongs post-treatment survival.

Materials/methods: In this sequential ascending dose escalation study, subjects [n=10-12/ dose level] with primary or first recurrent EIA toxin positive CDAD are treated with 125 mg, 250 mg, and lastly 500 mg bid for 10 days to assess initial cure at day 12 (IC) and followed for recurrence of CDAD 4 and 8 weeks post-treatment. Primary endpoints are safety, tolerability, and IC. Secondary endpoints includes sustained cure (SC) at 4 weeks post-treatment, pharmacokinetics of MGB in plasma and stool on days 1, 5, 10, 12, 14 and 17. Changes in the fecal microbiome over time as measured by qPCR and 16S sequencing are exploratory endpoints. In a subset of half of subjects, quantitative counts of *C. difficile* burden before, during and after treatment to day 38 assesses MGB effect on *C. difficile* in-vivo.

Results: As of 15 Feb. 2020, 30 subjects have been enrolled, and follow up to 4 weeks post-treatment will be completed before April 15. Of the 2 completed cohorts, in the 125 mg dose group, 10/11 attained IC; one subject failed despite microbiologic suppression of Cd, and SC was attained in 8/9 evaluable subjects (one protocol violation). Quantitative Cd cultures showed suppression to LLOD log 2 at day 10 in 7/8 subjects. In the 250 mg dose group, 11/11 attained IC and 8/8 completing follow up attained SC (3 pending). Including all subjects to date, MGB-BP-3 appears well tolerated with one subject in the lowest dose reporting transient dizziness. Safety testing to date has shown no drug related AE. qPCR showed preservation of Bacteroidetes and moderate reduction in Cluster IV and XIVa microbes.

Conclusions: MGB-BP-3 appears to be well tolerated and appears to merit further study as a CDAD treatment candidate.

Pharmacokinetics of a newly developed oral ceftriaxone formulation (VRT001-C) in mice and rabbits

Anmol Aggarwal1*, Kuntal Ganguly1, Manu Chaudhary1, Prashant Surve1, Dilip Roy1, Anand Sachdeva1, Saransh Chaudhary1

1Venus Medicine Research Centre, Baddi, India

Background: Ceftriaxone is among the most widely prescribed antibiotics globally due to its broad-spectrum activity and favourable pharmacokinetic properties. However, the clinical use of ceftriaxone in outpatient settings is limited by its poor oral bioavailability (<1%). VRT001-C, a novel oral ceftriaxone formulation, is currently in development and has previously reported bioavailability of 55% after intraduodenal administration in mice [Poster number: P4265, ECCMID 2020]. This formulation has since been updated to target faster drug release in human plasma (pH≈7.4) and in this study, we present the pharmacokinetic data of the revised formulation of VRT001-C after oral administration in mice and rabbits.

Materials/methods: 16 healthy Swiss albino mice (25-30g, both sex) and 6 New Zealand White rabbits (1.5-2kg, both sex) were fasted overnight and were administered either VRT001-C (Oral) or ceftriaxone (IV). Mice were dosed at 200mg/kg while rabbits were dosed at 50mg/kg (human equivalent dose of 1g across both species). After a single dose of either drug, plasma samples were withdrawn at various time points up to 24hrs and drug concentration was analysed using a validated HPLC method. PK parameters were calculated using noncompartmental analysis.

Results: In mice, the mean bioavailability of VRT001-C was 340% as compared to the IV group [AUC\text{0-inf} of 1424.03 ± 68.61 mg/L·h vs. 419.25 ± 5.36 mg/L·h]. This is likely due to the lower drug clearance of VRT001-C [5.61 ml/h vs 19.08 ml/h] resulting in a prolonged half-life [3.19 hrs vs. 0.82 hrs]. In rabbits, mean bioavailability of VRT001-C was 57% as compared to the IV group [AUC\text{0-inf} of 532.35 ± 46.5 mg/L·h vs. 930.82 ± 77 mg/L·h]. Similar to mice, the half-life of VRT001-C in rabbits was longer than that observed in the IV group [10.10 hrs vs. 2.18 hrs], however, unlike mice, the concentration-time curve for VRT001-C in rabbits depicted a sustained release profile. This was evidenced by a much higher C_{\text{max,IV}}/C_{\text{max,Oral}} ratio in rabbits as compared to mice [23x vs. 1.2x].

Conclusions: The high bioavailability of VRT001-C across both animal species indicates high intestinal permeability and provides promising evidence to further the development of VRT001-C for clinical use.

Legionellosis in solid organ transplantation: ten years of French experience

Guillaume Thizy*, Anne Scemla¹, Olivier Roux², Sophie Jarraud³, David Lebeaux⁴, Jacques Pouchot⁵, Florence Ader⁴, Fanny Lanternier⁶, Emmanuel Lafont⁷

¹University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France, ²Hôpital Necker Enfants Malades, Paris, France, ³Hôpital Beaujon, Clichy, France, ⁴Hôpital Croix Rousse, Lyon, France, ⁵Hôpital Européen Georges Pompidou, Paris, France, ⁶Hôpital Necker Enfants Malades, Paris, France

Background: Legionellosis is a life-threatening bacterial infection that may affect solid organ transplant (SOT) recipients. Little data are available on this rare though severe opportunistic infection among SOT recipients. So, we aimed to describe clinical manifestations, treatment features and outcome of legionellosis in SOT recipients.

Materials/methods: This French multicentric retrospective study included all patients with SOT and definite Legionella infection diagnosed from 2009 to 2019. We examined the hospital discharge databases to identify patients corresponding to the following codes: legionellosis (A481) and liver (Z944) or kidney (Z940) or lung (Z942) or heart (Z941) transplantation. Legionellosis was diagnosed in case of positive culture from respiratory sample, and/or positive urinary antigen test (UAT) and/or positive serology.

Results: Twenty-eight patients were included from 8 transplantation centers: 17 (61%) kidney, 7 (25%) liver and 4 (14%) heart transplant recipients. At diagnosis, median age was 61.5 years [range 27-81]. Median duration between transplantation and Legionella infection was 5 years [range 14 days to 42 years], 25% were health-care associated infections [7/28]. At diagnosis, 19 were febrile [68%], 22 had pulmonary symptoms [79%], 13 [46%] diarrhea, and 5 [18%] neurological symptoms. Thoracic imaging showed 25 [93%] alveolar consolidation, 19 [70%] interstitial pneumonia [8/11], 9 [33%] pleural effusion, 7 [26%] pulmonary nodules, 3 of them being excavated [11%]. Median duration between onset of symptoms and legionellosis diagnosis was 6.5 days [range 1-30]. UAT was performed in every patient: 4 [14%] were initially negative. Sixty percents of bronchoalveolar lavage culture were positive [6/10]. At time of diagnosis, 11% [3/28] of patients were already receiving empirical therapy active on Legionella. After diagnosis confirmation, 8 [29%] patients received monotherapy of spiramycin, 11 [39%] monotherapy of fluoroquinolone, 9 [32%] fluoroquinolone and spiramycin.

Median duration of antibiotic therapy was 19 days [range 3-114]. Fifteen patients [54%] were hospitalized in intensive care unit (ICU), 10 [36%] required mechanical ventilation, and 8 [29%] received catecholamine. Day-30 mortality rate was 11% [3/28].

Conclusions: Legionellosis in SOT recipients is rare [28 cases in 10 years], atypical [26% of nodular pneumonia, 14% with negative UAT], and severe [54% hospitalized in ICU, 11% of death].

Outcomes of the novel β-lactam/β-lactamase inhibitor combination of cefepime-enmetazobactam versus piperacillin-tazobactam in adult patients with complicated urinary tract infections – the ALLIUM phase 3 trial

Keith S. Kaye*1, Adam Belley2, Omar Lahlou3, Philip Barth1, Paola Motta2, Shikhar Kashyap3, Philipp Knechtle2, Patrick Velicitat*2

1University of Michigan Medical School, Ann Arbor, United States, 2Allegra Therapeutics SAS, Saint Louis, France

Background: Development of new agents to treat infections caused by 3rd generation cephalosporin (3GC)-resistant Enterobacteriales, specifically those producing extended spectrum β-lactamas (ESBL), is a critical priority. Enmetazobactam is a novel ESBL-inhibitor developed in combination with cefepime. We present the results of the ALLIUM phase 3 trial that evaluated the efficacy, safety, and tolerability of cefepime-enmetazobactam versus piperacillin-tazobactam in adult patients with complicated Urinary Tract Infections (cUTI) or Acute Pyelonephritis (AP).

Materials/methods: Patients randomized 1:1 in a double-blind multicenter trial received either 2 g cefepime/ 0.5 g enmetazobactam or 4 g piperacillin/ 0.5 g tazobactam q8h by 2h infusion for 7 to 14 days. The primary efficacy parameter was the proportion of patients in the microbiological modified ITT population (m-MITT) who achieved overall treatment success at test-of-cure, defined as the composite of clinical cure and microbiological eradication. Only patients with a Gram-negative isolate non-resistant to cefepime-enmetazobactam (MIC ≤8 mg/L) and piperacillin-tazobactam (MIC ≤64 mg/L) were included in the m-MITT population. Two-sided 95% CI were computed using the stratified Newcombe method. The prespecified noninferiority margin was -10% with superiority testing in the event of confirmed noninferiority.

Results: 516 randomized patients received at least one dose of cefepime-enmetazobactam, and 518 at least one dose of piperacillin-tazobactam. Overall success in the m-MITT population occurred in 273 of 345 (79.1%) patients treated with cefepime-enmetazobactam versus 196 of 333 (58.9%) treated with piperacillin-tazobactam (difference, 21.2% [95% CI, 14.3% to 27.9%]). Clinical cure rates were 92.5% and 88.9% for cefepime-enmetazobactam and piperacillin-tazobactam, respectively (difference, 3.5% [95% CI, -1% to 8%]). Overall success in the m-MITT subpopulation of ESBL co-producing-positive infections was 73.7% [56/76] and 51.6% [34/66] for cefepime-enmetazobactam and piperacillin-tazobactam, respectively (difference, 30.2% [95% CI, 13.4 to 45.1]). Treatment emergent adverse events were reported in 50.0% [258/516] of patients treated with cefepime-enmetazobactam and 44.0% [228/518] with piperacillin-tazobactam; most were mild to moderate in severity (89.9% and 88.6% with cefepime-enmetazobactam and piperacillin-tazobactam, respectively).

Conclusions: Treatment of cUTI/AP patients with cefepime-enmetazobactam exhibits superior treatment outcomes to piperacillin-tazobactam. Cefepime-enmetazobactam is intended as a new empiric carbapenem-sparing option in settings where 3GC resistance mediated by ESBL is prevalent.

Background: Since the first cases of severe acute respiratory infections associated with SARS-CoV-2 (former 2019-nCoV) in China, more than 60,000 cases have been reported. Rapid isolation, the cornerstone for containing the outbreak, must rely on rapid and performant PCR-testing. We evaluated the first rapid multiplex-PCR allowing detection of SARS-CoV-2, in about an hour and fully compatible with close-to-patient testing.

Materials/methods: QIAstat-Dx Respiratory 2019-nCoV Panel (QIA-RP-nCoV) is a research use only (RUO) qualitative multiplexed nucleic-acid-based in-vitro diagnostic test detecting a large panel of respiratory viruses including SARS-CoV-2. To assess its sensitivity, we used serial dilutions of a positive SARS-CoV-2 nasopharyngeal swab, obtained from one of the four COVID-19 patients hospitalized at Bichat Claude Bernard university hospital. They were tested with QIA-RP-nCoV and the WHO recommended SARS-CoV-2 PCR provided by the Charité hospital, Berlin, with E gene (Eg) and RdRp individual detection. A positive broncho-alveolar lavage (BAL), bronchial- and tracheal-aspirates were also tested. Cross-reaction with human-coronaviruses (OC43, NL63, HKU1, 229E) was assessed.

Results: QIA-RP-nCoV and Charité methods detected the positive sample at 21.1 and 21.5 Cycle threshold (Ct), respectively, and both detected 1/10 (n=1), 1/100 (n=1), 1/1000 (n=1) and 1/10,000 (n=3) dilutions. The 1/100,000 dilutions, corresponding to 100 copies/mL of transport media, were positive for 3/5, 5/5 and 0/5 replicates for QIA-RP-nCoV, Charité-Eg and Charité-RdRp, respectively. The 1/1,000,000 dilutions were positive for 1/5 replicates with QIA-RP-nCoV and Charité-Eg. The tested BAL, bronchial- and tracheal-aspirates provided similar results with QIA-RP-nCoV and Charité-Eg methods (27.9, 29.1 and 21.3 for QIA-RP-nCoV and 28.2, 29.0 and 22.7 for Charité-Eg, respectively). No cross reaction was identified with other human-coronaviruses.

Conclusions: The RUO-version of QIA-RP-nCoV assay allows sensitive, specific and rapid, about one hour on demand vs four hours for the WHO method, detection of SARS-CoV-2 coupled with detection of all clinically relevant respiratory viruses. Our results are in line with the limit of detection provided by the manufacturer at 300 copies/mL. The analyzer and cartridge design allow its use in any laboratory, even not PCR-trained, but also permit point-of-care testing by direct use of the nasopharyngeal swab without further manipulation.

Abstract third-party references: the NeoVanc Consortium

Background: Vancomycin remains one of the most widely prescribed antibiotics for Gram-positive neonatal late onset sepsis (LOS). Robust neonatal clinical outcome data comparing different vancomycin dosing regimens is lacking. NeoVanc (NCT02790996) is a European, multicentre, phase IIb, randomised controlled, non-inferiority trial comparing an optimised and standard vancomycin regimen in infants aged ≤90 days with known/suspected Gram-positive LOS.

Materials/methods: Infants with clinical sepsis (≥3 clinical/laboratory criteria) or confirmed sepsis (Gram-positive blood culture and ≥1 clinical/laboratory criterion) were included. Participants were randomised 1:1 to an optimised regimen (loading dose [25 mg/kg] followed by 5±1 days of 15 mg/kg q1 2h or q8h dependent on postmenstrual age [PMA] or a standard regimen [10±2 day course at 15 mg/kg q24h, q1 2h, or q8h dependent on PMA]). The primary endpoint was successful outcome at end of vancomycin therapy and no clinically/microbiologically significant relapse/new infection requiring treatment with anti-staphylococcal antibiotics within 10 days of stopping vancomycin.

Secondary endpoints included safety and pharmacokinetics. ‘Per protocol’ was all participants receiving/not receiving the loading dose as randomised and ≥48h of study vancomycin.

Results: 242 infants were randomised between March 2017 and July 2019 from 22 neonatal intensive care units in 5 European countries. Per-protocol population is presented (183 participants): 55% were male, with a median (IQR) postmenstrual age of 32(29–37) weeks and postnatal age at onset of LOS of 14(8–25) days. Mean weight was 1663g(924g SD) and central lines were present in 115/183(63%) participants at randomisation. 133/183(73%) received antibiotics in the 7 days before randomisation. 179/183(97%) had positive blood culture for Gram-positive organisms of interest at randomisation, and 141/183(77%) received vancomycin according to the randomised duration. There were 4 deaths and 4 withdrawals/loss to follow-up prior to TOC. There were 40 post-randomisation exclusions.

128/129(72%) had a successful primary outcome. 2/165(1%) of all randomised infants had abnormal renal function at short-term follow-up.

Conclusions: NeoVanc is the largest LOS vancomycin trial to provide clinical efficacy and safety outcome data associated with alternative dosing strategies. Preliminary results are included (some events not yet adjudicated): final results comparing randomised groups and outcomes will be presented.

Safety and immunogenicity of a replication deficient simian adenoviral vectored Chikungunya vaccine: results of a phase I, first-in-human, dose escalation trial.

Pedro Folegatti1, Kate Harrison1, Lorena Preciado-Llanes1, Fernando Ramos Lopez1, Mark W. Tilley1, Shannan Rossi2, Sasha Azar2, Amy Flaxman1, Mustapha Bittaye1, Ian Poulton1, Alison Lawrie1, Young Chan Kim1, Daniel Jenkin1, Mehreen Datoo1, Yrene Themistocleous1, Rachel Roberts1, Nguyen Tran1, Katie Ewer1, Eleanor Berrie1, Adrian Hill1, Arturo Reyes-Sandoval1

1University of Oxford, The Jenner Institute, Oxford, United Kingdom, 2The University of Texas Medical Branch at Galveston, Galveston, United States

Background: Chikungunya is a mosquito-borne alphavirus. The disease consists of an acute febrile illness with often incapacitating polyarthralgia and/or polyarthritis, which lasts weeks to months. Chikungunya disease lead to considerable economic losses and increased burden to already thinly stretched healthcare systems, especially in developing countries. There are currently no licensed vaccines against CHIKV. A handful of candidates have now entered clinical trials, but most of them require ≥2 doses to induce strong immune responses. ChAdOx1 Chik is a replication deficient simian adenoviral vectored vaccine expressing the structural polyprotein cassette of CHIKV. We report final safety and immunogenicity data from a first-in-human clinical trial where ChAdOx1 Chik was administered as a single un-adjuvanted intramuscular dose.

Materials/methods: 24 healthy adult participants aged 18-50 years received an intramuscular injection of ChAdOx1 Chik at 3 escalating doses in Oxford, UK. The primary endpoint was safety and tolerability, whilst assessment of humoral and cellular immunogenicity was the secondary endpoint. Antibodies were measured by ELISA against E2 and neutralising antibody titres by PRNT80. T-cell responses were measured by IFN-γ ELISpot and flow cytometry. Participants were followed for 6 months.

Results: ChAdOx1 Chik was well tolerated at doses up to 5 x 10¹⁰ vp with no serious adverse reactions. The vast majority of adverse events were mild or moderate [95%, CI 95%: 89-98] and all were self-limiting in nature [medium duration = 2 days]. T-cell responses peaked at day 14 and persisted significantly above baseline for 6 months, with greater cytokine production from CD4+ when compared to CD8+ T-cells. Up to 89% [CI 95%: 67-97] of participants in the intermediate and high dose groups seroconverted at day 28 on ELISA. PRNT80 data showed that a single dose of ChAdOx1 Chik elicits protective neutralising antibodies [titres ≥ 1:10] for a selection of Chik isolates and as early as 14 days after vaccination.

Conclusions: ChAdOx1 Chik was safe and well tolerated. A single dose induced robust T-cell and antibody responses, with protective neutralising titres for up to 6 months. These results support further clinical development of ChAdOx1 Chik.

Abstract 9983

**Microbiological and patients’ characteristics of excluded suspicions of SARS-CoV-19 infection in Paris, France**

Benoit Visseaux†, Lauréne Deconinck†, Annabelle Pourbaix†, Quentin Le Hingrat†, Marion Parisey†, Jean-Christophe Lucet‡, Diane Descamps§, Yazdan Yazdanpanah∥, Nadhira Fidouh∥, Xavier Lescure∥

†Bichat-Claude Bernard Hospital, Laboratoire de Virologie, Paris, France, ‡Université de Paris, UMR 1137-JAME, Inserm, team DESCID, Paris, France, §Bichat-Claude Bernard Hospital, Service des Maladies Infectieuses, Paris, France, ∥Bichat-Claude Bernard Hospital, Unité d’Hygiène, Paris, France

**Background:** Since last December, more than 660,000 COVID-19 cases have been declared worldwide. To date, Bichat Claude Bernard university hospital in Paris, a reference center hosting emerging infectious diseases in France, hospitalized 4 SARS-CoV-2 confirmed infections and excluded the infection among 86 other possible cases. Here, we describe the main characteristics of those excluded cases.

**Materials/methods:** Clinical and epidemiological data of possible patients addressed to our hospital up to the 12th of February 2020 were prospectively collected. We evaluated their demographic and microbiological characteristics.

**Results:** 35/86 (41%) were male, the median age was 32 years [IQR: 20-41]. 45 were Chinese foreigners visiting France, 26 travelers coming back from China (n=24) or Taiwan/Japan (n=2) and 15 had contacts with confirmed cases. 55 presented at least one general symptoms (42 fever, 4 chills, 13 headache, 14 myalgia and 10 asthenia) and 83 at least one respiratory symptom (77 cough, 25 odynophagia, 19 rhinorrhea, 7 dyspnea, 2 thoracic pain, 1 expectoration). Median duration between first symptoms and consultation was 2.5 days [1-31]. 42 (55%) were positive by multiplex PCR including 6 viral codetections and 1 associated to M.pneumonia. Among identified viruses, 27 were influenza (17 A, 7 B and 3 untyped), 9 rhinoviruses, 5 coronaviruses (2 NL63, 2 OC43 and 1 229E), 4 metapneumoviruses, 3 RSV, 3 adenoviruses and 2 parainfluenza. Virus negative and positive patients clinical presentation did not statistically differ despite a tendency to more fever among viral-infection (62 vs 31%, p=0.09). Influenza clinical presentation were not statistically different from other viruses despite higher proportion of fever (85 vs 39%, p=0.12) and myalgia (30 vs 8%, p=0.16). To note, 4/5 (80%) and 1/5 (20%) of patients presenting human coronaviruses also presented fever and myalgia, respectively.

**Conclusions:** Among the 86 first excluded suspicions of SARS-CoV-2 infections in our hospital in Paris, seasonal respiratory viruses, half influenza, were the leading cause of infections. Their epidemiology is similar to respiratory viruses currently circulating in France and they presented similar clinical characteristics to those reported for SARS-CoV-2 infections. Larger influenza vaccination should be use and help to reduce the number of suspicion.

Safety and immunogenicity of a replication deficient simian adenoviral vectored Zika vaccine: preliminary results of a phase I, first-in-human, dose escalation trial.

Pedro Folegatti¹, Lorena Preciado-Llanes¹, Luisa Hering¹, Fernando Ramos Lopez¹, Daniel Jenkin¹, Mark W. Tilley¹, Ian Poulton¹, Alison Lawrie¹, Mehreen Datoo¹, Yrene Themistocleous¹, Nguyen Tran¹, Eleanor Berrie¹, Adrian Hill¹, Arturo Reyes-Sandoval¹

¹University of Oxford, The Jenner Institute, Oxford, United Kingdom

**Background:** Zika belongs to the Flaviviridae family of arthropod-borne RNA viruses and is mainly transmitted by Aedes mosquitoes. However, vertical transmission during pregnancy can cause severe lifelong disability. Despite up to 80% of cases being asymptomatic, Zika is now known to be associated with an increased risk of serious and poor neurological outcomes. There are currently no licensed vaccines against ZIKV and several candidates have now entered clinical trials, but not all of them are suitable for vaccination of pregnant women and of childbearing potential (live attenuated or replication competent vectored vaccines). ChAdOx1 Zika is a replication deficient simian adenoviral vectored vaccine expressing structural proteins of ZIKV. We report preliminary safety and immunogenicity data from an ongoing first-in-human clinical trial where ChAdOx1 Zika is administered as a single un-adjuvanted intramuscular dose.

**Materials/methods:** The ChAdOx1 Zika antigenic cassette contains the ZIKV precursor of membrane (prM) and envelope protein with deletion of the 3' transmembrane domain, but does include the DIII domain which is associated with cellular receptor binding and contains epitopes for neutralising antibodies. Healthy adult participants aged 18-50 years will be recruited at 3 escalating doses in Oxford, UK. The primary endpoint is safety and tolerability of ChAdOx1 Zika. The secondary endpoint is to assess humoral and cellular immunogenicity examined by ELISA and IFN-γ ELISpot respectively, at different timepoints. Participants will be followed for 6 months.

**Results:** Preliminary safety data shows that ChAdOx1 Zika was well tolerated at low and intermediate doses with no severe or serious adverse events reported to date. Local and systemic AEs were mild or moderate and so far resolved within 4 days. ChAdOx1 Zika induced T-cell responses even at the low dose, with responses peaking at 14 days post vaccination. Recruitment and follow-up are still ongoing. Only 7 participants had been recruited by the time of this abstract submission.

**Conclusions:** Preliminary results of this first-in-human trial show that ChAdOx1 Zika was well tolerated at 5x10⁹ and 2.5x10¹⁰ vp doses. A single dose of ChAdOx1 Zika elicited T-cell responses. Further data on safety and immunogenicity will be presented at the conference as they become available.
Abstract 9989

Outbreak of listeriosis associated to deli meat in Andalusia, Spain: main clinical results highlighting large number of cases and very low mortality

Background: Listeria monocytogenes is an uncommon etiology of foodborne illness, the mortality of the outbreak-related invasive infection ranges 5-41%. Elderly people, immunocompromised patients, pregnant women and newborns have a higher risk of invasive listeriosis. At the end of July 2019, an increase in the cases of listeriosis was detected in Andalusia, Spain. A brand of deli meat was identified as the source of the outbreak through the epidemiological surveys and isolation of L. monocytogenes in the meat. The outbreak was publicly declared the August 15th 2019 and all the lots of this brand of deli meat withdrawn of sale.

Objective: to describe the clinical features and outcome of the outbreak-related patients with invasive listeriosis.

Materials/methods: We considered as outbreak-related cases those with a laboratory-confirmed invasive infection whose isolate of L. monocytogenes was the same subtype identified in the deli meat or could not be typed [including cases diagnosed through nucleic acid tests] but exposed to the contaminated product. All cases were notified to the Epidemiological Surveillance System of Andalusia. Clonal relationship was studied through by whole genome sequencing [cgMLST]. Clinical features were obtained from the clinical records.

Results: We identified 198 cases with invasive listeriosis as outbreak-related [176 confirmed by cgMLST: CT-8466] from July 22nd to September 24th 2019 in Andalusia.

One hundred and twelve (56.6%) patients received ampicillin, in 40 (20.2%) cases combined with gentamicin; oral amoxicillin was used in 101 (51%) patients; in 41 (20.7%) cases as sequential therapy and in 60 (30.3%) as the only treatment. Four (2%) patients died, all of them were more than 70 years old. Four pregnant women (11.4%) suffered a foetal loss and 5 (14.3%) a pre-term birth.

**Conclusions:** This outbreak of listeriosis showed a low mortality, which could be partially explained by the proportion of young and previously healthy people. Invasive infection was common in patients with gastroenteritis.

Abstract 9992

**Multisite viral evolution in a COVID-19 infected patient treated by lopinavir/ritonavir**

1University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France

**Background:** An outbreak of COVID-19 has spread worldwide from Wuhan, China, in January 2020. The first European imported case was reported in France on January 20th. The 6th COVID-19-infected patient was diagnosed and hospitalized in our isolation department on the 29/01/20, i.e., 6 days after exposure. He was a French physician who acquired the disease after examining two sick Chinese from Wuhan visiting Paris with their Taiwanese guide, who was secondarily confirmed COVID-19 infected. He had self-medicated with amoxicillin and oseltamivir since 28/01/2020, when he developed myalgia, sore throat and mild fever prior admission.

He was investigated in as many sites as possible for COVID-19 viral carriage during his hospitalization.

**Materials/methods:** From Day 2 after his first symptoms, viral semi-quantitative determination was regularly conducted from multisite swabs and body fluids. We used two real-time Polymerase Chaine Reactions (RT-PCRs), a first-line screening assay targeting E gene and a confirmatory assay targeting RdRp gene of COVID-19.

Chest X-Ray showed a mild pulmonary opacity in the right lung at day 7 even though the patient had no lower respiratory infection signs. Chest CT-scan confirmed small areas of ground-glass opacities in both lower lungs. Thus lopinavir/ritonavir 200/100mg was prescribed twice a day orally for 10 days and the patient was closely monitored during and after this treatment.

**Results:** Virological results presented in Table 1 showed the presence of COVID-19 DNA not only in the upper respiratory sites but also in the tears, saliva and plasma. However stools and urines tested were negative.

The all-sites indetectability by RT-PCR was observed only 14 days after the occurrence of symptoms and 7 days after the lopinavir/ritonavir start. The outcome was good: absence of evolution towards severe pneumonia, and only digestive side effects (unformed stools).

Blood and fluids specimens have been stored for lopinavir pharmacological levels measurements.

**Conclusions:** We describe CoViD-19 multisite and prolonged viral excretion in a paucisymptomatic patient. Lopinavir boosted with ritonavir, did not seem to have a rapid impact on viral load clearance in this single patient. However it’s efficacy in CoViD-19 infection should be better evaluated in a prospective controlled study.

**Presenter email address:** elisemma@hotmail.com
Abstract 9993

**Dissociation between sustained negative nasopharyngeal swab and positive endotracheal aspirate in a patient presenting with COVID-19 pneumonia**

Nicolas Benech1, Maude Bouscambert-Duchamp1, Florent Valour1, Anne Conrad1, Sandrine Roux1, Loïc Boussel1, Tristan Ferry1, Florence Ader1, Patrick Miaillès1, Alexandre Gaymard1, Thomas Perpoint1, Bruno Lina1, Christian Chidiac1

1Hospital La Croix-Rousse - HCL, Lyon, France

**Background:** Detection of SARS-CoV-2 in Coronavirus disease 2019 (COVID-19) patients relies on a reverse transcriptase polymerase chain reaction (RT-PCR) assay performed on oral or nasopharyngeal swab (NPS). We report a case of a patient included in the Haute Savoie cluster who was linked to a confirmed index case and who subsequently developed COVID-19 pneumonia diagnosed by positive endotracheal aspirate (ETA) despite persistent negative NPS.

**Materials/methods:** Patient’s clinical characteristics were monitored daily during the quarantine in a French tertiary hospital. SARS-CoV-2 diagnosis was based on a RT-PCR assay developed by the French National Reference Centre for respiratory viruses targeting RdRp-gene. Other pulmonary viruses were detected using FilmArray® RP2+ (BioFire Diagnostics, SLC, USA).

**Results:** A 53-year-old man with no major medical history was hospitalized for quarantine in strict isolation after having been in contact with confirmed COVID-19 cases. On admission, the patient was asymptomatic and NPS was negative for SARS-CoV-2 detection. On day 5, he presented isolated fever (38.1°C), with no sign of upper or lower respiratory tract infection. Chest radiography performed on day 6 showed mild bilateral basal interstitial lung infiltrates. Thoracic CT-scan on day 7 confirmed these findings with patchy peripheral ground glass images of the left lower and middle lobes. NPS remained negative for SARS-CoV-2 and other respiratory viruses. Biological findings only disclosed a mild inflammatory syndrome (C-reactive protein, 1.2 mg/L). While fever persisted 3 days, other clinical parameters – including SpO2 – remained normal, with no sign of lower or upper respiratory tract infection until day 9 when patient presented mild dry cough and rhinorrhea. An ETA performed on day 8 was positive for SARS-CoV-2 confirmed by an induced sputum (I.S) on day 9, whereas NPS remained negative. Clinical follow-up is currently ongoing.

**Conclusions:** This is the first description of dissociated results between negative NPS and positive ETA in a patient with COVID-19 pneumonia. This observation suggests that for patients at high risk of COVID-19, even mild symptoms (i.e., isolated moderated fever) should prompt clinicians to perform chest CT-Scan and lower respiratory tract sampling to detect infection.

[Figure 1. Temperature and results for SARS-CoV-2 testing during follow-up.]

Abstract third-party references: French Covid-19 Study Group

Background: On December 31, 2019, China reported a cluster of cases of pneumonia in Wuhan. The responsible pathogen is a novel coronavirus (SARS-CoV-2). Since the identification of the first imported cases in France, we launched a national cohort of patients with COVID-19.

Materials/methods: The objectives of this cohort are to describe: 1) clinical features of illness; 2) treatment used and their outcome; 3) virus replication, excretion and evolution in multiple sites; 4) host responses including innate and acquired immune responses; 5) host genetic variants associated with disease progression/severity. Patients are diagnosed with SARS-CoV-2 by semi-quantitative reverse-transcriptase polymerase chain reaction (RT-PCR) on nasopharyngeal (NP) swabs. Patients are hospitalised and discharged when symptoms resolve and two negative nasopharyngeal swabs 48 hours apart obtained. The cohort is sponsored by INSERM and approved by the French Ethics Committee on 05/02/2020 (NCT04262921). We used the ISARIC Clinical Characterisation Protocol to standardize data collection at the international level.

Results: On February 16, 2020, twelve patients (8 males, 4 females) were infected by SARS-CoV-2 in France: six in January and six in February (the ‘Haute-Savoie cluster’). Three were imported cases, two travelled to France with the index case, seven had transmission in France. Eleven were adults (median age=48) and one a child (age=9). Through analysis of clinical features and close monitoring of viral shedding, we characterized 3 clinical patterns: 1) pauci-symptomatic patients (n=9), when diagnosed early with high nasopharyngeal shedding decreasing over time, 2) patients with a two-step progression of the disease, worsening after 7-10 days, with lower respiratory tract infection despite a decreasing viral load (n=2); 3) rapid evolution towards multi-organ failures with stable SARS-CoV-2 shedding in NP swabs, and detection in blood (n=1, a 80 years-old patient). In three severe patients the investigational drug remdesivir was initiated, and in one pauci-symptomatic patient lopinavir/ritonavir. On February 16, 2020, five patients were discharged from the hospital and one died.

Conclusions: Standardised data and comprehensive virology and immunology sample collection implemented in this cohort, in line and in connection with other international cohorts, will contribute to a better understanding of the disease natural history and its treatment.

Description of patients hospitalized as possible cases of COVID-19 in a Parisian hospital

Johan Benhard*1, Nagisa Godefroy2, Oula Itani1, Dimitri Kornblum2, David Boutolleau1, Sonia Burrel2, Elise Klement1, Eric Caumes2

1Pitié Salpêtrière Hospital and University Pierre et Marie Curie, Paris, France, 2Pitié Salpêtrière Hospital and University Pierre et Marie Curie, Paris, France

Background: An outbreak of acute respiratory disease in China lead to the discovery of a new type of coronavirus on January 3rd, named COVID-19. Given the epidemic risk in France, the French health authorities asked infectious disease specialists from reference health establishments to classify the suspect cases. All patients classified as possible COVID-19 case (PCC) were hospitalized in isolation rooms. The objective of our study is to describe the patients admitted in our department as PCC.

Materials/methods: We included all patients admitted in our hospital as PCC between the 25th of January and the 13th of February. We collected epidemiological, clinical and microbiological data and performed a retrospective cohort study. Lower respiratory infections (LRI) were defined by the presence of cough and fever. Incubation period was defined as the time between exposure, if dated, and the onset of symptoms or as the time between the end of the at-risk trip and the onset of symptoms if the patient had traveled. All the PCC had 2 nose-throat swabs, one for COVID research (RT-PCR) and another one for differential diagnosis research (Multiplex RT-PCR).

Results: Seventy-one patients, 31 men and 40 women, aged from 11 to 69 years (median age 33), were included. Five patients were immunocompromised, 6 had pre-existing lung disease, and 2 were obese. Thirty-eight patients had traveled in China within 3 weeks, and 15 had traveled to another country. Nine patients were in contact with a confirmed case of COVID-19 and 14 with a symptomatic Chinese. The median incubation was 7 days. Most frequent symptoms were cough (54), fever (28), arthromyalgia (22), headaches (22), runny nose and/or sore throat symptoms (19) and diarrhea (5). Twenty-two patients had LRI. Five patients were asymptomatic. One patient was confirmed with COVID-19, other infections were found in 37 cases (11 rhinovirus or enterovirus, 8 influenza A, 6 influenza B, coronaviruses, 2 HRSV, 1 Mycoplasma pneumoniae).

Conclusions: Thirty-eight patient (54%) admitted as a PCC traveled to China, 66 patients had symptoms (93%) including 22 LRI. One case of COVID-19 was confirmed, other infections were found in 37 patients (52%).

Background: Antibiotic resistance of H. pylori is the main cause of failure of most current eradication regimens. As antimicrobial susceptibility testing [AST] is not always performed, it is important to have surveys to infer the treatments which can be used. For this purpose, European surveys were performed in 1998, 2008 and we report here the results of 2018.

Materials/methods: Centres were recruited on a voluntary basis, one for each small country and several for larger countries. The protocol was to include 50 adult patients who had not received previous eradication treatment. Information collected included demographic, clinical, and endoscopic results as well as AST results (clarithromycin, levofloxacin, metronidazole, amoxicillin, tetracycline, rifampicin) performed by Etest or disk diffusion according to a standardised procedure. Control strains were provided. A 10% random sample was sent from each centre to the coordinating centre. The Amplidiag® H. pylori+ClariR kit (Mobidiag) was used for clarithromycin testing and AST for the other antibiotics. A univariate and multivariate analysis were also carried out to define the risk factors of antibiotic resistance.

Results: The crude data show 1,234 H. pylori positive patients included in 24 centres from 18 countries. H. pylori resistance was present in 21.3% for clarithromycin, 16.0% for levofloxacin, 39.1% for metronidazole, 0.4% for amoxicillin, 2% for rifampicin compounds and none for tetracycline. The random selection of 142 strains showed an excellent concordance of results (>95%). The main discrepancies were linked to the presence of double populations not detected by Etest. In the multivariate analysis, the risk factors for resistance were essentially linked to the region of birth: Southern Europe for clarithromycin (OR: 3.7, 95% CI [1.4-9.5]) and outside Europe for metronidazole (OR: 2.7, 95% CI [1.2-6.2]).

Conclusions: These results indicate a global and continuous rise in H. pylori primary resistance to clarithromycin but lower than in the previous decade (9.9% in 1998, 17.5% in 2008, and 21.3% in 2018), a slight increase to levofloxacin, and a more important increase for metronidazole (from 33.1 to 39.5% since 2008). The risk factors for resistance were similar to those found 10 years ago.

Acknowledgments: The authors acknowledge bioMérieux for providing Etests and Mobidiag for providing PCR kits.

Abstract 10014

Using evidence-based infographics to increase parents’ understanding about antibiotic use and antibiotic resistance: a proof-of-concept study

Oliver Van Hecke¹, Joseph Lee¹, Christopher Butler², Michael Moore², Sarah Tonkin-Crine¹

Background: Public misconceptions about antibiotic use persist despite the efforts of antibiotic awareness campaigns. These campaigns have often followed a top-down approach and have not sought input from the public. Communities need to see antibiotic campaign messages as relevant, accessible and important in order to have an influence on health-seeking behaviour and antibiotic use. We aimed to develop a series of evidenced-based infographics (EBIs) on antibiotic use for common infections in children and to evaluate their effectiveness at increasing parents’ understanding of antibiotic use and antibiotic resistance.

Materials/methods: There were three phases to this research. In phase 1 we set out to identify and summarise scientific evidence for the use of antibiotics for three common infections in children (sore throat, acute cough and otitis media). Phase 2 focussed on co-design of a series of prototype EBIs for each infection in focus groups with parents of young children and graphic designers, to test the face- and content validity. Phase 3 is testing the feasibility of EBIs in increasing parents’ understanding about antibiotic use and the perceived relevance of antibiotic resistance in an online survey.

Results: Parents mostly found the evidence displayed in the infographics novel and relevant to their families. However, for some parents, the presented evidence was either too medically-focussed where the outcome was not relevant to parents or not of immediate concern to parents. The manner in which the information was displayed influenced their understanding e.g. difficulty interpreting graphs. Superfluous components of the infographic were often questioned. Parents preferred one health message per visual using accurate and consistent terminology to avoid misinterpretation.

Conclusions: We have co-developed a series of EBIs with parents and professional graphic designers and identified how parents interpret EBIs on antibiotic use and antibiotic resistance. Phase 3 will evaluate whether EBIs can increase parents’ understanding about antibiotic use. If shown to be beneficial, this will inform novel approaches to improving antibiotic stewardship initiatives in the community.
