Background: The greatest hurdle to the introduction of phage therapy in Western medicine remains the lack of an appropriate legal and regulatory framework. Since 2018, Belgium is implementing a pragmatic phage therapy framework that centers on the unlicensed ad hoc preparation of tailor-made phage medicines. Central to this approach is a two-step quality control of phage active pharmaceutical ingredients (APIs) effectuated by Sciensano.

Materials/methods: API QC consists of the construction of a genetic passport which contains information of phage's lifestyle, genome size and content, and its capacity for horizontal gene transfer. The host bacterium is checked for the presence of active prophages and phage-inducible chromosomal islands. Secondly, each production lot is checked for microbial contamination, endotoxin levels, pH and presence of the specific active component. The obtained results are condensed in a Certificate of Analysis which is returned to the manufacturer, and then transferred to the hospital pharmacy to enable preparation of the formulation upon a physician's prescription.

Results: To date, Sciensano controlled 7 seed lots and 15 production lots of phage APIs. All 7 phages, infecting either Pseudomonas aeruginosa, Staphylococcus aureus and Mycobacterium abscessus, were found to be strictly lytic and non-transducing. All but one propagation strain were approved; One particular P. aeruginosa strain was found to produce the toxin pyocyanine and contained at least two active prophages which were induced during phage production. All approved production lots were of high quality, with no microbial contamination detected so far, and endotoxin levels frequently below the detection limit of 0.5 IU/ml. However, our experience shows that certain hosts are correlated to much higher endotoxin contaminations.

Conclusions: With the implementation of a national regulatory framework, Belgium is enabling the treatment of desperate patients with phages upon prescription of a physician outside compassionate use. The relative small number of QC requests clearly reflect its current limited implementation and its use as agents of last resort. In addition the already obtained QC data, we will present our broader experience with the various aspects surrounding the implementation of phage therapy, including the political and economic context of the personalized approach pursued in our country.

Characterisation of NDM-producing Klebsiella pneumoniae isolates from different Roman hospitals

Carolina Venditti*, Ornella Butera1, Silvia Darezzo1, Antonella Vulcano1, Vincenzo Puro1, Simone Lanini1, Giovanna Adamo1, Giuseppe Ippolito1, Carla Nisii1, Antonino Di Caro1

1Lazzaro Spallanzani Hospital, Roma, Italy

Background: Multi-drug-resistant (MDR) Klebsiella pneumoniae producing NDM carbapenemase is a serious nosocomial pathogen causing a variety of infections. Treatment options are particularly limited, given their intrinsic and acquired resistance genes. The objective of the study was to investigate the molecular epidemiology of clinical K. pneumoniae isolates from different hospitals of the Latium region.

Materials/methods: Between May and September 2019, 7 K. pneumoniae strains were isolated from clinical samples of patients treated in 4 different hospitals. Identification and antimicrobial susceptibility testing were performed using the Phoenix system (BD). Genome sequences were generated by Next Generation Sequencing (NGS) using the Ion Torrent sequencer (Life Technologies). Antimicrobial resistance genes were extracted from the NGS data identified by in silico analysis using the ResFinder webserver. Molecular typing was performed using the core genome MLST (cgMLST) approach (Ridom), which uses 2358 target genes to characterize allelic profile of K. pneumoniae.

Results: All isolates showed an MDR profile; the blaNDM-1 gene was detected in 6/7 isolates, one isolates harboured blaNDM-5 gene variant. The blaOXA-48 was detected in two isolates, which carried additionally the ampC cephalosporinase blaCMY-6; 5/7 isolates were positive for blACTX-M-15. Five different Sequence Types (STs) were detected among the 7 NDM-producing K. pneumoniae: ST11, ST15, ST147, ST383 and ST307. Two strains belonging to ST15 and ST11. Clonal relationships within the STs using the cgMLST scheme showed the presence of 2 complex type, each composed by two isolates belonging to ST15 and ST11. The strains within each cluster showed a very high level of correlation (up to 8 allele differences) and K. pneumoniae strains ST11 were collected from the same hospital. No genetic correlation was observed for the remaining 3 isolates.

Conclusions: The emergence of NDM-producing K. pneumoniae in Italy is a real threat for the public health. There is a need for increased capacity to support surveillance and investigations with NGS to identify high-risk clones and to implement enhanced control measures in order to avoid further spread; the use of gene-by-gene analysis by cgMLST for epidemiological investigations allows an in-depth analysis, owing to its high discriminatory ability in determining clonal relatedness.

Abstract 1271

Characterisation of KPC-50, a novel transferable KPC-3 variant conferring resistance to ceftazidime-avibactam in a colistin-resistant Klebsiella pneumoniae from Switzerland

Laurent Poirel*1, Xavier Vuillemin1, Amandine Masseron1, Mario Juhas1, Stefano Mancini1, Reinhard Zbinden2, Simon Tiziani3, Ursina Bechtel-Grosch2, Patrice Nordmann1

1University of Fribourg, Fribourg, Switzerland, 2University of Zurich, Zurich, Switzerland, 3Universität Spital, Zürich, Switzerland

Background: The widespread of KPC-type carbapenemases in Klebsiella pneumoniae most often possessing additional resistance leading to multidrug resistance represent a very high clinical concern. Avibactam, a non-β-lactam inhibitor, is able to restore the efficacy of ceftazidime against KPC producers. However, resistance to the novel ceftazidime-avibactam (CAZ-AVI) association is increasingly reported among clinical strains producing KPC variants.

We described a novel KPC-3 variant, KPC-50, produced by the K. pneumoniae N859 clinical isolate, recovered in 2019 from an intraabdominal abscess of a patient hospitalized in Zürich, Switzerland. This isolate was resistant to carbapenems but also uncommonly resistant to CAZ-AVI.

Materials/methods: The blaKPC-50 and blaKPC-3 genes were amplified and transformed into E. coli TOP10. Antimicrobial susceptibility was performed by the disc diffusion method. Minimum inhibitory concentrations (MICs) were confirmed by broth microdilution and E-test. Further, KPC-X and KPC-3 enzymes were purified with a cation column and using a lab-scale chromatography system AKTA-prime. Finally, kinetic measurements were performed with a spectrophotometer.

Results: The KPC-50 β-lactamase possessed a 3-amino-acid insertion (E-A-V) located between amino acids 276 and 277 compared to the KPC-3 amino acid sequence. Cloning and expression of this plasmid-borne blaKPC-50 gene in Escherichia coli, followed by determination of MIC values and kinetic parameters, showed that KPC-50, compared to those of KPC-3, has an increased affinity to ceftazidime and a decreased sensitivity to avibactam, leading to resistance to ceftazidime-avibactam once produced in K. pneumoniae. Furthermore, KPC-50 exhibited a decrease of its carbapenemase activity. In addition this strain was resistant to colistin by modification of the pmrB gene that governs the lipopolysaccharide biosynthesis.

Conclusions: This report highlights that (i) insertion/deletion in the KPC sequence may be an important evolution pathway for conferring ceftazidime-avibactam resistance in K. pneumoniae, and (ii) the diversity of KPC variants conferring resistance to ceftazidime-avibactam already circulating in Europe.

Abstract 1272

The guideline compatibility of mucormycosis management: a retrospective review of the case reports from European quality (EQUAL) score perspective

Hatice Koc1, Gokhan Metan*

1Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Mucormycosis is a rare, but life-threatening disease. European QUALITY (EQUAL) score was recently developed that reflects the strongest recommendations from the international guidelines for the management of mucormycosis. Here, we investigated the compliance of the individual diagnostic and treatment approaches with the guideline recommendations in the published case reports.

Materials/methods: A Pubmed search was performed by using the keyword “mucormycosis” between 01 January 2015 and 31 December 2018. Cases with pulmonary and/or rhinocerebral involvement were included in the analysis. Only the items that were clearly described in the case report were scored.

Results: The search revealed 882 publications. A total of 165 cases were included in the study. The median age of patients was 48.5 years (Minimum 1.5, maximum of 77 years). The 96 were male. The most common underlying disease was diabetes mellitus in 82 patients, followed by hematological malignancy in 37 patients. Rhinocerebral involvement was the most common presentation in 84 patients, 68 patients had pulmonary mucormycosis, and 13 had pulmonary and rhinocerebral mucormycosis. The achievable score from the diagnostic approach was 1.31.4, the achieved score was 631 (48.1%). Direct microscopy was performed in only 18 of 44 patients, culture was performed in 33 out of 44 patients who underwent bronchoscopy, fungal culture from biopsy specimen was performed in only 65 of 135 patients who underwent biopsy, and species identification with antifungal susceptibility test was performed in 14 out of 43 culture-positive patients. The achievable score for treatment was 1024 but achieved to 424 (47.3%). Surgical debridement was performed in 95 patients, amphotericin B deoxycholate was first choice antifungal in 30 patients, the dose was lower than 5 mg/kg/day in 15 of 87 patients who received liposomal amphotericin B, none of the patients who received posaconazole or isavuconazole had therapeutic drug level monitoring, and the control of risk factors such as neutropenia, ketoacidosis, hyperglycemia, and corticosteroids was reported in only 37 patients. The mortality rate was 38.8% (64 out of 165).

Conclusions: The case reports achieved to 50% of the achievable scores, approximately. The management of mucormycosis is an area that needs continuous improvement.

Population pharmacokinetic modelling and simulations to support ceftazidime-avibactam dose selection for paediatric patients with nosocomial pneumonia

Margaret Lynn Mcfadyen1*, Manoli Vourvahis2, Mark Lovern3, Richard Franzese4, Todd Riccobene4, Timothy Carrothers4, Margaret Tawadrous1

1Pfizer, Sandwich, United Kingdom, 2Pfizer, New York, United States, 3Certara Strategic Consulting, Raleigh, United States, 4Allergan plc, Madison, United States, 5Pfizer, Groton, United States

Background: The ceftazidime-avibactam paediatric investigation programme includes one Phase I and two Phase II completed trials in children with complicated intra-abdominal infection or complicated urinary tract infection. A further single-dose Phase I PK trial in children with NP (NCT04040621) is underway. In this analysis, previously reported population PK models were used to guide ceftazidime-avibactam dosage selection for the paediatric NP trial.

Materials/methods: The ceftazidime and avibactam population PK models included 2130 subjects with 9628 samples and 2403 subjects with 14,223 samples, respectively, including 154 and 153 children with 509 and 488 samples, respectively. Both were two-compartment disposition models in which body weight and renal maturation (subjects ≤2 years) or body surface area-normalised creatinine clearance (nCrCL; subjects >2 years) were key covariates predicting ceftazidime and avibactam clearance. The final PK models using NP population effects were used to simulate steady-state exposures and probability of target attainment (PTA) for various ceftazidime-avibactam dosage regimens (1000 NP patients/simulation), and different age and renal impairment categories. Simulations used plasma-free fractions [85% ceftazidime, 92% avibactam] and a joint PK/pharmacodynamic target (achievement of free plasma ceftazidime ≥8 mg/L and avibactam ≥1 mg/L simultaneously for ≥50% of the dosing interval). Adult NP patients were used as reference for matching exposures and PTA.

Results: In simulated paediatric NP patients (age >3 to ≤6 months) with normal renal function, ceftazidime-avibactam 40-10 mg/kg 2-h infusions q8h achieved similar mean exposures to adult patients with normal renal function receiving 2000-500 mg q8h (Table), joint PTA was 98.0% and 95.4% respectively. In simulated paediatric patients (>6 months to <18 years) with NP and normal renal function, ceftazidime-avibactam 50-12.5 mg/kg (capped at 2000-500 mg) q8h achieved ≥91.8% joint PTA with exposures similar to adults with normal renal function. Dose adjustments for paediatric patients with renal impairment of equivalent magnitude as in adults resulted in similar exposures and PTA.

Conclusions: These analyses support evaluation of ceftazidime-avibactam 40-10 mg/kg (>3 to ≤6 months) and 50-12.5 mg/kg (>6 months to <18 years) q8h in paediatric patients with NP and normal renal function, with dose adjustments for renal impairment (nCrCL <50 mL/min/1.73 m²).

Study sponsored by Pfizer.

Table. Predicted steady-state exposures (geometric mean) and PTA in paediatric patients with NP and normal renal function following administration of ceftazidime-avibactam (40-10 mg/kg or 50-12.5 mg/kg q8h) and adults with NP receiving the standard ceftazidime-avibactam dose

1Normal renal function defined as body-surface area normalised creatinine clearance (nCrCL) >50 mL/min/1.73 m² or renal maturation based on post-menstrual age for subjects aged <2 years. All doses administered as 2-h IV infusions. Paediatric doses were capped to a maximum dose of 2000 mg ceftazidime and 500 mg avibactam. Exposure values are geometric mean (95% CI). Limit target (50% T >MIC) for ceftazidime and 1 mg/L for avibactam. AUC0-3 h = area under the plasma concentration-time curve over 24 h at steady-state; Cmax, maximum concentration at steady-state; IV, intravenous; NP, nosocomial pneumonia; PTA, probability of target attainment.

Abstract 1278

**Antimicrobial resistance and genotypic markers of trimethoprim resistance in *Escherichia coli* and *Klebsiella* spp. isolated from patients with urinary tract infections**

Yinka Somorin*, Nichola-Jane Weir, Maeve Higgins, Carmel Hughes, Deirdre Gilpin, Martin Crockard, Michael Tunney

1 Queen’s University Belfast, School of Pharmacy, Belfast, United Kingdom, 2 Randox Laboratories Ltd, Crumlin, United Kingdom

**Background:** Urinary tract infections are among the most common bacterial infections. Isolation of causative uropathogens and their resistance profiles are not routinely performed, hence antibiotic therapy is often empirical. This study aimed to determine antimicrobial susceptibility of urinary *Escherichia coli* and *Klebsiella* spp. isolates from two Health and Social Care Trusts in Northern Ireland and to assess the use of trimethoprim resistance (*dfrA*) and ESBL-encoding (*bla*TEM) genes as biomarkers for rapid detection of trimethoprim resistance.

**Materials/methods:** Antimicrobial susceptibility of *E. coli* and *Klebsiella* spp. (n=124) to trimethoprim, amoxicillin, ceftazidime, ciprofloxacin, co-amoxiclav and nitrofurantoin was determined by ETEST® and interpreted according to EUCAST breakpoints. The *dfrA* and *bla*TEM genes were detected by PCR while ESBL production was measured using the combined disc method.

**Results:** Trimethoprim resistance was found in 37/124 (29.8%) of the isolates with MIC>32 mg/L. Eighty-one of the 124 isolates (65.3%) were resistant to amoxicillin, while 18/124 (14.5%) were resistant to nitrofurantoin. *DfrA* and *bla*TEM genes were detected in 29/37 (78.4%) and 30/37 (81.1%) of the trimethoprim-resistant isolates respectively. The detection of *dfrA* was highly sensitive in predicting phenotypic trimethoprim resistance (93.6%) and resistance to both trimethoprim and amoxicillin (100%). *Bla*TEM was less sensitive in detecting phenotypic trimethoprim resistance (45.8%). ESBL production was observed in 13/124 (10.5%) isolates and there was no significant association (*P*>0.05) between ESBL production and trimethoprim resistance.

**Conclusions:** This study demonstrates that *dfrA* could be used to determine trimethoprim resistance among urinary *E. coli* and *Klebsiella* spp. and guide the timely prescription of appropriate antibiotics for treatment of UTIs.

Abstract 1280

Multiple mutations in dihydrofolate reductase gene in cotrimoxazole-resistant *Streptococcus pneumoniae* isolated from HIV adults in a community setting, Tanzania

Joel Manyahi*1,2, Sabrina Moyo1, Said Aboud3, Nina Langeland1, Björn Blomberg1,4

1Haukeland University Hospital, University of Bergen, Bergen, Norway, 2University of Bergen, Bergen, Norway, 3Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, 4University of Bergen, Bergen, Norway

**Background:** Cotrimoxazole, a combination of trimethoprim and sulfamethoxazole, is widely used in people living with HIV to prevent opportunistic infections, including pneumococcal infections. Resistance to trimethoprim may render pneumococci fully cotrimoxazole-resistant. This study characterizes the molecular mechanisms of trimethoprim resistance in pneumococcal isolates from newly HIV-diagnosed patients in Dar es Salaam, Tanzania.

**Materials/methods:** A total of 1877 nasopharyngeal swabs were collected from 537 individuals newly diagnosed with HIV at four clinic visits during one-year follow-up in 2017 - 2018. Swabs were screened for pneumococcal colonization. Isolates were identified by colonial morphology on sheep blood agar and optochin susceptibility and serotyped by latex agglutination. Antimicrobial resistance was characterized by disk diffusion, E-test, polymerase chain reaction and sequencing.

**Results:** The majority of the pneumococcal isolates (48/76, 63.2%) were penicillin non-susceptible (MIC 0.06 – 2 mg/ml). Isolates were frequently resistant to cotrimoxazole (80.3%), but less so to chloramphenicol (23.7%), tetracycline (21%), erythromycin (22.4%), azithromycin (18.4%) and clindamycin (10.5%). None were resistant to levofloxacin. Twenty-five percent were resistant to three or more antibiotic classes (multi-drug resistant, MDR). The majority (n=40, 59.7%) were conjugate vaccine (PCV 23) serotypes. Vaccine-type pneumococci were more frequently MDR (OR 7.5, 95% CI 1.55 – 36.27, p = 0.01). There was no difference in cotrimoxazole MIC-values between vaccine- and non-vaccine-types [median 4 for both groups, p=0.9]. Cotrimoxazole-resistant isolates carried from 1 to 11 different trimethoprim-resistance mutations, the majority (n=52) having 6-8 mutations. The most common mutations conferring trimethoprim-resistance were Ile100Leu (100%), Glu20Asp (92%), Glu94Asp (61%), Leu135Phe (57%), His26Tyr (53%), Asp92Ala (53%) and His120Gln (53%). There was no difference in numbers of mutations between vaccine-type (median 5.5) and non-vaccine type pneumococci (median 6, p=0.3). There was no significant association between cotrimoxazole MIC-values and type or number of mutations.

**Conclusions:** *Streptococcus pneumoniae* isolated from newly HIV-diagnosed patients are frequently non-susceptible to penicillin and resistant to cotrimoxazole. Most isolates carried multiple mutations in the *dhfr* gene.

Epidemiology typing and molecular analysis of vancomycin-resistant Enterococcus faecium in haematological patients

Matěj Bezdíček1,2, Marketa Nykrynova1,3, Kristýna Dufková1,2, Kristina Plevová1, Iva Kocmanová1, Martina Lengerová1,2

1University Hospital Brno, Brno, Czech Republic, 2Masaryk University, Brno, Czech Republic, 3Brno University of Technology, Brno, Czech Republic

Background: A long-term increased prevalence of vancomycin-resistant Enterococci (VRE) colonization has been observed in the haematological department of the University hospital Brno (CZ). The aim of this study was to describe the genetic diversity of the local VRE population and determine the nosocomial transmission rate. An additional goal was to focus on establishing a rapid VRE typing method suitable for routine practice.

Materials/methods: Between 06/2019-07/2019, all hospitalized patients in one ward were screened for VRE presence. In total, 99 patients were screened on admission, at discharge and once a week during their hospitalization using rectal swabs. All collected VRE isolates were analysed using mini-MLST and whole genome sequencing (WGS).

Results: In total, 331 samples were taken, from which 24 VRE strains and one linezolid-resistant Enterococcus faecium isolate were isolated from 16 patients (16%, n=99). Using mini-MLST, 22/24 (88%) VRE isolates were identified as MelT55 and 3/24 (12%) as MelT420. In silico MLST was performed and allocated the obtained isolates to 6 ST (ST17, ST80, ST117, ST761, ST787 and one new ST). All isolates were VanA positive, 5 isolates were both VanA and VanB positive. The single-nucleotide variant (SNV) number was determined using SeqSphere+ software and was in a range from 1 to 5,687 within the isolates belonging to the same ST.

Conclusions: The whole genome SNV analysis showed high genetic diversity in the VRE population in our haematology ward. Most patients had their unique strain, indicating a lower rate of transmission than expected considering the generally accepted assumption that hospital transmission is the main source of VRE. Thus, other factors such as ATB treatment or patient’s overall health condition are likely to affect higher VRE colonization rates.

The current mini-MLST scheme does not have sufficient resolution power to distinguish VRE strains within our population. Therefore, we developed a new universal algorithm for WGS data to find variable regions that can be used to extend the existing mini-MLST scheme or to replace it with population-specific markers.

Abstract 1290

The in vitro effect of azithromycin on *P. aeruginosa* biofilms

Adrian Jimenez San Mauro¹, Niels Høiby², Oana Ciofu*³

¹University of Copenhagen, Faculty of Health and Medical Sciences, Costerton Biofilm Center, Copenhagen N, Denmark, ²Rigshospitalet, Department of Clinical Microbiology, Copenhagen, Denmark, ³University of Copenhagen, Faculty of Health and Medical Sciences, Costerton Biofilm Center, Copenhagen, Denmark

**Background:** Azithromycin (AZM) is efficient for treatment of chronic *P. aeruginosa* biofilm infection in cystic fibrosis (CF) patients although conventional susceptibility testing according to EUCAST shows resistance to AZM. It has, however, been shown that planktonic *P. aeruginosa* are more susceptible to AZM when tested in RPMI 1640 medium due to increased cell-wall permeability and reduced expression of the MexAB-OprM (van Bambecke).

**Materials/methods:** The aim of this study was to investigate the effect of AZM on planktonic and biofilm *P. aeruginosa* in LB vs RPMI 1640 medium in wild-type (WT) *P. aeruginosa* (PAO1) and two different mutants with relevant phenotypes for chronic infections: the hypermutable (ΔmutS) and the antibiotic resistant phenotype (ΔnfxB) due to the expression of the MexCD-OprJ efflux pump. The effect of AZM exposure for 24h and 72h of young (1 day-old) and mature (3 days-old) biofilms was investigated by establishing the minimal biofilm inhibitory concentration (MBIC₉₀) in the modified Calgary Biofilm Device.

**Results:** The AZM MBIC₉₀ in LB/RPMI1640 on young biofilms treated for 24h was 16/4 µg/ml for PAO1, 32/8 µg/ml for ΔmutS and 256/64 µg/ml for ΔnfxB. The effect of AZM was improved when the treatment was prolonged to 72h, the AZM MBIC₉₀ of young biofilm decreased to 8/1 µg/ml for PAO1, 8/1 µg/ml for ΔmutS and 32/4 µg/ml for ΔnfxB supporting the intracellular accumulation of AZM.

The AZM MBIC₉₀ in LB/RPM1640 on mature biofilms treated for 24h was 256/2 µg/ml for PAO1 and ΔmutS and 16/1 µg/ml for ΔnfxB, and decreased to 4/1 µg/ml for PAO1 and 8/1 for ΔmutS and was measured to 32/4 µg/ml for ΔnfxB with 72h treatment.

**Conclusions:** Our results show that AZM has a better effect on *P. aeruginosa* biofilms in RPMI 1640 than in LB medium and AZM effect is time and concentration-dependent in biofilms, suggesting that prolonged treatment at high dosages is recommended.

We show also that the production of MexCD-OprJ efflux pump is an important resistance mechanism for the in vitro efficacy of AZM on *P. aeruginosa* biofilms. Our results may have implications for susceptibility testing and for the dosing of AZM to CF patients.

Abstract 1291

**Acinetobacter baumannii complex, the beast of the weakest**

Olga Perovic1,2, Wilhelmina Strasheim1, Michelle Lowe1, Ruth Mokokotleng1, Marshagne Smith1, Ashika Singh-Moodley1,2

1 National Institute for Communicable Diseases, a Division of the National Health Laboratory Service, Johannesburg, South Africa, 2 University of Witwatersrand, Faculty of Health Science, Johannesburg, South Africa

**Background:** We conducted surveillance for Acinetobacter baumannii (AB) blood isolates. Our objectives were: to describe the prevalence and trends of antimicrobial resistance; to characterize of colistin resistance; to identify risk factors and to provide data for policies and guidelines.

**Materials/methods:** Surveillance was conducted at 12 sentinel academic sites, in South Africa from September 2018 to 2019. Isolates were identified by MALDI-TOF MS. Susceptibility testing was performed on the MicroScan Walkaway System and broth microdilution assay for colistin. Results were interpreted by the CLSI guidelines. PCR assay for mcr 1-5 genes, followed by WGS on the MiSeq Instrument was completed for colistin resistant isolates. Genome assembly and single nucleotide polymorphism analysis, for the pmrCAB operon and the lpxA, lpxC, lpxD and lpxB genes was done in CLC Genomics workbench. Resistome prediction was done with ResFinder and the Comprehensive Antibiotic Resistance Database (CARD).

**Results:** We have received 1823 isolates (43%) with clinical information for 1409 (33%) patients from a total number of 4269 AB isolates. AB was more prevalent in male patients (54%) and in children less than 14 year (40%). Crude mortality was 34%. During hospitalization 54% patients received meropenem and 32% received colistin treatment. The majority of the patients had medical devices (83%); long stay in hospitals (67%); 20% had treatment with carbapenems and 14% with colistin prior to AB isolation. Amongst those with known HIV status (890) 20% were positive. Susceptibility to majority of antibiotic classes was extremely low, from 1 - 14% except for colistin (96%). Of the 45 colistin resistant isolates none harbored the mcr 1-5 genes. A subset of 21 isolates were established with chromosomal non-synonymous mutations in various genes [pmrCAB operon, lpxB, lpxD and lpxC]. Colistin resistance had no impact on patient outcome and no significant difference was noted in patients that died from susceptible versus resistant strains (p=0.689).

**Conclusions:** AB pathogen is a highly prevalent among children in South African hospitals. Low resistance to colistin was chromosomally mediated with no plasmid genes. Risk factors were duration of the stay in hospitals, prior antibiotic use and interventions. High crude mortality in patients with AB is of concern.

Whole genome sequencing to detect antimicrobial resistance-associated determinants in Staphylococcus epidermidis

Kevin Cole*, Bernadette Young², Daniel Wilson¹, Bridget Atkins³, John Paul⁴, Martin Llewelyn⁴

¹Brighton and Sussex Medical School, University of Sussex, Brighton, United Kingdom, ²Oxford University, Nuffield Department of Medicine, Oxford, United Kingdom, ³John Radcliffe Hospital, Nuffield Orthopaedic Centre, Headington, United Kingdom, ⁴Brighton and Sussex Medical School, University of Sussex, Brighton, United Kingdom

Background: Staphylococcus epidermidis is a common cause of opportunistic nosocomial infections including prosthetic device-related infection. Nosocomial strains are commonly resistant to multiple antibiotics necessitating antimicrobial susceptibility testing of clinically significant isolates to guide treatment. Genotypic prediction of antimicrobial resistance from whole genome sequencing (WGS) has been successfully demonstrated in Staphylococcus aureus. We investigated the accuracy of this method for predicting antimicrobial resistance from WGS in S. epidermidis.

Materials/methods: Thirty nine isolates from orthopaedic device-related infection specimens and 48 carriage isolates (total 87) underwent disc diffusion phenotyping for 13 antibiotics routinely tested in our hospital microbiology laboratory against S. epidermidis. A panel of 27 resistance conferring genes and mutations in 11 housekeeping genes associated with staphylococcal antibiotic resistance was generated from previously published studies. All 87 isolates were sequenced on an Illumina HiSeq. Genomes were assembled de novo using Velvet 2.0 and interrogated using Basic Local Alignment Search Tool (BLASTn) for the presence of resistance conferring genes and mutations. Discrepant results were checked by repeat phenotypic testing and manual inspection of the relevant antimicrobial resistance genes.

Results: A total of 1131 comparisons (13 antibiotics in 87 isolates) were performed. There were 12 (1.06%) major errors (susceptible phenotype, resistant genotype) and 1 (0.09%) very major error (resistant phenotype, susceptible genotype). Overall the sensitivity and specificity of resistance genotype detection were 100% (95% CI 97% – 100%) and 99% (95% CI 98% - 99%) respectively.

Conclusions: These data demonstrate that detection of resistance conferring genes and mutations concord well with current routine phenotyping methods. Major error and very major error rates were within the acceptable limits of <3% and <1.5% respectively stipulated by the United States Food and Drug Administration Guidance for Antimicrobial Susceptibility Test Systems. A validation study is now required to determine if antimicrobial resistance of S. epidermidis is accurate and clinically viable as has been demonstrated previously for S. aureus.

Transjugular intrahepatic portosystemic shunt and infections: a single-centre retrospective study

Andrea Lombardi1,2, Margherita Sambo1, Marta Colaneri1, Anna Cambianica1, Paolo Sacchi1, Valentina Zuccaro1, Angela Maria Di Matteo2, Pietro Quaretti1, Lorenzo Moramarco3, Nicola Cionfoni3, Mario Umberto Mondelli2,4, Raffaele Bruno1,5

1Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases I, Pavia, Italy, 2Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases II and Immunology, Pavia, Italy, 3Fondazione I.R.C.C.S. Policlinico San Matteo, Radiology, Pavia, Italy, 4The University of Pavia, Internal Medicine and Therapeutics, Pavia, Italy, 5The University of Pavia, Clinical, Surgical, Diagnostics and Pediatric Sciences, Pavia, Italy

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is a procedure employed in advanced liver disease to reduce portal hypertension and its complications. Few data are available on infectious complications of TIPS, the best described of which being endotipsitis. However, uncertainties remain on the real incidence of other infectious events, including their prevalence and impact on the overall survival.

Materials/methods: We retrospectively identified infections occurred during a 2-year follow-up after TIPS placement in a cohort of patients who underwent this procedure between January 2010 and October 2019 in a large referral hospital. We recorded the microorganism isolates, the antimicrobial agents administered and the mortality rate during follow-up.

Results: Overall, we identified 42 patients subjected to TIPS placement, mostly males (62%) with a mean age of 61.5 years and a median baseline MELD score of 11. The hepatic venous pressure gradient was 23 mmHg before and 10 mmHg after the procedure. Forty (95%) patients received antibiotic prophylaxis concomitantly with TIPS placement: 17 (40%) received ceftriaxone, 16 (38%) cefotaxime, 2 (5%) meropenem, 2 (5%) piperacillin/tazobactam and 1 (2.5%) each ampicillin, amoxicillin/clavulanate and ciprofloxacin. During follow-up, infections occurred in 21 (50%) patients, for a total of 45 events. The most frequently observed were sepsis (33%) followed by urinary tract infections (29%). Pneumonia and acute bacterial skin and skin structure infections accounted for 9% of the events. The most frequently identified microorganisms were Enterobacteriales (39%) followed by Staphylococcus spp., Enterococcus spp. and Candida spp., each accounting for 14% of the events. Overall mortality rate was 19%, 16% in patients who developed infection(s) during follow-up, which was not significantly different from the 22% of those who did not (p=0.5, Fig.1A). The types of infection are shown in Fig.1B.

Conclusions: Infections, particularly sepsis and those caused by Enterobacteriales, were common in patients during the 2-years following TIPS placement. Occurrence of infections did not modify mortality rates.

Figure: Overall survival rates at 2-year and stratified according to the occurrence of infections. (A) Infections recorded during the follow-up period subdivided in 5 time periods (B).

Development of intravascular microdialysis as a tool for therapeutic drug monitoring and intensive PK studies in children

Valentin Al Jalali*,1, Beatrix Wulkersdorfer1, Peter Matzneller1, Edith Lackner1, Stefan Poschner2, Walter Jaeger1, Markus Zeitlinger1

1Medical University of Vienna, Department of Clinical Pharmacology, Vienna, Austria, 2University of Vienna, Department of Clinical Pharmacy and Diagnostics, Vienna, Austria

Background: Pharmacokinetics (PK) of antibiotics in children differs considerably compared to adults. However, the limited blood volume of children and the ethical restrictions that are associated with repetitive blood sampling severely hamper PK studies and individualization of therapy by means of dense therapeutic drug monitoring (TDM) in children. Microdialysis (MD) overcomes the aforementioned obstacles of PK sampling in children. However, MD has rarely been used in children and the currently available MD probes do not fit the common intravenous lines used on pediatric wards.

Materials/methods: We conducted this study to develop and validate a method for PK measurements in blood of children using modified MD catheters that fit small intravenous lines. For this purpose, in-vitro and in-vivo experiments with cefturoxime (CEF) were performed.

In-vitro MD experiments were performed in triplicates with three sampling time-points of 1h and with CEF concentrations of 2.5, 25 and 250µg/ml.

For the in-vivo PK study, a single intravenous dose of CEF 1500mg was administered over 30minutes to ten healthy volunteers (HV). Two modified intravascular MD catheters were inserted and serial MD and blood samples were taken. The retrodialysis technique was employed to measure the in-vivo recovery.

Results: Mean recovery in the in-vitro experiments during forward dialysis ranged from 31% to 33% and mean loss during retrodialysis ranged from 30% to 41% for all sampling time-points and CEF concentrations. Mean recovery during the in-vivo MD experiments was 14.4±4.6%, markedly lower than the recovery found in the in-vitro experiments.

Figure 1 shows the representative concentration-time profiles of CEF and a scatter plot correlating the MD and plasma concentrations for one HV, demonstrating a strong linear correlation. Preliminary PK analysis of all samples yielded a mean half-life of 1.15±0.2h for MD and 1.3±0.26h for plasma.

Conclusions: We developed an innovative MD catheter that can be inserted into small intravenous lines, allowing PK measurements of free antibiotic concentrations in children and thereby enabling individualization of therapy through TDM. In our experiments with this new MD catheter we were able to correlate MD and plasma concentrations and show reproducibility over time and for different concentrations in-vitro and in-vivo.

Figure 1

Presenter email address: valentin.aljalali@meduniwien.ac.at
Background: Pre-prescription authorisation is a commonly employed carbapenem stewardship strategy however Tamma et al demonstrated that postprescription review with feedback (PPRF) had a greater impact in terms of carbapenem use. The introduction of the electronic prescribing record (EPR) to our institution enabled the development of a real time carbapenem list (RTCL) with robust identification of all carbapenem prescriptions in real-time. Our aim was to perform PPRF on all patients initiated on a carbapenem (outside of critical care) and to assess the safety, impact and efficiency of the system.

Materials/methods: A real-time carbapenem prescription list was designed using Cerner® electronic prescribing system that can be executed and updated by the antimicrobial stewardship (AMS) team. The PPRF was performed daily by the AMS team during the normal working week and consisted of a review of the patient EPR, microbiological results and a telephone consultation with patient’s clinician. Carbapenem use was measured in defined daily doses (DDD) per 100 bed days used (BDU).

Results: Over an 11-week period (June to August 2019), carbapenem PPRF was carried out on 163 patients (Table 1). The time required for the activity was 30 minutes of AMS pharmacist time and 90 minutes of consultant microbiologist time per day.

Conclusions: The design and implementation of a RTCL on EPR to perform carbapenem PPRF led to a safe and effective reduction in meropenem use and allowed for the identification of several areas to target for stewardship interventions. The group would recommend this approach be adopted by institutions with resource depleted AMS teams in which EPR is available.

Abstract 1298

Effect of short-term antimicrobial therapy on the tolerance and antibiotic resistance of multidrug-resistant *Staphylococcus capitis*

Xiao Yu* 1

1the First Affiliated Hospital, Zhejiang University, School of Medicine, Hangzhou, China

**Background:** Bacteria undergo adaptive mutation in the host under the selective pressure of an antimicrobial agent. However, the specific effect of clinical antimicrobial use on bacterial evolution and genome mutations related to bacterial survival within a patient is unclear.

**Methods:** Three *S.capitis* strains were continuously isolated from cerebrospinal fluid of a clinical inpatient. Antimicrobial susceptibility was determined by using agar dilution method. The growth rate and whole blood tolerance of the three *S.capitis* strains were measured and relative fitness were calculated. Biofilm formation were measured by crystal violet Staining. The virulence of the bacteria was examined in the *Galleria mellonella* model. Whole-genome sequencing(WGS) and in silico analysis was performed to explore the genetic mechanisms of the apparent changes in the antimicrobial resistance phenotype. Identification of hypothetical protein was done by molecular cloning.

**Results:** The first isolate was susceptible to rifampin (MIC=0.25 μg/ml), resistant to gentamicin (MIC=16 μg/ml), while the later two isolates were resistant to rifampin (MIC >64 μg/ml), susceptible to gentamicin (MIC=4 μg/ml). Growth curve showed the later two isolates grew faster than the first isolate with a relative fitness cost of 19.2%, and 15.0%, accordingly. Their ability to form biofilm and *in vitro* whole blood tolerance were enhanced. No significant differences of virulence in the *G. mellonella* model were observed.Genome SNPs analysis revealed three genes(*saeR*, *moaA*, and *rpoB*) harbored missense base substitution mutations and one hypothetical protein harbored frameshift mutation. The mutation of *rpoB* gene caused rifampicin resistance. Mutations in *saeR* *moaA* and hypothetical protein are associated with changes in other biological traits. Amino acid sequence-based structure and function identification the hypothetical protein indicated that a mutation in the encoding gene might be associated with altered aminoglycoside susceptibility.

**Conclusions:** We report here for the first time that short-term clinical antibiotic use causes resistance mutations, collateral sensitivity, and adaptive enhancement of *S. capitis*. The impact of clinical short-term antimicrobial use on bacterial ability to survive within the host should not be underestimated, and appropriate measures should be introduced to address the adaptive evolution of bacteria to antimicrobial agents.

Cold plasma activated liquid reduces bacterial biofilm produced by Staphylococcus aureus and Escherichia coli
Muireann Fallon*,1, Sarah Kennedy1, Sharath K. Babu2, Stephen Daniels2, Hilary Humphreys1,3
1Royal College of Surgeons in Ireland, Dublin, Ireland, 2Dublin City University, Dublin, Ireland, 3Beaumont Hospital, Dublin, Ireland

Background: Hospital surfaces are a source of infection due to contamination by bacteria. A novel potential method of hospital surface decontamination is the use of cold atmospheric pressure plasma (CAPP) systems. CAPP has antimicrobial properties that can inactivate bacterial cells on surfaces directly but also through the use of plasma activated liquid (PAL). Although the mechanisms of action are not fully understood, it is thought to be due, in part, to the production of reactive oxygen and reactive nitrogen species (RONS) in the liquid. To be an effective hospital decontamination tool, CAPP must also inactivate bacteria within biofilms. Multi-cellular, biofilm structures confer a higher resistance to disinfectants than singular, planktonic bacteria. Here we aimed to assess the microbial inactivation by CAPP and to examine the possible mechanisms of the antimicrobial action of CAPP treated phosphate buffered saline (PBS) against bacteria in bacterial biofilms.

Materials/methods: PBS was treated with CAPP for 300 seconds to generate PAL. PAL was then evaluated for levels of RONS using colorimetric assays. Planktonic Staphylococcus aureus (S. aureus) and Escherichia coli (E. coli) were incubated with PAL and viability was assessed using colony forming unit (CFU) assays. S. aureus and E. coli biofilms were grown for 48 hours and inoculated with PAL. Biofilm viability was assessed using metabolic assays. Damage throughout the biofilm structure was assessed via imaging using LIVE/DEAD staining and confocal microscopy.

Results: RONS levels were greatly increased in PAL compared to untreated PBS. A seven-log reduction in CFU was achieved in planktonic S. aureus and E. coli after incubation with PAL. S. aureus and E. coli biofilm viability decreased by 48% and 64%, respectively, after PAL treatment. Confocal microscopy showed membrane damage in treated bacterial cells throughout the biofilm structure. The bacterial inactivation in treated biofilms could be, in part, due to the RONS present in PAL.

Conclusions: CAPP treated PBS results in PAL that has antimicrobial and anti-biofilm activity, probably mediated in part by RONS. Further research is required to confirm these findings with other pathogens and under different conditions to conform the potential of PAL as an effective decontaminant.

Aztreonam-avibactam activity against carbapenemase-producing Enterobacterales collected in Europe, Asia and Latin America (2017-2019)

Helio S. Sader\(^1\); Timothy Doyle\(^1\), Rodrigo E. Mendes\(^2\), Valerie Kantro\(^3\), Mariana Castanheira\(^3\)

\(^1\)JMI Laboratories, North Liberty, United States

**Abstract**

**Background:** Aztreonam-avibactam (ATM-AVI) is under clinical development for treatment of serious infections caused by Gram-negative bacteria and has demonstrated potent activity against Enterobacterales producing all types of clinically relevant β-lactamases, including metallo-β-lactamases (MBL). We evaluated ATM-AVI activity against a worldwide collection of carbapenemase-producing Enterobacterales (CPE).

**Materials/methods:** A total of 748 clinical CPE isolates were collected in Europe (n=504; 27 centres in 15 nations), Latin America (LATAM; n=152; 7 centres in 4 nations), and Asia-Pacific region (APAC; n=92; 8 centres in 7 nations) in 2017-2019. All isolates were tested for susceptibility against ATM-AVI and comparators by reference broth microdilution method and submitted to whole genome sequencing analysis for identification of β-lactamase genes.

**Results:** The collection included 636 Klebsiella pneumoniae, 51 Enterobacter cloacae, 20 Escherichia coli and 41 isolates of other species. The most common MBL (n=219) was NDM-type [193; 88.1% of MBLs] and the most common OXA-type (n=234) was OXA-48 [188; 80.3% of OXA-type]. Among KPC-producers (n=294), KPC-2 and KPC-3 represented 51.7% and 48.3%, respectively. ATM-AVI was very active against the entire collection of isolates with overall MIC\(_{90}\) values of 0.25/0.5 mg/L and 99.3% of isolates inhibited at ≤4 mg/L (Table). Isolates with ATM-AVI MIC >4 mg/L demonstrated additional resistance mechanisms, including PBP3 alterations. Among comparators, the most active agents overall were tigecycline [MIC\(_{90}\), 1/2 mg/L; 92.6% susceptible [S] at ≤2 mg/L] and colistin [MIC\(_{90}\), 0.12/≤8 mg/L; 77.5%S at ≤2 mg/L]. ATM-AVI [MIC\(_{90}\), 0.12/0.5 mg/L; 98.6% inhibited at ≤4 mg/L], tigecycline [MIC\(_{90}\), 1/2 mg/L; 92.7%S at ≤2 mg/L], and colistin [MIC\(_{90}\), 0.12/≤8 mg/L; 79.4%S at ≤2 mg/L] were the most active compounds against MBL producers. When tested against KPC-producers and OXA-producers, ATM-AVI (100.0% and 99.1% inhibited at ≤4 mg/L, respectively) and ceftazidime-avibactam (MIC\(_{90}\), 1/2 mg/L and 100.0%S for both subsets) were the most active agents.

**Conclusions:** ATM-AVI displayed potent activity against MBL-, KPC-, and OXA-producing Enterobacterales from Europe, LATAM, and APAC, inhibiting >99% of isolates at ≤4 mg/L. Our results support further clinical development of ATM-AVI for treatment of infections caused by CPE, including MBL-producing isolates.

Hospital Univ Salamanca, Salamanca, Spain, 7Unidad de Enfermedades Infecciosas. Hospital Univ. 12 de Octubre, Madrid, Spain, 8Unidad de Gestión Clínica de Hematología. Hospital Univ. Reina Sofia, Córdoba, Spain

Background: To analyze the mechanisms of resistance to extended-spectrum β-lactams, aminoglycosides and quinolones in MDRE isolated between June 2017 and August 2019 in 44 patients of the 127 recruited in the study, who receiving an Allo-SCT in four Spanish hospitals.

Materials/methods: Overall, 117 MDRE, (AmpC-hyperproducing and/or producers of extended-spectrum β-lactamases (ESBLs) or carbapenemases), isolated in rectal swabs [pretransplant, weekly during the first month post-transplant, biweekly up to 100 days post-transplant and monthly up to 180 days post-transplantation] and 8 MDRE isolated from different clinical samples, were studied. The minimum inhibitory concentrations (MICs) of 24 antibiotics were determined by broth-microdilution (EUCAST breakpoints). PCR was performed for ESBLs (SHV, TEM, CTX-M), plasmid-mediated AmpC β-lactamases, carbapenemases (KPC, IMP, VIM, NDM, GES, OXA-48), plasmid-mediated quinolone-resistance [PMQR] (qnrA, qnrB, qnrC, qnrD, qnrE, qepA, oqxAB) and aminoglycoside-modifying-enzymes [AMEs] (aac(3)-Ia, aac(3)-IIa, aac(6’)-Ib, ant(2’)-Ia, aph(3’)-Ia, aph(3’)-Ia) and AME-genes were detected in 45.9%, being aac(6’)-Ib the most prevalent (85.3%), 50.0% of strains harboured two AME-genes. PMQR-genes were detected in 35/60 (58.3%) isolates quinolone-resistant and qnrB was the most prevalent (51.4%).

Results: The microorganisms isolated were: E.coli 52 (41.6%), Enterobacter spp. 36 (28.8%), K.pneumoniae 16 (12.8%), Citrobacter spp. 13 (10.4%) and others species 8 (6.4%) [5 K.oxytoca, 1 H.alvei, 1 K.intermedia, 1 S marcescens]. PFGE analysis identified 19 clonal patterns in E.coli, 9 in E.cloacae, 5 in K.pneumoniae and 3 in C.freundii. The antimicrobial susceptibility, corresponding 74 MDRE (one isolate per REP-PCR pattern/antibiogram and patient) are shown in Table 1. In seven patients MDRE were detected in clinical samples, in all but one patient, the same MDRE was detected in different rectal swabs days on the follow-up. ESBLs were detected in 60.8% and CTX-M was (47.3%) the most prevalent, 29.7% isolates were AmpC-hyperproducers. Carbapenemases were detected in 8 (10.8%) isolates: VIM (2 E.cloacae, one S.marcescens and K.intermedia), GES (2 K.oxytoca and one E.cloacae) and IMP (E.aerogenes). AME-genes were detected in 45.9%, being aac(6’)-Ib the most prevalent (85.3%), 50.0% of strains harbour two AME-genes. PMQR-genes were detected in 35/60 (58.3%) isolates quinolone-resistant and qnrB was the most prevalent (51.4%).

Conclusions: In 6 of the 44 transplant patients who were colonized by MDRE, an infection by the same microorganism was documented. E. coli producing CTX-M was the MDRE most prevalent followed by Enterobacter spp. AmpC-hyperproducer.
Table 1. In vitro activity to 24 antibiotics in 74 multidrug-resistance *Enterobacterales* (MDRE) isolated from patients with Allo-SCT transplant.

Abstract 1316

Antimicrobial activity of aztreonam-avibactam and comparator agents when tested against a large collection of contemporary Stenotrophomonas maltophilia isolates collected from medical centres worldwide

Hello S. Sader*, Cecilia Carvalhaes1, SJ Ryan Arends1, Leonard Duncan1, Robert Flamm1, Mariana Castanheira1

1JMI Laboratories, North Liberty, United States

Abstract third-party references: This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services related to preparing this abstract.

Background: Stenotrophomonas maltophilia represents a major cause of hospital-acquired pneumonia (HAP) and bloodstream infections (BSI). There are very limited therapeutic options to treat S. maltophilia infections due to intrinsic production of metallo-β-lactamases (MBL) by these organisms. Aztreonam-avibactam (ATM-AVI) is under clinical development for treatment of serious infections caused by Gram-negative bacteria, including MBL-producers.

Materials/methods: A total of 1,839 isolates were collected in Western Europe (W-EU; n=388; 24 centres in 9 nations), Eastern Europe (E-EU; n=156; 15 centres in 12 nations), North America (NA; n=1,095; 77 centres), Latin America (LATAM; n=92; 12 centres in 9 nations), and Asia-Pacific region (APAC; n=108; 17 centres in 8 nations) in 2016-2019. The isolates were mostly from HAP (70.4%) and BSI (12.6%). Susceptibility testing was performed by reference broth microdilution method at a central laboratory and CLSI breakpoints were applied when available.

Results: ATM-AVI was very active against isolates from all geographic regions and infection types (MIC50/90, 2-4/4 mg/L), inhibiting 90.7-96.7% of isolates at ≤4 mg/L (92.1% overall) and 96.3-100.0% at ≤8 mg/L (97.8% overall), which are the current CLSI susceptible [S] and intermediate breakpoints, respectively, for ATM alone (Table). Trimethoprim-sulfamethoxazole (MIC50/90, ≤0.5-1/1 mg/L) and minocycline (MIC50/90, 0.5-1.2 mg/L) were active against 93.5-96.9% and 99.0-100.0% of isolates at the respective, current CLSI susceptible breakpoints. Moreover, 74.1%/84.7% of TMP-SMX-non-susceptible isolates were inhibited at ≤4/≤8 mg/L of ATM-AVI. Levofloxacin (MIC50/90, 1/4-4 mg/L/L) was active against 74.0-87.0% of isolates at the current CLSI breakpoint ≤2 mg/L). Ceftazidime (MIC50/90, >32/≥32 mg/L; 16.7-30.4%S at ≤8 mg/L) and colistin (MIC50/90, 4-8/>8 mg/L; 29.3-42.9% inhibited at ≤2 mg/L) exhibited limited activity, whereas tigecycline (MIC50/90, 1/2.4 mg/L) inhibited 82.7-90.7% (85.0% overall) of isolates at ≤2 mg/L. Ceftolozane-tazobactam, meropenem, imipenem, amikacin, and tobramycin exhibited very limited activity against these organisms.

Conclusions: ATM-AVI demonstrated potent in vitro activity against a large collection of S. maltophilia isolated from patients with HAP, BSI, and other systemic infections. ATM-AVI may represent a valuable option to treat S. maltophilia infections, addressing a major unmet medical need.

Abstract 1317

**Rapid detection of fungal feet infection by LED-UV light**

Ester Fusté1, Guadalupe Jimenez Galisteo2, M. Jesus Sanchez3, Mercedes Aguilar4, Teresa Vinuesa*2

1University of Barcelona, Microbiology Unit/Dep Nursery, Public Health and Mental Health/IDIBELL, Hospitalet de llobregat, Spain, 2University of Barcelona, Microbiology Unit/Dep Pathology and Experimental Therapeutics/IDIBELL, Hospitalet de llobregat, Spain, 3Centre Medic Creu Blava, Podiatrics Unit, Esparraguera, Spain, 4Hospital Universitari Bellvitge, ICS/IDIBELL, Hospitalet de llobregat, Spain

**Background:** Fungal feet infections are usually torpid diseases whose specific diagnostic is compulsory as similar clinical entities are treated with steroids that can worsen the mycotic infection. To avoid inaccurate therapies, a fast and accurate detection of fungi is needed. Potassium hydroxide (KOH) treatment of samples is used for clarifying specimens (rich in keratin), before examination by bright light microscopy but it requires skilled observers. Fluorescent brighteners absorbing UV light and emitting blue light, with affinities for polysaccharides with β-links, have been used to facilitate observation. Our group uses for this purpose Leucophor®, a disulphonated stilbene brightener along with KOH treatment. Based on the report of Denny G et al referent to hand held UV illumination, we aimed to evaluate an alternative easy to use, none-expensive method to fasten the time elapsed between the clinical suspicion and the confirmation of the presence of a fungal infection. We examined patients with clinical suspicion of mycotic infection as well as nail or skin samples, by means of a hand held LED UV, comparing it with the visualization by a fluorescence microscopy.

**Materials/methods:** 40 patients with clinical suspicion of fungal feet infection and 40 healthy individuals were analyzed in vivo by both methods. Their collected specimens were KOH digested, Leucophor® stained and examined in a fluorescence microscopy (Nikon E800). After switching the UV source off, they were observed under tangential illumination from a hand-held LED UV Flashlight (HAN-WYB75*4) at 395 nm. Also a 1418 90X Phone LED UV Light Magnifier 90 x and 60 X adapted to a Smart Phone Huawei with a Leica Camera was used. Culture in appropriate media was performed in all cases. Moreover, a series of 30 nails and scrapings of our collection were examined and imaged (15 positive: Aspergillus sp., Trichophyton rubrum, Scopulariopsis sp.and 15 culture negative).

**Results:** Even that the brightness of the conidia and hyphae using the hand-held LED UV Flashlight diminished slightly, it appears still clear permitting an accurate diagnosis of the presence of fungi.

![](Hand_held_LED_UV.png)  ![Nikon_Ellipse_800.png]

**Conclusions:** The use of low cost devices seems feasible for detection of fluorescence from samples containing fungi with reasonable resolution.

Abstract 1319

MYCOPLASMA IST3, a new in vitro medical device to aid the diagnosis of urogenital mycoplasma infection: performance results from an international multi-centre trial

Yohann Bala\(^1\)*, Ian Boostrom\(^2\), Jelena Minic Vasic\(^3\), Andrew Barratt ?\(^2\), Emmanuel Chanard\(^4\), Jelena Gluvakov\(^3\), Brad Spiller\(^2\), Laurence Devigne\(^5\)

\(^1\)bioMérieux, Global Clinical Affairs, Marcy L’Etoile, France, \(^2\)School of Medicine, Cardiff University, Division of Infection and Immunity, Cardiff, United Kingdom, \(^3\)Public Health Institute, Pancevo, Pancevo, Serbia, \(^4\)Cerballiance, Plateau Technique MICROBIOLOGIE, région Centre-Est, Lyon, France, \(^5\)bioMérieux, Research and Development, La Balme les grottes, France

**Background:** Mycoplasma hominis (Mh) and Ureaplasma spp (Uspp) are possible pathogens associated with urogenital infections. This study assessed performance of MYCOPLASMA IST3, a new in vitro diagnostic test designed to detect, identify, enumerate and test the susceptibility of Mh and/or Uspp to relevant agents (Levofloxacin, Moxifloxacin, Tetracycline, Erythromycin, Telithromycin and Clindamycin).

**Materials/methods:** 516 vaginal/cervical or urethral swabs, semen and urines were included. For detection/identification, performance was expressed as the positive (PPA) and negative agreements (NPA) between MYCOPLASMA IST3 and sample status defined using A7 agar and PCR. For indicative enumeration, performance was expressed as the agreement between MYCOPLASMA IST3 and A7 agar results. For Antimicrobial Susceptibility Testing (AST) application, Category Agreement (CA, %) Major Error rate (ME, %) and Very Major Error counts (VME, #) were calculated comparing MYCOPLASMA IST3 category (S or R) to Broth Micro Dilution Minimum Inhibitory Concentration (MIC) results interpreted using CLSI M43-A interpretive breakpoints.

**Results:** 312 samples were negative, 109 grew viable Uspp, 73 grew Mh and 22 grew both. 38% of the positive samples were contrived (spiked) samples. Regarding the detection/identification application, MYCOPLASMA IST3 had a PPA of 98.5% (129/131) and 92.6% (88/95) and a NPA of 99.7% (384/385) and 99.0% (410/414) with A7 agar for Uspp and Mh, respectively. Among the 22 mixed samples, MYCOPLASMA IST3 recovered both species for 18 samples while only the Uspp was recovered for the remaining samples. Indicative enumeration results were in agreement between MYCOPLASMA IST3 and A7 agar in 84.6% (99/117) and 83.7% (72/86) of the cases for Uspp and Mh, respectively. MYCOPLASMA IST3 AST application produced CA ranging from 96.0% to 100.0% and ME rates from 0.0% to 4.2% (Table). Three VMEs were observed (1 Uspp with tetracycline, 1 Mh with tetracycline, 1 Mh with Moxifloxacin), 2 of them originated from isolates with MIC within ± 1 doubling dilution from the CLSI breakpoint value.

**Conclusions:** MYCOPLASMA IST3 is an accurate aid in the diagnosis of urogenital infections related to Uspp or Mh, providing clinicians with valuable information to guide treatment.

**Table:** MYCOPLASMA IST3 Antimicrobial Susceptibility Testing performance.

Abstract 1321

Comparison of the distribution of quinolone resistance markers in *Escherichia coli* in a human-animal health interface model

Jesus Silva-Sanchez*, Guillermína Sanchez2, Celia Mercedes Alpuche-Aranda1, Elsa Tamayo1, Víctor González4, Ulises Garza-Ramos3, Humberto Barrios3, Doris Arellano3

1Instituto Nacional de Salud Pública, Instituto Nacional de Salud Pública, Cuernavaca, Mexico, 2Instituto Nacional de Salud Pública, Cuernavaca, Mexico, 3Universidad Nacional Autónoma de México, Cuernavaca, Mexico

**Background:** Quinolone action is the inhibition of DNA gyrase and topoisomerase IV DNA enzymes. However, two types of resistance are detected for these antibiotics: chromosome (modifications in gyrase and overexpression of efflux pumps) and PMQR (production of qnr proteins, acetylases, and efflux pumps). The aim is to know the distribution of quinolone resistance genetic markers in *E. coli* obtained from humans and porcine in a close model.

**Materials/methods:** Total of 1,407 *E. coli* isolates (982 from pigs and 425 from humans with diarrhoea) were obtained from a farm located in Morelos, Mexico (June 2015- April 2016). MIC was obtained for CIP and NAL. Phylogroup according to Clermont system and the genes gyrA and PMQRs were amplified by PCR. The plasmid was performed according to Kieser.

**Results:** Three different phenotype were identified: I (NALr/CIPr), II (NALr/CIPs), and III (NALs/CIPs); the most frequent in both population porcine (PEI) and human (HEI), was phenotype II (PEI 56.3%; HEI 50.1%). A representative sample of isolates was selected: 47/425 PEI, and 100/982 HEI. The major phylogroup was A (PEI 56%, HEI 44.6%), follow by B1 (PEI 31%, HEI 17%), D (PEI 11%, HEI 25.5%) and B2 phylogroup (PEI 2%, HEI 12.8%). ORDR region of gyrA gene was wild type (HEI 57.4%, PEI 54%) follow by S83L (HEI 19.4%, PEI 19%) and S83L/D87N (HEI 19.1%, PEI 18%) mutations. The major PMQR was qnrB in PEI (43%) and HEI (23.4%). Additionally, 39% of PEI and 59.6% of HEI, no qnr genes were identified. OqxA/OqxB, qepA and aac(6’)-Ib-cr were detected at low frequency (<7%). The phylogenetic tree shows three clades: 1) phenotype I/S83L/D87N, 2) phenotype II/S83L, and 3) phenotype II and III/wild ORDR region and qnrB. A plasmid of 150 to 160 kb was identified in most of the isolates.

**Conclusions:** No difference of qnrB was identified in both groups of *E. coli*. Eflux pumps and acetylation enzyme are more frequent in PEI than in HEI. A 150-160 kb plasmid was detected in most of the isolates. Further studies will be conducted to know the structure of the plasmids.

Abstract 1322

Resistance mechanisms associated with pleuromutilins among Gram-positive clinical isolates from the worldwide surveillance programme for lefamulin in 2018

Rodrigo E. Mendes1, Timothy Doyle1, Mariana Castanheira1, Robert Flamm1, Steven P Gelone2, Susanne Paukner3, Helio S. Sader1

1 JMI Laboratories, North Liberty, United States, 2Nabriva Therapeutics Inc., King of Prussia, United States, 3Nabriva Therapeutics, GmbH, Vienna, Austria

Abstract third-party references: This study was performed by JMI Laboratories and supported by Nabriva Therapeutics, which included funding for services related to preparing this abstract.

Background: Lefamulin is a first-in-class, semi-synthetic pleuromutilin antibiotic that inhibits bacterial protein synthesis via a unique mechanism of action was approved by the United States Food and Drug Administration (FDA) in 2019 for the treatment of community-acquired bacterial pneumonia (CABP) in adults. This study characterized the resistance mechanisms associated with elevated lefamulin MICs in a global surveillance isolate collection from 2018.

Materials/methods: A total of 4,406 S. aureus, coagulase-negative staphylococci (CoNS), S. pneumoniae and β-haemolytic and viridans group streptococci were tested using reference broth microdilution. A total of 36 (0.8%) isolates met the criteria based on FDA breakpoints or MICs above the normal wildtype distribution. Bacterial genomes were sequenced (MiSeq Sequencer, Illumina) and screened in silico for possible lefamulin resistance genes and mutations in the 23S rRNA, L3, L4 and L22.

Results: 8 of 1,607 (0.5%) S. aureus harboured vga(A) (6/8; lefamulin MIC, 1–8 mg/L) or lsa(E) (2/8; lefamulin MIC, >32 mg/L). 20 of 270 (6.7%) CoNS carried either vga gene variants (18/20; lefamulin MIC, 2–>32 mg/L) or showed G2576T alterations in the 23S rRNA along L3 mutations at H146 and M156 or at position V154 (2/20; lefamulin MIC of 0.5 mg/L). Only 2 of 1,866 (0.1%) S. pneumoniae were non-susceptible to lefamulin (MIC, 1–2 mg/L); both isolates had mutations in ribosomal proteins (L4 or in L3 and L22). Among other streptococci, 3 of 522 (0.5%) β-haemolytic and 2 of 141 (1.4%) viridans group streptococci carried lsa(E) (lefamulin MIC, 2–32 mg/L), while one S. oralis (lefamulin MIC, 1 mg/L) did not show any resistance mechanisms. Other plasmid-mediated genes, such as cfr were not detected.

Conclusions: Gram-positive isolates from a global collection causing human infections exhibiting elevated lefamulin MICs are rare. The most common resistance mechanisms identified were vga and lsa(E); cfr was not detected. Longitudinal surveillance studies will monitor the stability of the in vitro activity of lefamulin.

Abstract 1329

Efficacy of bacteriophage-antibiotic combinations on two different phenotypes of methicillin-resistant Staphylococcus aureus

Razieh Kebriaei1, Katherine Lev1, Taylor Morrisette1, Philip Maassen1, Jacinda Abdul-Mutakabbir1, Sandra Morales2, Michael J. Rybak3

1Wayne State University, Detroit, United States, 2Phage consulting, Sydney, Australia, 3Wayne State University, Detroit, United States

Background: The widespread use of antibiotics has generated selective pressures that have driven the emergence of multi-drug resistant strains. The antimicrobial of choice for invasive methicillin-resistant Staphylococcus aureus (MRSA) infections has been vancomycin; however, treatment failures have continued to be reported secondary to poor drug performance or the development of various resistant phenotypes. Bacteriophages (phages) have been suggested as a potential adjunctive/alternative therapy. These phages exhibit bactericidal activity by infecting bacterial cells, redirecting the cellular machinery to produce progeny virions and killing the bacterial cell upon lysis and release of those progeny phages. Staphylococcus aureus naturally releases extracellular vesicles (EVs) during growth, which are known to play important functions in bacteria-bacteria interactions and potentially transferring antibiotic resistance genes. Unfortunately, there is limited data on the use of phage-antibiotic combinations and bacterial response to these. The objective of this study was to test the in-vitro activity of various standard of care (SOC) antibiotics with phages and their effects on EVs formation.

Materials/methods: Phage-antibiotic exposure was tested on two different phenotypes of MRSA, isolates MW2 (daptomycin non-susceptible) and D712 (vancomycin intermediate resistant S. aureus). Phage, bacterial counts and EVs formations were performed during time-kill analysis (TKA) experiments. MRSA isolates were examined against an array of antibiotics alone (daptomycin, vancomycin, ceftaroline and cefazolin) and in combination with phages. Bacteriophage Sb-1 was used for experiments at ~10⁵ PFU/ml. Bactericidal activity was defined as a >3 log₁₀ CFU/ml reduction from baseline. Synergy between two agents was defined as a ≥2 log₁₀ CFU/ml reduction at 24 hours compared to either agent alone.

Results: In vitro 24-hour TKA experiments demonstrated bactericidal activity with phage-antibiotic combinations. While addition of ceftaroline or cefazolin to vancomycin or daptomycin was synergistic, both daptomycin-phage and vancomycin-phage combinations resulted in bactericidal activity against the D712 strain. In addition, emergence of EVs in presence of phages was suppressed in antibiotic-phage combination regimens for both MRSA isolates.

Conclusions: The combination of antibiotic-phages showed promising results against MRSA. If shown to be reproducible in vivo, this phenomenon would be valuable in the treatment of clinical cases that are treatment refractory or have failed SOC antibiotics.

Vaccination Perception (VP) and Vaccination Coverage (VC) among healthcare students (HCS), a prospective French study: PERCEVAC Study

Aurelie Baldolli*, Anna Fournier1, Xavier Lecoutour1, Renaud Verdon1, Jocelyn Michon1

1Hospital Center University Of Caen Normandie, Department of Infectious diseases, Caen, France, 2Pôle de Formation et de Recherche en Santé, Caen, France

Background: Vaccine hesitancy has been increasing and spreading throughout the world. However data are scarce regarding HCS. The aim of this study was to determine VC and VP among HCS.

Materials/methods: A self-reporting electronic questionnaire, related to VP and VC, was prospectively sent to HCS (physicians, nurse, pharmacist, midwives, physiotherapist students and 1st year of health sciences students [PACES]) of Normandy University (France) between 18/03/2019 and 8/04/2019. Global VC was defined as being vaccinated for French mandatory and recommended vaccines. VP was evaluated through various binary questions and numeric scales.

Results: Out of a population of 4546 HCS, 542 took part in this survey (12%, mean age 22.3 year, female 79%).

*mandatory, **recommended, *** mandatory in HCS

On multivariate analysis only being a PACES student is associated with a lower global VC (OR 1.9 [1.2-3.3] p=0.04).

Regarding VP, 98% of HCS think that vaccine are effective. On a 0-10 scale, 91% think that vaccine safety is ≥ 7 and 80% have vaccine hesitancy < 3, the benefit/risk balance is judged as always positive in 66%. 81% of HCS follow French recommendations. Not recommended vaccines are against Haemophilus influenza b (69%), HPV (63%), Influenza (71%), zona (82%) and meningococcus (46.4%). 92% agree with the recent French law increasing the mandatory vaccines for infants, and 62% with a flu mandatory vaccination for healthcare workers.

Conclusions: Despite the good VP, less than half HCS are well vaccinated. Some vaccines are not considered useful nor indicated. Information regarding these vaccines should be done with a focus on PACES students.

Comparative in vitro activity of cefepime-enmetazobactam and other agents against 3rd-generation cephalosporin-resistant and extended-spectrum β-lactamase-producing clinical isolates of Enterobacterales collected between 2016-2018

Abstract 1331

Comparative in vitro activity of cefepime-enmetazobactam and other agents against 3rd-generation cephalosporin-resistant and extended-spectrum β-lactamase-producing clinical isolates of Enterobacterales collected between 2016-2018

Adam Belley*, Stephen Hawser, Ian Morrissey, Federica Monti, Nimmi Khotari, Philipp Knechtle

1Allecra Therapeutics SAS, Saint Louis, France, 2IHMA, Monthey, Switzerland

Background: Third generation cephalosporin (3GC)-resistant Enterobacterales are WHO critical priority pathogens in need of development of new agents. Enmetazobactam is a novel β-lactamase inhibitor targeting extended-spectrum β-lactamases (ESBL), the main resistance determinants in 3GC-resistant Enterobacterales. This study examined the in vitro activity of enmetazobactam combined with cefepime against clinical isolates of Enterobacterales collected between 2016-2018, including those resistant to 3GC or producing ESBL.

Materials/methods: µClinical isolates of Enterobacterales (n=7168) were collected from the US and Europe maintaining a proportion of clinically prevalent pathogens causing serious infections. Organisms were identified by MALDI-TOF mass spectrometry, and β-lactamase genotypes determined by multiplex PCR and sequencing for isolates with a ceftazidime or ceftriaxone MIC ≥ 1 mg/l. MIC and susceptibility were determined according to CLSI guidelines.

Results: Resistance to 3GC was 19.8% amongst the Enterobacterales collected, with 54.9% of those isolates expressing an ESBL with or without an AmpC and/or an OXA β-lactamase. The addition of enmetazobactam (fixed at 8 mg/l) to cefepime reduced the MIC90 >32-fold relative to cefepime alone against the Enterobacterales groups (table). Cefepime-enmetazobactam activity was comparable to meropenem against 3GC-resistant and ESBL-producing isolates and outperformed piperacillin-tazobactam and ceftolozane-tazobactam.

Conclusions: Cefepime-enmetazobactam may prove to be an important carbapenem-sparing therapy for serious infections caused by 3GC-resistant, ESBL-producing Enterobacterales.

Abstract 1334

Administration of ceftazidime to patients undergoing haemodialysis: are trough levels consistently above the EUCAST breakpoints for Enterobacterales and Pseudomonas?

Anne Tamigniau1, Danielle Govaerts1, Benoît Guillaume1, Serge Treille1, Soraya Cherifi1, Christophe Lelubre1, Isabelle Delattre1, Paul M. Tulkens2, Demeester Remy1*

1University Hospital of Charleroi, Charleroi, Belgium, 2Université catholique de Louvain, Louvain Drug Research Institute, Bruxelles, Belgium

Background: Patients undergoing haemodialysis should receive reduced ceftazidime doses. Based on a 6-patients study, a 1g interdialytic dose was considered sufficient to act on most frequent pathogens [Antimicrob Agents Chemother. 2013;57:5854-9]. Beta-lactams serum levels, however, are highly variable [Crit Care 2011;15:R137] while optimal PK/PD targets for beta-lactams are still under discussion [Expert Rev Anti Infect Ther. 2017;15:677-688]. Our aim was to measure actual ceftazidime trough serum concentrations in a larger cohort of haemodialysis patients to determine whether these would reach the current EUCAST ceftazidime R breakpoints for P. aeruginosa and Enterobacterales.

Materials/methods: Enrolment: 30 patients on long-term haemodialysis [3 times a week] suffering from infections justifying ceftazidime administration. Dosing: ceftazidime 1st dose: 2g, followed by 1g after each dialysis session. Sampling: serum obtained at approx. 44 or 68h after each administration, and after 1st and 4th dialysis session. Assay: validated HPLC-UV and UPLC-MS-MS. Calculations: since only trough levels were recorded, no pharmacokinetic model could be developed and data were used to fit [visual inspection and iterative optimization] a one-compartment decay model [k=0.032 h⁻¹; clearance 7.4 mL/min [non-renal clearance of ceftazidime]] to calculate values at two fixed standard post-administration times (44 and 68h).

Results: The Table shows the ceftazidime concentrations reached at 44 and 68h for each of the 4 successive administrations, and the number of evaluable patients for whom these concentrations were ≥ 8 or 4 mg/L. Levels were highly variable with significant correlation [simple and multivariate analysis] only demonstrable (i) with maintenance or not of a residual renal function and (ii) for 2d, 3d and 4th post-administration levels, with the 1st post-administration actual trough levels [multiple linear regression], suggesting larger inter-subject than within-subject variability. No correlation was seen with CRP, WBC, positive haemoculture, or clinical outcome of the infection. Ceftazidime concentration decrease by haemodialysis was 82.7±9.3%.

Conclusions: 2g of ceftazidime and post-administration times ≤44h are necessary to ensure > 73% of patients to have trough concentrations above the ceftazidime Pseudomonas R breakpoint. 1 g dosing and/or lengthening the post-administration time up to 68h will only ensure the same proportion of patients to show through concentrations up to 4 mg/L.

Abstract 1335

Human dirofilariasis in a changing world: evolving zoonosis just under the skin

Giacomo Stroffolini1, Andrea Calcagno1, Silvia Scabini1, Tommaso Lupia1, Giovanni Di Perri1, Roberto Angilletta*1, Pietro Caramello2

1Hospital Amedeo di Savoia, University of Torino, department of medical science, Torino, Italy, 2Hospital Amedeo di Savoia, ASL-TO, Torino, Italy

Background: Neglected tropical diseases are emerging in western countries due to migration routes, climate change and widespread access to travel for touristic or working reasons. Generally, clinicians are not aware of prevention measures linked to travel medicine outside vaccination schedules. Parasites are ubiquitous in the world and may mimic different medical conditions making diagnostic workup challenging.

Materials/methods: Case report.

Case report description: A 67-years old colleague, returning from 1-month fellowship in a rural hospital in Ethiopia, consulted our unit after three months of generalized pruritus and after the appearance of a palpable lump on his right forearm associated to intense generalized pruritus. His past medical history was unremarkable except for seasonal rhinitis well controlled by antihistamines. During his stay he remained asymptomatic except for a circumscribed arm swelling that progressed slowly in the following weeks. The lesion was evident at the time of consultation, appearing as a 20 mm swelling with intact superficial skin with no redness, warmness or pain. Baseline blood analysis showed normal leukocyte count without eosinophilia. All other laboratory parameters, including total IgE levels, tested within reference ranges. Ultrasonography found a well-circumscribed lesion, measuring 11x7x10 mm and containing anechogenic fluid with linear hyper echoic worm-like structures resting at the bottom of the cyst. Microscopic evaluation of three stool samples, blood specimens for microfilariae detection, as well as serologies for Filaria spp, Strongyloides spp, Trichinella spp. and Echinococcus spp. resulted negative. The nodule underwent excision and parasitological examination confirmed the presence of Dirofilaria repens [Figure attached].

Conclusions: Human dirofilariasis is currently considered a re-emerging mosquito-borne zoonosis caused by filarial worms of the genus Dirofilaria. Adults D. repens, the most significant Dirofilaria coupled with D. immitis, are commonly located in subcutaneous tissues, and the approach is primarily surgical. D. repens is currently found in Europe, Asia, and Africa, but has recently spread into colder regions; we are facing a continuous increase in the risk for humans to acquire dirofilariasis, because of climate changes, frequent travel and more extensive distribution of vectors outside tropical settings. The always evolving epidemiology should prompt physicians attention on neglected tropical diseases.

Kyriakou", Department of Microbiology, Athens, Greece, ³University of Thessaly, Department of Microbiology, School of Medicine, Larissa, Greece, ⁴University General Hospital of Patras, Department of Microbiology, Patras, Greece

Abstract 1336

Abstract 1336

Background: Staphylococcus aureus is associated with several infections, ranging from skin and soft tissue infections (SSTIs) to more invasive diseases. Various pathogenic factors are known, including methicillin resistance and virulent genes' carriage. In this study, S. aureus from SSTIs in patients among three tertiary care hospitals in different areas of Greece (Athens, Patras, Larisa) were compared in terms of antimicrobial resistance patterns, clonal distribution, toxins and adhesin genes’ carriage.

Materials/Methods: From a total of 10459 SSTIs recorded during five-year period 2014-2018, 5090 S. aureus were recovered. Of them, 4137 (81.28%) were methicillin-susceptible (MSSA). Antimicrobial resistance was determined by a gradient and the disk diffusion methods, according to EUCAST guidelines. Mupirocin-resistant were 1365/4137 (32.99%) of MSSA associated with SSTIs (mainly impetigo). Among 194 representative strains, genes encoding Panton-Valentine Leukocidin (PVL, lukS/lukF-PV), exfoliative toxins (eta, etb), adhesin FnB (fnbA) and the resistance genes mupA (mupirocin), fusB (fusidic acid), ermA, ermC (macrolides/lincosamides), were defined by PCRs with specific primers. Clones were determined by MLST.

Results: From 2014 to 2017, an increase of mupirocin-resistant isolates among MSSA causing SSTIs was observed, from 1.721% to 41.34%, followed by a decrease in 2018 [35.24%] (Figure 1). All tested isolates were mupA-positive with mupirocin MICs ranging from 64 to >1024 mg/L. Most strains were multi-resistant, with higher resistance observed against penicillin (100%), fusidic acid (92.78%) and tobramycin (89.95%). One major clone was identified, ST121, comprising of 192/194 (98.97%) tested strains. Most isolates carried eta (93.3%), etb (97.94%), fnbA (88.75%), and fusB (98.41%). The majority of erythromycin-resistant strains carried ermC (34/39, 87.18%). Only one MSSA out of 194 tested, classified as ST1, was PVL-positive. One more strain belonged to ST21 being negative for toxins’ genes.

Conclusions: An annual increase of mupirocin-resistant MSSA recovered from patients with SSTIs was observed from 2014 to 2017, with a decrease in 2018. The emergence of a predominant MSSA clone, ST121, resistant to mupirocin and highly resistant to tobramycin and fusidic acid was confirmed. This successful clone, comprised of PVL-negative isolates carrying resistance, exfoliative toxins and adhesin genes, predominated in SSTIs from patients in three different areas of Greece during the five-year period.

Abstract 1341

Community and nosocomial sepsis in older adults with bacteraemia: a retrospective study in a geriatric ward

Michele Saottini1, Gabriella Orlando*2, Olivia Moioli3, Chiara Mussi1, Marianna Menozzi2, Marianna Meschiari2, Erica Franceschini2, Cinzia Puzzolante1, Andrea Bedini2, Margherita Digaetano2, Cristina Mussini3, Marco Bertolotti2

1Policlinico Modena, Geriatric Unit, Modena, Italy, 2Policlinico Modena, Infectious Disease Clinic, Modena, Italy

Background: Sepsis is a global medical emergency that involves not only Intensive Care Units, but also Internal and Geriatric Wards. The incidence of sepsis is disproportionately higher in elderly adults and age is an independent predictor of mortality. Despite this, there are few available data about sepsis in elderly patients in order to help physicians to promptly diagnose and manage it.

Materials/methods: Retrospective study about 149 patients consecutively admitted to Acute Geriatric Ward from 1 January 2017 to 30 June 2019 with positive blood cultures. We evaluated clinical characteristics, autonomies, parameters and blood tests at admission and calculate the main validated scores predicting mortality and diagnosis of sepsis. We divided patients in 2 groups: community bacteremia (CB, positive blood cultures within 48h from admission) and nosocomial bacteremia (NB). Epidemiology, site of infection, antibiotic resistance and therapeutic choices has been studied.

Results: We classified 107 patients as CB and 42 patients as NB. Overall median (IQR) age was 86 (81-91) years, 51% of patients were male. 65% of the sample came from home, but were defined as frail and with limited autonomies (median (IQR) CSF 7 (6-8)). 57% were diagnosed with dementia at admission, and 54% developed delirium at onset. Classic symptoms of sepsis (fever, hypotension, tachycardia) were absent in the majority of patients. qSOFA score was >2 only in 35% and 45% of CB and NB respectively. Polimicrobial bacteremia was significantly higher in NB compared to CB patients (23.8% and 11.2%, p=.014). 65% of CB cases were due to Gram – only, while 50% of NB to Gram + only. 49.5% of CB originated from urinary tract infection, while 42.9% of NB from blood stream infection. Duration of antibiotic therapy was significantly higher in CB patients compared to NB ones. Mortality due to sepsis at day 21 was 14.3% in CB patients compared to 21.1% in the NB (p=ns).

Conclusions: Elderly patients with sepsis have clinical peculiar characteristics. Symptoms at onset are often atypical and not specific. Delirium appears in many patients, and it is an early sign of severity that should be recognized to promptly treat the leading cause.

Abstract 1346

Multinational performance evaluation of the BIOFIRE FILMARRAY Pneumonia plus (PNplus) panel
Christine Ginocchio*, Carolina Garcia2, Barbara Mauerhofer2, Cory Rindlisbacher2
1bioMerieux/BioFire Diagnostics LLC, Salt Lake City, United States; 2bioMerieux, bioMerieux, Marcy l’Etoile, France; 2BioFire Diagnostics, LLC, Salt Lake City, United States

Abstract third-party references: On behalf of the EMEA Evaluation Program Collaborative, Supported by bioMerieux/BioFire Diagnostics LLC

Background: Identification of pathogens causing community acquired, health-care and ventilated associated pneumonia can be problematic. The BioFire PNplus Panel detects 15 bacteria (with semi-quantification), three atypical bacteria, eight viral classes and seven antibiotic resistance markers (mecA/C/MREJ, CTX-M, KPC, VIM, IMP, NDM, OXA-48 like) directly from sputum-like specimens (induced or expectorated sputum; endotracheal aspirates), and bronchoalveolar lavage (BAL)-like specimens with results in about one hour.

Materials/methods: 52 laboratories from 13 countries across Europe and Israel compared the BioFire PNplus Panel results to standard of care (SOC) test results. SOC tests varied by site and included various combinations of culture, urinary antigen, molecular assays, and direct fluorescent antibody assays. A total of 2,501 samples (1,252 sputum-like and 1,249 BAL-like) were tested. Comparison of semi-quantification results for BioFire PNplus Panel and SOC bacterial pathogens were compared for 1,297 matched detections.

Results: A total of 3,278 bacterial analytes included on BioFire PNplus Panel were detected by at least one method. The BioFire PNplus Panel identified 3,128 (95%) analytes compared to 1,878 (54%) for SOC. The BioFire PNplus Panel detected 93 atypical bacteria and 618 viruses compared to 73 atypical bacteria and 135 viruses for SOC. Semi-quantitative values for the BioFire PNplus Panel were less than SOC values, equal to SOC values or greater than SOC values in 5.09%, 25.91% and 69.01% of the results, respectively. On average, BioFire PNplus Panel values were approximately 1 log higher than SOC values (57.75% 1-2 log; 11.26% 3-4 log). All resistance markers were detected at least once by the BioFire PNplus Panel and in various combinations, with mecA/C/MREJ the most prevalent in Staphylococcus aureus (20.35%), followed by CTX-M (8.0%) and KPC (4.3%) in applicable gram-negative bacteria.

Conclusions: Despite variations in laboratory testing methodologies across testing sites, BioFire PNplus Panel performed consistently with enhanced detection of all types of respiratory pathogens. In particular, limited SOC testing for viruses was shown to be a missed opportunity to define the potential cause of respiratory infection. Identification of the potential cause of pneumonia and associated resistance markers in approximately 1 hour could dramatically change antimicrobial selection and enhance patient outcomes.

Abstract 1350

In vitro activity of ceftolozane/tazobactam against clinical isolates of carbapenem-resistant Pseudomonas aeruginosa from Japan hospitals

Tatsuya Nakamura*1, Mayu Fujiwara1

1Kyoto Tachibana University, Kyoto, Japan

Background: Ceftolozane/tazobactam [TAZ/CTLZ], a new-generation cephalosporins, is the first drug combined with a β-lactamase inhibitor, i.e., a cephalosporin antibacterial agent, to be effective against drug-resistant bacteria such as multi-drug-resistant Pseudomonas aeruginosa and ESBL-producing Enterobacteriaceae. In the present study, we examined its antibacterial activity against carbapenem-resistant P. aeruginosa and performed genetic analysis for resistant strains.

Materials/methods: Clinically isolated carbapenem-resistant P. aeruginosa strains (40 non-carbapenemase-producing strains) were tested. In the drug susceptibility test, an E-test (bioMérieux) was performed to measure the MIC50/90 and sensitivity (CLSI M100-S29). In addition, strains with a MIC of 16 mg/L were compared with a PAO1 strain for mRNA expression of the AmpC gene by sequencing and qRT-PCR.

Results: The MIC50/90 values (mg/L) of TAZ/CTLZ of all 40 strains were 2/16, with a susceptibility rate of 85%. The AmpC gene was sequenced, revealing V239A and A97V mutations. The expression levels of the AmpC gene increased 8-43-fold in all strains except one.

Conclusions: The antibacterial activity of TAZ/CTLZ for carbapenem-resistant P. aeruginosa is higher than that of the other β-lactams, and should be effective against strains with drug resistance involving outer membrane proteins. In addition, we found that resistant strains existed before the use of TAZ/CTLZ in Japan, and that such strains were caused by mutations and increased expression of the AmpC gene, although no highly resistant bacteria were detected.

Abstract 1354

**Treatment status and prognosis of 203 cryptococcosis in non-human immunodeficiency virus-infected and nontransplant patients**

Su Yi*, Bijie Hu

1 Zhong Shan Hospital, Shang Hai, China

**Background:** To learn the treatment status and prognosis of cryptococcosis in non-human immunodeficiency virus-infected and nontransplant patients.

**Materials/methods:** We retrospectively analyzed the gender, age, diagnosis, treatment and prognosis of 203 non-human immunodeficiency virus-infected and nontransplant patients of cryptococcosis from 2012 to 2018.

**Results:** There were 196 pulmonary cryptococcosis patients and 7 disseminated cryptococcosis patients of all the 203 non-human immunodeficiency virus-infected and nontransplant patients. 196 pulmonary cryptococcosis patients included 127 men (64.80%) and 69 women (35.20%) and the average age of men was 49.57 years old and the average age of women was 54.52 years old. 5 patients (2.55%) were diagnosed by culture, 112 patients (57.14%) were diagnosed by biopsy and 79 patients (40.31%) were diagnosed by latex agglutination test. 104 patients have finished the course of treatment among the 143 patients in the department of medicine, 74 patients were cured (71.15%), 27 patients were improved (25.96%), 1 patient was in persistence (0.96%) and 2 patients were treated surgically (1.92%); among the patients who have finished the course of treatment, 77 patients (6.04%) use fluconazole effectively, 9 patients (8.65%) used voriconazole effectively, 2 patients (1.92%) used itraconazole effectively and 13 patients (12.50%) used amphotericin B or amphotericin B liposome effectively. 53 patients were diagnosed by the surgical pathology, 27 patients (50.94%) used anti-fungal after the operation, 23 patients (43.40%) didn’t get any treatment and no recurrence was found, 3 patients (5.66%) were loss to follow up. Among 7 patients of disseminated cryptococcosis, 2 patients were cured, 2 patients were undergo treatment and 3 patients were withdrawn. The starting dose and maintenance dose were various in the 77 non-human immunodeficiency virus-infected and nontransplant patients who were cured by fluconazole. 8 patients (57.14%) got renal impairment among 14 patients of pulmonary cryptococcosis who used amphotericin B or amphotericin B liposome.

**Conclusions:** Triazoles is always effective in the pulmonary cryptococcosis in the non-human immunodeficiency virus-infected and nontransplant patients; few patients relapses and the prognosis is favorable.

Abstract 1357

Roles of the FadRACB system in formaldehyde detoxification and antibiotic susceptibility in Stenotrophomonas maltophilia

Li-Hua Li1, Cheng-Mu Wu2, Yi-Tsung Lin1, Sz-Yun Pan2, Tsuey-Ching Yang*2

1Taipei Veterans General Hospital, Taipei, Taiwan, 2National Yang-Ming University, Taipei, Taiwan

Background: Formaldehyde toxicity is invariably stressful for microbes. Stenotrophomonas maltophilia, a human opportunistic pathogen, is widely distributed in different environments and has evolved an array of systems to alleviate various stresses. This study aimed to characterize the formaldehyde detoxification system FadRACB of S. maltophilia with respect to formaldehyde detoxification and antimicrobial susceptibility.

Materials/methods: Presence of fadRACB operon was verified by RT-PCR. Single or combined deletion mutants of fadRACB operon were constructed for functional assay. Formaldehyde quinolone susceptibilities were assessed by observing cell viability in formaldehyde- and quinolone-containing media, respectively. Agar dilution method was used to assess the bacterial susceptibilities to antibiotics. Expression of fadRACB was assessed by qRT-PCR.

Results: The fadR, fadA, fadC, and fadB genes are arranged in an operon. Mutants in fadA and/or fadB were more susceptible to formaldehyde than wild-type KJ. No significant difference was observed in the ability of fadC single mutant to defend formaldehyde; however, simultaneous inactivation of fadA, fadB, and fadC further enhanced the susceptibility toward formaldehyde. In addition, compared to wild-type KJ, the triple mutant KJΔFadACB was more susceptible to quinolone and more resistant to aminoglycosides. FadR functions as a repressor for fadRACB operon. FadRACB operon has a moderate expression in aerobically-grown wild-type KJ and is further de-repressed by formaldehyde challenge, but not by antibiotics.

Conclusions: FadACB system contributes to mitigation of formaldehyde toxicity and cross-protects S. maltophilia from attacks of quinolone.

Abstract 1358

**Antifungal susceptibility profiles of olorofim (formerly F901318), and currently available systemic antifungals against mould and yeast phases of Talaromyces marneffei**

Jing Zhang1, Hongfang Liu2, Liyan Xi1,2, Yun Chang3, K.J. Kwon-Chung3, Seyedmojtaba Seyedmousavi*3,4

1Sun Yat-sen Memorial Hospital of Sun Yat-sen University, guangzhou, China, 2Dermatology Hospital of Southern Medical University, guangzhou, China, 3National Institutes of Health, Bethesda, United States, 4National Institute of Health Clinical Center, Microbiology Service, Department of Laboratory Medicine, Bethesda, United States

**Background:** *Talaromyces marneffei* is a thermal dimorphic fungus and is the etiologic agent of talaromycosis, a life-threatening disease which affects immunocompromised host especially those with HIV infection. The fungus is endemic in Southeast Asia and is known to be associated with bamboo rats. Talaromycosis is initially treated with amphotericin B but its use is limited due to toxic side effects. Therefore, the need for new antifungals to treat talaromycosis is urgent. Olorofim is a novel fungicidal drug which targets dihydroorotate dehydrogenase in the de novo pyrimidine biosynthesis pathway. It is highly active against *Aspergillus* and other filamentous *Ascomycetes*. However, the *in vitro* efficacy of olorofim against *T. marneffei* has yet to be reported. We therefore aimed to evaluate the susceptibility of *T. marneffei* to olorofim and other currently available systemic antifungals in its yeast as well as in mold phases.

**Materials/methods:** We tested 32 clinical and environmental *T. marneffei* strains recovered from southern China against 8 different antifungals according to the Clinical and Laboratory Standards Institute M38-A2 and M27-A3 guidelines.

**Results:** The geometric means of the minimum inhibitory concentrations/minimum effective concentrations (MICs/MECs) of the antifungals against mold phase of all *T. marneffei* strains were (in increasing order): olorofim (0.0005 mg/mL), itraconazole and posaconazole (0.016 ug/mL), voriconazole (0.05 ug/mL), 5-flucytosine (0.08 ug/mL), terbinafine (0.1 ug/mL), caspofungin (0.4 ug/mL) and amphotericin B (2 ug/mL). The geometric means MICs/MECs against the yeast phase were, as follows: olorofim (0.0007 ug/mL), posaconazole (0.016 ug/mL), itraconazole (0.016 ug/mL), voriconazole (0.017 ug/mL), terbinafine (0.12 ug/mL), amphotericin B (0.13 ug/mL), 5-flucytosine (0.25 ug/mL), and caspofungin (4.5 ug/mL). Olorofim was the most active antifungal agent against both mold and yeast phases of all tested *Talaromyces marneffei* isolates, exhibiting an MIC range, MIC50, and MIC90 of 0.0005-0.002 ug/mL, 0.0005 ug/mL, and 0.0005 ug/mL, respectively.

**Conclusions:** In summary, olorofim demonstrated potent and consistent activity against all *T. marneffei* strains *in vitro*, and its activity was maintained in two different growth phases. Further studies are warranted to evaluate the *in vivo* efficacy of olorofim against this fungus.

**Presenter email address:** S.Seyedmousavi@nih.gov
Bloodstream infections caused by strong biofilm-producing bacteria increase the risk of end-organ disease and mortality in patients with haematologic malignancies

Enea Gino Di Domenico1, Francesco Marchesi2, Ilaria Cavallo*, Luigi Toma3, Grazia Prignano1, Fulvia Pimpinelli, Elena Papa1, Irene Terrenato4, Fabrizio Ensoli1, Andrea Mengarelli1

1San Gallicano Dermatological Institute, IRCCS, Microbiology and Virology, Roma, Italy, 2Regina Elena National Cancer Institute, IRCCS, Hematology and Stem Cell Transplant Unit, Rome, Italy, 4Regina Elena National Cancer Institute, IRCCS, Biostatistics and Bioinformatic Unit - Scientific Direction., Rome, Italy

Background: Bacterial bloodstream infection (BSI) represents a major complication in patients with hematological malignancies (HM). However, factors leading to BSI, as well as progression to end-organ disease and death, are only partially understood. The study aims at analyzing host and microbial risk factors and assesses their predicted impact on the development of BSI and mortality.

Materials/methods: A total of 96 patients with HM and BSI were included in the study. Host-associated risk factors and all-causes of mortality were analyzed by multivariable logistic regression at 30 days after onset of the first BSI in the first neutropenic episode. The multidrug-resistant (MDR) profile and biofilm production of bacterial isolates were included in the analysis.

Results: The median age was 60 years [range 20-77 years]. The underlying diagnoses were acute leukemia n=53 (55%), lymphoma n=30 (31%) and myeloma n=13 (14%). Bacterial isolates from BSI were 96. Escherichia coli was the most common isolate [n=28, 29.2%], followed by Pseudomonas aeruginosa [n=16, 16.7%]. MDR [n=10] caused 10.4% of bacteremia episodes. Weak biofilm producers were significantly (P<0.0001) more abundant (72.2%) than strong (27.8%) biofilm-producers. Specifically, strong biofilm-producers were 9.6% for E. coli, 100% for P. aeruginosa, 50% for K. pneumoniae, and 23.3% for Coagulase-negative Staphylococcus spp. (CoNS). Mortality at day 30 was 8.3% [8/96], and all deaths were attributable to Gram-negatives. About 22% of all BSI were catheter-related (CRBSI). The mortality rate (P=0.62) and the level of biofilm production (P=0.75) were not correlated with CRBSI. Notably, strong biofilm-producing bacteria were found to be an independent risk factor (P=0.018) associated with the end-organ disease. Besides, multivariate analysis indicated that the presence of strong biofilm-producing bacteria (P=0.013) and MDR strains (P=0.006) were independent risk factors associated with 30-day mortality.

Conclusions: Strong biofilm-producing bacteria and MDR strains caused a limited fraction of BSI in patients with HM. Strong biofilm-producing bacteria present a high risk of end-organ disease and that, together with an MDR phenotype, are significantly and independently associated with an increased risk of death. The rapid identification of biofilm-producing bacteria from BSI can offer a key biomarker to predict the clinical and therapeutic outcomes in patients with HM.

Abstract 1363

Genetic structure characteristics and treatment for Listeria monocytogenes infections
Wei Yu*, Yicheng Huang, Lihua Guo, Jiajie Zhang, Yaqiong Zhan, Li Zhang, Yunqing Qiu

1 The First Affiliated Hospital, College of Medicine, Zhejiang University, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China
2 Zhejiang Provincial People’s Hospital, People’s Hospital of Hangzhou Medical College, Department of Infectious Diseases, Hangzhou, China

Background: Invasive Listeria monocytogenes (Lm) carry a high mortality despite antibiotic treatment. The aim of this study was to investigate the mechanism of pathogenicity and resistance. In addition, the effect of existing treatment options against Lm were systematically evaluated as well.

Materials/methods: Three Lm isolates were collected and 15 antibiotics susceptibility tests were done. Subsequently, the genetic characteristics were investigated by genome sequencing and bioinformatics analysis. Furthermore, the effect of meropenem, linezolid, benzylpenicillin, vancomycin, trimethoprim/sulfamethoxazole were determined using the time-kill assay.

Results: Two sequence types (STs) were identified for isolate 23949 (ST87), 26530 (ST3), 34096 (ST87), respectively. All isolates were resistant to fosfomycin and daptomycin. The resistant genes fosX, mprF, norB and vgaALC were identified in all isolates. Furthermore, 80 virulence genes were detected and 72 genes were found in all three isolates. There were 26 virulent genes associated with the structure, biosynthesis, motor switch of flagellum. And other virulent genes were involved in chemotaxis, protease, internalin and metabolism. It is of note that 8 genes were only found in 26530 isolated from cerebrospinal fluid (CSF), 7 of which were associated with haemolysin. Further in vitro time-kill assay found trimethoprim/sulfamethoxazole at serum or CSF concentrations had bactericidal effect (>3.5 log10 CFU/ml) against three tested Lm strains at 24 h.

Conclusions: The involved virulence factors were mainly associated with bacterial pathogenicity. Notably, trimethoprim/sulfamethoxazole might be greater potential therapeutic option against Lm bloodstream infection or intracranial infection.

Epidemiology of nosocomial candidaemia in paediatrics: a multi-centre study in Iran

Fatemeh Ahangarkani1, Mohammad Sadegh Rezaiz, Tahereh Shokohi3, Sadegh Khodavaisy4, Macit Ilkit5, Reza Alizadeh Navai6, Zahra Abtahian7, Jacques F. Meis8, Hamid Badali9

1Invasive Fungi Research Center, Student Research Committee, Mazandaran University of Medical Sciences, Sari, Iran, 2Pediatric Infectious Diseases Research Center, Mazandaran University of Medical Sciences, Sari, Iran, 3Invasive Fungi Research Center, Mazandaran University of Medical Sciences, Sari, Iran, 4Department of Medical Parasitology and Mycology, Tehran University of Medical Sciences, Tehran, Iran, 5Division of Mycology, Department of Microbiology, Faculty of Medicine, University of Çukurova, Adana, Turkey, 6Gastrointestinal Cancer Research Center, Mazandaran University of Medical Sciences, Sari, Iran, 7Infectious Disease and Tropical Medicine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, 8Department of Medical Microbiology and Infectious Diseases, ECMC Excellence Center for Medical Mycology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands, 9Invasive Fungi Research Center, Mazandaran University of Medical Sciences, Sari, Iran

Background: Nosocomial bloodstream candidaemia is a life-threatening fungal infection with high morbidity and mortality, especially among paediatric patients undergoing intensive immunosuppressive therapy. Limited data on the epidemiology of candidaemia and susceptibility profiles are available in Iran. We aimed to characterize candidaemia epidemiology, comorbidity risk factors, species distribution, and antifungal susceptibility profiles among paediatric patients in Iran.

Materials/methods: A total of 26,189 hospitalized patients under 18 years old were involved. Blood samples from patients with suspected fungal bloodstream infection were analysed using the BACTEC culture system. Fungal isolates were identified using matrix-assisted laser desorption ionization–time of flight mass spectrometry (MALDI-TOF) and DNA sequencing. Antifungal susceptibility testing was performed using the Clinical and Laboratory Standards Institute broth microdilution method.

Results: Overall, 109 episodes of nosocomial candidaemia, with an incidence of 4.1 cases per 1000 admissions, were observed among paediatric patients with or without immunosuppressive therapy. The most common healthcare-associated factor was the use of a central vascular catheter (97.24%). The all-cause mortality rate was 40.36%, of which 48% was attributable to candidaemia. While Candida albicans (49%) was the most frequent causative agent, emerging and uncommon Candida species were also isolated. The mortality of candidaemia caused by non-albicans Candida species were significantly higher from those of candidaemia caused by C. albicans (P < 0.05). All fluconazole resistant species were non-albicans Candida species.

Conclusions: Uncommon Candida species with reduced susceptibility to antifungal agents are likely to become the major agents of nosocomial candidaemia in high-risk patients in Iran, such as paediatric cancer patients. Appropriate source control, antifungal regimens, and strengthening of antifungal stewardship policies are all needed for the management and decrease of the burden of nosocomial candidaemia.

Abstract 1367

Gentamicin-intercalated smectite as a new therapeutic agent against Helicobacter pylori infection and faecal microbiome analysis after eradication in mouse model

Su Jin Jeong1*, Kyoung Hwa Lee1, Kim Jie Hyun2, Soon Young Park1, Young Goo Song1

1Division of Infectious Disease, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea
2Division of Gastroenterology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea

Background: The eradication rate of Helicobacter pylori with conventional standard therapy shows a decreasing trend, because of antibiotics resistance especially clarithromycin. Thus, novel antibacterial strategies against H. pylori are needed. We evaluate the efficacy of a gentamicin-intercalated smectite hybrid [S-GM]-based treatment regimens including toxicity of S-GM using fecal microbiome analysis in a murine model of H. pylori infection.

Materials/methods: To evaluate anti-H. pylori efficacy, mice were divided into 8 groups, and H. pylori eradication was assessed by Campylobacter-like organism (CLO) test and H. pylori PCR of the gastric mucosa. For the test of toxicity of S-GM, four different model was designed. One week after the end of H. pylori eradication, the levels of proinflammatory cytokines and the atrophic changes of gastric mucosa were examined. In addition, stool specimens were collected, and analyzed for microbiome changes in each group.

Results: The S-GM-based triple regimen decreased bacterial burden in vivo, compared to that in untreated mice or mice treated with other regimens. The therapeutic reactions in the CLO test from gastric mucosa were 90, 90, 80, 80, 70, and 10% in Groups III-VIII, respectively. Those of H. pylori PCR in gastric mucosa of mice were significantly lower in Groups III-VIII than in the Group II. In the results of toxicity of S-GM, S-GM triple therapy also reduced the level of IL-8 and the atrophic change of gastric mucosa. In the analysis of stool microbiome, abundant microorganisms of phylum level were presented, and the diversity of microbiome was preserved in the S-GM triple therapy comparing the standard triple therapy.

Conclusions: These results suggest that S-GM is a promising and effective therapeutic agent for the treatment of H. pylori infection.

Abstract 1370

Features and outcomes of tuberculosis among internally displaced people in East Ukraine
Olha Konstantynovska*, Tetiana Synenko1, Anastasiia Kuznietsova2

V.N. Karazin Kharkiv National University, Kharkiv, Ukraine, Regional TB hospital #1, Kharkiv, Ukraine

Background: From the start of military conflict now there are about 1 500 000 officially confirmed internally displaced people (IDP) in Ukraine. In 2018 there were about 35,0 % of new and 62,0 % of re-treated confirmed cases of multiple and extensive drug resistant tuberculosis (MDR/XDR TB). This study aims to analyze the features and outcomes of TB among IDP in a given TB hospital.

Materials/methods: In 2014-2018 in a given TB hospital were treated 409 patients. Among them there were 51 cases of TB in IDP. Some patients were hospitalized more than one time – discharging from hospital was done mainly (85,0%) because of migration to and out of military conflict territory. Thus, 37 patients (IDP) with TB were treated in the hospital – 28 (75,7%) males and 9 (24,3 %) females. Patients` age was 23-87 years old, middle age 41,6.

Results: 22 (59,5 %) patients were without any temporary place of living, 7 (18,9 %) – HIV infected, 9 (24,3 %) – intravenous drug users. Medical help was provided according to national protocols. HIV-infected IDP had an opportunity to get antiretroviral therapy (ART), drug users – opioid substitutional therapy, as any other Kharkiv region citizens. 32 (86,4 %) patients had MDR/XDR TB. Treatment was prescribed by the results of drug susceptibility tests and previous case` s history (TB-manager – Ukrainian national TB database). Outcomes were analyzed according to WHO recommendations: 8 (21,6%) – treatment success (2 (5,4 %) – cured, 6 (16,2 %) – finished), 29 (78,4 %) – unsuccessful treatment (6 (16,2 %) – dead (2 (5,4 %)– brain stroke (elderly and senile aged IDP), 2 (5,4 %) – HIV-TB co-infection, 2 (5,4 %) – very severe cases of MDR-XDR TB), 15 (40,5 %) – lost to follow up, 8 (21,6 %) – treatment failure (all of them – MDR-XDR TB)).

Conclusions: Experience of working with IDP shows ways how to improve TB management: rapid diagnostics, social adaptation of TB patients, decreasing of stigma, availability of TB drugs, opioid substitution therapy and ART in all levels of medical support. National database as a TB-manager is very helpful to identify case even if it is from different territory and gives the mechanism to improve MDR/XDR TB epidemic.

Abstract 1376

Nasal colonisation by Staphylococcus aureus in nursing home residents in Crete, Greece

Katerina Moschou1, Petros Ioannou*,1, Eleni Moraitaki1, Dimitra Stafylaki1, Erasmia Boutakoglou1, Vasileia Koutsouroumpi1, Sofia Maraki1, Georgios Samonis1, Diamantis Kofteridis1

1University Hospital of Heraklion, Heraklion, Greece

Background: About 25% of healthy persons are asymptptomatically colonized by in the anterior nares S. aureus and may spread the pathogen to other individuals, while they carry a higher risk of infection.

Materials/methods: This is a point-prevalence study detecting nasal colonization by S. aureus in nursing home residents conducted in 6 long-term care facilities (LTCFs) on the island of Crete, Greece. Nasal swabs were cultured in order to detect for S. aureus while risk factors for colonization were evaluated. Nasal swabs were also collected from healthy non-residents of LTCFs of the same age that were used as controls. Data collected included age, gender, duration of stay in LTCFs, comorbidities, antibiotic exposure, and recent hospitalization.

Results: A total of 290 LTCF residents aged 65 years or more were enrolled. Mean age was 83.1 years; 30.7% were male (89 residents). The median length of stay at the LTCF was 23 months. Residents with a Charlson comorbidity index ≥3 were 24.7% (82 residents). Recent hospitalization and recent antibiotic use were recorded in 8.6% (25 residents) and 13.4% (39 residents) respectively. Among the 290 residents, 28.6% (83) were colonized by S. aureus, while 66.5% of them (55 residents) were MRSA carriers. Analysis of S. aureus and MRSA prevalence among the LTCF residents and 43 healthy controls of the same age did not reveal statistically significant differences. Statistical analysis revealed that S. aureus colonization was more common in women (34.3%) than in men (21.7%) and that the only factor associated with MRSA colonization was recent antibiotic exposure (23.6% if recently on antibiotics vs 3.6% if not; p=0.028).

Conclusions: Colonization by S. aureus is quite common in LTCFs, but the rate may not differ from that in the community. Recent antibiotic exposure significantly increases the risk for MRSA colonization.

Presenter email address: petros_io@hotmail.com
Background: Pyogenic liver abscess (PLA) is a severe disease, whose unfavorable evolution may be categorized by primary treatment failure, recurrence or death. Our objective was to assess predictive factors of unfavorable courses in patients with PLA.

Materials/methods: We conducted a retrospective population-based study in Beaujon hospital, a single tertiary care center of Paris area. All patients admitted for a PLA episode between 2010 and 2018 were included. An unfavorable course was defined by the occurrence of a primary treatment failure (clinical worsening and/or increased radiological size despite appropriate treatment, requiring modification of antimicrobial therapy and/or new drainage), a recurrence occurring at least 28 days after an initial cure, or death within 3 months after diagnosis.

Results: Overall, 317 patients were included. Median age at diagnosis was 60 years (19-92); 208 (65.6%) patients were male. Healthcare-related and nosocomial infections accounted for 86 (27.1%) and 38 (12%) of cases, respectively. A biliary origin (179/317, 56.5%) was the main mechanisms of PLA occurrence. In patients with a biliary origin, hepato-biliary tumoral obstruction and ischemic cholangitis were retrieved in 70/179 (39%) and 32/179 (17.8%) patients, respectively. E. coli was the first pathogen isolated (104 patients, 24.5%), followed by Enterococcus spp. (55 patients, 17.4%); 46/424 (10.8%) microorganisms isolated from an initial PLA episode were multi-drug resistant organisms (MDRO). An unfavorable course occurred in 91 (28%) patients: primary treatment failure and recurrence were reported in 56 (17.6%) and 28 (8.8%) patients, respectively; 32 (10%) patients died within 3 months. Factors independently associated with an unfavorable course were a healthcare-related infection (HR=1.74, p=0.033), an underlying metastatic liver (HR=2.76, p<0.001), a portal thrombosis (HR=2.46, p=0.001), an ischemic cholangitis (HR=2.16, 0.008), presence of fungi (HR=3.08, p=0.008), enterococci. (HR=1.81, p=0.020) or MDRO (HR=1.88, p=0.020); PLA drainage versus no drainage was associated with a better outcome (HR=0.52, p=0.005).

Conclusions: Unfavorable course after an initial PLA episode remains frequent and likely occurs in a healthcare setting. Identification of risk factors may help to improve management of PLA and to elaborate targeted recommendations according to patient and disease's characteristics.

Abstract 1378

**Infection incidence among patients colonised with carbapenem-resistant Enterobacteriaceae (CRE) and microbial aetiology**

Eugenio Sala¹, Roberto Mauri*, Marilena Valli¹, Beatrice Pini¹, Simona Cimetti¹, Eleonora Pozzoli¹, Paola Corti¹, Chiara Finco¹, Luigi Pusterla¹, Giuseppe Maurizio Catanoso¹

¹Sant’anna General Hospital, Como, Italy, ²Sant’anna General Hospital, San Fermo Della Battaglia, Italy

**Background:** CRE are important pathogens in Hospital Acquired Infections (HAI). Intestinal colonization with CRE precedes infection and has negative effects on the morbidity and mortality. There are conflicting data in the literature on the percentage of patients developing infection after intestinal colonization. The purpose of this study is to analyze the incidence of infection in colonized subjects detected through surveillance with rectal swab and hospitalized at ASST Lariana, also considering different bacterial species involved.

**Materials/methods:** A retrospective research is carried out evaluating the annual and cumulative incidence of CRE infection in rectal swab-positive patients, from January 2016 to June 2019. Isolation sites, hospitalization wards and bacterial etiology are considered. The surveillance first involved the patients admitted to intensive care, but was later extended to patients from long-term care, patients with hospitalization lasting more than 30 days, patients with hospitalization in the 60 days before. Furthermore, all patients admitted to Geriatrics and Neurorehabilitation are screened. Samples taken by rectal swab are seeded on chromogenic medium, with incubation at 24 hours; bacterial identification and antimicrobial susceptibility are performed with MALDI-TOF and VITEK2 (bioMerieux).

**Results:** From 2016 to June 2019, respectively: 60, 74, 72 and 30 (first six months) cases of carriers of CRE were identified. The wards were: Medicine (61%), Surgery (11%), Rehabilitation (12%) and Intensive care (16%). The total incidence of CRE infection in colonized patients was 23.7%. The most involved sites of infection were the urinary tract (56.2%) followed by the lower respiratory tract. The bacterial etiology was K. pneumoniae with the following percentages: 96.6% in 2016, 94.4% in 2017, 93.2% in 2018 and 80% in the first six months of 2019, with a growing finding of E. coli KPC.

**Conclusions:** Our study showed a 23.7% incidence of CRE infection in colonized patients, higher than verified in other research, suggesting the need for further longitudinal and epidemiological investigations. The bacterial etiology was found to be in line with the literature data, showing however a tendency towards an increase in the finding of bacterial species different from K. pneumoniae.

**Abstract 1381**

**Antibiotic use in French hospitals 2012-2018: improvements to be confirmed!**

Catherine Dumartin*1, Muriel Péfau1, Amélie Jouzeau1, Lory Dugravot1, Emmanuelle Reyraud1, Aurelie Chabaude2, Elodie Couve-Deacon1, Christian Martin1, Marie-Cécile Ploy1, Olivia Ali-Brandmeyer3, Christian Rabaud3, Julien Claver4, Anne-Marie Rogues1, Loïc Simon1

1Bordeaux University, Inserm CR 1219, Bordeaux, France, 2CPias Nouvelle-Aquitaine, Bordeaux University hospital, Bordeaux, France, 3CPias Grand-Est, Nancy, France, 4Limoges University Hospital, Limoges, France

**Background:** Surveillance of antibiotic consumption is at the core of mandatory antimicrobial stewardship programmes in hospitals. A national standardized method was developed to describe antibiotic consumption at hospital level. In order to assess the impact of antibiotic stewardship activities, namely guidelines on broad spectrum antibiotics, changes in antibiotic consumption between 2012 and 2018 were described.

**Materials/methods:** Antibacterials for systemic use (J01class, WHO Anatomical Therapeutic Chemical classification, ATC-DDD system), oral imidazole derivatives and fidaxomicin were surveyed for inpatients in voluntarily participating hospitals and expressed in number of defined daily doses (DDD) per 1 000 patient-days (PD). Data were retrospectively collected from pharmacy records and administrative services each year.

**Results:** The number of participating hospitals increased from 1 411 in 2012 to 1 630 in 2018 covering 73% of national PD in 2018. Antibiotic use increased between 2012 and 2015 (+1.8%) and decreased from 2016 (-8.5%) to reach 288 DDD/1000PD in 2018. Despite an overall increase in third generation cephalosporin use (+13% between 2012 and 2018), ceftriaxone use was 10% lower in 2018 compared to 2013; carbapenem use tended to remain stable since 2015. By contrast, the consumption of piperacillin-tazobactam, linezolid and daptomycin steadily increased from 2012 (+76%, 92% and 379% respectively). Proportion of broad spectrum antibiotics (ECDC secondary indicator for hospitals) was 32% in 2012 and 34% in 2018.

**Conclusions:** Recent surveillance data tend to show a stabilisation and even a decrease in antibiotic consumption, namely for antibiotics targeted by guidelines (ceftriaxone in 2014, carbapenems in response to increase in carbapenem-resistant Enterobacteriaceae cases), highlighting the usefulness of specific recommendations with clear messages. However, attention should be given to the increasing use of other antibiotics, namely in the context of emergence of linezolid-resistant staphylococci. To better inform next steps in promotion of prudent antibiotic use and antimicrobial resistance control, a new national project for surveillance and prevention of antimicrobial resistance in hospitals (SPARES) was set up in 2018. Hospitals are provided with standardized methods and webtools allowing 1) a more comprehensive antimicrobial resistance surveillance and 2) cross-transmission prevention audits in order to allow identification of areas for improvements at both local and national levels.

**Presenter email address:** catherine.dumartin@chu-bordeaux.fr
Whole genome sequencing and comparative analysis of echinocandin susceptible and resistant sequential *Candida glabrata* clinical isolates

Ahmed Albarrag*, Khaloud Alzahrani¹

¹Scool of Medicine, King Saud University, Riyadh, Saudi Arabia

**Background:** *Candida glabrata* ranks as the second most common cause of candidemia in many countries. Echinocandin resistance in *C. glabrata* is emerging. The aim of this study was to compare the genomes of two sequential echinocandins susceptible and resistant *C. glabrata* related isolates.

**Materials/methods:** Two bloodstream *C. glabrata* isolates were serially recovered from a 72-year-old female patient with candidemia post contrary artery bypass grafting procedure (CABG) before and after caspofungin treatment (<3 months interval). Whole-genome sequencing (WGS) was performed on these two isolates to determine genetic changes using 2x250bp paired-end sequencing using MiSeq system (illumina).

**Results:** In vitro antifungal susceptibility testing showed an increase in MIC against caspofungin and anidulafungin for the post-treatment isolate (8 mg/L, 2 mg/L respectively) compared to the pre-treatment isolate (0.03 mg/L for both), indicating the acquisition of echinocandins resistance. Isolates confirmed to be genetically related with same MLST type. Genomic analysis of pre-treatment isolate with post-treatment isolate identified 17 nonsynonymous SNVs, including a novel undescribed F1113C substitution in FKS2 gene in addition to the previously described F625S substitution in FKS1 gene. One novel SNV was detected in ERG2 gene (G92D substitution) that belongs to the ergosterol biosynthesis-related family which is known to mediate antifungal resistance in *C. glabrata*. Multiple SNVs were present in genes related to transcriptional and translational activation in response to cellular stress such as: MSS11, MIT1, FIR1, RNR1, DNA2, RPN9, BRE2, ROX3, and CMP2, while others were found in genes related to cell wall components and have functions in membrane transportation and localization such as: SECS, WSC4, and VMAS. Two SNVs were found in genes of unknown function.

**Conclusions:** *C. glabrata* has the ability to rapidly acquire echinocandin resistance. The genomic changes observed in the resistant isolate highlight the diverse mechanisms by which *C. glabrata* can adapt to the pressure of echinocandin therapy and host environment.

Abstract 1384

The ultrastructural visualisation of Severe Fever with Thrombocytopenia Syndrome (SFTS) virus in human PBMC sample

Yujeong Lee¹, Hayoung Lee¹, Edmond Changkyun Park¹,², Hye-Yeon Kim¹,², Seung Il Kim¹,², Chang-Seop Lee¹, Sangmi Jun*¹,²

¹Korea Basic Science Institute Ochang Center, Cheongwon-gun, South Korea, ²Korea Research Institute of Chemical Technology (KRICT), Daejeon, South Korea, ³Chonbuk National University, College of Medicine, Jeonju, South Korea

Background: Severe Fever with Thrombocytopenia Syndrome (SFTS) virus was first discovered in China. In Korea, it was first discovered in Gangwon-do in 2013 and the number of patients has been steadily increasing and has a high mortality rate of more than 30%. Before April 2017, symptoms of SFTS appeared only in humans by ticks as a medium, but since then, animals such as dogs and cats have developed symptoms of SFTS.

Materials/methods: We infected human-derived SFTS virus and dog-derived virus with vero cells and HEK cells, respectively, and then analyzed by Quantitative Real-Time PCR (qRT-PCR) analysis to identify genetic differences. Transmission electron microscopy (TEM) was also performed to confirm the morphology and composition of both cells. Furthermore, the ultrastructure of SFTS virus in human PBMC sample which is provided by Chonbuk national university hospital in Korea has been observed using TEM.

Results: SFTS is sphere and a dense nucleocapsid core of 90-120 nm which is characteristic of enveloped viruses, phleboviruses, commonly known as colonies. We also found the viral particles in monocytes from human samples.

Conclusions: The findings will help to provide a structural basis for the detection and diagnosis of SFTS infections.

Abstract 1388

Results of an outpatient parenteral antimicrobial therapy programme in Spain

Jorge Rodriguez Prida1, Sagrario Maria Santos Seoane1, Carlos Aparicio1, Jose Maria Cueto-Felgueroso1, Cristina Helguera1, Cristina Martinez-Mugica1, Joaquin Moris1, Azucena Rodriguez-Guardado*1

1Hospital Universitario de Cabueñes, Gijon, Spain

Background: Outpatient parenteral antimicrobial therapy (OPAT) is an alternative for the conventional therapy to infectious diseases. The main advantages it offers are the reduction of the complications of conventional hospitalization, better quality of life for the patient and his family and the saving of hospital stay, with the consequent reduction of the economic cost for the health system. The results of an OPAT program are described.

Materials/methods: A retrospective, observational study of all patients attended between 2018-2019 in OPAT program of University Hospital of Cabuñes, Spain were performed. Demographics, therapy characteristics, pathogens, adverse events (AEs), and clinical outcomes were evaluated. Effectiveness was assessed by analyzing readmissions to hospital for inadequate control of underlying infection. Safety was assessed by analyzing adverse events, catheter-related complications and readmission to hospital before 30 days after the end of treatment.

Results: Eighty-six patients (55.8% females, mean age: 73 years) were included. The most frequent underlying diseases were neoplasm (25.6%), respiratory diseases (16.3%), cardiovascular diseases (14%), and diabetes (9.5%). Urinary tract infections (39.5%) were the most frequent infection followed by respiratory infections/pneumonia (30.2%), intra-abdominal infections (7%), endocarditis, septic arthritis, hepatobiliary diseases (4.7% each), prosthesis joint infection and cellulitis (3.5% respectively) and catheter-related sepsis (2.3%). Twenty-five percent of patients had bacteremia. The most frequent microorganisms were Escherichia coli (24.2%), Pseudomonas aeruginosa (15%) Staphylococcus aureus (7%), Klebsiella pneumoniae (4.7%), Staphylococcus epidermidis, Citrobacter freundii, Streptococcus group viridans (3.5% each) among others. In thirty cases the microorganism produced extended spectrum beta-lactamases. The most frequent treatment was ertapenem (34.8%) followed by piperacillin-tazobactam (23.3%), ceftriaxone (19.8%) and daptomycin (7.5%). Only six patients (7%) patients had a recurrence Six patients dead due to the infection. There are not significantly differences in sex, age, or underlying diseases between relapses or not. Catheter-related complications occurred in 3 patients. Mean duration of treatment was 13 days. Twenty days of antibiotic treatment was saved.

Conclusions: OPAT programs are a safe and effective alternative that saves hospital stay even in patients with bacteremia. The readmission rate is low and the level of patient satisfaction high.

Extreme levels of diversity of *Mycobacterium tuberculosis* across a large genomic dataset: a map to disease pathogenesis and stress survival

Danai Papakonstantinou*1, Steven Dunn2, Adam Cunningham3, Matthew O’shea1, Alan Mcnally2

1University of Birmingham, Institute of Microbiology & Infection, College of Medical and Dental Sciences, Birmingham, United Kingdom, 2University of Birmingham, Institute of Microbiology & Infection, School of Biosciences, Birmingham, United Kingdom, 3University of Birmingham, Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, Birmingham, United Kingdom

**Background:** *Mycobacterium tuberculosis* (*M*. *tuberculosis*) is a bacterial pathogen causing tuberculosis (TB), an ancient disease, which is one of the biggest infectious “killers” worldwide. It is almost 20 years since the first *M*. *tuberculosis* genome sequence. Many landmark studies have been undertaken, but have mainly focussed on phylogenetic analysis, drug resistance and outbreak investigation. However, a deeper understanding of the diversity present across all *M*. *tuberculosis* genes at a population level is required, especially in the future discovery of novel drug targets or vaccine candidates. We performed an unbiased gene-by-gene analysis of 8535 *M*. *tuberculosis* genomes by studying the extremes of nucleotide sequence diversity distribution - i.e. genes with low and high levels of nucleotide sequence diversity across the sequenced population.

**Materials/methods:** Public genomic data covering all seven *M*. *tuberculosis* lineages was retrieved and curated. A total of 8535 genome sequences were mapped against the reference *M*. *tuberculosis* genome, H37Rv, in order to identify single nucleotide polymorphisms (SNPs). The results of the initial mapping were further processed and a diversity frequency distribution of all the genes was identified.

**Results:** We show that levels of diversity across genes are not normally distributed and that there are genes with extreme levels of diversity and others with extreme levels of conservation. In highly variable genes, variants were found to occur at hotspots, and largely encoded functions related to disease pathogenesis and drug resistance. Such diversity may make it problematic to create a vaccine or drug that successfully targets the known diversity of *M*. *tuberculosis* strains. Conversely, very conserved genes are associated with the protection of the *M*. *tuberculosis* under stress conditions, intra-macrophage infection and the latent stage of the disease. This suggests that these genes are highly important in the TB infection cycle, and may constitute more preferential drug and vaccine targets to combat TB.

**Conclusions:** This study can be used as a “map” of the evolutionary trajectory of *M*. *tuberculosis* genes across all lineages and might inform the development of future vaccine candidates and novel anti-TB medication.

Abstracts 2020

Abstract 1395

**Pathogen Box screening identifies novel antimicrobials that target *Mycobacterium chimaera***

Daire Cantillon*, Aaron Goff, Stuart Taylor, Simon Stoneham, Simon Waddell

1University of Sussex, Brighton and Sussex Medical School, Falmer, United Kingdom

**Background:** *Mycobacterium chimaera* is a slow growing nontuberculous mycobacterium that is part of the *Mycobacterium avium* complex (MAC). *M. chimaera* infection has been identified in patients having previously undergone cardiac surgery and it is also increasingly being detected in patients with chronic lung disease. Like many mycobacterial infections, *M. chimaera* is recalcitrant to antimicrobial therapy and require long treatment regimens. There is an urgent need to both identify novel antimicrobials and to re-purpose drugs to treat *M. chimaera* as current treatment regimens are inadequate with patient mortality as high as 50%.

**Materials/methods:** In this study, we screened the Pathogen Box library, which consists of 400 drug-like molecules against *M. chimaera* using a resazurin based microtiter plate assay to determine cell survival that was validated with Z-factor analysis. Selected hits were characterised with dose response curves and time kill kinetics.

**Results:** A total of 21 hits were identified based on a cut off of 70% or more *M. chimaera* growth inhibition when screened at the single concentration of 20 µM. Dose response curves of four compounds (MMV02248, MMV675968, MMV688179 and MMV688271) showed favourable activity against *M. chimaera*, with MMV675968 exhibiting activity similar to clarithromycin which forms part of front line treatment of *M. chimaera*. In addition, one of the hits identified was doxycycline, which is a broad-spectrum antimicrobial drug. Doxycycline generated a minimum inhibitory concentration of 6.25 µg/mL against *M. chimaera* and is bacteriostatic, based on time kill kinetic studies. Three oxazolidinone compounds linezolid, sutezolid and radezolid were also identified as hits against *M. chimaera*.

**Conclusions:** Here, we identified new chemical entities as well as oxazolidinone compounds that show good activity against *M. chimaera* that could lead promising new antimicrobials with further drug development. As well as identifying new compounds, we have identified the currently licensed antimicrobial doxycycline as showing efficacy against *M. chimaera*. Doxycycline is a commonly used and well-tolerated antimicrobial that should be investigated further as part of treatment regimens for *M. chimaera* infection.

Anaplasmosis in Poland: underestimated disease?

Anna Moniuszko*, Justyna Dunaj, Piotr Czupryna, Sambor S. Grygorczuk, Joanna Maria Zajkowska, Maciej Kondrusik, Slawomir Pancewicz

1 Medical University of Białystok, Białystok, Poland, 2 Medical University of Białystok, Białystok, Poland, 3 Medical University of Białystok, Białystok, Poland, 4 Medical University of Białystok, Białystok, Poland

Background: Human cases of *Anaplasma phagocytophilum* infection are not frequently reported in Europe. However, the disease may be underdiagnosed due to the nonspecific nature of presenting symptoms. The aim of our study was to clarify the clinical picture of anaplasmosis through analysis of the symptoms and clinical signs displayed by infected patients in a cohort of tick-bitten individuals.

Materials/methods: The study included 1375 patients after a tick bite. Finally, 120 patients (8.7%) were diagnosed with anaplasmosis. Routine laboratory tests, serological and molecular microbiologic investigations were performed. Blood samples were examined by PCR for *A. phagocytophilum*, *Candidatus Neoehrlichia micurcensis*, *B. burgdorferi*, *Babesia* spp., *Coxiella burnetii* and *Bartonella* spp. Positive samples were confirmed by sequencing. Serological analyses for tick-borne encephalitis virus and thin blood smears for detection of *Anaplasma* morulae were performed.

Results: Among 120 patients with HGA, there were 66 men (55%) and 54 women (45%). All patients had *A. phagocytophilum* DNA in blood samples that was detectable by standard PCR and confirmed by sequence analysis. 40 (33.3%) of patients were co-infected with *Borrelia burgdorferi*, 20 (17%) of patients were co-infected with TBEV, and one patient (0.83%) was co-infected with a *Babesia* spp. and 40 (33.3%) with *Borrelia burgdorferi*. Anaplasmosis patients presented with headaches, vertigo, nausea, vomiting, muscle pain, joints pain, and fever. Comparison of differences between patients with mono- and co-infection showed differences in symptoms and higher CRP concentration and AST activity in patients with co-infection. All patients recovered after doxycycline therapy.

Conclusions:

1. Anaplasmosis is not as rare in Europe, as it is thought to be.
2. Anaplasmosis often appears as a co-infection with other tick-borne pathogens.
3. Co-infection of *A. phagocytophilum* with *Borrelia burgdorferi* or TBEV may influence symptoms frequency.
4. PCR together with anamnesis, clinical picture and basic laboratory tests is a sufficient method for anaplasmosis diagnosis.
5. Doxycycline is an effective drug leading to complete recovery.

Abstract 1403

**Toxocariasis in children in south Russia: epidemiological and laboratory features**

Larisa Ermakova1,2, Yulia Kiosiva1, Anna Andreeva1, Natal’ja Golovchenko1, Tatyana Tverdokhlebova1,2, Anna Shirinyan1, Natalia Pshenichnaya*2,3, Antonina Grekova4

1Rostov Scientific Research Institute of Microbiology and Parasitology, Rostov-on-Don, Russian Federation, 2Rostov State Medical University, Rostov-on-Don, Russian Federation, 3National Medical Research Center of Phthisiopulmonology and Infectious Diseases, Moscow, Russian Federation, 4Smolensk State Medical University, Smolensk, Russian Federation

**Background:** Clinical features of toxocariasis depend on geographic localization and age of patients. Aim: to investigate: epidemiological, clinical and laboratory features of toxocariasis in children in the South of Russia.

**Materials/methods:** We analyzed official statistical data in the period from 2014 to 2018 and implemented a retrospective analysis of 57 medical records of patients (40 children and 17 adults) who received treatment and were under observation in the clinic of infectious and parasitic diseases of the Rostov Scientific Research Institution of Microbiology and Parasitology, Rostov-on-Don, Russia.

**Results:** According to official statistics, the proportion of children aged 0 to 17 ranged from 33% to 37%. Based on clinical and laboratory examination, the diagnosis was established in 26 patients (45.6%). Among patients with a verified diagnosis of toxocariasis, the proportion of children from 2 years and 5 months to 9 years old was 96.0%. An analysis of epidemiological data showed that 76.0% of children had close contact with the soil. The invasion occurred in the form of latent toxocariasis in 9 (35%) patients. In more than half of the children, the invasion was clinically manifested by geophagy (54.0%). A permanent laboratory indicator in patients with toxocariasis was the leukemoid eosinophilic type reaction. Peripheral blood eosinophilia ranged from 15.66 ± 9.31 with latent toxocariasis to 25.5 ± 15.0 with visceral. In some cases, this figure exceeded 60%. The coefficient of positivity (CP) in ELISA with toxocariasis antigen in patients with latent toxocariasis was higher than in the group of patients with visceral toxocariasis. No correlation between the level of eosinophilia and CP in ELISA with toxocariasis antigen was established in the each of group (r = 0.1).

**Conclusions:** The results of our analysis of the epidemiology of toxocariasis showed that preschool children (68.0%) who are in close contact with the soil (76.0%) are most susceptible to invasion, which does not correspond to the official statistical reporting data. Infestation in children is often asymptomatic (36% according to our data). If peripheral blood eosinophilia is detected, an ELISA test with a toxocariasis antigen is recommended.

Abstract third-party references: On behalf of the IRONIC study group

Background: We aimed to assess the rate and predictive factors of bloodstream infection (BSI) due to multidrug-resistant (MDR) Pseudomonas aeruginosa (PA) in neutropenic cancer patients.

Materials/methods: We performed a multicenter, retrospective cohort study including onco-hematological neutropenic patients with BSI due to PA conducted across 34 centers in 12 countries from January 2008 to May 2018. A mixed logistic regression model was used to estimate a predictive model for developing multidrug resistance.

Results: A total of 1217 episodes of BSI due to PA, 309 episodes (25.4%) were caused by MDR strains. The rate of multidrug resistance increased significantly over the study period (p=0.033). Predictors of MDRPA BSI were prior therapy with piperaci-
lin/tazobactam [odds ratio [OR], 3.48; 95% confidence interval [CI], 2.29-5.30], prior antipseudomonal carbapenem use [OR, 2.53; 95% CI, 1.65-3.87], fluoroquinolone prophylaxis [OR, 2.99; 95% CI, 1.92-4.64] underlying hematological disease [OR, 2.09 95% CI, 1.26-3.44] and the presence of a urinary catheter [OR, 2.54; 95% CI, 1.65-3.91], whereas older age [OR, 0.98, 95% CI, 0.97-0.99] was found to be protective.

Conclusions: Our prediction model achieves good discrimination and calibration thereby identifying neutropenic patients at higher risk of BSI due to MDRPA. The application of this model using a web-based calculator may be a simple strategy to identify high-risk patients, who may benefit from the early administration of a broad-spectrum antibiotic coverage against MDR strains in accordance with the local susceptibility patterns, thus avoiding the use of broad-spectrum antibiotics in patients at low risk of resistance.

Abstract 1408

**Long-term suppressive treatment of cardiac surgery-related *Mycobacterium chimaera* disseminated infection**

Vinicio Manfrin¹, Marta Mascarello*¹, Mario Rassu², Loredana Fallico², Loris Salvador³, Sara Mondino⁴, Romina Cazzaro⁴

¹San Bortolo Hospital of Vicenza, Infectious diseases Unit, Vicenza, Italy, ²San Bortolo Hospital of Vicenza, Microbiology Department, Vicenza, Italy, ³San Bortolo Hospital of Vicenza, Cardiac Surgery Unit, Vicenza, Italy, ⁴San Bortolo Hospital of Vicenza, Hospital Medical Direction, Vicenza, Italy

**Background:** *M. chimaera* infections after cardiac surgery are characterized by high morbidity and mortality rate due to dissemination of infection and high affinity of mycobacteria to form biofilm on the prosthetic devices. Prolonged anti-mycobacteria treatment and removal of all cardiovascular prosthetic material (redo-operation) are suggested to obtain source control and avoid breakthrough infection. Nevertheless, in some patients, owing to comorbidities redo-operation is not feasible. The management of inoperable patients remains undefined especially regarding the number of drugs, the regimen and the length of anti-mycobacteria treatment. We report our experience on long term treatment of inoperable patients.

**Materials/methods:** We retrospectively reviewed all cases of *M. chimaera* infection following cardiac surgery diagnosed in our hospital.

**Results:** Nine patients were diagnosed with disseminated *M. chimaera* infection. Two females and 7 males, mean age 59 years. All patients were treated with an initial combination therapy: clarithromycin, ethambutol and a rifamycin in addition to clofazimine or linezolid. Three underwent redo-operation, one died 48 hours after surgery owing to septic shock, the other had a breakthrough infection 9 months after surgery. One underwent redo-operation owing to a life-threatening periaortic abscess, before the diagnosis of *M. chimaera* infection was established. Among the six non re-operated patients three experienced a breakthrough infection, two of them died. Three are on long-term suppressive antibiotic therapy (clarithromycin+ethambutol) after respectively 8, 14 and 18 months of four drugs, lead-in, anti-mycobacteria treatment. The blood, urine and stool culture are persistently negative, the clinical condition and quality of life are good, the therapy is well tolerated, no side effects occurred after respectively 21, 26 and 27 months of follow up.

**Conclusions:** The long follow up of our non re-operated patients suggests that control of *M. chimaera* infection, in selected cases, is feasible with a long-term suppressive anti-mycobacteria therapy alone. We suggest that further studies should investigated the optimal timing and the criteria for redo-surgery and the final impact on patients survival. More clinical data are need to identify patients who will most benefit a conservative approach instead of implanted device substitution and to define the optimal medical therapy for inoperable patients.

Abstract 1409

**Usefulness of the 16S rRNA gene PCR and sequencing in the diagnosis of prosthetic joint infections**

Germam Traglia¹, Claudia Tosello*, Claudia Barberis¹, Gisela Arevalo Calderon¹, Liuco Zubeldia Brenner¹,², Silvia Repetto¹, Flavio Ivalde¹, Andres Ferrero¹, Marcelo Melo¹, Honorio Pueyrredon¹, Juan Ottolenghi¹, Daniel Ricardo Stecher², Carlos Yay³

1Hospital de Clínicas José de San Martín. Universidad de Buenos Aires, Buenos Aires, Argentina

**Background:** Microbiological cultures of prosthetic joint infections (PJI) often yield false negative results. We performed a prospective, comparative study to evaluate the usefulness of 16S RNA gene polymerase chain reaction and sequencing in the diagnosis of PJI.

**Materials/methods:** Patients older than 18 years who underwent surgery for a suspected joint prosthesis infection according to 2012 IDSA definitions were included as cases and primary arthroplasties as controls. We analyzed all surgical samples using conventional cultured (identification was performed using phenotypic methods and MALDI-TOF MS) and 16S PCR and sequencing. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated for both methods.

**Results:** Twenty cases and 38 controls were included. Average age for cases 69.5 years (23-91) and 70 (24-90) for controls. We included 12 hips and 8 knees as cases and 19 hips and 19 knees as controls. Microorganisms were isolated by culture in 11/20 cases (S. epidermidis 3, S. hominis 3, S. aureus 2, E. coli 1, E. cloacae 1 and Streptococcus viridans group 1) and negative in 9. 16S PCR was positive in 18/20 cases (S. epidermidis 3, S. aureus 3, S. hominis 3, Cutibacterium acnes 3, Streptococcus viridans group 1, E. faecalis 1, E. coli 1, E. cloacae 1 and non-culturable microorganisms 2). Of the 9 negative cultures 16S PCR was positive in 2: Cutibacterium acnes 3, E. faecalis 1, S. aureus 1 and non-culturable microorganisms 2. In one case Cutibacterium acnes was detected by PCR in addition to the microorganism isolated by culture. Cultures and PCR were negative in 100% of the controls. For 16S PCR sensitivity was 90 %, specificity 100%, PPV 100 % and NPV 95%. For culture sensitivity was 55 %, specificity 100%, PPV 100 % and NPV 80.45.

**Conclusions:** In our study 16S PCR and sequencing was a useful tool in the diagnosis of PJI in cases with negative culture and in polymicrobial infections, allowing the identification of bacteria not detected in the culture.

Hospital organisation, management and implementation of culture of excellence in infection control and prevention of hospital-acquired infections at Ziv medical centre, Israel

Jalal Tarabeia*,1, Shimon Edelstein1, Miriam Sudri1, Hila Ben-Amram1, Salman Zarka1

1Ziv Medical Center, Tsfat, Israel

Background: Infections associated with health-care institutes are a threat to the medical treatment safety and manifest in 5-10% of the hospitalized patients. During the last three years we implement culture of excellence on infection control. The intervention was based on the ministry of health incentive model on infection control in Israel which include 33 measurement elements stratified to 8 categories: Infection control team, hospital facility, hand hygiene training and compliance, computing support, quality parameters of microbiology laboratory, antibiotic stewardship, health care worker immunization and environmental cleaning and disinfection.

Materials/methods: Three years of implementation the culture of excellence and closing gaps in infection control elements supported by the hospital management. To achieve goals and excellence in infection control we empower nurses in infection control in each department, facility improvement, active surveillance of MDR bacteria, bacteremia and central line associated bloodstream infection (CLABSI) and hand hygiene, implementation of guidelines of antibiotic treatment and stewardship, immunization of health care worker, training of physicians and nurses on central line insertion, maintenance and infusion therapy including total parenteral nutrition.

Results: Comparing data from 2016 to 2019, the immunization coverage of health care workers (HCW) rise from 33% to 92% respectively. CLABSI declined from 6 per 1,000 line days to 0.8. Hospital acquired UTI decline from 2.4/1000 hospital days at 2018 to 1.2 at 2019, Carbapenemase producing Enterobacteriaceae (CPE) decline from 27.8/100K hospital days to 19.1, Carbapenem resistant Acinetobacter baumannii declined from 17.6/100k hospital days to 6.3. The score of excellence rise from 54.1% to 81.2%, being one of the higher score comparing with other governmental hospitals.

Conclusions: Management support and creating positive organization culture in infection control, bridging the facility gaps, training of staff, surveillance of processes and outcomes and monitor the quality of environmental cleaning are the main elements for hospital infection prevention of resistant bacteria and CLABSI, HCW protection from vaccine preventable diseases.

Abstract 1419

**Dose optimisation of cefotaxime in critically ill patients: a population pharmacokinetic study**

Eveline Elsbeth Roelofsen*1, Brenda De Winter2, Alan Abdulla2, Henrik Endeman2, Annemieke Dijkstra3, Anouk E. Muller1,2, Birgit Koch2

1HMC Westeinde, Den Haag, Netherlands, 2Erasmus MC, Rotterdam, Netherlands, 3Maasstad Hospital, Rotterdam, Netherlands

**Background:** Cefotaxime is a beta-lactam antibiotic used in critically ill patients to treat infections. Literature data on the pharmacokinetics (PK) of cefotaxime in these patients are lacking. A two-centre prospective, observational study in critically ill patients was undertaken. The aim of this study was to describe the PK of cefotaxime and propose a dosing regimen in critically ill patients.

**Materials/methods:** Critically ill patients treated with cefotaxime dosed 1g q6h or q4h were included. Five samples were drawn per patient during one dosing interval. PK parameters were estimated using NONMEM. Monte Carlo simulations (n=5000) were performed using Miclab 2.36 (Medimatics, NL) to determine Probability of Target Attainments (PTA). The percentage of patients reaching 100% T>MIC was used to compare different dosing regimens for Enterobacterales and S. aureus.

**Results:** 92 patients (57 males), median age (range) of 64 (23-85) years, weight 76 (45:150) kg and creatinine clearance 57 (4-347) ml/min were included. A total number of 437 observations were analyzed. The best structural model was a two-compartment model with a combined error, and interindividual variability (IIV) on clearance (CL), central volume (V1), and inter-compartmental clearance (Q). Correlations between IIV were included. CL increased with higher CKD-EPI (creatinine clearance) and higher albumin concentration and could explain 48% of IIV on CL. The estimates population parameters were 7.08 ml/min for CL; 15.7 L for V1; 25.0 L for V2 and 4.81 L/h for Q. For Enterobacterales (ECOFF 0.25 mg/L), 100% of patients reached the target with 1g q6h [15 minutes infusion time]. For S. aureus (ECOFF 4 mg/L) a PTA of 64.2% and 88.8% was reached for the regimen 1g q6h and 1g q4h, respectively. With an increased dose of 2g q4h 97.3% of critically ill patients reached the target for S. aureus.

**Conclusions:** In critically ill patients, cefotaxime PK is best described by a two-compartment model with CKD-EPI and albumin concentration as covariates influencing clearance. All dosing regimens are adequate to treat Enterobacterales. However, this study indicates that for S. aureus the dosing regimen needs to be increased to 2g q4h administered over 15 min.

Abstract 1420

High-resolution influenza mapping of a city reveals socioeconomic determinants of transmission within and between urban quarters

Adrian Egli1, Nina Goldman2, Nicola F. Mueller3, Myrta Brunner2, Daniel Wüthrich4, Sarah Tschudin-Sutter1, Emma Hodcroft6, Claudia Saalfrank2, Richard Neher7, James Hadfield7, Trevor Bedford7, Mohammedyaseen Syedbasha8, Thomas Vogel1, Noemie Augustin7, Jan Bauer3, Nadine Sailer2, Nadezhda Amar-Sliwa2, Daniela Lang8, Helena Seth-Smith1, Annette Blaich4, Yvonne Holenstein8, Olivier Dubuis2, Michael Naegle3, Andreas Buser10, Christian Nickel11, Nicole Ritz12, Andreas Zeller13, Tanja Stadler3, Manuel Battegay5, Rita Schneider-Sliwa14

1University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 2University of Basel, Human Geography, Basel, Switzerland, 3ETH Zürich, Department of Biosystems Science and Engineering, Basel, Switzerland, 4University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 5University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 6University of Basel, Biozentrum, Basel, Switzerland, 7Fred Hutchinson Cancer Research Center, Seattle, United States, 8University of Basel, Department of Biomedicine, Basel, Switzerland, 9Viollier AG, Clinical Microbiology, Allschwil, Switzerland, 10Swiss Red Cross, Blood Donation Center, Basel, Switzerland, 11University Hospital Basel, Department of Emergency Medicine, Basel, Switzerland, 12Children’s University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 13University of Basel, Basel, Switzerland, 14University of Basel, Human Geography, Basel, Switzerland

Background: With two-thirds of the global population projected to be living in urban areas by 2050, understanding the transmission patterns of influenza within cities is crucial for effective prevention strategies. Here, in unprecedented spatial resolution, we analysed the socioeconomic determinants of influenza transmission in a European city (Basel, Switzerland). We aimed to described the incidence rates of influenza cases and transmission patterns in context to socioeconomic determinants.

Materials/methods: Our dataset included all PCR confirmed influenza cases from 2013 to 2018. We conducted a large city-wide survey with more than 30,000 distributed questionnaires [2015/2016 season]. Whole genome sequencing (WGS) data of 663 viral isolates was used to analyse the transmission network [2016/2017 season]. We combined geographical and epidemiological data with WGS of influenza viruses at the scale of urban quarters and statistical blocks, the smallest geographic subdivisions within a city.

Results: We observed annually re-occurring geographic hotspots of influenza incidences, mainly associated with net income, and independent of population density and living space. In the questionnaire, vaccination against influenza was positively associated with household income and negatively linked to the likelihood of influenza-like illness within an urban quarter. Of WGS samples (n=663), a diverse set of 54 clusters (within 10 SNPs cut-off) were observed within the city. The phylogeny of isolates reflected the global diversity. A generally high exchange rate and complex transmission dynamic between different urban quarters was observed. Significant within quarter transmission was observed for two quarters with low socioeconomic scores and lower pre-seasonal herdimmunity as determined by heagglutination inhibition assays.

Conclusions: High-resolution city-level epidemiological studies combined with social science surveys such as this will be essential for understanding infectious disease transmission chains and delivering tailored public health information and vaccination programs at the municipal level.

Abstract 1430

**Outcome impact of a highly bactericidal scheme as initial treatment of acute staphylococcal PJI**

Alvaro Auñon1, Marta Martin-Garcia1, Raul Parron1, Antonio Blanco García1, Joaquín García Cañete1, Ricardo Fernández Roblas1, Ignacio Gadea Gironés1, Jaime Esteban-Moreno1*

1Fundacion Jimenez Diaz University Hospital, Madrid, Spain

**Background:** S. aureus is one of the most common pathogens involved with acute PJI. Management usually involves DAIR and antibiotic treatment. Here we present the evaluation of our experience with a scheme of treatment that combines a high bactericidal combination followed by an antibiofilm combination.

**Materials/methods:** Between April 2011 and October 2018, 48 acute PJIs caused by S. aureus were treated with DAIR in our center, (15TKA and 33 THA). Time between index surgery and DAIR, antibiotic treatment scheme and follow-up were revised. We have compared the results between the new antibiotic scheme (5 days of daptomycin + cloxacillin followed by levofloxacin+rifampicin) with the previous combinations, based in the use of less-bactericidal combinations, mainly comprising vancomycin plus rifampicin or levofloxacin plus rifampicin.

**Results:** 23 patients were treated with DAIR diverse antibiotic combinations, after a mean period of 22.7 days after index surgery (range 12-39) and received a mean of 102.8 days of antibiotic treatment (range 35-180). 16 of them (63.6%) were free of infection after 30.6 months of follow-up (range 2-60). 25 patients were treated with DAIR and a new antibiotic scheme, which includes 5 days of daptomycin + cloxacillin (a combination with high bactericide power), followed by levofloxacin+rifampicin, with anti-biofilm properties, during a mean period of 101.4 days (range 45-180). 21 of them (84%) were free of infection after 11.3 months of follow-up (range 1.5-30). Although the limited sample size does not let us talk in terms of statistical significance, the difference in the healing rate depending on antibiotic treatment shows high clinical relevance. We have observed that this difference is higher when the period between index surgery and DAIR is less than 30 days (89.3% vs 63.2%).

**Conclusions:** The combination of daptomycin +cloxacillin plus levofloxacin+rifampicin, which combines an initial high bactericidal therapy followed by an antibiofilm activity, shows higher healing rates for treatment of acute PJIs caused by S. aureus and treated with DAIR.

Diagnosis of acute dengue infection in Navarra

Estibaliz Erviti, Aitziber Aguinaga Perez, Ana Navascués Ortega, Isabel Polo Vigas, Irati Arregui, Marta Adelantado Lacasa, Maria Eugenia Portillo, Carmen Ezpeleta Baquedano

1Complejo Hospitalario de Navarra, Pamplona, Spain, 2Instituto de Investigación Sanitaria de Navarra (IdisNA), Pamplona, Spain

Background: The aim of this study is to analyze the new diagnosis of dengue virus infection in our hospital from January 2016 to September 2019.

Materials/methods: Retrospective study of 255 samples from 227 different patients with possible dengue virus infection; 82 PCR and 173 serology tests were performed. Clinical history of each patient was studied to obtain clinical and epidemiological information. Cases of dengue were defined by clinical symptoms, epidemiological link and positive PCR and/or IgM detection and/or seroconversion. PCR was performed by TropicalFeverCore real-time PCR kit (FastTrack Diagnostics); for serology tests we used Dengue IgM and IgG capture ELISA kit (Panbio) and Dengue Virclia® IgM and IgG monitest (Vircell).

Results: Among all patients studied, 23 (10.1%) were diagnosed of dengue infection; mean age was 38.6 years (SD±11.4 years) and 13 were females (56.5%). Regions of birth were: Europe (60.9%), Africa (8.7%) and South America (30.4%). All patients had travelled to any dengue endemic country in Africa (17.4%), Asia (30.4%) and South/Central America (52.2%). In all cases the onset of symptoms happened during the journey or within 10 days after returning.

Main clinical manifestations were fever (100%), arthralgia/myalgia (60.9%), headache (43.5%) and cutaneous rash (34.8%); 10 cases (43.5%) presented thrombocytopenia and leukopenia. No clinically severe manifestations were observed.

Regarding diagnosis, 7 (30.4%) were performed by PCR and 15 (65.2%) were based on serology: 11 (73.3%) with IgM+/IgG+ and 4 (26.7%) with IgM+/IgG-. One case (4.3%) was confirmed by both PCR and serology. Different serum samples were available only in 2 patients (8.7%) and in both seroconversion was demonstrated.

Conclusions:

- All diagnosis were of imported dengue infection in travellers returning from endemic countries.
- Due to the short period of viremia the possibility of PCR based diagnosis is low. 65.2% of diagnosis were performed only by serological assays, 26.7% of which were based only on IgM reactivity.
- The availability of a second serum sample should be taken into account as an improvement in diagnostic procedure to allow confirmation of diagnosis in these cases by seroconversion.

Abstract 1432

**Antimicrobial susceptibility of *Cutibacterium avidum* isolated from prosthetic joint infections: differences between biofilms and planktonic bacteria**

Llanos Salar Vidal¹, Yvonne Achermann², Rihard Trebse³, Mitja Rak⁴, Marjan Wouthuyzen-Bakker⁵, John-Jairo Aguilera-Correa¹, Jaime Esteban-Moreno⁶¹

¹Fundacion Jimenez Diaz University Hospital, Madrid, Spain, ²University Hospital Zurich. University of Zurich, Zurich, Switzerland, ³Orthopaedic Hospital Valdoltra, Ankaran, Slovenia, ⁴National Laboratory of Health, Environment and Food, Koper, Slovenia, ⁵University Medical Center Groningen. University of Groningen., Groningen, Netherlands

**Background:** *Cutibacterium avidum* is a Gram positive anaerobic rod and known to colonize human moist skin such as the groin. Rarely, it causes abscesses, and hip and shoulder peri- prosthetic joint infections (PJI), and is usually susceptible to Penicillin. However, data about antibiotic susceptibility against planktonic and biofilm *C. avidum* are limited.

**Materials/methods:** We tested the activity of different antibiotics against planktonic and biofilm *C. avidum* in vitro (n=11 isolates from different PJI cases, identified by MALDI-TOF MS). Minimal inhibitory concentrations (MIC) and minimal bactericidal concentrations (MBEC) were evaluated according to the microdilution method by EUCAST, using Mueller Hinton cation adjusted broth with a final bacterial inoculums of 10⁴ CFU per well. The minimal biofilm inhibitory concentration (MBIC) and the minimal biofilm eradication concentration (MBEC) were assessed following the protocol previously described by Coenye et al. (Res Microbiol. 2007 May; 158(4):386-92). Plates were incubated at 37°C for 48 hours under anaerobic conditions.

**Results:** The MIC, the MBC, and MBIC were low for amoxicillin-clavulanic acid, clindamycin, levofloxacin, linezolid, rifampin, and vancomycin (table 1). However, the MBEC to eradicate the biofilm *C. avidum* were high with > 32mg/l except for rifampin with 0.5 mg/L.

**Conclusions:** While all tested antibiotics showed bactericidal activity against planktonic *C. avidum* cells, eradication of biofilm *C. avidum* was only possible with rifampin. Currently, we are investigating the value of rifampin for cure of *C. avidum* PJs in a large multicenter study.

Abstract 1435

**Increased serum hydrogen sulfide as determinant of resolution of ventilator associated pneumonia caused by *P. aeruginosa***

Georgios Renieris*1, Konstantina Katrini1, Eleni Karakike1, Nikolaos Antonakos1, Athanasios Karageorgos1, Labros Sabrakos1, Evangelos Giamarellos-Bourboulis1

14th Department of Internal Medicine, National and Kapodistrian University of Athens, Medical School, Athens, Greece

**Background:** Previous data of our group in mice (Renieris G, et al. ECCMID 2018; abstract P0904) showed that host production of hydrogen sulfide (H2S) is modulating host defense against *Pseudomonas aeruginosa*. However, clinical data on the significance of host-derived H2S are lacking. This study investigated the role of host-derived H2S in the outcome of ventilator associated pneumonia (VAP).

**Materials/methods:** From a prospective cohort of 700 Greek patients with VAP, 219 cases caused by *P. aeruginosa* (group A, n=65), *Klebsiella pneumoniae* (group B, n=60) and *Acinetobacter baumannii* (group C, n=94) were selected. Pathogens grew at ≥ 105 cfu/ml in tracheobronchial secretions. H2S was measured by the blue methylene method in serum the first 24 hours.

**Results:** Serum levels of H2S were significantly higher in the resolved VAP cases of group A compared to the non-resolved cases (55.63 ± 10.93 vs 20.98 ± 4.30 μM respectively; p: 0.030). Respective values for group B were 16.03 ± 1.36 vs 16.15 ± 2.15 (p: 0.965) and for group C 17.90 ± 1.05 vs 17.16 ± 1.77 (p: 0.711). Further ROC curve analysis of group A indicated that serum H2S above 45μM could better discriminate resolved cases; 17 patients had more and 48 patients less than 45μM H2S. VAP resolved in 16 (94.1%) and in 27 (56.3%) patients, respectively (p: 0.004). Logistic regression analysis showed that serum H2S above 45μM was an independent protective factor for VAP resolution (Table).

**Conclusions:** Circulating H2S in a novel independent determinant of the outcome of VAP caused by *P. aeruginosa*. This may open new boundaries in personalized therapeutics of VAP.

Abstract 1437

Multi-centre study of common pathogen epidemiology in hospitalised children with acute respiratory tract infection in winter from 2017 to 2018, China

Leijun Meng*, Hong Zhang2, Xuejun Shao3, Jun Zhou4

1Shanghai Children's Hospital, Shanghai, China, 2Shanghai Children's Hospital, Shanghai, China, 3Children's Hospital of Soochow University, Soochow, China, 4Hangzhou Children's Hospital, Hangzhou, China

Background: Acute respiratory tract infections (ARTIs) are a major public health problem and a leading cause of morbidity and mortality in children under the age of 5 years, with the highest number of deaths occurring in developing countries. This study aimed to analyze the epidemiological characteristics of pathogens among children hospitalized with ARTIs during the winter, with the aim of providing a reliable basis for clinical diagnosis and treatment and for rational antibiotics use.

Materials/methods: A total of 563 hospitalized children with ARTIs in the children's hospitals of Shanghai, Hangzhou, and Soochow were enrolled between November 2017 and February 2018, and nasopharyngeal aspirates were collected. Real time PCR assays were performed to detect 14 common pathogens, including Mycoplasma pneumoniae (MP), Chlamydia pneumoniae (CP), Legionella pneumophila (LP), Chlamydia trachomatis (CT), respiratory adenovirus (ADV), influenza virus A and B (IFV-A and IFV-B), human parainfluenza virus types 1-3 (HPIV 1-3), human rhinovirus (HRV), respiratory syncytial virus (RSV), and human metapneumovirus A and B (hMPV-A and hMPV-B).

Results: Of the 563 specimens obtained from the patients, 467 (82.95%) were positive for at least one pathogen. RSV was the most commonly detected pathogen (48.66%), followed by HRV (21.49%). The detection percentages for each of the respiratory pathogens varied considerably by age. RSV was the most common pathogen detected in the children aged less than 6 months. Co-infections were found in 20.6% of the patients. Of these coinfections, the combination of RSV and HRV was the most common.

Conclusions: The detection percentages of respiratory viruses and atypical bacteria in ARTI children was relatively high during the winter in the children's hospitals in Shanghai, Hangzhou, and Soochow. The pathogen incidence varied depending on patient age and ARTI manifestation.

Abstract 1439

**Risk factors for hospital readmission following complicated urinary tract infection: a multinational, retrospective cohort study**

Tanya Babich*, Noa Eliakim - Raz¹, Adi Turjeman¹, Miquel Pujol², Jordi Carratalà², Evelyn Shaw², Aina Gomila², Cuong Vuong³, Ibironke Addy³, Irith Wiegand³, Sally Grier⁴, Alasdair P. Macgowan⁴, Christiane Vank⁵, Nienke Cuperus⁵, Leonardus Martinus Clemens Van Den Heuvel⁵, Leonard Leibovici¹

¹Beilinson Hospital, Rabin Medical Center, Petah-Tiqva, Israel, ²Hospital Universitari de Bellvitge, Institut d’Investigació Biomèdica de Bellvitge, Madrid, Spain, ³AiCuris Anti-infective Cures, Wuppertal, Germany, ⁴North Bristol NHS Trust, Bristol, United Kingdom, ⁵Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Patients surviving hospitalization are frequently readmitted. About 20% of patients are re-hospitalized during the first month after discharge. These readmissions have a vast implication by negatively influencing the patients’ quality of life and imposing a significant economic burden on the health care system. Understanding the avoidable risk factors for readmission may inform policy for optimal care during hospitalization and proper post-discharge ambulatory care. Therefore, we aimed to determine potentially preventable risk factors for 60-day readmission in patients surviving hospitalization for complicated urinary tract infection (cUTI).

**Materials/methods:** This was a multinational, multicentre retrospective cohort study conducted in Europe and the Middle East. Our cohort included survivors of hospitalization due to cUTI during the years 2013-2014. The primary outcome was 60-day readmission following index hospitalization. Patient characteristics that could have influenced readmission: demographics, infection presentation and management, microbiological and clinical data; were collected via computerized medical records from infection onset up to 60 days after hospital discharge.

**Results:** Overall, 742 patients were included. The median age of the participants was 68 years (interquartile range, [IQR] 55-80) and 43.3% (321/742) of patients were males. The all-cause 60-day readmission rate was 20.1% (149/742) and more than half were readmitted for infection [57.1%, (80/149)]. Recurrent cUTI was the most frequent cause for readmission [46.4% (65/140)]. A quarter of non-infection related readmissions were for urinary tract abnormalities or instrumentation. Statistically significant risk factors associated with 60-day readmission in the multivariable analysis were: older age (OR 1.02 for an one-year increment, CI 1.005-1.03), diabetes mellitus (OR 1.63, 95% CI 1.04-2.55), cancer (OR 1.7, 95% CI 1.05-2.77), previous UTI infection in the last year (OR 1.8, 95% CI: 1.14 - 2.83), insertion of an indwelling bladder catheter (OR 1.62, 95% CI 1.07-2.45) and insertion of percutaneous nephrostomy (OR 3.68, 95% CI 1.67-8.13). Length of hospital stay and discharge to long term facilities were not statistically associated with readmission.

**Conclusions:** Patients surviving hospitalization for cUTI are frequently re-hospitalized, mostly for recurrent urinary infections associated with a medical condition that necessitated urinary interventions. Interventions to avoid re-admissions should target these patients.

Abstract 1442

Clinical impact of rapid susceptibility testing in Gram-negative bloodstream infections
Vanessa Antón Vázquez*1, Cristina Suarez1, Samuel Adjepong2, Timothy Planche1,2

1St George’s, University of London, Institute of Infection and Immunity, London, United Kingdom, 2St George’s NHS Foundation Trust, Medical Microbiology, London, United Kingdom

Abstract third-party references: St. George’s University of London, National Institute for Health Research (NIHR) Collaboration for Leadership in Applied Health Research and Care (CLAHRC) South London, UK

Background: Rapid antimicrobial susceptibility testing (AST) might have the potential to improve patient care when results are available and communicated to clinicians in a timely manner. The aim of service evaluation is to assess the clinical impact of rapid susceptibility testing in patients with Gram-negative BSI.

Materials/methods: A prospective service-evaluation was conducted from March 2018 to December 2018 at St. George’s Hospital, London. Alfred 60AST system had been introduced to routine clinical management for AST of Gram-negative bacteria, directly from positive blood cultures. In routine practice, the Alfred 60AST was only run Monday-Friday before midday and results were communicated to clinicians in the same working day of positive blood culture. Patients in which the culture became positive after midday were tested by conventional AST (Phoenix). Times-to-antibiotic and clinical outcomes were compared between rapid and conventional AST. Odds ratio for discontinuation of antibiotics were generated.

Results: 191 patients were included, 93 in the rapid group and 98 in the standard group. The two groups did not differ with regard to co-morbidity, severity, source of infection, source control, multidrug-resistant organisms. The median time between blood culture collection and the reporting time of AST results was 36h (IQR; 16 – 123) in the rapid group and 63h (IQR; 34 – 5760) in the standard, p<0.001. Time to optimal antibiotic was shorter in the rapid group 43h (IQR; 3-339) vs 66.5h (IQR; 0-872), p=0.023. Aminoglycosides were stopped earlier in the rapid group 32h (IQR; 0-795) vs 54h (IQR; 4-216), p=0.002. Effective antibiotic escalation guided by AST results was initiated earlier in the rapid group 36h (IQR; 0-335) vs 51h (IQR; 2-408), p=0.028. Rapid AST and escalation of non-aminoglycosides by 48h were predictors for discontinuation of aminoglycosides at 48 hours [OR, 2.1; 95% [CI 1.1 - 3.9], p=0.03] and [OR, 3.4; 95% [CI 1.7 - 6.9], p<0.01] in binary logistic regression. No differences were found in 28-day mortality, length of stay, time to discharge, time to effective antimicrobial or time to stop all antibiotics.

Conclusions: Rapid susceptibility testing resulted in faster discontinuation of aminoglycosides and a shorter time to escalate beta-lactam therapy and to start optimal antibiotic.

**Antimicrobial susceptibility of bacteria isolated from patients with pneumonia in Brazil, Argentina, and Mexico: results from the SENTRY programme in Latin America (2015-2018)**

Ana Gales*, Ana Streling1, Carolina Silva Nodari1, Thais Rezende1, Cecilia Carvalhaes2, Helio S. Sader2

1Universidade Federal de São Paulo, São Paulo, Brazil, 2JMI Laboratories, North Liberty, United States

**Background:** The SENTRY Antimicrobial Surveillance Program monitors the frequency of occurrence and antimicrobial susceptibility of organisms from various infection types worldwide. We evaluated the frequency of occurrence and antimicrobial susceptibility results for organisms isolated from patients hospitalized with bacterial pneumonia in 3 Latin American countries.

**Materials/methods:** A total of 977 bacterial isolates were consecutively collected (1/patient) in 2015-2018 from 7 Latin American medical centres located in Brazil (n=427; 3 centres), Argentina (n=281; 2 centres) and Mexico (n=269; 2 centres). Organisms were tested for susceptibility by reference broth microdilution method in a central laboratory (JMI Laboratories). EUCAST and CLSI breakpoints were applied.

**Results:** The most common organism was *P. aeruginosa* in Brazil and Argentina, and *A. baumannii* in Mexico (Table). *P. aeruginosa, S. aureus, K. pneumoniae,* and *A. baumannii* represented the top 4 organisms in all 3 countries and accounted for 71.2-80.7% of the collection. Gram-negative bacilli (GNB) represented 75.6%, 81.9% and 92.6% of organisms; and non-fermentative (NF) GNB represented 45.4%, 43.8%, and 49.1% of organisms in Brazil, Argentina, and Mexico, respectively. *P. aeruginosa* susceptibility to ceftazidime, piperacillin-tazobactam, and meropenem were 87.0%, 79.7%, and 79.7% in Brazil, 72.3%, 69.1%, and 62.8% in Argentina, and 81.2%, 85.4%, and 79.2% in Mexico, respectively. Only 7.5% of all *A. baumannii* isolates (0.0-12.5%) were meropenem-susceptible. Besides colistin (96.9-100.0%), the most active agents tested against *A. baumannii* were minocycline and tobramycin, with susceptibility rates (CLSI) of 100.0% and 68.8% in Brazil, 56.0% and 36.0% in Argentina, and 69.2% and 33.8% in Mexico, respectively. Overall MRSA rates were 22.2% in Brazil, 25.0% in Mexico, and 40.4% in Argentina, and decreased during the study period. *K. pneumoniae,* susceptibility (EUCAST) to ceftriaxone and meropenem were 34.0% and 36.0% in Brazil, 44.1% and 73.5% in Argentina, and 49.3% and 84.9% in Mexico, respectively. CRE rates were 17.1%, 12.1%, and 12.0% in Brazil, Argentina, and Mexico, respectively.

**Conclusions:** GNB represented a large proportion (75.6-92.6%) and NF-GNB accounted for almost half of organisms isolated from patients with pneumonia, and resistance rates were extremely high among these organisms. In contrast, a decreasing trend was observed in MRSA rates.

Do patients colonised by carbapenemase-producing *Klebsiella pneumoniae* have greater crude mortality? ANGEL-KpS Study

Angela Cano Yuste*1, Manuel García2, Marina Gallo-Marín1, Isabel Machuca1, Irene Gracia-Ahufinger3, Julián Torre-Giménez4, Azahara Frutos4, Lara Kindelán-Segador4, Elena Perez-Nadales4, Alejandra M.Natera4, Juan José Castón1, Jesús Rodríguez-Baño5, Luis Martínez-Martínez5, Julián De La Torre Cisneros3, Belén Gutiérrez-Gutiérrez2

1Hospital Universitario Reina Sofia-Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC)—Universidad de Córdoba, Córdoba, Spain, 2Hospital Universitario Reina Sofia, Córdoba, Spain, 3Microbiology Unit, Hospital Universitario Reina Sofia-IMIBIC, Universidad de Córdoba, Córdoba, Spain, 4Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain, 5Hospital Universitario Virgen Macarena—Instituto de Biomedicina de Sevilla (IBiS) and Department of Medicine, Universidad de Sevilla, Seville, Spain

**Background:** Carbapenemase-producing *Klebsiella pneumoniae* (KPC-Kp) infections are associated with high mortality rate. Colonization has been associated with higher risk of death. We evaluated the association of intestinal colonization by KPC-Kp with crude and attributable mortality and investigated the impact of infection in this association.

**Materials/methods:** Observational, prospective, longitudinal cohort study of patients at risk of colonization by KPC-Kp, at Reina Sofia University Hospital in Córdoba, Spain from July’2012 to November’2017. Patients were studied by rectal swab and followed-up for 90 days; rectal swab was repeated in negative patients during the follow-up (weekly in the intensive care and hematology units and before completing the follow-up in the rest of services). Cox regression was used to study variables associated with mortality from any cause. Survival curves were represented according to Kaplan-Meier. A competitive risk analysis was performed to study mortality risk factors specifically related to KPC-Kp infection.

**Results:** 1244 patients (1078 not colonized and 166 colonized) were included. None of the non-colonized patients developed KPC-Kp infection, while 74 (44.6%) of the colonized did. The crude 90-day-mortality was: 194/1078 (18%) in non-colonized and 69/166 (41.6%) in colonized. The variables associated with crude mortality in the Cox regression analysis were: KPC-Kp infection with INCREMENT score >7 (HR:1.84; 95%CI:1.19-2.86; p=0.006), hospitalization in a high-risk service (HR:3.16;95%CI:2.31-4.32; p<0.001), neutropenia (HR:2.49;95%CI:1.56-3.98; p<0.001), neoplasia (HR:1.42;95%CI:1.08-1.88; p=0.01), chronic kidney disease (HR:1.56;95%CI:1.14-2.14; p=0.005), age (HR:1.02; 95%CI:1.01-1.03; p<0.001) and mechanical ventilation (HR:2.37; 95%CI:1.83-3.06; p<0.001). Competitive risk analysis using a risk subdistribution model (SHR) found that infection with INCREMENT score >7 (SHR:66.13;95%CI:32.23-135.70; p<0.001) but not colonization was associated with attributable mortality. The period July’2012-August’2014 was also associated with attributable mortality (SHR:3.19; 95%CI:1.62-6.28; p<0.001). After this period, the attributable mortality decreased from 8.5% to 1.4%, coinciding with the onset of intestinal decontamination in patients at risk and treatment with cefazidime-avibactam.

**Conclusions:** Being colonized was a necessary, but not sufficient condition, to develop an infection due to KPC-Kp infection and die. Intestinal colonization by KPC-Kp was not associated with increased mortality by itself. The risk of death from KPC-Kp is increased when colonized patients develop severe KPC-Kp infection (INCREMENT >7), and the lower mortality observed since August 2014 could be due to changes in the clinical management.

**Abstract 1452**

**Mandatory computerised decision support system is necessary for sustained control of carbapenems and piperacillin-tazobactam usage in a multi-faceted hospital antimicrobial stewardship programme: interrupted time series with segmented regression analysis**

Boon Hou Chua\(^1\), Shi Thong Heng\(^1\), LI Wei Ang\(^2\), Sock Hoon Tan\(^1\), Hui Lin Tay\(^1\), Min Yi Yap\(^1\), Jason Quek\(^1\), Christine Teng\(^1\), B.E. Young\(^1,2\), Ray Lin\(^1,2\), Brenda Ang\(^1,2\), Tau Hong Lee\(^1,2\), David Lye\(^1,2\), Tat Ming Ng\(^1\)

\(^1\)Tan Tock Seng Hospital, Singapore, Singapore, \(^2\)National Centre for Infectious Diseases (NCID), Singapore, Singapore

**Background:** As the use of piperacillin-tazobactam and carbapenems was rising in a public tertiary-care hospital in Singapore, antimicrobial stewardship (AMS) interventions targeting these two classes were introduced; empiric antibiotic guidelines and prospective review and feedback (PRF) in April 2009, and mandatory use of computerised decision support system (CDSS) in April 2011. Mandatory CDSS was lifted in March 2017 for half of the hospital’s wards for a 6-month cluster-randomised study. We aimed to examine the impact of the interventions on the utilisation of carbapenems and piperacillin-tazobactam.

**Materials/methods:** Monthly utilisation of carbapenems and piperacillin-tazobactam in defined daily doses [DDD] per 1,000 patient-days from January 2007 to December 2018 were obtained from the hospital’s database. The impact of AMS interventions was analysed by segmented regression analysis of interrupted time series.

**Results:** The starting level of the carbapenems and piperacillin-tazobactam utilization in January 2007 was 52.19 DDD/1,000 patient-days, and the average rate of increase was 1.17 per month prior to any interventions. When empiric antibiotic guidelines and PRF were implemented in April 2009, there was a reduction of 6.01 (95% confidence interval [CI]: -9.82, -2.20) in the same month, with an increase of 0.33 per month (95% CI: 0.18, 0.48) post-intervention. When mandatory CDSS usage was implemented, the utilisation level increased by 8.45 (95% CI: 2.82, 14.08) in the same month, followed by a reduction at a rate of 0.22 per month (95% CI: -0.33, -0.10). When mandatory CDSS usage was lifted in March 2017, the utilisation level increased by 8.29 (95% CI: 2.63, 13.94) in the same month, and the utilisation rate changed to an increase of 0.28 per month (95% CI: 0.02, 0.55).

By the end of the study period, we estimated an absolute reduction of 126.58 DDD/1,000 patient-days in the monthly utilisation of carbapenems and piperacillin-tazobactam due to the impact of the AMS interventions.

**Conclusions:** The AMS strategies led to a significant reduction of carbapenems and piperacillin-tazobactam utilisation over 10 years. However, the significant increase in utilisation when mandatory CDSS was lifted highlights the importance of having a mandatory CDSS combined with other strategies to ensure sustained control of antibiotic use.

Development and implementation of an electronic admission-screening tool for Candida auris at a large healthcare system in Miami, Florida

Adriana Jimenez*1,2, Kathleen Sposato1, Gemma Rosello1, Dennise De Pascale1, Ashley Flanagan Giroud1, Lilian Abbo1,4

1 Jackson Health System, Infection Prevention and Control Department, Miami, United States, 2Florida International University, Robert Stempel College of Public Health and Social Work, Epidemiology Department, Miami, United States, 3Jackson Health System, Clinical Information System Department, Miami, United States, 4University of Miami, Miller School of Med., Division of Infectious Diseases, Miami, United States

Background: Candida auris (C. auris), an emerging multidrug-resistant yeast, is considered an urgent public health threat worldwide. We describe the use of an electronic tool to screen all patients for risk factors associated with C. auris upon admission to all facilities within a large health system in Miami, Florida.

Materials/methods: Starting August, 2019, we implemented a mandatory questionnaire within the electronic medical record (EMR) applied to all patients at the time of triage to any of our facilities. The tool asked in a conditional branching fashion if the patient had: 1. History of C. auris; 2. Overnight hospital stay outside the continental USA in last 12 months; 3. Tracheostomy present on admission and transferred from a facility with high risk for C. auris; and 4. Recent history of extensively-resistant-organism. Answering “yes” to any of the questions automatically generated an order for contact precautions and requested notification to the infection control department (IPD). As follow up, the IPD verified placement in proper isolation precautions and coordinated collection of screening cultures from axilla and inguinal areas. Screening cultures were processed by the Antibiotic Resistance Laboratory Network in Tennessee, USA. If the screening culture was positive, the patient remained in enhanced contact precautions for the duration of admission; if the result was negative, isolation precautions were discontinued.

Results: A total 37390 patients (47428 encounters) were screened with the questionnaire from implementation to November 17th, 2019. Only 103 patients met criteria for isolation precautions and C. auris screening cultures; of those, four patients had previous history of C. auris, 23 had overnight hospital stay outside the USA (Bahamas, Canada, China, Colombia, Cuba, Dominican Republic, Haiti, Honduras, Jamaica, Nicaragua, Spain, US Virgin Islands, and Venezuela), and 76 had tracheostomy and were transferred from a facility with risk for C. auris. Of the 103 screening cultures collected, only the ones with previous history of C. auris were positive; all four cases were transferred from local long-term-care facilities.

Conclusions: Electronic screening tools incorporated in the EMR are effective means to detect carriers of highly resistant/transmissible organisms, thus facilitating early implementation of infection control interventions aimed to prevent the spread to such organisms within healthcare facilities.

1Hospital Universitario Reina Sofía-Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC)–Universidad de Córdoba, Córdoba, Spain, 2Hospital Universitario Reina Sofia, Córdoba, Spain, 3Microbiology Unit, Hospital Universitario Reina Sofia-IMIBIC, Universidad de Cordoba, Córdoba, Spain, 4Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain, 5Hospital Universitario Virgen Macarena–Instituto de Biomedicina de Sevilla (IBiS) and Department of Medicine, Universidad de Sevilla, Seville, Spain

Background: Carbapenemase-producing Klebsiella pneumoniae (KPC-Kp) infections are associated with high mortality risk. We previously reported that colonization by KPC-Kp is necessary but not sufficient for development of KPC-Kp infection. In this study, we analyzed the risk factors associated with development of infection during 90 days of follow-up.

Materials/methods: Observational, prospective, longitudinal cohort study of patients at risk of KPC-Kp colonization, from a tertiary hospital in the South of Spain from July'2012 to November’2017. All patients with risk factors for colonization were subjected to colonization study. Only those who became colonized by KPC-Kp at the beginning or during the follow-up were included in this analysis. Differences in the risk of infection were evaluated by CART analysis, according to different time periods. The infection risks were represented by Kaplan-Meier curves. Logistic regression was used to identify variables associated with the development of KPC-Kp infection after assessing that proportional hazard assumption for Cox regression was not fulfilled.

Results: 166 KPC-Kp colonized patients were included. Previously, CART established a high-risk period from July’2012 to August’2014, where the infection rate was 53% in comparison to the period from September’2014 to November’2017 in which it decreased to 38.5%. Among 118 patients who became colonized at the beginning of follow-up, 45 (38.1%) developed infection versus those colonized “during follow-up” (60.4%; 29/48). Through logistic regression, the variables associated with development of KPC-Kp infection were: colonization detection during follow-up (OR:2.68;95%CI:1.07-7.o0;p =0.04), Giannella risk score (OR:1.42;95%CI:1.27-1.62;p<0.001), high risk period (OR:3.60;95%CI:1.25-11.11;p =0.02), high risk ward (OR:4.97,95%CI:1.82-14.90;p=0.003) and urological manipulation after admission (OR:2.96;95%CI:0.95-10.75;p=0.07). A multivariate logistic regression analysis confirmed the same risk factors for developing KPC-Kp infection in patients with high risk of death [INCREMENT-CPE score>7].

Conclusions: According to our results, in addition to a high Giannella score, the moment in which the colonization occurs and the ward where the patient is admitted, would be factors to assess when considering empirical treatment to cover KPC-Kp in the case of a suspected infection.

Abstract 1457

**Necrotising external otitis (NEO): analysis of risk factor for relapse in 66 patients managed during a 12 year period in a reference centre**

William Danjou1, Sophie Chabbert2, Carine Fuchsmann1, Thomas Perpoint1, Antoine Pierrefeu3, Patrick Mailhes1, Agathe Becker1, Frederic Laurent1, Andre Boibieux1, Pierre Pradat1, Sandrine Roux1, Claire Triffault-Filit1, Florent Valour1, Tristan Ferry1

1La Croix-Rousse, Lyon, France, 2Edouard Herriot, Lyon, France, 3Centre Hospitalier Lyon Sud, Pierre-Bénite, France

**Background:** NEO is a complex bone and joint infection (BJI) of the skull base that occurred generally in the elderly and/or diabetic patients. There are few data in the literature about its therapeutic management. The aim of our study was to determine risk factor for relapse.

**Materials/methods:** Retrospective cohort study in a reference center for the management of complex BJI. Consecutive cases of NEO over 2006 to 2018 period were included. Diagnosis was done during otoscopy, supplemented by a dedicated imaging. Risk factor for relapse were analyzed by using Cox regression survival analysis with adjusted Hazard Ratio (aHR) and Kaplan Meier curve.

**Results:** Among the 66 patients included (median age, 74 years), most of them had diabetes (n=46, 72%), including 35 (53%) under insulin therapy. 11 (17%) had temporomandibular arthritis, 10 (15%) cranian nerve paralysis, 2 (3%) cerebrals thrombophlebitis, and 2 (3%) contiguity abscess. Samples were obtained during otoscopy: dedicated swab (n=49, 74%), 8 (12%) surgical biopsies, and 3 (4%) both of them. *P. aeruginosa* was involved in 44 patients (67%; all susceptible), 5 patients (7.5%) had fungal NEO at baseline (*A. fumigatus*; *C. albicans*). All patients were treated (average duration 13 weeks), orally and intravenously for 60 of them (91%), mostly with ceftazidime-ciprofloxacin. A subsequent surgery was required in 8 patients (12%), including 3 mastoidectomy. During a median follow-up of 27 months, 16 patients experienced a relapse (*P. aeruginosa* in cultures in 5 patients). Elevated ASA score, as endocranial complication, were potential risk factors for relapse: aHR 1.9 (CI, 0.9 to 3.9; P=0.07) and aHR 1.4 (CI, 0.4 to 4.9; P=0.6), respectively. Using a combination of antibiotics tended to have a protective effect: aHR 0.3 (CI, 0.1 to 1.2; P=0.08). Having a fungal infection at baseline was the only significant risk factor for relapse: aHR of 4.1 (CI, 1.1 to 15; P=0.03) (figure).

**Conclusions:** NEO is a severe BJI mainly due (but not exclusively) to *P. aeruginosa* in elderly and/or diabetic patients. Fungal infections at baseline significantly impact the outcome.

**Presenter email address:** williamdanjou@yahoo.com
A retrospective cohort study investigating the clinical features, outcomes and risk factors leading to a poor outcome in pyogenic liver abscesses (2017-2019)

James Cheaveau*1, Ben Tomlinson2,3, John Williams1, Igor Kubelka2, Monika Kalra3, John Widdrington1

1The James Cook University Hospital, Centre for Clinical Infection, Middlesbrough, United Kingdom, 2Royal Victoria Infirmary, Department of Infection and Tropical Medicine, Newcastle upon Tyne, United Kingdom, 3The James Cook University Hospital, Department of Microbiology, Middlesbrough, United Kingdom

Background: The aim of this study was to describe the clinical features and outcomes of individuals with a pyogenic liver abscess (PLA) in a tertiary centre, and to identify factors associated with mortality.

Materials/methods: A retrospective analysis of data obtained from clinical records of patients was performed, followed by multivariable regression analysis of patient and treatment-related factors.

Results: Fifty-three patients were included, with a mean age of 69 years and a male preponderance. At presentation, symptoms had been present for a median of 7 days; 75% were febrile and 58% had sepsis. Initial blood tests revealed abnormal liver function tests in 87% and an elevated C-reactive protein in 98%. Diagnostic imaging was carried out a median of 2 days following admission; 69% had an abscess >5cm diameter, 41% had multiple PLAs and 11% had metastatic abscesses. An underlying cause was identified in 91%; with a contiguous spread from a biliary source the most common. A microbiological diagnosis was confirmed in 74%; E.coli and Streptococcus anginosus group bacteria were most commonly isolated, while 15% had multiple bacteria cultured. Treatment involved complex, prolonged antibiotic therapy (>4 weeks in 66%) combined with percutaneous drainage in 43% and source control surgery in 23% (mainly cholecystectomy). The patients that had percutaneous drainage had significantly larger abscesses but drainage was not associated with significant differences in clinical outcome or duration of either antibiotic therapy or hospital admission. Mortality was 19%, 11% suffered C.difficile infection and only 53% had an uncomplicated clinical course. Follow-up imaging was carried out in 92%; at the time of the final scan there was complete resolution of the abscess in only 45%. Non-survivors were more likely to have cancer than survivors, but no other factors significantly impacted on survival.

Conclusions: PLA is associated with a considerable morbidity and mortality and requires complex antibiotic treatment alongside selective percutaneous drainage. Further research is required to confirm features that can risk stratify patients at diagnosis and to define the optimal treatment strategies.

Abstract 1459

Two novel fastidious anaerobes from the genus Bacteroides isolated from chicken gastrointestinal tracts

Stanislava Králová*1, Lenka Davidova Gerzova1, Matej Medvecky1, Ivan Rychlik2, Miroslav Cigánek3, Alois Cizek1

1University of Veterinary and Pharmaceutical Sciences Brno, Institute of Infectious Diseases and Microbiology, Brno, Czech Republic, 2Veterinary Research Institute, v. V. I., Department of Bacteriology, Brno, Czech Republic, 3Veterinary Research Institute, v. V. I., Department of Chemistry and Toxicology, Brno, Czech Republic

Background: Anaerobic bacteria inhabiting digestive tract of humans or animals have been a challenging object of microbiological studies for years. Bacteroides spp. make up half of microbiome and majority of these species is hardly cultivated in laboratory conditions. Aim of this work was to thoroughly characterize three Bacteroides spp. (AN20, AN421 and AN502) isolated on media with rumen fluid from chicken gastrointestinal tracts that showed novel properties and that were assigned as candidates for novel species.

Materials/methods: A polyphasic taxonomic approach was applied to characterize isolated strains. All three were subjected to biotyping (micro-, and microscopy, Gram-staining, API 20A and RAPID 32A tests, fermentation products), chemotaxonomy based methods (analysis of proteins, fatty acids and menaquinones) and genomic methods (sequencing of the 16S rRNA gene, whole-genome sequencing and phylogenetic analyses).

Results: Initial analysis of the 16S rRNA sequences showed that the closest relative of AN20 is Bacteroides uniformis (90.3% similarity) and of AN421 and AN502 Bacteroides eggerthii (93.4%). These results suggested that cultivated strains may represent novel species of the genus Bacteroides. Phylogenetic analysis of 16S rRNA gene sequences showed that studied strains formed two separate clades within the genus Bacteroidetes, however they clustered along with Bacteroides coprophilus, Bacteroides coprocola and Bacteroides plebeius. Final confirmation of novelty was done by comparison of whole genomes based on ANI and dDDH values. ANI values between all three strains and B. coprophilus DSM 18228T, B. coprocola DSM 17136T and B. plebeius DSM 17135T were between 70.0-72.0%. Moreover, AN421 and AN502 showed 97.7% identity between each other, whereas AN20 showed 74.1 and 75.3% similarity to AN421 and AN502 confirming these belong to two different species. Biochemical and chemotaxonomy-based methods showed differences between novel strains as well as towards their closest relatives which is important for their proper identification.

Conclusions: In this study, novelty of two Bacteroides species was clearly proved. These two fastidious species were thoroughly described in order to characterize their unique properties. ANI values showing less than 95% genomes similarities as required for species delineation definitely confirmed two novel species for which the names Bacteroides pullorum (AN421T) and Bacteroides brunensis (AN20T) are proposed.

Imported schistosomiasis in children: a French prospective multi-centre study of prevalence, clinical features and diagnostic methods

Claire Leblanc1, Sophie Brun2, Olivier Bouchaud2, Arezki Izri2, Marion Caseris3, Maya Husain4, Alice Bergevin2, Luu-Ly Pham5, André Paugam2, Luc Paris6, Stéphane Jaurégui6, Vincent Levy6, Coralie Bloch Queyrat7, Vichita Ok8, Marouane Boubaya8, Simon Escoda9, Frederic Sorge10, Alexis Mandelcwajg11, Albert Faye12, Patricia Mariani12, Loïc De Pontual1

1 Jean-Verdier Hospital AP-Hp, Bondy, France, 2 Avicenne, Bobigny, France, 3 Robert Debré, Paris, France, 4 Jean Verdier, Bondy, France, 5 Cochin, Paris, France, 6 La Pitié Salpêtrière, Paris, France, 7 Kremlin-Bicêtre, Le Kremlin-Bicêtre, France, 8 Avicenne Hospital (AP-HP), Bobigny, France, 9 Delafontaine, Saint-Denis, France, 10 Necker, Paris, France, 11 Delafontaine, Saint-Denis, France, 12 Hôpital Robert Debré, Paris, France

**Background:** Data on imported schistosomiasis are scarce especially in children. Screening in at risk population is recommended but the best diagnostic strategy remains uncertain and not evaluated in children. The aim of the study was to estimate the prevalence of imported schistosomiasis in children at risk in Paris and suburbs, and to compare diagnostic methods.

**Materials/methods:** All children at risk of schistosomiasis who consulted in four hospitals in the region of Paris were prospectively included from June 2017 to June 2018. Clinical and biological data were collected anonymously using an online software after parental and child consent. Direct parasitological diagnosis was urinary and feces microscopy and real-time polymerase chain reaction. Serological diagnosis was performed by Western blot, ELISA, indirect hemagglutination, immunochromatography and rapid test diagnosis circulating cathogen antigen. The Western blot assay and the microscopy were the reference methods used to estimate schistosomiasis prevalence. A latent class model has been used to evaluate each test performances.

**Results:** A total of 114 patients were included [sex ratio: 2.9 and mean age: 13.2 years]. Most of the children were newly arrived migrants from Sub-Saharan Africa. The prevalence of schistosomiasis was 26.3%. Half of the positive patients were asymptomatic. The performances of ELISA and Western blot assays were equal [sensitivity: 83%; specificity: 99%] according to statistical analysis using latent class models. Serum immunochromatography had interesting performances [sensitivity: 100%; specificity: 89%].

**Conclusions:** Imported schistosomiasis is a common pathology in at risk children which confirms the need for systematic screening. Clinicians should be aware of such high prevalence in children at risk. And Serum immunochromatography seems to be the most cost/effective as a mass screening method.

**Presenter email address:** claireleblanc@hotmail.fr
Utility of multiplex PCR in the screening, diagnosis and follow-up of malaria in patients attended in a tropical medicine referral centre

Javier Sánchez López1, Sandra Chamorro2, Belén Comeche1, Begoña Monge Maillo2, Francesca Norman1, Jose A. Perez-Molina2, Rogelio López-Vélez2, Jesus Echaon1, Marta Lanza Suárez3, Jose M. Rubio2, Diáne Martin1

1Hospital Ramón y Cajal, Microbiology Department, Madrid, Spain, 2Hospital Ramón y Cajal, Infectious Diseases Department, Madrid, Spain, 3Centro Nacional de Microbiología. Instituto de Salud Carlos III, Malaria and Emerging Protozoa Laboratory, Majadahonda, Spain

Background: Due to the increase in trips to endemic zones and migrations, the diagnosis of malaria is on the rise in our setting. PCR with its high sensitivity (higher than immunochromatography and microscopy) is a widely used diagnostic tool, especially in non-endemic countries.

The objective of this work is to evaluate the usefulness of PCR in the detection of low parasitaemias (observed in semi-immune patients, in patients with incomplete prophylaxis / treatment and in post-treatment control) and in the identification of mixed infections in patients attended in a Tropical Medicine Referral Centre.

Materials/methods: Data from patients attended between July-2017 and July-2019 with a request for malaria PCR were reviewed. Two periods, July-2017 to June-2018 and July-2018 to July-2019 were established for the analysis. Results were evaluated together with those obtained by other techniques such as immunochromatography for antigen detection (SD Bioline®) and microscopic examination of thin and thick blood smears. During this period, two PCRs were used, an in-house Nested-Multiplex-PCR in the National Microbiology Centre and a commercial Multiplex-PCR (Bio-Evolution®) in our hospital.

Results: In the first period, a total of 203 PCRs were performed with a 11.82% positivity rate. 176 were screening PCRs in health exams (86.7%), 22 diagnostic PCRs (10.84%) and 5 follow-up PCRs (2.46%). 9.09% of the screening PCRs were positive (all non-mixed infections). 8 diagnostic PCRs were positive (36.36%), all of them also positive by microscopy.

In the second, a total of 290 PCRs were performed with a 15.52% positivity rate. 203 were screening PCRs (70%), 71 diagnostic PCRs (24.48%) and 16 follow-up PCRs (5.52%). 13.3% of the screening PCRs were positive (5 mixed and 22 non-mixed infections), 16 diagnostic PCRs were positive (22.54%), 9 of them (56.25%) being also positive by microscopy and 14 by antigen detection (87.5%).

In both periods, the agreement was total at species identification level between PCR and microscopy and the follow-up PCRs were always negative.

Conclusions: Malaria PCR has demonstrated its usefulness in post-treatment follow-up and in the detection of submicroscopic mixed and non-mixed malaria infections, with an increase in the positivity rate in the second period.

**Abstract 1465**

**Plasmodium vivax diversity, population structuration and history of origin in Sudan**

Musab M. Ali Albsheer¹², Eyoab Iyasu³, Daniel Kepple⁴, Eugenia Lo⁴, Muntaser Ibrahim¹, Muzamil Mahdi Abdel Hamid⁴

¹University of Khartoum, Institute of Endemic Diseases, Khartoum, Sudan, ²College of Medical laboratory Sciences Sinnar University, Sennar, Sudan, ³Mai Nefhi College of Science, Mai-Nefhi, Eritrea, ⁴UNC Charlotte, Department of Biological Sciences, Charlotte, United States

**Background:** *Plasmodium vivax* was less common in Sub-Saharan African countries due to the lack of Duffy antigen receptor for chemokine's (DARC) on red blood cells. In last year *P. vivax* emerged in Africa. In Sudan in the recent years the parasite is becoming widely distrusted and number of cases showed risen trend and can reach up to 20% of total positive malaria cases. It is not known whether this expansion is due to parasite evolution or population migration to Sudan. In this study use microsatellite DNA loci are polymorphic, neutral and distributed throughout the genome and have been useful for determining haplotypes diversity, population structure, history and ancestral origin of parasite population.

**Materials/methods:** *P. vivax* microsatellite typing was conducted on 113 field isolates collected from two districts in Sudan: 21 from Halfa [2013] and 92 from Khartoum [2013 and 2015]. Microsatellite DNA (MS) loci across the parasite genome were amplified and length variation of labeled PCR products was measured on an ABI PRISM 3730XL DNA Analyzer. MS data diversity, HE, haplotype across loci, Analysis of Molecular Variance (AMOVA) indexes and Principal Coordinate Analysis (PCoA) were generated with Gen AlEX. Linkage disequilibrium (LD) was obtained using LIAN software version 3.5. Geographical clusters and ancestral origin of Sudanese isolates were determined using STRUCTURE 2.2 software.

![Figure 1](image)

**Results:** Microsatellite DNA analysis showed multiple haplotype per locus varying in number from 9 to 22 (mean = 12.57). A total of 49 (62.1%) isolates revealed mixed clonal infection. The virtual heterozygosity (HE) values ranged from 0.71 to 0.88 (mean HE ± SE = 0.8450 ± 0.0460) while multilocus linkage disequilibrium (LD) showed ISA value of 0.1486 (P < 0.001). The AMOVA analysis showed that most of the genetic variation (96%) lies within parasite population. Clustering analysis of Sudanese versus Ethiopian population showed distinct different clusters for each population while clustering analysis of Sudanese versus worldwide isolates showed distinct signature and global pattern.

**Conclusions:** Microsatellite-based analysis of *P. vivax* parasites from Sudan showed extensive genetic diversity and ancestral origin of Sudanese *P. vivax* population represent the worldwide clusters and this seem to suggest a double origin from Africa [or Europe] and Asia.

Abstract 1471

Relationship between intestinal microbiota and infantile colic
Christine Haddad1, Tarek Itani*, Adib Moukarzel2, Dolla Karam Sarkis1

1Saint Joseph University, Faculty of Pharmacy, Microbiology Laboratory, Beirut, Lebanon, 2Hotel Dieu de France Hospital, Saint Joseph University of Beirut, Beirut, Lebanon

Abstract third-party references: Supported by The Lebanese National Council for Scientific Research [CNRS]

Background: Infantile colic is a clinical condition in which a healthy infant suffers from paroxysms of excessive frequent crying that may be accompanied by irritability, flushing of the face, meteorism, drawing-up of the knees and arching the back. Approximately 10-30% of newborns will develop symptoms of infantile colic. In most cases, physicians are unable to determine the cause of the colicky behavior. An aberrant intestinal microbiota has been associated with infantile colic.

Materials/methods: This study compared 42 colicky infants with a control group composed of 46 non-colicky infants, all born at 37-42 weeks of amenorrhea, born by spontaneous delivery [n=33 newborns] or by caesarean section [n=54], exclusively breast fed [n=10] or exclusive formula fed [n=45] or receiving both feeding modes [n=33]. Fecal samples were collected in pediatric private clinics between January 2018 and September 2018 and microbiota was analyzed by 16S rRNA gene quantitative PCR (qPCR).

Results: Age was significantly higher in colicky infants [p=0.014], while other parameters such as, birth rank, number of siblings, birth weight and crowding index did not differ between both groups. Infants were mainly colonized by anaerobes such as Clostridium of cluster I, Bifidobacterium and Bacteroides/Prevotella group and facultative anaerobes such as Lactobacillus and enterobacterales. Differences were found by qPCR between colicky and non-colicky infants [figure 1]. Colicky infants are more colonized by Lactobacillus [p=0.015], enterobacterales [p=0.019], Klebsiella [p=0.002] and Clostridium of cluster XI [p=0.002]; whereas non colicky infants are more colonized by Bifidobacterium [p=0.005] and Clostridium leptum group [p=0.05]. Parents with depression and anxiety had 3 times more probability of having a colicky infant [p=0.03]. This could be bidirectional and can be the consequence of infantile colic and not the cause.

Conclusions: Our findings show that differences exist between the intestinal microbiota of colicky and non-colicky infants. On the long term, characterization of the intestinal microbiota in infants with colic may allow the implementation of prevention strategies to minimize the incidence and reduce crying in infants.

Abstract 1474

Knowledge and awareness of inadvertent use of yellow fever vaccine among renal transplant recipients
Lara Judith Cabral Miranda1, Fabiana Agena2, Ana Marli Sartori2, Luis Sergio Azevedo2, Elias David-Neto2, Ligia Pierrotti2

1University of São Paulo Medical School, São Paulo, Brazil, 2Hospital das Clínicas of the University of São Paulo Medical School, São Paulo, Brazil

Background: Yellow fever (YF) is a vaccine-preventable disease but the live attenuated YF vaccine is contraindicated in immunosuppressed patients due to the increased risk of life-threatening YF vaccine-associated viscerotropic disease in this population. The objective was to (i) estimate the prevalence of renal transplant recipients (RTR) inadvertently vaccinated against YF; (ii) evaluate the evolution of these patients, (iii) awareness of those unvaccinated to not to be vaccinated, and (iv) evaluate the knowledge of those patients about the contraindication of YF vaccine to them.

Materials/methods: A cross-sectional telephone contact study was conducted with 200 RTR, selected from the highest risk of YF vaccine exposure based on state vaccination policies against the YF outbreak in Brazil in 2017/2018. A questionnaire with information on previous use of YF vaccine before or after transplantation was applied. If the patient did not receive the vaccine post-transplantation, he was instructed not to get vaccinated; if the patient was vaccinated post-transplant, a second questionnaire was conducted to check for possible adverse events potentially associated with inadvertent vaccination. For each patient, up to 3 telephone contact attempts were performed. If the patient was not available in either of them, the attempt to contact was terminated.

Results: There were 116 successful telephone contacts (58%). A total of 11 vaccinated patients were identified - 5 in the pre-transplant and 6 in the post-transplant period. All patients received the full dose of the vaccine. Among those vaccinated post-transplant, only 1 reported adverse events (nausea) after receiving the vaccine. 100% of post-transplant vaccinated patients reported not knowing the vaccine contraindication due to their clinical condition. Among the unvaccinated patients, this rate was 12.4%.

Conclusions: There is no specific antiviral treatment for YF, which makes vaccination the main tool for disease prevention and control. However, despite increasing evidence that transplant recipients have tolerated YF vaccine, data are not strong enough to recommend this vaccine in transplant recipients. Thus, counseling RTR on the contraindication of YF vaccine is important to prevent inadvertent use of the vaccine in this population, while additional studies on the real effects of YF vaccination on RTR are pending.

Abstract 1475

An audit of latent tuberculosis management at a tertiary referral centre in Ireland

James O’Connell*1, Joy Oguntuase1, Sam Mcconkey1, Eoghan De Barra1

1Royal College of Surgeons in Ireland, Dublin, Ireland

Abstract third-party references: Royal College of Surgeons in Ireland

Background: Ireland is a low-incidence Tuberculosis (TB) country. Effective treatment of patients at high risk of latent TB infection (LTBI) reactivation is important for low-incidence TB countries because TB due to ongoing transmission is thought to be less frequent compared to high incidence TB countries.

Materials/methods: Our aim was to evaluate the effectiveness of LTBI management at our tertiary referral outpatient department (OPD) using national guidelines as an audit standard. We included all patients seen in the infectious diseases OPD who were referred querying a diagnosis of LTBI. Patients had to have attended the OPD at least once in between the 01/07/2018-31/12/2018. A retrospective review of each patient’s electronic record was performed. Data extraction was performed independently by two auditors. A data collection tool was designed using Microsoft Excel. We calculated the cost of screening and managing the patients referred to our OPD. We calculated the cost considering the cost of investigations, staff and treatment using national costing guidelines.

Results: We identified 25 patients who met our inclusion criteria. 14/25 (64%) were male. The median age at time of first review was 52 years (IQR=24). All patients had a valid indication for LTBI screening, 22/25 (88%) were offered LTBI treatment, 22/22 accepted treatment, 17/21 (81%) completed treatment. The treatment used was isoniazid for a duration of 6 months for 12/21 (57%), isoniazid for 9 months 6/21 (29%) and rifampicin and isoniazid for 3 months in 3/21 (14%). A risk assessment for hepatotoxicity was documented in 20/21 (96%). 1 patient had gastrointestinal upset on rifampicin. There were no other adverse events. There were 109 appointments attended by these 25 patients. The median number of appointments attended was 4 (IQR=2.5). The cost of screening, testing and managing the 25 patients referred was €34,466.62. The lowest cost treatment was Isoniazid plus Rifampicin for 12 weeks. The mean cost per patient seen in the clinic was €1,378.66. The mean cost per LTBI successfully treated was €2,027.45.

Conclusions: Our TB clinic is effective in the assessment and safe management of latent TB in accordance with national guidelines.

**Abstract 1479**

**Risk factors associated with daptomycin non-susceptible Staphylococcus aureus bloodstream infections**

Smitha Gudipati1, Amit Vahia*1, Mary Beth Perri1, Robert Tibbetts1, Marcus Zervos1, Geetha Suleyman1

1Henry Ford Hospital, Detroit, United States

**Background:** Daptomycin (Dap) is being increasingly utilized for treatment of methicillin-resistant Staphylococcus aureus (MRSA) infections. Consequently, daptomycin non-susceptible (DNS) SA strains have recently emerged, leading to limited treatment options for complicated MRSA infections. The purpose of this study was to evaluate risk factors associated with DNS SA bloodstream infections (BSI) at Henry Ford Health System in Michigan.

**Materials/methods:** Retrospective case-control study was conducted from 07/07/2008 through 09/18/2019 to identify clinical characteristics and risk factors in hospitalized patients with DNS SA BSI using electronic medical records (EMR). Patients with daptomycin-susceptible (DS) MRSA were used as controls. Data were analyzed using univariate analysis. Multivariate regression analysis was constructed using the PROC LOGISTIC from the univariate analysis. Statistical analysis was done using SAS 9.4 software.

**Results:** Thirty-one patients with DNS SA BSI were identified during the study period and compared to 59 patients with DS MRSA BSI. There was no significant difference in baseline characteristics and risk factors between the 2 groups with the exception of nursing home (NH) residence (p = 0.01), presence of central venous catheter (CVC) (p = 0.004) foley catheter (p=0.02), diabetes mellitus with end-organ damage (p=0.01), hemodialysis (p=0.04) or MRSA in the past year (p=0.03). Open wounds were more common in the DS MRSA group (p=0.026). Antibiotic use within 90 days was not significant with the exception of vancomycin (p=0.02). There was significant daptomycin MIC change in the DNS SA group (odds ratio (OR)=15.67; 95% confidence interval, 3.19-76.89; p = 0.007). Mean bacteremia duration was 7.4 and 3.8 days (OR=1.2; 95% confidence interval, 1.07–1.35; p = 0.004) for case patients and controls, respectively. Multivariate analysis implicated NH residence (OR=13.03; 95% confidence interval, 2.24–75.57; p = 0.004) and CVC (OR=3.2; 95% confidence interval, 1.05–9.89; p = 0.04) as risk factors for DNS SA infection.

**Conclusions:** DNS SA is an emerging pathogen associated with indwelling devices, poorly controlled diabetes mellitus, hemodialysis, history of MRSA, vancomycin use and longer duration of bacteremia. NH residence and CVC use confer risk for DNS SA acquisition. Further studies to determine strain relatedness and identify resistance genes and virulence factors are warranted.

Abstract 1480

A novel celecoxib-derivative kinase inhibitor, AR-12 (OSU-03012), is active against *Mycobacterium abscessus* complex *in vitro*

Bing Li*, Yuzhen Zou¹, Shaoyan Zhang¹, Haiqing Chu¹

¹Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

**Background:** Therapeutic options for *Mycobacterium abscessus* (*M. abscessus*) infections are extremely limited and therapy outcomes often end in failures. New or repurposed drugs are in urgent need. AR-12 (OSU-03012), a novel celecoxib-derivative kinase inhibitor, has a broad spectrum of antibiotic activity against various pathogens. In this study, we investigated the *in vitro* and intracellular potency of AR-12 against *M. abscessus* complex.

**Materials/methods:** The susceptibility, stability and pre-exposure assays of AR-12 against *M. abscessus* complex were performed. We also conducted the minimum bactericidal concentration (MBC) and Time-kill kinetics assays to evaluate the bactericidal/Static activity of AR-12. Using checkerboard synergy assay, we tested in vitro synergistic interactions between AR-12 and five clinically important antimycobacterial agents against *M. abscessus*. Finally, we evaluated the effect of AR-12 on intracellular survival of *M. abscessus* complex in macrophage infection experiments.

**Results:** AR-12 exhibited high *in vitro* killing activity against *M. abscessus* isolates, with MIC50 of 4 and 8 mg/L for both subspecies. Stability testing showed that at 30°C AR-12 maintained its susceptibility within three days, and gradually lost its antimicrobial activity over time. MBC and Time-kill kinetics assays demonstrated AR-12 dominantly exhibited a bactericidal activity. Pre-exposure to AR-12 didn't induce more pronounced resistance of *M. abscessus* subspecies. There were no antagonistic interactions of AR-12 with clarithromycin, amikacin, imipenem, cefoxitin and tigecycline. Although AR-12 was inferior to amikacin in *in vitro* Time-kill kinetics assays, its intracellular cfu was significantly lower than that of amikacin.

**Conclusions:** AR-12 is active against *M. abscessus* *in vitro*, and showed excellent stability and compatibility with clinically important antimycobacterial agents. AR-12 may be a potential candidate for a novel treatment modality of *M. abscessus* complex infections.

**Abstract 1481**

**Obstructive pyelonephritis associated with ureteral stones: microbiology, treatment and prognosis**

Jeongyeon Won1, Joong Sik Eom1, Yong Kyun Cho1, Young-Rock Jang*1

1Gachon University Gil Medical Center, Incheon, South Korea

**Background:** Acute pyelonephritis (APN) is often associated with obstruction of the upper urinary tract due to presence of urinary stones. It causes severe complications such as bacteraemia, sepsis, and septic shock. This study aimed to investigate the clinical outcomes and antibiotics susceptibilities of causative microorganisms in obstructive pyelonephritis associated with ureteral stones.

**Materials/methods:** This retrospective cohort study included female patients diagnosed with community-acquired APN at a tertiary care hospital from 2008 to 2017. A comparison between cases of APN associated with obstruction of the upper urinary tract due to presence of ureteral stones and cases of APN without complications was performed. Propensity score matching was used to adjust the heterogeneity within each group.

**Results:** Of the 588 female patients with community-acquired APN, 107 patients were diagnosed with obstructive pyelonephritis (OPU) and 481 patients were diagnosed with uncomplicated APN. *Escherichia coli* was the most common pathogen in both groups (61.7% vs. 65.5%, p = 0.502). *Proteus* species were determined as the causative agent in 9.3% OPU cases and 0.4% cases with uncomplicated APN (p < 0.001). After propensity score matching, Enterobacteriaceae strains isolated from OPU cases were more resistant to ciprofloxacin (51.9% vs. 16.0%, p < 0.001). In addition, extended-spectrum β-lactamase (ESBL) was detected in 22.2% and 21.0% of the Enterobacteriaceae strains isolated from OPU cases and cases with uncomplicated APN, respectively (p = 1.000). The overall in-hospital mortality (3.7% vs. 4.9%, p = 0.699) and urinary tract infection recurrence rates within 1 year were similar in OPU and uncomplicated APN groups (16.0% vs. 21.0%, p = 0.545).

**Conclusions:** Antibiotic treatment for patients with obstructive pyelonephritis associated with ureteral stones may be empirically selected in accordance with the treatment protocol for general pyelonephritis. Clinicians should exercise caution before prescribing ciprofloxacin for the treatment of obstructive pyelonephritis associated with ureteral stones.

Abstract 1485

**Comparison of β-lactamase-producing Escherichia coli ST131 C1-M27 and ST131 non-C1-M27 by whole genome analysis using next-generation sequencing in Japan**

Nobuyoshi Noguchi*, Akihiro Nakamura1, Masaru Komatsu1

1Tenri Health Care University, Health Science, Tenri, Japan

**Background:** In recent years, ESBL-producing *Escherichia coli* ST131 has become prevalent worldwide. Recent studies using whole-genome sequencing (WGS) analysis revealed that since the 2000s, clade C has become the most dominant lineage among the ST131 isolates, and one report shows that clade C1-M27 is increasing. In the present study, to pursue factors that spread the epidemic strains globally, we conducted a genome analysis of the C1-M27 epidemic strain and the non-epidemic strain non-C1-M27 using WGS and attempted to detect the mutations.

**Materials/methods:** We used 99 strains isolated from West Japan. The clades determined using PCR were A (n = 7), B (n = 6), C1 (n = 18), C1-M27 (n = 34), and C2 (n = 34). We used SnpEff, which classifies proteins by the level of gene mutation, to extract specific proteins. We extracted those proteins that were classified as “HIGH”. We analyzed the protein mutation sites, functions, and protein interactions identified *in silico* using SeaView, S-VAR, and STRING.

**Results:** The proteins extracted were AMP nucleosidase and GABA permease. As a result, the 68th proline of the non-C1-M27 strain was a common amino acid in AMP nucleosidase, but it was mutated to serine in the C1-M27 strain. GABA permease, the 85th alanine, was mutated to threonine. AMP nucleosidase was predicted to have no effect on protein function by point mutation, whereas GABA permease was predicted to effect protein function. Although GABA permease is possessed by all *E. coli*, a p.Ala68Thr mutation was observed in all clade C1-M27 and C1 6 strains, whereas it was not observed in the other clades. We used STRING to analyze the protein-protein interactions of GABA permease. The results suggested that GABA permease is indirectly associated with acid-resistance systems.

**Conclusions:** GABA permease is a high-affinity uptake system for GABA. The prediction of protein function from point mutations suggests that the point mutation revealed here affects the function of GABA permease, and protein-protein interaction prediction suggested a relation with acid-resistance systems. We surmise that the specific point mutation extracted in this research may be related to the worldwide pandemic.

Abstract 1486

**Colistin resistance increases fatality in bloodstream infections due to carbapenem-resistant Klebsiella pneumoniae**

Ilker Inanc Balkan*1, Mustafa Alkan2, Aygun Gokhan3, Mert Ahmet Kuskucu1, Handan Ankarali4, Alper Karagoz2, Sümeyye Şen5, Hatice Yaşar1, Mehtap Biçer1, Ritvan Kara Ali1, Bilgül Mete1, Nese Saltoglu1, Fehmi Tabak1

1İstanbul Üniversitesi-Cerrahpaşa Cerrahpaşa Tıp Fakültesi, Department of Infectious Diseases and Clinical Microbiology, istanbul, Turkey, 2İstanbul Üniversitesi-Cerrahpaşa Cerrahpaşa Tıp Fakültesi, Department of Infectious Diseases, istanbul, Turkey, 3İstanbul Üniversitesi-Cerrahpaşa Cerrahpaşa Tıp Fakültesi, Department of Medical Microbiology, istanbul, Turkey, 4Medeniyet Üniversitesi Göztepe Eğitim Ve Araştırma Hastanesi, Department of Biostatistics, İstanbul, Turkey, 5Usak University Medical School, Department of Medical Microbiology, Uşak, Turkey, 6İstanbul Üniversitesi-Cerrahpaşa Cerrahpaşa Tıp Fakültesi, Department of Medical Microbiology, istanbul, Turkey

**Background:** Mortality due to K. pneumoniae bacteremia is on rise. Defining risk factors for colistin resistance and mortality is of paramount importance particularly in regions with high rates of carbapenem resistance.

**Materials/methods:** Patients diagnosed with "carbapenem-resistant K. pneumoniae (CRKp) bacteremia were divided into two groups as "colistin susceptible (ColS)" and "colistin resistant (ColR)". Retrospective casecontrol study was conducted to compare characteristics and outcomes. Multiple logistic regression model was used to define independent risk factors for acquired colistin resistance and mortality.

**Results:** A total of 82 patients (39 ColS and 43 ColR) were included. Mean age was 61.5 years and 50 (61%) were male. Colistin resistance was significantly increased with age (p = 0.074) and duration of hospitalization (p = 0.007). Prior colistin use was significantly higher (p = 0.007) in ColR group. Mortality rates at 14-day, 28-day and final follow up were 55%, 66% and 70% respectively. Colistin resistance significantly increased 28-day (p=0.009) and in-hospital (p = 0.040) mortality. PFGE analysis revealed an outbreak with K. pneumoniae ST78 and ST45 clones. OXA-48-like carbapenemase was positive in 60% of the strains and related with increased mortality. No significant difference was found between the outcomes of treatment modalities (monotherapy, double-triplequadruple combined therapy) in terms of 14th-day, 28th-day and total survival.

**Conclusions:** Colistin resistance increases 28-day and in-hospital mortality in CRKp bacteremia. Existing antibacterial combinations have no apparent superiority to each other. Clinical or microbiological response to treatment within seven days, along with prompt source control, favors survival.

Abstract 1488

Geographical clustering of hantavirus isolates from Apodemus agrarius identified in the Republic of Korea indicates the emergence of a new hantavirus genotype

Dong-Min Kim*1, Jalal Sehrish2, Choon-Mee Kim2, Seo Jun-Won1

1Chosun University Hospital, Gwangju, South Korea, 2Chosun University, Gwangju, South Korea

Background: Several studies on hantavirus evolution have shown that genetic reassortment plays an important role in the evolution and epidemiology of this disease. Hantaan virus, a prototype hantavirus carried by Apodemus agrarius, is found throughout China, Russia, and Korea. The aim of this study was to investigate the distribution of hantaviruses in rodents in the Republic of Korea (ROK) and perform phylogenetic comparisons using the geographical distribution of their natural reservoir rodent hosts as a point of reference.

Materials/methods: To understand the genetic epidemiology of human pathogenic hantaviruses, we examined viral isolates from rodent reservoirs, captured at three different locations in the ROK, between 2017 and 2018. Each sample collected was subjected to reverse-transcription nested polymerase chain reaction (RT-N-PCR) targeting the L- and S-segments of the hantavirus genome. Positive isolates from Gwangju, Boseong-gun (Jeollanam-do Province), and Jeju Island were confirmed as Hantaan virus using DNA sequencing. Phylogenetic analysis showed that all isolates grouped together as Hantaan virus. The isolates from Jeju, Boseong-gun, and Gwangju tended to cluster together, but with each region forming a distinct cluster. In addition, these three clusters were distinct from other Hantaan isolates reported in previous studies from Korea and its neighboring countries China and Russia. This suggests the emergence of a new hantavirus genotype in southwestern ROK.

Conclusions: Hantaan viruses exhibit a considerable degree of geographical clustering, and there may be a novel Hantaan genotype in southwestern ROK. This study helps expand our knowledge regarding the emergence of new hantavirus strains and their degree of geographical variation.

Abstract 1495

**Swiss Pathogen Surveillance Platform: development of a surveillance database for molecular epidemiology of multidrug-resistant pathogens**

Aitana Lebrand1, Claire Bertelli2, Dominique S. Blanc1, Jerome Dauvillier1, Anne Gleizes1, Gilbert Greub2, Valerie Hinard1, Emma Hodcroft4, Vladimir Lazarevic5, Sebastien Moretti1, Richard Neher4, Vincent Perreten7, Tim Roloff7, Jacques Schrenzel8, Helena Seth-Smith1, Dillenn Terumalai1, Adrian Egli*7

1Swiss Institute of Bioinformatics, Lausanne, Switzerland, 2University Hospital Lausanne, Institute of Microbiology, Lausanne, Switzerland, 3University Hospital Lausanne, Service of Hospital Preventive Medicine, Lausanne, Switzerland, 4University of Basel, Biozentrum, Basel, Switzerland, 5University Hospital Geneva, Genomic Research Laboratory, Division of Infectious Diseases, Geneva, Switzerland, 6University of Bern, Institute of Veterinary Bacteriology, Vetsuisse Faculty, Bern, Switzerland, 7University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 8University Hospital Geneva, Bacteriology Laboratory, Division of Laboratory Medicine, Geneva, Switzerland

**Background:** Transmission of virulent and resistant pathogens can be described using molecular epidemiological methods. In particular, whole genome sequencing (WGS) allows high resolution typing. As the interactions between compartments (e.g. human, animal, food, and environment) are complex, molecular typing data alone often does not explain the route of transmission. Interoperable processes, standardized epidemiological vocabulary and metadata are key requirements for unmasking this complexity.

**Materials/methods:** Within a NRP72-funded project, we are developing and implementing a molecular surveillance platform for Switzerland allowing the integration of WGS typing and epidemiological data at high spatiotemporal resolution. Within the consortium framework (i) requirements are defined regarding the WGS workflows, data analysis and interpretation and (ii) a prototype for a web-based surveillance platform is established and (iii) the platform is tested using a set of methicillin-resistant *Staphylococcus aureus* (MRSA) isolates from all involved centers.

**Results:** The required functional specifications of the platform were agreed: minimal datasets on epidemiological data and visualization aspects of spatiotemporal information. Legal and governance frameworks were evaluated. Bioinformatics functionalities of the platform were determined and implemented based on open source software. These include whole genome typing methods (e.g. cgMLST, SNP-tree) and more classical methods such as MLST typing, that allow comparison to older datasets. A first prototype of the surveillance platform is hosted at a BioMedIT node of the Swiss Institute of Bioinformatics (SIB) to ensure secure data access and computational power. Data is managed and searchable through a user dashboard including visualization powered by an integrated version of Nextstrain. A current set of >200 MRSA isolates (genomic and metadata) will expand to >1000 isolates over the next few months.

**Conclusions:** Transferring powerful backend bioinformatic tools to an easily accessible and comprehensive frontend solution is critical for use by people with various knowledge backgrounds. The surveillance platform has been designed to be highly interactive and intuitive. The legal framework had to be carefully evaluated for epidemiological/research tools, as different laws are applicable. With this platform, we are increasing public health networking within Switzerland and enabling fast detection and real-time tracking of outbreaks on various scales. Expansion to other pathogens is planned.

Abstract 1499

Antibiotic resistance of 34,539 Campylobacter spp. isolated from human sources: National Surveillance Data of Switzerland from 2007 to 2018

Adrian Egli*, Deborah R. Vogt2, Peter Brodmann3, Helena Seth-Smith1, Josiane Reist1, Andreas Kronenberg4, Roger Stephan5
1University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 2University Hospital Basel, Clinical Trial Unit, Department of Clinical Research, Basel, Switzerland, 3Cantonal Laboratory of Basel-Landschaft, Liestal, Switzerland, 4University of Bern, Institute for Infectious Diseases, ANRESIS, Bern, Switzerland, 5University of Zurich, Institute for Food Safety and Hygiene, Zürich, Switzerland

Background: In Switzerland, acute gastroenteritis is commonly caused by bacteria, mainly, Campylobacter spp., with about 7,500 registered episodes annually, is of importance due to substantial healthcare costs. In recent years, more antimicrobial resistance (AMR) has been reported. However, little is known about temporal trends and geographical patterns of AMR within Switzerland.

Materials/methods: We used prospectively collected data from the ANRESIS antibiotic surveillance framework in Switzerland from 2007 to 2018. The network covers about two thirds of reported laboratory data. We conducted pre-defined, descriptive and exploratory statistical analyses. No a priori hypothesis was tested. For each year and geographic region the frequency of isolates resistant to specific antibiotics was calculated. Finally, we examined the association of AMR with demographic and epidemiological variables and invasiveness.

Results: The full dataset contained 34,539 human isolates of 11 Campylobacter spp. plus isolates identified to genus level only. The main analysis focused on C. jejuni (n=26,661) and C. coli (n=2,235) representing 99% of all isolates characterized on species level. A subset of 329 (1.1%) isolates was invasive. Per year, 2,273 to 3,308 isolates were collected for antibiotic resistance testing. Over time, we observed an increasing rate of resistance to ciprofloxacin and tetracycline in both species, to doxycycline in C. jejuni and to clarithromycin in C. coli. With exceptions, most geographic patterns of AMR were homogeneous. Noteworthy, in the South of Switzerland, as compared to the rest of Switzerland, a relatively higher rate of resistance to erythromycin was observed in C. coli. Further, in central-East and central-West Switzerland, as compared to the rest of Switzerland, a relatively lower rate of resistance to tetracycline was observed in both species. Our data provide no evidence for an association of AMR with demographic or epidemiological variables or in invasiveness.

Conclusions: We observed temporal and geographical differences in AMR patterns. As campylobacteriosis is epidemiologically often linked to handling and consumption of raw or undercooked chicken meat, travels abroad and no human-to-human transmission is known, these differences in AMR may be linked to practise changes outside of human medicine. Follow-up studies should include isolates from food samples.

**Abstract 1501**

**HIV is a risk factor for death among persons with candidaemia in South Africa**

Nelesh P. Govender*1,2, Jim Todd3, Cheryl Cohen*4

1University of the Witwatersrand, Johannesburg, South Africa, 2National Institute for Communicable Diseases, Johannesburg, South Africa, 3London School of Hygiene & Tropical Medicine, London, United Kingdom, 4National Institute for Communicable Diseases, Johannesburg, South Africa

**Background:** Mortality among critically-ill persons with candidaemia is high. We aimed to determine the effect of HIV on 30-day mortality risk among persons with candidaemia in South Africa.

**Materials/methods:** We included persons aged ≥18 months with an episode of culture-confirmed candidaemia at 29 sentinel hospitals, 1 January 2012 - 31 December 2017. Surveillance officers collected clinical data by interview/chart review. Candida isolates were identified at a reference laboratory. We used random-effects logistic regression to adjust for sentinel hospital and participant-level confounders, treating follow-up as a fixed length of time (30 days). We plotted Kaplan-Meier survival curves by HIV status.

**Results:** Of 2563 cases, clinical data were available for 1846 (72%). Of these, we retained 1040 cases with both HIV status and outcome data (56%). Of 1040 cases, 458 (44%) were HIV-seropositive. Among 404 with available data, 301 (75%) were antiretroviral treatment-experienced. Among 267 with a recorded CD4 count close to candidaemia diagnosis, the median CD4 count was 133 cells/µl [108, 42309]; 63% [166/267] had a CD4 count <200 cells/µl. The overall case-fatality ratio was 458/1040 (44%). The median age of 1037 participants was 37 years [IQR, 23-52 years] and 542/1040 [52%] were male. Overall, 50% [514/1023] were admitted to an intensive care unit [ICU] at time of diagnosis. The 30-day case-fatality was 37% [230/614] and 54% [228/426] for HIV-seronegative and -seropositive cases respectively (crude odds ratio [OR] 1.92, 95% compatibility interval [CI] 1.50-2.47, p<0.001). After adjusting for sentinel hospital, age, sex, year of diagnosis, ICU admission, receipt of systemic antifungal treatment and Candida species (n=907), the 30-day mortality was 1.89 times higher (95%CI 1.38-2.60; p<0.001) among HIV-seropositive vs. -seronegative participants. The stratum-specific mortality OR was higher among HIV-seropositive individuals not admitted to ICU [OR 2.27, 95%CI 1.47-3.52; p<0.001] than those who were [OR 1.56, 95%CI 1.00-2.43, p=0.05]. HIV-seropositive individuals had a 60% reduced adjusted odds of ICU admission than those HIV-seronegative [OR 0.40, 95%CI 0.25-0.64, p<0.001].

**Conclusions:** HIV-seropositive individuals had a two-fold increased adjusted risk of all-cause mortality within 30 days of candidaemia diagnosis, compared to their HIV-seronegative counterparts. HIV-seropositive individuals with candidaemia should be considered for ICU admission.

**Risk of death by HIV status**

Abstract 1502

**Microbiological validation of the BIOFIRE FILMARRAY Pneumonia Panel plus: a single-centre experience**

Vladimira Hinic, Beatrice Nickel, Veronika Bättig, Nina Khanna, Daiana Stolz, Michael Tamm, Annette Blaich, Daniel Goldenberger, Adrian Egli

1University Hospital Basel, Division of Clinical Bacteriology and Mycology, Basel, Switzerland, 2University of Basel, Swiss Tropical and Public Health Institute, Basel, Switzerland, 3University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 4University Hospital Basel, Division of Pneumology, Basel, Switzerland

**Background:** Culture-based identification and AMR-testing requires up to 72h. In addition, respiratory samples may have low sensitivities due to (i) small sample amounts being cultured and (ii) background (over)growth of oropharyngeal flora. Broad-panel PCR assays may overcome these gaps. We aim to evaluate the microbiological performance of the Biofire® FilmArray® Pneumonia Panel plus (BFPP) compared to culture-based techniques.

**Materials/methods:** We used consecutive collected bronchoalveolar lavage (BAL) and tracheal secretion (TS) samples from February-August 2019. Detection rates of the BFPP (200uL per sample) was compared to culture (BAL: 1uL and TS: approx. 50uL; internal gold-standard) on 5% sheep blood agar, CNA, Haemophilus, and MacConkey plates. The BFPP covered 15 bacterial (semi-quantitative), 3 atypical bacterial and 9 viral and 7 AMR targets (qualitative) and was performed according to company instructions.

**Results:** We compared 690 respiratory samples, corresponding to 18,630 BFPP targets. BFPP detected 517 targets (347 bacteria, 2 atypical bacteria, and 168 viruses). In comparison to culture, the BDPP found significantly more bacterial targets (+114%, 347/690 vs. 162/690). Some species were more frequently detected with BFPP: *Haemophilus influenzae*, *Moraxella catarrhalis*, *Streptococcus agalactiae*, *Streptococcus pyogenes*, and *Staphylococcus aureus* with additional 375%, 533%, 100%, 250% and 89%, respectively. These were often detected at low quantities in PCR (10e4 to 10e5 CFUs/mL). Samples with higher background flora (>50,000 CFUs/mL) showed a higher mismatch between the culture and BFPP results. Overall specificity and sensitivity were 98.1% and 89.9%, respectively. We detected only 5 AMR genes (3x CTX-M/2x mecA), of which 3 were confirmed by culture (2x CTX-M/1x mecA).

**Conclusions:** BFPP allows a rapid assessment of most common pneumonia pathogens and AMR genes. The difference in detection rates is most likely due to substantial differences in the culture workup or small quantities of target bacteria overgrown by oropharyngeal flora. The question remains if *S. aureus* and *H. influenzae* are pathogens or bystanders at low concentrations or presence of substantial background flora. Careful evaluation of clinical evidence for infection should be considered to avoid overtreatment of patients. The BFPP may benefit from a background flora target.

**Presenter email address:** adrian.egli@usb.ch
Abstract 1503

**Efficacy of pulsed xenon ultraviolet disinfection of multidrug-resistant bacteria and *Clostridioides difficile* spores**

Hiroki Kitagawa* 1,2; Kayoko Tadera1,3; Toshinori Hara1,3; Seiya Kashiyama1,3; Hiroki Ohge1,4

1Hiroshima University, Project Research Center for Nosocomial Infectious Diseases, Hiroshima, Japan, 2Hiroshima University, Graduate School of Biomedical and Health Sciences, Department of Surgery, Hiroshima, Japan, 3Hiroshima University Hospital, Department of Clinical Support, Section of Clinical Laboratory, Hiroshima, Japan, 4Hiroshima University Hospital, Department of Infectious Diseases, Hiroshima, Japan

**Abstract third-party references:** This study was funded in part by a grant from Terumo Co., Ltd., Tokyo, Japan. Terumo Co., Ltd.

**Background:** Contamination of healthcare environments by multidrug-resistant organisms (MDRO) and *Clostridioides difficile* is a risk for healthcare-associated infections. The efficacy of pulsed xenon ultraviolet (PX-UV) disinfection in healthcare environments has mainly been studied in the United States. However, there are few reports about PX-UV disinfection in Japan. The aim of this study was to investigate in vitro the efficacy of PX-UV disinfection of MDRO and *C. difficile* spores commonly isolated in Japanese hospitals.

**Materials/methods:** We investigated reductions in microbial counts after exposure to PX-UV of the following clinically-isolated organisms on seeding agar plates: methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant *Enterococcus faecium*, carbapenemase-producing *Klebsiella pneumoniae*, extended spectrum β-lactamase-producing *Escherichia coli*, multidrug resistant *Acinetobacter baumannii*, and *C. difficile* spores. We also visually assessed the attenuation of sterilization by shielding of MRSA and carbapenemase-producing *K. pneumoniae* from PX-UV exposure. The left half of the plate was exposed to pulsed xenon ultraviolet light and the right half the plate was covered with aluminum foil during the exposure.

**Results:** PX-UV disinfection for 5 min induced >5-log growth inhibition of all the MDRO. PX-UV disinfection for 15 min induced >3-log growth inhibition of *C. difficile* spores. Where a plate was shielded from PX-UV exposure the bacteria showed confluent growth (Figure, the right side), but no colonies were observed on unshielded [exposed] parts of the plates [Figure, the left side].

**Conclusions:** PX-UV is a powerful disinfectant of clinical MDRO. *C. difficile* spores were more resistant to PX-UV disinfection than vegetative bacteria. Further evaluation for the efficacy of PX-UV disinfection on reducing the contamination of real-world surface and the incidence of healthcare-associated infection are needed.

Abstract 1507

**Personalised production and administration of bacteriophages: lesson learned from a unique European academic collaboration to treat a patient with pandrug-resistant *Pseudomonas aeruginosa* spinal infection**

Tristan Ferry*1,2, Jean-Paul Pirnay3, Claude-Alexandre Gustave1,2, Camille Kolenda1,2, Maia Merabishvili3, Aurélie Marchet4, Cédric Barrey1, Thomas Perpoint1, Frédéric Laurent1, Frédéric Laurent1, Gregory Resch4

1Hospices Civils De Lyon - Hcl, Lyon, France, 2Claude Bernard University Lyon 1, Centre International de Recherche en Infectiologie, Villeurbanne, France, 3Queen Astrid Military Hospital, Bruxelles, Belgium, 4University of Lausanne, Lausanne, Switzerland

**Background:** As lytic phages act synergistically with antibiotics on biofilms, they could be a potent adjunct treatment for bone and joint infections (BJI). Currently, phage Active Pharmaceutical Ingredients (APIs) production follows minimal requirements of quality and safety, which guarantee adequate composition and acceptable levels of residual contaminants.

**Materials/methods:** A 74-year-old man experienced *P. aeruginosa* bacteremia in January 2018. In summer 2018, spondylo-discitis with spinal abscess due to pandrug-resistant *P. aeruginosa* was diagnosed [panel A]. Industrial phages under development were inactive, but 3 active phages (Phi4029, Phi4032 and Phi4034) were identified by the laboratory of G. Resch [panel B, C]. Dedicated production of the APIs, in compliance with a monograph describing the production process and Quality Control (QC) system for incorporation in magistral preparations, was done at Queen Astrid military hospital in Brussels under the supervision of the French National authority (ANSM) in collaboration with the hospital pharmacist.

**Results:** The patient was treated by open debridement and one local application of the phage cocktail after magistral preparation [dilution in 7 mL; final titer of 10^7 PFU/mL]. Cefiderocol was started after the surgery for a duration of 6 weeks. One month after, a new surgery, using intersomatic cages for stabilization, was performed. The patient had no systemic (no fever, CRP 10 mg/L) nor clinical signs of infection. The same phage cocktail with same dilution and titer was locally used. Cefiderocol was pursued pending the culture results. Unfortunately, *P. aeruginosa* still grew in culture from bone biopsies with small colony variant phenotype [panel D], but remained susceptible to the phage cocktail and cefiderocol. Colistin was added and phages were administered intravenously in 3-hours infusions [30 mL, phage titers 10^8 PFU/mL] every day during 28 days. Antibiotics (cefiderocol and colistin) were stopped at 3 months. The outcome was favorable after 6 months, and the patient is walking without pain [video available].

**Conclusions:** Personalized phage therapy is a potential adjunct treatment for patients with complex BJI due to pandrug-resistant bacteria. In addition to industrial phages under development, academic collaborative research is crucial to develop personalized phage therapiu.

Abstract 1508

**Serum active Granzyme A: a new biomarker that contributes to the pathogenesis of peritoneal sepsis**

Marcela Garzón*, José Luis Sierra Monzón†, Laura Comas‡, Iratxe Uranga Murillo§, Elena Morte Romea¶, Sonia Algarate†, Tatiana Khalilulina Ushakova†, Laura Comas‡, Iratxe Uranga Murillo§, Pilar Luque Gómez†, José Ramón Paño Pardo†, Eva María Gálvez‡, Maykel Arias§, Julián Pardo Jimeno†, Pilar Luque Gómez‡, José Ramón Paño Pardo†, Eva María Gálvez‡, Maykel Arias§, Julián Pardo Jimeno†

1Universidad de Zaragoza, Fundación Instituto de Investigación Sanitaria Aragón (IIS Aragón), Biomedical Research Centre of Aragón (CIBA), Zaragoza, Spain, 2Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain, 3Instituto de Carboquímica ICB-CSIC, Zaragoza, Spain, 4University of Zaragoza, Department Biochemistry and Molecular and Cell Biology and Dept. Microbiology, Preventive Medicine and Public Health, Zaragoza, Spain, 5Nanoscience Institute of Aragon (INA), Zaragoza, Spain

**Background:** Peritonitis is one of the most common leading cause of sepsis. Recent evidence suggests that Granzyme A (GzmA), a serine protease mainly expressed in NK cells and T cells, could act as a proinflammatory mediator and could play an important role in the pathogenesis of sepsis. This work aims to analyze the role of serum GzmA as a biomarker and therapeutic target in peritoneal sepsis.

**Materials/methods:** Concentration and enzyme activity of soluble GzmA were sequentially analyzed in serum from healthy donors and patients with peritonitis and were correlated with the Sequential Organ Failure Assessment (SOFA) score. Peritonitis was induced in C57Bl/6 (Wt) and GzmA-KO mice by cecal ligation and puncture (CLP). Mice were treated intraperitoneally with antibiotics and with serpinb6b, a specific GzmA inhibitor, for 5 days. Mouse survival was monitored during 14 days and the levels of serum proinflammatory cytokines and bacterial load in blood and spleen were analyzed at 6 and 24h from CLP.

**Results:** We have found high levels of GzmA in serum of patient with peritonitis. Most importantly, we observed that GzmA activity in serum correlates with SOFA score, suggesting that active GzmA could play an important role in sepsis development in peritonitis patients and could be a new biomarker of sepsis severity. In order to analyze the therapeutic potential of soluble GzmA in peritoneal sepsis, we used the CLP mouse model. After peritonitis induction, GzmA-KO mice exhibit increased survival compared with Wt mice, which correlated with reduced levels of proinflammatory cytokines in serum. The analysis of bacterial load in blood and spleen showed no differences between Wt and GzmA-KO mice suggesting that GzmA does not play an important role in bacterial control. Treatment with serpinb6b reduced mortality, which correlated with reduced cytokine serum levels in serum, confirming the therapeutical potential of gzmA to treat peritoneal sepsis.

**Conclusions:** Our findings confirm that soluble GzmA plays an important role in the pathogenesis of sepsis and could be a new therapeutic target and a biomarker for the treatment of peritoneal sepsis.

Abstract 1513

First case of *Gemmiger formicilis* bacteraemia identified using partial 16S rRNA gene sequencing
Shireen Yan Ling Tan*, Ian Liang En Wee², Yanhong Delphine Cao¹, Nurdyana Abdul Rahman¹, Ai Ling Tan¹,³, Kwan Ki Karrie Ko¹,³,⁴

¹Singapore General Hospital, Department of Microbiology, Singapore, Singapore, ³Singapore General Hospital, Department of Infectious Diseases, Singapore, Singapore, ⁴Duke-NUS Medical School, Singapore, Singapore, ⁵Singapore General Hospital, Department of Molecular Pathology, Singapore, Singapore

Background: *Gemmiger formicilis* is a Gram negative, strictly anaerobic, pleomorphic, budding-like organism previously isolated from human faeces and from chicken caecal contents. *G. formicilis* has not previously been reported as causing human infection. We report here the first case of *G. formicilis* bacteraemia.

Case report: A previously healthy 20 year old man was admitted with diarrhoea, abdominal pain, fever, chills, and rigors. On admission, he was febrile, with temperature 39.4°C, and inflammatory markers were raised. Blood cultures were taken. The anaerobic blood culture bottle taken on admission flagged positive after 42 hours of incubation. Gram stain of the positive blood culture broth showed microorganisms with an unusual morphology. The microorganisms appeared to be Gram variable cocci of varying sizes arranged in chains. The positive blood culture broth was sub-cultured onto solid media as per our laboratory’s routine processes, including incubating in anaerobic conditions. No growth was detected on sub-culture despite incubation for up to two weeks. A repeat sub-culture was also negative.

We extracted DNA directly from the positive blood culture bottle broth, and partial 16S rRNA gene sequencing identified the microorganisms as *G. formicilis*. This identity was in keeping with the distinctive Gram stain appearance, and with it being a fastidious, strictly anaerobic microorganism which may require stringent growth conditions. The patient had been treated with oral ciprofloxacin prior to admission, and was subsequently treated with intravenous ceftriaxone and oral moxifloxacin. He recovered well from this acute episode and was discharged on hospital day 11.

Conclusions: *G. formicilis* has not previously been reported as causing human infection. This might be because it is rarely pathogenic, but might also be because of difficulties with microbial growth and identification due to its fastidious, strictly anaerobic nature. This first case of *G. formicilis* bacteraemia highlights that this species may be able to cause clinically significant infection. Furthermore, direct partial 16S rRNA gene sequencing was necessary to identify the microorganisms in the blood culture broth. This case highlights the increasing need to integrate molecular diagnostics into routine clinical diagnostic bacteriology.

Five versus seven days nitrofurantoin for urinary tract infections in women with diabetes: a non-inferiority study

Kelly Hendriks-Spoor*1,2, Thijs Ten Doesschate2, Floor Wille2, Theo Verheij2, Marc J.M. Bonten2, Cornelis H. Van Werkhoven2

1Tergooi Hospital, Medical Microbiology, Hilversum, Netherlands, 2Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** In the Netherlands, the first choice therapy for cystitis in women with Diabetes Mellitus (DM) is seven days of nitrofurantoin. However, general practitioners often treat these patients as an uncomplicated cystitis with five days nitrofurantoin. The comparative effectiveness of either policy is unknown. The aim of this study was to compare the effectiveness between five and seven days of treatment.

**Materials/methods:** Data from the Julius General Practitioners’ Network, consisting of 75 GP practices, was retrospectively collected between January 2013 and June 2019. Inclusion criteria were nitrofurantoin prescription of five or seven days for cystitis, female sex, age > 12 and DM based on International Classification of Primary Care code T90. Patients with other reasons than DM for a seven day prescription were excluded, e.g. male gender, pregnancy, urologic abnormalities and immunosuppression. The primary endpoint early treatment failure was defined as a new prescription for a UTI within 28 days. The secondary endpoint was overall treatment failure within 90 days. Crude risk differences were estimated using linear regression. The adjusted risk differences were calculated by inverse probability weighting to account for confounders. The non-inferiority margin for the primary outcome was set at 2% absolute risk difference.

**Results:** We included 8,255 patients of whom 3,893 were treated for five days and 4,362 for seven days. Patients treated for seven days were overall older, used more co-medication and had more comorbidities. Treatment failure within 28 days occurred in 734 patients (18.9%) with five day treatment and 815 (18.7%) with seven day treatment (crude risk difference: 0.1% [95% CI -1.5 to 1.9]; adjusted risk-difference: -0.1% [95% CI -1.8 to 1.6]). Treatment failure within 90 days was 1239 (31.8%) and 1344 (30.8%) for five and seven day treatment, respectively (crude risk difference: 0.2% [95% CI -1.5 to 1.9]; adjusted risk-difference: 1.1% [95% CI -0.9 to 3.2]).

**Conclusions:** Five days treatment is non-inferior to seven days treatment with nitrofurantoin for early treatment failure in diabetic women with cystitis. Non-inferiority could not be demonstrated for overall treatment failure within 90 days, neither was there a statistically significant difference.

Abstract 1518

Clinical and microbiological characteristics in men with non-obstructive acute pyelonephritis

Jeong Woo Lee*1, Min Gu Park2, Se Yun Kwon3, Hoon Choi4, Kwang Taek Kim5, Sangrak Bae6, Sung Yong Cho7

1Dongguk University Ilsan Hospital, Goyang, South Korea, 2Seoul Paik Hospital, Seoul, South Korea, 3Dongguk University Gyeongju Hospital, Gyeongju, South Korea, 4Korea University Ansan Hospital, Ansan, South Korea, 5Gil Medical Center, Incheon, South Korea, 6Uijeongbu St. Mary’s Hospital, Uijeongbu, South Korea, 7Ilsan Paik Hospital, Goyang, South Korea

Background: Acute pyelonephritis (APN) is the most common cause of bacteremia in hospitalized patients. The objectives of this study were to investigate the differences in the clinical and microbiological features of hospitalized men with community-onset (CO) and healthcare-associated (HA) non-obstructive APN, as well as predictive factors associated with bacteremia.

Materials/methods: Five urological centers participated in this study. Men with non-obstructive APN as a discharge diagnosis were identified from January 2011 to December 2017 using an electronic medical records system. We compared the clinical and microbiological data in men with CO- and HA-APN.

Results: Of the 245 men with non-obstructive APN, 175 had CO- and 70 had HA-APN. The HA group was significantly older, had longer hospital stay and had a higher frequency of underlying disease, bacteremia, and ICU care than the CO group. Bacteria were identified in 154 of 245 patients (62.9%), and the most commonly cultured included Escherichia coli (41.7% and 50.0% in the CO and HA groups, respectively). The susceptibility of the cultured bacteria to fluoroquinolone was 68.7% in the CO group and 45.3% in the HA group (p=0.005). The proportion of ESBL-producing bacteria was 22.7% and 53.5% in the CO and HA groups, respectively (p<0.001). In the CO and HA groups, the sensitivity of piperacillin/tazobactam was 94.9% and 90.0%, respectively (p=0.297). Amikacin showed more than 95% sensitivity to bacteria isolated from both groups (p=0.555). The multivariate analysis revealed that age ≥65 years (p=0.043) and chronic liver disease (p=0.029) were independent predictive factors for bacteremia.

Conclusions: The HA group showed a higher incidence of antibiotic resistance and bacteremia than the CO group. However, the proportion of resistance for fluoroquinolone and ESBL-producing bacteria was high in both groups. Piperacillin/tazobactam and amikacin may be a feasible option as an empirical antibiotics for men with non-obstructive APN regardless of disease severity.

Abstract 1519

Evaluation of the QIAstat-Dx Gastro-intestinal Panel at the University Hospital of Liege (Belgium)

Justine Schmitt, Coumba Diop, Lauranne Schoneveld, Cécile Meex, Pierrette Melin, Marie-Pierre Hayette

Chu De Liège, Liège, Belgium

Background: The QIAstat-Dx Gastro-intestinal panel (QIAstat-Dx GI panel, Qiagen) detects the 24 most common gastro-intestinal pathogens by using qualitative real-time-PCR in stool samples. The system delivers results within 70 minutes with Ct values and amplification curves. The purpose of this study was to evaluate the QIAstat-Dx GI panel at the University Hospital of Liege (CHULiège) in comparison with the results obtained with the current techniques available in the laboratory.

Materials/methods: From 06/23/19 to 07/04/19, all stools addressed to the Microbiology lab for bacteriological, parasitological or virological analysis were tested with the QIAstat-Dx GI panel and the current diagnostic methods. These methods included bacteriological culture, Clostridium difficile antigenic tests (GDH and toxins A/B, Meridian), microscopy and rapid tests (Alere) for parasites.

Results: A total of 180 samples collected from 126 patients were included. Out of these samples, 51 (28%) were tested positive with the QIAstat-Dx panel with 61 pathogens detected in total. Co-infections were identified in 8 patients (4.5%). Four Campylobacter detected by PCR were not confirmed by culture nor by antigenic tests. Besides, 4 out of 13 C. difficile toxin-positive results detected by the GI panel were not confirmed by antigenic test or by culture. The results are summarized in the table 1.

Table 1. Summary of the results.

</tbody>
</table>

*not detectable by current methods

Conclusions: The QIAstat-Dx GI panel can detect many pathogens with higher sensitivity than the current non-PCR lab methods. The availability of Ct levels allows the evaluation of the nucleic acids content helping for differentiation between colonization and infection. The panel has a potential to improve the patient quality of care with reduction of turn-around time to result.

Abstract third-party references: This work was supported by Plan Nacional de I+D+i 2013-2016 and Instituto de Salud Carlos III, Subdirección General de Redes y Centros de Investigación Cooperativa, Ministerio de Ciencia, Innovación y Universidades, Spanish Network for Research in Infectious Diseases [REIPI R016/0016/0008; R016/0016/0001, R016/0016/0002, R016/0016/00010] - co-financed by European Development Regional Fund “A way to achieve Europe”, Operative program Intelligent Growth 2014-2020, ESCMID Study Group for Infections in Compromised Hosts [ESGICH grant to J.M.A.], Sociedad Andaluza de Trasplante de Órgano Sólido [SATOT grant to L.M.M.], ESCMID Study Group for Bloodstream Infections and Sepsis [ESGBIS], and ESCMID Study Group for Antimicrobial Resistance Surveillance [ESGARS].

Background: Treatment of carbapenemase-producing Enterobacteriales bloodstream infections (CPE-BSI) in solid-organ transplant recipients [SOT] is challenging. The objective of this study was to develop a specific score to predict mortality in SOT recipients with CPE-BSI.
**Materials/methods:** A multinational, retrospective (2004-2016) cohort study of CPE-BSI among SOT adult recipients (INCREMENT-SOT, ClinicalTrials.gov NCT02852902) was performed. The main outcome variable was 30-day all-cause mortality. The INCREMENT-SOT-CPE mortality score was developed using logistic regression and calculating the area under the ROC curve (AUROC). The impact of targeted therapy (monotherapy versus combination therapy) was analysed using Cox-regression.

**Results:** The INCREMENT-SOT-CPE score was developed using logistic regression. The global cohort included 216 patients. The final logistic regression model included the following variables: INCREMENT-CPE mortality score ≥8 (8 points), no source control (3 points), inappropriate empirical therapy (2 points), cytomegalovirus disease (7 points), lymphopenia (4 points), and the interaction between INCREMENT-CPE score ≥8 and CMV disease (minus 7 points, indicating that CMV disease does not further increase the risk of death if the INCREMENT-CPE-score is ≥8, but do so only if the score is <8). This score showed an area under the receiver operating characteristic curve of 0.82 [95% CI 0.76-0.88] and classified patients into three strata: 0-7 (low mortality), 8-11 (high mortality) and 12-17 (very-high mortality). We performed a stratified analysis of the effect of monotherapy versus combination therapy among 165 patients who received appropriate therapy. Monotherapy was associated with higher mortality only in the very-high [adjusted HR 2.82, 95% CI 1.13-7.06, P=0.03] and high [HR 9.93, 95% CI 2.08-47.40, P=0.004] mortality risk strata.

**Conclusions:** A mortality risk score of CPE-BSI in SOT recipients was developed. We propose a score-based algorithm (Figure 1), which can be used for therapy guidance.

Figure 1. Algorithm for clinical management of SOT patients with bloodstream infection due to carbapenemase-producing Enterobacterales (CPE-BSI), based on INCREMENT-SOT-CPE mortality risk score.

**Abstract 1522**

**Do cytomegalovirus infection and valgancyclovir exposure increase the risk of BK viraemia and associated nephropathy after kidney transplantation?**

Isabel Rodriguez Goncer 1, Laura Corbella Vazquez 1, Francisco Lopez-Medrano 1, Rafael San Juan Garrido 1, Tamara Ruiz Merlo 1, Patricia Parra 1, Natalia Polanco 2, Esther Gonzalez 2, Amado Andres 2, Jose M. Aguado Garcia 1, Mario Fernandez Ruiz 3

1 University Hospital 12 de Octubre, Unit of Infectious Diseases, Madrid, Spain, 2 University Hospital 12 de Octubre, Department of Nephrology, Madrid, Spain, 3 Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain

**Background:** Both CMV and BK polyomavirus [BKV] adversely affect graft outcomes after KT. Indirect immunomodulatory effects attributable to CMV would predispose to non-CMV infections. Recent studies have suggested that VGCV prophylaxis may increase the risk of BKV viremia and BKV-associated nephropathy (BKPyVAN) due to a presumptive drug-specific immunosuppressive effect. However, these apparently contradictory associations remain controversial. We investigated whether KT recipients exposed to CMV replication and/or VGCV therapy experienced higher incidence of BKV infection.

**Materials/methods:** Prospective cohort study including 423 consecutive KT recipients from November 2014 to September 2019 in which CMV and BKV DNAemia were periodically monitored throughout the first year. VGCV prophylaxis was given for 6 months to D+/R- patients and for 3 months to R+ patients receiving antithymocyte globulin. The remaining patients were pre-emptively managed. The impact of CMV replication and VGCV therapy [prophylaxis or treatment] during the first 90 and 180 pos-transplant days on the subsequent occurrence of BKV viremia and BKPyVAN was analyzed.

**Results:** VGCV prophylaxis was administered to 235 patients [55.6%], whereas 188 [44.4%] were managed by preemptive therapy. In the latter group, 47 [25.0%] and 53 [28.2%] received VGCV treatment for CMV infection and/or disease during the first 90 and 180 days. One-year incidence rates for CMV and BKV DNAemia were 48.9% [n = 207] and 18.4% [n = 78]. Only one patient [0.2%] developed BKPyVAN. The incidence of BKV viremia beyond days 90 [17.7% vs. 14.2%; P-value = 0.355] and 180 [9.7% vs. 8.9%; P-value = 0.785] was not different between patients that had previously received or not VGCV therapy, respectively. Likewise, no significant differences were found in the occurrence of BKV viremia beyond days 90 [12.9% vs. 17.9%; P-value = 0.218] and 180 [8.4% vs. 10.2%; P-value = 0.542] between patients with or without CMV exposure over the preceding periods. The lack of impact of VGCV therapy or CMV exposure during the first 90 and 180 days was confirmed after adjusting for various clinical covariates by Cox regression.

**Conclusions:** This large prospective study does not support an association between previous CMV replication or VGCV exposure and subsequent BKV viremia after KT.

High-resolution subtyping of *Escherichia coli* using optical DNA mapping

My Nyblom¹, Anna Johnning¹²³, Marie Wrande¹, Miriam Hitz¹, Vilhelm Müller¹, Gaurav Goyal³, Karolin Frykholm¹, Albertas Dvirnas⁵, Christian Giske⁶⁷, Tobias Ambjörnsson⁵, Linus Sandegren⁴, Erik Kristiansson¹², Fredrik Westerlund*¹

¹Chalmers University of Technology, Gothenburg, Sweden, ²Gothenburg University, Gothenburg, Sweden, ³Fraunhofer-Chalmers Centre, Gothenburg, Sweden, ⁴Uppsala University, Uppsala, Sweden, ⁵Lund University, Lund, Sweden, ⁶Karolinska University Hospital, Stockholm, Sweden, ⁷Karolinska Institute, Stockholm, Sweden

**Background:** Typing of bacteria on the sub-species level generally requires sequencing, but there is a need for faster and easier methods for efficient infection control in clinics. We have previously demonstrated that optical DNA mapping (ODM) can differentiate bacterial species with high specificity, and here extend this approach to subtyping of *Escherichia coli*.

**Materials/methods:** The DNA extraction was carried out in agarose plugs to protect the DNA from fragmentation and generate ultra-long DNA molecules (>200 kb). The DNA was then stained with YOYO-1 and netropsin to generate an emission profile along the DNA that reflects the sequence: a DNA barcode. To visualize the barcode, the DNA was stretched in nanofluidic channels and imaged using fluorescence microscopy. The barcodes were aligned to a database of theoretical barcodes from >2000 bacterial species where the included *E. coli* genomes were typed using the Warwick MLST scheme. Only barcodes with high-quality matches to a single species were retained after quality filtering. Barcodes matching discriminatively to *E. coli* were further analyzed and reported if all high-quality matches were to the same sequence type (ST).

**Results:** ODM was performed for clinical *E. coli* isolates, including clinically important STs. Preliminary experiments on eight isolates, belonging to ST38, ST131, ST156, ST405, ST410, and ST648, comprised of on average 37 mapped molecules per sample. The proportion of barcodes that matched discriminatively to a single ST was on average 25%. Importantly, the proportion of discriminative barcodes that matched the correct ST – i.e. the true positive rate – was 100% for all samples, except one where nine out of ten discriminative barcodes matched the correct type.

**Conclusions:** We demonstrate how ODM can classify *E. coli* down to the ST level. Sample preparation and data collection are significantly faster than for sequencing methods, which opens up possibilities for clinical use, in particular in infection control. Importantly, the approach is general and can likely be transferred to other clinically relevant bacterial species.

Abstract 1524

**Epidemiology of carbapenemase-producing Enterobacteriales in the Netherlands in 2018**

Cornelia C.H. Wielders1, Leo Schouls1, Daan Notermans2, Antoni P.A. Hendrickx1, Ed J. Kuijper1, Annelot Schoffelen1, Sabine C. De Greeff1

1RIVM, National Institute for Public Health and the Environment, Bilthoven, Netherlands, 2Amsterdam UMC, Amsterdam Medical Center (AMC), Amsterdam, Netherlands, 3Leiden University Medical Center (LUMC), Leiden, Netherlands

**Abstract third-party references:** on behalf of the Dutch CPE Surveillance Study Group

**Background:** The current epidemiology of carbapenemase-producing Enterobacteriales (CPE) in Europe varies from sporadic imported cases, to sporadic hospital outbreaks, (inter-) regional spread between hospitals, and CPE being endemic in healthcare settings. Here, we describe the epidemiology of CPE in the Netherlands in 2018 based on the enhanced CPE surveillance system.

**Materials/methods:** All Dutch medical microbiological laboratories are requested to submit Enterobacteriales isolates with a MIC for meropenem >0.25 mg/L and/or MIC for imipenem >1 mg/L to the National Institute for Public Health and the Environment (RIVM). MALDI-ToF, MIC for meropenem, carbapenemase inactivation method (CIM), and PCR for carbapenemase-coding genes are performed on all isolates and whole genome sequencing (WGS) is done for all CIM+ isolates. An epidemiological questionnaire is requested for all CIM+ isolates. Reported data were based on the first unique CIM+ species-gene combination per person in 2018 and epidemiological data were analysed on person level.

**Results:** 578 Enterobacteriales isolates were submitted of which 306 were unique CPE isolates obtained from 266 persons (mean age 60 years and 53% male). *K. pneumoniae* was most frequently identified (40%), followed by *E. coli* (29%) and *E. cloacae* complex (12%), and 19% were other species. The genes most often detected coded for OXA-048 (40%), NDM (34%; 20% of all CIM+ isolates was NDM-5, 12% NDM-1), VIM (6%) and KPC (6%). Epidemiological characteristics were available for 161 persons (61%). Forty-five persons (28%) were sampled for diagnostic reasons. Screening because of presumed risk, usually upon admission, was the reason for sampling in 115 (71%) persons. Hospitalization abroad was the most common risk factor (n=93; 58%), with Turkey (n=20) and Morocco (n=14) most often reported. In 50 persons no risk factor was identified (31%). Risk factors reported in <4% of the persons include contact with a foreign country in a different way in the past year, relation with a known outbreak of CPE, work-related exposure to livestock animals, and already known carrier of CPE.

**Conclusions:** Genes coding for OXA-048 and NDM were most frequently detected in CPE isolates submitted to the RIVM. Recent hospitalization abroad is the main risk factor for CPE in the Netherlands.

**Presenter email address:** lieke.wielders@rivm.nl
Impact of unrestricted movement of carbapenemase-producing Enterobacteriales (CPE) carriers on transmission of CPE in nursing homes: a prospective cohort study

Kyaw Zaw Linn*1,2, Pei Yun Hon1,2, Huan Xiaowei1,2, Sharifah Farhanah Syed Husen1,2, Leem Fatt John Chan3, Joanna Ng2, Don Tek Ng2,4,5, Shawn Vasoo1,2, Moi Lin Ling6, Dale Fisher7,8, Kalisvar Marimuthu1,2,8

1National Centre for Infectious Diseases (NCID), Singapore, Singapore, 2Tan Tock Seng Hospital, Singapore, Singapore, 3St. Andrew’s Nursing Home (Henderson), Singapore, Singapore, 4National Centre for Infectious Diseases (NCID), Singapore, Singapore, 5Nanyang Technological University, Singapore, Singapore, 6Singapore General Hospital, Singapore, Singapore, 7National University Hospital, Singapore, Singapore, 8National University of Singapore, Singapore, Singapore

Background: In September 2018, the National Infection Prevention and Control Committee (NIPC) of Singapore recommended standard precautions and unrestricted movements for CPE carriers in NH. We studied the impact of this recommendation on Carbapenemase-producing Enterobacteriales (CPE) transmission among NH residents.

Materials/methods: This prospective cohort study was conducted in a 255-bedded nursing home in Singapore. Eligible consenting residents were followed for 3 months. Stool and environmental samples (sink steel traps and shower drain traps) were collected at baseline and weeks 2, 8 and 12. We collected demographic, comorbidity, hospitalization, antibiotics and travel history at baseline and during follow-ups. We used CHROMID® CARBA SMART to detect CPE, with environmental samples undergoing an additional selective broth enrichment step prior to culture. CPE were identified with MALDI-TOF and PCR for carbapenemase genes. CPE acquisition was defined as having a positive CPE stool sample after an initial negative screening at recruitment. Statistical analysis was done with STATA15.

Results: Between April and July 2019, 32 residents including 6 known CPE carriers (identified in a recent acute hospital stay): 5 blaNDM and 1 blaOXA-48] were recruited and followed-up. Among the known CPE carriers, only 1 remained persistently stool-positive for blaOXA-48, while the rest reverted to negative throughout the study. After a total follow-up of 2699 patient-days, one resident acquired blaNDM-producing Enterobacter cloacae at week 12, giving an acquisition rate of 0.37 per 1000 person-days (95%CI 0.05, 2.63). A total of 164 environmental samples were collected from 28 sink steel traps and 13 shower drains. Of the 28 sink steel traps, 6 were positive for CPE [5 were blaNDM and 1 was blaKPC]. The shower drain traps remained negative for CPE throughout the study.

Conclusions: The recommendation to allow standard precautions during patient care and unrestricted movement of CPE carriers in nursing home appears to be acceptable because we were unable to demonstrate patient-to-patient transmission in this study. However, larger studies with longer follow-up periods are necessary to definitively confirm this finding.

Abstract 1528

Comparison of host immune responses in vivo versus ex vivo lipopolysaccharide stimulation in humans using an immune transcriptomic profiling panel

Dina Tawfik*, Jacqueline Lankelma*, Laurence Ganee†, Elisabeth Cerrato‡, Alexandre Pachot‡, Willem J. Wiersinga‡, Julien Textoris§

1bioMerieux / Lyon 1, Lyon, France, 2Amsterdam UMC, Amsterdam, Netherlands, 3BioMerieux, Grenoble, France, 4bioMerieux, Lyon, France, 5bioMerieux / Hospices Civils de Lyon, Lyon, France

Abstract third-party references: European Sepsis Academy, European Union’s Horizon-2020 research and innovation program grant agreement No. 676129

Background: Patients that suffer from sepsis exhibit an early hyper-inflammatory immune response which can lead to organ failure and death. In our study, we assessed the immune modulation in the human in vivo endotoxemia model and compared it to ex vivo lipopolysaccharide (LPS) stimulation using 38 transcriptomic markers.

Materials/methods: Eight volunteers were challenged with intravenous LPS in vivo. In parallel, blood from another 8 volunteers was challenged ex vivo. Blood was collected before and after 4 hours of LPS challenge and tested with the Immune Profiling Panel (IPP) using the FilmArray® system.

Results: The use of IPP showed that markers from the innate immunity dominated the response to LPS in vivo, mainly markers related to monocytes and neutrophils. Comparing the two models, in vivo and ex vivo, revealed that most of the markers were modulated in a similar pattern (68%). Some cytokine markers such as TNF, IFN-γ and IL-1β were under-expressed ex vivo compared to in vivo. T-cell markers were either unchanged or up-modulated ex vivo, compared to a down-modulation in vivo. Interestingly, markers related to neutrophils were expressed in opposite directions, which might be due to the presence of cell recruitment and feedback loops in vivo.

Conclusions: In both models, the majority of IPP markers showed similar patterns of expression post-LPS challenge, except for several markers related to neutrophils and T-cells. The IPP tool was able to capture the early immune response in the human in vivo endotoxemia model, which is a translational model mimicking the immune response observed in septic patients.

First report of \textit{bla}\textsubscript{NDM-1} and \textit{bla}\textsubscript{OXA-181} harbouring \textit{P. vermicola} from Nepal

Khandakar Mohammad Anwarul Haque*, Tetsuya Matsumoto¹, Tsuyoshi Sekizuka², Makoto Kuroda², Ranjit Sah³

¹Department of Infectious Diseases, International University of Health and Welfare School of Medicine, Narita, Japan, ²Pathogen Genomics Center, National Institute of Infectious Diseases, Tokyo, Japan, ³Tribhuvan University Institute of Medicine, Kathmandu, Nepal

\textbf{Background:} The genus \textit{Providencia} encompasses five common species i.e., \textit{P. alcalifaciens}, \textit{P. rettgeri}, \textit{P. stuartii}, \textit{P. rustigianii}, and \textit{P. heimbachae}. They are frequently isolated from wounds, respiratory tract, urinary tract, stool of humans, poultry, faeces from reptiles, throat, perineum, axilla and blood of humans. Other species and antimicrobial resistance in this genus are uncommon, especially in clinical samples. We executed whole genome analysis of a pan-drug resistant \textit{Providencia} spp. isolated from a septic patient in Nepal.

\textbf{Materials/methods:} In Nepal, the strain was isolated from urine sample and phenotypically identified as \textit{Providencia} spp. The strain was found resistant to 14 antimicrobials including colistin in disk-diffusion method. The pan-drug resistant \textit{Providencia} spp. was transported to our laboratory for further investigations. We cultured the bacteria on McConkey in 35\(^\circ\)C for overnight and prepared a pure stock. The susceptibility of the bacteria to 33 antimicrobials was measured by automatic microbiological system. We searched for ESBL and carbapenemase encoded genes in association with the isolate by disk-synergistic test and modified carbapenemase inactivation method (mCIM), respectively. Genomic DNA of the strain was extracted by boiling method and was sequenced using the PacBio RS II platform.

\textbf{Results:} Susceptibility test revealed that the isolate was susceptible only to monobactum and fosfomycin and was resistant to all other groups of antimicrobials including 3\(^{rd}\)-4\(^{th}\) generation cephalosporin, carbapenems, aminoglycoside, fluoroquinolone, colistin, etc. Disk synergistic test and mCIM conferred the isolate as non-ESBL encoded and carbapenemase producing isolate, respectively. 16S rRNA sequencing revealed the isolate is highly identical to the \textit{P. vermicola} (99.65%). A total of 13 resistance genes including \textit{qnrD}, \textit{aac(6')-Ib}, \textit{bla}_{\text{NDM-1}}, \textit{bla}_{\text{OXA-181}} etc. were detected in association with the isolate. No typable plasmid replicons, including IncF was detected.

\textbf{Conclusions:} To our knowledge, this is the first \textit{Providencia} strain concomitantly harboring \textit{bla}\textsubscript{NDM-1} and \textit{bla}\textsubscript{OXA-181} encoding genes. First clinical \textit{P. vermicola} was isolated in 2015 from India and we are reporting the second clinical and most resistant species in the genus \textit{Providencia} from Nepal. The findings suggest that the preparedness to emerging MDR organisms mandates more microbiological surveillances in Asia.

Abstract 1531

Clinical and microbiological characteristics and outcomes for community-onset sepsis patients in a teaching hospital in Latvia: a retrospective, single-centre, cohort study

Laura Puceta*1,2, Alise Grāmatniece1,2

1University of Latvia, Riga, Latvia, 2Pauls Stradins Clinical University Hospital, Riga, Latvia

Background: Sepsis is a complex life-threatening condition characterised by systemic inflammatory immune response, which may cause organ failure, septic shock and death. The objective of the study is to assess the mortality and associations between clinical and microbiological characteristics in patients with community-onset sepsis (COS) admitted to Pauls Stradins Clinical University Hospital (PSCUH).

Materials/methods: In retrospective cohort study we identified 395 adult patients with sepsis-related ICD-10 codes upon discharge, admitted to PSCUH between September 2017 and September 2018. Further analysis was performed on 289 COS cases, identified using consensus definitions (Sepsis-3). We collected demographic data, information on clinical presentation, risk factors, time-to-culture (TTC), blood culture (BC) turn-around-time (TAT) and mortality.

Results: The median age of the COS cohort patients was 74 years (IQR 59.0-82.5) with median Charlson Comorbidity Index of 6 points (IQR 4-8), 49.8% were male. The intrahospital mortality reached 47.2%. The reason of hospitalization was documented as infectious disease for 50.8% of COS cases; nevertheless, the BC were not taken in 12.2% of those patients. The most common sites of COS origin were pneumonia (22.7%) and urinary tract infection (16.3%). In 79.2% of cases BC were performed; furthermore, patients without BC were significantly older (p=0.004). Antimicrobials prior to the BC were administered in 36.2% of cases. From 173 BC performed 59.0% returned positive with Staphylococcus aureus MS, Escherichia coli and Streptococcus pneumoniae as the most common isolates – 47.1%, 27.5% and 14.7%, respectively. The rate of positive BC was significantly higher in COS survivor group (p=0.045). Median TTC was 4.8 hours (IQR 2.8-16.4). TTC was not dependent on age, comorbidities, previous exposure to long-term healthcare facilities, clinical presentation, source of infection or presence of septic shock. Median TTC in COS patients initially admitted for non-infectious reason was 5.4h (IQR 3.6-18.6). Median TAT was 93.7h (IQR 78.3-115.0).

Conclusions: Intrahospital mortality was remarkably higher than reported in other sepsis cohorts. Additional training is needed about the recognition of the community-onset sepsis and importance of blood cultures to improve outcomes, especially in the geriatric population. The data collection will be continued and larger cohort remains to be assessed.

**Abstract 1532**

**Bacteriophages in real-life: positive and negative experience in a difficult to access old-new therapeutic**

1University Hospitals Pitié Salpêtrière - Charles Foix, Infectious and Tropical diseases department, Paris, France, 2Hospital Robert Debré, Service de Médecine Interne, Maladies Infectieuses, Immunologie Clinique, Reims, France, 3Hôpital Européen Georges-Pompidou, Microbiology, Paris, France, 4University Hospitals Pitié Salpêtrière - Charles Foix, Centre d’Immunologie et des Maladies Infectieuses [U1135-E13], Paris, France, 5University Hospitals Pitié Salpêtrière - Charles Foix, Centre National de Référence des Mycobactéries et de la résistance aux antituberculeux, Service de Bactériologie-Hygïène, AP-HP Sorbonne Université, Paris, France, 6University Hospitals Pitié Salpêtrière - Charles Foix, Central Pharmacy, Paris, France

**Background:** Bacteriophages therapies as an alternative or in combination with antibiotics are regaining a place in the arsenal of occidental Infectious Diseases (ID) specialist’s after decades of neglect. In the last year bacteriophages as treatment increased in France with more than fifteen patients treated.

**Materials/methods:** Demographic and clinical data, bacteriophages indication, microbiological aspects including antibiotic susceptibility, procedure to obtain bacteriophages, health care authority statement and outcome after therapy are reported.

**Results:** Between November 2018 and November 2019, eight cases were discussed in our center. Four patients had bone and joint infection, two a central nervous system infection, one pulmonary abscess and one chronic sinusitis. After reviewing medical chart by a dedicated board, bacteriophages therapy was considered as an option for five patients out of eight. The three remaining cases could be treated with antibiotics optimization. These five cases were subsequently presented and validated by the French national drug agency (ANSM) who authorized compassionate use. Bacteriophages active against patient’s bacterial strains were available in three cases. In two cases, bacteriophages were provided by a French pharmaceutical biotech company. In the last case bacteriophages were available in a Swiss research lab. They were active *in vitro* but the patient’s family finally refused the treatment. Patients treated with Bacteriophages presented (i) a *Staphylococcus aureus* extradural empyema (ED) and osteitis and (ii) a prosthetic knee infection. Both previously experienced relapses despite adapted antibiotic treatment. Both patients received a combination of two different Bacteriophages through local instillation in association with active antibiotic therapy. The prosthetic infection relapsed one month after phage instillation while the patient with the ED is cured without relapse at one year follow up.

**Conclusions:** Bacteriophages therapy is a neglected therapy which came back in our therapeutic arsenal through the multi and pan resistance problem. One of the major limits for Bacteriophages use nowadays is the absence of bacteriophages active against clinical stains as experienced in our experience. Open source libraries of bacteriophages available for clinicians and patients might resolve this limitation. Finally bacteriophages were currently used as salvage therapy in desperate situation which might explain the experienced relapse.

Abstract 1533

**Anakinra for the treatment of protracted paradoxical inflammation in HIV-associated tuberculosis**

Alexander Keeley*1,2, Vivak Parkash1, Anne Tunbridge1, Julia Greig1, Paul Collini1,2, William Mckane3, Rachel Tattersall4

1Sheffield Teaching Hospitals NHS Foundation Trust, Department of Infectious Diseases and Tropical Medicine, Sheffield, United Kingdom, 2The University of Sheffield, The Florey Institute, Sheffield, United Kingdom, 3Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield Kidney Institute, Sheffield, United Kingdom, 4Sheffield Teaching Hospitals NHS Foundation Trust, Department of Rheumatology, Sheffield, United Kingdom

**Abstract third-party references:** University of Sheffield, United Kingdom

**Background:** Paradoxical inflammation including immune reconstitution inflammatory syndrome (IRIS), is well described in HIV-associated tuberculosis (TB). At the severe end of the disease-spectrum significant morbidity and mortality may occur particularly in TB of the central nervous system (CNS), or when protracted high dose corticosteroids are used. Interleukin-1 (IL-1) mediated inflammation has been implicated in the pathophysiology of IRIS. We describe two cases where anakinra (recombinant human IL1 antagonist) successfully controlled life-threatening protracted paradoxical inflammation.

**Materials/methods:** Case reports

**Results:**

Case 1: A 33-year-old woman from Ethiopia was diagnosed with HIV (baseline CD4 count of 60 cells/mm³) and fully-sensitive TB with cervical, thoracic and abdominal adenopathy and splenic micro-abscesses. She was treated with standard anti-TB therapy. Following antiretroviral therapy initiation, she had protracted IRIS with fever and massive adenopathy. No alternative infective, malignant or inflammatory cause was found. Pus from repeated lymphnode aspirations showed acid fast bacilli but no further growth of mycobacteria, consistent with IRIS. Over 3 years it was not possible to wean prednisolone below 20mg, nor achieve control of inflammation despite montelukast and colchicine. Protracted inflammation lead to nephrotic syndrome with AA amyloidosis on renal biopsy. This prompted initiation of anakinra, with rapid normalisation of inflammatory markers, proteinuria and quality of life.

Case 2: A 41-year-old man from Zimbabwe with known HIV (virologically suppressed with CD4 count of 275 cells/mm³) was diagnosed with isoniazid-monoresistant miliary TB. He had cerebral tuberculomata on magnetic resonance imaging (MRI). He was treated with rifampicin, moxifloxacin, pyrazinamide, ethambutol and dexamethasone. He had no neurological deficit at treatment initiation. Over 18 months had progressive episodic neurological deterioration whenever he weaned off corticosteroids with ataxia, aphasia, hemiparesis and inability to live independently. Serial MRI showed unstable tuberculomata in both hemispheres, cerebellum, pons and medulla. Brain biopsy demonstrated necrotizing granulomata with no mycobacterial growth consistent with a paradoxical inflammatory reaction. Anakinra was initiated after unsuccessful trial of thalidomide. Since anakinra initiation he had continual neurological and functional improvement with resolution of tuberculomata on MRI.

**Conclusions:** We describe, to the best of our knowledge the first reported usage of anakinra to control life-threatening paradoxical inflammation in HIV-associated TB.

Abstract 1541

One Health surveillance of extended-spectrum beta-lactamase-producing Enterobacteriales in urban and rural Malawi

Derek Cocker*1,2, Andrew Singer2,3, Tracy Morse4,5, Christopher Jewell6, Adam Roberts2, Nicholas Feasey1,2

1Malawi-Liverpool Wellcome Trust, Blantyre, Malawi, 2Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 3Centre for Ecology and Hydrology, Wallingford, United Kingdom, 4University of Strathclyde, Glasgow, United Kingdom, 5University of Malawi, Blantyre, Malawi, 6University of Lancaster, Lancaster, United Kingdom

Background: The greatest burden of drug-resistant infections is predicted to occur in low- and middle-income countries (LMICs). Given the limited availability of carbapenems and local resistance to 3rd generation cephalosporins, extended spectrum beta-lactamase (ESBL) bloodstream infections are often untreatable. It is therefore essential to understand the key drivers and environmental reservoirs of ESBL resistance within these settings to interrupt community transmission. We describe a one-health focused observational study of households in Malawi to describe the dynamics of ESBL E. coli (ESBL-E) and ESBL Klebsiella pneumoniae (ESBL-K) and their ecological niche.

Materials/methods: Longitudinal, microbiological surveillance of 195 households in urban (65), peri-urban (65) and rural (65) Malawi. Each household undergoes 3-4 visits over a 6-month period. At each visit human and animal stool, alongside an extensive environmental sweep of the household, and broader external environment are taken. Household sampling includes food, drinking water, clothing and key hand contact surfaces, whilst broader environmental sampling comprises nearby soil, drainage systems and local river water. Samples undergo concentration and enrichment culture (buffered peptone water), before plating onto ESBL chromogenic agar. ESBL-E and ESBL-K isolates are identified morphologically, and ESBL-K are confirmed with PCR.

Results: Microbiological surveillance of 112 households [1,700 samples] indicates a high prevalence of ESBL-E and ESBL-K within human stool [34.5% n=162], animal stool [26.4% n=43], on household food [17.1% n=29], in household drinking water [17.8% n=21], on participant clothing [8.2% n=8], on household environmental surfaces [8.6% n=38] and within the broader environment [71.6% n=53] (Figure 1).

Conclusions: In urban and rural Malawi there is a very high prevalence of ESBL Enterobacteriales in humans, animals and the environment. These data will be placed in the context of water sanitation and hygiene behaviour, human health and antimicrobial usage in order to develop a dynamical transmission model.

Clinical factors associated with empirical antibiotics resistance in febrile patients with urinary tract calculus

Jeong Woo Lee¹, Min Gu Park², Se Yun Kwon³, Hoon Choi⁴, Kwang Taek Kim⁵, Sangrak Bae⁶, Geehyun Song⁷

¹Dongguk University Ilsan Hospital, Goyang, South Korea, ²Seoul Paik Hospital, Seoul, South Korea, ³Dongguk University Gyeongju Hospital, Gyeongju, South Korea, ⁴Korea University Ansan Hospital, Ansan, South Korea, ⁵Gil Medical Center, Incheon, South Korea, ⁶Uijeongbu St. Mary’s Hospital, Uijeongbu, South Korea, ⁷Kangwon National University Hospital, Chuncheon, South Korea

Background: To investigate the clinical and microbiological features in the febrile patients with urinary tract calculus, as well as factors that affect empirical antibiotics resistance.

Materials/methods: A retrospective analysis was performed of 203 patients hospitalized between January 2011 and December 2016 for antibiotic treatment of febrile urinary tract infection with urinary calculus at 3 institutions. We investigated patient age, sex, body mass index, underlying diseases, stone-related factors and results of urine and blood culture examination and antibiotic sensitivity test.

Results: Bacteria were identified in 152 of 203 patients (74.9%), and the most commonly cultured included Escherichia coli (44.1%), followed by Enterococci spp. (11.8%), Proteus (8.6%), S. agalactiae (6.6%), Klebsiella spp. (5.3%), Pseudomonas spp. (4.6%), coagulase-negative Staphylococci (4.0%), Staphylococcus epidermidis (4.0%), Enterobacter (0.7%), Acinebacter (0.7%), mixed infection (7.2%) and other spp. (5.4%). The multivariate analysis revealed that multiplicity of calculus was independent predictive factor for fluoroquinolone resistance (p=0.008). Recurrent infection was determined to be significant predictor of cefotaxime resistance on multivariable analysis (p=0.041).

Conclusions: Based on the results from the present study, fluoroquinolone should not be considered as the empirical treatment in febrile patients with urinary tract calculus. Also, combination antibiotic therapy is recommended in case with recurrent infection, because cefotaxime resistance can occur.

Abstract 1545

Does iodine-impregnated incision drape prevent periprosthetic joint infection? One-year follow-up of 1187 patients in a randomised controlled trial

Anne Brun Hesselvig*, Magnus Arpi†, Thomas Bjarnsholt‡, Anders Odgaard§,

1Herlev and Gentofte Hospital, Department of Clinical Microbiology and Department of Orthopaedic Surgery, Hellerup, Denmark,
2Herlev and Gentofte Hospital, Department of Clinical Microbiology, Herlev, Denmark, 3Copenhagen University, Institute for Immunology and Microbiology, København N, Denmark, 4Herlev and Gentofte Hospital, Department of Orthopaedic Surgery, Hellerup, Denmark

Background: PJI is a devastating incident for the patients and in a population that is getting older and the incidence of arthroplasty surgery is rising it is vital to keep the infection rate as low as possible. Despite prophylactic measures as pre-operative decontamination, antisepsis and prophylactic antibiotics the infection rate has been constant at 1-2%.

The primary aim of this study was to examine whether the use of iodine impregnated incision drape (IIID) decreased the risk of periprosthetic joint infections (PJs). The secondary aim was to investigate whether intraoperative contamination could predict postoperative infection.

Materials/methods: We performed a prospective, randomized two arm study (IIID vs control group) of 1187 patients undergoing primary knee arthroplasty surgery. A database with patient demographics and surgical observations was established with the purpose of following the patients for ten years. Patients, who developed an infection within the first year of surgery were analysed for correlation with the intraoperative bacterial findings and the use of IIID.

Results: 31/1187 (2.6%) patients were re-operated during the follow-up period. 18/31 (58%) patients were deemed infected and received antibiotic treatment. 9/18 of infected patients were female. Of the 18 infected patients 2 were contaminated at primary surgery. 9 of the 18 infected patients were operated with IIID at the primary surgery. No correlation was found between the use of IIID at primary surgery and subsequent infection (OR 0.95, 95% CI 0.38-2.46, P=0.95) Chi square test showed no correlation between contamination and infection (OR 0.86, 95% CI 0.20-3.79, P=1).

Conclusions: We found no effect of the use of IIID and subsequent development of PJI. Nor did we find a correlation between the intraoperative contamination and development of PJI within the first year of follow-up. Longer follow-up time and larger studies are needed to determine if IIID can prevent postoperative infection.

Abstract 1546

**Bronchial abundance of Streptococcus as a potential biomarker for lung cancer**

1Servicio de Microbiología Clínica. Hospital Universitario Ramón y Cajal., Madrid, Spain, 2Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain, 3Servicio de Neumología. Hospital Universitario Miguel Servet, Zaragoza, Spain, 4Servicio de Microbiología Clínica. Hospital Universitario Miguel Servet., Zaragoza, Spain

Abstract third-party references: Supported by the Spanish Network for Research in Infectious Diseases-REIPI (Instituto de salud Carlos III) and by the Programa Operativo de Empleo Juvenil, co-financed by the European Social Fund Investing in your future (ESF) and ERDF (PEJD-2018- PRE/BMD-8237).

**Background:** Lung cancer has been associated to dysbiosis of the lung microbiota, but available data are scarce. The aims of this work were: i) to define the microbiota of the central bronchial tumour, in comparison with the contralateral bronchus of the same patient and with a cohort of controls; ii) to analyse the differences between the oral and pulmonary microbiota, and iii) to find potential microbiota-related biomarkers for lung cancer.

**Materials/methods:** We obtained bronchial samples by bronchoscopy from tumour and from contralateral lung of 25 patients diagnosed of central lung cancer. Sixteen healthy controls were also included, each contributing with a biopsy of their healthy bronchi. One salivary sample per participant was also obtained. None received antibiotics within the month prior sampling. Bacterial composition was determined by PCR amplification and sequencing of the V3-V4 regions (16S rDNA) using a MiSeq platform (Illumina). Bioinformatics was performed using QIIME2. Differential abundance was assessed by Linear discriminant analysis Effect Size (LEfSe). ROC curves were plotted using SPSS (v.22).

**Results:** After quality evaluation of the sequencing process, 22 tumour tissue (affected bronchi), 25 contralateral bronchi, and 25 saliva samples from patients (n=25), and 12 bronchi and 16 saliva samples from controls (n=16) were finally included. Alpha-diversity analysis showed higher Chao1 and Shannon indices in patients’ bronchi than controls’ (p<0.001), whereas no significant differences were observed between patients’ and controls’ saliva (p>0.05). Beta-diversity analysis (UniFrac distance) showed that both affected and contralateral bronchial microbiota were different from controls (p<0.001). Saliva from patients and controls were also different (p<0.005). LEfSe analysis showed a higher density of Firmicutes (particularly Streptococcus), in detriment of Proteobacteria, in patients’ samples. ROC curves using the relative abundance of Streptococcus [Figure1] showed that >14.6% of Streptococcus in bronchus predicted lung cancer with 90.9% sensitivity and 83.3% specificity (AUC=0.848, using affected and control bronchi data). Otherwise, streptococcal abundance in saliva did not perform well as biomarker.

**Conclusions:** Lung and oral microbiota showed an enrichment of Firmicutes and a reduction of Proteobacteria in lung cancer patients. Streptococcal abundance in lung samples obtained by bronchoscopy could be a potential biomarker for lung cancer diagnosis.

![ROC curves](image)

Figure1. ROC curves to discriminate patients from controls using their relative abundance of Streptococcus.

Abstract 1548

Comparison of antibiotic susceptibility of *Escherichia coli* between community-acquired and post-prostate biopsy acute bacterial prostatitis

Geehyun Song*1, Jeong Woo Lee2, Min Gu Park3, Se Yun Kwon4, Hoon Choi5, Kwang Taek Kim5, Sangrak Bae6

1Kangwon National University Hospital, Chuncheon, South Korea, 2Dongguk University Ilsan Hospital, Goyang, South Korea, 3Seoul Paik Hospital, Inje University College of Medicine, Seoul, South Korea, 4Dongguk University Gyeongju Hospital, Gyeongju, South Korea, 5Korea University Ansan Hospital, Ansan, South Korea, 6Gil Medical Center, Incheon, South Korea, 7Uijeongbu St. Mary’s Hospital, Uijeongbu, South Korea

**Background:** To compare the antibiotic susceptibility of *Escherichia coli* (*E. coli*) between community-acquired acute bacterial prostatitis (CA-ABP) and ABP following transrectal ultrasound-guided prostate biopsy (Bx-ABP).

**Materials/methods:** A total of 4,383 patients underwent prostate biopsy from January 2005 to June 2014. Among these patients, 34 had Bx-ABP, of which 22 patients had *E. coli* identified in their urine or blood culture. *E. coli* was also identified in 91 out of 209 patients with CA-ABP in urine or blood culture. We investigated patient and microbiological characteristics.

**Results:** The Bx-ABP (50.1%) group showed a higher bacteremia prevalence than the CA-ABP group (13.2%) (p<0.001). Significant differences in the antibiotic sensitivity to *E. coli* between the two groups were observed for fluoroquinolone, cephalothin, and gentamicin. The antibiotic sensitivity of fluoroquinolone in the Bx-ABP group was only 27.3%. Amikacin, imipenem, meropenem, amoxicillin/clavulanic acid, and piperacillin/tazobactam showed more than 95% antibiotic sensitivity in both groups. Bx-ABP was an independent predictive factor for bacteremia by multivariate analysis.

**Conclusions:** *E. coli* in Bx-ABP showed a higher incidence of antibiotic resistance and bacteremia than those in CA-ABP. Carbapenem may be a treatment of choice for patients suspected of having sepsis. Considering the recent emergence of carbapenem-resistant bacteria, piperacillin/tazobactam or amikacin may be considered.

Abstract 1556

**Rapid carbapenemase detection using the CARBA5 lateral flow device**

Holly Ciesielczuk*1

1Barts Health NHS Trust, Royal London Hospital, London, United Kingdom

**Abstract third-party references:** Supported by NG Biotech

**Background:** Colonisation and infection with carbapenemase-producing organisms is now frequently reported in the UK, with many diagnostic microbiology laboratories routinely screening for these organisms. Following validation of the NG-Biotech CARBA5 lateral flow device for the detection of the ‘Big 5’ carbapenemases, we implemented the test into our diagnostic service. Here, we report our carbapenemase detection rate for all rectal screens since March 2019.

**Materials/methods:** All Enterobacteriales recovered from rectal swabs, as part of our carbapenemase-producing organism screen, were identified by MALDI-ToF and underwent antibiotic susceptibility testing by disk diffusion. Isolates that matched our presumptive carbapenemase algorithm were tested on the CARBA5 according to the manufacturer’s instructions.

**Results:** Between March 2019 and October 2019, 3993 patient rectal swabs were screened for carbapenemase-producing organisms. Of these, 132 (3%) were positive for a carbapenemase-producing organism according to the CARBA5 device, including 12/132 that possessed two carbapenemase-producing organisms. Enzymes detected included OXA-48 (70%), NDM (21%), IMP (2%) and 6% of isolates possessed both OXA-48 and NDM. One presumptive carbapenemase-producer, that was resistant to ertapenem and meropenem, was negative on the CARBA5 device. This isolate was confirmed as negative for the common carbapenemases by the Public Health England reference laboratory.

**Conclusions:** The CARBA5 lateral flow device was successfully validated and implemented as part of our routine diagnostic service. Importantly, this test enables rapid identification of the most common carbapenemases in our Trust, and in the UK, which reduces the turnaround time for this test, as well as enabling prompt and appropriate infection control interventions.

Abstract 1557

Incidence of bloodstream infection from multidrug-resistant bacteria in haematological patients with rectal colonization

Marco Peradotto*, Gabriele Bianco1, Matteo Boattini1, Alessandro Bondi1, Marco Iannaccone1, Zaccaria Teresa1, Rossana Cavallo1, Cristina Costa1

1Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Torino, Italy

Background: Spread of multidrug-resistant (MDR) bacteria has a relevant impact on the clinico-therapeutic management in the hospital setting with epidemiological surveillance playing a crucial role in its containment. Patients with hematological malignancies are at high risk of infection due to deep immunodepression and long hospitalization periods. In Italy, approximately 5-10% of these patients are colonized by MDR bacteria (carbapenem-resistant [CR], extended spectrum beta-lactamase producers [ESBL] and vancomycin-resistant enterococci [VRE]); blood stream infection (BSI) develops in 25% of these patients with 60% of these infections being caused by colonizing MDR bacteria. In this study, the incidence of rectal colonization and subsequent MDR-BSI was evaluated in hematological adult patients referred to our laboratory.

Materials/methods: MDR-bacteria colonization was evaluated in 828 hematological patients referred to our laboratory over a two-year period (2017-18) by rectal swab screening; in these patients, blood cultures were analyzed for BSI development following MDR bacteria colonization.

Results: Overall, 43/817 patients (5.3%) were colonized by CR, 232/746 (31.1%) ESBL and 56/441 (12.7%) VRE. Thirty patients (3.6%) presented colonization by multiple MDR bacteria. Considering species, K. pneumoniae (KP) represented 78% of CR, E.coli (EC) 75.3% of ESBL (53% of all MDR bacteria) and E.faecium (EF) 98.2% of VRE. Over the study period, at least one episode of BSI developed in 223/828 patients (26.9%), with MDR bacteria in 17.9% of the cases (4.8% of all the patients). Among 43 MDR isolates, 30 were involved in BSI following colonization. Overall, the mean rate of BSI in colonized patients was 12% (3/32 KP CR, 16/174 EC ESBL, 9/45 KP ESBL).

Conclusions: Over the study period, at least one case of rectal colonization from MDR bacteria was found in 35.7% of patients with a high prevalence of ESBL producers (70.4%); this rate of colonization is higher than in other countries, in which however CR bacteria are prevalent (59%). The rate of BSI (26.9%) is similar to that reported in literature (25-26%), however BSIs from MDR bacteria following colonization result lower in comparison to those reported in literature (15-20%). Further studies are required to define the impact of colonization and subsequent BSI on the patient outcome.

Abstract 1559

**Pooled saliva cytomegalovirus-PCR: a viable laboratory technique for universal cytomegalovirus screening of healthy newborns**

Yulia Shlonsky1, Orit Golan-Shany*, Narmeen Shehade2, Raeda Mubariki1, Isaac Srugo3, Miri Hemo4, Arik Riskin4, David Bader4, Ellen Bamberger2

1Bnai Zion Medical Center, Clinical Microbiology Laboratory, Haifa, Israel, 2Bnai Zion Medical Center, Pediatrics Department, Haifa, Israel, 3Bnai Zion Medical Center, Pediatrics Department, Clinical Microbiology Laboratory, Haifa, Israel, 4Bnai Zion Medical Center, Nursery Department, Haifa, Israel

**Background:** The vast majority of congenital CMV (cCMV) infected infants have no overt manifestations at birth; still, CMV-related sensorineural hearing loss (SNHL) may be present. Valganciclovir initiated to neonates with moderate-severe cCMV disease has the potential to ameliorate long-term hearing outcome, yet with the customary target screening, many neonates with SNHL cases are missed. Given its ease of collection, saliva is recommended as the preferred screening specimen. Accordingly, we aimed to investigate the screening of healthy full-term neonates employing a pooled saliva specimen technique.

**Materials/methods:** This was a prospective laboratory universal CMV PCR screening conducted at a secondary hospital in Northern Israel, March 2019 until June 2019. All neonates underwent saliva sampling upon arrival to the nursery. Specimens were extracted in pools of 10 and individually (40 μL and 400 μL, respectively) by the QiaCube (Qiagen) automated extractor. Specimen extracts were analyzed for the presence of CMV DNA by the RealStar® CMV-PCR Kit 1.0 (Altona Diagnostics) using the Rotorgene 6 plex real-time platform (Qiagen). In cases where the pooled specimen was positive, the pool was opened and the individual specimens evaluated to determine the source[s] of CMV. A definitive cCMV was defined only after confirmation with positive urine testing.

**Results:** Of the 1000 saliva samples, there were 6 urine-confirmed congenital CMV patients attained by both laboratory techniques. The specificity of both techniques, was high with the pooled specimen yielding 98.94% (95% CI: 94.2-99.97%) and the individual sampling 98.1% (95% CI: 97.0-98.8%), respectively. The rate of false positive results was statistically significantly higher in individual sampling in comparison to the pooled specimens, 19/25 (76.0%) versus 1/7 (14.3%; p<.003), respectively. Similarly the PPV of the individual sample was only 22.4% in comparison to 98.2% in the pooled specimens.

**Conclusions:** Pooled saliva CMV PCR of full-term healthy newborns appears to be an effective laboratory technique for identification of asymptomatic cCMV infection. The pooling technique affords a higher specificity by decreasing the rate of saliva false-positive samples and may have the potential to improve the laboratory workflow and decrease costs. Further studies are needed to evaluate the clinical correlation of this widespread cCMV screening technique.

Abstract 1562

**Acquired resistome of *Escherichia coli***

Marie Petitjean*, Olivier Clermont, Bénédicte Condamine, Erick Denamur, Etienne Ruppé

*Université de Paris, IAME, UMR 1137 INSERM, Paris, France

**Background:** *Escherichia coli* is an ubiquitous bacterium found in the intestinal microbiota of vertebrates. Accordingly, *E. coli* is widely exposed to antibiotics and has evolved by acquiring different antibiotic resistance genes (ARGs). In the past, the exhaustive characterization of these genes was difficult because based on targeted PCRs. With the availability of next-generation sequencing, the identification of resistance genes has become easier. Here, we aimed at characterizing the census ARGs acquired by *E. coli*, leveraging a publicly available *E. coli* genome database.

**Materials/methods:** We downloaded the 82,084 genomes of Enterobase that includes *E. albertii*, *E. marmotae*, *Escherichia* clades, *E. fergusonii*, *E. coli*, *Shigella* or unspecified. *E. coli* genomes were identified by the ClermonTyper tool and in silico PCR. Plasmid incompatibility groups were determined by PlasmidFinder and ARGs by the Diamond tool using both the AMRFinder and ResFinderFG databases [minimum 80% nucleotide identity and/or 80% coverage]. In order to reduce selection bias of the strains in the database, the proportions of ARGs were normalized within each phylogroup. The different associations were studied with R.

**Results:** We identified 70,307 *E. coli* genomes that carried 311,348 antibiotic resistance genes: 382 genes sharing 100% identity with known genes (n = 164,534) and 328 genes for which variants of known genes were identified (n = 146,814). *bla TEM-1* was the most recovered gene (n = 16,766). We observed limited beta-lactamase diversity with only 22 different families.

However, we have identified a gene encoding a class A beta-lactamase from *Bacteroides* in a strain isolated in Germany. In addition, we observed the frequent presence of ARGs conferring resistance to antibiotics used in Gram-positive bacterial infections: rifampin (*arr*) and macrolide-lincosamines (*lnu, mef, mphA, erm, vga* and *msr*). Finally, we observed associations between ARGs as well as correlations between ARGs and plasmid incompatibility groups.

**Conclusions:** Using a substantial set of *E. coli* genomes, we could describe the acquired resistome of *E. coli*. While the diversity of acquired beta-lactamases – encoding genes was low, we could observe the frequent presence of ARGs conferring resistance to antibiotics not primarily targeting *E. coli*, reflecting the selective pressure exerted on *E. coli* in the gut.

Abstract 1563

Risk factors for readmission among OPAT patients in the Netherlands

Sabrine Douiyeb*, Jara De La Court1, Rogier Schade1, Tanca Minderhoud1, Ferdi Sombogaard1, Diana Lammers1, Kim Sigallof1

1Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands

Background: In the Netherlands, home treatment with intravenous antimicrobial therapy is a relatively new concept. Although several studies have shown that outpatient parenteral antimicrobial therapy (OPAT) can be administered safely, people receiving antimicrobials at home remain at risk for adverse events. The Infectious Disease Society of America (IDSA) guidelines recommend weekly follow-up of all OPAT patients, to monitor and reduce adverse events. The aim of our retrospective study is to determine rates of OPAT-related complications and to identify risk factors for readmission in patients discharged with OPAT.

Materials/methods: Electronic patient records from all patients, age > 18 years and discharged with OPAT during the period of 2016-2018 were included. Complications consisted of antibiotic-related adverse drug events (ADE) or catheter-related (infection, thrombosis, mechanical). Multivariate analysis was performed to identify demographic risk factors for readmission.

Results: A total of 247 patients were included in the analysis; mean age was 60 years. Most common reason for OPAT was bone and joint infections (17%). Penicillins (40%), cephalosporins (28%) and vancomycin (13%) were the most commonly prescribed antimicrobials. A total of 37 patients (15%) were discharged with aminoglycosides or vancomycin. The overall complication rate was 16%. Forty-one percent of readmission was OPAT-related (ADE, catheter- or mechanical complications). The overall readmission rate was 10%, respectively. Among the patients receiving aminoglycosides or vancomycin, 51% (19/37) received weekly therapeutic drug monitoring (TDM). The readmission rate in this group was 32%. Receiving aminoglycosides or vancomycin was found to be an independent predictor of readmission (p<0.05, OR 5.7; CI, 2.46-13.78). Age, gender, indication and discharge to skilled nursing facility were not found predictive for readmission in multivariate analysis.

Conclusions: OPAT patients receiving aminoglycosides or vancomycin have a higher risk of readmission, compared to the general OPAT population. Further research needs focus on the prevention of readmission by performance of weekly TDM and monitoring according to IDSA guidelines.

Table 1. Complications and readmission rate in patients discharged with OPAT from 2016 until 2018 at the VU Medical Center.

Abstract 1564

**Bordetella holmesii in suspected cough: a frequent pathogen?**
Sabine Trombert Paolantoni*1, Sophie Guillot2, Sylvain Brisse2, Julie Toubiana2

1Laboratoire Cerba, Saint-Ouen-l’Aumône, France, 2Institut Pasteur, Paris, France

**Background:** *Bordetella holmesii* is responsible for bacteremia in asplenic or sickle cell patients. *B holmesii* can also be found in nasopharyngeal samples of patients with a symptomatology compatible with whooping cough. Diagnostic PCR kits typically target IS1001 and IS481, which does not distinguish *B. pertussis* from *B. holmesii*. This lack of distinction leads to biases in vaccine efficacy analyzes, as the vaccine does not protect against *B. holmesii*. We investigated the frequency of detection of *B. holmesii* from March to August 2019, in outpatients (93%) and hospitalized patients (7%), following the implementation of PCR assays targeting IS481 and IS1001 but also hIS1001, which allows distinction between *B. holmesii* and *B. pertussis*.

**Materials/methods:** Automated DNA extraction from nasopharyngeal samples was performed on the Janus Chemagic 360 from 1 mL of sample with an elution volume of 100 μL. Automated amplification was performed using a CFX 96 ™ with the Viasure Bordetella kit. The absence of *B. pertussis* DNA in the 10 samples was controlled by the National Reference Center of whooping cough.

**Results:** Of the 7,161 nasopharyngeal samples analyzed, we detected *B. holmesii* in 10 samples, (0.14%), *B. pertussis* in 819 (11.4%) and *B. parapertussis* in 34 (0.47%). No co-infection was identified. The age of patients infected with *B. holmesii* was 24.7 years, whereas mean age was 27.5 and 14.9 years for *B. pertussis* and *B. parapertussis*, respectively. Cases were evenly distributed over time. The geographical origin of the *B. holmesii* cases was Paris, Ile de France outside Paris, South East, Aquitaine, Loire Valley and Great East.

**Conclusions:** *B. holmesii* was rarely found in the population studied, and represented only 2% of *Bordetella* infections among adults and adolescents, consistent with recent reports from Spain, Switzerland, Australia and Japan.

Abstract 1566

A mock-outbreak of carbapenem-resistant *Klebsiella pneumoniae*: using whole genome sequencing to correlate clinical and environmental samples and provide clues to improve infection control in real-time

Alexandra S. Simões*, Tiago Touret†, Nuno Alexandre Faria‡, Susana P. Ladeiro‡, João Costa‡, Ana Bispo‡, Mónica Serrano‡, Carlos Palos§, Maria Miragaia§, Ricardo Leite§, Raquel Sá-Leão†

1Laboratory of Molecular Microbiology of Human Pathogens, Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, 2Laboratory of Bacterial Evolution and Molecular Epidemiology, Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, 3Instituto Gulbenkian da Ciência, Oeiras, Portugal, 4Hospital Beatriz Ângelo, Loures, Portugal, 5Laboratory of Microbial Development, Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal

Background: ONEIDA is a Portuguese consortium of research institutions aiming to collaborate with hospitals to integrate bacterial real-time genotyping based on whole genome sequencing (WGS) to support infection control.

In Portugal, the incidence of nosocomial infections due to carbapenem-resistant *Klebsiella pneumoniae* (CRKP) is increasing exponentially.

We conducted a pilot study to simulate the investigation of a CRKP outbreak in a Portuguese hospital with two main goals: to test the capacity to obtain and interpret WGS data in a short period of time; to evaluate the relevance of concomitant analysis of hospital environmental samples to unveil potential routes of transmission.

Materials/methods: Ten CRKP clinical strains routinely isolated in the hospital microbiology laboratory were provided to simulate an outbreak situation. In parallel, 40 environmental samples (from sinks and sink drains) were obtained from the wards where the infected patients had stayed.

Environmental samples were plated in selective media and pure cultures suggestive of CRKP were isolated. DNA was extracted from clinical and environmental isolates and sequenced (Illumina NextSeq). Genomes were assembled using INNUca v3.1. MLST, cgMLST and antimicrobial resistance were determined using Pathogenwatch.

Results: The first conclusions were obtained within 48 hours: eight clinical samples were confirmed to be CRKP; the other two were *K. aerogenes*. The eight CRKP were of ST13 (n=6, all harboring *bla*<sub>KPC-3</sub>), ST14 (n=1, *bla*<sub>OXA-181</sub>) and ST111 (n=1, *bla*<sub>OXA-181</sub>).*

Results regarding the 40 environmental samples were obtained within six days: half of the samples yielded colonies compatible with CRKP. By WGS, eight were confirmed to be CRKP: five were ST13, one was ST117 and two were ST323. All harbored the *bla*<sub>KPC-3</sub> gene. Environmental CRKP were isolated mostly from sink drains (n=6). Importantly, ten out of the 11 clinical and environmental ST13 CRKP clustered closely together by cgMLST differing from each other in 0-19 alleles (out of 1927 core genes).

Conclusions: This pilot study demonstrated the ability of ONEIDA academic researchers and health care professionals to work closely together to investigate an outbreak in real time. The results further indicate that concomitant environmental sampling is informative to determine transmission routes allowing for rapid implementation of targeted infection control measures.

Transcriptome analysis of pneumococci isolated from meningitis patient’s cerebrospinal fluid identifies multiple genes important for pathogenesis, including a novel operon of unknown function

Emma Cecilia Wall1,2, Jose Guerra-Assunção1, Marie Yang3, Stavros Panagiotou1, Terrawit Audshasai1, Rieza Aprianto4, Elisa Ramos Sevillano1, Vanessa Terra1, Diederik Van De Beek6, Jan-Villem Veening4, David G. Laloo1, Brendan Wren5, Aras Kadioglu3, Rob Heyderman1,2, Jeremy Brown1

1University College London, London, United Kingdom, 2Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, 3University of Liverpool, Liverpool, United Kingdom, 4University of Lausanne, Lausanne, Switzerland, 5London School of Hygiene & Tropical Medicine, London, United Kingdom, 6University of Amsterdam, Amsterdam, Netherlands, 7Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: Pneumococcal meningitis (PM) remains a significant cause of mortality and long-term morbidity, despite antibiotics and corticosteroids. We sequenced the S. pneumoniae transcriptome in patient CSF during PM, to investigate which highly expressed genes are implicated in damaging inflammatory responses.

Materials/methods: CSF from adults with PM was collected prior to antibiotics and stored at -80ºC in PAXgene®. Total RNA was isolated and sequenced after ribodepletion on the Illumina Nextseq platform. Transcripts were mapped against multiple S. pneumoniae genomes, normalised and quantified. The clinical transcriptome was analysed against infection-relevant conditions in the in-vitro D39 transcription model PneumoExpress. Gene-deletion mutant bacteria were generated by targeting selected genes that were highly expressed during PM in a serotype 1 (ST5316) S. pneumoniae meningitis isolate. The mutant phenotypes were investigated using in-vitro models of neutrophil phagocytosis, growth in human CSF (hCSF), and in a murine model of PM.

Results: CSF transcriptomes were available for 11 adults with PM (median age 32 years, 60% male, 70% HIV-1 co-infected, 10/11 non-survivors, median bacterial load 1.6x10⁷ copies/ml CSF (IQR 4.1x10⁶ – 7.0x10⁷)). Transcripts mapping was optimal against Serotype 1 strains (gamPN10373, P1031). Genes with very high expression included multiple genes encoding proteins involved in avoidance of opsonophagocytic killing (BgaA, PsaA, PspC, CiaRH, NanA, ply, pepO, Pbp1A, CbpA) as well as several genes with unknown function. Highly upregulated genes were clustered and tested against a set of in-vitro conditions mimicking different infection models. Clinically expressed genes most closely correlated with S. pneumoniae D39 gene expression in the presence of A549 epithelial cells. Gene deletion mutants were constructed in two highly upregulated genes not previously described to be involved in PM, bgaA (encodes a betagalactosidase) and the operon SP_1800-5 (no previous published data). Neither mutant strain grew in ex-vivo human CSF, opsonophagocytic killing of both mutants was enhanced compared to WT bacteria, murine data pending.

Conclusions: S.pneumoniae expresses multiple virulence proteins in the CNS compartment during meningitis. Expression of an operon with previously unknown function implies that S.pneumoniae may invoke meningitis-specific responses in CSF. Further investigation of the meningitis-specific bacterial response may present novel therapeutic targets for this devastating disease.

Abstract 1569

Effectiveness of chlorhexidine-impregnated dressing and a bundle of interventions for prevention of central line-associated bloodstream infections
Bahar Madran*, Şirin Keske1, Veli Öğuzalp Bakır2, Önder Ergönül3
1American Hospital, Istanbul, Turkey, 2Koc University, Istanbul, Turkey, 3Koç University Hospital, Istanbul, Turkey

Background: The aim of this study was to assess the effectiveness of chlorhexidine-impregnated dressing and bundle practice to reduce the rate of central line associated bloodstream infections (CLABSIs).

Materials/methods: We performed a bundle of interventions to reduce the CLABSIs by the year 2012. As one component of the bundle, we started using the chlorhexidine impregnated catheter dressing. We used a form describing how to apply central venous catheter for the practicing physicians and nurses, and we organized several information meetings. Then we have compared the rate of CLABSI before and after the intervention.

Results: In total 76 CLABSI events were detected between January 1, 2011 and June 31, 2019. Twenty-six cases were detected before the intervention period which was between January 1 2011 and December 31 2011, and 50 cases were detected after the intervention period in seven and a half years (January 1, 2012 and June 31, 2019). Following interventions, the annual CLABSI rate was 2.60/1000 catheter days in pre-intervention period and 0.49/1000 catheter days (p=0.037) in post-intervention period. Additionally, the CLABSI rate among hematology-oncology inpatients decreased from 3.39 to 0.76 (p=0.010) in the same term.

Conclusions: The use of chlorhexidine impregnated dressing and bundle form decreased the rate of CLABSIs significantly. This protocol became the standard of care in our hospital.

Abstract 1571

**Effect of hybrid organo-inorganic sol-gel coating loaded with antifungals on Candida strains**

David Romera¹, John-Jairo Aguilera-Correa¹, Amaya García-Casas², Beatriz Dunia Toirac¹, Antonia Jimenez-Morales², Jaime Esteban-Moreno*¹

¹Fundación Jimenez Diaz University Hospital, Madrid, Spain, ²Universidad Carlos III, Leganés, Spain

Abstract third-party references: Funded by a grant from the Mutua Madrileña Foundation

**Background:** *Candida albicans* and *C. parapsilosis* are the major etiological agents of fungal prosthetic joint infections (PJIs). Although infrequent, these infections are difficult to diagnose and treat and display high recurrence rates. Here we evaluate two sol-gel coatings loaded with fluconazole and anidulafungin in order to treat fungal biofilms formed during PJIs.

**Materials/methods:** A hybrid organo-inorganic sol-gel coating was fabricated from a mixture of two organopolysiloxanes: 3-methacryloxypropyltrimethoxysilane and tetramethoxysilane in a molar ratio of 1:2, and the addition of tris (trimethylsilyl) phosphite in a molar ratio of 52:1 (organopolysiloxanes:phosphorus compound). Control coatings without additions of antifungal (P2) and three coatings loaded with three saturation percentages [50, 75 and 100%] of anidulafungin (A) or fluconazole (F) were used.

Biofilm formation of *C. albicans* ATCC 10231 (Cal ATCC) and *C. parapsilosis* ATCC 22019 (Cpar ATCC) was induced in a 96-well plate using 0.5 McFarland of yeasts in RPMI 1640 + 2% glucose for 48 h. After incubation, medium was renewed and the lid of the plate was replaced by a MBEC™ biofilm Incubator lid whose pegs had been coated a day before by dipping it in wells filled with 200 µL of each treatment, followed by incubation at 37 °C for 48 h. Biofilm viability was determined by adding 10 µl of Alamar Blue per well and measuring the fluorescence after 3 h. Experiments were performed in triplicate. Comparisons of the viability percentage were performed by using t-Student test with a level of statistical significance of 0.05.

**Results:** The presence of P2 was sufficient to produce a significant decrease (between 10-15%) of *C. albicans* ATCC 10231 biofilms, while the addition of antifungal contributed slightly to this effect. P2 alone did not affect biofilm viability of *C. parapsilosis* ATCC 22019 and the presence of antifungal decreased viability by up to 99% in the case of fluconazole.

![Graph A](image1.png) **Figure 1.** Biofilm viability after treatment with fluconazole-loaded (F50, F75, F100) (A) or anidulafungin-loaded (A50, A75, A100) (B) sol-gels. *P<0.05.*

**Conclusions:** The sol-gel coating loaded with antifungals is able to reduce fungal biofilm viability, being a promising tool for locally treating *Candida* PJI.

Abstract 1573

Prevalence and outcome of ampicillin-susceptible but penicillin-resistant Enterococcus faecalis bacteraemia: a multi-centre retrospective study

Elena Rosselli Del Turco1, Michele Bartoletti1, Sulamita Carvalho Brugger2, Simone Ambretti3, Merce Garcia4, Maddalena Giannella1, Renato Pascale1, Luigi Raumer1, Pierluigi Viale1, Juan Manuel Pericàs Pulido5

1Alma Mater Studiorum - Università di Bologna, Infectious Disease Unit – Department of Medical and Surgical Sciences, Bologna, Italy, 2IRB Lleida, Critical Care Division - Clinical Direction on Infectious Diseases and Clinical Microbiology, Lleida, Spain, 3S. Orsola-Malpighi University Hospital, Operative Unit of Clinical Microbiology, Bologna, Italy, 4IRB Lleida, Microbiology Department - Clinical Direction on Infectious Diseases and Clinical Microbiology, Lleida, Spain, 5IRB Lleida, Infectious Diseases - Clinical Direction on Infectious Diseases and Clinical Microbiology, Lleida, Spain

Background: Ampicillin-susceptible but penicillin-resistant Enterococcus faecalis (PRASEF) strains have been recently related to higher mortality in enterococcal bacteremia. The primary purpose of this study was to assess the prevalence and outcome of PRASEF bacteremia.

Materials/methods: This observational, retrospective, multicenter study was conducted between January 2010 and July 2019 in two Italian and one Spanish hospital. All hospitalized patients with monomicrobial bacteremia caused by ampicillin-susceptible E. faecalis were enrolled. Penicillin-susceptibility was defined based on CLSI criteria. Primary endpoint was clinical failure, defined as composite outcome consisting of a) modification of antibiotic therapy due to lack of efficacy, b) relapse, endocarditis or mortality within 90 days from the index blood culture.

Results: Study population consisted of 204 patients: median age was 73 years (IQR 60-81), 69% of the patients were male and median Charlson comorbidity index was 10 (IQR 10-12). Main bacteremia sources were urinary tract (32%), primary (29%), and gastro-intestinal tract (18%). PRASEF were observed in 28 (14%) cases. There were no differences in terms of demographics, source and severity of bacteremia among PRASEF and non-PRASEF groups. Median (IQR) length of hospitalization was significantly longer [18 (9-31) vs 28 (13-45), p 0.02] in PRASEF vs. non-PRASEF groups. Clinical failure occurred in 61% and 37% of patients in the two groups (p 0.033), respectively. Mortality at 90 days was also significantly higher in the PRASEF population (46% vs 26%, p 0.004). No differences were found among the other elements of composite outcome. Multivariate logistic regression analysis adjusted for Charlson comorbidity index, diabetes, sepsis or septic shock, isolation of PRASEF, immunosuppression, source of bacteremia, showed that isolation of PRASEF [OR 2.46 (95% CI 1.04-5.81) p 0.04], Charlson comorbidity index [OR 1.143 (95% CI 1.05-1.23) p 0.001], and sepsis or septic shock [OR 2.84 (95% CI 1.32-6.09) p 0.007] were independent risk factors for clinical failure.

Conclusions: Our study confirms the unfavorable outcome of bacteremia due to PRASEF strains and emphasizes the need for a timely evaluation of minimum Inhibitory concentrations [MICs] for penicillin and ampicillin. Further studies are needed in order to assess ad hoc therapeutic regimens for this peculiar resistance phenotype.

Abstract 1574

**Nontoxicogenic Clostridioides difficile strains against C. difficile colonisation: an experimental study**

Jeanne Couturier*1,2, Léa Franconeri2, Claire Janoir3, Laurent Ferraris2, Sandra Hoys1, Julio Aires2, Frédéric Barbut1,2

1Hôpital Saint-Antoine, Centre National de Référence «Clostridium difficile», Paris, France, 2Université Paris Descartes, Faculté de Pharmacie de Paris, INSERM UMR S-1139, Paris, France, 3Université Paris-Sud, Université Paris-Saclay, Unité Bactéries Pathogènes et Santé [UBaPS, EA 7359], Châtenay-Malabry, France

**Background:** Nontoxicogenic *Clostridioides difficile* strains (NTCD) are non-pathogenic and cannot acquire the toxin A and B genes. Their role in preventing *C. difficile* recurrence was demonstrated among hospitalized patients (Gerding et al., JAMA 313(17):1719-1727).

In a previous study we described a high *C. difficile* intestinal colonization rate of preterm neonates, mostly due to two NTCD. We hypothesized that these strains could be protective against *C. difficile* colonization and conducted an *in vivo* experiment in a hamster caecitis model to determine their potential protective role.

**Materials/methods:** 40 hamsters were treated by clindamycin to induce an intestinal dysbiosis (D-5). They were divided into 5 groups: 1 positive control group (n=8, A) was infected only by a toxigenic strain (PCR-ribotype 027), 2 groups (n=7, B and C) were administered only one NTCD each, and 2 groups (n=9, D and E) were administered one NTCD each (D-3), followed by the 027 strain (D0). Animals were daily monitored for 19 days (clinical activity score and weight). Stool colonization was determined from D-1 until death or sacrifice. After sacrifice (if euthanasia criteria were met or at D19), caeca were collected for histological analysis.

**Results:** All animals (8/8) in group A died within 2 days. The survival rate was significantly increased in groups D (4/9 deaths, p=0.029) and E (1/9 death, p=0.0004). The mean colonization rate of the toxigenic strain in the group A was 1.6x10⁷ CFU/g of stool, and was equivalent in the other groups. At D2, the colonization rate of NTCD in groups B, C, D and E was 2.3x10⁷, 2.4x10⁷, 1.5x10⁸ and 6.2x10⁷, respectively. In the group D, the toxigenic strain was steadily detectable at a lower rate in 4 animals [10⁶-10⁸ CFU/g], whereas in the group E, only 2 animals were colonized and only at D2. Histological analysis of the caeca revealed that co-infected animals with no clinical signs had no tissular alterations.

**Conclusions:** Both NTCD provide a potential protection against *C. difficile* colonisation. *In vitro* studies and genome analysis are ongoing to try to elucidate the protective mechanisms.

Abstract third-party references: BITRECS, IDIBAPS, Barcelona, Spain, CIBERES, Madrid, Spain, Merck & Co, Kenilworth, NJ, USA

Background: Nosocomial pneumonia is one of the most common hospital-acquired infections, associated with high morbidity and mortality. Gram-negative pathogens, particularly Pseudomonas aeruginosa, cause life-threatening infections specifically in hospital settings. Ceftolozane/tazobactam (C/T) is a novel antibiotic with activity against multidrug resistant (MDR) P. aeruginosa but still not fully characterized against other first-line antibiotics for nosocomial pneumonia.

Materials/methods: Twenty-one pigs (32.9±1.7 kg) were anesthetized and mechanically ventilated up to 76h. Severe pneumonia was developed by intra-bronchial inoculation of a clinical P. aeruginosa, intermediate to piperacillin/tazobactam (TZP) but susceptible to C/T. Following clinical pneumonia diagnosis, animals were randomly assigned into three groups: placebo (control), 50/25 mg/kg C/T and 200/25 mg/kg TZP. Antibiotic doses had previously been humanized. Ceftriaxone was administered to avert endogenous colonization. Inflammatory markers were measured throughout the study. P. aeruginosa was cultured in tracheal secretions and bronchoalveolar lavage (BAL) fluid and development of antibiotic resistance compared among groups. Upon autopsy, P. aeruginosa was cultured in lungs and histopathology injury scored.

Results: Development of pneumonia and treatment substantially affected systemic cytokines. In particular, IL-1β was significantly downregulated by C/T and returned to baseline levels after 48h of treatment, in comparison with control and TZP animals (p=0.031). Bacterial burden in tracheal secretions and BAL fluids varied among study groups (p<0.001) and times of assessments (p<0.001) [Figure 1A-B]. Specifically, C/T-treated animals achieved the greater eradication in both matrices. In contrast, P. aeruginosa burden in lung tissue was 5.30[4.00-6.30], 4.04[3.64-4.51], and 4.04[3.05-4.88] CFU/g in the control, C/T, and TZP groups, respectively (p=0.299), without histopathological differences (p=0.556) [Figure 1C-D]. An increase in resistance to TZP was found in 3 animals.

Conclusions: In a swine model of MDR P. aeruginosa severe pneumonia, C/T decreased respiratory secretions’ bacterial burden, while averting development of resistance and possibly reducing systemic inflammation. Yet, after only 2 days of treatment, P. aeruginosa tissue concentrations were moderately affected.

Abstract third-party references: This work was supported by Plan Nacional de I+D+i 2013-2016 and Instituto de Salud Carlos III, Subdirección General de Redes y Centros de Investigación Cooperativa, Ministerio de Ciencia, Innovación y Universidades, Spanish Network for Research in Infectious Diseases [REIPI R016/0016/0008; R016/0016/0001, R016/0016/0002, R016/0016/00010] - co-financed by European Development Regional Fund “A way to achieve Europe”, Operative program Intelligent Growth 2014-2020, ESCMID Study Group for Infections in Compromised Hosts [ESGICH grant to J.M.A.]; Sociedad Andaluza de Trasplante de Órgano Sólido [SATOT grant to L.M.M.]; ESCMID Study Group for Bloodstream Infections and Sepsis [ESGBIS]; and ESCMID Study Group for Antimicrobial Resistance Surveillance [ESGARS].
Background: Urinary tract infection (UTI) is the most common source of bloodstream infection (BSI) in kidney transplant recipients (KTR). Episodes caused by extended-spectrum β-lactamase-producing Enterobacterales (ESBL-E) are particularly frequent in these patients. We sought to evaluate risk factors for therapeutic failure and examine the impact of regimens based on carbapenems versus β-lactam/β-lactamase inhibitors (BLBLI) in a large multinational cohort of KTR diagnosed with BSI secondary to UTI.

Materials/methods: We retrospectively evaluated 306 KTR with BSI secondary to UTI caused by ESBL-E, admitted to 30 centers from January 2014 to October 2016 (INCREMENT-SOT, ClinicalTrials.gov NCT02852902). Therapeutic failure [lack of cure or clinical improvement and/or death from any cause] at days 7 and 30 from BSI onset were primary and secondary study outcomes, respectively. Univariate and multivariate logistic regression models were applied to identify factors predicting therapeutic failure. A propensity score (PS) was used to control the therapy indication bias.

Results: Carbapenem monotherapy (68.6%, primarily meropenem) was the most frequent active therapy used, followed by BLBLI monotherapy (10.8%, mostly piperacillin-tazobactam). Therapeutic failure at day 7 was 9.0% (13.8% at day 30) with carbapenems and 3.0% (9.1% at day 30) with BLBLI. Mortality at days 7 and 30 was 1% and 3%, respectively. Hospital-acquired BSI [adjusted OR (aOR): 3.89; 95% CI: 1.41-10.76] and Pitt bacteremia score at BSI onset [aOR: 1.53; 95%CI: 1.24-1.88] were independently associated with therapeutic failure at day 7. Age-adjusted Charlson Index [aOR: 1.25; 95%CI: 1.05-1.48], Pitt score [aOR: 1.72; 95%CI: 1.35-2.17] and lymphocyte count ≤500 cells/μL at presentation [aOR: 3.16; 95%CI: 1.42-7.06] were independently associated with therapeutic failure at day 30. In PS-adjusted analysis, BLBLI could not be found to be associated with increased risk of failure at day 7 or 30 (PS-adjusted OR: 0.79; 95%CI: 0.23-2.64 and PS-adjusted OR: 0.64; 95%CI: 0.23-1.77, respectively).

Conclusions: Significant differences in the risk of therapeutic failure at 7 and 30 days, according to the use of active therapy with BLBLI versus carbapenem-containing regimens, could not be identified in this large multinational cohort of KTR diagnosed with BSI secondary to UTI due to ESBL-E.

Abstract 1578

Aspirin reduces cardiovascular events in patients with pneumonia: a prior events rate ratio analysis in a large primary care database

Fergus Hamilton*, David Arnold¹, William Henley², Rupert Payne¹

¹University of Bristol, Bristol, United Kingdom, ²University of Exeter, Exeter, United Kingdom

Abstract third-party references: NIHR, NIHR HPRU

Background: Ischaemic stroke and myocardial infarction are common after pneumonia, and are associated with mortality. Aspirin may attenuate this risk, leading to significant reduction in post-pneumonia complications. Limited evidence from secondary care suggests that aspirin may have a beneficial effect, but studies so far have been small, and none have focussed on primary care.

Materials/methods: A prior event rate ratio (PERR) analysis, performed in the Clinical Practice Research Datalink (CPRD), a large UK primary care database, from inception until January 2019, linked to Office for National Statistics (ONS) mortality data. All patients over 50 with a coded diagnosis of pneumonia and adequate data quality, with follow-up data for at least one year after pneumonia, were included. The study period covered from one year before to 6 months after the pneumonia date. The PERR approach allows for control of measured and unmeasured confounding, as the ratio of events prior to and after a given event is considered, and each participant is a self-control. Diabetes, smoking, hypertension, previous cardiac and cerebral ischaemic events, age, gender, and socioeconomic deprivation were included as covariates. Time-to-event analysis was performed. The primary outcome was the combined outcome of ischaemic stroke and myocardial infarction. Secondary outcomes were ischaemic stroke and myocardial infarction individually.

Results: 48,260 patients were included in the final analysis. 8,099 of these were aspirin users, with 35,197 non-aspirin users, and 4,964 patients censored for intermittent aspirin use. Despite being older and more comorbid, aspirin users had a reduced risk of the primary outcome (adjusted hazard ratio, HR 0.68; 95% confidence interval 0.55 - 0.83) in the PERR analysis. For both secondary outcomes, aspirin use was also associated with a reduced risk (HR 0.52 (0.34 – 0.77) and 0.7 1 (0.55 – 0.94) for myocardial infarction and stroke respectively).

Conclusions: Aspirin use is strongly associated with reduced ischaemic events after pneumonia, in a primary care setting. Further work should explore the prophylactic benefits of aspirin prescription in pneumonia, in a prospective, randomised fashion.

Abstract 1580

Optimising the use of triazole therapeutic drug monitoring using quality improvement methodology

Richard Wilson*1, Frances Davies1, Renuka Palanicawandar1, Katie Mcdonough2, Meg Coleman1, Jim Woo1, Charlie Parkinson1, Laura Whitney1, Mark Gilchrist1

1Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Posaconazole and voriconazole are triazole antifungals indicated for prophylaxis and treatment of mycotic infections. Therapeutic drug monitoring (TDM) and individualised dosing are recommended to ensure clinical efficacy and prevent toxicity. Local audit data revealed 38% (n=8) of haematology inpatients administered triazoles received TDM at our tertiary London hospital. We undertook a Quality Improvement (QI) project to optimise triazole TDM.

Materials/methods: Haematology inpatients administered posaconazole or voriconazole were identified retrospectively from pharmacy dispensing records to calculate baseline TDM compliance over 16 weeks. Compliance was calculated by dividing the number of patients who received TDM by the number of patients eligible for TDM based on local guidelines: 1) 3-7 days post-treatment initiation, 2) repeated week 2, and 3) repeated every 4 weeks. Therapeutic ranges were taken from ESCMID guidelines (Ullman et al. Clin Microbiol Infect; 2018).

QI methodology was used to improve compliance with Trust guidelines. This included the development of a driver diagram and questionnaire to identify barriers to conducting TDM appropriately. Interventions were designed to prompt TDM when indicated.

- Intervention 1 (week 17): a pharmacist prospectively identified patients on triazoles from the electronic prescribing system (Cerner PowerChart) for discussion on a joint infection-haematology ward round. Additionally, a text reminder was built into Cerner.
- Intervention 2 (week 27): patients requiring TDM were sent directly to the haematology consultant.

Results: 111 encounters (n=38 patients) were prospectively reviewed over the course of 16 weeks. 51 levels were taken out of 87 recommended (59%). Subtherapeutic levels (n=13) and potentially toxic levels (n=4) were managed by dose adjustment (n=10). Remaining deviations were managed with repeat levels or alternative treatment.

Following the first intervention, compliance remained above the mean, demonstrating a shift (figure 1). Mean compliance was recalculated at almost three-times baseline (24% to 65%).

Conclusions: This QI project has improved appropriate use of TDM. Future work will focus on expanding to outpatient areas and other specialties such as respiratory medicine. Pharmacist-led TDM clinics incorporating other tests (e.g. liver function) could be used to ensure outpatients are effectively monitored and doses optimised.

Abstract 1581

The difficulties of differentiating central nervous system infection from disease relapse in a cohort of adult patients with haematological malignancy: 10 years’ experience from a central London hospital

Emma Lim1, Roshina Gnanadurai1, Michelle Escobedo-Cousin1, Lucy Bell*1, Naina McCann1, Jayne Ellis1, Damien Ming1, Kate Cwynarski1, Robert F. Miller1,2, Emma Cecilia Wall1,2, Rob Heyderman1, Harpreet Hyare1

1University College Hospital, London, United Kingdom, 2University College London, London, United Kingdom

Background: CNS infections occur in up to 15% of patients with haematological malignancy undergoing allogenic haemopoetic stem cell transplant (HSCT). Delays to identification of causative pathogens may contribute to worse outcomes, however diagnostic samples can be difficult to obtain. We sought to describe MRI head (MRH) features seen in a cohort of adult patients with haematological malignancy in who CNS infection was suspected.

Materials/methods: We undertook a retrospective case review of patients with haematological malignancy undergoing MRH for suspected CNS infection between 2007-2017. Cases were identified through electronic MRH database using a text search. MRI images were classified according to anatomical disease, reports divided into either high or low/equivocal suspicion of CNS infection by two radiologists (unaware of the final diagnosis). Laboratory and clinical records were subsequently searched for definitive diagnostic data.

Results: 5887 MRH scans were identified, 1855 in patients with haematological malignancy, of which 147 were for suspected CNS infection. After duplicate scan removal, 110 patients were included. Median age 52 years (13-81), 51% were female, 81% were inpatients. 50% were <12 months post bone marrow transplant (BMT) including allo-HSCT. Leukaemia (46%) and lymphoma (44%) predominated. 20/20 (100%) of extra-dural lesions were caused by disease relapse, other anatomical patterns were equally split between infection and relapse. Of 31 patients with MRH reports of high clinical suspicion of infection on MRH, 24/31 (77%) had proven infection, the remainder had tissue diagnosis of disease relapse or no cause found. Of those with low/equivocal suspicion of infection on MRH, seven had subsequently proven infection. CNS infection was diagnosed in 30 (26%) patients, disease relapse in 15 (14%) and alternative diagnosis/no cause found in 65 (59%). Of patients with proven CNS infection, viruses were identified in 15/30 (50%) (CMV 7/15, HSV 1, JC 3 and HHV6 4), bacteria and fungi were rare (6). Patients with CNS infection more frequently presented within 12 months of BMT (50%) than those with disease relapse (20%).

Conclusions: Reported imaging finding on MRH are relatively non-specific in patients with subsequently proven CNS infection. Multi-centre prospective data are required to confirm these findings and inform treatment guidelines.

Abstract 1583

**Evaluation of the filmarray GI panel in the microbiological diagnosis and management of the patient with infectious gastroenteritis**

Javier Parra Martínez, Rafael Carranza González*, María Jesús Castano Aroca, Verónica Solves Ferriz, Francisco Ferrer Amate, Caridad Sáinz De Baranda Camino

1University General Hospital, Albacete, Spain

**Background:** To evaluate the usefulness of a molecular diagnostic panel for the diagnosis and management of patients with gastrointestinal infections.

**Materials/methods:** Retrospective observational study of molecular panels for syndromic diagnosis of infectious gastroenteritis (GEI) Filmarray™ GI Panel, Biofire diagnostics (Biomérieux) conducted from January to October 2019. The results of the traditional microbiological techniques and variables obtained from the clinical history were also reviewed.

**Results:** RT-CRP was performed on 54 non-shaped feces, one sample per patient. The age range was from 10 months to 92 years with a median of 33.30 years. Thirty of them were men and 24 women. Cultures were performed in 94% of the cases, viral antigens in 50%, parasites in 26% and *Clostridioides difficile* toxins in 48%. The indications for requesting the microarray were the severity of the condition (invasive diarrhea and/or dehydration) in 50% of the cases, base immunosuppression in 30%, travel history in the previous week in 7% and others in 13%.

The panel was negative in 57% of cases, detected *Campylobacter sp* in 21%, *C. difficile* toxin in 8%, *Salmonella sp* 4% and other enteropathogens (8%). Seven coinfections were detected by the molecular panel (13%) and none by traditional techniques.

There was an agreement between the results of the microarray and traditional microbiological methods in 84% of cases (kappa 0.687).

**Table 1: Distribution of positive tests by classical techniques and by CRP**

<table>

</tr>
</tbody>
</table>

* CRP was performed in all cases (54) but traditional tests only when expressly requested under clinical criteria (the table reflects the total of tests of each type performed)

There was a therapeutic modification in 63% of the cases in which the panel was requested due to the severity of the diarrhea, in 54% of the cases in which the CRP was performed due to travel history, in 40% when the cause was immunosuppression and when the cause was unknown, no therapeutic change was assumed.

The filmarray results had an average delay of 1 hour vs an average of the traditional techniques of 26 hours (range: 2-72).

**Conclusions:** The agreement between traditional techniques and CRP is substantial (kappa 0.6) although it is far from perfect. The average time saved by CRP, its greater range of potential diagnoses per test and the possibility of detecting coinfections can allow effective and faster clinical decisions.

Abstract 1587

The pharmacodynamics of omadacycline against Escherichia coli and Acinetobacter baumannii studied in an in vitro pharmacokinetic model of infection

Alan Noel1, Marie Attwood2, Karen E. Bowker2, Alasdair P. Macgowan*2

1 North Bristol NHS Trust, BCARE, Bristol, United Kingdom, 2 North Bristol NHS Trust, BCARE, Bristol, United Kingdom

Abstract third-party references: North Bristol NHS Trust

Background: Omadacycline (OMC) is a broad spectrum aminomethylcycline tetracycline antimicrobial. OMC is approved for clinical use by the US FDA in community-acquired bacterial pneumonia and skin and skin structure infections as intravenous and oral formulations. The pharmacodynamics (PD) of OMC have been extensively studied against Gram-positive pathogens but less information is available for Gram-negatives. Here we describe the pre-clinical PD of OMC against E. coli and A. baumannii.

Materials/methods: An in vitro dilutional single compartment PK model was used. Exposure ranging experiments - freedrug Area Under Curve to MIC ratio (fAUC/MIC) 0-1200 were performed. Five strains of E. coli and 5 strains of A. baumannii were used. In addition, time-kill curves were conducted with a single strain of either E. coli or A. baumannii over a concentration range 0-80 mg/L OMC. 2% oxyrase was added to broth to stabilise OMC. The primary endpoint was - log change in viable count at 24h.

Results: E. coli OMC MICs ranged from 0.25-2 mg/L and A. baumannii OMC MICs ranged from 0.5-1 mg/L. In time-kill experiments with both E. coli and A. baumannii, OMC showed concentration dependant killing up to 80 mg/L: OMC was less bactericidal against A. baumannii than E. coli. The fAUC/MIC for 24h static, -1 log and -2 log reduction in E. coli bacterial load were 22.5±15.9, 38.1±28.3 and 83.6±64.4. For A. baumannii the fAUC/MIC for 24hr static and -1 log drop in bacterial load were 108.1±38.6 and 266.3±27.1. Emergence of resistance was observed with both E. coli and A. baumannii strains. OMC MICs of strains recovered at the end of 24-48h exposure to OMC were increased 2-32 fold.

Conclusions: The size of the OMC fAUC/MIC for static effect against E. coli is in alignment with published in vivo data from a murine thigh infection model. fAUC/MIC targets are higher for A. baumannii than E. coli. These OMC fAUC/MIC targets may be useful for translational modelling of possible OMC doses for therapy of these Gram-negative pathogens.

Abstract 1591

Rathmes Giulia*1, Susan Rumisha1, Tim C.D. Lucas1, Kathrine A. Twohig1, Andre Nguyen1, Anita K. Nandi1, Suzanne H. Keddie1, Jennifer A. Rozier1, Kathrine E. Battle1, Peter W. Gething1, Daniel J. Weiss1

1University of Oxford, Malaria Atlas Project, Oxford, United Kingdom

**Abstract third-party references:** Malaria Atlas Project [MAP]

**Background:** Monitoring spatiotemporal variation in antimalarial drug efficacy and effectiveness is of importance to understand and sustain the gains in reducing malaria burden globally. Therapeutic efficacy studies (TES) are the gold-standard for measuring drug efficacy and appropriate for characterizing global variations. This study utilizes data from 232 TES comprised of 89,713 individuals to estimate the effectiveness of artemisinin-based and non-artemisinin-based antimalarials in malaria-endemic countries between 1991 and 2019.

**Materials/methods:** Bayesian spatiotemporal models were fitted separately for the artemisinin-based and non-artemisinin-based antimalarial drugs, and used to predict effectiveness at the pixel-level [5km x 5km]. Median and interquartile range (IQR) of the effectiveness are presented.

**Results:** The global effectiveness levels of artemisinin-based antimalarials were high: 87.3% (IQR: 75.4-93.9) in 1994 and 94.6% (IQR: 89.2-97.4) in 2019. However, country-to-country variations exist. In Africa, the Democratic Republic of the Congo, Republic of Congo, Uganda, and parts of the Central African Republic face challenges of relatively low effectiveness. In Asia, effectiveness of these drugs remained >90% for an extended period. However, effectiveness fluctuations were observed from the mid-1990s to 2008/2009 with Cambodia, Malaysia, and Indonesia being the most affected countries. Use of artemisinin-based combination therapies (ACTs) with a competent partner drug and having multiple ACTs as first-line treatment were associated with sustained high levels of effectiveness. High levels of access to healthcare, human resource capacity, education, and proximity to cities were associated with increased effectiveness. Global effectiveness of non-artemisinin drugs remained low over time, 69.9% (IQR:48.5-89.3) in 1994 and 71.6% (IQR: 57.9-91.5) in 2019. These drugs are not effective in several Sub Saharan African countries and Asia but remained effective in Central and South America.

**Conclusions:** This study provides evidence that ACTs are effective for treating uncomplicated *Plasmodium falciparum* malaria. Other antimalarial drugs such as chloroquine and sulphadoxine-pyrimethamine remain useful for *P. falciparum* malaria in only a few locations. Low effectiveness is driven by type of drug, health system performance and climate factors. These results are useful to guide countries’ treatment policies and as critical inputs for malaria prevalence and incidence models utilized to estimate national levels of malaria burden.

Background: Surveillance cultures (SC) are routinely used to screen multidrug resistant microorganisms (MDR). The purpose of this study was to evaluate the epidemiological and molecular aspects between events of colonization and healthcare-associated infection (HAI) caused by the same MDR in critically ill patients.

Materials/methods: Study was performed in two ICUs (clinical and surgical) of a public tertiary hospital between January 2016 and May 2018. All patients had SC collected for institution of contact precautions in positive cases of MDR. The healthcare associated infections are notified according to CDC criteria. The bacterial identification was performed using mass spectrometry and the minimal inhibitory concentration of antibiotics was determined using the Vitek 2 System. The detection of the carbapenemases, VanA and VanB genes were determined by real time PCR and the genetic relatedness of the strains were characterized by Pulsed-Field Gel Electrophoresis (PFGE) only for available strains at the time.

Results: Thirty six patients colonized by MDR developed HAI by MDR, the mean between MDR colonization and HAI was 2.19 days. The most prevalent HAI was central line-associated bloodstream infections (CLABSI) in clinical ICU and surgical site infection (SSI) in surgical ICU. Twenty eight HAI episodes were caused by the same colonizing bacteria with identical antimicrobial susceptibility profile (ASP) (Table 1), 14 episodes could be analyzed by PFGE and the concordance rate was 100%. Other eight HAI episodes were caused by non-concordant MDR.

Conclusions: MDR colonization prevention measures are essential and must be performed prior to colonization in critically ill patients. The presence of colonization should be valued by the clinician to an appropriate choice of initial empirical therapy and stewardship in critically ill patients.

Abstract 1594

Ceftobiprole compared with vancomycin plus aztreonam in the treatment of acute bacterial skin and skin-structure infections: results of a phase III, randomised, double-blind trial (TARGET)

J. Scott Overcash1, Charles Kim2, Richard Keech3, Ilia Gumenchuk4, Borislav Ninov5, Yaneicy Gonzalez-Rojas6, Michael Waters7, Simeon Simeonov7, Marc Engelhardt5, Mikaël Saulay8, Daniel Ionescu8, Jennifer Smart8, Mark Jones8, Kamal Hamed8

Abstract third-party references: Supported by Basilea, Submitted on behalf of J. Scott Overcash and co-authors

Background: The development of novel, broad-spectrum antibiotics with efficacy against both Gram-positive and Gram-negative bacteria has the potential to enhance treatment options for acute bacterial skin and skin structure infections (ABSSSI). Ceftobiprole, the active moiety of the prodrug ceftobiprole medocaril, is an advanced-generation cephalosporin with broad in vitro activity against Gram-positive (including methicillin-resistant Staphylococcus aureus) and Gram-negative pathogens, and is approved in many European and several non-European countries for the treatment of pneumonia. The present study (TARGET) evaluated the utility of ceftobiprole in patients with ABSSSIs.

Materials/methods: TARGET was a randomised, double-blind, active-controlled, parallel-group, multicentre, phase 3, non-inferiority study that compared ceftobiprole with vancomycin plus aztreonam (NCT03137123). Main efficacy endpoints were: early clinical response 48–72 hours after therapy initiation ≥20% reduction in primary lesion area, survival, no concomitant antibacterials, and no unplanned ABSSSI surgery; and investigator-assessed clinical success [complete or near complete resolution of baseline signs and symptoms, with no further antibacterial treatment] at the test-of-cure (TOC) visit 15–22 days after randomisation. Non-inferiority was defined as the lower limit of the 95% confidence interval for the difference in success rates [ceftobiprole minus vancomycin/aztreonam] >10%. Safety was also assessed through adverse event and laboratory data collection.

Results: 679 patients were randomised to ceftobiprole (n=335) or vancomycin/aztreonam (n=344), of whom 676 received ≥1 dose of study medication. Median treatment duration was 6.0 and 7.0 days, respectively, with a median duration of 3.0 days for aztreonam in the comparator group. Main efficacy endpoint results are shown in the figure. Documented or presumed microbiological eradication rates at the TOC visit were similar between treatment arms [90.2% vs 86.6%]. The proportion of patients experiencing ≥1 treatment-related adverse events [n [%]: 66 [19.8%] vs 62 [18.1%]) was also similar between treatment arms. Treatment-related serious adverse events were uncommon, reported in only 1 and 2 patients in the ceftobiprole and vancomycin/aztreonam arms, respectively.

Conclusions: TARGET demonstrated that ceftobiprole is non-inferior to vancomycin/aztreonam in the treatment of ABSSSIs, both in terms of early clinical response and investigator-assessed clinical success at the TOC visit. Both treatment arms displayed similar microbiologic success and had similar safety profiles.

Figure: Main efficacy endpoint analyses

Abbreviations: CE, clinically evaluable; CI, confidence interval; ITT, intention-to-treat

*Proportion differences (95% CI) (ceftobiprole minus vancomycin/aztreonam) were computed using the Cochran–Mantel–Haenzel weights method adjusted for geographical region and actual type of ABSSSI.

1Secondary endpoint. The objective for the FDA-defined primary endpoint was based on a non-inferiority assessment of the ITT population only. The EMA-defined primary endpoint was based on a non-inferiority assessment in both the ITT and CE populations.
Routine use of whole genome sequencing for Salmonella Enteritidis surveillance in the Netherlands in 2019

Maaike J.C. Van Den Beld*1, Roan Pijnacker1, Anjo Verbruggen1, Kim Van Der Zwaluw1, Sjoerd Kuiling1, Eelco Franz1

1National Institute for Public Health and Environment, Bilthoven, Netherlands

In the Netherlands, national laboratory surveillance for Salmonella Enteritidis was based on conventional serotyping and Multi Locus Variable Number Tandem Repeat Analysis (MLVA). In January 2019, whole genome sequencing (WGS) was implemented as routine typing method for S. Enteritidis. Here we describe the relation between WGS-based cluster detection and MLVA types, and the presence of genetic and phenotypic β-lactamase resistance in S. Enteritidis isolates from Dutch national surveillance in 2019.

Submitted Salmonella isolates were serotyped using Luminex and conventional methods, minimum inhibitory concentrations (MIC) for antibiotics were determined on a selection of isolates. For those serotyped as S. Enteritidis, MLVA type was determined and WGS was performed using Illumina technology. An in-house pipeline based on SPAdes 3.10.0 was used for quality control, trimming and de novo assembly. Detection of resistance genes was performed using the bacterial analysis pipeline of the Center for Genomic Epidemiology. WGS Clustering was investigated with core genome multi-locus sequence type (cgMLST) using the Enterobase S. enterica cgMLST V2 scheme.

From January until October 2019, 1,171 Salmonella isolates were received, of which 399 S. Enteritidis (35%). A total of 377 isolates were from unique patients, resulting in 349 sequences (93%) of good quality. A β-lactamase gene was detected in 45 S. Enteritidis isolates (13%), in one isolate coding for extended spectrum β-lactamase. For 35 of these isolates the MIC for ampicillin was determined, for which 29 (83%) were phenotypically resistant according to EUCAST breakpoints. Using a threshold of five alleles distance in cgMLST, 43 clusters of ≥ 2 isolates were detected, containing a total of 254 isolates (73%). With MLVA, 60 types were found comprising 23 clusters of ≥ 2 isolates, 312 isolates (89%) were part of these clusters. Using WGS, clusters ranged from 2-36 isolates, and 15 clusters (35%) contained multiple MLVA types ranging from two to five types within the same cluster.

WGS showed a higher discriminatory power than MLVA. This is especially important during outbreak investigation to avoid misclassification of outbreak-related cases. Moreover, WGS allows us to monitor resistance and virulence genes.

Abstract 1599

High levels of resistance to recommended antimicrobial agents in *Pseudomonas aeruginosa* from patients with bronchiectasis

Roberto Cabrera*, Laia Fernandez Barat1, Nil Vázquez Burgos1, Ruben López-Aladid1, Victoria Alcaraz1, Leticia Bueno1, Rosanel Amaro1, Patricia Elena Oscanos1, Laura Muñoz1, Antoni Torres1

1Hospital Clínic de Barcelona, Barcelona, Spain

**Background:** Non-cystic fibrosis bronchiectasis (BE) is a chronic structural lung condition that facilitates chronic colonization by different microorganisms and courses with frequent exacerbations and recurrent infections. One of the main pathogens involved in chronic colonization and acute exacerbations is *Pseudomonas aeruginosa*. When not eradicated during early infection *P. aeruginosa* can accumulate high rates of resistance to the most antipseudomonal agents.

**Materials/methods:** A prospective observational study was carried out in Hospital Clinic. A total of 44 strains of *Pseudomonas aeruginosa* were isolated and characterized from sputum of BE patients. The antimicrobial susceptibility to: Aztreonam, ciprofloxacin, meropenem, imipenem, amikacin, tobramycin, pipertaz, ceftazidime and colistin was performed using the Kirby-Bauer method with the ATCC 27853 strain as a control. Interpretation of results was carried out according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST). Molecular characterization of each resistance mechanism was screened by PCR, electrophoresis in 2% agarose gels and sequencing.

**Results:** The frequency of *Pseudomonas aeruginosa* resistant isolates was: Aztreonam (68,18%), ciprofloxacin (45,45%), meropenem (31,81%), imipenem (31,81%), amikacin (20,45%), tobramycin (20,45%), pipertaz (11,36%), ceftazidime (11,36%) and colistin (2,27%). The strains showed different antimicrobial profiles: PS (9,09%), MR (6,1,37%), MDR (20,45%) and XDR (9,09%). Mutations in *gyrA*, *gyrB*, *ParC* and *ParE* genes were found in ciprofloxacin resistant *P. aeruginosa* strains. The most frequent mutation in *gyrA* was A33G, in *gyrB* S466F, in *ParC* S87W and in *ParE* D539E. Our study showed that a higher number of mutated genes was related to the increased of MIC in the ORDR. The presence of different β-lactamases was detected: *oxa50* (95,45%), *ges* (90,74%), *imi* (23,8%), *gim* (4,76%) and *sim* (4,76%), in the strains resistant to β-lactams. The *aac(3)*-la, *aac(3)*-lc, *aac(6'')*-Ib and *ant(2'')*-la genes were related to aminoglycoside resistance.

**Conclusions:** the high level of resistance to first-line antimicrobials recommended in BE guidelines and the great diversity of mechanisms of resistance found, threatens the treatment of BE and the eradication of *P. aeruginosa*.

Abstract 1603

In vitro Activities of ceftazidime-avibactam and comparator agents against Enterobacterales and Pseudomonas aeruginosa from Turkey collected through the ATLAS global surveillance programme 2013-2018

Samantha Pacha1, Meredith Hackel*1, Greg Stone2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

Background: Avibactam (AVI) is a non-β-lactam, β-lactamase inhibitor that can restore the activity of ceftazidime (CAZ) against organisms that possess Class A, C, and some Class D enzymes. This study examined the in vitro activity of CAZ-AVI and comparators against Enterobacterales and Pseudomonas aeruginosa collected in Turkey through the ATLAS global surveillance program from 2013 to 2018.

Materials/methods: A total of 2,205 non-duplicate, clinically isolated Enterobacterales and 567 P. aeruginosa were collected from six sites in Turkey during 2013-2018. Susceptibility testing was done using broth microdilution according to CLSI guidelines and interpreted using EUCAST 2019 breakpoints. CAZ-AVI was tested with a fixed concentration of 4 mg/L AVI. The presence of genes encoding resistance mechanisms was previously assessed via multiplex PCR, followed by amplification of the full-length genes and sequencing.

Results: Susceptibility data are provided in the table. CAZ-AVI exhibited potent activity against all Enterobacterales (MIC90, 0.5 mg/L; 98.2% susceptible). When MBL-positive isolates were removed from analysis, susceptibility to CAZ-AVI was 100%. CAZ-AVI showed consistently higher % susceptibilities than all comparators against MBL-negative meropenem-nonsusceptible isolates (CRE) and isolates positive for OXA-48. CAZ-AVI also showed good activity against the majority of P. aeruginosa isolates (MIC90, 8 mg/L; 94.2% susceptible).

Conclusions: CAZ-AVI showed potent in vitro activity against Enterobacterales and P. aeruginosa collected in Turkey, including isolates resistant to last-in-line agents.

Abstract 1607

Evaluating prophylactic post cardiac transplantation amphotericin B treatment by simulation

Camille Mane*1, Véronique Duhalde2, Isabelle Labadens2, Olivier Cointault2, Didier Concordet1, Peggy Gandia1,2

1INHERES, Université de Toulouse, INRA, ENVIT, Toulouse, France, 2Toulouse University Hospital, Toulouse, France

Background: Antifungal treatment is recommended to prevent invasive aspergillosis, a condition which occurs frequently and is associated with a poor prognosis in the first 3 months following cardiac transplantation. Current recommendations do not include a once a week administration of liposomal amphotericin B (L-AmB), despite its favorable safety profile. The objective of the current study was to simulate the efficacy of a once a week administration of L-AmB using a pharmacokinetic-pharmacodynamic (PK-PD) approach.

Materials/methods: Based on the population PK model published by Würthwein et al., 1000 plasma and tissue kinetic profiles were simulated over a 7-day period after administration of a single dose of 7.5 mg / kg of L-AmB as a 1-hour infusion. For each simulated plasma profile, the Area Under the Curve (AUC) for total concentrations over 24 hours was calculated from D1 to D7. These AUCs were compared with L-AmB PK-PD efficacy target (AUC / MIC > 167) to determine the percentage of simulated profiles achieving this target (i.e. probability of target attainment). The theoretical duration of effectiveness was determined using both the simulated tissue kinetic profiles and a concentration higher than the MIC for more than 90% of the profiles.

Results: At D1, more than 90% of the plasma profiles met the PK-PD target for Minimum Inhibitory Concentrations (MICs) ≤ 0.5 mg/L. This percentage dropped to 80.2% when the MIC was increased to 1 mg/L (i.e. Aspergillus breakpoint). At D7 and for a MIC corresponding to the breakpoint, only 3.3% of the plasma profiles achieved the PK-PD target. The treatment efficacy assessed at tissue level does not extend to 7 days regardless of the MICs tested. Indeed, efficacy is theoretically maintained during 3.2 and 1.3 days for MICs of 0.25 to 0.75 mg/L. For MICs ≥ 1 mg/L, less than 90% of the simulated profiles reached tissue concentrations ≥ 1 mg/L.

Conclusions: Regardless of plasma or tissue PK-PD target, our simulations suggest that a once a week administration of L-AmB does not guarantee antifungal efficacy throughout the entire one-week period. These results need to be confirmed in clinical practice.

Identification of host-specific genetic elements of Campylobacter jejuni in Germany based on whole genome data

Lennard Epping*, Rosario Piro2,3, Marie-Theres Knüver4, Maria Borowiak4, Charlotte Huber1, Andrea Thürmer6, Burkhard Malorny7, Kerstin Stingl7, Angelika Fruth8, Lothar H. Wieler6, Torsten Semmler1

1Robert Koch-Institut, Microbial Genomics, Berlin, Germany, 2Free University Berlin, Department of Mathematics and Computer Science, Berlin, Germany, 3Charité – Universitätsmedizin Berlin, Institute of Medical Genetics and Human, Berlin, Germany, 4Bundesinstitut für Risikobewertung, National Reference Laboratory for Campylobacter, Berlin, Germany, 5Robert Koch-Institut, Advanced Light and Electron Microscopy, Berlin, Germany, 6Robert Koch-Institut, Methodology and Research Infrastructure, Berlin, Germany, 7Bundesinstitut für Risikobewertung, Study Centre for Genome Sequencing and Analysis, Berlin, Germany, 8Robert Koch-Institut, National Reference Centre for Salmonella and other Bacterial Enterics, Wernigerode, Germany

Background: The zoonotic pathogen Campylobacter jejuni is the leading cause of bacterial food-borne infections in humans worldwide. Campylobacter are most commonly transmitted through the consumption of undercooked poultry meat or raw milk products. In silico multi locus sequence typing (MLST) of C. jejuni strains from different sources has revealed association of certain sequence types (STs) with specific hosts or a host-generalism lifestyle. While host restriction of C. jejuni lineages is known, the survival mechanisms allowing them to adapt to gut environments of different hosts have not been completely understood.

Materials/methods: To generate more in-depth knowledge about these mechanisms, 330 C. jejuni strains from different hosts (100 each from human, chicken, cattle and 30 from pig) across Germany were randomly selected, and whole genome sequencing (WGS) was performed. Additionally, 166 isolates from a Canadian study were included to extend the dataset and compare it with international samples. Host-specificity was investigated by a stratified random sampling approach on top of a k-mer based genome-wide association study (GWAS) to increase the accuracy of the identification of host specific determinants.

Results: We discovered that a strong host association can be observed in the core genome as well as in the accessory genome. The identified genetic elements encode for proteins, which play important roles in mobility, energy metabolism and genetic information processing. Although, we could discover a strong recombination barrier between C. jejuni lineages within the same host, identical allelic gene variants could be found amongst those genes.

Conclusions: Our research shows, that host-adaptation in C. jejuni takes place in a wide range of cellular functions within the whole pan-genome. This indicates that the adaptation towards a specific host niche is most likely a long evolutionary and multifactorial process rather than a spontaneous evolution or selection pressure.

Abstract 1610

An international quality control pilot programme for the measurement of antimicrobial drugs
Eveline Wallenburg*, Roger Brüggemann1,2, Anneke Hartevedt2, Linda Wisselo2, Eric Franssen2,3, Rob Aarnoutse1,2

1Radboud University Medical Center, Nijmegen, Netherlands, 2KKGT, Den Haag, Netherlands, 3OLVG location East, Amsterdam, Netherlands

Background: There is an increased interest in developing assays to determine plasma concentrations of antimicrobial drugs; used for pharmacokinetic research purposes as well as in clinical practice when performing TDM. Participation in an interlaboratory quality control (QC) program is an essential component of quality assurance. Therefore, we developed the first international QC program for the measurement of antimicrobial drugs.

Materials/methods: Antimicrobial drugs involved in the first two rounds of this pilot program were ceftazidime, ciprofloxacin, flucloxacillin, piperacillin, tazobactam, sulfamethoxazole, n-acetyl sulfamethoxazole and trimethoprim. Two QC samples (one sample per round) were prepared by spiking drug-free plasma with all eight antimicrobial drugs in either low or high concentrations. All participants were provided feedback anonymously on their performance. All weighed-in concentrations were considered true values. Acceptable accuracy was defined if measurements were within the 80-120% limits of the true weighed-in concentrations. A one-tailed unpaired t test was performed on the absolute inaccuracies to determine a difference between the high versus low concentrations.

Results: A total of 143 laboratories were approached. Seventeen laboratories participated in the first round and 22 laboratories in the second round. A total of 129 analyses were performed in both rounds. A total of 81% of the measurements was determined accurately. The measurements of flucloxacillin showed the best performance; 100% (21 out of 21) of the samples was determined accurately. The measurements of ceftazidime showed the worst performance; 56% (14 out of 25) of the samples was determined accurately. The measurements of the higher antibiotic concentrations showed a trend towards better performance than of the lower concentrations (p=0.052).

Conclusions: The initial results of this pilot program showed a relatively good performance of the participating laboratories compared to previous program initiated by us (HIV, TB and fungal). Nevertheless, still one out of five (19%) measurements was inaccurate. By participating in the program these laboratories were alerted, which may help them to improve their methods. Our results emphasize the importance of an ongoing QC program. In future rounds we will consider incorporating other antimicrobial drugs as well as the possibility the report free concentrations.

Review of enquiries to the UK national travel advice line by healthcare professionals regarding immunocompromised travelers

Blair Merrick*1, Sanch Kanagarajah2, Dipti Patel2

1Hospital For Tropical Diseases, London, United Kingdom, 2National Travel Health Network & Centre, London, United Kingdom

Background: Overseas travel is rising; UK residents made >70 million trips abroad in 2017. Concurrently, there has been a rise in individuals with primary/ acquired immunosuppression. The National Travel Health Network and Centre (NaTHNaC) offers a nurse-led telephone advice line for clinicians to discuss travellers with special health needs. A cohort of immunosuppressed patients from 2013 was described previously – we aimed to update this.

Materials/methods: Retrospective review of advice line data collected between January 2016 and December 2018 involving immunosuppressed travellers.

Results: 2107/17250 (12.2%) calls involved immunosuppressed travellers; a proportionate rise since 2013 [8.1%]. On review, 1085/2107 individuals [51.5%] did not fulfil CDC/ green book criteria for immunosuppressive condition/ treatment. The majority of enquiries originated from General Practice [82.1%], concerned male patients [55.7%], aged 21-59 [50%]. The majority of travel was to Africa [40%], and overall, most trips were 1-4 weeks duration [60.7%]. The most common purpose of travel was tourism [49%]. 792 callers [77.5%] asked for advice on vaccinations, most frequently Yellow fever [431, 54.4%]. A significant number of callers also asked about malaria prophylaxis [404, 39.5%]. There were 147 travellers with a diagnosis of HIV in the cohort; CD4 count was available for 44 [29.9%]. 123 patients had asplenia/ splenic dysfunction, 63 patients had renal failure, 128 chronic liver disease/ diabetes (or both), and 642 were severely immunocompromised, most frequently due to an immunosuppressive treatment [403, 62.8%].

Conclusions: Findings were broadly similar to 2013. As might be expected, there was a rise in travellers receiving monoclonal antibodies or small molecule inhibitors and individuals post solid organ/ stem-cell transplant. Criteria for immunosuppressive states and the risks facing these travellers do not appear be well understood. The majority of enquiries regarded live vaccinations [e.g. Yellow Fever] which account for a small minority of the total risk encountered by these individuals. Information provided [e.g. CD4 count, drug dose, timing of stem-cell transplant] by referring healthcare professional was frequently incomplete limiting advice that could be offered. A checklist of information to collect prior to contacting the NaTHNaC advice line may help to identify immunocompromised travellers and tailor guidance.

Suitability of citrate buffered piperacillin/tazobactam via continuous infusion in outpatient parenteral antimicrobial chemotherapy (OPAT)

Felicity Drummond1, Conor Jamieson*1, Laima Ozolina2, Alan-Shaun Wilkinson2

1British Society for Antimicrobial Chemotherapy, Birmingham, United Kingdom, 2BioPharma Stability Testing Laboratory, Nottingham, United Kingdom

Abstract third-party references: On behalf of Members of the BSAC Working Group on Drug Stability Testing

Background: Piperacillin/tazobactam is a broad-spectrum penicillin/beta-lactamase inhibitor combination antibiotic with activity against a wide range of pathogens including multi-drug-resistant Gram-negative organisms. Optimal administration of piperacillin/tazobactam is at 6-8 hourly intervals, which is unfeasible for OPAT services. This study assessed the stability of piperacillin/tazobactam solution for injection for up to 13 days followed by continuous 24-hour infusion in two different commercially available elastomeric devices. The stability for both actives must comply with the UK National Health Service (NHS) Yellow Cover Document (YCD) requirements throughout the study.

Materials/methods: Piperacillin/tazobactam was diluted in 0.3% w/v citrate-buffered saline (pH 7.0). Two clinically useful concentrations of drug (25 mg/mL and 90 mg/mL) were compounded into two different elastomeric devices (FOLFusor, Baxter and Easypump®II, B.Braun). Devices were refrigerated for 13 days at 2-8°C, followed by 2-3 hours at room temperature and 24 hours at 32°C (representing a simulated infusion period). All testing was in accordance with NHS YCD requirements.

Results: Results show piperacillin/tazobactam diluted in 0.3% w/v citrate-buffered saline pH 7.0 is stable for 13 days at 2-8°C, plus a 24-hour administration period in both elastomeric devices tested.

Conclusions: This study confirms piperacillin/tazobactam solutions for injection when prepared in buffered saline at both concentrations has the potential to allow for single infusion at 32°C over a 24-hour period following extended storage at 2-8°C, making this practical for use in OPAT.

*In vitro Activities of ceftazidime-avibactam and comparator agents against Enterobacterales and *Pseudomonas aeruginosa* from Israel collected through the ATLAS global surveillance programme 2013-2018*

Mary Person1, Meredith Hackel2*, Greg Stone2, Dan Sahm3

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

**Background:** Avibactam (AVI) is a non-β-lactam, β-lactamase inhibitor that can restore the activity of ceftazidime (CAZ) against organisms that possess Class A, C, and some Class D enzymes. This study examined the *in vitro* activity of CAZ-AVI and comparators against Enterobacteriaceae and *Pseudomonas aeruginosa* collected in Israel through the ATLAS global surveillance program from 2013 to 2018.

**Materials/methods:** A total of 2,585 non-duplicate, clinically isolated Enterobacterales and 663 *P. aeruginosa* were collected from five sites in Israel during 2013 to 2018. Susceptibility testing was done using broth microdilution according to CLSI guidelines and interpreted using EUCAST 2019 breakpoints. CAZ-AVI was tested with a fixed concentration of 4 mg/L AVI. The presence of genes encoding resistance mechanisms was previously assessed via multiplex PCR, followed by amplification of the full-length genes and sequencing.

**Results:** Susceptibility data are provided in the table. CAZ-AVI exhibited potent activity against all Enterobacterales (MIC₉₀, 0.5 mg/L; 99.7% susceptible). When MBL-positive isolates were removed from analysis, susceptibility to CAZ-AVI was 100%. CAZ-AVI showed consistently higher % susceptibilities than all comparators other than colistin against MBL-negative meropenem-nonsusceptible isolates (CRE) and isolates positive for KPC. CAZ-AVI also showed excellent activity against the majority of *P. aeruginosa* isolates (MIC₉₀, 4 mg/L; 98.8% susceptible).

Abstract 1625

Effects of prospective review and feedback and mandatory computerised decision support system for carbapenems and piperacillin-tazobactam on other broad-spectrum antibiotic use: interrupted time series with segmented regression analysis

Boon Hou Chua1, Shi Thong Heng1, Li Wei Ang1, Sock Hoon Tan1, Hui Lin Tay1, Min Yi Yap1, Jason Quek1, Christine Teng1, B.E. Young1,2, Ray Lin1,2, Brenda Ang1,2, Tau Hong Lee1,2, David Lye1,2, Tat Ming Ng1

1 Tan Tock Seng Hospital, Singapore, Singapore, 2 National Centre for Infectious Diseases (NCID), Singapore, Singapore

Background: As the use of piperacillin-tazobactam and carbapenems was rising in a public tertiary-care hospital in Singapore, antimicrobial stewardship (AMS) interventions targeting these two classes were introduced; empiric antibiotic guidelines and prospective review and feedback (PRF) in April 2009, and mandatory use of computerised decision support system (CDSS) in April 2011. Mandatory CDSS was lifted in March 2017 for half of the hospital’s wards for a 6-month cluster-randomised study. We aimed to examine if AMS interventions targeting piperacillin-tazobactam and carbapenems impacted the utilisation of other broad-spectrum antibiotics.

Materials/methods: In addition to piperacillin-tazobactam and carbapenems, monthly utilization of other broad-spectrum antimicrobials (co-amoxiclav, 3rd and 4th generation cephalosporins, fluoroquinolones and vancomycin) in defined daily doses (DDD) per 1,000 patient-days from January 2007 to December 2018 were obtained from the hospital’s database. We investigated the impact of AMS interventions using segmented regression analysis of interrupted time series.

Results: The baseline of other broad-spectrum antibiotic use was 1424.51 DDD/1,000 patient-days in January 2007. When empiric antibiotic guidelines and PRF were implemented in April 2009, there was an increase in the level of utilisation by 103.46 (95% confidence interval [CI]: 49.23, 157.68) in the same month, followed by a reduction at a rate of 11.1 per month (95% CI: -15.12, -7.08). Co-amoxiclav accounted for most of the changes in the broad-spectrum antibiotic use. After the implementation of mandatory CDSS, the reduction rate of other broad-spectrum antibiotic utilisation slowed to 2.10 per month (95% CI: -3.13, -1.07). When mandatory CDSS usage was lifted in March 2017, there was an increase in the level of other broad-spectrum antibiotic use by 109.20 (95% CI: 57.79, 160.61) in the same month with no significant changes in the monthly utilisation rate. By the end of the study period, we estimated absolute reductions of 126.58 DDD/1,000 patient-days in monthly utilisation of carbapenems and piperacillin-tazobactam, and 264.70 DDD/1,000 patient-days of other broad-spectrum antibiotic use due to the impact of the AMS interventions.

Conclusions: Despite AMS interventions being centred on piperacillin-tazobactam and carbapenems, unexpected reduction of other broad-spectrum antibiotic utilisation was observed.

Abstract 1626

Epidemiological aspects of ascariasis in the south of Russia
Maria Chernikova1, Irina Khutoryanina1, Larisa Ermakova2, Natalia Pshenichnaya*2,3

1 Rostov Scientific Research Institute of Microbiology and Parasitology, Rostov-on-Don, Russian Federation, 2 Rostov State Medical University, Rostov-on-Don, Russian Federation, * National Medical Research Center of Phthisiopulmonology and Infectious Diseases, Moscow, Russian Federation

Background: More than a quarter of the world’s population is at risk of invasion with the soil-transmitted helminths. Ascaris lumbricoides is the main species infecting people and it is represent a significant public health problem. Aim: to assess the epidemiological situation of ascariasis and determine the risk factors for invasion with Ascaris lumbricoides of the population in the South of Russia based on serological and parasitological investigations.

Materials/methods: Over the past 5 years a serological screening was carried out of 2600 serum samples of conditionally healthy residents of the southern Russia. Human samples were analyzed with a commercial ELISA test to detect anti Ascaris lumbricoides IgG antibodies. For the same period, 7800 parasitological studies of environmental objects (wastewater and their sediments, soil, sand, surface water) were carried out by the flotation method.

Results: According to official statistics the incidence rate of ascariasis in Russia ranges from 12.7 to 18.4 per 100 000 population over the past 5 years. Also, it is worth noting that about 70% of patients are children. As a result of the research, it was found that the detection rate of anti Ascaris lumbricoides IgG antibodies in the serum of residents of the South of Russia in average 19.8% for the period from 2014 to 2018. Parasitological investigation of environmental objects found that the intensive indicators of contamination by ascaris eggs amounted from 2 to 15 eggs per liter/kg for wastewater and their precipitation and 1-10 eggs per kg/liter for soil, sand and surface water.

Conclusions: Significant proportions of seropositive individuals, as well as the presence of facts of detection of ascaris eggs in environmental objects indicate the maintenance of a potential risk of infection of the population of southern Russia with ascariasis. In addition, the results mean the necessity to continue monitoring for ascariasis.

**Abstract 1627**

*In vitro activity of aztreonam-avibactam and comparator agents against Enterobacterales from Europe collected during the ATLAS global surveillance programme 2015-2018*

Krystyna Kazmierczak*1, Francis Arhin1, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Kirkland, Canada

**Background:** β-lactamase-producing Enterobacterales frequently co-carry resistance to antimicrobials from other classes, limiting treatment options. Avibactam inhibits class A, class C, and some class D serine β-lactamases, including extended-spectrum β-lactamases and KPC-type and OXA-48-like carbapenemases, while aztreonam is refractory to hydrolysis by metallo-β-lactamases (MBL). Aztreonam-avibactam is being developed for use against drug-resistant isolates of Enterobacterales, especially those co-producing MBLs and serine β-lactamases. This study evaluated the *in vitro* activity of aztreonam-avibactam and comparators against Enterobacterales collected in 2015-2018 in Europe as part of the Antimicrobial Testing Leadership and Surveillance (ATLAS) program.

**Materials/methods:** Non-duplicate clinical isolates were collected from 134 medical centres in 25 countries. Susceptibility testing was performed by CLSI broth microdilution and interpreted using EUCAST 2019 breakpoints. Aztreonam-avibactam was tested at a fixed concentration of 4 mg/L avibactam. PCR and sequencing were used to determine the β-lactamase genes present in all isolates with meropenem MIC >1 mg/L, and *Escherichia coli*, *Klebsiella* spp. and *Proteus mirabilis* phenotypically positive for ESBL activity (2015) or with aztreonam or ceftazidime MIC >1 mg/L (2016-2018).

**Results:** Aztreonam-avibactam was active *in vitro* against Enterobacterales isolates (MIC₉₀, 0.12 mg/L), with 99.9% (31 230 of 31 252) of isolates inhibited by ≤8 mg/L of aztreonam-avibactam. Aztreonam-avibactam tested with MIC₉₀ values of 0.5 mg/L against subsets of cephalosporin-resistant, aminoglycoside-resistant, colistin-resistant, and MBL-positive Enterobacterales and MIC₉₀ of 1 mg/L against meropenem-resistant isolates and those resistant to three last-line agents [meropenem, amikacin and colistin] (Table). In most cases, the tested comparators showed susceptibility of <80% against these subsets of resistant isolates.

**Conclusions:** Based on MIC₉₀ values, aztreonam-avibactam was the most potent agent tested against resistant and MBL-positive subsets of Enterobacterales collected in Europe, including isolates resistant to one or multiple last-resort agents from different drug classes. The promising *in vitro* activity of aztreonam-avibactam warrants further development of this combination for treatment of infections caused by drug-resistant Enterobacterales.

Abstract 1629

**Cardiovascular Disease risk in liver transplant recipients for hepatitis B, C and delta virus-associated cirrhosis**

Paolo Cirillo*, Federica Calò¹, Gianfranca Stornaiuolo¹, Giovanni Battista Gaeta¹, Paolo Maggi²

¹Infectious Diseases Unit. University of Campania Luigi Vanvitelli, Naples, Italy, Department of Mental Health and Public Medicine – Infectious Diseases Unit. University of Campania Luigi Vanvitelli, Italy, Naples, Italy

**Background:** Cardiovascular disease (CVD) is a cause of morbidity and mortality after liver transplantation (OLT), mostly in patients transplanted for NASH, obesity and diabetes-associated liver disease. Few data exist on CVD among patients transplanted for viral hepatitis. Our aim is to clarify the CVD risk and subclinical vascular damage among OLT recipients for HCV, HBV, HDV-associated liver disease.

**Materials/methods:** OLT patients due to viral hepatitis admitted for follow-up to University of Campania in the period June-July 2019 were prospectively enrolled. An estimation of cardiovascular risk was assessed using the main risk charts (Framingham, ASCVD, Heart Score), and by performing the ecocolordoppler of epiaortic vessels to assess subclinical endothelial damage. A Intima-Media Thickness [IMT] ≥1 mm was considered pathological. A carotid was classified as being affected by atherosclerotic plaque if the localized thickening was ≥1.3 mm.

**Results:** An overall of 76 patients were considered of whom 31 (40.8%) were transplanted for HCV, 14 (18.4%) for HBV, 24 (31.6%) for dual infection HBV-HDV, 5 (6.6%) for dual infection HBV-HCV and 2 (2.6%) for triple infection HBV-HDV-HCV. 30 patients (39.5%) had a familiarity for CVD, 39 (51.3%) for diabetes mellitus and 19 (25.2%) for dyslipidemia; 27 (35.5%) patients had diabetes and 19 (25%) were active smokers. More than half of the patients (63.1%) were taking antihypertensive therapy and 19.7% a lipid-lowering drugs. An overall of 43 patients (56.6%) were considered at high cardiovascular risk according to Framingham, 28 patients (36.9%) to ASCVD and 10 (13.1%) to Heart Score. Only 4 patients (5.3%) showed a normal carotid ultrasound, while 27 patients (35.5%) had a IMT and 45 (59.2%) an atherosclerotic plaque.

**Conclusions:** OLT recipients for HCV, HBV±HDV-associated liver disease are at high risk of CVD. Comparing the high percentage of subclinical carotid lesions with data of the risk charts, the latter seem to underestimate the real extent of the endothelial damage. In the pathogenesis of CVD in these patients, a chronic inflammatory status, could play a key role. It’s important to raise the awareness of CVD risk in OLT patients to prevent CVD and improve the timing of early diagnosis of premature vascular lesions.

Abstract 1630

Knowledge about transmission and determinants of tuberculosis among Pakistani adults: evidence from demographic and health survey

Atiqur Rahman*, Yasmin Jahan

1Linköping University, Norrköping, Sweden, 2Hiroshima University, Hiroshima, Japan

Background: Knowledge about symptoms and transmission of tuberculosis determines health-seeking behavior and helps in the prevention of tuberculosis transmission in the community. Such data is useful for policymakers to formulate information, education and communication strategies for tuberculosis control.

Materials/methods: A secondary data analysis of Pakistan demographic and health survey, 2017/18 was carried out. Questions about self-reported tuberculosis, transmission, and curability of tuberculosis were analyzed. Correct knowledge (without misconceptions) about tuberculosis transmission was used as a dependent variable and the explanatory variables tested were demographic data, education, wealth quintiles, frequency of exposure to media and the curability of tuberculosis. Determinants of correct knowledge without misconceptions were tested by univariate and multivariate analyses.

Results: The percent of correct knowledge of tuberculosis (TB) was 51.7. The 'Correct knowledge about TB transmission' was TB transmission "Through the air when coughing or sneezing" but had no misconceptions about TB transmission. The number of respondents who had "heard of an illness called tuberculosis" was 13,596 (90.2%). Of these 3015 (20.0%) participants did not know the correct mode of TB transmission. The common misconceptions about transmission were "Through food" (31.7%), "Sharing utensils" (35.7%), and "Touching a person with tuberculosis" (9.1%). Only 7793 (51.7%) participants had correct knowledge about TB transmission. Being rich (aOR 1.39, 95% CIs 1.26-1.52), urban residence (aOR 1.22, 95% CIs 1.12-1.32), age (25-49 years) (aOR 1.48, 95% CIs 1.35-1.62), education (secondary and higher) [(aOR 1.53, 95% CI 1.37-1.70) and (aOR 3.08, 95% CI 2.68-3.50)], and "Tuberculosis can be cured" (aOR 3.33, 95% CIs (2.89-3.83) were significantly associated with correct knowledge without misconceptions.

Conclusions: Knowledge about TB transmission is considerably poor, and misconceptions remain persistent. Among the traditional mass media, the frequency of watching television was associated with correct knowledge about TB transmission. Strategies to deliver information, education and communication campaigns could be improved.

**Insights into vaginal metabolic profiles throughout pregnancy**
Claudio Foschi¹, Luca Laghi², Chenglin Zhu³, Giulia Patuelli³, Sara Zagonari³, Maria Federica Pedna⁴, Vittorio Sambri⁴, Antonella Marangoni*¹

¹University of Bologna, DIMES, Microbiology, Bologna, Italy, ²University of Bologna, Department of Agro-Food Science and Technology, Centre of Foodomics, Cesena, Italy, ³Family advisory health Centres, Dipartimento Salute Donna Infanzia e Adolescenza - Ravenna, Ravenna, Italy, ⁴Unit of Microbiology, Greater Romagna Hub Laboratory, Pievesistina, Cesena, Italy

**Background:** During pregnancy, the vaginal microbiome plays an important role in both maternal and neonatal health outcomes. The vaginal microbiome undergoes significant changes during pregnancy, including a significant decrease in overall diversity, increased stability, and enrichment with *Lactobacillus* spp.

Since the changes in the microbial profiles are usually associated with significant shifts in the composition of vaginal metabolites, the aim of this study was to characterize the vaginal metabolic profiles throughout pregnancy at two different gestational ages, correlating them with a microscopic evaluation of the vaginal bacterial composition.

**Materials/methods:** A total of 67 Caucasian pregnant women, with a mean age of 31.3 years, and presenting to the Family advisory health Centres of Ravenna for prenatal care were enrolled. After a clinical examination, a vaginal swab was collected at gestational ages 9-12 weeks (first trimester) and 20-24 weeks (second trimester) from each woman. The composition of the vaginal microbiome was evaluated by a Gram stain scoring system (Nugent score), assessing for the presence of different bacterial morphotypes (*Lactobacillus* spp., *Gardnerella vaginalis* and *Mobiluncus* spp.). Based on this score, women were divided into 3 groups: 'H' [normal lactobacilli-dominated microbiota], 'I' [intermediate microbiota], 'BV' [bacterial vaginosis].

Starting from the cell-free supernatants of the vaginal swabs, a metabolomic analysis was performed by means of a 1H-NMR spectroscopy. Differences among experimental groups were assessed via PCoA and a two-ways ANOVA test.

**Results:** From the first to the second trimester of pregnancy, a greater number of women showed a normal lactobacilli-dominated microbiota (33 vs 45 women), with a reduction of cases of dysbiosis. These microbial shifts were clearly associated with profound changes in the vaginal metabolic profiles. Globally, over the weeks, a significant reduction in the levels of BV-associated metabolites [e.g. putrescine, acetate, propionate, methylamine, butyrate, formate, cadaverine] was observed. At the same time, the vaginal metabolome was characterized by higher concentrations of leucine, isoleucine, serine and phenylpropionate, typically found in healthy vaginal conditions.

**Conclusions:** Throughout pregnancy, the vaginal metabolic composition became less diverse and more homogeneous, reflecting the shift towards a lactobacilli-dominated microbiome.

Abstract 1632

**In vitro activity of tigecycline and comparator agents against Gram-negative and Gram-positive isolates from China in 2018**

James Karlowsky¹, Meredith Hackel*², Sam Bouchillon², Michael Dowzicky³, Dan Sahm²

¹University of Manitoba, Winnipeg, Canada, ²IHMA, Schaumburg, United States, ³Pfizer, Inc., Collegeville, United States

**Background:** The TEST (Tigecycline Evaluation and Surveillance Trial) global surveillance program monitors *in vitro* activities of tigecycline and a panel of marketed antimicrobial agents against clinically significant Gram-negative and Gram-positive bacterial pathogens. In this analysis we review recent TEST program data for Gram-negative and Gram-positive isolates tested by clinical laboratories in China.

**Materials/methods:** Clinically significant Gram-negative (*n=2,999*) and Gram-positive (*n=989*) isolates were cultured from multiple infection sites by 24 clinical laboratories in China in 2018. Isolates were identified to species level and MICs determined in each clinical laboratory using broth microdilution panels (supplied by IHMA, Schaumburg, IL, USA) following CLSI guidelines. Isolates were limited to one per patient. Data were submitted to IHMA for analysis. MICs were interpreted using current EUCAST [2019, v 9.0] and US FDA [tigecycline] MIC breakpoint criteria.

**Results:**

CRE, carbapenem-resistant Enterobacterales (meropenem MIC >2 mg/L); NA, MIC breakpoints not available; TGC, tigecycline; AMK, amikacin; FEP, cefepime; CAZ, ceftazidime; CRO, ceftriaxone; LVX, levofloxacin; MEM, meropenem; TZP, piperacillin-tazobactam; AMC, amoxicillin-clavulanate; AMP, ampicillin; LNZ, linezolid; VAN, vancomycin.

* US FDA MIC breakpoints applied. 91% (670/736) of *Escherichia coli* had tigecycline MICs ≤0.5 mg/L (EUCAST tigecycline-susceptible MIC breakpoint).

Conclusions: *In vitro* susceptibility of Enterobacterales was highest to tigecycline (97.4%); isolates were less susceptible to amikacin, meropenem, and the other agents tested. 12.9% of Enterobacterales isolates in China were CRE; 95.4% of CRE were susceptible to tigecycline. >90% of enterococci and *S. aureus* were susceptible to tigecycline; linezolid and vancomycin were slightly more active *in vitro* than tigecycline against common Gram-positive cocci. Country specific monitoring of susceptibility patterns among common bacterial pathogens provides useful information for determining empiric treatment strategies.

Background: Meropenem is an antibiotic used to treat infections in intensive care patients. Pharmacokinetic [PK] variability observed in critically ill patients leads to a high risk of suboptimal exposure. Recent observational data at the Charité-Universitätsmedizin Berlin shows that >70% of patient’s exposure is outside the C_{min} target range (1x-5x MIC). Consequently, improvement of current dosing practices is urgently needed. Model-based Bayesian dosing software for dose optimization have been suggested [1] to improve dosing practices, however several barriers exist [2] hindering implementation in clinical practice. We aimed to develop easy-to-use model-based dosing tables to optimise meropenem treatment at intensive care units (ICU) at Charité. To ensure suitability and user-friendliness a close collaboration with the antimicrobial stewardship (AMS) and ICU teams of the hospital was pursued.

Materials/methods: A previously developed meropenem PK model was used to perform Monte Carlo simulations considering PK parameter uncertainty [3]. In close discussion with the AMS and the ICU teams multiple clinically relevant dosing regimen (n=15) were evaluated with respect to target attainment (f_{T>MIC}=98%) and its probability (PTA≥90%). Dosing regimen reaching a PTA≥90% were further discriminated with regards to probability of reaching the predefined target range (1x-5x MIC) and potentially toxic \(C_{min}\) values (>16 mg/L or >64 mg/L).

Results: Optimised and easy-to-use model-based dosing tables are now available for clinical routine dosing at Charité-Universitätsmedizin Berlin. Dosing regimen stratified for a patient’s creatinine clearance and determined/assumed MIC are summarised in one concise table. Our result showed that for the same daily dose, (i) prolonged (4h) or continuous infusions reached higher PTA than short-time infusions and (ii) four-times-daily dosing was superior in PTA to three-times-daily dosing. Both can easily be integrated into clinical routine. 2-g meropenem loading doses provided little further benefit over 1-g loading doses and consequently were not further considered.

Conclusions: Model-derived dosing tables are a promising tool to improve dosing in ICU patients. To fully utilise their potential and integrate them into clinical routine a close collaboration between all parties of an interprofessional team is needed. The developed dosing tables are currently prospectively evaluated.

Abstract 1635

Feasibility studies of the WHO practical toolkit for antimicrobial stewardship programmes in healthcare facilities in low-and middle-income countries

Gina Maki*1, Ingrid Smith2, Sarah Paulin2, Watipaso Kasambara3, Pem Chuki4, Priscilla Rupali5, Lisa Barrow6, Eliaser Johnson6, Deepak Bajracharya7, Dipendra Singh8, Tyler Prentiss1, Linda Kaljee1, Marcus Zervos1

1Henry Ford Health System, Detroit, United States, 2World Health Organization, Geneva, Switzerland, 3Ministry of Health and Populations, Lilongwe, Malawi, 4Jigme Dorji Wangchuck National Referral Hospital, Thimpu, Bhutan, 5Christian Medical College & Hospital, Vellore, India, 6FSM Department of Health & Social Affairs, Pohnpei, Micronesia, 7Group for Technical Assistance, Kathmandu, Nepal, 8Ministry of Health and Population, Kathmandu, Nepal

Background: The overuse and misuse of antimicrobials are a main driver for development of antimicrobial resistance [AMR]. Antimicrobial stewardship (AMS) has emerged as a systematic approach to optimize antimicrobial use. To meet the increasing need for practical guidance on how to implement effective AMS programmes, the World Health Organization (WHO) developed a draft toolkit for AMS programmes in hospitals in low- and middle-income countries (LMIC). In this study, we evaluated the feasibility of implementing the toolkit in four LMIC settings.

Materials/methods: The study used a descriptive qualitative study design with semi-structured interviews with national- and hospital-level stakeholders. Four countries were included: Bhutan, the Federated States of Micronesia, Malawi, and Nepal. A total of 12 national policy makers, 20 hospital administrators and managers, and 64 hospital staff were interviewed.

Results: All study participants identified AMS as an important priority and responded that the AMS toolkit would be helpful in improving AMS programmes within their countries and hospitals. Key facilitators for implementing AMS included strong national and hospital leadership and support, and hospital staff engagement in AMS committees. Key barriers included lack of human and financial resources, limited access and supply of medicines particularly in remote regions, difficulty enforcing regulations for prescription only antibiotic sales, and inadequate AMS competencies training. Key recommendations to strengthen AMS included dedicated AMS financial resources, identification of dedicated hospital AMS leaders and champions, stepwise approach for AMS implementation based on country and hospital context, establishing mechanisms for reporting and feedback, and initiating AMS training workshops and AMS curricula. Key recommendations to improve the draft WHO toolkit included the need for guidance to prioritize AMS activities based on available resources, stronger linkage between existing programmes e.g. Infection Prevention and Control, and further guidance on establishing AMS committees.

Conclusions: The draft toolkit was well received throughout the four study countries. The overall consensus was that the toolkit will be an important asset as countries and hospitals move forward to combat AMR and implement AMS programmes. However, many barriers will need to be addressed at both the national and hospital levels in order to facilitate implementation.

Abstract 1636

HPV OncoPredict: analytical performance of a novel diagnostic tool allowing accurate determination of sample cellularity and normalised high-risk human papilloma virus genotype-specific viral load

Ivan Vallini*, Marzia Raimondi, Silvia Paganoni, Illari Sechi, Marianna Martinelli, Paolo Romano, Andrea Piana, Clementina Cocuzza

1Hiantis S.r.l, Brescia, Italy, 2Hiantis S.r.l, Milano, Italy, 3University Of Milano Bicocca, Department Of Medicine And Surgery, Monza, Italy, 4Department Of Medicine And Surgery, University Of Milano Bicocca, Monza, Italy, 5Department Of Medical, Surgical And Experimental Sciences, University Of Sassari, Sassari, Italy

Abstract third-party references: This Project is conducted in collaboration with GeneFirst as part of the EU funded programme (SME Instrument Grant GA 806551)

Background: Cervical cancer (CC) kills 330,000 people annually and requires persistent infection with high-risk Human Papillomavirus [hrHPV] for its development. Type-specific hrHPV viral load has been suggested to be a useful risk triage indicator for the development of high-grade squamous intraepithelial lesion (≥HSIL) as well as a clinically useful marker to monitor post treatment (“test-of-cure”). Most presently commercially available hrHPV tests do not provide type-specific hrHPV viral load or quantitative sample cellularity assessment as a measure of sample adequacy.

HPV OncoPredict is a new in-vitro diagnostic tool allowing accurate sample adequacy assessment and hrHPV type-specific viral load (E6/E7 DNA) determination. The aim of this study is to evaluate the intra- and inter-laboratory analytical performance of HPV OncoPredict prototype using international standards and reference samples.

Materials/methods: HPV OncoPredict prototype analytical performance has been evaluated using NIBSC [National Institutes of Biological Standards and Controls] standards for HPV16 [06/202] and HPV18 [06/206], WHO LabNet Proficiency Panels as well as commercially available Verification/Validation standards [Microbix] for HPV 16, 18, 31, 33, 39, 45 and HPV 67 [negative control].

Results: HPV OncoPredict was able to quantitatively assess and correctly identify hrHPV types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59 as well as a human gene, used to normalize viral load and assess sample adequacy. HPV OncoPredict assigned type-specific viral loads and human Genomic Equivalents [hGE] comparable to those indicated in the WHO LabNet 2018 report. Moreover, HPV OncoPredict demonstrated 100% accuracy in genotyping all 12 hrHPV types, as defined by IARC, on testing both NIBSC and Microbix control standards. Inter-laboratory performance is presently under evaluation in 2 external University Laboratories using 2019 WHO LabNet Proficiency Panel.

Conclusions: HPV OncoPredict analytical performance has demonstrated accurate assessment of sample’s cellularity and hrHPV type-specific viral loads, using both international standards and commercial controls. These promising results will support HPV OncoPredict future clinical validation studies aimed at evaluating the correlation between normalized viral loads and cervical lesions. References: This project is conducted in collaboration with GeneFirst as part of a EU funded Horizon 2020 SME Instrument Project (SME Instrument Grant GA 806551).

Abstract 1644

Prediction of antibiotic resistance in *Helicobacter pylori* by whole genome sequencing and open-source bioinformatics tools

Ana Miqueleiz¹, Ana Blanco Suárez², Claudio Alba Rubio³, Pedro Urruzuno⁴, Kaisa Thorell⁵, Teresa Alarcon Cavero*⁶

¹Royal Navarre Hospital, Pamplona, Spain, ²CatLab (Parc Logístic de Salut), Viladecavalls, Spain, ³UCM Faculty of Veterinary Medicine, Madrid, Spain, ⁴University Hospital 12 de Octubre, Madrid, Spain, ⁵Karolinska Institute, SOLNA, Sweden, ⁶Hospital de La Princesa, Madrid, Spain

**Background:**

Increasing antimicrobial resistance in *Helicobacter pylori* (Hp) is a worldwide problem. Whole genome sequencing (WGS) has recently emerged as a diagnostic tool in clinical microbiology for drug resistance prediction in bacteria. The aim of this study was to compare phenotypic drug susceptibility testing results with the presence of genetic resistance determinants identified in Hp genome using two open-source bioinformatics tools.

**Materials/methods:**

20 Hp strains isolated from gastric biopsies were selected. Antimicrobial susceptibility testing was performed on blood agar plates using the following E-tests: clarithromycin (CLA), metronidazole (MTZ), levofloxacin (LEV), amoxicillin (AMX) and tetracycline (TET). EUCAST breakpoints were used. After DNA extraction, WGS was performed using Illumina-MiSeq platform. Resistance Gene Identifier (RGI) 5.1 and ResFinder 3.2 were used to identify resistance mutations.

**Results:**

The following table shows the results from susceptibility testing (susceptible=S, resistant=R) and the resistance mutations found:

<table>

</tbody>
</table>

**Conclusions:** Both tools detected a clarithromycin resistance mutation in all clarithromycin-resistant strains, except in one. The most frequent clarithromycin mutation was A2147G. Metronidazole resistance is due to a combination of various complex mechanisms, so it is difficult to predict it with genotypic data. No resistance was detected in the amoxicillin-resistant strain. Hp WGS and open-source bioinformatics tools can be useful to predict clarithromycin resistance.

Distinct effectiveness of oritavancin against tolerance-induced Staphylococcus aureus

Lauren Harven1, Victoria Bingley1, Pushkar Kulkarni1,2, Sanket Khaire1, Somrita Dey1, Paula Smolenski1, Andrew Berti*1,3

1Wayne State University, College of Pharmacy, Pharmacy Practice Dept, Detroit, United States, 2Wayne State University, College of Engineering, Detroit, United States, 3Wayne State University, College of Medicine, Biochemistry Microbiology and Immunology Dept, Detroit, United States

Background: Within a sufficiently large bacterial population, some of the members will naturally adopt an alternate, metabolically-active state that favors small molecule synthesis over cell division. In Staphylococcus aureus this process can be sharply accelerated by multiple factors present during infection including nutrient limitation, host cationic peptide exposure and polymorphonuclear neutrophil internalization. These isogenic “tolerant” subpopulations have variable responses during antibiotic exposure and can remain viable in the presence of typically bactericidal concentrations. Survivors of the antibiotic exposure can restart cell division upon cessation of antibiotics and cause relapse or recurrent infection. In this study we determine the ability of typical and atypical antistaphylococcal therapies to reduce the viability of tolerant Staphylococcus aureus bacteria.

Materials/methods: S. aureus strain ATCC29213 as well as four clinical isolates (two MSSA, two MRSA) were selected for analysis. Overnight cultures were diluted in pre-warmed broth (MHB50) to approximately 1×10^6 cfu/mL. Tolerance was induced by exposure to mupirocin (low [0.032 µg/mL] or high [3.2 µg/mL]) for 30 min. Tolerant cultures were exposed to vancomycin (35 µg/mL), cefazolin (25 µg/mL), daptomycin (7 µg/mL), telavancin (10 µg/mL), dalbavancin (6 µg/mL) or oritavancin (14 µg/mL) and viability was assessed by dilution plating at pre-defined time points (0, 2, 6, 24, 48 h). The minimum duration for 3-log viability reduction from baseline (MDK99.9) and culture viability at 48h were calculated independently for each of three biological replicates.

Results: The rate of bacterial killing (MDK99.9) was reduced for all study antibiotics by the addition of mupirocin in a dose-dependent manner. In contrast to all other regimens, including lipoglycopeptide comparators, oritavancin was the only antimicrobial agent that maintained a similar extent of bacterial killing against tolerant staphylococci.

Conclusions: Antimicrobial tolerant staphylococci exhibit a decreased rate of killing by antistaphylococcal agents. However, oritavancin remained effective at maintaining a similar extent of killing. Further studies to investigate the role of oritavancin against recurrent or relapse staphylococcal infection is warranted.

Abstract 1651

CANDIMAD study: a prospective multi-centre laboratory based survey of antifungal resistance in Candida spp. causing invasive candidiasis in Madrid

Judith Diaz-Garcia1,2, Aina Mesquida1,2, María Ángeles Meléndez Carmona3, Fernando González-Romo4,5, Cuetara María Soledad6, Nelly Daniela Zurita Cruz7, María Muñoz Algarra8, Maria Del Coral Garcia9, Aída Sánchez10, Inmaculada Quiles11, María Teresa Duran-Valle12, Carlos Sanchez-Carrillo1,2,13, Patricia Muñoz1,2,6,13, Pilar Escribano1,2, Jesus Guinea Ortega1,2,13

1Gregorio Marañón Hospital, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3University Hospital 12 de Octubre, Madrid, Spain, 4Hospital Clínico Universitario San Carlos, Madrid, Spain, 5Universidad Complutense de Madrid, Madrid, Spain, 6Hospital Severo Ochoa, Leganés, Spain, 7Hospital de La Princesa, Madrid, Spain, 8Hospital Puerta de Hierro-Majadahonda, Majadahonda, Spain, 9Hospital Universitario de Getafe, Getafe, Spain, 10Hospital Infanta Sofía, San Sebastián de los Reyes, Spain, 11University Hospital La Paz, Madrid, Spain, 12Hospital de Móstoles, Móstoles, Spain, 13CIBER Enfermedades Respiratorias-CIBERES, Madrid, Spain

Background: Active surveillance studies are necessary to know local epidemiology and help clinicians start appropriate empirical antifungal treatment. Resistance rates in Candida spp. come mainly from isolates causing candidaemia and figures in Spain are relatively old (CANDIPOP study, 2014). We assessed the epidemiology and antifungal resistance of recent yeast isolates causing invasive infections in patients at hospitals located in Madrid, Spain.

Materials/methods: We studied 312 isolates from 282 patients (23 presented ≥2 isolates and 19 showed mixed cultures) admitted to 15 hospitals located in the Madrid metropolitan area from January 2019 to October 2019. Isolates sourced from blood (52.6%), abdominal samples (29.8%), peritoneal samples (10.9%) and other digestive tract samples (6.7%) were identified by MALDI-TOF and antifungal susceptibility to amphotericin B, azoles, micafungin, anidulafungin and investigational agent, ibrexafungerp (previously SCY-078) was tested according to EUCAST EDef 7.3.1 (Breakpoints table v.10.0). FKS genes were sequenced in echinocandin-resistant Candida isolates.

Results: The species distribution of isolates was C. albicans (48.7%, n=152), C. glabrata complex (19.2%, n=60), C. parapsilosis complex (17.6%, n=55), C. tropicalis (7.1%, n=22), C. krusei (2.9%, n=9), other Candida spp. (3.2%, n=10), and non-Candida yeasts (1.3%, Rhodotorula mucilaginosa [n=2], and Trichosporon inkin [n=2]). Overall, triazoles, candins and ibrexafungerp showed high activity. Ibrexafungerp was more active against C. parapsilosis than candins. Fluconazole resistance was detected in 6.1% of Candida isolates (n=19; C. krusei [n=9], C. glabrata [n=4], C. parapsilosis [n=2], C. albicans [n=1], C. tropicalis [n=1], C. guilliermondii [n=1], and C. inconspicua [n=1]) sourcing from blood (n=11), abdominal samples (n=6), and peritoneal samples (n=2). Rate of echinocandins resistance was lower than 1% and was found in isolates sourcing from blood (n=2) and abdominal samples (n=1): C. krusei (n=2; L701M FKS1) and C. glabrata (n=1, WT). Resistant isolates were from patients from nine out of the 15 hospitals. Non-Candida yeasts showed intrinsic echinocandin resistance. No resistance to amphotericin B was detected (Figure).

Conclusions: We found a low percentage of overall resistance (<7%), with anecdotal echinocandin resistance rate. Resistant isolates sourced from blood (4%), abdominal samples (2%), and peritoneal samples (0.6%), and were distributed across different hospitals. No multi-drug resistant species were found.

Abstract 1653

High diagnostic yield of splenic core biopsy in patients with pyrexia or inflammation of unknown origin: a descriptive analysis of imaging (including FDG-PET) and pathological findings at a major tertiary centre

Yee Ting Nicole Yim*1,2, Gabriel Wallis1, Jawad Saeed3, Stefan Voo4, Ian Proctor5, Christopher Mcnamara3, Michael Brown1,2

1Hospital For Tropical Diseases, University College London Hospital, London, United Kingdom, 2London School of Hygiene & Tropical Medicine, London, United Kingdom, 3Department of Haematology, University College London Hospital, London, United Kingdom, 4Department of Radiology, University College London Hospital, London, United Kingdom, 5Department of Histopathology, University College London Hospital, London, United Kingdom

Background: A proportion of patients with pyrexia and/or inflammation of unknown origin (PUO) are without a diagnosis following clinical and laboratory evaluation. Imaging, including with FDG-PET, may identify and characterise splenic abnormalities. Many specialists are reticent to undertake splenic biopsies because of the perceived risk. We aim to report on the diagnostic yield of targeted splenic biopsy in patients with febrile or inflammatory presentations showing splenic abnormalities, and explore predictors of definitive diagnosis.

Materials/methods: Cases were identified by searching the pathology archive at University College London Hospital over the 10 year period 2009-2019. We combined search terms ‘biopsy’ and ‘spleen’ and excluded non-core biopsy samples. We used electronic patient records to identify those investigated for unexplained fever or inflammation and collated data on prior and subsequent diagnostic tests, final diagnosis, complications and 6 month survival.

Results: 20 patients meeting these criteria were identified. All patients had splenomegaly. Microbiological diagnoses were made by culture or PCR. A diagnosis was made from splenic biopsy in 15 (75%) cases. Of the remaining cases, 1 biopsy showed reactive features only and responded to steroids; 2 were diagnosed at subsequent splenectomy, and 2 received a delayed final diagnosis from prior investigations. An infectious cause was found in 20%. 15 patients had a FDG-PET scan. While diagnostic yield was higher in those with the most abnormal splenic PET findings, biopsies were diagnostic even among those with mild FDG avidity. There were no complications.

Conclusions: We demonstrate the high utility of splenic core biopsy in diagnosing patients with inflammatory/infectious presentations and splenic imaging abnormalities who have undergone extensive investigation on other laboratory and imaging. In patients with splenomegaly, FDG-PET features cannot classify those for whom biopsies were non-diagnostic.

Abstract 1655

Comparison of prognostic capacity of presepsin and procalcitonin in adult septic patients: results from a prospective observational study in two university clinical centres

Ajete Aliu Bejta*1,2, Sadije Namani2, Bahrie Halili2, Donjeta Plana-Hajdari3, Bruno Baršić4, Anita Atelj4

1University Clinical Center of Kosovo, Clinic of Infectious Diseases, Prishtina, Kosovo, 2University Clinical Center of Kosovo, Clinic of Infectious Diseases, Prishtina, Kosovo, 3National Institute for Public Health, Department of Molecular Microbiology, Prishtina, Kosovo, 4University Clinical Center of Zagreb, Hospital for Infectious Diseases, Zagreb, Croatia

Background: Sepsis is a life-threatening condition that causes millions of death worldwide each year. Early recognition of disease is crucial for better outcome. Sepsis biomarkers are widely used for rapid diagnosis of sepsis. We evaluated a prognostic value of presepsin concentrations in patients with sepsis.

Materials/methods: A prospective observational study was conducted on 100 adult septic patients admitted at the Clinic of Infectious Diseases in Prishtina, Kosovo, and University Hospital for Infectious Diseases in Zagreb, Croatia. New Sepsis-3 definitions were used for disease stratification. Based on the disease outcome patients were grouped as survivors and non-survivors. During the disease course, sepsis biomarkers (presepsin and procalcitonin) were measured four times: on admission, after 24 hours, 72 hours, and on day 7. Multivariate generalized linear model (glimix) was performed to test the association of presepsin and procalcitonin levels during the course of the disease with outcome and multivariate logistic regression analysis was performed to test the association of initial sepsis biomarkers (presepsin and procalcitonin) with disease outcome.

Results: There were 68 survivors and 32 non-survivors. In Figure 1 are presented the differences in trends of presepsin and procalcitonin during disease course between two outcome groups. Initial and subsequent measurements of presepsin concentrations significantly differ between survivors and non-survivors. In non-survivors presepsin levels were significantly higher throughout the disease course. Procalcitonin concentrations did not differ in two outcome groups.

Figure 1. Concentration of presepsin and procalcitonin in two outcome groups

On the left side association of presepsin concentration with disease outcome. On the right side association of procalcitonin with disease outcome. Black line-survivors, black spotted line-non-survivors. Hosmer-Lemeshow test p=0.6226, with satisfactory explanatory value c=0.675.

Presepsin values but not procalcitonin values on admission were significantly associated with death. Procalcitonin didn’t show any prognostic value.

<table>
<thead>
<tr>
<th>Effect</th>
<th>Point Estimate</th>
<th>95% Wald Confidence Limits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Presepsin on admission</td>

Abstract 1658

**Accurate differentiation of carbapenemases by MALDI-TOF MS-typing: employment of bioinformatics**

Eva Gato1, Jorge Arca Suárez1, Bruno Kotska Rodiño1, Gema Méndez2, Manuel Arroyo2, Luis Mancera Pascual2, Germán Bou Arevalo1, Marina Oviñaño García*1

1Complejo Hospitalario Universitario A Coruña, a Coruña, Spain, 2Clover BioSoft, Granada, Spain

**Background:** Detection of Carbapenemase-Producing Enterobacterales (CPE) is one of the main goals of microbiology laboratories, as they constitute a health alarm worldwide. Rapid methods to detect resistance mechanisms and strain typing as part of routine data analysis could therefore greatly benefit infection control efforts. MALDI-TOF MS has demonstrated substantial utility for rapid organism identification. Here, we demonstrate that real-time, direct tracking of CPE is possible using MALDI-TOF MS and artificial intelligence in a manner that could be implemented for routine screening in clinical microbiology laboratories.

**Materials/methods:** A total of 102 previous molecular characterized CPE (20 KPC-2, 26 KPC-3 and 56 OXA-48) with different sequence types, were submitted to two different standard operating procedures, an in-target and a full formic acid-ethanol extraction. All isolates were spotted four times on the MALDI target plate and measured three times each. Thus, 12 spectra were acquired per sample using the automated functionality of FlexControl 3.3 software (Bruker Daltonik). Raw data was submitted to baseline subtraction using Top-Hat filter and smoothing via Savitzky-Golay filter (Clover BioSoft software). All replicates were aligned with a tolerance factor of 0.0002. The processed data set was submitted to Principal Component Analysis (PCA) and hierarchical clustering. Technical reproducibility was analyzed, along with the best extraction method in terms of spectral quality, discrimination against the gold standard (molecular characterization) and simplicity of the method.

**Results:** Both extraction methods provided similar results, so we chose the in-target extraction for further studies. KPC-3 strain was correctly classified by hierarchical clustering after applying PCA to the processed dataset and was accurately differentiated from OXA-48 and KPC-2 isolates (Image 1). Besides, potential biomarkers have been identified to classify OXA-48 different clones. In particular, the peaks 9831, 9845, 9857 y 9872m/z ± 1.5 Da discriminate ST 307, whereas 9342m/z ± 1.5Da identify ST 147.

**Conclusions:** Accurate differentiation of CPE by MALDI-TOF MS-typing was accomplished in as little as 10 min from isolated colonies, demonstrating the potential clinical utility for real-time screening in clinical practice. This software can be implemented in all currently available MALDI-TOF MS systems.

Abstract 1662

Approaches to identify new onset diarrhoea among hospitalised patients and the frequency of stool sample collection for *Clostridioides difficile* infection: a pilot for the CLOUD Louisville study

Stephen Furmanek1, Senen Pena-Oliva1, Ruth Carrico1, Elisa Gonzalez2, Kimbal Ford*2, Sharon Gray2, Julio Ramirez3

1University of Louisville, Division of Infectious Diseases, Louisville, United States, 2Pfizer Vaccines, Medical Development and Scientific/Clinical Affairs, Collegeville, United States

Abstract third-party references: On behalf of the CLOUD Louisville Study Group. This study was sponsored by Pfizer, Inc.

**Background:** Population-based surveillance studies defining the incidence of *Clostridioides difficile* infection (CDI) are important to inform policy makers. One challenge to perform these studies is the identification of all hospitalized patients with new onset diarrhea. Additionally, CDI may be underestimated if stool specimens are not collected from patients with diarrhea and tested for *C. difficile*. We conducted a pilot study to inform the development of a protocol for a population-based incidence study in all hospitals in Louisville, Kentucky. The objectives of this pilot study were to define the optimal approach to identify adult patients with new onset diarrhea and the frequency of stool collection for CDI testing.

**Materials/methods:** This was a cross-sectional pilot study conducted in all nine adult hospitals in Louisville, Kentucky. For seven consecutive days in December 2018, all adult Louisville inpatients were evaluated for new-onset diarrhea (≥3 loose stools within 24 hours, Bristol stool form scale 5-7) using a 3-level approach: 1) medical record review; 2) nurse interview; and 3) patient interview. The frequency of stool specimen collection for CDI testing according to local standard of care was ascertained.

**Results:** A total of 7,540 Louisville adult in-hospital patient days were evaluated (Figure 1). Patients with diarrhea were identified either by medical record review (50%), nurse interviews (42%) or patient interviews (8%). All cases identified by patient interviews were identified by nurses the following day. New onset diarrhea was identified in 167 patients (47% male; median age 64 years). Stool samples were submitted for *C. difficile* testing in 32% (53/167) of patients.

**Conclusions:** Medical record review and nurse interviews were the most effective approaches to identify inpatients with new onset diarrhea. Considering that stool specimens were collected from only one-third of the inpatients with new onset diarrhea, it is likely that CDI is underdiagnosed and the burden of CDI may be underestimated. Results were used to inform the design of the CLOUD Louisville study, an ongoing, prospective population-based surveillance study to define the incidence of CDI among hospitalized adults in the United States.

**Figure 1. Study Flow Chart**

Abstract 1663

**Bacterial DNA promotes tau and beta-amyloid aggregation and is suggested as a novel therapeutic target for Alzheimer’s disease**

George Tetz*, Sandra Pritzkow†, Michelle Pinho‡, Nicolas Mendez‡, Claudio Soto‡, Victor Tetz§

1Human Microbiology Institute, New York, United States; 2Mitchell Ctr. for Alzheimer’s Dis. and Related Brain Disorders, Huston, United States; 3Human Microbiology Institute, New York, NY, United States

**Background:** Different bacteria (including facultative intracellular parasites) and fungi have been detected in the cerebrospinal fluid and postmortem brains of individuals with Alzheimer’s disease (AD). We hypothesize that DNA from these microorganisms can act as an efficient promoter for protein misfolding and AD pathogenesis. In this study, we evaluated the effect of DNA extracted from diverse prokaryotic and eukaryotic cells in tau and beta-amyloid misfolding and aggregation. Our results show that DNA from various, unrelated gram-positive and gram-negative bacteria may play a previously overlooked role, in triggering the propagation of protein misfolding and AD pathogenesis.

**Materials/methods:** We used a protein misfolding cyclic amplification method, electron microscopy, sedimentation analysis and cell culture methods to evaluate the effects of DNA from different Gr+/- bacteria, fungi and human cells on Tau and beta-amyloid aggregation. 3xTG mouse model of AD was used to evaluate the effect of bacterial extracellular DNA destruction on tau and beta-amyloid deposition.

**Results:** The results showed that DNA from various (but not all) bacterial species significantly promoted tau and beta-amyloid aggregation. Thus, both ThT fluorescence and lag phase were over 5 times higher compared to untreated control (p<0.001). Conversely, addition of eukaryotic DNA, such as from yeast or human cells, had no effect in promoting tau aggregation. Data received indicate that the largest promoting effect was obtained in the presence of DNA from *Escherichia coli* and *Porphyromonas gingivalis*. Animal studies confirmed that the destruction of extracellular DNA decreased tau and beta-amyloid deposition in 3xTG mouse model.

**Conclusions:** Here we report the first evidence for the capacity of extracellular DNA from certain bacterial species to substantially promote tau and beta-amyloid misfolding, for the first time suggesting its role in AD.

Validation of a machine learning model for prediction of mortality among patients with community-acquired pneumonia

Logan Ward*, Mads Lause Mogensen¹, Raúl Méndez², Paula Gonzalez-Jimenez², Catia Cilloniz Campos³, Adrian Ceccato³, Antoni Torres³, Rosario Menendez²,⁴

¹Treat Systems, Aalborg, Denmark, ²Hospital Universitario y Politécnico La Fe, Pneumology Department, Valencia, Spain, ³Hospital Clinic of Barcelona, Respiratory Institute, Barcelona, Spain, ⁴Center for Biomedical Research Network in Respiratory Diseases, Madrid, Spain

Background: Scoring systems such as the PSI and CURB-65 predict short-term mortality and are useful tools in guiding the diagnostic workup and initial therapy for patients with suspected community-acquired pneumonia (CAP). To be operational, scores should be able to be calculated automatically based on routine clinical data available in the electronic health record. We assess the generalizability of a previously developed mortality prediction score based on a machine-learned causal probabilistic network (CPN).

Materials/methods: Retrospective observational study. Data were collected prospectively for consecutive patients 18 years or older admitted with CAP at Hospital Universitario y Politécnico La Fe, Valencia, Spain from January 2012 to December 2018. Pneumonia diagnosis was based on a new radiological infiltrate with at least two compatible clinical symptoms. Exclusion criteria were admission in the previous 15 days, immunosuppressive treatment or human immunodeficiency virus (HIV+). The SepsisFinder CPN (SF) was extended to include common respiratory variables; respiratory rate, pH, PaO₂, SaO₂, supplement oxygen flow rate or FiO₂ where available, using data collected at the Hospital Clinic of Barcelona. Results of learning were described previously (O0421, ECCMID 2019).

The updated SF was used to calculate the probability of death within 30 days. Discriminatory performance for predicting 30-day mortality was assessed using the area under the ROC curve (AUC) and compared with commonly used clinical scores: PSI and CURB-65. Mortality rates were also compared for risk cut-offs defined for SF according to the percentiles associated with each PSI risk class.

Results: 1034 patients were included in the study. 30-day mortality was 4.2%. The AUC was 0.803 for SF, which did not differ significantly from that obtained for the training data (0.811). For the validation data, the AUC for SF was not significantly different to that for PSI: AUC=0.830 (p=0.42) or CURB-65: AUC=0.763 (p=0.20). When cut-offs were set to stratify the patients into groups of the same size as the PSI risk classes, the SF-selected groups had similar mortality, as shown in the table.

Conclusions: SepsisFinder shows potential for improving mortality prediction among patients with CAP using structured health data. Additional external validation studies should be conducted to support generalizability.

Development of a user-friendly clinical decision support system (TREAT-Essential) for antimicrobial stewardship

Mads Lause Mogensen*, Logan Ward, Peter Leutscher1,2, Henrik Carl Schønheyder4, Marc Ludwig5, Christoffer Madsen6, Steen Andreassen7

1Treat Systems, Aalborg, Denmark, 2Regional Hospital Northern Jutland, Center for Clinical Research, Hjørring, Denmark, 3Aalborg University, Department of Clinical Medicine, Aalborg, Denmark, 4Aalborg University Hospital, Department of Clinical Microbiology, Aalborg, Denmark, 5Regional Hospital Northern Jutland, Emergency Department, Hjørring, Denmark, 6North Denmark Region, Strategic Digitilization, Aalborg, Denmark, 7Aalborg University, Center for Model-based Medical Decision Support, Aalborg, Denmark

Background: Clinical decision support systems (CDSS) for antimicrobial stewardship can reduce unnecessary antimicrobial use and change prescribing patterns away from resistance-promoting drugs without compromising coverage, thereby improving the quality of empiric therapy and reducing costs. Despite purported benefits, CDSS are faced with a number of barriers to successful implementation. Our aim was to overcome key barriers identified for the previously developed TREAT CDSS, which provided guidance for antimicrobial therapy. The barriers were incomplete integration into the clinical workflow and interface with IT systems, limited physician acceptance of the CDSS intervention and limited management commitment.

Materials/methods: We developed a new version of TREAT, TREAT-Essential. This involved a series of four workshops concerning functionality, user-friendliness, IT architecture and calibration/clinical relevance. Workshops were conducted with relevant stakeholders including specialists in infectious diseases, clinical microbiology, and IT management.

Results: The result of the workshops was a redesigned graphical user interface and simplified decision engine. By modifying the decision engine to take the physician’s diagnosis as an input rather than determining this from entered signs and symptoms, the data entry burden was reduced to a range of 5 clicks with a minimized loss of physician autonomy. Additional patient information is automatically extracted from the electronic health record and summarized as it pertains to the current infection. Keeping the detailed information out of view provided the clinician an easier overview, but easily displayed when required. Likewise, the recommended therapy is presented as a single recommendation, while probabilities for causative pathogens and expected coverage for the chosen treatment are hidden by default (Figure). The workshops also identified opportunities for deeper integration (thus less manual data input) and locations for activation within the current workflow with minimum interruption of current workflows.

Conclusions: Involving key stakeholders across disciplines [clinicians and IT developers] uncovered additional opportunities for improving the design that may have been missed with separate workshops. TREAT-Essential has improved integration into workflow and IT infrastructure and requires less user input. Whether this will improve clinical acceptance must be validated in clinical trials.
TREAT Essential is activated directly in the electronic prescription module at the time of prescribing.

1. Add background information

1a. (optional) Inspect summary of patient data

2. Select diagnosis

2a. Depending on diagnosis, severity, answer questions to confirm indication for antimicrobial therapy

3. View recommendation, select treatment (or no treatment), approve

3a. (optional) Inspect decision support output

User returns to the prescription module where the selected treatment is pre-filled. Audit-trail includes the recommendation and its basis for quality assurance.

Abstract 1669

First report of the discovery of amurin peptides: direct lytic agents with broad activity against carbapenem-resistant Enterobacteriaceae, Acinetobacter, and Pseudomonas, including colistin-resistant strains

Karen Sauvé1, Jun Oh1, Aubrey Watson1, Dario Lehoux1, Cara Cassino1, Raymond Schuch*1

1ContraFect Corporation, Yonkers, United States

Background: DLAs are new modalities in development to address antimicrobial resistance (AMR). Lysins, cell wall hydrolases enzymes, are at the vanguard of this field, with recently reported clinical Proof of Concept of the antistaphylococcal lysin, ex-ebacase to treat MRSA bacteremia. Here, we describe amurin peptides, previously unidentified bacteriophage-encoded DLAs, distinct from lysins, with bactericidal activity against a wide range of pathogenic Gram-negatives (GN) including CDC urgent threat/WHO critical priority pathogens: colistin-resistant CRE, CRA, and CRP.

Materials/methods: Amurin were identified in the viral genome database (NCBI) and synthesized by GenScript (Piscataway, NJ). In vitro characterization of bactericidal activity, antibiofilm effects, synergy with antibiotics, and resistance profile was conducted using standard methodologies. MICs were determined against MDR/XDR clinical isolates (n=188) from 5 CDC Antibiotic Resistance Panels.

Results: We identified a novel class of DLAs comprised of amurin peptides with antimicrobial activity against all GN ESKAPE pathogens, as well as E. coli, P. mirabilis, A. xylosidans, and S. maltophilia. Hallmark features of amurins include rapid bactericidality (>3-log10 kill), synergy with >13 antibiotics, antibiofilm activity (MBEC values of ≤2 µg/mL), and no detectable resistance in spontaneous. Strikingly, an MIC90 of 1 µg/mL (range=0.125-2 µg/mL) was demonstrated for several peptides against all CDC resistance panel isolates, including XDR strains of P. aeruginosa, K. pneumoniae, E. cloacae, A. baumannii, and E. coli with both carbapenem and colistin resistance (examples in Table 1).

Table 1: MIC (µg/mL) analysis of amurin peptides [AM1-3] and comparator antibiotics against select colistin-resistant CRE, CRA and CRP isolates from CDC resistance panel isolates.

Abstract 1671

**Imported malaria: overview of the diagnosed and suspected cases of malaria in a Spanish city (15 years of experience)**

José Manuel Ruiz Giardin*1, Juan Víctor San Martin1, Ibone Ayala Larrañaga1, Luis Rivas Prado1, Lorena Carpintero García1, Alba Hernandez Piriz1, Jeronimo Jaqueti1, Isabel Garcia Arata1, Laura Molina1, Jesús García-Martínez1, Noemí Cabello-Clotet2

1Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain, 2Hospital Clínico San Carlos, Madrid, Spain

**Background:** In our city, paludism is the first imported tropical disease. It is suffered all about in visiting friends and relatives (VFR). We describe 287 malaria cases and 367 suspected but not confirmed cases of malaria attended in the last 15 years.

**Materials/methods:** It is a retrospective, comparative and populational study of all malaria cases and not confirmed cases diagnosed during 2004-2018 period. We have used media or median values, chi square test and median test to describe and to compare both groups.

**Results:**

Malaria group: 287 cases of malaria were diagnosed. 72.6% VFR, 10.8% travelers VFR, 15.6% immigrants, 0.3% travelers. September (16%) and August (13.2%) were the two most frequent periods of diagnosis in front of March (2.1%) and April (3.5%). 53% were men. 47.6% came from Guinea Ecuatorial, 45.1% from Nigeria. *P. falciparum* 89.6%, *P. vivax* 1.4%, *P. ovale* 3.1%, *P. malariae* 1% mixed infections 2.4%.

Median values: age 33 years, days in risk areas 30, days in Spain to diagnosis 7, days with symptoms to diagnosis 4, Leucocytes 5450/mcl, Plaquets 109000/mcl, Hemoglobin 12.2 g/dl, Bilirrubin 2 mg/dl, C reactive protein (CRP) 9.1 mg/dl, LDH 281 mg/dl, and amount of parasitation 1%. Of all patients, 73.6% had thrombopenia, 52.2% had anemia and 95.7% had high values of CRP. 14.9% had splenomegaly, 94.8% fever, 50.3% headache, 51.4% digestive symptoms.

14 cases (4.9%) had submicroscopic malaria, the rest of them were diagnosed with antigenic test or gross gout. 11 patients (3.8%) needed an intensive care unit treatment. 14 cases were on pregnant (10.6% of all women). 12 cases were HIV positive (2 false positive 6 were new diagnosis of HIV infection, and 4 were known HIV positive. Median of CD4 364/mcl, and 75% under 500/mcl CD4, and 30% under 250/mcl CD4. 18 (6.3%) patients were diabetics.

Of all patients only 4.9% did appropriate prophylaxis. One death in all series.

Comparative values with confirmed and not confirmed Malaria (Figure).

**Conclusions:** Malaria is a prevalent imported infectious diseases. There are important prevalent groups as HIV, pregnant, and diabetic patients. Different clinical, and analytic characteristics could help us to diagnose risk patients with and without malaria.

Abstract 1674

**Georeferencing patients infected by Gram-negative bacteria producing extended-spectrum beta-lactamase, Pereira city, Colombia, 2012-2017**

Julián Andres Hoyos Pulgarín*, Deving Arias², Alexander Alzate³, Germán Moreno³, Juan Olaya³, Isabella Cortés³, Camila Vargas³

¹Universidad Tecnológica de Pereira, Pereira, Colombia, ²Universidad Tecnológica de Pereira, Pereira, Colombia

**Background:** Knowledge about the geographic distribution patterns of resistant Gram Negative Bacteria (GNB) is potentially valuable information that could help establish ecological factors associated with transmission and resistance acquisition in the community level. The aim of this study was to establish the existence of patterns of geographic distribution of patients with positive isolation for gram-negative bacilli resistant to third-generation cephalosporins with phenotype producing Extended Spectrum Beta lactamase (ESBL), in the city of Pereira, Colombia. Study period: 2012 to 2017.

**Materials/methods:** A georeferencing study was carried out. We took the database of a tertiary Hospital and a reference laboratory in the city on the isolates with phenotypic pattern of ESBL production. Ethical endorsement was obtained from the bioethics committee of the Universidad Tecnológica de Pereira Pereira. The georeferencing was done with the KOSMO GIS and QGIS open access programs.

**Results:** We obtained 1246 records of subjects with GNB ESBL infection. After applying the inclusion and exclusion criteria, the geographical distribution of 415 subjects with isolation from the community, from Pereira, was established (Figure 1). The highest concentration of events was found in the San Joaquin, Perla del Otún, Río Otún, Centro, Oriente, Villavicencio, Boston and Universidad districts.

**Conclusions:** The geographic distribution patterns of resistant GNB infections with ESBL producing phenotype are shown. The existence of local transmission foci is proposed mainly in the central and eastern areas of the city. We highlight the importance of controlling the sources of microbial resistance not only at the hospital level but also at different actors in the community.

Abstract 1675

Low horizontal transfer rate of mcr-8 may constrain the spread of mcr-8 genes
Qiu Yang*, Timothy R. Walsh

1Cardiff University, school of medicine, department of medical microbiology, Cardiff, United Kingdom

Background: Colistin has been regarded as a highest priority important antimicrobial for human medicine by World Health Organisation since 2017. Plasmid-borne mcr- genes are one of the main contributors for the success of the global spread of colistin resistance bacterial pathogens. This study aims to characterize a novel plasmid harbouring a mcr-8 gene in Klebsiella pneumoniae isolated from blowflies in Thailand, and examine the fitness effect of mcr-8 gene on plasmid maintenance and competitiveness.

Materials/methods: Hybrid assembly of Illumina and Oxford Nanopore sequencing was performed to identify a novel mcr-8-carrying plasmid and strain. The transferability of both co-existed mcr-1 and mcr-8 plasmids were investigated by conjugation experiments and qPCR. To assess the fitness effect of mcr-8 expression on bacterial growth, plasmid constructs and growth assays were conducted. Furthermore, the competition and persistence between mcr-1 and mcr-8 were investigated via 30-day passage experiments.

Results: The mcr-8 gene was identified in previous reported 17 mcr-1-positive K. pneumoniae strains isolated from blowflies in Thailand. The mcr-8 gene is located in an IncFII:FiB plasmid (pKP100-mcr8) that co-harboured with qnrS1, tet(A), blaTEM-1b and ampC. pKP100-mcr8 shares low sequence similarity (less than 60% coverage) of other plasmids in the NCBI database. The plasmid pKP100-mcr8 can be transferred from K. pneumoniae to Escherichia coli J53Azr, with significantly lower transfer frequency (as low as 3.4x10^-13) than that of mcr-1-IncX4 plasmid co-existed in the K. pneumoniae strains (approx.1x10^-4). The expression of mcr-8 did not affect bacterial growth rate, suggesting that there is no significant fitness burden conferred by the expression of mcr-8 gene. Furthermore, both mcr-1 and mcr-8 are very stable in an in-vitro competition model over a period of 330 generations.

Conclusions: The emergence of this newly identified mcr-8.1-positive plasmid from blowflies raise a great concern to our public health. Our data show that mcr-8 has fitness advantage and ability of maintenance and persistence, however, when comparing to its co-existed mcr-1 gene, its rate of horizontal transfer is relatively low, which explain the low occurrence of mcr-8 in the global level. It further suggests that horizontal transfer is a key factor for the global dissemination of AMR genes.

ESwab collection device allows both detection of human papilloma virus with molecular assays and culture with WASP automation

Raluca Gatej, Mihaela Giuca, Sabrina Constanda*, Roxana Musat, Mihaela Dinescu

1Sanador, București, Romania

Background: A multitasking specimen collection device that supports different testing methods is an asset for a centralized microbiology laboratory. Copan ESwab™ kit, consists of a FLOQSwab® and a tube with 1 ml Amies liquid medium for the collection of clinical specimens, resulting in a homogeneous sample suspension suitable for gram smear, antigens detection, bacteria culture, and molecular assays for the detection of microbial infectious agents. The objective of this study was to validate the performance of genital specimens collected with ESwab™ for the detection HPV genotypes with the Roche Linear Array and the detection of bacteria culture processed on the WASP™ automated system.

Materials/methods: In this study were analysed 427 genital samples, [383 females, 44 males] received in the SANADOR Molecular Laboratory from Gynecology, Dermatology and Urology Departments for HPV genotyping. ESwab™ codes 490CE for females and 491CE for males were used for sample collection. Nucleic acids were extracted from 200 ul of each ESwab™ sample using the High Pure PCR Template Preparation kit. Fifty µL of the extracted DNA were used for PCR amplification and analyzed for HPV genotyping with Roche Linear Array assay. HPV genotypes were visualised after reverse hybridisation in a Beeblot automated system. All ESwab™ samples were processed on the WASP™ for bacteria culture on Columbia and Sabourand agar plates.

Results: In the 427 samples investigated, 241 were negative and 186 were HPV positives. At least one HPV genotype was detected in 44% of patient’s samples. Most prominent HPV HR, present, in single or multiple co-infections, were HPV 16 [44/186], 51 [35/186], 52 [27/186], 31 [25/186], 39 [23/186], 58 [19/186], 18 [18/186], 35 [12/186]. HPV53 was most prominent [38/186] for the possible HR and 54 [33/186] for the LR. In the males 20/44 HR genotypes, and 10/44 possible HR were detected. In the 241 HPV negative samples, culture detected 13 Candida spp, 10 Streptococcus B, 4 Candida spp+Streptococcus B and 1 E. coli.

Conclusions: Data generated in this study demonstrated that ESwab™ is a versatile collection device that can be used for both the detection of HPV genotypes with molecular assay and bacteria culture with WASP™ automation.

Abstract 1678

**Decreasing reporting time of blood cultures by workflow optimisation with the WASPLab system**

Sylvie D’Haese*, Karolien Claeys, Marc Van Ranst, Katrien Lagrou, Melissa Depypere, Kirsten Jeuris, Katty Standaert, Ann Verdonck, Stefanie Desmet

1UZ Leuven, Leuven, Belgium

**Background:** One of the goals of lab automation is fast reporting to clinicians while maintaining high quality and efficiency. We describe the impact of WASPLab® and consecutive extension of the working hours of lab technicians in the bacteriology laboratory on reporting time of identification (ID) and antimicrobial susceptibility testing (AST) results of blood cultures (BC).

**Materials/methods:** At the University Hospitals Leuven, positive BCs are streaked manually on at least a blood and MacConkey agar and incubated afterwards. Based on tracking in the laboratory information system, the time from BC positivity to ID and AST results reporting to the clinician were calculated. Three 5-months periods were compared: period 1 with conventional incubation and reading at 8.30h, 14h and 17h; period 2 with WASPLab® incubation and reading at 8.30h, 14h and 17h of BCs positive during the day [same staff and working hours as period 1] and period 3 with WASPLab® incubation of all plates and reading at 8.30h, 14h, 17h and 21h [extended working hours]. Plates are photographed in WASPLab® at 4, 6, 10, 16, 24 and 48 hours of incubation. ID is performed with MALDI-TOF MS and AST with Vitek2® or disk diffusion.

**Results:** Median time between BC positivity and reporting of ID decreased from 19h50min in period 1 to 17h41min and 12h55min in respectively period 2 and period 3 (Table). The percentage of IDs reported within 8 hours increased from 0.7% to 7.2% and 16.5% in the consecutive periods. In period 3, 83.5% of IDs were reported within 24 hours compared to 63.4% in period 1. Also a decrease in median time between BC positivity and reporting of AST was seen from 40h32min in period 1 to 37h07min and 33h17min in respectively period 2 and 3.

**Conclusions:** Introduction of WASPLab® without change in staff and working hours resulted in a decreased reporting time of blood cultures. Extending the working hours of the bacteriology lab from 8:30-17:30 to 7:00-23:00, made it possible to further optimize the use of WASPLab®, which altogether resulted in a decrease of median reporting time of ID and AST of 7 hours compared to conventional workup.

**Table 1: Comparison of time to results for identification (ID) and antimicrobial susceptibility testing (AST) of blood culture isolates in periods 1 (conventional incubation and reading), period 2 (use of WASPLab® system) and period 3 (use of WASPLab® system with extended opening hours) for incubation and reading of agar plates.**

Background: Lysins are direct lytic agents which have shown efficacy against gram-positive bacteria in vivo and in a recent Phase 2 clinical study in MRSA bacteremia. However, lysins were considered to be inactive against gram-negative (GNs) pathogens when administered systemically in vivo. GN-370, a novel engineered lysin, was evaluated as systemic treatment for P. aeruginosa alone or in addition to meropenem, in a rabbit pneumonia model.

Materials/methods: Pneumonia was induced in New Zealand White rabbits by endotracheal inoculation with PA20 (3x10⁹ CFU). At 6h post-infection, rabbits were randomized to receive: no therapy (pretreatment); vehicle alone; meropenem alone (20 mg/kg, 3 doses x q8h, subcutaneously); GN-370 alone (3 or 10 mg/kg, single intravenous dose); or GN-370 plus meropenem at the same doses. Lung, kidney, and spleen tissues were collected 24h after the last dose of meropenem, were quantitatively cultured (log₁₀ cfu/gram of tissue; and mean counts (+/- SD)) and compared in the various groups.

Results: GN-370 was well tolerated. All GN-370-treated animals survived until end of study, whereas only ~40% of vehicle-controls survived. In animals receiving either meropenem or GN-370 alone, the mean bacterial lung counts decreased by ~1.5-2-log₁₀ CFU/g vs pretreatment or vehicle-treated controls, p ≤ 0.0016. GN-370 (10 mg/kg) in addition to meropenem was synergistic, with bacterial counts in all target tissues decreasing by an additional ~2 log₁₀ CFU/g vs meropenem or GN-370 alone (p ≤ 0.02).

Conclusions: These data represent the first evidence that GN-targeted lysins can be engineered to result in systemic efficacy in vivo. GN-370 was well tolerated and effective against P. aeruginosa when administered intravenously alone, and had marked synergy with meropenem in the rabbit pneumonia model. P. aeruginosa causes serious, life-threatening and ever-increasing antibiotic-resistant invasive infections, especially nosocomially. This study provides in vivo proof-of-concept for the further development of GN-370 to treat invasive P. aeruginosa infections. Moreover, these data represent a key proof of principle for GN-targeted lysins as new modalities to combat antimicrobial resistance in such pathogens.

Total knee and hip arthroplasty after septic arthritis: retrospective analysis of 53 cases managed in a reference centre for bone and joint infections

Elodie Portier1,2, Valérie Zeller*1,2, Sophie Godot1,2, Y. Kerroumi1,4, Beate Heym1,5, Vanina Meyssonnier1,3, Simon Marmor1,4, Pascal Chazerain1,2

Background: Arthroplasty after or during treatment of septic arthritis (SA) raises diagnostic and therapeutic questions. The objective was to describe characteristics of patients undergoing total knee (TKA) or hip arthroplasty (THA) after SA, results of cultures taken at implantation, management of antibiotic therapy and outcome after arthroplasty.

Materials/methods: Retrospective monocentric study from January 2005 to May 2019, including all the patients undergoing TKA or THA with a history or SA or current SA on the same joint.

Results: 51 patients, 31 men (61%), with a median age of 64 years, operated on 53 joints (32 knees, 21 hips) were included. SA occurred after joint infiltration (n=13), surgery (n=8), hematogenous spread (n=12), from a contiguous source (n=9) or was of undetermined origin (n=11). Median time between SA and arthroplasty was 31 [0-832] weeks. It was ≤2 years in 47 and ≤6 months in 21 cases. Arthroplasty was performed in 6 cases while the patient was still on SA treatment. Synovectomy and one-stage arthroplasty was carried out in 47 cases, two-stage arthroplasty in 8 cases. Intraoperative cultures were positive in 8 cases (15%) with the same microorganism in 3, a different one in 4, and SA was diagnosed on these cultures in one case. No antibiotic prophylaxis was administered, but all the patients received postoperative antibiotic therapy, targeting the SA microorganism and the skin flora. Median duration of treatment was 10 days, if cultures remained sterile, 82 days, if they confirmed an infection. To date, 32 patients (60%) were followed for ≥ 12 months. No SA relapse was observed. Five patients (3 TKA, 2 THA) developed a prosthetic joint infection with a different microorganism 5 months to 7 years after arthroplasty.

Conclusions: Arthroplasty may be considered after or during SA, even within a short period of time. Intraoperative cultures were positive in 15% of the cases. One-stage arthroplasty was performed if a thorough synovectomy is realized, intraoperative samples are taken systematically, and an antibiotic therapy is administered until the cultures results are available. We observed no SA relapse, but new prosthetic joint infections occurred.

Abstract 1681

Clinical utility of syndromic meningitis/encephalitis testing in children
Rebecca Yee, Utsav Pandey, Chloe Holifield, Jessica Flores, Margil Fahit, Samia Naccache, Jennifer Dien Bard

1Children’s Hospital Los Angeles, Los Angeles, United States, 2LabCorp Diagnostic Laboratories, Seattle, United States

Background: Rapid diagnosis and treatment of central nervous system infections is critical. The BioFire FilmArray Meningitis/Encephalitis Panel (FA-M/E) is a molecular syndromic test that can rapidly detect 14 pathogens in cerebrospinal fluid (CSF). Here, we sought to analyze the clinical utilization and impact of FA-M/E in children.

Materials/methods: Between June 2016-December 2017, FA-M/E was tested on 449 patients [Test group] and 412 patients received no FA-M/E testing [Control group]. Chart abstraction was conducted to compare patient medical history, antimicrobial course, and length of stay (LOS).

Results: FA-M/E testing in the Test group detected 62/449 (14%; 14 bacteria, 48 virus) targets compared to 8/412 (2%; 5 bacteria, 3 virus) in the Control group. The top three most common targets detected by FA-M/E were Enterovirus (n=25), HHV-6 (n=14), and Streptococcus agalactiae (n=7). The number of immunocompetent patients were slightly lower in the Test group compared to Control (57.9% vs 66.5%). The median time to discontinuation (TTD) of key antibiotics in patients with negative test results was shorter by 21.8 hours [32.7 vs 54.5 hrs, P=0.0002] in Test group. These drugs include gentamicin [32.2 vs 54.4 hrs, P=0.03], ampicillin [34.4 vs 54.4 hrs, P=0.0002], cefepime [28.9 vs 55 hrs, P=0.002], and meropenem [154 vs 215 hrs, P=0.52]. For a positive viral result, the median TTD of antibiotics in the Test group was 34.7 hours from time of test ordered. Results were not compared to Control group due to the low number of viral positives. Patients previously not placed on antibiotic therapy but tested positive for bacterial target were started on appropriate antibiotics 69 hours earlier in the Test group [14.5 vs 83.5 hrs, P=0.2]. Rapid FA-M/E results in the Test group resulted in a decrease in LOS by 4 days [2.7 vs 6.7 days, P<0.001] in positive patients. In the Test group, patients positive for viral targets were discharged 11.2 days [2.6 vs 13.8 days, P=0.002] earlier than those positive for bacterial targets.

Conclusions: FA-M/E significantly reduced time to identification of M/E pathogens. Use of FA-M/E was associated with accelerated optimization of therapy and decreased LOS in pediatric patients.

Rapid molecular diagnosis of Neisseria meningitidis, Streptococcus pneumoniae, Listeria monocytogenes, Enterovirus and parechovirus from blood in patients of the pediatric emergency department of a tertiary hospital

Mikel Urrutikoetxea-Gutierrez*, David Montero Vazquez, Manuel Imaz Perez, Estibaliz Ugalde Zarraga, Elisa Garrote Llanos, Gonzalez Hermosa Andres, José Luis Diaz De Tuesta

1Basurto University Hospital (Microbiology Department), Osakidetza, Bilbao, Spain, 2Basurto University Hospital (Pediatric Department), Osakidetza, Bilbao, Spain

Background: Early microbiological diagnostic of febrile illness in children under 3 years may be challenging, especially when no infectious focus is identified. New molecular techniques allow us to detect the most common pathogens in short time. The objective of this study was to evaluate the performance of molecular detection of Neisseria meningitidis, Streptococcus pneumoniae, Listeria monocytogenes, Enterovirus and Parechovirus from blood in patients of the pediatric emergency department of a tertiary hospital.

Materials/methods: We selected children under 3 years with fever (≥38ºC) without focus attending to the pediatric emergency department from January to October 2019. In addition to the routine analyses a 5ml whole blood tube was collected. Nucleic acids were extracted on MagNaPure® system under standard conditions and two different Progenie-Molecular® assays (bacterial and viral) were conducted on the SmartCycler®. We compared the results of the bacterial PCR to the gold standard blood culture and to the clinical manifestations

Results: 202 patients (123 male 79 female) were included on the study with a mean age of 0.96 years. There were 26 patients with positive samples (12.9%).

Only one patient with a positive assay for Streptococcus pneumoniae had a positive blood culture, one was contaminated, and the rest were negative. Three were clinically significant and two were doubtful about having also another infectious cause. There was no previous record of antibiotic consumption. All of them but one were vaccinated. The patient with a positive Neisseria meningitidis assay had also a positive blood culture. There were no positive blood cultures for the detected bacterial agents in the patients with negative bacterial assay or positive blood cultures when any of the viral targets were positive.

Conclusions: This diagnostic approach may be useful in this kind of patients when combined with the standard procedures, especially when an early viral diagnosis, which were almost a 10% in our series, may reduce the antibiotic burden at childhood. This molecular assay may outperform the blood culture particularly if the sample is from the early stages of the illness.

Abstract 1684

A retrospective study of pyogenic liver abscess caused by *Klebsiella pneumoniae* as a primary pathogen: computed tomography and clinical differentiation

Shinhee Hong¹, Young-Rock Jang*¹, Joong Sik Eom², Yong Kyun Cho¹

¹Gachon University Gil Medical Center, Incheon, South Korea

**Background:** The incidence of *Klebsiella pneumoniae* pyogenic liver abscesses (KP-PLA) is increasing. However, its diagnosis and treatment are often delayed, leading to complications. To retrospectively compare computed tomographic (CT) features of KP-PLAs with those of abscesses caused by other bacterial pathogens (non-KP-PLA) and to further identify prognostic factors for PLA.

**Materials/methods:** Data of 219 study patients including clinical presentation, comorbid conditions, metastatic infection, treatment duration, and mortality were retrospectively collated. CT characteristics of abscesses were recorded. Etiology was established by pus and/or blood culture. The differentiating CT features and clinical findings were compared between the monomicrobial KP-PLA and non-KP-PLA groups. Furthermore, factors related to in-hospital case fatality were analyzed.

**Results:** Our study identified thin-walled abscesses, absent rim enhancement, metastatic infection, and absence of underlying biliary tract disease as significant predictors of KP-PLA. With 3/4 criteria applied in combination, a specificity of 96.5% was achieved for KP-PLA diagnosis. The in-hospital mortality rate was 3.7%. In present study, multivariate analysis revealed that diabetes mellitus (P=.031), multiple abscesses (P=.026), internal gas bubbles (P=.041), metastatic infection (P=.004), and septic shock (P=.002) were significantly associated with mortality.

**Conclusions:** Our study suggested that thin-walled abscess, metastatic infection, absence of rim enhancement, and absence of underlying biliary tract disease are potentially useful CT findings for early KP-PLA diagnosis.

Abstract 1685

Comparing outcomes and clinical characteristics associated with carbapenemase-producing and non-carbapenemase-producing carbapenem-resistant Enterobacteriaceae bacteraemia

Michael Hovan*, Navaneeth Narayanan†, Vanessa Cedarbaum‡, Tanaya Bhowmick§, Thomas Kirn¶

*Rutgers Robert Wood Johnson Medical School, New Brunswick, United States

Background: Carbapenem-Resistant Enterobacteriaceae (CRE) bacteremia is associated with significant morbidity and mortality. CRE are classified as either carbapenemase-producing (CP-CRE) or non-carbapenemase-producing (non-CP-CRE). There are limited studies comparing the outcomes and characteristics of patients with each type of infection.

Materials/methods: We performed a chart review of 146 patients with CRE bacteremia from January 2010-July 2019. CRE was defined using the current CDC definition. The modified carbapenem inactivation method was performed on each CRE isolate to determine carbapenemase production. Electronic medical records were reviewed to obtain clinical characteristics and outcomes including prior antibiotic use, comorbidities, prior location, treatment, hospital course, and outcomes including in-hospital mortality, recurrence of bacteremia, and readmission.

Results: Of 145 cases included in our analysis, 87/145 (60%) were CP-CRE and 58/145 (40%) were non-CP-CRE. Patients with CP-CRE had a higher median Pitt Bacteremia score (4 vs. 2, p=<.001), were more likely to have been admitted from a healthcare facility (49.4% vs. 27.5%, p=.008), and to have received antibiotics in the 90 days prior to bacteremia onset (89.7% vs. 72.4%, p=.007). Patients with CP-CRE were less likely to receive active empiric therapy (19.54% vs. 51.72%, p=<.005) and active targeted therapy (74.4% vs. 86.2%, p=.08). Non-CP-CRE was associated with a 2.6 times higher hazard of death within 30 days compared to CP-CRE (hazard ratio, 2.6; 95% CI, 1.4, 4.9). Additional outcomes data are presented in Table 1.

Table 1. Outcomes

</tr>
<tr>
<td>Recurrence of CRE BSI within 90 days</td>
<td>2 (5%)</td>
<td>8 (13.8%)</td>
<td>0.158</td>
</tr>
</tbody>
</table>

Conclusions: Patients with CP-CRE were more likely to have exposure to healthcare facilities and antibiotics, have more severe illness at bacteremia onset and were less likely to receive active therapy. There was no significant difference in mortality between groups but non-CP-CRE was associated with a higher likelihood of death within 30 days.

Abstract 1693

Imipenem/relebactam pharmacokinetic/pharmacodynamic analyses from an in vivo neutropenic murine thigh infection model

Munjal Patel1*, Naveen Daryani1, Hwa-Ping Feng1, David W. Hilbert1, Maria J. Melchers2, Eleftheria Mavridou1, Katherine Young1, Matthew L. Rizk1

1Merck & Co., Inc., Kenilworth, NJ, United States, 2Radboud University Medical Center, Nijmegen, Netherlands

Background: Relebactam is a small molecule beta-lactamase inhibitor. The combination of relebactam with imipenem [in vitro] and imipenem/cilastatin [in vivo] showed significant antibacterial activity against imipenem nonsusceptible strains. We conducted pharmacokinetics/pharmacodynamics (PK/PD) analyses utilizing data from an in vivo neutropenic murine thigh infection model to derive relebactam PK/PD targets associated with stasis, 1-log kill and 2-log kill.

Materials/methods: Previously conducted PK/PD murine thigh studies were used for generation of the pooled PK/PD dataset. This dataset was obtained using two isolates of Klebsiella pneumoniae and four isolates of Pseudomonas aeruginosa at imipenem doses within two-fold of the humanized dose with varying total daily doses and dosing frequency of relebactam. Correlation analyses using the pharmacokinetic (PK) exposure and response (change in log_{10} colony-forming unit at 24 hours post-dose) was plotted against fAUC, fAUC/MIC, fCmax, fCmax/MIC, %fT>C at 1, 2 and 4 mg/L for both Pseudomonas aeruginosa and Klebsiella pneumoniae. Imipenem MICs in the presence of 4 mg/L of relebactam were used to derive the fAUC/MIC and fCmax/MIC for each strain. An Emax model with Hill coefficient was used to fit the data. Stasis, 1-log kill, and 2-log kill PK/PD targets were derived from this model.

Results: The PK/PD parameter fAUC/MIC was best correlated with response in this analysis. The derived stasis, 1-log kill, and 2-log kill fAUC/MIC PK/PD targets for Pseudomonas aeruginosa were 3.3, 4.3 and 7.0 respectively. This 2-log kill PK/PD target is consistent with previous analyses in an in vitro hollow fiber infection model.

Conclusions: PK/PD analyses using pooled data from four isolates of Pseudomonas aeruginosa and two isolates of Klebsiella pneumoniae demonstrated that fAUC/MIC is the best PK/PD driver for relebactam. The derived 2-log kill target can be used for dose justification and probability of target attainment (PTA) assessments for the fixed dose combination of imipenem/cilastatin/relebactam.

Figure. PK/PD Relationship of relebactam in the neutropenic mouse thigh infection model at imipenem 8 mg/kg and 15.9 mg/kg for Pseudomonas aeruginosa

Abstract 1697

**NK cell deficiency and cryptococcosis**

*Hôpitaux Civils de Colmar, Colmar, France, **Hopital de la Conception, Marseille, France, #University of Calgary, Calgary, Canada, AP-HM Timone, Marseille, France, #immunopole, Marseille, France*

**Background:** Human NK deficiency (NKD) is a rare primary immunodeficiency, characterized by less than 50 NK cells and < 1% of circulating lymphocytes and usually associated with *Herpesviridae* infections. We described a new phenotype of NK deficiency in a healthy 28-year-old man characterized by a predominant Dim NKD associated with a pulmonary cryptococcosis.

**Materials/methods:** The patient was admitted in December 2008 for a nonproductive cough and the discovery of non-calcified nodules on chest X rays. The patient had no medical history. He had no fever and medical examination was normal. The standard biological results were in the normal values including a normal leukocyte count and a CRP of 2mg/l. A broncho-alveolar lavage revealed the presence of many *Cryptococcus neoformans var. grubii* (serotype A). Cryptococcal antigenemia and/or fungal culture were negative in Cerebrospinal fluid, blood and urine. The patient was successfully treated by fluconazole 400mg per day for 12 months. The patient remains healthy 11 years after the diagnosis without relapse or new infection.

**Results:** Immune system evaluation revealed an isolated NKD with $7/mm^3$ [0.3%] CD3⁻CD56⁺ natural killer (NK), and $1943/mm^3$ [88%] CD3⁺ T cells stable during the 10 years follow up. Related to the NKD two adaptative immunological abnormalities were noted 1) an in vitro impaired lymphocyte proliferation assays after challenge with *Cryptococcus* antigens and 2) a stable TCD8 Vβ14 expanded population accounting for 50% of circulating TCD8 lymphocytes (figure). Cryptococcosis was therefore linked to a complex immunodeficiency via a lack of direct killing of *Cryptococcus neoformans* by NK cells, an inability to mount a Th1 response normally shaped by NK cells and a possible inhibition of anti-*Cryptococcus* TH1 lymphocytes response in relation to the huge TCD8 Vβ14 clonotype. This case illustrates the central role of NK cells in immunity against *Cryptococcus* and confirms the tight interplay between NK cells and adaptative immunity via TH1 modulation and regulation of CD8 expansion.

**Conclusions:** Two practical medical conclusions can be drawn: the need to perform NK cells determination in cases of idiothemic cryptococcosis, and the need to screen the Vβ repertoire in cases of NKD in other to better understand NKD.

Abstract 1699

**One day detection of live *Mycobacterium tuberculosis* from sputum by measuring heat-induced MPT64 secretion with ultra-sensitive ELISA**

Rikiya Takeuchi*1, Wen-Hung Wang2, Shu-Huei Jain3, Yong-Huang Jiang1, Sonoko Watanuki1, Yoshiharu Ohtaki1, Kazunari Nakaishi1,5, Satoshi Watabe3,5, Po-Liang Lu2, Etsuro Ito3,5,6

1TAUNS laboratories, Inc., R&D department, Izunokuni-shi, Japan, 2Kaohsiung Medical University Chung-Ho Memorial Hospital, Sanmin, Taiwan, 3TAUNS laboratories, Inc., R&D headquarters, Izunokuni-shi, Japan, 4Waseda University, Waseda Research Institute for Science and Engineering, Shinjuku, Japan, 5Waseda University, Department of Biology, Shinjuku, Japan, 6Kaohsiung Medical University, Graduate Institute of Medicine, Sanmin, Taiwan

**Background:** Although nucleic acid amplification tests (NAATs) are now widely used, they cannot discriminate live bacilli from dead ones because nucleic acids exist in dead bacilli. Detection of only live bacilli can be achieved by only a time-consuming culture test. In the present study, we propose a de novo TB diagnosis method for the detection of only live bacilli that has the same high-detection sensitivity as a culture test and can be performed within a day.

**Materials/methods:** TB patient sputum was pretreated, and the specimen was heated at 46°C for 1 h to induce secretion of MPT64 protein from live *M. tuberculosis*. This protein was detected with our new ultrasensitive diagnosis method that was based on an enzyme-linked immunosorbent assay (ELISA) coupled with thionicotinamide-adenine dinucleotide (thio-NAD) cycling. We compared our data with those of a culture test (MGIT), a smear test (Kinyoun staining) and a NAAT (Xpert).

**Results:** The limit of detection for MPT64 in our ultrasensitive ELISA was 0.2 amoles/assay. We confirmed that heat-induced MPT64 secretion was not observed when BCG was exposed with 8 μg/mL rifampicin. Using the cutoff value of the measuring absorbance at 17 mAbs, which corresponded to ca. 330 CFU/mL in a culture method, the sensitivity was 86.9% [93/107, 95% CI: 79.0 - 92.7%), and the specificity was 92.0% [770/837, 95% CI: 89.9 - 93.7%] compared to that of MGIT. These were better than those obtained from Kinyoun staining tests and were not significantly different from those of Xpert tests. Further, the validity for drug susceptibility examination was shown by our ultrasensitive ELISA tests better than by Xpert tests because our tests detected only live bacilli.

**Conclusions:** A de novo, culture-free, same-day TB diagnosis method detects only live *M. tuberculosis* with a high-detection sensitivity. This method is especially useful for the patients under TB-treatment to evaluate whether it is effective or not.

Abstract 1702

**Evaluation of voriconazole therapeutic drug monitoring practice: experience of a tertiary referral centre**

Yee Chin Kwang¹, Angela Netluch², Tony Lai³, Sharon Chen⁴,⁵,⁶, Hannah Yejin Kim*¹,², Indy Sandaradura⁴,⁵,⁶, Jan W. C. Alffenaar¹,⁷,⁸

¹The University of Sydney, School of Pharmacy, Faculty of Medicine and Health, Camperdown, Australia, ²Westmead Hospital, Department of Pharmacy, Westmead, Australia, ³The Children’s Hospital at Westmead, Department of Pharmacy, Westmead, Australia, ⁴Westmead Hospital, Centre for Infectious Diseases and Microbiology Laboratory Services, Institute of Clinical Pathology and Medical Research, New South Wales Health Pathology, Sydney, Australia, ⁵Westmead Hospital, Department of Infectious Disease, Sydney, Australia, ⁶The University of Sydney, Sydney Medical School, Faculty of Medicine and Health, Sydney, Australia, ⁷Westmead Hospital, Westmead, Australia, ⁸The University of Sydney, Marie Bashir Institute for Infectious Diseases and Biosecurity, Camperdown, Australia

**Background:** Therapeutic drug monitoring (TDM) is used to optimise the dosing of voriconazole. To maximize the benefit of TDM, evaluation of current TDM practice is needed. This study had three objectives: 1) to evaluate current voriconazole TDM practice by identifying patient characteristics that were associated with TDM being performed, 2) to identify potential barriers to the optimal conduct of TDM and 3) to make recommendations for practice improvement.

**Materials/methods:** This retrospective study was undertaken at Westmead hospital, an Australian tertiary hospital, and was approved by the local ethics committee. Medical records of inpatients who started voriconazole therapy with or without TDM between January 2017 and December 2018 were reviewed. TDM was evaluated for sample collection, turnaround time and actions taken for trough concentrations which were outside the therapeutic range of 1-5 mg/L. On-site and off-site sample analyses were compared with respect to turnaround time and costs in a scenario analysis.

**Results:** In total, 112 patients (median age 57 years) were included. A longer duration of voriconazole therapy rather than patient characteristics was found to predict the performance of TDM. TDM was initiated in 91 (81%) patients on a median of day 6 of voriconazole therapy with a median follow-up TDM interval of 5 days. Sample collections were frequently mistimed (n=101/253, 40%). Half (n=34/68) of the first trough concentrations were within the therapeutic range. Voriconazole dosages were adjusted for 20% (n=16/80) of trough concentrations which were outside the therapeutic range, with a follow-up measurement performed in 69% (n=11/16) of patients. Off-site sample analysis resulted in a median turnaround time of 7 days with a cost of AUD 37.10 per sample analysed. On-site implementation of immunoassay can potentially shorten the turnaround time to 3 hours and reduce the cost of TDM by up to 53%.

**Conclusions:** Mistimed sample collections, prolonged turnaround time and lack of recommendations when reporting results were barriers to the optimal conduct of TDM. On-site sample analysis, Bayesian software to guide dosing and antifungal stewardship are required to improve the current practice. Periodical evaluation of TDM practice should be established to ensure sustainable improvement in TDM practice.

Abstract 1706

Extended spectrum beta-lactamase producing Enterobacteriaceae urinary tract infections: is cefoxitin an effective therapy?

Wasim El Nekidy1, Manal Abdelsalam2, Ahmad Nusair1, Ruba Dajani1, Rania El Lababidi1, Islam Ghazi3

1Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates, 2Dubai Pharmacy College, Dubai, United Arab Emirates, 3Philadelphia College Of Pharmacy & Science, Philadelphia, United States

Background: Cefoxitin is a β-lactam antibiotic derived from substrate produced by Streptomyces lactamdurans. Cefoxitin resistance to β-lactamase hydrolysis is attributed to a 7α-methoxy group in the nucleus conferring activity against various bacteria including extended spectrum beta-lactamases (ESBL) producers. There is a growing interest in cefoxitin as a carbapenem-sparing agent; however, there is paucity in outcome data. Our study aim is to evaluate clinical and microbiologic cure rates for non-complicated Urinary Tract Infections [UTIs] caused by ESBL Enterobacteriaceae in which cefoxitin was used.

Materials/methods: We conducted a retrospective study to review all patients who were diagnosed with a UTI and received cefoxitin at our quaternary care hospital over 3 years. The primary end points were; clinical cure [defined as the resolution of urinary symptoms as documented by the treating physician] and microbiologic cure [negative repeat urinary culture if done at the end of therapy]. Relapse and recurrence data were documented and defined as repeat positive urine culture and/or clinical symptoms within 2 to 4 weeks and three months respectively.

Results: During the study period we identified 26 patients with 27 infection encounters who were diagnosed with UTI secondary to ESBL producing Enterobacteriaceae and received cefoxitin. The sample was comprised of 18 males, mean age 66.9±18.7 years, mean weight 76.8±18.7 kg, 22 patients had UTIs with an indwelling Foley catheter, and 16 were diabetic. Identified organisms were E.coli (n=17) and Klebsiella Pneumoniae (n=10). Minimum Inhibitory Concentration [MIC] was ≤4 mg/L for all isolates except for two [MIC was 8mg/L]. Cefoxitin doses ranged from 1-2 g IV q6-12 hours for mean therapy duration of 5.9±2 days. Clinical Cure was achieved in 24 of the treatment encounters (85%), and microbiological cure was confirmed in all 11 repeat cultures (100%). Five patients relapsed. Four patients had recurrence within 3 months. Mortality occurred with one patient.

Conclusions: Cefoxitin is an effective treatment for non-complicated UTIs causes by ESBL producing enterobacteriaceae. Randomized controlled studies are required to determine the efficacy of cefoxitin as a carbapenem-sparing agent.

Replication of MERS and SARS Coronaviruses in bat cells offers insights to their ancestral origins

Joshua Fung*, 1 Susanna K. P. Lau1,2,3, Hayes Luk1, Ulrich Wernery4, Patrick C. Y. Woo1,2,3

1The University of Hong Kong, Department of Microbiology, Hong Kong Island, Hong Kong, 2The University of Hong Kong, State Key Laboratory of Emerging Infectious Diseases, Hong Kong, Hong Kong, 3The University of Hong Kong, Carol Yu Centre for Infection, Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong, 4Central Veterinary Research Laboratory, Dubai, United Arab Emirates

Background: The Middle East Respiratory Syndrome coronavirus (MERS-CoV), which first emerged in Saudi Arabia 2012, has caused >2,000 cases including >800 deaths in 27 countries. Previous findings of MERS-CoV-related viruses in bats, and the ability of Tylonycteris-BatCoV HKU4 spike protein to utilize MERS-CoV receptor, human dipeptidyl peptidase 4 (hDPP4), suggest a bat ancestral origin of MERS-CoV.

Materials/methods: We developed 12 primary bat cell lines from 7 bat species, including Tylonycteris pachypus, Pipistrellus abramus and Rhinolophus sinicus (hosts of Tylonycteris-BatCoV HKU4, Pipistrellus-BatCoV HKU5, and SARS-related-CoV respectively), and tested their susceptibilities to MERS-CoVs, SARS-CoV, and human coronavirus 229E (HCoV-229E). Effort in constructing more cell lines from more relevant species and organs are on-going.

Results: 5 cell lines, including P. abramus and R. sinicus but not T. pachypus cells, were susceptible to human MERS-CoV EMC/2012. However, 3 tested camel MERS-CoV strains showed different infectivities, with only 2 strains capable of infecting 3 and 1 cell lines, respectively. SARS-CoV can only replicate in R. sinicus cells, while HCoV-229E cannot replicate in any bat cells. Bat dipeptidyl peptidase 4 (DPP4) sequences were closely related to those of human and non-human primates but distinct from dromedary DPP4 sequence. Critical residues for binding to MERS-CoV spike protein were mostly conserved in bat DPP4. Of the 5 bat cells susceptible to MERS-CoV DPP4 expression was detected, with significantly higher mRNA expression levels than those in non-susceptible cells, supporting that DPP4 expression is critical for MERS-CoV infection in bats. However, overexpression of T. pachypus DPP4 failed to confer MERS-CoV susceptibility in T. pachypus cells.

Conclusions: Our study suggested that a number of bat cell lines were susceptible to human MERS-CoV, and within those, some for camel MERS-CoV. There seems to be a correlation between susceptibility and DPP4 mRNA expression, yet other factors are at play. The broad cellular tropism of MERS-CoV should prompt further exploration of host diversity of related viruses to identify its ancestral origin. Further work is being conducted to illustrate other determinants for susceptibility and characterize the cellular response during an infection in these cell lines.

Abstract 1713

Mass PCR testing and targeted treatment for malaria in a low transmission area in Amazonia, French Guiana

Emilie Mosnier1,2, Felix Djossou2,3, Rodolphe Priam4, Magalie Demar1, Loïc Epelboin5, Majlis Douine6, Mathieu Nacher7, Aurel Carbunar8, Mélanie Gaillet8, Jordi Landier7, Yassamine Lazrek8, Lise Musset8

1Centre Hospitalier Andrée Roseman, Unité des Maladies Infectieuses et Tropicales, Cayenne, French Guiana, 1Centre Hospitalier Andrée Roseman, Unité des Maladies Infectieuses et Tropicales, Cayenne, French Guiana, 1Centre Hospitalier Andrée Roseman, Unité des Maladies Infectieuses et Tropicales, Cayenne, French Guiana, 1Centre Hospitalier Andrée Roseman, Centre d’Investigation Clinique Antilles Guyane – INSERM 1424, Cayenne, French Guiana, 1Centre Hospitalier Andrée Roseman, Laboratoire de Parasitologie - Mycologie, Cayenne, French Guiana, 1Centre hospitalier Andrée Roseman, Pôle des Centres Délocalisés de Prévention et de Soins, Cayenne, French Guiana, 1Aix Marseille University, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l’Information Médicale, Sciences Economiques & Sociales de la Santé & Traitement de l’Information Médicale (SESSTIM), Marseille, France, 1Institut Pasteur de la Guyane, Laboratoire de Parasitologie, Centre National de Référence du Paludisme, World Health Organization Collaborating Center for Surveillance of Anti-Malarial Drug Resistance, Cayenne, French Guiana

Background: Plasmodium vivax (Pv) and Plasmodium falciparum (Pf) are the main species found in French Guiana. The major difficulty for malaria elimination in the area is the prevalence of Pv, which causes relapses and asymptomatic gametocyte carriers. The aim of this study was to assess the impact of PCR-based mass screen and treat (MSAT) campaigns for malaria control in the general population of a malaria endemic area.

Materials/methods: A before-after study was conducted in 13 of 16 most affected neighborhoods (2,727/4,033 inhabitants) of the most impacted municipality of French Guiana, Saint Georges de l’Oyapock. Two MSAT interventions were implemented at a one-year interval relying on PCR for malaria detection followed by treatment of malaria positive individuals. RDT or PCR-positive consenting participants received artemether-lumefantrine against Pf or chloroquine and, in the absence of contraindication, primaquine against Pv. Symptomatic malaria incidence was passively monitored through the health center from one year before the first intervention until the end of the second intervention.

Results: More than half targeted inhabitants (1,566/2,727, 57.4%) were included in the study and 1,501 participated in the first screening, of which 1,276 (81.5%) also participated in the second screening. Overall, there were 1,231 individuals with complete PCR results. During the first MSAT, the PCR-positivity rate was 6.7% [6.0% Pv, 0.7% Pf with 73% of asymptomatic carriage], compared to 2.9% [2.4% Pv 0.5% Pf with 88% of asymptomatic carriage] during the second intervention (p<0.005). All positive participants received treatment and any severe side effect was reported. During the first intervention a large seasonal malaria epidemic was reported. A significant decrease of incidence was observed by passive monitoring among study participants (95 to 43/1566 person-years, p<0.005) but not in the non-participating population (38 to 59/2467 person-years p=0.24).

Conclusions: In French Guiana, a mass PCR screening and treatment intervention was operationally feasible and could reduce Plasmodium sp. carriage and incidence. Limitations of this study include seasonal variations and villager mobility, which may have limited the impact of the intervention. Strategies that only target populations with RDT testing and symptomatic cases treatment alone are likely to overlook a large part of the reservoir.

Abstract 1716

**Ceftobiprole and daptomycin concentrations in valve tissue in a patient with aortic native valve endocarditis**

Silvia Boni¹, Miriam Antonucci², Valeria Avataneo², Amedeo De Nicolò³, Luigi Martinelli¹, Stefania Artioli¹, Giovanni Di Perri², Antonio D’Avolio*²

¹ASL 5 Spezzino, La Spezia, Italy, ²Università di Torino, Torino, Italy, ³ICLAS, Rapallo, Italy

**Background:** A main determinant of clinical response to antibiotic treatment is drug concentration at the infected site. Data on ceftobiprole (CFB) valve penetration are lacking. We measured CFB and daptomycin (DPT) concentrations in a native infected valve to verify their pharmacokinetic penetration and relationship with pharmacodynamic microbiological markers.

**Materials/methods:** One patient undergoing surgical valve substitution for native valve endocarditis (NVE) with lung and brain embolism and receiving intravenous CFB and DPT was studied. Valve and plasma specimens were collected at a variable time in the operatory day (4.00pm and 8.00pm, respectively) after CFB (500mg 8.00am and 4.00pm) and DPT (500mg 8.00am) administration. Drug concentrations were measured by high-performance liquid chromatography with tandem mass spectrometry kit for plasma (CoQua Lab srl) and a modified-method for the valve tissue evaluation. The valve tissue quantifications were performed in triplicate [in two different days], from 3 different positions on valve.

**Results:** The isolated microorganism was a MRSA with CFB and DPT MIC<2 mg/L and <1 mg/L, respectively. The CFB and DPT plasma concentrations were 36.2 and 14.1 mg/L, respectively and the extrapolated concentration at the operatory time were 16.4 and 19.1 mg/L for CFB and DPT, respectively; the corresponding median CFB and DPT valve concentrations were 2.26 (IQR 1.44-2.69) and 12.9 mg/L (IQR 5.51-20.9), respectively. The estimated tissue/plasma ratios for CFB and DTP were 0.14 and 0.67, respectively.

**Conclusions:** NVE is a serious infection with potentially fatal consequences. From the data available, we can suppose that the time above the minimum inhibitory concentration (T>MIC) was probably near to 24h in all compartments. CFB valve penetration (>14%) is not high but seems to be enough to cover MRSA CFB MIC (the patient has had a good clinical and microbiological response). For DTP, valve penetration (>67%, 12.9 mg/L) and plasma concentration (12h post-infusion) 14.1 mg/L, seems to be enough to cover MRSA sensitivity both in plasma and in tissue. DTP tissue concentration has a very high variability, probably influenced by tissue blood irroration. This is the first data on CFB valve tissue penetration, and it needs to be confirmed in other patient valve tissues.

Abstract 1717

The effectiveness of nitrofurantoin, fosfomycin and trimethoprim for cystitis in relation to renal function

Thijs Ten Doesschate*, Eva Van Haren2, Rixt Anna Wijma2,3, Birgit Koch4, Marc J.M. Bonten5, Cornelis H. Van Werkhoven4

1University Medical Center Utrecht, University of Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2Erasmus University Medical Center, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands, 3Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands, 4Erasmus University Medical Center, Department of Hospital Pharmacy, Rotterdam, Netherlands, 5University Medical Center Utrecht, Department of Medical Microbiology, Utrecht, Netherlands

Background: Nitrofurantoin, fosfomycin-trometamol and trimethoprim are recommended for the treatment of cystitis in primary care in the Netherlands. In patients with impaired renal function, lower urinary concentrations have been reported for all three antibiotics, which may be associated with a higher risk of treatment failure. We evaluated the effects of renal function on clinical failure rates of treatment with nitrofurantoin, fosfomycin-trometamol and trimethoprim in cystitis patients in primary care.

Materials/methods: Data was retrospectively obtained from the Julius General Practitioners’ Network, consisting of 78 Dutch general practitioner (GP) practices between 2013 and 2019. Episodes were classified as uncomplicated or complicated cystitis if antibiotics were prescribed according to Dutch guideline. The estimated glomerular filtration rate (eGFR) was calculated using plasma creatinine, age and gender. Clinical failure was defined as a second antibiotic prescription for cystitis or pyelonephritis within 28 days post-prescription. We used mixed effects regression analysis, with patient and GP practice as random effects and demography, comorbidity, cystitis history as fixed effects.

Results: In 21,891 unique patients 42,473 episodes were included consisting of 31,014 uncomplicated cystitis, treated with 5 days nitrofurantoin (NF5, n=24,591), 1 dosage fosfomycin-trometamol (FT1, n=5,359) and 3 days trimethoprim (TMP3, n=1,064), and 11,459 complicated cystitis, treated with 7 days nitrofurantoin (NF7, n=10,628) and 7 days trimethoprim (TMP7, n=831). An eGFR below 60 mL/min was observed in 3,757 of 42,473 episodes (8.8%). Adjusted odds ratios (aOR) for clinical failure per 10 mL/min decrease in eGFR were 1.05 (95%CI:1.01-1.09) for NF5, 0.96 (95%CI:0.92-1.01) for FT1, 0.98 (95%CI:0.89-1.08) for TMP3, 1.05 (95%CI:1.02-1.09) for NF7 and 1.02 (95%CI:0.93-1.14) for TMP7. In patients with uncomplicated cystitis and normal renal function (eGFR ≥60 mL/min), FT1 or TMP3 resulted in more clinical failures than NF5, with aOR of 1.37 (95%CI:1.18-1.59) and 1.42 (95%CI:1.07-1.87), respectively. In patients with uncomplicated cystitis and impaired renal function (eGFR<60 mL/min), FT1 was associated with less clinical failures than NF5 (aOR 0.61,95%CI:0.39-0.95).

Conclusions: In patients with uncomplicated cystitis and impaired renal function treatment with nitrofurantoin was associated with more clinical failure than fosfomycin-trometamol. In patients with uncomplicated cystitis and normal renal function treatment with fosfomycin-trometamol or trimethoprim was associated with more clinical failure than nitrofurantoin.

Abstract 1720

Current use of baseline chest CT in haematology patients at high risk for invasive fungal infection

Jannik Stemler*1,2,3, Caroline Bruns1,2,3, Sibylle Mellinghoff1,2,3, Philipp Köhler1,2, Oliver A. Cornely1,2,4

1Hospital of the University of Cologne, Department I of Internal Medicine, ECMM Excellence Centre of Medical Mycology, University Hospital of Cologne, Köln, Germany, 2Universität zu Köln, Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Köln, Germany, 3Deutsches Zentrum für Infektionsforschung (DZIF) e. V., Partner Site Bonn-Cologne, Köln, Germany, 4Hospital of the University of Cologne, Clinical Trials Centre Cologne, ZKS Köln, Köln, Germany

Background: Baseline chest computed tomography (BCT) in high-risk hematology patients appears to allow early diagnosis of invasive pulmonary aspergillosis (IPA) since recent studies found CT abnormalities close to admission in 36% and 31%, respectively. Distribution of BCT implementation in hematology units and the impact on patient outcome is unknown.

Materials/methods: A web-based questionnaire was designed and disseminated via www.clinicalsurveys.net. Members of twelve international scientific bodies were invited. Estimated numbers of annually treated high-risk hematology patients, chest imaging timepoints and techniques, IPA rates, and follow-up imaging were assessed. BCT was defined as chest CT performed upon diagnosis of malignancy or hospital admission.

Results: Ninety-two of 142 participants (64%) from 43 countries answered all questions. Medical specialties included infectious diseases (n=69; 49%), hematology (n=68; 48%), microbiology (n=15; 11%), and other (n=26, 18%). Numbers of patients treated per year were estimated 5,505 acute myelogenous leukemia, 2,641 acute lymphoblastic leukemia, and 5,287 allogeneic hematopoietic stem cell transplantation.

Baseline CT was performed in 57% (n=54) of 92 hospitals. Upon diagnosis of malignancy or admission, 48% and 24% centers performed BCT, respectively. Overall, HSCT was the most frequent BCT indication (44.2%, n=42) and BCT was more frequently performed in relapsed than in de novo leukemia.

European centers performed BCT in 59%, whereas non-European centers did in 53%. CT was predominantly low-dose and contrast-enhanced in 38% of centers. Median estimated IPA rate was 8% and did not differ significantly between BCT centers [9%; IQR 5 - 15%] and non-BCT centers [7%; IQR 5 - 10%] (p=0.69). Follow-up CT after diagnosed IPA was performed in 98% (n=90), while only three (3.3%) centers did this at guideline-recommended timepoints.

Conclusions: In high-risk hematology patients baseline chest CT at diagnosis or admission became a standard-of-care. Randomized, controlled studies are needed to investigate its impact on patient outcome.

Abstract 1722

A rocky road: lessons learned from a case of disseminated Rhodococcus hoagii infection
Rena Hoffmann*1, Clinton Van Der Westhuizen1, Mae Newton-Foot1

1Stellenbosch University, National Health Laboratory Service, Tygerberg Hospital, Stellenbosch, South Africa

Background: Rhodococcus species are gram-positive bacilli that primarily infect immunocompromised patients. Rhodococcus equi, reclassified as R. hoagii, is the major pathogenic species that usually affects the pulmonary system, whereas bloodstream infections (BSI) are often catheter-related. We describe a case of BSI where the source was a soft tissue infection mimicking Actinomycosis. The identification was established by 16S rRNA sequencing. This case underscores how Rhodococcus infections may be undiagnosed or misdiagnosed due to identification challenges in the routine laboratory.

Clinical presentation: A 46 year old HIV-infected man (CD4+ count of 42 cell/mm³; defaulted antiretrovirals) was admitted to hospital due to progressive dysphagia. CT scans revealed extensive necrosis of the mouth floor and neck lymphadenitis with abscesses draining via sinus tracts. C. pseudotuberculosis and unidentified gram-positive bacilli were initially isolated from the affected site. Follow-up culture revealed an unidentified gram-positive bacillus – confirmed by 16S rRNA sequencing as Rhodococcus species. TB cultures yielded Mycobacterium intracellulare and only anti-mycobacterial therapy was initiated at this stage.

On a subsequent admission for C. neoformans meningitis, a Bacillus species was cultured from blood. Shortly afterwards, re-admission for pneumonia occurred. He developed a nosocomial BSI with K. pneumoniae. Other blood cultures during this admission showed Bacillus species and Corynebacterium species, respectively. Dysphagia and failure of clinical improvement persisted. Multiple specimens from the neck and blood cultured Turicella otitidis. However, molecular methods identified them all as R. hoagii.

On the basis of in-vitro antibiotic susceptibility testing performed on the R. hoagii, the patient was commenced on imipenem, levofloxacin and rifampicin. He improved and was discharged on levofloxacin, rifampicin and other M. intracellulare treatment. Antiretroviral therapy was re-initiated.

Conclusions: Our case represents a disseminated infection with R. hoagii, with co-infection of M. intracellulare. Before molecular diagnostics, Rhodococcus was often misidentified as Mycobacterium species based on its acid-fast staining properties. The patient responded to combination therapy – recommended for at least nine months. R. hoagii was unidentified, misidentified or not identified to species level. This led to a significant delay in diagnosis and initiation of appropriate treatment.

V., Partner Site Bonn-Cologne, Köln, Germany, 4Duke University Medical Center, Infectious Diseases Division, Durham, United States, 5University of Freiburg, Department of Internal Medicine I, Medical Center of Freiburg University, Faculty of Medicine, Freiburg im Breisgau, Germany, 6University of California San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States, 7Medical University of Graz, Section of Infectious Diseases and Tropical Medicine, Department of Internal Medicine, Graz, Austria, 8Strasbourg University, Department of Oncology and Hematology, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, 9Friedrich Alexander University of Erlangen Nuremberg, Department of Medicine 5 for Hematology and Oncology, Erlangen University Hospital, Erlangen, Germany, 10Hospital of the University of Cologne, Department of Hospital Hygiene and Infection Control, Köln, Germany, 11Universität zu Köln, Clinical Trials Centre Cologne (ZKS Köln), Köln, Germany

Background: The Rasamsonia spp. complex comprises filamentous fungi causing pneumonia and occasionally disseminated disease in immunocompromised patients. To provide a knowledge base of risk factors and for therapeutic decisions in invasive Rasamsonia spp. complex infection.

Materials/methods: A literature search was performed in PubMed aiming at all reported cases of invasive infection due to Rasamsonia spp. (formerly Geosmithia spp./Penicillium spp.) since data base inception. These were complemented by cases from the FungiScope® registry. Cases of mere colonization were excluded.

Results: We identified 23 invasive infections due to Rasamsonia spp., six (26.1%) in the FungiScope® registry and 17 (73.9%) in the literature. Main risk factors were chronic granulomatous disease (n=12, 52.2%), immunosuppressive treatment (n=10, 43.5%), hematopoietic stem cell transplantation (n=7, 30.4%), graft-versus-host disease, and major surgery (n=4, 17.4%, each). Predominantly affected organs were the lungs (n=21, 91.3%), disease disseminated in seven cases (30.4%). Initial misidentification of the fungus occurred in 47.8% (n=11) and sequencing was used in 69.6% of patients (n=16) to establish definite diagnosis. Breakthrough infection occurred in 13 patients (56.5%). All patients received antifungal treatment, mostly with posaconazole (n=11), caspofungin (n=10) or voriconazole (n=9). Combination therapy was administered in 13 patients (56.5%). Susceptibility testing showed high minimum inhibitory concentrations for azoles and amphotericin B, but not for echinocandins. No preferable treatment influencing favorable outcome was identified. Overall mortality was 39% (n=9) at last patient contact while attributable mortality to Rasamsonia spp. was 17.4% (n=4).

Conclusions: Rasamsonia spp. are emerging fungi causing life-threatening infections, especially in immunocompromised and critically ill patients. Breakthrough infection occurs frequently and sequencing methods are necessary for diagnosis. Mortality is high. Treatment is challenging and clinicians dealing with this patient population should become aware of this infection.

Abstract 1724

Emergence of novel recombinant Coxsackievirus A6 in Hong Kong

Kam Leng Aw Yong*, Susanna K. P. Lau1,2,3, Pyrear S. H. Zhao1, Siddharth Sridhar1,2,3,4, Cyril Yip1, Kelvin Kai Wang To1,2,3,4, Patrick C. Y. Woo1,2,3,4, Kwok-Yung Yuen1,2,3,4

1The University of Hong Kong, Department of Microbiology, Hong Kong, Hong Kong, 2The University of Hong Kong, State Key Laboratory of Emerging Infectious Diseases, Hong Kong, Hong Kong, 3The University of Hong Kong, Collaborative Innovation Centre for Diagnosis and Infectious Diseases, Hong Kong, Hong Kong, 4The University of Hong Kong, Carol Yu Centre for Infection, Hong Kong, Hong Kong

Background: Coxsackievirus A6 (CV-A6), a member of enterovirus A in the genus Picornaviridae, has recently emerged globally as serious public health threats. Since 2008, CV-A6 arose and replaced enterovirus A71 (EV-71) and CV-A16 as the main causative agents responsible for hand, foot and mouth disease (HFMD) outbreaks worldwide. Recombination is an important mechanism for genetic evolution in RNA viruses, and CV-A6 recombinant strains were reported in China, Thailand, United Kingdom and Spain. To determine whether recombination events play a role in the evolution of the emergence of CV-A6 strains in Hong Kong, CV-A6 strains isolated from hospitalized patients were sequenced. Potential recombinant CV-A6 strains were further proceed with complete genome sequencing and recombination analysis.

Materials/methods: Nasopharyngeal aspirates (NPAs) were collected from patients from regional hospitals in Hong Kong. All specimens were confirmed positive for CV-A6 by RT-PCR and partial 5' untranslated region (5' UTR) sequencing. The partial VP1, 2C and 3D regions were sequenced, and phylogenetic trees were constructed. Five CV-A6 were selected for complete genome sequencing and recombinant analysis.

Results: CV-A6 were detected positive in 40 NPAs collected from January 2010 to December 2018, and partial VP1 gene of 28 CV-A6 strains were amplified for genotyping. The phylogenetic analysis of VP1 gene revealed that CV-A6 strains circulating in Hong Kong were divided into two subgenotypes: D5 (n=24) and D4 (n=4). Subsequently, the phylogenetic analyses of 2C and 3D gene analysis showed that eight CV-A6 strains are potential recombinant strains. Complete genome sequencing was performed and four recombinant CV-A6 strains were identified. Recombination between CV-A6 and CV-A4, and recombination between CV-A6 and EV-A71 were observed in three and one recombinant CV-A6 strains, respectively. 3D gene was identified as the frequent recombination site for CV-A6 strains.

Conclusions: Recombination plays an important role in the emergence and evolution of CV-A6 strains in Hong Kong. Recombinant CV-A6 strains are generally recombinant with CV-A4 and EV-A71 strains at 3D gene.

Abstract 1725

Interim analysis: a large-scale clinical evaluation of QMAC-DST for rapid drug susceptibility testing of {\textit{Mycobacterium tuberculosis}}

Kwang-Hyuk Seok\textsuperscript{1}, Sujeoun Kim*\textsuperscript{2}, Jiyeon Na\textsuperscript{1}, Sangyeop Lee\textsuperscript{2}, Eunji Jo\textsuperscript{2}, Haeun Kim\textsuperscript{2}, Dongyoung Kim\textsuperscript{2}, Sunghoon Kwon\textsuperscript{2}

\textsuperscript{1}Korean Institute of Tuberculosis, Cheongju, South Korea, \textsuperscript{2}QuantaMatrix Inc., Seoul, South Korea

**Background:** The effective management of TB and MDR/XDR-TB relies upon rapid diagnosis and appropriate treatment of resistant infections. Culture-based phenotypic drug susceptibility testing (DST) methods are currently the gold standard for drug resistance detection. In the previous study, we examined the accuracy of QMAC-DST which is an automated rapid phenotypic DST system based on imaging technology. The results of the QMAC-DST for MDR/XDR-TB showed a high agreement rate compared to a conventional method, and the QMAC-DST could provide the fast result within around 1-week turnaround time. In the present study, we have been evaluating the accuracy and speed of the QMAC-DST system through a large number of clinical strains isolates collected from multi-centers. As an interim analysis, the result from 555 samples is presented.

**Materials/methods:** The Korean Institute of Tuberculosis (KIT, Osong, Republic of Korea) has provided laboratory services for public health centers. We conducted the conventional DST and the QMAC-DST for the 555 clinical strains which were sent to the KIT for DST from July 2019 to September 2019. Those strains were positive cultures in liquid or solid medium. The conventional DST was performed by the absolute concentration method with Lowenstein-Jensen (L-J) medium. And the QMAC-DST was performed by the automatic imaging and analyzing system with QMAC-DST panel. We compared the results of both methods and calculated the accuracy of QMAC-DST.

**Results:** Except for strains suspected of contamination or growth failure, The QMAC-DST for 480 clinical samples for 13 anti-tuberculosis drugs were showed a high agreement rate (98.73\%) compared to conventional DST. The average time required for QMAC-DST was 7.9 days, which was much faster than conventional DST (21 days).

**Conclusions:** The QMAC-DST was evaluated with 555 samples out of 3000 targets. The interim results of QMAC-DST were reported 2\textsuperscript{2}3 weeks earlier than conventional DST and showed a high concordance rate. In this study, we confirmed that the QMAC-DST can provide a rapid and accurate diagnosis for effective TB treatment so that it can be an alternative DST method replacing slow conventional DST methods.

Abstract 1726

Reactive hyperaemia measured by peripheral arterial tonometry correlates with glycocalyx degradation and the presence of sepsis in the critically ill patient

Luís Malheiro*1, Rita Gaio2, Manuel Vaz-Da-Silva1, Sandra Martins1, António Sarmento1, Lurdes Santos1

1Saint John Hospital, Porto, Portugal, 2Department of Mathematics FCUP, Porto, Portugal

Background: Sepsis is a life-threatening condition whose diagnosis relies on markers of organic damage in the presence of infection. The endothelium is virtually present in every organ and is highly influenced by the circulating cytokines and may be responsible for the microvascular organic damage seen in sepsis. We investigated if reactive hyperaemia correlates with the presence of sepsis and whether it may be used to distinguish between septic and non-septic patients in the Intensive Care Unit (ICU).

Materials/methods: We performed a prospective study of a cohort of ICU admitted patients. Patients were assessed for endothelial dysfunction quantifying the Reactive Hyperaemia Index (RHI) using peripheral arterial tonometry and biomarkers of glycocalyx degradation. Patients with infection were compared to a control group of patients without evidence of infection.

Results: Eighty-six patients were included in the study, 58 (67.4%) in the septic group and 28 (32.6%) in the control group. There were no significant clinical differences between groups except for age. The natural logarithm of RHI (Ln_RHI) was negatively correlated with cardiovascular comorbidities, disease severity and plasma levels of soluble E-selectin (p=0.024) and Syndecan-1 (p<0.001). Ln_RHI was lower in septic patients when compared with controls (0.53±0.48 vs 0.69±0.42, respectively) and multivariate analysis adjusted for age predicted that within each age group, each 0.1 unit decrease in the Ln_RHI increased the odds for infection by 14.6%.

Conclusions: Reactive hyperaemia measured by peripheral arterial tonometry seems to be closely related to endothelial glycocalyx degradation and endothelial activation. Sepsis is associated with lower RHI in critically ill patients when compared to non-septic patients and RHI may be a useful tool for the diagnosis of infection in this setting, especially in an older population.

Evaluation of the Aptima BV assay for detection of bacterial vaginosis by comparison with the BD MAX vaginal panel assay

Sanne Voogd1, Ben Ridwan2, Diana Willemse-Erix2*, Suzanne Lutgens-Dumont1, Mirjam Hermans1

1Jeroen Bosch Hospital, Laboratory for Medical Microbiology and Infection Prevention, ‘s-Hertogenbosch, Netherlands, 2Comi-cro, Hoorn, Netherlands

Background: Bacterial vaginosis (BV) is one of the most common lower genital tract conditions, of which the diagnosis is challenging due to its complex polymicrobial nature. To study the performance of the Aptima® BV assay (Hologic), 238 genital swabs were tested in parallel with the BD MAX™ Vaginal Panel (Beckton Dickinson). Both assays are nucleic acid target amplification-based, fully automated -sample in answer out- and include an internal control. Microbiome-based algorithms are used to determine BV test results.

Materials/methods: Two hundred thirty-eight swabs (97 cervical, 85 vaginal, 55 introitus, and 1 fluor) were from women ≥ 18 years (mean age 38, range 18-94) being seen by their general practitioner (symptomatic women, n=198) or for routine obstetric / gynaecological care (symptomatic and asymptomatic women n=40). Swabs were analysed by parallel testing on the same day. Two-hundred µl (BD Max) or 400 µl (Aptima) of Eswab medium were transferred to BD MAX™ UVE tubes or Aptima Specimen Transfer tubes, respectively, and tubes were placed directly on the BD MAX™ or the Panther system. At the same time, aliquots were frozen for discrepancy evaluation with the AmpliSens® Florocenosis / Bacterial vaginosis-FRT PCR kit (ATRiDA). If at least two tests were positive or negative for BV the sample was considered true positive or negative, respectively.

Results: Seventy-two samples tested positive in both assays, 133 samples negative, while 33 samples showed discordant test results. Further analysis of the discordant samples with the AmpliSens® kit yielded a BV-positive or BV-negative test result for 27 samples.

</tbody>
</table>

For the Aptima assay for BV detection the number of true positives was 84, false positives 5, true negatives 136 and false negatives 7, yielding a sensitivity, specificity, PPV and NPV of 92.3%, 96.45%, 94.4% and 95.1%. For the BD MAX™ Vaginal Panel assay these values for BV were 86.8%, 92.9%, 96.3% and 92.0%, respectively. One sample yielded an invalid test result in the Aptima test, 10 samples in the BD test [6 indeterminate, 4 unresolved].

Conclusions: We conclude that the Aptima® BV assay is an easy to carry out test, suitable for the reliable detection of bacterial vaginosis.

Abstract 1730

**Effects of penicillin V on the intestinal microbiota in patients with pharyngo-tonsillitis**

Petra Edquist*, Karin Rystedt, Christian Giske, Katarina Hedin, Sigvard Mölstad, Maj Ringman, Gunilla Skoog Ståhlgren, Pär-Daniel Sundvall, Charlotta Edlund

1Public Health Agency of Sweden, Solna, Sweden, 2University of Gothenburg, Gothenburg, Sweden, 3Karolinska Institutet, Stockholm, Sweden, 4Lund University, Malmö, Sweden

**Background:** Increasing antimicrobial resistance is a growing threat to human health. The commensal microbiota, in particular the rich intestinal microbiota, may function as a reservoir of antibiotic resistance genes. Studies on the ecological impact of penicillin V with current dosage regimens are lacking. The objective of the present investigation was to evaluate potential impact on the faecal microbiota with focus on beta-lactam resistance.

**Materials/methods:** Thirty-one patients, a subset from a recent study, treated with penicillin V for 5 days (n=14, daily dose 3.2g) or 10 days (n=17, daily dose 3.0g), contributed each with 3 faecal samples. The specimens were collected before penicillin V administration, directly after the last dose and 7-10 days after discontinuation of treatment. Samples were inoculated semi-quantitatively on non-selective and selective screening chromogenic agar plates, to study beta-lactam resistance, shift in Enterobacteriales, overgrowth and shift among enterococci, colonisation with candida and Clostridoides difficile. Susceptibility testing was performed on resistant isolates. Results were analysed by Wilcoxon paired-rank sum test and Mann-Whitney U-test.

**Results:** The amount of Enterobacteriales resistant to ampicillin and third generation cephalosporins, mainly Amp C producers, increased significantly from baseline (sample 1) to after the last dose of penicillin V (sample 2), p<0.01 and p<0.05, respectively. At follow-up (sample 3), the increase from baseline was no longer significant. There was a non-significant shift from E. coli to non-E. coli, between samples 1 and samples 2. Eight patients were newly colonised by unusual gram negative rods in sample 3. Three patients had new colonisation with Candida albicans in sample 2. One patient had moderate growth of toxin-positive C. difficile in sample 3 and symptoms consistent with C. difficile infection. No significant differences were seen between the two study groups (penicillin V for 5 or 10 days).

**Conclusions:** Treatment with penicillin V caused marked ecological impact on the faecal microbiota. The amount of beta-lactam resistant Enterobacteriales increased significantly during the treatment period. Ecological disturbances in the microbiota were still seen 7-10 days after treatment discontinuation. These results challenges the general perception that penicillin V is an "ecological safe" agent that can be prescribed without inducing resistance.

Abstract 1735

Genome-based surveillance of clinical vancomycin-resistant Enterococcus faecium reveals increased prevalence of vanB-type isolates of ST117/CT71 in German hospitals, 2010-2016

Bernd Neumann*, Michael Kresken2,3, Guido Werner1

1Robert Koch Institute, Division of Nosokomial Pathogens and Antibiotic Resistance, Wernigerode, Germany, 2Antiinfectives Intelligence GmbH, Rheinbach, Germany, 3Rheinische Fachhochschule Köln gGmbH, Cologne, Germany

Background: Enterococci are considered as common cause of nosocomial infections, where treatment options are limited due to intrinsic and acquired resistances. Particularly vancomycin-resistant E. faecium (VRE) represent a burden, since well-adapted lineages are widespread established in healthcare facilities. In recent years, the upcoming resistance to linezolid diminishes this last-line treatment option. For this study, microbiological and genome-based analyses of VRE clinical isolates were realized. VRE were collected as part of the tri-annual resistance studies of the Paul-Ehrlich-Society at 25 medical laboratories in Germany, Austria and Switzerland in 2010, 2013 and 2016.

Materials/methods: A total of 166 VRE isolates was collected. Susceptibility to 18 antibiotics was tested by applying the broth microdilution method. Resistance breakpoints were assessed according to EUCAST guidelines (v. 9.0). Whole genome sequencing was realized with Illumina technology. For high-resolution genotyping and to determine phylogenetic relations, cgMLST analyses were performed with the generated data.

Results: In 2010, 38 isolates were collected, in 2013 52 and in 2016 a total of 76. From 2010 to 2016, a change in vancomycin-resistance type from vanA to vanB was observed. 62 Different genotypes were identified and were assigned to distinct clusters in phylogenetic analysis, showing individual population composition for each study year. In total, the most abundant genotype was ST117 [45%]. In 2016, the predominant lineage was genotype ST117/CT71 [n=23], showing the vanB-type; the predominant genotype detected in 2010 (ST192, vanA) was almost absent in 2016, while ST203 with vanA-type was present in all study years. Additionally for 2016, 8 linezolid-resistant isolates were identified, so in 2016 LVRE (vanA and vanB) had a prevalence of about 10%.

Conclusions: Structured surveys like the PEG resistance studies allow a snapshot of hospital pathogens’ prevalence within a given time frame and geographical coverage. We observed the fluctuation of genetic lineages over time, like the rise of ST117 showing the vanB-type. cgMLST analyses determined various subtypes within ST117 such as CT71, which in turn ascertained a cross-hospital, regional or country-wide spread of distinct VRE strain types. At the same time, some lineages were present in all cohorts.

Abstract 1743

Risk for antibiotic resistance in patients hospitalised with urinary tract infection: a matched case-control study using the French health insurance database

Marion Opatowski1, Christian Brun-Buisson1, Mehdi Touat1, Jérome Salomon1, Didier Guillemot1, Philippe Tuppin2, Laurence Watier1

1Biostatistics, Biomathematics, Pharmacoepidemiology and Infectious Diseases (B2PHI), Inserm, UVSQ, Institut Pasteur, Université Paris-Saclay, Paris, France, 2Caisse nationale de l’assurance maladie, Direction de la stratégie des études et des statistiques, Paris, France

Background: Antibiotic resistance rates are increasing among urinary pathogens, both in community and hospital infections, leading to increased therapeutic difficulties, and resulting in worse clinical and economic outcomes. Several risk factors of acquiring antibiotic-resistant urinary tract infections (UTIs) have been highlighted by previous studies, but few are universally accepted. This study aims to assess the risk factors for infection due to antibiotic-resistant bacteria (ARB) in patients hospitalised for an UTI, using the comprehensive French national health insurance database (SNDS).

Materials/methods: Incident hospitalizations for UTI diagnosis, due to an Escherichia coli, Klebsiella pneumoniae, Staphylococcus aureus, Pseudomonas aeruginosa or an Enterococcus were identified from Jan 1st 2015 to Dec 31 2017. Only stays for which bacteria could be determined were included. Cases (UTIs due to ARB) were matched to controls (UTIs without ARB) according to age (± 5 years), gender, infection code, year of admission, and bacterial species. Healthcare-associated (HCAI) and community (CAI) infections were studied separately, and conditional multivariate logistic regressions were stratified by gender.

Results: For all three years, 9759 cases were identified from which 6606 CAIs and 3001 HCAIs were matched with controls. For all infections, consumption of antibiotic in the last 3 months was a risk factor for ARB UTI, with an OR reaching 3.84 [3.04−4.85] for men with CAI who had received ≥ 3 antibiotics. The risk increased when the last antibiotic taken was broad spectrum, whether associated with a previous UTI or not [OR 2.59 [2.15−3.11] vs. 1.35 [1.18−1.53], respectively]. Having undergone a surgical procedure on the urinary tract during the last 3 months increased the risk for men with CAIs (OR 1.39 [1.14−1.69]) and for women with HCAIs (OR 1.72 [1.37−2.17]). Staying in ICU > 7 days in the past 3 months increased slightly the risk for men with HCAIs [OR 1.44 [1.03−2.02]]. Diabetes, immunosuppression, neurological disease, urinary tract diseases, and pregnancy had no impact on ARB infection.

Conclusions: This study confirms the importance of broad antibiotic consumption on the risk of UTI with ARB, and the importance of prevention during surgical procedure on the urinary tract, and long ICU stays.

**Characterisation of the microbial community in patients with pharyngeal gonorrhoea infection**

Claudio Foschi*1, Camilla Ceccarani1, Tania Camboni2, Clarissa Consolandi2, Melissa Salvo1, Valeria Gaspari3, Antonietta D’antuono3, Matteo Belletti3, Maria Carla Re1, Marco Severgnini2, Antonella Marangoni1

1University of Bologna, DIMES, Microbiology, Bologna, Italy; 2National Research Council, Institute of Biomedical Technologies, Segrate, Milan, Italy; 3Sant’Orsola-Malpighi Hospital, UO Dermatology, Bologna, Italy

**Background:** Pharyngeal gonorrhoea is a common sexually transmitted infection among ‘men having sex with other men’ (MSM). To appropriately survive and persist in the oro-pharynx, Neisseria gonorrhoeae (NG) has to compete with the local commensal bacteria. The aim of this study was to characterize the pharyngeal bacterial community profiles during an ongoing NG infection in a well-selected cohort of MSM.

**Materials/methods:** A total of 70 HIV-negative MSM reporting condomless oral intercourse were enrolled: in particular 45 non-infected subjects and 25 patients with pharyngeal gonorrhoea were considered. Starting from pharyngeal swabs, the pharyngeal microbiome composition was analysed through sequencing of hypervariable V3-V4 regions of the 16S rRNA gene. Bacterial biodiversity and distribution were characterized via alpha and beta diversity evaluations. A functional prediction of the bacterial metabolic pathways was performed using PICRUSt software and KEGG pathways database. Differences in abundances of bacterial taxa and functional pathways among experimental groups were analyzed by Mann-Whitney t-test, using MATLAB software (Natick, MA, USA). p-values < 0.05 were considered as significant for each statistical analysis.

**Results:** The pharyngeal microbiome of all subjects was dominated by Prevotellaceae, Veillonellaceae and Streptococcaceae families. Patients with pharyngeal gonorrhoea exhibited significantly higher levels of Spirochaetaceae [in particular, bacteria belonging to Treponema genus] compared to non-infected individuals. Considering low-abundance bacterial genera, an imbalance between aerobe and anaerobe microorganisms was observed: the pharyngeal microbiome of NG-positive patients was richer in several anaerobes (e.g. Porvimonas, Peptococcus, Clostridiales, Prevotellaceae) and poorer in various aerobe genera (i.e. Pseudomonas, Escherichia). The metabolic functional prediction indicated a more abundant involvement of D-glutamine and D-glutamate metabolism, carbohydrate metabolism, as well as a greater activation of the energy metabolism in patients with pharyngeal gonorrhoea.

**Conclusions:** Information about the bacterial composition of the pharyngeal microbiome in case of gonorrhoea could shed light on the pathogenesis of the infection and open new perspectives for the prevention and control of this condition.

Abstract third-party references: This study was supported by a grant from the Taiwan Centers for Disease Control [MOHW108-CDC-C-114-000109 and MOHW-107-CDC-C-114-000104].

**Background:** Treatment of latent tuberculosis infection (LTBI) is a cornerstone strategy for control of TB. Drug adverse events (AE) leading to treatment interruptions compromise treatment of LTBI. Considerable progress has been made in identifying genetic risk factors for idiosyncratic adverse drug reactions. This study aims to identify human leucocyte antigen (HLA) risk alleles associated with serious drug AE, hepatotoxicity and skin rash, which may be used as a tool to predict AE prior to treatment.

**Materials/methods:** We prospectively recruited patients who received LTBI treatment from Jan 2018 to Dec 2019, in Taiwan, across 7 hospitals. Whole blood was drawn for HLA typing using the HLAssure SE SBT Kit (TB Diagnostics Ltd) using DNA-based methods for determination of HLA alleles using PCR amplification with sequence based typing. Patients were followed up at baseline, week 2, 4, 8 and 12 for adverse events and liver function testing, while under 3 months isoniazid-rifapentine treatment (3HP) and followed monthly after 8 weeks while under 9 months of isoniazid (9H) or 4 months of rifampin (4R) treatment.

**Results:** 216 patients were enrolled, 106 women, 110 men, average age 54.3 ± 15.5 years. 131 were TB contacts, 36 were candidates for transplantation and 23 were candidates for anti-TNF alpha blocker treatment. Treatment regimens were 3HP in 166 (76.9%), 9H in 45 (20.8%) and 4R in 5 (2.3%). AE occurred in 134/216 (62.0%), of which 117 were on 3HP and 16 on 9H and 1 was on 4R. AE of at least grade 2 occurred in 37 (17.1%). The most common AE include fatigue (31.5%), dizziness (27.3%), nausea (12.7%), fever (13.0%), myalgia (11.1%), hepatitis (10.2%), anorexia (7.4%), pruritis (10.2%), skin rash (9.3%), gastrointestinal upset (5.1%), limb numbness (5.1%) and diarrhea (2.3%). Associated genotypes for hepatitis included HLA-A*0101, A*0201, A*0203, B*4006. Associated genotypes for skin rash included HLA-A*0101, A*3501.

**Conclusions:** Several HLA genotypes are associated with serious adverse events of hepatitis and skin rash in patients undergoing treatment of LTBI. Further investigations are required to validate these risk alleles to predict AE in a larger population undergoing treatment for LTBI.

**Abstract 1750**

**Diversity and therapeutic potential of Klebsiella pneumoniae bacteriophages and their depolymerases: genomics and enzymatic activity**

Roobinidevi Ragupathy*, James Redfern¹, Mark Charles Enright¹

¹Manchester Metropolitan University, Manchester, United Kingdom

**Background:** *Klebsiella pneumoniae* has become a significant health threat in hospital settings. The rampant use of antibiotics has promoted the emergence of multidrug resistance (MDR) strains, particularly carbapenem-resistant and extended-spectrum-beta-lactamases (ESBL) producers. The unavailing use of current antibiotic treatments have prompted great interest in alternative treatments such as phage therapy. Lytic bacteriophages are considered an effective antidote against MDR pathogens for their ability to precisely adhere and degrade bacterial capsular polysaccharide, which acts as a protective layer to the bacterial cell and contributes to its pathogenicity. In this study, we have isolated and identified a large collection of obligately lytic *K.pneumoniae* phages that produce capsule depolymerases, enzymes that hydrolyse *Klebsiella* capsules. We conducted genotypic and phenotypic analyses to characterise these phages by studying their putative depolymerases genes against published homologues and over-expressing these enzymes to study their efficacy against MDR *K.pneumoniae*, respectively.

**Materials/methods:** The genomic DNA of *K.pneumoniae* phages (n=59) extracted by PCI/SDS extraction were sequenced by Illumina NexteraXT technology and assembled using various bioinformatics tools. The putative depolymerase genes were identified against published genomes of *K.pneumoniae* phages using a custom, in-house phage protein database. Homologues were identified using HHsearch which conducts a profile similarity searching based on protein function prediction. To examine the activity of these enzymes, the identified genes were cloned into pEXP5/TOPO vector and over-expressed using the Expressway cell-free *E.coli* expression system. The His-tagged proteins were analysed by SDS-PAGE and then purified using the HisPur-NiNTA purification kit.

**Results:** We successfully isolated and characterised 59 Caudovirales, obligately lytic *K.pneumoniae* phages consisting of the most common tailed phages *Siphoviridae, Podoviridae* and *Myoviridae*. We identified 33 putative depolymerase genes in 26 of our phages using stringent HHsearch criteria which showed similarity to several distinct capsular depolymerases such as hydrolases and lyases. Subsequently, eight putative structures were selected and five successfully cloned and over-expressed. SDS-PAGE analysis showed clear bands at expected sizes. The recombinant proteins were purified using nickel-affinity spin columns and the eluted fractions analysed by SDS-PAGE gel were pooled for further studies.

**Conclusions:** Characterization of novel depolymerases from our collection of *K.pneumoniae* phages may prove useful for effective treatment against MDR strains.

Abstract 1755

Evaluation of a new commercial disc susceptibility kit for detection and differentiation of carbapenemases produced by Enterobacterales

Emma Marrs¹, Andrew Anyakwo², Jon Hobson², John Perry*¹

¹Freeman Hospital, Newcastle upon Tyne, United Kingdom, ²Mast Group Ltd., Bootle, United Kingdom

Background: The MASTDISCS® Avibactam Combi set for OXA-48 detection and carbapenemase screen is a kit comprising 3 discs. Disc A contains temocillin with KPC and MBL inhibitors; Disc B contains temocillin plus avibactam and Disc C contains a penem antibiotic. The kit is intended to allow detection of carbapenemase-producing Enterobacterales (CPE) and differentiation of isolates with OXA-48-like enzymes from those with KPC or metallo-ß-lactamase (MBL). We describe here the first evaluation of this assay using standard EUCAST / CLSI methodology.

Materials/methods: The kit was evaluated with a diverse collection of 208 well characterised Enterobacterales including carbapenemase-producers [CPE; n = 159], isolates with ESBL and/or AmpC ß-lactamase [n = 47] and two control strains. Susceptibility testing was performed using EUCAST methodology on Mueller-Hinton agar. After overnight incubation, inhibition zone diameters were measured and the presence of carbapenemases was inferred following the kit instructions.

Results: All of the CPE isolates (n = 159) were correctly assigned as being carbapenemase-producers [sensitivity: 100%; specificity: 92%]. 4/49 other isolates were incorrectly assigned as carbapenemase-producers including isolates with TEM-10, LAT and two isolates with DHA-1. 61 out of 62 isolates with OXA-48-like enzymes were correctly assigned as OXA-48-like producers with one isolate inferred to be a producer of KPC or MBL. Of 97 isolates with KPC or MBL, all but one were correctly assigned as KPC/MBL producers. A single isolate with a combination of carbapenemases [VIM and OXA-48] was assigned as an OXA-48 producer. Finally, one isolate of CPE with NMC-A carbapenemase was falsely assigned as KPC/MBL.

Conclusions: The kit performed very well as a screening test with a challenging set of bacterial isolates. Most importantly, the presence of a carbapenemase was predicted with absolute sensitivity (100%) and high specificity (91.8%). Only 4 out of 49 non-CPE would require additional investigation as possible CPE – and the vast majority of these 49 isolates expressed ESBL or AmpC activity. This combination of 3 discs could be included with other antimicrobials for routine testing of Enterobacterales in clinical laboratories using EUCAST methodology.

Impact of corticosteroids on alveolar macrophage interaction with mucorales

François Arrivé1,2, Kevin Brunet1,2, Jean-Philippe Martellosio1,2, Isabelle Lamarche2, Sandrine Marchand1,2, Blandine Rammaert1,2

1Poitiers University Hospital, Poitiers, France, 2University of Poitiers, Poitiers, France

Abstract third-party references: INSERM U1070, Poitiers, France

Background: Alveolar macrophages (AM) are lung first line of defence against moulds from the Mucorales order. They are able to control inhaled spore growth. Since corticosteroid use is a known risk factor for mucormycosis, the aim of this study was to decipher the role of corticosteroids on AM phagocytic and killing functions using a new ex vivo model.

Materials/methods: Male BALB/c mice were untreated or treated with 500 mg/kg of cortisone acetate at day 1 and 3 before AM collection through bronchoalveolar lavage. AM from untreated and corticosteroid-treated mice were then exposed to Lichtheimia corymbifera spores at a ratio of 1:5 in DMEM without phenol red in a 96-well plate at 37°C with 5% CO2. Fungal growth was assessed using optical densities measured by spectrophotometer each hour for 48 hours at 800 nm. Flow cytometry was used for phagocytosis assay. After 1 hour of co-incubation, AM and spores were labelled with antibodies anti-CD11c+ and FITC, respectively. AM CD11c+FITC+ were considered having phagocytized spores. Statistical comparisons were performed using Mann-Whitney and Fisher tests.

Results: Absorbance of wells containing corticosteroid-treated AM was significantly higher than wells with untreated AM from 24h of coinoculation with spores (0.219 ± 0.007 vs. 0.200 ± 0.003, p=0.023). The difference in fungal growth persisted at 48h (p=0.001). Corticosteroid-treated AM showed a lower proportion of AM CD11c+FITC+ compared to that of untreated AM (7.6% vs 21.5%, p<0.001, figure 1.).

Conclusions: Corticosteroids enhanced fungal growth of L. corymbifera through AM phagocytosis alteration in our ex vivo model. Further studies are ongoing assessing killing functions of AM in this model.

Abstract 1758

Is strongyloidiasis currently endemic in Croatia?
Mirjana Balen Topić*1,2, Ena Marjanović2, Domagoj Tomasovic2, Sviben Mario1,3

1School of Medicine, University of Zagreb, Zagreb, Croatia, 2University Hospital for Infectious Diseases “Dr. Fran Mihaljević”, Zagreb, Croatia, 3Croatian Institute of Public Health, Department for Parasitology and Mycology, Zagreb, Croatia

Background: Due to its low prevalence and various clinical presentations, the Strongyloides stercoralis infection in temperate zones can be easily overlooked. As the majority of symptomatic cases are diagnosed during the stage of chronic infection reactivation in immunosuppressed hosts, with unknown time of primoinfection, current endemicity in European countries is difficult to assess. The epidemiological and clinical burden of the disease in Europe has not been well studied and there have been no such studies in Croatia yet. Knowing local epidemiological circumstances is important in managing immunosuppressed persons and in transplant medicine. This study explored the epidemiological and clinical features of patients with strongyloidiasis, with particular aim to find elements for current endemicity of the disease.

Materials/methods: A retrospective descriptive study was performed that included patients of both genders and all ages treated for strongyloidiasis from January 2010 to May 2019 at the University Hospital for Infectious Diseases in Zagreb, Croatia. The diagnosis was made directly [by light microscopy of fecal samples after salinic provocation, three stool samples for parasites and ova, and/or tissue or duodenal aspirate samples], or indirectly by blood serology (in 83.1 and 16.9% of patients, respectively). Statistical analysis was done.

Results: Among 65 patients with strongyloidiasis, 60% were men, and 78.5% were aged 50-79 (range 17-82 y.; average: 62 y.). The number of patients significantly increased over the study period (p=0.013). Clinical presentations were: asymptomatic eosinophilia [41.5%], chronic symptomatic disease [33.9%], hyperinfection [6.1%] and acute primoinfection [18.5%]. Altogether 20 patients [30.8%] were immunosuppressed [9 by corticosteroids, 4 cytostatic drugs, 7 immune-debilitating illness]; four developed hyperinfection, with two lethal outcomes. The initial therapy was: albendazole in 71.7% of patients, 13.3% thiabendazole, 13.3% ivermectin, 1.7% mebendazole. Six patients [9.2%] received repeated treatment. The parasitologic cure rate between albendazole and ivermectin group was equal (p=0.0878) [lost to follow up: 48.8% in albendazole and 25% in ivermectin group].

Conclusions: Records of patients with acute primary infection confirm current endemicity for strongyloidiasis in continental Croatia, and immunosuppressed travellers to this region should be advised to take precaution measures. Patients undergoing immunosuppression and organ donors from Croatia should be screened.

Abstract 1764

Epidemiology of *Clostridioides difficile* infections among hospitalised community-acquired pneumonia patients who received empiric treatment with ceftriaxone plus a macrolide

Kenneth Lapensee 1, Hoa Le 1, Stephen Villano 2, Thomas Lodise* 3

1Paratek Pharmaceuticals, Inc., King of Prussia, PA, United States, 2PAREXEL Access Consulting, Waltham, MA, United States, 3Albany College of Pharmacy and Health Sciences, Albany, NY, United States

**Background:** *Clostridioides difficile* infection (CDI) among hospitalized community-acquired pneumonia (CAP) patients receiving ceftriaxone + macrolide (CTX+M), the most commonly prescribed CAP regimen, is under-researched.

**Materials/methods:** This is a retrospective study (2012–2015) of hospitalized patients (≥18 years) in the MedAssets database with primary discharge diagnosis of CAP; patients received CTX+M on Days 1–2, had no CDI admitting diagnosis, and had ≥1-year enrollment before index date. Patients with an ICD-9 code for CDI ≤60 days from index admission for CAP were identified and further stratified by Charlson Comorbidity Index (CCI)/Pneumonia Severity Index (PSI) risk scores from diagnosis codes. CDI incidence was tabulated across CCI/PSI categories.

**Results:** In total 278/33,173 (0.8%) identified patients had a CDI diagnosis ≤60 days after index admission. CDI incidence among CTX+M CAP patients was similar to CAP patients who received a fluoroquinolone on Days 1–2 of hospitalization (1.1%). Among CTX+M patients, CDI incidence in bivariate analyses was: age ≥65/<65 (1.0%/0.5%), prior/no prior CAP (1.3%/0.8%), cancer/no cancer (1.5%/0.7%), coronary heart disease (CHD)/no CHD (1.1%/0.6%), congestive heart failure (CHF)/no CHF (1.4%/0.7%), acute respiratory failure (ARF)/no ARF (1.5%/0.7%), dementia/no dementia (1.2%/0.8%), immunocompromising conditions (IC)/no IC (1.4%/0.9%), renal failure (RF)/no RF (1.4%/0.7%), and prior versus no hospitalization in past year (1.5% versus 0.8%). CDI incidence increased with increasing CCI [0 [0.4%], 1 [0.6%], 2 [0.9%], and ≥3 [1.2%]], and PSI class [≤2 [0.2%], 3 [0.9%], 4 [1.2%], and 5 [2.2%]]. In multivariate analyses, PSI class, ARF, and CHD were independently associated with CDI; in a multivariate analysis that excluded PSI, age ≥65, ARF, and CHD, IC, and RF were independently associated with CDI (P<0.05, all analyses).

**Conclusions:** Certain CAP patient populations empirically receiving CTX+M may be at elevated risk for CDI. High-risk populations identified in this analysis are consistent with those identified in prior CDI risk-factor studies. Whether alternative antibiotics with a lower propensity to cause CDI than CTX-M can reduce this observed risk of CDI warrants further investigation.

Abstract 1765

Clinical feasibility of simultaneous microdialysis of voriconazole and its N-oxide metabolite at target site demonstrated by in vitro investigations

Josefine Schulz*, Robin Michelet¹, Franziska Kluwe¹², Charlotte Kloft¹

¹Freie Universitaet Berlin, Institute of Pharmacy, Dept. of Clinical Pharmacy & Biochemistry, Berlin, Germany, ²Graduate Research Training program PharMetrX, Berlin, Germany

Background: Antifungal resistance is globally rising and the demand for rational and effective dosing regimens with antifungals such as voriconazole (VRC) thus intensifies. Currently, detailed knowledge of VRC pharmacokinetics (PK) is lacking, resulting in inadequate exposure or adverse events in patients. Application of microdialysis (µD), a minimally invasive sampling technique, in clinical studies, allows for determination of unbound drug concentrations at target site. However, metabolite concentrations are frequently of equal interest, as they contribute to efficacy, alter the PK of the parent drug or cause adverse events. Therefore, in this in vitro study, VRC and its N-oxide (NO) metabolite were chosen to investigate the feasibility of simultaneous µD of drug and drug metabolite prior to in vivo studies.

Materials/methods: CMA63 µD catheters (n=4) were placed in a static in vitro microdialysis system and perfused with Ringer’s solution (RS). The medium consisted of RS containing (i) VRC, (ii) NO or (iii) VRC and NO combined at different concentrations ranging from 0.010 to 3.0 µg/mL. Relative recovery (RR) was determined as the ratio of the respective VRC or NO concentration in microdialysate and medium. Quantification was performed using a LC-MS/MS assay.

Results: Overall, mean RR of (i) VRC was 87.8% (95% CI: 87.0 – 88.7%, n=85) and did not change significantly when simultaneous µD with NO was performed ((iii) 88.4% (95% CI: 87.2 – 89.6%, n=82)). Non-significant were also the differences in the mean RR of NO with (ii) 91.7% (95% CI: 90.3 – 93.1%, n=85) in the absence and (iii) 89.8% (95% CI: 88.6 – 91.1%, n=82) in the presence of VRC.

Conclusions: The RR of VRC and NO were high, reproducible and independent of each other in vitro. Thus, the results provide a solid basis for unbiased measurements of target site concentrations in vivo. Since metabolites cannot be administered to humans, the substance-specific catheter calibration using retrodialysis must be replaced. In this regard the comparable RR of VRC and NO indicate the feasibility of VRC retrodialysis as surrogate to back-calculate the tissue fluid concentrations of NO. Ultimately, incorporating knowledge of target site PK into clinical decisions will contribute to the optimisation of dosing regimens.

Prevalence and risk factors of inappropriate use of intravenous and urinary catheters in surgical and medical patients

Bart Laan*, Margreet C. Vos1, Jolanda M. Maaskant2, Mark I. Van Berge Henegouwen3, Suzanne E. Geerlings1

1Amsterdam UMC, University of Amsterdam, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands, 2Erasmus University Medical Centre, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands, 3Amsterdam UMC, University of Amsterdam, Clinical Epidemiology, Biostatistics and Bioinformatics, Amsterdam, Netherlands, 4Amsterdam UMC, University of Amsterdam, Department of Surgery, Amsterdam, Netherlands

Background: Inappropriate use of catheters is common and associated with adverse patient outcomes, such as healthcare-associated infections. We previously conducted a successful project, entitled the RICAT-study, to reduce inappropriate use of intravenous and urinary catheters in medical wards. Broad-scale implementation should be started if inappropriate use is a hospital-wide problem. The current objective was to compare surgical and medical wards, and determine risk factors for inappropriate catheter use.

Materials/methods: We performed a prospective observational study from October, 2017 to May, 2018 in surgical wards of two university hospitals. We observed patients every other week for seven months, and assessed inappropriate use of intravenous and urinary catheters. Inappropriate use was compared with non-surgical wards of the RICAT-study. Primary outcomes were the percentages of inappropriate use of peripheral intravenous catheters (PIVCs) and urinary catheters on the days of data collection.

Results: We included 409 surgical patients [mean age 59.2 years; SD 15.3, 151 (37%) female] and compared this with 1781 medical patients [mean age 64.8 years; SD 17.6, 842 (47%) female]. Inappropriate use occurred in 36 (8.5%) of 425 peripheral intravenous catheters in 373 surgical patients, compared to 400 (22.9%) of 1747 peripheral intravenous catheters in 1665 medical patients. This represents a difference of 14.4% [95% CI 11.1% to 17.8%; P < 0.001]. Inappropriate use of urinary catheters occurred in 14 (10.4%) of 134 surgical patients, compared to 105 (32.4%) of 324 medical patients, a difference of 22.0% [95% CI 14.7% to 29.2%; P < 0.001]. The main risk factor for inappropriate use of peripheral intravenous catheters was admission to medical wards; odds ratio 3.50 [95% CI 2.15 to 5.69], which was also one of the main risk factors for urinary catheters; odds ratio 2.75 [95% CI 1.36 to 5.55].

Conclusions: Inappropriate use of catheters is more common in medical wards compared to surgical wards. Prevention strategies to reduce healthcare-associated infections should primarily focus on sites with high prevalence of inappropriate use.

Dalbavancin provides a second-line option for patients who fail conventional on outpatient parenteral antimicrobial therapy (OPAT): a case series in Aberdeen

Sharon Falconer*, Nathan Chafer

1Aberdeen Royal Infirmary, Aberdeen, United Kingdom

Abstract third-party references: Supported by NHS Grampian and NHS Scotland.

Background: Aberdeen Royal Infirmary’s outpatient parenteral antimicrobial therapy (OPAT) service treats a variety of infections across specialties. Although OPAT is effective for many patients, some do fail on first-line therapy and so require further antibiotics. Dalbavancin, a second-generation lipoglycopeptide bactericidal antibiotic that is active against susceptible Gram-positive pathogens and can be administered as just two doses on days 1 and 8, provides a second-line option.

Materials/methods: The OPAT team report a cohort of 15 patients from a larger case series of 202 patients with skin and soft tissue infections, in whom dalbavancin was used as second-line therapy after previous antibiotic failure (Table 1).

Results: The 15 patients had failed on a variety of previous antibiotics, including teicoplanin (n=1), daptomycin/ceftazidime (n=1), flucloxacillin/tigecycline (n=1), daptomycin (n=4), clindamycin (n=2), ceftriaxone/teicoplanin (n=1), doxycycline (n=2), co-trimoxazole (n=2) and daptomycin/ciprofloxacin (n=1). Fourteen patients were given 1,500 mg dalbavancin as two doses – alone or in combination with clindamycin (n=2), ciprofloxacin (n=1) or doxycycline (n=1). One patient received 1,000 mg dalbavancin. In all 15 cases, the infection resolved, with three admissions prevented.

Conclusions: For patients with skin and soft tissue infections who fail on first-line antibiotics in the OPAT setting, dalbavancin provides an effective, convenient and potentially cost-saving second-line option.

Abstract third-party references: On behalf of the Sectional Meeting of Clinical Research and Data Collection, Japan Infection Prevention and Control Conference for National and Public University Hospitals.

Background: Optimal surgical antimicrobial prophylaxis (SAP) can reduce surgical site infections, cost, and adverse events. In Japan, overall evaluation of SAP have not been performed. The purpose of this study was to reveal the adherence of Japanese Clinical Practice Guidelines for antimicrobial prophylaxis in surgery (JCPGL-AP), which was published in 2016, and to extract problems about SAP in Japanese university hospitals.

Materials/methods: This study was performed at 16 university hospitals (including 1 dental hospital). A total of 18 surgeries performed to over 18 year-old patients were selected to evaluate adherence of JCPGL-AP. Maximum 3 cases per each surgery within 4 weeks were collected from September to December 2018. To evaluate appropriateness of SAP, following items were surveyed: choice of antimicrobials during/after surgery, timing of administration before/during surgery, and duration of SAP. Surgeries were defined as appropriate SAP when all items were adhered to JCPGL-AP. Ophthalmologic- and neuro-surgeries were not listed in JCPGL-AP, thus open craniotomy and cataract surgery were excluded to evaluate the antibiotics choice and duration of SAP.

Results: A total of 688 cases were included in this study. Collected cases ranged from 22 to 45 (median 42) by the surgery, and 3 [dental hospital] to 54 (median 47) by the hospital, respectively. Percentage of appropriate items were as follows: choice of antimicrobials during surgery (467/601, 77.7%) / after surgery (475/601, 79.0%), timing of administration before surgery (632/664, 95.1%) / during surgery (612/665, 92.0%), and duration of SAP (375/601, 62.4%). Figure shows the percentage of appropriate SAP (281/601, 46.8%), duration of SAP over 3 days (115/688, 16.7%), and oral antimicrobial use after surgery (57/688, 8.3%). Percentage of appropriate SAP of general university hospitals ranged from 20.0% to 76.9% (median 48.8%).

Conclusions: Adherence rate of JCPGL-AP were significantly differed among surgeries and university hospitals. Oral Antimicrobial use after surgery and longer duration of SAP were seen in specific surgeries. Data of SAP about more surgeries and from community hospitals are necessary to reveal real-world SAP in Japanese hospitals.

Abstract 1774

Contact effect of a Methylobacterium sp. extract on biofilm of a Mycobacterium chimaera strain isolated from a 3T heater-cooler system

Ines Pradal¹, Jaime Esteban-Moreno*¹, John-Jairo Aguilara-Correa¹

¹Fundacion Jimenez Diaz University Hospital, Madrid, Spain

Abstract third-party references: Funded by a grant from the Instituto de Salud Carlos III (PI18/01068).

Background: Mycobacterium chimaera is an opportunistic, slowly growing, non-tuberculose mycobacterium currently gaining in importance due to the rise in mycobacteremia cases provoked by a strain that contaminates the 3T heater-cooler device (HCD) extracorporeal membrane oxygenator (ECMO). The aim of this study was to evaluate the effect of pre-treating a surface with a Methylobacterium sp. CECT 7180 extract to inhibit the biofilm development of M. chimaera ECMO strain.

Materials/methods: The extract of the Methylobacterium sp. CECT 7180 was performed according to García-Coca et al. (J Antimicrob. 2019 Sep 3). The effect of this extract on biofilm development of M. chimaera ECMO was evaluated at 24, 48, 72, 96, and 120 h using hydrophobic uncoated sterile slide 24-well plates (Ibidi GmbH, Martinsried, Germany) according to the methodology described previously by Muñoz-Egea et al. (Appl. Environ. Microbiol. 2013 Feb; 79(3):1065–1067). Pretreatment consisted of treating at room temperature for 15 min with 0.3 ml of PBS (control) or with 0.3 ml of Methylobacterium sp. CECT 7180 extract. After 15 min, the supernatant was removed and each well was washed once with PBS. Four parameters were studied: covered surface (%), thickness (μm), viability (%) and relative autofluorescence (%). Each condition was performed by triplicate.

The statistical data were analyzed by nonparametric pairwise comparisons using the nonparametric Mann-Whitney test with a level of statistical significance of p<0.05. The values are cited as median and interquartile range.

Results: The results obtained are represented in Figure 1.

![Figure 1. M. chimaera ECMO biofilm development over time on a control surface (gray) and on a surface treated with Methylobacterium extract (black). The four parameters evaluated were mycobacterial viability (A), biofilm height (B), biofilm covered surface (C), and relative autofluorescence (D). Bars indicate tenth and ninetieth percentiles. #: P-value < 0.001 for Wilcoxon test between control surfaces and surfaces treated with Methylobacterium extract. The bar represent 10th and 90th percentile.](image)

Conclusions: In conclusion, exposing a surface to the Methylobacterium sp. Extract inhibits M. chimaera ECMO biofilm development. This extract could be used as a pre-treatment prior to disinfection protocols for equipment contaminated with mycobacteria.

NDT80 transcription factor acts as a repressor of Candida parapsilosis virulence attributes

Joana Branco*1,2, Claudia Cruz1, Lisa Rodrigues1,4, Teresa Gonçalves1,4, Isabel Miranda2,5, Acácio Gonçalves Rodrigues1,2,6

1Division of Microbiology, Department of Pathology, Faculty of Medicine, University of Porto, Porto, Portugal., Porto, Portugal
2CINTESIS -Centre for Health Technology and Services Research, Faculty of Medicine, University of Porto, Porto, Portugal., Porto, Portugal
3CNC-Centre for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal, Coimbra, Portugal

5UniC –Cardiovascular R&D Center, Faculty of Medicine, University of Porto, Porto, Portugal., Porto, Portugal
6Burnit Unit, São João Hospital Center, Porto, Portugal

Background: Candida parapsilosis is a predominant species within non-albicans yeast responsible for invasive candidosis among immunocompromised patients. In fact, the prevalence of C. parapsilosis results from its notorious capacity to persist in the hospital environment for long periods. This ability is associated with its propensity to adhesion and form biofilm. In C. albicans, Ndt80 is one of the transcription factors that controls biofilm formation, hyphal growth and expression of genes related with cell wall organization. In C. parapsilosis, Ndt80 was associated with biofilm formation, however, its mechanistic role remain unveiled. This study aimed to understand the role of NDT80 - CPAR2-213640 in C. parapsilosis virulence attributes.

Materials/methods: From C. parapsilosis BC014S strain two independent lineages lacking one (ndt80Δ – NG2 strain) or both (ndt80ΔΔ - EF16 strain) copies of CpNDT80 gene were generated using the SAT1-Flipper cassette. ndt80Δ and ndt80ΔΔ adherence to polystyrene microspheres (as a representative of abiotic surface) was quantified using a flow cytometric adhesion assay. Biofilm formation was also quantified by two independent methods: CV staining and dry weight. Gene expression of a set of transcription factors recognized as regulators of virulence factors (ALS7, ALS3, CZF1, UME6, GZF3, CPH2, EFG1, BCR1, ACE2, STP3, CWH41, OCH1, RHR2 and MKC1) in C. parapsilosis were assessed by RT-qPCR. Using the murine macrophage cell line RAW264.7, the interaction of fungal-host immune system was characterized through macrophage fungal internalization and macrophage killing.

Results: Deleting NDT80 substantially changed colony and cell morphologies from smooth and yeast-shaped to crepe and pseudohyphal elongated forms. Adherence to polystyrene microspheres and biofilm formation were enhanced in both ndt80Δ and ndt80ΔΔ mutants comparatively to wild type strain. Additionally, we identify NDT80 as a repressor of ALS7, UME6, CPH2, CWH41, ACE2 and MKC1 transcription factors, being overexpressed in ndt80ΔΔ strain and associated with the trigger of virulence attributes exhibited by this strain. Ultimately, ndt80ΔΔ mutants, in their natural pseudohyphae phenotype, were more efficient in macrophage killing.

Conclusions: Our findings clearly demonstrate Ndt80 as a repressor of Candida parapsilosis virulence attributes (morphogenesis, adhesion and biofilm formation). Interestingly, phenotypes exhibited by ndt80ΔΔ mutants also confer enhanced ability to neutralize immune system response.

Abstract 1779

Cross-platform comparison of one qPCR assay with four leading technologies and six master mixes for the detection of Pneumocystis jirovecii

Sarah Dellière*, Maud Gits-Muselli1, Stéphane Bretagne1, Alexandre Alanio1

1Hospital Saint-Louis - APHP, Université de Paris, Paris, France; 2Institut Pasteur, Molecular Mycology Unit, Paris, France; 3National Reference Center for Invasive Mycoses and Antifungals, Paris, France

Background: Pneumocystis jirovecii is a fungus responsible for severe pneumonia in immunocompromised patients. Quantitative real-time PCR (qPCR) performed on respiratory samples is essential to detect and quantify this non-cultivable pathogen. Many molecular assays have been developed and lack of standardization results in significant differences among assays/centers. Studies initiated by the Fungal PCR Initiative evaluated 20 assays in 16 diagnostic centers pointing out the superiority in sensitivity of the mitochondrial small subunit (mtSSU) target. To further promote standardization, we compared four thermocyclers and six master mixes for the detection of P. jirovecii.

Materials/methods: Whole nucleic acid (WNA) from three qPCR-positive and ten qPCR-negative broncho-alveolar lavages were extracted on QiaSymphony with the Virus Kit Pathogen (Qiagen). Positive and negative extracts were pooled to provide sufficient homogeneous material. The positive pool was extemporaneously diluted at 1:5, 1:10, 1:50, 1:100 and 1:1000 in the negative pool. Three master mixes were tested to detect DNA by qPCR and three to detect WNA by reverse transcriptase qPCR (Table 1). All tests targeted mtSSU using the same primers and probes. Experiments were performed on four thermocyclers (LightCycler 480, ABI7500, QuantStudio and Rotorgene).

Results: Comparison of quantitative cycle (Cq) values between the methods targeting WNA and the methods targeting DNA showed lower Cq values with WNA independently from thermocycler and mix. For high (pure extract) and low (1:1000 dilution) fungal loads, ∆Cq values were 6.97 (± 2.95) and 5.81 (± 3.30) respectively (p<0.0001). Regarding DNA detection, lower Cqs were obtained with Mix1 compared to Mix2 and Mix3 with median ∆Cq of 2.6 (p=0.015) and 2.9 (p=0.039) respectively. Regarding WNA detection, no mix was superior to the others. The mean efficiency of PCR reactions was similar. PCR efficiency was not significantly different according to the qPCR equipment (p=0.14).

Conclusions: This study confirms that amplifying WNA is more sensitive than DNA alone to detect P. jirovecii nucleic acids. Variability observed due to enzyme/kit and thermocycler is a hurdle to harmonizing PCR protocol and producing comparable data among centers. Further studies should focus on developing a calibration method for accurate assessment of fungal load.

Association between susceptibility to quinolones in *Escherichia coli* and tetracycline use in the community: analysis of 9 communities with a single model

Marie-Anne Vibet1,2, François Javaudin1,2, Marcelo Low1, Batseahe Gottesman1, José-María López-Lozano4, Emmanuel Montassier1,2, Eric Batard*1;2

1University of Nantes, Microbiotas Hosts Antibiotics bacterial Resistances [MiHAR], Nantes, France, 2Nantes University Hospital, Nantes, France, 3Clalit Health Services, Tel Aviv, Israel, 4University of Murcia, Murcia, Spain

**Background:** Tetracyclines are extensively used in the community. We previously found that tetracycline use was associated with resistance to quinolones in *E. coli* in a French community, but this association was not described in other communities. Pharmaco-epidemiological studies are usually conducted with arima models, that only apply to a single site. However, results of a model derived from a given site may not be extrapolated to another site. Our aim was to assess the association between tetracycline use and quinolone susceptibility in *E. coli* isolates of several communities, using a single model.

**Materials/methods:** Monthly time series of proportions of quinolone susceptible *E. coli* and uses of quinolones and tetracyclines [in DDD/1000 inhabitants/month] were obtained from 9 communities (France, n=1; Israel, n=7; Spain, n=1), between 2009 and 2018. A single linear mixed effects model was used to assess the relationship between antimicrobial use and resistance in different sites, with site as a random effect, including a 1st order auto-correlation. Results were provided as estimate (95% confidence interval) of fixed effect (FE) and range of random effects (RE).

**Results:** Median (range) population was 434,000 (190,000 to 1,346,000). The proportion of susceptible isolates increased significantly with time [time FE, +0.032 (+0.012 to +0.052); RE range, -0.041 to +0.036]. Quinolone use significantly decreased [time FE, -0.21 [-0.30 to -0.11]; RE range, -0.30 to +0.15], but tetracycline use showed no significant temporal trend [time FE, 0.01 [-0.06 to +0.07]; RE range, -0.12 to +0.18]. In multivariate analysis, quinolone susceptibility was associated with both quinolone use [lag, 7 months; FE, -0.040 [-0.074 to -0.004]; RE range, -0.022 to +0.006] and tetracycline use [lag, 8 months; FE, -0.073 [-0.140 to -0.007]; RE range, -0.198 to +0.094].

**Conclusions:** A single linear mixed effects model with autocorrelation can be used to assess the relationship between antimicrobial use and resistance in several communities. Both community uses of tetracycline and quinolones were associated with decreased susceptibility to quinolones in *E. coli*, with high variability across communities. These results suggest that decreasing tetracycline use in the community may decrease quinolone resistance in community isolates of *E. coli*.

**Abstract third-party references:** Hanoi University of Pharmacy, Hanoi, Vietnam, Bach Mai Hospital, Hanoi, Vietnam, Hasselt University, Hasselt, Belgium, University of Antwerp, Antwerp, Belgium, National Centre of Drug information and Adverse drug reactions Monitoring, Hanoi, Vietnam

**Background:** Klebsiella pneumoniae (K. pneumoniae) infections, especially infections with multidrug-resistant strains, can be life-threatening and are a critical public health concern. K. pneumoniae infections are even more critical and the antibiotic resistance rate is much higher in intensive care unit (ICU) patients. This study aimed to develop and evaluate the accuracy of a prediction model and risk score to predict 14-day mortality in adult ICU patients infected with K. pneumoniae in a tertiary hospital.

**Materials/methods:** For this retrospective cohort study, data were extracted from the medical records of adult patients admitted to the ICU of a 1900-bed tertiary hospital in Vietnam in 2016-2018 and in whom K. pneumoniae was isolated. We used univariable and multivariable logistic regression analyses to develop a valid prediction model and a simplified risk score for 14-day mortality. We assessed their discriminative ability by optimism-corrected area under a receiver operating characteristic curve (AUC) and their calibration by calibration plots and Hosmer-Lemeshow test statistics.

**Results:** In total, 249 patients were included in the analysis. Their 14-day mortality was 28.9%. Out of 18 prognostic determinants, the final prediction model comprised of route of referral, Sequential Organ Failure Assessment score and Charlson comorbidity index at infection onset, presence of central venous catheter, intracerebral haemorrhage operation within 72 hours before infection onset, and the absence of adjunctive treatment to remove the probable focus of infection [see Table 1; AUC (95% CI): 0.80 (0.76-0.82); Hosmer-Lemeshow test: p=0.165, after bootstrapping]. The simplified risk score corresponded to a very low (0%), low (7.8%), moderate (18.2%), high (50.6%) and very high (100%) risk of mortality for scores 0-1, 2-3, 4-5, 6-8 and 9-13, respectively.

**Table 1.** Independent predictors of 14-day mortality, the corresponding odds ratios and contribution to risk score

Abstract 1786

**Temporal and regional prevalence of carbapenemase-producing Enterobacterales in Switzerland from 2013 to 2018**

Michael Gasser*, Alban Ramette, Reinhard Zbinden, Jacques Schrenzel, Patrice Nordmann, Damir Perisa, Andreas Kronenberg

1University of Bern, Swiss Centre for Antibiotic Resistance, Institute for Infectious Diseases, Bern, Switzerland, 2University of Zurich, Institute for Medical Microbiology, Zurich, Switzerland, 3Geneva University Hospitals, Laboratory of Bacteriology, Geneva, Switzerland, 4University Fribourg, Molecular and Medical Microbiology, Department of Medicine, Fribourg, Switzerland, 5Federal Office of Public Health, Bern, Switzerland

**Background:** Increasing rates of carbapenemase-producing Enterobacterales (CPE) have been observed in Europe and all over the world. CPE represent a great concern since they are frequently associated to resistance to multiple antibiotics thus reducing therapeutic options.

**Materials/methods:** Data on human CPE isolates from 2013 to 2018 were collected by the Swiss Centre for Antibiotic Resistance (ANRESIS) and analysed for temporal and regional trends. A statistical detection of regional clusters was performed with the SaTScan software embedded in WHONET.

**Results:** From 2013 to 2018, yearly detection of CPE isolates has increased considerably from 65 to 212. The most frequently isolated species were *Klebsiella pneumoniae* (54% of the cases), followed by *Escherichia coli* (28%). The most frequent carbapenemase genotypes were OXA-48-types (43%), KPC (21%), and NDM (14%). At the regional level, highest numbers of CPE isolates per 100'000 inhabitants were identified in the Geneva and the Ticino regions. Multivariable analyses of regional and temporal trends of CPE cases confirmed an increase in total number, higher prevalence in the Geneva region and in male patients. In contrast to the French speaking parts (Western and Geneva regions) where OXA-48-types were the predominant genotypes (55% and 60%, respectively), KPC was the most frequently detected genotype in the Italian speaking region of Ticino (62%). SaTScan outbreak detection analysis identified a total of seven clusters in five different regions of Switzerland.

**Conclusions:** In a first continuous surveillance of CPE in Switzerland it was shown that the epidemiological situation aggravated nationwide and that regional patterns of CPE genotypes mirror the situations in neighbouring European countries.

Abstract 1788

**Characterisation of immune response of patients with rheumatic disorders and latent tuberculosis infection**

Elisa Petruccioli¹, Valentina Vanini¹, Gilda Cuzzi¹, Tonino Alonzi¹, Linda Petrone¹, Fabrizio Palmieri², Giuseppe Ippolito², Delia Goletti*¹

¹Translational Research Unit, National Institute for Infectious Diseases "L. Spallanzani, ROME, Italy, ²Department of Clinical and Clinical Research, INMI, ROME, Italy, ³Scientific Direction INMI, ROME, Italy

**Background:** The use of antitumor necrosis factor agents (anti-TNF) (biologics) for the treatment of inflammatory rheumatic disorders has reopened the tuberculosis (TB) problem also in countries with low TB incidence, due to the increased risk of TB reactivation in subjects with latent tuberculosis infection (LTBI). This study aims to evaluate the effect of biologics on acquired immunity to Mtb, at enrolment and at the end of preventive treatment.

**Materials/methods:** We enrolled 11 RD-LTBI at the baseline and at the end of preventive treatment. LTBI subjects started the biological agent after the first month of TB-therapy. As controls, we enrolled 11 LTBI subjects without RD. Cells were stimulated with antigens contained in TB1 and TB2 tubes of QFT-Plus. We characterized the cytokine (IFNγ, TNFα, IL2) and phenotypic profile (CD45RA, CD27) of Mtb-specific T-cells by cytometry. Wilcoxon signed rank test was performed.

**Results:** We found that the use of biological drugs does not reduce the ability of CD4 and CD8 T-cells to respond to Mtb stimulation. Moreover, we found an increased CD8 T-cell response at the end of TB preventive therapy in both LTBI groups.

Regarding the CD4 T-cell response, LTBI subjects had higher proportion of IFNγ+TNFα+IL2+CD4+ T-cells [p=0.04] and IFNγ+TNFα+IL2+CD4+ T-cells [p=0.01] at the baseline compared to end of therapy. Differently, RD-LTBI subjects had a similar cytokine profile of CD4 T-cells before and after TB-therapy.

Regarding the CD8 T-cell response, this response was characterized by a high proportion of IFNγ producing T-cells both before and after TB-therapy, independently of the RD status.

Regarding the phenotype, the Mtb-specific CD4 T-cells showed predominantly a central memory phenotype before and after TB-therapy, independently of the RD status.

**Conclusions:** The increased risk to develop active-TB disease is an emerging aspect in the use of biological drugs of patients with rheumatic disorders. These preliminary data show that the use of biological agents does not reduce the ability of CD4 and CD8 T-cells to respond to Mtb-stimulation. This study is helpful to understand the immunological safety of the biological drugs and to identify new candidate biomarkers of Mtb-infection.

**Presenter email address:** delia.goletti@inmi.it
Background: Distinctive characteristics of *Strongyloides stercoralis* are its ability to persist and replicate within a host for life and its potential to cause life-threatening infection in an immunocompromised host as HIV patients. The aims of this cross-sectional study were to describe the results of a systematic serological screening program for strongyloidiasis in HIV positive patients.

Materials/methods: Between 2009 and 2018, a prospective serological screening program for strongyloidiasis in all immigrant patients diagnosed of HIV infection with infection confirmed by Western-Blot, in Asturias, a region in the north of Spain was conducted. Three formalin-ether concentrated stool samples and an enzyme-linked immunosorbent assay for anti-*S. stercoralis* antibodies were used as screening tools. We considered that infection exists if the microscopic visualization of larvae in stool sample and/or the ELISA was positive. In positive patients was discarded the presence of other nematodes or filarias.

Results: Of the 83 screened patients (average age 39 [10] years, 61.8% of them female, average time in Spain 760 days), Twelve patients (13.5%) had a positive serological test for *S. stercoralis* and in only four of them was the microscopic visualization of larvae of *S. stercoralis* by formalin-ether concentration of faeces positive. The areas of origin were Central Africa (61.4%), South America (26.5%), West Africa (7.2%), North Africa and Mexico and Central America (2.2% respectively). Fifty percent of *Strongyloides* positive patients come from Central Africa (6/51, prevalence 11.7%) and the rest from South America (6/22; prevalence 27.2%; P= 0.0550; OR 3.4375 [0.9739 - 12.1325]). Infection was significantly more frequent in patients from Paraguay (P = 0.0042 OR 81 [4.0066 – 1637]). There is not differences in CD4+ count, viral load, sex, age or time in Spain between infected and no infected patients. No patients had HTLV-I co-infection. Fifty-two percent of patients were asymptomatic at the moment of diagnostic. *Strongyloides* positive patients had higher levels of eosinophilia (842,42 ±724,989 cells/mm$^3$ versus 280,91 ± 428,765 cells/mm$^3$; p=0.003)

Conclusions: Strongyloidiasis is frequent in immigrant HIV positive patients, specially proceeding from Equatorial Guinea and Paraguay. Screening for Strongyloidiasis, even in asymptomatic patients should be taken fully into account. Serological test are useful in screening programs.

Anidulafungin-loaded hybrid organo-inorganic sol-gel coating can prevent the prosthetic joint infections provoked by Candida albicans

Hugo Garlito-Diaz¹, Beatriz Dunia Toirac², Amaya Garcia-Casas², Antonia Jimenez-Morales², Jaime Esteban-Moreno*², John-Jairo Aguilera-Corra²

¹Fundacion Jimenez Diaz University Hospital, Madrid, Spain, ²Universidad Carlos III de Madrid, Leganés, Spain

Abstract third-party references: Funded by a grant from the Mutua Madrileña Foundation

Background: Prosthetic joint infections occur infrequently, but they represent the most devastating complication. Nowadays, yeast belonging to Candida genus, mainly C. albicans, are gaining relevance. These PJIs are infrequent, they use to show high recurrence rates. Local antibiotic therapy is a desired feature which would allow locally preventing or treating these infections. In order to overcome prosthetic joint infection, sol-gel technology allows loading the coating with antifungal and osteointegrative molecules such as organophosphate compounds. The aim of this work was to evaluate the prophylactic effect of coatings loaded with anidulafungin using an in vivo murine model of candidal prosthetic joint infection.

Materials/methods: Sol-gel coating was produced using a molar ratio of 1:2 (MAPTMS:TMOS) and an organophosphate dispersed in ethanol. The unloaded coating was loaded with 20 mg of anidulafungin per 20.3 mL and was used to coat chemical polished Ti6Al4V samples (CP+A). Chemical polished Ti6Al4V samples without coating were used as control (CP). The surgical procedure was performed as described previously by Lovati et al. (PLoS One. 2013 Jun 20;8(6):e67628) using only one of two femurs of each mouse treated ad libitum with 4 mg/mL of dexametasone and 100 mg/mL of enrofloxacin from a week before surgery and upwards and infected with a C. albicans isolated from a hip PJI (Cal 35). During five weeks, weight, limping and piloerection of animals were monitored. After five weeks, the animals were sacrificed and the bacterial load was estimated and confirmed in the peri-implant bone tissue and the implant using the methodology described by Esteban et al. (J. Clin. Microbiol. 2008 vol. 46 no. 2 488-492). Each treatment was performed five times

Results: The results are shown in the Figure 1. Fifty percent (3/6) of Cal 35-infected CP group were positive culture and 100% percent Cal 35-infected CP+A group were negative culture (0/6) (p-value=0.0228).
Figure 1. Median weight (A), limping (B), piloerection (C), and survival (D) in different noninfected group (black), and Cal 35-infected group (green) with CP (left column) and CP+A (right column) over time.

Conclusions: Anidulafungin-loaded hybrid organo-inorganic sol-gel coating can prevent at local level PJII provoked by C. albicans.

Seredagnosis of Lyme borreliosis: is IgM in serum more harmful than helpful?

Henrik Hillerdal¹, Anna J. Henningsson*²,³

¹Region Jönköping County, Department of Paediatrics, Jönköping, Sweden, ²Region Jönköping County, Department of Clinical Microbiology, Jönköping, Sweden, ³Linköping University, Clinical and Experimental Medicine, Linköping, Sweden

Background: Interpretation of serological findings in suspected Lyme borreliosis (LB) may be challenging in endemic areas and IgM antibodies in serum are often associated with false positive reactivities. There is a risk for over-diagnosis of LB, inadequate use of antibiotics and potential delay of proper diagnosis. The clinical value of IgM analysis in serum in LB diagnosis is therefore questioned. The aims of this study were to investigate how well the clinical recommendations for the diagnosis of LB and when to test for borrelia-specific antibodies were followed in Jönköping County, Sweden, and to evaluate the clinical value of IgM antibodies in serum.

Materials/methods: In total, 4428 borrelia-specific antibody tests in serum were analyzed in Jönköping County during 2017. Of these, 643 individual patients had positive results (IgM and/or IgG), of which we had to exclude 33 patients due to inaccessible medical records. The remaining patients (n=610) with positive test results were then divided into separate groups of either IgM and/or IgG-positivity. Based on current European recommendations, we defined the criteria for correct indication for serological testing and how to evaluate the diagnosis made by the clinician. Medical records and laboratory test results for each patient were then assessed according to these criteria.

Results: Only 183/610 (30%) of patients were tested according to the European recommendations. The groups positive for either isolated IgG or both IgM and IgG antibodies showed a similar pattern with high number of diagnoses assessed as being confident or doubtful. Isolated detection of IgM (without concomitant IgG) was only helpful in 50% of the diagnoses assessed as being confident or doubtful. Thus, 50% of the LB diagnoses in patients with isolated IgM reactivity in serum were assessed as incorrect (LB unlikely).

Conclusions: Isolated IgM positivity in serum shows limited clinical value in LB diagnostics and needs further assessment before being reported by the laboratory.

Abstract 1800

Application of a new molecular biology method for carbapenem-resistant Enterobacteriaceae detection in rectal swabs

Gabriella Parisi1,2*, Aurelia Denaro1, Sonia D’inzeo1, Roberta D’arrigo1, Domenica Gallone1, Bruno Martani1, Rosa Oliverio1

1Regional Hospital San Camillo-Forlanini, Roma, Italy

Background: The extreme ease with which the CPEs (Carbapenemase Producing Enterobacteriaceae) spread, requires the implementation of an effective screening program that allows the rapid identification of resistant strains. In this study we evaluated the diagnostic utility of an innovative molecular biology method for CPE detection in rectal swabs. Furthermore, we verified the percentage of rectal colonization as a predictive event for CPE bacteremia in the patients.

Materials/methods: In February-March 2019, 153 rectal swabs from intensive care unit (36%), hematology (19%), cardiology (17%), and other departments (28%) were examined. All the samples were analyzed by phenotypic method on McConkey with Ertapenem disk and E-test on MH for Meropenem (Biomerieux) and examined by Real-time PCR multiplex, using Allplex Entero-DR Assay kit (Allplex, Seegene, Republic of Korea) on automatic system Nimbus IVD (Seegene) which allows to identify simultaneously 8 resistance genes: KPC, VIM, NDM, IMP, OXA-48; van-A, vanB; CTX-M. Blood cultures were analyzed with automatic Bactec FX (BD) system, subcultures from positive vials and identification by mass spectrometry (MALDI-TOF Bruker). Antibiograms were performed with Phoenix instrument (BD) and interpreted according to EUCAST criteria.

Results: The results obtained by phenotypic method and molecular screening indicate a perfect agreement between the two tests for 135 samples (88%). In particular, 20 (13%) were positive for the molecular method only, for CPE resistance genes, 115 samples (75%) agreed on negativity and positivity to resistance genes for ESBL and VRE genes, 59% (10 of 17) of patients with positive molecular analysis and negative culture had already been positive before. We also evaluated how many of the examined patients, positive for CPE rectal colonization, subsequently developed bacteremia: 25% (39 patients) of patients tested were affected by bacteremia caused by the same micro-organism.

Conclusions: The application of new molecular biology techniques in surveillance allows the rapid detection of CPE and given the extreme sensitivity of the method, is able to detect the presence of resistance genes early even in conditions of low bacterial load. This approach offers the clinician useful information for patient management and the possibility of promptly administering the most appropriate antibiotic therapy to counteract a possible bacteraemia.

Presenter email address: gaParisi@scamilloforlanini.rm.it
Abstract 1801

**Impact of ribotype on *Clostridioides difficile* diagnostics**

Kristina Rizzardi*1, Thomas Åkerlund2, Torbjörn Norén3, Andreas Matussek4,5,6

1Public Health Agency of Sweden, Microbiology, Solna, Sweden, 2Public Health Agency of Sweden, Solna, Sweden, 3Örebro University, School of Medical Sciences, Örebro, Sweden, 4Karolinska Universitetssjukhuset Huddinge, Huddinge, Sweden, 5Karolinska University Hospital, Division of Clinical microbiology, Huddinge, Sweden, 6Region Jönköping, Jönköping, Sweden

**Background:** *Clostridioides difficile* infection (CDI) is one of the most common health-care associated infections worldwide. The ability of a strain to produce toxins is crucial for clinical disease. An accurate diagnosis of CDI remains a challenge, and underdiagnosis is an issue in Europe. A wide variety of diagnostic tests are available and the choice of reference method or gold standard is crucial in order to assess the accuracy of a test. One drawback of many studies comparing diagnostic techniques is that the local epidemiology is not taken into consideration, and several studies have been carried out in high prevalence or outbreak settings. This prospective study investigates the performance of diagnostic methods for detection of *C. difficile* infection in Sweden, including impact of PCR ribotype on diagnostic performance.

**Materials/methods:** Between 2011 and 2016, a total of 17,878 stool samples from 26 laboratories were tested by either well-type enzyme immunoassays (EIAs), membrane bound EIAs, cell cytotoxicity neutralization assay (CTA) or nucleic acid amplification tests (NAATs) and subsequently cultured for *C. difficile*. Roughly half of the samples (9,454/17,878) were subjected to diagnostic testing both on the fecal sample and on the 1,323 isolated *C. difficile* strains. All *C. difficile* isolates were typed by PCR ribotyping, and classified as toxigenic or non-toxigenic based on the empirical knowledge of the association between toxin-positivity and ribotype.

**Results:** The overall sensitivity, specificity, and positive and negative predictive values were highest for NAATs and membrane EIAs. Ribotype specific sensitivity varied greatly between methods and ribotypes. All methods had 100% sensitivity against ribotype 027 and 013. For other types the sensitivity ranged from 33% to 85% in fecal samples and from 78% to 100% on isolates. For the most prevalent ribotypes (014, 020 and 001) the sensitivity varied between 38% and 100% in the fecal samples, with the lowest sensitivity observed for well-type EIAs and CTA.

**Conclusions:** The large variation in diagnostic sensitivity implies that type distribution significantly affects the outcome when evaluating diagnostic performance. Furthermore, performing comparative studies of diagnostic tests in settings with high prevalence of ribotype 027 will overestimate the general performance of diagnostic tests.

Abstract 1802

Changes in the gut microbiota due to smoking in patients with inflammatory bowel disease

Toshifumi Ohkusa*1,2, Kan Uchiyama2, Eiji Miyachi2, Hiroshi Arakawa2, Shigeo Koido2, Nobuhiro Sato1, Hiroshi Ono2,5

1 Juntendo University Graduate School of Medicine, Department of Microbiota Research, Tokyo, Japan, 2 The Jikei Medical University Kashiwa Hospital, Department of Gastroenterology and Hepatology, Chiba, Japan, 3 RIKEN Center for Integrative Medical Sciences, Laboratory for Intestinal Ecosystem, Yokohama, Japan, 4 The Jikei University Kashiwa Hospital, Division of Endoscopy, Chiba, Japan, 5 Kanagawa Institute of Industrial Science and Technology, Intestinal Microbiota Project, Yokohama, Japan

Abstract third-party references: Smoking Research Foundation

Background: Smoking is one of the important factors affecting the onset and pathogenesis of inflammatory bowel disease (IBD). The effects of smoking are different depending on the disease types, and it is thought to promote the aggravation and relapse of Crohn’s disease (CD), but to suppress those of ulcerative colitis (UC). However, the underlying mechanisms by which smoking affects IBD has not been fully studied. In this study, we investigated the effects of smoking on the composition of oral and intestinal microbiota.

Materials/methods: Saliva, feces, and colonoscopy aspirates from 77 UC (smokers 10, ex-smokers 28, non-smokers 39) and 12 CD (smoker 3, ex-smoker 3, non-smoker 6) patients. The gut microbiota was analyzed by 16S rRNA gene sequencing.

Results: The subjects were classified into 4 clusters (Cluster A to D) from the microbial composition of colonoscopy aspirates rich in mucoadhesive bacteria. Smokers were predominantly classified (8 out of 13), whereas non-smokers were not (19 out of 76), in Cluster D. Co-abundance groups analysis revealed that patients clustered in Cluster D had increased abundance of oral bacteria, including Streptococcus, in the colonic aspirates. Streptococcus and Megasphaera were also increased in the saliva of smokers.

Conclusions: Smoking seems to facilitate the colonization of oral bacteria in the colonic mucosa. This might affect the mucosal immune system and the pathology of IBD.

Abstract 1804

Comparison of Cutibacterium acnes biofilm formation between strains isolated from prosthetic joint infection and healthy skin microbiota

Llanos Salar Vidal1, John-Jairo Aguilera-Correa1, Yvonne Achermann2, Dominique Salmon-Ceron1, Philippe Morand2, Marta Fernandez Sampedro4, Daniel Pablo-Marcos4, Rihard Trebse5, Mitja Rak6, Stephane Corvec7, Line Happi8, Marjan Wouthuyzen-Bakker9, Natividad Benito10,11, Alba Ribera12, Jaime Esteban-Moreno*1
1 Fundacion Jimenez Diaz University Hospital, Madrid, Spain, 2 University Hospital Zurich. University of Zurich, Zurich, Switzerland, 3 Hôpitaux Universitaires Paris Centre - Hôtel Dieu - Hôpital Cochin Université Paris Descartes, Paris, France, 4 Hospital Universitario Marques de Vadicella, Santander, Spain, 5 Orthopaedic Hospital Valdoltra, Ankaran, Slovenia, 6 National Laboratory of Health, Environment and Food, Koper, Slovenia, 7 Institut de Biologie - CHU de Nantes, Nantes, France, 8 Institut de Biologie - CHU de Nantes, Nantes, France, 9 University Medical Center Groningen. University of Groningen, Groningen, Netherlands, 10 Universitat Autònoma de Barcelona , Barcelona, Spain, 11 Infectious Diseases Unit, Hospital de la Santa Creu i Sant Pau - Institut d’Investigació Biomèdica Sant Pau, Barcelona, Spain, 12 Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Cutibacterium acnes is a Gram-positive facultative anaerobe rod. It colonizes human skin and can causes invasive infections such as periprosthetic joint infection (PJI). C. acnes causes disease through a number of virulence factors, such as biofilm formation during implant infection. In this study, we compared the biofilm formation of C. acnes isolates recovered from healthy skin with isolates recovered from deep tissue in PJI patients.

Materials/methods: We used the modified in-vitro biofilm test by Stepanovic et al. (APMIS 2007, 115 (8): 891-9) as a static biofilm assay, using BHI+ 2% glucose with a bacterial inoculum of 10⁷ CFU/mL at 37°C for 48h in anaerobic conditions and crystal violet for staining. One hundred and twenty-five C. acnes isolates recovered from PJI (n=89) from eight European centers, and healthy skin from face (HS) volunteers (n=36) were used. Biofilm formation of isolates was based on the optical density (OD) of each strain and the optical density control (ODc) measured at 570 nm, and classified into weak (ODc<OD<2xODc), moderate (2xODc<OD<4xODc), and strong (OD>4xODc) biofilm-former. The statistical data were analyzed by using a comparison test of proportions with a level of statistical significance of p<0.05.

Results: All isolates were biofilm-former types (Table 1). There was no statistical significant difference in between the biofilm-forming ability of strains isolated from these different sources.

<table>
<thead>
<tr>
<th>Biofilm-former type (%)</th>

<tbody>
<tr>
<td>Moderate</td>
<td>57.30 [51]</td>
<td>72.22 [26]</td>
<td>0.120</td>
</tr>
</tbody>
</table>

Table 1.

Conclusions: Although some reports suggest that C. acnes strains isolated from PJI produce more biofilm in vitro [Holmberg et al. Clin Microbiol Infect. 2009; 15 (8): 787-95], according with our data, both infection-associated and skin commensal isolates of C. acnes have the potential to form a static biofilm in vitro independently of the source of isolation.

Abstract 1805

Prevalence of non-tuberculous mycobacteria in a tertiary hospital in Beijing, China, January 2013 to December 2018

Jing Jing Huang*1, Meng Xiao1, Timothy Kudinha2

1Peking Union Medical College Hospital, Beijing, China, 2Charles Sturt University, Orange, Australia

Background: In China, patients diagnosed with tuberculosis (TB) or suspected of having TB, are referred to a thoracic specialist hospital for further treatment. However, clinical manifestations of non-tuberculous mycobacteria (NTM) diseases and TB are quite similar. A considerable number of patients TB or suspected TB, are lost in tertiary hospitals. This study retrospectively analyzed the identification data of NTM samples to provide a general outline of the prevalence of NTM in a tertiary hospital in China.

Materials/methods: Clinical data of patients who tested positive/negative for Mycobacterium tuberculosis (MTB) or NTM using a screening test (Real-time fluorescent PCR detection) from January 2013 to December 2018 at Peking Union Medical College Hospital [Beijing], were collected. Data on Mycobacteria species identification, which was carried out by DNA microarray chip, was also collected. Trend analysis of annual constituent ratio was carried out by trend Chi-square tests using SPSS 22.0 and a P value < 0.01 was considered statistically significant.

Results: Mycobacterial species were detected in 1514 specimens from 1508 patients, among which NTM accounted for 37.3% (565/1514), increasing from a prevalence of 15.6% in 2013 to 46.1% in 2018 (P<0.001). Among the 565 NTM positive specimens, the majority (55.2%) were from female patients. Furthermore, patients aged 45-65 years accounted for 49.6% of the total patients tested. Among 223 NTM positive specimens characterised further, the majority (86.2%) were from respiratory tract, whilst 3.6% and 3.1% were from lymph nodes and pus, respectively. Mycobacterium intracellulare (31.8%) and Mycobacterium chelonae / Mycobacterium abscessus (21.5%) were the most frequently detected species, followed by M. avium (13.5%), M. gordonae (11.7%), M. kansasii (7.6%), and others.

Conclusions: The proportion of NTM among mycobacterial species detected in a tertiary hospital in Beijing, China, increased rapidly from year 2013 to 2018. Middle-aged patients are more likely to be infected with NTM, especially females. Mycobacterium intracellulare and Mycobacterium chelonae/ Mycobacterium abscessus were the most frequently detected NTM pathogens. Accurate and timely identification of NTM is important for diagnosis and treatment.

Novel organism verification and analysis (NOVA) study: identification of potentially novel bacterial species from a diverse spectrum of clinical isolates

Daniel Goldenberger*1, Adrian Egli1, Vladimira Hinić2, Annette Blaich2, Tim Roloff2, Helena Seth-Smith1

1University Hospital and University of Basel, Basel, Switzerland, 2University Hospital Basel, Basel, Switzerland

Background: During routine diagnostic work, a small number of bacterial isolates may not be identified reliably using the conventional identification method MALDI-TOF MS, due to insufficient reference data or the presence of a novel organism. We have established an algorithm to identify and characterize such strains using 16S rRNA gene sequence analysis and whole genome sequencing (WGS) in a prospective and systematic manner. Here we present preliminary data.

Materials/methods: Bacterial isolates from diverse clinical specimens which could not be identified definitely by MALDI-TOF MS (Bruker Daltonics, database version 4.1) were subject to partial 16S rRNA gene sequencing (approx. 800bp). All strains with 16S rRNA sequence identities ≤99.0% compared to validly described species were analyzed by WGS (MiSeq/NextSeq, Illumina) in our institution, for full 16S rRNA gene, rMLST, and digital DNA-DNA-hybridization (dDDH) analysis. Isolates are stored to enable further characterization.

Results: Since 2016, 28 novel clinical isolates were collected (19 Gram-positive, nine Gram-negative). Twenty represent aerobic or facultatively anaerobic organisms and eight are anaerobic strains. Among the aerobic bacteria 12 are Gram-positive rods, four Gram-negative rods, three Gram-negative cocci, and one a Gram-positive coccus. The anaerobic bacteria include four Gram-positive cocci, two Gram-positive rods, and two Gram-negative rods. The strains were isolated from 11 biopsies and 11 swabs with localization of extremities [8], ear [6], miscellaneous [10] as well as three blood cultures, one urine and two with unknown source. Identities of the 28 corresponding 16S rRNA gene sequences ranged from 90-98.5% and 24/28 have a dDDH of <70%, as determined by WGS data. Two novel species were detected repeatedly: three independent isolates belonging to the Microbacteriaceae family; and an unknown Corynebacterium sp. was detected in two patients. Clinical relevance of the isolates has not yet been investigated.

Conclusions: Our preliminary data indicate a diverse spectrum of hitherto undescribed cultured bacterial organisms from various body sites. We have defined an algorithm for rapid characterization of these isolates, within a well-equipped clinical microbiological laboratory. Publications arising to date include an emendation of Auritidibacter ignavus (Bernard K et al. IJSEM, 2019) and description of Mycobacterium basiliense (Seth-Smith, Frontiers in Microbiology, 2019).

Abstract 1812

**Once-daily dose ceftriaxone plus ampicillin: an alternative for Enterococcus faecalis infective endocarditis OPAT treatment**

Laura Herrera-Hidalgo¹, Alicia Gutiérrez-Valencia², Luque Rafael², Luis E. Lopez-Cortes*¹, Arístides De Alarcón², Juan Gálvez-Acebal², Luis F. Lopez-Cortes², Maria Victoria Gil-Navarro¹

¹Hospital Universitario Virgen del Rocío, Unidad de Farmacia, Sevilla, Spain, ²Hospital Universitario Virgen del Rocío, Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Sevilla, Spain, ³Hospital universitario virgen macarena, Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Sevilla, Spain

**Abstract third-party references:** on behalf of the Grupo Andaluz para el estudio de las infecciones Cardiovasculares de la Sociedad Andaluza de Enfermedades Infecciosas (GAEICV-SAEI)

**Background:** Ceftriaxone 2g/12 hours plus ampicillin 2g/4 hours is a safe and effective strategy for the treatment Enterococcus faecalis infectious endocarditis. Ceftriaxone administration as 4g once-daily short infusion allows its inclusion in outpatient parenteral antibiotic therapy programs (OPAT), avoiding the use of two infusion pumps simultaneously. Given the importance of ceftriaxone exposure to obtain the synergistic effect with ampicillin, an examination of ceftriaxone high once-daily dose pharmacokinetic profile is warranted.

**Materials/methods:** This Phase II, open-label, crossover, pharmacokinetic study, enrolled healthy adult volunteers, who underwent two sequential treatment phases. During Phase A all volunteers received 2g of ceftriaxone each 12 hours during 24 hours followed by 7-day washout. Then, all the participants received Phase B medication, which consisted on 4g single dose of ceftriaxone. Throughout both phases each volunteer underwent intensive PK sampling over 24 hours. For concentrations lower than 100 mg/L, ceftriaxone unbound plasma concentrations were estimated assuming 10% of total drug. Ceftriaxone total concentrations were measured using validated LC-MS/MS methods, following FDA criteria.

**Results:** Twelve participants were enrolled and completed both phases. Five were female and median age and BMI were 28 years and 26.1 kg/m2. Mean concentration (GM±SD) 24 hours after the first dose (C24h) and estimated unbound C24h (uC24h) were 83.39±25.90 mg/L (range 47.98-135.73) and 8.34±2.59 mg/L (range 4.80-13.57) in phase A and 34.60±11.16 mg/L (range 18.50-51.07) and 3.46±1.12 mg/L (range 1.85-5.11) in phase B, respectively. In both cases mean uC24h were superior to 2 mg/L, the concentration required to maintain ceftriaxone synergistic activity. All patients achieved estimated unbound plasma concentrations superior to the concentration suggested to maintain ceftriaxone synergistic activity at least 20 hours, and most of them (>80%) 24 hours. Ceftriaxone total exposure, measure by AUC0-24, was similar in both phases and mean values were (GM±SD) 3319.6±573.3 mg.h/L in phase A vs 3035.4±573.3 mg.h/L in phase B (p=0.266). No grade 3 or 4 adverse events or laboratory abnormalities were observed.

**Conclusions:** Ceftriaxone plasma concentrations 24 hours after 4g single-dose administration are adequate to maintain the synergistic activity with ampicillin during 24 hours, allowing patient inclusion in OPAT programs without risk of inadequate exposure.

Abstract 1813

**Does automated susceptibility testing overcall temocillin resistance?**

Mark Campbell*1

1Oxford University Hospitals, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

**Background:** Temocillin is a semi-synthetic penicillin with narrow spectrum activity against *Enterobacteriaceae*, including AmpC and extended spectrum beta-lactamase (ESBL) producing organisms. Temocillin has the potential to be an important tool in clinical practice to treat serious infections caused by multi-resistant organisms and for antimicrobial stewardship purposes, including reducing use of critical antibiotics such as carbapenems. Common current clinical microbiology laboratory practice involves use of automated susceptibility testing methods such as the Becton-Dickinson (BD) Phoenix™. However, reported resistance rates to temocillin for *Enterobacteriaceae* isolates at our clinical microbiology laboratory far exceeds that expected by our knowledge of temocillin’s stability in the presence of beta-lactamase enzymes, leading to a hypothesis that Phoenix is overcalling temocillin resistance. This potentially poor quality data may lead to greater reluctance to utilise the antibiotic in clinical practice and give incorrect antimicrobial resistance epidemiology data.

**Materials/methods:** Prospective data was collected on *Enterobacteriaceae* blood culture isolates at our clinical microbiology laboratory from July 2017 to October 2018. Isolates were routinely tested for susceptibility on Phoenix and results recorded. Isolates that were deemed temocillin resistant on Phoenix had the temocillin susceptibility test repeated using an alternative method, for example a temocillin E-test and the concordance of the results was investigated.

**Results:** 87% (117/134 isolates) of *Enterobacteriaceae* blood culture isolates initially reported to be temocillin resistant, were found to be susceptible when re-tested using an alternative method. This reduced the overall reported temocillin resistance rate from 26% (209/805 isolates) to 2% (17/730 isolates).

**Conclusions:** Temocillin resistance in *Enterobacteriaceae* blood cultures isolates reported using automated susceptibility testing on BD Phoenix was only confirmed to be true using a second susceptibility testing method in 13% of cases. Phoenix overcalls temocillin resistance. All laboratories relying on BD Phoenix for temocillin susceptibility testing should confirm initial resistant results using a 2nd susceptibility testing method, such as a temocillin Etest. Becton-Dickinson should consider withdrawing temocillin from their Phoenix automated susceptibility testing panels until more reliable resistance results can be obtained.

Background: Surgical site infections (SSI) after solid organ transplantation (SOT) result in increased morbidity due to antibiotic therapy and surgical revision, and have been associated with a negative impact on graft function and patient survival. Studies addressing this important hospital-acquired infection after SOT are very limited and mostly derived from retrospective studies.

Materials/methods: The Swiss Transplant Cohort Study prospectively collects clinical data of lung, heart, kidney, liver, pancreas, and combined [e.g. kidney-pancreas, kidney-liver] transplant recipients. We analyzed SSIs occurring within 90 days post-transplant that were related to all transplant surgical procedures in Switzerland between June 2008 and October 2018. We excluded patients that received serial transplants.

Results: A total of 193 SSIs were observed in 4794 transplantations [378 heart, 449 lung, 1052 liver, 2564 kidney, 195 kidney-pancreas, 149 other combined transplants], corresponding to an incidence of 4.0%. Median time from surgery to SSI was 18 days [interquartile range [IQR] 10-32 days]. The incidences of SSIs were 6.9%, 4.7%, 4.9%, 2.2%, 1.4%, 2.7% after heart, lung, liver, kidney, pancreas, combined kidney pancreas and other simultaneous transplantations, respectively. In 161 (83.4%) SSIs a causative pathogen was identified, whereas in 16.5% diagnosis was established based solely on clinical findings. The majority of SSIs was caused by bacteria [n= 131, 67.9%] and presented in 19 cases with concomitant bacteremia. SSIs were most frequently caused by gram-positive bacteria [n= 105, 80.2%], with enterococcal infections being most common [n= 54, 41.2%, 12 polymicrobial infections] (Figure). Fungal SSIs were identified in 15.5% of transplant recipients. Candida spp. were the main cause of fungal SSIs [n= 30, 6 SSIs with detection of more than one fungal pathogen] with a predominance of Candida albicans [n= 21, 70.0%].

Conclusions: In our cohort of SOT recipients we found a SSI rate of 4.0%. The highest SSI rate was observed after combined kidney pancreas transplantations and the lowest SSI rate after kidney transplantation. Most SSIs were caused by gram-positive bacteria, with enterococci being most frequent.

Figure: Frequency of detected pathogens in surgical site infections

a) Gram-positive pathogens
b) Gram-negative pathogens
c) Fungal pathogens

Abbreviation: CNS coagulase-negative Staphylococcus spp.

Abstract 1817

Epidemiological investigation of newly detected highly lethal Borna disease virus 1 cases reinforcing indirect shrew contact as possible source of infection: results from in-depth interviews, Germany, 2019

Pörtner Kirsten1,2, Christina Frank1, Hendrik Wilking1, Dennis Rubbenstroth4, Merle Böhmer5

1Robert Koch Institute, Department of Infectious Disease Epidemiology, Berlin, Germany, 2Robert Koch Institute, Postgraduate Training for Applied Epidemiology [PAE], Berlin, Germany, 3European Centre for Disease Prevention and Control (ECDC), European Programme for Intervention Epidemiology Training [EPIET], Stockholm, Sweden, 4Friedrich-Loeffler-Institute, Institute of Diagnostic Virology, Greifswald, Insel Riems, Germany, 5Bavarian Health and Food Safety Authority, Department of Infectious Disease Epidemiology, München, Germany

Background: In 2018, Borna disease virus 1 (BoDV-1) was first confirmed as a zoonotic pathogen causing severe human encephalopathy in Germany with an extremely high case fatality (15/16). Bicoloured white-toothed shrews (Crocidura leucodon) have been identified as reservoir hosts shedding virus in urine, saliva and faeces in endemic areas. Clinical presentation, risk factors and transmission routes for human infection are unknown. We aimed to generate hypotheses about transmission routes and provide evidence to guide prevention.

Materials/methods: We defined cases as BoDV-1-confirmed by pro- or retrospective nucleic acid detection. Viruses were sequenced. We conducted interviews with family members at patients´ homes in 2019 using a standardized semi-qualitative questionnaire covering a broad spectrum of clinical presentation and pre-existing conditions. Queried exposures included housing environment, profession, animal contacts, outdoor activities, travel, and nutrition.

Results: We identified family members of five patients deceased 1996 through 2019 [4/5 female, median age 25 years, range 13-56]. Immunosuppression was known for none. Four had presented with fulminant encephalitis starting with headache and fever, the fifth had initially shown signs of Guillain-Barré-syndrome. All had developed confusion, deep coma and had died within a median of 2.5 (range 1 - 11) months after symptom onset. All had lived their whole life in rural areas of Germany. Other than private gardening no communalities were identified. Three families kept domestic or farm animals [cat, dog, hare, duck, chicken]. Family members did not know of any direct contact to shrews, but all had observed irregular peridomestic presence of shrews. Three families reported domestic cats bringing home shrews. All human BoDV-1 sequences clustered with animal BoDV-1 sequences from the respective regions.

Conclusions: Rural residence is a common denominator of all five patients but transmission routes remain poorly understood. Phylogenetic analysis and shrew presence suggest peridomestic infection from the local reservoir. In the absence of direct shrew contact, most likely transmission may be via indirect contact. Interviews with other patients´ families are ongoing. To prevent cases of this fatal zoonosis, we recommend against avoidable contact to shrews and their secretions and published an online-handout on prevention measures targeting the public in endemic areas.

### T2 magnetic resonance technology in the diagnosis of sepsis and clinical impact in patient management

Riccardo Paggi*1, Giuseppe De Socio1, Alessandra Belati1, Filippo Allegrucci1, Antonella Repetto1, Elio Cenci1, Antonella Mencacci1

1University of Perugia, Department of Medicine - Medical Microbiology Section, Perugia, Italy, 2Hospital Santa Maria della Misericordia in Perugia, Infectious Diseases, Perugia, Italy, 3Hospital Santa Maria della Misericordia in Perugia, Microbiology, Perugia, Italy

**Background:** Rapid and effective antimicrobial therapy is crucial to improve septic patient outcome, while inappropriate empirical therapy is a well-known, strong, independent predictor of mortality. Multidrug resistant organisms (MDRO) have reached pandemic level during the last two decades. A delay of 3-5 days has been found for effective therapy of systemic infections by MDRO. Thus, a rapid identification of pathogens, especially of bacterial species known to be multi-drug resistant, is a major goal in the diagnosis of sepsis.

Differently from technologies applicable on positive blood culture, dependent on the time of positivization of the sample, molecular tests performed directly on whole blood samples allow rapid identification of the etiological agents and are supposed to dramatically impact on patient outcome. Recently, the T2 Magnetic Resonance technology (T2Dx®) has been approved by FDA for laboratory diagnosis of sepsis by ESKAPEc organisms, with high sensitivity and specificity.

**Materials/methods:** The aim of this study was to evaluate the accuracy and the clinical impact of T2Bacteria Panel of T2Dx® system in comparison with the standard blood culture protocol in the early detection of ESKAPEc pathogens in patients with sepsis. Blood samples for culture and T2 testing were collected from 61 patients and diagnostic accuracy was evaluated. Duration of empirical therapy, and switch to target therapy were compared in patient with positive or negative T2 results.

**Results:** T2Bacteria Panel sensitivity and specificity were 100% (panel targets) and 94.6%, respectively. Time to report of positive T2Bacteria results was significantly lower than that of positive blood cultures [4.24 h ± 3.4 h vs 24.2 h ± 33.4 h, *p* < 0.001]. The percentage of patients in which antibiotic therapy was switched to target therapy the same day of sample collection was significantly higher in patients with positive T2 results [37.5% vs 11.4%, *p* = 0.031 2]. Duration of empirical therapy was shorter in these patients [34.11 h ± 23.87 h vs 80.48 h ± 73.40 h].

**Conclusions:** T2Bacteria Panel, allowing rapid detection of ESKAPEc pathogens, significantly impacts on the switch from empiric to target therapy, and represents a novel, valuable tool to improve the management of septic patients.

Abstract 1823

Marine organisms from Yucatán Peninsula (México) as a potential natural source of new antimicrobial compounds against multidrug-resistant pathogens

Cristina Lasarte*1, Marta Martínez Guitián1, Dawrin Pech Puch1, Mar Anabel Pérez Povedano1, Juan Vazquez-Ucha1, Germán Bou Arevalo1, Jaime Rodríguez González2, Carlos Jiménez González2, Alejandro Beceiro1

1INIBIC, Department of Microbiology, A Coruña, Spain, 2University of A Coruña, Centre for Advanced Scientific Research (CICA), A Coruña, Spain

Background: Antibiotic resistance has become a global health emergency and new therapeutic options to treat multidrug-resistant pathogen infections are indisputably needed. Oceans constitute an important natural source of bioactive molecules mainly due to their high biological diversity. Porifera (sponges) and Cnidaria (soft coral) are the most productive phyla regarding this aspect. Here we report the antimicrobial activity found in organic extracts of marine invertebrate species collected along the coasts of the Yucatan Peninsula and selected according to chemotaxonomical criteria.

Materials/methods: Samples were collected in different coastal zones of the Yucatan Peninsula, during three different periods of time [2016-2018]. Taxonomic identification of sponges was performed and the organic extracts were prepared. In vitro antimicrobial screening of sixty-three marine organisms (50 sponges and 13 ascidians) against four bacterial species of multidrug-resistant pathogens, three gram-negative (Acinetobacter baumannii, Klebsiella pneumoniae, Pseudomonas aeruginosa) and the gram-positive Staphylococcus aureus, was conducted in this study. MICs were evaluated through microdilution assay.

Results: Eight out of sixty-three species displayed activity against the bacteria tested (TABLE 1), being the organic extracts of Agelas citrina and Haliclona curacaoensis the most active, and reflecting respectively MICs of 0.5-8 and 32 mg/L. Four extracts (A. dilatata, A. citrina, H. curacaoensis and A. compressa) showed antibacterial activity against all pathogenic species tested, while the rest exhibited a narrow-spectrum antibiotic activity. Other extracts of marine organisms did not present antimicrobial activity (MICs ≥512 mg/L).

Conclusions: This work constitutes the first wide antimicrobial screening report of the marine sponges and ascidians collected from the Yucatan Peninsula, México. Extracts of some marine species showed a relevant antimicrobial activity. Purification and identification assays of the active compounds are currently being developed.

**Abstract 1824**

**Influence of empirical piperacillin-tazobactam on 30-day mortality in bacteraemia due to ESBL-producing versus non-ESBL-producing non-AmpC Enterobacteriaceae**

Daiana Lorena Agüero González*, Laura Morata2, Marta Bodro Marimont2, Carolina García Vidal2, Pedro Puerta2, Celia Cardozo2, Juan Ambrosioni2, Marta Hernández-Meneses2, Laura Linares2, Laia Albiach2, Estela Moreno2, Mariana Chumbita2, Veronica Rico Caballero2, Cristina Pitart2, Climent Casals2, Alex Soriano2, José Antonio Martínez Martínez2

1Hospital Clinic, Infectious Diseases Service, Barcelona, Spain, 2Hospital Clinic, Barcelona, Spain

**Background:** The comparative efficacy of piperacillin-tazobactam (PTZ) against non-ampC Enterobacteriaceae depending on the production of ESBL is unclear. The aim of the study was to assess the possible influence of empirical therapy with piperacillin-tazobactam (PTZ) on 30-day mortality in patients with bacteraemia due to susceptible non-ampC ESBL-producing compared with non-ESBL-producing *Escherichia coli*, *Klebsiella* spp. and *Proteus mirabilis* (EKP).

**Materials/methods:** Retrospective analysis of a prospectively collected database of patients with bacteraemia diagnosed at a 750-bed university hospital in Barcelona (Spain) from January 2003 to December 2018. Monomicrobial episodes due to EKP susceptible to PTZ (MIC≤ 8 mg/L) and empirically treated with PTZ were selected. Multivariate analysis was performed by a step backward logistic regression procedure.

**Results:** A total of 1323 EKP bacteraemia episodes were included of which 109 (14.7%) were due to ESBL-producers. In univariate analysis, 30-day mortality was associated with ESBL-producers in episodes with a urinary tract infection source (7/42 [16.7%] vs. 26/412 [6.3%]; OR 2.9, 95%CI 1.2-7.3, p=0.02) but not in those with other sources (9/67 [13.4%] vs. 89/802 [11.1%]; OR 1.2, 95%CI 0.5-2.5, p=0.5). In episodes with a urinary source, ESBL-producers remained an independent predictor of 30-day mortality (OR 3.1, 95%CI 1.1-9.1) along with age over 65 (OR 3.8, 95%CI 1.3-10.5), an ultimately/rapidly fatal prognosis of underlying disease (OR 3.6, 95%CI 1.5-8.4), chronic corticosteroid therapy (OR 6.8, 95%CI 2.7-16.9), neutropenia (OR 5.3, 95%CI 1.4-19.1) and shock (OR 5.2, 95%CI 2.2-12.3).

**Conclusions:** In patients with PTZ-susceptible *E.coli*, *Klebsiella* spp. or *P.mirabilis* bacteraemia receiving empirical therapy with PTZ, a very good outcome (30-day mortality below 10%) seems to be a reasonable expectation only for those with a urinary tract infection due to non-ESBL producers.

Abstract 1826

**Respiratory ß-2-microglobulin exerts direct antimicrobial activity**

Armin Holch¹, Richard Bauer², Jan Münch², Ludger Ständker³, Armando Rodriguez⁴,⁵,⁶, Sebastian Wiese⁷, Paul Walther⁸, Yasser Ruiz Blanco⁹, Elsa Sanchez-Garcia⁹, Barbara Spellerberg*¹

¹University Hospital of Ulm, Institute of Medical Microbiology and Hygiene, Ulm, Germany, ²University Hospital of Ulm, Institute of Molecular Virology, Ulm, Germany, ³Ulm University, Core facility functional peptidomics, Ulm, Germany, ⁴Ulm University Medical Center, Core Facility Functional Peptidomics, Ulm, Germany, ⁵Ulm University Medical Center, Core Unit Mass Spectrometry and Proteomics, Ulm, Germany, ⁶Ulm University Medical Center, Core Unit Mass Spectrometry and Proteomics, Ulm, Germany, ⁷Ulm University, Central facility for electron microscopy, Ulm, Germany, ⁸Ulm University, Central facility for electron microscopy, Ulm, Germany, ⁹University Duisburg-Essen, Computational Biochemistry, Essen, Germany

**Background:** The respiratory tract is a major entry site for pathogens into the human body. To combat bacterial infections, the immune system has a large variety of host defense mechanisms at its disposal. Part of the innate immune system and a first line of defense are antimicrobial peptides (AMPs). To search for novel AMPs from the human respiratory tract, a peptide library established from human broncho-alveolar-lavage (BAL) fluid was screened for antimicrobial activity against Gram-positive and Gram-negative bacterial pathogens.

**Materials/methods:** The peptide library was prepared from 20 liter of pooled human BAL. Peptides and small proteins were extracted by acetic acid and separated through ultrafiltration (cut-off 20 kDa). Employing reversed phase chromatography 76 different peptide fractions were generated from the BAL pool. Antimicrobial activity was determined by agar diffusion assays allowing the efficient detection of antibacterial activity within a small sample size. Bacterial membrane integrity was measured by sytox green uptake and bacterial cells were visualized by transmission electron microscopy (TEM).

**Results:** After three testing-cycles and subsequent purification of active BAL fractions we identified ß-2-microglobulin (B2M) for its antimicrobial activity. B2M is a subunit of the MHC-1 receptor complex present at the surface of every nucleated cell. It is known to inhibit the growth of *Listeria monocytogenes* and *Escherichia coli* and to facilitate phagocytosis of *Staphylococcus aureus*. Using commercially available B2M we could confirm a dose-dependent inhibition of *Pseudomonas aeruginosa* as well as *L. monocytogenes*. To localize AMP activity within the B2M sequence, peptide fragments of the molecule were tested for antimicrobial activity. Sytox green uptake into bacterial cells following the exposure to B2M was determined and revealed a dose-dependent loss of bacterial membrane integrity. TEM analysis showed areas of disrupted bacterial membranes in *L. monocytogenes* incubated with B2M and high amounts of lysed bacterial cells.

**Conclusions:** In conclusion B2M as part of an ubiquitous cell surface complex may represent a potent antimicrobial agent by interfering with bacterial membrane integrity.

**Abstract 1828**

**Improved detection of van-B bearing *E. faecium* isolates in a German hospital laboratory by a modified routine workflow for antimicrobial susceptibility testing**

Christiane Scherer*1*

1Evangelical Hospital Bethel (EvKB) - Johannesstift, Institut für Laboratoriumsmedizin, Mikrobiologie und Hygiene, Bielefeld, Germany

**Background:** Vancomycin-resistant *E. faecium* (VRE) are an emerging problem in the German health care system. Various factors are under discussion to enhance VRE-spread. One factor that may contribute to the spread of VRE is the low expression of Vancomycin-resistance. Facing a significant increase of VRE in the past two years, our hospital laboratory started to improve the detection of Vancomycin-susceptible Van-B positive isolates in developing a new workflow for antimicrobial susceptibility testing (AST) adding a Van-A/Van-B-PCR and chrome agar plates to the routinely performed AST.

**Materials/methods: Routine workflow:** AST was performed with VitekII AST-611 (biomerieux) alternatively with agar diffusion (biorad) following EUCAST standard procedures and breakpoint interpretation guidelines. First time isolated VRE in a patient underwent Van-A/Van-B-PCR (TiBMol). **Modified workflow:** Every Vancomycin susceptible *E. faecium* isolate underwent Van-A/Van-B-PCR-testing (TiBMol). *E. faecium* isolates from material other than VRE-screening material were streaked on chromagar (bioMerieux) in parallel to the purity control. Data analysis was performed with hybase®-system to eliminate copy-strain counts of isolates.

**Results:** From 01.03. to 31.08.19 a total amount of 686 *E. faecium* AST from 361 patient was carried out. 186 isolates were tested Vancomycin resistant, 175 Vancomycin susceptible. From the Vancomycin susceptible strains 35 (20%) beared the Van-B-Gene detected by PCR, none show a Van-A gene. The parallel to AST streaked chromagar showed a positive VRE result in 32 cases.

**AST result for Vancomycin**

**Conclusions:** We found a remarkable 20% proportion of phenotypically Vancomycin-susceptible and Van-B-positive *E. faecium* -isolates after modification of the AST-workflow. Those isolates would normally be undetected by routine AST and therefor escape surveillance and further hygiene measures. VRE chromagar additionally streaked out to the purity control may help to detect these strains. Further investigation has to be done on the performance on other automated or manual AST systems. Of further interest would be the genomic analysis of these strains in comparison to phenotypically vancomycin resistant strains to understand their role in VRE-epidemiology.

Human endogenous retroviruses as markers of severity in sepsis

Marine Mommert1, Olivier Tabone2, Karen Brengel-Pesce1, Elisabeth Cerrato2, Valérie Cheynet1, Mélanie Denizot1, Paola Fournier1, Audrey Guichard1-2, Magali Naville1, Guillaume Monneret2, Guillaume Monneret2, Fabienne Venet2, Jean-Nicolas Volff3, Julien Textoris2;6, François Mallet*1;2

1Joint research unit Hospices Civils de Lyon - bioMerieux, Pierre-Benite, France, 2EA 7426 University of Lyon 1 - Hospices Civils de Lyon - bioMérieux, Lyon, France, 3Institut de Genomique Fonctionnelle de Lyon, Lyon, France, 4Hospices Civils de Lyon, Intensive Care Unit, Pierre-Benite, France, 5Hospices Civils de Lyon, Immunology Laboratory, Lyon, France, 6Hospices Civils de Lyon, Department of Anaesthesiology and Critical Care Medicine, Lyon, France

Abstract third-party references: bioMerieux, Hospices Civils de Lyon

Background: Sepsis is defined as a life-threatening organ dysfunction caused by a dysregulated host response to infection. The heterogeneity of the disease present a major clinical challenge with regard to the therapeutic coverage, and this day the proposed markers are not enough to stratify patients. The human endogenous retroviruses (HERVs) could be relevant markers, due to their expression in inflammatory and autoimmune diseases and their emerging immunological properties (envelopes and non-coding sequences).

Materials/methods: In order to determine to what extent the HERVs are expressed and modulated in the blood compartment, in inflammatory and immunocompromised contexts in vitro and in vivo, we used a custom high density DNA chip allowing the transcription analysis of 360,689 HERVs. The HERVs expression was objectified in endotoxin tolerance (ET) ex vivo model in peripheral blood mononuclear cells (PBMCs) of healthy volunteers and in whole blood of healthy volunteers and 120 septic shock patients, stratified or not according to the immune status determined by mHLA-DR level.

Results: About 7% of HERVs are expressed in the blood compartment including notably hundreds of identified HERV-H and PRI-MA-41 loci. The HERV transcriptome is modulated in ex vivo ET model, letting appear two major transcriptional phenotypes. Major differences in HERVs expression was observed between septic patients and healthy volunteers. More, the HERVs transcriptome was modulated between septic patients, according to their immune status. Using a signature of modulated elements, we have been able to stratify an independent validation cohort with a clear difference in severity between two clusters of patients.

Conclusions: We illustrated the importance of addressing both the exome and repetitive DNA repertoires to increase our understanding of sepsis pathophysiology. The added value of these newly identified HERVs markers should be evaluated in a larger cohort of septic patients. If they prove to be robust, they could further serve as a stratification tool prior to immunostimulatory treatment and to monitor drug efficacy, which could contribute to the reduction of mortality in sepsis patients.

Detection of rifampin and isoniazid resistance using molecular testing to initiate an ethambutol-free 3-drug regimen in pulmonary tuberculosis: a French non-inferiority multi-centre randomised clinical trial

Nathalie De Castro1, Frédéric Méchaï2, Delphine Bachelet1, Ana Canestri3, Veronique Joly4, Marie-Anne Vandenhende5,6, David Boutoille7, Mallorie Kerjouan8, Nicolas Veziris9,10, Jean-Michel Molina11,12, Nathalie Grall14, Pierre Tattevin15,16, Cedric Laouenan3, Yazdan Yazdanpanah1,17

1 Hospital Saint-Louis AP-HP, Infectious Diseases Department, Paris, France, 2 Avicenne Hospital (AP-HP), Infectious Diseases Department, Bobigny, France, 3Bichat-Claude Bernard Hospital, URC, Paris, France, 4 Hospital Tenon AP-HP, Infectious Diseases Department, Paris, France, 5 Bichat-Claude Bernard Hospital, Infectious Diseases Department, Paris, France, 6 Hospital Saint-André - Hospital Group Saint-André Chu De Bordeaux, Infectious Diseases Department, Bordeaux, France, 7 Université BORDEAUX, Bordeaux, France, 8 Chu Nantes, Infectious Diseases Department, Nantes, France, 9 University of Nantes, Nantes, France, 10 Pontchaillou University Hospital Center, Infectious Diseases Department, Rennes, France, 11 Hospital Saint-Antoine Ap-Hp, Paris, France, 12 Sorbonne Université, CIMIT, Paris, France, 13 University of Paris, Paris, France, 14 Bichat-Claude Bernard Hospital, Bacteriology Department, Paris, France, 15 University of Rennes 1 Beaulieu, Rennes, France, 16 Inserm, IAME UMR 1137 INSERM, Paris, France

Background: Current guidelines recommend initiation of a 4-drug regimen (rifampin RIF, isoniazid INH, pyrazinamide PZA and ethambutol EMB) for drug- susceptible tuberculosis [TB]. The rationale behind the use of EMB is to prevent the emergence of resistance to RIF in case of primary resistance to INH (5% prevalence in France in 2018). Early detection of INH resistance using molecular testing may allow to initiate treatment with an EMB-free 3-drug regimen. This strategy has not been evaluated in settings with low incidence INH resistance.

Materials/methods: FAST-TB, a phase 4 French multicenter, open-label non-inferiority trial, compared two strategies: (i) PCR-based detection of INH and RIF resistance at baseline using Genotype MTBDR Plus v2.0® and then start a 3-drug containing TB regimen without EMB if no resistance detected [PCR arm], vs. (ii) standard 4-drug combination and treatment initiation, pending phenotypic drug-susceptibility testing results [C arm]. Adult patients with acid-fast bacilli [AFB+] on respiratory samples were enrolled; patients with previous TB treatment were excluded from the study. The primary endpoint was the proportion of patients with treatment success defined as bacteriological and clinical cure within the first year after enrollment. A non-inferiority margin of 10% was used.

Results: 201 patients were randomized, 104 in the PCR arm and 99 in the C arm: 27% were female, median age was 37 [IQR: 27-51] years, 72% were born in Africa, and 5.4% were HIV-infected. Chest X-ray showed excavations in 64% of the cases and half of the participants had bilateral abnormalities. We detected 7 [3.5%] patients with INH phenotypic resistance, 2 in the PCR arm and 5 in the C arm. Overall, 167 patients met criteria of treatment success: 86/104 (82.7%) in the PCR arm and 81/99 (81.8%) in the C arm with a difference of +0.87% (95%IC: -9.64; 11.39), meeting non-inferiority criteria.

Conclusions: In a setting with low incidence of TB and INH resistance, the use of a 3-drug combination with RIF, INH and PZA based on early detection of INH and RIF resistance using MTBDR Plus® test on AFB+ sputum samples was non-inferior to a 4-drug containing regimen.

Bacterial profile associated with oral cancer: metagenomic analysis in oral micro-niches
Dabeiba Adriana Garcia Robayo*, Fredy Gamboa1, Herlinto Alveiro Tupaz Erira1

1Pontificia Universidad Javeriana, Pontificia Universidad Javeriana, Bogotá, Colombia

Background: Oral microbiota is associated with Oral Squamous Cell Carcinoma (OSCC), mainly by persistent inflammatory processes and production of acetaldehyde. Variation of bacterial communities within the oral cavity depending on anatomical location [niches] is well established. Studies with high-throughput sequencing describe the composition and abundance total bacteria in the oral micro-niches. However, at present no studies have characterized different oral micro-niches in OSCC. The objective of this study was to determine and compare tumoral tissue, saliva and dental plaque bacterial profiles, in patients with OSCC.

Materials/methods: A total of nine OSCC patients were included. Samples included saliva, dental plaque and tumor tissue. DNA was extracted from all samples. Subsequently, libraries were prepared using Illumina Nextera XT®. For sequencing paired-end MiSeq of Illumina® was used. Trimmomatic software was used to evaluate quality. Moreover, identification of bacteria in each sample was performed with Kraken Aligner V1.0. Initially, bacteria associated with tumoral tissue was identified. Subsequently, intra and inter-patient samples where bacteria in saliva and dental plaque samples were statistically significant (p-value < 0.05) were compared.

Results: In tumoral tissue of patients with OSCC, eighteen species of bacteria were identified. The more characteristic bacteria in OSCC were a profile of nine species of bacteria Riemerella anatipestifer, Chlorobium phaeobacteroides, Yersinia enterocolitica, Proteus mirabilis, Mycoplasma hyorhinis, Flavobacterium psychrophilum, Streptococcus pyogenes, and Mycoplasma hyopneumoniae in a sub-group of patients, and Alteromonas mediterranea in other sub-group of patients. After saliva and dental plaque comparison high similarity was observed, where the more abundant bacteria were Prevotella melaninogenica, Capnocytophaga ochracea, Fusobacterium nucleatum and Haemophilus influenzae, nevertheless no sub-groups were observed. Last, bacterial profile associated which OSCC in saliva and dental plaque was scarce or absent representing less than 3% of the total bacteria in those samples.

Conclusions: A profile of nine species of bacteria were predominant in tumoral tissue. Saliva and dental plaque samples do not contain bacteria associated with OSCC.

Abstract 1834

Vancomycin pharmacokinetics in patients undergoing extracorporeal membrane oxygenation after 48 hours of treatment

Laura Herrera-Hidalgo1, Marina Munoz-Burgos1, Joao Laimerao2, Marta Mejias-Trueba1, Adela Garcia-Avello1, Javier Martinez1, Luis E. Lopez-Cortes*3, Maria Victoria Gil-Navarro1

1Hospital Universitario Virgen del Rocio, Unidad de Farmacia, Sevilla, Spain, 2Hospital Universitario Virgen del Rocio, Unidad de Cuidados Intensivos, Sevilla, Spain, 3Hospital universitario virgen macarena, Unidad Clinica de Enfermedades Infecciosas, Microbiologia y Medicina Preventiva, Sevilla, Spain

Background: Extracorporeal membrane oxygenation (ECMO) could affect drug pharmacokinetics (PK), which is critical for antimicrobial effectiveness. Vancomycin PK during ECMO has been previously studied, but only in the first 48 hours of treatment (Initial-48h). The aim of this study was to assess vancomycin PK during ECMO after 48 hours of treatment (After-28h) and compare with those estimated from the complete cohort and initial-48h.

Materials/methods: A retrospective observational study was carried out in patients under simultaneous treatment with vancomycin and ECMO between January 2016 and January 2019 whose vancomycin serum concentrations were measured. The variables recorded were: ECMO type and indications, renal replacement therapy, dose, creatinine, exitus, vancomycin serum concentration and day of the analysis. The PK analysis was performed using Abbottbase Pharmacokinetics Systems software (Abbott Diagnostics Division, Irving, TX, USA), adjusting experimental data according to a compartmental linear model using Bayesian estimates. Two-sided t-student test was used for comparing vancomycin PK parameters (PKp) obtain from i48h, a48h and the complete cohort.

Results: Six patients were excluded for lack of data and 13 patients were analyzed. Most patients 84.6%(11) underwent venoarterial ECMO. ECMO indications were 7(53.8%) cardiogenic shock, 3(23%) ventricular dysfunction and others 3(23%). Exitus occurred in 6(46.2%) patients, and 3(23%) underwent concomitant renal replacement therapy. Vancomycin was measured in 38 samples, 28(73.7%) after 48 hours of treatment.

Vancomycin PK-p estimated from a48h, i48h and the complete cohort are depicted in table 1. No significant differences were observed in any case (p>0.05), but a48h, a tendency towards higher Vd, Cl and T1/2 and lower AUC were detected.

Table 1

<table>
<thead>
<tr>
<th>PKp</th>
<th>After-48h</th>
<th>Initial-48h</th>
<th>Complete cohort</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vd [L/kg]</td>

<td>0.847±0.267</td>
</tr>
<tr>
<td>Cl [L/h/kg]</td>
<td>0.039±0.017</td>
<td>0.036±0.010</td>
<td>0.039±0.015</td>
</tr>
<tr>
<td>AUC [mg*h/L]</td>
<td>605.6±165.6</td>
<td>831.4±402.3</td>
<td>671.1±270.6</td>
</tr>
<tr>
<td>T1/2 [h]</td>
<td>18.38±11.64</td>
<td>1786±6.9</td>
<td>18.24±10.5</td>
</tr>
</tbody>
</table>

Vd: Volume of distribution, Cl: Vancomycin clearance, AUC: Area under the curve, T1/2: Half-life

Conclusions: Vancomycin PKp estimated from our population are similar to those previously described, including high variability. Vancomycin PKp after-48h were not previously described, and despite being similar to other populations, the tendencies observed warranted further studies in bigger populations to detect finest variations.

Tuberculosis impacts immune-metabolic pathways resulting in perturbed cytokine responses

Alba Llibre1, Vincent Rouilly2, Munyaradzi Musvosvi2, Elisa Nemes2, Celine Possemee1, Simba Mabwe2, Bruno Charbit1, Violaine Saint-Andre1, Vincent Bondet1, Pierre Bost1, Humphrey Mulenga2, Nicole Bilek2, Matthew Albert3, Thomas Scriba2, Darragh Duffy*1

1Institut Pasteur, Paris, France, 2SATVI, Cape Town, South Africa, 3Insitro, San Francisco, United States

Background: Tuberculosis (TB) is a major public health problem for which host-directed therapeutics are proposed as novel treatment strategies. However, their successful development still requires a more comprehensive understanding of how Mycobacterium tuberculosis (M.tb) infection impacts immune and metabolic host responses.

Materials/methods: To address this challenge we applied standardised immunomonitoring tools to compare induced immune responses between individuals with latent M.tb infection (LTBI) and active TB disease (n=50). Whole blood was collected and stimulated with TB antigens (TB Ag), Bacillus Calmette-Guérin (BCG), IL-1β, and a Null control. Immune responses were analyzed at proteomic, transcriptomic, metabolomic and cellular levels. The TB patients were analyzed both prior to, and after, successful antibiotic treatment.

Results: This approach revealed multiple differential immune responses in active TB disease at transcriptomic, proteomic, metabolomic and cellular levels. These immune differences were absent after successful antibiotic treatment highlighting their disease-specific nature. Integrative analysis of these different datasets permitted a detailed characterisation of the perturbed IFNγ response in TB disease. Specifically TB patients had different IFNγ responses as compared to LTBI controls, at the proteomic, but not transcriptomic level. We also identified dysregulated IL1 responses to BCG stimulation in TB patients, for both agonist (IL1a/b) and antagonist (IL1RA) responses. Furthermore, the combination of novel digital ELISA readouts with Mass Spectometry identified novel immune-metabolic drivers of IL1RA secretion.

Conclusions: This study improves our knowledge of how M.tb alters key immune responses, and will support the design of improved diagnostic, prophylactic and therapeutic tools.

Abstract 1839

**Actinotignum schaalii in breast abscesses, an emerging pathology? Report on five cases**

Luc Deroche,* Cédric Nadeau, Vincent Huguier, Maxime Pichon, Lauranne Broutin, Plouzeau Chloé, Christophe Burucoa, Anthony Michaud

1Centre Hospitalier Universitaire de Poitiers, Service de Bactériologie-Hygiène hospitalière, Poitiers, France, 2Centre Hospitalier Universitaire de Poitiers, Service de Gynécologie, Poitiers, France, 3Centre Hospitalier Universitaire de Poitiers, Service de Chirurgie Plastique, Reconstructrice et Esthétique, Poitiers, France, *Poitiers University Hospital, Infectious Agents Department, Poitiers, France

**Background:** *Actinotignum schaalii* are Gram-positive rod-shaped bacteria known to be responsible for urinary tract infection in elderly and patient with urological conditions. Breast abscesses caused by *A. schaalii* are rare (only two cases previously described), so few clinical or microbiological data were available. This review of five cases describes the clinical profile of patients with breast abscesses caused by *A. schaalii*, as well as the antimicrobial susceptibility.

**Materials/methods:** From 2017 to 2019, clinical isolates of *A. schaalii*, isolated from breast abscesses from patients hospitalized in the University Hospital of Poitiers were included. Culture identification was performed by MALDI-ToF (Vitek-MS, bioMérieux). Antimicrobial susceptibility was assessed by the E-test method (bioMérieux), on Brucella Blood Agar media plates (bioMérieux). MICs were interpreted using the EUCAST 2019 v9.0 breakpoint table. In order to determine the analytical performance of culture to identify *A. schaalii*, 20 breast abscess samples with similar clinical presentation were tested. The presence of *A. schaalii* DNA was challenged using a specific qPCR assay targeting the *gyrB* gene, as previously described [1].

**Results:** Among the five patients, the median age was 46 years (from 37 to 50 years). All patients had a polymicrobial infection, 80% were active smokers, 60% had an underlying immunodepressive condition (diabetes, cancer, immunodepressive therapy) and 40% had a chronic abscess. Evolution was favorable in every case, without recurrence at six months. Treatment was based in all cases on surgical drainage of the abscess. Three out of five patients also received a short course of antibiotics. Antimicrobial susceptibility is detailed in Table 1. *A. schaalii* DNA was detected in all samples with positive *A. schaalii* culture. The qPCR assay was negative for all *A. schaalii* negative breast abscess samples (*n*=20). These latter included negative and positive bacterial cultures.

**Table 1: In vitro activity of 11 antimicrobial agents against 5 clinical isolates of *A. schaalii* recovered from breast abscesses.**

Abstract 1840

Comparison of early effects of *Streptococcus pneumoniae* vaccination policies on nasopharyngeal carriage in a Palestinian population

Mahmoud Ramlawi*, Kifaya Azmi², Ziad Abdeen²

¹Augusta Victoria Hospital, Jerusalem, Palestine, ²Al-Quds University, Jerusalem, Palestine

Abstract third-party references: my abstract supported by Al-Quds University

**Background:** *Streptococcus pneumoniae* can asymptptomatically colonize the nasopharynx and cause a various range of illnesses. Pneumococcal conjugate vaccines (PCVs) are at present used in different countries. The aim of the study is to determine the effect of different vaccination policies PCV7/13 to that PCV10 on the carriage rates and comparing the impact of different vaccination policies in East Jerusalem and West Bank region.

**Materials/methods:** Five cross-sectional surveillances of *S. pneumoniae* were carried out in East Jerusalem and Palestinian authority (PA), where two Palestinian populations with different vaccination policies were screened, with an annual average of 348 and 616 children, respectively, were performed during 2009-2016. Nasopharyngeal swabs and data were collected from children less than 5 years old. In East-Jerusalem (EJ), PCV7 was implemented in 2009 and replaced by PCV13 in late 2010, while in Palestine (PA), PCV10 was implemented in 2011.

**Results:** A total of 4686 children were screened in EJ (n=1615) and PA (n=3070), the overall rate of *S. pneumoniae* carriage did not change significantly during the 5 first years of the study, in either population. The pediatric subjects from EJ were determined to carry *S. pneumoniae* during the 5 years study, 2009, 2010, 2011, 2014, and 2016 as 28.9%, 29.3%, 28.6%, 30.7% and 16.9%, respectively. In addition 35.9%, 33.6%, 28.8%, 28.6% and 32.9% of the pediatric subjects from PA were shown to carry *S. pneumoniae* in 2009-2016, respectively. By year 2016, *S. pneumoniae* carriage was reduced significantly in EJ from ~29% on average to ~17%, following seven years application of PCV7/13. In PA, where follow-up included only 5 years after PCV10 application, *S. pneumoniae* carriage remained ~30%.

Interestingly, VT7 strains gradually decreased following PCV implementation. Following vaccine implementation, during the study period, there was a significant decrease in carriage of *S. pneumoniae* in the EJ between 2009 and 2016. No significant variation was seen in the overall carriage of *S. pneumoniae* between 2009 to 2016 in PA. PCV10 was introduced to PA late in 2011, but *S. pneumoniae* carriage was approximately [160/566] 28% in 2011, prior to vaccine introduction, and [216/656], 32.9% in 2016, five years following vaccine implementation.

**Conclusions:** Following PCV implementation, a decrease in the prevalence of VT strains was observed in EJ, and PA.

Abstract 1842

**A selective culture medium for screening ceftazidime/avibactam resistant Gram-negative isolates**

Patrice Nordmann*1, Mustafa Sadek1, Camille Tinguely2, Laurent Poirel1

1University of Fribourg, Fribourg, Switzerland

**Background:** The emergence of carbapenemases in Enterobacterales, in particular of the Klebsiella pneumoniae carbapenemases (KPCs) that are associated to multidrug resistance, represent a high priority for the development of novel antibacterials. Avibactam, a non-β-lactam inhibitor, is able to restore the efficacy of ceftazidime against KPC producers. However, resistance to the novel ceftazidime-avibactam (CAZ-AVI) association is increasingly reported among clinical strains expressing KPC variants. Taking in account the increasing isolation of those CAZ/AVI-resistant enterobacterales, a selective culture medium for screening CAZ-AVI-resistance in Gram-negative bacteria (Enterobacterales, Pseudomonas aeruginosa) was developed.

**Materials/methods:** This medium (SuperCAZ/AVI) contains ceftazidime, avibactam, zinc sulfate, daptomycin, and amphotericin B. It was evaluated with 50 CAZ/AVI-susceptible (40 Enterobacterales including Enterobacter cloacae, Klebsiella pneumoniae, and Escherichia coli, 10 Pseudomonas aeruginosa), and 42 CAZ/AVI-resistant (20 Enterobacterales including Enterobacter cloacae, Klebsiella pneumoniae, and Escherichia coli, 22 Pseudomonas aeruginosa) Gram-negative isolates. In addition, testing was performed by spiking stools with a series of resistant isolates, at different concentrations.

**Results:** Sensitivity and specificity of detection of the SuperCAZ/AVI medium were ca. 100%. By testing stools spiked with CAZ/AVI-resistant or -susceptible Gram-negative bacteria (92 isolates), an excellent performance of the medium was observed, with a lowest detection limit ranging from $10^1$ to $10^2$ CFU/ml.

**Conclusions:** The Super CAZ/AVI medium constitutes a screening medium aimed to detect CAZ/AVI-resistant bacteria regardless of their resistance mechanism. This Super CAZ/AVI medium may be used for prospective screening, and epidemiological surveys that may contribute to rapidly detect carriers of CAZ/AVI resistant isolates, and consequently to rapidly implement infection control measures in order to limit their spread.

Is it realistic to offer an antibiotic susceptibility bonus to developers?

Chantal Morel*, Olof Lindahl, Stephan J. Harbarth, Marlieke De Kraker, Suzanne Edwards, Aidan Hollis

1University of Geneva Medical Faculty, Geneva, Switzerland; 2Uppsala University Business Faculty, Uppsala, Sweden; 3University of Geneva Hospitals, Geneva, Switzerland; 4Berlin University of Technology, Berlin, Germany; 5University of Calgary, Calgary, Canada

Background: Return on investment for antibiotic development needs to be amended, without jeopardizing the future efficacy of novel compounds through high volume sales. This study explores the feasibility of a financial bonus that depends on levels of antibiotic susceptibility over time after approval. This bonus is intended to align pharmaceutical industry interests with public health interests through prolongation of efficacy through time. But how could such a bonus scheme work, with regards to magnitude and eligibility?

Materials/methods: This multidisciplinary (business, economics and microbiology) study utilized literature study, market analyses, Delphi consultation, informal interviews, and investment analysis.

Results: Findings from this (public-sector funded) project show that a suitable bonus magnitude should be sufficiently high to deter profit-driven mass marketing, low value or riskier sales, but not so high that the company would prevent access to their product where there is justified need. To be effective it must be clear that it is not intended as a traditional R&D incentive (indeed a large-scale monetary reward is needed independently from this scheme). What is proposed here is a proper bonus paid for strong product performance -- i.e. proven ability to stave off resistance. Since not all factors contributing to resistance will be under company control, falling below the susceptibility threshold does not imply being penalized – it is simply that the product did not perform to this higher standard. With regard to the susceptibility criterion, there are advantages in utilizing epidemiological cut-offs to determine bonus eligibility rather than MIC break points to avoid gaming strategies. Linear eligibility thresholds could run from 100% wild type (weight=1) to ≤50% (weight=0). Additional binary weights can be applied to ensure that only useful and accessible products are eligible.

Conclusions: The theory underlying an Antibiotic Susceptibility Bonus and its different components is backed by market dynamics and experts in the field, and can be facilitated by on-going efforts in microbiology and lab quality standardization and widespread AMR surveillance initiatives. The bonus could be considered alongside -- or as a performance-related component of -- a pull-based R&D reward such as a market entry reward or an insurance/supply contract.

Abstract 1844

**Clinical and laboratory features of mixed invasive mycoses in adult haematologic patients with invasive aspergillosis**

Olga Shadrivova1, Sofya Khostelidi1, Yuliya Borzova2, Ekaterina Desyatik1, Julia Chudinovskikh1, Olga Uspenskaya4, Marina Popova2, Alisa Volkova1, Tatjana Shneyder1, Tatjana Bogomolova2, Svetlana Ignatyeva2, Ludmila Zubarovskaya2, Boris Afanasjev2, Natalya Vasiljeva2, Nikolai Klimko*1

1North-Western State Medical University named after I.I.Mechnikov, St. Petersburg, Russian Federation, 2North-Western State Medical University named after I.I.Mechnikov, Kashkin Research Institute of Medical Mycology, St. Petersburg, Russian Federation, 3Petrov Scientific and Research Oncology Institute of the Ministry of Health of Russia, St. Petersburg, Russian Federation, 4Leningrad Regional Clinical Hospital, St. Petersburg, Russian Federation, 5I.Pavlov First Saint Petersburg State Medical University, St. Petersburg, Russian Federation

**Background:** We investigated the features of mixed invasive mycoses (IM) in hematologic patients.

**Materials/methods:** Retrospective study in 1998-2019 y.y. Diagnostic criteria EORTC/MSG, 2008 were used.

**Results:** In group I we included 72 adult hematologic patients with combination of invasive aspergillosis (IA) and non-Aspergillus caused mycoses, median age – 41 years (18 - 75), males – 71%. The comparison group consisted of 519 hematologic patients with IA, median age – 46.5 years (18 – 79), males – 56%.

The predominant underlying diseases were acute leukemia (51% vs 44%) and lymphomas (35% vs 34%). Mixed IM less often developed in patients with chronic leukemia (6% vs 9%) and multiple myeloma (3% vs 8%). The main risk factors were severe neutropenia (79% vs 73%), and steroid therapy (72% vs 69%). Mixed IM occurred significantly more frequently in patients with lymphocytopenia (63% vs 52%, p = 0.01), immunosuppressive therapy (33% vs 23%, p = 0.04), ICU stay (29% vs 7%, p = 0.0001), and after allo-HSCT (33% vs 23%, p = 0.04).

In patients with mixed IM ≥ 2 organs (29% vs 5%, p = 0.001), CNS (15% vs 2%, p = 0.03), and paranasal sinus involvement (10% vs 4%) were more often observed; respiratory failure (51% vs 34%, p = 0.0001), hemoptysis (13% vs 5%, p = 0.005), and hydrothorax (9% vs 3%) were more often noted. The main causative agents of IA were *A. fumigatus* (40% vs 43%) and *A. niger* (34% vs 33%). Non-Aspergillus pathogens were: mucormycetes – 35%, *Pneumocystis jirovecii* – 25%, *Candida* spp. – 22%, hyalohyphomycetes – 9%, *Cryptococcus neoformans* – 4%, rare yeasts – 4%, and pheohyphomycetes – 1%. Overall 12-week survival in the mixed-infection group was significantly lower (52% vs 84%, p = 0.0001).

**Conclusions:** Mixed invasive mycoses occurred in patients with persistent lymphocytopenia (63%), long-term immunosuppressive therapy (33%), ICU stay (29%), and after allo-HSCT (33%). Non-Aspergillus etiological agents were mucormycetes – 35%, *Pneumocystis jirovecii* – 25%, and *Candida* spp. – 22%. In patients with mixed invasive mycoses, ≥ 2 organs (29% vs 5%, p = 0.001) and CNS involvement (15% vs 2%, p = 0.03) were more often observed. Overall 12-week survival: 52% vs 84%, p = 0.0001.

Abstract 1848

Investigation and control of measles outbreak in Balkh province, Afghanistan, Dec 2016-2017

Aminullah Shirpoor*1

1Regional Hospital, Mazari Sharif, Afghanistan

**Background:** Measles is a most contagious infection known to humans, and ranks among the top four childhood killers worldwide. Despite immunization progression, unfortunately Afghanistan is still an endemic country for measles outbreaks. Over 20 of the 34 provinces in Afghanistan, of the 25,000 reported cases in 2017, 1235 cases reported by Balkh province.

**Materials/methods:** On December 2016 the index suspected measles case reported by surveillance focal point from an internally displaced people (IDP) encampment in Dehdadi District of Balkh province. Outbreak investigation conducted, a measles case defined as any person with fever, maculopapular rash, conjunctivitis and cough or coryza in the affected area since 3rd Dec 2016. Rapid assessment conducted in the area for vaccine coverage and active case finding. Blood serum specimen collected and shipped to Central Public Health Laboratory in Kabul and confirmed by ELISA-IgM test.

**Results:** Of the 546155 population 359 suspected measles cases identified attack rate AR = 6.6/10000 and male to female ratio 1.3:1. Of the 173 cases tested for measles IgM, 131 (75.7%) [95% CI 68.6, 81.9] confirmed. There were 17 deaths that indicated case fatality rate (CFR) (4.7%) [95% CI 2.5, 6.9]. The mean age of cases was 30.6 months and ranged 1 month -29 years. One dose of vaccination coverage among the IDP population was 18%, while only 6 (1.67%) of all cases had received one dose of measles vaccine. We conducted two rounds village-wide immunization campaign and vaccinated 61084 children, subsequently, cases ceased.

**Conclusions:** To eradicate measles, high vaccination coverage must be maintained, and this must be the focus of local and national authorities. Low vaccination coverage looks likely caused of the outbreak. The high contagiousness of measles requires initial widespread supplemental vaccination to stop a large epidemic; small efforts will not be successful.

Abstract 1851

**An ultrasensitive test for the detection of Clostridiodes difficile toxins in stool samples using a single-molecule counting method**

Don Straus*1, Ann Zuniga1, Alejandra Garces1, Andrew Tempesta1, Adam Williams1, Bill Lauzier1, Jennifer Hickey1, Sadanand Gite1, Selina Clancy1, Yismel Rosario1, Jayson Bowers1

1First Light Diagnostics, Inc., Chelmsford, United States

**Background:** Clostridiodes difficile infection is considered an urgent antibiotic resistance threat by the CDC, accounting for ≈225,000 hospitalizations, 12,800 deaths, and ≈$1B in healthcare costs in the US in 2017. The presence of the secreted toxins A and B, that cause the devastating symptoms of this gastrointestinal infection are diagnostic of C. difficile infection (CDI). However, the rapid testing methods currently used to detect CDI lack accuracy: Enzyme immunoassays are specific but lack sensitivity and nucleic acid amplification tests (NAAT) are sensitive but lack specificity. This has resulted in the adoption of complex algorithms for C. difficile diagnosis. We present results for a new toxin test that demonstrate both high sensitivity and specificity for C. difficile toxins A and B on a fully automated benchtop platform.

**Materials/methods:** The detection technology uses non-magnified digital imaging to count single toxin molecules that are tether together target-specific magnetic and fluorescent particles. The 30 minute method includes the use of a dye-cushion to eliminate wash steps and the need for time consuming specimen preparation steps. We determined analytical performance characteristics of the test using negative clinical stool samples spiked with purified toxin. To assess clinical performance, we tested 787 stool samples from 5 clinical sites and compared the results with the cellular cytotoxicity neutralization assay (CCNA).

**Results:** The test’s LoD for toxin B was 60 pg/mL. Comparison of the new test to the CCNA reference method gave 95% positive percent agreement (PPA) (83/87 samples) and 95% negative percent agreement (NPA) (667/700 samples).

**Conclusions:** The results presented demonstrate the potential of the C. difficile toxin test to aid in the diagnosis of CDI and reduce the need for testing algorithms that require multiple assays.

Activity of the β-lactamase inhibitor LN-1-255 against plasmid-mediated Class C cephalosporinases enzymes from Enterobacteriaceae

Juan Vazquez-Ucha*, Cristina Lasarte, Marta Martínez Guitián, Jorge Arca Suárez, Concepción Gonzalez-Bello, Germán Bou Arevalo, Alejandro Beceiro

1INIBIC, Servicio de Microbiología, A Coruña, Spain, 2CiQUS - Centro Singular de Investigación en Química Biolóxica e Materiais Moleculares, Santiago de Compostela, Spain

**Background:** Class C β-lactamases are clinically relevant cephalosporinases encoded on the chromosomes or plasmids of many Enterobacteriaceae. Overexpression can confer resistance to broad-spectrum cephalosporins, such as cefotaxime or ceftazidime. Classical inhibitors such as clavulanic acid, sulbactam, and tazobactam have a very limited effect on AmpC β-lactamases. Avibactam, approved in 2015, was the first β-lactamase inhibitor that provide activity against these enzymes. The aim of the study was to evaluate the inhibition ability of the experimental inhibitor LN-1-255 against plasmid-mediated AmpC enzymes.

**Materials/methods:** bla<sub>DHA-1</sub>, bla<sub>DHA-7</sub>, bla<sub>CMY-2</sub>, bla<sub>CMY-54</sub> and bla<sub>FOX-4</sub> genes encoding plasmid-mediated class C enzymes were cloned to pBG18S and transformed into Escherichia coli TG1. MICs were performed to cefoxitin (FOX), ceftazidime (CAZ) and the combinations cefoxitin/LN-1-255 and ceftazidime/LN-1-255. bla<sub>CMY-2</sub> and bla<sub>CMY-54</sub> genes were cloned into the p-GEX-6P-1 plasmid, electropored into E. coli BL21 and encoded proteins were then purified. For inhibition kinetics, IC<sub>50</sub> for tazobactam, avibactam and LN-1-255 was calculated.

**Results:** The inhibitor LN-1-255 displayed a relevant ability to decrease the MICs to cephalosporins, decreasing 2-32 and 8-2056-fold the MICs to FOX and CAZ, respectively. The IC<sub>50</sub> of LN-1-255 was in the nanomolar range, 24 and 17 nM for the CMY-2 and CMY-54 β-lactamases, showing excellent hydrolysis efficiency. Avibactam showed a similar efficacy inhibiting CMY-2, being less efficient against CMY-54. Tazobactam displayed an inhibition efficacy 68 and 22-fold lower than LN-1-255 against CMY-2 and CMY-54, respectively.

**Conclusions:** We describe the inhibitory activity of LN-1-255 against the plasmid-mediated AmpC of Enterobacteriaceae. Cephalosporins in combination with LN-1-255 were effective against cephalosporins-resistant strains. LN-1-255 displayed better IC<sub>50</sub> than tazobactam or avibactam. Therefore, LN-1-255 represents a potential new therapeutic option in combination with cephalosporins against plasmid-mediated AmpC Enterobacteriaceae. A complete analysis of kinetic and microbiological assays for all enzymes and inhibitors are currently being developed.

Abstract 1854

**Infection and mortality rates due to carbapenem-resistant organisms in infants admitted to the neonatal unit**

Reenu Thomas*1,2, Claude Ondongo-Ezhet1,2, Nini Motsoaledi1,2, Prenika Jaglal3,4, Jeannette Wadula3,4, Firdose Lambey Nakwa1,2, Sithembiso Velaphi1,3

1Chris Hani Baragwanath Academic Hospital, Department of Paediatrics, Johannesburg, South Africa, 2University of the Witwatersrand, School of Clinical Medicine, Johannesburg, South Africa, 3Chris Hani Baragwanath Academic Hospital, Department of Clinical Microbiology and Infectious Diseases, National Health Laboratory Services, Johannesburg, South Africa, 4University of the Witwatersrand, School of Pathology, Johannesburg, South Africa

**Background:** Healthcare-associated multidrug resistant bacterial infections, particularly due to carbapenem resistant organisms (CRO), has been on the rise globally. Most studies on CRO prevalence are from high-income countries, with very few from low-middle income countries (LMIC). Although limited, the reported prevalence of infections and mortality due to CRO in LMIC has been alarmingly high. This study evaluated the rates of infection and all-cause mortality due to CRO in infants admitted in a hospital from a low-middle income country.

**Materials/methods:** Positive bacterial cultures from sterile sites in infants admitted to the neonatal unit at Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa, in 2018, was retrieved from the microbiology laboratory and reviewed retrospectively. Type of organism, susceptibility results and outcomes were recorded. Among these, the Gram-negative isolates, including the CRO, were extracted. Rates and outcomes were analysed.

**Results:** There were 804 positive cultures (excluding coagulase-negative Staphylococci) from sterile sites, giving an infection rate of 12.6/1000 patient days. Of these 539 (67%) were Gram-negative isolates. The common Gram-negatives were *Acinetobacter baumannii* (225/539; 42%) and *Klebsiella pneumoniae* (229/539; 42%). 176 (78%) of the *Acinetobacter baumannii* isolates and 75 (33%) of the *Klebsiella pneumoniae* isolates were CRO, accounting for 47% of all Gram-negatives. The rate of carbapenem resistant *Acinetobacter baumannii* (CRAB) was 2.8/1000 patient days and carbapenem resistant *Klebsiella pneumoniae* (CRE) was 1.2/1000 patient days. The rates of CRAB varied from a trough of 0.8/1000 patient days to a peak of 5.8/1000 patient days per month, and those of CRE varied from 0.2/1000 patient days to 2.5/1000 patient days per month. The all-cause mortality rate in infants with Gram-negative isolates was 20%. The mortality was 26% in infants with CRAB and 40% in infants with CRE. The all-cause mortality rate in infants with CRO was 30%. The mortality rate in infants with CRO was higher than those with non-CRO (30% vs 11%; p <0.05).

**Conclusions:** There was a high rate of positive cultures from sterile sites in 2018. Gram-negative organisms predominated, and among these carbapenem resistance was high. Rates of CRO varied over the months, suggesting outbreaks. CRO were associated with high mortality rate.

Abstract 1855

Colonisation and infection with ESBL-producing and carbapenem-resistant Enterobacteriaceae in kidney transplant recipients: risk factors, impact on renal graft function and use of hospital resources

Eleonora Salsi1, Alessandra Palmisano2, Omar Simonetti*, Marco Cotrufo1, Paride Fenaroli2, Umberto Maggiore2, Enrico Fiaccadori2, Carlo Ferrari1, Anna Maria Degli Antoni1

1Infectious Diseases and Hepatology Unit, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy, 2Nephrology Unit, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy

Background: ESBL-producing and carbapenem resistant (CR) Enterobacteriaceae are a common cause of severe infection, morbidity and mortality in kidney transplant recipients (KTR). Few studies have investigated the risk factors for ESBL-producing/CR Enterobacteriaceae colonization and infection in this group of patients, the effect of colonization and infection on KTR's renal graft function, and the use of hospital resources.

Materials/methods: Retrospective follow-up study on a consecutive series of patients undergoing kidney transplantation at Parma University Hospital (Italy) between January-2016 and December-2018. We examined the difference in risk factors by two-sample Mann-Whitney test, and Fisher's exact test for continuous and categorical variables. Crude and adjusted (donor's/recipient's age, recipient's gender) renal function (eGFR) decline was compared by mixed-effects random-coefficients models, hospital resources by negative binomial regression.

Results: We enrolled 180 KTR (mean recipient's age: 52.42 [SD 12.40]; males 65%; mean donor's age: 54.59 [SD 15.57]) and followed them up for 2-years post transplantation. Cumulative prevalence of colonization 3-months post-transplantation and cumulative incidence of infection were 26.1% and 9.4% for ESBL, and 4.4% and 1.6% for CR. ESBL colonization was associated with hemodialysis vs peritoneal dialysis (93% vs 70% non-colonized), dialysis vintage (mean months: 65.00 vs 41.93) and retention of ureteral stent for more than one month after transplant (28% vs 12%) (p<0.05 for all); ESBL infection was associated with retention of ureteral stent (47% vs 13%; p=0.002) whereas CR colonization was associated with surgical complication during transplant admission (50% vs 15% p=0.027). Two patients (both with CR) died over the study follow-up, whereas none of the patients lost the graft. There was a non-statistically significant trend of eGFR yearly decline, being sharper (up to -5mL/min/year) in patients with CR colonization compared to non-colonized. In comparison with non-colonized patients, adjusted mean days of carbapenem treatment in ESBL/CR colonized/infected was 5.6 vs 0.7 (p=0.002); length-of-hospital stay 5.6 vs 0.7 (p=0.002); days on drug-resistant-infection intravenous-outpatient-therapy 1.6 vs 0.07 (p=0.005).

Conclusions: The study shows that ESBL and CR colonization and infection in KTR are associated with longer hemodialysis vintage, urological procedures, and surgical complications, and that they cause an increase in the hospital resources use.

Abstract 1865

Risk score for non-ventilator-associated hospital-acquired pneumonia (nvHAP)
Aline Wolfensberger*1, Viacheslav Kachalov1, Werner Jakob2, Stefan P. Kuster1, Suraj Balakrishna1, Roger Kouyos1

1University Hospital of Zürich, Division of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland, 2University Hospital of Zürich, Department of Medical Data Management Systems, Zürich, Switzerland

Background: Pneumonia is one of the most common healthcare-associated infections, and the burden of disease is higher in non-ventilated than in ventilated patients. Identifying patients at high risk for non-ventilator-associated hospital-acquired pneumonia [nvHAP] allows targeting prevention measures to high-risk patients. We derived and validated a risk score to predict nvHAP in a broad patient collective.

Materials/methods: We included all inpatients ≥18 years of age, discharged during a 2.5-year period from the University Hospital Zurich, Switzerland. The derivation cohort consisted of patients from the first two years; the remainder of patients was included in the validation cohort. The derivation cohort was used to identify distinct and easily available risk factors for nvHAP by applying uni- and multivariable Cox proportional hazards models. These risk factors were used to compute a risk score. Receiver operator characteristics (ROC) analyses were performed in the derivation and validation cohort to evaluate the nvHAP risk score’s ability to predict pneumonia incidence ≥2 days, ≥4 days, and ≥6 days after the assessment of risk factors.

Results: The derivation and validation cohort comprised 69,608 and 17,642 patients with an nvHAP rate of 0.69% (n=483) and 0.61% (n=107), respectively. After assessing 18 risk factor candidates, eight risk factors were incorporated in a simple ‘nvHAP risk score’ ranging from 0 to 11 points (age ≥60 = 1 point; male sex = 1 point; severely impaired activity and mobility = 2 points; acute problems with breathing = 1 point; impaired orientation = 1 point; moderate/severe pain = 1 point; affiliation to high risk clinic = 1 point; swallowing difficulties or tube feeding = 3 points). The areas under the ROC in the derivation and validation cohort were 0.78 and 0.72 to predict nvHAP ≥2 days in advance, 0.77 and 0.70 ≥4 days in advance, and 0.76 and 0.69 ≥6 days in advance.

Conclusions: We developed a simple risk score for nvHAP that is applicable on a very broad acute care patient population. It allows identification of patients at high risk for nvHAP ≥6 days in advance with a fairly good predictive accuracy.

Abstract 1873

**Spatiotemporal mapping of Bartonella bacilliformis in Peru and qualitative analysis of local perceptions and understanding of the disease**

Naomi Kokkinos¹*, David Moore¹², Cesar Munayco Escate³, Cesar Augusto Ugarte Gil¹⁴⁵

¹London School of Hygiene & Tropical Medicine, London, United Kingdom, ²Universidad Peruana Cayetano Heredia, Lima, Peru, ³Centro Nacional de Epidemiología, Prevención y Control de Enfermedades - MINSA, Ministry of Health, Jesús María, Lima, Peru, ⁴Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru, ⁵Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru

**Background:** Carrion’s disease is a biphasic illness caused by *Bartonella bacilliformis* and is endemic to parts of Peru. Understanding its spatiotemporal behavior is a key factor to improve pre-emptive measures. This study aims to identify spatiotemporal clusters of disease in Peru and elucidate local perceptions about the disease, to provide the basis for further research to guide elimination strategies.

**Materials/methods:** Spatial autocorrelation, hotspot and spatiotemporal analysis were carried out using ArcGIS and SatScan software to identify disease clusters over time. Data from the department of Ancash [Peru], showing absolute number of cases of Carrion’s disease was analysed to look for trends in the data between January 2000 and June 2019. Focus group discussions took place among health workers and community members in Ancash and core themes were identified.

**Results:** The departments of Ancash and Cajamarca contained significant hotspots of disease and were part of the eight clusters identified by spatiotemporal analysis. Clusters were also identified in previously non-endemic departments, with one significant secondary spatiotemporal cluster identified in the department of Puno from 2006 to 2007. In general, within Ancash, males and females were similarly affected (most commonly in the youngest age group), with similar number of cases of acute and chronic forms of the disease reported each year. Five core themes emerged from the focus groups – presentation, aetiology, prevention, diagnosis, treatment. Community members were aware of the disease and most would visit the clinic if unwell. Health workers discussed preventive interventions and the influence of experience and antibiotic availability on treatment.

**Conclusions:** This study provides evidence supporting the theory that Carrion’s disease is spreading into previously non-endemic areas and highlights the beliefs of local health workers and communities regarding this disease. Carrion’s disease could still be targeted for elimination, but further research is needed for this to occur, before the window of opportunity closes.

Abstract 1876

**Reduced production of bacterial membrane vesicles predicts mortality in ST45/USA600 methicillin-resistant Staphylococcus aureus bacteremia**

Somrita Dey*1, Smitha Gudipati1, Christopher Giuliano1, Marcus Zervos2,3, Jonathan Monk4, Richard Szubin4, Sarah Jorgensen2, George Sakoulas5,6, Andrew Berti1,3

1Wayne State University, College of Pharmacy, Pharmacy Practice Dept, Detroit, United States, 2Henry Ford Hospital, Detroit, United States, 3Wayne State University, College of Medicine, Biochemistry Microbiology and Immunology Dept, Detroit, United States, 4University of California San Diego, Department of Bioengineering, La Jolla, United States, 5University of California San Diego, School of Medicine, Pediatrics Dept, La Jolla, United States, 6Sharp Memorial Hospital, San Diego, United States

**Background:** Staphylococcus aureus is one of the major causes of infection-related morbidity and mortality in humans. Prognostic biomarkers such as IL-10 and TNFα produced after manifestation of symptoms are not routinely orderable tests in standard clinical microbiology. Therefore, identification of a prognostic microbial factor may pave ways for early identification. We hypothesize that membrane vesicles (MV), detached portions of the staphylococcal membrane enriched with multiple immunomodulatory effectors, may represent a microbial factor that can be detected early in infection and predict clinical outcome. In the present study we establish that clinical isolates from survivors of endovascular ST45/USA600 staphylococcal infection produce significantly more MV than from decedents.

**Materials/methods:** Forty-four well-characterized sequential ST45/USA600 isolates were selected for this study. Of these 44 isolates, 21 were isolated from patients who survived the infection and 23 were isolated from decedents. Isolates were confirmed to be ST45 by multi-locus sequence typing. Pertinent clinical data along with calculated clinical risk scores were recorded. Phenotypic and genomic strain characterization was performed. MV were isolated by three different methods and detected using a vesicle membrane-specific styryl dye (FM1-43). Descriptive data was expressed as mean and standard deviation, median and interquartile range, or frequencies and percentage. Univariable analysis was performed using Student’s t-test, Wilcoxon rank sum, or Fisher’s exact. Classification and Regression Trees (CART) were used to determine an RFU breakpoint for mortality.

**Results:** In ST45/USA600 clade, low MV production *ex vivo* is strongly associated with 30-day mortality. Preliminary targeted genome sequence analysis does not identify any significant differences between isolates in agrABDC, sigAB, sle1 or psmα1-4 sequence suggesting some other, unknown factor is responsible for differences in MV production. Therefore, the genetic differences between strains that result in differential MV production remain unclear.

**Conclusions:** Low production of MV is associated with an increased risk of mortality in staphylococcal bacteremia caused by ST45/USA600 MRSA. MV can be rapidly quantified allowing for facile integration into existing clinical microbiology workflows.

Abstract 1879

Prevention of pneumocystis pneumonia by Ibrexafungerp in a murine prophylaxis model

Stephen Barat1, Katyna Borroto-Esoda1, Alan Ashbaugh2, David Angulo Gonzalez*1, Melanie Cushion2

1SCYNEXIS, Inc., Jersey City, United States, 2University of Cincinnati, Cincinnati, United States

Abstract third-party references: Supported by SCYNEXIS, Inc.

Background: Pneumocystis pneumonia (PCP) is an opportunistic fungal infection that affects immunocompromised patients. Ibrexafungerp (IBX) is an oral and intravenous antifungal from a novel class of glucan synthase inhibitors, triterpenoids, and has shown activity against Candida, Aspergillus, and PCP in a murine therapy model. We evaluated the ability of IBX to prevent PCP in a prophylaxis model of murine PCP.

Materials/methods: Experiment 1: Balb/c mice (10 mice/group) were infected by intranasal inoculation with Pneumocystis murina, immune-suppressed with dexamethasone in acidified drinking water and treated with 30-, 15- and 7.5 mg/kg, IBX/BID. Control groups treatment included TMP-SMX (50/250 mg/kg QD) and vehicle. After 6 weeks, mice were sacrificed and prevention was determined by organism burdens (asci and total nuclei).

Experiment 2: Balb/c mice were immune-suppressed and infected as in Exp. 1. Treatment groups included: 1) 30 mg/kg BID x 6wk; 2) 30 mg/kg/BID x 6wk followed by cessation of treatment with IBX but with immune-suppression for 3 additional weeks; 3) 15 mg/kg BID 1 week prior and 6 wks after infection and immune suppression; 4) 15mg/kg BID for 8 wks; 5) 15 mg/kg BID for 6 wks then IBX was discontinued but with immune suppression; 6) untreated, vehicle control.

Results: Experiment 1: No P. murina nuclei or asci were observed after 6 weeks of treatment at a dose of 30 mg/kg/BID in the prophylaxis mouse model of PCP, similar to positive control, TMP/SMX. Some nuclei and asci were observed in the lower dose IBX groups. Experiment 2: To investigate whether any P. murina remained after different regimens of prophylaxis, treatment of IBX was withdrawn at both doses for an additional 3 wks of immune suppression to provoke the growth of any remaining fungi. Group 1 showed reduction in total nuclei and asci to undetectable. Group 2 did not result in any recrudescence of infection. Group 3 and 4 showed similar reduction in organism burden. Group 5 was similar to untreated control.

Conclusions: These results demonstrate that 30 mg/kg BID IBX prevented PCP in a murine model. We suggest that IBX could be a viable option for preventing PCP in immunocompromised patients.

Background: Malaria prophylaxis aims at reducing infection with Plasmodium. In those infected with Plasmodium vivax or Plasmodium ovale, it may alter the clinical course since it does not target hepatic forms. This study aimed at describing the clinical course of P. vivax or P. ovale malaria in travelers, based on chemoprophylaxis use.

Materials/methods: We conducted a case-control analysis of the outcomes of P. vivax and P. ovale infections nested in the cohort of imported malaria cases in civilian travelers reported to the French National Reference Center for Malaria from January 2006 to December 2017. We assessed the effect of chemoprophylaxis on the incubation period, delay between symptoms and diagnosis, type of medical care, biological findings at admission, type of symptoms and duration of hospitalization using adjusted logistic regression. As only infected travelers were observed, we assessed prophylaxis effect on post-infection outcomes using a counterfactual approach.

Results: Among 360 P. vivax and 756 P. ovale civilian travelers cases, 33% and 48%, respectively, reported a chemoprophylaxis use. There were 16 and 7 severe cases respectively, one patient died. Eighty percent of patients had symptoms less than 6 months after return. Chemoprophylaxis users had a greater risk to present symptoms more than 2 months after returning for both species (P. vivax OR: 3.40, 95% CI: [1.76-6.56], p<0.001, P. ovale OR: 2.42, 95% CI: [1.74-3.36], p<0.001), and those infected by P. ovale had a greater risk of having diagnosis more than 3 days after onset of symptoms (OR: 1.52, 95% CI: [1.07-2.17], p<0.05). Attributing these changes to prophylaxis was possible as long as the proportion of overall travelers to endemic areas under prophylaxis was less than 50%. There was no impact on the other studied characteristics.

Conclusions: Civilian travelers infected by P. vivax or P. ovale reporting chemoprophylaxis use had a greater risk of delayed onset illness after infection (probably first relapse). The full impact of chemoprophylaxis on infection with relapse-causing species should consider both reduction in infection and delay onset of symptoms, hence the need of new recommendations of chemoprophylaxis for travelers exposed to these species, acting against both erythrocytic and liver stages.

¹Complejo Asistencial Universitario de Salamanca, Salamanca, Spain, ²Hospital Sousa Martins, ULS Guarda, Guarda, Portugal, ³Universidad de Salamanca, Salamanca, Spain, ⁴Complejo Hospitalario Universitario Insular-Materno Infantil de Gran Canaria, Las Palmas de Gran Canaria, Spain

**Background:** Murine typhus (MT) is a zoonosis caused by Rickettsia typhi. Its main host is the rat and its vector to the human is the rat flea. The clinical picture is characterized by headache, fever, skin rash and liver function alteration. The severe pattern affects up to 10% of patients with pulmonary or renal involvement and even admission to Intensive Care Units. The prevalence of MT is considered underestimated since most cases are mild and self-limited. The aim of our study is to analyze the epidemiological impact of MT in patients who required hospitalization in the Spanish National Health System (NHS) between 1997 and 2015.

**Materials/methods:** Retrospective longitudinal descriptive study of in-patients diagnosed with Rickettsia typhi in Spanish public hospitals between 1997 to 2015. We obtained the data from the Minimum Basic Data Set of patients admitted to the NHS with a diagnosis of Rickettsia typhi: International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM), 081.0, provided by the Health Information Institute of the Ministry of Health and Equality.

**Results:** A total of 99 cases were registered. Most cases were men (63, 63.6%). Mean age (±SD) was 46.4 years (±19.0). 85 (85.9%) cases were an urgent hospital admission. The period incidence rate (IR) was 0.12 (95% CI, 0.09-0.14) cases per million person-years. An irregular distribution was observed throughout the study period, although there was a slight upward trend between 2013 and 2015. Canary Islands had the highest IR (2.17), followed by Andalusia (IR: 0.07). Esporadic cases were evenly distributed without other clear geographical aggregates. The average (±SD) hospital stay was 11 days (±9.9). Only 1 (1%) case died.

**Conclusions:** Despite of the small sample, our data suggests that MT is an emerging disease in Spain, as literature reflects. Regardless of its low incidence, all the authors agree with the huge underestimation of this zoonosis, due to the self-limited nature of most cases and the low clinical suspicion. In our study, the highest number of cases is recorded in the Canary Islands and Andalusia. The mortality rate remains very low. The control of MT should focus on primary prevention.

Abstract 1883

Post-transplant lymphoproliferative disorders and association of antiviral prophylaxis in a nationwide cohort study

Laura Walti*, Catrina Mugglin1, Daniel Sidler1, Matteo Mombelli2, Oriol Manuel3, Hans H. Hirsch4, Nicolas Mueller5, Katia Boggian6, Christian Garzoni7, Dionyssios Neofytos8, Cédric Hirzel1

1Bern University Hospital, University of Bern, Department of Infectious Diseases, Bern, Switzerland; 2Bern University Hospital, University of Bern, Department of Nephrology, Bern, Switzerland; 3University Hospital and University of Lausanne, Infectious Diseases Service and Transplantation Center, Lausanne, Switzerland; 4University Hospital Basel and University of Basel, Infectious Diseases & Hospital Epidemiology, Basel, Switzerland; 5University Hospital Zurich, University of Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland; 6Hospital of St. Gallen, Division of Infectious Diseases and Hospital Epidemiology, St. Gallen, Switzerland; 7Clinica Luganese, Clinic of Internal Medicine and Infectious Diseases, Lugano, Switzerland; 8University Hospital of Geneva, Division of Infectious Diseases, Geneva, Switzerland

Background: Post-transplant lymphoproliferative disorder (PTLD) is a serious complication of transplantation. Most PTLD in solid organ transplant recipients (SOT) are induced by Epstein-Barr virus (EBV) infection. However, the role of antiviral prophylaxis in the prevention of EBV-associated PTLD is controversial.

Materials/methods: SOT recipients enrolled in the Swiss Transplant Cohort Study (STCS) transplanted from 2008 to 2018 were included. We assessed incidence, presentation and outcome of histologically proven PTLD. In addition, we assessed the impact of anti-viral prophylaxis (Val-)Acyclovir, (Val-)Ganciclovir) on the incidence of PTLD using adjusted stratified Cox regression models.

Results: We included 4'811 patients with a follow-up duration of 24'455 patient-years (py) (median follow-up time 4.68y/patient, IQR 2.35-7.74). 54 histology proven PTLD-cases were identified, 36 were EBV positive (EBV-PTLD). Median age at transplantation was 54 years overall (IQR 42-62), 61y (IQR 54-63) for non-EBV-PTLD cases and 41y (IQR 24-60) for EBV-PTLD. Histopathological-classification revealed early lesions in 6 (11%), polymorphic in 15 (28%) and monomorphic PTLDs in 33 (61%) of cases. Extra-nodal sites were common (74%), CNS involvement was present in 7 cases (13%). PTLD incidence rate was 2.21/1000py and 1.47/1000py for EBV-PTLD. Highest incidence was found among lung transplant recipients with 4.47/1000py (4.19/1000py for EBV-PTLD). Incidence for EBV-PTLD at 1, 2 and 3 years post-transplantation were 2.81;1.94;1.71/1000py respectively vs. 0.43;0.35;0.28/1000py for non-EBV-PTLD (Figure1), median time post-transplantation to EBV-PTLD was 14.5 months vs. 61 months to non EBV-PTLD (p <0.001). We did not find a significant effect of antiviral prophylaxis ((Val-)Acyclovir or Val-)Ganciclovir) on EBV-PTLD incidence, however some evidence towards lower risk for early EBV-PTLD (<2y post-transplantation) was seen for patients with ganciclovir prophylaxis (HR 0.34 [95%CI: 0.12-1.02, p=0.054). Overall mortality during follow-up was 14.45%, in patients with PTLD, related mortality was 31% for EBV-PTLDs, and 33% for non-EBV-PTLDs.

Conclusions: PTLD incidence in our cohort was low, although associated with high mortality. Incidence of EBV-PTLD declined over time and was highest in the first 2 years post-transplantation, while non-EBV-PTLD incidence did not decline. Antiviral prophylaxis had no significant effect on EBV-PTLD occurrence.

Figure 1. EBV- and non-EBV-PTLD Incidence per 1000 patient-years
Symbols represent point-estimates, whiskeys 95% confidence intervals.

Viral meningitis in adults: what are we missing? The use of viral capture sequencing to detect pathogens in the cerebrospinal fluid of adults with meningitis

Fiona Mcgill*1,2,3, Rafal Tokarz4, Emma Thomson5, Anna Da Silva Filipe1, Stephen Sameroff6, Shirin Ashraf5, Ian Lipkin4, Caroline Corless3, Chitra Pattabiraman7, Michael Griffiths1,2, Caroline Corless3, Anna Maria Geretti2,9, Benedict Michael1,2,10, Nick Beeching9, David Mckee11, Ian Hart8, Ken Mutton12, Agam Jung3, Alastair Miller2, Tom Solomon1,2,10

1University of Liverpool, NIHR HPRU Emerging and Zoonotic Infections, Liverpool, United Kingdom, 2University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom, 3Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, 4Columbia University, Center for Infection and Immunity, New York, United States, 5University of Glasgow, Centre for Virus Research, Glasgow, United Kingdom, 6The Royal Liverpool University Hospital, Infection and Immunity, Liverpool Clinical Laboratories, Liverpool, United Kingdom, 7National Institute of Mental Health and Neurosciences, Bengaluru, India, 8Alder Hey Children's Hospital - Liverpool, Liverpool, United Kingdom, 9The Royal Liverpool University Hospital, Tropical Infectious Diseases Unit, Liverpool, United Kingdom, 10The Walton Centre, Liverpool, United Kingdom, 11Salford Royal NHS Foundation Trust, Salford, United Kingdom, 12The University of Manchester, Manchester, United Kingdom

**Background:** Many patients with meningitis never have an aetiology identified, leading to unnecessary courses of antibiotics and antivirals, prolonged hospitalisation, and uncertainty for patients. Viruses are the most common cause of meningitis where a pathogen is found. Therefore, we used new viral capture sequencing methods to identify any viruses present in cerebrospinal fluid (CSF) from patients with meningitis and no pathogen identified.

**Materials/methods:** CSF from 76 adults was tested by VirCapSeq-VERT, an oligonucleotide probe set designed to capture viral targets using high throughput sequencing. Patients were categorised as either a) suspected viral meningitis – CSF pleocytosis and no pathogen found on routine molecular testing with a suspicion of viral aetiology based on validated clinical scores and/or negative 16s rRNA PCR testing (n=38), b) proven viral meningitis – CSF pleocytosis and virus identified on routine molecular testing (n=17), or c) not meningitis – symptoms and signs of meningitis but no CSF pleocytosis (n=21).

**Results:** VirCapSeq-VERT detected twelve individual viruses in 16/38 (42%) CSF samples from patients with suspected viral meningitis. Most viruses detected [58% (7/12)] were clinically relevant and included - *Herpes simplex virus* type 2, *Enteroviruses*, *Varicella zoster virus*, HIV, *Toscana virus*, *Rotavirus* and *Saffold virus*. Other viruses detected, unlikely to be clinically relevant, were *Epstein barr virus*, *Human herpes virus 6*, *Human pegivirus*, *Merkel cell polyomavirus* and *Human papillomavirus*. In the proven viral meningitis group one virus, additional to what had previously been found, was detected in one sample – *Human pegivirus* – not thought to be clinically relevant. 14% (3/21) of samples from patients without meningitis had a virus detected. The only viruses detected in this group were *Human pegivirus* (x2) and *Merkel cell polyomavirus*, neither of which are clinically relevant.

**Conclusions:** Sequencing methods enable the detection of a wide variety of pathogens. VirCapSeq-VERT increases the chances of detecting a virus due to its agnostic approach. This study shows that new diagnostic methods can allow more patients with meningitis to have an aetiological cause identified. Further work is needed to determine the prevalence of atypical viral candidates in meningitis and the clinical impact of using sequencing methods in real time.

ABSTRACTS 2020

Abstract 1885

**Optimising the combination of ceftazidime/avibactam and gentamicin against KPC-producing Klebsiella pneumoniae (KPC-Kp) with aminoglycoside-modifying enzymes**

Yanqin Huang1, Karol Sokolowski1, Amisha Rana1, Neera Kadiyala1, Zackery Bulman*1, Fiorella Krapp2, Egon Ozer3, Alan Hauser1

1University Of Illinois At Chicago, College of Pharmacy, Chicago, United States, 2Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, 3Northwestern University, Feinberg School of Medicine, Chicago, United States

**Background:** Although the β-lactam/β-lactamase inhibitor ceftazidime/avibactam is active against KPC-Kp, treatment failure rates up to 45% have been reported. Combinations with ceftazidime/avibactam and an aminoglycoside may be synergistic, however, ~90% of KPC-Kp harbor the aminoglycoside-modifying enzyme aac(6′)-Ib, which partially inactivates gentamicin. An alternate allele, aac(6′)-Ib′, is also harbored by some KPC-Kp and fully inactivates gentamicin. The purpose of this study was to evaluate bacterial killing by combinations of ceftazidime/avibactam with gentamicin against KPC-Kp with aac(6′)-Ib or aac(6′)-Ib′.

**Materials/methods:** Clinical KPC-Kp isolates containing aac(6′)-Ib [KPC-Kp-085 and -213] and aac(6′)-Ib′ [KPC-Kp-061 and -078] were used in all experiments. Ceftazidime/avibactam and gentamicin MICs were determined using broth microdilution. Time-kills were performed using a starting inoculum of ~10^8 CFU/mL and viable bacterial counts were quantified at 0, 1, 2, 4, 6, 8, and 24 hours, to examine clinically relevant concentrations of ceftazidime/avibactam [5/0.94, 20/3.75, and 80/15 mg/L] and gentamicin [0.625, 1.25, 2.5, 5, and 10 mg/L] alone and in combination. Synergy was defined as a ≥2log₁₀ CFU/mL reduction by the combination compared to each agent alone.

**Results:** Each isolate was susceptible to ceftazidime/avibactam and gentamicin according to CLSI. KPC-Kp-085, -213, -061, and -078 ceftazidime/avibactam MICs were 0.5, 0.03, 0.25, and 0.5 mg/L and gentamicin MICs were 0.25, 0.25, 4, and 4 mg/L, respectively. Ceftazidime/avibactam concentrations of 5/0.94, 20/3.75, and 80/15 mg/L achieved ≤1, 1 - 3, and >3log₁₀ CFU/mL reductions at 24 hours, respectively against all isolates. For aac(6′)-Ib containing isolates, gentamicin concentrations ≥2.5 mg/L were bactericidal [≥3log₁₀ CFU/mL reduction] whereas no gentamicin concentration was bactericidal for aac(6′)-Ib′ containing isolates. For aac(6′)-Ib containing isolates, ceftazidime/avibactam 20/3.75 mg/L combined with gentamicin ≥2.5 mg/L achieved ≥7log₁₀ CFU/mL reductions, whereas gentamicin ≥10 mg/L was needed for aac(6′)-Ib′ containing KPC-Kp. Gentamicin combined with ceftazidime/avibactam was synergistic for all isolates. However, lower gentamicin concentrations were required to achieve synergy against aac(6′)-Ib containing KPC-Kp.

**Conclusions:** Ceftazidime/avibactam failed to eradicate susceptible KPC-Kp as monotherapy. Combinations of gentamicin and ceftazidime/avibactam were synergistic but displayed more activity against isolates with aac(6′)-Ib than aac(6′)-Ib′. Using rapid diagnostics to differentiate between aac(6′)-Ib and aac(6′)-Ib′ may be useful to quickly optimize combination therapy for KPC-Kp infections.

Abstract 1886

**Longitudinal (2011-2018) activity of oritavancin against Gram-positive isolates causing bacteraemia and endocarditis in Europe, including enterococcal infections requiring adjusted daptomycin dosing**

Cecilia Godoy Carvalhaes*1, Helio S. Sader1, Jennifer Streit1, Robert Flamm1, Rodrigo E. Mendes1

1JMI Laboratories, North Liberty, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by A. Menarini Farmaceutica Internazionale s.r.l (AMFI), which included funding for services related to preparing this abstract.

**Background:** Oritavancin is a long-acting lipoglycopeptide antibiotic with rapid bactericidal activity. This study assessed oritavancin activity against *Staphylococcus aureus* (SA), *Enterococcus faecalis* (EF), and *E. faecium* (EFM) causing bloodstream infection (BSI), including infective endocarditis (IE) and vancomycin-resistant enterococci (VRE) displaying elevated-daptomycin (EDAP) MIC values (≥2 mg/L). The longitudinal activity of oritavancin was also evaluated.

**Materials/methods:** A total of 4,198 SA, 1,211 EF, and 953 EFM were recovered from BSI in 44 European medical centres [2011-2018], including 146 SA isolates causing IE and 111 EDAP-VRE isolates. Species identification was confirmed by MALDI-TOF MS, when necessary, and susceptibility testing were performed by broth microdilution method following CLSI/EUCAST guidelines.

**Results:** Overall, oritavancin showed similar MIC₅₀ (0.03 mg/L) and MIC₉₀ results (0.06 mg/L) against MRSA, MSSA, and SA isolates causing IE (28.1% MRSA). Oritavancin displayed potent activity against EF regardless of susceptibility to daptomycin (MIC₅₀/₉₀, 0.015/0.03-0.06 mg/L; Table). Only 15 (1.2%) EF isolates were resistant to vancomycin, and 84.7% of those displayed VanA phenotypic profile. In contrast, VRE were observed in 19.8% of EFM isolates, among which VanA was also the predominant phenotype (84.7%). Although, EFM isolates displaying VRE and EDAP MIC phenotypes showed slightly higher oritavancin MIC values (MIC₅₀/₉₀, 0.015/0.06 mg/L) than VSE-EFM with daptomycin MIC ≤1 mg/L (MIC₅₀/₉₀ ≤0.008/≤0.008 mg/L), all isolates but one [oritavancin MIC, 0.25 mg/L] were inhibited by oritavancin at MIC of ≤0.12 mg/L. MRSA rates were 27.0% in 2011, 22.8% in 2018 and varied from 20.9% to 29.4% during the 8-year period. Yearly oritavancin MIC₅₀ results were 0.015 mg/L or 0.03 mg/L and MIC₉₀ results varied from 0.03 mg/L to 0.12 mg/L against MRSA. Against EF, yearly oritavancin MIC₅₀ results remain at 0.015 mg/L and MIC₉₀ results were 0.03-0.06 mg/L. No variation was observed on oritavancin MIC₅₀ results (≤0.008 mg/L) against EFM isolates and MIC₉₀ were 0.015-0.03 mg/L.

**Conclusions:** Oritavancin showed potent activity against this collection of isolates causing BSI and IE in Europe, including enterococci with decreased susceptibility to daptomycin. In addition, oritavancin maintained stable *in vitro* potency throughout the 8-year study period with no apparent temporal trends.

**Organism / Phenotype (No. of isolates) | Cumulative % inhibited by oritavancin at (mg/L): | MIC₂₅/₉₀**
---|---|---
S. aureus (4,198) | ≤0.008 | 0.015 | 0.03 | 0.06 | 0.12 | 0.25 | 0.5 | 0.03/0.06

**Abstract 1887**

**Delafloxacin activity against drug-resistant Streptococcus pneumoniae, Haemophilus influenzae, Haemophilus parainfluenzae, and Moraxella catarrhalis from European medical centres (2014-2018)**

Dee Shortridge*1, Jennifer Streit1, Michael Huband1, Robert Flamm1

1JMI Laboratories, North Liberty, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by A. Menarini Farmaceutica Internazionale s.r.l (AMFI), which included funding for services related to preparing this abstract.

**Background:** Delafloxacin (DLX) is an anionic fluoroquinolone (FQ) that has been approved in the United States and in Europe for the treatment of acute bacterial skin and skin structure infections and was recently approved in the US for the treatment of community-acquired bacterial pneumonia (CABP). In the present study, in vitro susceptibility (S) results for DLX and comparator agents were determined for CABP pathogens including *Streptococcus pneumoniae* (SPN), *Haemophilus influenzae* (HI), *H. parainfluenzae* (HP) and *Moraxella catarrhalis* (MC) clinical isolates from European hospitals participating in the SENTRY Program during 2014-2018.

**Materials/methods:** A total of 2,111 SPN, 1,087 HI, 701 MC, and 17 HP isolates were collected from community-acquired respiratory tract infections (CARTI) during 2014-2018 from European hospitals. Sites included only 1 isolate/patient/infection episode. Isolate identifications were confirmed at JMI Laboratories. Susceptibility testing was performed according to CLSI broth microdilution methodology, and EUCAST (2019) breakpoints were applied where applicable. Other antimicrobials tested included levofloxacin (LEV) and moxifloxacin (MOX; not tested in 2015). Multidrug-resistant (MDR) SPN isolates were categorized as being nonsusceptible (NS) to amoxicillin-clavulanate, erythromycin (ERY), and tetracycline; other SPN phenotypes were ERY-NS, or penicillin (PEN)-NS. β-lactamase (BL) presence was determined for HI, HP, and MC.

**Results:** The activities of the 3 FQs are shown in the table. The most active agent against SPN was DLX, with the lowest MIC<sub>50</sub> values of 0.015/0.03 mg/L. DLX activities were similar when tested against the MDR or PEN-NS for SPN phenotypes. ERY-NS isolates had DLX MIC<sub>50</sub> results of 0.015/0.03 mg/L. DLX was the most active FQ against HI, HP, and MC. BL presence did not affect FQ MIC values for HI or MC; only 1 HP isolate was BL-positive.

**Conclusions:** DLX demonstrated potent in vitro antibacterial activity against SPN, HI, HP, and MC. DLX was active against MDR SPN that were NS to the agents commonly used as treatments for CABP. These data support the utility of DLX in CABP including when caused by antibiotic resistant strains.

**Abstract 1891**

**Typing of emm1 Group A streptococci using MALDI-TOF MS**

Megumi Sakuma¹, Keisuke Shima*,² Shinji Funatsu³, Koretsugu Ogata², Miyuki Morozumi¹, Satoshi Iwata¹

¹Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, ²Shimadzu Corporation, Global Application Development Center, Kyoto, Japan, ³Shimadzu Corporation, MS business unit, Kyoto, Japan

**Background:** In recent years, invasive infections caused by group A streptococcus (GAS) are increasing. Among them, emm1-type GAS are highly pathogenic, and it is said that the invasive infections are significantly more cases of fulminant type, and the mortality rate and the persistence survival rate are high. Here, we propose a new technique which is able to discriminate highly pathogenic emm1 type and other types using MALDI-TOF MS and statistical analysis software.

**Materials/methods:** We searched biomarkers that were able to discriminate emm types using frequently isolated types of the invasive infectious disease-derived GAS strain, emm1 strain, emm12 strain, emm28 strain, and emm89 strain. The above four types of emm strains were cultured on sheep blood agar plate for 24 hours. MALDI mass spectra were observed by positive linear mode for m/z 4000-20000. Biomarkers were selected by using eMSTAT Solution statistical analysis software (Shimadzu, Japan). To evaluate the selected biomarker, a blind test was conducted using 379 strains derived from pharyngitis / tonsillitis, including B, C, and G hemolytic streptococci.

**Results:** We used eMSTAT Solution to search marker peaks that contribute to discriminate emm1 from other types. As a result of the search, it can be confirmed that the peak of m/z 10932 was detected in all samples of emm1 while the peak was not detected in other types. Next, a blind test of 379 clinical isolates was performed using the peak of m/z 10932 as a biomarker. In the gene analysis of the conventional method, 97 out of 379 strains were typed to emm1. Similarly, 92 (94.8%) of the 97 strains were typed to be emm1 using the biomarker. Both methods showed a high positive concordance rate. In this method, three emm1 strains were typed to be non-emm1 strains [emm11 strain (n = 1) and emm28 strain (n = 2)], and the negative concordance rate was 98.9%.

**Conclusions:** This is the first result that discriminates emm1 type of GAS by MALDI-TOF MS. This new MALDI-based method is easier and faster than conventional methods like DNA sequencing.

**Presenter email address:** k.shima@shimadzu.co.jp
Background: universal screening for tuberculosis (TB) before anti-TNFα therapy and treatment of those who have latent TB (LTB) resulted in a significant reduction of active TB. However, we still diagnose TB in this population. We aimed to review severe TB cases in patients treated with anti-TNFα admitted to a tertiary hospital ID department between 2013-19.

Materials/methods: clinical records from patients with active TB were reviewed with data pertaining the inflammatory immunemediated disease, anti-TNFα treatment, TB screening and TB episode collected.

Results: ten cases of TB were documented (mean age 42.6 years, 7 men), 5 were under adalimumab, 3 under infliximab and 1 under golimumab and certolizumab pegol each. Five patients had a diagnosis of Inflammatory Bowel Diseases, 5 rheumatologic immune disease (2 psoriatic arthritis, 2 ankylosing spondylitis, 1 rheumatoid arthritis). All underwent LTB screening prior to anti-TNFα therapy with average time between screening and therapy of 4.8 months [range: 1-15]. Eight were negative and TB screening during anti-TNFα therapy was not repeated. LTB diagnosis was made in the remaining: one was treated with rifampicin [6 months], the other with isoniazid [9 months]. In these two cases, active TB was diagnosed, respectively, 4 and 3 years after LTB screening and treatment. Time between anti-TNFα therapy onset and TB diagnosis was 55 months [range: 3-138] and between TB symptoms and its diagnosis 1.6 months [range: 1-5]. Six patients had disseminated TB (involvement of central nervous system 2, lymphatic 5, hepatic 4, pleural 2), 2 pulmonary tuberculosis (PTB) with hepatic and pleural involvement each, and 2 PTB. Multisensitive Mycobacterium tuberculosis was recovered from biological samples in 9 patients, the remaining case being a presumptive diagnosis. All patients were treated with a 4-drug regimen with average treatment duration of 10.1 months [range: 9-15] and overall favorable evolution. Immunosuppressive therapy was resumed without anti-TNFα.

Conclusions: TB under anti TNFα therapy remains an important diagnosis despite TB screening. As before, 60% of our cases comprise disseminated forms. A high level of TB suspicion should be maintained, regular screening of TB under anti-TNFα therapy is probably worth being done and better tests for TB screening are welcomed.

Abstract 1893

Comparison of the microbiological efficacy of disinfection using ultraviolet and aerosolised hydrogen peroxide system for carbapenemase-producing Enterobacteriaceae in a healthcare setting

So-Yeon Park, Jeong-Young Lee, Eun-Ju Kim, Sun-Hee Kwak, Min-Jee Hong, Eun-Ok Kim, Jiwon Jung, Mi-Na Kim, Sung-Han Kim

1Asan Medical Center, Seoul, South Korea, 2Asan Medical Center, Seoul, South Korea

Background: Carbapenemase-producing Enterobacteriaceae (CPE) are a growing problem in the worldwide. Environmental cleaning is important strategy to prevent CPE transmission and "no-touch" methods including ultraviolet C (UV-C) and aerosolized hydrogen peroxide (aHP) system have been evaluated to overcome the shortcomings of manual cleaning. However, data regarding efficacy of UV-C and HP system against CPE are limited. We thus compared the microbiological efficacy of disinfection using UV-C and aHP as area decontamination in a healthcare setting.

Materials/methods: This study was conducted in empty single patient rooms with dimension of 48.3 m3 at a tertiary hospital, Seoul, South Korea from May to October, 2019. We ran 4 rooms with 2 UV-C and 2 aHP, respectively and 30 formica sheets contaminated with KPC-producing Klebsiella pneumoniae \(10^6 \text{CFU}\) were placed in the room, both direct and indirect sites. After intervention, median log reduction and decontamination rate were assessed using Rodac plates.

Results: We observed median 5.52 log reduction after UV-C (n=60) and median 5.37 log reduction after aHP (n=60) (P=0.86), and 50% decontamination rate after UV-C and 45% decontamination rate after aHP (P=0.71) (Table 1). At direct sites, UV-C showed higher median log reduction (5.91 vs. 5.61, P=0.002) and decontamination rates (83% vs. 53%, P=0.03) than aHP. Conversely, at indirect sites, aHP showed higher median log reduction (4.63 vs. 5.07, P=0.02) and decontamination rate (17% vs. 37%, P=0.01) than UV-C.

Conclusions: Both UV-C and aHP reduced bacterial contamination in a single room. aHP was significantly more effective at indirect sites, and UV-C was significantly more effective at UV direct sites. Depending on the shadow area, healthcare facilities might choose between UV-C and aHP.

Identification of novel mobile colistin resistance gene mcr-10

Chengcheng Wang¹, Yu Feng¹, Zhiyong Zong*¹

¹West China Hospital, Sichuan University, Chengdu, China

**Background:** Mobile colistin resistance (mcr) genes represent an emerging challenge. We found and characterized a gene that is likely a new variant of mcr.

**Materials/methods:** An *Enterobacter roggenkampii* (a member of *Enterobacter cloacae* complex) clinical strain with a mcr-like gene encoding a new phosphoethanolamine transferase was subjected to whole genome sequencing using both Illumina short-read and MinION long-read platforms. This gene was cloned on pBC SK and then transferred into a colistin-susceptible *E. roggenkampii* strain. Conjugation and electroporation experiments were performed to examine the location of the mcr-like gene. The prevalence of mcr-10 was screened for depositions of GenBank. The 3D and secondary structures of this MCR-like protein were predicted using Phyre2 and ESPript 3 and were compared with known MCR proteins (MCR-1 to 9) and chromosomally encoded MCR-like phosphoethanolamine transferases [designated MCR-B here] of various *Buttiauxella* species.

**Results:** Here we describe a novel mcr gene, mcr-10, on an non-self-transmissible IncFIA plasmid of an *E. roggenkampii* clinical strain. mcr-10 has the highest nucleotide identity (79.69%) with mcr-9 and encodes MCR-10 with 82.93% amino acids identical to MCR-9. mcr-10 confers 4-fold increase of colistin MIC (from 1 to 4 mg/L) when cloned into a colistin-susceptible *E. roggenkampii* strain. By screening GenBank, mcr-10 was found in various *Enterobacteriaceae* species of countries in four continents, suggesting that this gene has widely spread. MCR-10 shows 79.04% to 83.67% amino acid identity and highly conserved predicted protein structures with MCR-Bs. MCR-10, MCR-9 and MCR-B proteins may therefore originate from a common ancestor. mcr-10 was adjacent to a site-specific recombinase-encoding gene and was bracketed by IS903 and may be mobilized by site-specific recombination or composite transposon (Fig).

**Conclusions:** Our results indicate that mcr-10 is a novel plasmid-borne colistin resistance gene and warrants immediate monitoring and further studies.

**Figure.** Genetic context of mcr-10 on pMCR10 090065. Gene int encodes a XerC-type tyrosine recombinase, which may mediate mobilization of adjacent genetic components via site-specific recombination. Δ represents truncated insertion sequences. Two copies of IS903 are located at upstream and downstream of int-mcr-10 and the 9-bp abutting sequences are indicate.

Abstract 1895

**Dalbavancin as definitive therapy for Gram-positive infections in patients with haematologic malignancies and haematopoietic cell transplant recipients**

Catessa Howard1*, Aaron Cumpston1, Douglas Slain2

1West Virginia University Hospitals, Ruby Memorial Hospital, Morgantown, United States, 2West Virginia University, Health Science Center, Morgantown, United States

**Background:** Patients with hematologic malignancies and hematopoietic cell transplants (HCT) are at an increased risk of infection due to the use of immunosuppressive agents, neutropenia, and central venous catheters. These infections are frequently caused by Gram-positive bacteria and are often complicated requiring extended courses of intravenous (IV) antibiotics. Dalbavancin is an IV lipoglycopeptide antibiotic with unique pharmacokinetics allowing for once weekly dosing. The aim of this study was to assess the efficacy of dalbavancin for definitive treatment of Gram-positive infections in patients with hematologic malignancies and HCT recipients at an academic medical center.

**Materials/methods:** This was a retrospective, single-center observational study from January 2016 – May 2019 of patients receiving dalbavancin at West Virginia University Hospitals. Patients were included if they were greater than 18 years of age, active hematologic malignancy or HCT recipient, and received at least one dose of dalbavancin for a Gram-positive blood stream infection (BSI) or skin and soft tissue infection (SSTI). The primary outcome was to evaluate clinical resolution of infection. Secondary outcomes were to determine infection recurrence within 30 days after dalbavancin completion, difference in efficacy for indication, and length of inpatient stay prior to outpatient dalbavancin.

**Results:** Fifty-seven patients met inclusion criteria, 24 (42%) were HCT recipients. Most patients were male (65%) with a median age of 60 years and weight of 87.4 kg. Acute myeloid leukemia was the most common malignancy (28.3%). BSIs were the most common dalbavancin indication, (52.6%). Overall, the clinical resolution rate was 78.9% (95% CI 0.6656 – 0.8767). Resolution was observed in 80% of BSIs versus 77.8% of SSTIs \( P = 0.8372 \). In patients without resolution, failure occurred in 10% of BSIs versus 7.4% of SSTIs \( P = 0.7297 \) and recurrence was observed in 10% of BSIs versus 14.8% of SSTIs \( P = 0.7014 \). The most frequent dosing regimens were 1,000 mg weekly and one 1,500 mg dose for BSIs and SSTIs, respectively. The median length of stay was seven days.

**Conclusions:** Dalbavancin appears to be an adequate treatment option for Gram-positive BSIs and SSTIs in this population. Using dalbavancin allows for outpatient treatment and may allow for earlier hospital discharge.

Excess length of acute inpatient stay attributable to acquisition of hospital-onset Enterobacteriaceae bloodstream infection with and without antimicrobial resistance: a multistate model analysis

Michihiko Goto*,1,2, Hiroyuki Suzuki1,2, Rajeshwari Nair1,2, Daniel Livorsi1,2, Eli Perencevich1,2

1University of Iowa, Roy J. and Lucille A. Carver College of Medicine, Iowa City, United States; 2Iowa City VA Health Care System, Iowa City, United States

Background: Hospital length of stay (LOS) is an important outcome impacted by healthcare-associated infections (HAIs) and antimicrobial resistance (AMR). However, measurement of excess LOS can be subject to survival bias when considering death as a censoring event due to variable timing of HAI onset and high mortality. We aimed to estimate unbiased change in LOS attributable to hospital-onset (HO) Enterobacteriaceae bloodstream infections (BSI) using multistate models without considering death as a censoring event.

Materials/methods: We analyzed a retrospective matched-cohort that included all case patients who developed HO BSI due to Escherichia coli or Klebsiella spp. (BSI onset >48 hours after the admission) during the period 2003 to 2013 at 130 hospitals within the US Veterans Health Administration System. Up to three uninfected control patients per case were identified and matched at patient-level based on gender, hospital and LOS before the onset of BSI. Case patients were further categorized by the resistance profile to fluoroquinolones (FQ) and extended-spectrum cephalosporins (ESC). A multistate model (Figure) was utilized, and change in LOS was estimated as an effect of the intermediate state (HO BSI: State 1 in Figure). We stratified analyses by isolate susceptibilities to FQ (FQ-S and FQ-R) and ESC (ESC-S and ESC-R) and assessed extra LOS for each category.

Results: 5,964 patients who had HO BSI due to E. coli (2,663/44.7%) or Klebsiella spp. (3,301/55.3%) and 15,213 uninfected patients were analyzed. 957 patients (16.9%) and 1,638 patients (28.9%) had organisms resistant to FQ and ESC, respectively. AMR was associated with larger change in LOS for both FQ (FQ-S: 12.13 days [95% CI: 6.25-17.88] vs. FQ-R: 12.94 days [95% CI: 2.35-24.31], difference: 0.81 days [95%CI: 0.56-1.05], p<.001) and ESC (ESC-S: 11.57 days [95%CI: 6.25-17.42] vs. ESC-R: 16.56 days [95%CI: 3.63-30.38], difference: 4.99 days [95%CI: 4.75-5.24], p<.001).

Conclusions: In this large matched cohort study, HO Enterobacteriaceae BSI with or without resistance to FQ or ESC was associated with attributable excess LOS. Resistance to FQ or ESC was associated with longer increases in LOS than seen in cases infected with susceptible isolates, and the impact was greater in ESC resistance compared to FQ.

De-escalation of carbapenems to ciprofloxacin in the treatment of bacteremia caused by extended spectrum beta-lactamase-producing Enterobacteriaceae

Jin Rui Nicholas Lim1, Wei Xiang Tong1, Jonathan Seah1, Humaira Shafi*1, Christine B. Teng2

1Changi General Hospital, Singapore, Singapore, 2National University of Singapore, Singapore, Singapore

Background: Carbapenems are recommended for the treatment of bacteremia caused by extended spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae. However, increased use also selects for carbapenem resistance. Alternatives to carbapenem have yielded conflicting results in recent studies, with limited data evaluating fluoroquinolones (FQ) as carbapenem-sparing options. This study aimed to evaluate the use of ciprofloxacin as step-down from carbapenems in the treatment of bacteremia due to ESBL-producing Enterobacteriaceae.

Materials/methods: Patients with ESBL-producing Enterobacteriaceae bacteremia were evaluated in a retrospective cohort study. We compared patients who received definitive carbapenem therapy throughout (carbapenem group) versus those who were switched from carbapenem to ciprofloxacin (ciprofloxacin group) within 8 days of definitive therapy. The primary outcome evaluated was 30-day all-cause mortality. Secondary outcomes included re-infection and readmission rates, incidences of Clostridioides difficile and carbapenem-resistant infections, and length of hospitalisation. Factors influencing mortality were analysed via logistic regression.

Results: A total of 179 patients were included. There were 148 patients in the carbapenem group and 31 patients in the ciprofloxacin group. Median age was 74 years old and 52% were males. Patient demographics and treatment-related characteristics were similar between groups. Duration of carbapenem use prior to ciprofloxacin switch was 5 days (interquartile range [IQR] 3-6 days). The 30-day mortality were not statistically different between groups (0/31 [0%] vs. 16/148 [10.8%]; p=0.07). The median total duration of antibiotic treatment was longer in the ciprofloxacin group (16 vs.15 days; p=0.01). However, the median duration of hospitalisation was significantly shorter for the ciprofloxacin group [8 [IQR 8-13] vs. 15 days [IQR 9-19]; p=0.01]. Other secondary outcomes were not statistically different between both groups. Failure to reach clinical stabilisation by day 5 was associated with mortality (adjusted odds ratio 7.95% confidence interval 1.66-29.4).

Conclusions: Ciprofloxacin can be an effective carbapenem-sparing therapy for the treatment of bacteremia caused by ESBL-producing Enterobacteriaceae. Switching from carbapenem to ciprofloxacin can be considered when the patient achieved clinical stabilisation, and may result in shorter hospital stay.

Abstract 1901

**Evaluation of rapid extraction methods coupled with recombinase polymerase amplification assay for point-of-need diagnosis of post-kala-azar dermal leishmaniasis**

Rajashree Chowdhury*, Prakash Ghosh1, MD. Anik Ashfaq Khan1, Faria Hossain1, Khaledul Faisal1, Rupen Nath1, James Baker1, Ahmed Abd El Wahed2, Shomik Maruf1,3, Proggananda Nath1, Debashis Ghosh1, MD. Masud-Ur Rashid2, Malcolm Duthie6, Dinesh Mondal1

1International Centre for Diarrhoeal Disease Research, Bangladesh, (icddr,b), Dhaka, Bangladesh, Dhaka, Bangladesh, 2University of Göttingen, Department of Microbiology and Animal Hygiene, Göttingen, Germany, 3London School of Hygiene and Tropical Medicine, University of London, United Kingdom, *Mymensingh Medical College and Hospital (MMCH), Mymensingh, Bangladesh, 2National Heart Foundation Hospital and Research Institute, Dhaka, Bangladesh, 4Infectious Disease Research Institute, Washington, USA, Seattle, United States

**Background:** Post kala-azar dermal leishmaniasis (PKDL) usually develops as sequelae of visceral leishmaniasis (VL) and can manifest in multiple dermatological forms. Since PKDL patients harbor Leishmania donovani parasites and can potentially trigger inter-epidemic transmission of the disease, the success of kala-azar elimination programme could be jeopardized by these cases. Although several molecular methods with promising diagnostic efficacy have been developed to detect PKDL cases, albeit complicated and expensive DNA extraction methods limit their application in resource poor settings. To address this, in comparison to a reference DNA extraction method (Qiagen), we evaluated two rapid DNA extraction methods and determined their impact on the detection of the parasite DNA using our newly developed recombinase polymerase amplification (RPA) assay.

**Materials/methods:** Thirty suspected PKDL cases were enrolled after diagnosis by clinical examination and a positive rk39 strip test. DNA was extracted from three skin biopsy samples using either a spin column-based method (Qiagen) or one of two rapid DNA extraction methods, (Boil & Spin (B&S) and SpeedXtract (SE)). RPA and qPCR were subsequently performed with the extracted samples to detect L. donovani DNA.

**Results:** Using DNA extracted by Qiagen method, the qPCR and RPA assays exhibited sensitivities of 86.7% and 93.3% respectively. In contrast, the sensitivity of RPA assay dropped to 76.7% and 63.3%, respectively, when the B&S and SE rapid extraction methods were performed. Despite this compromised sensitivity, B&S-RPA technique yielded an excellent agreement with both 0-qPCR (k = 0.828) and 0-RPA (k =0.831) techniques. Moreover, SE-RPA showed good agreement with 0-qPCR (k = 0.755), 0-RPA (k =0.692) and B&S-RPA (k =0.635) assays. As expected, with all of the three DNA extraction methods, both qPCR and RPA assay showed absolute specificity.

**Conclusions:** This study finding substantiates the superior diagnostic efficacy of Qiagen DNA extraction method over B&S and SE method in detecting LD DNA through RPA assay from skin biopsy of PKDL patients. To apply these rapid DNA extraction methods in resource-constrained settings, further methodological refinement is warranted to improve DNA yield and purity through rigorous experiments.

Abstract 1902

Application of matrix-assisted laser desorption ionisation: time of flight mass spectrometry for Mycobacterium tuberculosis Beijing and Non-Beijing genotyping

Fanli Yi*1

1Sichuan University/West China Hospital, Chengdu, China

Background: The widely prevalent and highly virulent Mycobacterium tuberculosis (MTB) Beijing genotype strains were closely related to tuberculosis outbreaks and multiple drug resistance. Therefore, rapid and accurate preliminary diagnosis of the MTB Beijing strains is crucial.

Materials/methods: Recently, the advanced proteomic profiling method by matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) in identifying a variety of pathogenic microorganisms has shown promising results. Our study was to evaluate the performance and feasibility of the MALDI-TOF MS for genotyping MTB Beijing and Non-Beijing strains using a panel of 263 MTB isolates with the most reliable MALDI-TOF MS identification scores of ≥ 1.8.

Results: As a standard method, RD207 gene fragment deletion assay classified 263 MTB isolates into Beijing (195/263) and Non-Beijing (68/263) genotypes. The MS fingerprints of 133 MTB isolates (98 Beijing and 35 Non-Beijing strains) were used for modeling with various machine learning such as Genetic algorithm (GA), Supervised Neural Network (SNN) and Quicker Classifier (QC) in ClinProTools 3.0 software of MALDI-TOF MS. The GA model showed the best diagnostic performance with 90.31% sensitivity and 70.98% specificity and was externally validated by correctly identifying 130 MTB strains (97 Beijing and 33 Non-Beijing strains) into 82.47% Beijing strains (80/97) and 63.64% Non-Beijing strains (21/33), which showed 77.69% accuracy (101/130) and 95%CI (70.40%-84.90%). The GA model identified 2 characteristic mass peak biomarkers (4485.05 Da, AUC=0.74; 5785.67 Da, AUC=0.73) for the identification of MTB Beijing and Non-Beijing strains.

Conclusions: MALDI-TOF MS technology with ClinProTools software is easy and suitable to distinguish the MTB Beijing and Non-Beijing genotypes and has a promising application in homology analysis of Mycobacterium tuberculosis complex (MTBC).

Graph 1 Comparison of the average spectral characteristic peaks of Beijing (1) and non Beijing (2) strains (a: 4485.05 Da; b: 5785.67 Da)

Abstract 1904

The positive impact of infectious diseases consultation on antimicrobial appropriateness in hospitalised patients with antimicrobial stewardship oversight: a propensity-score matched study

Jacqueline Bork*, Kimberly Claeyss, Emily Heil, Mary Banoub, Surbhi Leekha, John Sorkin, Michael Kleinberg

1University of Maryland School of Medicine, 29 S. Greene St., MD, United States, 2University of Maryland School of Pharmacy, Baltimore, United States, 3University of Maryland Medical Center, Baltimore, United States, 4University of Maryland School of Medicine, Baltimore, United States

Background: Hospital-based antibiotic stewardship (AS) programs provide oversight and guidance for appropriate antimicrobial use in acute care settings. Infectious Diseases expertise is beneficial in the care of hospitalized patients with infection. The impact of Infectious Diseases consultation (IDC) on antibiotic appropriateness in a large tertiary hospital with an established AS program was investigated.

Materials/methods: This was a cross-sectional study from 10/2017 to 3/2019 at a large, academic hospital with an AS-directed prospective audit and feedback process and multiple IDC services. Antimicrobial appropriateness was adjudicated by an AS team member at 3-6 days after antimicrobial start. Antimicrobial appropriateness was compared among antimicrobial orders with and without IDC using propensity-score matching and multivariable logistic regression. Analyses were stratified by primary services caring for the patients.

Results: There were 10,508 antimicrobial orders from 6,165 unique patient encounters. Overall appropriateness was 92% with higher appropriateness among patients with IDC vs. without IDC, (94% vs 84%, p<0.0001). After propensity-score matching and adjustment for certain antibiotics, organisms, syndromes and locations, IDC was associated with greater antimicrobial appropriateness odds ratio (OR) 2.4 (95% confidence interval (CI) 1.9, 3.0). Stratification by primary service showed OR of 4 (95% CI 1.3,12) for vascular surgery and OR of 1.5 (95% CI 0.9,2.4) for medicine.

Conclusions: Even with a high overall antimicrobial appropriateness rate, patients with IDC had greater odds of antimicrobial appropriateness than those without IDC with greatest impact in vascular surgery and least in medicine. Infectious disease consultation can be synergistic with antimicrobial stewardship programs.

Abstract 1906

**Hantavirus registry (HantaReg): a novel worldwide platform for epidemiological and clinical studies of hantavirus diseases**

Felix Carlo Köhler*1;2, Martin Späth1;2, Johanna Hoyer-Allo1;2, Manuel Wanken1, Oliver A. Cornely2;3;4, Veronica di Cristanziano5, Franz Schaefer6, Roman-Ulrich Müller1;2;7, Volker Burst1

1University of Cologne, Faculty of Medicine and University Hospital Cologne, Department II of Internal Medicine and Center for Molecular Medicine Cologne, Cologne, Germany, 2University of Cologne, Faculty of Medicine and University Hospital Cologne, CECAD Research Center, Cologne, Germany, 3University of Cologne, Department I of Internal Medicine, ECMM Diamond Center of Excellence in Medical Mycology, German Centre for Infection Research (DZIF), Cologne, Germany, 4University of Cologne, Clinical Trials Centre Cologne (ZKS Köln), Cologne, Germany, 5Faculty of Medicine and University Hospital Cologne, Department of Virology, Cologne, Germany, 6Heidelberg University Medical Center, Division of Pediatric Nephrology, Heidelberg, Germany, 7University of Cologne, Systems Biology of Ageing Cologne (Sybacol), Cologne, Germany

**Background:** Frequent outbreaks of globally emerging hantavirus infections emphasize the substantial threat to patients due to hantavirus associated diseases. Increasing incidence rates, worrisome trends of changing distribution of hantaviruses and new insights into clinical course of hantavirus diseases call for multinational surveillance.

**Materials/methods:** HantaReg serves as a novel worldwide registry project facilitating multinational research of hantavirus caused diseases, such as nephropathia epidemica, hemorrhagic fever with renal syndrome (HFRS) and hantavirus cardiopulmonary syndrome (HCPS). HantaReg includes an electronic Case Report Form (eCRF) and is accessible via the General Data Protection Regulation (GDPR) compliant platform clinicalsurveys.net. Data entry is carried out via any internet browser and is spontaneously encrypted. All documented cases are automatically collected into the database. To assess attributable mortality, HantaReg partly uses matched case-control design. HantaReg has a modular structure, as the registry platform is designed to display or hide questions and items according to the documented case (e.g. patient with HFRS vs. control patient). For quality control, each case entered is reviewed by a team of physicians for consistency and completeness.

**Results:** HantaReg facilitates the straightforward and standardized documentation of hantavirus diseases. Information categories documented into HantaReg are demographics, pre-existing diseases, clinical signs and symptoms, diagnostic and therapeutic approaches, as well as outcome. Details on management of hantavirus diseases include virology findings, imaging procedures, admission to the intensive care unit, diuretic treatment, renal replacement therapy and treatment response. Documented information on outcome of hantavirus diseases contains the development of kidney function and both overall and attributable mortality.

**Conclusions:** HantaReg is a novel, ready to use platform for clinical and epidemiological studies, as well as outbreak situations. Therefore, HantaReg enables the monitoring of changing epidemiological trends and of outbreak situations of hantavirus diseases locally and globally over time. HantaReg facilitates the worldwide, standardized documentation of disease course associated with hantavirus infections. HantaReg is a novel worldwide registry project promoting international collaboration and contributes to improving patient management by analysis of diagnostic and treatment approaches for hantavirus diseases.

Epidemiology, clinical characteristics and outcomes of central nervous system infections in solid organ transplant recipients: a nationwide cohort study

Lorena Van Den Bogaart,1,2 Dionysios Neofytos,3 Laura Walti,4 Nicolas Mueller,5 Nina Khanna,6 Katia Boggian,7 Karine Hadaya,8 Christian Garzoni,9 Matteo Mombelli2, Oriol Manuel2

1Department of Biomedical and Clinical Sciences, FBF-Sacco Hospital, University of Milan, Milan, Italy, 2 Service of Infectious Diseases and Transplantation Center, Lausanne University Hospital, Lausanne, Switzerland, 3 Transplant Infectious Diseases Unit, Geneva University Hospital, Geneva, Switzerland, 4Department of Infectious Diseases, Bern University Hospital, Bern, Switzerland, 5Division of Infectious Diseases and Hospital Epidemiology, Zurich University Hospital, Zurich, Switzerland, 6 Division of Infectious Diseases and Hospital Epidemiology, Basel University Hospital, Basel, Switzerland, 7Division of Infectious Diseases and Hospital Hygiene, Cantonal Hospital St Gallen, St Gallen, Switzerland, 8 Division of Nephrology, Geneva University Hospital, Geneva, Switzerland, 9 Clinic of Internal Medicine and Infectious Diseases, Clinica Luganese, Lugano, Switzerland

Background: The epidemiology and clinical presentation of central nervous system (CNS) infections after solid organ transplantation [SOT] has not been systematically assessed in the current era.

Materials/methods: Patients from the Swiss Transplant Cohort Study [STCS] transplanted from 05/2008 to 12/2017 with a CNS-infection were included. Epidemiological, microbiological, and clinical data were extracted from the STCS database and patients’ medical records. Descriptive statistics were used to characterize the patient population, diagnostic and therapeutic management. We analysed the incidence rate of CNS-infections and 90-day patient survival, according to presenting clinical syndrome.

Results: 37 cases of CNS-infection in 36/4249 (0.8%) SOT recipients were included in this study, with an overall incidence rate of 2.12 per 1000 patient-years. Incidence did not differ by transplanted organ. There were 13 space-occupying lesions and 24 meningoencephalitis cases. 2/13 (15.4%) space-occupying lesions were bacterial, 4/13 (30.8%) viral and 7/13 (53.8%) fungal infections [all invasive aspergillosis]. 2/24 (8.3%) of meningoencephalitis cases were bacterial, 15/24 (62.5%) viral, 3/24 (12.5%) fungal, and 4/24 (16.7%) cases were of unknown etiology (Fig.1). Median time of CNS-infection onset following SOT was 17 months [0.8-97]. Most fungal infections occurred <6 months after transplant [7/10, 70%]. Median time from symptoms onset to diagnosis was 8 days [IQR 3-25]. Most patients [75.6%] had a Glasgow Coma Scale >14 at presentation. The majority of space-occupying lesions had a histopathologic and/or culture-proven diagnosis obtained from biopsy or post-mortem samples. Patients with meningoencephalitis had more frequently a viral etiology documented by PCR performed on cerebrospinal fluid [CSF]. In 30% of meningoencephalitis cases CSF cellular count was normal with mild elevation of protein. In 16 [43%] cases, infection was disseminated involving the respiratory tract or the skin. Notably, 32.4% of infections required intensive-care-unit hospitalization. The majority of patients with a treatable etiology [20/23, 86%] received an effective antimicrobial treatment and in 48.6% at least one immunosuppressive drug was withdrawn. 90-day mortality was 29.7% [8.3% for meningoencephalitis, and 69.2% for space-occupying lesions, p<0.0002].

Conclusions: In the STCS, a low incidence of CNS-infections was observed, with viral meningoencephalitis being the most common presenting syndrome. Space-occupying lesions were associated with an elevated mortality rate.

Abstract 1908

Burden and impact of carbapenem resistance caused by Enterobacterales in a Bangladeshi hospital: an epidemiological, clinical and molecular study

Refath Farzana1,2, Lim Jones2, Anisur Rahman3, Kirsty Sands1, Edward Portal1, Ian Boostrom1, Monirha Pervin3, Brekhna Hassan1, Andrew Barratt2, Timothy R. Walsh1

1Cardiff University, Cardiff, United Kingdom, 2Public Health Wales, Cardiff, United Kingdom, 3Dhaka Medical College, Dhaka, Bangladesh

Background: Despite the high prevalence of antimicrobial resistance (AMR) in developing countries, limited data is available informing the actual health burden. We undertook a prospective cohort study at Dhaka Medical College Hospital (DMCH) to investigate the impact of AMR on health.

Materials/methods: Microbiology of Enterobacterales included minimum inhibitory concentration of antimicrobials and whole genome sequencing. Both unadjusted and adjusted logistic regression and Cox proportional subdistribution hazard model were performed to analyse risk and outcome for infections caused by carbapenem-resistant Enterobacterales (CRE) compared to carbapenem-sensitive Enterobacterales (CSE).

Results: Patients positive for at least one CRE from any clinical specimen were considered as ‘CRE infections’ and patients without any CRE positive clinical samples were included as ‘CSE infections’. Crude mortality was 26% (64/246) with CRE infections and 11.7% (29/248) with CSE infections. CRE infections were significantly associated with in-hospital mortality ($p<0.0000001$) and significant inverse correlation with discharge alive ($p<0.0000001$) in both baseline model with time from infection as the timescale (time 0 is infection) by adjusting time from admission (time 0 is admission) and adjusted for the subdistribution hazard model. E. coli and K. pneumoniae were significantly responsible for mortality compared to other infections ($p<0.01$), but carbapenem resistance did not change p value for the mortality due to E. coli or K. pneumoniae in adjusted logistic regression. There was a trend towards prolonged hospital stay in patients with CRE; however, result was not statistically significant. Demographic and clinical parameters for CRE acquisition were mostly insignificant except the CREs recovery from urine ($p<0.0001$). Epidemiological evidence of CRE dissemination in Bangladeshi clinical setting was apparent: A. carbapenem resistance in E. coli was prevalent in ST167 ($p<0.0000001$) B. outbreak of K. pneumoniae ST23 (n=35) was detected and carbapenem resistance was associated with this particular clone ($p<0.05$) C. CRE faecal colonization was higher among inpatients than outpatients ($p<0.0001$) D. plasmids with identical backbone, IncFIA, IncFIB, IncFIIC and IncX3 were found in association with blaNM5 among the species of Enterobacterales.

Conclusions: Our data suggests that the magnitude of the impact of AMR associated with CRE on health outcomes in Bangladesh is worrying and needs immediate attention.

Abstract 1918

**Tuberculosis in renal failure: clinical presentation and outcome from a TB endemic area**

Sunil Kumar*1, Asma Naseem1, Zaheeruddin Babar1

1SIUT, Karachi, Pakistan

**Background:** Tuberculosis (TB) is a major cause of morbidity and mortality. Patients with renal failure are 6 to 25 times more likely to develop TB than the general population. The diagnosis of TB disease is difficult because of lack of classic symptoms and extra-pulmonary involvement. The atypical presentation, delay in diagnosis and difficulty in management may be cause of increase mortality, ranging from 17% to 75% in different studies. Our aim is to find out the clinical presentation and treatment outcome of TB in renal failure from a TB endemic country.

**Materials/methods:** A retrospective cohort study was done at Sindh Institute of Urology and Transplantation (SIUT), Karachi, Pakistan. SIUT is a 700 bedded tertiary care hospital mainly caters to renal and urological diseases. It runs the country's largest renal transplantation and dialysis unit and a very busy nephrology and urology department. All patients diagnosed as tuberculosis are included in the study from May 2017 till May 2019. Tuberculosis was diagnosed on, clinical features and/or sputum smear, culture and/or PCR, biopsy specimens or on radiological grounds. Renal failure was defined as creatinine clearance <30ml/min, needing dosage adjustment of ATT. The presentation, diagnosis and outcome till the end of the treatment was noted.

**Results:** A total of 286 patients were diagnosed as TB, out of whom 70 (24.4%) had renal failure. Around 64% were male. Out of 70, 46 (66%) had extra pulmonary (EPTB) among which 9 (19.5%) patients had genitourinary, 11 (24%) lymphadenitis, 5 (10.8%) central nervous system disease, 7 (15%) abdominal. The diagnosis of genitourinary and lymph node TB was made through histopathology (18/20, 90%). A total of 24 (34%) were pulmonary TB in whom 75% were diagnosed on microbiologic grounds [smear or GeneXpert for MTB or TB culture]. All-cause mortality was 17.1% in renal failure having tuberculosis where as it was 9.7% in patients who did not have renal failure.

**Conclusions:** We found that majority of patients having renal failure have extra pulmonary tuberculosis, of which lymphadenitis and genitourinary were more common. Among pulmonary, majority were diagnosed microbiologically. All-cause mortality was slight more in patients having renal failure.

Abstract 1919

**Anti-apoptotic role of human cytomegalovirus miRNAs, miR UL-70-3p and UL-148D on hydrogen peroxide-induced apoptosis in HEK 293T cells**

Sunil Babu Gosipatala1*, Abhishek Pandeya1, Sangeeta Saxena1

1Babasaheb Bhim Rao Ambedkar University, Department of Biotechnology, Lucknow, India

**Abstract third-party references:** Babasaheb Bhimrao Ambedkar University, Lucknow-226025, India, Department of Biotechnology, Ministry of Science & Technology, Government of India

**Background:** Human Cytomegalovirus (HCMV), an ubiquitous human pathogen, belongs to the family Herpesviridae, exhibits more than 70% seroprevalence in adult population. It is reported to encode 26 mature miRNAs from 16 precursors. The viral miRNAs garnered attention by the scientific community for their spectacular biological roles, as they can regulate both the viral as well as cellular pathways. Most of the reports indicate that these molecules play an augmentative role in making the conducive environment for viral survival in their host by subverting the antiviral responses of the host besides the viral proteins. By using various bioinformatic tools we predicted the HCMV miRNAs which inhibit the cellular apoptosis. Further, these results were validated in *in vitro* by using HEK 293T cell lines.

**Materials/methods:** miRNA sequence homology between human and HCMV miRNAs were evaluated through T-Coffee (global alignment) by using the URL: http://tcoffee.vital-it.ch/apps/global/tcoffee/do:regular. The potential binding sites in 3'UTR regions of the apoptotic genes for HCMV miRNAs were probed through the online algorithms, i.e., RNA hybrid and RNA 22 by using the URL's http://www.bibiserv.cebitec.uni-bielefeld.de; http://cm.jefferson.edu/rna22/interactive respectively. The *in vitro* studies were performed in HEK293T cells, apoptosis was induced through H2O2 and the antiapoptotic effect of the HCMV miRNAs were evaluated through fluorescent microscopy and flow cytometry. Further, the potential genes targeted by these miRNAs were examined through qRT PCR.

**Results:** The sequence homology studies between human and HCMV miRNAs show there was no single HCMV miRNA shares sequence homology with the Human miRNAs. The mRNA:miRNA binding studies reveals that the 3'UTR of cellular proapoptotic genes such as MOAP1 and ERN1 has potential binding sites for the HCMV miR UL-70-3p and UL-148D. Further, the *in vitro* results augmented the *in silico* findings that these HCMV miRNAs inhibit the H2O2 induced apoptosis in HEK293T cells by targeting the MOAP1.

**Conclusions:** The study shows that no HCMV miRNA shares sequence homology with the human miRNAs. HCMV uses its miRNA machinery to inhibit the cellular apoptosis. The HCMV miR's UL-70-3p and UL-148D inhibit the H2O2 induced apoptosis. Fig. Antiapoptotic effect of HCMV miR UL 70-3p on H2O2 induced apoptosis

Leptospirosis registry: LeptoScope. A novel global registry for emerging leptospirosis infections

Felix Carlo Köhler*1,2, Martin Späth1,2, Johanna Hoyer-Allo1,2, Oliver A. Cornely1,3,4, Franz Schaefer1, Roman-Ulrich Müller1,2, Volker Burst1

1University of Cologne, Faculty of Medicine and University Hospital Cologne, Department II of Internal Medicine and Center for Molecular Medicine Cologne, Cologne, Germany, 2University of Cologne, Faculty of Medicine and University Hospital Cologne, CECAD Research Center, Cologne, Germany, 3University of Cologne, Department I of Internal Medicine, ECMM Diamond Center of Excellence in Medical Mycology, German Centre for Infection Research (DZIF), Cologne, Germany, 4University of Cologne, Clinical Trials Centre Cologne [ZKS Köln], Cologne, Germany, 5Heidelberg University Medical Center, Division of Pediatric Nephrology, Heidelberg, Germany, 6University of Cologne, Systems Biology of Ageing Cologne (Sybacol), Cologne, Germany

Background: Leptospirosis is a worldwide zoonotic disease caused by pathogenic Leptospira spp. During bacteremia, Leptospira spp. may lead to invasive, deep-seated leptospirosis often with infection of kidney, liver, heart and the central nervous system. Incidence of invasive leptospirosis is rising and there have been frequent outbreak situations in many parts of the world. Therefore, a global surveillance in epidemiology and species distribution is needed.

Materials/methods: The leptospirosis registry – LeptoScope is a novel worldwide registry project for invasive leptospirosis facilitating multinational research. LeptoScope consists of an electronic Case Report Form (eCRF) and it uses the General Data Protection Regulation (GDPR) compliant platform clinicalsurveys.net. LeptoScope can be accessed from any browser and it uses highly-encrypted communication for data entry. Cases documented are collected into the LeptoScope database automatically. A team of physicians reviews each case entered for completeness and consistency for quality control.

Results: LeptoScope is a novel registry project enabling fast, but standardized documentation of invasive leptospirosis using a modular structure. Items categories are patient characteristics, pre-existing diseases, clinical signs and symptoms, microbiological diagnostics, imaging procedures, admission to the intensive care unit, complications including acute kidney injury, acute liver failure and acute respiratory distress syndrome, as well as antibiotic, diuretic and renal replacement therapies and outcome. Additionally, LeptoScope facilitates the monitoring of changing epidemiological trends and outbreak situations locally and globally.

Conclusions: LeptoScope is a novel global, ready to use registry platform for invasive leptospirosis enabling worldwide, standardized documentation of disease course and outcome. LeptoScope may be employed for a variety of epidemiological and clinical studies including outbreaks. LeptoScope promotes international collaboration and may contribute to improve patient management by the standardized analysis of clinical course, prognostic factors, as well as diagnostic and treatment pathways.

Abstract 1925

**Preliminary results of microRNA expression profile in patients with cystic echinococcosis and identification of possible cellular pathways**

Serra Orsten*1, Türkmen Çiftçi2, Samiye Yabanoğlu Çiftçi3, Aynur Azizova4, Gökhan Yüce4, Emre Ünal2, Ahmet Bülent Doğru2, Devrim Akıncı2, Yakut Akyon6, Okan Akhan2

1Hacettepe Üniversitesi Sıhhıye Kampüsü, Vocational School of Health Services, Ankara, Turkey, 2Hacettepe University, Faculty of Medicine Department of Radiology, Ankara, Turkey, 3Hacettepe University, Faculty of Pharmacy Department of Biochemistry, Ankara, Turkey, 4Ankara City Hospital, Department of Radiology, Ankara, Turkey, 5Hacettepe University, Faculty of Medicine Department of General Surgery, Ankara, Turkey, 6Hacettepe University, Faculty of Medicine Department of Medical Microbiology, Ankara, Turkey

**Background:** Although CE can be diagnosed with imaging techniques such as ultrasonography (US) and magnetic resonance imaging (MRI), these modalities may be insufficient to diagnose some cysts especially young CE1. However, differential diagnosis is crucial as WHO-IWGE recommends a stage-specific approach for treatment of CE. Recently discovered microRNAs (miRNAs) are small, stable, tissue specific RNA molecules encoded by the genome that are not translated into proteins. Circulating miRNA expression profiles vary in health and disease. The aim of this study is to determine the altered cellular pathways in CE by comparing miRNA profiles of CE patients having active cysts with either CE patients having inactive cysts or control group.

**Materials/methods:** Following abdominal US examination 20 patients diagnosed with active or inactive cystic echinococcosis and three healthy individuals were included in the study. Total RNA extraction and DNA (cDNA) synthesis were performed from plasma of the patients/controls by miRNeasy Mini Kit (Qiagen) and miScript II RT system (Qiagen) respectively following the manufacturer’s instructions. Detection and quantitation of miRNAs were performed using miScript SYBR Green PCR Kit and miScript miRNA HC PCR Arrays with a LightCycler 480 instrument II (Roche, Germany), according to the manufacturers’ instructions. Data analysis was performed using online Geneglobe data analysis center. For miRNA target prediction miRDB, Targetscan and DIANA databases were used. p< 0.05 was considered as statistically significant.

**Results:** Compared to control group, expression of 5 miRNAs (hsa-miR-4659a-5p, hsa-miR-4518, hsa-miR-3977, hsa-miR-4692, hsa-miR-181b-3p) and 2 miRNAs (hsa-miR-4522, hsa-miR-4687-5p) were found to be down regulated in CE patients with active and inactive cysts respectively [p<0.05]. For down-regulated miRNAs, predicted targets were found to be associated mainly with biological membrane lipids.

**Conclusions:** These results indicate that in CE miRNA expression profiles of inactive and active cysts of the liver differ from each other. In the future, miRNA profiles of the patients will possibly provide accurate diagnosis of the nature of CE cysts by eliminating the necessity of US.

Abstract 1926

**Spectrophotometric MICs reading of azoles and amphotericin B shows high agreement with visual reading MIC interpretation using EUCAST 9.3.1 methodology**

Julia Serrano Lobo1, Pilar Escribano1, Judith Diaz-Garcia1, Waldo Sanchez-Yebra Romero1, Leyre Lopez Soria1, Miguel Fajardo4, Belen Lorenzo5, Ferrán Sánchez Reus2, Inmaculada Vidal Catala2, Marina Fernandez Torres5, Isabel Sanchez-Romero3, Carlos Ruiz De Alegría-Puig10, Jose Luis Del Pozo11, Patricia Munoz1, Jesus Guinea Ortega11

1Hospital General Universitario Gregorio Marañon, Madrid, Spain, 2Complejo Hospitalario Torrecárdenas, Almería, Spain, 3Hospital del Cruces, Bilbao, Spain, 4Hospital Universitario de Badajoz, Badajoz, Spain, 5Hospital Río Hortega, Valladolid, Spain, 6Santa Creu y Sant Pau, Barcelona, Spain, 7Hospital General de Alicante, Alicante, Spain, 8Hospital Txagorritxu, Vitoria, Spain, 9Hospital Puerta de Hierro, Madrid, Spain, 10Hospital de Valdecilla, Santander, Spain, 11Clínica Universitaria de Navarra, Pamplona, Spain

**Background:** EUCAST 9.3.1 procedure recommends visual MIC reading (complete fungal growth inhibition) with azoles and amphotericin B against *Aspergillus* spp. As visual MIC setting may be challenging, we obtained spectrophotometric MICs readings of azoles and amphotericin B against *A. fumigatus* complex isolates and compared them with visual method to overcome subjectivity.

**Materials/methods:** A total of 848 *A. fumigatus* complex clinical isolates collected in a 30-hospital survey conducted in Spain were studied. *A. fumigatus* sensu stricto isolates included 45 azole-resistant isolates with the following cyp51A gene mutations: TR34-L98H [n=24], G54R [n=5], TR46/Y12F/T289A [n=1], F46Y/M172V/N248T/D255E/E427K [n=2], F46Y/M172V/N248T/D255E/E416Q/E427K [n=1], F165L [n=1], S496L [n=1], and wild type [n=10]. Antifungal susceptibility to amphoter, itraconazole, voriconazole, posaconazole, and isavuconazole was performed according to EUCAST 9.3.1 methodology. Visually-set MICs were compared with spectrophotometrically-obtained MICs (fungal growth reduction >95% compared to control and read at 540 nm); essential (±1 twofold dilution) and categorical agreement were calculated. Errors were classified as very major (isolate classified as resistant by visual MIC and as susceptible by spectrophotometric reading) and major (isolate classified as susceptible by visual MIC and as resistant by spectrophotometric reading).

**Results:** Overall, essential agreement was 97%, with amphotericin B and posaconazole showing the highest agreement [%Table]. Categorical agreement was very high [98%] as well, with a total of 1.8% very major errors found in six *A. fumigatus* sensu stricto isolates that were resistant to either voriconazole and isavuconazole [n=3] or to isavuconazole [n=3], and four cryptic species (*N. udagawae* [n=2], *A. fumigatioaffinis* [n=2]). No very major errors were found with amphotericin B or itraconazole. Major errors were scarce and exclusively found with voriconazole and posaconazole against *A. fumigatus* sensu stricto (<1%; n=5 isolates). All cyp51A gene mutants were correctly classified as resistant. Most of errors occurred in MICs just one two-fold dilution above the breakpoint.

**Conclusions:** MICs of azoles and amphotericin B against *A. fumigatus* obtained either by spectrophotometer or visually showed very high agreement. Cyp51A mutants were correctly classified as resistant and most misclassifications occurred in MICs just one two-fold dilution above the breakpoint.

Abstract 1929

Antifungal cost in the patients with febrile neutropaenia episodes due to haematological malignancies
Habip Gedik*1

1University of Health Sciences, Bakirköy Dr. Sadi Konuk Training and Research Hospital, Department of Infectious Diseases and Clinical Microbiology, istanbul, Turkey

Background: The aim of this study was to assess the cost of antifungal drugs used in the treatment of febrile neutropenic episodes of patients with hematological malignancies.

Materials/methods: The cost of antifungal drugs used in the treatment of adult patients who were followed at the department of Hematology of Ministry of Health Okmeydani Research Hospital between November 2010 and November 2012 due to hematological malignancies and had febrile neutropenia attacks (FNA) were assessed, retrospectively.

Results: The cost of antifungal drugs was calculated and evaluated in 126 patients, who had 282 FNA were evaluated. The mean age of patients, who 60 patients were female, was 51.73 ± 14.4 years (range: 17–82 years). The mean MASCC score was 17.18 ± 8.27. The mean duration of FNA was 29.38 ± 6.95 days. During 282 febrile episodes of 126 patients, systemic antifungal drugs were administered to 23 patients with 31 culture-proven invasive fungal infection (IFI), 19 patients with probable invasive pulmonary aspergillosis (IPA) in 25 febrile neutropenia episodes, 38 patients with possible IPA in 42 febrile neutropenia episodes, and 30 patients with suspected IFI in 31 febrile neutropenia episodes, respectively.

Liposomal amphotericin B (L-AmB) was calculated to cost $29322.98 per month, $366537.43 per year with 0.21 patient daily dose/100 patient days as the most costly antifungal drug. Total cost were calculated to be $1,271,789.08/year and $18039/patient for antifungal drugs. The costs of antifungal drugs were found to be $3857.85 for voriconazole (VOR), $15783.34 for caspofungin, $21561.02 for L-AmB per febrile neutropenic episode, respectively. The cost of posaconazole was $32167.39/patient for the prophylaxis use.

Conclusions: Antifungal drugs pose a serious cost in the treatment of IFI. The costs could be reduced with those measures, including an accurate and fully implemented infection control measures, an administration of preemptive antifungal treatment instead of empirical antifungal treatment, switching from intravenous form of VOR to tablet form when it is possible, an administration of VOR for the secondary prophylaxis of invasive aspergillosis, and use of L-AmB as a secondary choice or in the salvage therapy.

**Nasal methicillin-resistant Staphylococcus aureus colonisation among adults and children in Russia: predominance ST22-subclone “Gaza Strip”**

Vladimir Gostev*1,2; Ksenia Ivanova1; Ekaterina Kalisnikova1; Alexander Kruglov1; Irina Ryabchenko3, Sergey Zyryanov4;5, Olga Kalinogorskaya1; Marina Wolkowa1; Ludmila Zhelezova1; Elvira Martens1; Sergey Sidorenko1*2

1Pediatric Research and Clinical Center for Infectious Diseases, Saint Petersburg, Russian Federation, 2North-Western State Medical University named after I.I Mechnikov, Saint Petersburg, Russian Federation, 3National Agency for Clinical Pharmacology and Pharmacy, Moscow, Russian Federation, 4Federal University of Peoples’ Friendship University of Russia, Moscow, Russian Federation, 5City Hospital No 24, Moscow, Russian Federation

Abstract third-party references: The Russian Science Foundation [Grant No. 18-75-10114] supported this study.

**Background:** S. aureus nasal carriage can be considered as a risk factor for subsequent invasive staphylococcus infections. Carriage of MRSA poses the greatest potential threat. In the present study we characterize molecular epidemiology of MRSA colonizing healthy adults and children in Russia.

**Materials/methods:** For the present study, healthy adult individuals (2,000) and children (14,026) in Moscow and Saint Petersburg were sampled with nasal swabs during routine medical screening from 2016 to 2019. S. aureus isolation, identification and susceptibility testing was performed using conventional methods, PCR was used for detection of mecA gene. Selected isolates were sequenced on the MiSeq platform.

**Results:** MRSA carriage rate of was 0.84% (118) among children, and 0.85% (17) among adults. Several lineages were predominant: ST22-t223-SCCmec IVa (32.6%), ST8-t008-SCCmec IVce (10%), ST59-t1950-SCCmec V (7%) and ST1-t321-SCCmec IVa (7%). PVL genes were identified in 4.4% isolates which belonging to different STs and seb were identified in 4% and associated with ST59. Isolates of ST22 lineage (n=44) were tsst-positive and harbored chp, sak, scn and selK virulence genes. Phylogenetic tree for ST22 was constructed using 18,546 core-SNPs in 1,514 core genome loci from 1,252 public available genomes of ST22. Russian ST22 genomes (Figure, red color nodes) were located among tsst-positive “Gaza Strip” clade which was described recently (Chang et al, 2018). We found that ST22 isolates shared high-level similarity, all Russian ST22 isolates had only 14±4.3 SNPs in spite of differences in host age, geographic region and time of collection. Comparing two clades EMRSA-15 and “Gaza Strip” the number of SNPs were also low: 41.4±4.5. Most of carriers isolates demonstrated susceptibility to non-β-lactam antibiotics and 29% were oxacillin susceptible (MIC≤2 mg/L). We compared (PCR mecA as reference) several susceptibility tests for detection oxacillin-susceptible MRSA, high positive predicative value [PPV] were for chromogenic agar [PPV = 0.94] and cefoxitin test based on disk diffusion or broth dilution methods [PPV = 0.88].

**Conclusions:** Overall rate of MRSA carriage in healthy children and adults coincides with the global data. In adults and children ST22, subclone “Gaza Strip” was the most prevalent. High prevalence of oxacillin susceptibility was detected among carrier isolates.

**Differential innate immune responses of human macrophages and bronchial epithelial cells against Talaromyces marneffei**

Chi-Ching Tsang,*1 Yen-Pei Tan1, Kin-Hang Kok1, Susanna K. P. Lau1;2;3, Patrick C. Y. Woo1;2;3

1Department of Microbiology, The University of Hong Kong, Pokfulam, Hong Kong, 2State Key Laboratory of Emerging Infectious Diseases, The University of Hong Kong, Pokfulam, Hong Kong, 3Collaborative Innovation Centre for Diagnosis and Treatment of Infectious Diseases, The University of Hong Kong, Pokfulam, Hong Kong

**Abstract third-party references:** This work was supported by the General Research Fund [No. 17104318], Research Grants Council, University Grants Committee, Hong Kong; Health and Medical Research Fund [No. HKM-15-M07 [commissioned project]], Food and Health Bureau, Government of the Hong Kong Special Administrative Region, Hong Kong; Seed Fund for Basic Research, The University of Hong Kong, Hong Kong; as well as the Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Ministry of Education, China. We thank Dr PJ Punt and Dr ML Yeung for generously providing us the plasmids pAN7-1 and pEGFP-C1, respectively. We are also grateful to the staff members from the Centre for Genomic Sciences and Faculty Core Facility of Li Ka Shing Faculty of Medicine, The University of Hong Kong, for their technical support in RNA–Seq and image analyses, respectively.

**Background:** *Talaromyces marneffei* is a thermally dimorphic fungal pathogen endemic in Southeast Asia. As inhalation of airborne conidia is believed as the major infection route, airway epithelial cells followed by pulmonary macrophages are the first cell types which the fungus encounters inside the host. However, there is a lack of knowledge on how the fungus interacts with host cells during infection.

**Materials/methods:** Human peripheral blood-derived macrophages [hPBDMs] cultured with the supplementation of autologous plasma were used as the *in vitro* infection model for the study of innate immune response to *T. marneffei* infection. Transcriptomic changes of hPBDMs upon infection were profiled by RNA–sequencing and mRNA expression changes in immune-related genes were confirmed by reverse-transcription–quantitative polymerase chain reaction [qRT–PCR]. Differential cytokine responses in human bronchial epithelial cells [hBECs] were also determined and compared to macrophages. A green fluorescent protein-tagged *T. marneffei* strain [GFP-PM1] was constructed to visualise the interactions between *T. marneffei* and hBECs using confocal microscopy and live cell imaging.

**Results:** *T. marneffei* infection could activate hPBDMs to the M1-like phenotype and trigger a potent induction of chemokine (CXCL8, CXCL10, CCL5 and CCL20) and pro-inflammatory cytokine (TNF) production as well as the expression of other immunoregulatory genes (SOD2, CCL3, STAT1, CLEC4E, IL1B, IER3, PIK3R2 and L3). In contrast to hPBDMs, there was no detectable innate cytokine response (CXCL8, CXCL10, IFNA2, IFNB1, IFNL1, IFNL2, IL1B, IL6, and TNF mRNA expression) against *T. marneffei* in hBECs. Under confocal microscopy, internalisation of *T. marneffei* by hBECs was confirmed. Live cell imaging further demonstrated that the infected cells exhibited normal cellular physiology, especially that the process of cell division could be observed.

**Conclusions:** Our results illustrated a potential role of hBECs to serve as reservoir cells for *T. marneffei* to evade immunosurveillance by phagocytes, from which the fungus reactivates when the host immunity is weakened and causes infection. Such immunoevasion and reactivation may also help explain the long incubation period observed for talaromycosis, in particular the travel-related cases.

**Presenter email address:** microbioc@connect.hku.hk
Abstract 1936

Comparison of clinical findings and risk factors of community-acquired and nosocomial Legionella pneumonia cases in Konya, Turkey

Hale Turan Özden*1, Keziban Ucar Karabulut2

1Baskent University Faculty of Medicine, Konya, Turkey, 2Baskent University Faculty of Medicine, Konya, Turkey

Background: Legionella pneumophila is an important cause of community and hospital-acquired pneumonia. The aim of this study was to compare the clinical findings and risk factors retrospectively in 20 nosocomial and 26 community-acquired cases with the diagnosis of L. pneumophila pneumonia.

Materials/methods: Twenty patients with nosocomially acquired Legionella pneumonia (NALP), and twenty six patients with community-acquired Legionella pneumonia (CALP) were included in the study. We applied to the Centers for Disease Control and World Health Organization criteria for diagnosis both of nosocomial infection and Legionella pneumonia. The diagnosis was based on the positivity of urinary antigen test for Legionella pneumonia Acro Biotech, USA). Statistical analysis was performed using chi-square and independent student t test using SPSS Statistics 25.0 program.

Results: Among the risk factors, the older age was more common in the NALP group than in the CALP group, whilst chronic lung disease and cancer were more common in the NALP group than in the CALP group. The difference for other risk factors, such as cardiopathies, chronic renal failure, diabetes, smoking habit, corticosteroid therapy was not statistically significant [p>0.05]. Some of the most common clinical manifestations are shown in the table. Statistical analysis showed that myalgia was more common in the CALP group than in NALP group [p<0.05]. The difference among other common clinical manifestations, such as fever, cough, expectoration, chest pain, dispnea, headache, confusion, abdominal pain, fatigue, diarrhea, loss of appetite was not statistically significant [p>0.05].

Conclusions: The mean age of the patients in the NALP group was higher than the CALP group. Chronic lung disease and cancer were found to be risk factors in NALP group. In conclusion, other demographic and clinical data of Legionella pneumonia in our nosocomial and community-acquired patients were quite similar.

Table: Statistical analysis of risk factors and clinical data of 20 NALP and 26 CALP patients

Abstract 1940

**Pattern of osteoarticular infections caused by non-tuberculous mycobacteria: 9 years’ experience**

Alexandre Bleibtreu*, Isabelle Bonnet¹²³, Stéphane Jauréguiberry¹, Bruno Fautrel⁴, Eric Caumes¹, Jerome Robert²³, Eric Fourniols⁵, Alexandra Aubry²³

¹University Hospitals Pitié Salpêtrière - Charles Foix, Infectious and Tropical diseases department, Paris, France, ²University Hospitals Pitié Salpêtrière - Charles Foix, 1 Centre d’Immunologie et des Maladies Infectieuses, Sorbonne Université [U1135-E13] Paris, France, Paris, France, ³University Hospitals Pitié Salpêtrière - Charles Foix, Centre National de Référence des Mycobactéries et de la résistance aux antituberculeux, Service de Bactériologie-Hygiène, AP-HP Sorbonne Université, Paris, France, ⁴University Hospitals Pitié Salpêtrière - Charles Foix, Service de Rhumatologie, Paris, France, ⁵University Hospitals Pitié Salpêtrière - Charles Foix, Service de Chirurgie Orthopédique et Traumatologie, Paris, France

Abstract third-party references: CRIOAC Pitié-Salpêtrière

**Background:** Non-tuberculous mycobacteria (NTM) are ubiquitous organisms associated with various types of infection and reports of osteoarticular NTM infection (OAI-NTM) remain infrequent. We aimed to describe OAI-NTM over a 9-year period in a French Reference Center for OAI and for Mycobacterial infection.

**Materials/methods:** Case identification and ascertainment was done through laboratory and clinical file review between January 2010 and December 2018. The American Thoracic Society/Infectious Disease Society of America criteria were used to define cases of OAI-NTM.

**Results:** A total of 11 patients (3 females and 8 males) were identified: 7 with slow growing NTM, i.e. *Mycobacterium avium* complex (n=4), *M. xenopi* (n=2), and *M. marinum* (n=1); and 4 with rapidly growing NTM, i.e. *M. chelonae* (n=2), *M. fortuitum* (n=1), and *M. wolinsky* (n=1). Locations were solely OA in most of the cases (n=9), including one associated with prosthesis. All patients were immunocompromised (4 autoimmune diseases, 3 HIV, 1 solid organ transplant, 1 cancer), except one (*M. marinum* infection related to aquarium use) and information was lacking for the remaining case. Infected sites were: spine (n=4), wrist (n=1), hand (n=1), knee joint (n=2), hip (n=1), and elbow (n=2). Eight patients had delayed NTM infection diagnosis because of wrong initial diagnosis. Treatment regimens were retrieved for 8 patients: five tri-therapies and 3 bi-therapies, a majority containing both clarithromycin and rifamycins. Eight patients underwent surgery. With regard to outcome, 6 patients achieved healing with a two year follow up without relapse, 1 patient experienced relapse, 3 were lost for follow up but alive and 1 patient died during the treatment course.

**Conclusions:** Pattern of NTM infections is diverse, and difficult to diagnose. Awareness about NTM as a causative organism of OAI should be brought to clinicians and laboratories, especially in immunosuppressed patients in order to reduce the diagnosis delay.

Involvement of walK gene mutations in antibiotic resistance increase in daptomycin-unsusceptible methicillin-resistant Staphylococcus aureus

Angelina Hugo Campano1, Natalia Gómez Casanova1, Juan-Luis Munoz-Bellido*1
1Salamanca, Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

Background: Resistance to peptide antibiotics (daptomycin (DAP), dalbavancin (DLV)) in Staphylococcus aureus is uncommon. DAP non-susceptibility is a complex process, in which several genes may be involved. WGS studies allow to complete the map of genes involved in these processes, and help to understand the importance of different genes in DAP resistance. Otherwise, since vancomycin (VAN) is the most used peptide antibiotic, is useful to know how the exposition to different concentrations of VAN can affect susceptibility to other newer peptide antibiotics. We exposed a previously DAP non-susceptible MRSA clinical isolate to increasing VAN concentrations, in order to obtain mutants with higher VAN MICs and study their genetic changes and their behavior against other peptide antibiotics.

Materials/methods: A clinical MRSA isolate [St6] was grown in a serial VAN gradient (1-32 mg/l). A mutant growing on 1 mg/l VAN plates was obtained. MICs of VAN, DLV, DAP and oxacillin (OXA) were determined by E-test. The DNA was extracted, and the whole genome of the parent isolate and the mutant obtained were sequenced by using Illumina Miseq.

Results: Parent clinical isolate harbored several mutations in the genes mprF, cls1, cls2, rpoB and rpoC. Moreover, this isolate showed mutations in the region mw1109, coding for a hypothetical protein. The MICs of both isolates appear in Table 1. The genome of the mutant was identical to the parent isolate in terms of protein translation, with the only significant modification of a Leu10Phe change in the gene walK, coding for a sensor protein kinase that regulates genes involved in cell wall metabolism.

Table 1. MICs of VAN, DLV, DAP and (OXA).

<td>6</td>
<td>0.75</td>
</tr>
</tbody>
</table>

Conclusions: Mutations in walK gene seems to increase VAN, DAP and especially DLV MICs, at least in microorganisms harboring previous mutations affecting cell membrane and/or cell wall metabolism. The loss of the methicillin resistant phenotype has been associated to a highly modified bacterial wall, whose alteration in structure and fluidity might prevent PBP2a from anchoring properly to the membrane.

Abstract 1945

Alterations in the gut microbiome of HIV-infected patients under antiretroviral therapy
Shilpa Ray*,1, Aswathy Narayanan1, Christian Giske1,2, Ujjwal Neogi1, Anders Sönnerborg1,3, Piotr Nowak1,3

1Department of Laboratory Medicine, Division of Clinical Microbiology, Karolinska Institutet, Stockholm, Sweden, 2Department of Clinical microbiology, Karolinska University Hospital, Solna, Stockholm, Sweden, 3Department of Medicine Huddinge, Division of Infectious Diseases, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Background: Millions of individuals currently living with HIV globally are receiving antiretroviral therapy (ART) that suppresses viral replication and improves host immune responses. The crucial involvement of gut microbiome during HIV infection has been extensively studied; correlating microbiome changes with immune deficiency and inflammation. However understanding the direct effect of ARTs on gut commensals of HIV infected individuals has been mostly overlooked in microbiome studies.

Materials/methods: The microbiota composition was determined by 16s rRNA sequencing (Illumina MiSeq) of stool samples from 16 patients before and during ART. We also tested the direct effect of 15 antiretrovirals on predominant gut microbes of high clinical relevance namely, Escherichia coli, Enterococcus faecalis, Bacteroides and Prevotella spp. to assess their individual antibacterial effect. Thus, we screened 35 isolates of E. coli, 20 isolates of E. faecalis, 22 isolates of Bacteroides spp and 10 isolates of Prevotella spp. which were cultured from patient samples received at Karolinska University Hospital.

Results: Our 16s rRNA analysis showed that effective ART does not reestablish the microbiome diversity within HIV infected patients, thereby showing moderate reduction in α-diversity and β-diversity (NMDS2 and NMDS1) for clustering of microbial communities before and after ART. Escherichia genus (phylum Proteobacteria) showed enrichment under therapy. On the contrary, the relative richness of Prevotella (phylum Bacteroidetes) was significantly reduced after ART. Our study also found the direct effects of antiretrovirals on gut microbes, where the thymidine analog zidovudine showed in vitro antibacterial activity with an MIC of 0.5-1 mg/l against E. coli, 4-8 mg/l against Bacteroides fragilis and 4 mg/l against Prevotella spp. Efavirenz also showed a consistent MIC of 32 mg/l against E. faecalis, 32 mg/l for Prevotella spp. and 32-128 mg/l against Bacteroides spp.

Conclusions: HIV infection induces gut microbiome dysbiosis and ART does not reverse these changes after one year follow-up. In this study, we found that the antivirals directly have a broad effect on the gut bacteria, which in HIV infected individuals might aggravate microbiota alterations. Therefore restructuring the microbiota could be a potential therapeutic target in HIV-1 patients since effective ART itself may not be sufficient to reverse the microbiota dysbiosis.

Abstract 1947

**Characterisation of the kinetics and LPS dose-response profiles of presepsin, procalcitonin and sTREM-1 as potential biomarkers for severe infections and sepsis in a human endotoxemia model**

Linda Aulin*, Anne Kleijburg¹, Pieter Hameeteman², Hemme Hijma³, Piet Hein Van Der Graaf³, Matthijs Moerland², Coen Van Hasselt¹

¹Leiden University, Leiden, Netherlands, ²Foundation Center for Human Drug Research (CHDR), Leiden, Netherlands, ³Cetara QSP, Canterbury, United Kingdom

**Background:** Sepsis constitutes a major healthcare challenge associated with high mortality. Specific and sensitive new clinical biomarkers are required for personalized antibiotic treatment. Current sepsis biomarkers, such as interleukin-6, white blood cell count, and C-reactive protein, are non-specific or suffer from a delayed onset of production and slow half-life, making them poorly suitable for guiding treatment decision making. Procalcitonin (PCT), presepsin, and soluble triggering receptor expressed on myeloid cells-1 (sTREM-1) are important new biomarkers with clinical potential to guide treatment. However, even though several studies in critically ill patients have been conducted, the kinetics of these biomarkers are poorly characterized. There is a lack of quantitative understanding of the relationship between infection burden and biomarker kinetics, which is crucial for allowing biomarker guided treatment. To this end, we characterized the kinetics and LPS dose-response of PCT, presepsin, and sTREM-1 in a human endotoxemia model and in an ex vivo incubation experiment.

**Materials/methods:** Ten healthy volunteers received a single dose (1 or 2 ng/kg bodyweight) of LPS. In parallel, blood samples collected prior to LPS injection were incubated with LPS (0.01 – 40 ng/mL). The concentration-time profiles of PCT, presepsin, and sTREM-1 were quantified in plasma samples after the in vivo and ex vivo LPS challenges.

**Results:** The median in vivo C_max for presepsin, sTREM-1, and PCT were 274, 182, and 1500 pg/mL, respectively, with a corresponding T_max of 3, 8, and 9 hours. The median in vivo elimination half-lives for presepsin, sTREM-1, and PCT were 9.13, 39.2, and 139 hours. A dose-response relationship between LPS and presepsin was observed both in vivo (Mann-Whitney-Wilcoxon test, p<0.05) and in the ex vivo incubation experiments (E_max 1373 pg/mL, EC_50 2.82 pg/mL, likelihood ratio test, p<0.05). No dose-response relationship was found for PCT and sTREM-1.

**Conclusions:** This is the first study that quantitatively describes the kinetic and dose-response profiles for novel immune response biomarkers after administration of LPS to healthy volunteers and in ex vivo incubation experiments. The rapid pronounced induction and short half-life of presepsin and its distinct LPS dose-response relationship support further studies of presepsin as biomarker for severe infections and sepsis.

Abstract 1950

Retrospective evaluation of appropriate dosing of cefmetazole for invasive urinary tract infection due to ESBL-producing Escherichia coli

Kayoko Hayakawa1, Yasufumi Matsumura2, Yukihiro Hamada3, Sho Saito1, Maki Nagashima1, Kohei Uemura4, Norio Ohmagari1, Yohei Doi5*,6

1National Center for Global Health and Medicine, Tokyo, Japan, 2Kyoto University Graduate School of Medicine, Kyoto, Japan, 3Tokyo Women’s Medical University Hospital, Tokyo, Japan, 4Tokyo University, Tokyo, Japan, 5University of Pittsburgh School of Medicine, Pittsburgh, USA, 6Fujita Health University School of Medicine, Aichi, Japan

Background: Cefmetazole (CMZ) is active against most ESBL-producing E. coli (ESBLEC) strains. Previous reports suggest it to be a potential candidate for carbapenem-sparing regimen for the treatment of invasive urinary tract infection (iUTI) due to ESBLEC. However, information regarding appropriate dosing is limited.

Materials/methods: We reviewed records of adult patients with iUTI due to ESBLEC who were treated with CMZ > 4 days at two tertiary hospitals in Japan. iUTI was defined as UTI with fever ≥ 37.5°C, or low back/flank/renal pain. Patients who received prior active antibiotic therapy, who were on renal replacement therapy, and who had ESBLEC without known CMZ MICs were excluded. Microbiological efficacy was defined as ≥ 1-log reduction of post-treatment CFU from pre-treatment in the urine. Clinical efficacy was defined as complete resolution or improvement of symptoms compared with the baseline.

Results: Thirty-nine patients were included (Table). CMZ was clinically efficacious in 38 (97.4%) cases. Among 18 cases with available follow-up urine cultures, CMZ was microbiologically efficacious in 16 (88.9%) cases. For cases with CrCl > 60 ml/min, 13 case received CMZ 1g every 8 hours, and CMZ was clinically efficacious in 12 (92.3%) with median time above MIC (TAM) of 93%.

Conclusions: "Three time a day" dosing of CMZ was shown to be effective against majority of iUTI due to ESBLEC.

**Abstract 1952**

**A comparative prospective study for the qualitative detection of Helicobacter pylori specific antigens in stool samples at Sheffield Teaching Hospitals Foundation Trust, England**

Sarah Coleman*, Steve Davies, Helen Carr

1Northern General Hospital, Sheffield Teaching Hospitals Foundation Trust, Sheffield, United Kingdom

**Background:** Helicobacter pylori (H. pylori), a Gram negative spiral shaped bacterium found in the human gastric mucosa of around 25% of people living in the UK, is linked to the development of significant gastrointestinal disease including chronic gastritis, gastric ulcers and gastric malignancy. Successful eradication of H. pylori is shown to significantly reduce the incidence of gastric symptoms including gastric cancers, highlighting the importance of rapid and reliable detection. Current methods employed for the detection of H. pylori include; stool antigen test, urea breath test, culture, histopathology, immunohistochemistry and serological testing. At Sheffield Teaching Hospitals Foundation Trust (STHFT), stool antigen EIA is routinely used as a primary, non-invasive, method of detection. In this small prospective study, we aimed to assess the accuracy and usability of three palette tests through comparison with our current methodology (Amplified IDEIA™ HP Star) as reference.

**Materials/methods:** 250 stool samples received for routine H. pylori testing using Amplified IDEIA™ HP Star were tested in parallel with; RIDA®QUICK Helicobacter, Proflow™ and ImmunoCard STAT!® HpSA® palette tests. Any discrepant results produced were repeated using all four tests. Stool samples were excluded if they were greater than 2 days old, had not been stored at 4-8°C and if there was not sufficient sample to complete all tests plus required repeats.

**Results:** Testing showed RIDA®QUICK Helicobacter to have the highest sensitivity and specificity (98% and 100% respectively pre repeat testing) in comparison to the reference method. All three test kits showed discrepancies when compared against the reference, with PPV and NPV of 97.0% and 99.2% (RIDA®QUICK Helicobacter), 89.5% and 97.2% (Proflow™) and 88.9% and 97.2% (ImmunoCard STAT!® HpSA®). Overall, compared to the reference method, RIDA®QUICK Helicobacter was shown to produce the most comparable results and performed well on repeat testing.

**Conclusions:** RIDA®QUICK Helicobacter was shown to produce the best results in comparison to the reference method. Repeat testing, although initially used for the confirmation of discrepant results, highlighted difficulties in reproducibility for all kits including Amplified IDEIA™ HP Star.

Molecular and clinical characterisation of methicillin-resistant Staphylococcus aureus isolates carrying Panton-Valentine leucocidin in Northern Bavaria, Germany, 2009-2016

Tobias Szumlanski1*, Alexandra Simbeck2, Renate Ziegler3, Stefan Monecke3, Ralf Ehricht3, Thomas Holzmann4, Ralph Bertram4, Wulf Schneider-Brachert2, Jörg Steinmann1

1Klinikum Nürnberg, Institute for Hospital Hygiene, Medical Microbiology and Clinical Infectiology, Nürnberg, Germany, 2University Hospital Regensburg, Department of Infection Control and Infectious Diseases, Regensburg, Germany, 3Leibniz Institute of Photonic Technology e.V., Optisch-Molekulare Diagnostik und Systemtechnologien, Jena, Germany

Background: The spread of community-acquired MRSA carrying Panton-Valentine-leukocidin [PVL] as a distinctive virulence factor has been recognized as a worldwide threat, causing recurring and persistent human infections. The following study investigated the epidemiology as well as clinical characteristics of PVL-positive MRSA-strains in Northern Bavaria, Germany over the course of 8 years.

Materials/methods: 131 PVL-positive MRSA were collected between 2008-2016 from different hospitals in Northern Bavaria, Germany. Identification was performed by MALDI-TOF mass spectrometry, susceptibility testing by VITEK-II or agar diffusion. The presence of mecA and PVL genes was confirmed by PCR, the isolates were then subjected to genotyping by using a DNA microarray (Alere), and assigned to clonal complexes (CC)/sequence types (ST) accordingly. Furthermore, the molecular characteristics of the isolates were correlated to the clinical presentation of the patients.

Results: The predominant strains overall were „ST8-MRSA-[IV+ACME] [PVL+], USA300“ (27/131; 20,6%), followed by „CC30-MRSA-IV (PVL+)“, Southwest Pacific Clone“ (26/131; 19,8%) and „CC80-MRSA-IV (PVL+)“ (25/131; 19,1%). Whereas detection of CC80 followed no clear tendency, the percentage of CC30 per year showed a slight increase. ST8 was declining over the last three years of observation. Other clonal complexes (CC5, CC1, CC722, CC22, CC59, CC88, CC152 and CC93) were detected in smaller numbers. Notably, CC1 (n=7) was not detected before 2015, and clinical data indicate that migration could be a major factor leading to its emergence in this area.

The majority (77.9%) of the collected specimens were skin swabs and swabs taken from surgical sites. In total, 100 cases (76.3%) were causally linked to an infection (mostly skin and soft tissue) in the respective patients, with the department of dermatology ranking first in terms of samples provided (23/131; 17.6%). Resistance rates aside from penicillins fluctuated over the years, being the highest for erythromycin (48/125 tested isolates; 38.4%), levofloxacin (14/47; 29.8 %) and clindamycin (29/125; 23.2%). Resistance against vancomycin, linezolid and mupirocin was not found.

Conclusions: This study demonstrated the molecular epidemiology and variability of clones of PVL-positive MRSA in Northern Bavaria, Germany. Migration, travel and evolutionary factors could lead to further diversification and change in the landscape of PVL-positive MRSA in the region.

Healthy people in Zanzibar are frequently colonised at intestinal level with MDR Enterobacterales identical to those detected in poultry and retailed chicken meat

Thomas Büdel1, Esther Kuenzli2, Odette J Bernasconi1, Edgar Campos-Madueno1, Jakob Zinsstag3, Christoph Hatz2, Andrea Endimiani*1

1University of Bern, Institute for Infectious Diseases, Bern, Switzerland, 2University of Zurich, Department of Public Health, Epidemiology, Biostatistics and Prevention Institute, Zurich, Switzerland, 3University of Basel, Swiss Tropical and Public Health Institute, Basel, Switzerland

Background: Extended-spectrum cephalosporin- (ESC-R) and colistin-resistant (COL-R) Enterobacterales [Ent] can colonize the intestinal tract of people in the community posing an important health issue. This phenomenon can be driven by contamination of the food chain and contact with colonized animals. However, studies analyzing simultaneously human and non-human settings are scarce. Here, we evaluated the prevalence and molecular characteristics of ESC-/COL-R-Ent colonizing healthy people (HP) and poultry (P), as well as contaminating chicken meat (CM) in Zanzibar (Tanzania).

Materials/methods: During June-July 2018, we collected rectal swabs from HP (n=59) and P (n=62), together with retailed CM (n=37). Samples were plated on ChromID ESBL/Carba/Colistin-R. Species ID was achieved using the MALDI-TOF/MS. Strains were characterized with microarray, multiplex PCRs for mcr-1/-8, rep-PCR, and Illumina WGS (Res/PlasmidFinder and MLST).

Results: The prevalence of ESC-R-Ent, COL-R-Ent, and mcr-1-positive E. coli [Ec] were, respectively: 91.5%, 66.1%, 18.6% in HP; 88.7%, 48.4%, 25.8% in P; 43.2%, 18.9%, 18.9% in CM. In total, we collected 124 ESC-R-Ec (3 COL-R), 67 ESC-R-K. pneumoniae [1 COL-R], 41 non-ESC-R but COL-R-Ec, and 38 non-ESC-R but COL-R-K. pneumoniae. The following main resistance mechanisms were found: ESC-R-Ec [CTX-M-15-like, 61.8%; CTX-M-1-like, 21.6%; mcr-1, 2%], ESC-R-K. pneumoniae [CTX-M-9-like, 46.6%; CTX-M-15-like, 29.3%; no mcr-1/-8], 41 non-ESC-R but COL-R-Ec [mcr-1, 80.5%], 38 non-ESC-R but COL-R-K. pneumoniae [no mcr-1/-8]. Several clones of Ec were found in the three settings: ST46 carrying mcr-1 in an IncX4 plasmid (43.5%, HP; 34.8% P; 21.7%, CM) and ST361 possessing CTX-M-15 (46.2%, HP; 15.4%, P; 38.4%, CM). This was also observed for K. pneumoniae: ST17 possessing CTX-M-14/-15 (64.7%, HP; 29.4%, P; 5.9%, CM) and ST1741 harboring CTX-M-15 (50%, HP; 37.5%, P; 12.5%, CM).

Conclusions: Identical clones of ESBL-producing and/or COL-R-Ent were concomitantly detected in the three settings. We therefore speculate that the frequent gut colonization observed in community people might be favored by contamination of the food chain and/or colonization of food animals in direct contact with humans. However, it cannot be excluded that human subjects are actually responsible for the spread of MDR-Ent in the non-human settings. Further studies with a One-Health approach should be planned to investigate this overall phenomenon.

Abstract 1958

Detection of viable microorganisms and molecular Gram categorisation from whole blood in less than 4 hours
Aram Kadoom*1, Daniel Stephen Lockhart1, Helen V. Bennett1, Andrew Rogers1, James Turner1, Yassar Kadoom1, Sonia La Fauci1, Paul Jay1, William Mullen1, Sumi Thaker1

1Momentum Bioscience Ltd, Oxford, United Kingdom

Background: Diagnosis of bloodstream infections (BSI) and successful treatment with appropriate antimicrobials are reliant upon rapid and accurate information about the causative pathogens. The time required for positive blood cultures, subsequent microbial identification and antimicrobial susceptibility testing (AST) can lead to poor antimicrobial stewardship outcomes. A large proportion of antimicrobial change decisions are based on Gram stain results, as these are the first blood results to be available. Results from a rapid direct-from-blood test can confirm BSI and provide Gram information, thus providing a clear advantage in improving patient care, whilst also benefitting antimicrobial stewardship.

Materials/methods: MagRAPID is a molecular test, developed by Momentum Bioscience Ltd, that uses whole blood for the detection and molecular Gram delineation of BSI. The test involves microbial capture by magnetic beads together with Enzymatic Template Generation and Amplification (ETGA®) for ultra-sensitive, universal detection of viable bacterial and fungal species. Simultaneously, molecular testing provides key information about Gram status and genus/species identification of the organism. This assay was used to identify analytical detection limits for a broad panel of microorganisms, comprising 97% of BSI reported to Public Health England (2018 report).

Results: Here we present results demonstrating detection down to 1 cfu/mL of blood, with a time-to-result of less than 4 hours, including a 1.5-hour qPCR. Importanty, the most prevalent microbes associated with sepsis, such as E. coli, S. aureus and S. pyogenes were detected at these low levels.

Conclusions: MagRAPID has been shown to have the performance to detect microbes in low numbers, with a turnaround time substantially faster than traditional blood culture. With the aim of further shortening the time of detection to less than 3 hours, the assay is able to benefit both identification of BSI and antimicrobial selection and stewardship. Future studies in a clinical setting will seek to further demonstrate the efficacy and rapid turnaround time of the assay.

**Candida parapsilosis...not so "candid"! The burden of Candida parapsilosis bloodstream infections and azole-resistance pattern in a tertiary care university hospital**

Cristina Sarda*1;1, Raffaele Bruno1;2, Bianca Mariani3, Alba Muzzi4, Annalisa De Silvestri5, Alessandra Morea1, Caterina Cavanna1, Fabiola Lallitto1, Elena M. Seminari2

1Fondazione I.R.C.C.S. Policlinico San Matteo, Infectious Diseases Department, Pavia, Italy, 2University of Pavia, Department of Medical, Surgical, Diagnostic and Pediatric Science, Pavia, Italy, 3Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Microbiology and Virology, Pavia, Italy, 4Fondazione I.R.C.C.S. Policlinico San Matteo, Hospital Health Direction, Pavia, Italy, 5Fondazione I.R.C.C.S. Policlinico San Matteo, Scientific Direction, Clinical Epidemiology and Biostatistics Unit, Pavia, Italy

**Background:** The rate of Candida spp. bloodstream infections (BSI) remains high, especially in critically ill patients. A recent shift of invasive candidiasis from *C. albicans* to non-*albicans* species was reported worldwide. *C. parapsilosis* has emerged as an important antifungal-resistant pathogen because of its ability to form biofilm and to survive in hospital environment.

**Materials/methods:** A retrospective study of *C. parapsilosis* BSI episodes was carried out from January 1st, 2015 to August 31th, 2019 in a tertiary referral University Hospital, northern Italy. Data regarding clinical characteristics, risk factors and antifungal resistance rate were collected. Molecular and MALDI-TOF analyses have been performed to better identify *C. parapsilosis* subspecies and to evaluate the possible phenotypical correlation between isolates.

**Results:** A total of 77 episodes of *C. parapsilosis* BSI were reported. The isolation rate for *C. parapsilosis* in Intensive care unit (ICU) was greater than that in medical and surgical wards (41.15%, 34/77). The incidence rate ranged to 0.96 to 12.2 cases/10^4 admissions, with a 12-fold increase [p=0.001]. Fluconazole resistance rate was 56% [43/77]. Presence of solid neoplasms, tracheostomy, urinary catheter, *Candida* spp. multifocal colonization, mechanical ventilation and previous 30-day azole therapy were significantly associated with BSI due to resistant *C. parapsilosis*. Molecular and MALDI-TOF analyses classified strains as *C. parapsilosis sensu stricto*. Y132F mutation of ERG11 gene was the major mechanism of azole resistance among 13/14 analyzed strains. In 2018 and 2019, ICU resistant isolates (87.5%, 23/34) were grouped in the same MALDI-TOF cluster, showed a similar resistant profile and belonged to patients recovered during the same period and in nearby beds. Overall 30-day mortality was 25%.

**Conclusions:** Nosocomial transmission of *C. parapsilosis* should be considered in the clinical practice, especially among ICU patients. Patient’s treatment history and periodic evaluation of colonization may predict the development of *C. parapsilosis* BSI in patients at risk. Local epidemiology reports and infection control policies are also fundamental to monitor the incidence trend and the antifungal susceptibility profiles. MALDI-TOF appears to be a reliable technique for the identification of *C. parapsilosis* subspecies and for evaluate the possibility of interstrains relationship during outbreak.

**Abstract 1970**

**The role of Staphylococcus aureus surface protein G (sasG) and its allelic variants in biofilm formation**

Anna Carrera-Salinas*, Aida González Díaz, Daniel Antonio Vázquez-Sánchez, Mariana Adriao Camoez, Jordi Niubó, Sara Martí, Mª Ángeles Domínguez Luzon

1Microbiology Department, Bellvitge University Hospital. IDIBELL-UB, L’Hospitalet de Llobregat, Spain, 2Research Network for Respiratory Diseases (CIBERES), ISCIII, Madrid, Spain, 3Spanish Network for Infectious Diseases (REIPI), ISCIII, Madrid, Spain

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) is one of the most frequent causes of nosocomial infections and may persist for long periods colonizing the host, due to biofilm formation. This study describes the distribution of *S. aureus* surface protein G (*sasG*) and its allelic variants, along with their putative connection with biofilm formation.

**Materials/methods:** 80 MRSA bloodstream isolates representative of the endemic (CC5, CC8, CC22) and sporadic clones (CC1, CC30, CC45, CC72, CC88, CC398) isolated in Spanish hospitals (2000-2015) were studied by DNA-microarray methodology (*S. aureus* Genotyping Kit 2.0, Alere Technologies) to detect *sasG* and its allelic variants (alleles 1 and 2, described in NCTC8325 and MW2 strains, respectively). Biofilm formation was assessed by crystal violet staining. *S. aureus* closed genomes available on NCBI (n=429), were classified in endemic and sporadic clones according the in silico MLST, and analysed to determine the distribution of *sasG*.

**Results:** Regarding the MRSA collection, all the endemic clones carried *sasG*, while only some sporadic clones (CC1, CC72, CC88) presented the gene. Isolates belonging to endemic clones, except CC22, carried allele 1, while sporadic clones, and CC22, carried allele 2. The analysis of *S. aureus* closed genomes confirmed the distribution of *sasG* and its allelic variants by clone, observed in the selected MRSA bloodstream isolates (Table), in spite of being resistant or susceptible to methicillin.

Clones with *sasG* developed stronger biofilms than clones without *sasG* (p-value=0.001 2). Specifically, strains carrying allele 1 formed significantly stronger biofilms than those without *sasG* (p-value=0.0002). Differences in biofilm formation were not statistically significant among strains carrying allele 1 and 2; nevertheless, those with allele 1 tended to produce more biofilm than strains carrying allele 2 (p-value=0.1166).

**Conclusions:** *sasG* is strongly associated with biofilm formation, being more common in endemic than in sporadic clones. Specifically, *sasG* allele 1 has a direct connection with endemic clones and high biofilm formation, while allele 2 is associated with sporadic clones and lower biofilm production.

**Background:** The prevalence of antimicrobial resistance [AMR] is increasing globally not only in pathogenic bacteria causing infections, but also in commensal bacteria. Commensal bacteria, such as *Escherichia coli*, may serve as reservoir for AMR genes in both humans and animals. Antimicrobial resistant *E. coli* strains can be transmitted within or between host species and can disseminate resistance genes via horizontal gene transfer. However, there is a paucity of information regarding whether lineages of *E. coli* are adapted/restricted to certain host or if they have lost such specialization. Furthermore, genomic determinants contributing to either a narrow or a broad host range are unknown.

**Materials/methods:** 1,198 *E. coli* strains from different hosts (cattle, chicken, pig, human and wild-boar, both healthy and diseased) and geographical locations [Germany, Spain, UK, and Vietnam], isolated between 2003 and 2018 were randomly picked from existing strain collections for whole genome-sequencing. The core-genome phylogeny and accessory gene profiles were analysed. The presence of genes enriched in strains isolated from a specific host was determined by bacterial Genome-Wide Association Study (GWAS).

**Results:** The strains are randomly distributed over the core-genome phylogeny as well as on accessory gene profiles but appeared to be partially host-restricted at sub-population level. We identified adaptation of ST131 and ST117 lineages to human and chicken hosts, respectively. Neither the geographical origin of the strains nor AMR genes were associated with either a specific host or phylogenetic lineage. The GWAS resulted in k-mers associated with chicken, human and cattle hosts, but not for pigs. Genes involved in molecular functions such as sialic-acid catabolism, iron acquisition, outer-membrane proteases were found to be associated with these host species.

**Conclusions:** In general, strains were randomly distributed throughout the entire *E. coli* phylogeny, but various phylogenetic clusters were observed which exhibited a significant enrichment of strains from specific hosts. Mapping of k-mers significantly associated with a host to reference genomes showed different gene sets enriched in *E. coli* isolates from different hosts. In silico analysis of gene functions revealed a potential role in adaptation to or colonization of different hosts, which may determine broad or narrow host range adaptation.

Variable anti-Hepatitis B surface titres in vaccinated birth-cohorts: a cross-sectional population based study in northwestern Romania

Alexandru Istrate¹, Amanda-Lelia Radulescu*¹

¹Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: After the introduction of hepatitis B (HB) vaccination in 1995 in newborns, two catch-up campaigns targeted unvaccinated 9 years old children in 1999-2008 [born in 1990-1998] and 18 years old adolescents in 2004-2008 [born in 1986-1990], resulting in 4 unique birth-cohorts [Lexis diagram]. More than expected vaccinated young people have inadequate protection against HB. Our objective was to assess the anti-AgHBs titres in each birth-cohort.

Materials/methods: We included outpatients [78.5%] and hospitalized patients with measured anti-AgHBs titres, the Teaching Hospital of Infectious Diseases in Cluj-Napoca, Romania, during 2014-2018. Exclusion criteria were: repeated examinations, confirmed HB history during the study period and infants. We compared the anti-AgHBs titres in all birth-cohorts using the Lexis surface visualization [titres by age, time period and cohort patterns]. We also evaluated the number of acute cases of hepatitis B in corresponding inpatient birth-cohorts.

Results: Please We included 2968 participants, mean age=31.0 ±14.2, 64.0% women. The birth-cohort [1998-2006], vaccinated at birth (n=330, 3-dose HB vaccine coverage >90%), had significantly lower protective titres [31.2% >10 PEI/L] compared to other birth-cohorts vaccinated at birth: >2006 [67.0%, n=106] or later: [1990-1995] [74.5%, n=941], [1986-1990] [74.8%, n=-481]. In the unvaccinated cohort [few independently vaccinated, n=1105, mean age=45.5 ±12.4] protective titres were found in 44.7%, probably after self-limited HB infection. Concordant results were found using median titres [PEI/L]: [1998-2006] - 3, >2006 - 29.8, [1990-1995] - 53, [1986-1990] - 108, <1986 - 4. Despite low protective levels in the birth-cohort [1998-2006], no acute HB cases were identified in the corresponding inpatient cohort. Only 4 and 35 acute HB cases were found in inpatients corresponding to all the other vaccinated and unvaccinated cohorts, respectively. Data on a few tested infants [n=47, not included in the main study] demonstrated good protection levels: 89.4%.

Conclusions: Please A sub-cohort vaccinated at birth had lower protection against HB with no clear explanation. However, very few cases occurred in vaccinated cohorts, suggesting that the vaccine is capable of sustained immune memory.

Abstract 1980

Rapid identification of uropathogens by combining Alfred 60 system with matrix-assisted laser desorption ionisation-time of flight mass spectrometry technology

Karem Athamna*1, Albira Zbriger1, Maanit Shapira1, Yana Tal2, Sarit Freimann2

1Hillel Yaffe Medical Center, Clinical Microbiology Laboratory, Hadera, Israel, 2Hillel Yaffe Medical Center, Hadera, Israel

Background: Urinary tract infections can lead to life-threatening sepsis. Rapid identification of uropathogens is needed to determine appropriate antimicrobial therapy. This study evaluated performance of the Alfred 60 system combined with matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) technology for rapid identification of uropathogens.

Materials/methods: The Alfred 60 system was used to screen urine cultures, followed by identifying the microbial pathogen in positive cultures using MALDI-TOF MS. The Alfred 60 detected positive cultures by measuring the turbidity of urine samples, which were transferred automatically to vials containing liquid medium and incubated for 3.5 hours at 35°C in the Alfred 60 system. Vials that showed growth were removed and centrifuged. The pellet was subjected to MALDI-TOF MS identification. In parallel, positive urine samples were inoculated onto Agar plates for identification by conventional culture.

Results: The time required to detect positive urine cultures with Alfred 60 and identify the uropathogens with MALDI-TOF MS ranged from 15 minutes to 3.5 hours. Among 146 positive urine samples tested, conventional cultures showed three culture groups. Group 1, 101 samples with growth of a single type of microorganism, group 2 included 34 samples with 2 types of microorganisms, and group 3 included 11 samples with ≥3 types of microorganisms. Direct identification by MALDI-TOF MS was concordant with 95% of the samples in group 1, 100% of the principal microorganism in group 2, but could not identify microorganisms in group 3.

Conclusions: This combination of methods provides rapid, reliable microbial identification for most positive urine cultures.

Abstract 1981

**BacterialTyper: a bioinformatics pipeline for the integrative analysis of bacterial whole genome sequencing**

Jose Sanchez-Herrero¹, Alicia Lacoma*, Bárbara Molina-Moya², Montserrat Gimenez¹, Sònia Molinos³, Cristina Prat², Lauro Sumoy⁴

¹High Throughput Genomics and Bioinformatics Facility, Institut Germans Trias i Pujol, Badalona, Spain, ²Microbiology, Hospital Universitari Germans Trias i Pujol. CIBER Enfermedades Respiratorias, Badalona, Spain, ³Microbiology, Hospital Universitari Germans Trias i Pujol. Institut Germans Trias i Pujol, Badalona, Spain, ⁴High Content Genomics and Bioinformatics Unit, Institut Germans Trias i Pujol, Badalona, Spain

**Background:** Recent advances in bacterial whole genome sequencing (WGS) methodology make it feasible to consider its implementation for deep molecular characterization of isolates in clinical research laboratories and public health agencies. Here we present BacterialTyper, a pipeline for the analysis of bacterial WGS data that integrates and facilitates the interpretation of results generated from multiple software analyses.

**Materials/methods:** The pipeline is written in Python with a modular architecture and based on open-source software and databases engines (Figure 1). Multiple tasks are performed by each of several modules including: preparation of raw data; assembly and annotation; bacterial strain identification; mobile genetic elements identification (plasmids, putative pathogenicity islands or phage insertions regions); generation of a virulence and resistance profile; clustering based on sequence similarity; phylogenetic analysis and integration of metadata. The tool allows the comparison of obtained results with those previously generated (internal database) but it also uses and updates periodically external databases from different sources.

**Results:** We analyzed a set of 22 *Staphylococcus aureus* clinical strains that underwent WGS using Illumina HiSeq4000. We recovered DNA microarray results [Clondiag] reported as presence/absence of a list of genes as well as phenotypic results regarding drug susceptibility testing and virulence factor secretion. We found a high correlation between the tests. Interestingly, we identified novel resistance and virulence genes that could not be detected by previous DNA microarray results. WGS data allowed to more easily and clearly cluster samples according to sequence similarity with high precision and sensitivity, enhancing outbreak analysis capabilities in relation to classical methods. Also, the data generated from the virulence and resistance profiling and the mobile genetic elements analysis enabled a richer interpretation and better inference of clinical implications for each bacterial isolate tested.

**Conclusions:** We report the development of a bioinformatic pipeline capable of processing and identifying bacterial species, identifying resistance and virulence genes, and generating data for outbreak analysis using WGS results from microbial cultures. WGS analysis results agreed with conventional tests used with improved resolution. This encourages the use of this tool to support WGS analysis for clinical diagnostics and outbreak analysis settings.

Spatial and temporal genomic homogeneity among *Haemophilus influenzae* serotype f

Aida González Díaz*1,2, Miguel Pinto3, Meritxell Cubero1,2, Jeroen Langereis4,5, Arie Van Der Ende6, Paula Bajanca-Lavado7, Carmen Ardanuy Tisaire1,2, Sara Martí1,2

1Microbiology Dept. Hospital Universitari Bellvitge, IDIBELL-UB, Barcelona, Spain, 2Research Network for Respiratory Diseases (CIBERES), ISCIII, Madrid, Spain, 3Department of Infectious Disease, National Institute of Health, Lisbon, Portugal, 4Section Pediatric Infectious Diseases, Laboratory of Medical Immunology, Radboud Institute for Molecular Life Sciences, Radboudumc, Nijmegen, Netherlands, 5Radboud Center for Infectious Diseases, Radboudumc, Nijmegen, Netherlands, 6Amsterdam UMC, Department of Medical Microbiology and the Netherlands Reference Laboratory for Bacterial meningitis, Amsterdam, Netherlands

**Background:** *Haemophilus influenzae* is an opportunistic pathogen highly adapted to the human respiratory tract which is often reported as the etiologic agent of infectious diseases. After the introduction of serotype b vaccine, non-typeable *H. influenzae* (NTHi) has become the most frequent cause of respiratory infection, followed in frequency by serotype f strains (Hif). The aim of this study was to analyze the genomic diversity among invasive and colonizing Hif isolates by whole genome sequencing (WGS).

**Materials/methods:** Thirty-seven Hif isolated from Spain (n=16), The Netherlands (n=18) and Portugal (n=3) between 2004 and 2016 were characterized by WGS. A core-based phylogenetic tree was constructed with Parsnp from the Harvest suite, followed by a core and accessory genome analysis with Roary and roProfile. The MLST was determined in silico and single nucleotide analysis was done through Snippy to detect polymorphisms (SNPs) among bacterial genomes. To better understand the phylogenetic diversity in this species, all available genomes on RefSeq were downloaded and included in the analysis.

**Results:** Among 37 *H. influenzae*, four were collected from the oropharynx of healthy children and the remaining were from adult invasive infection. All isolates belonged to ST124 or a single locus variant. Although all strains were closely related, two major clusters were observed in the phylogenetic tree, one of them contained the four colonizer strains. The estimated core genome was 92% and 12,825 core-SNPs were detected. A total of 1,853 genes were predicted, of them, 1,691 were present in more than 95% of the strains. From 732 *H. influenzae* genomes available on NCBI, 8 were Hia, 56 Hib, 4 Hic, 1 Hid, 20 Hie and 9 Hif and the remaining were NTHi. Duplicated NTHi were removed to construct a phylogenetic tree of 347 *H. influenzae* that revealed a very low core genome (21%) compared to the Hif values (92%).

**Conclusions:** In contrast to the high genomic heterogeneity described in NTHi, capsulated Hif strains presented very low variability suggesting genomic stability conferred by the presence of the capsule. No genomic variation was observed among countries or the colonizing strains.

Additional testing and prevalence of Enterobacterales with elevated carbapenem MIC in the Netherlands, 2014-2018

Sjoukje Woudt*, Annelot Schoffelen1, Ascelijn Reuland1,2,3

1Centre for Infectious Disease Control (Cib), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, 2Department of Medical Microbiology, University Medical Centre Utrecht, Utrecht, Netherlands, 3Saltro Diagnostic Centre for Primary Care, Utrecht, Netherlands

Abstract third-party references: ISIS-AR study group

Background: Carbapenem-resistant Enterobacterales (CRE) and carbapenemase-producing Enterobacterales (CPE) have been reported globally. Because carbapenems represent a last-resort drug for treatment of many enterobacterial infections, they pose significant challenges for patient care. Measured prevalence of CRE/CPE is influenced by test procedures and methods, and the Dutch national guideline suggests a gradient test as the first step in further investigation of isolates with automated elevated MIC. We assessed practices of additional testing by Dutch laboratories, and determined the prevalence of Enterobacterales with gradient test confirmed elevated MIC.

Materials/methods: We searched the Dutch surveillance system for antimicrobial resistance (ISIS-AR) for diagnostic and screening E. coli and K. pneumoniae isolates (years 2014-2018). Based on crude automated test values, we categorized them as either having elevated MIC for meropenem (>0.25 mg/L) and/or imipenem (>1 mg/L), as defined by the national guideline ‘Laboratory detection of highly resistant microorganisms’, or not. Subsequently, we searched the ISIS-AR database and the bacteriological typing network (Type-Ned) database for data on additional tests (gradient tests and tests for carbapenemase production and carbapenemase genes). Including one isolate per patient per species and based on data from 28 laboratories, we assessed the percentage of isolates with 1) elevated automated MIC that underwent further testing, and 2) gradient test confirmed elevated MIC, by year.

Results: The use of gradient tests increased between 2014 and 2016 but decreased thereafter, to 73% (E. coli) and 64% (K. pneumoniae) in 2018 (Figure). There was an increase in tests for carbapenemase production (E. coli: 2%-10%, K. pneumoniae: 5%-32%) and carbapenemase genes (E. coli: 1%-7%, K. pneumoniae: 5%-19%) in the past five years. The prevalence of gradient test confirmed strains increased slightly between 2014 and 2018 (E. coli: 0.02%-0.05%, K. pneumoniae: 0.25%-0.52%).

Conclusions: The percentage of isolates with a gradient test performed has not increased further since 2016. This is probably partly compensated by an increase in tests for carbapenemase production or carbapenemase genes in the past five years. Our data show a slight increase in E. coli and K. pneumoniae with gradient test confirmed elevated MIC between 2014 and 2018, which is worrying although it is still low.

Host adaptative changes of *Staphylococcus aureus* through respiratory colonisation and bloodstream infection

Anna Carrera-Salinas*1; Aida González Díaz1,2; Daniel Antonio Vázquez-Sánchez1,3; Ileana P. Salto4; Maria Mrakovcic4; Meritxell Cubero1,2; Mª Ángeles Domínguez Luzon1,3; Silke Niemann4; Sara Marti1,2

1Microbiology Department, Bellvitge University Hospital. IDIBELL-UB, Hospitalet de Llobregat, Spain, 2Research Network for Respiratory Diseases (CIBERES), ISCIII, Madrid, Spain, 3Spanish Network for Infectious Diseases (REIPI), ISCIII, Madrid, Spain, 4Institute of Medical Microbiology, University Hospital of Münster (UKM), Münster, Germany

**Background:** Prolonged persistence of *Staphylococcus aureus* in biofilms or inside the host’s cells may cause adaptative bacterial changes, modifying host interaction. This study aimed to explore differences in biofilm formation and intracellular invasion that may induce a commensal respiratory *S. aureus* strain into progression to cause invasive disease.

**Materials/methods:** The study included *S. aureus* isolated from respiratory colonization episodes that caused a later bacteremia (Hospital Universitari de Bellvitge, 2013-2017). The genetic profiles were compared by PFGE to select persistent strains with the same clonal origin. Lung epithelial cells (A549) were infected to determine *S. aureus* intracellular invasiveness and host cells viability by flow cytometry. Biofilm formation was determined by crystal violet staining. Whole genome sequencing (Illumina MiSeq) was performed to analyze single nucleotide polymorphisms (SNPs) by Snippy.

**Results:** Three patients (P5, P7, P9) presented persistent *S. aureus* isolates in respiratory samples that progressed into a bacteremic episode (Table). The last respiratory and the first bacteremic strains were phenotypically compared. Intracellular invasion analysis revealed that bacteremic strains had significant lower capability to invade A549 cells in comparison with the respiratory isolates. Regarding the viability of A549 cells and biofilm formation, only strains from patient 9 showed significant differences among isolates: the respiratory strain caused higher cell mortality and weaker biofilm formation than the bacteremic strain. Genetic changes were observed between respiratory and bacteremic strains. A few SNPs and open reading frame (ORF) modifications were found (Table), such as the alteration of fibronectin-binding protein in patient 5.

**Conclusions:** *S. aureus* persist intracellularly or within biofilms for long-periods of time. Despite the host’s condition, some phenotypic changes occur, which may lead to facilitate the entrance of the microorganism into the bloodstream.

Abstract 1986

Testing EEG-LORETA and CSF Biomarkers in patients with HIV-associated neurocognitive disorders
Alessandro Lazzaro1, Veronica Pirriatore1, Giacomo Stroffolini1, Ambra Barco*, Giuseppe Noce2, Daniela Vai3, Giovanni Di Perri1, Stefano Bonora1, Andrea Calcagno1

1Hospital Amedeo di Savoia, Unit of Infectious Diseases, Torino, Italy, 2Sapienza University of Rome, Department of Physiology and Pharmacology “V. Erspamer”, Roma, Italy, 3Maria Vittoria Hospital, Unit of Neurology, Torino, Italy

Background: HIV-associated neurocognitive disorders (HAND) are diagnosed in people living with HIV (PLWH) successfully treated with antiretroviral therapy. Brain function can be probed estimating cortical sources of resting state EEG (rsEEG) rhythms. Our aim was to test whether rsEEG markers are related to specific cognitive domains and cerebrospinal fluid (CSF) biomarkers in a novel cohort of HIV-positive patients with HAND.

Materials/methods: Patients diagnosed with HAND according to the Frascati’s criteria, without significant comorbidities and with plasma HIV RNA < 50 copies/mL were enrolled. Statistical analysis compared rsEEG (LORETA freeware) source estimates with scores of 10 neuropsychological tests and CSF biomarkers including tTau, pTau, βAmyloid42, neopterin, S100β [thresholds validated in HIV-negative subjects]. Data are described with median values (IQR) and analysed through non-parametric tests.

Results: 42 patients were included: 31 (73,8%) were male, with median age and BMI of 56,3 years (48-63.2) and 24.48 Kg/m² (22.17-24.82), respectively. Current and nadir CD4+ cell count were 724 (496-863) and 299 (152-441) cells/µL; 12.3 (4-14) years of virological suppression were recorded. All but five patients (11.9%, MND) were diagnosed with ANI. Abnormal tTau, pTau, βAmyloid42, neopterin and S100β were observed in 7.1%, 14.3%, 11.9%, 16.6% and 7.1% individuals, respectively.

Occipital delta source activity (< 4 Hz) and parietal delta source activity (< 4 Hz) were associated with longer executive functions (Trail making B and AB test) (p values <0.05, rho >0.5).

Parietal delta source activity (< 4 Hz) and alpha3 source activity (10-12 Hz) were strongly associated with CSF neopterin (p values <0.05), with an opposite trend: neopterin directly correlated with delta source activity (rho 0.544) while inversely correlated with alpha3 source activity (rho -0.405).

Conclusions: rsEEG source activity at delta and alpha rhythms may reflect brain dysfunction in HIV patients with HAND and were specifically related to altered executive functions. The association of rising neopterin CSF levels with a parallel rise in delta activity and a decay in alpha activity, in both occipital and parietal areas, might reflect an impairment of cortical activity, suggesting that electrical cortical activity registration could be used to assume CSF alteration. Further studies are needed to assess neurotoxicity and ageing among PLWH.

Abstract 1987

**Seroepidemiology of Helicobacter pylori infection in different regions of Croatia: new perspective after 20 years**

Dijana Varda Brkić, Miroslava Katičić, Lidija Zele-Starcevic, Natasa Beader, Vesna Tripkovic, Branka Bedenic, Ivana Mareković

1University Hospital Centre Zagreb, Dpt of Clinical and Molecular Microbiology, Zagreb, Croatia, 2School of Medicine, University of Zagreb, Zagreb, Croatia, 3University Hospital Centre Zagreb, Zagreb, Croatia

**Background:** The aim of the study was to analyze the seroprevalence of *Helicobacter pylori* infection in four different Croatian regions. The last time the data about seroprevalence in different Croatian regions were published, was in 1997 and 1998 by other Croatian authors. Therefore, the goal was also to compare our results with those published 20 years ago.

**Materials/methods:** The sera were collected in the period from 2015 to 2017 from the patients without the symptoms of peptic or other chronic diseases in four different Croatian regions - central, north-adriatic, south-adriatic and eastern Croatia. Informed consent with demographic data was completed for each patient. The sera were tested for specific IgG antibodies by ELISA method.

**Results:** A total of 306 patients, 142 (46.4%) male and 164 female (53.6%), were analyzed. The age range was 20-89 years and the mean age was 49.9. *H. pylori* IgG was detected in 141 (46.7%) patients, out of which 73 (51.8%) were male and 86 (48.2%) female. The highest prevalence (70.0%) was found in the age group of 60-69 years and the lowest (16.0%) in the age group of 20-29 years. Seroprevalence according to the geographic region was as follows: central (54/138, 39.0%), north-adriatic (20/40, 50.0%), south-adriatic (28/68, 41.1%) and eastern Croatia (39/60, 65.0%).

**Conclusions:** Overall seroprevalence of *H. pylori* infection in Croatia decreased in the last 20 years from 60.0 – 68.0% to 46.0% which is in concordance with the decreasing trend in recent decades worldwide. This change is also characteristic for the transition from a developing to a developed country.

The seroprevalence of *H. pylori* infection varied among studied geographic areas of Croatia and is higher in eastern region. In comparison to data 20 years ago, the seroprevalence in central and south-adriatic region decreased from 58.4% to 39.0% and from 66.0% to 41.1%, respectively. Regarding the seroprevalence in north-adriatic and eastern Croatia, our study is the first one analyzing the seroprevalence in these two regions so far. Further investigation is needed that will include larger population from different regions of Croatia.

Optimisation of a series of salicylamide derivatives of niclosamide as potent antiviral agents against human adenovirus

Jimin Xu¹, Judith Berastegui-Cabrera², Haiying Chen¹, Jeronimo Pachon-Diaz², Jia Zhou¹, Javier Sánchez Céspedes*²

¹The University of Texas Medical Branch at Galveston, Galveston, United States, ²Instituto de Biomedicina de Sevilla, Sevilla, Spain

Background: The effective treatment of human adenovirus (HAdV) infections in immunocompromised patients still poses great challenges. Despite the significant clinical impact, there remains no specifically approved antiviral therapy for HAdV infection to date. Accumulated studies indicated that niclosamide, an FDA-approved anthelminthic drug used in humans to treat tapeworm infections, can modulate multiple signaling pathways and biological processes and it has great antiviral potential against various viruses, including HAdV, Zika virus, Ebola Virus, or influenza. Herein, we reported the optimization of a series of salicylamide derivatives of niclosamide as potent inhibitors of HAdV infection.

Materials/methods: The anti-HAdV activity of 54 niclosamide analogues has been evaluated in vitro. Inhibition of HAdV infection was evaluated by plaque assay. The cytotoxicity (CC₅₀) of compounds which showed significant HAdV inhibition was measured using the AlamarBlue Kit (Invitrogen). The effect of the selected compounds on HAdV genome accessibility to the nucleus was evaluated by qPCR and their effect on the virus yield was evaluated in a burst assay.

Results: Nine out of the 54 derivatives showed IC₅₀ values at sub-micromolar concentrations, ranging from 0.05 to 0.68 µM, and with CC₅₀ values ranging from 10.9 to 200 µM. They showed yield reductions of the HAdV progeny ranging from 1.8 to 989-fold. As for their mechanism of action, our results showed that compounds 1, 3, 62 and 70 exerted their activities in the HAdV entry pathway, while compounds 11, 17, 20 and 58 inhibited later steps after DNA replication. With regard to compounds 14 and 60, they seem to be targeting the HAdV DNA replication process.

Conclusions: The niclosamide derivatives evaluated here have great potential for the development of new anti-HAdV drugs. In addition, considering the broad antiviral activities of niclosamide, these salicylamide derivatives could be repurposed to treat other viral infections, including influenza, Zika, or Ebola virus, among others. The next step in the development of these new antiviral drugs will be the in vivo evaluation of their efficacy and safety in the animal model of infection of the immunosuppressed Syrian hamster.

### Abstract 1993

**Characterisation of differences in infectious disease events between first liver transplantation and re-transplantation in the STCS**

Peter W. Schreiber*1, Katharina Kusejko¹, Dionysios Neofytos¹, Hans H. Hirsch³, Pascal Meylan⁴, Oriol Manuel⁵, Katia Boggian⁶, Cédric Hirzel⁶, Christian Garzoni⁶, Roger Kouyos¹, Nicolas Mueller¹, Swiss Transplant Cohort Study⁷

¹University Hospital of Zürich, Division of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland, ²Hôpitaux Universitaires de Genève (HUG), Division of Infectious Diseases, Genève, Switzerland, ³University Hospital of Basel, Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, ⁴Lausanne University Hospital, Infectious Diseases Service, Lausanne, Switzerland, ⁵Kantonsspital St. Gallen, Division of Infectious Diseases and Hospital Epidemiology, St. Gallen, Switzerland, ⁶Inselspital, Division of Infectious Diseases and Hospital Epidemiology, Bern, Switzerland, ⁷University Hospital of Basel, Data Center of Swiss Transplant Cohort Study, Basel, Switzerland

**Background:** Re-transplantation after graft failure has become a valuable option, but graft survival, patient survival and quality of life is decreased after liver re-transplantation. Data describing the role of infectious disease (ID) events on this worse outcome is scarce. We analyzed ID events after first liver transplantation and re-transplantation in the Swiss Transplant Cohort Study (STCS).

**Materials/methods:** All liver transplant recipients that experienced a liver re-transplantation were included. We required at least 30 days between the transplantations and follow-up after re-transplantation. Symptomatic bacterial, viral or fungal infections and probable infections (suspected infections prompting empiric antimicrobial treatment without pathogen identification) were included. We performed a survival analysis to compare the time to the first infection after first transplantation and re-transplantation and a Poisson regression to test whether the number of ID events after the first transplantation is predictive of the number of ID events after the re-transplantation.

**Results:** 29 patients were included (male: 69%, median age at first transplantation: 56). The most common underlying diseases resulting in first transplant were viral hepatitis (14, 29.2%), malignancies (9, 18.8%) and chemical cirrhosis (5, 10.4%). Median time between first and re-transplantation was 1.4 years [range: [0.1, 7.2]]. The 29 patients had 255 ID events, 132 (51.8%) after the first and 123 (48.2%) after re-transplantation (Figure). Bacterial infections were most prevalent (159, 62.4%) with enterococci, *Escherichia coli* and *Klebsiella* spp being most common, viral (24, 9.4%) and fungal infections (20, 7.8%) were less frequent. The median time to first infection was 33 days after the first transplantation and 60 days after re-transplantation (hazard ratio = 0.68, confidence interval: [0.36, 1.3]). The number of infections in the first 30 days after the first transplantation was predictive of the number of infections in the first 30 days after re-transplantation (p=0.0005).

**Conclusions:** On the patient-level, ID events after first transplantation were predictive of ID events after liver re-transplantation. Overall, a comparable number of infections were observed after first liver transplantation and re-transplantation. The time period until the first incident infection was slightly, albeit not significant, longer after re-transplantation. Hence, in this cohort, infections did not contribute to the reported worse outcome after re-transplantation.

**Infecions after 1st liver transplantation and re-transplantation**

Prevalence, correlates and outcomes of plasma cryptococcal antigen postivity among HIV-infected patients with a CD4+ T-cell count under 100/mm3, diagnosed in Spain

María Asunción Pérez-Jacoiste Asín1, Otilia Bisbal1, Jose Antonio Iribarren Loyarte2, Santiago Moreno Guillén3, Rafael Rubio1

1University Hospital 12 de Octubre, Madrid, Spain, 2Hospital Universitaria Donostia, San Sebastián-Donostia, Spain, 3Hospital Ramón y Cajal, Madrid, Spain

Background: Cryptococcal meningitis (CM) is a major cause of AIDS-related mortality. WHO recommends routinely screening HIV-infected patients with CD4+-count<100/mm3 for cryptococcal infection, to prevent CM among infected. This recommendation is based on studies in regions where the prevalence of positive cryptococcal-antigen (CrAg) is ≥3%, mainly Sub-Saharan Africa. There are no available data about such prevalence in Spain and Spanish AIDS-Study Group (GESIDA) guidelines do not recommend routinely screening. Our objective is to determine the prevalence of cryptococcal infection in HIV-infected patients with CD4+-count≤100/mm3 diagnosed in Spain, through detection of CrAg in plasma.

Materials/methods: We determined CrAg using lateral-flow-assay (CryptoPS, Biosynex, France) in stored plasma samples from participants in the Cohort of Spanish AIDS-Research Network, a multicenter-prospective cohort of HIV-seropositive patients diagnosed in Spain, >18 years-old and naïve to antiretroviral treatment when included. Eligible patients were those with CD4+-count ≤100/mm3 when plasma sample was collected, with a follow-up>4 weeks, unless death.

Results: 576 patients fulfilled the inclusion criteria and had available stored plasma, from June 2004 to December 2017. The overall prevalence of CrAg-positivity (CrAg+) was 7.5% [CI95% 5.35%-9.65%]. There were no differences in prevalence depending on birthplace: Spain 7.4%, other European countries 5.9%, Latin-America 6.8%, sub-Saharan Africa 9.8% (p=0.951). When comparing the group with CrAg+ with those with CrAg-negativity (CrAg-), there were no differences by age, education level, CD4-/mm3-count and HIV-viral load. CrAg+ was more common among injecting-drug users than those with sexually-transmitted HIV (17.9% vs 5.7%, p=0.003). Those with CrAg+ had a reduced survival compared to those with CrAg- (Figure). CM was reported in 10 of the 43 cases with CrAg+ (23.25%), in five when plasma-sample was collected and in the remaining during follow-up, after a median-time of 35 days [0.1-0.3=11.5-60.5].

Conclusions: The prevalence of CrAg+ in HIV-infected patients with CD4+-count≤100/mm3 diagnosed in Spain, including those born in Spain, is >7%. There are no identifiable factors associated with CrAg+, apart from injected-drug use. According to these results, it seems necessary to update GESIDA-guidelines and recommend routinely screening cryptococcal infection in this group of patients in Spain. Future studies should explore if this recommendation could apply to other European countries.

Abstract 1995

Evaluation of a fully automated prototype version of the BD Kiestra ID/AST system

James Snyder1, Gina Thomson2, Kira Jamros2, Stacy Heckman2, Sameh Abdelghani2,4, Kenneth Thomson*3

1University of Louisville, Louisville, United States, 2University of Louisville Hospital, Louisville, United States, 3University of Lou-
isville, Louisville, United States, 4Beni-Suef University, Beni-Suef, Egypt

Abstract third-party references: BD Diagnostics

Background: The BD Kiestra™ TLA automates specimen processing, plate streaking, incubation and digital visualization of cul-
tures prior to a technologist initiating manual or semi-automated identification and antibiotic susceptibility (AST) procedures [current system]. This study aimed to compare the performance of the current system to that of a fully automated research use only prototype BD Kiestra™ IdentifA/SusceptA [automated system] in a clinical setting.

Materials/methods: Five hundred twenty three isolates from culture-positive de-identified, remnant/left-over urines, lower respiratory tract specimens, wounds, abscesses, blood cultures and miscellaneous specimens were processed for microbiological identifications and AST by both systems. Colonies were selected manually [current system] and from digital images [automated system] for Bruker MALDI-TOF (MALDI) identification and BD Phoenix™ AST system. The current system required separate inocula for identification and AST. The automated system used an onboard automated colony picker to prepare a single inoculum suspension for identification and AST. Results were extracted from BD EpiCenter™ and evaluated to determine agreement between the systems. Tests were repeated if MALDI scores were below 1.7 or identifications differed or if categorical differences existed in susceptibility results.

Results: On initial testing 89.0% and 92.4% of identifications yielded acceptable MALDI log scores ≥ 1.7 for the automated and current identification systems respectively. Problems encountered included rare instances of inaccurate automated MALDI target spotting, and difficulties in handling mucoid and Streptococcus isolates. By managing these issues on repeat testing, the respective acceptable MALDI scores were 97.1% and 98.1%. On initial testing, the automated and current systems yielded 97.5% categorical agreement for 7,325 drug-organism tests. After omitting discrepant MICs that differed by only one dilution and categorical discrepancies that were not reproducible, 0.2% unresolved discrepancies remained thus yielding 99.8% categorical agreement.

Conclusions: The high agreement between the systems indicated that the automated prototype offers potential for develop-
ment into an accurate, fully automated ID/AST system which could be integrated with BD Kiestra™ TLA. This walkaway system could optimize workflow and offer benefits such as reduced hands-on time and associated cost savings, improved efficiency, improved ergonomics and better standardization.

* Components of system are under development and not for sale or use.

Abstract 1996

**New polysaccharide capsule identification in urogenital *Haemophilus parainfluenzae* related to capsular locus present in *Haemophilus* spp.**

Aida González Díaz*1,2, Yanik Sierra Urueña1, Fe Tubau1,2, Josefina Ayats1, Meritxell Cubero1,2, Carmen Ardanuy Tisaire1,2, Sara Marti1,2

1Microbiology Dept. Hospital Universitari Bellvitge. IDIBELL-UB, Barcelona, Spain, 2Research Network for Respiratory Diseases (CIBERES), Madrid, Spain

**Background:** *Haemophilus parainfluenzae* is part of the human oropharyngeal and genitourinary microbiota. This bacterium is increasingly recognized as an opportunistic pathogen causing invasive, chronic or recurrent diseases frequently associated with antibiotic resistance. The polysaccharide capsule is one of the most important virulence factors and has been used for vaccine development in important pathogens, including the *Haemophilus influenzae* serotype b

**Materials/methods:** The detection of the capsular gene *bexA* was done by PCR in 154 *H. parainfluenzae* strains isolated in Hospital de Bellvitge from urogenital samples between 2013 and 2017. Whole genome sequencing (WGS) was performed in *bexA* positive samples. All *Haemophilus* spp. genomes available on NCBI were downloaded for *in silico* detection of capsular operon using hicap. The *bexA* positive *H. parainfluenzae* were compared to the *Haemophilus* spp. capsular operons. The visualization of the new capsular operon was done by Transmission electron microscopy (TEM).

**Results:** Nine different capsular operons were found within the *Haemophilus* spp; the six well known types [a-f] of *H. influenzae*, two types in *H. sputorum* [HSBU-type 1 and 2] and one type in *H. haemolyticus* [HHAE-type 1]. In the *H. parainfluenzae* collection, a total of 18 urogenital isolates were *bexA* positives. After WGS, 17 *bexA* positive isolates presented a capsular operon close to *H. influenzae* serotype c [HPAR-type 1] and one similar to *H. sputorum* type 2 [HPAR-type 2]. One HPAR-type 1 presented one specific gene truncated by the insertion of a transposase. To visualize the presence of the polysaccharide capsule, one representative HPAR-type 1, one *H. influenzae* serotype b [positive control] and one *H. parainfluenzae bexA* negative [negative control] were analyzed by TEM. The cellular visualization revealed that the non-encapsulated *H. parainfluenzae* was surrounded by a defined bacterial cell membrane, which was significantly thinner than that of the encapsulated *H. influenzae* serotype b and *H. parainfluenzae* HPAR-type 1.

**Conclusions:** This study identified the presence of capsular operon in urogenital *H. parainfluenzae*. Since the capsule is a relevant virulence factor, the presence of capsulated *H. parainfluenzae* isolates among urogenital samples highlights its putative role as cause of sexually transmitted diseases. Nevertheless, further surveillance studies should be considered.

Abstract 2000

Report of the national reference centre for multidrug-resistant Gram-negative bacteria on carbapenemases in Germany in 2019

Niels Pfennigwerth*1, Jennifer Schauer1, Martina Cremanns1, Jörg B. Hans1, Agnes Anders1, Sören G. Gatermann1

1Ruhr-Universität Bochum, Department of Medical Microbiology, Bochum, Germany

Background: Multidrug-resistance in Enterobacterales, Pseudomonas aeruginosa and Acinetobacter baumannii is of utmost therapeutic importance since hardly any innovative antimicrobial drug against gramnegative bacteria will be introduced into clinical practice within the next years. Among all resistance mechanisms the worldwide spread of carbapenemases is the most worrisome development. However, the correct identification of carbapenemases is still challenging for the microbiological laboratory.

Materials/methods: The National Reference Centre for Multidrug-Resistant Gramnegative Bacteria offers the free service of carbapenemase detection in bacterial isolates with elevated carbapenem MICs. All isolates are tested by a wide array of phenotypic and molecular methods. A bioassay based on cell-free extracts and WGS methods allow the detection of still unknown \(\beta\)-lactamases.

Results: A total of 5993 isolates were investigated for carbapenemases in the National Reference Centre in 2019 until November 6th. Carbapenemases were found in 1724 Enterobacterales strains, 428 of A. baumannii and 325 of P. aeruginosa. The most frequent carbapenemases in Enterobacterales were OXA-48 \(n = 468\), VIM1 \(n = 292\), KPC-2 \(n = 184\), NDM1 \(n = 163\), OXA-244 \(n = 135\), NDM5 \(n = 134\), OXA-181 \(n = 67\) and KPC-3 \(n = 62\). OXA-162, OXA-232, VIM-4, GIM-1 and others were found in less 30 isolates each. In P. aeruginosa, VIM-2 was the most frequent carbapenemase \(n = 228\), followed by GIM-1 \(n = 20\), GES-5 \(n = 12\), VIM-1 \(n = 11\) and VIM-4 \(n = 10\). IMP-13, IMP-7, NDM-1 and others were found in less than 10 isolates each. OXA-23 was the most frequent carbapenemase in A. baumannii \(n = 287\), followed by OXA-72 \(n = 92\) and NDM-1 \(n = 25\). GIM-1, OXA-143, OXA-58 and others were found in less than 10 isolates each.

Conclusions: A variety of different carbapenemases is detected in Germany. The molecular epidemiology in Germany differs significantly from observations made in other countries like Greece, Italy or the USA with a predominance of OXA-48. Compared to previous years, variants of OXA-48, especially OXA-244, are again on the rise.

Presenter email address: niels.pfennigwerth@rub.de
**Abstract 2001**

**Streptococcus pneumoniae: an uncommon possible cause of male urethritis?**

Francesca Menotti1, Sara Comini1, Cristina Crocillà1, Rosaria Sparti1, Giuseppina Amarù2, Carmela Solimine2, Anna Maria Cuffini1, Valeria Allizond1, Giuliana Banche*1

1University of Torino, Turin, Italy, 2Infermi Hospital, Rivoli, Italy

**Background:** Streptococcus pneumoniae is not a common agent of urinary tract infections (UTIs); indeed, literature data about its isolation in genitourinary samples of both adults and children are limited. In this study, we report cases of S. pneumoniae isolated from male urethral samples

**Materials/methods:** From June 2018 to October 2019, a total of 408 urethral swabs, transferred to the ASL-TO3 Microbiology Laboratory of the Infermi Hospital (Rivoli, Turin, Italy), was examined for suspected urethritis. Specimens were analyzed for the presence of opportunistic bacteria, fungi, Mycoplasma spp and Trichomonas spp with cultural examination and for Chlamydia trachomatis and gonococci by strand displacement amplification. All the isolates were tested for antimicrobial susceptibilities to many widely used antibiotics. Resistant ones were confirmed by manual susceptibility testing

**Results:** 42.7% of male patients was microbiologically positive: in details, bacteria or fungi were isolated in pure culture in 87.5% of samples, whereas the remaining 12.5% was characterised by coinfections. Remarkably, S. pneumoniae was detected in 10.83% of men with symptoms of urethritis. Examination of their urethral specimens revealed the presence of Gram-positive cocci, confirmed as S. pneumoniae. In three patients microscopy and cultural analysis highlighted a polymicrobial infection caused by S. pneumoniae with Staphylococcus haemolyticus, or Streptococcus agalactiae, or Ureaplasma urealyticum, respectively. The majority of analyzed S. pneumoniae was resistant to erythromycin and clindamycin. In some isolates, further resistance was noted; in particular, one case presented multi-resistance to different classes of antibiotics

**Conclusions:** This study described an unusual high number of male urethritis cases caused by S. pneumoniae in a relatively short period (16 months) in an enclosed area (ASL-TO3), confirmed by its isolation in pure culture in the majority of cases. As pneumococci are commensal of the upper respiratory tract, orogenital sexual contact has been suggested to be responsible for their direct inoculation in the male urethral mucosa. With the increase in sexually transmitted diseases and variable human sexual behaviors, the significance of S. pneumoniae as a sexually transmitted pathogen should be more considered and it would be useful to look for S. pneumoniae during routine screening for UTIs

**Presenter email address:** giuliana.banche@unito.it
Whole genome analysis of non-PCV13 emergent serotypes 8, 12F, 9N and 22F causing invasive pneumococcal disease in Spain

Aida González Díaz*1,2, Jordi Càmara1,2, Maria Ercibengoa Arana2,3, Emilia Cercentad2,4, Nieves Larrosa1, María Dolores Quesada6, Dionisia Fontals2, Meritxell Cubero1,2, Jose Maria Marimon Ortiz De Zarate2,3, Jose Yuste2,8, Carmen Ardanuy Tisaire9,10

1Microbiology Dept. Hospital Universitari Bellvitge. IDIBELL-UB, Barcelona, Spain, 2Research Network for Respiratory Diseases [CIBERES], ISCIII, Madrid, Spain, 3Microbiology Dept. Biodonostia, Infectious Diseases Area, Respiratory Infection and Antimicrobial Resistance Group; Osasائدetza Basque Health Service, Donostiaide Integrated Health Organisation, San Sebastian, Spain, 4Microbiology Dept. Hospital General Universitario Gregorio Marañón, Madrid, Spain, 5Microbiology Dept. Hospital Universitari Vall d’Hebrón, Barcelona, Spain, 6Microbiology Dept. Clinical Laboratory North Metropolitan Area, Hospital Universitari Germans Trias i Pujol, UAB, Barcelona, Spain, 7Microbiology Dept. Corporació Sanitària Parc Taulí, IU-UAB, Barcelona, Spain, 8Pneumococcal Reference Laboratory, Centro Nacional de Referencia, ISCIII, Madrid, Spain, 9Pathology and Experimental Therapeutics Dept. School of Medicine, University of Barcelona, Barcelona, Spain

Background: Invasive pneumococcal disease (IPD) is a major cause of morbidity and mortality. Although conjugated vaccines (PCVs) are highly effective preventing the serotype associated disease, their introduction changed the epidemiology of IPD mainly due to serotype replacement.

Materials/methods: Invasive episodes in adults from three periods 2008-2009 (pre-PCV13), 2012-2013 (early-PCV13) and 2015-2016 (late-PCV13) were collected from 6 Spanish hospitals. After serotyped (Quellung) and genotyped (PFGE and/or MLST), 10 representative strains of major clonal complexes (CC) of emergent non-PCV13 serotypes [S] (S8-CC53, S8-CC404, S12F-CC989, S9N-CC67 and S22F-CC433) were selected for WGS analysis (n=50).

Results: A total of 2187 IPD episodes were collected (949, 609 and 639, respectively). In the last period the most frequent non-PCV13 serotypes were S8 (n=92, 15.6%), S12F (n=48, 7.8%), S9N (n=33, 5.4%) and S22F (n=25, 4.1%). Within CC, the WGS analysis showed an identical capsular operon. Among S8, the operon was almost identical (identity >99%) in the two major CC. Acquired resistance genes were only found among S12F-CC989: six isolates had cat (pC194) and seven isolates presented a Tn916-like transposon carrying tet(M). No amino acids changes were observed among resistance-associated determinants (PBPs, ParC, ParE, GyrA and DHFR) with the exception of one S12F strain presenting T338A in PBP2X and another S12F with I100L in DHFR. Pan-genome analysis revealed a total of 3,022 genes, of them 1,537 were present in all genomes (core-genomes). Among accessory genome, 21 genes were only present in S8-CC53, 21 in S8-CC404, 50 in S12F-CC989, 62 in S9N-CC67 and 51 in S22F-CC433. The zinc metalloprotease C (ZmpC) was found only in S8-CC53 whereas neuraminidase B (NanB) was absent only in S8-CC404. Within clonal complexes, the core-genome accounted for 54% of genome for S8-CC53 and S8-CC404; and 87% for S12F-CC989, S22F-CC433 and S9N-CC67. In addition, the core-genome of S9N-CC67 had the highest number of SNPs (2449 SNPs).

Conclusions: Emerging CC linked to non-PCV13 serotypes balanced the previous decline of IPD in adults. In general these CC were genetically highly homogenous, a hallmark of highly invasive clones. The highest diversity CC was S9N-CC67 and the presence of acquired resistance was only seen in S12F-CC989.

In vitro efficacy of miltefosine on chronic cutaneous leishmaniasis compared to meglumine antimoniate

Varol Tunali*1,2, Ibrahim Cavus3, Ahmet Yıldırım3, Orcun Zorbozan2, Mehmet Harman4, Cumhur Gündüz5, Ahmet Özbilgin3, Nevin Turgay2

1Mugla Sıtkı Koçman University Medical Faculty Emergency Department, Muğla, Turkey, 2Ege University Medical Faculty Department of Parasitology, İzmir, Turkey, 3Manisa Celal Bayar University Medical Faculty Department of Parasitology, Manisa, Turkey, 4Dicle University Medical Faculty Dermatology Department, Diyarbakır, Turkey, 5Ege University Medical Faculty Department of Medical Biology, İzmir, Turkey

Background: Cutaneous Leishmaniasis (CL) is the most common form of leishmaniasis. CL can be divided into two major groups: acute CL (ACL) and chronic CL (CCL). CL lesions are called CCL if they do not heal by treatment or spontaneously within 2 years. The aim of this study is to compare the efficacy of miltefosin and pentavalent antimony compounds in vitro with the CCL patient samples.

Materials/methods: Five isolates previously isolated from 5 CCL patients were included in this study. Following genotyping, in vitro drug efficacy tests were applied to these five isolates to determine their activity against meglumine antimoniate (MA) and miltefosine. Serial dilutions (512, 256, 128, 64, 32, 16, 8 and 4 µg/ml) prepared from MA and miltefosine were prepared in 96-well flat-bottom cell culture plates with 100 µL leishmania culture (RPMI 1640; 15% FCS and 1x10^6 promastigotes/ml) in every well and incubated at 24 °C for 48 hours. The efficacy of the drug on leishmania promastigotes after 24 and 48 hours was evaluated by counting with the hemocytometer slide and XTT cell viability test.

Results: All of the samples were genotyped as L. tropica. In the first 24 hours, 128 µg/ml and 256 µg/ml concentrations of miltefosine and MA were enough to kill all the promastigotes respectively. After 48 hours, 32 µg/ml and 64 µg/ml of miltefosine and MA were enough to kill all the parasites respectively. The results of hemositometer slide and XTT were consistent.

Conclusions: There are no studies investigating the in vitro efficacy of miltefosine with the CCL patient group. In order to overcome the treatment challenges experienced in this special patient group, more studies are needed. According to our results, it is concluded that miltefosine is an efficient treatment option for the treatment of CCL and further clinical studies with miltefosine will reveal valuable data.

Abstract 2005

Single-shot azithromycin in treatment of Legionella pneumophila: 18-year experience at the Vienna General Hospital, Austria

Matthias Karer*1,2, Manuel Kussmann1, Markus Obermüller1, Heinz Burgmann1, Heimo Lagler1

1Medical University of Vienna, Division of Infectious Diseases and Tropical Medicine, Wien, Austria, 2Medical University of Vienna, Department of Clinical Pharmacology, Wien, Austria

Background: Pneumonia caused by the intracellular atypical pathogen Legionella (L.) pneumophila remains a life-threatening infection despite fast point of care diagnostic tools and specific antimicrobial treatment with mainly fluoroquinolones or macrolides. The overall mortality in Europe in 2015 was 8.1%, according to the data of the European Centre of Disease Prevention and Control (ECDC).

A recent study by Garcia-Vidal et al. (2017) demonstrated an equal efficiency of levofloxacin, clarithromycin and azithromycin when treated for a median of 3-5 days intravenously. Given concerns regarding adverse effects of fluoroquinolones, low bioavailability of oral macrolides and the costs of long hospital stays we demonstrate a feasible treatment option of Legionnaires’ disease with an intravenous single-shot of 1500mg azithromycin (diluted in 1000mL Ringer’s lactated solution; duration of infusion: 4 hours).

Materials/methods: In this single-centre retrospective analysis at the Vienna General Hospital 74 patients with L. pneumophila infections, confirmed by urinary antigen test and/or serology and/or PCR from respiratory tract specimens were included between 2000 and 2018.

Results: Five patients (6.8%) died during the observation period due to sepsis and/or multi-organ failure. These five patients either received a combination therapy with fluoroquinolones and macrolides or fluoroquinolones alone. Twelve patients (16%) only received a single-shot of 1500mg azithromycin without any additional L. pneumophila active therapy.

Neither adverse events, nor treatment failures were observed in those patients treated with azithromycin single-shot. The median hospital stay was 6.5 days [Q1-Q3: 5-8] in the single-shot group, in contrast to 12.5 days [Q1-Q3: 7-26] in patients with other therapy regimes.

Conclusions: This retrospective data provides a safe and feasible treatment alternative for patients with L. pneumophila infections, which could also be administered as outpatient parenteral antimicrobial therapy (OPAT), while avoiding potential adverse events of fluoroquinolone antibiotics.

Abstract 2007

**Association of the prophage BTP-1 with anti-virulence of *Salmonella* typhimurium sequence type 313**

Ana Herrero*¹, Malene R. Spiegelhauer², Priscilla R. Guerra³, John E. Olsen⁴

¹University of Copenhagen, Frederiksberg Denmark, Denmark, ²Copenhagen University Hospital, Copenhagen, Denmark, ³Technical University of Denmark, Kgs. Lyngby, Denmark, ⁴University of Copenhagen, Frederiksberg, Denmark

**Background:** The prophage BTP-1 is highly conserved among strains of the human invasive lineage *Salmonella* Typhimurium (*S. Typhimurium*) ST313. Little is known on the influence of BTP-1 on fitness of the host-bacterium during infection. The aim of the current study was to determine the virulence effect of the full prophage BTP-1 and the gene bstA encoded from the phage in the ST313 reference strain D23580. The gene bstA was previously found to play a role in virulence of a strain of *S. Typhimurium* ST313 from Congo-Africa, and in a strain of the human invasive serovar *S. Dublin.*

**Materials/methods:** D23580 mutants lacking bstA (D23580ΔbstA) and BTP-1 (D23580ΔBTP-1) were constructed and tested during infection of THP-1 human macrophages [where uptake, survival and net replications were estimated] and mice [single and competition assays]. Cytokines expression by macrophages and cytotoxicity towards these cells were also analyzed. CFU counts in the liver, spleen and mesenteric lymph nodes (MLNs) together with analysis of organs enlargement, and histology studies were performed during mice infections.

**Results:** The mutant D23580ΔbstA showed significantly higher survival and net replication rates within the human macrophages than the wild-type [WT] strain, while the mutant D23580ΔBTP-1 did not significantly differed from the WT. Interestingly, both mutants displayed an hypervirulent phenotype during infection of mice. Thus, D23580ΔBTP-1 yielded significantly higher counts in all tested organs than the WT, and all three organs were significantly enlarged indicating higher cell infiltration. D23580ΔbstA significantly out-competed the WT during competitive infection of mice, and yielded significantly enlarged spleens and MLNs compared to WT-infected animals during single infection. Besides, significant histopathological changes [increased cellular infiltration and focal necrosis] were observed in the liver samples of mice infected with D23580ΔbstA and D23580ΔBTP-1 compared to WT-infected animals.

**Conclusions:** The presence of the prophage BTP-1 is associated with anti-virulence since a hyper-virulent phenotype was observed for the mutants lacking bstA and BTP-1 during mice infection. Removal of the gene bstA in *S. Typhimurium* ST313 led also to increased virulence during macrophages infection. These results agree with a previous study on *S. Dublin* where the gene was regarded as an anti-virulence gene.

**Tuberculosis screening among newly arrived asylum seekers in Denmark**

Kristina Langholz Kristensen*1,2, Marie Norredam1,4, Sidse Graff Jensen3, Niels Seersholm3, Marie Louise Joergensen1, Banoo Bakir6, Franziska Grundtvig Huber6, Ebbe Munk Andersen2, Pernille Ravn6, Troels Lillebaek2,8

1Nordsjaellands Hospital, Department of Pulmonary- and Infectious Diseases, Hilleroed, Denmark, 2Statens Serum Institut, International Reference Laboratory of Mycobacteriology, Copenhagen, Denmark, 3University of Copenhagen, Research Centre for Migration, Ethnicity and Health, Copenhagen, Denmark, 4University Hospital Hvidovre, Section of Infectious Medicine, Department of Infectious Diseases, Hvidovre, Denmark, 5Herlev-Gentofte Hospital, Section of Respiratory Medicine, Department of Medicine, Copenhagen, Denmark, 6Herlev-Gentofte Hospital, Section of Infectious Diseases, Department of Medicine, Copenhagen, Denmark, 7Danish Red Cross, Copenhagen, Denmark, 8University of Copenhagen, Global Health Section, Department of Public Health, Copenhagen, Denmark

**Background:** Asylum seekers are in high risk of tuberculosis (TB) due to both the precarious conditions they are escaping from, and to the often dangerous conditions faced during migration such as overcrowding, imprisonment and poor access to health care. Upon arrival in host countries, TB screening programmes among asylum seekers tend to focus on chest radiography (CXR), whereas knowledge on spot sputum screening is limited. Among other high-risk groups spot sputum screening including *M. tuberculosis* culture has proven useful in identifying cases earlier and at a less infectious stage. We evaluated active TB screening including both spot sputum and CXR among asylum seekers arriving in Denmark. In addition, we assessed the coverage of a voluntary health assessment.

**Materials/methods:** Between February 1st 2017 and March 31st 2019, all newly arrived asylum seekers in Denmark ≥ 18 years from TB high-risk countries or risk groups, who attended a voluntary health assessment, were offered active TB screening with CXR and spot sputum including culture for *M. tuberculosis*.

**Results:** The coverage of the voluntary health assessment was 65.1%. Among 1154 referred for active TB screening, 923 (80.0%) attended. 34.1% were from countries with a WHO incidence ≥100/100,000 population. Among 854 screened by CXR, one case of active TB was identified equivalent to a yield of 0.12%. Sputum samples were collected from 758 and one *M. tuberculosis* culture-positive case (also identified by CXR) was identified, equivalent to a yield of 0.13%. No cases were found by spot sputum culture only.

**Conclusions:** CXR and spot sputum screening identified one case of active TB. Sputum screening did not identify additional TB cases compared with CXR in our study. However, sputum screening may be relevant among asylum seekers from TB high-incidence countries. In general, TB screening among asylum seekers should focus on asylum seekers from TB high-incidence countries. Furthermore, encouragement of health assessment attendance should be of high priority among newly arrived asylum seekers.

Evaluation of sample preparation method by the liquid nitrogen for identification of Aspergillus fumigatus and Schizophyllum commune in matrix-assisted laser desorption ionisation-time of flight mass spectrometry analysis

Noriyuki Abe*1, Masaru Komatsu2, Kotone Nakanishi1, Gaku Matsumoto1, Yuki Ohno2, Hiroko Matsutani1, Saori Fukuda1, Masashi Shimada1, Shuji Matsuo1

1Tenri Hospital, Department of Laboratory Medicine, Nara, Japan, 2Tenri Healthcare University, Tenri, Japan

Background: Filamentous fungi have a robust cell wall that requires particular sample preparation to ensure good-quality mass spectra for matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS). In this study, we compared five unique sample preparation methods to obtain extracted protein from filamentous fungi.

Materials/methods: Seven strains of Aspergillus fumigatus including ATCC 204305 and three of Schizophyllum commune were isolated in clinical samples from our hospital. These strains were grown at 30°C on Sabouraud dextrose broth. Then, the following five protein extraction methods were performed: ethanol/formic acid standard extraction, freezing in liquid nitrogen, cell disruption with silica beads, combination of liquid nitrogen and silica beads, and homogenization by non-freezing. We compared the number of common specific peaks used for identification in A. fumigatus/S. commune databases (Microflex version 3.1, Bruker Daltonics Inc.) with the number of peaks obtained by the five methods.

Results: Thirteen specific peaks were found in the mass spectra of A. fumigatus and 9 specific peaks were found in those of S. commune. In the ethanol/formic acid standard extraction method, the average appearance rates in A. fumigatus and S. commune were 66% and 4%, respectively. The methods with the best rates were the combination of liquid nitrogen and silica beads method and the freezing in liquid nitrogen method. In the combination of liquid nitrogen and silica beads method, the rates were 74% and 59% for A. fumigatus and S. commune, respectively, whereas the rates with the freezing in liquid nitrogen method were 74% and 54%, respectively.

Conclusions: The two methods using liquid nitrogen obtained a larger number of mass spectra than the other methods including the ethanol/formic acid standard extraction method. These methods have high protein extraction efficiency and increase the identification accuracy of A. fumigatus and S. commune.

Abstract 2015

External validation of the NOVA and DENOVA scores for clinical prediction of endocarditis in patients with Enterococcus faecalis bacteraemia

Pierre Danneels¹, Floris Chabrun¹, Aurélie Beaudron², Camille Rihet¹, Clémence Vannier¹, Marie Kempf¹, Vincent Dubée¹

¹Centre Hospitalier Universitaire d’Angers, Angers, France, ²Centre Hospitalier - Le Mans, Le Mans, France

Background: Enterococcus faecalis (Ef) is a frequent cause of bacteraemia, and between 10 and 15% of patients with Ef bacteremia are diagnosed with endocarditis. Several scores have been developed in order to estimate the clinical probability of endocarditis in Ef bacteraemia, including the NOVA score, which carries a sensitivity (Se) of 97% and a specificity (Sp) of 23%. The recently developed DENOVA score could have enhanced diagnostic performances but has not been validated. The objective of this study was to compare the diagnostic performances of the NOVA and DENOVA scores in an external cohort of Ef bacteremia and endocarditis.

Materials/methods: In this retrospective study, we included all cases of Ef bacteraemia diagnosed in two French hospitals between January 2015 and October 2019, as well as additional cases of Ef endocarditis diagnosed in four other French hospitals during the same period. Only endocarditis cases classified as “definite” according to Duke criteria were included. NOVA and DENOVA scores were determined for each case based on data collected during hospitalization. Patients with missing data precluding calculation of the scores were excluded.

Results: The study population comprised 490 patients, including 128 endocarditis cases. Median age was 74 years (IQR 62-83), and 70% of patients were males. Diagnostic performances of the NOVA and DENOVA scores are presented in Table 1.

In a theoretical cohort of 100 patients with Ef bacteremia including 13 with an endocarditis, use of the NOVA score for selection of patients at risk of endocarditis would lead to the realization of 52 echocardiograms, versus 25 with DENOVA. The number of false negative would be 0.2 and 0.7, respectively.

Conclusions: These results confirm the excellent sensibility of the DENOVA score for screening of patients at risk for Ef endocarditis, with an improved specificity compared with the NOVA score. Use of the DENOVA score could markedly reduce the number of unnecessary echocardiograms.

Evaluation of the performance of three chromogenic culture media for the detection of carbapenemase producing Enterobacterales to manage healthcare-associated infections

Corine Fulchiron*1, Justine Oliger1, Joelle Pujol2, Geraldine Durand1

1bioMérieux, La Balme les Grottes, France, 2bioMérieux, Marcy l’Étoile, France

Background: The increasing incidence of infections caused by Carbapenemase-Producing Enterobacterales [CPE] emerging worldwide at an alarming rate becomes a significant clinical and public health concern.

The aim of the study was to compare the performance of three chromogenic media: CHROMID® CARBA SMART agar [bioMérieux], a bi-plate for the screening of CPE, Brilliance™ESBL/Brilliance™ CRE agar [Thermofischer], a bi-plate for the detection of ESBL producers and carbapenem-resistant Enterobacterales, and BD BBL™CHROMagar™ CPE agar for CPE screening.

Materials/methods: A total of 54 strains: 42 Enterobacterales (10 Escherichia coli, 23 KESC [Klebsiella, Enterobacter, Serratia, Citrobacter] and 9 Proteae) harboring various types of carbapenemase [11NDM, 6 KPC, 8 OXA 48 or OXA48 like, 4 VIM], 5 resistant to carbapenems but carbapenem-negative, 7 ESBL producers and 1 carbapenem-susceptible were selected to evaluate the performances of each carbapenemase medium. Seven non-fermenting Gram negative bacilli (NFGNB): 6 carbapenemase and 1 ESBL producers and 5 other species (3 enterococci, 1 S.aureus and 1 C.albicans) were added. Strains were diluted in saline solution at 1.5x10^5 CFU/mL and inoculated on each medium. After 18h and 24h of incubation the presence of growth and coloration of colonies were recorded for each medium.

Results: The overall sensitivity of each medium [all species] for the detection of CPE was respectively 76.9%, 68.3% and 61.5% for CHROMID® CARBASMART, Brilliance™ CRE, and BD BBL™CHROMagar™ CPE at 18h of incubation and 82.1%, 83.7% and 64.1% at 24h of incubation. Regarding the performance of each medium for the claimed species only (E.coli and KESC for CHROMID® CARBASMART, E.coli, KESC and NFGNB for Brilliance™ CRE, and E.coli, KESC, proteae group for BD BBL™CHROMagar™ CPE), the sensitivity reached respectively 95.8 %, 75%, and 57.6% for the three media. The specificity of each medium was respectively 80% for CHROMID® CARBASMART and BD BBL™CHROMagar™ CPE and 100% for Brilliance™ CRE agar at 18h and 24h.

Conclusions: CHROMID® CARBASMART shows a better sensitivity of detection of Carbapenemase Producing Enterobacterales compared to Brilliance™ CRE and BD BBL™CHROMagar™ CPE at 18h and 24h. Specificity of Brilliance™ CRE is higher than CHROMID® CARBASMART and BBL™CHROMagar™ CPE agar which remains acceptable due to the number of specimens tested.

Miltefosine as a promising agent for chronic cutaneous leishmaniasis: an in vivo model
Varol Tunali*1,2, Ibrahim Cavus3, Ahmet Yildirim1, Orcun Zorbozan2, Mehmet Harman4, Cumhur Gunduz5, Ahmet Ozbilgin3, Nevin Turgay2

1Mugla Sıtkı Kocman University Medical Faculty Emergency Department, Muğla, Turkey, 2Ege University Medical Faculty Department of Parasitology, Izmir, Turkey, 3Manisa Celal Bayar University Medical Faculty Department of Parasitology, Manisa, Turkey, 4Dicle University Medical Faculty Dermatology Department, Diyarbakir, Turkey, 5Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey

Background: Cutaneous Leishmaniasis (CL) is the most common form of leishmaniasis. CL can be divided into two major groups: acute CL (ACL) and chronic CL (CCL). The aim of this study is to compare the efficacy of miltefosin and pentavalent antimony compounds in vivo with the CCL patient samples.

Materials/methods: Three study groups were formed, each consisting of 5 male Mus musculus (Balb/C) mice. In this model, promastigotes from the culture of a CCL patient was utilized. 100 μL L. tropica promastigote suspension with a density of 10^8 promastigotes/ml were injected into the rear-right sole of each experimental animal intradermally. Soles of the mice were measured every two weeks until 24th week. From the 13th week following the inoculation, miltefosin 50 mg/kg/day was administered orally using gavage for 21 days, Meglumin antimoniate (MA) was administered by intramuscular (IM) injection daily for 21 days at 50 mg/kg/day and Saline was administered IM for 21 days for the miltefosine, MA and control group respectively. The mice were sacrificed at the 24th week and tissue suspensions were prepared from the infected foot and the visceral organs of the mice.

Results: The sole measurements of the miltefosine group were lower than the control group statistically. Between the miltefosine group and the MA group and MA group and the control group, there was no statistically significant difference. Giemsa stained slides revealed amastigotes in one, two and all of the slides for the miltefosine, MA and control group respectively. Molecular tests were performed with the Rotor Gene (Qiagen GmbH, Hilden, Germany) device using prepared tissue suspensions and L. tropica consistent peaks were obtained in one of the miltefosin group, four in the MA group and all mice in the control group.

Conclusions: Demonstration of both clinical and laboratory improvement in four of the five experimental animals provides strong evidence that miltefosine is an effective drug in the treatment of CCL compared to MA. In the literature, no clinical or laboratory studies using miltefosine have been reported with CCL patient groups. We conclude that miltefosine can be a valuable treatment option for CCL patient group.

**Abstract 2020**

**In vitro dynamics and mechanisms of resistance development to imipenem and imipenem/relebactam in Pseudomonas aeruginosa**

Maria Antonia Gomis Font*, Gabriel Cabot1, Irina Sánchez-Diener1, Laura Zamorano1, Antonio Oliver1

1Hospital Universitario Son Espases, Palma, Spain

**Background:** Pseudomonas aeruginosa is a major cause of nosocomial and chronic infections, being considered a paradigm of antimicrobial resistance development. The main objective of this study was to analyze the dynamics and mechanisms of resistance development to imipenem alone or combined with the novel β-lactamase inhibitor relebactam in P. aeruginosa wild type (PAO1) and mutator (PAOMS; ΔmutS) strains.

**Materials/methods:** In vitro resistance development assays started by incubating PAO1 and PAOMS in Müller-Hinton Broth (MHB) for 24 h with 0.125 to 64 µg/mL of imipenem alone or plus relebactam at a fixed concentration of 4 µg/mL. Tubes from the highest antibiotic concentration showing growth were reinoculated in fresh medium containing concentrations of imipenem up to 64 µg/mL or imipenem with relebactam for 7 days. The susceptibility profiles for PAO1 and PAOMS mutants were determined by MHB microdilution. The mutants were further characterized by whole-genome sequencing (WGS) and those mutations related to ampC and efflux pumps hyperexpression were tested by RT-PCR. Finally, the virulence of the mutants was studied in a Caenorhabditis elegans infection model.

**Results:** As shown in the figure, imipenem/relebactam combination reduced imipenem resistance development for both strains, although resistance emerged much faster for PAOMS, as expected. Moreover, WGS indicated that imipenem resistant mutants showed mutations in the carbapenem porin OprD and regulators of ampC expression, while the mutations in imipenem/relebactam resistant mutants were located in oprD and regulators of the expression of the efflux pump MexAB-OprM. Moreover, high-level imipenem/relebactam resistance was only documented in the PAOMS strain, and was associated with additional mutations in penicillin-binding proteins (PBPs) and with reduced virulence in the C. elegans model.

**Conclusions:** Our results suggest that imipenem/relebactam could be a useful alternative for the treatment of MDR P. aeruginosa infections, potentially reducing resistance development during treatment. Moreover, this work deciphers the potential resistance mechanisms that may emerge upon the introduction of this novel combination in the clinical practice.

The impact of transport media, shipping time and DNA extraction kits on the absolute abundance of key vaginal bacterial species
Thor Haahr1, Jorgen Skov Jensen*2

1Aarhus University, Department of Clinical Medicine, The Fertility Clinic, Skive Regional Hospital Denmark, Skive, Denmark, 2Statens Serum Institute, Copenhagen, Denmark

Background: A variety of different commercially available kits exists for both microbial specimen collection as well as for microbial DNA extraction. Sample preparation with the chelating resin Chelex-100 is a simple, cheap and universal method for DNA extraction, whereas newer more complex and more expensive DNA extraction methods might yield more optimal DNA extraction – especially in Gram positives - by using mechanical lysis with bead-beating. Previously, it has been reported that different methods could yield different results. Hence, this study aimed to evaluate two commercially available transport systems, two DNA extraction methods and shipping/storage time effect on the qPCR bacterial abundance of key vaginal bacterial species.

Materials/methods: A total of 20 Caucasian women were recruited for vaginal swab collection. Three swabs were collected from the same woman and stored in two different tubes, 1 sample in ESwab™ and 2 samples in eNAT™ (Copan, Brescia, Italy). One eNAT was stored at room temperature for 7 days until analysis, whereas the other samples were stored -80 degrees Celsius until analysis. The bacterial abundance of common vaginal Lactobacillus spp., A.vaginae and G.vaginalis was analyzed using qPCR. Bacterial DNA was extracted from the ESwab™ and the eNAT specimens using Chelex DNA extraction and Fast DNA™ SPIN Kit for Soil (© MP biomedicals).

Results: In the present study, we did not observe significant differences in bacterial abundance [counts/mL] by qPCR analysis of L.crispatus (P=0.92), L. iners (P=0.60), G. vaginalis (P=0.86) and A. vaginae (P=0.62) comparing Eswab and eNAT samples when the MPbio DNA extraction method was used. Moreover, the bacterial abundance in Eswab samples was non-significantly different with a Chelex DNA extraction compared to MP bio extraction. Chelex DNA extraction method was not compatible with eNAT resulting in inhibition. A storage time of 7 day at room temperature yielded similar results to immediate freeze at -80°C and dry-ice shipment of vaginal specimens.

Conclusions: In conclusion, qPCR analysis of Eswab and eNAT vaginal samples yield comparable copies/mL for L.iners, L. crispatus, A. vaginae and G. vaginalis when the MPbio extraction method was used. Only, Eswab was compatible with Chelex extraction and this method was non-inferior to MPbio extraction.

The sink as source of transmission of VIM metallo-β-lactamase-producing Pseudomonas aeruginosa in the intensive care unit

Vanstokstraeten Robin*1, Deborah De Geyster2, Ingrid Wybo2, Florence Crombe2, Denis Pierard2

1Vrije Universiteit Brussel (VUB), Brussels, Belgium, 2Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, Belgium

Background: Hospital-acquired infections, caused by multi-drug resistant, Verona Integron-encoded Metallo-β-lactamase (VIM)-producing P. aeruginosa, are a major problem in intensive care units (ICU). A previous study conducted in our hospital revealed that sinks drains of the ICU were a possible source of various multi-drug resistant pathogenic germs and suggested that transmission from these drains could indeed play a role in nosocomial infections colonized/infected by germs present in the sink drains.

Materials/methods: Thirty-six sinks located in the ICU of the UZ Brussel were sampled on 28/10/2019 with Eswabs® (Copan, Italy). Samples were inoculated on MacConkey agar (Biomérieux, France) and identification of suspicious colonies was performed by MALDI-TOF (Bruker, US). Twenty sinks were found to be positive and isolates were analyzed by whole-genome sequencing (WGS) together with 83 P. aeruginosa strains from 31 patients in the hospital, positive for P. aeruginosa between 01/2019 and 09/2019, in order to investigate the relationship between those strains. DNA-purification was done with a Maxwell® RSC Instrument (Promega, US) and WGS was performed on a NovaSeq® 6000 (Illumina, US) by Brussels Interuniversity Genomics High Throughput core (BRIGHTcore). The sequencing data was analysed using the wgMLST schema for P. aeruginosa of the BioNumerics software v.7.6 3 (Applied Maths, Biomérieux, Belgium).

Results: Twenty-five % of the P. aeruginosa strains found in the sink drains carried the VIM2-gene. 9.6% of the 83 patient samples carried the VIM2-gene and 2.4% carried the VIM4-gene. Twenty-two different P. aeruginosa sequences types (ST) were identified among 83 isolates, of which 15 belong to 22 ICU-patients. Seven of these were also found in strains recovered from the sink samples. WgMLST- analysis of all VIM2-positive isolates showed that isolates within each ST were very closely related. Transmission in both directions is suspected: patients who contaminated the sink drains with P. aeruginosa strains, but also patients who became infected over time by VIM-producing P. aeruginosa strains present in the sink drains.

Conclusions: This study points out that sink drains are a possible source of VIM-producing P. aeruginosa strains after contamination with patients’ materials. We also show that patients could get infected from sink drains containing VIM-producing P. aeruginosa.

Systematic validation of blood transcriptional biomarkers for active pulmonary tuberculosis in a high-burden setting: a prospective diagnostic accuracy study
Carolin Turner1, Rishi Gupta2, Evdokia Tsaliki1, Jennifer Roe1, Prasenjit Mondal2, Georgina Nyawo3, Zaida Palmer3, Robert F. Miller2, Byron Reeve3, Grant Theron3, Mahdad Noursadeghi*1

1UCL, Division of Infection & Immunity, London, United Kingdom, 2UCL, Institute for Global Health, London, United Kingdom, 3Stellenbosch University, Division of Molecular Biology and Human Genetics, Cape Town, South Africa

Background: Blood transcriptional signatures are candidates for non-sputum triage or confirmatory tests of tuberculosis (TB). Prospective head-to-head comparison of their performance in real-world settings is necessary to evaluate their clinical utility.

Materials/methods: Consecutive, symptomatic adults presenting to a TB clinic in Cape Town, South Africa, provided blood for RNA sequencing, and sputa for liquid culture and molecular testing using Xpert MTB/RIF and Xpert MTB/RIF Ultra (Ultra). We assessed the diagnostic accuracy of 27 candidate signatures identified by systematic review, compared to culture or Xpert MTB/RIF positivity as the standard reference.

Results: Among 181 patients, 54 (30%) had TB. Four signatures achieved the highest diagnostic accuracy with comparable area under receiver operating characteristic curves of 86.8% (95% confidence interval 80.6-93.1%-90.6% (85.6-95.6%), independent of age, sex, HIV, previous TB, or sputum smear result. At test thresholds that give 70% specificity, these signatures achieved sensitivities of 83.3% (71.3-91%-90.7% (80.1-96%), thus meeting or approximating the minimum World Health Organization target product profile (WHO TPP) for a triage test. No signature met the optimum criteria for a triage test at any threshold, or the minimum criteria for a confirmatory test, but all four correctly identified Ultra-positive, culture-negative patients.

Conclusions: Four blood transcriptional signatures achieved minimum target criteria for a triage test. None were suitable for confirmatory tests, but they may be used to identify false-positive Ultra results. Further development of the signatures is warranted for these applications, in order to test their impact on clinical and health economic outcomes.

Performance metrics of the four best-performing signatures, benchmarked against minimum WHO TPP criteria. 95% confidence intervals are indicated in brackets.

| Sensitivity at 70% specificity (= minimum specificity for a triage test) |
|-----------------|-----------------|
| BATF2           | 88.9% [77.8-94.8%] |
| Kaforou25       | 83.3% [71.3-91%]  |
| Roe3            | 90.7% [80.1-96%]  |
| Sweeney3        | 90.7% [80.1-96%]  |

| Specificity at 65% sensitivity (= minimum sensitivity for a confirmatory test) |
|-----------------|-----------------|
| BATF2           | 85.8% [78.7-90.8%] |
| Kaforou25       | 92.1% [86.1-95.7%] |
| Roe3            | 92.1% [86.1-95.7%] |
| Sweeney3        | 93.7% [88.1-96.8%] |

Abstract third-party references: Supported by Instituto de Salud Carlos III (PI16/01432), On behalf of PROBAC REIPI/GEIH-SEIMC/SAEI Group

Background: Bacteraemia due to *Escherichia coli* presenting with sepsis/septic shock is associated with considerable morbidity and mortality. The objective of this study was to analyze the presence of microbiological factors of *E. coli* that may be related to the presentation of sepsis/septic shock in adult patients with bacteremia.

Materials/methods: 143 *E. coli* isolates from blood cultures of patients with sepsis/septic shock (2016 criteria) from 21 Spanish hospitals were included. Clinical data were collected prospectively. *E. coli* isolates were sent to the Microbiology Service of the University Hospital Virgen Macarena where Whole Genome Sequencing (WGS) (MiSeq, Illumina Inc) was performed. The assembly was done with the CLC Genomic WorkBench (Qiagen) software. Sequence type, WGS-based serotyping, virulence factors and antibiotic resistance genes were assessed in MLST 2.0, SerotypeFinder 2.0, VirulenceFinder 2.0, and ResFinder 3.2 databases, respectively. Phylogenetic group was determined using the Clermont scheme.

Results: Isolates were grouped into 60 clonal groups; ST131 (n=21; 14.7%), ST69 (n=17; 11.9%), ST73 (n=14 9.8%) and ST95 (n=9; 6.3%) were the most frequent. Overall, the virulence genes most frequently detected were the serum survival increase (*iss*) gene (124/143; 86.7%) and the glutamate decarboxylase (*gad*) enzyme gene (117/143; 81.8%). Among the most frequent clones, ST73 had the highest virulence score (median: 11 factors, range 7-14), while clone ST131 had the lowest value (median 5, range 4-7). Clones ST131, ST73 and ST95 were included in the phylogenetic group B2, and clone ST69 belonged to the phylogroup D. The most common types of polysaccharide (O) antigen and flagellar (H) antigen were O25 (27/143; 18.9%) and H4 (38/143; 26.6%), respectively. ST131 comprised the 95.4% of isolates with serotype O25:H4 (21/22); and 86.3% of ST131 isolates [19/21] presented the type 1 fimbrae fimH30 allele. In 17 (11.8%) isolates the presence of ESBL genes was detected, especially *bla*<sub>CTX-M-15</sub> (n=10; 6.9%) and *bla*<sub>CTX-M-14</sub> (n=4; 2.8%).

Conclusions: *E. coli* isolates from patients with severe sepsis/septic shock showed high clonal variability, although ST131, ST69, ST73 and ST95 were detected more frequently. Different profiles of virulence were observed for each sequence type. ESBL genes were detected in 11.8% of the isolates.

Abstract 2037

In vitro Activities of ceftazidime-avibactam and comparator agents against Enterobacterales from Europe stratified by region, ATLAS global surveillance programme 2018

Mark Estabrook, Kristyna Kazmierczak*, Greg Stone, Dan Sahm

IHMA, Schaumburg, United States, Pfizer, Inc., Groton, United States

Background: Ceftazidime-avibactam (CAZ-AVI) is a cephalosporin combined with a diazabicyclooctane β-lactamase inhibitor for treatment of Gram-negative infections. CAZ-AVI is active against Enterobacterales (Eba) isolates that produce Class A, C and some Class D β-lactamase, but not Class B metallo-β-lactamases (MBLs). The in vitro activity of CAZ-AVI and comparators against Eba isolated from different countries in Europe in 2018 is evaluated herein.

Materials/methods: 9,179 non-duplicate Eba isolates were collected from 103 sites in 23 countries in Europe during 2018 for the ATLAS global surveillance program. Antimicrobial susceptibility testing was by broth microdilution using CLSI guidelines and EUCAS 2019 breakpoints. CAZ-AVI was tested with a fixed concentration of 4 mg/L AVI. Isolates with meropenem MICs >1 mg/L were genetically screened for β-lactamases.

Results: CAZ-AVI was active against more isolates than comparator agents in Northern/Western and Central/Eastern Europe (MIC₉₀ 0.5 and 1 mg/L; 99.2% and 96.1% susceptible, respectively). CAZ-AVI was the most active agent among meropenem-non-susceptible MBL-negative isolates in both regions (MIC₉₀ 8 and 2 mg/L; 97.3% and 100% susceptible, respectively). 12/16 meropenem-non-susceptible and MBL-negative isolates with CAZ-AVI MICs >128 mg/L were KPC-positive and collected in Italy. Comparator agents were active against fewer isolates than CAZ-AVI in Northern/Western and Central/Eastern Europe (≤97.7% and ≤90.8% susceptible respectively).

Conclusions: CAZ-AVI demonstrated potent in vitro activity against Eba isolates collected in 2018 from Northern/Western Europe and Central/Eastern Europe. MBL-positive isolates were responsible for a modest decrease in the percentage of CAZ-AVI-susceptible isolates in both regions, but more notably Central/Eastern Europe where more of them were collected.

**Streptococcus pneumoniae: the chameleon of ocular diseases**
Camille Andre*1, John Rouhana1, Michael S. Gilmore1, Paulo Bispo1

1Massachusetts Eye and Ear, Department of Ophthalmology, Boston, United States

**Background:** *Streptococcus pneumoniae*, an inhabitant of the upper respiratory tract, is a leading cause of invasive infections as well as ocular surface infection. We previously reported that *S. pneumoniae* conjunctivitis is mainly caused by unencapsulated strains that form a specialized clade termed Epidemic Conjunctivitis Cluster (ECC). To determine whether the pathogenicity of ECC is limited to the conjunctiva or extends to other ocular tissues, and to determine the influence of the Pneumococcal Conjugate Vaccine (PCV-13) on the etiology of ocular infection, we determined the identity and relatedness of *S. pneumoniae* isolated from all ocular infections from 2014 to 2017 at Massachusetts Eye and Ear.

**Materials/methods:** *S. pneumoniae* isolated from 46 separate ocular infections were characterized by genome sequencing. We used CLC Genomics workbench to trim and assemble the sequences. We used the Center for Genomic Epidemiology pipeline to obtain species identification, sequence type (ST) and to identify antibiotic resistance genes present. STs were grouped into clonal complexes using goeBURST. Capsule serotype was predicted from genome sequence using Pneumocat.

**Results:** *S. pneumoniae* were mainly isolated from keratitis (n=22, 47.8%) or conjunctivitis (n=13, 28.2%). The remaining isolates were recovered from endophthalmitis and dacryosystitis. Strains from conjunctivitis generally lacked capsule operons (88.9%) and grouped within the ECC (53.8%). On the contrary, 90.9% of the *S. pneumoniae* responsible for keratitis possessed capsule operons. Most of these (96.8%) had an inferred capsule type not covered by the PCV-13. Inferred encapsulated strains were highly diverse with 22 different STs found with 3 most common STs: ST199 (16.2%), ST558 (6.6%) and ST100 (6.6%). Overall, 41.3% of the isolates were resistant to erythromycin, with no significant differences between unencapsulated and encapsulated strains (33.3% and 45.2%, respectively). All isolates were susceptible to levofloxacin.

**Conclusions:** Our study demonstrates that the tropism of ECC *S. pneumoniae* is limited to the conjunctiva, and does not extend to the cornea or other ocular tissues. In contrast to conjunctivitis, keratitis is caused by a highly diverse population of *S. pneumoniae* that escape the current vaccine. These data will be useful in the designing of next generation vaccines that cover common and sometimes sight-threatening ocular *S. pneumoniae* infections.

Abstract 2041

**Real-world experience of bictegravir/emtricitabine/tenofovir alafenamide in a diverse Dublin cohort**

Miriam Moriarty*, Gail Melanophy, Emma Devitt

*St. James’s Hospital, Dublin, Ireland; †St. James’s Hospital, Dublin, Ireland*

**Background:** Biktarvy contains Bictegravir, a potent Integrase Inhibitor, co-formulated with emtricitabine/tenofovir alafenamide. The aim of this analysis was to review the characteristics, indications and outcomes of those switching to or initiating Biktarvy.

**Materials/methods:** All PLWH who attended the Guided clinic in St James’s Hospital, Dublin who were commenced Biktarvy between January - June 2019 were identified via the Pharmacy Dispensing system. A retrospective case notes analysis of these patients was undertaken and information regarding demographics, treatment experience, ART history, switch indication, virological response, and tolerability was determined.

**Results:** 144 Patients were commenced on Biktarvy. Five were lost to follow up and excluded from the analysis. 6 were ART naïve and 132 (95%) were switched to Biktarvy from another regimen. 111 (80%) were White, 19 (14%) were Black. 107 (77%) were male, mean age was 46 years, and mean time on prior ART was 9.3 years.

Reasons for switching included: simplification to a Single tablet regimen 44 (32%), side effects 43 (31%), and drug interactions 31 (22%).

Analysis of viral load was divided into 3 groups.

**Treatment Naïve patients:**

Of the 6 (4%) Naïve patients: 5 (83%) were virally suppressed at week 4 and 100% at week 12.

**Patients Virally suppressed pre switch:**

115 (87%) were virally suppressed at the time of switch. At the time of analysis the VL was available for 113 patients: 112 (99%) remained Virally suppressed at week 4 with 100% suppressed at week 12.

**Patients Virally detectable pre switch:**

17 (13%) were detectable at the time of switch.

Of the 16 for whom a VL was available 4 weeks post switch, 10 (63%) were suppressed. Of the 15 for whom a VL was available at 12 weeks 100% were suppressed.

Most patients tolerated Biktarvy, 5 (3.4%) patients discontinued, due to GI upset, weight gain and joint pain.

**Conclusions:** Biktarvy has shown to be effective in both treatment naïve and experienced patients. It has the potential to effectively suppress and maintain viral suppression, with 99% of treatment experienced patients remaining virally suppressed 4 weeks post switch. It is well tolerated with 3% of patients discontinuing treatment due to side effects.

Abstract 2042

In vitro activities of ceftazidime-avibactam and comparator agents against Pseudomonas aeruginosa from Europe stratified by region: ATLAS global surveillance programme 2018

Mark Wise1, Krystyna Kazmierczak*, Greg Stone2, Dan Sahm3

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

Background: Avibactam (AVI) is a non-β-lactam, β-lactamase inhibitor that can restore the activity of ceftazidime (CAZ) against organisms that possess Class A, C, and some Class D enzymes. The aim of this study was to investigate the in vitro activity of ceftazidime-avibactam (CAZ-AVI) and comparators against contemporary Pseudomonas aeruginosa (Paer) collected in Europe during 2018 with isolates divided into two geographic regions, North/Western and Central/Eastern Europe.

Materials/methods: 2517 non-duplicate Paer isolates were collected from 103 sites in 23 countries in Europe as part of the ATLAS surveillance study in 2018. Susceptibility testing was by broth microdilution according to the ISO standard method and interpreted using EUCAST 2018 breakpoints. CAZ was tested with a fixed concentration of 4 mg/L AVI. When meropenem MIC values were >2 mg/L, the β-lactamase gene content was assessed by PCR and sequencing.

Results: CAZ-AVI demonstrated potent in vitro activity against the collection of 1715 Paer isolates from North/Western Europe (MIC90, 8 mg/L, 95.5% susceptible), but was less effective against the collection (n=802) from Central/Eastern Europe (MIC90, 64 mg/L, 79.6% susceptible). When metallo-β-lactamase (MBL)-positive isolates were removed from this latter set, the activity of CAZ-AVI increased marginally (MIC90, 32 mg/L, 82.9% susceptible). The in vitro activity of CAZ-AVI was the highest among all comparators for both regions except for colistin.

Conclusions: The in vitro activity of CAZ-AVI against the Paer isolates collected in North/Western Europe was higher than that against isolates from Central/Eastern Europe. Some of this difference can be attributed to the large percentage of MBL-carrying isolates originating from Central/Eastern European countries. However, much of the resistance apparently stems from other mechanisms. More isolates were susceptible to CAZ-AVI than to any comparator except colistin, suggesting that it remains an effective treatment versus Paer infection.

Abstract 2043

**Effective control strategies for cutaneous leishmaniasis after Syrian influx in Turkey**

Gamze Kalın Ünüvar*, Seher Topluoglu, Tuba Kayman, Huseyin Ilter, Fatih Kara, Emine Alp Mese

1Ministry of Health, Ankara, Turkey

**Background:** Turkey hosts the largest refugee population in the world, which may carry some potential risk on public health. Infectious diseases are the first one to be considered. Cutaneous leishmaniasis (CL) is also known as a disease emerging among migrants and travelers. Although, CL has been seen in Southeastern part of Turkey for years, strict control strategies implemented by Ministry of Health decreased the incidence significantly. These strategies include; vector control, raising awareness and knowledge of health staff and public, early diagnosis and prompt treatment of cases, and active and passive case detection. House to house search, index case approach and screening are major strategies implemented for active case detection. After the huge number of migrants influx from Syria, Ministry of Health adopted CL control strategies in order to cover migrants’ needs. However, Syrians are mostly living in Southeastern Anatolian cities, they are living in all cities. All the services provided to Turkish citizens are also being delivered to migrants. The objective of this study is to evaluate the influence of migration on CL epidemiology in Turkey and the efficiency of control strategies.

**Materials/methods:** CL is a mandatorily notifiable disease since 2004, and health care facilities are obliged to report all the cases compatible with the case definition. Incidence of CL and geographical distribution of cases were analysed seven years prior and after the migrants’ influx.

**Results:** In total, 34,643 CL cases were identified between 2005 and 2018. The incidence (per 100 000) was mostly increase in Marmara (0.03/0.20), Black Sea (0.02/0.10), Central Anatolia (0.11/1.13) and Southeastern Anatolia (11.95/24.28) compared between 2005-2011 and 2012-2018 due to Syrians population. The total number of CL cases increased two-fold in 2013 and gradiently decreased since then (Graphic 1).

**Conclusions:** Increase in the incidence of CL cases in 2013 seems to be attributable to massive Syrian influx, however steady decrease of incidence in both Syrian and Turkish citizens can only be explained by the efficiency of control measures. It is clear that internationally acknowledged strategies pave the way to success if implemented thoroughly.

Graphic 1. Distribution of CL cases by years and by nationality, Turkey, 2005-2018

Are *Pseudomonas aeruginosa* biofilms a major issue in non-cystic fibrosis bronchiectasis?

Laia Fernandez Barat*, Ruben López, Nil Vázquez Burgos, Victoria Alcaraz, Giulia Scioscia, Patricia Elena Oscanoa, Leticia Bueno, Anna Motos, Rosanel Amaro, Lena Lingren, Daniel Martinez, Roberto Cabrera, Laura Muñoz, Jordi Vila Estape, Niels Hoiby, Antoni Torres

1Cellex laboratory, CibeRes (Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, 06/06/0028)- Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), School of Medicine, University of Barcelona, Barcelona, Spain, 2Pneumology Service, Hospital Clinic of Barcelona, Barcelona, Spain, 3Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy, 4Department of Clinical Microbiology of Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, 5Pathology Service, Hospital Clinic of Barcelona, Barcelona, Spain, 6Microbiology Service, Hospital Clinic of Barcelona, Barcelona, Spain

Abstract third-party references: FIS (ISCIII) PI1800145, Icrea Academy, SEPAR 624, Ciberes [P101/2018]

**Background:** During chronic infection in Cystic Fibrosis (CF) an adaptation of *Pseudomonas aeruginosa* (PA) to different lung niches occurs through biofilms which are associated to worse outcomes and mortality. However, scarce information exists on whether PA biofilms are also a major issue in non-CF bronchiectasis (BE). Thus, the diagnostic methods applied in BE are not those applied during biofilm associated infections. **Aim:** To determine whether PA biofilms are a major issue in BE patients with PA chronic infection and to evaluate the early diagnostic of PA by applying recommended diagnostic methods for CF biofilm infections compared to standard methods.

**Materials/methods:** Prospective collection of sputum and serum samples every 3 months; Use of DTT (1:1) and sonication; >72h incubation, non-mucoid and mucoid PA isolation and MALDI-ToF. Biofilms imaging by Gram-staining and Fluorescent in situ Hybridization and Confocal Laser Scanning Microscopy (FISH+CLSM), respectively. Quantification of specific serum antibodies against PA (precipitins) by crossed immunoelectrophoresis. Metagenomics 16SrRNA sequencing was carried out to analyze the microbiome diversity by PA-phenotype.

**Results:** Three-hundred and sixty-five BE patients were screened. Of those, 46 vs 19 were chronically or intermittently colonized by PA, respectively. Comparison between standard vs biofilm recommended methods increased the sensitivity of PA cultures, specifically 29/103 (28%) sputa were false negative PA by standard but true positive PA by recommended (p<0.001). The mucoid PA was difficult to detect by standard cultures and a marker of decreased biodiversity in sputum (Figure). Biofilms were identified by Gram (Figure) and FISH+CLSM and the presence of alginate in images was associated to the mucoid phenotype (p>0.001) and ≥5 years of chronic PA (p=0.040). Precipitins were higher in BE patients with chronic vs those with intermittent PA 11.0 [6.3-17.0] vs 0.5 [0-3.2], p<0.001, respectively. Compared to the chronic, the intermittently PA colonized patients had higher number of exacerbations during the follow up.

**Conclusions:** *Pseudomonas aeruginosa* biofilm is a major issue in BE since mucoid PA, that produces alginate and biofilms, is a marker of decreased sputum biodiversity and chronic respiratory infection. Applying recommended methods for biofilm infections allows an earlier PA diagnostic which may have clinical implications.

Quality of care indicators in the management of bloodstream infections caused by Enterobacteriaceae: systematic review (MAMBOO-E study)

Pietro Malosso*1, Luigia Scudeller1, Stefano Ianniruberto1, Linda Bussini1, Renato Pascale1, Livia Pancaldi2, Michele Bartoletti3, Milo Gatti3, Pierluigi Viale1, Mical Paul4, Maddalena Giannella1

1Alma Mater Studiorum - University of Bologna, Dipartimento di Scienze Mediche e Chirurgiche, Bologna, Italy, 2IRCCS Ca’ Granda Ospedale Maggiore Policlinico di Milano Foundation · Scientific Direction, Milan, Italy, 3Alma Mater Studiorum - University of Bologna, Dipartimento di Scienze Mediche e Chirurgiche, Bologna, Italy, 4Infectious Diseases Unit, Rambam Health Care Campus, Technion Israel Institute of Technology, Haifa, Israel

Background: Evidence-based care bundles have received increasing attention in recent years to improve the outcome of patients with infectious diseases. However, an evidence-based bundle for the management of patients with Enterobacteriaceae BSI (E-BSI) does not exist. To investigate the impact on outcome of five interventions in patients with E-BSI aimed at drawing a bundle.

Materials/methods: We searched for randomized controlled trials (RCTs) and observational studies, published in all languages from January 2008 to March 2019 on PUBMED, EMBASE and COCHRANE library. Five searches corresponding each to a population-intervention-control-outcome (PICO) were performed. In all of them population consisted of patients with microbiologically confirmed E-BSI. Interventions were: i. performance of imaging to assess BSI source and/or complications; ii. follow-up blood culture (BCs); iii. use of loading dose followed by extended/continuous infusion (E/CI) of beta-lactams; iv. short treatment duration; and v. infectious disease (ID) consultation. Patients without intervention were considered as controls. Main outcome for all PICOs was all-cause 30-day or nearest mortality. RoB 2.0 and ROBINS-I tools were used for bias assessment.

Results: For PICO 1, 2 and 5 there were no RCTs, observational studies included together bacteremic and non-bacteremic patients; separate data for E-BSI and adjustment for confounders were not provided. Thus, no qualitative or quantitative synthesis for these PICOs could be done. PICO 3: Three RCTs were included, comprising 263 patients with E-BSI. No study evaluated the impact of intervention on mortality. Lower relapse and higher microbiological cure rates among patients receiving intervention were observed in one and two studies, respectively. PICO 4: Five studies, one RCT and four observational studies, were included comprising 3036 patients with E-BSI. Treatment duration was classified as short (7 or 10 days) and long groups. We found no significant difference between short and long treatment groups for all-cause mortality (OR 1.10, 95% CI 0.83-1.44, p=0.41) (see Figure).

Conclusions: There is a gap in the literature regarding the optimal management of patients with E-BSI. In particular regarding the need of systematic imaging, follow-up BCs, and ID consultation. Current data seem to support the use of beta-lactams by E/CI and a short treatment duration. CRD42019127225.

Performances comparison between rapidly growing mycobacteria medium for direct-isolation of non-tuberculous mycobacteria, and its industrial version

Marjorie Vrignaud*, Eugénie Déléage1, Sylvain Orenga1, Dominic Stephenson2;3, John Perry2;3

1R&D Microbiology, bioMérieux, La Balme les Grottes, France, 2Department of Microbiology, Freeman Hospital, Newcastle upon Tyne, United Kingdom, 3Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, United Kingdom

Background: Pulmonary nontuberculous mycobacteria (NTM) represent an increasing threat. Consideration of NTM pathogenicity has increased but diagnosis remains difficult due to slow growth of mycobacteria and to pulmonary flora that can be abundant, especially in the case of cystic fibrosis (CF) patients. RGM medium has been designed at the Freeman Hospital (Newcastle Upon Tyne, UK). This medium shows increased specificity and sensitivity compared to reference methods. NTM Elite agar [bioMérieux] is the industrial version derived from RGM medium dedicated to the isolation of NTM from respiratory specimen without prior decontamination. RGM and NTM Elite agar have been compared with pure strains and sputum specimens.

Materials/methods: Pure strains (51 NTM; 46 non-mycobacteria) and 83 sputa (77 patients including 70 with CF) were inoculated on both RGM and NTM Elite agar. Media were incubated at 30°C for 28 days with regular readings, minimum once a week. The number of colonies isolated on both media were then compared. Clinical isolates were identified by MALDI-ToF MS.

Results: Among the 51 NTM strains inoculated, 46 grew on RGM (90%) and 47 on NTM Elite agar (92%) after 28 days incubation. Among the 46 non-mycobacteria strains, 34 were inhibited on RGM (74%) and 36 on NTM Elite agar (78%). From 83 sputa, respectively 5 and 6 isolates belonging to Mycobacterium avium complex were isolated on NTM Elite agar and RGM media. 7 isolates belonging to Mycobacteroides abscessus were isolated on both media. A higher number of Mycobacteroides chelonae isolates were recovered on NTM Elite agar, but this may be artefactual since an important proportion grew only after 21 days of incubation. Among the 83 sputa tested, no overwhelming growth of pulmonary flora was observed at final reading. 15 non-mycobacteria were isolated on both media (17 recovered in total). 4 NTM were isolated in the presence of contaminants.

Conclusions: NTM Elite agar, industrial version of RGM, appears as efficient as RGM for the culture of NTM. These media enable a simple, sensitive and highly selective screening of NTM in sputa without prior decontamination. Therefore, they have a real contribution to the diagnosis of NTM pulmonary infection.

Abstract 2048

**Formation of enterobacterial aggregates in presence of bovine synovial fluid**

Alicia Macías-Valcayo*1, John-Jairo Aguilera-Correa1, Amelia Staats2, Tripti Thapa Gupta2, Devendra Dusane2, Paul Stoodley2, Jaime Esteban-Moreno1

1Fundación Jimenez Diaz University Hospital, Madrid, Spain, 2The Ohio State University, Columbus, OH, United States

**Abstract third-party references:** AM was funded by a SEIMC grant for a short-term visitor scholar, Funded by NIH R01 GM124436-(PS)

**Background:** Septic arthritis (SA) and prosthetic joint infection (PJI) are mostly caused by Gram-positive cocci, but an increase of cases provoked by Enterobacteria has been recently reported. Once bacteria invade synovial joints, they can form free-floating clumps or aggregates in synovial fluid which are more resistant to antimicrobial treatments in comparison to the single cells. Thus, we evaluated the formation of enterobacterial aggregates and their size in presence of synovial fluid.

**Materials/methods:** Two bacterial strains of *Klebsiella pneumoniae*, *Escherichia coli*, *Proteus mirabilis* and *Enterobacter cloacae* isolated from PJI in Hospital Universitario Fundación Jiménez Díaz were used. All PJI were diagnosed according to internationally accepted criteria. One antibiotic susceptible strain and another antibiotic multidrug-resistant strain (resistant to at least three antibiotic families) of each species were used. 25 μL of bacterial overnight tryptic-soy broth culture were added to 100 μL of Ringer solution with or without 10% bovine synovial fluid. After 24-h incubation at 37ºC and 5% CO₂, images of the aggregate formation were taken using the SpectraMax i3x plate-reader. The images were analyzed using ImageJ. Data were examined using non-parametric Wilcoxon test. The values are represented as median and interquartile range.

**Results:** Results obtained are shown in Figure 1.

![Figure 1](image-url)

**Conclusions:** The presence of synovial fluid increases the size of aggregates of *E. cloacae*, *P. mirabilis* and susceptible *E. coli* strain. The size of aggregates increased over time in *P. mirabilis* and susceptible *E. coli*. Further studies and a higher number of strains are necessary. Research about aggregate size by enterobacteria will lead to greater understanding of SA and PJI pathogenesis and to develop new treatment strategies.

Antimicrobial treatment and treatment duration for urinary tract infections in adult males

Karen Farrell1, Anja Brænd2, Ildikó Gágyor3, Filip Jansåker4, Gail Hayward5, Marius Skow2, Virginia Santiago6, Meera Tandand7, Ingvild Vik3, Akke Vellinga*1

1National University of Ireland Galway, School of Medicine, Galway, Ireland, 2University of Oslo, Division of Medicine, Oslo, Norway, 3Universitätsmedizin Göttingen, Department of General Practice, Göttingen, Germany, 4Copenhagen University Hospital, Rigshospitalet, Department of Clinical Microbiology, Rigshospitalet, København, Denmark, 5University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, 6University of St Andrews, Division of Population and Behavioural Sciences, School of Medicine, Scotland, United Kingdom, 7University of North Carolina at Chapel Hill, The Cecil G. Sheps Center for Health Services Research, North Carolina, United States

Abstract 2049

Background: Male urinary tract infections (UTIs) represent up to 20% of UTI consultations in primary care, however, little research has been done into the most appropriate antimicrobial regimen. Most of the knowledge is focused on urological patients with prostatitis, pyelonephritis/urosepsis, infections related to surgery and hospitalised patients. Generally, male UTIs are considered complicated, which implies longer antimicrobial treatment duration. However, some UTIs can be considered uncomplicated in otherwise healthy males. Uncertainties exist with regard to clinical diagnosis as well as the type and duration of antimicrobial use for male UTIs including the consideration of adverse effects, risk of relapse and emergence of resistance. The aim of this systematic review and meta-analysis is to review randomised controlled trials (RCTs) evaluating the effectiveness of different antimicrobial treatments and duration of treatment for UTIs in adult males.

Materials/methods: We searched MEDLINE, EMBASE, PubMed, Cochrane Register of Controlled trials (CENTRAL), Cochrane library and Wiley) and CINAHL EBSCOhost using selective search strategies, detailing interventions and randomised controlled trials (RCTs) in primary care focusing on UTIs in adult males. Eligible studies compared oral administration of any type of antimicrobial with either no treatment (placebo) or other (antimicrobial) treatment and/or different duration in primary care/non-hospitalised patients.

Results: 1,052 references were imported to Covidence for title and abstract screening of which 115 studies were included in full-text screening [101 were subsequently excluded]. There were fourteen papers selected for data extraction of which six had to be dismissed due to lack of male specific data and/or inability to contact the authors. The remaining eight papers include two with a specific focus on males and six reporting on both males and females for which data for males only are requested by contacting the authors. The antimicrobials used to treat male UTIs were quinolones, trimethoprim/co-trimoxazole and cephalosporins. Few similarities are observed between papers, which makes meta-analysis challenging.

Conclusions: Research on antimicrobial treatment for male UTIs is scarce and few RCTs exist to determine the best treatment. Further research is needed to examine the effectiveness of antimicrobial treatment for male UTIs in primary care.

Abstract 2050

Pharmacokinetic model for intravenous vancomycin in pregnant rats and pups
Michelle Pham*1,2, Sean Avedissian1,2, Gwendolyn Pais3,4, Medha Joshi5, Brooke Griffin3, Jack Chang3, Khrystyna Hlukhenka3, Walter Prozialeck3, Marc Scheetz3,4
1University of Nebraska Medical Center, Center for Drug Discovery, Antiviral Pharmacology Lab, Omaha, United States, 2University of Nebraska Medical Center, College of Pharmacy, Omaha, United States, 3Midwestern University, College of Pharmacy, Department of Pharmacy Practice, Downers Grove, United States, 4Midwestern University, College of Pharmacy, Pharmacometrics Center of Excellence, Downers Grove, United States, 5Midwestern University, College of Pharmacy, Department of Pharmaceutical Sciences, Downers Grove, United States

Background: Vancomycin can be used to treat methicillin-resistant Staphylococcus aureus in pregnant patients. Literature suggests maternal vancomycin crosses the placental barrier into the fetus. Thus, during pregnancy, describing the mass transit of vancomycin to the fetus is important in the design of dosing regimens. We employed a translational rat model to: 1) identify a relevant physiological based pharmacokinetic (PK) model of vancomycin in pregnancy, 2) estimate PK parameters and describe the mass transit of vancomycin from mother to pup.

Materials/methods: Pregnant female Sprague-Dawley rats were divided randomly into 3 groups: Trimester 1, Trimester 2, and Trimester 3 (T1, T2, and T3). All dosages were administered via double jugular vein catheters. Rats from each group received doses of 250 mg/kg daily for three days. Dams delivered pups vaginally after completion of the pregnancy term. Vancomycin levels in plasma and homogenized pup kidneys were quantified via LC-MS/MS. Population PK analyses were conducted using Pmetrics for R. PK parameters for trimester comparison were calculated from Bayesian posteriors utilizing noncompartmental analysis (NCA).

Results: Sixteen vancomycin treated rats and 10 pups contributed PK data. A 3-compartment model fit the data well [serum Bayesian: observed vs. predicted R²=0.918, pup Bayesian: observed vs. predicted R²=0.999] shown in Figure 1. The median rate constant for vancomycin mass transit to the pup kidney was 9.14 hr⁻¹. The fourteen population PK parameters exhibited shrinkages less than 14%. NCA of the Bayesian posteriors revealed similar median clearance [T1: 0.39L/hr vs. T2: 0.35L/hr vs. T3: 0.25L/hr, P-value: 0.32] and volume of distribution between trimesters [T1: 0.47L vs. T2: 0.73L vs. T3: 0.80L, P-value: 0.12].

Conclusions: The model is an explanatory PK model for the transfer of vancomycin through the placenta. Vancomycin transit to the fetus from the mother is rapid and predictable in the rat model. This model can be highly useful for understanding the distribution of vancomycin in pregnancy to ensure efficacious and safe doses for mother and fetus.

Figure 1. Log-scale observed concentrations versus Bayesian predicted concentrations. Fetus concentrations are in orange (R²=0.999). Mother concentrations are in blue (R²=0.929). Line of unity is shown in black.

Comparison of genetic diversity in *Streptococcus pyogenes* isolates from Gambia and United Kingdom causing skin and soft tissue infections

Saikou Bah*1,2*, Alexander Keeley1, Edwin Armitage2, Elina Senghore2, Jarra Manneh2, Lisa Tilley1, Saffiatou Darboe2, Abdul Karim Sesay2, Thushan I De Silva1,2, Claire Turner1

1University of Sheffield, Florey Institute, Department of Molecular Biology and Biotechnology, Sheffield, United Kingdom, 2Medical Research Unit The Gambia at the London School of Hygiene and Tropical Medicine, The Gambia, Fajara, United Kingdom, 3Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK, Sheffield, United Kingdom

**Background:** *Streptococcus pyogenes* causes diseases ranging from mild superficial skin infections to severe invasive disease. Despite having a high burden of disease, few isolates from sub-Saharan Africa have been included in large-scale *S. pyogenes* genetic diversity studies. Furthermore, the leading 30-valent M-protein *S. pyogenes* vaccine candidate in development is based primarily on dominant emm genotypes circulating in high income countries (HIC). We investigated the diversity and genetic variation of *S. pyogenes* isolates causing skin and soft tissue infection (SSTI) from The Gambia and UK, and compared these with an existing global *S. pyogenes* whole genome sequence dataset.

**Materials/methods:** *S. pyogenes* isolates causing SSTI were collected during a community prevalence study of skin disease in The Gambia and routine clinical isolation in a UK clinical microbiology laboratory. WGS data was generated using the Illumina Miseq platform. Spades and Prokka were used for genome assembly and annotation, and emm type determined using the CDC typing tool. Roary was used to determine the core genome and RAxML used to infer phylogenetic relatedness by maximal likelihood.

**Results:** 105 *S. pyogenes* genomes from The Gambia and 160 from the UK were newly generated. We identified 44 different emm genotypes in Gambian isolates but, unlike in HIC, there was no dominant genotype. Unusually, there were no emm1, emm3 or emm12 genotypes which typically dominate in HIC among the Gambian isolates. Overall, there was only 26.67% coverage of Gambian emm types in the 30-valent M vaccine, much lower than that of the UK collection. We also identified a high number of multilocus sequence types, which indicated high chromosomal diversity within the Gambian collection compared to UK isolates, which was confirmed by whole genome comparisons. A similar pattern was observed when contextualised within the global collection of >5000 genomes. Although isolates belonging to HIC clustered distinctly by emm-type, higher diversity was observed when isolates from low/middle income countries, including The Gambia, were included.

**Conclusions:** Our study provides insights into *S. pyogenes* diversity and generates much needed data from neglected areas of high disease burden. Understanding this diversity will enable better vaccine development to provide greater coverage and efficacy.

Screening and management of Chagas disease in at-risk blood donors in a non-endemic country: experience of a north-western tertiary care centre in Italy

Giovanni Sarteschi*, Laura Ambra Nicolini, Paola Stura, Rachele Fincino, Monica Soracco, Paola Tatarelli, Laura Magnasco, Matteo Bassetti

1Division of Infectious Diseases, Department of Health Sciences (DiSSal), San Martino Polyclinic Hospital and IRCCS, University of Genoa, Genoa, Italy, 2Infectious Diseases Unit, San Martino Polyclinic Hospital and IRCCS, Genoa, Italy, 3Blood Transfusion Center, San Martino Polyclinic Hospital and IRCCS, Genoa, Italy, 4Infectious Diseases Unit, Santa Maria delle Croci Hospital, AUSL Romagna, Ravenna, Italy, Ravenna, Italy, 5Division of Infectious Diseases, Department of Health Sciences (DiSSal), San Martino Polyclinic Hospital and IRCCS, Genoa, Italy

Background: Chagas Disease (CD) represents an emerging health concern in non-endemic countries due to migration and vector-free routes of transmission, including blood transfusion. Since 2016 international guidelines recommend CD screening protocols for first-time donors from or who recently travelled to endemic countries (at-risk blood donors).

Aim of the study: to report CD seroprevalence and management of individuals tested positive for CD in a north-western Italian Hospital.

Materials/methods: Retrospective monocentric study. From 2016 to 2019 serological screening for CD was performed in at-risk blood donors and patients with likelihood of CD symptoms by using a specific chemiluminescent microparticle immunoassay (CMIA) Trypanosoma cruzi serology. For those tested positive, a second serological assay was performed at a reference centre. Subjects with two different positive serology were considered CD confirmed cases and underwent screening for evaluating the extent of disease (acute, chronic indeterminate or symptomatic). Screening included ECG, chest X-ray, echocardiography and, for those with gastrointestinal symptoms, oesophageal manometry. CD treatment was then proposed according to current guidelines.

Results: Of 4327 blood donors tested, 16 (0.37%) had a positive CMIA serology. Nine blood donors and 6 patients tested for clinical suspicion (three achalasia, two suspected cardiomyopathies, a mother of CD confirmed case) were referred to our outpatient’s department. Overall, 6 subjects (40%) resulted positive at confirmatory serology, four of them were blood donors. All CD confirmed cases had chronic indeterminate stage of disease. They were all females, born in endemic country (three from Bolivia, one from Ecuador, Paraguay and Mexico), with a mean age of 38.8 years [range 24-48]. Three of them (50%) reported relatives with CD. Five patients received benznidazole at standard dose -150 mg bid for 60 days, weight-based prolongation of treatment-, three of them developed side effects [1 peripheral neuropathy, 2 skin rash]. One patient still has to start treatment.

Conclusions: Despite low prevalence rates, implementation of T. cruzi screening in blood donors led to identification of 4 CD cases, while none of clinically suspected subjects had symptomatic disease. Scaling-up screening protocols in low-endemic countries is crucial to prevent iatrogenic transmission and identify positive individuals before the onset of symptomatic disease.

Comparative efficacy of piperacillin-tazobactam versus third-generation cephalosporins or carbapenems against susceptible ampC-bearing Enterobacteriaceae

Veronica Rico Caballero¹, Daiana Lorena Agüero González², Laura Morata³, Marta Bodro Marimont¹, Carolina García Vidal¹, Pedro Puerta¹, Juan Ambrosioni¹, Marta Hernández-Meneses¹, Celia Cardozo¹, Laura Linares¹, Laia Albiach¹, Laura Linares¹, Laura Linares¹, Mariana Chumbita¹, Cristina Pitart¹, Climent Casals¹, Alex Soriano¹, José Antonio Martínez Martínez¹

¹Hospital Clinic, Barcelona, Spain, ²Hospital Clinic, Infectious Diseases Service, Barcelona, Spain

Background: The comparative efficacy of PTZ versus 3-CEF or carbapenems against susceptible ampC-bearing Enterobacteriaceae is unknown. The aim of the study was to assess the possible influence of empirical therapy with PTZ vs. 3-CEF or a carbapenem on 30-day mortality in patients with bacteraemia due to ampC Enterobacteriaceae.

Materials/methods: Retrospective analysis of a prospectively collected database of patients with bacteraemia diagnosed at a 750-bed university hospital in Barcelona (Spain) from January 2003 to December 2018. Episodes due to ampC-bearing Enterobacteriaceae susceptible to PTZ (MIC≤ 8 mg/L), 3-CEF (≤2 mg/L) and carbapenems and empirically treated with these antibiotics were selected. Multivariate analysis was performed by a step backward logistic regression procedure.

Results: Among 599 episodes of monomicrobial bacteraemia due to ampC-bearing Enterobacteriaceae, 182 (30.3%) were empirically treated with PTZ, 171 (28.5%) with a 3-CEF and 246 (41%) with a carbapenem. In comparison with PTZ, 30-day mortality was not significantly different in episodes treated with a 3-CEF (13/182 [7.1%] vs 14/171 [8.2%]; OR 0.86, 95%CI 0.3-1.8, p=0.7) but was higher in those receiving a carbapenem (40/246 [16.3%]; OR 2.5, 95%CI 1.3-4.8, p=0.005) regardless of the source. In episodes empirically treated with a carbapenem or PTZ, the best predictors of 30-day mortality were to receive a carbapenem (OR 1.5, 95%CI 1.06-2.2), an ultimately/rapidly fatal underlying disease (OR 4, 95%CI 1.9-8.5), indwelling urinary catheter (OR 2.2, 95%CI 1.1-4.5), chronic corticosteroid therapy (OR 3.1, 95%CI 1.5-6.3), shock (OR 5.2, 95%CI 2.5-10.7), cirrhosis (OR 3.6, 95%CI 1.4-10.2), chronic pulmonary disease (OR 3.1, 95%CI 1.4-8.6), and a non-urinary source (OR 7.2, 95%CI 1.8-28).

Conclusions: In terms of 30-day mortality, empirical use of PTZ for patients with susceptible ampC-bearing Enterobacteriaceae bacteraemia was not worse than that of other active beta-lactams and may even perform better than a carbapenem.

**Arthroscopic debridement, antibiotic and implant retention (DAIR) with local administration of Exebacase [Lysin CF-301] (LysinDAIR) followed by suppressive tedizolid as salvage therapy in elderly patients for relapsing multidrug-resistant *Staphylococcus epidermidis* prosthetic knee infection**

Tristan Ferry*1,2*, Batailler Cecile1, Camille Kolenda1,2, Cara Cassino3, Christian Chidiac1, Thomas Perpoint1, Claire Le Corvaisier1, Jérome Josse1,2, Aubin Souche1,2, Sebastien Lustig3, Frédéric Laurent1,2

1Hospices Civils De Lyon - Hcl, Lyon, France, 2Université Claude Bernard Lyon 1, Centre International de Recherche en Infectiologie, Lyon, France, 3ContraFect Corporation, Yonkers, United States

**Abstract third-party references:** on behalf of the Lyon BJ1 study group

**Background:** Exebacase, a recombinantly-produced lysin has recently: (i) reported Proof of Concept data from a phase II study in *S. aureus* bacteremia; and (ii) demonstrated activity *in vitro* against embedded-biofilm *S. epidermidis*. In patients with relapsing MDR *S. epidermidis* prosthetic knee infection (PKI), the only surgical option is prosthesis exchange. In elderly patients who have undergone several revisions, prosthesis explantation could be associated with definitive loss of function and mortality. Arthroscopic DAIR is considered to be not appropriated, as this procedure is associated with a considerable failure rate.

**Materials/methods:** We proposed in our BJ1 reference regional center ”CRIOAc Lyon” to perform arthroscopic DAIR with local administration of exebacase [LysinDAIR] followed by suppressive tedizolid as salvage therapy in elderly patients with recurrent MDR *S. epidermidis* PKI with no therapeutic option or therapeutic dead-end (for whom revision or transfemoral amputation was not feasible, and for whom no other oral option was available). Each use was decided in agreement with French health authority (ANSM) and in accordance with the local ethics committee. A written consent was obtained for each patient. Exebacase (75 mg/mL; 30 mL) was administered directly into the joint during arthroscopy.

**Results:** Four patients (79 to 89 yo) were treated with the LysinDAIR procedure. All had several previous prosthetic knee revisions, without prosthesis loosening (panel A). Three had relapsing PKI despite suppressive antibiotics following open DAIR. Two had clinical signs of septic arthritis (panel B); the two others had fistula. No adverse events occurred during arthroscopy; all patients received daptomycin (8 mg/kg) and linezolid (600 mg bid) for 4 to 6 weeks, followed by tedizolid 200 mg/day as suppressive therapy. At 6 months, recurrence of the fistula occurred in the two patients with fistula at baseline. After 1 year follow up, the outcome was favorable for the two last patients, with disappearance of clinical signs of septic arthritis (panel C).

**Conclusions:** Exebacase has the potential to be used as salvage therapy during arthroscopic DAIR in patients with relapsing MDR *S. epidermidis* PKI, to improve the efficacy of suppressive antibiotics, and to avoid considerable loss of function.

In vitro activity of ceftazidime-avibactam and comparators against isolates of Enterobacterales and Pseudomonas aeruginosa collected from pediatric patients as part of the ATLAS global surveillance program: 2013-2018

Krystyna Kazmierczak1, Meredith Hackel1, Greg Stone2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

Background: Ceftazidime-avibactam (CAZ-AVI) is a β-lactam/non-β-lactam β-lactamase inhibitor combination with in vitro activity against Enterobacterales and Pseudomonas aeruginosa isolates carrying Class A, C and some Class D serine β-lactamas. CAZ-AVI is approved in Europe and the United States (US) for treatment of adults with complicated intra-abdominal (cIAI), complicated urinary tract (cUTI), and lower respiratory tract (LRTI) infections, and in the US for treatment of pediatric patients 3 months and older with cIAI and cUTI. We examined the in vitro activity of CAZ-AVI and comparators against isolates collected from pediatric patients (newborn to 17 years old) as part of the ATLAS surveillance program in 2013-2018.

Materials/methods: Isolates were collected from 272 medical laboratories in 52 countries located in Europe (EUR; n=3561), Middle East/Africa (MEA; n=834), Asia/Pacific (AP, excluding China and India; n=745), and Latin America (LA; n=1175) from patients with LRTI (n=2414), IAI (n=1395), and UTI (n=2506). Susceptibility testing was performed by CLSI broth microdilution and values were interpreted using EUCAST 2019 breakpoints. CAZ-AVI was tested at a fixed concentration of 4 mg/L AVI.

Results: The in vitro activity of CAZ-AVI was comparable to or greater than that of meropenem against Enterobacterales and P. aeruginosa collected globally from pediatric patients with LRTI, IAI and UTI (Table).

|     | EUR, Europe; MEA, Middle East/Africa; AP, Asia/Pacific; LA, Latin America; LRTI, lower respiratory tract infection; IAI, intra-abdominal infection; UTI, urinary tract infection; CAZ-AVI, ceftazidime-avibactam; MEM, meropenem. % Susceptible was determined using EUCAST 2019 breakpoints. |

MIC90 values ranged from 0.25-0.5 mg/L (98.6-100% susceptible) against Enterobacterales collected in the four geographic regions surveyed, while MIC90s ranged from 4-8 mg/L (90.9-97.5% susceptible) against P. aeruginosa collected from LRTI in LA and from all examined infection sources in EUR, MEA and AP. MIC90 values were higher against P. aeruginosa collected from IAI and UTI in LA, which included an elevated proportion of isolates carrying Class B metallo-β-lactamas. Overall, 99.2%, 99.2% and 99.4% of Enterobacterales collected from pediatric patients with LRTI, IAI and UTI, respectively, and 92.7%, 93.0% and 94.3% of P. aeruginosa, respectively, were inhibited by ≤8 mg/L of CAZ-AVI; higher percentages of susceptibility were only observed for colistin tested against P. aeruginosa isolates (not shown).

Conclusions: CAZ-AVI demonstrated potent in vitro activity against the majority of Enterobacterales and P. aeruginosa isolates collected globally from pediatric patients in 2013-2018, regardless of infection source.

Abstract 2063

In vitro activities of ceftazidime-avibactam and comparator agents against Enterobacterales from Europe stratified by infection type from the ATLAS global surveillance programme 2016-2018

Mark Estabrook1, Krystyna Kazmierczak*, Greg Stone2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

Background: The global spread of multi-drug resistant (MDR) Enterobacterales (Eba) has limited the number of options available to treat Gram-negative infections. Ceftazidime-avibactam [CAZ-AVI] is a β-lactam-β-lactamase inhibitor combination developed for treatment of carbapenem-resistant and MDR infections caused by β-lactamase-producing Gram-negative bacteria. CAZ-AVI has activity against Eba that carry Class A, C and some Class D β-lactamases, but not Class B metallo-β-lactamases (MBLs). The in vitro activity of CAZ-AVI against Eba collected from patients in Europe from various body sites for the ATLAS Global Surveillance Program in 2016-2018 is evaluated herein.

Materials/methods: 23,655 non-duplicate Eba isolates were collected from 123 sites in 24 countries in Europe from patients with lower-respiratory-tract infections (LRTI), urinary-tract infections (UTI), skin/soft-tissue infections (SSTI), intra-abdominal infections (IAI), and blood infections. Antimicrobial susceptibility was determined by broth microdilution according to CLSI guidelines and EUCAST 2019 breakpoints. Avibactam was tested at a fixed concentration of 4 mg/L. β-lactamase carriage was determined by PCR and sequencing for isolates with meropenem MIC values >1 mg/L.

Results: CAZ-AVI was active against more Eba isolates from LRTI, UTI, SSTI, IAI, and blood than any other comparator (98.5%-99.1% susceptible; Table). Meropenem was also active against these isolates, however when compared to other sources, relatively fewer isolates from LRTI and blood were meropenem-susceptible [95.3% and 95.2% susceptible, respectively]. Among isolates from all sites, ≤82.5% were susceptible to other comparator agents.

Conclusions: CAZ-AVI demonstrated in vitro potency against Eba isolates collected from different infection sites from 2016-2018 in Europe. In contrast to comparator agents, the percentage of isolates susceptible to CAZ-AVI did not vary greatly by infection site.

Bordeaux, Inserm, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, ³Centre de Recherche Cardio-Thoracique de Bordeaux, U1045, F-33000, Bordeaux, France, ⁴CHU Bordeaux, Department of Public Health, Bordeaux, France, ⁵Centre de Recherche Cardio-Thoracique de Bordeaux, U1045, F-33000, CRCM Pédiatrique, CHU de Bordeaux, Bordeaux, France, ⁶CHU de Bordeaux, Univ. Bordeaux, FHU ACRONIM, Bordeaux, France, ⁷Service de Parasitologie Mycologie, FHU ACRONIM, Bordeaux, France

**Background:** Lung infections play a critical role in cystic fibrosis (CF) pathogenesis, especially in CF pulmonary exacerbation (CFPE) and decreases in respiratory function (i.e., FEV1 decline). CF respiratory tract is now considered as a polymicrobial ecosystem that NGS allowed to analyze deeply in terms of mycobiome and microbiome. To the best of our knowledge, no data have been generated in regards of the mycobiome and the microbiome together during CFPE.

**Materials/methods:** Thirty-three sputa isolated from patients with and without CFPE underwent targeted metagenomics, based on analysis of bacterial and fungal rRNA regions (16S and ITS2 regions). Inter-kingdom network and adapted Phy-Lasso method were used to highlight correlations in compositional data. Given the limited number of samples, we chosen to apply a penalized regression method with bootstrap (bootstrap-enhanced Phy-Lasso) for examining associations between microbial genera and clinically relevant features (here CFPE and/or FEV1 decline).

**Results:** As previously described, the decline in respiratory function (FEV1) was associated with a decrease in bacterial diversity. The inter-kingdom network revealed three main clusters organized around Aspergillus, Candida, and Scedosporium genera. We confirmed by in vitro experimentations the cross-domain positive interactions between Aspergillus and Streptococcus predicted by the correlation network. We identified Aspergillus and Malassezia to be associated with CFPE. Scedosporium plus Pseudomonas were associated with a decline in FEV1. Collectively, our findings (inter-kingdom network analysis, in vitro co-culture results, and feature selection based on bootstrap-enhanced Phy-Lasso) pave the way for deciphering the role of fungi in CF lung disease at the ecological level by proposing a new version of the recently-described Climax-Attack Model (CAM).

**Conclusions:** Altogether, these results highlighted the complexity of the microbial community interacting within the CF respiratory tract, and suggested the suitability of developing ecological models such as CAM. For the first time, we included documented mycobiome data into CAM that opens new lines of thoughts about the physiopathology of CF lung disease and future perspectives to improve its therapeutic management.

Abstract 2068

Effects of a strict postoperative glycaemic control on surgical site infection’s incidence following liver transplantation: a randomised clinical trial

Ramon Antonio Oliveira*1, Jorge Marcelo Padilla Mancero2, Judith Tanner3, Vanessa Brito Poveda1

1 University of Sao Paulo School of Nursing, Av Dr Eneias de Carvalho Aguiar, São Paulo, Brazil, 2 Santa Casa of Sao Jose dos Campos, R. Dalzani Ricardo, Sao Jose dos Campos, Brazil, 3 University of Nottingham Faculty of Medicine & Health Sciences, Queen’s Medical Centre Nottingham NG7 2UH, Nottingham, United Kingdom

Abstract third-party references: São Paulo Research Foundation (FAPESP) Brazil, Comissão de Aperfeiçoamento de Pessoal de Nível Superior (CAPES - Ministry of Education) Brazil

Background: Hyperglycemia is an independent risk factor for the development of surgical site infections among liver transplantation recipients. We compared the effects of a postoperative strict blood glucose control protocol against a conservative protocol on the incidence of surgical site infection among liver transplantation recipients.

Materials/methods: In this open-label, two-arm controlled clinical trial we recruited liver transplant recipients in a Brazilian referral centre. Eligible patients were 18 years or older whose allograft came from a deceased donor. We excluded patients who had undergone any kind of surgery in the 30 days before the transplantation. Patients were randomly assigned into two groups: 21 with a conservative blood glucose of 180 mg/dL and 20 with a strict blood glucose of 130 mg/dL. Subcutaneous insulin or continuous intravenous insulin therapy were employed. A blinded adjudication committee analysed the endpoint adopting the surgical site infection criteria given by the CDC. The analysis was by intention to treat.

Results: 41 patients were assigned to either the conservative or strict groups and followed up until 30 days after the liver transplantation. At baseline, the median age was 55.2 years (IQR 49.6-69.4), 31 (75.6%) were male, 30 (75.0%) were white and the median of the model of end-stage liver disease was 18 (IQR 13-21). Within the conservative and strict groups, we have observed: 8 (38.0%) and 6 (30.0%) had diabetes, and the median glycaemia immediately before the anaesthesia was 117.5 mg/dL (IQR 82.5-132.5) and 98 mg/dL (IQR 81-123), respectively. Participants enrolled to strict control presented lower glycaemia median in the first 24 hours after liver transplantation in comparison to those in the conservative group (145 mg/dL [IQR 130-160.3] versus 221.9 mg/dL [IQR 181.3-235.8]; p<0.001). Furthermore, the length of stay was higher among recipients enrolled on the conservative compared to the strict group (17 days [IQR 13-29] versus 15 days IQR 10-19; p<0.05). Five (23.8%) patients in the conservative group developed surgical site infection in contrast to three (15%) from the strict group (RR 0.63 [95% CI 0.17-2.29]; p=0.48).

Conclusions: Using intravenous strict insulin protocol did not reduce the occurrence of surgical site infections among liver transplant recipients.

Safety and efficacy of fumagillin for the treatment of intestinal microsporidiosis: a French prospective cohort study

Alexis Maillard*, Anne Scemla1, Benjamin Laffy2, Nadir Mahloul4, Jean-Michel Molina1

1Department of Infectious Diseases, St-Louis Hospital, APHP and University of Paris, Paris, France, 2Kidney Transplant Unit, Hôpital Necker Enfants Malades, APHP and University of Paris, Paris, France, 3Kidney Transplant Unit, St-Louis Hospital, APHP and University of Paris, Paris, France, 4Sanofi, Gentilly, France

Background: Intestinal microsporidiosis due to Enterocytozoon bieneusi is a rare cause of chronic diarrhea in immunocompromised patients. Fumagillin has been approved in France since 2005 for its treatment. We report on the real-life use of fumagillin.

Materials/methods: As required by the French Medicine Agency, all patients receiving fumagillin were enrolled in a prospective study to assess its safety and parasitic efficacy. Fumagillin was given orally at a dose of 20 mg tid for 14 days. At baseline patients demographics and comediations were collected. Stool examination for the detection of microsporidial spores and identification of E. bieneusi by PCR was performed at baseline, end of treatment [with a window of -5 to + 20 days], and monthly thereafter for 6 months. Safety was monitored up to the 6-month follow-up visit. The primary endpoint was safety. Parasitic clearance and relapse were secondary endpoints. Descriptive statistics were used.

Results: From July 2007 to October 2018, 169 patients from 40 sites received fumagillin. Ninety-nine (59%) were males; median age: 49 years (range: 5-81), 139 (82%) were recipients of solid organ or hematopoietic stem cell transplants, 21 (12%) had HIV-infection, and 9 (5%) other causes of immunosuppression. More than 90% had comediations [antiretrovirals or immunosuppressive drugs]. Median duration of treatment was 14 days (range: 5-23) and treatment was prematurely discontinued in 58 patients (35%). Forty-five patients (26.6%) presented at least one AE, mainly thrombocytopenia (15.4%), neutropenia (4.1%), anemia (1.8%), hepatic disorder (3%) and cutaneous rash (1.8%). Thrombocytopenia (<150 G/L) occurred in 13 patients (81%) with spontaneous recovery after treatment discontinuation. Thirty-five patients (21%) presented a serious AE, mainly thrombocytopenia (13%), and neutropenia (4%), and one patient died of peritoneal hemorrhage following a liver biopsy. At the end of treatment, 122/128 patients (95%) who had a stool examination in the window had no spore detected. Three patients presented a parasitic relapse during follow-up, and 3 patients were treated twice (2 failures and one relapse) with parasitic clearance.

Conclusions: E. bieneusi microsporidiosis was mainly diagnosed in transplant recipients. Fumagillin was associated with hematological toxicity but showed high efficacy with a low relapse rate.

In vitro Activities of ceftazidime-avibactam and comparators against Pseudomonas aeruginosa from Europe stratified by infection type: ATLAS global surveillance programme 2016-2018

Mark Wise1, Krystyna Kazmierczak*1, Greg Stone2, Dan Sahm1

1IHMA, Schaumburg, United States; 2Pfizer, Groton, United States

Background: The non-β-lactam β-lactamase inhibitor avibactam (AVI) is active against class A, class C and some class D β-lactamases, and in combination with ceftazidime (CAZ) has been approved by the FDA and EMA for treatment of infections caused by Gram-negative bacteria including Pseudomonas aeruginosa (Paer). This study reports susceptibility data for CAZ-AVI and comparators for recent (2016-2018) clinical Paer isolates from Europe stratified by infection source.

Materials/methods: From 2016-2018, 6574 non-duplicate Paer isolates were collected from 123 sites in 24 countries in Europe as part of the ATLAS surveillance study from lower respiratory tract infections (LRTI), urinary tract infections (UTI), intra-abdominal infections (IAI), skin and soft tissue infections (SSTI) and blood infections. Susceptibility testing was by broth microdilution according to the ISO standard method and interpreted using EUCAST 2019 breakpoints. CAZ-AVI was tested with a fixed concentration of 4 mg/L avibactam. When meropenem MIC values were >2 mg/L, the β-lactamase gene content was assessed by PCR and sequencing.

Results: Among the various infection sources, CAZ-AVI susceptibility percentages ranged from 90.7% (UTI and blood) to 93.5% (SSTI). The addition of AVI to CAZ increased its activity against Paer from all infection sources, with the most dramatic being LRTI isolates (% susceptibility increasing from 73.7% to 90.7%, and MIC90 falling to 8 mg/L from 64 mg/L for this population). Among the comparators, only colistin exhibited superior activity against Paer.

*CAZ-AVI, ceftazidime-avibactam; CAZ, ceftazidime; MEM, meropenem; TZP, piperacillin-tazobactam; LVX, levofloxacin; CST, colistin.

Conclusion: CAZ-AVI continues to demonstrate good in vitro activity against Paer isolates in Europe regardless of infection site. It was the second most active agent tested, eclipsed only by colistin, a last-resort agent with known toxic side effects.

**Abstract 2074**

**In vitro activities of ceftazidime-avibactam and comparator agents against Gram-negative isolates from China as part of the ATLAS global surveillance programme 2018**

Meredith Hackel*1, Greg Stone2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Groton, United States

**Background:** Avibactam (AVI) is a β-lactamase inhibitor with potent inhibitory activity against Class A, Class C, and some Class D serine β-lactamases. The combination of ceftazidime (CAZ) with AVI has been approved in Europe and in the United States for several indications. This study evaluated the *in vitro* activity of CAZ-AVI and comparators against Enterobacterales (Eba) and *Pseudomonas aeruginosa* (Pae) isolates collected from patients in China as part of the ATLAS surveillance program in 2018.

**Materials/methods:** A total of 1,425 Eba and 386 Pae non-duplicate clinically significant isolates, were collected by 24 clinical laboratories in China in 2018. Organism identification was confirmed by MALDI-TOF mass spectrometry and susceptibility testing was performed by broth microdilution following CLSI guidelines at a central laboratory [Peking Union Medical College Hospital, Beijing, China] using broth microdilution panels [supplied by IHMA, Schaumburg, IL, USA]. CAZ-AVI was tested at a fixed concentration of 4 mg/L AVI. MICs were interpreted using current EUCAST [2019, v 9.0] MIC breakpoint criteria.

**Results:** Susceptibility data are shown in the Table. CAZ-AVI showed potent *in vitro* activity against all Eba isolates, including CAZ-NS and colistin-resistant (CST-R) subsets (87.2% and 95.8% S, respectively), with reduced activity against MEM-NS Eba (66.5% S). CAZ-AVI also showed good *in vitro* activity against all Pae isolates (MIC90, 8 mg/L, 90.7% S). Activity was reduced against CAZ-NS, MEM-NS and CST-R subsets (70.8%-87.5% S), but exceeded the activity of CAZ and MEM against these subsets. CST and amikacin were the only tested comparators that demonstrated comparable or greater activity against Pae isolates.

Neurological manifestations of rickettsiosis

Fatma Hammami¹, Koubaa Makram¹, Abrakhom Zayni¹, Khaoula Rekik¹, Fatma Smaoui¹, Emna Elleuch¹, Chakib Marrachi¹, Mounir Ben Jemaa*¹

¹Infectious Diseases Department, Hedi Chaker University Hospital, Sfax, Tunisia

Background: Rickettsiosis, a relatively benign disease, typically manifests with fever, skin rash, and headache. Neurological complications may occur, changing the prognosis and could even become permanent. In this perspective, the aim of this work was to determine the clinical, biological and therapeutic characteristics of neurorickettsiosis.

Materials/methods: We conducted a retrospective study including all patients hospitalized for rickettsiosis in infectious diseases department between 1998 and 2018. The diagnosis was confirmed by serological tests.

Results: During the study period, 410 patients with rickettsiosis were identified, among whom 48 patients (11.7%) had neurological manifestations. There were 28 male (58.3%). The median age was 25 years [9-82 years]. Thirty-three patients had a close contact with dogs (68.7%). The majority of cases occurred during the hot season, between May and October (44 cases; 91.6%). The most common revealing symptoms was fever and headache, noted in all cases, followed by arthralgia, noted in 35 cases (72.9%). Vomiting was noted in 33 cases (68.7%). Physical examination showed meningeal syndrome in 31 cases (64.5%) and maculopapular skin rash in 16 cases (33.3%). Laboratory investigations revealed thrombocytopenia (37.5%) and liver cytolysis (35.4%). The most common clinical presentation was meningitis, noted in 42 cases (87.5%). There were 29 cases of lymphocytic meningitis (69%) and 13 cases of meningitis with neutrophil predominance (31%). Meningoencephalitis was noted in 6 cases (12.5%). The patients received doxycycline in 39 cases (81.2%) and fluoroquinolones in 9 cases (18.8%). The mean duration of treatment was 10 ± 2 days. The disease evolution was favorable in all cases. Complications such as epileptic seizure were noted in 2 cases (4.1%).

Conclusions: Rickettsiosis is a benign disease once diagnosed and treated on time. It should be bearded in mind in front of acute fever and maculopapular rash, especially during hot season.

Abstract 2080

Differential drug susceptibility patterns of Mycobacterium avium complex isolates recovered in Greek university hospitals

Fanourios Kontos*,1, Georgios Mavromanolakis2, Spyros Pournaras1

1Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 2University Hospital of Heraklion, Heraklion, Greece

Background: Mycobacterium avium complex (MAC) includes a group of mycobacterial pathogens that causes disease in susceptible hosts. Current treatment recommendations for MAC infections include a macrolide, a rifamycin (rifampin or rifabutin) and ethambutol with or without a fourth agent such as amikacin. In this study, we investigated the in vitro drug susceptibility patterns of individual MAC species for antimicrobial agents commonly used to treat MAC infections.

Materials/methods: We studied 73 M. avium and 55 M. intracellulare clinical strains recovered from 128 different patients. The minimum inhibitory concentrations (MICs) for clarithromycin, amikacin, moxifloxacin, linezolid, streptomycin, ethambutol, rifampicin and rifabutin were determined using a commercial broth microdilution method (SLOMYCOI, TREK Diagnostic systems), according to the CLSI recommendations and MICs were interpreted based on CLSI breakpoints for clarithromycin (S ≤ 8 mg/l) and amikacin (S ≤ 16 mg/l) and tentative breakpoints for moxifloxacin [S ≤ 8 mg/l] and linezolid (S ≤ 8 mg/l) (CLSI documents M24 and M62, 2018). Also, the MIC50 and MIC90 were determined and finally “tentative” epidemiological cutoff (ECOFF) values were determined by the ECOFFinder algorithm.

Results: Clarithromycin wild-type populations were mostly classified as susceptible, with MIC90 of M. avium and M. intracellulare to be equal to ECOFF (8 mg/l and 4 mg/l respectively). Overall, 121 MAC strains (94.5%) were susceptible to clarithromycin, while only 4 (3.5%) M. avium and 3 (5.5%) M. intracellulare strains were resistant (MIC > 64 mg/l). For amikacin, the CLSI breakpoints split the wild-type populations for both species (MIC90 = MIC50 = 32 mg/l). Thirty-eight (70.4%) of M. intracellulare but only 32 (43.8%) M. avium strains were categorized as susceptible to amikacin. Tentative moxifloxacin and linezolid CLSI breakpoints split also the wild-type populations. Only 2.3% (3/128) of MAC strains were categorized as susceptible to moxifloxacin and linezolid. Rifabutin MICs for both species were lower than those of rifampicin. No ECOFFs could be set for rifampicin, ethambutol and streptomycin due to truncation of MIC distributions.

Conclusions: The in vitro drug susceptibility patterns of the different MAC species studied are comparable to each other. Except for clarithromycin, current breakpoints for MAC categorization should be reevaluated.

Drain water as a potential source of in-hospital room-to-room transmission of carbapenemase-producing Klebsiella pneumoniae

Laura Heireman*1, Hannelore Hamerlinck1, Jerina Boelens1, Stien Vandendriessche1, Liselotte Coorevits1, Isabel Leroux-Roels1, Monika Chlebowicz2, John Rossen3, Bruno Verhasselt1

1Department of Laboratory Medicine, Ghent University Hospital, Ghent, Belgium, 2Department of Medical Microbiology and Infection Prevention, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, 3University of Groningen / University Medical Center Groningen, Department of Medical Microbiology and Infection Prevention, Groningen, Netherlands

Background: Carbapenemase-producing Enterobacterales [CPE] have rapidly emerged in Europe with OXA-48 producing Klebsiella pneumoniae as one of the prominent causes of nosocomial outbreaks. Toilets may produce potentially infectious aerosols during flushing to which subsequent toilet users may be exposed. The study of an outbreak suggests that CPE can also be transmitted between patients staying in different hospital rooms via toilet plume aerosols.

Materials/methods: A total of 14 OXA-48 producing K. pneumoniae isolates collected over 4 months’ time were sequenced, including 12 isolates involved in an outbreak at the burn center (containing six linearly positioned rooms with open bathrooms) of Ghent University Hospital and two random strains. The outbreak isolates were five isolates obtained from rectal swabs [patients residing in rooms 1,3,6], four from toilet water [rooms 2,3,4,6], two from toilet water after 2 months of daily disinfection with bleach [rooms 3,4], one from drain water [between rooms 4 and 5]. Whole genome sequencing was performed on a HiSeq300 instrument (Illumina,USA) in single-end mode generating 50-bp reads. FASTQ files were quality-trimmed and de novo assembled using CLC Genomics Workbench [CLC Bio,Denmark]. Whole-genome Multilocus Sequence Typing was performed to determine phylogeny by using Ridom SeqSphere+ [Ridom GmbH,Germany].

Results: A coverage of 262 to 485-fold was obtained with 196 to 260 contigs per isolate. Phylogenetic analysis revealed isogenicity (<15 allele differences) of all isolates obtained from the outbreak (Figure 1). This suggests that the isolate persisted despite disinfection and may have spread between different rooms by drain water. Unexpectedly, one random isolate obtained from a patient who became colonized whilst residing at the geriatric ward in another building belonged to the same genetic cluster, suggesting the outbreak to be larger than expected. There was no obvious link between this patient and the burn center.

Conclusions: Drain water may be a potential source of hospital room-to-room transmission of carbapenemase-producing K. pneumoniae. Further research is needed to map the actual size of the hospital outbreak.

Figure 1:Phylogenetic tree of Klebsiella pneumoniae isolates with isogenic isolates indicated in blue, the non-isogenic isolate in red, control isolates underlined and number of allele differences presented on the branches.

Abstract 2086

Imipenem/relebactam pharmacokinetic/pharmacodynamic analyses from an in vivo neutropenic mouse delayed lung infection model

Naveen Daryani*,1, Munjal Patel1, Amy Flattery1, Katherine Young1, Matthew L. Rizk1

1Merck & Co., Inc., Kenilworth, NJ, United States

**Background**: Relebactam (REL) is a small molecule beta-lactamase inhibitor which has shown significant antibacterial activity against imipenem-resistant strains in combination with imipenem/cilastatin. Based on previous analyses using an in vitro hollow fiber model and an in vivo mouse thigh infection model, we assumed the REL PK/PD driver was $\frac{AUC_{0-24hr}}{MIC}$. We conducted PK/PD analyses utilizing data from an in vivo neutropenic mouse delayed lung model to derive REL $\frac{AUC_{0-24hr}}{MIC}$ associated with stasis, 1-log kill and 2-log kill targets.

**Materials/methods**: Previously conducted PK/PD murine delayed lung model studies were used for generation of the pooled PK/PD dataset. This dataset consisted of nine isolates of *Pseudomonas aeruginosa* at imipenem doses thirteen-fold below the humanized dose with varying total daily doses of REL. A Population PK model was used to estimate the $AUC_{0-24hr}$ for each mouse from measured concentrations in each respective study. Correlation analysis using the pharmacokinetic (PK) exposure and response [change in log$_{10}$ CFU at 24 hours post-dose] was plotted against $\frac{AUC_{0-24hr}}{MIC}$. Imipenem MICs in the presence of 4 mg/L of REL were used to derive the $\frac{AUC_{0-24hr}}{MIC}$ for each strain. An Emax model with Hill coefficient was used to fit the data. Stasis, 1-log kill, and 2-log kill PK/PD targets were derived from this model.

**Results**: There appeared to be a relationship between $\frac{AUC_{0-24hr}}{MIC}$ and change in log$_{10}$ CFU at 24 hours in the murine delayed lung model data. The derived stasis, 1-log kill, and 2-log kill $AUC/MIC$ PK/PD targets for *Pseudomonas aeruginosa* were 0.1, 0.3 and 8.0 respectively. This 2-log kill PK/PD target is consistent with previous analyses in an in vitro hollow fiber infection model and an in vivo mouse thigh model.

**Conclusions**: PK/PD analyses using pooled data from nine isolates of *Pseudomonas aeruginosa* confirmed that $\frac{AUC_{0-24hr}}{MIC}$ is the PK/PD driver for REL. The derived 2-log kill target can be used for dose justification and probability of target attainment (PTA) assessment for fixed dose combination of imipenem/cilastatin/relebactam.

Figure. PK/PD Relationship of REL in the Neutropenic Mouse Lung Infection Model at imipenem 5 mg/kg for *Pseudomonas aeruginosa* [Left] and overlaid with observed mouse thigh infection model [Right]

Abstract 2088

Evaluating the usefulness of whole genome sequencing in tuberculosis treatment decisions in a low-incidence clinical setting

Mirae Park*, Giovanni Satta1, Onn Min Kon1,2

1Imperial College Healthcare NHS Trust, London, United Kingdom, 2National Heart & Lung Institute, London, United Kingdom

Abstract third-party references: This work is funded by the National Institute for Health Research (NIHR) Imperial Biomedical Research Centre (BRC).

Background: Whole genome sequencing (WGS) has been implemented in the UK as part of routine diagnostics for the detection of Mycobacterium tuberculosis and susceptibilities. No study has yet described the impact of WGS on clinical decision making for TB drug treatment regimens in a real-life clinical setting.

Materials/methods: A retrospective analysis of 189 cases from January 2018 to March 2019 in London. Demographics and clinical data were collected. Susceptibility results by WGS and turn-around times (TAT) were correlated to alterations in drug treatment.

Results: 80/189 cases had positive culture and WGS results. The median age was 40 years (IQR 28-53.5), Male:Female was 46:34, 3 patients with HIV and 3 had previous TB.

50/80 had fully sensitive TB to 1st line treatment on WGS. In the remaining 30/80 cases, WGS showed drug resistance, failed or unknown results for 1st line treatment and required additional phenotypic drug sensitivity testing (DST).

20/80 had treatment decision changes but only 12 were defined by WGS. 9/12 were due to isoniazid resistance (excluding the 2 MDR-TB cases). For these 12 cases the median time for culture positivity was 16 days (IQR 13.5-19.5). Median TAT from collection to WGS results in the centralised lab was 35 days (IQR 32.5-36.25) resulting in the median time on the incorrect treatment of 42 days (IQR 27-59). The median time for DST results was 86 days (IQR 70.5-94.25).

63/80 had rapid TB PCR of which 50 cases were positive. 4/9 of the isoniazid resistant cases were PCR positive with an additional 2/9 with ‘Trace’ readings. Both MDR-TB cases were positive on PCR with rifampicin resistance being identified.

Conclusions: WGS is helpful in determining the correct treatment regimen but in our cohort this took over a month. We highlight the important issue of isoniazid resistance and delayed identification of this. This stresses the need for an extended panel of susceptibilities using rapid PCR at the point-of-care [in addition to rifampicin] in order to inform immediate treatment choices and reduce the number of days on suboptimal treatment. WGS continues to have a valuable role especially for transmission data and outbreak detection.
Abstract 2089

In vitro antimicrobial susceptibility testing of rapidly growing mycobacteria isolated in a university hospital, Athens, Greece

Fanourios Kontos†1, Spyros Pournaras1

1Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Several species of rapidly growing mycobacteria (RGM) are now recognized as human pathogens and antimicrobial susceptibility testing is important since susceptibility pattern is variable within RGM species. In this study we recorded the antibiotic susceptibilities of clinical RGM strains recovered over 13 years (1/2007-10/2019) in a University Hospital in Athens, Greece.

Materials/methods: We studied 25 Mycobacteroides abscessus (16 M.abscessus subsp. abscessus, 6 M.abscessus subsp. bolletii, and 3 M.abscessus subsp. massiliense), 23 Mycolicibacterium fortuitum, 9 Mycobacteroides chelonae, 7 Mycolicibacterium peregrinum, 3 Mycolicibacterium mucogenicum, 4 Mycolicibacterium neoaurum, 2 Mycolicibacterium canariense and 1 Mycolicibacterium phlei non-duplicate clinical strains recovered from 73 different patients. Identification was performed with sequencing of hsp65 gene. The minimum inhibitory concentrations [MICs] for clarithromycin, amikacin, ciprofloxacin, moxifloxacin, linezolid, cefoxitin, imipenem, trimethoprim-sulfamethoxazole, doxycycline, tigecycline, minocycline and tobramycin were determined using a commercial broth microdilution assay (RAPMYCOI, TREK Diagnostic systems), according to the CLSI recommendations and MICs were interpreted based on CLSI breakpoints (documents M24 and M62, 2018), except for tigecycline and minocycline, for which only MIC90 were determined. To investigate possible inducible clarithromycin resistance that is common among M.abscessus isolates, the incubation period was extended up to 14 days.

Results: The RGM species tested were commonly susceptible to amikacin and linezolid (susceptibilities 77.8-100%) and resistant to doxycycline (susceptibilities 4-34%) and cefoxitin (susceptibilities 8-29%). Only 20% of the M.abscessus strains were susceptible to clarithromycin, 18 (72%) strains had inducible and 2 (8%) acquired resistance. On the other hand, 90% of M.chelonae, and 57% of M.fortuitum strains were susceptible to clarithromycin. The M.abscessus and M.chelonae strains were highly resistant to ciprofloxacin, moxifloxacin, imipenem and trimethoprim-sulfamethoxazole (resistances 88-96%), while M. fortuitum strains (susceptibilities 64-87%) were susceptible to these drugs. Of the M.chelonae strains, 80% were susceptible to tobramycin, while 84% of M.abscessus and 68% of M.fortuitum strains were tobramycin-resistant. The MIC50/MIC90 values for tigecycline were 0.5/1 μg/ml for M.abscessus and 0.1 2/0.5 μg/ml for M.fortuitum while the respective values for minocycline were >8 μg/ml for both species.

Conclusions: The high variation of susceptibility profiles within RGM species confirms the need for accurate identification and susceptibility testing for clinically relevant strains.

Abstract 2091

**Which HIV-positive men who have sex with men patients benefit of anal cancer screening?**

Carmen Hidalgo Tenorio*, Concepcion Gil-Anguita², Miguel Ángel López-Ruiz³, Javier Lopez Hidalgo³, Juan Pasquau³

¹University Hospital Virgen de las Nieves, Granada, Spain, ²Hospital Marina Baixa, Alicante, Spain, ³University Hospital Virgen de las Nieves, Granada, Spain

**Background:** Our main objective was to analyze the incidence of HSILs and ASCC (HSIL+) in anal mucosa of HIV+ MSM, and the risk factors related.

**Materials/methods:** The study included consecutive HIV-infected MSM between May 2010 and December 2018. Data were gathered at baseline and annually on their sexual behavior, CD4 and CD8 levels, HIV VL, and anal cytology, HPV PCR, and high-resolution anoscopy (HRA). Patients with normal HRA and LSIL were evaluated annually with cytology, HPV PCR, and HRA besides in case of LSIL. There were two options for HSIL: mucosectomy with electrosurgical procedure (from May 2010 onwards); or self-administration of 5% imiquimod 3 times/week/16 weeks (from November 2012 onwards). When ASCC was detected, patients were sent to the oncology Service. Between May 2012 and May 2014, the qHPV vaccine was administered to 66 patients.

**Results:** Among the 405 patients, 87.2% had at least two control HRA with a median follow-up of 36 months (IQR: 12-69). During this period, there were 38 new cases of HSIL (incidence of 30.86/1,000 patient-years) and 1 new case of ASCC (incidence of 81.22/100,000 patient-years). One ASCC was resolved with wide local surgery; another was treated with abdominal-pelvic amputation, chemotherapy, and radiotherapy and has been in remission for 12 months; and the third patient with ASCC died at 15 months post-diagnosis after chemotherapy and radiotherapy. 49 HSILs were treated by mucosectomy and 34 with intra-anal 5% imiquimod. None of HSIL progressed to ASCC. We found significant reductions in HSIL+ between 2010 and 2018 (42.9% vs. 4.1%, p=0.034). Risk factor related to HSIL+ were HPV 11 (OR 4.153; CI95% 1.85-9.3), HPV 16 (OR 2.74, CI 95% 1.189-6.34), HPV 53 (OR 3.67, CI95% 1.141-11.79); HPV 61 (OR 13.98, CI 95% 3.74-52.2); HPV 68 (OR 2.773 CI 95% 1.121-6.86); presence of mixture infection by Low and High-Risk HPV (OR 1.058; CI95% 1.003-1.116), and low CD4 nadir (OR1.002; CI95% 1-1.004).

**Conclusions:** The reduction in HSIL+ rate observed in our patients may be attributable to the bundle of measures adopted at our center. The chronic mixture infection by HPV and low level of CD4 nadir were related to HSIL

Abstract 2092

**Blood culture contamination is commonly associated with divergent blood culture sets**

Eli Ben-Chetrit*, Phillip Levin

*The Hebrew University of Jerusalem, The Division of Infectious Diseases, Shaare Zedek Medical Center, Jerusalem, Israel, **The Hebrew University of Jerusalem, Intensive Care Unit, Shaare Zedek Medical Center, Jerusalem, Israel

**Background:** Contamination of blood cultures by nonpathogenic bacteria is associated with diagnostic uncertainty and health care costs. Diversion of the initial blood specimen during venipuncture, potentially containing skin organisms, is suggested to reduce contamination. Since blood culture sets include two bottles taken sequentially directly from the Vacutainer device (used for all blood cultures in our institution), the first bottle could act as a "diversion device" for the second bottle. If diversion is effective in reducing blood culture contamination, it might be expected that contaminated sets would be positive in only one bottle, whereas both bottles would grow true pathogens.

**Materials/methods:** We retrospectively reviewed all blood cultures drawn over 15 years. Blood isolates were defined prospectively as pathogens or contaminants. Blood culture sets were **convergent** if both culture bottles were positive for the same organism and **divergent** if only one bottle was positive. Convergent and divergent sets of blood cultures were compared. Growth patterns in aerobic or anaerobic media were not taken into account.

In order to test the results in a homogeneous bacterial population, we assessed the subgroup of blood cultures growing only *Staphylococcus aureus* (SA) or *Coagulase-negative Staphylococci* (CoNS). These bacteria have similar growth patterns in aerobic and anaerobic media, and yet commonly represent a true pathogen and a common contaminant.

**Results:** From 2004 to 2019, blood cultures sets were collected on 384,284 occasions. Most culture sets were sterile (n=332,510, 87%). One or both bottles were positive in 51,774 (13%) sets and overall 55,247 isolates were identified. Pathogens grew in 29,088 (7.6%) of all sets taken. Of these sets 12,577 (43%) were divergent. Contaminants grew in 26,159 (6.8%) of all sets taken. Of these sets 19,591 (75%) were divergent (p<0.001 vs pathogens, Figure). Amongst sets positive for SA and CoNS, 14,605/54,455 (27%) and 11,700/18,148 (64%) were divergent, respectively (p<0.001).

**Conclusions:** Blood culture sets growing contaminants are much more frequently divergent than sets growing pathogens. This may support the theory that diversion is a tool to reduce culture contamination.

Epidemiology of *Pneumocystis jirovecii* pneumonia in HIV-negative patients from 2005-2014 in the United States

Brian Hollenbeck*1, Kevin Counterman2, Gerald Miley3

1Harvard Medical School / New England Baptist Hospital, 125 Parker Hill Ave, Boston, United States, 2College of Osteopathic Medicine / University of New England, Portland, United States

**Background:** *Pneumocystis jirovecii* pneumonia (PJP) is an opportunistic infection seen in patients with immunosuppressive conditions. Systematic studies to identify patients at greatest risk are lacking.

**Materials/methods:** Using the Nationwide Inpatient Sample, a 20% stratified sample of hospital discharges in the United States, we performed a cross-sectional study from 2005-2014 to estimate relative risk of PJP. Human Immunodeficiency Virus (HIV)-negative patients with hospital admission for PJP were identified using International Classification of Diseases, 9th Edition (ICD-9) codes. All ICD-9 and Disease Related Group (DRG) codes were reviewed and ranked to identify the most common associated conditions. Relative risk of PJP was calculated using all other adult non-obstetric hospitalizations as a comparator group.

**Results:** Among 77,177,931 hospitalizations, a total of 14,245 HIV-negative patients with PJP were identified (1.84 PJP cases / 10,000 admissions). Relative risk for PJP was greatest among nonmalignant hematologic conditions and autoimmune conditions (RR = 26.8 and 25.6, respectively) (Figure 1). Elevated risk was also observed for solid organ transplant (RR = 17.1), hematologic malignancy (RR 14.6), and disorders affecting cortisol (RR 14.1). Solid organ malignancy demonstrated only slight increased risk (RR = 3.7). Zero patients with multiple sclerosis, muscular dystrophy, or myasthenia gravis required hospital admission for PJP over this 10-year period, despite prolonged high-dose corticosteroid administration to many of these patients.

**Conclusions:** Among all immunosuppressive conditions, risk for PJP varies widely and is likely affected by corticosteroid use, T-cell and B-cell function, and provider awareness of PJP risk and prophylaxis. However, neurologic conditions associated with high-dose prolonged corticosteroid use confer no increased risk of PJP.

**Occurrence, susceptibility profiles, evaluation of synergistic activity of isavuconazole or voriconazole plus anidulafungin and genetic characterisation of Candida auris detected in a surveillance programme**

Mariana Castanheira*1, Lalitagauri M. Deshpande1, Paul R. Rhomberg2, Eric Utt2, Shawn A. Messer1, Michael A. Pfaller1

1JMI Laboratories, North Liberty, United States, 2Pfizer, Inc, Hospital Business Unit, Groton, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services related to preparing this abstract.

**Background:** C. auris have recently emerged worldwide as a cause of nosocomial outbreaks. This organism often displays high fluconazole MIC values and some strains also have high MIC results for echinocandins and amphotericin B. We evaluated the occurrence of C. auris in 13 years of surveillance, performed synergy testing for an echinocandin and 2 azoles and genetically characterized these isolates using whole genome sequencing analysis.

**Materials/methods:** A total of 15 C. auris isolates were identified in the SENTRY Program and susceptibility tested by CLSI reference broth microdilution. These and other 21 isolates from other collections were tested for synergy against anidulafungin plus voriconazole or isavuconazole using checkerboard CLSI panels. Surveillance isolates were analyzed for genetic relatedness and resistance mechanisms described in C. auris.

**Results:** During 2006-2018, 15 C. auris isolates were collected among 16,273 Candida species consecutively collected from invasive infections (0.09%). Only 1 isolate was recovered before 2013 (2009) and 1-2 isolates were recovered in 2013-2017, but 7 (0.4%) isolates were collected in 2018. Applying the CDC tentative breakpoints, all isolates were susceptible to echinocandins, 2 were resistant to amphotericin B and 12 were resistant to fluconazole. Among the fluconazole-resistant, 10 had an Erg11 K143R alteration, 1 had the Y501H and no resistance mechanism was observed in the remaining isolate. Synergy or partial synergy was noted in 4 (11.1%) and 16 (44.4%) of the isolates with the combination of anidulafungin plus voriconazole and 13 (36.1%) and 24 (66.6%) isolates for the combination anidulafungin plus isavuconazole. Noteworthy, synergy was not observed among the surveillance isolates but only among isolates from other collections and antagonism was not noted. MLST analysis was performed based on ITS, D1/D2, RPB1 and RPB2 sequences showed that isolates from US were genetically related, but different from isolates from Latin America (Panama and Colombia) that were related and Germany.

**Conclusions:** The increase in C. auris worldwide was also captured by the SENTRY Program. Isolates collected from invasive candidiasis were not as resistant as the ones described in the literature, with exception of fluconazole. Combinations of echinocandins and azoles displayed synergy/partial synergy against C. auris.

Abstract 2100

Particularities of brucellar spondylodiscitis

Fatma Hammami1, Koubaa Makram1, Abrahom Zayni1, Khaoula Rekik1, Fatma Smaoui1, Emna Elleuch1, Chakib Marrakchi1, Mounir Ben Jemaa*1

1Infectious Diseases Department, Hedi Chaker University Hospital, Sfax, Tunisia

Background: Osteoarticular involvement is the most frequent complication of brucellosis. A delayed diagnosis of brucellar spondylodiscitis (BSD) may lead to serious complication and neurologic sequelae. We aimed to study the epidemiological, clinical and evolutionary features of BSD.

Materials/methods: We conducted a retrospective study including all cases of spondylodiscitis hospitalized in infectious diseases department between 2001 and 2017. The diagnosis of BDS was based on positive Brucella seroagglutination test (100%) or the isolation of Brucella species from blood culture (21%) associated to signs of spondylodiscitis on imaging.

Results: During the study period, we enrolled 160 cases of spondylodiscitis, among whom 44 patients had BSD (27.5%). There were 34 males (77.3%). The mean age was 50 ±16 years. Thirty-nine patients (88.6%) came from rural area and 40 patients (90.9%) consumed non-pasteurized milk. Six patients had a history of treated brucellosis (13.6%). Patients consulted after a median duration of 4 months [1-13 months]. All patients presented back pain, which was associated to fever in 35 cases (79.5%) and night sweats in 32 cases (72.7%). Thirteen patients had neurologic deficit (29.5%). Laboratory tests investigations revealed an elevated erythrocyte sedimentation rate in 29 cases (65.9%) and an elevated C-reactive protein in 25 cases (56.8%). Lumbar involvement was the most common level of involvement, noted in 30 cases (68.1%). Fine-needle aspiration biopsy was performed in 10 cases (22.7%). All patients were treated with doxycycline and rifampicin. Cotrimoxazole was associated in 20 cases (45.4%). The mean duration of treatment was 8 ±4 months. Immobilisation was required in 26 cases (59%). The disease evolution was favourable in all cases. However, 16 patients had persistent back pain (36.3%).

Conclusions: Brucellar spondylodiscitis is not rare. It can lead to severe sequelae. In front of back pain and fever, Brucella seroagglutination test and imaging should be performed in order to rule out the diagnosis of BSD.

Abstract 2105

**Tuberculous spondylodiscitis: diagnostic and therapeutic approach**

Fatma Hammami1,2, Koubaa Makram1,2, Abrakhom Zayni1,2, Khaoula Rekik1,2, Fatma Smaoui1,2, Emna Elleuch1,2, Chakib Marrachi1,2, Mounir Ben Jemaa*1,2

1Infectious Diseases Department, Hedi Chaker University Hospital, Sfax, Tunisia, 2Extra-pulmonary Research Unity, Hedi Chaker University Hospital, Sfax, Tunisia

**Background:** Tuberculous spondylodiscitis (TSD) is one of the most common forms of extrapulmonary tuberculosis. Surgical treatment might be associated with antitubercular therapy. The aim of this work was to identify the diagnostic and the therapeutic approach of TSD.

**Materials/methods:** We conducted a retrospective study including all cases of TSD hospitalized in infectious diseases department between 2001 and 2017.

**Results:** In total, we identified 70 cases of TSD. There were 40 females (57.1%). The mean age was 48 ± 19 years. Consumption of non-pasteurized milk was noted in 34 cases (48.6%). Fifty-two patients came from rural area (74.3%) and 4 patients (5.7%) had a history of tuberculosis. The most common clinical presentation was back pain (64 cases; 91.4%) associated to weight loss (36 cases; 51.4%) and night sweats (33 cases; 47.1%). Twenty-two patients had neurologic deficit (31.4%). Abnormal laboratory investigations included elevated inflammatory markers such as elevated erythrocyte sedimentation rate (58 cases; 82.8%), an elevated C-reactive protein level (49 cases; 70%) and leukocytosis (13 cases; 18.6%). Tuberculin intradermal reaction was positive in 55.7% of the cases. Fine-needle aspiration biopsy of vertebral and intervertebral disc lesions was performed in 45 cases (64.3%). It confirmed the diagnosis showing caseous granuloma (71.1%) and/or the presence of *Mycobacterium tuberculosis* (22.2%). The mean duration of antitubercular therapy was 13 ± 6 months. Besides medical treatment, immobilization was required in 54 cases (77.1%). Abscess drainage was performed in 14 cases (20%) and surgical treatment in 13 cases (18.5%). The outcome was favourable in 67 cases (95.7%). Three patients (4.3%) were dead. Sequelae were noted such as persistent back pain in 27 cases (40.2%) and spinal deformity in 18 cases (26.8%).

**Conclusions:** Tuberculous spondylodiscitis was a severe form of tuberculosis requiring antitubercular therapy for the appropriate duration and a regular follow up in order to avoid significant complications.

Abstract 2106

**Application of whole genome sequencing analysis to detect the azole-resistance mechanisms in Aspergillus fumigatus in a global surveillance programme**

Mariana Castanheira*, Andrew P. Davis¹, Lalitagauri M. Deshpande¹, Paul R. Romberg¹, Michael A. Pfaller¹

¹JMI Laboratories, North Liberty, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services related to preparing this abstract.

**Background:** Azole-resistance is uncommon among *A. fumigatus* clinical isolates and is mainly associated with mutations in *cyp51A* and its promoter region or its homologue *cyp51B*. We evaluated 35 *A. fumigatus* isolates nonwildtype (NWT) to isavuconazole, itraconazole or voriconazole collected during a 2-year surveillance using whole genome sequencing (WGS) to detect alterations in the genes involved in the ergosterol biosynthesis and others associated with azole resistance.

**Materials/methods:** Among 297 *A. fumigatus* isolates collected worldwide in 2017-2018, 35 isolates displayed NWT MIC values to isavuconazole, itraconazole or voriconazole when tested by the CLSI reference broth microdilution method. These 35 isolates were submitted to WGS and data analysis using previously described tools.

**Results:** Among the 35 NWT isolates, 29 were NWT to isavuconazole, 16 to itraconazole and 9 to voriconazole (M59Ed2 criteria). A total of 9 isolates carried 

Cyp51A L98H/TR34 alterations: 8 from different patients hospitalized in a single Italian hospital and 1 from Belgium. All 9 Cyp51A L98H/TR34 isolates were NWT to both isavuconazole and itraconazole and 8 were voriconazole-NWT. Cyp51A L98H/TR34 isolates belonged to sequence type (ST) 6, ST26 or its single loci variant ST1. None of the other azole-NWT isolates belonged to these STs. Five isolates were NWT to itraconazole alone, 3 of 5 containing Cyp51A I242V. A Cyp51B O42L mutation was detected in 3 isolates, 1 voriconazole-NWT and 2 isavuconazole-NWT of which 1 also harboured multiple mutations in Cyp51A (F46Y, M172V, N248T, D255E and E427K). Two isolates NWT to isavuconazole and itraconazole possessed F46Y, M172V, E427K ± N248T, D255E. Among the 29 isavuconazole-NWT strains, 16 contained alterations in other ergosterol biosynthesis or efflux genes that have not been implicated in azole resistance.

**Conclusions:** Cyp51A L98H/TR34 were noted in 9 isolates that were NWT to both isavuconazole and itraconazole and 8 were NWT to all azoles tested. Other alterations, including F46Y, M172V, E427K± N248T, D255E that have been reported in 10% of the azole-NWT isolates worldwide, were only detected in isolates NWT to isavuconazole and itraconazole. Mutation driven azole resistance mechanisms were not detected in 16 isolates displaying isavuconazole-NWT MIC values that had WT MIC values for other azoles.

Abstract 2108

Pre-emptive therapy utilisation after haematopoetic cell transplantation

Genovefa Papanicolaou*

1Memorial Sloan Kettering Cancer Center, New York, United States

Background: Preemptive therapy for CMV after HCT is effective in preventing CMV end organ disease but requires antiviral utilization, is associated with toxicities and may require hospitalization. Objectives 1) describe patterns of preemptive therapy (type, duration, setting) 2) describe frequency of toxicities at discontinuation of first PET: 3) impact of letermovir on antiviral days

Materials/methods: Study cohort comprised of adults, CMV R+ HCT recipients of first peripheral blood or marrow allograft at Memorial Sloan Kettering Cancer Center (MSKCC) from 3/2013 to 12/2017. HCT recipients were routinely monitored for CMV using quantitative PCR assay and administered PET as per the standards of care. Data on clinical characteristics, CMV outcomes, PET administration and all-cause and CMV-related inpatient hospitalization were extracted from the electronic medical records/databases.

Results: Of 368 HCT recipients, 176 (48%) received unmodified graft from matched related or unrelated donors [low CMV risk], and 192 (52%) received either ex vivo T-cell depletion or convention graft from mismatched donors [high CMV risk]. Overall, 208 (57%) HCT recipients received PET; and 72% of them were high risk. PET started a median XX (range ) post HCT. The median duration of PET by D180 was x days (Figure 1). Of x antiviral days x [%] were vGCV, x(%) fosc. X(%) days were given before D100 and x(%) were given as outpatient. PET recipients had more readmissions compared to NO PET recipients, and x(%) readmissions were due to CMV at discontinuation of first PET neutropenia (ANC<100 ) was observed t 11.2% and 2% of vGCV and FCN recipients respectively. AKI was observed in nx% and X% of vGCV and FCN recipients respective. After letermovir implementation the incidence of CMV reactivation bD100 was 5.1% compared to PET 53%. There was an overall 95% reduction in antiviral days bD100, including 94% of vGCV days and 88% reduction FCN days.

Background: Since May 2019 “National Tuberculosis Diagnosis and Treatment guidelines” have been established, active and latent tuberculosis infection (LTBI) screening is recommended in the pretransplant evaluation of the solid organ transplant (SOT) recipients. However, there is still a lack of routine tuberculosis (TB) risk stratification in most of the transplant centers in our country. Therefore, we decided to investigate the pretransplant TB risk evaluation, posttransplant follow up, registry rates, and TB prevalence in a given period.

Materials/methods: Adult (1 > 18) SOT recipients who were evaluated in the pretransplant period between January 2015 and December 2018 and who had undergone tuberculin skin test (TST) and/or interferon gamma releasing assay (IGRA) were included in the study. Five mm induration of TST was accepted positive. Demographic characteristics, prior TB exposure, LTBI screening method and treatment, pre/posttransplantation TB history were recorded from the electronic database of each transplantation unit nationwide and collected in single center for a united database. The findings were shared with “Ministry of Health, General Directorate of Public Health, and Department of Tuberculosis” and checked from the national registry.

Results: In this period, 2266 SOT patients from 14 centers were included. TST and/or IGRA was administered to 766 (33.8%) of them. LTBI screening rate varied according to different centers (2.2-100%). Within these 766 patients, 485 (63.4%) were kidney, 206 (26.8%) liver, 45 (5.9%) lung, and 30 (3.9%) heart transplantation recipients. Isoniazid was given to 203 (26.5%) patients, 104 (51.2%) of whom started treatment post transplantation first day. Among the patients who were under LTBI treatment, 112 (55.2%) were registered in the national registry and 82 (73.2%) of them completed the treatment. We did not observe active...
TB in patients who had undergone LTBI treatment, however within 563 patients who were not treatment for LTBI, 6 (1.06%) of them developed TB.

Conclusions: In our country, we found that only one third of SOT recipients has been evaluated for TB risk, depending on the transplantation units’ pretransplant procedures and transplanted organs. Only one out of four SOT recipients had received LTBI treatment and half of them were registered. As we showed the compliance to national guidelines is low, we suggest performing pretransplant TB risk stratification as a national imperative.

Background: While most carbapenem-resistant Enterobacteriaceae (CRE) infections are healthcare-associated, community-associated (CA) CRE infections are increasing worldwide. Our goal is to define CA-CRE epidemiology.

Materials/methods: CRACKLE-2 is a prospective, multicenter study of hospitalized patients with CRE. Patients with possible CA-CRE (pCA-CRE) were admitted from home with a CRE culture within 48 hours, not immunocompromised, and had no history of malignancy, renal failure, or liver disease. Patients not meeting the pCA-CRE criteria were classified as having non-CA-CRE with either home origin (HO-non-CA-CRE) or non-home origin (nHO-CRE). Clinical outcomes at 30 days post-culture date were compared by Desirability of Outcome Ranking (DOOR) analysis adjusted for culture source. Outcomes were categorized as clinical response with 0 events (readmission, renal failure, or Clostridioides difficile infection), no clinical response with 1 event, no clinical response with > 1 event, or death. Genetic diversity between strains was characterized by a comparative gene analysis.

Results: Between 06/2016 to 08/2017, 807 patients in the US with CRE were included; pCA-CRE (n=83), HO-non-CA-CRE (n=362), and nHO-CRE (n=362). Klebsiella pneumoniae was the most common CRE; pCA-CRE (72%), HO-non-CA-CRE (58%), and nHO-CRE (76%). Patients with pCA-CRE were more likely to have bacteriuria (65%) than HO-non-CA-CRE (36%) and nHO-CRE (37%; p<0.001, Chi-Square). Of note, pCA-CRE strains, versus HO-non-CA-CRE and nHO-CRE, were less likely to be susceptible to gentamicin (46% vs 62% vs 56%; p=0.031), tigecycline (54% vs 82% vs 73%; p=0.006) and ciprofloxacin (10% vs 25% vs 15%; p<0.001). Overall, CRE genomes had similar distributions of adhesin, virulence and biofilm-associated genes and plasmid types. Using DOOR analysis, where 50% indicates equivalence between groups, the probability that a randomly selected person with pCA-CRE had a better clinical outcome versus HO-non-CA-CRE or nHO-CRE was 65% [95% CI: 56-74%] and 67% [95% CI: 58-76%], respectively.

Conclusions: In this cohort of patients with CRE, 10% had pCA-CRE. The percentage of true CA-CRE is likely lower. Interestingly, while resistance rates to non-carbapenem antibiotics were higher, patients with pCA-CRE had better overall clinical outcomes. Identifying characteristics important for CA-CRE strains will improve early detection of strains with the potential to cause community outbreaks.

Abstract third-party references: This project has been funded in whole or in part with Federal funds from the Department of Health and Human Services; Office of the Assistant Secretary for Preparedness and Response; Biomedical Advanced Research and Development Authority (BARDA), under OTA number HHSO100201600026C.

Background: Gut colonization by antimicrobial-resistant bacteria have been pointed as the culprit for the increasing prevalence of urinary-tract infections (UTIs) caused by antimicrobial-resistant organisms. Isolates producing β-lactamases that include ESBL and less frequently carbapenemases have been reported as a cause of community-acquired UTIs and are often resistant not only to β-lactams, but also quinolones and aminoglycosides. We tested several IV and oral β-lactams in combination with QPX7728, a novel β-lactamase inhibitor (BLI) active against all β-lactamate classes, against a collection of 407 β-lactam-resistant UTI Enterobacterales isolates collected from a global surveillance study.

Materials/methods: A total of 407 UTI Enterobacterales isolates displaying an MIC ≥2 mg/L for ceftazidime, ceftriaxone, and/or aztreonam were susceptibility tested by reference broth microdilution against various β-lactams ± QPX7728. Among the isolates tested 234 were screened for β-lactamases using whole genome sequencing analysis and included 7 isolates producing KPC, 174 producing CTX-M, 86 oxacillinases with cefepime activity and 24 producing transferrable AmpC enzymes.

Results: Cefepime [MIC50/90, 16/32 mg/L, 25.3% susceptible [EUCAST breakpoints]], ceftriaxone [MIC50/90, 16/>32 mg/L, 23.6%], and ceftolozane [MIC50/90, 8/>32 mg/L] had limited activity against these isolates [Table]. MIC50/MIC90 values for these agents in the presence of QPX7728 at 4 or 8 mg/L were ≤0.015/0.06 or ≤0.015/0.03 mg/L for cefepime, 0.12/0.25 mg/L or 0.03/0.25 mg/L for ceftolozane, 0.06/0.25 mg/L or ≤0.015/0.12 mg/L for ceftriaxone with QPX7728 at 2 or 4 mg/L, respectively. Tebipenem [oral carbapenem; MIC50/90, 1/8 mg/L] combined with QPX7728 at 2 or 4 mg/L had MIC50/MIC90 values at 0.06/0.5 mg/L or ≤0.015/0.25 mg/L. Ertapenem [MIC50/90, 0.06/0.5 mg/L] and meropenem [MIC50/90, 0.03/0.12 mg/L] inhibited all isolates at 1 or 0.5 mg/L, respectively, in the presence of 4 or 8 mg/L of QPX7728. Among comparator agents, the susceptibility rates were lowest for levofloxacin (33.9%) and highest for amikacin (92.9%).

Conclusions: QPX7728 tested at 2 [tested for ceftriaxone and tebipenem only], 4 or 8 mg/L lowered the MIC values for all agents tested to clinically achievable levels where these agents could be active for most isolates tested, including isolates producing common β-lactamases detected worldwide.

Abstract 2114

Incidence of medically-attended influenza and influenza-related hospitalisations by co-morbidities among a commercially insured population in the United States

Aimee Near1, Jenny Tse1, Yinong Young-Xu2, Lynn Connolly3, Carolina Reyes*3

1IQVIA, Durham, United States; 2Veterans Affairs Medical Center, White River Junction, United States; 3Vir Biotechnology, Inc., San Francisco, United States

Background: Despite broad availability of vaccination, influenza poses a substantial clinical and economic burden, contributing to morbidity, mortality, and healthcare utilisation. This study describes medically-attended influenza incidence and hospitalisation rates among patients with underlying medical conditions.

Materials/methods: All patients enrolled in a health plan in IQVIA’s Real-World Data Adjudicated Claims – US database at the beginning of any of 4 influenza seasons (October 1, 2014 – May 31, 2018) were included in analyses of medically-attended influenza incidence. The seasonal incidence proportion was calculated for patients with ≥1 diagnosis for a medical condition of interest before the start of the influenza season, categorized by Agency for Healthcare Research and Quality (AHRQ) and Centers for Disease Control and Prevention (CDC) definitions. Medically-attended incident influenza cases were defined as an influenza diagnosis with a record of influenza testing within ±14 days or an influenza diagnosis in the primary position during an influenza season. For analyses of influenza-related hospitalisation, the index date was the date of the earliest influenza diagnosis during an influenza season between October 1, 2014 – May 31, 2018. Patients were required to have ≥12 months continuous enrolment before (baseline) and ≥30 days after (follow-up) index. The outcome of interest was hospitalisation during the 30-day follow-up period with a diagnosis of influenza or a pre-defined influenza-related complication in any position.

Results: The average medically-attended influenza incidence proportion over the 2014-2017 influenza seasons was 1.7% and varied by medical conditions of interest (from 2.2% for immunodeficiency/HIV/AIDS, 2.1% for B-cell deficiency, 1.7% for chronic obstructive pulmonary disease, 1.7% for congestive heart failure/valvular disease, and 1.6% for leukaemia/lymphoma/metastatic cancer) and by age. Medically-attended influenza rate was higher in young children than the elderly. Average influenza incidence among all patients ≥65 years of age was 0.8%. Of 1,601,367 influenza patients, 18,509 (1.2%) had ≥1 influenza-related hospitalisation; hospitalisation rates were higher among patients ≥65 years (9.4%) and patients with the above comorbid conditions (7.7%, 15.2%, 13.3%, 9.3%, 13.7%, respectively).

Conclusions: Patients with specific underlying conditions have elevated risks of influenza-related hospitalisation. Additional research is needed to address and alleviate influenza burden in these high-risk populations.

Abstract 2116

Whole genome sequencing investigation of iGAS outbreak in elderly care

Juliana Coelho1, Natalie Groves1, Derren Ready*, Colin Brown, Oluwakemi Olufan1, Rohini Manuel1, Karthik Paranthaman1, Isobel Braithwaite1, Martina Cummins6, Clare Ebberson3, Danielle Lawrence1, Theresa Lamagni2, Edward Wynne-Evans3

Background: In the UK, cases of invasive group A streptococcal (iGAS) disease are reported to local Health Protection Teams (HPT) and isolates sent to PHE reference laboratory for emm typing. emm 94.0 is the 6th most common type identified, comprising 5.6% of all typed iGAS isolates in 2019. Six cases in London developed iGAS sepsis due to emm 94.0 strain over a 7-month period in 2019. Prior to disease onset, all six had received care from a community district nursing (DN) team in a care home setting, where it was initially detected, and in the community. We investigated whether there was microbiological evidence to support the epidemiological link identified among these six cases.

Materials/methods: Whole genome sequence (WGS) data was obtained using the Illumina Nextera protocol and run on HiSeq platforms. The analysis included the iGAS emm 94.0 isolates from the six individuals in the cluster, four sporadic cases from same geographical region (1) and four from bordering region (2), all received since January 2019, and 3 isolates (2 patients and 1 staff) linked to a cluster investigated in 2014. These data were used to generate a SNP-based phylogenetic tree of isolates using an in-house pipeline.

Results: Six of the cases from region 1 were within 0-3 SNP (average 1.3 SNP, Cluster 1), and all were cared for by the same DN team. A second cluster (Cluster 2) with 3 isolates from 2019 was identified, with average 3.3 SNP (2-4SNPs), and separate from Cluster 1 by 8-12 SNPs. An average of 28.8 SNPs (0-52 SNPs) was observed for the 18 remaining isolates.

Conclusions: WGS SNP analysis is a powerful method to discriminate between iGAS isolates of the same emm type. In Cluster 1, WGS provided strong microbiological evidence to confirm the outbreak and led to institution of GAS screening and chemoprophylaxis to all members of the DN team. WGS also identified Cluster 2 that was previously undetected and led to further investigations to identify epidemiological links. The large genetic diversity among remaining cases provided evidence to infer that they were sporadic and no further investigations of these cases undertaken.

*Lawsonella clevelandensis: an emerging cause of vascular graft infection*

Rommel Ramesh*1,2, Zerelda Esquer Garrigos1, Kyle G. Rodino1, Bobbi Pritt1, M. Rizwan Sohail1

1Mayo Clinic College of Medicine and Science, Rochester, United States, 2Charles University – Faculty of Medicine in Hradec Kralove, Hradec Králové, Czech Republic

**Background:** Vascular graft infections (VGI) pose a significant risk of morbidity and mortality. In up to 50% of VGI cases, the causative organism is not established by conventional culture. With the incorporation of 16S ribosomal (r) RNA gene PCR methods, a causative agent may be identified from clinical samples of extracted vascular grafts. We report the first case of VGI due to *Lawsonella clevelandensis*, an anaerobic Gram-positive, partially acid-fast, fastidious organism identified using 16S ribosomal rRNA gene PCR approach.

**Materials/methods:** We reviewed medical records of a 65-year old patient with inferior abdominal aortic aneurysm, status post endovascular aneurysm repair with stent graft who presented with a one-month history of progressive bilateral inguinal pain, fever, chills, night sweats and unintentional weight loss of 30 pounds.

**Results:** Labs revealed leukocytosis of 17.5 x10⁹/L, elevated C-reactive protein at 132.8 mg/L, erythrocyte sedimentation rate at 100mm/hr, and thrombocytosis of 758x10⁹/L. Positron emission tomography showed high fluorodeoxyglucose avidity within the aneurysm wall and graft, along with bilateral psoas abscesses. Vascular graft was removed and replaced with cryopreserved aortobi-iliac graft. Operative specimens including aortic aneurysm sac fluid and aortic tissue were obtained. Aerobic and anaerobic bacterial cultures, fungal culture, and mycobacterial cultures, along with corresponding direct smears, were negative. Histopathology revealed mild to moderate acute inflammatory infiltrate and a cluster of weakly acid-fast, Gram-variable bacilli [Figure 1]. A 16S rRNA gene PCR identified *L. clevelandensis*. As the organism did not grow on cultures for susceptibility testing, the patient was treated with a six-week course of intravenous vancomycin and oral doxycycline therapy, followed by chronic suppression with cefadroxil. The patient’s symptoms resolved, and he recovered well since surgery.

**Conclusions:** *L. clevelandensis* is a highly fastidious anaerobic organism, primarily detected by molecular methods. Clinical infection due to this organism appears to be characterized by localized abscess formation. Cases of disseminated infection have not been reported in the literature. Our case highlights the importance of incorporating molecular methods in cases of vascular graft infection, where conventional cultures are negative.

Abstract 2118

ESBL-producing *Enterobacteriaceae* in patients with travellers’ diarrhoea: a prospective cohort study

Oskar Ljungquist*, Shoeib Nematzadeh1, Christian Giske2,3, Fredrik Resman1, Kristian Riesbeck4, Johan Tham1

1Lund University, Clinical Infection Medicine and Clinical Microbiology, Department of Translational Medicine, Malmö, Sweden; 2Karolinska Institute, Department of Laboratory Medicine, Stockholm, Sweden; 3Karolinska University Hospital, Department of Clinical Microbiology, Stockholm, Sweden; 4Lund University, Clinical Microbiology, Department of Translational Medicine, Malmö, Sweden

**Background:** Patients with traveller’s diarrhoea frequently acquire extended spectrum beta-lactamase (ESBL)-producing *Enterobacteriaceae* (EPE) upon return from endemic areas. The aim of this study was to investigate the rate and characteristics of EPE carriage in Swedish travellers.

**Materials/methods:** Clinical samples sent for culture of *Campylobacter, Salmonella,* *Yersinia* or *Shigella,* for which the referral stated foreign travel, were included in the study and selectively cultured for EPE on chromogenic selective media (Chrom ID® ESBL and Uri-Select agar with vancomycin). Antimicrobial susceptibility testing was done according to the EUCAST disk diffusion test methodology. Patients positive for EPE were asked to provide cultures after 1, 3, 6 and 12 months to determine prolonged EPE colonization. EPE strains were subjected to WGS on a HiSeq (Illumina) platform, followed by in silico mapping of sequence types, as well as known virulence and resistance genes in the microSAL T pipeline.

**Results:** Eighty-four of 303 patients (28%) carried a total of 92 ESBL-producing *Enterobacteriaceae*. The majority (85; 92%) were *Escherichia coli* and the remaining 7 (8%) were *Klebsiella pneumoniae*. ESBL acquisition was highest for isolates from Africa (54%, 26/49), Asia (45%, 43/95) and North America and the Caribbean (25%, 4/18). For specific countries, highest ESBL acquisition rates were seen for India (100%, 8/8), Egypt (78%, 7/9), Tanzania/Zanzibar/Kenya (78%, 7/9), Cuba (57%, 4/7) and South Africa (50%, 5/10). No imipenem, meropenem, ceftazidime-avibactam or amikacin-resistant strains were found. Out of 82 strains available for WGS, 48 different sequence types were identified, of which 2 were novel. Only 5 strains belonged to ST131. Out of the 75 *E. coli* isolates, 76% carried at least one type 1-fimbriae gene, 29% carried at least one *pap* (encoding p-fimbriae) gene and 31 (41%) were ExPEC/UPEC. Out of 27 EPE positive patients submitting a culture after one year, 8 patients (30%) were positive for EPE.

**Conclusions:** A relatively high proportion of patients with travellers' diarrhoea carry EPE with a broad diversity of sequence types. A comparatively high proportion of the strains were ExPEC/UPEC, many expressing virulence genes *pap* and/or *fim*. Continuous EPE carriage one year after travel was common but with heterogeneity in EPE strains.

Abstract third-party references: Supported by Merck

Background: Gram-negative (GN) bloodstream infections (BSI), that occur during febrile neutropenia (FN), cause significant morbidity and mortality in high-risk (HR) patients receiving chemotherapy for HSCT or hematologic malignancy (HM). Antibiotic regimens to empirically treat FN should be driven by BSI microbiological epidemiology in this population, yet no recent U.S. data exists. The BISHOP study aimed to describe contemporary BSI profiles among HR patients at U.S. cancer centers. Herein we describe GN BSI data to aid rational development of empirical antibiotic recommendations.

Materials/methods: In a prospective survey (12/2016-06/2019) at 14 high-volume US cancer center, bacterial isolates and 30-day clinical data were collected from consecutive HR FN patients with BSI with first fever after cytotoxic chemotherapy. UNMC laboratory determined MICs using broth microdilution susceptibility panels. Isolates were coded as Susceptible (S) or Non-susceptible (NS) using breakpoints defined by CLSI. NS included both intermediate and resistant.

Results: Among 442 patients, 478 aerobic GNR, were identified, including polymicrobial BSIs. 460 were available for testing, including most commonly, E. coli (49%), Klebsiella pneumoniae (18%), Pseudomonas aeruginosa (15%), and Enterobacter cloacae (9%). The most frequent initial antibiotic regimen (IAR) was cefepime (63.3%). Susceptibility to common IARs and fluoroquinolone prophylaxis is displayed (figure). Notably, 22% and 74% of E. coli isolates are NS to cefepime and levofloxacin respectively. Carbapenems retain excellent activity against the Enterobacteriaceae, but piperacillin-tazobactam susceptibility is reduced among Enterobacter spp. Variability in carbapenem susceptibility was noted in Pseudomonas aeruginosa; 29% of Pseudomonas are levofloxacin-resistant. Overall, 82% of patients were treated with IAR that was active against identified isolates, with modifications increasing coverage to 88% in the first 24 hours.

Conclusions: BISHOP data represents the only contemporary multicenter profile of GNR BSI in HM or HSCT patients in the US. Reduced in vitro susceptibilities (<80%) of some organisms to mainstage IAR agents are observed. However, clinicians chose antibiotic regimens with in vitro activity against bloodstream isolates in 88% of cases within 24 hours of presentation. Correlations of drug susceptibility and clinical outcomes are planned. Finally, the limited activity of fluoroquinolones against E. coli underscores concerns about utility of FQ prophylaxis.

GN Susceptibilities

Abstract 2123

**Activity of meropenem-vaborbactam and single-agent comparators against Enterobacterales isolates, including KPC-producing isolates, from European patients hospitalised with pneumonia (2014-2018)**

Dee Shortridge*,1, Lalitagauri M. Deshpande1, Leonard Duncan1, Jennifer Streit1, Mariana Castanheira1

1JMI Laboratories, North Liberty, United States

**Abstract third-party references:** This study was performed by JMI Laboratories and supported by A. Menarini Farmaceutica Internazionale s.r.l (AMFI), which included funding for services related to preparing this abstract.

**Background:** Meropenem-vaborbactam (MVB) was recently approved in Europe for the treatment of complicated UTIs, including acute pyelonephritis, complicated intra-abdominal infections [cIAI], hospital-acquired bacterial pneumonia [HABP], ventilator-associated pneumonia [VABP], and bacteremia. KPC-producing Enterobacterales [ENT] isolates have disseminated worldwide and are considered endemic in various countries and several hospitals. We evaluated the activity of MVB and single-agent comparators against 5,648 ENT isolates from patients hospitalised with pneumonia [PHP] in European hospitals from 2014–2018.

**Materials/methods:** Among 5,648 ENT clinical isolates from PHP collected in 40 European hospitals located in 20 countries that were susceptibility [S] tested using reference broth microdilution methods, Of the carbapenem-resistant isolates submitted to whole genome sequencing, 59 carried *bla*<sub>KPC</sub>. ENT isolates were also characterized for an extended spectrum beta-lactamase (ESBL) phenotype as described (CLSI, 2019). EUCAST (2019) interpretive criteria were used. %S from intensive care unit (ICU) and non-ICU isolates were also analysed.

**Results:** The most common ENT pathogens isolated from PHP were *Klebsiella pneumoniae* [KPN; n=1,539] and *Escherichia coli* [EC; n=1,344]. The %S of MVB and comparators to ENT, ICU, and non-ICU are shown in the table. Overall, 98.2% of ENT were S to MVB. For 2,663 ENT isolates from ICU patients, MVB %S was 97.5% and for 2,187 non-ICU isolates MVB %S was 98.6%. The %S of comparators for ICU vs non-ICU isolates were similar, except for levofloxacin (76.3%S ICU/70.1%S non-ICU). 21 KPC-producing isolates were from ICU patients, 38 from non-ICU. KPC-producing isolates were mainly KPN [n=55] and included 44 *bla*<sub>ESBL</sub>, 14 *bla*<sub>KPC-3</sub>, and 1 *bla*<sub>KPC-2</sub> from 6 countries. 4 EC contained *bla*<sub>KPC-3</sub>. Italy had the highest number of KPC-producing isolates at 38 (64%). MVB inhibited 100% of KPC-producing isolates. Against isolates with an ESBL-phenotype, MVB inhibited 91.4%. Amikacin was the most active comparator against all ENT (94.3%S); colistin was the most active comparator against KPC-producing isolates (79.7%S).

**Conclusions:** These results demonstrate MVB has potent activity against ENT isolates from PHP including those producing KPC enzymes and suggest MVB is a useful treatment option for ICU and non-ICU PHP.

Abstract 2125

Evaluation of the cobas MTB and MTB RIF/INH assays on samples from Sierra Leone and Germany at a supranational reference laboratory for tuberculosis serving both low-incidence and high-burden settings

Darshaalini Nadarajan1*, Daniela Sievert1, Margit Kernbach1, Rashidatu Kamara2, Lynda Foray2, Matthias Merker1, Alison Kuchta3, Jasmine Lau3, Merlin Njoga1, Smitha Krishnamurthy3, Anne-Kathrin Witt1, Katharina Kranzer4, Florian P. Maurer1,5

1National and WHO Supranational Reference Laboratory for Mycobacteria, Research Center Borstel, Leibniz Lung Center, Borstel, Germany, 2National TB programme of Sierra Leone, Sierra Leone, Sierra Leone, 3Roche Molecular Systems, Pleasanton, United States, 4London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, 5Institute of Medical Microbiology, Virology and Hospital Hygiene, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Abstract third-party references: Supported by Roche Molecular Diagnostics/Submitted on behalf of Dr. F. Maurer

Background: Rapid and sensitive detection of Mycobacterium tuberculosis complex (MTBC) DNA from clinical samples is critical for tuberculosis management. The Roche cobas® MTB and MTB-RIF/INH assays use PCR for the direct detection of MTBC DNA from inactivated human respiratory specimens. Samples positive for MTBC DNA are subsequently tested for rifampicin (RIF) and isoniazid (INH) resistance-associated mutations in the rpoB, katG and inhA genes, respectively. The objective of this study was to evaluate sensitivity and specificity of these assays at the German National Reference Center using specimens from low and high burden settings.

Materials/methods: Sensitivity, specificity and overall percent agreement (OPA) were determined on 326 sputum samples (smear-positive n=94 [28.8%]; smear-negative n=232 [71.2%]; MTBC culture-positive n=103 [31.6%]; MTBC culture-negative n=223 [68.4%]; 18 NTM culture-positive) collected from treatment-naïve, non-duplicate patients with presumptive TB in Germany (n=280) and Sierra Leone (n=46). MTBC PCR was compared to culture as reference. RIF and INH-resistance were compared to a combined reference standard (phenotypic DST and HAIN MTBDRplus, with sanger sequencing on selected isolates). Whole-genome sequencing was used to resolve discrepancies.

Results: In MTBC culture-positive samples, the overall sensitivity of the cobas MTB assay was 89.3% (95%CI, 81.8-93.9%). The majority of culture-positive samples were smear-positive (n=76) for which the cobas MTB assay demonstrated a sensitivity of 98.6% (92.9-99.8%) compared to 63% (44.2-78.5%) in smear-negative samples (n=27). Overall specificity of the cobas MTB assay was 98.6% (96.1-99.5%). OPA for RIF-resistance was 90.9% (85.4-96.7%) (n=44/85 with RIF-resistance). OPA for INH-resistance was 86.0% (77.2-91.8%) (n=48/86 with INH-resistance). Discrepant results for RIF and INH were mainly due to uncommon mutations in the Sierra Leone group not included in the intended target mutations for the cobas assays. When removing the Sierra Leone data the RIF-resistance OPA was 95.1% (83.9-98.7%).

Conclusions: The Roche cobas MTB and RIF/INH assays provide rapid, sensitive and specific detection of MTBC DNA and resistance-associated mutations in clinical specimens. The large capacity of the cobas 6800/8800 instruments makes the assays particularly suited to high-throughput laboratories. The local prevalence of undetectable/uncommon resistance mutations should be investigated before implementation of PCR-based rapid molecular tests.

Evaluation of a novel high-definition PCR multiplex assay to identify nine genetic targets associated with multidrug-resistant organisms

Derek Gerstbrein\textsuperscript{1}, Brian Mesich\textsuperscript{2}, Nathan Ledeboer\textsuperscript{1}, Matthew Faron\textsuperscript{1}, Blake Buchan\textsuperscript{*2}

\textsuperscript{1}Medical College of Wisconsin, Wauwatosa, United States, \textsuperscript{2}Medical College of Wisconsin, Wauwatosa, United States

Abstract third-party references: Supported by ChromaCode, Inc

Background: Multidrug-resistant organisms (MDROs) are an emerging threat requiring immediate attention. Screening to identify asymptomatic carriers aids in preventing the spread of MDROs within healthcare facilities, and accurate identification of resistance mechanisms can inform early therapy. High-definition PCR (HDPCR) uses limiting-probe chemistry and data analytics to enable detection of multiple targets in a single fluorometric channel. This approach increases the multiplexing capabilities of existing 4 channel PCR instruments by 3 to 5-fold. We evaluated the performance of the HDPCR Multi-Drug Resistance (MDR) Panel RUO (ChromaCode, Carlsbad, CA) to identify nine genetic targets commonly associated with MDROs.

Materials/methods: The MDR Panel specifically identifies carbapenemases (KPC, NDM, VIM, IMP, OXA-48), the ESBL CTX-M groups 1 and 9, \textit{mcr-1} (colistin resistance), \textit{vanA} (vancomycin resistance), and \textit{tcdB} (toxigenic \textit{C. difficile}). A total of 131 genetically characterized isolates of Enterobacteriaceae, \textit{P. aeruginosa}, and \textit{A. baumannii} obtained from the CDC Antibiotic Resistance Isolate Bank were used to challenge the MDR Panel. This included 89 isolates containing ≥1 on-panel target and 42 isolates containing resistance genes not detected by the MDR Panel. Isolates were tested as pure 0.5 McFarland suspensions following 10 min. heat lysis step (n=67) or as contrived stool specimens in ESwab (final concentration of 4 log\textsubscript{10} CFU/mL) requiring nucleic acid extraction (eMag, bioMerieux) prior to HDPCR.

Results: Among 67 isolates tested from pure suspension, MDR Panel demonstrated 100% sensitivity and 99.5% specificity. This included accurate identification of 55/55 unique targets in 42 unique isolates including 13 isolates containing multiple MDR targets. Three false-positive results included one each for \textit{tcdB}, NDM, and CTX-M in isolates lacking these markers. Among 64 contrived stool specimens, MDR Panel demonstrated 98.5% [66/67] sensitivity and 100% specificity. This included 29 specimens containing a single MDR target, 16 containing two targets, and 2 containing three targets. The single false-negative result was failed detection of NDM in a specimen containing NDM and CTX-M.

Conclusions: MDR Panel provides a sensitive and specific method for detection of 9 common targets associated with MDROs. It can be applied for characterization of pure bacterial isolates or as a method to screen for MDROs in stool specimens.

Presenter email address: bbuchan@mcw.edu
Background: Clostridioides difficile infection (CDI) is the most common cause of infectious health-care associated diarrhea in hospitalized patients, affecting primarily elderly patients with comorbidities and antibiotic exposure. Large scale patient level data sets including information on symptoms, diagnosis, treatment, response and recurrence, as well as the associated cost of treating CDI within the German health care system are missing.

Materials/methods: Using an observational, retrospective/prospective, multi-center study design, we collected data from 9 hospitals in Germany through the epidemiological research platform www.ClinicalSurveys.net.

Results: Out of 288 patients with CDI analyzed, 162 (56.3%) patients were male and the median age was 71 years (range 20-96 years; IQR 19). The most common comorbidities were cardiovascular (72.3%), endocrine (45.0%) and kidney (44.6%) diseases. Overall, 34 (11.8%) received hemodialysis and 88 (30.6%) patients were immunocompromised at study inclusion. Immunosuppression was defined by current neutropenia (<500 neutrophils/mm³), a history of allogenic stem cell transplantation, prolonged use of corticosteroids or inherited severe immunodeficiency. Median Charlson comorbidity index was 6 (range 1-19; IQR 4) and median Karnofsky score was 50% (range 20-100%; IQR 30%). At the time of CDI diagnosis, 37 patients (12.8%) were treated in an intensive or intermediate care unit. After initial diagnosis of CDI, 209 (72.6%) patients received vancomycin, 70 (24.3%) metronidazole, 2 (0.7%) fidaxomicin, 2 (0.7%) metronidazole + vancomycin and 2 (0.7%) received no treatment. If treated, the median duration of treatment of CDI was 10.0 days (range 1-26 d; IQR 3). At day 10+/-2 d 92 patients (31.7%) were discharged, 188 patients (65.5%) were still hospitalized and 8 patients (2.8%) had died during treatment. Overall, 228 (79.2%) patients responded to CDI treatment. When compared to treatment with metronidazole, response to vancomycin treatment at day 10+/-2 d was significantly higher (70.0% vs 83.3%; p<0.05). At follow up on day 45+/-4 d, 98 (34.0%) patients were lost to follow up. Among patients that were followed-up, 8 (15.2%) presented with first recurrence of CDI.

Conclusions: These preliminary results from the IBIS study provide valuable epidemiological information on the incidence, treatment and clinical outcomes of hospitalized patients diagnosed with CDI in the German health care system.

Abstract third-party references: Nchinda W. Godwin

Background: Malaria blood stage parasite is a main causal pathogen of adverse outcomes in pregnant women and their babies. However, Immunoglobulin G (IgG) specific responses against the antigens of this parasite stage were associated with malaria control, although with law efficiency. Hence, we assessed the profile of antibody responses specific to MSP3 and UB05 antigens displayed Qβ phage system of in mother-neonate couple.

Materials/methods: Plasmodium infection was screened in mother’s peripheral blood and Placental impression smears. Mother-neonate paired plasma samples were collected at delivery and used to determine the levels of IgG and IgG subclasses specific to recombinant phages QβUB05, QβMSP3 and, QβUB05MSP3.

Results: Irrespective of malaria status, both mothers and neonates had significantly higher IgG responses to QβUB05 and QβUB05MSP3 phages compared to anti-QβMSP3 IgG (P < 0.05). A significant negative correlation was shown between IgG levels specific to the three antigens and parasitaemia. anti-QβUB05 and anti-QβUB05MSP3 IgG in neonates showed a significant positive correlation with the corresponding mothers’ antibodies (rs = 0.25 with P= 0.04; rs = 0.31 with P= 0.01 respectively). QβUB05MSP3 specific IgG3 and IgG1 responses were significantly higher than IgG4 subclass (p<0.01). The neonates IgG1 and IgG3 levels positively correlated with the corresponding antibody subclasses of mothers.

Conclusions: These findings suggest an association between QβUB05 and QβUB05MSP3 specific antibody responses and malaria control during pregnancy. Maternal-foetal transfer of MSP3 and UB05 specific IgG occurs during pregnancy, suggesting the development of future malaria vaccination strategies for pregnant women required for early baby protection to malaria.

Abstract 2136

Predicting phenotypic polymyxin resistance in *Klebsiella pneumoniae* through machine learning analysis of genomic data

Nenad Macesic*1, Oliver Bear Don’t Walk IV2, Itsik Pe’er2, Nicholas Tatonetti2, Anton Peleg1, Anne-Catrin Uhlemann2

1Monash University, Melbourne, Australia, 2Columbia University, New York, United States

**Background:** Polymyxins are treatments of last resort for Gram-negative infections but increased use has led to emerging polymyxin resistance (PR). Phenotypic polymyxin susceptibility testing is resource-intensive and difficult to perform accurately. We therefore aimed to use machine learning (ML) on *Klebsiella pneumoniae* clonal group (CG)258 whole genome sequencing (WGS) data to predict phenotypic PR.

**Materials/methods:** We classified 619 *K. pneumoniae* genomes with broth microdilution polymyxin susceptibility data as phenotypically susceptible (MIC ≤ 2 mcg/ml) or non-susceptible (MIC > 2 mcg/ml). We assessed performance of a non-ML rule-based approach that predicted phenotypic PR if variants were present in known PR genes. We then implemented an ML pipeline in Python Sci-kit Learn and compared performance using a reference-based representation of genomic data with a reference-free representation as k-mers. We also assessed performance when a bacterial genome-wide association study (GWAS) was used to prioritize genes prior to ML, and clinical polymyxin exposure data were added.

**Results:** Using a reference-based representation of WGS with ML outperformed the rule-based approach (area under receiver operator curve [AUROC] 0.894 vs 0.791, P=0.006). Using a GWAS to filter relevant genes and integrating clinical polymyxin exposure led to modest increases in performance. Conversely, reference-free representation of WGS as k-mers decreased performance (AUROC 0.692 vs 0.894, P=0.015). Choice of ML algorithm (logistic regression, Support Vector Machine, Gradient Boosted Trees and Random Forests) did not impact performance. When ML models were interpreted to extract genomic features, 6/7 known PR genes were correctly identified without prior programming and several genes were identified as potential novel PR determinants.

**Conclusions:** These findings are a proof-of-concept that WGS can accurately predict PR in *K. pneumoniae* CG258 and may be applicable to other forms of complex antimicrobial resistance. Use of ML for resistance prediction may need to be tailored to specific organisms and antimicrobial agents.

Rapid detection of ceftazidime/avibactam-resistant Enterobacteriaceae by VITEK MALDI-TOF mass spectrometry using direct-on-target microdroplet growth assay

Shenglei Huang*, Bijie Hu1, Wei Guo1, Jue Pan1, Beili Wang1, Zhou Chunmei1, Yan Ma1, Yuzhang Shan1, Yuyi Zhang1

1Fudan University/Zhongshan Hospital, Shanghai, China

Abstract 2137

**Background:** We evaluated the direct-on-target microdroplet growth assay for rapid detection of ceftazidime-avibactam resistant CRE (carbapenem resistant Enterobacteriaceae)

**Materials/methods:** In our study, a total of 47 non-duplicate CRE isolates were used to evaluate the performance of ceftazidime-avibactam resistance detection, including 19 *Klebsiella pneumoniae*, 8 *Escherichia coli*, 6 *Enterobacter cloacae*, 5 *Serratia marcescens*, 4 *Klebsiella aerogenes*, 3 *Citrobacter freundii* and 2 *Klebsiella oxytoca* clinical isolates. These isolates were incubated for 3h, 4h, 5h, and 6h with and without 16 µg/ml ceftazidime-avibatam in broth as microdroplets directly on matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) target spots. The microdroplet volume was 6µl. After the incubation period, the broth is separated from microbial cells by pipette. MALDI-TOF MS was used to determine the growth of the isolates in each spot and identify the microorganism at the same time. The micro-broth dilution method recommended by the European Committee on Antimicrobial Susceptibility Testing (EUCAST) was used as a reference method. Polymerase chain reaction based assay were used to determine the carbapenem-resistance mechanisms by screening the presence of β-lactamase-encoding genes, including Ambler class A (SME, IMI, KPC and GES), class B (NDM, IMP and VIM), and class D (OXA-48).

**Results:** We observed that incubation duration of 3 h was not sufficient for isolates. At that time, the identification valid results of the growth control were only 25.0%. Therefore, this time-point was not carried in further experiments. For CRE strain detection, 83.7% of growth controls were successfully detected after 4 hours incubation. At this time point, sensitivity and specificity for resistance detection were both 100%. 5 h of incubation droplets resulted in 98.0% of valid tests with 100% sensitivity and 100% specificity. However, 6 h of incubation droplets resulted in 100% of valid tests with 100% sensitivity and 100% specificity.

**Conclusions:** Newly developed MALDI-TOF MS-based direct-on-target microdroplet growth assay is a rapid, convenient and accurate tool which is able to detect ceftazidime-avibactam resistant CRE within 5 hours. This assay can determine the susceptibility status of the isolate and the underlining resistance mechanisms could also be revealed.

Breakthrough blood culture isolates whilst on broad spectrum antimicrobial therapy for high-risk neutropenic fever: more common and resistant that previously thought

Abby Patricia Douglas1,2, Shio Yen Tio1, Karin Thursky1,2,3, Leon Worth1, Ashish Bajel4, Monica Slavin1,2,3

1Peter MacCallum Cancer Centre, National Centre for Infections in Cancer, Melbourne, Australia, 2University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia, 3Royal Melbourne Hospital, Victorian Infectious Diseases Service, Parkville, Australia, 4The Royal Melbourne Hospital, Clinical Hematology and Bone Marrow Transplant Service, Parkville, Australia

Background: We aimed to review the frequency and spectrum of breakthrough positive blood cultures (BT-BC) during broad spectrum antimicrobial therapy (BS-AMT) for neutropenic fever (NF) in those with acute leukaemia receiving induction/consolidation chemotherapy (CTx), autologous (autoHCT) or allogeneic haematopoietic cell transplant (alloHCT).

Materials/methods: The PIPPIN study (Clinicaltrials.gov identifier: NCT03429387) is a prospective, multicentre, randomised trial of conventional CT versus PET/CT for prolonged or recurrent NF in adults with acute leukaemia receiving CTx or conditioning for alloHCT or autoHCT. First-line empiric NF BS-AMT was piperacillin-tazobactam, with ceferpine or ciprofloxacin/vancomycin in penicillin allergy. Participants had BCs (Bactec) collected at the clinician’s discretion plus at three timepoints: (1) at onset of NF (temp≥38.0, neutrophils≤0.5 cells/L), (2) persistent NF (>72 hours), (3) recurrent NF (new fever beyond 72 hours of initial onset, with 48 hours defervescence). A BT-BC was defined as a positive BC >72 hours after commencement of BS-AMT. An isolate was deemed resistant if it was intrinsically resistant or had an acquired resistance mechanism (e.g. ESBL). The data of the first 120 participants consented were analysed.

Results: Participants were enrolled between January 2018 and March 2019 (n=120: 57 acute leukaemia CTx, 63 alloHCT, 4 autoHCT). NF occurred in 128/140 cycles observed. During these NF episodes, 154 of 1,574 (9.8%) BCs collected were positive. Eighty-one unique isolates were identified (Figure 1). There were 45 BT-BC isolates: 25 initial BC negative and BT-BC positive, 4 persistent positive BC with same isolate, 16 initial BC positive and BT-BC positive with different pathogen. BT-BC occurred at 14.5 days median duration of neutropenia [IQR 8-26 days] and 12 days median continuous BS-AMT [IQR 8-18]. Of the 39 gram negative isolates, 17 were BT-BCs, and 12/17 (70.6%) were resistant to BS-AMT used, compared to 3/22 (13.6%) of the non-BT-BCs (p=0.003 by chi-square test).

Conclusions: Rates of BT-BC are high in the setting of prolonged neutropenia. Repeat BCs are indicated in prolonged and/or recurrent NF as a different causative pathogen is likely, which in turn is likely to be resistant to the current antimicrobials. Continuing BS-AMT in the setting of defervescence may have selected out for such resistance.

Multidisciplinary treatment model led by infectious physician reduce the unreasonable use of antibiotics and improve the efficacy in the treatment of patients with diabetic foot infection

Li Xiangyan*, Xin Qi, Shuohan Tian, Shan Jiang, Rui He

1Peking University First Hospital, Beijing, China, 2 Peking University First Hospital, Beijing, China

Background: Diabetic foot infection (DFI) is common cause of hospitalization and nontraumatic amputation in patients with diabetic mellitus. In this study, we aimed to explore the effectiveness of antibiotic management implementation in multidisciplinary collaborative therapies (MDT) led by infectious physicians. We hypothesized that this treatment model could make rational use of antibiotics and improve patient prognosis.

Materials/methods: This is a historical cohort study to assess antibiotic use and prognosis in patients with DFI between the two intervention models. One cohort received a multidisciplinary collaborative treatment model led by infectious physicians, in conjunction with surgeons and pharmacists, from October 2018 to September 2019. The control cohort was patients who were treated in the traditional mode from September 2017 to August 2018. In this mode, the surgeon led the treatment, and infectious physician was consulted if necessary. Data for the control group included demographic, clinical, laboratory, and surgical data, all from electronic medical records.

Results: There were 32 patients in the control cohort and 35 patients in the intervention cohort. Patients in intervention cohort present higher percentage of peripheral neuropathy (80.5% vs 53.1%, p=0.016) and polymicrobial infections (47.2% vs 12.5%, p=0.002), longer duration of diabetic foot ulcer (120 days vs 30 days, p=0.002) and more site of osteomyelitis involved (p=0.031). The rate of correct initial empirical treatment in MDT group was 100%, compared with 48% in the control group (p<0.001). The median duration of fever persistance decreased from 7 days to 1 day (p=0.004). The median intravenous antibiotic treatment time in the intervention and control groups was 12 days and 13.5 days (p = 0.692), with median hospital stay of 22 days and 21 days (p = 0.425) respectively. There was no significant difference in the number of surgical debridements between the two groups (p = 0.224).

Conclusions: Multidisciplinary treatment model led by infectious physician can reduce the unreasonable use of antibiotics and improve the efficacy in the treatment of patients with diabetic foot infection.

Abstract 2154

Sub-inhibitory concentrations of mupirocin stimulate Staphylococcus aureus biofilm formation by up-regulating cidA

Ye Jin*

1 The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China

Background: Previous studies have shown that the administration of antibiotics at sub-inhibitory concentrations stimulates biofilm formation by the majority of MRSA strains. Here, we investigated the effect of sub-inhibitory mupirocin concentrations on biofilm formation by the community-associated (CA) mupirocin-sensitive MRSA strain USA300 and highly mupirocin-resistant clinical S. aureus SA01-SA05 isolates.

Materials/methods: Cell lysis and eDNA quantification studies were used to investigate whether mupirocin increased the ability of S. aureus to attach to surfaces and form biofilms, which was correlated with eDNA production. The RNA-Seq and RT-qPCR were used to evaluate the expression of different genes in the mupirocin-treated and untreated strains in more detail. As follow-up functional analysis, we generated a cidA knock out mutant to form biofilms comparable to that formed by the parent strain in presence of antibiotic.

Results: We found that mupirocin increased the ability of MRSA cells to attach to surfaces and form biofilms. Confocal laser scanning microscopy (CLSM) demonstrated that mupirocin treatment promoted thicker biofilm formation, which also correlated with the production of extracellular DNA (eDNA). Furthermore, RT-qPCR results revealed that this effect was largely due to the involvement of holin-/antiholin-like proteins (encoded by the cidA gene), which are responsible for modulating cell death and lysis during biofilm development. We found that cidA expression levels significantly increased 6.05-35.52 fold (P < 0.01) on mupirocin administration. We generated a cidA-deficient mutant of the USA300 S. aureus strain. Exposure of the ΔcidA mutant to mupirocin did not result in thicker biofilm formation compared with that in the parent strain.

Conclusions: The increase in biofilm formation mediated by mupirocin was due to cell death and lysis. Mupirocin-induced stimulation of S. aureus biofilm formation may involve the upregulation of cidA. Our study supports the recommendation to clinicians regarding the prudent usage of sub-concentrations of antimicrobials agents, which may possibly contribute to poor prognosis of MRSA infections.

Viral and immunologic factors associated with fatal outcome of patients with severe fever with thrombocytopenia syndrome in Korea

Jisoo Kwon*, Jiyeun Kim, Sang Hyun Ra, Taeeun Kim, Se Yoon Park, Min-Chul Kim, Seong Yeon Park, Dasarang Kim, Hye Hee Chae, Hyun Jung Lee, Na Young Jeon, Min-Jae Kim, Yang Pil Chong, Sang-Oh Lee, Sang-Ho Choi, Yang Soo Kim, Jun Hee Woo, Keun Hwa Lee, Sung-Han Kim, Sun-Ho Kee

1Asan Medical Center, Seoul, South Korea, 2Nowon Eulji Medical Center, Seoul, South Korea, 3Soonchunhyang University Seoul Hospital, Seoul, South Korea, 4Chung-Ang university, Seoul, South Korea, 5Dongguk University Ilsan Hospital, Goyang-si, South Korea, 6Korea University, Seoul, South Korea, 7Jeju National University, Ara Campus, Cheju, South Korea

Background: Severe fever with thrombocytopenia syndrome (SFTS), which is caused by a novel phlebovirus SFTS virus (SFTSV), is an emerging tick-borne disease in East Asia with a high fatality (16.2-32.6%). Significant progress has been made on the molecular biology of the virus, however, many parts of pathophysiological mechanisms of mortality in SFTS remain unclear. In the present study, we investigated virologic and immunologic factors for fatal outcomes of patients with SFTS.

Materials/methods: We prospectively enrolled 34 confirmed cases of SFTS admitted to 5 university-affiliated hospitals in South Korea from July 2015 to September 2018. SFTSV infection was confirmed by real-time reverse transcription polymerase chain reaction for the detection of viral RNA; segment S and M. We simultaneously measured the levels of cytokines in the plasma samples by multiplex-microbead immunoassay for 18 cytokines selected. Serological testing for the presence of anti-SFTSV IgG titer was tested by immunofluorescence antibody assay.

Results: A total of 34 patients with SFTS were enrolled, including 31 (91.2 %) survivors and 3 (8.8 %) non-survivors. Sixteen (47.1%) patients were previously healthy but the others had a broad range of underlying diseases. Non-survivors had 4 log copies/mL higher plasma SFTSV load than survivors at admission [seg S; median 6.40 vs 2.54 log, p = 0.001, seg M; median 6.87 vs 2.73 log, p = 0.001] and the viral load in non-survivors increased progressively during the hospitalization. In addition, non-survivors did not develop adequate anti-SFTSV IgG response, whereas survivors exhibited anti-SFTSV IgG during the hospitalization. Among the cytokines measured in this study, the plasma concentrations of IL-10, IFN-α, MIP-1α, IP-10, MCP-1, IL-6, IL-8 and G-CSF were significantly elevated in non-survivors than survivors and not reverted to normal ranges during the hospitalization [p < 0.05]. Of note in particular, the plasma IL-10, IFN-α, MIP-1α concentrations were markedly higher in non-survivors throughout the disease course.

Conclusions: Our findings suggest that high plasma concentrations of cytokines, uncontrolled viremia and failure of the antibody response were critical determinants of fatal outcomes of SFTSV infection.
Figure 1. Plasma SFTSV load, antibody titer, interleukin-10, interferon-α, and macrophage inflammatory protein 1α concentrations in patients with SFTS.

Abstract 2157

Rising clarithromycin resistance in *Helicobacter pylori* in a Hong Kong regional hospital and molecular characterisation by next-generation sequencing

Candy Lau*, Ws Chan¹, Ch Au¹, Tm Chan¹, Ti Chan¹, Sk Ma¹, Bone Tang¹

¹Hong Kong Sanatorium & Hospital, Hong Kong, Hong Kong

**Background:** Helicobacter pylori, which causes chronic stomach infections and associated with gastric malignancies, infects one-third to half of the population in Hong Kong. Current recommended eradication therapy is a standard 7-day amoxicillin-clarithromycin-containing triple therapy, given the low prevalence of clarithromycin resistance in the locality (<15%). Antibiotic susceptibility testing prior to eradication therapy is not commonly performed in Hong Kong due to reported low resistant rate (7.8%-14%). This study aims to report the increasing prevalence of antibiotics resistance in *H. pylori* in a Hong Kong regional hospital and the potential use of molecular methods in resistance prediction.

**Materials/methods:** A total of 503 *H. pylori* strains, which were isolated from patient gastric biopsies during a 22-month period, were included in this study. Susceptibility testing on clarithromycin, metronidazole, amoxicillin, levofloxacin, tetracycline and rifampicin were performed. Forty-seven clarithromycin-resistant strains were selected in the preliminary study for whole genome sequencing using Illumina MiSeq system.

**Results:** The resistance rates of *H. pylori* to clarithromycin, metronidazole, amoxicillin, levofloxacin, tetracycline and rifampicin were 46.7%, 60.2%, 12.3%, 39.2%, 2% and 19.1% respectively. Among the clarithromycin-resistant strains, 89.4% (42/47) carried resistant genotype in 23S rRNA gene; 10.6% (5/47) of them did not contain any mutations. Mutations in *gyrA* or *gyrB* genes, which were responsible for fluoroquinolone resistance, were identified in 70.8% (17/24) of resistant strains and 39.1% (9/23) of susceptible strains. Mutations in *rdxA* and/or *frxA*, which were responsible for metronidazole resistance, were observed in 78.8% (26/33) of resistant strains and 35.7% (5/14) of susceptible strains. Among the rifampicin-resistant strains, 25% (2/8) carried resistant genotype in *rpoB* gene and none of these mutations was detected in susceptible strains. Although none of the sequenced strains was amoxicillin or tetracycline-resistant, resistance-associated mutations in *pbp1A* and 16S rRNA were observed in 23.4% (11/47) and 21.3% (10/47) of strains respectively.

**Conclusions:** The prevalence of clarithromycin-resistant *H. pylori* was higher than previously reported and exceeded the 15% threshold level. Antibiotic resistance profiling is recommended to be performed prior to eradication therapy prescription. Further studies are necessary for studying the association of antibiotic resistance and mutations and the usefulness of molecular testing in resistance prediction.

Abstract 2163

**Chagas disease in Japan, 2012-2019: clinical presentation and diagnostic delay**

Kazuo Imai\*1, Norihito Tarumoto1, Jun Sakai1, Takashi Murakami2, Shigefumi Maesaki1, Sachio Miura3, Takuya Maeda4

1Saitama Medical University, Department of Infectious Disease and Infection Control, Saitama, Japan; 2Saitama Medical University, Department of Microbiology, Saitama, Japan; 3Nonprofit organization MAIKEN, Tokyo, Japan; 4Saitama Medical University hospital, Clinical Laboratory Medicine, Saitama, Japan

**Background:** Chagas disease, caused by *Trypanosoma cruzi*, is the neglected tropical disease in both endemic and non-endemic countries. Chagas disease was considered a public health problem in non-endemic countries because the epidemiology of Chagas disease has radically changed in accordance with the increasing numbers of immigrants from Latin America to non-endemic countries. There is little information of clinical characteristics of Chagas disease in non-endemic countries, although the 3,000 patients were estimated to live in Japan. The current study aimed to clarify the clinical characteristics of Chagas disease in Japan.

**Materials/methods:** Twenty nine patients with suspected Chagas disease between 2012 and 2019 were included in the study. Patients were diagnosed with Chagas disease based on the two different serological tests for antibodies to *T. cruzi*. The real-time PCR assay and blood culture technique were performed to confirm the parasitemia of *T. cruzi*. The discrete typing units (DTUs) of clinical isolates were determined by PCR-RFLP method.

**Results:** Of the 29 patients, 23 were immigrants from Latin America. Finally, 13 patients were diagnosed with Chagas disease. Of the 13 patients, median age was 51 years, 12 patients were immigrants from Latin American [Brazil, 5; Bolivia, 7], and 1 was Japanese case of congenital infection. Nine patients developed chronic phase (Chagas cardiomyopathy, 8; megacolon, 1). A patient died from Chagas cardiomyopathy. Six had confirmed parasitemia of *T. cruzi*, and 2 were positive for blood culture. DTUs of 2 clinical isolates were identified as *T. cruzi* DTUs I. Finally, 4 patients were initiated treatment with Benznidazole.

**Conclusions:** Our study demonstrated that patients of Chagas disease living in Japan have developed chronic phase when they diagnosed with the disease because of diagnostic delays. This study indicates an urgent need for the Chagas disease screening program for the Latin American immigrants in non-Chagas disease-endemic countries, including Japan.

Systematic assessment of available data on the incidence of bloodstream infections and hospital-acquired pneumonia caused by carbapenem-resistant Acinetobacter baumannii in Europe: the ABOUT-MDRO-CRAB study

Blanca Anaya-Baz*, Natalia Maldonado, Zaira Palacios Baena, Virginia Palomo, Maria Diletta Pezzani, Sheila Chiesi, Elisa Razzaboni, Monica Compri, Evelina Tacconelli, Jesús Rodríguez-Baño

1Unidad Clínica de E. Infecciosas, Microbiología y M. Preventiva, Hospital Universitario Virgen Macarena / Department of Medicine, University of Seville / Biomedicine Institute of Seville (IBIS), Seville, Spain, Seville, Spain, 2Infectious Diseases, Department of Diagnostic and Public Health, Verona, Italy, Verona, Italy

Abstract third-party references: Funded by the Innovative Medicines Initiative Joint Undertaking, EPI-Net/COMBACTE-MAGNET project [grant agreement number 115737], European Union 7th Framework Programme [FP7/2007–2013] and EFPIA companies in-kind contribution, EPI-Net/COMBACTE-MAGNET investigators

Background: Acinetobacter baumannii (AB) is an important cause of hospital-acquired and ventilator-associated pneumonia (HAP, VAP) and bloodstream infection (BSI). Carbapenem-resistant AB (CRAB) is increasing worldwide. However, a precise assessment of the incidence of HAP/VAP and BSI due to CRAB is not available and current figures are mainly based on modelling methodologies using proportion of resistant isolates. The aim of this study is to estimate the correlation between incidence of HAP/VAP and BSI due to CRAB and the proportion of carbapenem-resistance in Europe.

Materials/methods: A systematic review (following PRISMA recommendations) was performed for data on incidence of CRAB and proportion of carbapenem-resistance in AB data for BSI, HAP and VAP in Europe from 2005-2018, from scientific literature and European surveillance systems in SUSPIRE/EPI-NET databases. Correlations between incidence data and proportion of carbapenem-resistance in AB were analysed by linear regression.

Results: Overall 2,687 and 5,537 articles containing data for BSI or HAP/VAP, respectively were identified. Finally, 32 and 20 studies were included. Incidence of CRAB BSI, HAP and VAP were extracted from 13, 22 and 14 studies, respectively, from 5 countries. Incidence of HAP/VAP ranged 2.38-2.52/100 ICU admissions in Greece (2 studies), 0.45-3.76 in Italy (2 studies), 0.3-1.66 in Spain (2 studies), 0.70-23.30 in Poland (7 studies) and 0.16-3.5 in Turkey (2 studies). Incidence of BSI/100 ICU admissions ranged: 0.35-0.87 in Greece (2 studies), 0.41 in Italy (1 study), 1.49 in Spain (1 study), 0.94-1.84 in Poland (2 studies) and 4.08 in Turkey (1 study). No statistically relevant correlation was found between incidence and resistance proportion for CRAB \([R^2=0.197\text{ for BSI in ICU}, 0.010\text{ for HAP in ICU and 0.170 for VAP, respectively}]\) in the 5 countries analysed.

Conclusions: This systematic review on European data showed: [a] scarce data on incidence of BSI and HAP/VAP due to CRAB; [b] high heterogeneity in incidence and resistance proportions within countries; [c] lack of correlation between incidence and proportion of carbapenem-resistance in AB. These data strongly call for improved surveillance systems to inform burden assessment and drive infection control and antibiotic policy decisions.

Abstract 2166

Risk factors of severe dehydration among children under five
Anna Mkhoyan*, Anahit Demirchyan

1Yerevan State Medical University, Yerevan, Armenia, 2American University of Armenia, Yerevan, Armenia

Background: Dehydration is the leading cause of hospitalization from diarrhea among children under five years old. The degree of dehydration is measured using capillary refill time, skin turgor, respiratory rates and signs of shock. According to demographic and health survey 2010, the prevalence of diarrhea was 9% among under-five children in Armenia and 7% of all infant deaths were related to diarrheal diseases.

Objective: The aim of this study was to identify the risk factors of moderate-to-severe dehydration among children under five years old hospitalized because of acute diarrhea.

Materials/methods: The study utilized a case-control study design to identify the risk factors of severe/moderate dehydration among children under five years old. Cases (n=62) were under-five children admitted to “Nork” infectious clinical hospital with the initial diagnosis of acute diarrhea and with severe or moderate dehydration at the admission. Controls (n=125) were under-five children admitted to “Nork” infectious clinical hospital with the initial diagnosis of acute diarrhea and with no or mild dehydration at the admission. Face to face interviews were conducted with mothers of the children.

Results: From all 187 children, 105 (56.1%) were males and 82 (43.9%) were females. The mean age of children of cases was 14.8 (14.6) and 24.4 (15.4) for controls. Mother’s higher KAP (knowledge, attitude and practices) score was negatively associated with the child’s dehydration status (OR0.68, CI 0.53; 0.87). Being vaccinated against rotavirus (OR 0.29, CI 0.08; 0.61), child’s good general health rating by the mother (OR0.23, CI 0.09; 0.62), child’s age (OR0.94, CI 0.90; 0.97) and high socioeconomic status score (OR (0.70, CI 0.49; 1.01) of the family were among factors protecting from severe/moderate dehydration, while higher birth order OR(2.21, CI 1.10; 4.42) and repeating vomiting during the disease (OR 5.10 CI 1.84; 14.08) were among its risk factors.

Conclusions: The study recommends increasing mother’s KAP on diarrhea home management through public education interventions. The coverage of under-five children with rotavirus vaccination and mothers’ awareness about diarrhea danger signs should be increased.

**Abstract 2167**

**Sensitivity of C-reactive protein and procalcitonin to diagnose urinary tract infections in nursing home residents**

Sacha Danielle Kuil*, Soemeja Hidad, Johan Fischer, Janneke Harting, Cees Hertogh, Jan M. Prins, Frank Van Leth, Menno De Jong, Caroline Schneeberger

1Amsterdam UMC, University of Amsterdam, Department of Medical Microbiology, Amsterdam Infection & Immunity Institute, Amsterdam, Netherlands, 2Amsterdam UMC, University of Amsterdam, Department of Clinical Chemistry, Amsterdam, Netherlands, 3Amsterdam UMC, University of Amsterdam, Department of Public Health, Public Health research institute, Amsterdam, Netherlands, 4Amsterdam UMC, VU University Medical Center, Department of General Practice and Elderly Care Medicine, Amsterdam, Netherlands, 5Amsterdam UMC, University of Amsterdam, Division of Infectious Diseases, Department of Internal Medicine, Amsterdam Infection & Immunity Institute, Amsterdam, Netherlands, 6Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands

**Abstract third-party references:** This study is funded by The Netherlands Organization for Health Research and Development (ZonMW) grant 541001003

**Background:** Urinary tract infections (UTI) are common in elderly nursing home residents. Diagnosis of UTI is complex since signs and symptoms are often nonspecific, especially in residents with cognitive impairments. The high prevalence of asymptomatic bacteriuria (ASB) limits the usefulness of bacterial culture or dipstick-based diagnostics, and potentially leads to antibiotic overuse. The aim of this study is to assess the sensitivity of blood C-reactive protein (CRP) and procalcitonin (PCT) measured by Point-of-Care tests (POCTs) for UTI diagnosis, thereby potentially providing supportive diagnostics to distinguish ASB from true UTIs.

**Materials/methods:** In an 18-month prospective study in three nursing home organizations in the Netherlands, residents with a suspected UTI were included. The target sample size was 440 to detect a minimal clinically relevant sensitivity of 65% of either tests and a 10% difference between tests, with a power of 90% and two-sided p-value of 0.05. CRP and PCT sensitivities were derived empirically from Receiver Operator Curves, using a predefined stringent definition of ‘true’ UTI which included microbial culture results and symptom resolution during adequate antimicrobial treatment.

**Results:** After enrolment of 293 residents (66.6% of planned sample size) a previously unplanned and funder-mandated interim analysis was performed. In residents with suspected UTI 41% of CRP and 47% the PCT POCT results were below the lower limit of detection (similar in UTI and ASB). The sensitivities of CRP (cut-off 6.5 mg/L) and PCT (cut-off 0.025 μg/L) were 49% and 45% respectively. To achieve the required minimal sensitivity of 65%, POCT sensitivities in remaining study participants would have to be at least 96%. Based on these results, the study was discontinued prematurely for futility.

**Conclusions:** Sensitivities of CRP and PCT POCTs to diagnose UTIs in nursing home residents are low. Our results indicate that CRP and PCT are not suitable to distinguish UTI and ASB in this setting.

Abstract 2168

Systematic assessment of available data on the incidence of hospital-acquired pneumonia and bloodstream infections due to carbapenem-resistant *Pseudomonas aeruginosa* in Europe: the ABOUT-MDRO-CRPA project

Blanca Anaya-Baz*1, Natalia Maldonado1, Zaira Palacios Baena1, Virginia Palomo1, Maria Diletta Pezzani2, Sheila Chiesi2, Elisa Razzaboni2, Monica Compri2, Evelina Tacconelli2, Jesús Rodríguez-Baño1

1Unidad Clínica de E. Infecciosas, Microbiología y M. Preventiva, Hospital Universitario Virgen Macarena / Department of Medicine, University of Seville / Biomedicine Institute of Seville (IBIS), Seville, Spain, 2Infectious Diseases, Department of Diagnostic and Public Health, Verona, Italy, Verona, Italy

**Background:** *Pseudomonas aeruginosa* (PA) is a leading cause of bloodstream infections (BSI), hospital-acquired pneumonia (HAP) and ventilator-associated pneumonia (VAP). Carbapenem-Resistant *P. aeruginosa* (CRPA) is a “critical” priority pathogen, nonetheless, most available data are obtained from proportion of resistant isolates, and the incidence of infections is not precisely characterized. The aim of this study is to provide data on incidence of BSI and HAP/VAP by CRPA in European countries, and its correlation with carbapenem-resistance among PA isolates.

**Materials/methods:** A systematic review (following PRISMA recommendations) was performed for data on incidence of CRPA and proportion of carbapenem resistance in PA for BSI and HAP/VAP in European countries from 2005-2018, from scientific literature and available data from European surveillance systems from SUSPIRE/EPI-NET databases. Correlations between incidence data and proportion of carbapenem resistance in PA were analyzed by linear regression.

**Results:** Literature review identified 12,960 and 4,223 articles containing data for BSI and HAP/VAP, respectively; 20 studies for BSI and 17 for HAP/VAP were finally included. BSI and HAP/VAP incidence for CRPA were measured as cases per 100 admissions, 1,000 patient-days (PD), and 1,000 ventilator-days (VD). Incidence of HAP/VAP ranged from 0.62 to 0.65/100 admissions in Poland, 1 to 1.7 in Italy, and 1.11 and 2.0 in Turkey and Greece, respectively; for BSI, incidence ranged from 0.0015 in Sweden, from 0.02 to 0.6 in Italy, from 0.71 to 3.8 in Turkey, and 0.64 and 0.71 in Greece and Spain, respectively. HAP/VAP incidence in cases per 1,000PD ranged from 0.57 in Poland to 15.4 in Serbia, and CRPA incidence in BSI ranged from 0.013 in Italy to 2.1 in Turkey. Carbapenem-resistance in *P. aeruginosa*, ranged from 31.5%-100% in HAP/VAP, and 6.3%-88.9% in BSI. No statistically significant correlation was found between incidence and carbapenem-resistance in PA ($R^2=0.433$ and 0.317 in BSI and pneumonia, respectively).

**Conclusions:** Data on incidence of BSI and HAP/VAP due to CRPA are scarce and showed heterogeneous results within countries. No correlation was found between available data on incidence of CRPA infections and proportion of carbapenem resistance in PA. These data suggest that improved surveillance data are needed to inform burden assessment of CRPA infections.

How an inflammatory marker Point-of-Care test can reduce inappropriate antibiotic use in urinary tract infections: perceptions of physicians and nurses in Dutch nursing homes

Sacha Danielle Kuil1*, Caroline Schneeberger1, Menno De Jong1, Frank Van Leth2, Janneke Harting3

1Amsterdam UMC, University of Amsterdam, Department of Medical Microbiology, Amsterdam Infection & Immunity Institute, Amsterdam, Netherlands, 2Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 3Amsterdam UMC, University of Amsterdam, Department of Public Health, Amsterdam Public Health research institute, Amsterdam, Netherlands

Abstract third-party references: This study is funded by The Netherlands Organization for Health Research and Development (ZonMW) grant 541001003. ZonMW, Laan van Nieuw Oost Indië 334, 2593 CE Den Haag, The Netherlands.

Background: Diagnosing Urinary tract infections (UTI) in nursing home residents is challenging. Due to the high prevalence of non-specific symptomatology and asymptomatic bacteriuria (ASB), current urine tests have limited usefulness and often result in inappropriate antibiotic use. A sufficiently sensitive blood inflammatory marker Point-of-Care test (POCT) could help verifying the presence of a UTI. However, apart from its sensitivity, the effectiveness of a POCT highly depends on its correct use in practice. We explored the perceptions of physicians and nurses in Dutch nursing homes how to use a POCT in practice.

Materials/methods: In this multicenter multiple case study, we used 18 semi-structured face-to-face interviews to identify physicians’ and nurses’ intended use of POCT in diagnosing UTI in nursing home residents. Both the development of the interview guide and the analysis of the interview transcript were based on the Consolidated Framework for Implementation Research (CFIR).

Results: Most respondents acknowledged positive POCT results could decrease the diagnostic uncertainty in residents presenting non-specific symptoms and reduce inappropriate antibiotic use. However, most respondents also expected that new diagnostic uncertainties would arise. First, other infections with non-specific symptoms causing positive POCT results might be overlooked. Second, the respondents were not sure how to deal with negative POCT results. These new uncertainties could again provoke inappropriate antibiotic use. Furthermore, many respondents intended – improper – use of POCT, such as diagnosing other infections, assessing infection severity, monitoring infections and deciding about emergency referrals.

Conclusions: In order to effectively contribute to diagnosing and properly treating UTI in nursing homes, practical guidelines on POCT use are needed, when sufficient sensitivity of POCT is demonstrated. These guidelines should include the indications for testing and guidance on interpretation of results, to prevent inappropriate use and consequently inappropriate antibiotic use.

Severe Plasmodium falciparum malaria in non-immune travellers admitted to the intensive care unit: assessment of parasite clearance in response to antimalarial medication and exchange transfusion

Vladimir Chentsov1, Anatoly Tokmalaev2, Svetlana Krasnova1, Galina Kozhevnikova2, Natalia Tsvetkova1, Karl Emerole*2

1Infectious Diseases Clinical Hospital №2, Moscow, Russia, Moscow, Russian Federation, 2Peoples’ Friendship University of Russia (RUDN University), Moscow, Russia, Moscow, Russian Federation

Background: Most of the Severe P. falciparum malaria complications occur in non-immune subjects and involves damage to multiple organ systems. To optimize the management of severe P. falciparum we developed an algorithm which includes exchange transfusion (ET) methods [continuous venovenous hemodiafiltration and plasmapheresis] and mechanical ventilation under medically induced coma as preventive measures for cerebral forms. ET was implemented not only to reduce parasite load in cases of high parasitaemia but also to reduce the mortality of severe cases. Jinfeng Lin, Xiaoying Huang et al. 2018 conducted a recent study in which the authors did not identify substantial evidence supporting the use of exchange transfusion in severe P. falciparum malaria.

Materials/methods: 72 patients treated for severe P. falciparum malaria, admitted to the intensive care unit (ICU) at the Infectious Diseases Clinical Hospital №2, Moscow, Russia between 2002 and 2019 were included in this retrospective study. Parasite clearance was determined using the Worldwide Antimalarial Resistance Network’s parasite clearance estimator. The primary end point was the parasite clearance time.

Results: All patients had obtained antimalarial medication in accordance with the World Health Organization treatment guidelines. Data from 54 patients were suitable for estimation of parasite clearance. 38 (71%) patients were managed with parenteral antimalarial medication and ET as an adjunct treatment while 16 (29%) patients received only intravenous (IV) antimalarial treatment. The median parasite clearance time was 37.50 (95% CI 36.21 to 38.18) hours for patients who received ET under antimalarial treatments and 47.56 (95% CI 46.26–48.70) patients managed with antimalarial drugs only, p value < 0.05. The median parasite clearance rate in the ET intervention group had a slope half-life of 3.12 (95% CI 1.91–4.88) hours and 4.00 (95% CI 2.14–5.20) hours for patients who received antimalarial drugs only, p = 0.671. Majority of mortality cases was observed in the group of patients managed with antimalarial drugs only.

Conclusions: Our investigation does reveal ET contributes significantly to parasite clearance in ICU patients treated with antimalarial drugs, although the slope half-life did not differ significantly. Extensive investigations would be conducted to reveal the accurate scope of ET intervention in severe malaria

Outcomes of the antibiotic stewardship programme in a teaching hospital of southern Italy: an interrupted time-series analysis

Margherita Macera*1, Federica Calò1, Lorenzo Onorato1, Nicola Coppola1

1University of studies of Campania “Luigi Vanvitelli”, Naples, Italy

Background: The widespread of antimicrobial resistance is a global health problem, significantly increasing the hospital mortality, the need for Intensive Care Units (ICUs) admission, the length of stay, and the healthcare costs. The antimicrobial resistance is hugely accelerated by the selective pressure exerted by antibiotics overuse. The implementation of the “Antibiotic Stewardship Programme” (ASP) is essential to improve the appropriateness of antibiotic prescriptions. In the present study we aimed at evaluating the impact of an ASP in selected departments of 3 different clinical areas (medical, surgical and intensive areas) of an acute-care teaching hospital in Naples, Italy.

Materials/methods: We conducted a prospective, interventional, before and-after study, based on prospective audit and feedback in 3 surgical units, 4 medical units and 2 ICUs (January 2017-April 2019). The outcomes were the difference in the antibiotic consumption (as DDD/100 patient-day), the mean length of stay and the antibiotic costs. Additional outcomes in critical area were the difference in incidence of bloodstream infections (BSI) caused by multidrug-resistant (MDR) bacteria (as cases/100 patients-day) and the hospital mortality rate.

Results: During the study period, 231 audit were performed in ICUs, 210 in medical units and 184 in surgery units, evaluating a total of 4,312 patients. The program led to a significant reduction in the use of fluoroquinolones (p<0.001), teicoplanin and azoles (p=0.04) in ICUs, of carbapenems (p<0.001) and tygecilcline (p=0.01) in medical units and of third-four generation cephalosporins (p=0.002) in surgical units (Figure 1); in these latter a simultaneous increase in the use of cefazolin (p<0.001) and metronidazole (p=0.01) was observed. The antibiotic costs were reduced in medical units and ICUs. No significant differences were found on length of hospital stay in all three areas and on hospital mortality in ICUs. Instead, we registered in ICUs a significant decrease in BSI due to MDR Gram-negative bacteria (p=0.043) (Figure 1).

Conclusions: Our study demonstrated that the implementation of an ASP in a teaching hospital induced a significant reduction in high impact antibiotic use and a positive ecologic impact in the incidence of BSI due to MDR Gram-negative bacteria, without impact on the mortality rate.

Whole genome sequence of a pan-resistant Klebsiella pneumoniae sequence type 11 harbouring an IncR-F33:A-B-plasmid carrying multiple resistance determinants identified in Japan in 2016

Satoshi Nishida*, Yasuo Ono

1Teikyo University School of Medicine, Tokyo, Japan

**Background:** Klebsiella pneumoniae carbapenemase (KPC)-producing Klebsiella pneumoniae has expanded rapidly and is associated with severe nosocomial infections. Last-line antibiotics such as colistin and tigecycline remain the only treatment option. Here, we describe the genetic background of a novel pan-resistant KPC-producing K. pneumoniae isolate from Tokyo, Japan.

**Materials/methods:** The antibiotic susceptibility of clinical isolates from a patient hospitalized in 2016 was tested using a MicroScan WalkAway instrument and the broth microdilution method. Susceptibility was defined according to breakpoints provided by the Clinical and Laboratory Standards Institute (CLSI). Whole-genome sequencing was performed to detect acquired resistance genes and gene mutations, using Single-Molecule Real-Time (SMRT) sequencing.

**Results:** The isolates were identified as part of a laboratory stool and swab surveillance-screening program for infection control. The carbapenem-resistant strain was resistant to β-lactams, including broad-spectrum cephalosporins and carbapenems, and to aminoglycosides, chloramphenicol, fosfomycin, fluoroquinolones, polymyxins (colistin and polymyxin B), tetracyclines (minocycline and tigecycline), and trimethoprim/sulfamethoxazole. The K. pneumoniae isolate harbored an IncR-F33A-B-plasmid carrying catA2, fosA3, rmtB, blaCTX-M-65, blaTEM-1, blaSHV-1, and blaKPC-2 in a non-Tn4401 mobile element (NTE). Colistin and tigecycline resistance was associated with mutations in mgrB gene, which regulates the PhoP/PhoQ two-component system, and ramR gene, respectively. The K. pneumoniae isolate belongs to sequence type (ST) 11, a successful epidemic-type strain.

**Conclusions:** We identified molecular resistance markers in a pan-resistant isolate and provided a genomic description of the pan-resistance and the origins of the isolate and plasmid. The isolate is closely related to a recent highly pathogenic carbapenem-resistant K. pneumoniae identified in China; however, it lacks a virulence plasmid (but it could still act as a reservoir for a virulence plasmid). This K. pneumoniae isolate is of concern in hospital and community care settings. Whole-genome sequencing would be useful for detection and prevention of the spread of newly emerging K. pneumoniae.

**Evaluation of QuantiFERON-TB Gold Plus test in the diagnosis of Mycobacterium tuberculosis infection**

Melike Yasar1*, Cengiz Cavusoğlu1, Tansu Gülbahar Aydoğan3

1Ege University Medical Faculty, Department of Medical Microbiology, İzmir, Turkey

**Background:** The aims of this study were to evaluate the sensitivity of QuantiFERON®-TB Gold Plus (QFT) test and to investigate possible factors associated with indeterminate QFT test results and to explore the relationship between latent tuberculosis infection (LTBE) prevalence and the rate of tuberculosis (TB) cases in our region.

**Materials/methods:** 750 cases with QFT test performed in Ege University Faculty of Medicine Hospital in 2016 were included in the study. The QFT results of the cases were compared according to their gender, age groups and clinical characteristics.

**Results:** Among 750 cases, 250 (33.3%) were QFT positive and 33 (4.4%) had an indeterminate QFT result. When the indeterminate results were excluded, QFT positivity was found as 34.9%. The highest indeterminate results were determined among 0-4 year-old group as 11.5% and lowest among the 25-34 age group as 0%. Immunosuppressive patients had nearly two times more indeterminate QFT results when compared with cases without any cellular immunity defect. Among 10 culture-positive cases, 8 had QFT positive, two negative results. The sensitivity of the test was 80% (8/10) among culture-positive active TB cases. The ratio of QFT positivity has increased as the age increased. Interestingly, QFT positivity was higher among females than males in the 15-34 age group and higher among males in the other age groups. The rates of QFT positivity were lower among immunocompromised patients. When QFT positivities were compared with the rate of TB cases among age groups, QFT positivity was observed as parallel to the rate of TB cases.

**Conclusions:** In conclusion, although the sensitivity of QFT was, 80% in culture-positive active TB cases, it was found that it could not be considered as a gold standard in LTBE diagnosis. As active TB cases originate from the LTBE pool, QFT test results might be considered a better indicator of active TB development risk.

**Risk factors for developing BK virus associated nephropathy: a single-centre retrospective cohort study of kidney transplant recipients**

Camilla Lorant*, Gabriel Westman1, Anders Bergqvist1, Bengt Von Zur-Mühlen1, Britt-Marie Eriksson1

1Uppsala University Hospital, Department of Medical Sciences, Section of Infectious Diseases, Uppsala, Sweden, 2Uppsala University Hospital, Department of Medical Sciences, Section of Clinical Microbiology and Infection Control, Uppsala, Sweden, 3Uppsala University Hospital, Department of Surgical Sciences, Section of Transplantation Surgery, Uppsala, Sweden

**Background:** BK virus (BKV) infection after kidney transplantation leads to BKV associated nephropathy (BKVAN) in up to 10% of recipients, and is associated with an increased risk of allograft dysfunction or loss. There is no established antiviral therapy available for BKV infection but a pre-emptive strategy to reduce immunosuppression when BK viremia is detected, has been shown to lower the incidence of BKVAN. The objective of this study was to analyse whether the sub-group of patients receiving enhanced immunosuppression have an increased risk of BKVAN, justifying more intensive surveillance.

**Materials/methods:** This was a single centre retrospective cohort study. All patients aged ≥18 years who underwent kidney transplantation or simultaneous pancreas/kidney transplantation at the Uppsala University Hospital in Sweden between 2005 and 2014 were included, a period when BKV screening was not yet implemented at our centre. Most patients received basiliximab and methylprednisolone as induction and a combination of prednisone, mycophenolate mofetil and tacrolimus as maintenance immunosuppression. Enhanced immunosuppression was defined as treatment with thymoglobulin, rituximab, ecuizumab, IVIG, glycosorb and/or plasmapheresis/apheresis. Other risk factors included in the multivariate Cox proportional hazards model were sex, age, cytomegalovirus (CMV) mismatch (donor +/recipient -) and rejection treatment.

**Results:** 44 out of 928 (4.7%) patients developed a biopsy verified BKVAN 4.8 (1.5-35.0) months after transplantation. 141 (15.2%) patients received enhanced immunosuppression. Only male sex showed to be a significant risk factor (Table 1). Patients who presented with BKVAN experienced a significantly higher risk of early graft loss than patients without BKVAN (hazard ratio 4.4).

**Conclusions:** Male sex, but not enhanced immunosuppression, is a significant risk factor for developing BKVAN after kidney transplantation.

Abstract 2188

Decontamination strategies used for AFB culture significantly reduce the viability of Mycobacterium abscessus in sputum samples from patients with cystic fibrosis

Dominic Stephenson1, Audrey Perry1, Andrew Nelson2, Ali Robb1, Matthew Thomas1, Stephen Bourke3, John Perry*1, Amanda Jones2

1Newcastle Freeman Hospital, Newcastle upon Tyne Hospitals, High Heaton, United Kingdom, 2Northumbria University, Newcastle upon Tyne, United Kingdom, 3Royal Victoria Infirmary, Newcastle upon Tyne Hospitals, Newcastle upon Tyne, United Kingdom

Background: Nontuberculous mycobacteria (NTM) are important respiratory pathogens in patients with underlying lung diseases and particularly in patients with cystic fibrosis (CF). For diagnosis, international guidelines recommend culture of sputum that has been decontaminated via chemical treatment e.g. using 2% N-acetyl L-cysteine with 2% sodium hydroxide (NALC-NaOH). RGM medium is a highly selective agar-based culture medium allowing isolation of NTM without decontamination of sputum samples. RGM medium therefore provides a convenient tool to quantitatively assess the impact of various decontamination strategies on the viability of NTM.

Materials/methods: Sputum samples from 41 distinct patients known to be colonized with NTM were subdivided and the aliquots were subjected to six different decontamination strategies followed by quantitative culture for NTM using serial dilutions inoculated onto RGM medium. 38 samples were from patients with CF. Thirty sputum samples contained Mycobacterium abscessus complex (MABSC) and 11 contained Mycobacterium avium complex (MAC). Decontamination strategies included treatment with NALC-NaOH, 4% NaOH, 1% chlorhexidine, N/2 sulfuric acid, 5% oxalic acid and double decontamination with NALC-NaOH followed by 5% oxalic acid. As a control, a further aliquot was treated with sterile saline (0.85%). The sputum samples were also cultured directly with no treatment.

Results: The standard NALC-NaOH treatment resulted in an average reduction in colony count of 85% for MABSC when compared with saline-treated controls. 4% NaOH, which is commonly used in the UK, caused a 98% average reduction in colony count. All treatments that included NaOH resulted in colony counts that were statistically lower than the saline-treated control (P <0.05). Standard treatments using sulfuric or oxalic acids were less deleterious but still resulted in an average reduction in colony count of at least 30%. The viability of MAC was much less affected by most decontamination treatments with the biggest impact caused by 1% chlorhexidine, which caused a 66% reduction in viability (Fig.1).

Conclusions: The viability of MABSC was severely compromised by the standard decontamination regimen recommended by international guidelines. This supports an abundance of recently acquired evidence to show that optimal recovery of MABSC is achieved by culture on selective agar media without decontamination of sputum samples.

Is it safe to use rapid molecular tests for the detection of microorganisms in blood to optimise antimicrobial therapy in septic patients?

Cristhieni Rodrigues*1, Tania Maria Varejao Strabelli1, Rinaldo Focaccia Siciliano1, Rogerio Zeigler1, Ludhmila Hajjar1, Ana Paula Matos Porto1

1Heart Institute, University of São Paulo, São Paulo, Brazil

Background: Sepsis is a healthcare problem worldwide with high mortality rate even in intensive care unit. In the era of antimicrobial resistance [AMR], rapid detection of microorganisms in septic patients associated with antimicrobial stewardship program should be used to avoid inappropriated antimicrobial prescription.

Materials/methods: Prospective randomized study including 200 heart disease adult patients with nosocomial sepsis and septic shock. Outcomes and antimicrobial consumption were measured comparing early optimize antibiotic therapy guided by rapid molecular test results or convencional blood culture.

Results: 25% of patients had positive rapid molecular test (group A) and 21% positive blood culture (group B) to detect microorganisms in blood. Antimicrobial de-escalation was performed after 8 hours in group A and 54 hours in group B (p<0.001). There was a 25% decrease in antimicrobial consumption (measured by DOT-days of therapy /1000 patients-day) comparing groups A and B (p 0.017). Hospital mortality was similar in both groups (42% vs 64% in groups A and B respectively) (p=0.149). We also observed that antimicrobial de-escalation suggested by the stewardship team was easily accepted by the physicians in group A patients (results available after 6 to 8 hours) compared to group B (results after 48 hours).

Conclusions: The use of a rapid molecular test to guide antimicrobial therapy in septic patients allowed for earlier de-escalation with clinical evolution similar to conventional blood culture. This strategy could be used safely in stewardship antimicrobial programmes.

Presenter email address: cristhieni@uol.com.br
Background: Coagulase-negative staphylococci (CoNS) are frequently isolated in clinical specimens and are important reservoirs of resistance genes. The clinically defined Staphylococcus epidermidis-like group include S. epidermidis, S. haemolyticus and others distinguished from S. saprophyticus, S. lugdunensis and animal associated species. Some strains are frequently associate with resistance to anti-staphylococcal agents and the resistance to methicillin/oxacillin mediated by a modified penicillin-binding protein (PBP2a) encoded by the meca gene is a severe concern.

Materials/methods: The study included CoNS species of S. epidermidis-like group, except S. epidermidis, obtained from clinical specimens between March to August 2018 in south of Brazil. The isolates were identified at species level by MALDI-TOF/MS and a PCR were conducted to determine the presence of meca gene. For methicillin/oxacillin resistance screening, the disk-diffusion with cefoxitin disc was done according with EUCAST (version 9.0) recommendations for Staphylococcus spp.. The institutional Ethics committee approved the research procedure (2.649.105).

Results: We tested 22 isolates (16 S. haemolyticus, 4 S. warneri, 1 S. cohnii and 1 S. caprae) and evaluate the results of disk-diffusion screening using the criteria for CoNS others than S. epidermidis and the criteria for S. epidermidis. The screening criteria recommended by EUCAST for CoNS others than S. epidermidis correctly spotted one isolate (4.5%) meca positive but failed in detected eight isolates (36.4%) carrying meca, with sensitivity of 11% (5.8 – 49.3%) and specificity of 100% (71.6 – 100%). When adopting the criteria for S. epidermidis, seven isolates (31.8%) were correctly identified as resistant, two (9.1%) showed high inhibition zones and were incorrectly classified as susceptible and three (13.6%) meca negative meted the criteria of technical uncertainty (ATU), showing sensitivity and specificity of 77.8% (40.1 – 96.1%) and 76.9% (45.9 – 93.8%). Of all CoNS, nine (40.1%) were positive for meca.

Conclusions: The prevalence of meca in CoNS is high and the screening by disk-diffusion is recommend by EUCAST. In our sample, we observed a low sensitivity of screening criteria to CoNS species others than S. epidermidis. But applying the current criteria available for S. epidermidis, including the ATU, to all species of S. epidermidis-like group we observed increased sensitivity with acceptable specificity.

Proof of concept: efficacy of surgical titanium implants coated with linear gentamicin against osteomyelitis in pigs

Mickael Riou1, Aurélien Voisin2, Nathalie Kasal-Hoc1, Céline Barc1, Christelle Rossignol3, Hans Adriaensen4, José Delaval5, Anne-Lyse Lainé6, Sandrine Mélo3, Marie-Pierre Foulc2

1UE-1277 Plateforme d’Infectiologie Expérimentale (PFIE), INRA, Nouzilly, France, 2Rescoll, Pessac, France, 3UE-1282 Infectiologie et Santé publique, INRA - Université de Tours, Nouzilly, France, 4Plateforme Chirurgie et Imagerie pour la Recherche et l’Enseignement, INRA, Nouzilly, France, 5Laboratoire Touraine, Parçay-Meslay, France, 6UMR-0085 Physiologie de la Reproduction et des Comportements, INRA - CNRS - HARAS NATIONAUX - IFCE - Université de Tours, Nouzilly, France

Abstract third-party references: The project was managed and supported by Rescoll, and funded by FUI, INRA and Rescoll.

Background: Implant infections in human surgery are serious clinical conditions that result in high mortality rates. The treatment of these infections almost systematically requires the combination of long-term antibiotic treatment and concomitant surgical treatment, as well as implant replacement. However, standard antibiotic treatment protocols have a low efficacy for this type of infection and the surgical procedure is often complex. These practices represent a high risk to the patient and a significant cost to society. It is necessary to find alternative solutions, such as using a surface treatment on titanium to deliver antibiotics locally only in case of infection. To meet this objective, it is therefore essential to develop an animal model for the surgical placement of titanium implants with bone infection and to measure the antibiotic efficacy of coated implants.

Materials/methods: The objective of this study is therefore to demonstrate the concept of the efficacy of gentamicin-coated surgical implants against S. aureus osteomyelitis in pigs. We have defined two sizes of titanium cylinder implants (4 and 8 mm length by 4 mm diameter). Double and bilateral partial osteotomy surgery of the porcine tibia was performed, followed by local bone infection with S. aureus SAHOS (human bone clinical isolate) at two different concentrations (10^2 CFU and 10^6 CFU). Once the bacteria have been deposited in the bone hole, the 4 mm and/or 8 mm titanium implant with or without coated gentamicin were deposited.

Results: Clinical and bacteriological results from implants with or without gentamicin confirmed local bone infection at both concentrations tested, as early as 7 days post-infection. However, a significant reduction in bacterial load is observed in the presence of gentamicin-coated implants. In both cases, inflammation of the implanted bone area was observed through clinical and medical imaging (MRI) follow-up and confirmed by the increase in cytokines. As with bacteraemia, the results show that the clinical condition of the pigs is better and inflammation is less spread in the presence of gentamicin coated implants.

Conclusions: This porcine model therefore validates the proof of concept on the therapeutic efficacy of biomedical implants coated against acute postoperative osteomyelitis for human use.

Biochemical characterisation of GPC-1, a novel class A carbapenemase from a clinical Pseudomonas aeruginosa isolate

Jennifer Schauer*1, Sören G. Gatermann1, Niels Pfennigwerth1

1Ruhr-University Bochum, Bochum, Germany

Background: The increasing number of multidrug-resistant Gram-negative bacteria constitutes a serious threat to healthcare systems. Strains of P. aeruginosa are already known to exhibit intrinsic and acquired resistance to many antibiotic classes, including β-lactams. Especially carbapenemase producers are of great concern because they are generally able to hydrolyze many β-lactams. Masked by the intrinsic resistance of Pseudomonas aeruginosa, novel carbapenemases with only low sequence identity to known carbapenemases and an unknown substrate spectrum are difficult to detect and therefore pose a serious challenge for carbapenemase detection by routine diagnostic laboratories. Here we describe the biochemical characterization of GPC1, a novel class A carbapenemase found in a clinical P. aeruginosa isolate from Germany.

Materials/methods: The GPC-1 encoding gene was cloned into the pASGIBA103 vector, that promotes expression of Twin-Strep-tag®-fusion-proteins. The thus-obtained recombinant plasmid was expressed heterologously in Escherichia coli TOP10. Cells were lysed by sonication and the crude lysate was prepared for purification by centrifugation and desalting. Purification of the enzyme was performed by a two-step-Fast Protein Liquid Chromatography (FPLC), including affinity chromatography and gel filtration. The catalytic behavior of GPC-1 was analyzed by in vitro hydrolysis assays through photometrical measurement of the absorbance decrease during β-lactam hydrolysis, followed by determination of the kinetic parameters $K_m$ and $k_{cat}$ using the Michaelis Menten equation. The 50 % inhibitory concentration (IC$_{50}$) for clavulanic acid, tazobactam and avibactam were determined using penicillin G as an indicator substrate.

Results: Determination of kinetic parameters of GPC1 showed that the enzyme was able to hydrolyze penicillins, oxyimino-cephalosporins, monobactams and imipenem. For meropenem and ertapenem an absorbance decrease was only observed under unsaturated conditions indicating that GPC1 seems to bind and capture these carbapenems but without hydrolyzing them efficiently. GPC-1 was inhibited most efficiently by avibactam, followed by tazobactam and clavulanic acid.

Conclusions: The biochemical characterization of GPC-1 illustrates that it shows only weak carbapenemase activity. In strains with various resistance mechanisms, the expression of such a weak carbapenemase might be difficult to detect by routine laboratories. This could also increase the risk of inadequate hygiene measures for patients infected or colonized with bacteria expressing those carbapenemases.

Presenter email address: jennifer.schauer@ruhr-uni-bochum.de
Impact of combining vancomycin with piperacillin/tazobactam or with meropenem on vancomycin-induced nephrotoxicity

Razan Tokhi1, Noran Kabli2, Maram Hantool1, Abrar Thabit*1

1King Abdulaziz University, Pharmacy Practice Department, Faculty of Pharmacy, Jeddah, Saudi Arabia

Background: The major adverse effect of vancomycin (VAN) is nephrotoxicity especially in patients administered large doses. VAN is a broad-spectrum antibiotic against Gram-positive cocci and is used empirically with other broad-spectrum antibiotic such as piperacillin/tazobactam (TZP), cepham, or meropenem (MEM). Literature on the incidence of acute kidney injury (AKI) of VAN with MEM is limited. Therefore, this study aimed to evaluate the incidence of AKI in patients receiving VAN with either TZP or MEM.

Materials/methods: A retrospective cohort study of patients who received either VAN-TZP or VAN-MEM for ≥72h. Patients with a baseline serum creatinine (SCr) of ≥1.5 mg/dL were excluded. The primary outcome was the incidence of AKI [increase in SCr by ≥0.3 mg/dL or ≥1.5-time baseline, whichever is greater]. SCr was recorded at baseline and 3-5 days post antibiotics initiation. Secondary outcomes included all-cause mortality, and length of stay.

Results: A total of 164 patients were included, 81 in the VAN-TZP group vs. 83 in the VAN-MEM group. No difference in baseline characteristics was observed between the two groups in terms of age, sex, race, hospital location, Charlson comorbidity index, diabetes, nephrotoxic drugs, and baseline SCr levels. Change in SCr at day 3-5 was not significantly different between the two groups [-9.4 vs. -6.1%; P=0.78]. While the percentage of patients meeting the definition of AKI was higher in the VAN-MEM group, this difference did not meet statistical significance [11.1 vs. 20.5%; P=0.1]. All-cause mortality was higher in the VAN-MEM group [39.8 vs. 23.5%; P=0.03] possibly because this combination was used in more critically ill patients [31.1% of VAN-MEM patients were admitted to the intensive care unit vs. 18.5% of VAN-TZP patients]. Median length of stay did not differ between the groups [20 vs. 22 days; P=0.64].

Conclusions: This study shows that combining MEM with VAN did not offer the benefit of a lower incidence of acute kidney injury compared with a combination with TZP. Therefore, patients with no risk factors for infections resistant to TZP can continue to receive TZP with VAN without risking AKI development. Hence, conserving MEM and reduce the risk of emergence of carbapenem resistance.

Presenter email address: akthabit@kau.edu.sa
Abstract 2200

**Long-term immune response to yellow fever vaccination in HIV-infected and non-infected adults: ANRS EP46 study**

Christine Durier*, Séverine Mercier-Delarue, Nathalie Colin De Verdiere, Vincent Meiffredy, Sophie Matheron, Assia Samri, Martine Resch, Lucie Marchand, Brigitte Autran, Odile Launay, François Simon

**Abstract third-party references:** For the ANRS EP46 Study Group

**Background:** Duration of immune response after yellow fever (YF) vaccination in HIV-infected patients has been questioned. We evaluated the persistence of YF vaccine antibodies in HIV-infected and HIV-uninfected primary vaccine recipients from the NDVAA-ANRS EP46 prospective study up to 5 years post-vaccination.

**Materials/methods:** The long-term study included 30 of 41 YF vaccine-naïve HIV-infected adults under antiretroviral therapy (ART) with CD4 >350/mm3 and HIV-RNA<50 cp/ml for 6 months minimum, and 20 of 30 healthy adults. All received one YFV17D full dose vaccine. Neutralizing antibody responses were measured by a reference 80% Plaque Reduction Neutralization Test (PRNT) and by a West Nile Virus-YFV17D pseudotype neutralization assay.

**Results:** Up to month 60 (M60) post-vaccination, YF neutralizing antibodies remained above the level for protection of 1:10 in 100% of HIV-infected and uninfected vaccinees. PRNT titers declined significantly at M60 vs M12 in both groups [see Table]. PRNT Geometric Mean Titers (GMT) of HIV-infected and non-infected were not statistically different. With the pseudotype assay, median neutralizing activities were 94% [IQR:86-99] and 99% [93-100] at M12, decreased at 80% [54-98] and 94% [84-97] at M36 and 83% [47-97] and 90% [75-97] at M60 in HIV-infected and non-infected respectively. At M60, no significant association was seen with baseline characteristics of HIV-infected patients [age, CD4, CD8, CD4/CD8, CD4 nadir and zenith, duration of ART, duration of HIV infection]. No SAEs related to vaccination were reported.

**Conclusions:** After a single dose of YF vaccine, the persistence of protective antibodies up to 5 years was similar in HIV-infected patients with CD4 counts >350/mm3 and suppressed viral replication and in healthy subjects. The decrease in neutralization titers over time suggests surveillance over a longer period regardless of the HIV status of participants.

Abstract 2202

Exclusive oral post-surgical antibiotherapy is effective for infectious flexor hand tenosynovitis: a study of 127 patients

Clement Dujeux1, Anna Fournier2, Mélanie Malherbe1, François Guérin1, Goulven Rochcongar1, Aurelie Baldolli2, Renaud Verdon2, Jocelyn Michon*2

1Hospital Center University Of Caen Normandie, Orthopaedics department, Caen, France, 2Hospital Center University Of Caen Normandie, Department of Infectious Diseases, Caen, France, *Hospital Center University Of Caen Normandie, Microbiology laboratory, Caen, France

Background: Infectious flexor hand tenosynovitis (IFHT) are frequent conditions with serious consequences in the absence of adequate treatment. Several surgical modalities are possible but antibiotic therapy is not well codified.

Materials/methods: We retrospectively reviewed IFHT managed at Caen University Hospital Center between 01/01/2013 and 01/01/2018. The inclusion criteria were: confirmation of the clinical diagnosis during surgery and a post-antibiotic follow-up of at least 6 months. We evaluated patient’s demographics, type of surgery, antibiotic therapy modalities (molecule, route of administration oral [O] or intra venous [IV] and duration) and the clinical outcome at 6 months.

Results: 127 patients were included. From the classification of Michon we found 62 Stage I, 36 stage II, 1 stage III and 28 unclassified due to missing data. Comorbidities were present in 46.5%, 34.6 % had negative culture due to pre-operative antibiotherapy, the most common bacteria was Staphylococcus (54.2%). The surgery was open-air in 32.3% cases and minimally invasive for 58.3%. All patients received postoperative antibiotic therapy. The most commonly used was Amoxicillin + Clavulanic Acid, it covered 94.5% of the identified organisms.

116 (91.3%) patients were cured of their infection and 11 (8.7%) had a recurrent infection. In multivariate analysis, administration of IV or IV + Oral antibiotic therapy was of no benefit compared to exclusively oral treatment (p = 0.65). Treatment for less than 7 days in comparison with treatment for 7 to 14 days appeared to be associated with a 4.5 times greater risk of failure, although not significant (p = 0.07). We didn’t find any significant difference of outcome according to the duration of antibiotic therapy less than 7 days, 7 to 14 days or more than 14 days (p = 0.14). Diabetes, smoking, surgical technic or immunosuppression were not associated with infectious relapse. The unique factor associated to recurrence was a positive surgical bacteriological sample (p= 0.03).

Conclusions: For stage 1 and 2 IFHT surgical management followed by an exclusive post-operative oral treatment with Amoxicillin + Clavulanic Acid 7 to 14 days seems effective, thus allowing outpatient management. The duration of antibiotic treatment should be better defined by prospective studies.

Abstract 2203

Stx2k-producing Escherichia coli in China
Yanwen Xiong*, Xiangning Bai1, Xi Yang1

1National Institute for Communicable Disease Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China

Background: Shiga toxin (Stx) is the key virulence factor in Shiga toxin-producing Escherichia coli (STEC), which can cause mild diarrhea to fatal hemolytic uremic syndrome (HUS). Stx comprises two toxin types, Stx1 and Stx2. Several Stx1/Stx2 subtypes have been identified, which are variable in sequences, toxicity and host specificity. Here, we report the wide distribution of our newly-identified Stx2k subtype in E. coli strains from diarrheal patients, animals, and raw meats. A comprehensive whole genome sequence (WGS) analysis was performed to characterize the Stx2k strains and to elucidate the evolution of new STEC variant.

Materials/methods: STEC strains from animals, foodstuffs, patients and healthy carriers were collected through our systematic STEC investigation conducted in China. All strains were sequenced by Illumina platform to obtain the draft genomes, and further molecularly characterized by WGS analysis. Stx subtype was confirmed by a phylogeny scheme based on holotoxin amino acid sequences of Stx. The production and cytotoxicity in vitro of Stx was assessed by Vero cell assay. The complete genomes of specific strains were sequenced by PacBio platform. In-depth comparative genomics analysis was performed to assess the genetic variations in relation to pathogenic capacity, and to identify mobile genetic elements (MGE) impacting the molecular evolution of new STEC variants.

Results: Stx2k was widely identified from STEC strains from diarrheal patients, animals and raw meats, with particularly high prevalence in goats-derived strains. Stx2k exhibits diverse cytotoxicity in vitro among strains from different hosts. The Stx2k converting prophages displayed considerable heterogeneity in terms of insertion site, genetic content and structure. Phylogenomic analysis showed that Stx2k strains formed two major phylogenetic clusters closely with strains belonging to STEC, enterotoxigenic E. coli (ETEC), and STEC/ETEC hybrid. Interestingly, one stx2k-containing strain harbored one plasmid-encoded heat-stable enterotoxin stA gene and two identical copies of chromosome-encoded stb gene, which were virulence determinants of another pathotype, ETEC.

Conclusions: Our findings highlight the extraordinary genomic plasticity of E. coli strains. Given the wide distribution of the Stx2k-producing strains in diverse sources and their pathogenic potential, Stx2k should be taken into account in global epidemiological STEC surveillance and clinical diagnosis of STEC infections.

Abstract 2206

**Development of novel inhibitors of metallo-β-lactamases in carbapenem-resistant Gram-negative pathogens**

Victoria Savage*1, Nicola Ooi1, Andrew Wilkinson1, Rebecca Newman1, Victoria Lee1, Kathryn Maskew1, Nathan Chalam-Judge1, David Orr1, Adam Bunt1, Sally Lee1, Derek Lindsay1, Ian Cooper1

1AMR Centre, Alderley Edge, United Kingdom, 2Sygnature Discovery, Macclesfield, United Kingdom

**Background:** Metallo-β-lactamases (MBLs) are rapidly becoming a major mechanism to carbapenem resistance in Gram-negative bacteria. These enzymes hydrolyse the majority of β-lactam antibiotics (including carbapenems) and the organisms carrying them are frequently multidrug resistant, owing to co-carriage of multiple resistance determinants on transferable genetic elements. Indeed, they have been categorized as a critical threat to human health according to the World Health Organisation. MBL-positive pathogens represent an urgent medical need as there is currently no effective MBL inhibitor (MBLI), meaning treatment options are often few to none. The AMR Centre has identified and optimised an MBLI (AMRC-835) for use with β-lactam antibiotics in MBL-positive infections.

**Materials/methods:** Susceptibility testing and time of kill analysis was performed according to CLSI guidelines. Enzyme assays were performed using nitrocefin and recombinant NDM-1, VIM-2 and IMP-1. Off-target activity was evaluated in a human receptor and enzyme panel (SafetyScreen44, Cerep) and a panel of Matrix metallopeptidases (MMPs). Cytotoxicity, cardiotoxicity and genotoxicity were investigated using standard methods. Resistance frequencies and serial passage were also performed to standard methods. *In vivo* efficacy was assessed in a mouse thigh infection model using *E. coli* (NDM-1). *In vivo* safety was determined in a rat 3-day repeat-dose toxicology study.

**Results:** MBLIs demonstrated broad spectrum activity versus NDM, IMP and VIM enzymes; no inhibition of human matrix metallopeptidases (MMPs) was observed. A representative compound from the series restored meropenem activity in Enterobacterales and *Acinetobacter baumannii*; Enterobacterales (n=115) MIC\textsubscript{90} = 0.12 µg/mL (from 128 µg/mL) and *A. baumannii* (n=6) MIC\textsubscript{90} = 2 µg/mL (from >128 µg/mL). The resistance profile of the series was equivalent to meropenem alone. Addition of MBLI to meropenem restored efficacy in time of kill assays and a mouse thigh infection model (*E. coli* NDM). An excellent safety profile was established *in vitro* [no flags identified in SafetyScreen44, cardiotoxicity or genotoxicity assays] and the lead MBLI (AMRC-835) was safe in a 3-day repeat-dose rat toxicology study up to 900 mg/kg.

**Conclusions:** Evaluation of this series has led to nomination of AMRC-835 as a preclinical candidate for development towards a novel combination therapy for the treatment of MBL-positive Gram-negative infections.

**Necrotising otitis externa: a retrospective cohort study and treatment protocol proposal**

James Frost*1, Anda Samson2

1Hull York Medical School (HYMS), Hull, United Kingdom, 2Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom

**Background:** In England, the incidence of Necrotising otitis externa (NOE) has increased 6.3 times increase over 14 years. The most common pathogen is *Pseudomonas Aeruginosa*, and patients are often diabetic and frail. No randomized controlled trials are available in the current literature, and case series include 5-88 patients. Hence no consensus on the most effective treatment protocol for NOE has been agreed. We aim to produce local NOE treatment protocol using a a retrospective cohort study in our hospital.

**Materials/methods:** A retrospective cohort study on the treatment of patients with NOE in Hull University Hospitals Trust was done according the STROBE criteria. Case notes coded for NOE from December 2013 to December 2018 were reviewed. There were no exclusion criteria. Relevant data on demographics, risk factors, diagnosis, microbiology results, morbidity and mortality and follow-up were extracted from the paper notes and electronic hospital systems.

**Results:** Twenty-nine patients aged 47-94 years were included; Eighteen patients (62%) had diabetes or were immunosuppressed. *Pseudomonas aeruginosa* was the most commonly identified micro-organism (64%); other organisms included MSSA, and *E.Coli; Aspergillus Niger and Candida spp* were only encountered in polymicrobial infections. In 12.5% no growth was seen possibly reflecting prior topical antibiotic use. Ceftazidime or meropenem monotherapy was mostly used, with ciprofloxacin as an oral step-down option. There were no relapses, but one patient died directly due to NOE related sepsis. Daily microsuction of the ear was performed in 82.8% of patients and hyperbaric oxygen treatment was used in 25%. Treatment lasted for an average of 6 weeks, which is in keeping with other treatment protocols for osteomyelitis. Based on our findings we proposed a local treatment protocol as described in figure 1.

**Conclusions:** To the best of our knowledge, this study is the second UK based large case series on the management of NOE. Extrapolating these results, we proposed a practical management protocol for necrotizing otitis externa in the UK focusing on identification of the causal pathogen, culture tailored antibiotics and supportive measures. This protocol will need further validation.
Figure 1 – Suggested treatment algorithm for Necrotising Otitis Externa based on a case series of 29 patients in Hull and East Yorkshire Hospitals. Side boxes – optimisation of patient outcomes

Suspicion of Necrotising Otitis Externa (NOE)

Ear and Pus Swab for culture and sensitivity analysis (MC/S)

Empirical IV Ceftazidime monotherapy antibiotics

Pre-diagnosis

CT Scan via radiologist for confirmation

Modify IV antimicrobials according to MC/S result

Negative culture from MC

Punch Biopsy

Hickman Line/PICC Line

Modify for combinational therapy or antifungals

Post Diagnosis

Absence of presenting symptoms and signs of infection

Post discharge Oral antibiotics, typically Ciprofloxacin for at least 4/52

Follow up via outpatients

Post Discharge

Clinical Resolution of NOE

- Control BMs
- Microsuction daily
- Topical drops antibiotics
- Correction of immunosuppression
- Analgesia
- CRP

- Surgery - debridement, polypectomy
- Hyperbaric oxygen Chamber
- CRP

Relation of risk factors and mortality in carbapenem-resistant *Klebsiella pneumoniae* ST11 bloodstream infections

Tingting Xiao*, Xiao Yonghong†

†Zhejiang University, Zhejiang, China

**Background:** Carbapenem-resistant *Klebsiella pneumoniae* (CRKP) is rapidly emerging as a life-threatening nosocomial infection. It is valuable to identify the clinical characteristics, particularly the outcomes and antibiotic therapy for CRKP infections.

**Materials/methods:** A retrospective, comparative analysis of data from patients treated for CRKP bloodstream infections (BSIs) at a single tertiary teaching hospital during 18 months. All statistical analyses were executed by using the SPSS version 23.0.

**Results:** Data from 90 patients with CRKP BSI were included, 84.4% (N=76) with ST11. Among ST-11 CRKP, 82.9% (N=63) were K64. There were no significant differences in 30-day mortality among patients with ST11-CRKP and nonST11-CRKP (56.6% versus 35.7%, P=0.087). Univariate analysis showed that hemodialysis within 30 days prior to BSI, lower total protein, lower platelet, high Pitt score, prior exposure to corticosteroid, and inappropriate empirical treatment after BSI, tigecycline therapy after BSI were associated with mortality. Prior exposure to corticosteroid (OR=7.300, P=0.027) and lower total protein (OR=0.909, P=0.002) were identified as independent risk factors for the 30-day mortality of CRKP BSI patients.

**Conclusions:** There was not significantly different in mortality of patients with BSI caused by ST11-CRKP or non-ST11 CRKP during the study period. Exposure to corticosteroid and lower total protein were strong risk factors for mortality of CRKP-BSI.

**Figure 1.** Kaplan–Meier survival curves for patients with Non-ST11 and ST11 carbapenem-resistant *Klebsiella pneumoniae* (CRKP) bloodstream infection.

Abstract 2211

Monitoring of difficult-to-treat tuberculosis patients in Ghana identifies additional pre-XDR and XDR cases

Isaac Darko Otchere*1, Portia Morgan1, Prince Asare1, Adwoa Wiredu1, Sebastien Gagneux2, Stephen Osei-Wusu1, Dorothy Yeboah-Manu1

1Noguchi Memorial Institute of Medical Research, University of Ghana, Accra, Ghana, 2Swiss Tropical And Public Health Institute, University of Basel, Basel, Switzerland

Abstract third-party references: The West African Network for TB, AIDS, Malaria (WANETAM), National Tuberculosis Control Program, Ghana, Swiss-African Research Cooperation (SARECO)

Background: Emergence of drug resistant TB (DR-TB) threatens to make TB untreatable. Early identification of the causation of TB and its drug susceptibility profile are essential for appropriate treatment regimen. We report here preliminary findings of our monitoring of difficult to treat TB-cases (DTT-TB) in Ghana.

Materials/methods: Sputum samples obtained from DTT-TB (i.e treatment failures, relapsed, retreatment and known drug resistant TB) from health facilities across Ghana were processed for rapid diagnosis using the Genotype MTBDRplus, Genotype MTBDRsl, direct smear-microscopy and culture.

Results: A total of 244 (73.7%) out of the 331 sputum samples processed gave interpretable bands out which 54 (22.1%), 48 (19.7%) and 78 (31.9%) were INH-mono-resistant (INHr), RIF-mono-resistant (RIFr) and MDR respectively. Two (1.3%) of the MDR samples were resistant to second line fluoroquinolones (FQs) and aminoglycosides (AMGs) hence termed XDR-TB whereas 16 (20.5%) were resistant to either drugs and termed pre-XDR-TB. More so, 8 samples (6 RIFr and 2 INHr) were additionally resistant to at least one of the second line AMGs or FQs hence termed poly-drug-resistant samples. Eighty-two (62.1%) of INH-resistant samples had katG-mutations where as 34 (25.7%) had inhA-pro-mutations. The remaining 16 (12.1%) had mutations at both loci. Out of the 26 samples with resistance to at least one second-line drug, 16 (61.5%) and 3 (11.5%) were resistant to FQs (gyrA mutations) and AMGs (rrs mutations) respectively whereas 7 (26.9%) were resistant to both. With the exception of the 2 XDR samples and 3 RIF-poly-resistant samples, no sample had eis mutations.

Conclusions: Detection of additional XDR and pre-XDR TB cases in Ghana following the first report from our lab last year calls for intensified monitoring of TB patients to ensure compliance

Abstract 2212

**Efficacy of memory B lymphocytes in experimental model of pneumonia caused by Pseudomonas aeruginosa**

Tania Cebreiro Cangueiro¹,², Gema Labrador Herrera³, Marta Claudia Carretero Ledesma¹, Younes Smani¹, Jeronimo Pachon-Diaz¹, María Eugenia Pachon-Ibáñez¹

¹Institute of Biomedicine of Seville (IBiS), University of Seville/CSIC/University Hospital Virgen del Rocio, Sevilla, Spain

**Background:** There is an urgent need for new alternatives to treat infections multidrug-resistant (MDR) *P. aeruginosa* infections. Immunotherapy as adjuvant to antibiotics might be a good option by increasing the host innate immunity. In this study we evaluate the efficacy of memory B lymphocytes in the treatment of a pneumonia murine model by clinical strains of *P. aeruginosa*.

**Materials/methods:** Two MDR clinical strains of *P. aeruginosa* (Pa147, colistin-susceptible and PaM1, colistin-resistant) were used. C57BL/6J male mice, 20g were inoculated with the minimum lethal dose calculated for each strain. Antimicrobial treatment was initiated 4h post-infection and lasted 72 hours, while memory B lymphocytes therapy was a single dose 30 minutes after infection. Treatments groups were: a) controls (infected, untreated); b) memory B lymphocytes (2x10⁶ B lymphocytes, intravenously) c) colistin; 20mg/kg/8h/intraperitoneally and d) Ceftazidime; 100mg/kg/12h/intraperitoneally. After death or sacrifice, bacterial counting in lung and blood was performed, and percentages of bacteremia and survival were analyzed. The two-tailed Fisher’s test, analysis of variance (ANOVA), and the Dunnet and Tukey *post hoc* tests were used. *P*<0.05 was considered significant. The SPSS v22.0 was used (SPSS Inc).

**Results:** Efficacy results of antimicrobials and B lymphocytes.

CTL: Control, CMS: Colistin methate sodium, CAZ: Ceftazidime. * P≤0.05 compared to CTL, ^ P<0.05 compared to CMS and ^ P<0.05 compared to memory B lymphocytes.

**Conclusions:**

1) Memory B lymphocytes reduced bacterial concentration and improved survival and bacteremia compared to controls and colistin in a murine model by a MDR *P. aeruginosa* colistin-susceptible strain.

2) Immunotherapy as adjuvants to antimicrobials might be an option for these infections, nevertheless further studies must be done.

Abstract 2215

A novel spectrophotometric assay for rapid detection and differentiation of KPC-, MBL- and OXA-48-producing Enterobacteriaceae

Dimitris Tsakogiannis1, Georgia Vrioni1*, Dionysia Marinou1, Maria Mavrouli1, Athanassios Tsakris1, John Routsias1

1National and Kapodestrian University of Athens, Medical School, Department of Microbiology, Athens, Greece

Background: The augmented prevalence of carbapenemase-producing enterobacteriaceae (CPE) in hospitals and healthcare facilities has made crucial the development of more rapid tests for the specific detection of multidrug-resistant pathogens. The present study focused on the development of a simple methodology that is based on the measurement of hydrolytic activity of β-lactamases through UV-visible spectrophotometry.

Materials/methods: In the present analysis a total of 86 CPE clinical isolates were tested, while CPE isolates were characterized as KPC, VIM, NDM and OXA-48 producers through phenotypic disc testing and PCR assay, as well. Moreover, detailed susceptibility test was conducted in all tested clinical isolates. The hydrolysis of imipenem was measured through spectrophotometry in bacterial extracts. The initial absorbance of imipenem was measured immediately after the insertion of the antibiotic in bacterial extracts. Phenylboronic acid (PBA) and EDTA were also incorporated in the newly developed spectrophotometric assay in order to identify the different groups of carbapenemase producers.

Results: The spectrophotometric assay enables the sufficient differentiation of CPE and non CPE strains in 45 minutes of incubation (t test, P < 0.0001). Moreover, the presence of PBA and EDTA in the reaction mixtures inhibited the hydrolytic capacity of KPC and MBLs, respectively [P<0.001], while OXA-48 producers were not affected in the presence of the respective inhibitors. The outcomes of spectrophotometric assay were compared with that of phenotypic disc test and PCR [gold standard] and it was suggested that the newly developed assay demonstrates 100% sensitivity and specificity in detecting KPC, MBLs and OXA-48 producers.

Conclusions: In conclusion, the newly established spectrophotometric methodology can be considered as a highly sensitive and specific diagnostic tool that offers healthcare providers in short time considerable information concerning the proper antimicrobial therapy.

Abstract 2220

**Effective antimicrobial combination testing: linking rapid microcalorimetry screening to in vivo efficacy**
Kasper N. Kragh*1,2, Desirèe Gijón3, Ainhize Maruri1, Alberto Antonelli4, Marco Coppi4, Mette Kolpen1, Stephanie Crone1, Chaitanya Tellapragada1, Badrul Hasan1, Corné De Vogel6, Willem J.B. Van Wamel6, Annelies Verbon1, Christian Giske5,7, Gian M. Rossolini4,8, Rafael Canton Moreno3, Niels Frimodt-Moller1

1Rigshospitalet, Department of Clinical Microbiology, København, Denmark, 2Copenhagen University, Department of Immunology and Microbiology, Kbh, Denmark, 3Hospital Ramón y Cajal, Departamento de Microbiología y Parasitología, Madrid, Spain, 4University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy, 5Karolinska Institute, Department of Laboratory Medicine, Stockholm, Sweden, 6Erasmus MC, Department of Medical Microbiology and Infectious Diseases, Rotterdam, Netherlands, 7Karolinska University Hospital, Clinical microbiology, Stockholm, Sweden, 8Careggi University Hospital, Clinical Microbiology and Virology Unit, Firenze, Italy

**Background:** The emergence of antibiotic resistant bacterial strains worldwide calls for an effective exploitation of existing antibiotics. A possible approach is combination of antibiotics with different modes of action, which can synergize and allow for successful treatment. This approach must involve rapid testing to ensure effective treatment at the initial stages of serious infections.

Here we present a study of the use of a microcalorimetry-screening platform for protagonistic combination treatment, against clinical multi-drug-resistant (MDR) strains of *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Acinetobacter baumannii*, and the verification in a murine in vivo model.

**Materials/methods:** 98 resistant clinical isolates were screened for protagonistic effectiveness of meropenem in combination with either colistin, rifampicin or amikacin, compared to single drug treatment, in a calScreener micro calorimeter based on metabolic activity.

One *E. coli*, 4 *K. pneumoniae*, 2 *P. aeruginosa* and 3 *A. baumannii* strains expressing either antagonistic or protagonistic effect of combination treatment were chosen and further tested in a murine peritonitis/sepsis model. MNRI mice where inoculated intraperitoneally with approx. 10E7 CFU. After 1-hour mice were treated with either saline, drug X, drug Y or both antibiotics. After 4 hours of treatment mice where sacrificed and the quantity of bacteria determined by CFU count in both blood and peritoneal fluid.

**Results:** Several (8) strains exhibited drastically reduction in MICs for drugs when used in combination, with fractional inhibitory concentration index’s (FICI) <1. Together with 5 strains with increased MIC in combination FICI >2 these were tested in vivo. There was a significant negative correlation (P = 0.0296) between FICI-value found in the microcalorimetry-screening and log-reduction in peritoneal fluid from mice treated with the combination treatment compared to the best mono-drug treatment, indicating that microcalorimetry could effectively predict the possible antimicrobial synergy in vivo.

**Conclusions:** These data support the ability of the calScreener micro calorimeter to predict protagonistic or synergistic effect of combinations of antibiotics for the treatment of MDR infections and therefore be used as a viable tool for screening for new treatment regimen.

**Fractional inhibitory concentration index**

**Peritoneal fluid**

\[ R^2 = 0.47, P = 0.0296 \]

**Blood**

\[ R^2 = 0.35, P = 0.0702 \]

**Log-reduction of combination treatment better than best mono-treatment**

Abstract 2221

Microbiome analysis of samples from patients with idiopathic pulmonary fibrosis in the A Coruña University Hospital, Spain: a pilot study

Kelly Conde*,1, Juan A. Vallejo1, Laura Alvarez-Fraga1, Soraya Rumbo-Feal1, Bruno Kotska Rodiño-Janeiro1, Germán Bou Arevalo1, Carmen Montero Martínez2, Iria Vidal García1, Margarita Poza Dominguez1

1Microbiology group, Hospital Universitario A Coruña (HUAC), Instituto de Investigación Biomédica de A Coruña (INIBIC) - Universidade da Coruña (UDC), A Coruña, Spain, 2Pneumology, Hospital Universitario A Coruña (HUAC), A Coruña, Spain

Background: Idiopathic pulmonary fibrosis (IPF) is a chronic lung disease with an unknown etiology which causes progressive loss of pulmonary function showing high mortality. Previous works linked the presence of Streptococcus, Staphylococcus, Haemophilus, Neisseria and Veillonella in the lungs with the IPF. The aims of this work were: (i) to perform a metagenomic analysis of samples from both the oropharyngeal cavity and lungs of IPF patients, (ii) to know if the lung colonization could be due to microaspirations from the oropharyngeal cavity harboring the infectious agents.

Materials/methods: Oropharyngeal samples, obtained by scraping (OS), and lung samples, obtained from bronchoalveolar lavage (BAL), from IPF patients of the Hospital of A Coruña (HUAC, Spain), were collected. After an enzymatic treatment, samples were subjected to DNA extraction. DNA was used for the PCR-amplification of a hypervariable region of the bacterial 16S rRNA gene. PCR products were used for metabarcoding libraries preparation and sequencing was performed using a MiSeq equipment, following Illumina procedures. Bioinformatic analysis were done using QIIME 2. The taxonomic assignment was performed by querying the representative sequence variants against the SILVA reference database.

Results: Streptococcus [6-36% BAL, 10-79% OS], Veillonella [4-8% BAL, 0.1-16% OS], Haemophilus [3.8-4.6% BAL, 0-4.6% OS] and Neisseria [1.9-17% BAL, 21-27% OS] genus were found both in BAL and in OS samples, whereas Staphylococcus was not present in any sample. A significant abundance of other bacteria such as Fusobacterium, Porphyromonas, Prevotella, Granulicatella, Rothia, Gemella, Orobacterium and Parvimonas were found in both the oropharyngeal and the broncoalveolar regions.

Conclusions: The great abundance of bacteria previously associated with IPF, found in lungs and in the oropharyngeal region of IPF patients, suggested that these microorganisms living on the oral and the pharyngeal cavities could be recruited through microaspirations, causing secondary lung colonization and, consequently, disturbing the internal pulmonary environment leading to IPF. Other bacteria, some of them being oral inhabitants previously described as important infectious agents, such as Fusobacterium or Porphyromonas, were also detected in both BAL and OS samples. We suggest that these bacteria could be involved in IPF development, although major studies are needed to confirm it.

Abstract 2224

Increased carriage of *Streptococcus pneumoniae* serotype 19A three years after a PCV13 to PCV10 vaccine switch in Belgian children

Liesbet Van Heirstraeten¹, Ine Wouters², Stefanie Desmet³, Christine Lammens¹, Jan Verhaegen¹, Herman Goossens¹, Pierre Van Bamme⁴, Philippe Beutels⁴, Heidi Theeten², Surbhi Malhotra-Kumar⁴

¹University of Antwerp, Laboratory of Medical Microbiology, Vaccine and Infectious Disease Institute, Wilrijk, Belgium, ²University of Antwerp, Centre for the Evaluation of Vaccination, Vaccine and Infectious Disease Institute, Wilrijk, Belgium, ³University Hospitals Leuven, Reference Centre for Pneumococci, Leuven, Belgium, ⁴University of Antwerp, Centre for Health Economics Research and Modelling Infectious Diseases, Wilrijk, Belgium

**Background:** The predominantly "2+1" Belgian infant pneumococcal conjugate vaccine (PCV) programme changed from PCV13 to PCV10 in 2015-2016. Nasopharyngeal carriage of PCV13 pneumococcal serotypes (STs) was evaluated by real-time PCR in children (6-30 months) attending day-care centres (DCC) or seeking care for acute otitis media (AOM) over a three year period between March 2016 and April 2018.

**Materials/methods:** Nasopharyngeal swab samples were obtained from 2615 DCC and 366 AOM children in Belgium, stored in STGG medium at -80°C and analysed by real-time PCR targeting *lytA*. All *lytA*-positive samples were screened by pooled, singleplex real-time PCRs for presence of PCV13 STs. For serogroup 6, analysis of the *wciP* and *wciN* gene was carried out by three real-time PCRs targeting, respectively, the single nucleotide polymorphism at codon 195 (Ser for ST6A/6C; Asn for ST6B/6D) and the *wciN* gene which is 200 bp shorter (*wciNβ*) for ST6C/6D. Pearson's Chi square test was used for statistical analysis.

**Results:** Total pneumococcal carriage remained at a high and stable level during the three year study period, ranging between 75.7% and 80.0% in DCC and 77.9% and 82.1% in AOM. Carriage of PCV13 STs among *lytA*-positive samples (n=2329) increased from 4.6% to 10.4% in DCC (P<0.001) and from 6.3% to 9.8% in AOM. This increase could be attributed to the increase in PCV13-non-PCV10 STs, which was in turn almost completely due to the rise in carriage of ST19A from 0.5% to 8.0% in DCC (P<0.001) and 0.0% to 5.5% in AOM. Meanwhile, prevalence of PCV10 STs decreased from 3.3% to 1.7% in DCC and 6.3% to 2.5% in AOM, the most prevalent among PCV10 STs was 19F. Finally, increased prevalence of ST6C was noted in the third year for both DCC and AOM, respectively from 1.3% to 6.1% (P<0.001) and 3.2% to 8.0%. Even though ST6C is not part of PCV13, it has been shown that cross-protection might occur based on its close relation to ST6A.

**Conclusions:** Following a switch in the PCV programme from PCV13 to PCV10, we have shown a rise of ST19A and ST6C among pneumococcal carriage in children.

Impact of antibiotic stewardship programme in an intensive care unit in Brazil

Wania Freitas*1, Maria Silvana Alves2, Simone Nouer3

1Hospital Universitário Clementino Fraga Filho, Unidade Cardio-intensiva/UFRJ, Rio de Janeiro, Brazil, 2Universidade Federal de Juiz de Fora, Departamento de Ciências Farmacêuticas/Faculdade de Farmácia, Juiz de Fora, Brazil, 3Hospital Universitário Clementino Fraga Filho, Programa de Pós graduação em Doenças Infecto-parasitárias/UFRJ, Rio de Janeiro, Brazil

Background: In an intensive care unit (ICU), the multiple drug-resistant (MDR) pathogens present challenges for patients’ survival. The antimicrobial stewardship programs (ASP) aim to improve and measure antibiotic use, but also to decrease the MDR’s incidences. With this context in mind, the present study analyzed the impact of ASP at the MDR’s incidence and global mortality in an Intensive Care Unit in Brazil.

Materials/methods: Data from 4 ICUs (68 beds) from a private hospital in Rio de Janeiro city, Brazil, were analyzed. Data from the first period (May 2015 to May 2017) and from the second period (June 2017 to June 2019) were retrospectively and prospectively collected, in this order. Since June 2017, the ASP group focused activities on infection control and daily antimicrobial prescription audits. Data of antimicrobial consumption were obtained from the hospital pharmacy and expressed as defined daily doses (DDD) per patients-days; MDRs were expressed as density of incidence (DI) for carbapenem-resistant Enterobacteriaceae (CRE) and carbapenem-resistant Pseudomonas (CRP). Global mortality at the ICU was also evaluated.

Results: 3,074 and 3,733 patients were hospitalized and reviewed at 1st and 2nd periods, respectively. The consumption of meropenem decreased between the two periods from 48.58 [95% CI 9.63 – 9.80] to 17.32 DDD per pts-days [95% CI 3.41 – 3.52]. The density of incidence of CRE decreased through the study period from 6.45 [95% CI 5.74 – 7.21] to 4.56 cases per 1,000 pts-days [95% CI 3.96 – 5.22]. The density of incidence of CRP also decreased from 5.24 to 3.09 cases per 1,000 pts-days [95% CI 4.61 – 5.93]; [95% CI 2.60 – 3.64], respectively. The mortality rate decreased during the study period. In the 1st period was 30.03 per 1,000 pts-days [95% CI 2.85 – 3.16] and in the 2nd period was 22.45 [95% CI 2.11 – 2.40]; the rate ratio was 1.34 [95% CI 1.23 – 1.45].

Conclusions: Despite all the difficulties in implementation, ASP in the ICU setting resulted in the decrease of antimicrobial consumption, MDR incidence and mortality.

Efficacy of immunoglobulin enriched in IgM, alone and in combination, in experimental model of pneumonia caused by Pseudomonas aeruginosa

Tania Cebrero Cangueiro, Gema Labrador Herrera, Marta Claudia Carretero Ledesma, Younes Smani, Jeronimo Pachon-Diaz, María Eugenia Pachon-Ibáñez

1Institute of Biomedicine of Seville (IBiS), University of Seville/CSIC/University Hospital Virgen del Rocio, Sevilla, Spain

Background: New therapeutic alternatives for the treatment of multidrug-resistant (MDR) P. aeruginosa infections. The aim of this study was to evaluate the efficacy of immunoglobulin enriched in IgM [IVIG-IgM], as adjuvant to antimicrobials in a pneumonia murine model by clinical MDR P. aeruginosa strains.

Materials/methods: Two clinical MDR P. aeruginosa strains were used, Pa147, colistin-susceptible and PaM1, colistin-resistant. C57BL/6J mice were inoculated intratracheally with the minimum lethal doses of each strain. Antimicrobial therapy was initiated 4h post-infection, while an only dose of IVIG was given 30 minutes post-infection. Therapy groups were: a) controls (infected, untreated); b) IVIG-IgM, 430mg/kg/intravenously; c) colistin, 20mg/kg/8h/72h/intraperitoneally; d) Ceftazidime, 100mg/kg/12h/72h/intraperitoneally; e) IVIG-IgM+CMS and d) IVIG-IgM+CAZ. After death or sacrifice, bacterial counts in lung and blood, and bacteremia and mortality percentages were analyzed. The two-tailed Fisher’s, ANOVA, and the Dunnet and Tukey post hoc tests were used. P<0.05 was considered significant. The SPSS v22.0 was used.

Results: Efficacy results of immunoglobulin (IVIG-IgM) enriched in IgM and antimicrobials. Controls animals and IVIG-IgM treated group had high bacterial concentrations and 100% bacteremia and mortality with both strains.

Conclusions: 1. IVIG-IgM in combination with colistin and ceftazidime reduced bacterial concentration and improved bacteremia and survival in a pneumonia model by MDR P. aeruginosa strains. 2. IVIG-IgM as adjuvants to antimicrobials might be a good option to treat these kind of infections, further studies are necessary.

Abstract 2227

**Chlamydia psittaci /C. abortus detection in respiratory samples (England and Wales, 2012-2018)**

Sanaa Mayet*, Jessica Day¹, Lalita Vaghji¹, Alice Peace¹, Derren Ready¹, Victoria Chalker¹, Meera Chand¹, Baharak Afshar²

¹Public Health England, London, United Kingdom

**Background:** Human psittacosis is caused by *Chlamydia psittaci* from inhalation of urine/faeces from infected birds via occupational or recreational exposure in the home or workplace. Infection presents as a non-specific flu-like illness or community-acquired pneumonia (CAP). Psittacosis is not often tested for in cases of CAP. The proportion of CAP caused by *C. psittaci* remains unclear with 1% attributed by meta-analysis¹. *Chlamydia abortus* infection is associated with human contact and inhalation of infected material from livestock such as foetal loss in sheep, cattle and goats.

**Materials/methods:** Respiratory specimens referred to RVPBRU PHE from 2012-2018 by laboratories from England and Wales for psittacosis investigations were tested using a *C. psittaci*/abortus qPCR assay. However, this assay is not able to distinguish between the two species.

**Results:** A total of 59 respiratory specimens were received between August 2012 and October 2018, from patients ranging in age from 8-80 years. 29 specimens (49.2%) were from males. *C. psittaci /abortus* was detected in 9/59 (15.2%) specimens. Positive specimen types included bronchoalveolar lavage; BAL [5], sputum [2], throat swab [1] and one nucleic acid extract [sample type unspecified]. Referral documentation from positive cases indicated three had recent exposure to birds, two of these regularly handled parrots and one case worked in a wildlife centre, with no reference to sheep, cattle or goat exposure. Seven of the cases required intensive care/high dependency with severe respiratory signs, with two requiring extracorporeal membrane oxygenation.

**Conclusions:** Of the samples tested, 15.2% had detectable *C. psittaci /abortus* DNA. The increased use of the qPCR assay could support detection of further cases. Psittacosis is not a common cause of CAP, however in patients with relevant animal exposures, such as those with exposure to avian species, faecal matter, occupational or recreational exposure, it is an important differential diagnosis. The cases detected herein are presumed to represent the more severe spectrum of disease, stimulating clinical suspicion of *C. psittaci /abortus* infection with subsequent specimen collection and testing.

**Abstract 2232**

**In vitro virulence of Staphylococcus schweitzeri**

Almut Grossmann¹, Neele Froböse¹, Alexander Mellmann¹ ², Silke Niemann¹, Frieder Schaumburg*¹

¹University Hospital Münster, Institute of Medical Microbiology, Münster, Germany, ²University Hospital Münster, Institute for Hygiene, Münster, Germany

**Background:** Although *Staphylococcus schweitzeri* is part of the *Staphylococcus aureus* complex, it is not considered a human pathogen. The aim of this work was to assess the virulence of *S. schweitzeri*.

**Materials/methods:** Whole genome sequencing was done to screen for virulence factors and to assess the population structure of *S. schweitzeri* (n=58) from Gabon, DR Congo, Nigeria and Côte d’Ivoire. The invasion, induction of cell death, cytotoxicity, phagosomal escape, coagulase activity and host cell activation of *S. schweitzeri* was compared with *S. aureus* comparator isolates representing the most common clonal complexes (CC) in Africa (CC15, CC121, CC152) using different host cells (Vero, A549). A collection of clinical isolates from Gabon provisionally identified as *S. aureus* (n=159) were screened for *S. schweitzeri*.

**Results:** *S. schweitzeri* were grouped into five geographical clusters and isolates from humans were found in two different clades within the Gabonese cluster. The comparison of *S. schweitzeri* vs. *S. aureus* comparator isolates showed a similar host cell invasion (0.9 vs. 1.2 CFU/ml), host cell activation (4.1 vs. 1.7 normalized fold expression of CCL5 and 7.3 vs. 9.9 normalized fold expression of IL8) and intracellular cytotoxicity (31.5% vs. 25%). The extracellular pathogenicity (52.9% vs. 28.8%) was higher for *S. schweitzeri* than for *S. aureus*. All tested *S. schweitzeri* were able to escape from phagosomes. *S. schweitzeri* was not detected in clinical samples.

**Conclusions:** *S. schweitzeri* is as virulent as *S. aureus* in the applied in-vitro assays. Its transmission to humans was demonstrated on two occasion but clinical infections were not detected.

Background: Staphylococcus aureus bloodstream infection (SAB) is a common, life-threatening infection. Several factors associated with poor clinical outcome have been previously identified. However, large studies examining mortality and long-term complications in patients under immunosuppressive agents are lacking.

Materials/methods: Data from two prospective, multicentre cohort studies (INSTINCT and ISAC) conducted in 20 tertiary care hospitals in 6 countries (Germany, Korea, Spain, Taiwan, United Kingdom, USA) between 2006 and 2015 were analysed. Patients taking immunosuppressive agents (defined as >40mg/day prednisolone-equivalent, calcineurin or mTOR inhibitors, MMF, cyclophosphamide, high dose DNA biosynthesis inhibitors and newer biological agents) were identified. A 1:2 propensity score matched analysis was performed to adjust for baseline characteristics of patients. Overall survival and time to SAB-related late-complications (SAB relapse, infective endocarditis, osteomyelitis or other deep-seated manifestations) were analysed by Cox regression models, properly adjusting for competing risks.

Results: Of 3,191 analysed patients, 174 were under immunosuppressive treatment according to our definitions. 173 were successfully matched to 344 non-immunosuppressed patients. Median age of 517 included patients was 58 years and 345 (67 %) were male. After propensity score matching, baseline characteristics were well balanced. In the Cox regression analysis we observed no significant difference in survival between the two groups [death during follow-up: 27.9% non-immunosuppressed vs. 29.5% in immunosuppressed patients, hazard ratio 1.02 [0.70; 1.48]]. However, a trend towards higher survival within the first 30 days after SAB onset among immunosuppressed patients was noticed [Fig. 1]. Competing risk analysis showed a cause-specific hazard (CSH) of 3.95 [1.21; 12.82] for SAB-related late-complications in patients under immunosuppressive agents.

Conclusions: While immunosuppression was not associated with an overall higher mortality during follow-up, we observed lower mortality rates early in the course of SAB. Conversely, patients under immunosuppressive agents were more likely to develop SAB-related late-complications. Immunosuppressive agents might prevent hyperinflammation early in the course of (severe) SAB cases (and are therefore associated with a transiently lower mortality), but may also lead to inefficient pathogen clearance and relapsing or disseminated disease.

Clinical features of acute Q fever in Réunion Island: a retrospective cohort study

Alexandra Aubin1, Carole Eldin2*, Eric Braunberger3, Julien Jaubert1, Yatrika Koumar4, Marie-Pierre Moiton3, Patrice Poubey4, Nael Zemali1, Patrick Gerardin5, Antoine Bertolotti5

1CHU La Réunion, Saint-Pierre, Reunion, 2IHU Méditerranée infection, Marseille, France, 3CHU La Réunion, Saint-Denis, Reunion, 4CHU La Réunion, Saint-Pierre, Reunion, 5INSERM CIC1410/CHU La Réunion, Saint-Pierre, Reunion

Background: Q fever is an underreported and underdiagnosed zoonotic disease due to Coxiella burnetii, an intracellular bacterium. In Reunion Island, a French department under the tropics, which has known a rapid epidemiologic transition, zoonoses are believed to be more common than in temperate regions. Among these, the situation of Q fever has been well characterized in ruminants with seroprevalence as high as 13.4% in goats, the most likely contributors to transmission with shedding rate as high as 20% in vaginal fluids. In human, the seroprevalence has been estimated at 6.8% in the community, which prefigures Reunion Island as an endemic setting. The aim of this study was to report clinical and first incidence data of acute Q fever in Réunion Island from 2004 to 2017.

Materials/methods: Cases were retrieved from hospital databases using "Q fever" or "Coxiella burnetii" as search terms and enrolled in a retrospective regional cohort study conducted from the chart reviews of the four hospitals of the Island. Inclusion was based either on a positive Coxiella burnetii serology (defined as phase IgG II ≥ 200 and phase IgM II ≥ 50), or a seroconversion or a positive PCR of hospitalized patients. Given the retrospective nature of the study design, the regional cumulative incidence over the study period was estimated from municipalities where cases had been observed in order to limit underreporting.

Results: One hundred and forty-five patients were screened during the study period. Forty-two patients matched the case definition. Cumulative incidence was estimated at 9.3 per 100,000 inhabitants (95%CI: 6.4-12.1) with cases diagnosed yearly all throughout the study period except in 2006. Ninety percent of the cases were dwelling in the south (n=38). Most common manifestations were pulmonary [n=26 with 45.24% pneumonia], digestive [n=11] and cardiac [endocarditis, n=2].

Conclusions: Together with some previously known seroprevalence figures [Bouche du Rhône, French Guiana], these data suggest that Q fever reaches low to moderate endemic levels on Réunion Island. As previously reported, pulmonary symptoms are on the foreground.

Abstract 2240

The novel resistance mechanism of tigecycline in Acinetobacter baumannii
Xiaoting Hua¹, Jintao He*, Yunsong Yu¹
¹Zhejiang University, Hangzhou, China

Background: Tigecycline is a potent antibiotic for treating infections with multi-drug resistant Acinetobacter baumannii (MDR-AB). With the increasing usage of tigecycline, isolates resistant to tigecycline have constantly been reported. However, the definitive mechanism of tigecycline resistance in MDRAB has not been fully determined. This study aimed to explore the molecular mechanisms of tigecycline resistance in A. baumannii.

Materials/methods: Spontaneous mutants with reduced susceptibility to tigecycline were selected both in liquid and solid medium by serial passage experiments. Mutations were identified by illumina sequencing and bioinformatics analysis, then confirmed using PCR and Sanger sequencing. Complementation experiments were performed to evaluate the contribution of the mutations to decreased susceptibility to tigecycline. The significance of mutations were further investigated in terms of growth rates, antibiotic susceptibilities, and RNA-seq.

Results: Four mutations were identified, including three non-synonymous substitutions in adeS, rrf, rpoB and one insertion mutation in adeS. The rpoB and rrf gene were confirmed to cause decreased susceptibility to tigecycline by reconstruction experiments and antimicrobial susceptibility tests. Two types of mutations were observed in adeS gene (adeS::ISAba1 and adeS E51K) and both of them were confirmed to cause tigecycline resistance. By constructing an ISAba1 knockout strain on XH354, we demonstrated that the insertion of ISAba1 in adeS was correlated with tigecycline resistance. By measuring the relative growth rate, two adeS mutants exhibited faster growth than the parental strain with or without tigecycline and the ISAba1 knockout strain showed slower growth than XH354 with tigecycline. RNA-seq analysis was performed to determine the role of rpoB and rrf on the transcriptomes of A. baumannii MDR-ZJ06, and the result showed that hundreds of genes were upregulated or down-regulated.

Conclusions: Two kinds of mutations were found in adeS and both had been confirmed to cause decreased susceptibility to tigecycline. Besides, rrf and rpoB might play important roles in decreased susceptibility to tigecycline in A. baumannii.

Abstract 2241

Isoquinolinesulfonamide H89 reduces the intestinal inflammation and promotes Candida albicans clearance from the gut

Corentin Dumortier1,2,3, Rogatien Charlet*1,2,3, Boualem Sendid1,2,3, Ali Bettaieb4,5,6, Samir Jawhara1,2,3

1Inserm, U995/Team2, Lille, France, 2University of Lille, U995-LIRIC, Lille Inflammation Research International Centre, Lille, France, 3CHU Lille, Service de Parasitologie Mycologie, Pôle de Biologie Pathologie Génétique, Lille, France, 4EPHE, Tumor Immunology and Immunotherapy Laboratory, Dijon, France, 5Inserm U866, dijon, France, 6University of Burgundy, EA7269, Dijon, France

Background: The gastrointestinal microbiota acts a natural barrier to colonization and proliferation of opportunist pathogens. Deregulation of the dynamic crosstalk between the microbiota, intestinal epithelial cells and immune cells is critically involved in the development of inflammatory bowel disease. Clinical and experimental studies have shown that Candida albicans overgrowth aggravates the intestinal inflammation induced by dextran sulfate sodium (DSS) in mice, and, conversely, that DSS colitis promotes the fungal colonization. Candida albicans is an opportunistic yeast pathogen that has adapted to colonize all segments of the human gut. Recently, we showed that blocking of P2X7R by pyroglutamide-based P2X7 antagonists attenuate the intestinal inflammation. The isoquinolinesulfonamide H89 molecule is thought to compete with ATP at its binding site within the protein kinase A and to some purinergic receptors including P2X7R. In the present study, we investigated the impact of H89 on the intestinal inflammation and C. albicans clearance from the gut and determined the diversity of the gut microbiota in a dextran sulfate sodium (DSS)-induced colitis model.

Materials/methods: Mice were administered a single inoculum of C. albicans and were exposed to DSS treatment for 2 weeks in order to induce acute colitis. For H89, mice were administered with H89 orally and daily, for 5 days, starting on day 1. The number of C. albicans colonies and changes in microbiota diversity were assessed in freshly collected stool samples from each tagged mouse, using traditional culture methods based on agar plates.

Results: We showed that H89 reduced the clinical and histological scores of inflammation and promoted the elimination of C. albicans from the gut. An increase in Escherichia coli and Enterococcus faecalis populations and a reduction in Lactobacillus johnsonii and Lactobacillus reuteri populations were observed during colitis development. H89 administration to mice decreased the overgrowth of aerobic bacteria while L. johnsonii and L. reuteri populations increased significantly.

Conclusions: In conclusion, H89 reduced the intestinal inflammation and promoted the elimination of C. albicans from the gut. Further studies are ongoing to understand the direct effect of H89 on C. albicans and the aerobic bacteria.

Abstract 2242

Prevalence of carbapenemase-producing Gram-negative bacilli in a health area of southern Spain

Fernando Cobo1, Felipe Fernández-Cuenca2, Lina Martín-Hita2, Inmaculada López-Hernández2, José Gutiérrez Fernández1, Alvaro Pascual Hernandez2, José María Navarro-Marí2

1Hospital Virgen de las Nieves, Granada, Spain, 2University of Sevilla, Sevilla, Spain

Background: Carbapenemase-producing Gram-negative bacilli (CPGNB) represent a threat. There is considerable heterogeneity across EU countries and across different regions. To assess the burden of CPGNB in our hospital, we report the cases studied during a 4 year period.

Materials/methods: Isolates from 1st October 2015 to 30th June 2019 were included. Only the first isolate for each patient was considered. Species identification was confirmed by MALDI-TOF (Bruker Biotyper). Detection of carbapenemase-production was performed by immunocromatography (NG-Test CARBA 5, NG Biotech) and PCR (Xpert Carba-R, Cepheid). All isolates were sent to the Andalusian Reference Centre “PIRASOA” (Sevilla, Spain) for molecular genotyping (XbaI-PFGE, MLST) and characterization (MiSeq, Illumina).

Results: 104 isolates from 102 patients were included. Seventy-two (70.5%) were obtained from clinical samples: urine (36/50%), respiratory tract (16/22.2%), blood (11/15.2%) and exudates (9/12.5%), and remaining were for colonization studies (30/29.4%). Main CPGNB were K. pneumoniae (49/47.1%), P. aeruginosa (24/23%), E. cloacae (17/16.3%), and K. oxytoca (11/10.5%). Overall, the most common carbapenemases were VIM-type (32/30.4%), followed by the KPC-type (31/29.5%), IMP-type (24/22.2%) and OXA-48-type (18/17.1%). For Enterobacteriaceae the most common carbapenemase was KPC-type (31/38.2%), followed by VIM-type (30/37%), and OXA-48-type (18/22.2%). The most common carbapenemase in P. aeruginosa was IMP-type (22/91.6%). KPC-3 variant from K. pneumoniae was obtained in 26 (83.8%) isolates and they belonged to the hyperendemic ST258 clone. The main VIM variant was VIM-1 (29/90.6%), and the most common ST clone was ST78 (12/37.5%). The most prevalent IMP variant from P. aeruginosa was IMP-8 (12/50%), followed by IMP-16 and IMP-23 (6/25%, each one). The main ST clone for IMP variants was the ST348 (9/37.5%). Regarding OXA-48, the main ST clone was ST307 (14/77.7%).

Conclusions: Among Enterobacteriaceae, the most prevalent carbapenemases were KPC-3 and VIM-1. KPC-3 was associated with the K. pneumoniae high-risk clone ST258, whereas VIM-1 with the K. oxytoca ST36 clone and the E. cloacae ST78 clone. Among P. aeruginosa, the most prevalent carbapenemase was IMP-8, which were associated with the ST348 clone. These data contrast with those previously reported from Spain, where OXA-48 is the most prevalent carbapenemase, and reinforce the need for epidemiological control at the regional level.

Exploration of gonococcal MtrE-based antigens as prophylactic and therapeutic vaccines
Shuyi Wang*, Stijn Van Der Veen

Zhejiang University, Department of Microbiology and Parasitology, School of Medicine, Hangzhou, China

Background: Neisseria gonorrhoeae has become a global public health problem due to the high burden of disease and the rise in multidrug resistance. No vaccine is available due to antigenic and phase variability of surface-expressed proteins and the absence of clear correlates of protection.

Materials/methods: An in silico approach was used to predict surface-expressed proteins and analyze sequence conservation and phase variability. The most conserved protein, MtrE, and its surface-exposed Loop 2, which was displayed as both a structural and linear epitope on an established immunogenic protein, were used to immunize mice. Immunogenicity was subsequently analyzed by determination of antibody titers and serum bactericidal activity. To further define whether Th1 polarization is beneficial for the development of a vaccine against N. gonorrhoeae, MtrE and Loop 2 containing proteins were formulated with various Th1-stimulating adjuvants and investigated for polarizing in vitro dendritic cell stimulation and T cell activation assay. The best Th1 stimulating adjuvant, CpG, was used in immunogenicity and infection studies with MtrE and Loop 2 containing proteins in mice.

Results: MtrE and its surface exposed Loop 2 were identified as the most conserved surface-expressed antigens. Furthermore, MtrE and both Loop 2 containing proteins raised high specific antibody titers with good bactericidal activity. The vaccine formulations again raised high IgG titers against both MtrE protein and Loop 2 peptide and displayed a clear Th1-polarized IgG1/IgG2a ratio. In addition, immune sera showed stronger bactericidal activity compared with vaccine formulated with Alum, a well-established Th2-polarizing adjuvant. Finally, MtrE and Loop2 containing proteins formulated with CpG showed protection against a gonococcal challenge in a mouse vaginal tract infection model, as well strong therapeutic activity in this model when used as a therapeutic vaccine to clear an already established infection.

Conclusions: MtrE and Loop 2 are promising novel fully conserved surface-expressed antigens for vaccine development against N. gonorrhoeae and formulated with the Th1-polarizing adjuvant CpG provided both prophylactic and therapeutic activity in a mouse challenge model.

Complementary inhibition of penicillin binding proteins by cefepime and zidebactam in presence of VIM-1 results in potent in vitro and in vivo bactericidal action against metallo-β-lactamase producing Pseudomonas aeruginosa

Bartolome Moya¹, Sachin Bhagwat², Gabriel Cabot³*, Germán Bou Arevalo³, Mahesh Patel², Antonio Oliver¹

¹Hospital Universitari Son Espases, Fundació Institut d’Investigació Sanitària Illes Balears – IdISBa, Palma de Mallorca, Spain, ²Wockhardt Research Centre, Wockhardt Ltd., Aurangabad, India, ³Hospital Universitaria A Coruña, instituto de investigación biomédica de a coruña - INIBIC, A Coruña, Spain

Background: WCK 5222 is a combination of cefepime and a novel β-lactam enhancer, zidebactam. Zidebactam, a high-affinity PBP2 binding antibiotic, inhibits class A, and C β-lactamases but not metallo-β-lactamases (MBLs). Against MBL-producing pathogens, WCK 5222 triggers bactericidal action at sub-minimal inhibitory concentrations of cefepime and zidebactam suggesting effective PBP3 and PBP2 inhibition. The objective of this study was to establish PBP binding assay-based mechanistic evidence for cefepime-zidebactam mediated bactericidal effect against MBL P. aeruginosa in vitro and in vivo.

Materials/methods: VIM-1 was purified from E. coli BL21 harbouring pGEXVIM-1. PBP binding affinities were determined using Bocillin-FL assay. The activity of cefepime-zidebactam combination against MBL-expressing P. aeruginosa was assessed using time-kill and neutropenic mouse lung and thigh infection studies. Neutropenic animals were infected (inoculum ~6-log_{10} CFU/mL in lung/thigh), treatment regimens were initiated 2h post-infection. Bacterial loads (CFU/lung or thigh) were determined before and after treatment. Doses and regimens that generated human simulated exposures in mice (q2h for cefepime, zidebactam and q4h for carbapenems) were selected.

Results: Cefepime showed effective binding to PBP3 amidst cefepime-hydrolyzing concentrations of VIM-1 with minimal IC_{50} change in absence or presence of VIM-1 (PBP3 IC_{50} = 0.07/0.13 mg/L). Zidebactam binding to PBP2 remained intact (IC_{50} = 0.3/0.27 mg/L); however, imipenem binding to its target PBPs was adversely affected (PBP2 IC_{50} = 0.04/1.64 mg/L). Kinetic studies showed fast cefepime PBP3 binding rates with slight IC_{50} changes (IC_{50} 5' = 0.22 mg/L; IC_{50} 30' = 0.07). Imipenem PBP2 IC_{50} lowered significantly only after 30 min (IC_{50} 5' = 0.59 mg/L; IC_{50} 30' = 0.03), showing slower binding. Effective PBP inhibition amidst MBL translated in potent bactericidal activity of cefepime-zidebactam combination in time-kill study (ff1.5-log_{10} kill in 8h) against P. aeruginosa isolates expressing VIM. In vivo studies showed that although standalone cefepime, zidebactam and imipenem were not bactericidal, cefepime-zidebactam combination resulted in potent bactericidal activity (ff2.5-log_{10} bacterial killing in lung/thigh CFU).

Conclusions: The results show that cefepime and zidebactam effectively bind to respective target PBPs in the presence of MBL; presumably, as a result of cefepime faster rate of PBP binding which helps evade β-lactamase mediated hydrolysis.

Abstract 2250

Efflux pump inhibitors based on novel cyclic peptides as an approach against ESKAPE pathogens
Javier Moreno Morales*1, Clara Cosgaya Castro1, Clara Ballesté1, Ernest Giralt2,3, Jordi Vila Estape1,4
1ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, 2Institute for Research in Biomedicine (IRB Barcelona), The Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, 3Department of Inorganic and Organic Chemistry, Universitat de Barcelona, Barcelona, Spain, 4Hospital Clínic – University of Barcelona, Department of Clinical Microbiology – CDB, Barcelona, Spain

Background: Multidrug resistant Gram-negative pathogens represent a global health threat and overexpression of multidrug efflux pumps is one of the most prevalent resistance mechanisms. Therefore, efflux pump inhibition arises as a promising strategy for new auxiliary therapies to restore antibacterial potency and cyclic peptides (CPs) could be used as a powerful tool to develop this approach.

A library of 27 CPs was screened for its ability to inhibit efflux pumps in the presence of antibiotics.

Materials/methods: Antibiotic susceptibility profiles of a collection of Acinetobacter baumannii (8 strains) and Pseudomonas aeruginosa (8 strains) presenting RND efflux pump overexpression were determined using broth microdilution assay for netilmicin, norfloxacin, chloramphenicol, nalidixic acid, gentamicin and tigecycline. This assay was also performed in the presence of constant concentrations of the reported Efflux Pump Inhibitor (EPI) phenyl-arginine β-naphthylamide (PAβN) for the sake of comparing its activity against that of the CPs library.

Results: After phenotypic characterization of the efflux pump overexpression, one strain of each pathogen was selected to assess the EPI activity of the CP library since they showed the greatest PAβN inhibitory activity for chloramphenicol and netilmicin in A. baumannii, and norfloxacin in P. aeruginosa.

Out of 27 CPs, 3 presented putative efflux pump inhibition on the selected A. baumannii strain. These exerted a reduction of the MICs of chloramphenicol and netilmicin of at least 2 folds when compared to their MICs when tested alone against that strain as shown below:

<table>
<thead>
<tr>
<th>Component</th>
<th>Chloramphenicol MIC (µg/mL)</th>
<th>Netilmicin MIC (µg/mL)</th>
<th>Fold change</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alone</td>
<td>128</td>
<td>128</td>
<td>2X</td>
</tr>
<tr>
<td>+ CP1*</td>
<td>32</td>
<td>128</td>
<td>8X</td>
</tr>
<tr>
<td>+ CP3*</td>
<td>32</td>
<td>256</td>
<td>1X</td>
</tr>
<tr>
<td>+ CP14*</td>
<td>64</td>
<td>8</td>
<td>4X</td>
</tr>
<tr>
<td>+ PAβN*</td>
<td>32</td>
<td>64</td>
<td>1X</td>
</tr>
</tbody>
</table>

*Tested at a constant concentration of 100 µg/mL.

Conclusions: These preliminary results suggest that CP1, CP3 and CP14 have potential auxiliary activity in vitro when tested with chloramphenicol and netilmicin in A. baumannii overexpressing efflux pumps.

Further studies regarding the characterization of the strains and compounds are being performed to disclose if the active compounds found in our study act as EPIs in A. baumannii.

Presenter email address: javier.moreno@isglobal.org
Abstract 2252

**Influence of inflammation on pharmacokinetics and protein binding of tedizolid in healthy volunteers**

Beatrix Wulkersdorfer*, Christian Schörgenhofer1, Peter Matzneller1, Valentin Al Jalali1, Martin Bauer1, Edith Lackner1, Frieder Kees1, Christoph Born2, Bernd Jilma1, Markus Zeitlinger1

1Medical University of Vienna, Wien, Austria, 2University of Regensburg, Regensburg, Germany

**Background:** For combating bacterial infections a complex interplay between pathogen, host and antibiotic is decisive for treatment success. Most commonly the focus of infection models is put on the “pathogen-antibiotic” interaction, especially the intrinsic antimicrobial activity. In the following study pharmacokinetics and protein binding of the reserve antibiotic tedizolid (TZD), a second-generation oxazolidinone with strong activity against multi-resistant gram-positive bacteria, was investigated. Further, by introducing an endotoxin (LPS) based sepsis model, the impact of inflammation on TZD pharmacokinetic parameter was studied for the first time.

**Materials/methods:** Fourteen healthy volunteers received 3 single oral doses of 200 mg TZD phosphate, followed by an intravenous infusion of the same dose once a day over 60 minutes on 3 consecutive days (study days 1 to 6). Additionally, on day 6 subjects received an intravenous bolus of LPS (2 ng/kg body weight). Blood collections were performed at given time points at baseline and after drug application during study day 5 and 6. Free TZD concentration was obtained by ultrafiltration, total and unbound TZD was assayed using a validated HPLC-UV method. Pharmacokinetic parameters were compared between normal and artificial "septic" condition, validated by a significant increase in heart rate (p < 0.001), body temperature (p < 0.001) and c-reactive protein (p = 0.002).

**Results:** Under steady state conditions mean concentration-time profiles of total and unbound TZD in plasma showed almost identical concentration-time courses before and after LPS application (fig. 1). Further, for TZD plasma C_max was 2.96 prior and 2.94 mg/L after "sepsis" induction and for free plasma concentration 0.64 mg/L and 0.63 mg/L, respectively. AUC_{0-10} was 13.6 and 2.91 mg*h/ml before and 13.91 and 2.98 mg*h/ml after LPS for total and free TZD in plasma, respectively. Unbound fractions at 1 and 8 hours delivered similar values before (21.6 vs. 21.64%) and after (21.48 vs. 21.66%) LPS treatment, without statistical significant difference (p = 0.90).

**Conclusions:** The induction of inflammation by application of LPS did not have a significant effect on TZD pharmacokinetic data or protein binding.

![Mean concentration-time profile of TZD for total and free plasma before and after inflammation (LPS)](image)

Abstract 2253

Prevalence and clinical characteristics of *Mycoplasma pneumoniae* in Navarra (Spain), 2014-2018

Álvaro Varela Ana Isabel1,2, Ana Navascués Ortega1,2, Aitziber Aguinaga Perez12, Jesús Castilla Catalan23, Carmen Ezpeleta Baquedano*1,2

1Complejo Hospitalario de Navarra, Pamplona, Spain, 2Instituto de Investigación Sanitaria de Navarra (IdisNA), Pamplona, Spain, 3Instituto de Salud Pública de Navarra, Pamplona, Spain

**Background:** *M. pneumoniae* (MP) is one of the main pathogens of atypical pneumonia. It affects all ages, especially children under 14 years. Infections appear at any time of the year and usually have cyclic episodes every 4-8 years. The aim of our work is to know the characteristics of MP infection in Navarre in the period 2014-2018.

**Materials/methods:** Prospective study of cases of MP infection in Navarra during the period 1/1/2014-31/12/2018. All patients with positive MP PCR (Atypical CAP, FastTrack) are included. Clinical history was consulted to know the clinical characteristics

**Results:** There were 136 patients with positive PCR MP (136/1426; 9.53%). The distribution of cases/year was: 2014: 21.4% (25/117), 2015: 7.7% (14/182), 2016: 5.7% (18/318), 2017: 5.9% (19/318), 2018: 12.2% (60/492).

We had access to 123 patients (123/136; 90.4%). 56% of the population with MP infection were males with a mean age of 11 +/- 2.2 years. 65% (80) were between 5-14 years old and 19.5% (24) were <5 years old.

Clinical manifestations: 92.7% (114) cough, 66.7% (82) fever, 28.4% (35) upper respiratory symptoms and 18.7% (23) gastrointestinal symptoms. The only comorbidity detected was asthma, 14.6% (18) patients, which 77.7% (14) were male. 82.9% (102) had clinical and radiological diagnosis of pneumonia, 8.9% (11) with acute bronchitis, 4.9% (6) with upper respiratory tract infection and 3.2% (4) had no respiratory symptoms (1 diarrhea, 2 fever, 1 nausea and 1 urticaria).

A 3.2% (4) developed extra-respiratory complications: 2 dermatological (rash and urticaria) and 2 neurological (encephalitis and S. Guillén Barré).

44.7% (55) of the patients required hospitalization, with an average stay of 3.4 +/- 1.7 days.

47.1% (58) of the episodes developed during the warm months (June, July and August).

**Conclusions:**

- An epidemic situation was not clearly observed during the study period, although in 2014, 21.3% of the samples studied were positive.
- The main symptomatology is respiratory and the most frequent diagnosis is pneumonia.
- Forty-five percent of confirmed cases required hospital admission.
- CNS complications, although infrequent, may be important.
- Infections caused during this period are predominantly stationary, with half of cases occurring in warm months.

**Presenter email address:** carmen.ezpeleta.baquedano@navarra.es
Polyarginine nanocapsules carry and deliver genetic material inside bacteria

Laura Alvare-Fraga, José Crecente-Campo, Kelly Conde*, Alejandro Cés-Martínez, Juan Vazquez-Ucha, Alejandro Beceiro, Germán Bou Arevalo, María José Alonso, Margarita Poza Dominguez

1Microbiology group, Microbiology Service, Hospital Universitario A Coruña (CHUAC), Instituto de Investigación Biomédica de A Coruña (INIBIC) - Universidade de A Coruña (UDC), A Coruña, Spain, 2Nanobiofar group, Molecular Medicine and Chronic Diseases Research Centre (CIMUS), Santiago de Compostela, Spain

Background: Acinetobacter baumannii is considered one of the most challenging pathogens partly due to its antimicrobial resistance profile, having developed resistance to almost all the antibiotics. This feature, added to the lack of new antibiotics, highlights the urgent demand for alternative antimicrobial strategies. Nanocapsules (NCs) can be used as nanocarriers for controlled delivery of different molecules inside the cells, such as polynucleotides. The aims of this study were to design a nanosystem able to internalize into bacteria and to evaluate the potential role of NCs in vehiculation and delivery of genetic material inside the bacterial cell.

Materials/methods: NCs with different polymer composition such as polyarginine (PArg NCs), protamine (Pr NCs) and octoarginine (R8 NCs) were designed to be internalized into bacterial cells. pAcGFP2 oriAb plasmid containing the green fluorescent protein (GFP) was used as a control to demonstrate the capacity of DNA-vehiculization of the NCs. Two different strategies were used to associate the plasmid to the NCs: a) association to the nanoemulsion and coating with the external polymer, and b) association to the outer shell of the NCs. A. baumannii ATCC 17978 cultures were incubated in the presence of NCs loaded with pAcGFP2 oriAb (20 µg/mL) in 0.9% NaCl from 30 min to 20 h. Confocal microscopy was used to visualize the NCs internalization and plasmid release by GFP expression.

Results: Confocal microscopy images revealed that, among all the NCs tested, only PArg NCs were able to penetrate into bacterial cells after 2 h of incubation. These NCs, with the pAcGFP2 oriAb entrapped between the nucleus and the outer polymeric shell, were able to pass through the bacterial membrane and to release the plasmid inside bacterial cells. These bacteria were cultured and the GFP expression was detected by confocal microscopy.

Conclusions: This study revealed that it is possible to internalize polyarginine nanocapsules inside bacteria and represents a proof of concept of genetic material mobilization inside the bacteria using these NCs as a vehicle. This finding opens the door to future studies dealing with the blocking of messenger RNA via the release of antisense molecules contained within NCs.

Abstract 2257

Clonal attack: number of vancomycin-susceptible, -variable and -resistant E. faecium clones in individual rectal swabs

Karen Leth Nielsen*, Stine Radmer1, Karoline Knudsen List1, Niels Frimodt-Møller1

1Rigshospitalet, København, Denmark

Background: Rectal swabs are routinely used in hospitals to screen for vancomycin resistant Enterococcus faecium during outbreaks. Today the most detailed molecular typing is derived from whole-genome sequencing of the isolates. For a successful sequencing it is important that the sample only contains a single clone. Today, the number of (VSE, VVE and VRE, respectively) clones within a swab is unknown.

Materials/methods: We investigated 43 rectal swabs to determine the number of E. faecium clones within each swab. From VSE swabs we picked 20 colonies on a chromogenic agar, without antibiotics. From VRE swabs we picked ten VRE colonies from a chromogenic VRE agar plate. To describe the VSE population in a VRE swab we picked ten colonies from a chromogenic agar plate similar to the VSE swabs. All isolates [N=846] were tested for antibiotic phenotype [vancomycin, linezolid, ampicillin, gentamicin, ciprofloxacin and tigecycline] and RAPD PCR to estimate the number of clones in each sample. Any differences in RAPD fingerprint or antibiogram resulted in whole-genome sequencing of the isolate [N=232]. Determination of number of clones in each sample was based on individual phylogenetic trees with SNP distance calculations [same clone= <40 SNPs] combined with phenotypic antibiogram.

Results: The number of VRE/VVE containing swabs was 22 of which 17 contained a single VRE/VVE clone (77%) whereas five swabs [white triangles] contained >1 VRE/VVE clone [23%] [figure]. In 28/43 swabs we observed a single clone and in 15/43 swabs we identified ≥2 distinct clones [N=15]. In two swabs we observed identical clones according to SNP distance, however, with different phenotype - VVE and VRE as well as VSE and VRE.

Conclusions: The results show that 23% of swabs contain more than one VRE/VVE clone, which makes molecular typing during outbreaks less efficient in predicting spread of VRE/VVE infection between patients based on phylogenetic relationship. A combination of clonal relationship and transposon typing could be proposed to overcome this.

Figure: Rectal swabs [one per patient, N=43] stratified according to classification of E. faecium and number of different clones/swab. White triangles represent swabs with more than one VRE/VVE clone.

Abstract 2258

Community-acquired and hospital-acquired Clostridioides difficile infections in the context of a trans-sectoral antibiotic stewardship intervention in Berlin, Brandenburg and Thuringia

Sandra Schneider¹, Christin Schröder¹, Florian Salm¹, Inga Petruschke¹, Anne Moeser¹, Stefan Hagel⁴, Mathias Pletz⁴, Petra Gastmeier*¹

¹Charité – Universitätsmedizin Berlin, Institute of Hygiene and Environmental Medicine, Berlin, Germany, ²Heidelberg University Hospital, Department of Infectious Diseases, Division of Infection Control and Hospital Epidemiology, Heidelberg, Germany, ³Jena University Hospital, Institute of General Practice and Family Medicine, Jena, Germany, ⁴Jena University Hospital, Institute for Infectious Diseases and Infection Control, Jena, Germany

Abstract third-party references: On behalf of the RAI study group

Background: The association between antibiotic use and Clostridioides difficile infections (CDI) is well known. Within the RAI project (Rational Antibiotic Use via Information and Communication), we simultaneously carried out knowledge- and communication-based interventions in the outpatient and inpatient sector to reduce unnecessary antibiotic prescriptions. Aim of this study was to investigate effects on the occurrence of community-acquired and hospital-acquired CDI.

Materials/methods: RAI intervention tools were introduced in 271 GP practices, as well as intensive care units (ICU) and surgical departments from 29 hospitals in Berlin, Brandenburg and Thuringia between August 2016 and July 2017. The tools had been tailored to the specific needs of general practitioners and hospital physicians. CDI admission prevalences (proxy for community-acquired CDI) were measured in hospitals in Berlin, Brandenburg and Thuringia, which continuously joined the CDI module of the German Hospital Infection Surveillance System (KISS; n = 39, I-hospitals). The 356 CDI-KISS participating hospitals from the rest of Germany served as comparison group (C-hospitals). The effect of the inpatient intervention was investigated in those RAI participants whose wards participated continuously in the ICU module of KISS before and during intervention (n = 6, I-wards). The comparison group consisted of 3 times the number of structurally similar ICU-KISS participants from Germany (C-wards).

Results: The prevalence of CDI cases per 1000 admissions in the I-hospitals dropped significantly by 20% from 1.78 in the year 2016 to 1.42 in 2017 [rate ratio (RR) 0.80; 95% confidence interval (CI) 0.73–0.86]. Whereas the admission prevalence in the C-hospitals dropped only by 8% from 1.98 to 1.83 [RR 0.93; CI 0.90–0.95]. The incidence density of hospital-acquired CDI per 1000 patient days in the I-wards decreased statistically significant by 75% from 0.64 in the pre-intervention period to 0.16 in the intervention period [RR 0.25; CI 0.08–0.76] whereas in the C-wards it stayed nearly the same [0.41 pre-intervention versus 0.39 intervention period [RR 0.94; CI 0.54–1.64]].

Conclusions: Both, the outpatient and inpatient parts of the RAI intervention appear to have had an effect on the occurrence of CDI, although the study design of course, is not able to demonstrate causality.

Abstract 2259

Dual therapy with aztreonam & ceftazidime/avibactam against multi-drug resistant Stenotrophomonas maltophilia on tricuspid valve endocarditis

Jose Alexander*, 1, Amy Carr1, Sarah Minor1, Daniel Navas1

1AdventHealth Orlando, Orlando, United States

Abstract 2259

Background: Antimicrobial resistance in Stenotrophomonas maltophilia is one of the most complex among Gram-negatives. Presence of regulating non-specific antimicrobial class efflux pumps and chromosomal encoded L1 metallo-beta-lactamase (Ambler Class B) and L2 beta-lactamase (Ambler Class A) are responsible for few clinically active antimicrobials and the rapid raise of pan-drug resistant strains.

Materials/methods: A 38-year old male with a history of IV drug use, chronic hepatitis C, and recent MSSA endocarditis was admitted with sepsis. Workup revealed tricuspid valve endocarditis with pulmonary septic emboli due to Stenotrophomonas maltophilia. Initial antibiotics were levofloxacin, metronidazole, and piperacillin/tazobactam followed by levofloxacin and minocycline. He had valve replacement on day 6. Repeat blood cultures and valve tissue culture revealed Stenotrophomonas maltophilia had become pan-drug resistant (resistant: ceftazidime, levofloxacin, minocycline, trimethoprim/sulfamethoxazole, chloramphenicol; intermediate: minocycline; eravacycline MIC 8 μg/mL; tigecycline MIC 16 μg/mL). Microbiology Department was consulted for additional antimicrobial options based on susceptibility patterns. In vitro testing for a combination of aztreonam (AZT) and ceftazidime/avibactam (C/A) was recommended.

Results: Synergy testing between AZT and C/A was performed by positioning AZT strip (bioMerieux®, Inc.) over the area where C/A (bioMerieux®, Inc.) had been previously placed and removed after 10 minutes of incubation. The interception of the growth with the AZT strip was read. In presence of avibactam, AZT MIC was 4 μg/mL, 6 two-fold dilutions lower than AZT without C/A. MIC for AZT (256 μg/mL), ceftazidime (256 μg/mL) and C/A (32 μg/mL) were tested individually. AZT with C/A was recommended as a salvage treatment based on in vitro result. Patient completed 6 weeks of AZT with C/A along with minocycline. He achieved microbiologic clearance and clinical recovery from infection. At the end of treatment, he experienced episodes of refractory ascites. With complex cardiac, renal, and hepatic disease, patient was not a transplant candidate and transitioned to hospice two weeks later.

Conclusions: Although the surgical excision was key in the management, antimicrobial therapy with AZT and C/A provided effective antimicrobial treatment in the setting of persistent positive blood culture. AZT with C/A should be considered for cases of pan-drug resistant Stenotrophomonas maltophilia with limited treatment options.

Abstract 2261

Genomic analysis of cardiac surgery-associated Mycobacterium chimaera infections in Italy
Arash Ghodousi*, Marta Peracchi1, Emanuele Borroni1, Giorgio Palu3, Loredana Fallice1, Virginia Quaresima1, Vinicio Manfrin1, Mario Rassu1, Vincenzina Monzillo4, Riccardo Manganelli2, Enrico Tortoli1, Daniela M. Cirillo1

1San Raffaele Scientific Institute, Emerging Bacterial Pathogens Unit, Milan, Italy, 2University of Padova, Padova, Italy, 3San Bortolo Hospital, Vicenza, Italy, 4Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: A clonal outbreak of over 150 cases of Mycobacterium chimaera (M. chimaera) infections were notified, linked to contaminated heater-cooler units (HCUs) used during cardiac surgery. We report the results of whole genome sequencing (WGS) analysis conducted on M. chimaera isolates from cardiac surgery (CS) related and unrelated patients and from HCUs in different centers in Italy.

Materials/methods: We investigated 122 Italian isolates of M. chimaera from HCUs (n=79), cardiothoracic surgery (CS-related) (n=23) and CS-unrelated patients (n=14) collected between 2015-2019. WGS was performed on the Illumina NextSeq500 platform and the reads were mapped on M. chimaera DSM-44623 as reference genome. The combined set of detected high quality SNP positions was used to construct a maximum likelihood phylogenetic tree using RAxML Version8 with a general time reversible substitution model, 1,000 re-samples and Gamma20 likelihood optimization to account for rate heterogeneity among sites. In order to detect the mixed populations in the samples we reduced the threshold of variant detection (at least 2-fold coverage and 5% allele frequency).

Results: Out of 122 strains only three belonged to groups other than Group 1. All M. chimaera isolates from CS-related patients grouped within Group 1; of these, 19 belonged to Subgroup 1.1, 3 to Subgroup 1.8 and 1 to Branch 1. Moreover, Subgroups 1.1 and 1.8 included 51 out of 79 isolates from HCUs. The isolates from CS-unrelated patients were heterogeneous and were distributed across the phylogenetic tree, mostly belonging to Branch 1. Overall, the isolates within Subgroup 1.1 showed comparatively little diversity, with a median pairwise distance of only 4 SNPs (range 0-20).

Conclusions: A common source of M. chimaera infection has been recognized on the basis of the remarkable similarity between almost all the isolates from patients with a history of cardiac surgery and the ones recovered from most HCUs. Three distinct strains of M. chimaera, belonging to Subgroups 1.1, 1.8, and 2.1, have been reported responsible of contamination of LivaNova HCUs at the production site. This finding is in agreement with our results showing large prevalence of Subgroups 1.1 and 1.8 among the isolates from CS-related patients and HCUs.

Initiation of an immunisation and catch-up programme in schools in a country with a high vaccine hesitancy: yes we can!

Jocelyn Michon*, Anna Fournier, Fanny Appia, Sophie Villedieu, Christelle Porterie, Anne Leprieur, Renaud Verdon, Aurelie Baldacci

*Hospital Center University Of Caen Normandie, Department of Infectious Diseases, Caen, France, Hospital De La Miséricorde, Pass, Cpmi Et Réadaptation Cardiaque, Centre de vaccination interdépartemental 14 50 61, Caen, France

Background: Childhood immunization programs in schools are attractive because of their ability to reach large numbers of children in a short period of time. Such programs were stopped in France in 1998 after a controversy about a link between HBV vaccine and multiple sclerosis. Vaccine hesitancy has recently increased, leading to low vaccine coverage (VC) and outbreaks such as measles. A school immunization program was launched in Normandy in April 2019 to improve VC. We performed a study to identify factors associated with VC and vaccine acceptance (VA).

Materials/methods: We performed a prospective study to describe acceptability of a proposal for free vaccine catch-up or initiation of vaccination, if needed, for all pupils of 12 year old in high school by two vaccination teams in Normandy between April and October 2019.

An information letter and a consent form were sent to parents one month before the vaccination meeting. Parents could choose for each of the mandatory (diphtheria tetanus poliomyelitis [DTP], pertussis) and recommended vaccines (hepatitis B virus [HBV], human papilloma virus [HPV], meningococcus C, measles mumps rubella [MMR]) those they allowed. All children who’s parents allowed one vaccine were evaluated. During the meeting the doctor checked the vaccination notebook and the child was vaccinated when needed and authorized. We prospectively collected VC and VA for each vaccine. Two multivariate analysis were performed to identify factors associated to the need for an update of vaccination and VC.

Results: We intervened in 34 high schools located in 3 departments. Out of 3296 pupils, 879 (27%) accepted at least one vaccine. M/W ratio was 0.47, 689 (78%) pupils were vaccinated, they received a mean of 1.66 vaccine.

In multivariate analysis boys had a better VC (OR=0.38, IC95% 0.27-0.54), one of the 2 teams had a better post intervention VC (OR=0.65, IC95% 0.46-0.94). Post meeting VC was higher in low income area (OR=4.04, IC95% 1.5-10.91).

Conclusions: In high school pupils, despite a low VA, this program helped increase the VC. Further researches are needed to increase VA.

Abstract 2268

Prosthetic joint infections treated with two-stage revision procedure: a case series

Anastasia Saade-Antypas*, Jean-Michel Urvoy, David Luque Paz, Harold Common, Pierre Tattevin, Anne Gougeon-Jolivet, Cedric Arvieux

1CHU de Rennes, Rennes, France

Abstract third-party references: CRIOGO study group

Background: Two-stage revision procedure is the gold standard surgical treatment for the most complicated prosthetic joint infection (PJI), as it allows a window period with no prosthetic material. However, optimal duration of antimicrobial regimen after reimplantation of a new prosthesis remain poorly standardized. We aimed to characterize patients with PJI managed by a two-stage revision procedure in our institution, and identify prognosis factors.

Materials/methods: We performed a retrospective study in Rennes University Hospital, a referral center for complex PJI in western France. We identified all cases of PJI managed by two-stage procedures during years 2015-2018. Patient management was designed by a multidisciplinary team according to international guidelines. Standard follow-up included systematic consultation at 3, 6, 12 and 24 months after treatment discontinuation. Failure was defined as microbiologically documented relapse, the need for unplanned surgery or antibiotic treatment for PJI during follow-up. A Cox regression model was performed to identify risk factors for treatment failure.

Results: Fifty patients fulfilled inclusion criteria (18 women, 32 men, mean age 67±14 years), with PJI involving the hip (n=24), knee (n=22), or shoulder (n=4). PJI occurred as a relapse in 27 patients (54%), and was mostly classified as late (>12 months, n=35, 70%). Most common microorganisms were Staphylococcus aureus (n=18), coagulase-negative staphylococci (n=12) and streptococci (n=9). Twenty-three patients (46%) received antibiotic before prosthesis removal. The mean duration of antibacterial treatment after prosthesis removal was 10±4 weeks, the mean duration of antibiotic-free period was 16±7 weeks. Microbiological samples obtained during the second-stage were positive in 14 patients (28%), for Staphylococcus aureus (n=4), coagulase-negative Staphylococcus (n=8), and Cutibacterium acnes (n=2), after a median of 2 [min-max: 1-12] days. The mean duration of antimicrobial regimen after prosthesis reimplantation was 24.4±19.9 weeks. With a mean follow-up of 26.8±11.9 months after reimplantation, 5 patients (10%) presented criteria for failure. No variable associated with failure were identified, including microorganisms, second-stage antimicrobial treatment duration, and positive cultures at the second-stage.

Conclusions: Two-stage revision procedure was successful in most cases of complex PJI.

Abstract 2270

**Colistin, turns active an otherwise ineffective rifampicin-linezolid combination in Gram-negatives**

Eva Armengol Rivero*, Isabel Perez-Guillen1, Marta Jorba1, Rocio Herraez Moral1, Josep Maria Sierra1

1University of Barcelona, Molecular Microbiology & Antimicrobials. Dept. Pathology and Experimental Therapeutics, Barcelona, Spain

**Background:** The emergence of antimicrobial resistance is currently one of the most relevant healthcare concerns worldwide and the WHO has included it among its most urgent priorities. Combinations of already known antimicrobials offer a strategy to combat antimicrobial resistance, together with the design and development of new antimicrobials. Cationic antimicrobial peptides (CAMPs) are thought to induce alterations in membrane permeability through different mechanisms, as described by barrel-stave, toroidal pore, carpet, aggregate models, increasing fluidity, and some others, thus facilitating the entry of other antimicrobials into the bacterial cell. Synergies between different (C)AMPs and between CAMPs and classical antibiotics may therefore offer a method for the re-sensitization of bacteria that have become resistant to several antibiotics. This work deals with the effect on *Escherichia coli* clinical strains of sub-inhibitory concentrations of colistin administered together with combinations of linezolid-rifampicin, otherwise inactive in these bacteria.

**Materials/methods:** A checkerboard method was used to compare the effect of sub-inhibitory concentrations of colistin on the activity of the linezolid-rifampicin combinations. The effect of the linezolid-rifampicin combination was compared in presence and absence of ½ MIC colistin.

**Results:** Linezolid alone was absolutely inactive against *E. coli*, evidenced by its minimum inhibitory concentration (MIC) of 256 mg/L, while the MIC of rifampicin was much lower (8 mg/L). The combination of the two antimicrobials linezolid-rifampicin did not lead to their interaction (0.5< FICI [fractional inhibitory concentration index] >4), but in the presence of sub-inhibitory concentrations of colistin the interaction between linezolid-rifampicin was highly synergistic (FICI < 0.5).

**Conclusions:** Our results demonstrate that colistin either enhances the activity of linezolid-rifampicin combinations or re-sensitizes bacterial cells to these drugs. Thus, a triple antibiotic combination that includes colistin may be a promising alternative treatment of infections caused by multidrug resistant bacteria.

Pharmacokinetic/pharmacodynamic analysis of tedizolid phosphate compared to linezolid for the treatment of infections caused by Gram-positive bacteria

Amaia Aguirre Quinonero\textsuperscript{1,}, Alicia Rodríguez\textsuperscript{2,}, Marian Soliní\textsuperscript{3,}, Andrés Canut\textsuperscript{1,}

\textsuperscript{1}University Hospital of Álava, Servicio de Microbiología, Hospital Universitario de Álava, Instituto de Investigación Biosanitaria, BioAraba, Vitoria-Gasteiz, Spain, \textsuperscript{2}Universidad del País Vasco UPV/EHU, Farmacia y Tecnología Farmacéutica. Facultad de Farmacia, Centro de investigación Lascaray Ikergunea, Vitoria-Gasteiz, Spain, \textsuperscript{3}Universidad del País Vasco UPV/EHU, Farmacia y Tecnología Farmacéutica, Facultad de Farmacia, Centro de investigación Lascaray Ikergunea, Vitoria-Gasteiz, Spain

\textbf{Background:} Tedizolid phosphate (TZD) is a novel oxazolidinone launched into the market for the treatment of acute bacterial skin and skin-structure infections (ABSSSIs) caused by Gram-positive bacteria. Pharmacokinetic (PK) and pharmacodynamic (PD) properties of TZD allow its once-daily administration, either orally or intravenously, at equivalent dosage. This study aimed to evaluate the probability of attaining targeted pharmacodynamic exposure of TZD compared to linezolid (LNZ) at standard dosing regimens against different clinical isolates using Monte Carlo simulation.

\textbf{Materials/methods:} PK/PD parameters of TDZ and LNZ and minimum inhibitory concentrations (MIC) for Staphylococcus aureus, coagulase negative staphylococci (CoNS) and Enterococcus spp. were retrieved from published studies. All strains had been isolated either in Europe or in the United States. Using Monte Carlo simulation, PK/PD target attainment (PTA) by MIC and cumulative fraction of response (CFR) were determined for each bacterial collection for TDZ (200 mg q24h) and LNZ (600 mg q12h) in simulated patients with normal renal function.

\textbf{Results:} Table 1 shows the CFR values obtained for both antibiotics against staphylococci and enterococci. For all microorganisms studied, TDZ provided higher CFR values than LNZ. Regarding staphylococci, CFR values obtained for TDZ were always higher than 95% except for methicillin- and LNZ-resistant S. aureus (MLRSA) (CFR of 62%). However, CFR>80% was only obtained with LNZ against methicillin-resistant S. aureus [MRSA] and CoNS. For enterococci, both TDZ and LNZ provided CFR values higher than 80% except for LNZ- and vancomycin-resistant (LVR) E. faecium.

\textbf{Conclusions:} For both staphylococci and enterococci, TDZ provided higher CFR values, indicative of higher probability of empirical treatment success. Differences were more relevant for staphylococci.

Table 1. Cumulative fraction of response (CFR) for tedizolid (TZD) and linezolid (LNZ) against staphylococci and enterococci. In bold, CFR≥80%.

Abstract 2274

Molecular characterisation of methicillin-resistant Staphylococcus aureus isolates from the United Arab Emirates: emergence of novel strains and variants

Abiola Senok*1, Rania Nassar1;2, Handan Celiloglu1;3, Anju Nabi4, Mubarak Alfarsi5, Stefan Weber6, Elke Müller7;8, Annett Reissig7;8, Darius Gawlik9, Stefan Monecke7;8;10, Ralf Ehricht7;8;11

Background: Although recent reports on methicillin resistant Staphylococcus aureus (MRSA) from Arabian Gulf countries have demonstrated an emergence of novel strains and variants, data from the United Arab Emirates (UAE) are insufficient. This study aimed to determine the clonal distribution and genetic characteristics of MRSA in the UAE.

Materials/methods: MRSA [associated with clinical infections] identified between December 2017-January 2019 in four hospital laboratories were studied. Molecular characterisation was done using DNA microarray-based assays.

Results: The 466 MRSA isolates investigated belonged to 22 clonal complexes (CC) and 80 distinct strains as defined by CC affiliation, SCCmec type and Panton-Valentine leukocidin (pvl) genes carriage. The predominant CCs were CC30 (n=69), CC6 (n=65), CC5 (n=63) and CC22 (n=62), CC1 (n=34), CC772 (n=31), CC8 (n=27) and CC361 (n=26). There were 18 isolates each for CC60, CC97, with CC88 (n=15), CC239 (n=9), CC15 (n=7) and the rare CC121 (n=6). Other CC were CC152 (n=5), ST72, CC45, CC398, CC1153 [two isolates each], CC9 (ST834), CC96 MRSA and CC2250 S. argenteus (single isolates). A strain with a novel SCC-element was CC5-MRSA-[V/VT+cas+fus+ccrA/B-1]. Other variant/rare MRSA strains were CC5-MRSA-V (edinA+), CC5-MRSA-[V/VT+fus], CC5-MRSA-V (tst1+). CC8-MRSA-V, CC45-MRSA-[IV+fus+tr]; CC121-MRSA-V/VT; CC152-MRSA-[V/VT+fus] (PVL+), CC361-MRSA-V (SCCmec V/cos composite element). Our findings also demonstrate the emergence of ST5/ST22-MRSA-II, Rhine-Hesse EMRSA/New York-Japan Clone, CC5-MRSA-IV (sed/j/r+, PVL+), “Sri Lanka Clone”, CC398-MRSA-V/VT (PVL+); CC772-MRSA-V (PVL+), “Bengal Bay Clone” in this region. Another emerging clone was a CC22-MRSA-IV harbouring pvl and tst1 genes. A variant CCBD-MRSA-IV strain uncharacteristically with SCCmec IVa, harboured enterotoxin genes and was negative for the pvl genes. Two variants of the pandemic CC8-MRSA-[IVA+ACME1] (PVL+), USA300 – one putative PVL-deletion mutant and one with SCCmecIVa+ACMEIII were detected. The pvl genes were present in 221 (47.4%) isolates while 124 (26.6%) harboured fusC [SCC-borne fusidic acid resistance] gene.

Conclusions: An extensive MRSA repertoire which includes CCs previously unreported in the region, plus rare and novel strains are present in the UAE. Some strains detected occur in other countries, so a travel connection is possible. Others which have not been described elsewhere, probably evolved locally. Continued surveillance and further studies to understand the drivers of MRSA evolution are needed.

Presenter email address: abiola.senok@mbru.ac.ae
Colonisation dynamics of *Streptococcus pneumoniae* in a remote African population: a prospective cohort study

Frieder Schaumburg*1, Arnaud Flamen2, Abraham Alabi3,4, Jonas Ehrhardt3,4, Mark Van Der Linden5

1University Hospital Münster, Institute of Medical Microbiology, Münster, Germany, 2Hôpital Albert Schweitzer, Lambarene, Gabon, 3Centre de Recherches Médicales, Lambarene, Gabon, 4Eberhard-Karls-Universität Tübingen, Institut für Tropenmedizin, Tübingen, Germany, 5German National Reference Center for Streptococci, Aachen, Germany

**Background:** Increased exposure to the outside world can change the microbiome of isolated communities. We aimed at analyzing the population dynamics of *Streptococcus pneumoniae* in a remotely living African Pygmy population in a time of increasing contact with foreigners.

**Materials/methods:** We conducted a prospective cohort study to analyze the nasopharyngeal *S. pneumoniae* in the same Babongo pygmy population in Gabon in 2011 (n=103), 2013 (n=104) and 2017 (n=107). Only non-duplicate isolates were included (n=126), serotyped and tested for antimicrobial resistance (broth microdilution, EUCAST clinical breakpoints).

**Results:** Resistance rates were highest for tetracycline (36–58%), followed by penicillin (parenteral, meningitis-breakpoints, 6–39%) and chloramphenicol (3–15%). Resistance rates increased for tetracycline and chloramphenicol while self-reported contact to foreigners increased as well from 6.8% (2011) to 17.8% (2017). The majority of isolates was non-typeable (NT, n=18/126, 14.3%) followed by serotype 6B (n=17/126, 13.5%), 21 and 15A (n=9/126, 7.1%, each). The distribution of serotypes was highly dynamic as only three serotypes (14, 17F, NT) were detected during all three visits.

**Conclusions:** Resistance rates and serotypes of nasopharyngeal *S. pneumoniae* markedly changed in the remote Babongo population. This rapid change in serotypes could challenge the selection of pneumococcal vaccine.

Abstract 2279

Evaluation of faecal calprotectin as a predictor of severity and relapse in *Clostridioides difficile* infection

Julia Origüen Sabater*1, Mario Agreda 1, Mario Fernandez Ruiz2, Laura Corbella Vazquez1, Patricia Parra1, Jennifer Villa1, Ma Angeles Orellana Miguel1, Tamara Ruiz Merlo1, María Ruiz-Ruígomez2, Isabel Rodriguez Goncer1, Francisco Lopez-Medrano1, Rafael San Juan Garrido1, Manolo Lizasoain1, Jose M. Aguado Garcia1

1University Hospital 12 de Octubre, Madrid, Spain, 2Hospital Universitario “12 de Octubre”, Instituto de Investigación Sanitaria Hospital “12 de Octubre” (imas12), Unit of Infectious Diseases, Madrid, Spain

**Background:** The assessment of fecal calprotectin (FCp) has been applied to rule out organic gastrointestinal diseases. Its potential value as predictive biomarker of outcome in *Clostridioides difficile* infection (CDI) remains unknown.

**Materials/methods:** A stool sample was collected at CDI diagnosis during a 10-month period and frozen at -80°C until analysis. Epidemiological and clinical variables were prospectively recorded. The fCAL® ELISA kit with the CALEX® Cap Extraction Device (both from Bühlmann Laboratories, Switzerland) were used for assessing FCp values. According to manufacturer's recommendations, cut-off values of 50 and 200 µg/g were used to define assay positivity, as well as alternative thresholds at the second (Q2) 741.5 µg/g and third (Q3) 2,194.7 µg/g quartiles. Study outcomes were severity of the index CDI episode and CDI relapse within the first 8 weeks.

**Results:** Overall, 170 samples (146 first CDI episodes and 26 relapses) were included. The presence of FCp values below Q2 was more common among patients with diabetes mellitus (64.3% [27/42] vs. 44.5% [57/128]; P-value = 0.03), solid organ transplantation (65.6% [21/32] vs. 45.6% [63/138]; P-value = 0.04) and chronic renal failure (63.8% [30/47] vs. 43.1% [53/123]; P-value = 0.02), whereas solid cancer was associated with FCp values above this threshold (73.3% [22/30] vs. 45.0% [63/140]; P-value = 0.005). Patients with non-severe CDI had more frequently FCp values below 50 µg/g (12.5% [14/112] vs. 3.4% [2/58]; P-value=0.05) or 200 µg/g (27.7% [31/112] vs. 15.5% [9/58]; P-value=0.07) than those with severe or fulminant episodes. Patients with FCp values >200 µg/g exhibited higher leukocyte count at diagnosis (median of 9,050 [IQR: 6,650-14,075] vs. 7,700 [IQR: 5,350-12,250] cells/µl). When we analysed the subset of 146 first episodes, we also found a higher proportion of patients with a non-severe CDI with FCp values <50 µg/g (13.7% [14/102] vs. 2.3% [1/44]; P-value = 0.03), whereas the rate of relapse was similar between patients with FCp values below or above 200 µg/g (5.9% [2/34] vs. 11.6% [13/112]; P-value = 0.52).

**Conclusions:** In our single-center study, patients with non-severe CDI showed lower FCp values, although none of the cut-off points explored appeared to be useful to predict CDI relapse.

Laboratory stewardship initiative on repeat blood culture collection practices led to reduction of collection rates but electronic best practice alerts are needed to sustain reduction rates

Joseph Gastaldo1, Patrick Ozbolt2, Kathleen Krupinski-Shaw1, Katherine Kerr1, Sarah Hohman1, Stella Antonara*1

1OhioHealth Riverside Methodist Hospital, Columbus, United States

Background: Blood cultures (BCs) remain the gold standard and the first line tool for detecting blood stream infections. Indiscriminate repetition, after an initial culture is positive, is unnecessary and is associated with excessive use of resources, unnecessary additional testing and puts patients at risk for adverse effects. In our health system, we calculated the number of BCs during the first 48 hours of admission and implemented a laboratory stewardship initiative with the goal to reduce the number of repeat blood cultures by 5% within a year.

Materials/methods: The number of BCs, positivity rates and repeat BCs in the first 48 hours were calculated during a pre-implementation period from January- June 2018. From July 2018-June 2019, a large educational initiative was put in place detailing the significance of BCs and best practices regarding their recollection. The three parameters followed during the pre-implementation period were also recorded for 12 months following the educational efforts. The data were collected from the hospital's electronic medical record system (EPIC) as part of the quality improvement project.

Results: From January-June 2018 there were 74,760 BCs collected with an average BC positivity rate of 11.04%±0.01. At the initial site of collection, 2 sets were obtained. Depending on the collection site throughout the system 50.2-76.5% of BCs were repeated within the first 48hrs. Educational efforts starting in August 2018 resulted in an average decrease in BCs of 1.86%±4.24 during July 2018- June 2019. Initially, there was a big decrease up to 12.4% but six months following the educational efforts there was an increase of BC collection reaching 3.51%. During these 12 months the average BC positivity rate was 11.79%±0.01.

Conclusions: The educational efforts helped with the reduction of BCs recollection and did not affect positivity rates. However, the stewardship initiative was partially effective demonstrating the need for continuous reminders of best practices. To effectively impact practice the introduction of best practice alerts at the point of ordering through the hospital electronic system would be a permanent solution in addition to learning initiatives.

**Abstract 2283**

**Vaccination perception and factors influencing MMR vaccination decisions during a university measles outbreak in a country with a high vaccine hesitancy**

Jocelyn Michon*1, Anna Fournier1, Fanny Appia2, Sophie Villedieu1, Anne Leprieur2, Christelle Porterie1, Renaud Verdon1, Aurelie Baldoli2

1Hospital Center University Of Caen Normandie, Department of Infectious diseases, Caen, France, 2Foundation Hospital De La Miséricorde, Pass, Cpmi Et Réadaptation Cardiaque, Centre de vaccination inter départemental 14 50 61, Caen, France

**Background:** Recent MO found a low vaccine coverage in young adults, including university students. Few studies evaluated VP and factors influencing MMR vaccination decisions during a MO in country with a high vaccine hesitancy.

**Materials/methods:** We performed a prospective cohort study in a French university during a MO. The 13/05/19 a measles case occurred in the University of Caen. Informations about the disease and a recommendation to check vaccination was sent by mail to all students, apprentices and university staff, and broadcasted on video screens. The 27/05/19 a second case occurred; leading to an oral presentation by an infectious disease specialist. The 28/05/19 a medical consultation was proposed to all university members to up-to-date MMR vaccination according to their vaccination notebook. They were then proposed to complete a questionnaire to assess their perception of the information and of the vaccination. A logistic regression was performed to identify the factors that influence their willingness to accept a MMR vaccine and factors associated to a positive perception of global vaccination (coted >6 on a scale of 0 to 10).

**Results:** Out of 331 university members, 268 (81%) were included. Immunization was demonstrated in 81%, negative in 14% and doubtful in 5%, 13% received immediate vaccine shot. 184/268 (69%) answered the questionnaire: 148 (65%) students, 17 (33%) apprentices and 19 (33%) staff. 63% were men, mean age was 22.5 years. Mean VP before the outbreak was of 7.9 and increased to 8.5 after the intervention, 37% of participants with negative perception before outbreak changed their perception positively. 87% accepted vaccination if needed, 91% of students, 63% of apprentices and 69% of staff.

In multivariate analysis: acceptance of MMR vaccination was correlated to the global VP (OR=1.5, IC95% 1.2-2.0), it was lower for apprentice and staff members compared to students [respectively, OR=0.13; IC95% 0.02-0.78 and OR= 0.14; IC95% 0.03-0.63]. The positive perception of vaccination after the MO was proportional to the level of understanding of the presentation (OR=1.7; IC95% 1.2-2.4).

**Conclusions:** A rapid human intervention seems efficient for vaccine implementation and improvement of vaccine perception during MO, with focus on staff and apprentices.

Abstract 2284

**Temporal acquisition of IS1548 in Streptococcus agalactiae clonal complexes**
Sarah Khazaal*1,2, Rim Al Safadi2, Dani Osman2, Aurélia Hiron1, Philippe Gilot1

1University of Tours, University of Tours/ INRA, ISP, Bactéries et Risque Materno-Foetal, Tours, France, 2Lebanese University, Tripoli, Lebanon

**Background:** Insertion sequences (ISs) play a critical role in the evolution and the plasticity of *Streptococcus agalactiae* genomes. Fourteen different ISs were identified in this species. Among them, IS1548 was found to be linked with strains of clonal complex (CC) 19, associated with neonatal meningitis and endocarditis. Thereby, IS1548 was proposed to serve as a marker of this lineage. In this work, we took advantage of the release of the genome sequences of a huge number of epidemiologically unrelated *S. agalactiae* strains of various origins to better understand the prevalence and the temporal acquisition of IS1548 in *S. agalactiae* strains.

**Materials/methods:** To identify strains with an IS1548 genomic insertion, nine hundred and eleven *S. agalactiae* genomes, available as whole genome contigs or as complete genome sequences at the NCBI database, were blasted with the IS1548 complete DNA sequence of strain Mc1. A sequence type (ST), based on the allelic profile of seven housekeeping genes, was assigned to each strain possessing IS1548 by submitting the complete genome sequence or all of the contigs sequences of each strain to the *S. agalactiae* MLST databases. Strains were then grouped into clonal complexes (CCs) with the eBURST software.

**Results:** One hundred and twenty-two of the analyzed strains (13.3 % of the strains) possess IS1548 in their genome. These strains belong to twenty-nine different STs and to ten CCs. The majority of them were clustered within ST19 (55.3% of the strains) and ST22 (15.5% of the strains), belonging to CC19 and CC22, respectively. The fact that strains possessing IS1548 are not in equivalent proportion in each of the identified STs suggests that IS1548 was not acquired by a common ancestor of the main clonal complexes of *S. agalactiae*, but that independent integration occurred firstly in CC19, then in CC22 and later in the eighth other CCs. This hypothesis is strengthened by the finding that the average number of IS1548 insertion sites is twelve in CC19 strains, whereas it is eight and six in CC22 and CC10 strains, respectively.

**Conclusions:** IS1548 is expanding from CC19 to other lineages of *S. agalactiae*.

Abstract 2286

**Destruction of Staphylococcus aureus biofilm matrix by innovative combination therapies between antibiotic and non-antibiotic substances**

Jingjing Liu*, Alain Bousquet-Melou†, Jean-Yves Madec‡, Marisa Haenni§, Aude Ferran¶

1 Université Toulouse III - Paul Sabatier, INTHERES, Université de Toulouse, INRA, Toulouse, France, 2 Université Toulouse III - Paul Sabatier, ENVT, INTHERES, Université de Toulouse, INRA, Toulouse, France, §Anses site de Lyon Unité Antibiorésistance et Virulence Bactériennes, Anses site de Lyon Unité Antibiorésistance et Virulence Bactériennes, Lyon, France

**Background:** Staphylococcus aureus forms biofilms in which bacteria are embedded in a matrix of extracellular polymeric substances (EPS). Due to the tolerance of biofilms to many antimicrobial drugs, we aimed at selecting innovative therapies on clinical S. aureus isolates leading to EPS destruction and to biofilm bacteria detachment.

**Materials/methods:** A collection of 14 MSSA and 10 MRSA originating from bovine mastitis were selected from 73 isolates based on the biofilm mass (OD value) and cultured in BHI (1% glucose). Ca2+ and subtilisin A selected from 8 non-antibiotics (proteinase K, Subtilisin A, DNase I, lactorrefin, EDTA, Phyto sphingosine, Chlorhexidine, and Calcium gluconate), as well as eight antibiotics, were tested on 24h mature biofilm of each isolate. The OD value and the detachment of biofilm bacteria after treatments were assessed after crystal violet staining and by bacteria counting, respectively.

**Results:** According to the OD values obtained from 73 isolates, the bacteria were classified into three levels (low, medium or high) of biofilm mass. A minimal decrease of OD values was observed after antibiotic monotherapies, whereas Ca2+ (1.25 mMol/mL) and subtilisin A (0.01U/mL) led to most effectively and significantly decline of the OD values in 2 1/24 isolates. Based on their MIC and MBC, Ca2+ (11.2.5mMol/mL) and subtilisin A (0.05U/mL) had no killing effect on the 24 isolates and the counting of biofilm bacteria shown no significant detachment effect. However, when Ca2+ or subtilisin A were combined with oxytetracycline (10 μg/mL), the detachment effect of biofilm bacteria was significantly enhanced.

**Conclusions:** Since Ca2+ and subtilisin A have no killing effect and no significant effect of detachment on biofilm bacteria, the low OD values obtained after both monotherapies suggest a destruction of EPS. In addition, we first demonstrated that the combination of oxytetracycline with Ca2+ or subtilisin A produced synergistic effects on biofilm bacterial detachment. The effect of two combinations is currently being evaluated by confocal laser scanning microscopy and studied in a dynamic system.

Abstract 2289

**Increasingly limited options for the treatment of enteric fever in travelers returning to England, 2014-2017**

Michael Trent Herdman*, Basel Karo1, Jayshree Dave1, Parisha Katwa1, Joanne Freedman1,2; Gauri Godbole1, Sooria Balasegaram1

**Abstract third-party references:** Public Health England

**Background:** Enteric fever (caused by *Salmonella enterica* serovar Typhi or Paratyphi) frequently presents as an acute, febrile illness in returning travellers, requiring timely empirical antibiotics. More than 90% of enteric fever in England occurs in travellers returning from South Asia. Characterising risks of antibiotic resistance associated with travel destination helps guide treatment.

**Materials/methods:** All English isolates of *S*. *Typhi* and *S*. *Paratyphi* between 2014-2017 underwent antimicrobial susceptibility testing; results were compared to a previous survey in London 2005-2012 by chi-squared test. Risk factors for antimicrobial resistance were analysed for each organism, constructing a stepwise, subtractive multivariate logistic regression model to predict adjusted odds ratios (aOR) for resistance to individual antibiotics and multi-drug resistance.

**Results:** We identified 584 isolates of *S*. *Typhi*, 442 *S*. *Paratyphi A*, 56 *S*. *Paratyphi B*, and one *S*. *Paratyphi C*. Overall, 87% of *S*. *Typhi* and 97% of *S*. *Paratyphi* isolates were resistant to ciprofloxacin; 21% of *S*. *Typhi* were resistant to ciprofloxacin, amoxicillin, co-trimoxazole, and chloramphenicol (MDR4). No isolate was resistant to azithromycin; a single *S*. *Paratyphi A* isolate was resistant to azithromycin; a single *S*. *Paratyphi A* isolate was resistant to third-generation cephalosporins. Comparison with the previous survey (Figure 1) indicates substantial increases in resistance of *S*. *Typhi* isolates to ciprofloxacin among travellers to Pakistan (from 79% to 98% resistant; P<0.001) and Africa (from 12% to 63% resistant; P<0.001). For *S*. *Typhi* isolates, resistance to ciprofloxacin was associated with travel to Pakistan (aOR 27.6, 95%CI: 9.2-83.0), India (aOR 5.3, 95%CI: 2.8-9.9), and Bangladesh (aOR 3.2, 95%CI: 1.3-8.3) compared to travel elsewhere. After adjustment for confounding by sex, MDR4 multi-drug resistance in *S*. *Typhi* isolates was associated with travel to Pakistan (aOR 3.1, 95%CI: 1.8-5.4) and less likely with travel to India (aOR 0.15, 95%CI: 0.07-0.33) compared with other travel areas.

**Conclusions:** Third-generation cephalosporins and azithromycin remain appropriate choices for empirical treatment of enteric fever in returning travellers. Prescribing guidelines should reflect high rates of ciprofloxacin resistance for travellers from South Asia and Africa and potential multi-drug resistance in travellers to Pakistan. Results will be reflected in forthcoming national treatment guidelines.

Abstract 2291

**Rapid molecular screening for vancomycin-resistant Enterococcus faecium (VRE) allows to expedite evaluation of VRE-exposed patients and is cost saving**

Andrea Büchler*1, Silvio Ragozzino1, Daniel Goldenberger1, Melanie Wicki1, Adrian Egli1,3, Andreas F. Widmer1

1University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland, 2University Hospital Basel, Clinical Bacteriology and Mycology, Basel, Switzerland, 3University of Basel, Applied Microbiology Research, Department of Biomedicine, Basel, Switzerland

**Background:** Outbreaks of Vancomycin-resistant E. faecium (VRE) are an emerging problem. The SwissNoso national guideline recommends to contact-isolate VRE-colonized patients, as well as those after VRE-exposure. Preemptive contact isolation often leads to lack of rooms and adds to cost. Culture-based screening may take up to 4 days to determine the VRE status and three weekly negative screenings are recommended before termination of contact isolation. Our study aimed to shorten the clinical turn-around-time using molecular testing and to estimate the saving costs of the shortened contact isolation.

**Materials/methods:** During two outbreaks with VRE vanB and vanA in 2019, we prospectively evaluated a subgroup of patients exposed to VRE-colonized patients with molecular screening. We used Xpert vanA/vanB (Cepheid) 24h after enrichment in broth medium (bioMérieux) in comparison to a full culture-based detection algorithm consisting of first broth enrichment, followed by 48h subculture on selective plates (bioMérieux) as current internal standard. Preemptive contact precautions were lifted after a first negative PCR result, but we continued culture-based screening for VRE by three rectal swabs. The primary outcome variable was the number of pre-emptive contact isolation days with cultures compared to PCR.

**Results:** Index patient samples were used to validate the PCR-based screening method. All index patients could be detected. A total of 848 contact patients at risk were identified. Of those, we performed in 111 patients the Xpert vanA/vanB PCR. 107 of 111 patients were screened negative by PCR and all of those had negative follow-up cultures saving a total of 639 isolation days. The saving costs were estimated 93,000 Euros calculated on a 145 Euros saving per isolation day. Four PCRs showed vanB, which were later confirmed to be false positive, since follow-up cultures remained negative.

**Conclusions:** A negative PCR can reliably identify patients without VRE colonization. The implementation of the procedure based on PCR and the linked reduction of isolation days leads to high cost savings. Our study is limited by the fact that no real transmission occurred and the sensitivity assay could not be extensively analysed. Nevertheless, we recommend the fast procedure with a molecular method for lifting of contact precautions.

Abstract 2295

Epidemiological, clinical and prognostic comparison of Gram-positive cocci (GPC) and Gram-negative bacilli (GNB) in native bone and joint infections (BJI): a multi-centre retrospective study of 538 patients

Marie Beaufrere1*, Gilles Avenel1, Elise Fiaux1, Vero Rasoldier1, Olivier Vittecoq3, Christian Marcelli3, Aurelie Baldoli4, Jocelyn Michon4

1Hospital Center University Of Caen Normandie, Department of Rheumatology, Caen, France, 2CHU-Hospitals of Rouen -ERFPS, Department of Rheumatology, Rouen, France, 3CHU-Hospitals of Rouen -ERFPS, Department of Infectious diseases, Rouen, France, 4Hospital Center University Of Caen Normandie, Department of Infectious diseases, Caen, France

**Background:** The majority of BJI are due to GPC, while GNB are responsible of less than 15%. The aim of this study was to compare these BJI from an epidemiological, clinical and prognostic point of view.

**Materials/methods:** We performed a multicenter, retrospective study on the patients hospitalized for a BJI in 2 tertiary hospitals between 2007 and 2017. Inclusion criteria were: more than 18 years old, native BJI, positive microbiological culture on blood, synovial fluid or biopsy for GPC or GNB and at least one blood culture performed. Polymicrobial infections with GPC and GNB were excluded. Statistical analysis was performed using Fisher and Mann-Whitney tests.

**Results:** 538 patients met the inclusion criteria. 64% of patients presented a comorbidity with: diabetes (21%), connective tissue disease (10%), immunosuppression (9%), renal failure (11%) and liver cirrhosis (4%).

</table>

The infection developed in the limbs in 50% (knee 33%, shoulder 22%, wrist and hand 12%, hip 11%), and in the spine in 57% (lumbar 64%, thoracic 26%, cervical 14%). Multifocal infections (20%) were more frequent in the GPC group [23 vs 7% p=0.02]. The joint puncture culture was positive in 55%. Bacteria identified in the GPC group were: *Staphylococcus* (56%), *Staphylococcus aureus* (47%), Coagulase negative staphylococci (8%), *Streptococcus* (27%), *Streptococcus pneumoniae* (5%), *Enterococcus spp* (4%). In the GNB group we identified: *Escherichia coli* (52%), *Pseudomonas aeruginosa* (18%), other enterobacteriae (11%), and other GNB (19%).

In multivariate analysis parameters associated to a GNB BJI were: monoarticular involvement (OR=3.02; IC95% 1.14-8), polymicrobial infection (OR=5.15; IC 95% 1.41-18) and older age (OR=2.59; IC95% 1.48-4.5). The parameters associated with a GPC BJI were: bacteriemia (OR=1.86; IC95% 1.07-3.2), and higher level of C-reactive protein (OR=2.43; IC95% 1.2-4.7).

**Conclusions:** This large retrospective cohort permits to identify the characteristics of GNB BJI and to compare them to GPC BJI. The GNB BJI symptomatology differs (less fever) and occurs in older patients, but no differences in mortality or management were observed.

Abstract 2297

Genetic diversity evident from comparative genome analysis of ESBL-producing Escherichia coli isolated from swine microbiomes in Cameroon and South Africa

Luria Leslie Njoungang Yontchoung Epse Founou*, Raspail Carrel Founou Zangue1;2, Sabiha Y. Essack2

1Centre of Expertise and Biological Diagnostic of Cameroon, Yaounde, Cameroon, 2University of KwaZulu-Natal, Antimicrobial Research Unit, College of Health Sciences, Durban, South Africa

Abstract third-party references: College of Health Sciences UKZN, Supported by the National Research Foundation, Supported by South African Medical Research Council

Background: In a multicentre comparative study conducted in pig abattoirs in Cameroon and South Africa, extended spectrum beta-lactamase producing Enterobacterales (ESBL-PE) were screened from pooled nasal and rectal samples of 432 pigs and nasal and hand swabs of 82 humans. An overall high ESBL-PE prevalence (>70%) was observed in both sample types. Of the total of 162 Enterobacterales isolates, 11 phenotypic ESBL-producing E. coli isolates and clonally related were selected for whole genome sequencing (WGS). The purpose of this study was to characterize the resistome, virulome, mobilome and phylogenetic diversity of these presumptive and clonally related ESBL-producing E. coli using WGS.

Materials/methods: The E. coli isolates were de novo assembled using the Qiagen CLC Genomics Workbench and SPAdes. The assembled contigs were annotated using RAST and PROKKA. Prediction of antibiotic resistance genes, virulence factors, plasmids, bacteriophages, and CRISP/Cas system was performed using ResFinder, VirulenceFinder and PlasmidFinder, PHASTER and CRISP/CasFinder, respectively. Enterobase server (http://enterobase.warwick.ac.uk/species/ecoli) was used for serotypes, phylogroups, fimH and multilocus sequence types (STs) prediction.

Results: Diverse STs were detected within the circulating E. coli isolates but sequence type (ST) 2144 and 88 dominated. blaAmpC (73%), blaCTX-M-15 (55%) and blaTEM-1B (45%) were the most common β-lactamase genes identified. Additionally, several genes encoding for resistance to aminoglycosides, phenicols, fosfomycin, fluoroquinolones and polymyxins were identified, the latter including the mcr-1 gene. The isolates were assigned to phylogroups A/B1 (45/28.3%), C/D (18.18/9.09%). The serotype O-:H49 (18.18%), O-:H9 (18.18%), O-:H18 (18.18%) were the principal serotypes detected while the fimH1250 (18.18%) and fimH89 (18.18%) were the predominant fimH gene observed. At least one (100%) and up to nine virulence factors (27.27%) were detected in the isolates. Forty-five percent of the isolates harboured IncFIB and IncY plasmid incompatibility groups, while IncX (18.18%) and IncHI2 (27.27%) were also detected.

Conclusions: This Sub-Saharan multicentre survey shows that the gut microbiota of swine is colonized by ESBL-producing E. coli predominantly CTX-M-15. Although the phylogenetic diversity observed precludes any suggestion for clonal dissemination, the resistance and high pathogenicity potential demonstrate the urgent need to implement effective strategies to contain the dissemination of antibiotic resistant bacteria in Cameroon and South Africa.

Too much of a good thing? Evaluation of respiratory viral panel usage in paediatric bone marrow transplant patients

Mimi Precit\textsuperscript{1,2}, Marisa Glucoft\textsuperscript{1}, Kanokporn Mongkolrattanothai\textsuperscript{1}, Jennifer Dien Bard\textsuperscript{1,2}

\textsuperscript{1}Children’s Hospital of Los Angeles, Los Angeles, United States, \textsuperscript{2}University of Southern California, Los Angeles, United States

Background: Viral upper respiratory tract infections (URIs) are a significant cause of morbidity in pediatric bone marrow transplant (BMT) patients. The speed and increased sensitivity of the FilmArray Respiratory Viral Panel (FA-RVP) is valuable but may prompt inappropriate testing. We investigated FA-RVP usage, test outcomes, and clinical response in our pediatric BMT population to determine whether implementation of testing restrictions are warranted.

Materials/methods: Retrospective data was collected for 682 respiratory specimens tested by FA-RVP from 214 unique BMT patients between 01/01/2016–01/01/2019. Information including age, underlying conditions, and frequency of FA-RVP testing were recorded. Data on patients with multiple specimens tested within a 14-day period were also examined to determine consistency of target detection, the presence of URI symptoms, and modifications in management.

Results: 312/682 (45.8\%) specimens were positive by FA-RVP. Detection of rhinovirus/enterovirus (179, 57.3\%) was most common, followed by coronaviruses (40, 12.8\%), parainfluenza (33, 10.6\%), and respiratory syncytial virus (19, 6.1\%). 66 patients had multiple specimens tested within a 14-day period, consisting of 105 repeat tests on 195 total specimens; of these, the same target was detected in 79 (75.3\%) cases. In contrast, 26 (24.7\%) patients with additional specimens tested yielded a different result: 13 (6.7\%) positive patients became negative and 13 (6.7\%) negative patients became positive. In the negative to positive group, the most common target detected was rhinovirus/enterovirus and only five patients were symptomatic during original test and retest. 27\% (53/195) of specimens were collected from asymptomatic patients, of these four cases of rhinovirus/enterovirus were detected. FA-RVP result informed addition of antiviral agents. No de-escalation of antimicrobial therapy was observed regardless of FA-RVP result. Influenza detected in one patient prompted chemotherapy suspension and there were no recorded instances in which FA-RVP results delayed BMT.

Conclusions: There is a high incidence of inappropriate FA-RVP testing in asymptomatic BMT patients and results seldom influence patient management. Moreover, testing of additional specimens over a 14-day period infrequently provides useful information. These findings support implementing diagnostic stewardship measures including potentially limiting repeat testing within a 14-day period without negatively affecting patient outcome.

Abstract 2299

Characterisation of the vaginal DNA virome in health and dysbiosis: an opening study in patients with non-female factor infertility

Thor Haahr1, Rasmus Riemer2, Dennis Sandris Nielsen2, Thomas Leser3, Witold Kot4, Josue Castro2, Peter Humaidan1, Jorgen Skov Jensen*5

1Aarhus University, Skive, Denmark, 2University of Copenhagen, Copenhagen, Denmark, 3Christian Hansen A/S, Hørsholm, Denmark, 4Aarhus University, Risa, Roskilde, Denmark, 5Statens Serum Institut, København, Denmark

Background: Bacterial vaginosis (BV) is characterised by a reduction in the abundance of Lactobacillus spp. and a subsequent increase in the abundance of facultative anaerobes, such as Gardnerella vaginalis. Despite recent advances, the BV aetiology is not fully understood, but bacteriophages could play a pivotal role during perturbations of the vaginal bacterial community. Here we investigate the viral community of the vagina, including bacteriophages, and its association to the bacterial community.

Materials/methods: Vaginal samples collected in Eswab (Copan™) from 48 patients undergoing IVF treatment for non-female factor infertility were subjected to metagenomic sequencing of purified virus-like particles. The overall composition of the vaginal viral community was characterized and correlated with bacterial vaginosis (BV) status (Nugent score), bacterial community by 16S rRNA sequencing and presence/absence of key vaginal bacterial species by qPCR. Correlation between bacterial and viral abundance was performed using the mixOmics R package with CSS-normalized OTU-tables.

Results: A total of 773 viral vOTUs were retained after de novo assembly and filtering, sized from 3 to 85 kb with a median of 7.5 kb in length. The majority of identified vaginal viruses belonged to the class of double-stranded DNA bacteriophages, with eukaryotic viruses constituting 4% of total reads. Clear links between viral community composition and BV (q = 0.006, R = 0.26) as well as presence/absence of qPCR L. crispatus (q = 0.001, R = 0.43), L. iners, Gardnerella vaginalis and Atopobium vaginae were found (q < 0.002, R > 0.15). Interestingly, also the eukaryotic viral community was significantly correlated with BV-status (q = 0.018, R = 0.20).

Conclusions: This study provides the first in-depth characterization of the vaginal DNA virome based on virus like particle purification followed by metagenomic sequencing and de-novo assembly. We found that the composition of both the prokaryotic and the eukaryotic viral communities varied strongly between BV-negative and BV-positive samples. Further, clear co-abundance patterns between certain bacteria and vOTUs indicate that these two components of the vaginal microbiome are strongly interlinked. Interestingly, the eukaryotic viral component differed significantly between BV-positive and negative samples although these viruses are not directly interacting with the bacterial community.

Abstract 2300

**Multi-centre evaluation of cephalexin MIC results for Enterobacterales using EUCAST breakpoints on MicroScan dried Gram-negative MIC panels**

Omai Garner¹, Christopher L. Emery², Amanda Harrington³, Sharon Desjarlais¹, Christine Hastey⁴, Regina Brookman⁴, Zabrina C. Lockett⁴, Jennifer Chau*⁴

¹UCLA David Geffen School of Medicine, Los Angeles, United States, ²Indiana University School of Medicine, Indianapolis, United States, ³Loyola University Medical Center, Maywood, United States, ⁴Beckman Coulter Inc, West Sacramento, United States

**Background:** A multicenter study was performed to evaluate the accuracy of cephalexin on a MicroScan Dried Gram-negative MIC (MSDGN) Panel when compared to a frozen ISO/CLSI broth microdilution reference panel.

**Materials/methods:** An evaluation was conducted at three U.S. sites by comparing MIC values obtained using the MSDGN to MICs utilizing an ISO/CLSI broth microdilution reference panel. A total of 450 Enterobacterales clinical isolates were tested using the turbidity and Prompt® methods of inoculation during the efficacy phase. A subset of 12 organisms was tested on MSDGN panels at each site during reproducibility. MSDGN panels were incubated at 35 ± 1°C and read on the WalkAway System, the autoSCAN-4 instrument, and read visually. Read times for the MSDGN panels were at 16-20 hours. Frozen reference panels were prepared according to ISO/CLSI methodology, incubated for 16-20 hours and read visually. All frozen reference panels were incubated at 35 ± 2°C for 16-20 hours and read visually. EUCAST breakpoints (mg/L) used for interpretation of MIC results were: Enterobacterales ≤ 16 S, > 16 R.

**Results:** Essential and categorical agreement when compared to frozen reference panel results, for all isolates tested in efficacy as follows:

<table>
<thead>
<tr>
<th>Read Method</th>
<th>Essential Agreement %</th>
<th>Categorical Agreement %</th>
<th>Very Major Error (VMJ)* %</th>
<th>Major Error (MAJ)* %</th>

Abstract 2301

**Multiplex PCR for the detection of traveller’s diarrhoea: a nested case-control study**

Frieder Schaumburg*, Carlos Correa-Martinez†, Silke Niemann‡, Robin Köck§, Karsten Becker

*Universitätsmedizin Greifswald, Friedrich Loeffler-Institut für Medizinische Mikrobiologie, Greifswald, Germany, †University Hospital Münster, Institute of Medical Microbiology, Münster, Germany, ‡Münster, Institute for Hygiene, Münster, Germany, §DRK Krankenhaus Berlin, Berlin, Germany

**Background:** Traveler’s diarrhea (TD) can cause high morbidity among travelers. Multiplex methods have been developed recently for the molecular detection of causative agents of TD. However, these approaches are not yet sufficiently validated. The aim of this study was to test a multiplex-PCR approach in patients with TD and asymptomatic controls.

**Materials/methods:** A total of 91 travelers (61 TD cases, 30 asymptomatic controls) prospectively collected stool samples during travel and documented gastrointestinal symptoms. Samples were analysed using the BioFire® FilmArray® Gastrointestinal Panel, which covers 13 enteric bacteria (e.g. diarrheagenic Escherichia coli), four protozoan parasites (*Cryptosporidium* spp., *Cyclospora cayetanensis*, *Entamoeba histolytica*, *Giardia lamblia*) and five viruses (adenovirus, astrovirus, norovirus, rotavirus, sapovirus).

**Results:** TD cases had more likely a positive test compared to controls (75 vs. 57%, p=0.07). The most common enteric pathogens were enteroaggregative *E. coli* (36/91, 40%), followed by enterotoxigenic *E. coli* (31/91, 34%) and enteropathogenic *E. coli* (EPEC, 29/91, 32%). The only pathogens significantly associated with TD were EPEC (p=0.01) and ETEC (p=0.047). Others were detected both in TD cases and asymptomatic controls without a clear association with disease. Protozoan parasites were not detected.

**Conclusions:** The results challenge the use of multiplex-approaches covering numerous enteric pathogens in the diagnostic workup of TD because only few (i.e. diarrheagenic *E. coli*) were related to symptoms of TD.

Visual antibiogram of *Staphylococcus aureus* using machine learning demonstrates multidrug resistance as associations between individual antimicrobials

Casey Cazer*1, Lars Westblade1,2, Matthew Simon1, Reed Magleby3, Mariana Castanheira4, Stephen Jenkins2,3, Yrjo Grohn1

1Cornell University College of Veterinary Medicine, Department of Population Medicine & Diagnostic Sciences, Ithaca, United States, 2Weill Cornell Medicine, Department of Pathology and Laboratory Medicine, New York, United States, 3Weill Cornell Medicine, Division of Infectious Diseases, Department of Medicine, New York, United States, 4JMI Laboratories, North Liberty, United States

**Background:** Phenotypic antimicrobial susceptibility testing (AST) data, generated in clinical settings, can be used as surveillance for co-antimicrobial resistance or cross-resistance that could lead to co-selection of antimicrobial resistance; i.e., the use of one antimicrobial selects for resistance to multiple antimicrobials. We created an antibiogram using association mining, an unsupervised machine learning method, to identify and measure high-order relationships between antimicrobial resistance in *Staphylococcus aureus*.

**Materials/methods:** We examined 1,091 isolates collected from one New York hospital between 2008 and 2018 and performed AST using reference broth microdilution. Methicillin-resistant *S. aureus* (MRSA) and methicillin-susceptible *S. aureus* (MSSA) isolates were examined separately. The Apriori algorithm was used to identify patterns of antimicrobial resistance that occurred in at least one isolate. We only included patterns that were unlikely to occur due to random chance by using the expected cross-support ratio (P value < 0.05 in simulation study) and conditional lift (bootstrap 95 percentile interval excluding the null value of 1).

**Results:** Overall, 39% of isolates were MRSA and 39.5% of all isolates were MDR (resistant to ≥3 antimicrobial classes). There were more non-MDR MRSA isolates than expected if all the antimicrobial resistances were independent. Resistance associations were visualized by connecting all antimicrobials in each pattern and overlaying them, revealing distinct subnetworks of resistance associations at the antimicrobial class level (Figure 1). The MRSA sub-networks are connected through β-lactam resistance although different β-lactams are involved in each subnetwork: ceftaroline resistance is associated with aminoglycoside, tetracycline and sulfonamide resistance; whereas penicillin and ertapenem resistance are associated with fluoroquinolone resistance.

**Conclusions:** The antibiogram suggests a potential for co-selection of ceftaroline resistance with tetracycline or sulfonamide treatment, although antimicrobial use data was unavailable to confirm this hypothesis. MRSA and MSSA isolates demonstrated dissimilar antimicrobial resistance associations, suggesting different co-resistance mechanisms. An antibiogram created with association mining can uncover clinically-relevant antimicrobial resistance patterns.

**Figure 1:** Resistance patterns decomposed into nodes (antimicrobials) connected by edges (e.g. pattern {A,B,C} decomposes into A—B, B—C, A—C). Darker edges, stronger association; thicker edges, more frequent pattern. Node pie chart represents resistance prevalence: color, non-susceptible; gray, susceptible; white, not-tested.

**Luminogenic phosphatase substrate for rapid susceptibility testing of Gram-positive strains**

Valérie Chalansonnet*1, Florian Macé1, Sylvain Orenga1

1bioMérieux, La Balme Les Grottes, France

**Background:** Antibiotic susceptibility testing (AST) using fluorogenic and colorimetric reporters are well-established methods. Despite the superior sensitivity of luminescence, AST based on bioluminescence remains unexploited due to the need for addition of reagents addition and its limitations with respect to end-point analysis. Chemiluminescence detection is limited by the lack of stable luminogenic substrates compatible with microorganisms in an aqueous medium. The AquaSpark™ substrates recently commercialized by BIOSYNTH are claimed to fulfill these criteria. We evaluated a luminogenic substrate of this range for AST. The study was focused on the AST of Gram positive bacteria using the broad range phosphatase substrate.

**Materials/methods:** 40 strains (30 staphylococci and 10 enterococci) were tested by broth microdilution with 10µM of broad range phosphatase substrate [BIOSYNTH]. Cefoxitin, ciprofloxacin, erythromycin, gentamicin, levofloxacin, tetracycline and vancomycin were tested with appropriate strains. Medium, inoculum and antibiotic dilutions were based on CLSI standard M07 method. Incubation at 35°C, absorbance (OD660nm) and luminescence (LUM) measurements were performed using a micro-plate reader (TECAN). Kinetics of OD660nm and LUM signals were compared to the MIC obtained visually.

**Results:** LUM and OD660nm signals were correlated at 96% [16/16 antibiotic/strain tests for enterococci; 57/60 for staphylococci]. All discordances were observed in presence of ciprofloxacin: no luminescence was detected while growth of resistant strains was obvious at high concentrations [above 8 mg/L].

For rapid MIC determination, analysis criteria were calculated for both OD660nm and LUM. Average time gain using LUM was 415 minutes for enterococci and 290 minutes for staphylococci. Application of these criteria led to 3 major errors for LUM [previous discordances with ciprofloxacin] and 4 very major errors [VME] for both OD660nm and LUM when comparing to the MIC obtained visually. VME were obtained for vancomycin and could be resolved by modifying the interpretation criteria for this drug.

**Conclusions:** AquaSpark™ broad range phosphatase substrate can be used for chemiluminescence detection in kinetics in the presence of antibiotics and bacterial strains. LUM signal correlates to growth detection and can predict MIC with confidence. Its optimized use for AST requires definition of interpretation criteria which is challenging due to the diversity of resistance mechanisms.

Impact of respiratory panel PCR assay on antibiotic use in patients with community-acquired pneumonia admitted to intensive care unit

Antoine Hamon*1, Xavier Repessé2, Marie-Anne Welti1, Guillaume Geri1, Clara Duran1, Antoine Vieillard Baron1, Elsa Salomon1, Elyanne Gault1, Aurélien Dinh1

1Hôpital Ambroise Paré, 92100, France

Background: Community-acquired pneumonias (CAP) hospitalized in intensive care units (ICU) are a common cause of antibiotic prescriptions. The recent availability of respiratory multiplex PCR assays, that identify a panel of viral and intracellular pathogens in less than 2 hours, could be a useful tool for antimicrobial stewardship and thus optimize and reduce antibiotic consumption. Nevertheless, data concerning the real-life impact of those tools are lacking.

Materials/methods: We performed a monocentric retrospective study including all patients admitted to the ICU for a CAP with a positive FilmArray® respiratory panel, from September 2018 to July 2019. This test detects 15 virus and 4 bacteria (Mycoplasma pneumoniae, Chlamydia pneumoniae, Bordetella pertussis, Bordetella parapertussis). Definition of CAP for inclusion in this study was: at least one respiratory clinical symptom and temperature ≥38 or <36°C or leucocyte ≥10 or <4 G/L and radiological image compatible with CAP. All medical charts were reviewed by 2 infectious-disease specialists and 1 intensive care specialist.

Results: During the period study, 70 respiratory multiplex PCR assays were performed among patients hospitalized in the intensive care unit, 33 were excluded because they did not meet inclusion criteria. Among the 37 patients included, sex ratio was 0.46 and mean age was 69.9. The mean IGS II score was 43 (median: 41, IQR: 13) and the mean Fine score was 125 (median: 122, IQR: 73). Thirty-five PCR test results (94.6%) were positive for viral agents (15 influenza viruses, 2 respiratory syncytial viruses and 22 other viruses) and 2 for Mycoplasma pneumoniae. Regarding usual bacterial respiratory samples, 26/37 (70.3%) cultures were positive for bacteria. Modification of the antibiotic treatment was assessed for the 2 cases with a PCR positive for Mycoplasma. For every other patient (n=35), antibiotherapy was not modified, even for patients with no microbiological identification of bacterial infection (n=9).

Conclusions: In our experience, the impact of respiratory PCR assays on antibiotic use in patients hospitalized for CAP in ICU is weak. Only flu and intra cellular bacteria detection seem useful for patient management. Cost effective study should evaluate more precisely the interest of those tests.

Abstract third-party references: Supported by Pfizer, On behalf of Katalin Kristóf

Background: Ceftazidime-avibactam is a cephalosporin/beta-lactamase inhibitor combination for use in Gram-negative infections. The ATLAS study compares its in vitro activity with comparator agents.

Materials/methods: In vitro antimicrobial susceptibility of Gram-negative isolates collected during 2018 from 28 sites in 9 countries (Croatia, Czech Republic, Hungary, Israel, Poland, Romania, Ukraine, and Latvia/Lithuania combined) was determined using CLSI broth microdilution methodology and EUCAST 2019 breakpoints. Ceftazidime-avibactam was tested with a fixed concentration of 4 mg/L avibactam.

Results: The table shows the in vitro activity of ceftazidime-avibactam and comparators for isolates across all countries.

*Excludes Morganella, Proteus, Providencia and Serratia spp. due to intrinsic colistin resistance.

Susceptibility among Enterobacterales was highest to ceftazidime-avibactam, followed by colistin, meropenem, and amikacin. For Klebsiella pneumoniae (N=607) and E. coli (N=713), susceptibility rates were high to ceftazidime-avibactam (98.5%, 99.3%) and colistin (94.9%, 99.7%). Colistin was the most active agent for P. aeruginosa [see Table].

Susceptibility of Enterobacterales isolates in each country was ≥94.9% to ceftazidime-avibactam and ≥94.7% to colistin [excluding intrinsically-resistant organisms]. Among K. pneumoniae, ceftazidime-avibactam and colistin susceptibility was ≥93.7% and ≥84.0%, respectively, in all countries, including Ukraine (N=50), which had the lowest susceptibilities to amikacin (64.0%) and meropenem (66.0%). Among P. aeruginosa, ceftazidime-avibactam susceptibility was >90% in 5 countries, and susceptibility to all agents except colistin (100%) was lowest in Ukraine (N=53).

Conclusions: Ceftazidime-avibactam demonstrated potent in vitro activity against Enterobacterales and P. aeruginosa isolates collected from each of 8 countries in Central Europe and Israel.

Abstract 2309

Microbiology and molecular characterisation of Enterobacterales from children enrolled in global, prospective, controlled paediatric clinical trials for complicated intra-abdominal and urinary tract infections for ceftazidime-avibactam

Rodrigo E. Mendes1, Timothy Doyle1, Greg Stone2, Annie Gardner2, Mariana Castanheira1, John Bradley3

1 JMI Laboratories, North Liberty, United States, 2 Pfizer Inc., Groton, United States, 3 Rady Children’s Hospital/UCSD, San Diego, United States

Abstract third-party references: This study was performed by JMI Laboratories and supported by Pfizer, Inc., which included funding for services related to preparing this abstract.

Background: The efficacy, safety and tolerability of ceftazidime-avibactam (CAZ-AVI) were demonstrated in several clinical trials for adult patients. Randomized, prospective, comparative trials for complicated urinary tract infections (cUTI) and complicated intra-abdominal infections (cIAI) evaluated, respectively, CAZ-AVI and CAZ-AVI plus metronidazole for treating these infections in infants/children. This study characterized the baseline Enterobacterales recovered from the microbiological intended-to-treat (Micro-ITT) population.

Materials/methods: These single-blind, randomized, multicenter, active-controlled, studies (NCT02497781 and NCT02475733) were conducted to evaluate the safety, tolerability, efficacy and pharmacokinetics of CAZ-AVI in children (≥3 months to <18 years) diagnosed with cIAI or cUTI, including acute pyelonephritis. Isolates were tested for susceptibility by broth microdilution. Isolates that met pre-defined MIC criteria were molecularly characterized by genome sequencing and in silico analysis.

Results: A total of 77 and 69 subjects (both study arms) were included in the Micro-ITT populations of cUTI and cIAI trials, respectively. Among these patients, 72 (5 species; 91.7% E. coli) Enterobacterales were recovered at baseline during the cUTI trial and 57 (4 species; 91.2% E. coli) baseline Enterobacterales in the cIAI trial. CAZ-AVI (Table) inhibited all cUTI Enterobacterales at ≤0.5 mg/L and cIAI isolates at ≤0.25 mg/L. Four (5.6%) baseline cUTI E. coli from Taiwan (2), Turkey (1) and Czech Republic (1) met the MIC screening criteria and carried bblaCTX-M-15 or bblaCMY-2, except for 1 isolate that had high transcriptional levels of bblaTEM-1 based on promoter configurations (called Pa/Pb). This latter isolate had low MICs for extended-spectrum β-lactams, but met the screening criteria due to a ceftazidime MIC of 2 mg/L. Three (5.3%) baseline cIAI E. coli from Turkey (2) and Taiwan (1) met the MIC screening criteria and carried bblaCTX-M-15, bblaCMY-2 or bblaDH A-1. These 7 isolates belonged to distinct MLST types, including 1 ST131.

Conclusions: E. coli predominated among Enterobacterales recovered from the Micro-ITT populations in the cUTI and cIAI clinical trials. CAZ-AVI (100.0% susceptible) was active against these baseline pathogens, as were comparator agents (94.4–100.0% susceptible). A small percentage (7.5%) of isolates with distinct genetic backgrounds showed non-wildtype susceptibility phenotypes and, in general cUTI isolates carried bblaTEM-1 variants, while cIAI isolates had plasmid AmpC genes.

Abstract 2310

Deciphering the biochemical features of PDC-315, a ceftolozane-hydrolyzing Pseudomonas-derived cephalosporinase selected in vivo

Jorge Arca Suárez*, Juan Vazquez-Ucha, Pablo A. Fraile Ribot, Gabriel Cabot, Cristina Lasarte, Manuel Rodriguez-Iglesias, Fatima Galan-Sanchez, Alejandro Beceiro, Antonio Oliver, Germán Bou Arevalo

1Servicio de Microbiología and Instituto de Investigación Biomédica de A Coruña, Complexo Hospitalario Universitario A Coruña, A Coruña, Spain, 2Servicio de Microbiología and Unidad de Investigación, Hospital Universitario Son Espases, Instituto de Investigación Sanitaria Illes Balears, Palma de Mallorca, Spain, 3Servicio de Microbiología and Instituto de Investigación e Innovación Biomédica de Cádiz, Hospital Universitario Puerta del Mar; Universidad de Cádiz, Cádiz, Spain

Background: Resistance to ceftolozane/tazobactam (CTZ) may occur in Pseudomonas aeruginosa through the selection of mutations in ampC. These mutants typically exhibit rearrangements on the ampC Ω loop that confer increased MICs toward CTZ and ceftazidime-avibactam (CZA), but mitigated effects over penicillins and carbapenems. However, the contribution to the substrate profile of the enzyme of specific mutations is still largely unknown. Here we aim to characterize PDC-315, a novel ampC selected during CTZ therapy which exhibited a previously undescribed D245N substitution in the Ω loop.

Materials/methods: A pair of CTZ susceptible/resistant isolates of MDR P. aeruginosa recovered before and during CTZ therapy from a patient admitted to the ICU of Puerta del Mar University Hospital (Cádiz) were evaluated. Minimum inhibitory concentrations were determined by broth microdilution. Resistance mechanisms were depicted through whole genome sequencing on an Illumina MiSeq benchtop (Illumina INC, USA). bla ampC genes from the clinical isolates were cloned in parallel into the PAO1 ampC knock-out mutant (PAODC) to evaluate the resistance profiles, and in E. coli BL21 for protein purification. Steady-state kinetics and the IC50 values were determined using a Nicolet Evolution 300 spectrophotometer (Thermo Fisher Scientific, Waltham, MA, USA).

Results: A CTZ MIC elevation from 2/4 mg/L to >32/4 mg/L was observed between the two isolates. WGS revealed oprD loss and ampC upregulation in both isolates, but the CTZ-resistant isolate additionally harbored a mutation in ampC (D245N). PAODC transformants proved that this mutation caused resistance [CTZ MIC=16 µg/mL]. Kinetic assays revealed that the new ampC variant, designated PDC-315, exhibited a Kcat/Km ratio 10-fold higher than the WT ampC for ceftolozane, but impaired hydrolysis of piperacillin and imipenem (Kcat/Km ratios of 0.3 and 0.2 compared to WT ampC, respectively). Inhibition kinetics showed that PDC-315 was efficiently overcomed by avibactam but poorly inhibited by cloxacillin compared to WT ampC (IC50 ratios of ≈1 and ≈ 318, respectively).

Conclusions: PDC-315 exhibited enhanced catalytic efficiency towards ceftolozane, impaired hydrolysis of penicillins and carbapenems, and was potently inhibited by avibactam. Thus, piperacillin/tazobactam, carbapenems and ceftazidime/avibactam may play a role in the treatment of certain strains with evolved resistance to CTZ.

Descriptive epidemiological analysis of antimicrobial resistance in strict anaerobes in Scotland, 2013-2018

Julie Wilson1, Adriana Zalewska2, Michael Lockhart*, Edward Mcardle2, William Malcolm2

1Health Protection Scotland, NHS National Services Scotland, Glasgow, United Kingdom, 2Health Protection Scotland, NHS National Services Scotland, Glasgow, United Kingdom

Background: Antimicrobial resistance in anaerobic bacteria has been recognised to be increasing globally, with growing resistance to metronidazole and carbapenems being of particular concern. Health Protection Scotland receives clinical microbiology results, including susceptibility data from all Scottish diagnostic laboratories via a national database [ECOSS].

Materials/methods: Data from 2013 to 2018 relating to strict anaerobes isolated from clinical samples was extracted from ECOSS (de-duplicated based on a 14 day episode definition). Predominant species, sample types and susceptibility to a variety of antibiotics was assessed. A literature review was conducted to compare resistance in Scottish isolates, to that reported globally.

Results: The most commonly reported organisms were Cutibacterium acnes (n = 2433), Bacterioides fragilis (n= 2253) and Clostridium perfringens (n = 2252). The most frequently associated sample type varied by species. Of the clinically relevant antibiotics, susceptibility testing was performed most commonly for metronidazole (ranging from 54-76%, depending on species). Reported resistance varied by agent and species.

Conclusions: Nationally, limited susceptibility testing is carried out for the majority of anaerobic bacteria. Where tested, resistance to most antibiotics including metronidazole was broadly comparable to that reported in the published literature, although comparatively higher resistance to clindamycin was observed for several species including C. perfringens. Work is ongoing in Scotland to improve identification of anaerobes and standardisation of susceptibility testing for isolates from sterile sites. It is anticipated that this will support more targeted treatments for individual patients and antimicrobial stewardship programmes.

Abstract 2316

**Optimisation of blood components sterility testing: impact of small volumes in analytical sensitivity**

Daria Vay¹, Franca Gotta¹, Laura Carrabba¹, Roberta Mazzeo¹, Andrea Rocchetti*¹

¹Azienda Ospedaliera SS. Antonio e Biagio e Cesare Arrigo, Alessandria, Italy, EU, Microbiology and Virology Unit, Alessandria, Italy

**Background:** sterility testing of blood components is pivotal to prevent bacterial and/or fungal transfusion-transmitted infections. This is particularly challenging for lymphocyte apheresis, hematopoietic stem cells, platelet concentrates, cord blood and serum, for which very small volumes (from 0.5 to 1 ml) are inoculated into culture bottles. Aim of this study was to find and validate the most effective and rapid method in detecting a possible contamination of blood components.

**Materials/methods:** 15 strains were used, 13 from ATCC®: *Aspergillus brasiliensis* 16404; *Aspergillus niger* 16888; *Candida albicans* 10231; *Bacillus subtilis* subsp.*spizizenii* 6633; *Bacteroides fragilis* 25285; *Campylobacter jejuni* 33560; *Clostridium sporogenes* 19404; *Cutibacterium acnes* 11827; *Haemophilus influenzae* 49247; *Neisseria gonorrhoeae* 49226; *Pseudomonas aeruginosa* 9027; *Staphylococcus aureus* subsp.* aureus* 6538; *Streptococcus pyogenes* 19615; and two strains from clinical samples: *Corynebacterium striatum*; *Micrococcus luteus*; Colonies of each strain grown on chocolate agar were resuspended in separate tubes containing sterile saline solution until a standard turbidity of 1.0 McFarland (equivalent to about 3x10⁸ CFU/ml) was obtained. From these tubes, a series of four 1:100 dilutions were made, resulting in a final concentration of ~3x10⁶ CFU/ml (3 CFU/ml) of inoculum. The final suspension was inoculated into BD Bactec plus Aerobic, Anaerobic, Pediatric and Mycosis (the latter only for *Candida albicans* and *Aspergillus* spp.), with a volume of 1 ml and 0.5 ml.

**Results:** among bottles inoculated with 1 ml: 6/15 (40%) Aerobic, 5/15 (33.3%) Anaerobic and 8/15 (53.3%) Pediatric were positive. In the 0.5 ml group: 3/15 (20%) Aerobic, 4/15 (26.6%) Anaerobic and 5/15 (33.3%) Pediatric were positive. Time to positivity: for the 1 ml group: the 6 Aerobic bottles flagged positive in a mean time of 60.1 hours with a standard deviation of ±43.1 hours; the 5 Anaerobic bottles in 58.8 ±51.9 hours; the 8 Pediatric bottles in 31.9 ±27.6 hours. For the 0.5 ml group: 81.3 ±78.4 hours for the 3 Aerobic bottles; 50.8 ±45.9 hours for the 4 Anaerobic bottles; 24.2 ±15.2 hours for the Pediatric bottles.

**Conclusions:** this study showed how the combined use of both pediatric and anaerobic bottles improves detection of possible contamination even dealing with small volumes of blood components.

Abstract 2319

The impact of consolidating molecular sexually transmitted infections screening and viral load testing on a new fully automated platform

Emily Goldstein* 1, Eileen Campbell1, Jane Stewart1, Melissa Johnson1, Rory Gunson1

1Glasgow Royal Infirmary, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom

Background: Our laboratory processes 100,000 STI screens and viral load tests (HIV-1, HBV and HCV) annually, all of which are batched and performed on the Abbott m2000 System. The Alinity m System (Abbott Molecular) is the new fully automated, random and continuous access molecular diagnostics analyser. This platform performs multiple assays in parallel, eliminating the need for sample batching, resulting in a fast turn-around-time (TAT), streamlined workflow and reduced staff requirements. This platform also offers a STAT function.

Materials/methods: To investigate the impact of workflow consolidation to a single Alinity instrument from batch testing, currently performed on four m2000 instruments, we replicated seven days of routine testing on the Alinity using archived clinical samples, comparing TAT and assay results to our current system. Testing included 162 HIV-1, 92 HBV, 240 HCV viral loads and 1608 STI tests.

Results: Consolidated testing on Alinity lead to significant savings in TAT. Results for all four assays were reported in an average of 4:12 to 4:35 hours, with all results reported within 7:45 hours of sample arrival. Samples tested using the STAT function were available within an average of 3 hours (Table 1.).

Quantified viral load results from HIV-1 (n=9), HBV (n=42) and HCV (n=51) assays tested on both platforms were highly correlated (R² = 0.981, 0.964, 0.961, respectively). PPV and NPV for Chlamydia trachomatis were 100% and 99.8% respectively, for Neisseria gonorrhoeae (NG) PPV and NPV were 73.7% and 99.9% respectively. Five samples tested NG positive by Alinity and negative by m2000, however all had low cycle numbers and two of these samples were unvalidated sample types.

**Abstract 2323**

**In vivo acquisition of oxacillinase-mediated resistance to ceftolozane/tazobactam and ceftazidime/avibactam in *Pseudomonas aeruginosa***

Jorge Arca Suárez*1, Cristina Lasarte1, Juan Vazquez-Ucha1, Inmaculada Guerrero Lozano2, Manuel Rodriguez-Iglesias2, Fatima Galan-Sanchez2, Alejandro Beceiro1, Germán Bou Arevalo1

1Servicio de Microbiología and Instituto de Investigación Biomédica A Coruña; Complexo Hospitalario Universitario A Coruña, A Coruña, Spain, 2Servicio de Microbiología and Instituto de Investigación e Innovación Biomédica de Cádiz; Hospital Universitario Puerta del Mar, Universidad de Cádiz, Cádiz, Spain

**Background:** Narrow-spectrum oxacillinases such as OXA-2 and OXA-10 are disseminated among *Pseudomonas aeruginosa* strains worldwide. The contribution of these enzymes to the β-lactam resistance profile of *Pseudomonas aeruginosa* is limited. However, point-mutation derivatives may be selected during therapy upon exposure with certain β-lactams, resulting in new variants able to compromise the clinical utility of multiple antipseudomonalbs, including the recently marketed cephalosporin/β-lactamase inhibitor combinations ceftolozane/tazobactam (CTZ) and ceftazidime/avibactam (CZA). Here we describe the emergence of different extended-spectrum OXA-10 variants conferring resistance to CTZ and CZA in multiple patients during treatment with cephalosporins.

**Materials/methods:** Four pairs of CTZ and CZA-susceptible/resistant *P. aeruginosa* isolates recovered from 4 patients treated with ceftazidime at Hospital Universitario Puerta del Mar (Cádiz, Spain) between September 2018 – February 2019 were evaluated. Minimum inhibitory concentrations of ticarcillin, piperacillin/tazobactam, aztreonam, ceftazidime, ceftazidime/avibactam, cefepime, ceftolozane, ceftolozane/tazobactam, imipenem, imipenem/relebactam, meropenem, tobramycin, amikacin, ciprofloxacin and colistin were determined by broth microdilution. Clonal relatedness was assessed by REP-PCR and MLST. Characterization of chromosomal and acquired β-lactamases was performed by PCR and sequencing. The different *bla*_{OXA-10} alleles detected were cloned in parallel in plasmid pUCP24 and electroporated into reference strain PAO1 to evaluate their impact on β-lactam resistance.

**Results:** All isolates exhibited multidrug resistance. However, whereas all initial isolates exhibited wide susceptibility to ceftazidime, CTZ and CZA, the isolates obtained after treatment exhibited a substantial increase in the MIC of ceftazidime, CTZ and CZA. Imipenem partnered with relebactam retained activity against all strains (MIC=1-2 µg/mL). All isolates yielded similar REP-PCR patterns, were assigned to the ST253, and yielded positive results for *bla*_{OXA-10}. DNA sequencing demonstrated that the isolates obtained after treatment had additionally developed mutations in the *bla*_{OXA-10} gene, resulting in four OXA-10 derivatives: the classic OXA-14 (G157D) and three new variants, designated OXA-794 [W154C], OXA-795 [Δ(F153-W154)] and OXA-824 [N143K]. PAO1 transformants proved that the new variants conferred high-level resistance to CTZ (MIC≥8 µg/mL) and CZA (MIC≥32 µg/mL).

**Conclusions:** Selection of extended-spectrum mutations in narrow-spectrum OXA-type β-lactamases is an emerging mechanism of resistance to CTZ and CZA in *P. aeruginosa*. Imipenem-relebactam may represent a therapeutic option when this kind of resistance emerge in the clinical setting.

Abstract 2324

Modelling the impact of antibiotic use and infection control agents on the incidence of methicillin-resistant Staphylococcus aureus incidence rates in hospital, informed by identifying antibiotic usage thresholds utilising non-linear time series analysis

Sara Gardner* 1, Paul Mccarron1, Geraldine Conlon-Bingham2, David Farren2, Michael Scott2, Kathryn Burnett1

1School of Pharmacy and Pharmaceutical Sciences, Ulster University, Coleraine, United Kingdom, 2Craigavon Area Hospital, Southern Health and Social Care Trust, Craigavon, United Kingdom, 3Antrim Area Hospital, Northern Health and Social Care Trust, Antrim, United Kingdom

Background: Evidence has shown the relationship between antibiotic use and antimicrobial resistance to be linear; the more antibiotics consumed the higher the resistance levels seen, irrespective of the intensity of antimicrobial use. However mathematical models have suggested that the relationship between antibiotic use, infection control agents and antimicrobial resistance is non-linear and that there is a threshold level of drug, above which the persistent selection of the antibiotic in the environment will lead to the development and spread of antimicrobial resistance. These thresholds may define safe usage levels for antibiotic stewardship activities, avoiding over restriction and bringing restricted antibiotics back into practice.

Materials/methods: We applied a NLTS model to identify thresholds in population antibiotic use and infection control agent use that influence MRSA incidence rates within a secondary care hospital in Northern Ireland in order to inform an antibiotic stewardship policy (ASP).

Results: The NLTS model identified critical thresholds for hospital consumption of fluoroquinolones, co-amoxiclav and alcohol-based hand rub (ABHR). The thresholds identified for fluoroquinolones and co-amoxiclav were 6.1 Defined Daily Doses (DDDs)/100 Occupied Bed Days (OBDs) and 37.17 DDDs/100 OBDs respectively, the consumption of both was identified to be above the thresholds. An inverse relationship was observed with increases in hospital consumption of ABHR up to 0.81 Litres/100 OBDs, above which further increases were not associated with further declines in MRSA. The identified thresholds were then translated into ASP suggestions, based on consumption in the previous 12 months. Fluoroquinolone and co-amoxiclav consumption should be reduced by 30% and 10% respectively in order to reduce consumption below the identified thresholds, ABHR levels need to be maintained.

Conclusions: NLTS can provide quantitative goals for antibiotic stewardship interventions by identifying critical thresholds in antimicrobial consumption. An ASP has been devised that restricts fluoroquinolone and co-amoxiclav consumption to a level below threshold to determine if the reduction in consumption has an effect on MRSA incidence within the hospital.

Insights into reservoir and pathogenicity of *Escherichia coli* ST83: role of haemolysin A operon duplication in severity of urinary tract infections

Magdalena Ksiezarek*, Ângela Novais¹, Helena Felga¹, Fátima Mendes¹, Marta Escobar¹, Luisa Maria Vieira Peixe¹

¹UCIBIO-REQUIMTE. Laboratory of Microbiology, Faculty of Pharmacy, University of Porto, Porto, Portugal, ¹Clinica dos Gatos. Veterinary Clinic, Porto, Portugal

**Background:** The characterization of the virulence genes content of *Escherichia coli* populations causing urinary tract infections (UTI) has been the subject of intensive research to find critical features for pathogenesis. However, genetic determinants conditioning severe forms of disease are poorly understood. We used comparative genomics, histological and clinical data to support the origin and pathogenicity of an aggressive *E. coli* strain causing a feline acute pyelonephritis and glomerulonephritis that resulted in kidney damage.

**Materials/methods:** An *E. coli* strain (Ec_151217) was identified in purulent fluid and urine. In vitro antibiotic susceptibility testing was performed for 17 antibiotics (EUCAST/CLSI). Genomic DNA was sequenced by Illumina MiSeq system, and this information was used to characterize phylogenetic group, serotype, sequence type, virulence potential and virulence gene content (n=49 ExPEC genes in-house database) (CGE in silico tools). The genome was compared with 27 ST83 *E. coli* genomes retrieved from NCBI and EnteroBase public databases to generate a SNP-based phylogeny (CSI phylogeny 1.4).

**Results:** Strain Ec_151217 (B2, ST83, O83:H5:K5) was susceptible to all antibiotics tested. High virulence score was detected (n=28/49), including adhesins (pap, fim, sfa/foc, matB, yfcV), toxins (hly, cnf1, vat), siderophores (fyuA, iroN), invasins (ibeA, gimB) amongst others (e.g. malX, usp, upaH), many important to urinary epithelium adhesion. The SNP-based ST83 phylogeny showed a high relatedness with ST83 O83:H5 and O6:H5 genomes carrying a similar array of virulence genes, from animals and human infections [including bacteremia] further supporting their pathogenic potential and the risk of host-to-host transmission. Interestingly, Ec_151217 strain contains two copies of the hemolysin A operon (hlyCABD). Though they encode highly similar HlyA proteins, they can be discriminated by their highly dissimilar 1.6 Kb upstream regions (~50% homology). Comparative genomics and epidemiological data showed that the presence of these hlyA paralogues is sporadic in ExPEC population (1%) but in strains that caused acute pyelonephritis [e.g. *E. coli* 536], supporting preliminary experimental data that the presence of two operons conditions higher pathogenicity.

**Conclusions:** Our data support a higher pathogenic potential for specific serotypes within ST83 *E. coli*, potentially associated with a duplication of hlyA operon conditioning higher virulence and severe forms of UTI.

Increases in environmental cleaning and reduction in in-hospital mortality in multi-patient rooms with single-use disinfection wipes hung at the patient bed: a prospective, crossover trial

Khalil Chedid*1, Mor Dadon2, Idan Shaul2, Idan Katz2, Ori Greiver2, Margarita Alfaro2, Liron Hod2, Tsilia Lazarovitch1, Hodaya Saadon2, Galit Ben-Yossef2, Sharon Moscovich2, Akram Shorbaje2, Ronit Zaidenstein2, Emily Martin1, Dror Marchaim2

1University of Michigan School of Public Health, Ann Arbor, MI, United States, 2Unit of Infection Control, Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel

Background: The hospital environment, particularly high-touch surfaces, plays an established role in mediating human pathogen transmission between patients. In resource-limited facilities with multi-patient rooms, this mode of transmission is enhanced, but environmental cleaning initiatives are challenging to implement. We evaluated the impact of hanging cleaning/disinfecting wipes at patient bedside in improving patient outcomes.

Materials/methods: A crossover-prospective trial was conducted at four medical departments in Shamir (Assaf Harofeh) Medical Center, Israel. We compared the effect of installing single-use quaternary ammonium-based wipes (Clinell®) at patient bedside and in close proximity to medical care areas in the unit to the standard practice of using reusable cloths with bleach. Each department was randomly assigned to an intervention (six months) and control period (six months) separated by a one month washout period. The patient environment (five predefined high-touch surfaces) was tested for cleaning indicators (fluorescent markers) twice weekly. Patient outcomes, including rates of in-hospital mortality, central line-associated bloodstream infections (CLABSI) and catheter-associated urinary tract infection (CAUTI), and cleaning frequency were compared between intervention and control departments using Poisson regression and generalized estimating equations, respectively.

Results: Among 7,725 patients (47,670 person-days) followed, 3,932 (23,792 person-days) were in intervention rooms and 3,793 (23,878 person-days) were in control rooms. In-hospital mortality rate among patients in intervention units was significantly lower, with 92.0 deaths/10,000 person-days versus 111.9 deaths/10,000 person-days in control units [IRR=0.8; 95% CI=(0.69, 0.98)]. No significant incidence rate differences of CLABSI [IRR=1.8; 95% CI=(0.7, 4.3)], CAUTI [IRR=1.4; 95% CI=(0.8, 2.4)] or CLABSI and CAUTI combined [IRR=1.4; 95% CI=(0.9, 2.3)] were noted. Effective environmental cleaning of all five tested locations occurred in 34% of intervention rooms versus 12% of control rooms [OR=3.7; 95% CI=(1.9, 7.1)].

Conclusions: By increasing their proximity to end users, easily accessible single-use quaternary ammonium-based wipes significantly increased the frequency in which high-touch surfaces cardinal to transmission were being cleaned in departments with multi-patients rooms while in-hospital mortality was significantly reduced in intervention departments. Single-use cleaning/disinfecting wipes may provide a more effective and acceptable alternative to bleach for reducing environmental transmission of pathogens.

Abstract 2330

**Antibiotic with novel lipid A pathway target shows activity against Gram-negative bacteria**

Ed Siegwart*, John George1, Ajay Mistry1, Tony Raynham1

1Oppilotech Ltd, London, United Kingdom

**Background:** Gram negative bacteria such as *Acinetobacter baumannii*, *Escherichia coli*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* cause a wide range of infections and pose a significant risk to human health. Additionally, resistance to commonly used first line treatments represent a significant clinical problem which is compounded by a lack of new development compounds. Using a computational model involving the biogenesis of the *E. coli* cell envelope, Oppilotech identified a novel target enzyme within the Lipid A biosynthetic pathway. Lipid A is an essential component of the outer membrane and is involved in virulence and cellular integrity. To date only engineered strains of *Neisseria* and *Acinetobacter* can survive without this important physical barrier. Defects in lipid A synthesis often lead to cells with compromised membrane integrity and increased permeability making enzymes within this pathway attractive to drug discovery and development efforts.

**Materials/methods:** Gram negative bacterial isolates taken from HAP/VAP patients were tested against the OPT molecule in combination with various antimicrobials, following standard broth microdilution checkerboard methods.

**Results:** Fractional inhibition concentration indices (FICI) were calculated from inhibitory values taken from a antimicrobial checkerboard assay and interpretations from Odds (2003). Activity of the Oppilotech compound was seen in combination with other antimicrobials against MEM and AMC *E. coli*, CT and AMC *P. aeruginosa* and ESBL positive *K. pneumoniae* isolates.

**Conclusions:** OPT200 5/37, an early ‘hit to lead’ stage molecule, shows direct acting activity against various Gram-negative species as well as potentiating activity with other antimicrobials. This data is consistent with the essentiality of Lipid A enzymes along with the chemical protection provided by the LPS barrier. Importantly, activity of the Oppilotech compound was also seen against MEM and AMC *E. coli*, CT and AMC *P. aeruginosa* and ESBL positive *K. pneumoniae* isolates.

Detection and genotyping Lymphogranuloma venereum in Tenerife, Spain

Berta Pino-Calm1, Diego García Martínez De Artola*1, Julia Alcoba-Florez1, Óscar Díez Gil1

1Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

Background: Chlamydia trachomatis (CT) is the world's leading sexually transmitted infection (STI) and is increasing every year. The serovars L1, L2 and L3 invade the connective tissue and can produce Lymphogranuloma venereum (LGV) that is characterized by a genital ulcer at the site of inoculation. A secondary stage can be presented with an inflammatory reaction in the inguinal nodes and proctocolitis can also be present with rectal discharge, anal pain and/or tenesmus.

The aim of this study was to assess LGV infection prevalence and investigate genotype distribution in our region.

Materials/methods: A total of 460 samples from the routine screening of sexual transmitted infections (STI) patients were submitted to the Microbiology Laboratory from August 2019 to November 2019. Those samples were processed by a multiplex Real-time PCR Allplex STI-7 (Seegene®) that detects simultaneously CT, Neisseria gonorrhoeae (NG), Mycoplasma hominis (MH), Mycoplasma genitalium (MG), Ureaplasma urealyticum (UU), Ureaplasma parvum (UP), Trichomonas vaginalis (TV).

In case of a CT positive result, pmpH-real-time PCR was used to discriminate between LGV and non-LGV genotypes and ompA amplification and sequenced was used to identify the different genotypes.

Results: During the study period we found 47 positive samples for CT. The prevalence of CT infection was 10%, with a significant difference between genders (infected males 64% [30/47] vs infected female 36% [17/47]). NG co-infection was detected in 15% of CT positive patients.

Only 41 of 47 samples could be analyzed for LGV detection. Two percent (9/451) of samples were positive for LGV and all of them were male. Most of positive samples (5/9) were rectal swabs. The study of ompA gene was possible in only four samples, and the most common genotype in our population was L2 (75% [3/4]), followed by D (25% [1/4]).

Conclusions: In the present study we found that genotype L2 was the most frequent in our region. Considering sexual behavior, LGV infection was more prevalent in men who have sex with mean (MSM) population. It should be underlined that CT genotyping is fundamental in order to rule out LGV infection, often underdiagnosed, since the treatment for LGV is different from that for non-LGV Chlamydia.

Proposing the spike gene of Coronavirus OC43 as a target for nosocomial outbreak investigation in long-term care facilities

Henna Mistry*1, Lily Yip1, Katie Bozek1, Hamza Mbareche1, Amber Linkenholt-Sturk1, Rob Kozak3, Victoria Williams2, Dariusz Pajak2, Jerome Leis1,2,4, Samira Mubareka1,2,3,4

1Sunnybrook Health Sciences Centre, Sunnybrook Research Institute, Toronto, Canada, 2Sunnybrook Health Sciences Centre, Infection Prevention and Control, Toronto, Canada, 3Sunnybrook Health Sciences Centre, Department of Microbiology, Toronto, Canada, 4University of Toronto - St. George Campus, Department of Medicine, Toronto, Canada

Background: Viral genome sequencing for the investigation of respiratory virus outbreaks has been described, but data remains limited, particularly for non-influenza respiratory viruses. Coronaviruses are frequently implicated in long-term care home (LTC) respiratory outbreaks, coinciding with increased levels of viral activity in the community. Here, we propose the spike (S) gene as a sequencing target to determine relatedness between isolates of coronavirus OC43 during outbreaks at a veteran’s LTC.

Materials/methods: A total of 54 outbreak samples from ten distinct outbreaks through 2015 to 2017 were collected using traditional infection prevention and control (IPC) criteria. The S gene from these isolates were sequenced after amplification using multiple primer combinations. Near-complete (>99% coverage) spike gene sequences were obtained for 48 samples.

Results: Sequencing results demonstrated that the S gene was sufficient to resolve epidemiologically-related viruses into their respective outbreak classifications. A phylogenetic tree showed that clades were distinctive to the year in which the outbreak occurred [see figure]. That is, the sequences from the one presumed outbreak in 2015 were highly dissimilar from sequences of 2016 and 2017 outbreaks. Although four outbreaks were called in 2016, phylogenetic analysis revealed near-identical sequences across outbreaks in the different wards, suggesting either inter-unit transmission, or a limitation to using the spike gene as a candidate reference gene for outbreak investigation. Additionally, S gene phylogenetic analysis of isolates from 2017 outbreaks was sufficient to distinguish between the four unique outbreaks identified by traditional IPC. Moreover, sequencing results linked strains that were retrospectively epidemiologically-associated, though initially classified as unrelated by conventional outbreak definitions. In some instances, epidemiologically-unassociated isolates from the same catchment area shared identical or near-identical S gene sequences with outbreak strains.

Conclusions: Although whole genome sequencing or genotyping may be advantageous for outbreak investigation, spike gene sequencing paired with epidemiological classification has the potential to provide additional insight compared to epidemiological investigation alone.

Abstract 2334

Multi-centre evaluation of meropenem/vaborbactam MIC results for Enterobacterales and Pseudomonas aeruginosa using EUCAST breakpoints on MicroScan dried Gram-negative MIC panels

Amanda Harrington¹, Sharon Desjarlais¹, Omai Garner², Maria Traczewski³, Denise Beasley¹, Christine Hastey⁴, Regina Brookman⁵, Zabrina C. Lockett⁶, Jennifer Chau⁷, Barbara L. Zimmer⁸

¹Loyola University Medical Center, Maywood, United States, ²UCLA David Geffen School of Medicine, Los Angeles, United States, ³Clinical Microbiology Institute, Wilsonville, United States, ⁴Beckman Coulter Inc, West Sacramento, United States

Background: A multicenter study was performed to evaluate the accuracy of testing meropenem/vaborbactam on a MicroScan Dried Gram-negative MIC (MSDGN) Panel when compared to a frozen ISO/CLSI broth microdilution reference panel

Materials/methods: An evaluation was conducted at three U.S. sites by comparing MIC values obtained using the MSDGN to MICs utilizing an ISO/CLSI broth microdilution reference panel. A total of 775 Enterobacterales and P. aeruginosa clinical isolates were tested using the turbidity and Prompt® methods of inoculation during the efficacy phase. A subset of 14 organisms for reproducibility was tested on MSDGN panels at each site. MSDGN panels were incubated at 35 ± 1°C and read on the WalkAway System, the autoSCAN-4 instrument, and read visually. Read times for the MSDGN panels were at 16-20 hours. Frozen reference panels were prepared according to ISO/CLSI methodology, incubated for 16-20 hours and read visually. EUCAST breakpoints (mg/L) used for interpretation of MIC results were: Enterobacterales ≤ 8/8 S, > 8/8 R and P. aeruginosa ≤ 8/8 S, > 8/8 R.

Results: Essential and categorical agreement when compared to frozen reference panel results, for all isolates tested in efficacy as follows:

Abstract 2335

Antibiotic exposure and the risk of CRE acquisition

Nasreen Hassoun Kheir1,2, Khetam Hussein1,2, Maram Saffuri2, Sally Badaan2, Shani Peleg2, Yuval Geffen1,2, Mical Paul1,2

1Rambam Health Care Campus, Infectious diseases institute, Haifa, Israel, 2Technion - Israel Institute of Technology, The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel

Background: Carbapenem Resistant Enterobacteriaceae (CRE) are increasingly prevalent worldwide. In this study, we aimed to examine the association between CRE acquisition in hospitalized patients and exposure to different classes of antibiotics.

Materials/methods: We conducted a matched case:control 1:2 study in Rambam-healthcare campus (RHCC) between Jan 2014 – Jun 2017. Enrolled cases included adult patients who acquired CRE in RHCC, both colonized and infected. Controls were matched from negatively screened-CRE hospitalized patients by age, hospitalization unit and number of hospital days in the 90 days prior to swab date. Antibiotic exposure was measured as sum of treatment days to a certain class of antibiotics during the preceding 90 days. We analyzed the data using univariate and multivariate analysis controlling for matching, adjusting other significant clinical risk factors for CRE acquisition found in our study.

Results: we included 267 patients: 90 cases and 177 matched controls. Mean age was 64±18 years, and 118 patients were female (44.2%). Exposure to carbapenems, cephalosporins vancomycin and piperacillin/tazobactam were significantly associated with the risk for CRE acquisition on univariate analysis (Table).

Other significant risk factors for CRE acquisition included anemia, referral from another facility and number of non-invasive imaging procedures before acquisition. Adjusted to these and all significant antibiotics, carbapenem and cephalosporins were significantly associated with CRE acquisition (Table).

Conclusions: Exposure to carbapenems and cephalosporins is significantly associated with CRE acquisition. Antibiotic stewardship targeting these classes can selection pressure for CRE. We plan to increase the cohort and conduct separate analyses for CPE and non-CPE, assuming that associations will be stronger for non-CPE.

Abstract 2337

**Drug repositioning as a possible strategy to combat bacterial infections: evaluation of non-antibiotic human therapeutics as quorum-sensing inhibitors**

Márió Gajdács*1,2, Gabriella Spengler3

1University of Szeged Faculty of Pharmacy, Department of Pharmacodynamics and Biopharmacy, Szeged, Hungary, 2Hungarian Society for Clinical Microbiology and Infectious Diseases, Budapest, Hungary, 3University of Szeged - Faculty of Medicine, Department of Medical Microbiology and Immunobiology, Szeged, Hungary

**Background:** Since the 21st century, antibacterial drug development has been slow to keep up with the developing bacterial resistance. Quorum sensing (QS) is a distinct mechanism of bacterial cell-cell communication, during which bacteria sense the density of cells in the surrounding environment by the detection of various signal molecules. The influence of QS on the expression of bacterial virulence determinants has been described. Drug repositioning is a promising drug development strategy, during which novel pharmacological applications are identified for drugs already approved for human therapeutic uses.

**Materials/methods:** Forty-five pharmacological agents, encompassing a wide range of chemical structures and mechanisms of action were screened for their antibacterial and QS-inhibitory activity. Screening for QS-inhibition was carried out using the cross-inoculation method, while quantitative assessment of compounds was performed by the parallel inoculation method. *Chromobacterium violaceum* wt85, *C. violaceum* CV026 and *Serratia marcescens* AS-1 were utilized as acyl-homoserine lactone (AHL) sensory strains, while *Enterobacter cloacae* 31298, *Sphingomonas paucimobilis* Ezf 10-17 and *Novosphingobium* spp. Rr 217 were used as AHL-producers. QS-inhibition experiments were performed on a modified Luria-Bertani agar supplemented with 2 g/L glucose and a microelement stock solution. Acridine orange was used as a positive control during QS-experiments. MIC determination was performed using broth microdilution, according to CLSI standards. *Staphylococcus aureus* ATCC 25923 and *Escherichia coli* ATCC 25922 were used as control strains.

**Results:** Among the tested pharmaceutical agents, fourteen (namely celecoxib, mebendazole, ivermectin, verapamil, promethazine, chlorpromazine, thioridazine, methotrexate, doxorubicin, bleomycin, atorvastatin, simvastatin, clotrimazole and fluconazole) showed antibacterial activity on various bacterial strains in the tested concentration range (0.25-250 µg/mL). Eight drugs (namely 5-fluourouracil, metamizole-sodium, cisplatin, methotrexate, bleomycin, promethazine, chlorpromazine and thioridazine) presented with concentration-dependent (3.12-50 µg/mL) QS-inhibitory activity on the tested bacterial model systems.

**Conclusions:** Compared to antibiotics, the use of virulence inhibitors may be advantageous as the selection pressure exerted by these drugs [and the consequent development of resistance] is expected to be much lower. Currently marketed pharmaceutical compounds can be considered as potential sources of QS inhibitory agents, as the pharmacokinetic parameters and tolerability of these compounds have already been verified in vivo.

Evaluation of tedizolid and comparators activity against Gram-positive bacterial isolates causing skin and skin structure infections from paediatric patients in Europe and surrounding countries (2015-2019)

Cecilia Godoy Carvalhaes1,2, Helio S. Sader1, Jennifer Streit1, Robert Flamm1, Rodrigo E. Mendes1

1JMI Laboratories, North Liberty, United States

Abstract third-party references: This study was performed by JMI Laboratories and supported by Merck, which included funding for services related to preparing this abstract.

Background: Tedizolid is approved in many European and non-European countries for treating acute bacterial skin and skin structure infections (SSSI) in adults. The efficacy, safety and tolerability of tedizolid was evaluated in phase 3 clinical trials for treating complicated SSSI caused by Gram-positive organisms in paediatric patients. The activity of tedizolid and comparators was evaluated against clinical surveillance isolates collected from paediatric patients with SSSI in Europe and surrounding countries during a 5-year period.

Materials/methods: A total of 861 Gram-positive isolates were collected from paediatric patients with SSSIs in 36 medical centres in European countries and surrounding regions (2015–2019). Bacterial identification was confirmed by MALDI-TOF MS and susceptibility testing applied reference broth microdilution method. CLSI and EUCAST interpretive criteria followed current guidelines.

Results: The major Gram-positive bacterial species and pathogen groups causing SSSI included S. aureus (73.5%) and β-haemolytic streptococci (BHS; 16.4%), followed by small numbers of Enterococcus faecalis (2.9%), and other microorganisms (7.2%). Similar frequency was also observed in both age groups (<12 and 12-18 years of age). Tedizolid was highly active against S. aureus [MIC50/90, 0.12/0.25 mg/L; 100% susceptible by EUCAST criteria]. Equivalent tedizolid MIC50/90 values were observed (100% susceptible) against methicillin-resistant S. aureus (MRSA; n=12.5%; MIC50/90, 0.12/0.25 mg/L) and methicillin-susceptible [MSSA; MIC50/90, 0.12/0.25 mg/L] isolates. Tedizolid was also very active against BHS [MIC50/90 values, 0.25/0.25 mg/L]. Susceptibility rate of 100% was obtained for tedizolid, linezolid, vancomycin and daptomycin against the main Gram-positive species and organism groups (Figure). Ceftaroline and clindamycin showed susceptibility rates of >90% against MRSA, MSSA, S. pyogenes and S. dysgalactiae, but lower susceptibility rates were observed for clindamycin tested against VGS (85.0%) and S. agalactiae (62.5%).

Conclusions: Tedizolid was highly active against Gram-positive clinical isolates responsible for SSSI in paediatric patients from hospitals located in European and surrounding countries recovered in a 5-year period. Tedizolid was equipotent or more potent than comparators against MSSA and MRSA isolates.

**Prevalence of *Mycoplasma genitalium* and frequency of resistance to macrolides and fluoroquinolones in Tenerife, Spain.**

Berta Pino-Calm1, Diego García Martínez De Artola*1, Julia Alcoba-Florez1, Óscar Díez Gil1

1Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

**Background:** Information of macrolide and fluoroquinolone resistance in *Mycoplasma genitalium* (MG) is limited in certain geographic areas in Spain. MG is a common cause of non-gonococcal urethritis, cervicitis, pelvic inflammatory disease, preterm birth and spontaneous abortion. An increasing incidence of treatment failure suggests the emergence of antibiotic resistance associated to mutations in the 23S rRNA gene (Azithromycin, the recomended treatment) and in parC and gyrA genes (Moxifloxacin, alternative treatment).

The aim of this study is to establish the current prevalence of resistant strains in our region.

**Materials/methods:** The study was conducted retrospectively/prospectively with a total of 1842 samples from the routine screening of sexual transmitted infections (STI) patients. Between December 2018 and November 2019, samples where MG was detected using PCR (Allplex® STI-7, Seegene) were also studied for susceptibility to macrolides and fluoroquinolones.

Resistant was investigated by sequencing the 23S rRNA studying changes in positions A2058TCG, A2059CG, A2062GCT, A2098C, C2055G considered to be associated with resistant to macrolides and point mutations in the quinolone resistante determining region (QRDR) of the topoisomerase IV gene parC and mutations in the DNA gyrase gene gyrA for quinolones.

**Results:** Forty-four patients, most of them male (59% [26/44]) with a median age of 32 years (19-59) were studied. The specimens with a positive result were: 38% (17/44) endocervical swabs, 50% (22/44) urethral swabs, 7% (3/44) pools of different samples and 2% (1/44) of a rectal and ulcer specimen. The prevalence of MG was 3.9% (70/1772). A total of 41% (16/39) of MG strains had at least resistant to one antibiotic. Macrolide resistant strains were detected in 25% (10/39) patients. The most frequent single nucleotide polymorphism (SNP) was at position A2059G (Escherichia coli numbering) with 60% (6/10). We identified point mutations in QRDR of gyrA or parC in 15% (6/39) patients. Five percent (2/39) of patients had a multiresistant strain. Regarding patients follow-up, the test of cure have been performed, only in 25% (11/44) of patients.

**Conclusions:** Mutations associated with first line treatment are present in a high percentage (25%). Resistant test should be done in order to adjust antibiotic treatment and prevent spread of resistant strains. According to the current guidelines a test of cure have to be done in all patients due to high prevalence of macrolide resistant.

Antimicrobial use for asymptomatic bacteriuria: first, do no harm

Yana Shpunt1, Inna Estrin1, Hodaya Saadon1, Galit Ben-Yossef1, Lilly Goldstein1, Dan Klafter1, Yossi Levi1, Shani Zilberman-Itskovich1, David Katz1, Tzilia Lazarovitch1, Ronit Zaidenstein1, Shani Zilberman-Itskovich1, David Katz1, Tzilia Lazarovitch1, Ronit Zaidenstein1, Dror Marchaim*1

1Shamir Medical Center, Zerifin, Israel

Background: Antimicrobials administered to patients with asymptomatic bacteriuria (ASB) is a common medical error that can lead to devastating clinical and fiscal outcomes. However, controlled analyses quantifying the commonality and impact of this practice are lacking. Our study aims were to conduct an epidemiological investigation to define the characteristics of patients with ASB, to identify independent risk factors for instituting antimicrobials for this population, and quantify the impact of this practice on clinical and fiscal outcomes.

Materials/methods: A retrospective cohort study for calendar year 2017 was conducted at the Shamir Medical Center, Israel. All adults’ urine cultures were reviewed, and ASB was determined according to CDC criteria. Pregnant women, renal transplant recipients, and patients who underwent urologic procedures, were excluded. Multivariable logistic regression models were constructed in order to analyze the predictors and outcomes associated with use of antimicrobials for ASB.

Results: In our study population, we identified 1,530 patient-unique positive urine cultures, of which 610 (40%) patients were determined to have ASB. Of the 696 offending isolates, 219 (36%) were MDROs: i.e., mainly extended-spectrum beta-lactamase-producing Enterobacteriaceae (n= 143, 23.4%) and Pseudomonas aeruginosa (n= 33, 5.4%). There were 178 patients (29%) who received antimicrobials for ASB. Independent predictors for improper administration of antimicrobials for patients with ASB were male sex (aOR=2; p<0.001) and dependent functional status upon hospital admission (aOR=2.3; p<0.001). In three separate multivariable outcome models, “treatment” for ASB was independently associated with longer length of stay (p=0.04), with additional hospitalization (aOR=1.7; p=0.02) and with acute Clostridioides difficile infection (i.e., CDI) in the following 90 days (aOR=4.5; p<0.001).

Conclusions: ASB is a common condition, frequently resulting from MDROs. Approximately one-third of patients in our study population were improperly treated for ASB. This futile usage of antimicrobials was independently associated with longer length of stay, with re-hospitalization, and with later acute CDI. Future research and focus should be directed towards men with poor functional status.

Abstract 2342

Comparative effectiveness of macrolides, fluoroquinolones or combination therapy for the treatment of Legionnaires’ disease in the US Department of Veterans Affairs health system

Vanessa Stevens*1,2, Shantini Gamage3,4, Annie Jasper5,6, Gary Roselle3,4,7, Nasia Safdar5,6

1Informatics, Decision Enhancement, and Analytic Sciences Center of Innovation, VA Salt Lake City Health Care System, Salt Lake City, United States, 2Division of Epidemiology, Department of Internal Medicine, University of Utah School of Medicine, Salt Lake City, United States, 3US Veterans Health Administration, National Infectious Diseases Service, Specialty Care Services, Washington DC, United States, 4Division of Infectious Diseases, Department of Internal Medicine, University of Cincinnati College of Medicine, Cincinnati, United States, 5William S. Middleton Memorial Veterans Hospital, Madison, United States, 6Division of Infectious Disease, Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, United States, 7Cincinnati VA Medical Center, Cincinnati, United States

Background: The incidence of Legionnaires’ Disease (LD) is increasing worldwide. Scant data are available to guide the selection of optimal antimicrobial therapy. We evaluated the impact of treatment with macrolides, fluoroquinolones, or both on the risk of mortality and other clinical outcomes among patients with LD.

Materials/methods: Retrospective cohort study of patients diagnosed with LD reported to VA Inpatient Evaluation Center October 2013 - March 2019. Patients with no record of treatment in VA were excluded. Treatment was classified as macrolides only, fluoroquinolones only, or both. The primary outcome was 30-day all-cause mortality. Secondary outcomes included new onset acute renal failure or dialysis and apyrexia. Propensity scores were fit using generalized boosted models and included age, history of hospitalization, comorbidities, setting of diagnosis, and abnormal laboratory values as defined by the pneumonia severity index. Relative risks (RR), risk differences (RD) and 95% confidence intervals (CI) were estimated with propensity-weighted modified Poisson regression using generalized estimating equations clustered at the facility level.

Results: There were 718 LD patients; 96.7% were male and 63.5% were white. One-third of patients received fluoroquinolones, 37.3% received macrolides, and 30.1% received both. Before weighting, patients treated with fluoroquinolones were more likely to be diagnosed as outpatients than those treated with macrolides or both drugs (53.0% vs 42.9% and 40.7%, respectively). A comparison of the risks of primary and secondary outcomes across treatment groups is shown (Table). Outcomes were similar, with small increases in the risk of mortality and dialysis for patients treated with fluoroquinolones compared to both drugs.

Conclusions: We found no difference between fluoroquinolones, macrolides, or the combination in the risk of mortality or other clinical outcomes among this large cohort of patients with LD. Given the known adverse event profile of fluoroquinolones, macrolides may be preferred therapy for LD.

Abstract 2344

Organisation of an ID consultation: are medical reports more important than patients?

Jonathan Tschopp*1, Benoit Guery1

1 University Hospital of Lausanne, Service of Infectious diseases, Lausanne, Switzerland

Background: The clinical practice of an infectious diseases' (ID) specialist mostly consists in a transversal activity as a consultant for physicians of other specialties. The daily workload may be highly variable, depending on the number of demands, and therefore difficult to plan. Accordingly, the needed number of fellows and attending physicians (AP) to allow a smooth functioning of the ID clinic is hard to predict. The aim of this study was to better understand the global workload and time needed to fulfill key daily tasks and improve the overall efficiency of our ID clinic.

Materials/methods: Lausanne University Hospital is a 1500-bed tertiary care hospital in Switzerland. ID consultations are provided 24 hours/day, 7 days/week either by ID fellows or internal medicine (IM) fellows. All clinical cases are overseen by an AP. Data from all ID consultations were collected from our hospital’s electronic medical database over a 12-month period (August 2018 to July 2019), excluding pediatrics, orthopedics, and immunosuppressed patients (solid organ transplant, haematology-oncological, HIV/AIDS). A smartphone app was created to monitor the time for each consultation. Fellows reported the time needed to answer phone calls, visit patients and write medical reports. AP reported the time to oversee each clinical case, visit patients and validate fellows’ reports. Only working days/hours were considered for this part of the study.

Results: 3242 ID reports were made during this period, of which 1360 (41.2%) during working hours (8am – 6pm), 1208 (37.3%) out of working hours (6pm – 8am), and 674 (20.1%) during weekends. Reports were classified as first consultations (39.3%) and follow-up consultations (60.7%). According to the smartphone app, mean time for each clinical case was 109.9 minutes for the fellows and 60.5 minutes for the AP, including a shared supervision time (Table 1).

Conclusions: Offering ID consultations 24/7 seems to be essential in our hospital as only 41% of all consultations were made during working days/hours. ID fellows spent more time with patients than IM fellows but were more efficient in writing medical reports, which was the longest task of each clinical case.

Opportunistic screening for sexually-transmitted infections in young men with leukocyturia and negative urine culture in primary care

Itziar Angulo López1, Ander Gonzalez Sarria*,1, Julia Aragón-Díez1, Manuel Imaz Perez1, Leonora Hernandez Ragpa1, Jose Angel Alava Menica1, José Luis Díaz De Tuesta1

1Hospital Universitario Basurto, Bilbao, Spain

Background: Conventional midstream urine culture is usually the only microbiological test ordered at primary care when lower urinary tract symptoms are the chief complaint in young men, despite urinary tract infections (UTI) being rare in this population and sexually transmitted infections (STIs) increasingly prevalent. The aim of this study was to assess the impact of screening for STIs on sexually active men with clinical diagnosis of suspected UTI and sterile pyuria.

Materials/methods: A prospective study was conducted since June 2019 with the midstream urine samples received in the Microbiology Laboratory in men between 15-59 years old. Negative urine cultures with leukocyturia (≥20/µL) detected by flow cytometry (UF-1000i®), with no other clinical condition that could have justified it, were tested with a real-time PCR assay, Anyplex™II STI-7 (Seegene), which detects 7 pathogens: Chlamydia trachomatis, Neisseria gonorrhoeae, Trichomonas vaginalis, Mycoplasma hominis, Mycoplasma genitalium, Ureaplasma urealyticum, and Ureaplasma parvum.

Results: A total of 107 urine samples were subject to PCR, with a positive result in 47 cases (43.9%). Among them, 12 patients (25.5%) had admitted an unprotected sexual intercourse at the first consultation. The microorganisms detected and the variables of study are shown in Table 1.

</table>

Table 1. Variables studied for each microorganism detected by PCR. SD: standard deviation; IQR: interquartile range; MSM: men who have sex with men. Antibiotic treatments were optimized in 32 cases (68.1%) because of these results, and 28 (59.6%) were referred to specialized STI centers, where 6 patients (21.4%) had an additional finding: 1 HIV positive serology result to be confirmed, 3 cases of lack of immunity for HVA and 1 for HVB (who were advised to get vaccinated), 1 N. gonorrhoeae proctitis and 1 C. trachomatis detection in a semen sample.

Conclusions:

- Analyzing the midstream urine samples from men with genitourinary tract symptoms and sterile pyuria improves the diagnostic yield for STIs.
- Promotion of a greater awareness of clinical presentation forms of STIs is needed among primary care practitioners.
- An STI diagnosis should involve referring the patient to a specialized center for correct management and systematic screening.

Abstract 2347

Evaluating the effectiveness of current microbiological tools on time to diagnosis of pulmonary tuberculosis

Onyeka Umerah*1, Hemu Patel2, Raman Verma1, Nelun Perera2, Michael Barer3, Gerrit Woltmann1, Pranabashis Haldar1

1Glenfield Hospital, Leicester, United Kingdom, 2Leicester Royal Infirmary, Leicester, United Kingdom, 3University of Leicester, Leicester, United Kingdom

Background: Early diagnosis of pulmonary TB is essential for limiting infection transmission and relies heavily on the availability of sputum. However only 65% of patients in England have a recorded sputum result, suggesting a significant proportion are unable to provide sputum, leading to additional investigation and consequent diagnostic delay.

Leicester City is a UK TB hotspot (incidence 40 per 100,000) providing a rapid access pathway for accelerated assessment of pulmonary TB suspects. The pathway incorporates clinico-radiological triage with systematic microbiological investigation of respiratory tract samples using Xpert MTB/RIF (Xpert) and mycobacterial culture (MGIT). Our objective was to evaluate factors influencing time from referral and symptoms onset to microbiological diagnosis and start of treatment respectively.

Materials/methods: A retrospective cohort study of 290 consecutive incident pulmonary TB patients diagnosed and treated at Leicester between 2016-2018. Data was collected from the University Hospitals of Leicester health informatics warehouse.

Results:

- 113 patients [41.8%] required invasive respiratory tract sampling with bronchoscopy due to either no or inadequate sputum [89 and 24 patients] expectorated.
- Compared with sputum producers, the requirement for bronchoscopy was associated with a significant delay (mean difference [95% CI]) in time to microbiological diagnosis from referral [25.1 (13.7 – 36.5) days] and time to treatment from symptom onset [28.8 (8.9 – 48.6) days].
- Concomitant Xpert and mycobacterial culture was performed on respiratory tract samples from 170 [59%] patients. The culture confirmation rate was 80% and increased to 84% with combined Xpert testing. A positive Xpert result was associated with shorter time to treatment from symptom onset [94 days], compared with not performing the test [106 days].

Conclusions: The predominant delay in pulmonary TB diagnosis occurs prior to accessing healthcare review. However, in a high-income setting with optimized referral and diagnostic pathways, time to microbiological diagnosis and treatment is significantly reliant upon sputum expectoration. However, this is achievable in less than 60% of patients of our population. Xpert testing provides a modest improvement in microbiological confirmation and time to treatment commencement but significant improvements will require novel non-invasive diagnostic tools, targeting universally accessible tissue.

Co-trimoxazole resistance in Stenotrophomonas maltophilia

Ahlström Magnus*, Jenny Knudsen

1Rigshospitalet, Department of clinical microbiology, København, Denmark

Background: Stenotrophomonas maltophilia (Sm) is an environmental bacterium naturally resistant to many broad-spectrum antibiotics (including all carbapenems). The drug of choice for treating Sm is Co-trimoxazole. We aimed to evaluate the amount of Co-trimoxazole resistance in our clinical setting, further we aimed at elucidating whether the prevalence of Co-trimoxazole resistant strains of SM has increased over time.

Materials/methods: We extracted all samples with Sm from our local clinical database for our tertiary referral hospital, from Jan 1 2002 – Oct 1 2019. Patients were divided into time-groups based on the first available Sm isolate (2002-2005, 2005-2010, 2010-2014 and 2014-2019). We calculated time to Co-trimoxazole resistant Sm and used Kaplan-Meier plots to compare differences in the different time-periods.

Results: We identified 3,497 patients with a total of 14,482 samples. 2,740 (18.9%) samples were obtained from cystic fibrosis patients. Most samples 9,693 (67%) were from the lower respiratory tract, 515 (3.6%) samples were from blood cultures and 4,277 samples were obtained from other sites. 252 (7.2%) individuals and 552 (3.8%) samples contained Co-trimoxazole resistant SM strains. 6 individuals (2.2%) had positive blood cultures containing resistant Sm strains. When we compared different time periods, we did not find any statistically significant differences in the rates of resistant Sm strains.

Conclusions: In this large series of Sm we found that Co-trimoxazole resistance rate was generally low. For invasive Sm infections, we found only 2.2% resistant strains in blood cultures. We did not find evidence to suggest substantial changes of resistance over time.

Time to resistant strain

Abstract 2352

Molecular epidemiology of carbapenem-resistant Acinetobacter baumannii in the United States, 2013–2017

Susannah McKay*, Jonathan Daniels, Valerie Albrecht, Nicholas Vlachos, Valerie Stevens, James K. Rasheed, Maria Karlsson, Alison Laufer-Halpin

Centers for Disease Control, Atlanta, United States

Background: Acinetobacter baumannii has emerged as an important healthcare-associated pathogen worldwide. Carbapenem-resistant A. baumannii (CRAB) are increasingly common and found to be associated with epidemic global clones and different classes of carbapenemase genes. Here we describe the molecular epidemiology of CRAB collected through public health efforts in the United States.

Materials/methods: From 2013-2017, CDC received CRAB isolates from sixteen sites via reference testing and surveillance activities. Testing was performed to assess antimicrobial susceptibility profiles and identify carbapenemase genes. Whole genome sequencing (WGS; Illumina MiSeq® System) was performed on select, nonredundant isolates to determine sequence type and identify antibiotic resistance genes.

Results: Of 94 isolates characterized by WGS, nearly all (n=92, 98%) carried an OXA-type carbapenemase gene, among which we identified a total of 20 blaOXA variants. While 90 isolates (96%) had an intrinsic blaOXA51-like gene, 67 isolates (71%) harbored an additional acquired blaOXA gene, most commonly blaOXA-23 (n=45). Compared to intrinsic oxacillinases, acquired OXA-type carbapenemases were associated with a higher prevalence of imipenem nonsusceptibility (70 vs 100%) and higher median imipenem MIC (8 vs 64ug/ml). Isolates harboring acquired blaOXA carbapenemase genes were also more likely to be resistant to other drug classes including aminoglycosides, cephalosporins, and polymyxins.

Twenty-nine STs were identified using the Oxford MLST scheme, with the majority of isolates (n=59, 63%) representing STs belonging to the international clonal complex 92 (CC92). Among these, ST208 (n=21) and ST281 (n=20) were the most common and each displayed unique epidemiology. ST208 was widely distributed and associated with six different acquired blaOXA variants. Conversely, ST281 isolates were largely restricted to the Mid-Atlantic region (n=15, 75%) and only found associated with the blaOXA-23 variant.

Conclusions: Taken together these data illustrate the wide distribution of CC92 in the United States and high prevalence of acquired blaOXA carbapenemase genes among CRAB. Previous work has identified ST281 as an emerging ST that is rapidly replacing STs from established clades such as ST208, the predominant ST in the United States. Our data provide a snapshot of the dynamic epidemiology of CRAB and identify ST-antibiotic resistance gene combinations that may warrant further attention through detection and containment activities.

Abstract 2359

**Tedizolid activity against a global collection of Gram-positive bacterial isolates causing bone and joint infections (2017-2019)**

Cecilia Godoy Carvalhaes*, Helio S. Sader¹, Jennifer Streit¹, Robert Flamm¹, Rodrigo E. Mendes¹

¹JMI Laboratories, North Liberty, United States

Abstract third-party references: This study was performed by JMI Laboratories and supported by Merck, which included funding for services related to preparing this abstract.

**Background:** Despite the advances in current health care, bone and joint infections (BJI) remain difficult-to-treat infections that frequently involve prolonged systemic antibiotic use. Tedizolid has been considered as a candidate for therapy in adults and children with BJI. This study assessed the in vitro activity of tedizolid and comparator agents against a contemporary global collection of Gram-positive isolates causing BJI.

**Materials/methods:** A total of 523 Gram-positive cocci, including 379 S. aureus (SA), 81 β-hemolytic streptococci (BHS) isolates, 25 CoNS, 20 E. faecalis and 11 Viridans group streptococci (VGS), were collected from patients with BJI from the United States (USA; n=224 isolates), Europe (EUR; n=200), Asia-Pacific (n=47), and Latin America (n=52) during 2017–2019. Bacterial identification was confirmed by MALDI-TOF MS and MIC obtained by broth microdilution method according to current CLSI and EUCAST guidelines and interpretation criteria.

**Results:** Tedizolid was active against S. aureus isolates (MIC<sub>50</sub>/MIC<sub>90</sub>, 0.25/0.25 mg/L) and retained potent in vitro activity against methicillin-resistant S. aureus (MRSA; MIC<sub>50</sub>/MIC<sub>90</sub>, 0.12/0.25 mg/L). Tedizolid, linezolid, vancomycin and daptomycin inhibited all S. aureus isolates at the respective susceptible breakpoints (Table). MRSA rates varied among regions (17.2%-35.1%); however, based on MIC<sub>90</sub>, tedizolid showed consistent potencies (MIC<sub>90</sub>, 0.25-0.5 mg/L), regardless of geographic region. Tedizolid (MIC<sub>50</sub>/MIC<sub>90</sub>, 0.25/0.5 mg/L) was also active against E. faecalis isolates, as well as linezolid (100% susceptible) and vancomycin (100% susceptible). All BHS isolates were inhibited at ≤0.5 mg/L of tedizolid (MIC<sub>50</sub>/MIC<sub>90</sub>, 0.25/0.25 mg/L; 100% susceptible). Linezolid, vancomycin, and daptomycin were also active against BHS. Among the entire collection, only 1 CoNS isolate [S. cohnii] was resistant to linezolid (MIC, 8 mg/L) and/or tedizolid (MIC, >1 mg/L). Tedizolid and vancomycin inhibited all VGS isolates at the respective susceptible breakpoints. No differences on tedizolid activity against BHS or VGS were observed among geographic regions.

**Conclusions:** Tedizolid demonstrated potent in vitro activity against this worldwide collection of contemporaneous Gram-positive isolates causing BJI. High susceptibility rates were observed by tedizolid and comparators agents against the most frequent organisms and organism groups, including MRSA. These findings support the clinical development of tedizolid for treating BJI infections caused by Gram-positive pathogens.

**In vitro activities of aztreonam-avibactam and comparator agents against carbapenemase-producing Enterobacterales collected during the ATLAS global surveillance programme 2015-2018**

Krystyna Kazmierczak*, Francis Arhin², Dan Sahm¹

¹IHMA, Schaumburg, United States, ²Pfizer Canada, Kirkland, Canada

**Background:** Carbapenemase-producing Enterobacterales (CPE) cause significant morbidity and mortality. Aztreonam-avibactam is a β-lactam/β-lactamase inhibitor combination with activity against both serine carbapenemases and metallo-β-lactamases (MBL) in development for treatment of infections caused by CPE. We evaluated the *in vitro* activity of aztreonam-avibactam against CPE collected in 2015-2018 through the ATLAS global surveillance program.

**Materials/methods:** Non-duplicate, clinically significant isolates of Enterobacteriaceae, Proteaceae and *Serratia* spp. were collected from 237 medical centres in 51 countries in Europe, Latin America, Asia/Pacific (excluding China and India), and the Middle East/Africa region. Susceptibility testing was performed by CLSI broth microdilution and results were interpreted using EUCAST 2019 breakpoints. Avibactam was tested at a fixed concentration of 4 mg/L. All organisms with meropenem MIC >1 mg/L and *Escherichia coli*, *Klebsiella* spp. and *Proteus mirabilis* phenotypically positive for ESBL activity (2015) or with aztreonam or ceftazidime MIC >1 mg/L (2016-2018) were screened for the presence of β-lactamase genes.

**Results:** A total of 2290 isolates (1733 *Klebsiella pneumoniae*, 181 *Enterobacter cloacae*, 124 *E. coli*, and 252 isolates of 17 other species) were CPE. Of these, 69.6% (n=1594) carried serine carbapenemases (KPC, OXA-48-like, GES), 26.6% (n=610) carried MBLs (NDM, VIM, IMP), and 3.8% (n=86) carried both serine- and metallo-carbapenemases (Table). Aztreonam-avibactam tested with MIC₉₀s of 0.5 mg/L against the overall collection of CPE, CP-*K. pneumoniae*, and subsets of KPC-positive, OXA-48-like-positive and MBL-positive isolates. The MIC₉₀ was 4 mg/L against the subset of CP-*E. coli*, which included isolates harboring a YRIX insertion in PBP3. 99.9% (2288/2290) of CPE were inhibited by ≤8 mg/L of aztreonam-avibactam. The tested comparators showed reduced activity against subsets of CP organisms stratified by carbapenemase type and by species except for GES-positive isolates (100% susceptible to all agents but aztreonam) and CP-*E. cloacae* (98.9% susceptible to colistin) and CP-*E. coli* (99.2% susceptible to colistin).

**Conclusions:** Based on MIC₉₀ values, aztreonam-avibactam demonstrated potent *in vitro* activity against CPE, including MBL-positive isolates and those carrying multiple carbapenemases, and retained activity against isolates resistant to the last-resort agent colistin. The promising *in vitro* activity of aztreonam-avibactam warrants further development of this combination for use against infections caused by CPE.

**Acute cystitis symptom score questionnaire for patient-reported outcome measure in female patients with acute uncomplicated cystitis: clinical validation as part of a phase III trial comparing antibiotic versus non-antibiotic therapy**

Jakhongir Alidjanov¹, Andre Overesch², Dimitri Abramov-Sommariva³, Martina Höller², Hubert Steindl², Florian Wagenlehner¹, Kurt G. Naber*³

¹Justus-Liebig University, Giessen, Germany, ²Bionorica SE, Neumarkt, Germany, ³Technical University of Munich, Munich, Germany

Abstract third-party references: The study was supported by Bionorica SE, Neumarkt, Germany

**Background:** Since non-antibiotic therapy has become an alternative approach to treat uncomplicated acute cystitis (AC) in women, clinical criteria for diagnostics and patient-reported outcome measure (PROM) become more important as main study objectives. The Acute Cystitis Symptom Score (ACSS) was developed as a standardized self-reporting diagnostic questionnaire, which has proven its efficacy in the clinical diagnosis of AC in women and in monitoring possible changes after therapy.

**Materials/methods:** In a double-blind, randomized, multicentre, clinical Phase-3 trial including a total of 657 patients with AC in 51 centres in Europe, 325 women with AC were treated with the phytodrug Canephron®N (BNO-1045) for 7 days and 332 patients with a single oral 3g-dose of fosfomycin trometamol (FT). The main aim of the study was to compare the number of patients using any additional antibiotics. The ACSS used in this study was evaluated as a PROM in this post-hoc analysis.

**Results:** Between Days 1 and 38, 238 (83.5%) patients in the BNO-1045 group and 272 (89.8%) patients in the FT group received no additional antibiotic. At a 15% non-inferiority margin, BNO-1045 was non-inferior to FT in treating AC [non-AB rate difference: –6.26%; 95%CI –11.99 to –0.53%; 2-sided p = 0.0014]. The mean sum-scores of the six typical symptoms (ACSS typical domain) were comparable between the groups on Day 1 (BNO 1045: 10.2; FT: 10.1), and decreased at Day 4 (BNO-1045: 5.1, FT: 4.5), to the end of treatment at Day 8 (BNO 1045: 2.1; FT: 2.1) and to late follow-up at Day 38 (BNO-1045: 0.8; FT: 0.9). Predefined thresholds using the scoring system of the ACSS could be established and validated to define „clinical cure“.

**Conclusions:** In this post hoc evaluation, it could be demonstrated that the ACSS questionnaire, now translated and validated in several languages [www.acss.world], has the potential to be used as a suitable instrument for diagnostics and PROM in well-designed clinical studies investigating different treatment modalities of AC.

A single dose of gentamicin in patients with sepsis in the emergency department is safe with regard to renal function

Maarten Cobussen*1, Michiel Haeseker2, Paul H.M. Savelkoul1, Patricia Stassen3

1Academic Hospital Maastricht, Maastricht, Netherlands, 2Reinier de Graaf Gasthuis, Delft, Netherlands

Background: Aminoglycosides are frequently used in the empirical treatment of sepsis. Since aminoglycosides can cause acute kidney injury (AKI), it is questioned whether it is safe to administer aminoglycosides in patients with sepsis visiting the emergency department (ED). With increasing antibiotic resistance the options for appropriate empirical antibiotic therapy are becoming fewer. Therefore, our aim was to evaluate the renal safety of aminoglycosides.

Materials/methods: We retrospectively enrolled 1573 patients with sepsis in the ED in three hospitals. Local antibiotic guidelines recommended gentamicin as part of empirical therapy in one hospital, whereas the other two hospitals did not. Patients with and without gentamicin were compared. Subsequently, the effect of gentamicin and other potential risk factors on the incidence of AKI was evaluated. AKI was defined according to the KDIGO-criteria.

Results: Of 1573 patients, 32.9% received a single-dose of gentamicin. At admission, 32.6% of the gentamicin, and 23.3% of the non-gentamicin patients had AKI (p<0.001). After admission, AKI occurred in 12.4% of the gentamicin, and in 9.1% of the control group (p=0.06). Multivariate analysis showed that shock (OR 2.72 [95%CI, 1.31-5.67]), diabetes mellitus (OR 1.49 [95%CI, 1.00-2.23]), and higher baseline (i.e. pre-admission) serum creatinine (OR 1.007 per point increase [95%CI, 1.005-1.009]) were associated with the development of AKI after admission, but not gentamicin (OR 1.29 [95%CI, 0.89-1.86]). Persistent AKI was rare (6.6% in the gentamicin, compared to 3.3% in the non-gentamicin group, p=0.09). No differences were seen in the median serum creatinine concentrations over a 14-day period between those with, and without gentamicin and AKI on admission (p=0.85) (Figure).

Conclusions: Our study shows that a single-dose of gentamicin in patients with sepsis in the ED is safe with regard to renal function, as gentamicin was not associated with AKI after admission. The development of AKI after admission was associated with shock, diabetes mellitus, and a higher baseline creatinine.

Median serum creatinine levels [IQR] during 14 days follow up.
Baseline: most recent creatinine value prior to admission; Admission: creatinine value on admission; 1-2 days: 1-2 days after admission; 3-7 days: 3-7 days after admission; 8-14 days: 8-14 days after admission.

In vitro activities of ceftaroline and comparator agents against bacterial pathogens frequently causing community-acquired respiratory tract infections in patients from Latin America: ATLAS surveillance programme 2016-2018

James Karlowsky¹, Meredith Hackel*², Sam Bouchillon², Greg Stone³, Dan Sahm²

¹University of Manitoba, Winnipeg, Canada, ²IHMA, Schaumburg, United States, ³Pfizer, Inc., Groton, United States

Background: Community-acquired bacterial pneumonia (CABP) is a frequent cause of patient morbidity and mortality. *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* are frequent etiologic agents of CABP. Ceftaroline fosamil is a parenteral cephem approved for treatment of patients with CABP caused by *S. pneumoniae* (including cases with concurrent bacteremia), methicillin-susceptible *Staphylococcus aureus* (MSSA), *H. influenzae*, and some species of Enterobacteriales. Published data reporting the in vitro activity of ceftaroline against current isolates of bacterial pathogens causing community-acquired respiratory tract infections in patients in Latin America are limited.

Materials/methods: Clinically relevant, non-duplicate, isolates cultured from respiratory specimens by clinical laboratories in 9 countries in Latin America in 2016-2018 were collected by the ATLAS Surveillance Program central laboratory (IHMA, Inc., Schaumburg, IL, USA). In total, 436 isolates of *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, MSSA, and methicillin-resistant *S. aureus* (MRSA) were tested. The isolates (n) originated from Argentina (73), Brazil (79), Chile (116), Colombia (23), Costa Rica (4), Dominican Republic (15), Guatemala (21), Mexico (79), and Venezuela (26). Ceftaroline and comparator agent MICs were determined by CLSI broth microdilution methodology. MICs were interpreted using current EUCAST MIC breakpoints.

Results: Ceftaroline and comparator agent in vitro activities are summarized below.

<table>

Abstract 2365

**Treatment of Erythema migrans with doxycycline for 7 days versus 14 days: a non-inferiority randomised open-label study**

Maša Velušček¹, Anja Gomišček², Rok Blagus³, Tjasa Cerar Kišek⁴, Katarina Boršič⁵, Mirijam Nahtigal Klevišar⁶, Eva Ruzic-Sabljic⁷, Dasa Stupica*⁶

¹University Medical Centre Ljubljana, Ljubljana, Slovenia, ²Medical Faculty Osijek, Osijek, Croatia, ³Institute for Biostatistics and Medical Informatics, Faculty of Medicine Ljubljana, Ljubljana, Slovenia, ⁴Institute of Microbiology and Immunology, Faculty of Medicine Ljubljana, Ljubljana, Slovenia, ⁵University Medical Centre Ljubljana, Ljubljana, Slovenia, ⁶University Medical Centre Ljubljana and Faculty of Medicine Ljubljana, Ljubljana, Slovenia

**Background:** With awareness of increasing bacterial resistance globally, it is important to re-evaluate the duration of therapies needed for particular infections. Doxycycline for 10 days is the shortest treatment duration recommended for adult patients with erythema migrans, but shorter regimens have not been assessed.

**Materials/methods:** In an open-label randomized clinical trial, performed at the University Medical Centre Ljubljana, Slovenia, the efficacies of 7-day versus 14-day of oral doxycycline therapy were compared on a noninferiority premise in adult patients with solitary erythema migrans. The efficacy of treatment was assessed based on clinical and microbiologic parameters, as assessed at 14 days and at 2, 6, and 12 months after enrolment.

**Results:** Out of 300 randomized patients, 147 patients (50.5%) completed treatment with doxycycline for 7 days, and 144 patients (49.5%) received doxycycline for 14 days. Patients in the two treatment groups did not differ regarding basic demographic, clinical, and microbiologic characteristics at enrolment. The proportion of patients with incomplete response decreased during follow-up, and was comparable between 7-day and 14-day treatment groups [14 days: 25/144 [17.4%] vs 29/141 [20.6%]; P=0.295; 2 months: 27/136 [19.9%] vs 23/132 [17.4%]; P=0.638; 6 months: 15/118 [12.7%] vs 14/124 [11.3%]; P=0.557]. At the 12-month visit, 8/101 [7.9%] patients in the 7-day vs 9/102 [8.8%] patients in the 14-day group showed incomplete response [difference -0.9 percentage points; 1-sided 95% CI, –1 to 0.06 percentage points; P=0.5]. None of the patients developed new objective manifestations of Lyme borreliosis during follow-up and none had positive skin re-biopsy culture result for borreliae.

**Conclusions:** The 7-day regimen of oral doxycycline was noninferior to the 14-day regimen for treating adult European patients with solitary erythema migrans. At 12 months post-enrolment, only a minority of patients had incomplete response, manifested as post-Lyme borreliosis symptoms.

Using T2Bx and rapid AST with blood culture pre-sampling for combined ID and AST before blood culture positivity

Christer Malmberg1,2, Linnea Flinkfeldt2, Pikkei Yuen2, Jenny Fernberg2, Håkan Öhrn2, Cecilia Johansson2, Thomas Tängdén3, Johan Kreuger1

1Uppsala University, Department of Medical Cell Biology, Uppsala, Sweden, 2Gradientech AB, Uppsala, Sweden, 3Uppsala University, Department of Medical Sciences, Uppsala, Sweden

Abstract

Background: Rapid diagnostic methods are important for antibiotic stewardship and for improving quality of care in severe disease like sepsis. New culture-independent methods for identification (ID) within hours directly from blood are becoming available, such as T2Bacteria – however, blood cultures (BC) remain necessary for bacteria isolation and follow-up analysis such as antibiotic susceptibility testing (AST). QuickMIC is a rapid diagnostic tool under development, capable of AST at very low bacterial concentrations. Here we evaluate a combined rapid ID+AST diagnostic workflow using T2Bacteria and the QuickMIC AST system.

Materials/methods: Two diagnostic workflows were simulated, “standard” using blood culture followed by MALDI-TOF MS (ID) and AST by broth microdilution (BMD); or “rapid” using T2Bacteria followed by AST using QuickMIC. Escherichia coli (n=5), Klebsiella pneumoniae (n=9), Acinetobacter baumannii (n=6), Pseudomonas aeruginosa (n=5), and Staphylococcus aureus (n=13) clinical strains were inoculated in horse blood and BC started simultaneously with T2Bacteria. After T2Bacteria positive identification, the BC bottle was presampled for rapid AST. After BC positivity, samples were subcultured and MSID was performed. Specificity, sensitivity and turnaround time were compared between the two workflows, and QuickMIC results were compared to BMD with regards to categorical agreement.

Results: The rapid diagnostic workflow was significantly faster than the standard workflow (9.5±2.5h vs. 52.9±0.4h, p<0.001), and significantly faster for Gram-negative (GN) compared to Gram-positive (GP) bacteria (7.4±0.6h vs 12.2±0.4h, p<0.001). For 68% of the samples, the rapid ID+AST result was available before BC positivity (86% for Gram-negatives, 45% for Gram-positives). For 100% of the samples, rapid ID+AST was available before MSID. Diagnostic sensitivity/specificity at the species level were 94.7%/99.5% and 97.4%/100% for T2ID and MSID, respectively. QuickMIC (GN/GP panel) results took on average 167±15 min, and categorical agreement to BMD was 82% (GN) and 83% (GP).

Conclusions: We conclude that QuickMIC has the potential to be a suitable companion diagnostic to T2Bacteria for delivering rapid ID+AST results. The value of same-shift results for improved antibiotic stewardship and quality of care is high, and further evaluation beyond this pilot study will be conducted.

Abstract 2367

European regional analysis of the in vitro activities of ceftaroline and comparator agents against bacterial pathogens frequently isolated from patients with community-acquired respiratory tract infections: ATLAS surveillance programme 2015-2018

James Karlowsky1, Meredith Hackel*2, Sam Bouchillon2, Greg Stone3, Dan Sahm2

1University of Manitoba, Winnipeg, Canada, 2IHMA, Schaumburg, United States, 3Pfizer, Inc., Groton, United States

Background: Regional variation in resistance to many antimicrobial agents is widely appreciated. Ceftaroline fosamil, the prodrug of ceftaroline, is a parenteral cephem approved by both EMEA and the US FDA for the treatment of patients with community-acquired bacterial pneumonia caused by susceptible isolates of Staphylococcus aureus, Streptococcus pneumoniae, and Haemophilus influenzae as well as susceptible isolates of Escherichia coli and Klebsiella spp. The current analysis intended to determine whether regional variation in susceptibility to ceftaroline existed amongst its indicated respiratory pathogens in Europe.

Materials/methods: From 2015 to 2018, 118 clinical laboratories in Europe submitted 4,457 bacterial isolates cultured from respiratory samples of patients diagnosed with community-acquired respiratory tract infections to IHMA, Inc., (Schaumburg, IL, USA), the coordinating laboratory for the ATLAS (Antimicrobial Testing Leadership and Surveillance) program. At IHMA the identities of all isolates were confirmed using MALDI-TOF mass spectrometry and antimicrobial susceptibility testing was performed following standardized CLSI broth microdilution methodology [M07, 2018; M100, 2019]. Percent susceptibilities were determined using current EUCAST MIC breakpoints (2019, v. 9.0) where available.

Results: The in vitro activity of ceftaroline against respiratory pathogens is summarized below.

* PSSP, penicillin-susceptible S. pneumoniae; PNSSP, penicillin-nonsusceptible S. pneumoniae; MSSA, methicillin-susceptible S. aureus; MRSA, methicillin-resistant S. aureus; NA, MIC breakpoints not available

** mg/L

*** NW Europe, Northern and Western Europe

**** CE Europe, Central and Eastern Europe

Conclusions: Ceftaroline demonstrated potent in vitro activity against a 2015-2018 European collection of bacterial pathogens commonly associated with community-acquired respiratory tract infections. All isolates of MSSA and PSSP were susceptible to ceftaroline; overall, 94.8% of MRSA and 98.4% of PNSSP were susceptible to ceftaroline. A statistically significant (P<0.5) difference between NW Europe and CE Europe in vitro susceptibility to ceftaroline was only identified for MRSA [7.9% difference]. PNSSP susceptibility to ceftaroline only differed by 1% for isolates from NW Europe and CE Europe.

Abstract 2368

**Prolonged versus intermittent infusion of beta-lactam antibiotics: a systematic review and meta-regression of bacterial killing in preclinical infection models**

Sofie Dhaese*1,2, Aaron Heffernan1,4, David Liu4, Mohd Hafiz Abdul Aziz4, Veronique Stove2, Vincent Tam5, Jeffrey Lipman4,6,7, Jason Roberts4,6,7, Jan De Waele2

1AZ Sint-Jan Brugge, Brugge, Belgium, 2Ghent University Hospital, Ghent, Belgium, 3Griffith University, Brisbane, Australia, 4University of Queensland, Brisbane, Australia, 5University of Houston, Houston, United States, 6Royal Brisbane and Women’s Hospital, Brisbane, Australia, 7Nîmes University Hospital, Nîmes, France

**Background:** Administering beta-lactam antibiotics using prolonged infusions in critically ill patients have been proposed to improve efficacy but is mainly based upon preclinical evidence. Preclinical data on this topic have not been systematically reviewed before. Our objectives were to describe the pharmacokinetic/pharmacodynamic (PK/PD) indices and targets reported in preclinical models and to compare the bactericidal efficacy of intermittent and prolonged beta-lactam infusions.

**Materials/methods:** The Medline and EMBASE databases were searched from their inception until the 15th of April 2019. To compare the bactericidal action of beta-lactam antibiotics across different modes of infusion, the reported PK/PD outcomes of individual studies were recomputed relative to the area-under-the-curve of free drug to MIC ratio, ($fAUC_{0-24}/MIC$) for an equal reduction in CFU/mL. An $E_{max}$ model was then fitted and the mean and standard error (SE) $fAUC_{0-24}$ for a 1 log10 reduction in CFU/mL was predicted. A linear mixed effects meta-regression was performed to evaluate the impact of the antibiotic exposure (expressed as $fAUC_{0-24}$/MIC), the beta-lactam class, the initial inoculum, the host immune system, the gram-stain, and infusion-type on the reduction in the number of bacteria after 24 h of antibiotic treatment. The study protocol was published online with the PROSPERO (CRD42018085202) and CAMARADES database.

**Results:** Overall, 32 articles were included for review, of which 7 provided enough data for the simulation of a stable $E_{max}$ model and were included in the meta-regression. For maximal bactericidal activity, intermittent experiments reported a PK/PD target of 40%-70%$f_{MIC}$ while continuous experiments reported a steady-state concentration to MIC ratio ($C_{ss}$/MIC) of 4-8. The results of the metaregression indicated that the adjusted effect of a prolonged infusion on bacterial killing was small [coefficient and 95% CI of 0.81 [-0.47;2.10]].

**Conclusions:** Beta-lactam antibiotic PK/PD indices and targets are different for intermittent and continuous infusion. The additional effect of a prolonged infusion for enhancing bacterial killing on bactericidal action could not convincingly be demonstrated.

Abstract 2369

Turnaround time for pathogen identification and antimicrobial susceptibility testing of bronchoalveolar lavage specimens in U.S. acute care hospitals

Shawn Macvane,* 1, Niels Oppermann1, Romney Humphries1

1Accelerate Diagnostics, Inc., Tucson, United States

Background: Identification of respiratory pathogens and antimicrobial susceptibility testing (AST) results are fundamental to the diagnosis and management of patients hospitalized with pneumonia. Here, we examine the turnaround time (TAT) for reporting of results of the most prevalent bacterial pathogens among bronchoalveolar lavage (BAL) from patients hospitalized with suspected or confirmed pneumonia.

Materials/methods: Using the Premier Healthcare Database, a comprehensive database of U.S. hospitals, BAL samples from in-patient encounters with microbiology culture data were identified. BALs were excluded if they were from patients age < 18 years old, diagnosis of cystic fibrosis, time to organism identification > 7 days, and > 3 pathogens. Time from collection to reporting of gram stain, first organism identification (ID), and first organism AST were summarized descriptively.

Results: From June 2015 through May 2018, a total of 43,129 BALs met all study criteria, of which 28.6% were no growth, 43% were normal respiratory flora (including yeast), and 0.7% molds. Bacterial pathogens were recovered from 11,956 (27.7%) BALs. S. aureus and P. aeruginosa were recovered in 3,391 (7.9%) and 2,184 (5.1%) of all BALs, respectively and were the most common bacterial pathogens, followed by Haemophilus spp. (2.6%), Klebsiella spp. (2.1%), S. pneumoniae (1.8%), E. coli (1.6%), and Enterobacter spp. (1.3%). Median (interquartile range) TAT from specimen collection for bacterial pathogens were 10.6 (4.1-20.4), 41.0 (22.6-52.9), and 63.8 (46.5-72.4) hours for Gram stain, ID, and AST respectively. Median TAT for major respiratory pathogens is shown in Figure 1, ranging from 32.0 (S. aureus) to 47.3 (S. pneumoniae) hours for ID and from 47.9 (Klebsiella spp.) to 72.9 (S. pneumoniae) hours for AST. ID for BALs with bacterial pathogens was reported during the day shift (7:00 A.M. to 2:59 P.M.) for 75% of samples and 16% during the evening (3:00 P.M. to 10:59 P.M.). Similarly, AST was reported during the day shift for 74% of samples and 6% during the evening.

Conclusions: The average BAL TAT from specimen collection to ID and AST were approximately 40 and 65 hours, respectively. Most ID/AST results are reported during the day shift. BALs represent an area of interest for improved TAT.

Abstract 2371

**In vitro activity of ceftaroline and comparator agents against bacterial pathogens collected from patients with skin and soft tissue infections in Europe: a regional analysis of results from the ATLAS surveillance programme 2015-2018**

James Karlowsky1, Meredith Hackel*2, Sam Bouchillon2, Greg Stone1, Dan Sahm2

1University of Manitoba, Winnipeg, Canada; 2IHMA, Schaumburg, United States; 3Pfizer, Inc., Groton, United States

**Background:** Ceftaroline fosamil, the prodrug of ceftaroline, is a parenteral cephem approved by the EMA for the treatment of adults and children aged ≥2 months with complicated skin and soft tissue infections (SSTIs) caused by susceptible isolates of *Staphylococcus aureus* [including methicillin-resistant isolates], β-hemolytic streptococci, *Streptococcus anginosus* group, and members of Enterobacterales. The current analysis intended to determine whether regional variation in susceptibility to ceftaroline existed amongst its indicated SSTI pathogens in Europe.

**Materials/methods:** From 2015 to 2018 the ATLAS (Antimicrobial Testing Leadership and Surveillance) program received 17,445 bacterial isolates (130 laboratories; 25 countries) from samples of European patients diagnosed with SSTIs. All isolates were transported to IHMA (Schaumburg, IL, USA) where their identities were confirmed using MALDI-TOF mass spectrometry and CLSI broth microdilution antimicrobial susceptibility testing performed against ceftaroline and comparator agents. MICs were interpreted using EUCAST breakpoints (2019, v. 9.0) where available. *Streptococcus pyogenes* MICs were interpreted using the CLSI M100 breakpoint (≤0.5 mg/L; 29th edition, 2019) because EUCAST does not publish criteria for this organism-antimicrobial agent combination. Phenotypic ESBL screening was performed using the CLSI M100 method.

**Results:** The *in vitro* activity of ceftaroline is summarized below.

a MSSA, methicillin-susceptible *S. aureus*; MRSA, methicillin-resistant *S. aureus*  
b mg/L  
c NW Europe, North and Western Europe  
d CE Europe, Central and Eastern Europe  
e ESBL-negative Enterobacterales: 1,578 *Escherichia coli*, 763 *Klebsiella pneumoniae*, 361 *Klebsiella oxytoca*, 496 *Proteus mirabilis*

**Conclusions:** All isolates of MSSA were susceptible to ceftaroline as were 96.5% of MRSA isolates. Of the 160 ceftaroline-non-susceptible isolates of MRSA, 154 (96%) had MIC values of 2 mg/L (intermediate). Statistically significant regional differences (P<0.05) in *in vitro* susceptibility of isolates to ceftaroline were observed for MRSA (4.6% higher in NW Europe) and for all isolates of Enterobacterales (7.5% higher in NW Europe). Ceftaroline demonstrated potent *in vitro* activity against a 2015-2018 European collection of bacterial pathogens commonly associated with SSTI.

Abstract 2372

Using the Antibiotic Spectrum Index (ASI) score to assess antibiotic exposure for patients with Bloodstream Infections (BSI): an analysis of the Accelerate PhenoTest BC Kit (AXDX) IOAS study

Shawn Macvane*, Amira Bhalodi1, Margie Morgan1, Michael Ben-Aderet2, Meghan Madhusudhan2, Johann Kolev2, Ryan Dare3, Eric Rosenbaum3, Kaleb Wolfe3, Bradley Ford4, Dilek Ince4, Patrick Kinn4, Kelly Percival4, Romney Humphries1

1Accelerate Diagnostics, Inc., Tucson, United States, 2Cedars-Sinai Medical Center, Los Angeles, United States, 3UAMS - University of Arkansas for Medical Sciences, Little Rock, United States, 4University of Iowa Hospitals & Clinics, Iowa City, United States

Background: Rapid diagnostic tests (RDTs) that expedite organism identification (ID) and antimicrobial susceptibility testing (AST) allow clinicians to optimize antibiotic therapy sooner. Measuring antibiotic use is essential to assessing an RDT’s effectiveness. The purpose of this study to investigate the impact of fast ID/AST on antibiotic exposure in the early course of BSI.

Materials/methods: Antibiotic exposure received during the initial 96 hours following blood culture positivity from the IOAS study were assessed using the antibiotic spectrum index (ASI). This multicenter, quasi-experimental study compares clinical and antimicrobial stewardship metrics among patients with BSI before and after implementation of AXDX. Total ASI scores for each patient were calculated using the Gerber et al scoring system [with a lower score representing a shorter duration and/or narrower spectrum of antibiotic exposure] and compared between pre-AXDX and post-AXDX groups. To objectively measure antibiotic exposure, the ASI scoring system assign points to each antibiotic based on the antibiotic’s spectrum of activity against clinically relevant pathogens, ranging from a score of 1 to 13. Antibiotic exposure was calculated by multiplying duration of antibiotic exposure (days) by the ASI. All hospitals had antimicrobial stewardship programs throughout the study period.

Results: There were 462 patients with BSI who contributed ASI scores; 238 pre-AXDX, 224 post-AXDX. Patient demographics, comorbidities, and severity of illness were similar between groups, as were distributions of gram-negative (~60%) and gram-positive (~35%) BSI. The most prevalent gram-negative and gram-positive organisms were E. coli and S. aureus, respectively. The average total ASI score for pre-AXDX was 36.7 [SD 16.6] compared to post-AXDX 32.8 [SD 15.0], an overall reduction in ASI of 3.9 [95% Confidence Interval, 1.0 to 6.7; P=0.009] in the post-AXDX group.

Conclusions: In this study, implementation of the AXDX improved antibiotic prescribing among patients with BSI as evident by a reduction in the ASI score of approximately 4 units [equivalent to a day of ceftazidime or clindamycin exposure]. Use of antibiotic spectrum index scoring in patients with BSI can enhance the understanding of the impact of RDTs on antibiotic use, particularly when compared across several institutions that may have differing formulary or antibiotic prescribing practices.

Can MALDI-TOF MS provide enough discrimination between *Aspergillus fumigatus* sensu stricto and cryptic species?

Estreya Zvezdanova1,2, Pilar Escribano1,2, Julio García Rodríguez1, Julia Lozano-Serra4, Rosa María Jimenez Barrena5, Inmaculada Guerrero Lozano6, Carmen Castro7, Victoria Sánchez Hellín3, Patricia Muñoz1,2, Jesus Guinea Ortega1,2, Belen Rodriguez-Sanchez1,2

1Gregorio Marañón Hospital, Madrid, Spain, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, 3University Hospital La Paz, Madrid, Spain, 4Complejo Hospitalario Universitario de Albacete, Albacete, Spain, 5Hospital Toledo, Toledo, Spain, 6Hospital Universitario Puerta del Mar, Cádiz, Spain, 7Hospital Virgen de Valme, Sevilla, Spain, 8Hospital General Universitario de Elche, Elche, Spain

**Background:** Accurate species identification is of particular interest in the case of *A. fumigatus* complex given that sibling species show systematically low susceptibility to antifungal agents. MALDI-TOF could be a good alternative for the discrimination of *A. fumigatus* sensu stricto and cryptic species but information about this topic is limited.

**Materials/methods:** Morphologically identified *A. fumigatus* complex isolates (*n*=617) collected in a multicentre surveillance study conducted in Spain were further submitted to antifungal susceptibility testing. Resistant species were also molecularly identified by β-tubulin sequencing. All isolates, cultured on Sabouraud agar plates during 2-3 days, were identified by MALDI-TOF. Conidia were mechanically disrupted by vortexing for 5 min. The sample was centrifuged and the pellet was dried thoroughly and submitted to a standard protein extraction. 1µl of the supernatant was spotted on the MALDI target plate and covered with 1µl of matrix. All isolates were analysed in duplicates.

**Results:** MALDI-TOF accurately identified all *A. fumigatus* sensu stricto isolates (*n*=592) as such, showing score values ≥2.0 in 87.7% of them. The remainder isolates were identified as cryptic species (*n*=25); in 14/25 of them, identification was concordant with β-tubulin sequencing: *A. lentulus* (*n*=10), *Neosartoria pseudofisheri* (*n*=1) and *N. udagawae* (*n*=3) isolates. However, *A. fumigataffinis* (*n*=7) were consistently misidentified as *A. lentulus* [CBS 117267 strain] with score values ≥1.8; the remaining cryptic species isolates – *A. novofumigatus* (*n*=2) and *N. tsurutae* (*n*=2) – were also misidentified as *N. pseudofisheri*. The latter misidentifications could be detected since they were considered as unreliable reports due to their low scores and inconsistency through the top ten identifications provided by MALDI-TOF.

**Conclusions:** MALDI-TOF proved high reliability to discriminate between *A. fumigatus* sensu stricto and cryptic species within the *A. fumigatus* complex. Although the identification of cryptic species was poor (53.8%), particularly for non-*A. lentulus* species, the presence of cryptic species may be suspected by low scores and inconsistent results by MALDI-TOF. Inclusion in the databases and/or peak analysis may improve identification of cryptic species in the near future.

Abstract 2374

Detection of dengue virus antibodies in febrile patients suspected of malaria attending a health centre in Jos, Nigeria

Nantip Miri*, John Mawak1, Nyam Chuwang2, Teme Ezekiel3, Shedrach Acheng1, Chukwu Chukwu4

1University Of Jos, Jos, Nigeria, 2University Of Jos, Jos, Nigeria, 3Plateau State Virology Research Center, Jos, Nigeria, 4National Veterinary Research Institute, Jos, Nigeria

Background: Despite the public health importance of dengue infections, it is less investigated by clinicians and rarely considered in the differential diagnosis of febrile illnesses in Nigeria. This study was aimed at determining dengue seroprevalence and malaria infection.

Materials/methods: We conducted a cross sectional study on ninety four (94) consenting febrile patients suspected of malaria in Jos. Detection of dengue antibodies (IgG/IgM) were determined by Enzyme Linked Immunosorbent Assay technique. Total RNA and DNA was extracted from patient serum with a commercial kit and quantified to determine concentration and quality of the extraction process. Malaria was detected by the amplification of a conserved region of 18S rRNA gene in a Real Time Polymerase Chain Reaction. Ethical clearance and consent were obtained accordingly before study was conducted on human subjects.

Results: Dengue antibodies were detected in 55.3% (52/94) of the febrile patients. The mean age was 29.9±1.2. Highest dengue seroprevalence of 75% (39/52), 50% (26/52) and 59.6% (31/52) were recorded among females, students and non-users of mosquito nets, respectively.

Only 11.7% (11/94) tested positive for malaria. Dengue and Malaria co-infection recorded 5.3% (5/94). There was a significant difference in the prevalence of dengue and malaria among febrile subjects. No association of dengue infection with gender and use of Insecticide Treated Nets.

Conclusions: The lower prevalence of Malaria as compared to Dengue suggests that, febrile illnesses in our study population are more associated with dengue infection than malaria infection. The co-infection of dengue and malaria reported in this study is of clinical importance, and deserves more investigation. An inclusion of dengue in the differential diagnosis of febrile illnesses should be given consideration. We recommend a continuous surveillance of dengue infection and a determination of the circulating serotypes in this population.

**Abstract 2375**

**In vitro activity of imipenem/relebactam against Gram-negative organisms collected globally from patients with different infection types: SMART 2018**

Sibylle Lob¹, Krystyna Kazmierczak¹*, Katherine Young³, Mary Motyl¹, Fakhar Siddiqui², Dan Sahm¹

¹IHMA, Schaumburg, United States, ²Merck & Co., Inc., Kenilworth, United States

**Background:** Relbeactam (REL) inhibits class A and C β-lactamases and was approved in the USA in combination with imipenem (IMI) and clastatin for the treatment of complicated intraabdominal and urinary tract infections. We evaluated the activity of IMI/REL against non-Morganellaceae Enterobacterales (NME) and *Pseudomonas aeruginosa* (PA) isolates collected globally as part of the SMART surveillance program from patients with various infection types.

**Materials/methods:** In 2018, 195 clinical laboratories in 54 countries each collected up to 250 consecutive aerobic or facultative gram-negative pathogens from bloodstream (BSI), intraabdominal (IAI), lower respiratory tract (LRTI), and urinary tract infections (UTI). MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints for all agents except IMI/REL for which FDA breakpoints were used. Isolates testing with IMI MIC ≥2 mg/L (NME) or ≥4 mg/L (PA) were screened for β-lactamase genes.

**Results:** The three most common species found among all gram-negative isolates collected from BSI (n=8472), IAI (n=7939), and UTI (n=9424) were *E. coli* (EC; 42.4%, 44.3%, and 51.7%, respectively), *K. pneumoniae* (KP; 18.9%, 15.0%, 16.4%, respectively), and PA (8.7%, 10.5%, 8.0%, respectively). The ranked order was different for LRTI isolates, with PA being most common (27.7%), followed by KP (18.9%) and EC (12.2%). All NME combined composed 77.7%, 78.4%, 51.1%, and 79.7% of gram-negative isolates collected from BSI, IAI, LRTI, and UTI. Among NME, 1.4% [393/28265] were metallo-β-lactamase (MBL)-positive; among *P. aeruginosa*, 4.8% [318/6642] were MBL-positive. Excluding these MBL-positive isolates, the table shows susceptibility to IMI/REL among the three most common species, combined isolate collections, and carbapenem-resistant subsets.

²Percent susceptible not shown when n<10: number of susceptible isolates is shown instead

IMI/REL maintained activity of >99%, ≥95%, >96%, and >91% against MBL-negative EC, KP, NME, and PA, respectively, regardless of infection source. IMI/REL maintained susceptibility rates of 54-72% against IMI-resistant isolates across infection sources, with lower rates of 29-49% among meropenem-resistant PA. Among molecularly characterized IMI/REL-susceptible isolates of IMI-resistant MBL-negative NME (n=367) and PA (n=1071), 94.0% and 0.1%, respectively carried KPC, 2.2% and 2.5%, respectively, carried only ESBL±AmpC, and in 3.3% and 97.3%, respectively, no acquired β-lactamases were detected.

**Conclusions:** IMI/REL could provide an important treatment option against antimicrobial-resistant gram-negative pathogens from BSI, IAI, LRTI, and UTI.

Abstract 2380

An imported case of West Nile virus neuroinvasive disease in the UK
Nuzhath Khan*, Robyn Lewis1, Padmasayee Papineni1, William Lynn1, Gurjinder Sandhu1

1Ealing Hospital, London, United Kingdom

Background: Since its discovery in 1937, West Nile Virus (WNV) has rapidly emerged as the commonest cause of arboviral neurological disease worldwide. Neuro-invasive disease accounts for less than 1% of presentations but carries a significant 10% mortality rate. There is currently no cure or human vaccine available. There have been large human outbreaks in Europe and North America since the 1990s and the disease is now endemic in the USA with over 24000 cases of neuro-invasive disease since WNV first crossed the Atlantic in 1999.

Materials/methods: An imported case of WNV infection with neuro-invasive disease in the UK is discussed.

Results: A 59 year-old British male, resident in Philadelphia, USA, presented with confusion and fever, four days after arrival to London to visit family. He deteriorated within 48 hours with reduced Glasgow Coma Scale (GCS) to 9/15, neck stiffness and flaccid paralysis requiring intubation and ventilation. Magnetic resonance imaging showed high-signal intensity within the left thalamus and right frontal parietal subcortical region. Cerebrospinal fluid (CSF) showed white cell count 252/mm3 with lymphocytic predominance and extensive tests for infection were negative. A diagnosis of West Nile Virus (WNV) was established with assistance from the Rare Imported Pathogens Laboratory based on strongly positive serum and CSF IgM. Patient had a long period of supportive management, spending a total of three months in the intensive care unit, with slow and limited recovery of function.

Conclusions: There have been increasing reports of imported cases of WNV neuro-invasive infection in the UK. There are limited treatment options with highest efficacy of treatment likely in early phase of the disease, warranting early recognition. There is a clear need for increased awareness, early recognition and further development of treatment and preventative strategies for WNV.

Abstract 2381

Cost-effectiveness analysis of pneumococcal vaccines in older adults in Argentina
Norberto Giglio*, Vanesa Castellano, Patricia Mizrahi, Paula Micone

1Buenos Aires, Hospital de Niños Ricardo Gutierrez, Buenos Aires, Argentina, 2Buenos Aires, Hospital de Niños Ricardo Gutierrez, Buenos Aires, Argentina, 3Buenos Aires, Opinion Sur, Buenos Aires, Argentina, 4Buenos Aires, Hospital General de Agudos Carlos Durand, Buenos Aires, Argentina

Background: In 2017, the Argentine Ministry of Health implemented a sequential vaccination scheme with pneumococcal conjugate vaccine 13 serotypes [PCV-13] plus 23 valent pneumococcal capsular polysaccharide vaccine [PPSV23] for adults ≥ 65 years with the purpose of reducing pneumonia burden of disease, complications, and related mortality. Previously in 2012, PCV13 was introduced in the national immunization program for infants in a 2+1 schedule. During 2020, Argentinean NITAG will reassess this recommendation for older adults. Objective: The aim of this study was to perform a cost-effectiveness analysis of the pneumococcal vaccines, PCV-13 plus PPSV23 for adults ≥ 65 years old in Argentina.

Materials/methods: A cost-effective Markov model was developed to quantify the impact of pneumococcal vaccination based on a cohort of 314,690 people ≥ 65 years old. The model considered outpatient pneumonia, hospitalized pneumonia in patients with low risk/at risk of comorbidities, immunsupression [high risk] and invasive pneumococcal disease [IPD]. Updated local cost data, pneumococcal burden of disease and serotype coverage were incorporated into the model. The vaccine efficacy/effectiveness were obtained from a systematic review. With the aim of minimizing the uncertainty, alternative scenarios, univariate and probabilistic sensitivity analyses were developed. The Microsoft Excel program was used to perform the model of effectiveness adjustment by serotypes and drop in effectiveness over the time. Results were described as life years gained; event and cost of illness averted at a time horizon of 15 years.

Results: PCV13 in sequential schedule with PPSV23 vaccine resulted cost saving for Argentina in the main scenario with, 2,308 life years gained, 1,021 outpatient pneumonia, 2,977 hospitalized pneumonia, 1,072 IPD, and 707 related deaths averted, saving USD 4,304,808. Additionally, results were cost saving and highly cost effective in additional scenarios. Conditions associated with pneumonia incidence, lethality and serotype coverage inputs, were some of the most important factors that support these results.

Conclusions: The sequential schedule turned out to be cost saving for Argentina in the population of adults ≥ 65 years old in many of the assumptions.

Cidofovir-associated nephrotoxicity in adult allogeneic haematopoietic cell transplant recipients
Anat Stern1, Genovefa Papanicolaou1, Carolina Garcia Vidal2, Celia Cardozo2, Carolyn Alonso1, Philipp Köhler4,5, Christof Scheid4, Oliver A. Cornely4,5,6,7, David Epstein8, Stavroula Masouridi Levrat9, Yasmin Abi Aad3, Yves Chalandon9, Dionysios Neofytos9

1Memorial Sloan Kettering Cancer Center, Infectious Diseases service, New York, United States, 2Hospital Clínic de Barcelona, Barcelona, Spain, 3Beth Israel Deaconess Medical Center (BIDMC), Harvard University, Boston, United States, 4Universität zu Köln, Faculty of Medicine and University Hospital Cologne, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf (CIO ABCD), Excellence Center for Medical Mycology (ECMM), Köln, Germany, SÜniversität zu Köln, Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Köln, Germany, 5Universität zu Köln, Clinical Trials Centre Cologne (ZKS Köln), Köln, Germany, 6German Centre for Infection Research, Partner Site Bonn-Cologne, Cologne, Germany, 7Stanford, Stanford University, Stanford, United States, 8Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland

Background: Concerns about nephrotoxicity may limit cidofovir (CDV) use in allogeneic hematopoietic cell transplant recipients (allo-HCTr). In this multi-center study, we aimed to assess real-life use and nephrotoxicity of CDV in allo-HCTr.

Materials/methods: Data on all consecutive adult allo-HCTr treated with intravenous CDV (2011-2018) were retrospectively collected in six centers. We report preliminary descriptive data on CDV nephrotoxicity.

Results: We included 123 allo-HCTr (5% bone marrow, 77% peripheral blood stem cells, 15% cord blood), from a matched-related (16%), mismatched/matched-unrelated (76%) or haploidentical (7%) donor. Seventy-three (59%) patients received a T-cell depleted HCT, mostly by ex-vivo CD34-selection (61%) and 54 (44%) patients had acute graft-versus-host disease at CDV initiation. CDV was administered for: adenovirus (58, 47%), cytomegalovirus (54, 44%), BK-virus (35, 28%), human herpes virus 6 (7, 6%), herpes simplex virus (5, 4%) or JC-virus (1, 1%) infections. In 24 (20%) patients >1 viral indication was present. Patients received a median of 3 (interquartile ratio, IQR 2-4) CDV doses. CDV doses were 5 mg/kg/week, 3 mg/kg/week, 1 mg/kg in various frequencies in 88 (71.5%), 11 (8.9%), and 19 (15.4%) patients, respectively. Median time from HCT to CDV initiation was 90 days [IQR 59-163]. Mean creatinine was 0.9 mg/dL (±0.42, N=123) at baseline, 1.07 mg/dL (±0.71, N=103) at end-of-treatment (EOT; p-value=0.0001) and 1.34 mg/dL (±0.98, N=54) at EOT+14D (p-value baseline-EOT+14D=0.002, p-value EOT-EOT+14D=0.023; Figure 1). Out of 62 patients with reported glomerular filtration rate (GFR), 52 (83.9%) and 46 (74%) patients had GFR>60 mL/min at baseline and EOT, respectively (p-value=0.11). Using the RIFLE-criteria, ≥50% creatinine increase and ≥25% GFR decline by EOT compared to baseline were observed in 19/105 (18.4%) and 13/62 (21%) patients, respectively. Patients receiving 5 mg/kg/week CDV were more likely to develop acute kidney injury (AKI) by EOT compared with those receiving 1-3 mg/kg/week (32.8% versus 4.5%, p-value=0.032). None of the patients developed end-stage-renal-disease. No significant associations were found between AKI and CDV number of doses or cumulative dose.

Conclusions: Based on preliminary analyses, renal impairment developed in 20% of allo-HCTr treated with CDV. CDV dose of 5 mg/kg/week appeared to be associated with a higher rate of AKI.

Abstract 2385

Unravelling the potential utility of novel β-lactam/β-lactamase inhibitors against Enterobacter cloacae complex

Erin Mccreary*, Abigail Rubio1, Alina Iovleva1, Ellen Kline1, Chlesea Jones2, Yohei Doi2, Ryan Shields2

1University of Pittsburgh Medical Center, Pittsburgh, United States, 2University of Pittsburgh, Pittsburgh, United States

Background: Enterobacter cloacae complex are genetically diverse pathogens increasingly reported as resistant to cefepime and/or carbapenems. Our objective was to investigate the in vitro activity of novel β-lactam/β-lactamase inhibitor (BL/BLI) combinations against E. cloacae.

Materials/methods: Isolates non-susceptible to cefepime or a carbapenem by automated testing methods were selected. Minimum inhibitory concentrations (MICs) were determined by broth microdilution methods and interpreted using CLSI breakpoints. β-lactamases were identified by PCR and/or whole-genome sequencing.

Results: 86 isolates from unique patients were included; 50%, 63%, and 24% were resistant to cefepime, ertapenem, and meropenem, respectively. Carbapenemases were detected in 17 isolates (15 KPC, 2 VIM); 41%, 6%, and 53% of carbapenemase-producing (CP) isolates were susceptible to cefepime, ertapenem, and meropenem, respectively. Rates of susceptibility were 12%, 91%, 88%, and 95% to ceftolozane-tazobactam, ceftazidime-avibactam, imipenem-relebactam, and meropenem-vaborbactam, respectively (Table). Ceftolozane-tazobactam susceptibility rates were similar to piperacillin-tazobactam (13%). Median fold-reductions in ceftazidime, imipenem, and meropenem MICs following the addition of avibactam, relebactam, and vaborbactam for all isolates were 128, 4, and 4, respectively. Against CP isolates the corresponding fold-reductions were 128, 32, and 16. 51% and 62% of meropenem-resistant isolates demonstrated imipenem-relebactam or meropenem-vaborbactam MICs ≥ 2µg/mL, respectively. Conversely, 52% of meropenem-resistant isolates had meropenem MICs ≤8 µg/mL. Only 38% of meropenem-resistant isolates were CP. Against non-CP meropenem-resistant isolates, the addition of relebactam and vaborbactam to imipenem and meropenem, respectively, lowered median MICs by 4-fold; median ceftazidime MICs were lowered 1.28-fold with the addition of avibactam. 8 isolates were resistant to ceftazidime-avibactam, 2 produced VIM and 6 had substitutions in the R2 or Ω-loop of AmpC. 3 isolates were resistant to meropenem-vaborbactam, 2 harbored substitutions in R2 loop of AmpC and OmpC/OmpF, 1 produced VIM.

Conclusions: Against diverse E. cloacae, ceftazidime-avibactam, imipenem-relebactam, and meropenem-vaborbactam demonstrated susceptibility rates ranging from 88–95%; however, novel resistance mechanisms were identified. >50% CP-E. cloacae were susceptible to meropenem. Against non-CP E. cloacae, relebactam and vaborbactam both lowered carbapenem MICs suggesting possible β-lactamase inhibition beyond stability of carbapenems. In the setting of β-lactam resistance, most novel BL/BLIs provide excellent in vitro activity, but the preferred treatment approach merits further investigation.

Abstract 2386

**T2Bacteria panel in diagnostics of sepsis: the first experience at the University Hospital Centre Zagreb**

Ivana Mareković*1,2, Zrinka Bosnjak1,2, Sanja Pleško1, Vesna Tripkovic1

1University Hospital Centre Zagreb, Zagreb, Croatia, 2School of Medicine, University of Zagreb, Zagreb, Croatia

**Background:** T2Bacteria® Panel (T2 Biosystems®) is the first and only FDA and CE-marked test to identify sepsis-causing bacteria directly from whole blood in 3 to 5 hours, which would aid in prescribing earlier appropriate antimicrobial treatment. The aim of the study was to show our first experience with this unique new technology in septic patients.

**Materials/methods:** From December 2018 to March 2019 T2Bacteria® Panel (T2BP) was used in the following groups of septic patients: medical and surgical intensive care unit (ICU), hematology and solid organ transplant. Four mL of blood for T2BP was collected in a K2EDTA tube and one set of blood cultures (BC) was simultaneously obtained. T2BP results were compared against concomitant drawn blood cultures and additional microbiological results within 14 days of T2BP sample.

**Results:** A total of 29 patients, 21 (72,4%) male and 8 (27,6%) female, were included with age ranging from 0 – 83 years and twenty-six (89,6%) of them at the ICU. T2BP was positive in 13 (44,8%) and BC in 6 (20,7%) of patients. When T2BP results were compared to BC (on panel bacteria only), 2 patients were T2BP+BC+, 11 patients T2BP+BC-, 16 patients T2BP-BC-, and no patients T2BP-BC+. Average time to positive result with T2BP was 4 hours and 40 minutes and in two patients with concomitantly positive BC for panel organisms 86 hours and 30 minutes. Average time to negative result was 5 hours and 6 minutes with T2BP and 120 hours with BC. When analyzing the significance of 13 T2BP+BC- results in the context of all other available microbiological data, 11 additional results otherwise missed by BC were identified, one was probably false-positive and for one there were no data available. Statistical analysis showed 100,0% positive percent agreement (PPA), 90,0% negative percent agreement (NPA), 100,0% negative predictive value (NPV) and 84,6% positive predictive value (PPV).

**Conclusions:** Our first experience with T2Bacteria® Panel showed this is highly promising molecular method reducing time to species identification as well as to negative result. It demonstrated high PPA and NPV as well as proving etiology of additional cases otherwise missed with conventional diagnostics.

Coque5

1Ramón and Cajal Hospital, Microbiology Service, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 2Ramón and Cajal Hospital, Bioinformatics Unit, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain, 3Ramón and Cajal Hospital, Department of Intensive Care, Madrid, Spain, 4University of Porto, Laboratory of Microbiometry, Faculty of Pharmacy, Porto, Portugal, 5Ramón and Cajal Hospital, Department of Microbiology, Ramón and Cajal Research Institute (IRYCIS), Madrid, Spain

**Background:** Extended-Spectrum Beta-Lactamase (ESBL) or carbapenemase-resistant (CR) *Klebsiella* spp. (Ki) are increasing in hospitals, environmental Kl reservoirs being often detected in built hospital environment (BE) during ESBL/CRKl outbreaks. We screened Kl in abiotic surfaces of an ICU-Intensive Medicine ward fully enrolled in infection control programs of antimicrobial resistance.

**Materials/methods:** 5 samples/patient room (sinks-SK; ventilator’s-touchscreen-VT; washbasin-WB; bedrails-BR) and 2 samples from staff-areas (keyboards) were weekly collected using EZ-Reach-Sponges [April-October 2019]. 1,728 samples were plated [(5x14rooms+2)x24weeks] on ChromagarOrientation and bacterial colonies were characterized [1/morphotype; 10,180 colonies]. Identification (MALDI-TOF-MS), antimicrobial-susceptibility (disk-diffusion, Hodge-test, PCR-bla) and clonal typing (FT-IR spectroscopy, XbaI/S1 -PFGE, whole genome sequencing, WGS) were analysed. REDCap [Research Electronic Data Capture] application was used to integrate and further exploit comprehensive metadata [clinical records, IC, BE surveillance]. ICU-metrics for this period include 95%-ICU occupancy, 244 patients, 27.9%-MDR colonization-rate (23% ESBLKP, 6.8% CRKP).

**Results:** We detected Kl in BE of 9/14 rooms [K. pneumoniae (KP), K. oxytoca (KO), K. variicola (KV)] in 7, 4 and 1 rooms, respectively. KP appears in all samples, KO in SK+BR while KV was confined to SK. BE-KP isolates clustered in 11 clones [1ESBL+/-, 3CRs (OXA-48), 7 non-ESBL and non-CR]. All CRKP were collected from BR of rooms with patients colonized by CRKP. A KP clone (ESBL+/- variants), together with other ESBL-producing species, was detected in a SK for ≥3 months. Some KP were high-risk lineages (CG258,CG405)/K-types (K19, K24, KL151), often recovered from inpatients. All non-ESBL/non-CRKP clones were sporadically detected [1-2 weeks in SKs]. KO clustered in 6 clones [5 capsular types], one being an ESBL producer recovered in a single SK for 4-months. All KV isolates belong to a single clone [different variants] for 6months. Preliminary WGS confirms different transmission routes within and between abiotic and biotic samples.

**Conclusions:** BE surveillance revealed hidden and persistent KP, KO and KV reservoirs in SK of specific rooms able to occasionally acquire and retain *bla*<sub>ESBL</sub>, and also the ability of some KP and KO human clones for transiently colonize surfaces. Analysis of metadata from different human and BE surveillance programs improves risk assessment analysis for the transmission of multidrug resistant pathogens.

Abstract 2390

Improving Outcomes and Antibiotic Stewardship for patients with bloodstream Infections (IOAS): a quasi-experimental multi-centre analysis of time to optimal therapy

Amira Bhalodi*, Shawn Macvane1, Margie Morgan2, Michael Ben-Aderet2, Meghan Madhusudhan1, Johann Kolev2, Ryan Dare3, Eric Rosenbaum1, Kaleb Wolfe1, Bradley Ford4, Dilek Ince4, Patrick Kinn4, Kelly Percival4, Romney Humphries1

1Accelerate Diagnostics, Inc., Tucson, United States, 2Cedars-Sinai Medical Center, Los Angeles, United States, 3UAMS - University of Arkansas for Medical Sciences, Little Rock, United States, 4University of Iowa Hospitals & Clinics, Iowa City, United States

Background: Measuring impact of diagnostic technologies on patient care can be complex. For hospitals with established antimicrobial stewardship programs, initiatives focused on improving quality of care are key and can be demonstrated by measuring the impact on time to optimal therapy. Effect of antibiotic optimization for patients with bloodstream infections (BSI) was evaluated in the Accelerate PhenoTest™ BC kit (AXDX) registry program, with emphasis on time to optimal therapy (TTOT).

Materials/methods: This multicenter, quasi-experimental study compares clinical and antimicrobial stewardship metrics, prior to and after implementation of AXDX, to evaluate the impact this technology has on patients with BSI. Laboratory and clinical data from hospitalized patients with BSI (excluding contaminants) were compared between two groups, one that underwent testing on AXDX (post-AXDX) and one that underwent alternative organism identification and susceptibility testing (pre-AXDX). Interim analysis of data collected from 3 centers was performed. Pre-AXDX methods for each of the 3 sites were: Verigene®, MALDI-TOF MS, and BD Phoenix™ at Hospital A; MALDI-TOF MS and VITEK® 2 at Hospital B; and MALDI-TOF MS, VITEK® 2, and Sensititre™ at Hospital C. All institutions had active antimicrobial stewardship programs throughout the study period. Primary outcome was TTOT; multiple linear regression analysis was performed to identify clinical factors associated with TTOT.

Results: 464 patients with BSI (239 pre-AXDX, 225 post-AXDX) were included in this analysis. Patient demographics, comorbidities, and severity of illness (median Pitt bacteremia score of 2) were similar between groups, as were distributions of gram negative (~60%) and gram positive (~35%), with polymicrobial (~11%) BSI. The most prevalent gram-negative and gram-positive organisms were E. coli and S. aureus, respectively. Median TTOT was 42.0 hours [interquartile range [IQR], 20.5 - 65.3] in the pre-AXDX group and 28.2 hours [IQR, 12.8 - 49.2] in the post-AXDX group (p=0.003). Independent factors associated with shorter TTOT were BSI with AXDX on-panel organisms (p=0.01), absence of intravenous vasopressors (p=0.01), and post-AXDX group (p=0.01).

Conclusions: Implementation of AXDX improves antimicrobial stewardship in patients with BSI reducing both TTOT and unnecessary antimicrobial exposure.

Abstract 2392

High burden and undetected clusters of pneumococcal disease in long term care in Ontario, Canada

Allison Mcgeer1, Wallis Rudnick1, Walter Demczuk1, Wayne Gold3, Ian Kitai4, Sigmund Krjaden5, Reena Lovinsky6, Irene Martin2, Matthew Muller7, Jeff Powis1, Neil Rau5, Greg Tyrrell10, Andrew E. Simor11, Toronto - Tibdn12

1Sinai Health System, Toronto, Canada; 2National Microbiology Laboratory, Winnipeg, Canada; 3University Health Network, Toronto, Canada; 4The Hospital for Sick Children, Toronto, Canada; 5St. Joseph’s Health Centre, Toronto, Canada; 6The Scarborough Hospital, Toronto, Canada; 7Unity Health, Toronto, Canada; 8Toronto East Health Network, Toronto, Canada; 9Halton Healthcare, Oakville, Canada; 10Alberta Public Laboratories, Edmonton, Canada; 11Sunnybrook Health Sciences Centre, Toronto, Canada; 12Toronto Invasive Bacterial Diseases Network, Toronto, Canada

Abstract third-party references: Toronto Invasive Bacterial Diseases Network

Background: Despite PPV23 and herd immunity from pediatric PCV, there are reasons to be concerned about persisting burden of illness in long-term care residents (LTCR), as pneumococcal carriage and congregate living may reduce herd protection. We analyzed invasive pneumococcal disease (IPD) in LTCR in Toronto/Peel region, Canada, post PCV13 implementation.

Materials/methods: TIBDN conducts population-based surveillance for IPD in Toronto/Peel, Canada (Pop=4.5M). Serotyping and antimicrobial susceptibility testing are performed. Incidence in LTCR was calculated per 1000-bed-days. The odds of occurrence of >1 case of a particular serotype in any one LTC home was calculated by comparing incidence in that home due to that ST from first to last case to incidence in all other homes due to that ST during the same period; P<.0005 was considered statistically significant.

Results: From 1995-2018, 566 episodes of IPD occurred in LTC; incidence decreased from 224 to 70/1000 bed-days after adult PPV23 (1996)/infant PCV (2005/2010) programs; but 37% of 2014-18 isolates were of PCV13 STs. In cases of IPD, LTCR were more likely than age-matched community controls to have received PPV23 (55v44%, P=.002), but case fatality was higher (49 vs 14%, P<.0001), and isolates more resistant to penicillin (20 vs 14%, P=.03) and levofloxacin (4.9 vs 1.0%, P<.001). Although no outbreaks were reported, 29 clusters of ≥3 cases (total 134/500, 27% of IPD) were retrospectively identified in which the serotype incidence in the affected home was significantly higher than in other homes at the same time (P<.0005). The largest clusters are in the Table; clusters were more likely of serotypes 14, 3, 38 and 31.

Conclusions: The burden of IPD in LTC is high. Unrecognized transmission appears to contribute to this burden.

Table: Largest case clusters in LTC, 1995-2018

Abstract third-party references: ALK Abello

Background: Nearly 90% of self-reported penicillin allergies are negative upon assessment or skin testing. Allergy assessment and penicillin skin testing (PST) are useful tools to increase use of beta-lactams (BL), which are frequently the antibiotic of choice for many infectious syndromes. PST has been successfully implemented in both inpatient and outpatient care settings; however, longitudinal effects of PST have not been evaluated.

Materials/methods: This was a retrospective, observational study of adult patients who had a negative PST between August 2014 and October 2019 across one academic medical center and one community hospital. Time period assessed per patient was defined as the twice the number of days between PST and most recent day of discharge. Primary outcome was percent of antimicrobial courses containing a BL before and after PST in patients who received at least one antimicrobial course before and after PST. Secondary outcomes were percent of antibiotic days containing a beta-lactam, percent of beta-lactam days of penicillin, and percent antibiotic days of penicillin. Results were considered significant if p ≤0.05.

Results: In total, 337 patients with a negative PST completed per protocol over the study time period were included. One hundred thirty-nine patients received at least one antibiotic course during any readmission after PST, and 64 received at least one course before and after PST. The proportion of patients that received a BL course after PST was 50% higher than before PST. (Table 1)

Data presented as Mean ± SD; PCN: penicillin

Conclusions: Negative PST leads to sustainable improvements in patient care, as patients received significantly more BL days of therapy, including penicillins, after negative PST. Our results confirm the importance of allergy assessment and intervention for patients labeled as penicillin allergic.

Abstract 2395

Shorter duration of antibiotherpy in super-infection pneumopathy occurring in viral infection
Simon Bessis*1, Martin Trichet1, Alina Beresteanu1, Morgan Matt1, Benjamin Davido1, Aurélien Dinh1

1Raymond Poincaré University Hospital - [AP-HP], Garches, France

Background: Bacterial superinfections during respiratory viral infections are common. In this situation, the optimal antibiotic treatment duration is unknown. We aimed to demonstrate that a short treatment duration [3 days] is as effective as a longer duration [>3 days].

Materials/methods: We performed a retrospective cohort study including all patients hospitalized for respiratory viral infection with bacterial superinfection.

Our case definition was:
- adult hospitalized patient with positive PCR assay for respiratory viruses
- and fever (≥38°C) + at least one clinical symptom of pneumonia (dyspnea, cough, muco-purulent sputum, crackles)
- and bacterial superinfection defined as the presence of: muco-purulent sputum + hyperleukocytosis [with high neutrophil count] + elevated CRP and/or PCT levels + a new infiltrate on chest X-ray compatible with bacterial infection + positive bacterial sputum culture + antibiotic treatment prescribed by the physician in charge.

Cure was assessed at hospital discharge. It was a composite criterion: no resumption of antibiotic therapy and/or extension of the initially planned duration, associated with apyrexia and improvement of initial clinical symptoms. Death from any cause was considered as failure.

Results: From January 1st to April 1st 2019, 36 patients were included. The mean age was 74.7 years with a sex ratio (M/F) of 1.4. Overall, 17/36 (47.2%) patients had a chronic respiratory disease, 17/36 (47.2%) were smokers, 9/36 (25.0%) were immunocompromised. At admission, 21/36 (58.3%) patients presented fever, 14/36 (38.9%) needed oxygen supplementation. Main positive results of the multiplex PCR assay were: influenza A H3N2 [28/36], rhinovirus [4/36], and Respiratory Syncitial Virus [2/36].

Finally, 19 patients received 3 days of antibiotic treatment and 17 patients were treated more than 3 days. There was no significant difference regarding clinical and therapeutic characteristics between the 2 groups. The cure rate was 84.2% [16/19] in the group treated 3 days and 70.6% [12/17] in the group treated more than 3 days, with no significant difference (p=0.43).

Conclusions: A short duration [3 days] of antibiotic seems to be sufficient for bacterial superinfections of respiratory viral infections. Larger sample size study and randomized controlled trials are needed to confirm these preliminary data.

Abstract 2396

Elucidation of environment-dependent antibiotic resistance mechanisms
Henrique Machado*, Yara Seif¹, Nicholas Dillon¹, Hannah Tsunemoto¹, Joseph Pogliano¹, Victor Nizet¹, Bernhard Palsson¹², Adam M. Feist¹²

¹University of California San Diego, La Jolla, United States, ²Technical University of Denmark, Kgs. Lyngby, Denmark

Abstract third-party references: University of California San Diego

Background: The propensity of pathogens to evolve resistance to antibiotics used in clinical infectious disease therapeutics has been an increasing concern in recent decades. Acquisition of resistance often translates into treatment failure and puts patients at risk of serious adverse outcomes. Current laboratory testing of antibiotic susceptibility does not account for the different microenvironments that bacteria encounter within the human body, providing results that often do not translate into the clinic. Our goal is to better understand evolutionary strategies employed by the major human pathogen Staphylococcus aureus in development of resistance in distinct environments.

Materials/methods: We used adaptive laboratory evolution (ALE) to generate isogenic strains resistant to several antibiotics (nafcillin, vancomycin, and azithromycin). Different media were used to mimic distinct environments and multi-omics approaches applied in the understanding of resistance mechanisms.

Results: Evolved strains were able to grow in the presence of higher concentrations of the antibiotic under study, and corresponding phenotypes were similar to those observed in clinical resistant isolates. Mutational analysis indicated that mutations conferring antibiotic resistance were specific and condition-dependent. Distinct mutations led to resistance phenotypes under a particular environmental condition, but these mutations did not necessarily translate into resistance under a different environmental condition. In particular, resistant strains possessed distinct transcriptional landscapes, even when the same systems were mutated, suggesting that similar evolutionary paths translate into distinct resistance mechanisms.

Conclusions: We identified several resistance mechanisms employed by S. aureus that were not only environment-dependent, but also environment specific. Additionally, we showed that ALE can be applied in pathogens of interest to study antibiotic resistance evolution and prediction of clinical resistance mechanisms, as supported by the significant overlap of mutations identified via ALE and those reported in clinical isolates.

Meso-2,3-dimercaptosuccinic acid in combination with a carbapenem against metallo-β-lactamase-producing Escherichia coli in murine peritonitis: a proof-of-concept

Geoffrey Cheminet*1, Victoire De Lastours1,2, Nicolas Kieffer1, Françoise Chau1, Katell Peoc’h1,4, Laurent Massias1,4, Bruno Fantin1,2, Patrice Nordmann1

1Faculty Of Medicine - University Paris Diderot Université De Paris, Paris, France; 2Hospital Beaujon AP-HP Service de médecine interne, Clichy, France; 3University of Fribourg, Unité de Microbiologie Médicale et Moléculaire, Département de Médecine, Faculté des Sciences et de Médecine, Fribourg, Switzerland; 4Bichat-Claude Bernard Hospital, Paris, France

Background: Carbapenemase-producing Enterobacteriales (CPE) represent a major therapeutic challenge. Among carbapenemases, metallo-beta-lactamases (MBL) require the presence of zinc at their active site to inactivate carbapenems. Meso-2,3-dimercaptosuccinic acid (DMSA), a heavy metal chelator, may have a chelating activity on the zinc/carbapenemases binding, restoring carbapenems’ activity against MBLs.

Materials/methods: Six isogenic derivatives of wild-type E. coli CFT073 strain producing the MBL NDM-1, VIM-2, IMP-1 and the serine carbapenemases OXA-48 and KPC-3 were constructed. Minimum inhibitory concentrations (MICs) of imipenem, meropenem and ertapenem were determined alone or in combination with DMSA. Time-kill assays were performed to evaluate the existence of a synergy between imipenem and DMSA. Mice infected with CFT073, NDM-1 and KPC-3 strains were treated intra-peritoneally every 4h for 24h with imipenem 100 mg/kg, DMSA 200 mg/kg, or both. Bacterial counts in peritoneal fluid (PF) and spleen were determined at 24h. DMSA concentrations in plasma of uninfected mice were measured.

Results: DMSA alone had no antibacterial effect against any of the tested strains. DMSA in combination with each carbapenem permitted a significant decrease of the MICs against all MBL-producing strains, but not the non-MBL strains, in a concentration-dependent manner, and a full recovery of susceptibility to carbapenems for MBL-producing strains at a maximum concentration of 6 mM. A synergistic bactericidal effect between imipenem at the MIC and DMSA 6 mM was observed in vitro only against the NDM-1 strain, with a reduction in bacterial load superior to 3 log10 colony forming units (CFU)/mL at 24h. No benefit was observed against non-MBL strains. In mice infected with NDM-1 strain, combination of imipenem and DMSA significantly reduced bacterial counts in PF and spleen as compared with imipenem alone (P<0.001), with no benefit against CFT073 and KPC-3. This in vivo benefit of DMSA was achieved with a dose of 200 mg/kg, generating peak serum levels of 21 to 85 µmol/L, in the range of those obtained in human with therapeutic doses of DMSA.

Conclusions: DMSA is highly effective in restoring carbapenems’ activity against MBL and appears as a promising strategy in combination with carbapenems for the treatment of NDM-1 E. coli related infections.

Abstract 2398

Outpatient clinic for tuberculosis screening: an opportunity to promote healthcare access among applicants for international protection

Jacopo Testa1*, Maria Grazia Pizzi2, Maddalena Farinazzo2, Barbara Menzaghi2, Fabio Franzetti2

1University of Insubria, Center for Clinical Ethics, Varese, Italy, 2ASST-Valle Olona, Busto Arsizio Hospital, Infectious Diseases Unit, Busto Arsizio, Italy

Background: In a global context, the health of migrants remains a huge and often neglected medical and political challenge. In March 2017 we implemented an Outpatient Clinic (OC) at our hospital for second-level screening of latent tuberculosis infection (LTBI) among refugees and asylum-seekers.

Materials/methods: We retrospectively analysed data from all subjects who accessed the OC.

Results: 150 subjects [all Mantoux test-positive] were sent to our OC. They were mostly males (98%), with a mean age upon arrival in Italy of 25 years. They came mainly from Sub-Saharan Africa (83%), less frequently from Asia (14%). Only 44 subjects reported having stayed in Libya. First access to the OC dated on average 10 months after entering Europe. A mean of 3 visits and 2 blood panels were performed for each subject.

Upon first visit, we detected respiratory symptoms in 16 cases (11%), gastrointestinal in 11 (7%) and itching in 9 (6%). Blood tests showed hypereosinophilia in 36 subjects (24%), polycythemia/thrombocytopenia in 8 (6%). Twenty-five subjects (17%) refused to have their blood drawn, discontinuing all clinical follow-up.

After performing an Interferon-Gamma Release Assay, 76/150 subjects (51%) were diagnosed with LTBI: 69 of them (91%) agreed to start prophylaxis, which was completed in 36 cases (52%). We observed 5 cases (3%) of scabies, 2 of diabetes and 1 of arterial hypertension (all treated accordingly).

Since August 2018 a wider serological screening was introduced (Table 1). In 19/38 patients (50%) a schistosomal infection was identified and treated. All patients found positive for chronic HBV infection were taking care and regularly followed up, whereas HBV-negative subjects were referred to our Vaccine Centre.

Conclusions: Through our OC we were able not only to diagnose and treat several LTBI, but also to diagnose and treat other chronic diseases and neglected tropical infections, guaranteeing an acceptable compliance to therapies and managing to promote healthcare access among a very fragile population, such as immigrants.

Examining discordance in blood culture and T2 positivity in the detection of candidaemia: modelling the odds of blood culture and T2 discordance as a function of candidaemia risk factors

Amit Vahia*, George Alangaden, Geehan Suleyman

1Henry Ford Hospital, Detroit, United States

Background: The T2Candida® Panel (T2) is a rapid molecular diagnostic that detects 5 Candida species (C. albicans/C. tropicalis, C. glabrata/C. krusei, and C. parapsilosis) directly from whole blood samples in patients candidemia with excellent sensitivity and negative predictive value. Henry Ford Health System implemented both T2 in 2015 and BacT/Alert Virtuo® (bioMérieux, Inc., Durham, NC) blood culture (BC) system in 2019 for the detection of pathogens, including Candida causing bloodstream infection (BSI). In practice, there are discrepancies in test results when employing both tests simultaneously. We evaluated the potential factors associated with discordance between these two tests for the detection of candidemia.

Materials/methods: We screened all patients who had a T2 performed since implementation of the Virtuo system in February 2019 through August 2019, focusing on patients who had discordant results between the two testing methodologies. This study reports the types of discrepancy seen between the two tests, the turn-around times (TAT), and frequency of risk factors for candidemia in these patients. Finally, we performed a univariate analysis modeling the odds of discordant T2/BC results as a function of risk factors for candidemia.

Results: A total of 675 T2 tests were performed during the study period. Only 33 (5%) T2s were positive. Of these, 23 (70%) were discordant (T2+/BC-) and 10 (30%) concordant (T2+/BC+). Three patients had T2-/BC+. The most common Candida species found in blood by both culture and T2 were C. albicans (5), followed by C. glabrata (4). Blood culture TAT was 15 hours faster detecting bacteria than yeast, on average (P=0.3918). T2 was 40 hours faster than BC in detecting candidemia. The vast majority of our patients presented in septic shock (72%), had intravascular devices (94%), were exposed to broad spectrum antimicrobials (92%), or had corticosteroids administered (50%). Univariate analysis showed no statistical association between candidemia risk factors and discordant test results.

Conclusions: Discordant T2/BC results were mostly a function of T2 being more sensitive than BC, despite the implementation of an enhanced BC system to increase yield. Traditional risk factors for candidemia did not predict discordance in testing results.

Appropriacy of empirical antibiotic therapy in percutaneous endoscopic gastrostomy site infection among head and neck cancer patients: a 15-year retrospective study

So Yeon Park*, Jihyu Oh, Jungok Kim, Eun-Jeong Joo, Jin Seo Lee

*Hallym University Kangdong Sacred Heart Hospital, Seoul, South Korea, †Chungnam National University Hospital, Daejeon, South Korea, ‡Sungkyunkwan University/KANGBUK SAMSUNG HOSPITAL, Soul, South Korea

Abstract

Background: Wound infection is the most common complication associated with Percutaneous endoscopic gastrostomy (PEG) placement, with an incidence between 4% and 30%. In this study, we compare characteristics of PEG site infection between head and neck cancer group and non-head and neck cancer group.

Materials/methods: We retrospectively collected data on patients who underwent PEG insertion from October 2003 through May 2019 at Kangdong Sacred Heart Hospital, Seoul, Korea. A total 314 cases with PEG insertion, 129 cases in head and neck cancer group and 187 in non-head and neck cancer group, were included in this study.

Results: A total of 314 patients were eligible for this study, 187 for non-head and neck cancer patients and 129 for head and neck cancer patients. PEG site infections were significantly higher rate in head and neck cancer group than non-head and neck cancer group (32.6% vs. 13.4%; p<0.001). In head and neck cancer group, PEG wound isolates included Pseudomonas aeruginosa in 33.3% (14/42) of patients, MRSA in 26.2% (11/42) of patients and Klebsiella pneumoniae in 21.4% (9/41) of patients. Pseudomonas aeruginosa is most common pathogen of PEG site infection. 31 of 42 head and neck cancer patients with PEG infection (73.8%) were chronic infection. 40.6% of these patients were isolated P. aeruginosa, but only 21.4% of these patients had proper antibiotics for empirical treatment. In the 25 clinical isolates of P. aeruginosa, the overall drug resistance to all anti-pseudomonal drugs tested was higher in the head and neck cancer group compared with in the non-head and neck cancer group (fig1).

Conclusions: PEG site infection is more prominent on head and neck cancer patients than non-head and neck cancer patients. Unlike other skin and soft tissue infection, gram negative bacteria, especially P. aeruginosa, were major causative pathogen in PEG site infection in Head and neck cancer patients. For appropriate treatment, we should consider P. aeruginosa when start empirical therapy of PEG site infection on head and neck cancer patients.

Abstract 2402

Rethinking the involvement of patients in infection prevention and control and antimicrobial stewardship

Holly Seale* 1

1UNSW Sydney, School of Public Health and Community Medicine, Sydney, Australia

Background: Interventions developed to date to support patient participation in hand hygiene advocacy have failed to meaningfully transition patients from 'being willing to participate' to actively speaking up. To inform the development of a new hospital-based strategy to improve patient participation in infection prevention and control activities (including those focused on reducing the risk of antimicrobial resistance), our team undertook a series of studies to examine the current landscape around patient participation.

Materials/methods: A multi method study involving three major public hospitals in Sydney, Australia was undertaken that involved in-depth interviews with patients and healthcare providers, a survey of patients and a co-design workshop to understand the current landscape around strategies to promote and involve patients, as well as the understanding and attitudes of patients and healthcare providers toward the concept. We also explored the perceptions of participants towards new ways that could be used to improve patient involvement.

Results: We identified that: (1) the health system focuses on information provision as the primary strategy (generally reactive not proactive); (2) there is a level of misunderstanding about what patient involvement entails amongst providers and patients; and (3) that both healthcare workers and patients acknowledge that 'everybody has a role to play in IPC' but are not sure about activities. In support of the need to renew the focus on patient participation in infection control, is our finding that 88% (449/511) of patients surveyed want to partner with healthcare providers to help prevent infections while at hospital.

Conclusions: While building awareness about healthcare associated infections has been the traditional approach to date, this is an outdated model. If we are going to move towards a patient centered system for IPC, we need to start focusing more on the enablers of participation. We need to support change using theory-driven behavioral change interventions that are grounded in an understanding of the enablers and barriers impacting on patient participation.

Abstract 2403

Examining factors impacting influenza vaccination amongst healthcare workers in Asia and the Pacific
Holly Seale*, Angus Thomson1, Rajneesh Kaur2

1University of New South Wales, Sydney, Australia, 2Sanofi Pasteur, Lyon, France

Background: Despite clear recommendations from leading health organisations, hospital healthcare workers (HCWs) continue to reject the influenza vaccine. Research has focused on the perceptions towards influenza and the influenza vaccine have centered on HCWs in high- and middle-income countries. Understanding the factors impacting on acceptance amongst HCWs located within Asia and the Pacific is important for the development of relevant strategies.

Materials/methods: A cross sectional survey was undertaken with HCWs from nine countries across the Asia/Pacific region in 2014-2015. A 9-item measure of cognitive empowerment towards flu vaccination (MoVac) and an 11-item measure of cognitive empowerment towards vaccination advocacy (MovAd) was used.

Results: One thousand and forty-eight HCWs were included. A high mean motivation (mean=77) and advocacy score (mean=84) was shown from these countries. HCWs scored high on individual items of vaccination motivation and advocacy score. In the regression model: males (P<0.01 OR: 1.54; 95% CI 1.19-2.01), being a paediatrician (P=0.002), GP (P<0.001), perceived severity of getting the flu if unvaccinated (P=0.009, OR:1.12; 95% CI=1.01 - 1.21) and having a high vaccine motivation score (P<0.001, OR=1.27; CI=1.12-1.47) were the strongest predictors of getting the flu vaccine.

Conclusions: There has been a lot of focus on monitoring vaccine acceptance amongst the general community but very little work on using validated measures for HCWs. Using this MoVac/MovAd tool we have not only been able to identify the factors that are predicting vaccination acceptance within a population that doesn't usually get a lot of focus but also can compare these results to HCWs in other countries.

Evaluation of the antimicrobial activity of ridinilazole and six comparators against Chinese, Japanese and South Korean isolates of \textit{Clostridioides difficile}

Deirdre Collins*1, Yuan Wu2, Kazuhiro Tateda3, Heejung Kim4, Richard Vickers5, Thomas Victor Riley6

1Edith Cowan University, Nedlands, Australia, 2Chinese Center for Disease Control and Prevention, Beijing, China, 3Tokyo University School of Medicine, Tokyo, Japan, 4Yonsei University College of Medicine, Seoul, South Korea, 5Summit Therapeutics plc, Abingdon, United Kingdom, 6Edith Cowan University, Nedlands, Australia

Background: \textit{Clostridium (Clostridioides) difficile} is the most common cause of antibiotic-associated diarrhoea in high-income countries. Risk of recurrent infection is high, occurring in up to 25% of cases, due to slow recovery of the gut microflora following broad-spectrum antimicrobial treatment. Fluoroquinolone resistance facilitated the emergence and spread of the ribotype (RT) 027 strain of \textit{C. difficile} in the early 2000s. Despite frequent inappropriate antimicrobial use in Asia, RT027 is rarely isolated in the region, but other strains of global importance, including the often fluoroquinolone- and clindamycin-resistant RT017 strain, predominate. The aim of this study was to evaluate the antimicrobial activity of ridinilazole, a novel antimicrobial agent with highly specific activity for \textit{C. difficile}, against isolates of \textit{C. difficile} from Asia.

Materials/methods: A collection of 140 \textit{C. difficile} isolates from Japan (n=64), South Korea (n=32), and China (n=44) were tested by the agar dilution method for susceptibility to ridinilazole and six comparators (Table 1) according to the Clinical and Laboratory Standards Institute guidelines.

Results: Overall resistance rates and minimum inhibitory concentrations (MICs) are shown in Table 1. All isolates were susceptible to ridinilazole with low MICs. Several RTs showed enhanced resistance profiles, particularly RT017 (100% clindamycin-resistant, 91.3% moxifloxacin-resistant, 82.6% rifaximin-resistant) and RT369 (94.4% clindamycin-resistant, 100% moxifloxacin-resistant). Rifaximin resistance was absent in all isolates from Japan. Multi-resistance to clindamycin, moxifloxacin and rifaximin was found in 19 RT017 isolates from China and Korea, two RT001 isolates (Korea) and one RT046 isolate (Korea).

Conclusions: Ridinilazole showed potent activity against a range of Asian \textit{C. difficile}, which otherwise displayed resistance to several comparator antimicrobial agents. Ongoing surveillance of antimicrobial resistance profiles is required to monitor and control spread of resistant strains.

Table 1. Overall susceptibility of 140 \textit{C. difficile} isolates to test antimicrobial agents.

Abstract 2411

Co-evolutionary adaptations of Acinetobacter baumannii and an OXA-23-encoding plasmid under carbapenem pressure

Linyue Zhang*, Xiaoting Hua1, Yunsong Yu1

1Zhejiang University, Department of Infectious Diseases, Sir Run Run Shaw Hospital, School of Medicine, Hangzhou, China

Background: The carbapenemase OXA-23 is the predominant cause for carbapenem-resistant Acinetobacter baumannii [CRAB], with the conjugative plasmid pAZJ221 being a vehicle for the horizontal transmission of OXA-23 in China. However, the resistance phenotype comes with a reduction in growth when pZAJ221 is introduced to hosts. We aimed to investigate the co-evolutionary adaptations between pAZJ221 and A. baumannii ATCC 17978 under carbapenem pressure.

Materials/methods: Four colonies of the ancestor strain XH565 (ATCC 17978 pAZJ221) were daily passaged independently in media containing 16 mg/L imipenem for 60 days. Every ten days stocks were generated for each of the populations. Grow rates of evolved populations were measured. Whole-genome sequencing and breseq were employed to detect the mutations occurred during the evolution. We re-constructed mutants to demonstrate the impact of mutations on growth rates in A. baumannii. OXA-23 copy number was estimated by quantitative PCR and verified by Nanopore sequencing.

Results: We observed genetic adaptations in both plasmid and the chromosome over 400 generations. Fluctuating growth rates with dynamic mutational changes in populations were observed during the evolution process. Common adaptational mutations were found in internal or intergenic regions of global regulation genes. When reconstructing six such mutations in ATCC 17978, we observed increased growth rates only in the presence of the plasmid pAZJ221 (all P<0.001). Interestingly, in all lineages, the OXA-23 copy number in the plasmid doubled in the early phase but decreased back to a single copy in three out of four lineages (Fig.1A). We confirmed the existence of two copies of Tn2009 containing OXA-23 in the evolved plasmid pAZJ221 evolved (pAZJ221E) (Fig.1B). The introduction of pAZJ221E into ATCC 17978 led to a growth rate higher by 19.45%±3.84% compared to XH565 (P=0.0173).

Conclusions: Our study described the co-evolution pathway of pAZJ221 and its A. baumannii host, via OXA-23 duplication on plasmid at the early stage and genetic adaptations on chromosome conferring a fitness advantage in the presence of the plasmid. The results provide a possible explanation for the widespread of pAZJ221 among CRAB in China.

Comparison of the clinical features of human metapneumovirus infections in children between paediatric patients with severe mental and physical disabilities and those without underlying diseases at a children’s hospital in Japan

Akihiko Shimizu*1

1Gunma Prefectural Children’s Medical Center, Shibukawa-shi, Japan

Background: Human metapneumovirus (HMPV) is a common etiologic pathogen of respiratory tract infections in children. This study describes the differences in clinical characteristics of HMPV infection in children with severe mental and physical disabilities (SMPD) and those without underlying diseases.

Materials/methods: This was a retrospective, single-center cohort study of HMPV infection at Gunma Children’s Medical Center. All of the HMPV cases were detected in respiratory tract samples between January 2015 and August 2018 and identified from the Medical Center’s database. The patients’ demographic and clinical data were analyzed in order to compare the characteristics of HMPV infection between the two groups.

Results: Seventeen patients with SMPD and 20 without underlying diseases were included. The patients with SMPD were significantly older than those without underlying diseases [Median months; 68.9 vs. 17.0, p=.002]. Median length of stay was longer in the patients with SMPD (11.5 days vs. 6.0 days, p=.002). The proportion of supplemental oxygen, systemic steroids and antibiotics administration was higher in the patients with SMPD (oxygen; 82% vs. 35%, p=.007, systemic steroids; 35% vs. 0%, p=.005, antibiotics; 88% vs. 40%, p=.005).

Conclusions: HMPV infection was proved to be a substantial burden for children with SMPD.

Clinical evaluation of a novel rapid test for Aspergillus galactomannan

He Wang*1, Jie Peng1, Yuan Zhang1, Kevin Sun1, Junli Wen1, Yan Su1, Zeqi Zhou1

1Beijing Key Laboratory for Mechanisms Research and Precision Diagnosis of Invasive Fungal Disease, Beijing, China

Background: Invasive Aspergillosis (IA) is a life-threatening complication in patients with hematological malignancy, early and rapid diagnosis is crucial for the treatment. Aspergillus Galactomannan (GM) has been proved as a biomarker for detection of IA. Recently, GM Lateral Flow Assay (QuicGM™, Dynamiker, China) was released as a screening test of IA. It is a fluorescent immunochromatographic cassette test which using a monoclonal antibody against GM and Europium nanoparticles (Eu NP). After pretreatment of serum samples, pretreated supernatant was added into the pad and then read the fluorescent signal after 15 mins (Fig). It is a semi-quantitative test as compared with the traditional GM ELISA assay (Bio-Rad, USA).

Fig: Diagram of a rapid fluorescence LFA for the detection of GM

Materials/methods: A total of 209 serum samples were collected according to the revised EORTC/MSG guideline [2008], and tested by QuicGM™ (Dynamiker, China). Those included 82 IA samples (proven, n=30; probable, n=52) and 127 negative samples. Those samples were compared with Platelia™ GM ELISA (Bio-Rad, USA).

Results: A total of 209 serum samples were analyzed by ROC, the sensitivity and specificity of QuicGM™ was 87.8% and 90.6%, respectively. The positive coincidence rate, negative coincidence rate and total coincidence rate of QuicGM™ compared with Platelia™ was 87.8%, 90.55% and 89.47%, respectively. The Kappa value was 0.821>0.75.

Conclusions: The Dynamiker QuicGM™ was significantly consistent with Bio-Rad Platelia™ GM ELISA. It could be used as an aid for the early rapid screening test for the IA. Additionally, the Dynamiker QuicGM™ test was showed significant consistency with that Bio-Rad Platelia™ GM.

Abstract 2419

Impact of a continuous improvement programme on central venous catheter care in reducing the incidence of primary bloodstream infection in neonatal intensive care unit

Ricardo Cantarim Inacio*, Eduardo Alexandrino Medeiros

1Hospital E Maternidade Santa Helena, São Bernardo do Campo, Brazil

Abstract third-party references: United Health Group - Amil

Background: Healthcare-Related Infections, particularly central venous catheter-associated bloodstream infections (CVC), are recognized as one of the most important causes of morbidity and mortality in hospitalized neonates.

Materials/methods: A cohort study was conducted in the neonatal intensive care unit (ICU) during the period from January to December 2017. The study was divided into two periods: first: January to June 2017 (reference period); second: July to December 2017 (period of continuous improvement). During the period of continuous improvement, the process of exchanging spray alcohol for alcohol gel was finalized, the disinfectant product was exchanged in terminal and concurrent cleanings, and a group of peripherally inserted central catheters (PICC) was formed. From August 2017, the CVC bundle and dressing film change were revised due to difficulty in adhering and intensifying hand hygiene campaigns. Beginning in November 2017, a multi-professional working group was set up with weekly meetings to evaluate bloodstream infection prevention practices, 2% chlorhexidine liquid soap exchange and daily catheter maintenance and passage audits. A specific professional for the neonatal ICU for guidance on hand hygiene of family members and employees.

Results: The incidence density of CVC-associated bloodstream infection in the reference period (1) was 21.59 (32/1482) per 1000 CVC / day and in the period of continuous improvement (2) was 5.74 (7) / 1218) per 1000 CVC / day (p = 0.0021). In 2018 it was 5.50 (12/2181) per 1000 CVC / day and in 2019 (January to August) it was 3.53 (5/1414) per 1000 CVC / day. The consumption of alcohol gel in period 1 was 34.61 mL / pct-day and in period 2, implantation of good quality alcohol gel in place of alcohol spray, 56.43 mL / pct-day. In 2018 it was 76 mL / pct-day and in 2019 it was 106 mL / pct-day.

Conclusions: We have evaluated that effective infection prevention bundle implementation measures and measures to encourage the use of alcohol in hand hygiene are effective measures to reduce bloodstream infection in hospital units.

Abstract 2420

**Carbapenem resistance development in an OXA-499-harbouring, non-resistant *Acinetobacter pittii* isolate under imipenem selective pressure**

Linyue Zhang*, Yan Chen, Yunsong Yu

1Zhejiang University, Department of Infectious Diseases, Sir Run Run Shaw Hospital, School of Medicine, Hangzhou, China

**Background:** Carbapenem-resistance in *Acinetobacter pittii* poses crucial challenges to clinical treatments. Understanding the resistance development in carbapenem non-resistant strains could complement mechanisms for carbapenem resistance in *A. pittii*.

**Materials/methods:** *A. pittii* A1254 is an OXA-499-harboring clinical strain which is susceptible to imipenem (MIC, 2 mg/L) and intermediate to meropenem (MIC, 4 mg/L). Four colonies of the A1254 were passaged in media supplemented with 0.75 mg/L imipenem for 9 days. Breseq was employed to detect the mutations in four evolved populations at 9th day. Expression levels of *bla*OXA-499* were measured by quantitative reverse transcription PCR in two mutants. *bla*OXA-499* with its promoter (original or mutated) from A1254 and two mutants were respectively cloned into a vector pYMAb2-hyg* and transformed into *A. baumannii* ATCC17978, *A. pittii* LMG 1035 and A1254. MICs were evaluated by the broth microdilution method.

**Results:** Two carbapenem-resistant mutants (CAB009 and CAB010) with mutations at the promoter region of *bla*OXA-499* were isolated from two independently evolved populations. The mutation at position -14 (A to G) in CAB009 resulted in higher imipenem MIC (32 mg/L) and a higher *bla*OXA-499* expression level (4.53±0.19 fold relative to A1254) than another mutation at position -42 (G to A) in CAB010 (imipenem MIC, 8 mg/L). However, all transformed strains with either initial or mutated promoter were resistant to imipenem (16-64 mg/L) and meropenem (64-128 mg/L). Compared with transformed strains with the original promoter, *bla*OXA-499* with promoter from CAB009 (P009) conferred the highest MICs of imipenem (32-64 mg/L) among *A. baumannii* and *A. pittii* strains, but the increase of meropenem MIC (128 mg/L) was only observed in A1254 and LMG 1035, indicating that mutations at the promoter region were not indispensable for carbapenem resistance in transformed strains, but essential to the development of higher carbapenem resistance.

**Conclusions:** We demonstrated that carbapenem non-resistant *A. pittii* A1254 could turn carbapenem-resistant by a single base substitution at the promoter region of *bla*OXA-499* under imipenem pressure, indicating the need to monitor potential development of carbapenem-resistance when treating infections caused by non-resistant strains.

![Locations of mutations (blue), the start codon (red), the transcription initiation site (grey), -10 and -35 boxes (green) in CAB009 and CAB010.](image)

Abstract 2424

Molecular evidence of bacteria with medical relevance in fleas parasitising cats and dogs
Georgios Dougas*1, Athanassios Tsakris2, Anastasia Mageropoulou3, Athanassios Priftis2, Theodore Lytras1, Stavroula Beleri3, Eleni Patsoula1, Maria Linou1, Charalambos Billinis4, Joseph Papaparaskevas2

1Greek National Public Health Organization, Athens, Greece, 2Department of Microbiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece, 3Department of Public Health Policy, School of Public Health, University of West Attica, Athens, Greece, 4Hellenic Pasteur Institute, Athens, Greece, 5Dpt. of Microbiology and Parasitology, Faculty of Veterinary Science, University of Thessaly, Karditsa, Greece

Background: Even though a few microbial species are recognized as flea-borne human pathogens, a multitude of microbes may be identified in the microbiome of fleas. In this study we present medically relevant bacteria identified in the microbiome of cat and dog fleas in Greece.

Materials/methods: Fleas were collected in pools from individual cats and dogs presenting in small-animal clinics in Attica, Greece, during the period 2016-2017. The per pool extracted DNA was screened with 16s metagenomics for bacterial genera and/or species associated with human disease based on the International Statistical Classification of Diseases and Related Health Problems by WHO (ICD-10, 2016 version).

Results: Among the 100 flea-pools, collected from 67 cats and 33 dogs and stratified by flea species to 96 Ctenocephalides felis, two C. canis and two Pulex irritans pools, 19 phyla, 319 genera and 439 species of bacteria were recognized; 19 bacterial genera with potential medical relevance according to ICD-10 were identified in 93 flea-pools; a median of two bacterial genera were identified per flea-pool in cats [IQR=1;min=0,max=12] and a median of three in dogs [IQR=3;min=0,max=11] without significant difference between the two animal species (Mann-Whitney test, \( p=0.95 \)). The detected bacterial genera were Brucella spp., Coxiella spp., Legionella spp., Mycobacterium spp., Campylobacter spp., Salmonella spp. Bartonella spp., Clostridium spp., Corynebacterium spp., Haemophilus spp., Klebsiella spp., Nocardia spp., Pasteurella spp., Proteus spp., Pseudomonas spp., Rickettsia spp., Spirochaeta spp., Staphylococcus spp. and Streptococcus spp. Significantly increased prevalence was noted in Bartonella spp. from cat-borne flea-pools \( [OR=276, p<0.001] \) with no difference of the occurrence rate of the other bacterial genera between fleas collected from cats and the ones collected from dogs. Species identified included Clostridium perfringens, Haemophilus parainfluenzae, Klebsiella pneumoniae, Pasteurella multocida, Proteus mirabilis, Pseudomonas aeruginosa, Salmonella enterica and Streptococcus suis.

Conclusions: The vectorial capacity and potential human health implications for many bacterial genera and species identified in fleas with molecular methods such as 16s metagenomics, is not meticulously investigated. DNA occurrence of medically important bacteria supports the rationale of more study about the potential role of fleas as vectors or disseminators of pathogens.

**Abstract 2425**

**Assessing the impact of using sepsis bundle to salvage critically sick patients admitted with sepsis in a tertiary care hospital in India**

Malvika Srivastava¹, Summy Kumari², Rashmi Datta³

¹Hospital, Narayana superspeciality Hospital, Gurugram, India, ²Hospital, Narayana Superspeciality Hospital, Gurugram, India, ³Hospital, Atal Bihari Institute of Medical Sciences, New Delhi, India

**Background:** Advances in our understanding of heterogeneity of sepsis pathogenesis have made it clear that any single therapeutic intervention is ineffective in salvaging the affected patients. Bundles are a group of “therapies” built around the best evidence-based guidelines, which, when implemented together, produce greater benefit in terms of outcome than the individual therapeutic interventions.

**Materials/methods:** A prospective observational study was conducted in a new multi-speciality hospital over twenty months from February 2018 to October 2019 to demonstrate the impact of complying to the six sepsis bundle elements within the first six hours of presentation to the hospital. The six elements were as follows:

1. Measuring serum lactate
2. Obtaining Blood cultures prior to administration of antibiotics
3. Broad spectrum antibiotics administered within 3 hours of admission
4. Treat hypotension and elevated lactate (>4mmol/l) with fluids [Crystalloids at 30ml/kg]
5. Vasopressors [to maintain Mean Arterial Pressure (MAP) more than 65 mmHg]
6. Central venous pressure (CVP) to be maintained more than 8mmHg and Central venous oxygen saturation (ScvO2) of more than 70%

A total of 758 patients, more than eighteen years of age admitted to ICU and emergency with proven or suspected features of septic shock were included in the study.

**Results:** Among 758 patients admitted, 492 could be salvaged in ICU. Out of 492, complete compliance to 6 hours sepsis resuscitation bundle was seen in 340 patients. In 152 of 492 patients, partial or no compliance to sepsis bundle was seen. Of 266 who died, compliance to sepsis bundle was seen in 86 and non-compliance in 180 patients. Patients compliant to sepsis bundle got the mortality benefit. (odds ratio: 4.68, C.I. 3.4,6.45, p value < 0.5)

<table>
<thead>
<tr>
<th></th>
<th>Number of patients salvaged</th>

Detection of norovirus major capsid protein using M-class UPLC/MSE

Pei-Yu Chu*, Michittra Boonchan*, Hui-Wen Huang*, Kazushi Motomura*, Liang-Yin Ke*

1Kaohsiung Medical University, Kaohsiung, Taiwan, 2Thailand-Japan Research Collaboration Center on Emerging and Re-emerging Infections, Nonthaburi, Thailand, 3Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan

Background: Norovirus is the most common foodborne pathogen, and norovirus-associated disease is a worldwide economic burden. Noroviruses are still uncultivable in the clinical laboratory, so specimens are usually detected using variable polymerase chain reaction. However, the high amplification sensitivity of RT-PCR can obtain false-positive results, and sequence-dependent amplification of RNA viruses with high mutation rates may obtain negative results in variant strains. Alternatively, M-class ultra-performance liquid chromatography (UPLC) with quadrupole time-of-flight (Q-TOF) MSE is a promising tool for high sensitivity and coverage in viral typing and identification.

Materials/methods: The GII.4 2006b VP1 proteins were constructed and used for peptide mapping and post-translational modification detection using UPLC/Q-TOF MSE for proteomic analysis of tryptic digests. The best region for identification was estimated using the Tree-Puzzle program.

Results: More than 95% total coverage of the 2006b of VP1 and each functional sub-domain was shown in VP1 digests. The missing residues were located at the N- and C-termini. The dominant peptide signal was located at P2-P1b, but it highly accumulated at the S domain. The phosphorylation sites accumulated in four of the five strongest peptide signals, especially in the hinge region. The full VP1 and S domains show the best identification signal based on tree-puzzle analysis.

Conclusions: The results of this study suggest that M-class UPLC combined with Xevo G2 Q-TOF/MS outperforms provide high sensitivity and sequence coverage. The P2-P1b and S domains were efficient targets for high-throughput diagnostic methods. Interestingly, the detected phosphorylation sites had a strong peptide signal, especially in the hinge region. This suggests an essential role of hinge region in the viral life cycle.

Abstract 2429

The clinical and economic burden of mucormycosis in Japan

Rie Ueno*, Shinichi Nishimura1, Go Fujimoto1, Dilinuer Ainiwaer2, Seok-Won Kim2

1MSD K.K., Tokyo, Japan, 2IQVIA Solutions Japan K.K., Tokyo, Japan

Abstract third-party references: MSD K.K., IQVIA Solutions Japan K.K.

Background: Mucormycosis is an uncommon but life-threatening infection that occurs in immunocompromised patients which may lead to high mortality and morbidity. Mounting evidence demonstrates an increasing economic burden attributed to mucormycosis. However, the majority of mucormycosis studies conducted in Japan are case reports or studies with small sample sizes with limited information. This study analyzed data evaluating clinical outcomes, resource utilization and costs associated with mucormycosis among inpatients in Japan.

Materials/methods: A descriptive, retrospective study was conducted including all patients, within a commercially available database (the MDV database), who were hospitalized with a diagnosis of mucormycosis [ICD-10 code (B46.x)] between January 1, 2010, and January 31, 2019 in Japan. Patient baseline characteristics and clinical information was collected as well as outcomes which included length of stay, mortality, readmission, utilization of IV antifungals, and costs. During the study period, data from a total number of 126 patients (main group) who had a record of hospitalization on the same month as the diagnosis, and a subgroup of 105 patients received L-AMB or AMPH-B treatment were analyzed.

Results: Approximately half of the patients were over 65 years old, of which 68.2% were male. The most common comorbidities were hematological malignancies (61.9%), followed by diabetes mellitus (46.0%). Mean duration of the index stay was 94 days for the main group, and 106 days for the subgroup. Mortality during the index stay was 35.7% in the main group, and 41.9% in the subgroup. The 30-day readmission rate in the main group and in the subgroup was 19.8% and 18.03%, respectively. The mean duration of IV amphotericin-containing regimen was around 37 days. For the main group, median total costs exceeded US $55,000 which included around US $37,000 in drug costs. Similar or even higher costs were observed in the subgroup who received LAMB or AMPH-B treatment during the index hospitalization.

Conclusions: This study demonstrated a high mortality rate based on the database results, and the considerable clinical and economic burden of mucormycosis in Japan.

Abstract 2431

Performance of two rapid influenza diagnostic testing compared to real-time PCR
Yejin Oh*, Soojung Jin1, Soojung Yoon1, Seungman Park1, Hye Gyung Bae2

1Green Cross Laboratories, Yongin, South Korea

Background: Influenza viruses cause acute respiratory diseases which is associated with morbidity and in some cases mortality. Since it is easily transmitted between human, rapid and accurate diagnosis is important for optimal patient care. At present, rapid influenza diagnostic testing (RIDT) is widely used in clinical setting due to its faster turn-around-time for results and its ease of use. However, test performance varies widely. In this study, we evaluated the performance two RIDT compared to real-time reverse transcription (RT)-PCR, using nucleic acid amplification test (NAAT) as the gold standard.

Materials/methods: Total 431 nasopharyngeal swabs were randomly collected from March, 2017 to March, 2019 (Influenza A, n=173; Influenza B, n=115; negative, n=143). Two RIDT, QuickNavi-Flu (Denka Seiken, Tokyo, Japan) and Genedia Greencare Flu A&B Antigen (Green Cross Corp., Korea) were compared to Allplex Respiratory Panel 1 (Seegene, Korea) real-time reverse transcription (RT)-PCR. Interpretation was done according to the manufacturer’s instructions.

Results: For influenza A, the sensitivities and specificities of the QuickNavi-Flu were 72.8%, 100% and Genedia Greencare Flu A&B Antigen were 75.7%, 98.1%, respectively. For influenza B, the sensitivities and specificities of the QuickNavi-Flu were 58.3%, 100% and Genedia Greencare Flu A&B Antigen were 57.4%, 99.4%, respectively. The agreement between QuickNavi-Flu and Genedia Greencare Flu A&B Antigen was 96.5% for influenza A and 98.6% for Influenza B. The Kappa ratio for those were 0.92 and 0.96, respectively.

Conclusions: This study indicates that RIDT has suboptimal sensitivity for both influenza A and influenza B, despite high specificity. The key advantage of RIDT is the production of quick result, in less than 10 minutes, which can help making clinical decision at that time. However, due to the limited sensitivities, negative results of RIDTs do not exclude influenza virus infection in patients with symptoms suggestive of influenza. Thus, confirmatory testing is always recommended.

Genomic and environmental investigation of hospital room occupied by an imported case of meningitis due to extensively drug-resistant (XDR) *Pseudomonas aeruginosa*

Hiroaki Baba*1,2, Hajime Kanamori1,2,3, Makoto Katsumi4, Takami Sato3,4, Keiko Ishikawa1, Takae Chida3, Shinobu Ikeda1, Koichi Tokuda1,2,3

1Department of Infectious Diseases, Internal Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan, 2Department of Intelligent Network for Infection Control, Tohoku University Graduate School of Medicine, Sendai, Japan, 3Division of Infection Control, Tohoku University Hospital, Sendai, Japan, 4Department of Laboratory Medicine, Tohoku University Hospital, Sendai, Japan

**Background:** Importation of highly resistant bacteria from high prevalence foreign countries is a major global public health concern. To prevent further spread, we investigated environmental contamination of a hospital patient room in Japan that was occupied by an imported case of meningitis due to extensively drug-resistant *Pseudomonas aeruginosa* (XDR-PA) who had undergone craniotomy in southeast Asian country with known colonization of XDR-PA and extended-spectrum β-lactamase-producing *Klebsiella pneumoniae* (ESBL-KP) using whole-genome sequencing (WGS), and conducted room decontamination using ultraviolet-C (UV-C) device.

**Materials/methods:** Five XDR-PA and 2 ESBL-KP isolates were obtained from the patient. A total of 76 environmental cultures were taken from 19 sites in the patient's room, including 13 high-touch surfaces, 2 medical devices, and 4 sink components at following 4 different time points: before and after daily cleaning/disinfection, after discharge cleaning/disinfection, and after UV-C decontamination. UV-C decontamination was performed using Optimum UV™ with three 10-minute cycles. WGS was performed to determine the relatedness of clinical and environmental isolates with multiple resistance genes.

**Results:** Among the 19 sampling sites, XDR-PA and ESBL-KP isolates were detected in 2 sites (a bedside table and a sink surface) and 6 high-touch surfaces respectively before daily cleaning/disinfection (Figure). A sink surface and 3 high-touch surfaces (right bed rail, infusion pump control panel, spinal drain unit) were positive for XDR-PA and ESBL-KP, respectively, even after discharge cleaning/disinfection. After UV-C decontamination, these isolates were not detected from targeted environmental sites. WGS analysis revealed XDR-PA isolates from the patient and a bedside table and ESBL-KP isolates from the patient and 6 high-touch surfaces belonged to ST2613 and ST29 with similar resistance genes, respectively. XDR-PA isolates also harbored *bla*<sub>IMP-26</sub> carbapenemase that is rarely found in Japan.

**Conclusions:** Sink and high-touch surfaces were heavily contaminated with XDR-PA and ESBL-KP from an imported case despite standard terminal cleaning/disinfection, highlighting the need for enhanced disinfection methods to reduce a risk of acquiring these pathogens in patients subsequently admitted to the room. The use of UV-C device in addition to standard cleaning/disinfection was effective for decontamination of hospital room environment surfaces and medical equipment that were contaminated with XDR bacteria.
Abstracts 2020

Figure. (A) Sampling sites. Red and blue circles indicate XDR-PA-positive and ESBL-KP-positive respectively. Four boxes below the circle respectively indicate organism positive before and after daily cleaning/disinfection, after discharge cleaning/disinfection, and after UV-C decontamination from left to right. Abstract 2441

Short-term environmental contamination with MRSA explained by in-room activity of MRSA-colonised patients
Aline Wolfensberger*, Nora Mang1, Kristen Gibson2, Marco Cassone2, Kyle Gontjes2, Hugo Sax1, Lona Mody2,3

1University Hospital of Zürich, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland, 2University of Michigan Medical School, Division of Geriatric and Palliative Medicine, Department of Internal Medicine, Ann Arbor, United States, 3Veterans Affairs Ann Arbor Healthcare System, Geriatrics Research Education and Clinical Center, Ann Arbor, United States

Background: Rooms with methicillin-resistant Staphylococcus aureus (MRSA) colonized patients are often contaminated with MRSA. Little is known about influence of in-room patient activity on short-term hand and environmental contamination.

Materials/methods: An observational study was conducted at two hospitals, Hospital 1 in Zurich, Switzerland, and Hospital 2 in Michigan, USA. Inpatients with an MRSA infection and/or colonization were included. At first visit, groin, axilla, and nares were swabbed to assess the patient’s ‘colonization status’. Additionally, cultures were taken from the patient’s dominant hand and his environment. After disinfection of all sampled areas, microbiological cultures of hands, environment, and air (Hospital 1) were taken every 90 minutes for 5 hours, always followed by disinfection of sampled sites. Patient activity was assessed by questioning patients (Hospital 1) or by videotaping (Hospital 2).

Results: Ten patients were included in the study, of whom six received an MRSA-active antibiotic due to MRSA infection. The majority (7/10) was female, the average age was 52.8 years. In total, 360 patient and environmental swabs were obtained over 40 visits. MRSA was detectable in the groin, axilla, and nares in six, two, and four patients, respectively. At the first visit, a mean of 1.2 of six environmental sites were contaminated with MRSA. During the 90 minutes time intervals, 27% (95% Confidence interval: 12–46%) of patient hands newly acquired MRSA. Environmental sites were contaminated with a frequency of 6% (95%CI: 3–10%), with toilet seats being the most frequently contaminated site (17%, 95%CI: 6–35%), followed by the bed rail (13%, 95%CI: 2–40%). Patient activity explained the majority of environmental contaminations (8/10), e.g. all six toilet seat contaminations were preceded by toilet use. Conversely, not all toilet uses lead to seat contamination. Air samples were positive in 27% (95%CI: 8–55%), but we were not able to clearly identify a causative activity for this result.

Conclusions: Contamination of patient’s hands and environment with MRSA changes over short periods of time. Environmental MRSA can mostly be explained by patient activity and seems to correlate with the patient’s ‘colonization status’. The significance of frequently found airborne MRSA remains unclear.

Figure 1. Depiction of patient colonization status, hand and environmental contamination, and description of patient activity

Abstract 2444

Clinical evaluation of a novel chemiluminescent microparticle immunoassay of Aspergillus galactomannan in diagnosis of invasive aspergillosis

He Wang*, Chunlong Liu1, Yuan Zhang1, Kevin Sun1, Junyang Du1, Yan Su1, Zeqi Zhou1

1Beijing Key Laboratory for Mechanisms Research and Precision Diagnosis of Invasive Fungal Disease, Beijing, China

Background: Aspergillus galactomannan (GM) ELISA assay has been proved as an important indicator of probable invasive aspergillosis (IA), and it has been widely used especially for patients with haematological malignancy. The disadvantage of ELISA includes cumbersome procedures, false positive problems and numerous interference factors. Other proposed manual or semi-automatic strategies cannot meet the large-scale requirement either. Therefore, developing a specific, sensitive and automatic detection and quantitation strategy for clinical diagnosis and therapeutic monitoring of GM is in urgent demand. In this study, we used galactomannan monoclonal antibodies to establish a chemiluminescent quantitative detection method based on an automatic chemiluminescent analyzer (Fig). The clinical assessment was also carried out.

Fig: Schematic of the magnetic microparticle-based automatic chemiluminescent immunoassay for GM

Materials/methods: A total of 321 serum samples were collected according to the revised EORTC/MSG guideline (2008), and tested by Automatic Chemiluminescent microparticle immunoassay for GM (Dynamiker, China). All the samples from the Shan-dong and Tianjin Provincial Chest Hospital. Those including 126 IA samples (proven, n=43; probable, n=83) and 195 negative samples. Those samples were compared with PlateliaTM GM ELISA (Bio-Rad, USA).

Results: Through the analysis of 321 serum samples, the Automatic Chemiluminescent microparticle immunoassay sensitivity and specificity was 83.33%, 82.05%, respectively. The positive coincidence rate, negative coincidence rate and total coincidence rate of automatic chemiluminescent microparticle immunoassay compared with PlateliaTM was 91.03%, 96.30% and 95.02%, respectively.

Conclusions: The Dynamiker automatic chemiluminescent microparticle immunoassay for GM, with competent specificity and sensitivity, is highly consistent with Bio-Rad PlateliaTM GM ELISA. It could be used as a rapid test to support the diagnosis of IA.

Abstract 2445

Molecular epidemiology and clinical features of human adenovirus: a 20-year retrospective observational study in Bern, Switzerland

Joyce Odeke Akello* 1;2;3, Richard Kamgang1, Maria Teresa Barbani1, Franziska Suter-Riniker1, Stephen L. Leib1, Alban Ramette1

1University of Bern, Institute for Infectious Diseases, Bern, Switzerland, 2Spiez Laboratory, Spiez, Switzerland, 3Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland

Background: Human adenovirus (HAdV) is an important viral pathogen, especially in young children. It is often implicated in keratoconjunctivitis, pharyngoconjunctival and various respiratory illnesses.

Materials/methods: In this retrospective observational study, we analysed data of HAdV positive patients who presented at the University Hospital of Bern, one of the largest hospitals in Switzerland. Various biological samples (conjunctivitis swabs, respiratory tract, stool, urine, blood, or genital swab) were tested for HAdV positivity using routine diagnostic methods including PCR, immunofluorescence, virus culture, or ELISA. Multivariate analysis was used to identify epidemiological trends and risk factors associated with increased number of HAdV cases over the study period. HAdV genotyping was performed by sequencing PCR amplicons targeting the hexon gene. Phylogenetic comparison of the obtained sequences with HAdV reference strains was performed to determine genotype relatedness.

Results: HAdV infection was confirmed in 1,302 samples that were collected between 1998 and 2017. Cases of HAdV infection were reported throughout the years with no clear seasonality, with the exception of reoccurring peaks in HAdV cases occurring every four years among young children. Increased number of HAdV cases were observed in years 2009 [n = 110] and 2010 [n = 112]. Upper respiratory tract samples, conjunctivitis swabs, and stool were associated with the highest positivity rates, with 56.2%, 18.7% and 14.2% of the cases, respectively. HAdV infection was highest among young children (on average 57.2%). HAdV genotyping for 145 positive samples from years 2009 and 2010 identified HAdV8 as the predominant genotype contributing to HAdV infection among young adults (20-44 years), middle aged (45-64 years), and elderly (65-100 years) patients. Predominant genotypes among young children were HAdV1, HAdV2, and HAdV3. The most prevalent genotypes circulating among young children in the 20-year period belonged to HAdV species C. Phylogenetic analysis showed close relationship among the identified genotypes and international reference strains.

Conclusions: Our study gives novel insights on long-term epidemiological trends and genotypic relatedness among HAdV strains causing infections in patients from one of the largest hospitals in Switzerland, country in which little data on HAdV prevalence and diversity was so far available.

Abstract 2447

Molecular epidemiological survey of Staphylococcus lugdunensis isolates with different copies of the repeat region in the gene encoding the von Willebrand factor-binding protein

Jang-Jih Lu*, Lee-Chung Lin

Chang Gung Memorial Hospital, Department of Laboratory Medicine, Taoyuan, Taiwan

Background: The von Willebrand factor binding protein (vWbl) is a surface protein and a virulence factor of staphylococcus lugdunensis. The vWbl gene has 4 major regions, including S (signal peptide), A (non-repetitive region), R (repeat-region), and W (wall-associated region). Previous studies demonstrated that the R region of the vWbl gene contains ten copies of repeated sequences, referred to as vWbl repeats. Our preliminary study revealed that the number of vWbl repeats vary among different clinical isolates. In this study, we conducted an epidemiological surveillance of S. lugdunensis to determine whether the copy number of vWbl repeats correlates with the types of infections caused by the isolates.

Materials/methods: Two hundred and nine isolates including 164 oxacillin sensitive and 45 oxacillin resistant S. lugdunensis were collected during the period of 2003 to 2014 from different patients in Taiwan. SCCmec typing and MLST were performed on each isolate, and the copy number of vWbp repeats in each isolate was determined based on the sizes of PCR products.

Results: Approximately 50% (105 of 209) of the isolates were from blood, and most of them contained thirteen (36, 34%), nine (30, 28.5%), or twelve (20, 19%) copies of vWbl repeats. The 45 oxacillin resistant isolates were found to have nine (28, 62%) or thirteen (14, 31%) vWbl repeats. Twenty-seven of the 28 isolates with 9 vWbl repeats were SCCmec V or Vt and belonged to ST3, and all isolates with 13 vWbl repeats were SCCmec II and of ST6. Most isolates (49 of 55) with 9 vWbl repeats had a stop codon at the codon in the third repeat, suggesting the production of a nonfunctional vWbl. None of the isolates from endocarditis patients had 9 vWbl repeats.

Conclusions: The number of vWbl repeats varied among Staphylococcus lugdunensis isolates from different patients. None of isolates from patients with endocarditis contained 9 vWbl repeats. Results of this study suggest that the number of vWbl repeats in S. lugdunensis may correlate with its pathogenicity.

Characterisation of a fibronectin binding protein in the virulence of Streptococcus parasanguinis FW213

Yi-Ywan Margaret Chen*1

1Chang Gung University, 259 Wen-Hwa 1st Street, Taoyuan, Taiwan

Background: Streptococcus parasanguinis is a dominant isolate and a primary colonizer of the dental biofilm. Upon gaining entrance to bloodstream, S. parasanguinis could potentially cause life-threatening subacute endocarditis and other systemic infections. By using BLASTP, a fibronectin binding protein (Fbp) homolog, Spaf_1 409 was identified from the genome of strain FW213. As fibronectin exists widely on host tissues and in bloodstream, Fbps are known to play important roles in establishing infection by many pathogens. Thus, this study was designed to investigate the function of Spaf_1 409 in the pathogenicity of S. parasanguinis FW213.

Materials/methods: By using a Spaf_1 409 knockout strain (MPH4) and various in vivo and in vitro analyses, including ELISA, western blotting, a flow-cell biofilm system couple with CLSM examination, macrophage survival assays, flow cytometry analysis, and the the Galleria mellonella larva model, the binding specificity and location of Spaf_1 409, and the role of Spaf_1 409 in biofilm formation, survival within macrophages and systemic infections were determined.

Results: Spaf_1 409 is the key ligand of S. parasanguinis FW213 for fibronectin and could be found both on the cell-wall fraction and growth supernatant of S. parasanguinis cultures. Inactivation of Spaf_1 409 reduced the ability of S. parasanguinis to withstand the shearing force from the medium flow in a flow-cell biofilm system, suggesting that Spaf_1 409 mediates bacterial cell-cell interaction. The phagocytic rate of MPH4 by RAW264.7 macrophages was lower than that of wild-type FW213, and less viable MPH4 cells could be detected within RAW264.7 macrophages. Thus, the reduced survival rate of MPH4 compared to wild-type FW213 may result from a reduced phagocytic rate and/or intracellular survival ability. Suprisingly, MPH4 exhibited an enhanced virulence in G. mellonella larvae.

Conclusions: Spaf_1 409 mediates the binding of S. parasanguinis FW213 to fibronectin and cell-cell interaction during the development of biofilm. Spaf_1 409 is also a target for RAW264.7 macrophages during phagocytosis, but inactivation of Spaf_1 409 increased the virulence of S. parasanguinis FW213 in G. mellonella larvae. Thus, inactivation of Spaf_1 409 may reduce the killing by macrophages due to reduced phagocytosis, but Spaf_1 409-null S. parasanguinis is more virulent in systemic infections.

Abstract 2449

Risk factors for healthcare-associated infections caused by cefepime resistant Pseudomonas aeruginosa in a tertiary care hospital in Serbia

Ivana Petrovic*, Zorana Djordjevic2, Marko Folic3,4, Slobodan Jankovic3,4

1Clinical Centre of Kragujevac, Clinical Microbiology Department, Kragujevac, Serbia, 2Clinical Centre of Kragujevac, Epidemiology Department, Kragujevac, Serbia, 3Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia, 4Clinical Centre Kragujevac, Clinical Pharmacology Department, Kragujevac, Serbia

Background: Cefepime can be considered as one of the agents of potential choice for treatment of moderate to severe healthcare-associated infections (HAIs) causing Pseudomonas aeruginosa. However, new reports point to growing frequency of cefepime resistant P. aeruginosa (CRPA) as a causative agent of mentioned infections and associated poorer treatment outcomes. Previous research has tried to identify some of the risk factors for the onset of HAIs caused by this pathogen, but there is still a gap in clinical knowledge regarding the risk factors, especially those associated with fatal outcome. The aim of our study was to identify risk factors associated with HAIs caused by CRPA, not only in whole population of patients with HAIs, but also in the subgroups of patients who died in hospital.

Materials/methods: The study was conducted as combination of two nested case/control studies within the cohort of patients with HAIs caused by P. aeruginosa, regardless of localization, prospectively followed from January 2009 to December 2017 in a tertiary care hospital in Serbia. Influence of risk factors on specific outcomes was estimated by adjusted odds ratios calculated from multivariate logistic regressions.

Results: Six independent risk factors for CRPA infections were identified: the existence of another HAI (aOR=2.257; p=0.001), hospitalization in ICU longer than one month (aOR=2.440; p=0.007), longer stay in hospital until infection (aOR=1.049; p=0.004), longer use of mechanical ventilation (aOR=1.035; p=0.036), administration of antibiotics before infection (aOR=1.755; p=0.001) and previous use of fluoroquinolones (aOR=2.024; p=0.030). Further, independent risk three independent risk factors have been identified for the fatal outcome: traumatic injury (aOR=12.639; p=0.020), existence of another HAI (aOR=4.599; p=0.001) and long-term use antibiotics before HAI (aOR=1.118; p=0.034).

Conclusions: Risk factors for HAIs with CRPA are primarily linked to pre-infection use of systemic antibiotics, which is a common pathway for selection of multi, extensive or pan-resistant strains of P. aeruginosa that invade tissues and cause infection or to increased use of antibiotics, which is common way for induce HAI in general, including that caused by CRPA. Implementation of adequate corrective measures in order to improve the actual situation in healthcare associated infections area is necessary.

Impact of Point-of-Care testing on the surveillance of respiratory viral infections in West Midlands, England

Dean Ironmonger*, Amardeep Bains¹, Tina Hong¹, Dan Todkill¹, Jeremy Hawker¹, Obaghe Edeghere¹

¹Birmingham, Public Health England, Birmingham, United Kingdom

**Background:** Respiratory viruses cause 44% of hospital admissions due to acute respiratory illness in central England. To support clinical management of these cases, Point-of-Care Testing (PoCT) for selected respiratory viruses is being introduced into hospitals in the UK.

In England, routine laboratory surveillance of infections is via Public Health England's Second Generation Surveillance System (SGSS), which is based on electronic reports from Laboratory Information Management Systems (LIMS). Reports generated from this system are a key component of national and local NHS winter planning. If PoCT devices are not interfaced with LIMS, these results may be excluded from routine surveillance. We therefore undertook a survey and case study in August 2019 to determine the extent of PoCT’s in West Midlands hospitals and identify potential gaps in surveillance.

**Materials/methods:** We sent a questionnaire to all microbiology laboratories in West Midlands to determine whether PoCT was being planned or already implemented; and whether these data are captured in LIMS. PoCT data was provided by one hospital during the 2018/19 influenza season to compare with PHE SGSS surveillance data for the same period.

**Results:** All thirteen West Midlands microbiology laboratories responded. Three hospitals reported using PoCT, with two performing influenza A & B and RSV and one performing just RSV tests. Four hospitals plan to introduce PoCT for respiratory virus infections for the 2019/2020 season. The two hospitals performing PoCT for influenza A & B and RSV did not send results to their LIMS; however, the hospital performing only RSV PoCT entered their positives cases into their laboratory system.

PoCT data from one hospital collected between December 2018 and May 2019 showed 461 positive records (433 influenza A, 6 influenza B and 22 RSV). Only 8 (2%) of these records were found in the PHE SGSS database.

**Conclusions:** PoCT testing has major implications for current surveillance systems. Our finding highlights the need for healthcare organisations to ensure UK statutory reporting obligations are met to prevent the serious misrepresentation of the incidence of key public health infections, and consequent loss of utility for public health functions such as winter planning.

Benzimidazole SPR719/720 is a potent new candidate for treatment of non-tuberculous mycobacterial infections
Lian Pennings*, Troy Lister1, David Melnick2, Nicole Cotroneo2, Ian Critchley2, Michael Pucci2, Tom Parr1, Suzanne Stokes2, Jakko Van Ingen1

1Radboud University Medical Center, Department of Medical Microbiology, Nijmegen, Netherlands, 2Spero Therapeutics, Cambridge, United States

Background: The outcomes of antibiotic treatment of nontuberculous mycobacterial (NTM) disease are very poor and new drugs and regimens are urgently needed. A novel benzimidazole SPR719, the active moiety of SPR720, showed low minimum inhibitory concentrations (MIC) against Mycobacterium abscessus, Mycobacterium avium complex (MAC) and Mycobacterium kansasii. Therefore we aimed to explore the potential role of SPR719/720 in the treatment of NTM disease.

Materials/methods: MICs and minimum bactericidal concentrations (MBC) of SPR719 against clinical and reference strains of M. avium complex, M. kansasii and M. abscessus were determined by broth microdilution, according to CLSI guidelines. Synergy between SPR719 and key antimycobacterial drugs was assessed using checkerboard microdilution assays. To study pharmacodynamics, time-kill assays with SPR719 alone were performed and in the combination with drugs that proved to have the most synergistic effect.

Results: The MIC50 and MIC90 for SPR719 were 1 and 2 mg/L, respectively for MAC and M. kansasii and 2 and 8 mg/L, respectively for M. abscessus. SPR719 was bacteriostatic against all tested NTM strains (MBC/MIC ratio ≥8). SPR719 had no interaction with other anti-mycobacterial drugs, but showed low fractional inhibitory concentration index values with ethambutol (∑FIC =0.8) for M. avium and M. kansasii and with clarithromycin for M. abscessus (∑FIC =0.8). SPR719 as monotherapy displayed significant concentration-dependent activity in time-kill assays (Figure 1) and the combination of SPR719 with ethambutol (for M. avium and M. kansasii) and clarithromycin (for M. abscessus) showed more killing over time than SPR719 alone.

Conclusions: SPR719 exhibits potent antimycobacterial activity against the NTM strains of MAC, M. kansasii, and M. abscessus evaluated. Time-kill assays indicate SPR719 is a potent monotherapy against M. avium and displays increased activity when used in combination with ethambutol. For M. abscessus SPR719 in combination with clarithromycin outperformed either agent alone. These data confirm that SPR719 is active against key NTM pathogens and that SPR-720 could serve an important role as a new oral agent for the treatment of NTM pulmonary disease.

Abstract 2457

Clinical impact of ceasing isolation procedure using a single molecular test for suspected pulmonary tuberculosis in The Royal Melbourne Hospital

Lluïsa Guillem*, Nor Zaila Zaidan1,2, Belinda Lin3, Justin Denholm4, Deborah Williamson4, Caroline Marshall4

1Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat, Spain, 2Melaka General Hospital, Melaka, Malaysia, 3The Royal Melbourne Hospital, Melbourne, Australia, 4The Royal Melbourne Hospital, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

Background: Active pulmonary tuberculosis (aPTB) transmission in health care centers is concerning and infection prevention policies previously recommended isolation in airborne precautions until three daily samples of sputum became acid-fast bacilli (AFB) negative. Recently, the use of molecular testing was assessed regarding accuracy and cost-effectiveness in hypothetical situations. Newer guidelines recommend using Xpert MTB/RIF testing in strategies around patient isolation, however, few studies examine the real impact of this. Since November 2018, our hospital changed procedure to follow these recommendations in patients with a low index of suspicion of aPTB.

Materials/methods: We performed an observational retrospective study examining all cases admitted with suspected aPTB in airborne precautions during two 4-month periods: Period A, when the three negative AFB sputum were required and Period B, requiring only one single Xpert MTB/RIF negative sputum to cease isolation in patients with a low index of suspicion of active disease. We used infection prevention software to detect cases and reviewed electronic medical records to collect clinical and microbiological data.

Results: 76 cases were isolated for suspected aPTB (40 vs. 36), from which 15 confirmed cases were excluded (8 vs. 7). Six patients in period A and 16 in period B had Xpert MTB/RIF performed on the first sputum. There was no significant difference in the mean isolation days between the periods (3.9 vs. 4.7 days, P=0.4). Time taken to de-isolate was shorter in the infectious diseases and respiratory units compared with other units overall (3.4 vs. 5.1 days, P=0.01), although the time stayed the same for the infectious diseases/respiratory units in each time period (3.5 vs. 3.4 days, P=0.90) and lengthened in the other units (4.3 vs. 5.82 days, P=0.25).

Conclusions: We did not find the expected reduction in isolation time in our hospital using a new protocol including molecular testing. This may be because the decision and practicalities around de-isolation are affected by a range of logistic issues as well, for example the workflow on ward. The impact of a new test needs more than just change of policy, so future work could be more explicit about the ‘cascade of management’ needed around this.

Abstract 2459

**Comparison of two commercial platforms for identification of bacteria and Candida isolates at species-level by MALDI-TOF MS in Shenzhen, China**

Wing Tong Lau*, Jasper Chan¹, Simon Lo¹, Li Yan¹, Yi Ting¹, Li Caiguan¹, Li Huijuan¹, Kwok-Yung Yuen²

¹Department of Clinical Microbiology and Infection Control, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China, ²Department of Microbiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China

**Background:** MALDI-TOF mass spectrometry is a revolutionary technology for identification of microorganisms. We aim to compare the performance of two commercial MALDI-TOF MS Systems.

**Materials/methods:** A total of 541 clinical isolates including 448 clinical specimens collected from patients who admitted to an accredited hospital in Shenzhen, China from November 2018 to January 2019 and 93 archived strains stored at -80°C were identified by MicroIDSys system (ASTA, Korea) and Microflex LT system (Bruker Daltonics, Germany). Direct transfer-formic acid and/or ethanol-formic acid extraction procedures with α-cyano-4-hydroxycinnamic acid matrix solution were used to acquire the peptide profiles by the systems, and subsequently analyzed using Biotyper and MicroIDSys database softwares respectively. The identification scores ≥2 and ≥140 were considered to be reliable at species-level for Microflex LT and MicroIDSys systems respectively. 16S rRNA gene sequencing were applied to verify the discrepancies between the two systems and the protein spectra with scores <2.0 (Microflex LT) and/or <140 (MicroIDSys).

**Results:** Among the 541 isolates involving 90 strains, 95.7% (518/541) obtained the identical results achieving species-level with scores ≥2 for Microflex LT and ≥140 for MicroIDSys. The top twenty frequently isolated strains were Escherichia coli (n=40), Klebsiella pneumoniae (n=37), Pseudomonas aeruginosa (n=32), Staphylococcus aureus (n=29), Acinetobacter baumannii (n=26), Enterococcus faecalis (n=21), Streptococcus agalactiae (n=19), Streptococcus pneumoniae (n=19), Staphylococcus epidermidis (n=18), Enterococcus faecium (n=16), Stenotrophomonas maltophilia (n=15), Haemophilus influenzae (n=14), Moraxella catarrhalis (n=14), Proteus mirabilis (n=12), Streptococcus pyogenes (n=12), Enterobacter cloacae (n=11), Citrobacter koseri (n=10), Candida albicans (n=9), Serratia marcescens (n=9), Candida tropicalis (n=9), Klebsiella oxytoca (n=8), Staphylococcus hominis (n=8) and Streptococcus mitis (n=8). Except for A. baumannii (96.2%), the agreement rate with identical results achieving species-level with scores ≥2 for Microflex LT and ≥140 for MicroIDSys for other 19 top twenty strains were 100%. Nine rare strains including Actinomyces euopeuse (n=1), Achromobacter mucicolens (n=1), Bacillus velezensis (n=1), Burkholderia ambifaria (n=1), Comamonas terrigena (n=1), Enterobacter xiangfangensis (n=1), Neisseria cinerea (n=2), Pantoea agglomerans (n=1), and Streptococcus tigurinus (n=1) were not identified or misidentified by both platforms.

**Conclusions:** The ASTA MicroIDSys system has comparable identification performance to the Bruker Microflex LT system.

Abstract 2460

**Encephalitis in French travellers, 2016-2019**

Alexandra Mailles*, Martin Martinot, Xavier Argemi, Frédéric Bourdain, Pierre Jaquet, Jessica Krause, Etienne Canoui, Jean Paul Stahl

1Santé publique France, Saint-Maurice, France, 2CH de Colmar, Colmar, France, 3CHU de Strasbourg, Strasbourg, France, 4Hôpital Foch, Suresnes, France, 5Hôpital Cochin, Paris, France, 6Hôpital Saint-Antoine, Paris, France, 7CHU de Grenoble, Grenoble, France

**Abstract third-party references:** French public health agency [Santé publique France], French Infectious Diseases Society

**Background:** Encephalitis diagnosis in travelers is challenging, especially when they return from areas with different vectors and animal reservoirs. However, they might also be exposed to very common infectious agents, or be infected before they travel. Therefore, solid data is needed to prioritizing the etiological investigation in returning travelers presenting with encephalitis. Our study aimed at describing returning travelers enrolled in the ENCEIF cohort with regards to their cause of encephalitis, destination, and reported at-risk exposures.

**Materials/methods:** Patients matching the case definition of encephalitis [Venkatessan et al. CID 2013] were prospectively enrolled. Demographic data, medical history, clinical and diagnosis characteristics were gathered in a standardized manner. Travelers were defined as people who reported a travel out of France during the 6 months before onset, or who were resident of another country and diagnosed during a stay in France.

**Results:** As of 16th October 2019, 69/ 476 [15%] enrolled patients were travelers. They had visited or lived in Europe [n=34], Africa [n=20], Asia [n=5], Middle-East [n=4], North America [n=4], South America [n=1], and South Pacific [n=1]. With regards to visited countries, 18/69 [26%] had stayed in a tropical area. The most frequent diagnosis in travelers were HSV [13%] and tuberculosis [9%], but 13 [19%] had an arboviral encephalitis (West Nile, Japanese Encephalitis, Tick-borne Encephalitis, Chikungunya, Toscana and Zika). Arboviruses accounted for 20% of travelers returning from a European country. On discharge, 66% had minor or no sequelae on Glasgow outcome scale, and none died. 4 reported being bitten by a carnivore during their travel, but none were diagnosed with rabies or another zoonotic infection.

**Conclusions:** In our cohort, travelers were more frequently infected with a flavivirus or alphavirus than with HSV. However, HSV accounted for 13% of cases and tuberculosis for 9%. Our results suggest that specific arboviruses should be investigated early in travelers, even those visiting Europe, but the usual culprits should not be excluded. In our cohort, only few patients were exposed to animals during their travel, making it impossible to discuss this as an at-risk exposure.

Performance evaluation of the BD Kiestra ID/AST prototype for automatic colony picking, Bruker MALDI Biotyper target plate spotting and Phoenix AST panel preparation and loading

Garance Sarton-Lohéac¹, Alix Coste¹, Guy Prod'hom¹, Claire Bertelli¹, Antony Croxatto*¹

¹Lausanne University Hospital and University of Lausanne, Institute of Microbiology, Lausanne, Switzerland

Background: The emergence of automation in bacteriology opens a new era in clinical diagnostic laboratories. The development of additional automated solutions is required to provide a fully automated solution from sample to results. We thus evaluated in this study the performance of a Becton Dickinson Kiestra™ IdentifA/SusceptA prototype for automatic colony picking, bacterial suspension preparation, MALDI-TOF target plate spotting and Phoenix AST panels preparation and loading.

Materials/methods: The performance of the IdentifA/SusceptA prototype controlled by dedicated research software designed for this study was compared to conventional manual processing (direct spotting on the MALDI target plate) for MALDI-TOF identification (ID) and Phoenix M50 antibiotic susceptibility testing (AST). The evaluation was performed on 1305 clinical microbial isolates for ID and 336 isolates for AST representing 66 species isolated from 22 different clinical specimen types.

Results: The IdentifA exhibited a higher performance than manual processing for Gram-negative bacteria with an ID at the species level (score >2) of 96.3% and 86.8%, respectively. A significant better performance (score >2) was observed with the IdentifA (95.3%) compared to manual spotting (75.3%) from colonies on MacConkey agar. Compared to manual processing, the IdentifA exhibited a lower ID performance at the species level (score >2) for streptococci, coagulase-negative staphylococci (ConS) and yeasts with 76.2% and 92%, 73.4% and 90%, 41.3% and 73.2%, respectively. Staphylococcus aureus and enterococci were similarly identified by the two approaches with 92% ID rate (score >2).

For AST, the SusceptA exhibited an overall essential agreement and category agreement of 98.8%, 0.22% (14/6295) major errors (ME) and 1.23% (7/570) very major errors (VME) compared to the reference Phoenix M50 manual AST checked and corrected by Etest MICs for discrepant results. ME and VME were reported for 7 and 5 antibiotics, respectively.

Conclusions: The IdentifA prototype exhibited a high identification performance for the majority of isolates. The reduced performance with streptococci and ConS was observed with tiny colonies on CHROMagar. Similarly, the SusceptA prototype showed a high performance for AST with only 14 ME and 7 VME out of 6950 antibiotics tested. Five VME would have been corrected due to unusual profiles, natural resistance or laboratory routine confirmatory procedures.

Presenter email address: antony.croxatto@chuv.ch
Abstract 2466

Duration of colonisation with vancomycin-resistant Enterococcus faecium in a large ST796 vanB hospital outbreak: a cohort study

Vanja Piezzi1, Yvonne Schmiedel1, Tanja Kaspar1, Magi Baechli1, Pascal Bittel2, Jonas Marschall1, Rami Sommerstein*1

1 Bern University Hospital, Department of Infectious Diseases, Bern, Switzerland, 2 University of Berne, Institute for Infectious Diseases, Bern, Switzerland

Background: During a large hospital outbreak with predominantly vanB vancomycin-resistant Enterococcus faecium (VRE), ST 796, we identified more than 500 VRE-carriers. Colonized patients are placed on contact isolation precautions, including upon subsequent admissions. As these measures are resource-intensive, we aimed at determining the optimal interval for rescreening to document VRE clearance.

Materials/methods: Cohort study from January 2018 to November 2019 in the six Insel Group hospitals (~1600 beds), Bern, Switzerland. We included newly identified VRE carriers with at least one follow-up rectal swab. Testing was PCR-based with prior enrichment in selective broth and subsequent culture-based confirmation. Follow-up swabs were collected (not systematically) during subsequent hospitalizations. VRE clearance was defined as a VRE-negative rectal PCR; however, for the definitive discontinuation of contact precautions we required a minimum interval of six months after the last VRE detection in addition to confirmatory negative screenings. We predicted VRE clearance at given time points with a generalized additive model.

Results: We included 77 VRE-carriers with a median of one (interquartile range [IQR] 1-2) follow-up swabs, 67/77 (87.0%) being VRE vanB. Follow-up screenings were conducted at a median of 85 days (IQR 8-232) after initial VRE detection. The predicted likelihood of a VRE carrier to remain colonized (Figure 1) at 30 days was 67.8% (95% confidential interval [CI] 51.5-84.1), at 90 days 26.1% (95% CI 6.1-46.0) and at 180 days 20.6% (95% CI 4.2-36.9). We observed no VRE recolonization once a follow-up was negative.

Conclusions: VRE colonizations halved within 50 days and were reduced substantially [by roughly 80%] within 3-6 months. Depending on the availability of isolation rooms and the lab capacity during a VRE outbreak, follow-up swabs of VRE-carriers should be taken earliest at 3 months after the last VRE detection.

Figure 1: Probability of persistent VRE carriage as a function of time interval since detection (bright blue dots = PCR positive, dark blue dots = PCR negative).

Prevalence of carriage and characterisation of extended-spectrum beta-lactamase-producing Escherichia coli in healthy pregnant women living in Madagascar

Milen Milenkov1,2, Emilie Westeel1, Saïda Rasoanandrasana1, Lalaina Rahajamanana1, Rivo Solotiana Rakotomalala1, Olivier Clermont1, Laurent Raskine1, Luc Hervé Samison1, Hubert Endtz1, Antoine Andremont2, Florence Komurian-Pradel1, Laurence Armand-Lefevre2,6

1Fondation Mérieux, Lyon, France, 2IAME, UMR 1137, Université de Paris, Paris, France, 3RESAMAD Network, Antananarivo, Madagascar, 4Centre d’Infectiologie Charles Mérieux, University of Antananarivo, Antananarivo, Madagascar, 5University of Antananarivo, Centre d’Infectiologie Charles Mérieux, Antananarivo, Madagascar, 6Hôpital Bichat-Claude Bernard, AP-HP, Paris, France, Paris, France

Background: ESBL dissemination in the community is a major public health concern worldwide. WHO has developed a one-health surveillance project called «Triycle» focusing on ESBL -E. coli in humans, the environment and the food chain. Here we present the first results from the human component in Madagascar.

Materials/methods: Rectal swabs were collected prospectively in 2018 from Malagasy pregnant women close to delivery from two maternity wards in the capital (Antananarivo) and one in province (Mahajanga). Samples were plated on MacConkey agar supplemented with 4 mg/L cefotaxime in the laboratories of the RESAMAD network [Madagascar]. Isolates were then shipped to France for identification on a Vitek2 system and antibiotic susceptibility testing by disk-diffusion according to EUCAST guidelines. Whole genome sequencing was performed on an Illumina NextSeq system.

Results: In all, 299 pregnant women [mean age = 27 year old] were sampled, of those 93 (31.1%) were ESBL -E. coli positive. Prevalence was 23% (45/199) in women from the capital and 48% (48/100) in province [p<0.01]. 16% of the strains were resistant to piperacillin/tazobactam, 10% to amikacin, 39% to gentamicin, 68% to ciprofloxacin and 80% to co-trimoxazole. All isolates were susceptible to colistin and fosfomycin. A single one was resistant to carbapenems. Whole genome sequencing was performed on 86 of 111 isolates. blaCTX-M-15 was the most frequent ESBL gene, observed in 86% (n=74) of the isolates, followed by blaCTX-M-27 (8%, n=7). One strain harboured the blaCMY-2 plasmid-borne cephalosporinase gene and the carbapenem resistant strain carried the blaNDM-5 gene. Most isolates belonged to commensal phylogenetic groups: A (73%), B1 (14%) and C (1%) and to a lesser extent to extra-intestinal virulent groups B2 (5%), D (6%) and F (1%). Multi locus sequence typing showed 42 different sequence types (ST) gathered in 24 clonal complexes (CC), the most frequent being CC10 (37% of the isolates), CC155 and CC450 (6.7% each) and CC131 (4.5%).

Conclusions: Prevalence of ESBL-E. coli in the community in Madagascar is high, especially in province and is consistent with the ESBL global epidemiology with the predominance of blaCTX-M-15 and E. coli CC10. The detection of carbapenemase producing E. coli in the community is worrying.

Abstract 2471

Predictors of mortality of influenza virus infections in a Swiss hospital during four influenza seasons: role of quick sequential organ failure assessment

Matthaios Papadimitriou Oliveris1,2*, Nikitas Gkikopoulos1, Melissa Wust1, Aurelie Ballif1, Valentin Simonin1, Marie Maulini1, Charly Nusbaumer1, Luce Bertaiali Monnerat1, Jonathan Tschopp2, Eleftheria Kampouri1, Patrick Wilson1, Hervé Duplain1

1Hospital Du Jura, Delémont, Switzerland, 2Lausanne University Hospital, Lausanne, Switzerland

Background: Influenza infections have been associated with high morbidity. The aims were to determine predictors of mortality among patients with influenza infections and to ascertain the role of quick Sequential Organ Failure Assessment (qSOFA) in predicting poor outcomes.

Materials/methods: All adult patients with influenza infection at the Hospital of Jura, Switzerland during four influenza seasons (2014/15 to 2017/18) were included. Cepheid Xpert Xpress Flu/RSV was used during the first three influenza seasons and Cobas Influenza A/B and RSV during the 2017/18 season.

Results: Among 1684 influenza virus tests performed, 441 patients with influenza infections were included (238 for influenza A virus and 203 for B). The majority of infections were community onset (369; 83.7%). Thirty-day mortality was 6.0% (25 patients). Multivariate analysis revealed that infection due to A virus (P 0.035; OR 7.1; 95% CI 1.1-43.8), malnutrition (P<0.001; OR 25.0; 95% CI 4.5-138.8), hospital-acquired infection (P 0.003; OR 12.2; 95% CI 2.3-65.1), respiratory insufficiency (PaO2/FiO2<300) (P<0.001; OR 125.8; 95% CI 9.6-1648.7) and pulmonary infiltrate on X-ray (P 0.020; OR 6.0; 95% CI 1.3-27.0) were identified as predictors of mortality. Among 287 patients requiring hospitalization, mortality was independently associated with infection due to A virus (P 0.035; OR 7.1; 95% CI 1.1-43.6), malnutrition (P<0.001; OR 24.0; 95% CI 4.5-137.8), hospital-acquired infection (P 0.003; OR 12.1; 95% CI 2.3-64.7), respiratory insufficiency (PaO2/FiO2<300 mmHg) (P<0.001; OR 123.7; 95% CI 9.4-1635.2) and pulmonary infiltrate on X-ray (P 0.021; OR 5.9; 95% CI 1.3-26.8). qSOFA showed a very good accuracy (0.89) equivalent to other more specific and burdensome scores such as CURB-65 and Pneumonia Severity Index (PSI).

Conclusions: qSOFA was equivalent to specific severity scores (PSI, CURB-65) in predicting mortality. Infection by influenza A virus, respiratory insufficiency and malnutrition were associated with worse prognosis.

Comparative analysis of diagnostic utility of microbial metagenomic next-generation sequencing among different sample types

Qing Miao*, Bijie Hu1, Jue Pan1, Wenting Jin1

1Fudan University, Zhongshan Hospital, Shanghai, China

Background: Microbial metagenomic sequencing was suggested to potentially replace traditional microbiological methodology because of its comprehensiveness and sensitivity. Here we aim to systematically compare the sensitivity and specificity of various clinical sample types for maximizing its diagnostic performance.

Materials/methods: From April 2017 to October 2019, 2,725 clinical biospecimen were collected, with 2419 samples were retrospectively diagnosed as infectious disease (1647, 68.1%), non-infectious (467, 19.3%) and unknown causes (305, 12.6%). 2,206 specimens were tested on-site with a fast turnaround time of 48h. using BGI platform localized in Zhongshan Hospital in Shanhgai, China. 583 of these patients were collected with multiple specimens for diagnosis The positivity rate of various sample types was compared, including plasma (n=757, 27.8%), sputum (n=515, 18.9%), bronchoalveolar lavage fluid (BALF) (n=460, 16.9%), tissue (n=430, 15.7%), body fluid (n=379, 13.9%), cerebrospinal fluid (CSF) (n=85, 3.1%), and the other (99, 3.6%). The pathogen biomass level in different sample types was also assessed.

Results: In infectious diseases, the positive rate of metagenomic test was higher in sputum (254/515, 55.2%), followed by BALF (206/460, 44.8%), plasma (202/757, 43.9%), while the least detection rate was shown in CSF (5.9%). In most cases, plasma was inferior to samples from primary infectious site, even in infectious endocarditis (22.2% vs 52.6%, p<0.01) and intra-abdominal infection (36.0% vs 52.4%, p<0.05) where blood stream infection is common. Importantly, for some microbes such as virus and Pneumocystis carinii, plasma shared the same detection rates with other specimen. Interestingly, a higher positivity in BALF than that in sputum and tissue (82.4 vs 50.0%, p<0.01) were observed for non-tuberculosis mycobacteria but not mycobacteria tuberculosis or fungus.

Conclusions: In most cases, a higher sensitivity for pathogen identification could be obtained by testing samples from primary infectious sites, and by choosing appropriate specimen depending on potential microbes consideration. Therefore, sample selection of metagenomic sequencing, not the technique itself, needs hypothesis.

**Serotype is associated with high rate of colistin resistance among clinical isolates of Salmonella from China**

Qixia Luo*, Hao Fu1, Xiao Yu1, Yuan Wang1, Yonghong Xiao2

1Zhejiang University, The first affiliated hospital of Zhejiang University, Hangzhou Shi, China

**Background:** To investigate the reason that the ratio of colistin resistant clinical isolated *Salmonella* (MIC >2 mg/L) were significantly higher than other Enterobacteriaceae, such as *Escherichia coli* and *Klebsiella pneumoniae* in China.

**Materials/methods:** *Salmonella* isolates were collected from fecal and blood samples of patients. Serotyping was conducted according to the White–Kauffmann–Le Minor scheme. Broth microdilution was used for colistin MIC determination. Representative isolates were subjected to detailed characterization and phylogenetic analysis by whole genome sequencing (WGS).

**Results:** In this study, 42.77% (136/318) clinical isolated *Salmonella* were resistant to colistin. *mcr-1* gene and mutations in PmrAB confer little for high rate of colistin resistant *Salmonella* isolated from human patients, because only two of the 136 colistin resistant isolates were *mcr-1* positive (both serotype Typhimurium) and other two possessed PmrAB mutations (serotype Gallinarum and Goldcoast). MIC distribution for colistin at serotype level among the two most prevalent serotypes originating from humans in China indicated that *Salmonella* Enteritidis (83.9% resistance, 125/149) were significantly less susceptible than *Salmonella* Typhimurium (15.3% resistance, 9/59, P<0.01). The high isolation rate of *S.* Enteritidis and high rate of colistin resistance in *Salmonella* bloodstream infection indicated that not only was *S.* Enteritidis more likely to be colistin-resistant compared to *S.* Typhimurium, but also more frequently cause severe infections. Phylogenetic tree based on core-genome single nucleotide polymorphisms (SNPs) was separately by the serotypes but not MICs and implied a diffused distribution of MICs in the same serotype isolates.

**Conclusions:** Colistin susceptibility of clinical isolated *Salmonella* not only associated with *pmrAB* and *mcr-1* genes, but more importantly, were closely associated with specific serotypes. We suggest clinical microbiology laboratory interpreting *Salmonella* colistin MIC results in the serotype level.

Abstract 2479

**Impact of universal infectious diseases consultation on the management of Staphylococcus aureus bloodstream infection in a Swiss community hospital**

Matthiaios Papadimitriou Olivgeris\(^{1,2}\), Vera Portillo Tunon\(^1\), Charly Nusbaumer\(^1\), Luce Bertaiola Monnerat\(^1\), Eleftheria Kampouri\(^1\), Hervé Duplain\(^2\)

\(^1\)Hospital Du Jura, Delémont, Switzerland; \(^2\)Lausanne University Hospital, Lausanne, Switzerland

**Background:** Due to the complexity of *Staphylococcus aureus* bacteraemia (SAB), an infectious diseases (ID) consultation is usually recommended to improve diagnostic work-up and treatment. The aim of this study was to identify adherence to IDSA guidelines before and after implementation of a systematic ID consultation in a community hospital in Switzerland.

**Materials/methods:** This retrospective study was conducted at the Hospital of Jura, Switzerland during 54 months (June 2014 to December 2018). During the pre-intervention period (June 2014 to September 2016), infectious diseases consultation was at the discretion of the treating physician and obtained by telephone from the university hospital of Basel. During the post-intervention period (September 2016 to December 2018), an on-site infectious disease specialist was notified by email for each *S. aureus* positive blood cultures.

**Results:** A total of 107 episodes of SABs were included: 60 during the pre-intervention period and 47 in the post-intervention period. The most commonly identified sources of bacteremia were skin and soft tissue infections (23 episodes; 21%), primary bacteremia (19; 18%) and lower respiratory tract infection (18; 17%). Endocarditis accounted for 7% (7 patients). Only two (2%) methicillin-resistant *S. aureus* (MRSA) were detected. Patients in the post-intervention period were more likely to benefit from a transthoracic echocardiography, have follow-up blood cultures drawn, receive appropriate anti-staphylococcal agent and intravenous antibiotics for at least 14 days (Table). Thirty-day mortality was 22%. Multivariate analysis revealed that septic shock (\(P<0.001\); OR 7.1, CI 2.4-20.8) and lower respiratory tract infection (\(P=0.022\); OR 4.4, CI 1.2-15.8) as independent predictors of mortality.

**Conclusions:** The addition of a universal bedside consultation for all SAB in a community hospital led to a better adherence to IDSA guidelines. However, no difference in mortality was detected. Our study reinforces the growing number of published evidences exhibiting the importance of an ID consultation in the complex background of SAB, especially in community hospitals were adherence to guidelines is low.

Abstract 2481

Self-reported health status in ambulatory acute bacterial skin and skin structure infection patients who inject drugs, who received oral therapy with omadacycline or linezolid

Kenneth Lapensee*1, Surya Chitra1

1Paratek Pharmaceuticals, Inc., King of Prussia, United States

Background: Persons who inject drugs (PWID) are at elevated risk for acute bacterial skin and skin structure infections [ABSSSI]. Literature regarding health-related quality-of-life (HRQoL) outcomes for PWID with ABSSSI are scant, and these outcomes are not well understood. This study investigated PWID-reported outcomes in OASIS-2 (ClinicalTrials.gov NCT02877927), a randomized, double-blind Phase 3 clinical study comparing oral omadacycline versus oral linezolid for treatment of adults with ABSSSI.

Materials/methods: Participants were asked to complete the 36-item Short Form Health Survey Version 2 [SF-36v2R; Optum Inc., MN, USA] at screening and post-treatment evaluation [PTE; 7–14 days after last dose]. Responses to each item within the eight domains [physical functioning, social functioning, role physical, role emotional, bodily pain, mental health, vitality, and general health] were combined to generate a score from 0 to 100, where 100 indicates best health. Results were analysed in accordance with established norm-based standards for the survey, where each scale is scored to have the same mean [50 points] and the same standard deviation [10 points]. Analysis was performed for the intent-to-treat (ITT) population [all randomized participants].

Results: In total, 68.6% of participants in OASIS-2 had ABSSSI that was a result of intravenous drug use. Among PWID, improvement in patient-reported health status and HRQoL measures at PTE were greater for omadacycline than for linezolid-treated PWID [Table]. Improvement in role physical and role emotional were significantly higher for omadacycline than for linezolid-treated PWID [95% CI 0.63–9.45 and 1.1–10.59, respectively].

Conclusions: In this exploratory analysis, PWID with ABSSSI who received omadacycline experienced a greater improvement in patient-reported health status than PWID with ABSSSI who received linezolid. Greatest improvement was in performance of self-maintenance and social functions impacted by physical and mental health status. Further research among the population of PWID, including real-world studies, are warranted to determine the short- and long-term impact of ABSSSI treatments in improving patient physical and social role functioning, and whether treatments can have a differential effect on such functioning.

Molecular diagnosis of toxoplasmosis: impact of sample storage duration for five types of biological samples

Marie-Pierre Brenier-Pinchart1, Emmanuelle Varlet2, Florence Robert-Gangneux3, Denis Filisetti4, Juliette Guitard5, Yvon Sterkers2, Hélène Yera6, Hervé Pelloux*1, Patrick Bastien2

1Academic Hospital of Grenoble Alpes, Parasitology-Mycology Laboratory, Grenoble, France, 2 Academic Hospital of Montpellier, Parasitology-Mycology Laboratory, Montpellier, France, 3Academic Hospital of Rennes, Parasitology-Mycology Laboratory, Rennes, France, 4Academic Hospital of Strasbourg, Parasitology-Mycology Laboratory, Strasbourg, France, 5 Saint-Antoine Hospital, AP-HP, Parasitology-Mycology Laboratory, Paris, France, 6 Cochin Hospital, AP-HP, Parasitology-Mycology Department, Paris, France

Background: Toxoplasma-PCR is essential to diagnose disseminated, cerebral and congenital toxoplasmosis. As samples may travel for more than 24 hours before arriving in proficient laboratories, it seems important to evaluate the impact of the delay between sampling and technical support. This multicentric study evaluated the impact of samples storage at +4°C on Toxoplasma-PCR performances, aiming at proposing guidelines for the shipment and the delay before DNA extraction is performed.

Materials/methods: Five matrices, amniotic fluid (AF), cerebrospinal fluid (CSF), bronchoalveolar lavage fluid (BAF), whole blood (WB) and buffy coat (BC), were artificially spiked with various amounts of Toxoplasma gondii (20, 100 and 500 tachyzoites of RH strain/mL of sample). Moreover, blood was also spiked with the PRU strain and with THP1 cells previously infected with a Type II strain. Each spiked sample was made in triplicate at each parasite concentration. Sample processing and DNA extractions were performed at day 0 and after 2, 4 and 7 days of storage at +4°C using routine diagnostic techniques in each centre. Each extract was amplified at least in duplicate by real-time PCR assays targeting the ‘rep529’ DNA target. Results were analyzed using Fisher’s exact and Wilcoxon rank tests.

Results: 252 spiked samples were amplified by PCR. No increase in Ct was observed and 100% of PCR reactions were positive for AF, BAF, BC and WB plus infected-THP1, up to 7 days at 4°C. For CSF with low T. gondii concentrations, the number of positive PCR reactions decreased with time and only 50% of reactions were positive at D7 (p<0.05). For WB + PRU strain, amplification was significantly delayed from D2 but all reactions remained positive; for WB + RH strain, the number of positive reactions decreased for the three concentrations at D7.

Conclusions: T. gondii parasites appear robust in routine samples. The diversity of samples, extraction and PCR methods used in this multicentric study allows us proposing guidelines for good laboratory practices: sample storage at +4°C is possible up to 7 days; for CSF and whole blood, particularly from the 5th day at +4°C, we recommend to perform the PCR at least in triplicate.

Abstract 2484

**Encephalitis in elderly patients in France, 2016-2019**

Alexandra Mailles*, Martin Martinot†, Emilie Piet†, Charlotte Biron‡, Gagneux Brunon Amandin*, Gueit Isabelle*, Xavier Argemi‡, Solène Patrat-Delon†, Jean Paul Stahl‡

1Santé public France, Saint-Maurice, France, 2CH de Colmar, Colmar, France, 3CH d’Annecy-Genevois, Annecy, France, 4CHU de Nantes, Nantes, France, 5CHU Saint-Etienne, Saint-Etienne, France, 6CHU de Rouen, Rouen, France, 7CHU de Strasbourg, Strasbourg, France, 8CHU de Rennes, Rennes, France, 9CHU de Grenoble, Grenoble, France

Abstract third-party references: French Infectious Diseases Society, French public health agency (Santépublique France)

**Background:** Infections are challenging diseases in elderly patients due to immune senescence, and to their increased incidence and prevalence of chronic diseases. Moreover, elderly patients can experience cognitive decline making the detection and management of encephalitis more complicated. In France, the ENCEIF cohort enrolled encephalitis patients from 2016 to 2019. The present work aimed at describing the characteristics of enrolled elderly patients.

**Materials/methods:** Patients matching the case definition of encephalitis (Venkatessan et al. CID 2013) were prospectively enrolled. Demographics, medical history, clinical and diagnosis characteristics were gathered in a standardized manner. Elderly patients were defined as patients aged 65 y.o. or older. They were compared to patients younger than 65 y.o., using Pearson’s chi square, Student t-test and when needed, non-parametric tests.

**Results:** As of 16th October 2019, among 476 enrolled patients 251 (52%) were elderly including 120 (25%) 75 y.o. or older and 29 (6%) 85 y.o. or older. Among 251 elderly patients, 82 (32%) were being treated for another disease at the time of onset of encephalitis, vs 27 in non-elderly patients (12%, p<10⁻⁴). The most frequent causes of encephalitis in elderly patients were HSV (26%), VZV (18%) and L. monocytogenes (8%). Elderly patients were less likely to be admitted in ICU than younger patients (37% vs 47%, p=0.03), but more likely to die during hospitalization (12% vs 2%, p<10⁻³). The case-fatality rate increased to 14% in patients 75 y.o. or older, and to 18% in patients 85 y.o. or older. On discharge, 122/204 (60%) elderly patients had minor sequelae or no sequelae on Glasgow outcome scale, but 29 (14%) had severe disability or were in vegetative state. 108/203 (53%) were discharged home and 85/203 (42%) to a rehabilitation facility.

**Conclusions:** Elderly patients represented more than half of the ENCEIF cohort. Like younger patients, the most frequent causes of encephalitis were HSV and VZV, but listeriosis was more frequent than in younger patients. Elderly patients experienced a high case-fatality rate during hospitalization but the majority of those surviving the acute phase of the disease had a favorable outcome on discharge.

**Abstract 2488**

**Community outbreak of OXA-48-producing Escherichia coli linked to a food premises: New Zealand, 2018-19**

Craig Thornley*, Matthew Kelly, Maxim Bloomfield, Annette Nesdale, Xiaoyun Ren

1Regional Public Health, Hutt Valley District Health Board, Lower Hutt, New Zealand, 2Hutt Hospital, Hutt Valley District Health Board, Lower Hutt, New Zealand, 3Wellington Regional Hospital, Capital and Coast District Health Board, Wellington, New Zealand, 4Institute of Environmental Science and Research, Porirua, New Zealand

**Background:** Carbapenemase-Producing Enterobacterales (CPE) are a serious threat to healthcare. CPE transmission is well described in hospitals and long-term care facilities (LTCFs) however little is known about community outbreaks.

**Materials/methods:** CPE are infrequently detected in New Zealand with almost all cases linked to international travel. Between August 2018 and June 2019, an OXA-48 and CTX-M-174-producing ST131 *Escherichia coli* was detected in 14 people from routine diagnostic testing of urine (11) or faecal (3) specimens. One case had urosepsis; the remainder had uncomplicated infection or asymptomatic colonisation. An outbreak investigation collected data on hospital, LTCF, travel and community exposures during the 12 months before CPE detection. A closed reference genome was generated for the index case using minION; whole-genome sequencing and pair-wise core SNP distances were used to estimate relatedness.

**Results:** The 14 cases were aged 44-94 years (median 74y). Nine were female. None had travelled internationally. Ten had prior admission (>4 hours) to Hutt Hospital, in 8 different wards; none of the remaining 4 had been admitted to the hospital or had household contacts who had been admitted. Three pairs of cases had concurrent ward admissions involving 2 different wards. Extensive screening of other ward contacts did not detect the organism. Ten cases had visited a particular food premises (Premises A), at which food hygiene concerns were identified. The outbreak organism was detected in faecal specimens from 4 Premises A food-handlers; one of these had a prior concurrent admission with a case. The organism was not detected in Premises A environmental samples. Isolates from the 14 original cases and 2 food-handlers had pair-wise core SNP distances of <8; the remaining 2 food-handlers' isolates had SNP distances of 49 and 21 compared to the index case. Action was undertaken to improve hygiene standards at Premises A.

**Conclusions:** These findings suggest probable community transmission of OXA-48 CPE at a food premises, with additional hospital transmission. Improvements in hygiene standards at the premises appear to have halted further transmission related to the premises. Clusters of OXA-48 CPE may have community origins; guidelines for investigation and control of community transmission are important.

1Hospital Universitario Virgen de las Nieves, Granada, Spain, 2Hospital Virgen de las Nieves Granada, Granada, Spain, 3Hospital Virgen de las Nieves Granada, Granada, Spain, 4Hospital San Cecilio, Granada, Spain, 5Hospital Clínico, Valencia, Spain, 6Hospital Reina Sofia, Córdoba, Spain, 7Hospital Virgen de la Victoria, Málaga, Spain, 8Hospital Lozano Blesa, Zaragoza, Spain, 9Hospital Torrecárdenas, Almería, Spain, 10Hospital Puerto Real, Cádiz, Spain, 11Hospital Costa del Sol, Marbella, Spain, 12Hospital 12 de Octubre, Madrid, Spain, 13Hospital de Donostia, San Sebastián, Spain

Background: The benefits of new antiretroviral drugs (ARV) allow treatment simplification and a reduction of potential toxicity associated to antiretroviral treatment (ART) in patients who have previously been exposed to many ART combinations and have a long-term, difficult-to-manage HIV infection. The objective of this study was to analyze the effectiveness and safety of a dual therapy (DT) with dolutegravir and boosted darunavir (DTG+bDRV) in these patients.

Materials/methods: Observational, retrospective, multicenter study to analyze the effectiveness of DTG+bDRV, defined as the ability to achieve or maintain complete viral suppression, i.e. viral load (VL) <50 copies/mL. Three analyses were carried out: "ITT-Snapshot" (proportion of patients with VL<50 copies/mL at week 48 of all patients with complete follow up, including treatment discontinuations), "Per Protocol" (PP) (excluding non virological-related drops-out) and "Observed Data" (OD) (proportion of last VL<50 copies/mL of all patients with any VL determinations after switch to DT).

Results: We analyzed 163 patients with a median age of 52 years, with a CD4 nadir of 171 cells/μL, 49.4% had a history of AIDS and 58.7% had a history of virological failures (VF) (31.3% had VF with protease Inhibitors and 60.7% to at least, 2 different ARV families).

Baseline VL was >50 copies/mL in 40.5% of patients and >200 copies/mL in 26%. The reason for switch was simplification/optimization in 53%, VF in 30.2%.

From the initial 163 patients 19 were discontinued: 6 were lost to follow-up, 4 discontinuations due to adverse events [1 insomnia, 2 digestive issues and 1 non-specified], 2 were non-related exitus [both virologically suppressed in their last VL] and 7 VF [associated to bad adherence and without resistance mutation appearance]. 43 haven’t completed 48 weeks yet.

At week 48 ITT analysis, the virological success (lack of VF) and virologically suppressed was 84.2% (101/120) and 93.5% (101/108) at PP analysis. At week 48 OD analysis, 149/156 subjects, with a global exposition to DT of 162 patients-year, has their last VL<50 copies/mL (95.5%), with a VF rate of 4.3 x 100 patients-year.

Conclusions: Dual therapy with DTG+bDRV is an attractive and highly effective simplification/rescue strategy for patients with an advanced and difficult-to-treat HIV infection.

Abstract 2494

Clinical performance of a novel Point-of-Care testing automation of fungus (1-3)-β-D-glucan assay

He Wang*1, Baoxue Wang1, Yankai Fu1, Yuan Zhang1, Junyang Du1, Yan Su1, Zeqi Zhou1

1Beijing Key Laboratory for Mechanisms Research and Precision Diagnosis of Invasive Fungal Disease, Beijing, China

Background: At present, Invasive fungal diseases [IFD] have been emerging globally, especially in immunocompromised patients. Diagnostic of IFD still remains a big challenge due to the limit of conventional methods like culture and microscopy. Fungus [1-3]-β-D-Glucan (BDG) had been proved as a useful biomarker for Panfungal detection, except for cryptococcus and zygomycetes. However, the current version of BDG assay needs to pool samples and is easy to be contaminated due to complicated operation. We evaluated a novel POCT Automation of Fungus BDG assay (Dynamiker Funguy D240, China). By using of Funguy D240, the result could be reported within 30mins after adding the sample [only one step operation]. The monotest card is based on MICRO-FDSPHERES technology, which could achieve POCT for each sample due to internal standard curve. It contains 24-test channels and allow emergency test. Funguy D240 provides a rapid, flexible and POCT solution for Fungus BDG assay (Fig).

25μl Serum

30min

Fig: Dynamiker Funguy D240

Materials/methods: In total, 210 clinical serum samples previously defined according to revised EORTC/MSG guideline, including 30 proven Invasive Candidiasis [proven IC], 52 Invasive Aspergillosis [probable IA], and 128 negative samples from patients without IFD. All the samples were tested in parallel using Funguy D240 (Dynamiker, China) and Fungitell BDG assay (Associate of Cape Cod, USA).

Results: Through the analysis of 210 serum samples, the sensitivity and specificity of Funguy D240 was 82.92%, 85.15%, respectively. The positive coincidence rate, negative coincidence rate and total coincidence rate of Funguy D240 compared with Fungitell was 87.21%, 96.77% and 92.86%, respectively.

Conclusions: The Dynamiker Funguy D240 is a rapid and flexible POCT to detect Fungus BDG Glucan and could be used as an adjunct diagnostic for IFD.

Proof of concept of a low-cost tropicalised device to detect bacterial growth in equipment-free blood cultures: results from the Turbidimeter pilot study

Liselotte Hardy*, Ellen Corsmit1, Jasper Jans2,3, Kamalpreet Kaur2,3, Roel Baets2,3, Jan Jacobs1,4

*Institute of Tropical Medicine, Antwerp, Belgium, NB-Photonics, Ghent, Belgium, Ghent University, Ghent, Belgium, KU Leuven, Leuven, Belgium

Background: Bloodstream infections (BSI) are an important cause of mortality and their misdiagnosis/mistreatment is an important factor in the rise of antimicrobial resistance, in particular in low resource settings (LRS). Diagnosis of BSI in LRS is done using manual blood culture bottles (BCBs), visually checked for signs of growth. The most consistent parameter of growth is broth turbidity, but visual inspection of turbidity is inaccurate. To overcome this inaccuracy, we have developed the open-access, tropicalized Turbidimeter, that objectively assesses BCB broth turbidity.

Materials/methods: The Turbidimeter is built using cheap off-the-shelf electronics components and a customizable 3D-printed holder. Because of bacterial growth in the BCB, the turbidity of the broth increases. This causes a change in light intensity: transmitted light decreases while scattered light increases. The graph of OD versus time represents the bacterial growth curve. In addition to the detection of turbidity, a colour sensor is built in the bottom of the Turbidimeter to measure the color change at the bottom of the commercially available BacT/ALERT BCBs. To demonstrate the Turbidimeter performance, we compared time-to-positivity between BCBs spiked with Escherichia paracoli (clinical isolate from DR Congo) in the BacT/ALERT automate (reference) and the Turbidimeter incubated in a conventional incubator. Turbidimeter measurements were done every 10 minutes for 48 hours in total.

Results: The average time-to-positivity of the reference was 12.27 hours. Using the Turbidimeter, we found a comparable shift in signal from both the colour sensor and the turbidity sensor (Example given in figure 1). For the tested strain, we could demonstrate a steep growth curve, with both sensors, that reached a plateau after 2 to 3 hours. On average over four measurements, the increase in signal started after 10.07 hours (colour sensor) and 10.93 hours (turbidity sensor) and reached a plateau after 12.45 hours and 13.07 respectively.

Conclusions: Pilot results of the Turbidimeter demonstrate that the system was performant and that time-to-detection was comparable to the reference test. More testing is needed to validate the system.

Comparison of 28-day mortality rates of recently completed prospective, randomised treatment studies of adult patients with carbapenem-resistant Gram-negative bacterial infections

Thomas Lodise¹, Matteo Bassetti², Ricardo Ferrer³, Thierry Naas⁴, Yoshihito Niki⁵, David L. Paterson⁶, Markus Zeitlinger⁷, Glenn Tillotson⁸, Roger Echols⁹

¹Albany College of Pharmacy and Health Sciences, Albany, United States, ²University of Genova Infectious Diseases Clinic, Genova, Italy, ³Department of Care with a Specialized Interest, Hospital Universitari Vall d’Hebron, Barcelona, Spain, ⁴Université Paris-Saclay, Paris, France, ⁵Division of Clinical Infectious Diseases, Showa University, Tokyo, Japan, ⁶UO Centre for Clinical Research, Faculty of Medicine, The University of Queensland, Herston, Australia, ⁷Department of Clinical Pharmacology, Medical University, Vienna, Vienna, Austria, ⁸GST Micro LLC, Durham, United States, ⁹Infectious Disease Drug Development Consulting, LLC, Easton, United States

Background: Several randomised, prospective treatment studies of adult patients with serious CR-GNBIs have been conducted in the past 6 years. Recently, the CREDIBLE-CR study assessed the efficacy and safety of cefiderocol, a novel siderophore cephalosporin, for the treatment of patients with serious CR-GNBIs versus best available therapy (BAT). This analysis compares 28-day mortality rates observed in CREDIBLE-CR versus other recent CR-GNBi-focused treatment studies.

Materials/methods: Six open-label and one double-blind trials assessing antibiotics for the treatment of patients with CR-GNBIs were included. Two trials focused on carbapenem-resistant Enterobacteriaceae [CRE] [CARE, n=37; (primary analysis population); TANGO II, n=47]; 3 primarily included non-fermenters [NF] CR-GNBIs [AIDA, n=406; Durante-Mangoni, n=209; Sirijatuphat, n=94]; and 2 included both CRE and CR-NF-GNBIs [RESTORE-IMI, n=31; CREDIBLE-CR, n=118]. Participants were adults with hospital-acquired pneumonia, ventilator-associated pneumonia, bloodstream infections, complicated intra-abdominal or urinary tract infections caused by CR-GNB. Data were obtained from publicly disclosed information including FDA documents, publications, or presentations at congresses. Antibiotic treatments included: plazomicin, colistin, meropenem-vaborbactam, imipenem-relebactam, cefiderocol, meropenem, rifampicin, fosfomycin, and BAT. 28-day all-cause mortality (ACM) per study was collated and compared with ACM in CREDIBLE-CR by Forest plot.

Results: In the analysis, 824 patients were included with patient numbers varying from 37 to 406. Mortality at day 28 was 23.8% [20/84] for patients in studies of CREs and 45.0% [319/709] in NF studies. Day 28 ACM rates in CREDIBLE-CR and CR-GNBi-focused studies by CRE and NF and treatment are shown in the Figure. In studies with CRE and mixed pathogens [CRE or Pseudomonas aeruginosa], mortality rate for cefiderocol aligned with plazomicin, meropenem-vaborbactam, and imipenem-relebactam. For patients with NF, the mortality rate for cefiderocol-treated patients (35.3%) was similar to that seen for the treatment arms in comparator studies (45.0%). Mortality for the BAT in CREDIBLE-CR was lower (18.5%) than would be expected based on contemporary comparator studies.

Conclusions: Mortality rates in recently completed CR-GNBi-focused studies were high and consistent, particularly for patients with infections caused by CR NFs. Mortality rates for cefiderocol among patients with infections due to CRE and NFs were comparable to that reported with other investigational treatments in recently completed prospective, randomised trials.

Abstract 2501

**MixinYeast: a multi-centre survey on mixed yeast infections**

**Background:** Invasive candidiasis (IC) is one of the most prevalent mycoses worldwide. Infections caused by mixed yeast species may increase the risk of recurrence; despite this possible consequence, the incidence is mostly unknown. This analysis describes the epidemiological, clinical and microbiological characteristics of mixed yeast infections (Miy) isolated in several centers over a period of six months.

**Materials/methods:** A prospective study was conducted at 34 medical centers in 14 countries between April and September 2018. Miy were defined as the isolation of more than one yeast species in the same sterile specimen. Clinical data of these patients were recorded with denominators in all centers. Miy isolates were sent to a Reference Center (CNM-ISCIII) to confirm identification by ITS sequencing and to perform antifungal susceptibility testing, according EUCAST procedures.
Results: During the study period, 325,809 samples were processed. A total of 6553 positive cultures for yeasts were obtained; 150 (2.3%) involved MIY. The patients mean age was 53.7 years; 80 (53.3%) were males. Frequent risk factors were major surgery (85, 56.6%), use of central venous catheters (72, 48%), ICU stay (69, 46%) and hematological underlying disease (53, 35.3%). The principal sites of infections were blood (57, 38%) and peritoneum (50, 33.3%). Antifungal information was available for 94 (62.6%) cases; of whom 25 (26.6%) had previously received antifungal agents. Among MIY cases listed, 145 had available isolates; the mixed species most frequently found were *Candida albicans/C. glabrata* 42 (28.9%), *C. albicans/C. parapsilosis* 16 (11%), and *C. glabrata/C. tropicalis* 8 (5.5%). *C. albicans* was involved in 85 (58.6%) cases and *C. glabrata* in 64 (44.1%). The rest of the cases presented high diversity species combinations. All isolates were susceptible to amphotericin B, and 7.3% were fluconazole-resistant. Two isolates, *C. albicans* and *C. tropicalis*, were resistant to echinocandins, with *fks*1 hot spot 1mutations.

Conclusions: We documented a 2.3% of MIY in a six-month study. While *C. albicans* and *C. glabrata* were frequently identified, a high diversity of combinations was found; hence, it is important to accurately identify the species involved. Fluconazole-resistance was observed in 7.3% of the isolates; echinocandins resistance was uncommon but present.

Abstract 2507

**On non-tuberculous mycobacteria in human alveolar macrophages**

Inês João¹, Vitor Borges², Sara Sousa³, João Paulo Gomes², Luisa Jordão*³

¹INSNA, Instituto Nacional de Saúde Doutor Ricardo Jorge (INSNA), Departamento de Doenças Infecciosas (DDI), Laboratório Nacional de Referência de Micobactérias, Lisboa, Portugal, ²INSNA, Instituto Nacional de Saúde Doutor Ricardo Jorge (INSNA), Departamento de Doenças Infecciosas (DDI), Núcleo de Bioinformática, Lisboa, Portugal, ³INSNA, Instituto Nacional de Saúde Doutor Ricardo Jorge (INSNA), Departamento de Saúde Ambiental (DSA), Unidade de Investigação e Desenvolvimento (UID), Lisboa, Portugal

**Background:** Despite growing relevance of nontuberculous mycobacteria (NTM) infections, namely pulmonary infections, accurate data on incidence and pathogenesis is lacking. Here, we evaluated the intracellular persistence of three NTM species in a human alveolar macrophages model in order to get insight on the contribution of innate immune mechanisms to mycobacteria intracellular fate. The NTM genome diversity was also explored.

**Materials/methods:** *M. smegmatis* mc²155, reference strains (*M. avium* ATCC25291; *M. fortuitum* ATCC6841) and clinical isolates (*M. avium* 60/08; *M. fortuitum* 747/08) were used. Mycobacteria intracellular persistence was assessed via: 4x10⁴ THP-1 cells plated/well and incubated for 72h with 100nM PMA. Then fresh medium without PMA was added and the cells incubated for further 24h. The cells were infected for 1h (fast) or 3h (slow growers). Intracellular persistence was evaluated by CFU enumeration at different time points. NO production was evaluated using the Griess reagent, phagosome acidification and apoptosis was followed by confocal microscopy. Persistence ability of mycobacteria at different pHs was evaluated using BACTEC-MGIT960. NTMs virulence factors were characterized by whole-genome sequencing.

**Results:** NTMs experienced different intracellular fates: *M. smegmatis* and *M. fortuitum* ATCC6841 were cleared within 24h; whereas the remaining strains replicated. Still, unexpectedly, high percentages of acidified phagosomes were found harbouring Rab7, but not CD63. All NTM were able to survive in vitro at acidic pHs, with the exception of *M. smegmatis*. Our data further suggest a minor role for NO in intracellular persistence and that apoptosis mediated by caspase 8 and 3/7, but not necrosis, is triggered during NTM infection. Insights on the genomic backbone corroborated the virulence potential of *M. avium* and *M. fortuitum*.

**Conclusions:** Phagosome maturation arrest plays a secondary role in intracellular survival of *M. avium* and *M. fortuitum* in comparison to *M. tuberculosis*. NO seems to play a minor role in NTM intracellular persistence. Contrarily, apoptosis mediated by the caspase 8- caspase 3/7 pathway influences survival probably by promoting mycobacteria spread to neighboring cells. Our insights on the genomic traits underlying virulence further emphasized the importance of carrying out multidisciplinary studies in the NTM field.

Abstract 2509

**Hospital-acquired pneumonia in liver transplant recipients**

Vikas Khillan*, Girisha Pindi1, Vinayendra Pamecha3, Pratibha Kale3

1Institute of Liver and Biliary Sciences, Institute of Liver and Biliary Sciences, New Delhi, India, 1Institute of Liver and Biliary Sciences, Institute of Liver and Biliary Sciences, New Delhi, India, 3Institute of Liver and Biliary Sciences, New Delhi, India

**Abstract third-party references:** Institute of Liver and Biliary sciences

**Background:** Pneumonia is a serious complication in liver transplantation (LT) recipients. The pre, intra and post operative condition of the recipients influence the risk of developing pneumonia, especially, during the early period. Hence this study was taken up to determine the incidence, aetiology and outcomes of bacterial and fungal pneumonia in liver transplant recipients.

**Materials/methods:** This study was conducted from January 2018 to January 2019. Patients undergoing LT were followed up for 30 days post operatively for signs & symptoms of pneumonia. Respiratory samples were sent for microbiological analysis. Bacteriological identification and antibiotic susceptibility testing was performed using VITEK2 system.

**Results:** 89 patients underwent LT. 87.6% were males with age ranging from 4-65 years. The most common indication for transplantation was alcoholic liver disease. 31 (34.8%) had developed pneumonia during the study period, with the median time to development being 6 days post operatively. Ventilator associated pneumonia was seen in 8 (25.8%).

51 samples were sent for microbiological analysis, which included 16 endotracheal aspirates (ET), 10 broncho alveolar lavage (BAL), 9 blind BAL (b-BAL), 9 sputum and 7 pleural fluid samples. 58.8% were culture positive. The most common bacterial isolates were *Klebsiella pneumoniae* (21.56%), *Pseudomonas aeruginosa* (7.8%) & *Stenotrophomonas maltophilia* (7.8%). There was high level of multi drug resistance amongst isolates with colistin and fosfomycin being the drug of choice. There were 3 isolates of *Aspergillus flavus* from ET aspirate and BAL, 2 isolates of *Candida auris* from ET and 1 isolate of *Aspergillus niger* from BAL, isolates of *Rhizopus* from ET aspirate was confirmed with the same growth from BAL.

Patients who had pneumonia had greater need for non invasive ventilation (74.2%, p=<0.01), mechanical ventilator support (48.4%, p=<0.01) and tracheostomy (19.4%, p=<0.01). Post operative development of sepsis (74.2%, p=<0.01), requirement for vasopressors (71%, p=<0.01) and mortality (32.3%, p= 0.003) was observed more frequently in patients with pneumonia than those without.

**Conclusions:** Hospital acquired organisms and multi drug resistant Gram negative bacteria are frequently associated with the causation of pneumonia in the immediate post transplant period. Pneumonia is a significant cause of morbidity and mortality.

**Distribution of isolates amongst samples (n=51)**

**Presenter email address:** khillanv@yahoo.com
Clinical and echocardiographic predictors of embolism in infective endocarditis

Matthais Papadimitriou Olivgeris*1, Ching-Chia Ting1, Cécilia Soldini1, Nicola Ciocca1, Matthias Kirsch1, Stefano Giulieri1, Benoit Guery1, Pierre Monney1

1Lausanne University Hospital, Lausanne, Switzerland

Background: Systemic embolization remains an important complication of infective endocarditis (IE) leading to high morbidity and mortality. The aim of the present study was to determine the factors associated with systemic emboli among patients with IE.

Materials/methods: This prospective observational study included all patients with suspected IE hospitalized at the University Hospital of Lausanne, Switzerland during a 21-month period (January 2018 to September 2019). IE was defined according to modified criteria of 2015 European Society of Cardiology Guidelines and patients with definite or possible IE were further evaluated.

Results: Among 453 patients with suspected IE, 121 were included (84 were categorized as definite IE and 37 as possible). Most commonly isolated pathogens included Staphylococcus aureus (40; 33%), Streptococcus spp. (27; 22%) and Enterococcus spp. (9; 7%). Surgical treatment was performed in 20 patients (17%). The most common area of embolization was the central nervous system (17 patients; 14%). Embolic events were observed in 63 patients (52%). The most common areas of embolization were the central nervous system (39 patients; 32%) and the limbs (23; 19%). Surgical treatment was performed in 49 patients (41%). Embolic events were more common in patients with fever (81% vs 62%; P 0.026), bacteraemia due to S. aureus (43% vs 22%; P 0.021), mitral valve (51% vs 16%; P<0.001), left heart vegetation >10mm (41% vs 12%; P<0.001), confusion upon admission (9% vs 25%; P 0.017), younger age (60 vs 65 years; P 0.046). Multivariate analysis found that S. aureus (P 0.038; OR 3.0, CI 1.1-8.6), mitral valve (P 0.005; OR 4.4, CI 1.6-12.3) and left heart vegetation >10mm (P 0.037; OR 3.4, CI 1.1-10.5) were independently associated with systemic emboli. The accuracy of the size of left heart vegetation in the prediction of embolic events was 0.708 (Figure 1).

Conclusions: Rate of systemic embolization was high among IE patients. S. aureus was the most commonly isolated pathogen and was independently associated with systemic embolization. Large vegetation (>10 mm) and involvement of the mitral valve put the patient at increased risk from embolic episodes.

Abstract 2513

Role of enteroaggregative Escherichia coli in people with diarrhoea in Gipuzkoa

Marta Gómez Ruiz De Árbulo1, Pedro Vallejo Recuna2, Maitane Arrastia Erviti1, David Grandioso Vas1, Tania Martín Peñaranda1, Miriam Alkorta Gurrutxaga1

1Biodonostia, Infectious Diseases Area, Respiratory Infection and Antimicrobial Resistance Group; Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Microbiology Department, 20014 San Sebastian, Spain,, Donostia, Spain

Background: Enteroaggregative Escherichia coli (EAEC) is one of the most recently identified diarrheagenic Escherichia coli. Nowadays EAEC infection is increasingly recognised as a cause of acute and persistent diarrheal illness among infants and young children worldwide. It has also been linked with travellers of industrialised regions who visited developing countries. On the contrary, some authors question the clinical relevance of these pathogens. The pathogenesis of EAEC infection is not fully understood. The aim of this study is to examine the role of EAEC in children and adult patients from Gipuzkoa suffering from acute and persistent diarrhea

Materials/methods: This study was conducted in the microbiology department of Donostia University Hospital (Spain) from November 2018 to October 2019. Overall, 10344 stool samples were analysed by multiplex pcr [allplexTM GI-bacterial (II) assay, seegene], which includes the detection of the aggR gene.

Results: A total of 10344 stool samples were analysed, EAEC was detected in 360 (3.5%) of them. Altogether, 126 patients (35%) were children under 3 years of age, of which 82% had acute diarrhea. The majority of patients in whom EAEC was detected had a self-limited diarrhea, not associated with outbreaks. 245 patients (68%) were reported to have had acute diarrhea (lasting less than 15 days). Only 16% of cases would be associated with traveller’s diarrhea. 248 patients (69%) were not only infected with EAEC, but also with an additional microorganism. The following table shows the characteristics of EAEC-positive patients.

<table>
<thead>
<tr>
<th>DIARRHEA TYPE</th>
<th>No. of episodes (n=360)</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short-term (≤15 days)</td>

<tr>
<td>Coinfection</td>
<td>248</td>
<td>&lt;0.0001</td>
</tr>
<tr>
<td>No coinfection</td>
<td>112</td>
<td></td>
</tr>
</tbody>
</table>

Conclusions: EAEC was regularly identified in diarrhea episodes and the identification of truly pathogenic strains is difficult. The presence of EAEC was more frequent in children under 3 years of age than in adults, and the rate of coinfections was high. In our region this pathogen does not seem to have a great impact on health. It appears to cause subclinical infection or only intestinal colonization. Further investigation of the clinical relevance of these putative pathogens would be needed.

Presenter email address: martagz11@hotmail.com
Empiric treatment with fluconazole, as compared to echinocandins or amphotericin B, was associated with lower mortality among intensive care unit patients with sepsis due to candidaemia

Matthaios Papadimitriou Olivgeris*, Anastasia Spiliopoulou1, Fevronia Kolonitsiou1, Anastasia Lambropoulou1, Vasileios Karamouzos1, Alexandra Georgakopoulou1, Iris Spiliopoulou1, Fotini Fligou1, Markos Marangos1, Myrto Christofidou1

1University Of Patras, Panepistimioupoli Patron, Greece

Background: Candidaemia is associated with high mortality, with echinocandins being associated with better outcome as compared to fluconazole. The aim of the present study was to identify predictors of mortality of candidaemia among critically ill patients.

Materials/methods: During a 9-year period (2010-18), all candidaemias among Intensive Care Unit (ICU) patients, at University Hospital of Patras, Greece, were studied. Susceptibility of antifungals was assessed by Etest and was evaluated according CLSI.

Results: Among 2780 ICU hospitalized patients, 150 (5.4%) candidaemias were observed (133 patients). Non-albicans species predominated (97 patients; 64.7%) with C. parapsilosis being the most commonly isolated species (66; 44.0%), followed by C. tropicalis (16; 10.7%) and C. glabrata (13; 8.7%); C. albicans was the cause of candidaemia for 53 patients (35.3%). Fluconazole resistance was found in 34 isolates (22.7%), whereas, resistance to at least one echinocandin was found in 15 (10.0%); no isolate was resistant to amphotericin. The most common cause of candidaemia was catheter-related (68 episodes; 45.3%), followed by primary (56; 37.3%). 14-day mortality was 25.3% (38 patients). Appropriate empiric antifungal treatment was administered in 122 patients (81.3%); fluconazole was administered in 33 patients (22.0%), echinocandins in 76 (50.7%) and liposomal amphotericin B in 13 (8.7%). Fluconazole administration was associated with better outcome (P<0.014) as compared to echinocandins, liposomal amphotericin B or no appropriate empiric treatment (Figure 1). Multivariate analysis identified septic shock (P=0.010; OR 6.1, CI 1.5-23.9) and SOFA score upon BSI onset (P<0.001; OR 1.6, CI 1.3-2.0) as independent predictors of mortality, whereas treatment with at least one appropriate antifungal was a predictor of survival (P=0.002; OR 0.108, CI 0.026-0.448). Among septic shock patients (68; 45.3%), multivariate analysis revealed SOFA score upon BSI onset (P=0.024; OR 1.3, CI 1.0-1.6) as independent predictor of mortality, whereas treatment with at least one appropriate antifungal was a predictor of survival (P=0.018; OR 0.066, CI 0.007-0.624).

Conclusions: Most candidaemias were catheter-related, which can explain the predominance of non-albicans species. Empirical administration of an appropriate antifungal, especially fluconazole, was associated with better survival probably due to the high prevalence of C. parapsilosis.

Abstract 2517

**Surveillance for epidemic of Mycoplasma pneumoniae and macrolide resistance (A2063G and A2064G) using consecutive multiplex real-time PCR in Korea**

Kyoung Ho Roh*, Juhyeong Park, Yong-Jin Yang, Young Ah Kim, Hyukmin Lee, Seong Geun Hong

1NHIS Ilsan Hospital, Department of Laboratory Medicine, Goyang-si, South Korea, 2Center of Molecular Diagnostics, Seegene Medical Foundation, Seoul, South Korea, 3Department of Laboratory Medicine, National Health Insurance Service Ilsan Hospital, Goyang, South Korea, 4Department of Laboratory Medicine and Research Institute of Bacterial Resistance, Yonsei University College of Medicine, Seoul, South Korea, 5Department of Laboratory Medicine, CHA Bundang Medical Center, CHA University, Seongnam, South Korea

**Background:** Pneumonia caused by *Mycoplasma pneumoniae* is a major cause of community-acquired pneumonia (CAP) in children. Three epidemics of *M. pneumoniae* pneumonia have occurred in Korea in 2006-2007, 2011 and 2015. Molecular diagnostic method is now replacing a Mycoplasma IgM/IgG Ab test. The macrolide-resistant *M. pneumoniae* is reported in worldwide and the resistance rate was very high (50-70%) in Korea. Detection of *M. pneumoniae* and macrolide resistance at same time is very important for appropriate antibiotics treatment during epidemic. We tested respiratory pathogens multiplex PCR and validated multiplex real-time PCR assay for reporting macrolide resistance related mutations (A2063G and A2064G in 23S rRNA) in *M. pneumoniae*.

**Materials/methods:** The Seegene Medical Foundation (SMF) has a nationwide network of 43 province local offices that collect and transport specimens in Korea. More than 200 pediatrics clinics and children's hospitals send nasopharyngeal swabs and respiratory specimens every day, and the results are reported the next working day. From January 2019 to November 2019, 56,103 samples were tested and analyzed at SMF using Seeplex PneumoBacter (Seegene, Seoul, Korea). This multiplex PCR could detect six respiratory infection causing pathogens including *M. pneumoniae*. In cases of *M. pneumoniae* were detected, macrolide resistance PCR was done consequently.

**Results:** The overall prevalence of first half year 2019, *M. pneumoniae* was 2.4% (633 from 26,590). However epidemic and outbreak was noticed from early July. The positive rate was increased to 8.5% in July and 32.5% in October. Macrolide resistance of *M. pneumoniae* was also increased in epidemic season. The prevalence rate of A2063G mutation positive cases was 61.3%. However, this positive rate was increased up to 68.7% in October.

**Conclusions:** We conclude this epidemic is fourth epidemic in Korea after 2006. The prevalence of *M. pneumoniae* in different by province in Korea and by season (usually high in winter and recent epidemics). Macrolide resistance rate is also increased in epidemic season in Korea. In clinical independent laboratory, high throughput multiplex real-time PCR is very convenient and these epidemiologic data of resistance pattern could be indicator of finding epidemics and also helpful guide for selecting antibiotics to clinicians.

Abstract 2519

Whole genome sequence-based PCR for the rapid identification of *Pseudomonas aeruginosa* ST175 high-risk clone isolates directly from clinical samples

Gabriel Cabot*,1, Paula Lara-Esbri1, Xavier Mulet1, Antonio Oliver1

1Hospital Universitari Son Espases, Institut d’Investigació Sanitària Illes Balears, Palma, Spain

**Background:** *Pseudomonas aeruginosa* is a major nosocomial pathogen frequently showing MDR/XDR profiles associated with world-wide disseminated high-risk clones (HRC). ST175 HRC is widespread in European countries and especially in Spain, where it is the most frequent HRC. Current approaches for the detection of HRC include MLST, that is expensive and time consuming, or other simple but less reliable techniques such as serotyping or Maldi-TOF. All these approaches require cultured isolates, delaying their detection in the clinical laboratory. Thus, the objective of this work was to develop of a specific PCR assay, based on whole genome sequence data analysis, for the fast diagnosis of infections caused by isolates belonging to ST175 HRC.

**Materials/methods:** Whole-genome sequence was obtained for one ST175 isolate by a PacBio RSII sequencer and then assembled and annotated to be used as consensus reference genome. Available PAO1 whole-genome data was used as comparator, and sequenced isolates from diverse clones from previous works were used to verify the adequacy of the designed tool. Reads from multiple isolates belonging to ST175, and PAO1 reference strain were mapped against ST175 consensus genome to comparatively identify potentially specific regions. Once curated, using the blast database to search for presence of those regions in any other organism, we designed a specific PCR for the identification of infections caused by ST175 isolates.

**Results:** We analysed the presence/absence of 4 potentially specific regions in 229 fully sequenced isolates from previous works. All ST175 isolates (73/229) were identified and there was no misidentified isolate. Furthermore, we tested blindly a PCR assay to identify ST175 directly from 69 clinical samples (17 positive blood cultures, 27 urine samples and 25 respiratory samples), compared with culture results followed by MLST analysis. All 5 clinical samples yielding ST175 isolates were identified correctly, whereas none of the negative clinical samples were misidentified as ST175.

**Conclusions:** A PCR assay showing high sensitivity and specificity for the fast detection of ST175 HRC directly from clinical samples was developed, and thus could become a useful tool for guiding infection control and treatment strategies in areas with high prevalence of this clone, such as Spain.

Abstract 2525

Disease course, management and predictors of fatality in hospitalised patients with real-time PCR confirmed Lassa fever in Nigeria: a prospective cohort study

Alexandre Duvignaud1,2, Marie Jaspard1,2, Ijeoma Etafo3, Delphine Gabillard1, Béatrice Serra1, Chukwuyem Abiejegah4, Camille Le Gal5, Abiodun Abidoye1, Sampson Owhi1, Augustin Augier1, Alex Salam2, Liasu Ahmed4, Jean-Paul De Bruyne Mushenvula1, Ephraim Ogbanimi-Emovon6, Stephan Günther7, Peter Horby5, Akin Adedosu4, Xavier Anglaret1, Oladele Ayodeji1, Denis Malvy1,2

1Inserm 1219, Université de Bordeaux, Bordeaux, France, 2CHU de Bordeaux, Department of Infectious Diseases and Tropical Medicine, Bordeaux, France, 3Alliance for International Medical Action, Dakar, Senegal, 4Federal Medical Center Owo, Owo, Nigeria, 5University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, 6Irrua Specialist Teaching Hospital, Institute for Lassa Fever Research and Control, Irrua, Nigeria, 7Bernhard Nocht Institute for Tropical Medicine, Department of Virology, Hamburg, Germany

Abstract third-party references: Supported by Institut National de la Santé et de la Recherche Médicale (Inserm)

Background: Lassa fever (LF) is a viral haemorrhagic fever that is endemic in West Africa. As the risk benefit ratio of ribavirin is debated and promising agents are available for evaluation in humans, we need robust data to inform the design of future trials. We set up a prospective cohort study in Nigeria to: i) estimate in-hospital mortality of LF under the best available standard of care, ii) identify key prognostic factors, iii) build capacities needed for the implementation of clinical trials.

Materials/methods: Patients with RT-PCR confirmed LF hospitalised at the Federal Medical Centre, Owo, Nigeria, were eligible. Data concerning habits, exposure, disease history and presentation, management and outcomes were collected during hospitalisation. Patients had free access to optimized standard of care (including ribavirin, oxygen and dialysis), routine biology and Lassa RT-PCR. This analysis focus on participants included between April 2018 and August 2019.

Results: Among 2 1 7 patients with confirmed LF, mortality was 15.7%. 193 signed consent, of whom 78% were aged between 18 and 59; 47 % were female, 20% of them being pregnant. The median delay from first symptom to presentation was 9 days (IQR 7 – 14). On admission, the most frequent symptoms were fever (74%), headache (27%), dizziness (25%), vomiting (20%), abdominal pain (26%) and watery diarrhoea (20%). During follow-up, the following warning signs were noticed: tachycardia (30%), systolic BP < 90 mmHg (21%), SpO2 < 92% (19%), impaired consciousness (14%) and bleeding (31%). Regarding management: 100%, 21% and 25% received intravenous ribavirin, oxygen and transfusion respectively; 11% developed acute kidney failure (AKF) and 9% were dialysed. Baseline factors most associated with death were: AKF (58% vs. 2.5%, p<0.0001), AST ≥ 3 times the upper limit of normal (ULN) vs. < 3 ULN (18.9% vs 0%, p<0.0001), ALT ≥ 3 ULN vs. < 3 ULN (33% vs 3.1%, p<0.0001), RT-PCR cycle threshold (Ct) value < 30 vs. ≥ 30 (25 vs. 0.9%, p<0.0001).

Conclusions: The observed 15.7% mortality suggests that a composite primary endpoint, rather than mortality alone, should be considered for future efficacy trials. AKF, hepatitis and Ct value, should also be considered as randomisation stratification factors.

New freeze-dried multiplex one-step real-time qPCR assay with room temperature storage for hepatitis A virus and norovirus detection in clinical and food/environmental samples

Cristina Pilotti*, Cristina Casali¹, Michela Savoldi Boles¹

¹Bioside srl, Lodi, Italy

**Background:** Food-borne diseases are an important worldwide public health issue. Their main cause are diarrheal disease agents, in particular Norovirus GI and GII, which cause 120 million cases/year and 200,000 deaths; among other food-borne hazards, HAV is responsible for 14 million cases/year. The majority of these cases occurs in low-resource countries, where food-borne diseases management is hampered by many limitations. Rapid detection is crucial for timely infection source identification and therapy. Bioside developed freeze-dried multiplex One-Step RT-qPCR assay with room temperature (RT) storage for HAV and NoV detection in clinical and food/environmental samples. The objective of this study was to validate the performance of this RT-qPCR assay for the concurrent detection of HAV, NoV GI and GII in fecal/food/environmental samples.

**Materials/methods:** In this study 56 analyses were performed on naturally/artificially HAV/NoV-contaminated samples and on negative samples. We developed a workflow for extraction and detection of HAV and NoV GI-GII in fecal/food/environmental samples according to ISO 15216-1 for food/environmental sources and to clinical guidelines for fecal samples. All samples were processed as per kit procedure’s with qualyfast® RNA extraction kits, based on starting volume [200ul-1ml], and analyzed with freeze-dried multiplex One-Step RT-qPCR assay qualyfast® HAV, NoV GI and GII for detection/discrimination of these viruses. Study analysis and stability tests were performed on 3 different batches.

**Results:** qualyfast® HAV, NoV GI and GII, validated with WHO standards on different matrices, allows simultaneous detection/discrimination of HAV [all genotypes], NoV GI and GII in positive samples, with LOD of 10 copies/reaction for HAV and NoV GI and 3 copies/reaction for NoV GII [see graph], with 100% specificity. Shelf-life testing confirmed the freeze-dried format performance up to 12 months.

**Conclusions:** Data generated in this study demonstrated that this RT-qPCR assay accurately detected samples for HAV [all genotypes], NoV GI and GII with 100% specificity and a 12 months RT storage stability. This freeze-dried assay is easy to use, fast and suitable device for HAV, NoV GI and GII detection in fecal/food/environmental samples especially in areas with limited technological/instrumental resources.

Abstract 2527

**Imported malaria: the innovative approach of machine learning on clinical management and severity prediction**

Alessandra D’Abramo*1, Francesco Rinaldi2, Luciana Lepore1, Angela Corpolongo1, Laura Scorzolini1, Nazario Bevilacqua1, Andrea Mariano1, Tommaso Ascoli Bartoli1, Claudia Palazzolo1, Maria Letizia Giancola1, Giuseppe Ippolito1, Emanuele Nicastri1

1Lazzaro Spallanzani Hospital, Roma, Italy, 2University of Padua, Department of Mathematics "Tullio Levi-Civita", Padova, Italy

**Background:** Malaria is currently a major clinical problem with high risk of unfavourable outcome. A prompt identification of patients with a poor prognosis is a challenge. Machine Learning (ML) approaches represent a new frontier in medicine. ML uses datasets to recognize complex connections between several patient characteristics, make predictions and provide personalized treatment. The aim of this study is to design ad hoc ML approaches to predict clinical outcome in all patients with imported malaria and therefore to identify the best clinical setting.

**Materials/methods:** In this single-centre cross sectional study, 259 patients consecutively hospitalized with confirmed malaria were retrospectively recruited at the National Institute for Infectious Diseases, Lazzaro Spallanzani, Rome, Italy, from January 2007 to December 2017. Demographical, epidemiological, travel history, clinical, laboratory and parasitological data, anti-malarial and supportive treatment and clinical outcome were collected. Different machine learning approaches were used to perform the analysis of this dataset: support vector machines, random forests, feature selection approaches and clustering analysis.

**Results:** From 2007 to 2017, a total of 259 patients with malaria were enrolled. Out of them, 111 had severe malaria. Four baseline parameters, aspartate aminotransferase (AST), platelet count, total bilirubin and parasitemia, were all independently associated to an unfavorable outcome. At the clustering analysis, two groups were identified (19 and 92 patients, respectively). The consistency of the cluster analysis among severe cases was confirmed by the evidence that all the 19 patients clustered in the smallest group has the prolonged hospital stay complicated by comorbidities, bacterial infections and/or ICU admissions. In this cluster, baseline AST, acute renal and respiratory failures were strongly associated to the unfavorable outcome.

**Conclusions:** ML is a new challenge to solve health problem and its applicability could help physicians to improve diagnosis and the specific management. In particular, an early assessment of the severity status is required in patients with malaria. In this setting, ML can help to identify unknown parameters as shown in our preliminary data in which AST and platelet are associated to severe malaria but are not included in the current list of WHO severe malaria criteria.

In vitro evaluation of ceftolozane/tazobactam-aztreonam and ceftolozane/tazobactam-fosfomycin combinations by time-kill assays against SPM-1-producing Pseudomonas aeruginosa clinical strains

Gerlan Santos¹, Gabriel Cuba*¹, Carolina Silva Nodari², Ana Streling², Rodrigo Cayó Da Silva², Ana Gales², Antônio Pignatari¹, David Nicolau³, Carlos Kiffer¹

¹Universidade Federal de São Paulo – Unifesp, Laboratório Especial de Microbiologia Clínica, São Paulo, Brazil, ²Universidade Federal de São Paulo – Unifesp, Laboratório Alerta, São Paulo, Brazil, ³Center of Anti Infective Research and Development, Hartford Hospital, Hartford, United States

Background: Carbapenem-resistant Pseudomonas aeruginosa (PSA) is a pathogen with critical priority for research and development of new antibiotics. Metallo-beta-lactamase (MβL) producing PSA is associated with extremely drug resistance, and effective treatment options against MβL PSA are still scarce. Previous study showed synergistic activity of ceftolozane/tazobactam (C/T) with fosfomycin (FOS) and aztreonam (ATM) against the locally endemic São Paulo MβL (SPM-1) producing PSA.

We evaluated the in vitro activity of C/T+ATM and C/T+FOS combinations by time-kill assays using clinically relevant concentrations against SPM-1-producing PSA clinical isolates.

Materials/methods: Six genetically unrelated SPM-1-producing PSA clinical strains were studied. C/T, FOS, and ATM MICs were determined by epsilometric test. Time-kill assays were performed with C/T, FOS, and ATM alone and in combinations, at plasmatic peak and through concentrations. Viable colonies were determined at 3, 6, and 24h of exposure to the drugs. A reduction of the original inoculum ≥3log_{10} CFU/mL when the combination was compared to the most active compound was considered bactericidal, and a ≥2log_{10} CFU/mL reduction was considered synergistic.

Results: C/T MICs were of 512 mg/L for all strains, and ATM and FOS MICs varied between 3-16 and 1-28 mg/L, respectively. Peak ATM concentrations (with or without C/T) provided a ≥2log_{10} CFU/mL reduction at 6h and a ≥3log_{10} CFU/mL reduction at 24h to all strains, but addition of C/T did not improve the extent of bacterial killing. Trough ATM (with or without C/T) concentrations provided ≥2log_{10} CFU/mL reduction at 6h for all isolates, with regrowth at 24h for 4 of 6 isolates. C/T+FOS and FOS peak concentrations exhibited a mean growth reduction of 1.93 and 1.41 log_{10} CFU/mL at 6h, respectively, but a marked regrowth was observed at 24h for 4 of 6 isolates. No inoculum reduction was observed with FOS trough and C/T+FOS trough concentrations at any time.

Conclusions: Plasmatic peak concentration of C/T+FOS combination were synergistic by time-kill assay for one tested isolate. Bactericidal reduction at ATM peak and trough concentrations was observed in all SPM-1-producing PSA. These findings suggest that the use of such clinical combinations may be applicable under certain circumstances.

Abstract 2532

**Cascade of HIV care in three different settings in Morrumbene, Mozambique**

Paola Magro¹, Carlo Cerini², Aldorada Da Gloria², Stelio Tembe³, Francesco Castelli*¹, Lina Rachele Tomasoni¹

¹University of Brescia, Brescia, Italy, ²Medicus Mundi Italia ONLUS ONG, Morrumbene, Mozambique, ³Direção Provincial de Saúde de Inhambane, Inhambane, Mozambique

Abstract third-party references: Medicus Mundi Italia ONLUS ONG, University of Brescia

**Background:** Mozambique estimates 2 million people being HIV-positive. In 2013, the UNAIDS set the target of 90-90-90 to be reached by 2020. Aim of our study was to evaluate the state of the retention in care of HIV patients in a country with high prevalence of HIV infection.

**Materials/methods:** This is a retrospective, observational study. We collected data on patients diagnosed with HIV infection in 2017 in three health services in Morrumbene: Centro de Saúde de Morrumbene (CSM), Centro de Saúde de Mahangue (MAH) and TARV Movel service (TM). Demographic, clinical, immunological and therapeutic data were retrieved. The follow-up period lasted until the 31st of December 2018. Data on follow-up were collected at 6 and 12 months. Data were analyzed by Epi-Info 7. Descriptive statistics were obtained for all variables; for group comparison, for categorical variables chi square test or exact Fischer test, for numeric variables ANOVA test, when appropriate, were applied. Two tailed tests were used. Only p-values <0.05 were considered statistically significant. Uni and multivariate analysis were performed by logistic regression.

**Results:** In 2017, 960 patients were diagnosed with HIV infection. At 6 months, 49% of patients showed up at medical visit, where only 34% of them were still on follow-up after one year. In the multivariate analysis, factors associated with being lost after one year were male sex (OR 0.41, IC95% 0.26-0.63, p<0.001) and an advanced WHO status (OR 0.54, IC95% 0.32-0.92, p=0.024). Adherence to ART was observed in 157 (25%) patients in the first 6 months, where only 72 patients have been adherent to ART for one year. Interestingly, being prescribed an ART regimen the same day of the diagnosis correlated with an early loss at follow-up (AOR 1.8, IC95% 1.15-2.7, p=0.009).

**Conclusions:** Our study shows that only one third of patients resulted adherent to follow-up after one year, where as little as 13% of patients resulted adherent to ART. Male sex and a late diagnosis led to poor outcome, showing that more efforts are needed for diagnosis and follow-up in this population. Interestingly, the test-and-threat strategy correlated with an early loss at follow-up.

The cost-effectiveness of isavuconazole compared to voriconazole, the standard of care in the treatment of patients with invasive fungal infection prior to differential pathogen diagnosis in Spain

José Ramón Azanza1, Santiago Grau Cerrato2, Lourdes Vázquez3, Pablo Rebollo4, Carmen Peral5, López Alejandra6, Vanessa López Gomez*7

1Clinica Universidad de Navarra, Clinical Pharmacology Department, Pamplona, Spain, 2Hospital del Mar, Pharmacy Department, Barcelona, Spain, 3Hospital Universitario de Salamanca, Hematology Department, Salamanca, Spain, 4Ingress-health, Scientific Director, Oviedo, Spain, 5Pfizer, Pharmacoeconomics Department, Alcobendas, Spain, 6HE&OR Department, Pfizer SLU, Alcobendas, Madrid, Spain, 7Pfizer, Medical Department, Alcobendas, Spain

Background: Invasive mold diseases are associated with high morbidity, mortality, and high economic impact. Isavuconazole is an antifungal azole approved for the treatment of invasive aspergillosis (IA), a systemic infection caused by Aspergillus spp., and for invasive mucormycosis (IM) when amphotericin-B is not indicated. This model designed to evaluate the cost-effectiveness of isavuconazole vs. voriconazole for the treatment of adult patients with possible IA prior to differential pathogen diagnosis was adapted to the Spanish context.

Materials/methods: The analysis consisted of a decision tree (Figure 1) using the Spanish Healthcare System perspective, with 7.81% possible IA patients having mucormycosis, in order to reflect that in clinical practice differential diagnosis between IA and mucormycosis can be extremely challenging. Inputs for the model were obtained from Spanish publications, clinical guidelines and from a panel of experts. Direct medical resources and effects considered were: costs for laboratory analysis, management of adverse events, hospitalization and drugs per patient, deaths and long-term effects in life years (LYs) and quality-adjusted life years (QALYs). Efficacy data were obtained from clinical trials and utilities from the literature. Local unitary costs (€, 2019) were applied. Costs and outcomes were discounted at 3%. Deterministic and probabilistic sensitivity analyses (PSA) were conducted.

Results: In patients with possible IA, isavuconazole was found to be more costly (+2,175€) and effective (+0.49 LYs and +0.41 QALYs per patient) than voriconazole, with an Incremental Cost Effectiveness Ratio (ICER) of 4,398€ per additional LY gained and 5,363€ per additional QALY gained. The higher cost of isavuconazole is mainly due to drug acquisition costs since the rest of direct costs considered (management of adverse events, laboratory tests and hospitalization days) are reduced when using isavuconazole in comparison to voriconazole. Main parameters influencing results were mortality, treatment duration and hospitalization days. The PSA results showed that isavuconazole has a probability of being cost-effective of 75%, being dominant in 34.4% of cases.

Conclusions: Isavuconazole is a cost-effective treatment compared to voriconazole for patients with possible IA for a Willingness to Pay (WTP) threshold of 25,000€ per QALY.
Figure 1. Decision tree.

Target attainment and pharmacokinetics of frequently used antimicrobials in surgical patients (TAPAS study)

Peter Declercq*, Eric Van Wijngaerden1, Greet Van De Sijpe1, Roxanne Poncelet1, Stefaan Nijs4, Willem-Jan Metsemakers4, André D’hoore4, Albert Wolthuis5, Joost Wauters2, Isabel Spriet1;6

Background: Despite the high prevalence of bacterial infection and the broad scale use of antibiotics in surgery patients, few attention is paid in literature whether optimization of antimicrobial exposure is necessary in this setting. The primary objective was to document pharmacokinetic/pharmacodynamic (PK/PD) target attainment (TA) of frequently used β-lactam antibiotics in adult non-critically surgery patients.

Materials/methods: A prospective single-centre PK point-prevalence study was conducted in adult non-critically ill abdominal, trauma orthopaedic patients. Per patient, six blood samples were obtained during a single dosing interval. The PK/PD target was defined as unbound antibiotic concentrations above the minimum inhibitory concentration (MIC) of the pathogen for at least 40% of the dosing interval (40% fT>MIC). Both European Committee on Antimicrobial Susceptibility Testing (EUCAST) susceptibility breakpoints and local MIC90 values were applied as target MICs.

Results: Eighty-one non-critically ill surgery patients receiving amoxicillin [-clavulanic acid], flucloxacillin, piperacillin-tazobactam or meropenem were included. Overall, 81 % [66/81] did attain 40% fT>MIC when EUCAST susceptibility breakpoints were applied as target MICs. When local MIC90 values were applied, 93% [75/81] did attain 40% fT>MIC.

n.a., not applicable; ND, not determined; *Staphylococcus aureus, lugdunensis, saprophyticus; **CNS, Coagulase-negative Staphylococci (except Staphylococcus lugdunensis and Staphylococcus saprophyticus)

Conclusions: Implications for clinical practice in our hospital are limited as TA is 93% when considering our local susceptibility data. On the contrary, when MIC values would increase to the extent of the EUCAST breakpoints, TA will decrease towards 81%. Further population PK modelling and simulations might reveal the optimal dosing regimen and covariates explaining variability in PK parameters.

Abstract 2538

A retrospective matched cohort study evaluating the rate of acute kidney injury in patients with severe Gram-negative infections treated with colistin or new β-lactam + β-lactamase inhibitor antibiotics

Casey Doremus1, Stephen Marcella1, Bin Cai1, Roger Echols2

1Shionogi Inc, Florham Park, United States, 2Infectious Disease Drug Development Consulting, LLC, Easton, United States

Background: Colistin is a polymyxin class antibiotic originally discovered in the 1950's and was one of the first antibiotics with significant activity against Gram-negative bacteria. However, concerns over toxicity led to limited use. With the rise of antibiotic resistance, colistin has been used as a "last-line" or "salvage" therapy for multidrug-resistant Gram-negative infections, including infections caused by carbapenem-resistant Acinetobacter baumannii, Pseudomonas aeruginosa, and Enterobacterales spp. Despite recent increased usage, there are an increasing number of anecdotal reports describing the rates of acute kidney injury (AKI) in patients treated with colistin, but few are population based.

Materials/methods: Electronic healthcare records from 2016 to 2018 in the US Premier Healthcare Database were used to identify adult hospitalised patients with confirmed Gram-negative infections that were treated with colistin or one of the three recently approved β-lactam + β-lactamase inhibitor antibiotics (ceftazidime-avibactam, ceftolozane-tazobactam, and meropenem-vaborbactam). Patients with acute renal failure (ARF), identified by ICD-9 code 584.X or ICD-10 code N17.X, or evidence of haemodialysis prior to initiation of study antibiotic were excluded from analysis. Rates of AKI, defined as ARF or haemodialysis after initiation of study drug, were compared between the two cohorts using 1:1 propensity score matching. Results were further stratified by baseline status of renal disease and treatment duration.

Results: Rates of AKI for the matched population are displayed in the Table. Median duration of treatment was 6 vs. 7 days, respectively, for colistin cohort and the new agents’ cohort. Neither cohort was observed to have an increased incidence of AKI as treatment duration increased. Observed rates of AKI were higher in the colistin cohort, for both patients with baseline renal disease (55.6% versus 40.8%, P=0.153) and patients without (17.1% versus 6.8%, P=0.001).

Conclusions: This real-world database confirms expectations that for the treatment of severe Gram-negative bacterial infections, colistin is associated with a higher risk of AKI in comparison to new β-lactam + β-lactamase inhibitor antibiotics.

Quantifying the intestinal load of genes of antibiotic resistance among two paediatric patient populations: not all “positives” are equal

Elias Dahdouh*, Fernando Lázaro Perona1, Emilio Cendejas1, Guillermo Ruiz-Crrascoso1, Jesus Mingorance1

1University Hospital La Paz, Servicio de Microbiología, Hospital Universitario La Paz-idipAZ, Madrid, Spain, Madrid, Spain

Abstract third-party references: Supported by the European Commission through a Marie Curie Individual Fellowship (Grant Number: P96084), Supported by Instituto de Salud Carlos III, PI16-01209

Background: Intestinal colonization with Multi-Drug Resistant (MDR) organisms carries a risk of developing difficult-to-treat infections, and could be a source of dangerous hospital outbreaks. Though numerous studies have aimed at detecting resistant organisms in the intestinal microbiome, few have quantified the load of resistance genes.

Materials/methods: Four-hundred-thirty-four rectal swabs were collected from 51 transplanted and 70 non-transplanted paediatric patients in the Hospital Universitario La Paz. Total DNA was extracted and qPCRs targeting the 16SrDNA, the blaCTX-M1-Family ESBL, blaOXA-1, and the carbapenemases blaOXA-48 and blaVIM genes were performed. The loads of the antibiotic resistance genes were calculated relative to the 16SrDNA (i.e. total bacterial load) using the △Ct method.

Results: The loads of the investigated genes in the positive swabs ranged from 0 to -5.9, representing ≈100% to ≈0.0001% of the bacterial population, respectively. The average load for the carbapenemases blaOXA-48 and blaVIM was higher for transplanted patients, and had an asymmetric distribution that is aggregated around loads similar to those calculated for pure MDR bacterial cultures (△Ct ≈ 0). In comparison, the loads of these genes for non-transplanted patients had a broad but more uniform distribution (Figure 1). Clinically relevant samples of MDR organisms harbouring the same gene(s) as those detected in the intestine were collected from other body sites (including urine, bloodstream, and biliary ducts) in 12 patients, 9 of which have high loads.

Conclusions: The intestinal loads of blaOXA-48 and blaVIM were higher among transplanted patients (that typically consume more antibiotics), and closer to loads calculated from pure MDR bacterial cultures. Clinically significant MDR bacterial isolates in extra-intestinal sites were isolated from 9 patients with high loads. These findings highlight the possible usefulness of stratifying patients based on the intestinal load of antibiotic resistance genes.

Figure 1: Intestinal loads of blaOXA-48 and blaVIM among transplanted versus non-transplanted patients.

*University of Pittsburgh, Pittsburgh, United States, †Genesis Research Inc, Hoboken, United States, ‡Shionogi Inc, Florham Park, United States

**Background:** Urinary tract infections (UTIs) complicated by bacteraemia exacerbate the burden of illness in hospitalised patients. We aimed to evaluate the risk factors of UTIs developing into bacteraemia and the impact of UTI on readmission.

**Materials/methods:** Data from the US Premier Healthcare Database of adults hospitalised between 2014 and 2018 with UTIs (defined as positive urine culture and receipt of antibiotics for a Gram-negative infection within –2 to 3 days) with bacteraemia (blood culture positive for the same pathogen as index urine culture) or without bacteraemia, caused by carbapenem-resistant (CR) or -susceptible (CS) Gram-negative bacteria were analysed retrospectively. We used univariate analysis to select potential risk factors and a multivariable logistic regression model to identify risk factors for bacteraemia development among patients hospitalised with UTI. We also described patients who were readmitted with the same pathogen as that identified at index hospitalisation, and evaluated the time to readmission by CR and urosepsis status.

**Results:** A total of 46,076 patients had index UTI; 11,212 (24.3%) developed concomitant bacteraemia. Urosepsis patients were more likely to have a positive urine culture on the day of the admission than UTI patients without bacteraemia (93.0% [10,428/11,212] vs. 74.8% [26,078/34,864], P<0.001, respectively. Multivariable logistic regression analysis (OR; 95% confidence interval) showed that patients who had ICU admission (2.118; 2.012–2.23), urinary catheter (1.238; 1.164–1.316) or surgery (1.449; 1.352–1.554), *E. coli* infection (1.552; 1.45–1.662), CS infection (1.669; 1.431–2.011), male sex (1.972; 1.88–2.069), non-white race (1.233; 1.171–1.297) and aged 46–65 years vs 18–45 years (1.19; 1.094–1.294) were strongly associated with urosepsis versus UTI without concomitant bacteraemia. Patients with UTI >3 days of admission (0.231; 0.21–0.254), *Acinetobacter* (0.423; 0.251–0.711), *Pseudomonas* (0.44; 0.388–0.499), or *Stenotrophomonas* (0.301; 0.155–0.585) were significantly less likely to develop urosepsis. Patients with CR infections were more likely to be readmitted within 30 days (Table).

**Conclusions:** Urosepsis patients were more likely to be male, non-white, developed a UTI within 3 days, admitted to the ICU, had urinary surgery, and urinary catheter. CR pathogens increased the risk of readmission, but not the risk of bacteraemia.

Abstract 2544

**Evaluation of difficult-to-treat resistant Gram-negative bacilli from European respiratory isolates: SIDERO-WT-2014–2018**

Melinda Soriano*1, Sean Nguyen2, Meredith Hackel1, Daniel Sahm3, Roger Echols3, Miki Takemura4, Yoshinori Yamano4

1Shionogi Inc, Florham Park, United States; 2IHMA, Inc., Schaumburg, United States; 3Infectious Disease Drug Development Consulting LLC, Easton, United States; 4Shionogi & Co., Ltd., Osaka, Japan

**Background:** Cefiderocol (CFDC) is a novel siderophore cephalosporin with potent activity against Gram-negative pathogens. Among resistant Gram-negative bacteria, difficult-to-treat resistant (DTR) pathogens represent a subset of organisms demonstrating non-susceptibility (NS) to first-line antibacterials. This analysis evaluated the in vitro activity of CFDC and contemporary broad-spectrum Gram-negative antibiotics against DTR pathogens collected over four years (2014–2018) from the SIDERO-WT study.

**Materials/methods:** Gram-negative non-duplicate clinical isolates were collected as part of the multinational SIDERO-WT surveillance study and underwent susceptibility testing at a central laboratory (IHMA, Schaumburg, IL). European respiratory isolates collected from 2014 to 2018 were included in this analysis. Pathogens were defined as DTR if they were non-susceptible to cefepime (FEP), ciprofloxacin (CIP), and meropenem (MEM) according to CLSI breakpoints. Minimum inhibitory concentrations (MIC) were determined for CFDC, ceftazidime-avibactam (CZA), ceftolozane-tazobactam (C/T), and colistin (CST). For SIDERO-WT Year 4 (i.e. 2018) isolates, aztreonam-avibactam (ATM/AVI, ATM in the presence of 4 µg/mL AVI) and meropenem-vaborbactam (MVB) were added as comparators. CFDC was tested in iron-depleted cation adjusted Mueller-Hinton broth (ID-CAMHB), while comparators were tested in CAMHB.

**Results:** Of 7,179 Gram-negative European respiratory isolates collected from 2014 to 2018, 22.4% [n=1,611] were DTR. DTR was most frequently observed in *Acinetobacter* spp. (55.6%), followed by *Stenotrophomonas maltophilia* (15.3%), *Burkholderia cepacia*-complex spp. (24%), *Pseudomonas aeruginosa* (15.0%) and *Enterobacterales* (1.6%). The MIC₅₀/₉₀ of tested compounds are shown in the Table. CFDC demonstrated the most potent in vitro activity relative to comparators against DTR *Acinetobacter* spp. with MIC₅₀/₉₀ of 0.25/2 µg/mL versus MIC₅₀ of >8 µg/mL for ATM/AVI and CST, and >64 µg/mL for CZA, C/T, and MVB. Against DTR *P. aeruginosa*, CFDC MIC₅₀/₉₀ was 0.25/2 µg/mL and was several fold lower than the MIC₅₀/₉₀ of 16/>64 µg/mL for CZA and C/T. CFDC was the most potent tested antibiotic against *S. maltophilia* [MIC₅₀/₉₀ of 0.06/0.25 µg/mL].

**Conclusions:** In a subset of DTR European respiratory isolates from a multinational collection of Gram-negative bacteria, cefiderocol demonstrated potent in vitro activity relative to contemporary broad-spectrum β-lactam/β-lactamase inhibitor combinations.

Staphylococcus aureus intestinal colonisation in patients undergoing bowel preparation for colonoscopy

Julie Gagnaire*1,2, Leslie Rinaldi2, Florence Grattard1,2, Anne Carricajo1,2, Emilie Del Tedesco1, Nicolas Williet1, Josselin Rigaill1,2, Elisabeth Botelho-Nevers1,2, Xavier Robin2, Paul Verhoeven1,2, Philippe Berthelot1,2

1GIMAP EA 3064, University Jean Monnet, University of Lyon, Saint-Etienne, France, 2University hospital of Saint-Etienne, Saint-Etienne, France

Background: Staphylococcus aureus intestinal colonization investigated by using perineal, stools or rectal samples has been reported in various populations. However data about this reservoir in the gut are scarce. The aim of this study was to estimate the prevalence of intestinal S. aureus carriage and to investigate the dynamics of S. aureus colonization before and after bowel cleansing preparation.

Materials/methods: Prospective study in community patients undergoing a colonoscopy for cancer screening. The bowel preparation was based on polyethylene glycol or sodium picosulfate administration. Nasal, throat, groin and rectal swabs were screened for S. aureus, by a semi quantification on a chromogenic medium, before and at the day of colonoscopy. Colonic biopsies from the right and the left colon were cultured with or without broth enrichment.

Results: Among the 113 enrolled patients, according to the screening of 4 colonization sites, the overall prevalence of S. aureus carriage, was estimated at 41.6 % [CI 95% 32.5 – 50.7] with only one methicillin resistant S. aureus carrier. At the inclusion, 11 (9.7 %) and 12 (10.6%) patients were identified as groin and rectal carriers, respectively. Among S. aureus carriers, at the day of colonoscopy, 3 (8.8 %) patients were identified as S. aureus intestinal carriers with positive colonic biopsies. After the bowel preparation, there was a significant decrease of S. aureus carriage in the studied population (p = 0.02, McNemar test), a significant decrease of nasal S. aureus carriage (p = 0.004, McNemar test) and a trend to a decrease for groin S. aureus carriage (p = 0.06, McNemar test). As a whole, the S. aureus load decreased significantly for the nose, throat and the groin sites (p=0.01, p=0.04, p=0.06, respectively for the three sites, Wilcoxon signed-rank test).

Conclusions: We report for the first time in community patients the identification of S. aureus in colonic biopsies. Interestingly, we document the decolonizing effect of bowel preparation on 4 S. aureus colonization sites including the nose.

In vitro antibacterial activity of cefiderocol against a multinational collection of difficult-to-treat resistant Gram-negative bacteria from respiratory and bloodstream infections: SIDERO-WT-2014–2018

Sean Nguyen*, 1, Melinda Soriano1, Meredith Hackel2, Daniel Sahm2, Roger Echols3, Miki Takemura4, Yoshinori Yamano4

1Shionogi Inc, Florham Park, United States; 2IHMA, Inc., Schaumburg, United States; 3Infectious Disease Drug Development Consulting LLC, Easton, United States; 4Shionogi & Co., Ltd., Osaka, Japan

Background: Cefiderocol (CFDC) is a novel siderophore cephalosporin with in vitro activity against a broad range of Gram-negative pathogens, including carbapenem non-susceptible strains. Difficult-to-treat resistant (DTR) organisms are defined as being non-susceptible to all high-efficacy and low-toxicity antibiotics (e.g. penicillins, cephalosporins, carbapenems, and quinolones). This study evaluated the in vitro activity of CFDC and contemporary broad-spectrum Gram-negative antibiotics against clinical DTR respiratory and bloodstream infection (BSI) isolates collected from 2014 to 2018 as part of the multinational SIDERO-WT surveillance program.

Materials/methods: Clinical non-duplicate, respiratory and BSI isolates of Gram-negative bacteria collected in Europe and North America from 2014 to 2018 were tested for antimicrobial susceptibility. MICs were determined for CFDC, ceftazidime-avibactam (CZA), ceftolozane-tazobactam (C/T), colistin (CST), cefepime (FEP), meropenem (MEM), and ciprofloxacin (CIP) by broth microdilution according to CLSI guidelines. For SIDERO-WT Year 4 (i.e. 2018) isolates, aztreonam-avibactam (ATM/AVI, ATM in the presence of 4 µg/mL AVI) and meropenem/vaborbactam (MVB) were added. CFDC was tested in iron-depleted cation adjusted Mueller-Hinton broth (ID-CAMHB), while all other comparators were tested in CAMHB. DTR pathogens were defined as being non-susceptible to FEP, MEM, and CIP according to CLSI breakpoints. For SIDERO-WT Year 4 *S. maltophilia* isolates, DTR was defined as NS to MEM, CIP, and TMP/SMX to account for the absence of FEP as a comparator.

Results: Among 18,863 Gram-negative respiratory and BSI isolates collected, 15% were defined as DTR. DTR strains were most frequently observed in *Acinetobacter* spp. (86.3%), followed by *Stenotrophomonas maltophilia* (45.7%), *Burkholderia* spp. (23.6%), *Pseudomonas aeruginosa* (11.6%) and Enterobacterales (3.3%). The MIC90 of tested compounds are shown in the table. CFDC was the most active antibiotic tested against DTR isolates as 93.6% DTR *A. aeruginosa* and 96.7% DTR Enterobacterales had an MIC ≤4 µg/mL, which has been shown to be effective in non-clinical in vivo models under humanised pharmacokinetics.

Conclusions: In a subset of respiratory and BSI isolates from a multinational collection of Gram-negative bacteria, CFDC demonstrated potent in vitro activity against DTR Gram-negative pathogens with limited first-line treatment options.

Abstract 2551

Ceftaroline for severe community-acquired pneumonia: a real-world two-centre experience in Italy and Spain
Matteo Bassetti¹, Alessandro Russo*¹, Catia Cilloniz Campos¹, Daniele Roberto Giacobbe¹, Antonio Vena¹, Rosanel Amaro³, Elena Graziano⁴, Alex Soriano³, Antoni Torres³

¹Genoa, Genoa, Italy, ²Pisa, Pisa, Italy, ³Barcelona, Barcelona, Spain, ⁴Udine, Udine, Italy

Background: Ceftaroline is one of latest additions to the armamentarium for the treatment of community-acquired pneumonia (CAP). In this study, we aimed to describe the outcome of SCAP in a cohort of hospitalized patients treated with ceftaroline.

Materials/methods: Retrospective, observational study of patients with SCAP treated with ceftaroline in two hospitals in Spain and Italy. The primary objective was to describe 30-day mortality after the diagnosis of SCAP. Secondary objectives were: (i) to identify predictors of 30-day mortality; (ii) to identify predictors of clinical failure; (iii) to describe the rate of clinical success.

Results: During study period we observed 89 cases of SCAP treated with ceftaroline, used in combination with other antibiotics in 53 cases (60%). The causative agent was identified through blood cultures (n = 11) or respiratory specimens (n = 20), with the most frequently involved pathogen being Streptococcus pneumoniae (39%), followed by MRSA (29%). A concomitant laboratory-confirmed influenza was reported in 33 (37%) patients. Ceftaroline was used as first line and salvage therapy in 36% (32/89) and 64% (57/89) of cases, respectively. Overall, 30-day mortality and clinical failure were 20% (18/89) and 36% (32/89), respectively. Independent predictors of 30-day mortality were increasing age (odds ratio [OR] for one year increase 1.0, 95% confidence intervals 1.0 - 1.1, P = 0.043), presence of solid neoplasm (OR 4.0, 95% CI 1.0 - 15.1, P = 0.044), and concomitant therapy with oseltamivir (OR 8.5, 95% CI 1.2 - 57.3, P = 0.029). The only independent predictor of clinical failure was the time elapsing from SCAP diagnosis to ceftaroline therapy (OR for each passing day 1.5, 95% CI 1.1 - 1.9, P = 0.003). The clinical success rate was 64% (57/89). In the subgroups of patients with proven S. pneumoniae, methicillin-susceptible Staphylococcus aureus, and methicillin-resistant S. aureus (MRSA) infection, clinical success was 83% (10/12), 75% (3/4), and 56% (5/9), respectively.

Conclusions: Ceftaroline could represent an important therapeutic option for SCAP, especially if initiated early during the course of the disease. Further studies are needed to delineate the precise clinical success rate against MRSA in a larger cohort of patients.

Figure 1. Clinical success in patients with confirmed Streptococcus pneumoniae, MSSA, or MRSA infection

Abstract 2553

**Evolution and adaptation of *Pseudomonas aeruginosa* in biofilms exposed to ciprofloxacin: beyond the resistance to antibiotic**

Marwa Ahmed\(^1\), Ahmed Abdelsamad\(^1\), Tina Wassermann\(^3\), Andreas Porse\(^4\), Janna Becker\(^1\), Morten Sommer\(^4\), Niels Heiby\(^1\), Oana Ciofu*\(^1\)

\(^1\)University of Copenhagen, Costerton Biofilm Center, Copenhagen, Denmark, \(^2\)University of Cairo, Faculty of Agriculture, Department of Genetics, Copenhagen, Denmark, \(^3\)Rigshospitalet, Department of Clinical Microbiology, Copenhagen, Denmark, \(^4\)Technical University of Denmark, Novo Nordisk Foundation Center for Sustainability, Lyngby, Denmark

**Background:** Ciprofloxacin is widely used to treat *P. aeruginosa* intermittent colonization and chronic biofilm infection in the lungs of cystic fibrosis (CF) patients. We have recently shown in experimental evolution studies of *P. aeruginosa* (PAO1) wild-type (WT) and \(\Delta katA\) in the presence of sub-inhibitory levels of ciprofloxacin (CIP) that biofilm mode of growth promote the development of low-level resistant mutants and that oxidative stress increases the mutagenesis and the development of resistance.

**Materials/methods:** Growth curves, competition studies with ancestor colonies, cross-resistance to other anti-pseudomonal antibiotics, swimming, swarming and twitching motility as well as whole-genome sequencing were performed on CIP-resistant isolates from the previous evolution experiments.

**Results:** We report here that the CIP resistance was due to mutations in negative regulators of the efflux pumps in biofilm isolates (\(nfxB, mexR, nalC, nalD\)) and in target genes (\(gyrA, gyrB, parC\)) in planktonic PAO1 isolates as well as in \(\Delta katA\) biofilm isolates with hypermutable phenotype. In addition, mutations in genes involved in cell-wall recycling (\(ftsZ, murC\)) could explain the cross-resistance to beta-lactams aztreonam and ceftazidime. Mutations in arginine catabolism leading to a metabolic rewiring to anaerobic metabolism and in the TCA cycle (\(sdhA\)) were also identified and might contribute to increased tolerance to other antibiotics which bactericidal effect depends on reactive oxygen species formation. Maintenance of swarming and loss of twitching motility was observed in colonies from CIP-exposed populations. Prolonged lag-phase of the growth curves of CIP-resistant colonies from the CIP-exposed populations was observed and might represent an additional mechanism for persistence of these colonies. In spite of the high fitness-cost, the CIP-resistant colonies persisted in the biofilms in competition with the WT in the absence of antibiotics and were selected by exposure to ciprofloxacin.

**Conclusions:** Overlapping to a large number of the published patho-adaptive genes in *P. aeruginosa* CF isolates was observed suggesting the important role of the antibiotic stress in shaping the bacterial evolution in biofilms in vivo that leads to the so-called chronic phenotype which becomes well adapted to the conditions of the respiratory tract of CF patients and therefore persists in spite of antibiotic therapy.

Abstract 2554

Fatal babesiosis in a non-HIV immunocompromised host
Uli Schwab*1
1Royal Victoria Infirmary, Department of Infection and Tropical Medicine, Newcastle upon Tyne, United Kingdom

Background: Human Babesiosis is a protozoan intra-erythrocytic-infection. We report a fatal infection with Babesia microti complicated by haemophagocytic-lymphohistiocytosis (HLH).

Materials/methods: Case report

Results: A 83 year old man presents with a 3 day history of malaise, anorexia, rigors and a dry cough to a peripheral hospital following a cruise along the Scandinavian coastline (Copenhagen, Oslo, Stavanger, Bergen) and the British Isles (Shetland, Orkney). He is febrile at 38.7°C, tachycardic but haemodynamically stable, with a marked thrombocytopenia (41), abnormal PT (15), renal impairment (Creatinine 199) raised CRP 117 but normal white cells including differential. CXR, throat swab, serial blood cultures, MSU were culture-negative. Despite receiving iv fluids, broad spectrum antibiotics for presumed lower respiratory tract infection with AKI and delirium his pyrexia persists, his CRP rises to 223, and he develops abdominal pain with jaundice (Bilirubin 158, AST 249, ALT 94, AlkP 277), worsening renal function (Crea 543) oliguria, anaemia (Hb 7.6, haptoglobin <0.03g/l) with worsening confusion and bruising suggestive of a hepato-renal syndrome with DIC prompting transfer to the regional ID-unit. PMH includes AVR/TAVI, PUD, Waldenstroem’s macroglobulinaemia previously receiving IVIG’s and Rituximab, last 3 months prior. Extensive travel history; Nigeria (‘60ties,’90 and 2003), Kenya, Malaysia/Taiwan, Indian Subcontinent (‘70ties), South Africa (‘97) Korea (2011). A blood film suggest malaria parasitaemia (20-30%) posing speciation difficulty. Of note he spent most summers on the Great pond in Belgrade (Maine/USA), most recently 4 weeks before presentation, pointing towards epidemiological babesiosis exposure particularly in a immunocompromised individual with a negative RDT for P.falciparum, later confirmed as 22% parasitaemia, B.microti ELISA+ve, IFAT+ve 1:320 (negative blood-borne-virus-screen, leptospira-DNA, hantavirus-IF, B.burgdorferi and anaplasma-IF). A pan-reactive auto-Ab panel, prevented exchange-transfusion. Despite iv cefotaxime, artesunate, po doxicicline, atovaquone/azithromycin together with iv clindamycin/quinine, he deteriorates rapidly despite full organ support and dies due to multiorgan failure. Ferritin elevation >16,000 suggests HLH confirmed on post-mortem. Epidemiology, diagnosis, prognosis and treatment of Babesiosis will be discussed.

Conclusions: Diagnosis of Babesiosis requires a high index of suspicion, in part because the clinical manifestations are non-specific. In the age of increasing immunomodulators and global travel, early diagnosis and treatment are essential to reduce mortality from babesiosis.

Antibiotic and biocide resistance among staphylococci causing skin and soft tissue infections in companion animals in Portugal

Sofia Santos Costa*, Rute Ribeiro¹, Valéria Oliveira¹, Maria Serrano², Carolina Ferreira¹, Catarina Morais¹, Maria Constança Pomba², Isabel Couto¹

¹Global Health and Tropical Medicine (GHTM), Instituto de Higiene e Medicina Tropical (IHMT) - Universidade NOVA de Lisboa, Lisboa, Portugal, ²Laboratory of Antimicrobial and Biocide Resistance, CIISA, Faculty of Veterinary Medicine, University of Lisbon, Lisboa, Portugal

Background: Skin and soft tissue infections (SSTIs) are among the most frequent pathologies affecting companion animals. Staphylococci other than *S. pseudintermedius* account for 10-15% of these infections. The increasing prevalence of methicillin-resistant staphylococci (MRS) and multiresistant strains in animals has become an emerging problem.

Materials/methods: We studied a collection comprising all *S. aureus* (n=55), *S. schleiferi* (n=28) and *S. epidermidis* (n=14) isolates associated with SSTIs in companion animals from two laboratories in Lisbon, collected between 1999 and 2018. Identification was confirmed by species-specific nuc gene PCR. Antibiotic and biocide susceptibility profiles were established by disk diffusion or determination of minimum inhibitory concentrations (MICs). The distributions of biocide MICs were used to identify non-wild-type (NWT) populations. Biofilm production was evaluated by the crystal violet method. Strain clonality was evaluated by SmaI-PFGE and MLST.

Results: Methicillin resistance (mecA⁺) was identified in 31 *S. aureus* (56.4%, 31/55), two *S. schleiferi* (7.1%, 2/28) and eight *S. epidermidis* (57.1%, 8/14), often associated with multidrug resistance (MDR). Resistance was most frequently observed for beta-lactams (*blaZ* and/or *mecA*), fluoroquinolones and macrolides/lincosamides [linked with *erm*(A)/*erm*(C) in *S. aureus*, *erm*(B) in *S. schleiferi* and several genes in *S. epidermidis*]. We also detected resistance to fusidic acid, tetracycline and/or aminoglycosides, mostly linked to carriage of *fusC*, *tet*(K)/*tet*(M), and *aadD*, respectively. For *S. aureus* and *S. epidermidis*, we identified NWT populations towards biocides linked with several efflux pump genes (e.g., quaternary ammonium compounds, arsenate and cadmium associated with *qacA/B* or *smr; orsB* cadA or *cadB*, respectively). Several *S. epidermidis* isolates and one methicillin-resistant *S. schleiferi* were strong biofilm-producers. SmaI-PFGE revealed high heterogeneity among *S. aureus* and *S. epidermidis* isolates, contrary to *S. schleiferi*. The CC22 lineage was predominant amongst *S. aureus* isolates, whereas CC5 was the most frequent *S. epidermidis* lineage.

Conclusions: We demonstrate a high prevalence of antimicrobial resistant staphylococci, particularly MRS and MDR strains, associated with SSTIs in companion animals, evidencing a growing limitation of available therapeutic options for the management of these infections.

In vitro antibacterial activity of cefiderocol against a multinational collection of Gram-negative bacteria from urinary isolates: SIDERO-WT-2014–2018

Raymond Pecini1*, Sean Nguyen1, Meredith Hackel2, Daniel Sahm3, Roger Echols3, Miki Takemura4, Yoshinori Yamano4

1Shionogi Inc, Florham Park, United States, 2IHMA, Inc., Schaumburg, United States, 3Infectious Disease Drug Development Consulting, LLC, Easton, United States, 4Shionogi & Co., Ltd., Osaka, Japan

Background: Cefiderocol (CFDC) is a siderophore cephalosporin with potent activity against a wide range of Gram-negative pathogens including carbapenem non-susceptible (CarbNS) strains of Enterobacterales and non-fermenting bacteria. This study evaluated the in vitro activity of CFDC and comparator agents against Gram-negative clinical isolates collected from urinary sources of infection as part of the multinational SIDERO-WT surveillance studies [a pool of 4 consecutive years/studies from 2014 to 2018, totalling >30,000 recent clinical isolates].

Materials/methods: A total of 8,549 clinical non-duplicate urinary isolates of Gram-negative bacteria from Europe and the USA were collected and underwent susceptibility testing at a central laboratory (IHMA, Schaumburg, IL). MICs were determined for CFDC, cefepime (FEP), ceftazidime-avibactam (CZA), ceftolozane-tazobactam (C/T), ciprofloxacin (CIP), colistin (CST), and meropenem (MEM) by broth microdilution and interpreted according to CLSI guidelines. For SIDERO-WT Year 4 (i.e. 2018) isolates, aztreonam-avibactam (ATM/AVI, ATM in the presence of 4 µg/mL AVI), meropenem/vaborbactam (MVB) and sulfamethoxazole/trimethoprim (SXT) were added. As recommended by CLSI, CFDC was tested in iron-depleted cation-adjusted Mueller-Hinton broth.

Results: CFDC exhibited potent in vitro activity with MIC90 values ranging from 0.25 to 1 µg/mL for isolates of P. aeruginosa, Acinetobacter spp., S. maltophilia, and Enterobacterales, and 1 to 4 µg/mL for CarbNS subsets. Against CarbNS P. aeruginosa, CFDC MIC90 was 1 µg/mL and was lower than the MIC90 of 64 and >64 µg/mL for CZA and C/T, respectively. CFDC demonstrated potent in vitro activity against CarbNS Acinetobacter spp. with MIC90 of 2 µg/mL versus MIC90 of >8 µg/mL for ATM/AVI, CZA, C/T, and MVB. Against S. maltophilia, CFDC was the most potent tested antibiotic with an MIC90 value of 0.25 µg/mL, including SXT with an MIC90 of 0.5 µg/mL.

Abstract 2560

In vitro activity of cefiderocol against Stenotrophomonas maltophilia clinical isolates in Europe and North America: multinational surveillance SIDERO-WT-2018 study

Naoki Ishibashi*1, Meredith Hackel2, Hideki Maki1, Takafumi Satou1, Roger Echols3, Daniel Sahm2, Yoshinori Yamano1

1Shionogi & Co., Ltd., Osaka, Japan, 2IHMA, Inc., Schaumburg, United States, 3Infectious Disease Drug Development Consulting, LLC, Easton, United States

Background: Cefiderocol (CFDC) is a novel siderophore cephalosporin with activity against a wide range of Gram-negative bacteria. In this study, we analysed the in vitro activity of CFDC against Stenotrophomonas maltophilia clinical isolates collected in 2018 in the multinational surveillance study SIDERO-WT-2018 and compared it with the activity of comparator agents.

Materials/methods: A total of 392 S. maltophilia isolates were collected from 79 medical centres in Europe (n=192) and North America (n=200). Minimum inhibitory concentrations (MICs) were determined for CFDC, ceftazidime-avibactam (CZA), ceflozane-tazobactam (C/T), meropenem (MEM), meropenem-vaborbactam (MVB), ciprofloxacin (CIP), colistin (CST) and trimethoprim-sulfamethoxazole (SXT) by broth microdilution according to Clinical and Laboratory Standards Institute (CLSI) guidelines. The MIC for aztreonam (ATM) in the presence of 4 µg/mL of avibactam (AVI) was also determined. Susceptibility rates of comparators were calculated based on the breakpoint by European Committee on Antimicrobial Susceptibility Testing (EUCAST) or CLSI, and the breakpoint against P. aeruginosa was used when the breakpoint against S. maltophilia is not available. Susceptibility to ATM/AVI was provisionally calculated using breakpoints of AZT.

Results: CFDC showed an MIC90 of 0.5 µg/mL, which was the lowest among the tested compounds [Table]. 389 among 392 S. maltophilia isolates showed MIC of ≤2 µg/mL, against which cefiderocol has been shown to be effective in non-clinical in vivo studies under humanised PK profile. Among 392 isolates, 17 isolates were non-susceptible to SXT, and only two isolates had CFDC MIC >4 µg/mL. Among the 17 SXT non-susceptible isolates, one isolate showed CFDC MIC >4 µg/mL. Six ATM/AVI non-susceptible isolates based on ATM breakpoint showed CFDC MIC ≤4 µg/mL.

Conclusions: CFDC was active against S. maltophilia isolates, with in vitro activity against SXT and ATM/AVI non-susceptible isolates. CFDC has favourable potency that is similar to SXT, which is a standard therapeutic agent for S. maltophilia infection.

Abstract 2564

**Single dose cefazolin is feasible in orthopaedics: behavioural change success with collaborative working**

Fatma Şebnem Erdinç¹, Necla Tülek*,¹, BahadırAlemdaroğlu², Serkan İltar¹, Gunay Ertem¹, S. Kinikli¹, Çiğdem Ataman Hatipoğlu¹

¹Ankara Training and Research Hospital, Infectious Diseases and Clinical Microbiology, Ankara, Turkey, ²Ankara Training and Research Hospital, Orthopedics and Traumatology, Ankara, Turkey

**Background:** Compliance to surgical antibiotic prophylaxis recommendations is an essential problem and duration of antibiotic use has a priority for improvement. Each centre may have its own surgical infection prevention priorities and strategies. The aim of this study was to evaluate the change in appropriateness of antibiotic prophylaxis after a collaborative work with orthopaedists in the hospital.

**Materials/methods:** The study was performed in a 468-bed tertiary care teaching hospital in Ankara, Turkey. Surgical prophylaxis appropriateness in selected categories of surgical procedures has being followed by infection control team routinely since 2006. The first hospital-specific surgical prophylaxis guideline had been published in 2013. That guideline was introduced and explained to the surgeons of the hospital in a general information meeting after publication. To update the existing guideline in 2018, infection control team of the hospital performed a collaborative study with the related surgeons according to current international guidelines and scientific articles. After a series of meetings with participation of surgeons, the updated guideline was published in May, 2018. Surgical prophylaxis appropriateness percentages of Orthopaedic and Traumatology department, one year before and one year after the “2018 Hospital-specific Surgical Prophylaxis Guideline” publication were evaluated retrospectively. Time intervals were June 2017-May 2018 for the before and June 2018-May 2019 for the after groups.

**Results:** Selected orthopaedic surgery categories for surveillance were knee prosthesis, open reduction of fracture and hip prosthesis. Total number of those procedures were 555 in the before group and 665 in the after group. Appropriateness of surgical prophylaxis percentages are shown in the figure. Single dose cefazolin percentage was less than 1% in the before group while more than 70% in the after group. Prophylaxis more than 24 hours was the most frequent reason for inappropriate prophylaxis.

**Conclusions:** Although both hospital-specific guidelines [2013 and 2018] did include almost the same recommendations, dramatic increase in the compliance after collaborative work emphasized that being involved in the process has an important effect on behaviour change.

Abstract 2566

Rapid increase in occurrence of carbapenem-resistant Enterobacteriaceae in healthy rural residents in Shandong province, China, from 2015 to 2017

Baoli Chen¹, Björn Berglund², Shuang Wang¹, Stefan Börjesson²,³, Hong Yin⁴, Zhenwang Bi¹, Maud Nilsson², Zhenqiang Bi¹, Lennart E. Nilsson*²

¹Shandong Center for Disease Control and Prevention, Jinan, China, ²Linköping University, Linköping, Sweden, ³National Veterinary Institute (SVA), Uppsala, Sweden, ⁴Falun Hospital, Falun, Sweden

Background: The rapid increase of carbapenem-resistant Enterobacteriaceae (CRE) globally during the last decade has led to the World Health Organization listing the prevention and control of CRE in health care facilities as a priority. Infections caused by CRE are associated with increased mortality and length of hospital stays, emphasizing the health and economic burden posed by these pathogens. Although CRE can inhabit the human gut asymptomatically, colonisation with CRE is associated with increased risk of CRE infection and mortality. Monitoring the carriage rates of healthy individuals is therefore relevant for assessing the epidemiological situation regarding CRE.

Materials/methods: In 2015 and 2017, we investigated carriage rates of CRE in a rural region of Shandong province, China, by collecting faecal samples from healthy individuals of 12 villages in the region. In July 2015, 758 households in the study region were selected and in 2017, 628 of these households where sampled again. One individual from each household was sampled on each occasion. Samples were screened for CRE by cultivation on selective agars and suspected CRE-isolates were verified as Enterobacteriaceae with MALDI-TOF and MICs of meropenem by using agar dilution. Isolates were defined as CRE by using the EUCAST recommended meropenem-screening cut-off of >0.125 mg/L and subsequently whole-genome sequenced.

Results: A total of 18 and 86 individuals were positive for CRE in 2015 and 2017 respectively, corresponding to an increase of CRE occurrence ratios from 2.4% in 2015 to 14% in 2017. Most isolates were of Escherichia coli (>90% at both sampling occasions) and all isolates carried blaNDM genes, with blaNDM-5 (71%) being the most common.

Conclusions: This study shows a worrying and rapid five-fold increase in colonisation rates of CRE carrying blaNDM genes among rural residents in Shandong, China, indicating an increased risk of severe and difficult-to-treat infections and the potential for further dissemination of carbapenemase-encoding genes. Further studies and monitoring are essential to understand the rapid increase. Interventions may also need to be considered in China to prevent a further worsening of the epidemiological situation.

Abstract 2567

In vitro activity of cefiderocol against carbapenem non-susceptible Enterobacterales from multiple countries in Europe and North America: multinational surveillance SIDERO-WT-2018 study

Naoki Kohira*1, Meredith Hackel2, Hideki Maki1, Takafumi Satou1, Roger Echols3, Daniel Sahm2, Yoshinori Yamano1

1Shionogi & Co., Ltd., Osaka, Japan, 2IHMA, Inc., Schaumburg, United States, 3Infectious Disease Drug Development Consulting, LLC, Easton, United States

Background: Cefiderocol (CFDC) has demonstrated potent activity against Gram-negative pathogens including carbapenem non-susceptible (NS) Enterobacterales strains. We conducted a multinational surveillance study (SIDERO-WT-2018) to evaluate in vitro activity of CFDC against clinical isolates collected in 2018 from Europe and North America. In this study, we evaluated in vitro activity of CFDC and comparator agents against carbapenem NS Enterobacterales.

Materials/methods: A total of 145 carbapenem NS Enterobacterales isolates from a total of 5046 Enterobacterales isolates from SIDERO-WT-2018 were studied (115 from Europe, 30 from North America). Minimum inhibitory concentrations (MICs) were determined for CFDC, cefepime (FEP), ceftazidime-avibactam (CZA), cefotaxime-tazobactam (C/T), ciprofloxacin (CIP), colistin (CST), meropenem (MEM) and meropenem-vaborbactam (MVB) by broth microdilution according to Clinical and Laboratory Standards Institute (CLSI) guidelines. CFDC was tested in iron-depleted cation-adjusted Mueller–Hinton broth according to CLSI guidelines. The MIC for aztreonam (ATM) in the presence of avibactam 4 µg/mL (AVI), which can be used clinically in combination, was also determined. Carbapenem-NS isolates were defined using the European Committee on Antimicrobial Susceptibility Testing (EUCAST) breakpoints for MEM.

Results: The MIC90 values for CFDC and comparators for all isolates, MEM-NS isolates and ATM/AVI-NS isolates of Enterobacterales are shown in the Table. CFDC MIC90 was 4 µg/mL against MEM-NS isolates and ATM/AVI-NS isolates. 93.8% of MEM-NS isolates had CFDC MIC of ≤4 µg/mL, against which CFDC has been shown to be effective in non-clinical in vivo studies under humanised PK profile. Among 145 MEM-NS isolates, nine isolates were found with CFDC MIC >4 µg/mL (six from Russia and one each from Spain, UK and USA) and 20 isolates showed ATM/AVI MIC >1 µg/mL (seven from USA, six from Greece, four from Russia, two from Italy, and one from UK).

Conclusions: CFDC showed potent antibacterial activity with low MIC values against carbapenem NS Enterobacterales isolates, indicating that CFDC has high potential for treating infections caused by these difficult-to-treat strains.

Abstract 2568

**Genomic characterisation of multidrug-resistant Klebsiella michiganensis strains**

Preetha Shibu¹, Frazer Mccuaig², Magdalena Kujawska¹, Lindsay Hall³, Anne Mccartney⁴, Lesley Hoyles*²

¹University of Westminster, London, United Kingdom, ²Nottingham Trent University, Clifton Campus, Clifton, United Kingdom, ³Quadram Institute Bioscience, Norwich, United Kingdom, ⁴University of Reading, Reading, United Kingdom

**Background:** While much attention has focused on the clinical relevance of *K. pneumoniae*, bacteria identified as *K. oxytoca* in clinical laboratories have received little attention. *K. oxytoca* represents 17% of all *Klebsiella*-positive blood culture isolates in UK clinical settings, and the bacterium is becoming increasingly associated with nosocomial infections, particularly in immunocompromised patients.

**Materials/methods:** Whole-genome sequences were generated for three carbapenem-resistant outbreak strains identified by MALDI-TOF and API 20E as *K. oxytoca*. Antimicrobial susceptibility profiles were determined according to EUCAST guidelines, with ertapenem resistance confirmed by E-test. Average nucleotide identity (ANI) and phylogenetic analyses of genome data, by comparison to type strains, were used to determine the strains’ species affiliation. Capsule and O antigen types of the strains were determined using Kaptive. Multilocus sequence typing was done via the online *Klebsiella oxytoca/Klebsiella michiganensis* MLST databases. Antibiotic resistance and virulence gene profiles of the strains were determined using BLASTP with the Comprehensive Antibiotic Resistance Database and Virulence Factor Database, respectively. BLASTP was also used to determine whether the strains encoded the tilimycin biosynthetic gene cluster (BGC) thought to be unique to *K. oxytoca* isolates associated with non-*C. difficile*-antibiotic-associated haemorrhagic colitis. Over 7000 publicly available *Klebsiella* spp. genome sequences were also screened to determine the prevalence of the BGC.

**Results:** The strains were resistant to a range of antimicrobials, including ertapenem. Genomic analyses revealed the three strains to be *K. michiganensis* ST138 (unknown capsular and O antigen types), encoding SHV-66 and GES-5, and the complete tilimycin BGC. Only 1% of all publicly available *Klebsiella* genomes screened encoded one or more genes of the BGC, with all belonging to the *K. oxytoca* complex of six species.

**Conclusions:** Whole-genome sequence data are required to allow accurate taxonomic classification of strains identified as *K. oxytoca* using MALDI-TOF and/or API 20E. This is the first report of *K. michiganensis* encoding SHV-66 and GES-5, and the tilimycin BGC. We also demonstrate that the tilimycin BGC is represented in a minority of strains belonging to representatives of the *K. oxytoca* complex (*K. oxytoca*, *K. michiganensis*, *K. grimontii*, *K. huaxiensis*, ’*K. pasteurii’* and ’*K. spallanzanii’*).

Abstract 2569

Baseline resistance to ceftazidime-avibactam and aztreonam-avibactam in carbapenemase-producing Enterobacterales from Argentina mediated by the co-expression of PER ESBL: role of imipenem-relebactam and aztreonam-relebactam as therapeutic alternatives

Fernando Pasteran1,2, Juan Manuel De Mendieta1, Melina Rapoport1, Soledad Ramirez1, Diego Faccone1, Celeste Lucero1, Paola Ceriana1, Alejandra Corso1

1Servicio Antimicrobianos, Laboratorio Nacional de Referencia, INEI ANLIS “Dr. Malbran”, buenos aires, Argentina, 2Cza working group, buenos aires, Argentina, 3Center for Applied Biotechnology Studies, Department of Biological Science, College of Natural Sciences and Mathematics, Fullerton, United States

Background: Carbapenemase-producing Enterobacterales (CPE) isolates have reached 20% during 2018 in Argentina, with KPC nationwide endemicity and outbreaks of NDM and OXA-48-like. PER is the second most frequent ESBL in Argentina and have a weak inhibition by avibactam, significantly lower than other class A enzymes. We describe the emergence of CPEs with baseline resistance to ceftazidime-avibactam (CAZ-AVI) and aztreonam-avibactam (ATM-AVI) mediated by the co-expression of PER and explore therapeutic alternatives, such as imipenem-relebactam (IPM-REL) and aztreonam-relebactam (ATM-REL).

Materials/methods: Since 2017, susceptibility to CAZ-AVI and ATM-AV was prospectively monitored against CPE submitted to the NRL. Strains non-susceptible to AVI combinations were tested for IPM-REL and ATM-REL. AVI and REL (4ug/ml final concentration), with the indicated beta-lactams, were tested by reference dilution methods, while susceptibility to other agents was performed either by disk diffusion or MIC methods (CLSI/EUCAST criteria). Due to the absence of breakpoints for ATM-AVI/ATM-REL, we used the EUCAST criteria for ATM. Molecular characterization of β-lactamases genes was carried out by PCR/sequencing.

Results: 606 CPE isolates (119 Hospitals) were analyzed: i) KPC: 18/365 (4.9%) were ATM-AVI non-susceptible, of which 9/365 (2.5%) were also CAZ-AVI resistant, being 16/18 PER co-producers. CAZ-AVI resistant strains harbored KPC-2 allele. ii) OXA-48-like: 6/119 (2.5%) were ATM-AVI non-susceptible, of which 3/119 (0.8%) were also CAZ-AVI resistant, being 4/6 PER co-producers. iii) MBLs (107 NDM, 11 IMP, 4 VIM): 5/122 (4.1%) were ATM-AVI non-susceptible, all PER co-producers (Figure-A). Additionally, 14 (7 KPC, 1 OXA, 6 MBL) and 17 (14 KPC, 3 OXA) CPE+PER remained susceptible to ATM-AVI and CAZ-AVI, respectively, with MIC values shifted towards higher levels compared to PER non-producers (Figure-A). IPM-REL and/or ATM-REL were the most active agents for CPE+PER (Figure-B).

Conclusions: The co-expression of PER in CPEs was a determining factor for the MIC creep of avibactam combinations. PER seems to be the cause of non-susceptibility to CAZ-AVI and ATM-AVI in KPC and MBL, respectively. An ATM-AVI MIC >=1.0ug/ml was selected as an ECOFF for further screening of PER co-production among CPE. Rellebactam combinations resulted key alternatives for CPE+PER. Considering the dissemination potential of PER, IPM-REL should be part of the therapeutic armamentarium.
Figure A: MIC distributions for CAZ-AVI and ATM-AVI for CPEs. Number of isolates with the indicated MIC value (in μg/ml) according to the type of carbapenemase and the co-production of blaPER. The dotted line indicates the cutoff values:

- Non PER coproducers
- PER coproducers

Ceftolozane/tazobactam-resistant *Pseudomonas aeruginosa* isolates in a teaching hospital in central Italy

Morroni Gianluca¹, Lucia Brescini¹,², Andrea Brenciani¹, Alberto Antonelli¹, Vincenzo Di Pilato¹, Sefora Castelletti¹,², Simona Fioriti¹, Tommaso Gian¹,², Gian M. Rossolini¹,², Andrea Giacometti¹,², Oscar Cirioni¹,²

¹Marche Polytechnic University Faculty of Medicine, Dep. of Biomedical Sciences and Public Health, Ancona, Italy, ²Ospedali Riuniti Torrette Di Ancona, Clinica Malattie Infettive, Torrette, Ancona, Italy, ³University of Florence, Dep.of Experimental and Clinical Medicine, Firenze, Italy, ⁴Careggi University Hospital, Clinical Microbiology and Virology Unit, Firenze, Italy

**Background:** Ceftolozane/tazobactam (C/T) is a novel cephalosporin/β-lactamase inhibitor combination with a potent activity against *Pseudomonas aeruginosa* isolates. Despite its recent introduction, several resistant *P. aeruginosa* isolates have been reported. We performed a survey on the activity of C/T against clinical strains of *P. aeruginosa* isolated at "Ospedali Riuniti" of Ancona, Italy, characterising the resistant isolates.

**Materials/methods:** MICs to C/T were determined with gradient test for all *P. aeruginosa* recovered at the clinical laboratory of "Ospedali Riuniti" from October 2018 to March 2019. Resistant strains were characterized and typed by SpeI-PFGE. NGS with an Illumina Miseq platform was performed on representative strains to identify the mechanisms of C/T resistance.

**Results:** Over 317 isolated and screened isolates, 15 were resistant to C/T (MIC > 8 mg/L; 4.73%). PFGE showed that 8/15 were strictly related. NGS revealed 6 different STs. The resistance mechanisms to C/T included the metallo-β-lactamase (MBL)-encoding genes *bla*<sub>VIM</sub>-2 in 8 isolates belonging to ST111, and *bla*<sub>IMP</sub> in 2 isolates (*bla*<sub>IMP</sub>-19 in ST175 and *bla*<sub>IMP</sub>-13 in ST621). Additionally, *bla*<sub>PER</sub> β-lactamase gene was detected in 2 isolates (ST235) and the *bla*<sub>GES</sub> β-lactamase gene in 1 isolate (ST175). Notably, in 2 strains (ST70 and ST3354) no acquired β-lactamase genes involved in C/T resistance has been detected but they showed alterations in *ampC*. Modifications in these genes and in *ampC* promoter (*ampR*) were also detected in all resistant strains except in ST175 isolates (possessing a wild type *ampC* and *ampR*).

**Conclusions:** Although our study confirmed a low rate of resistance to C/T, several resistance mechanisms were identified, among which production of MBLs was the most common. Moreover, we found a possible mini-outbreak of *bla*<sub>VIM</sub> positive strains, representing a concern for the clinicians and also a possible reservoir for the transmission of MBL to other species. Determination of MIC to C/T should be always performed prior administration to avoid the spread of resistant *P. aeruginosa*.

Abstract 2577

In vitro and in vivo antimicrobial activity of cefiderocol and comparators against Stenotrophomonas maltophilia

Rio Nakamura1, Merime Oota1, Toriko Yoshitomi1, Takafumi Satou2, Yoshinori Yamano*2

1Shionogi TechnoAdvance Research & Co., Ltd., Osaka, Japan, 2Shionogi & Co., Ltd., Osaka, Japan

Background: Stenotrophomonas maltophilia is a ubiquitous multidrug-resistant (MDR) opportunistic pathogen. Regarding β-lactam resistance, the presence of at least two different types of β-lactamases – L1 metallo-type carbapenemase and L2 extended-spectrum type β-lactamase – are involved. Cefiderocol (CFDC), a novel siderophore cephalosporin, is active against carbapenem-resistant Gram-negative bacteria, including S. maltophilia. In this study, in vitro and in vivo antibacterial activity of CFDC were evaluated versus comparators including trimethoprim-sulfamethoxazole (SXT), levofloxacin (LVX) and minocycline (MIN).

Materials/methods: Minimum inhibitory concentrations (MICs) of CFDC and comparators were determined by broth microdilution method as recommended by Clinical and Laboratory Standards Institute guidelines using iron-depleted cation-adjusted Mueller–Hinton broth for CFDC. The stability against L1 and L2 β-lactamases was evaluated by their activity against Escherichia coli BL21 (DE3) expressing these enzymes. In vivo efficacy of CFDC and comparators (SXT, MIN, ciprofloxacin [CIP], LVX, ceftazidime [CAZ], cefepime [FEP], meropenem [MEM] and colistin [CST]) was evaluated using a murine lung infection model (5-week-old neutropenic ICR mice; n=5) caused by two strains, including a SXT-resistant strain. Treatment was given 2, 5 and 8 hours post-infection, and the numbers of viable cells in lungs were determined 26 hours post-infection.

Results: MIC increases for CFDC and FEP were not observed (≤2-fold) in the presence of either β-lactamase. In contrast, presence of L1 β-lactamase resulted in MIC increases for MEM and CAZ (both 16-fold), whereas presence of L2 caused the MIC to increase by 4-fold for CAZ only. In the murine lung infection model, CFDC showed >3 log10 reduction of viable bacteria in lungs at 100 mg/kg dose (%T>MIC: <50%) against both test strains (CFDC MIC: 0.5 and 0.1 mg/L). No decrease of viable cells in lungs was observed for the other comparators except that MIN, CIP, and LVX showed 2.1, 2.8, and >3 log10 reduction, respectively, at 100 mg/kg only against a low-MIC isolate.

Conclusions: CFDC is stable against both L1 and L2 β-lactamas, and showed potent in vivo efficacy in a murine lung infection model reflecting in vitro activity against S. maltophilia. These results suggest that CFDC has high potential as an effective therapeutic option for S. maltophilia infections.

Abstract 2581

**Evaluation of Colibrí for antimicrobial susceptibility testing**

Jérémy Bayette*, Amandine Roché, Thibaud Bayol, Rémi Fournier, Guillaume Teissier

1LABOSUD, Montpellier, France

**Background:** Colibrí™ (Copan) is a system which automatizes the picking of isolated colonies grown on petri dishes and allows the preparation of Maldi-tof targets for bacterial identification, microbial suspensions for antimicrobial susceptibility testing, and inoculation of purity plates.

**Materials/methods:** A total of 239 urine specimens were inoculated onto CHROMID®CPS elite (bioMérieux) and processed into the WASPLab® system. Isolated colonies of *E. coli* (n=165), *Enterococcus spp* (n=42) and *Staphylococcus spp* (n=32) were selected by a technician on the image. Plates were transferred to the Colibrí™ for the colony picking and the automated preparation of the bacterial suspension for the realization of the VITEK2® susceptibility cards with respectively AST-N340 card for *E. coli*, AST-P606 for *Enterococcus spp* and AST-P631 for *Staphylococcus spp*. In parallel, a microbial suspension was realized manually with the same plate using the procedure of the laboratory. Results were compared in term of Essential Agreement (EA) and Categorical Agreement (CA) globally for the card and individually per antibiotic. Acceptance criteria used for the comparison were based on ISO 20776-2.

**Results:** For the EA, a total of 2796 MIC (Minimum Inhibitory Concentration) for *E. coli*, 380 for *Enterococcus spp* and 570 for *Staphylococcus spp* were compared to the manual methodology. The global EA was respectively 99.7%, 100% and 99.3%. The individual EA varied from 93.8% to 100% for other antibiotic/species. Concerning the CA, among a total of 2781 data for *E. coli*, 376 for *Enterococcus spp* and 545 for *Staphylococcus spp*, the global CA varied from 98.4% to 99.1% with an individual CA from 95.2% to 100%.

**Conclusions:** The performance of Colibrí™ for the automated preparation of bacterial suspensions are equivalent to the manual procedure for the realization of VITEK® 2 susceptibility cards for *E. coli*, *Enterococcus spp* and *Staphylococcus spp*. Colibrí™ allows the total automation of urine specimens from the sampling to the results of VITEK®2 antimicrobial susceptibility testing. The introduction of Colibrí™ in the workflow of a laboratory allowed a consequent gain in reproducibility, productivity and traceability with a real medical added value for the patient.

Abstract 2583

Healthcare workers in Kyrgyzstan and QuantiFERON-TB Gold Plus testing for the detection of latent tuberculosis infection

Caroline Corbett*1, Nagira Umetalieva1, Monica Vogel1, Harald Hoffmann1

1IML Red GmbH, Gauting, Germany

Background: The Kyrgyz Republic has a high incidence of TB, and health care workers (HCW) are at an increased risk of infection, despite training and effective control measures being in place, due to close contact with a high density of infected individuals as well as performing high risk procedures. The aims of this study were to assess the prevalence of LTBI among HCW in major hospitals in the Kyrgyz Republic using Quantiferon-TB Gold plus (QFT), and determine if there is any difference in risk of positivity between positions, department or hospitals.

Materials/methods: Hospital employees working in the major hospitals in Karakol, Kemin, Karabalta and the National Tuberculosis Centre (NTC) in Bishkek were invited to participate in the study. Following informed consent a questionnaire was used to collect age, position, and department of employment. Blood was drawn for QFT testing for all participants. A univariate and multivariate analysis were performed using logistic regression to assess risk factors with positivity using the “Administrative” position as the base. Participants from the three hospitals were combined and compared to those working at the NTC due to differences between sites.

Results: A total of 404 HCW provided valid QFT results (NTC=220, Karabalta=98, Karakol=49, Kemin=37). Age was significantly associated with positivity (OR=1.02 per year, p-value=0.03) and therefore controlled for in all analysis. At the NTC, there was an increased odds of being QFT positive among doctors (OR=12.6, 95%, p=0.03) and lab personnel (OR=29.8, 95% p<0.001). Additionally, working in the drug resistance ward (OR=9.1, p=0.049) and smear negative ward (OR=13.2, p=0.03) had higher odds of positivity in the NTC. There was no effect of position or department on QFT positivity for the combined hospital sites.

Conclusions: Health care workers have an increased odds of being QFT positive once controlling for age differences among positions at the NTC, but the effect of position is not detected at the major hospitals combined. This study highlights the importance of monitoring LTBI in HCWs, as well as highlighting the need for increased training and protective measures against transmission of TB.

Abstract 2585

A case of Lomentospora prolificans (LoPro) treated with the novel antifungal olorofim

Sharon Chen1, Neela Joshi Rai1, Sam Cunneen2, Karen Cornelissen3, John H. Rex3, Christopher Hamilton Heath4, Emma Harvey3

1Westmead Hospital, Westmead, Australia, 2Sir Charles Gairdner Hospital, Nedlands, Australia, 3F2G Ltd, Eccles, United Kingdom, 4Fiona Stanley Hospital, Murdoch, Australia

Abstract third-party references: F2G Ltd

Background: LoPro is difficult to treat with currently approved antifungals. Only voriconazole is approved for the treatment of LoPro and mortality remains high despite combination therapy and prolonged therapy is common. Olorofim is a novel antifungal agent of the orotomide class, acting via inhibition of the enzyme dihydroorotate dehydrogenase. Olorofim has shown strong in vitro and in vivo inhibition of LoPro.

Materials/methods: Case summary: Following bilateral breast enhancement in August 2018, an otherwise healthy 49-year-old woman from rural Western Australia developed infection of her right implant with L. prolificans that spread to adjacent soft tissues, rib and sternum. Implant removal (October 2018), repeated debridement, hyperbaric oxygen, voriconazole, terbinafine, miltefosine, posaconazole, and anidulafungin were employed serially, and in combination; with no control of the infection. She was transferred to Sydney and enrolled in an open-label study of the novel antifungal olorofim in November 2018 (ClinicalTrials.gov Identifier: NCT03583164), with continuing surgical debridement as needed.

Results: She was treated from 29 Nov 2018 to 16 Oct 2019 (322 days) with olorofim, initially at a dose of 60 mg twice daily. Gradual healing of the surgical site occurred with wound closure in July 2019. Wound cultures were intermittently positive for LoPro prior to wound closure, but olorofim MICs of these isolates remained at 0.25 ug/ml throughout. Because of blood trough levels at the lower end of the target range, the dose was increased to first 90 mg, and then 120 mg twice daily. Olorofim was well tolerated throughout.

Conclusions: In this case, a progressive, disfiguring, and potentially life-threatening chest wall infection due to LoPro that was unresponsive to all available therapies, however improved steadily on olorofim. In addition, olorofim was well tolerated during the extended duration required to control this complex infection.

Abstract 2586

Genomic and phenotypic characterisation of invasive neonatal and colonising Group B Streptococcus isolates from Slovenia, 2001-2018

Tina Perme1, Daniel Golparian2, Manica Mueller-Premru3, Maja Bombek Ihan1, Miha Lučovnik1, Lilijana Kornhauser Cerar1, Petja Fister1, Jana Lozar Krivec1, Alojz Ihan1, Štefan Grosek1, Magnus Unemo5, Samo Jeverica*3

1University Medical Center, Ljubljana, Ljubljana, Slovenia, 2WHO Collaborating Centre for Gonorrhoea and other STIs, National Reference Laboratory for STIs, Department of Laboratory Medicine, Microbiology, Örebro, Sweden, 3Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, 4National Laboratory of Health, Environment and Food, Maribor, Slovenia, 5WHO Collaborating Centre for Gonorrhoea and other STIs, National Reference Laboratory for STIs, Department of Laboratory Medicine, Microbiology, Ljubljana, Sweden

Background: Group B Streptococcus (GBS) is the leading cause of invasive neonatal infection in the industrialized world. We aimed to genomically and phenotypically characterise invasive GBS isolates in Slovenia from 2001-2018 and compare them with contemporary colonising GBS isolates.

Materials/methods: One-hundred-and-fourteen invasive GBS isolates from 101 patients and 71 colonising isolates from 70 pregnant women were analysed for basic clinical characteristics, antimicrobial susceptibility and capsular serotype. Whole-genome sequencing was performed to assign multilocus sequence type (ST) and clonal complex (CC), pathogenicity/virulence factors and genome-based phylogeny. Clustered regularly interspaced short palindromic repeat (CRISPR) analysis was performed for epidemiological typing. Diagnostically important cfb region was analysed for deletions that may influence molecular diagnostic accuracy.

Results: Among invasive isolates, 41.6% and 58.4% were responsible for early-onset (EOD) and late-onset (LOD) including very late-onset disease (vLOD), respectively. All isolates were susceptible to benzylpenicillin with MIC≤0.125 mg/L. Clindamycin susceptibility was 83.6%. Overall, 7 serotypes were identified (Ia, Ib, II-V and VIII), serotype III being the predominant (59.6%). Twenty-nine MLST STs were detected that grouped into 6 CCs. The hypervirulent CC-17 was the predominant CC overall (53.2%) and within invasive (67.3%) and non-invasive (32.9%) isolates (p<0.001). It was more common among LOD (81.4%) compared to EOD (47.6%) (p<0.001). The prevalences of other CCs were 12.9% (CC-23), 11.1% (CC-12), 10.5% (CC-1), 8.2% (CC-19), 1.8% (CC-498). The remaining 2.3% of isolates were singletons. A CRISPR analysis revealed specific patterns for different CCs. CC-17 contained the shortest CRISPR loci with the lowest number of spacers. Finally, no deletions were detected in the cfb region in our study.

Conclusions: This is the first genomic characterisation of GBS isolates in Slovenia and provides a valuable background microbiological data for influencing policy changes with regards to the urgent implementation of universal screening for GBS colonisation in pregnancy. Molecular diagnostic tests based on cfb region detection can be used for this purpose. However, constant surveillance of its performance is warranted.

Abstract 2587

**Evaluation the impact of dengue infection in gestation and conception: an ecological study using time series analysis**

Otilia Lupi*, Fabiao Meque†, Daniel Villela‡, Patricia Brasil§

1Oswaldo Cruz Foundation, Instituto Nacional de Infectologia, Rio de Janeiro, Brazil, 2Oswaldo Cruz Foundation, Instituto Nacional de Infectologia, Rio de Janeiro, Brazil, 3Oswaldo Cruz Foundation, Programa de Computação Científica, Rio de Janeiro, Brazil

**Background:** The World Health Organization estimates that 40% of the world’s population lives in dengue fever (DF) endemic areas, occurring about 390 million cases/year (24% symptomatic). In the last 40 years, Brazil had recurrent epidemics, approximately 1.5 million cases/year and more than 500 deaths/year were reported between 2010 and 2016. However, the consequences of infection in pregnancy and conception are still uncertain.

**Materials/methods:** In order to demonstrate the effect of DF on the pregnancy outcomes, an ecological analytical study of time series was carried out. The time series of DF incidence in women in childbearing age, incidence of prematurity, incidence of low birth weight and prevalence of congenital malformations were constructed. In order to analyze different scenarios, in addition to Brazil, eight cities with different DF transmission rates were selected. For the analysis of the time series, a Bayesian approach was used in the construction of dynamic models that describe the series and eventual association between DF and outcomes related to the newborns. The calculation of the association measure (coefficient of effect) used the Integrated Nested Laplace Approximation (INLA) method.

**Results:** In the period between January/2001-December/2013, 2,967,606 cases of DF were reported in Brazil in women aged 10-59 years (67.38/100,000) and 38,512,280 live births were registered. A significant positive association between the incidence of DF and the incidence of prematurity was detected in Brazil and four cities. The association observed suggests that epidemiological characteristics in 2010 are relevant to explain the phenomenon. It should be noted, the huge epidemic secondary to the reintroduction of DENV-4 in Brazil, from 2010. The expansion of this serotype was earlier, intense and lasting, in the capitals where the positive association was detected, whether by direct action of primary and secondary infection in pregnancy, either by the collapse of overburdened health systems or simply by the accumulation of exposed pregnancies.

**Conclusions:** The study corroborates previous findings, signals an unprecedented evidence of no proportionality, suggesting that the observed phenomenon is multifactorial, and extrapolates previous hypothesis, which attributed exclusively to the intense inflammatory state observed in the acute phase of DF the risk of prematurity.

**Presenter email address:** otilia.lupi@ini.fiocruz.br
Abstract 2588

A novel standardised artificial sputum for external quality control of the whole TB-diagnostic workflow

Markus Beutler*1, Uladzimir Antonenka1, Fabian Gerbl1, Marina Mihalic1, Sara Plesnik1, Elena Romancenco1, Sabine Hofmann-Thiel1, Harald Hoffmann1

1Institute of Microbiology and Laboratory Medicine, Department research, education and development, WHO-Supranational Reference Laboratory of Tuberculosis, Gauting, Germany

Background: Fighting tuberculosis (TB) relies on early, fast and accurate diagnosis including resistance screening. Besides a well-equipped laboratory infra structure, external quality assessment (EQA) monitoring standard diagnostic procedures is essential for guaranteeing good laboratory performance. However, till to date there is no validated, standardized test matrix that can be used for monitoring all disciplines of sputum based TB diagnostics including smear microscopy, culture, nucleic acid extraction and PCR. Since human sputum is not easily obtainable and requires extensive pre-testing for Mycobacterium tuberculosis complex (MTBC) negativity, artificial sputum (AS) would be an alternative test matrix performing such EQAs.

Materials/methods: We have developed a novel mucin-based artificial sputum (MUCAS). MUCAS was macro- and microscopically (Ziehl-Neelsen) compared to established AS based on methyl cellulose or polyacrylamide as well as to human sputum. The performance of decontaminated MUCAS samples in MGIT and Löwenstein-Jensen (LJ) cultures was also investigated. For validating MUCAS in a clinical setting, we conducted an EQA trial including five partner laboratories in Tajikistan. The laboratories received a blinded panel of 20 MUCAS samples for LJ and MGIT culture with different H37Ra concentrations and negative controls. Samples were also analyzed in the Supranational Reference Laboratory Gauting (SNRL, Germany).

Results: In contrast to other AS, MUCAS macro- and microscopically resembled human sputum. After NALC-NaOH decontamination of spiked MUCAS samples, high loads of MTB could be recovered and LJ as well as MGIT cultures could be subsequently performed. MTB survived for up to 13 days in MUCAS, which enabled shipping of viable MTB strains to Tajikistan for EQA purposes: 4 of 5 and 2 of 5 labs had false positive and negative culture results, respectively. In one lab an extremely high MGIT contamination rate was observed (14/20). No false positive results were obtained in the SNRL. 15% of MGIT cultures were contaminated and could not be analyzed. Auramine staining was only possible with high H37Ra concentrations.

Conclusions: MUCAS is a suitable matrix for EQA panels assessing Ziehl-Neelsen microscopy, mycobacterial culture and –as previously shown– molecular diagnostics.

Multiplex detection of SNPs conferring rifampicin resistance in *Mycobacterium tuberculosis*

Florence Nazé*, Brigitte Gicquel, Pascal Mertens, Laetitia Avrain

1Coris BioConcept, Gembloux (Les Isnes), Belgium, 2Institut Pasteur, Paris, France

**Abstract third-party references:** The research leading to these results has received funding from the Seventh Framework Programme [FP7/2007/2013] under Grant Agreement n° 604237.

**Background:** Rifampicin resistance in *Mycobacterium tuberculosis* is conferred by single nucleotide polymorphisms (SNPs). These SNPs lead to different resistance levels. The detection of *M. tuberculosis* and the identification of the SNPs conferring the rifampicin resistance is of upmost importance in the control of Multi-Drug Resistant *Mycobacterium tuberculosis* (MDR-TB) infections.

**Materials/methods:** A TB/RIF test on a cartridge was developed, fitting into the TRAPIST v6 microfluidic platform that includes a continuous-flow amplification followed by an oligochromatographic detection.

A set of three fluorescent primer pairs was selected to amplify the *Mycobacterium tuberculosis* complex and two different sequences of the *rpoB* gene covering the SNPs involved in the rifampicin resistance.

One specific probe for bacterial identification and 29 different probes, distributed on 10 *rpoB* SNP positions (430-431-432-435-441-445-448-450-452-491) to detect specifically wild type (WT) as well as mutated amino acids, were spotted on a nitrocellulose membrane.

The TB/RIF tests were performed on extracted DNA from a representative panel of characterised wild type and rifampicin resistant TB strains. The dedicated equipment measures the fluorescence intensity of each spotted probe allowing the identification of the amino acid present in the sample at each *rpoB* SNP position.

**Results:** All the DNA samples were correctly identified as *Mycobacterium tuberculosis* complex strains. All amino acids at each *rpoB* SNP position were also correctly identified and are presented in the table. The amino acid detected conferring rifampicin resistance are on the black compartments.

Abstract 2590

**Impact of a training activity on collecting blood samples regarding a correct bloodstream infections diagnosis: The risks of overseeing the foundations**

Silvia Velasco De La Fuente*, Ana Rodriguez Fernandez, Vanesa Arranz García, Silvia Alonso Madrazo, Ana De Malet, Jorge Calvo-Montes

*Marqués de Valdecilla University Hospital, Microbiology Service-IDIVAL, Santander, Spain, †Marqués de Valdecilla University Hospital, Nurse-Emergency Service, Santander, Spain

**Background:** Sepsis is one of the main causes of morbidity and mortality worldwide. Community-acquired sepsis is the most frequent source placing the Emergency Service (ES) as a crucial department to improve sepsis diagnosis. Blood cultures have high clinical relevance and early microorganisms identification involved is essential for a successful management of patients. Recommendations regarding appropriate blood culture sampling are needed being the volume inoculated in flasks and the number of sets extracted the most crucial steps.

The objective of this study was to evaluate the impact of a training activity in terms of contamination rate, number of flasks and sets received in the Microbiology Service from the ED and also the number of clinically valuable bacteremia following the ESCMID-SFM Manual of Microbiology within the pre- and post-training period.

**Materials/methods:** A prospective observational study was conducted based on the elaboration and divulgence of a blood culture extraction protocol in May-2018. Nurse training sessions were carried out monthly from June-December 2018. The number of flasks and sets received from January 2017-December 2018 were obtained from the Laboratory Information System and retrospectively analyzed. Pre-training period was considered from January 2017-April 2018, and the post-training period between May-December 2018.

**Results:** Data showed an increase in the average number of flasks received between the pre- and post-training period. Regarding the number of sets, the percentage of blood cultures collected with a double extraction improved significantly. The contamination rate (contaminated flasks/total flasks*100) decreased between both periods. The monthly average of clinical valuable bacteremia also increased (Table 1). The percentage of clinical valuable bacteremia (positive blood culture/total blood culture*100) was 10.7% in the pre-period and 15.5% in the post-period, showing a significant growth.

**Conclusions:** Nurse training sessions based on a correct blood culture extraction have high clinical impact on BSIs diagnosis. More formative initiatives should be established to guarantee a correct microbiology diagnosis in this critical situations.

**Table 1:** Results before and after training sessions.

A mechanism-based pharmacokinetic/pharmacodynamic model based on pharmacokinetic and static time-kill data alone can predict the \textit{in vitro} bacterial regrowth of 3 fluoroquinolone-resistant \textit{Escherichia coli} strains after dynamic exposure

Robin Michelet* 1, Johanna Seeger1, Charlotte Kloft1

1FU Berlin, Dept. of Clinical Pharmacy and Biochemistry, Institute of Pharmacy, Berlin, Germany

\textbf{Background:} In order to prevent the further increase of antimicrobial resistance and improve current clinical dosing practices, a profound understanding of the underlying mechanisms of bacterial regrowth and their link to exposure and time is necessary. Rather than solely using metrics such as the minimal inhibitory concentration [MIC] [1], mechanism-based pharmacokinetic/pharmacodynamic (PK/PD) models can elucidate the link between exposure and response.

\textbf{Materials/methods:} In this work, data from static \textit{in vitro} infection models obtained from 3 fluoroquinolone resistant clinical isolates of the model pathogen \textit{E. coli} [MIC 8, 2 and 8 mg/L] under levofloxacin exposure, was combined with PK of dynamic time-kill curve experiments mimicking \textit{in vivo} antibiotic pressure at target site. This data was analysed using non-linear mixed effects modelling in NONMEM v.7.4, where sequentially the growth behaviour, PK, antibacterial effect and persister formation were characterised. Model selection was based on plausibility and accuracy of parameter estimates, goodness-of-fit and the log likelihood ratio test.

\textbf{Results:} A two-compartmental PK model with linear elimination linked to a bacterial growth model consisting of a growing and non-growing persister fraction best described the current data. Separate levofloxacin killing potencies (EC\textsubscript{50}) and maximum persister formation rates P\textsubscript{max} supported differences in underlying mechanisms of resistance and persistence between the strains. Indeed, two isolates with the same MIC, had vastly different killing and regrowth behaviour, which was represented by different EC\textsubscript{50} and P\textsubscript{max} values. Although model development was based solely on static experiments, the final model was then applied to predict time-kill curves generated under dynamic C(t) profiles mimicking clinically relevant dosing regimens and was able to predict the regrowth behaviour for all three strains, for one and two doses of levofloxacin.

\textbf{Conclusions:} In this work, we further underline the importance of alternative strategies beyond the MIC to investigate optimal dosing strategies of antibiotic drugs. We showed that the use of mechanism-based PK/PD modelling using \textit{in vitro} exposure-response data with multiple strains allows for elucidation of resistance and persistence mechanisms. It was shown that even for strains with the same MIC, these differences have a profound impact on efficacy of established dosing regimens.

Evaluation of Colibrí for the identification of Gram-negative bacilli

Amandine Roché, Guillaume Teissier, Rémi Fournier, Pierre Mion, Jérémy Bayette

1LABOSUD, Montpellier, France

Background: Colibrí™ is a system which automatizes the picking of isolated colonies grown on petri dishes and allows the preparation of matrix-assisted laser desorption/ionization time of flight targets. Fast and reliable identification of microorganisms is a key task in microbiology to improve time to result.

Materials/methods: A total of 92 clinical urine specimens previously selected with Gram negative bacilli (Klebsiella spp n=25, Enterobacter spp n=16, Citrobacter spp n=9, Proteus spp n=19, other Proteae group n=7, Pseudomonas aeruginosa n=12, other species n=4) were inoculated onto CHROMID®CPS elite (bioMérieux) and processed into the WASPLab® system. One colony with size > 0.6mm was selected by a technician on the image and plates were transferred to Colibrí™ for the picking of the colonies, the automatic spotting and the matrix HCCA dispensing on disposable MBT Bio targets for identification with BRUKER MALDI biontyper®. In parallel, the spotting was realized manually with the same plate using the procedure of the laboratory. Identification were compared between manual and Colibrí™ spotting. In case of discrepancy spots were realized again with both methodology for confirmation.

Results: The comparison between Colibrí™ and the manual process was evaluated on a total of 114 results (including 22 re-tests). The concordance was 78.1% (n=89). The rate of discrepancies of 21.9% (n=25) concerned in majority Klebsiella species (n=9) and Proteus mirabilis (n=6) for which no peaks was observed with a Colibrí™ spotting and a score of identification > 2 with the manual methodology. Only 5 discrepancies were confirmed by the retest without any link to a specific specie. No errors of identification were observed with Colibrí™ compared to manual spotting.

Conclusions: Colibrí™ for automatic spotting of Gram negative bacilli on disposable MBT Bio targets can be implemented in microbiology laboratory for the diagnostic of urinary tract infections with a good confidence level. The use of formic acid treatment for mucous species used in the routine of the laboratory can reduce the number of unidentified isolates observed with Colibrí™

**Whole genome sequencing for Neisseria meningitidis for health protection action**

Sharif S. M. Shaaban*, Laura Macdonald1, Heather Murdoch1, Fiona Johnston1, Roisin Ure2, Kevin Scott2, Derek Brown2, Andrew Smith2,3, Matthew Holden1,4, Claire Cameron1

1Health Protection Scotland, Glasgow, United Kingdom, 2Scottish Microbiology Reference Laboratories Glasgow, Glasgow, United Kingdom, 3University of Glasgow, Glasgow, United Kingdom, 4University of St Andrews, St Andrews, United Kingdom

**Abstract third-party references:** NHS Scotland

**Background:** Whole genome sequencing (WGS) is rapidly becoming a key component of microbial typing and outbreak tracking in public health. The highly reproducible fine discrimination offered to determine relatedness and clustering is a key advantage. However, there remain potential limitations, such as the requirement for isolates and receiving results within the time frame for health protection action. Moreover, the evidence base for what degree of genomic relatedness should trigger such action is not yet fully established.

**Materials/methods:** In Scotland, we retrospectively analysed data, from 2009-2018, to evaluate the potential impact WGS may have had for health protection purposes, had it been available real-time. This was achieved by retrospectively examining core genome MLST (cgMLST) profiles derived from WGS data for clusters that had previously been identified epidemiologically, and conversely, analysing cgMLST data to ascertain whether potentially linked cases may previously have been overlooked through traditional methods.

**Results:** Epidemiological analysis identified 10 clusters in a variety of settings. Of these, for 5, WGS could offer no further insight, as isolates were not available, or available for only one case. Four clusters were independently detected using WGS data, and one putative epidemiological cluster was dismissed using WGS data, having a difference of more than 900 alleles. In contrast, WGS detected an additional eight novel putative clusters, and an additional case for one of the existent epidemiologically defined clusters. These putative clusters have undergone further analysis to determine the likelihood of them being genuinely linked cases. However, in general, a preliminary distance threshold of ≤ 30 alleles has been deemed appropriate to initiate such further investigation.

**Conclusions:** WGS data has shown great potential in aiding public health intelligence. However, this can only be utilised when the appropriate primary samples are available. Furthermore, the thresholds at which clustering investigation is triggered, for public health purposes, and linked cases confirmed needs further definition; a challenge with an organism displaying inherent marked differences in strain variability. This analysis therefore significantly contributes to the limited evidence base, particularly the proposed analytical threshold.

**PhenoMATRIX TAG and Colibrí for a faster workflow of the management of urine specimens**

Amandine Roché¹, Guillaume Teissier¹, Rémi Fournier¹, Thibaud Bayol¹, Pierre Mion¹, Jérémy Bayette*¹

¹LABOSUD, Montpellier, France

**Background:** LABOSUD’s department of microbiology manage more than 1000 urine samples per day. PhenoMATRIX™ (expert system of the WASPLab® solution combining plate reading algorithms and clinical information from LIS system) was installed in June 2018 for the management of clinical urine specimens. In July 2019, PhenoMATRIX™TAG and Colibrí™ were added in synergy to the initial configuration. PhenoMATRIX™TAG permits to tag isolated colonies (pick point) on the image for Colibrí™ workflow. Colibrí™ automatizes the picking of isolated colonies and allows the preparation of MALDI-TOF targets, microbial suspension for antimicrobial susceptibility testing and inoculation of purity plates.

**Materials/methods:** A qualitative study was performed on 699 clinical urine samples positive to *E. coli* to determine the capabilities of PhenoMATRIX™TAG to select available isolated colonies on CHROMID®CPSE Elite incubated 16h into the WASPLAB™. Number of plates was evaluated with 0, 1, 2 and ≥ 3 colonies tagged on the image. A quantitative study was realized on 91 positive *E. coli* plates by measuring the time spent by an user for the assignment of pick points without the implementation of PhenoMATRIX™TAG.

**Results:** Among the 699 results, 96,4% [n=674] images were marked with pick points. 91,4% [n=639] were displayed with more than 3 pick points, 2,4% [n=17] with 2 pick points and 2,6% with 1 pick point. The remaining 3,6% [n=25] not tagged plates represented high concentrated isolates without any available colonies. Regarding the quantitative study, average time for picking assignment before the implementation of PHENOMATRIX™TAG was 25,8 seconds.

**Conclusions:** The performance of PhenoMATRIX™TAG allowed to tag automatically 91,4% of the plates with more than 3 pick points, saving an average time of 1h10 min per day. In addition, the high precision of Colibrí™ for the picking of the colonies enabled the suppression of the purity plate for the Antimicrobial Susceptibility Testing. Thanks to the traceability, reproducibility, accuracy of the combined artificial intelligence and Colibrí™ system, the diagnosis of urinary tract infections to *E. coli* is completely automated with a high level of confidence.

Abstract 2603

**ART24, a novel live biotherapeutic product, in development for the prevention of *Clostridioides difficile* infection (CDI) recurrence is effective in a mouse model of CDI infection**

Christopher Murphy¹, Tim Murphy², Ronald Farquhar¹, Laurent Chesnel*¹

¹Artugen therapeutics USA, Inc, Concord, United States, ²NeoSome Life Sciences, LLC, Lexington, United States

**Background:** ART24 is being investigated as a live biotherapeutic product (LBP) treatment to prevent recurrence of *Clostridioides difficile* infection (CDI) following successful antibacterial therapy. ART24 was isolated from a human fecal sample, purified and identified as a member of the *B. amyloliquefaciens/B. velezensis* group. We have determined that the strain has potent *C. difficile* killing activity *in vitro* and sought to determine if this activity translated in an *in vivo* infection model setting.

**Materials/methods:** A series of independent studies were conducted in a mouse model of *C. difficile* infection. These studies were modeled to simulate clinical conditions and determine the efficacy of orally-dosed ART24 as measured by adverse clinical signs, body weight loss, and mortality. Mice received an antibiotic cocktail for eight consecutive days in the drinking water. Five days prior to *C. difficile* infection, the antibiotic water was removed. Animals were placed in clean cages and sterile drinking water provided to the mice. Three days prior to infection with *C. difficile*, mice were dose with Clindamycin at 10 mg/kg via oral gavage in a volume of 10 mL/kg. Mice were dosed with 5x10⁸ ART24 CFU QD or TID, or saline for 10 days starting 1 day prior to infection and until study day 9. Animals were infected with *C. difficile* strain ATCC 43255 (6.3x10⁵ to 1.97x10⁶ CFU) via oral gavage. A total of 65 and 40 mice were treated with ART24 and saline respectively across the 3 studies conducted.

**Results:** Oral gavage of freshly cultured ART24 cells demonstrated protective effects in animals subsequently infected with *C. difficile* with improved survival (90% in ART24 dosed groups versus 70% in the saline control group), and a reduction in disease-related clinical observations including weight-loss, wet tail, diarrhea, hunched posture, dehydration and lethargy. ART24, washed and resuspended in sterile PBS, had equivalent efficacy in this infection model.

**Conclusions:** ART24 is efficacious in a mouse model of CDI. ART24 is a promising LBP clinical candidate being assessed for safety in a Phase 1 trial in recently cured CDI patients.

**Abstract 2608**

**Not all candidaemias are the same: utility of a rapid identification**

Christian Leli¹, Luigi Di Matteo¹, Simone Busso¹, Valeria Cavallo¹, Andrea Roccetti*¹

¹Azienda Ospedaliera SS. Antonio e Biagio e Cesare Arrigo, Alessandria, Italy, EU, Microbiology and Virology Unit, Alessandria, Italy

**Background:** Fungemia is a serious life-threatening illness associated with high mortality. The gold standard for the diagnosis of fungemia is blood culture. Conventional biochemical methods for species identification typically take from 24 to 72 hours and a delay of 12 to 48 hours in appropriate antifungal therapy is associated with an increased risk of mortality. Rapid identification of fungi allows a more targeted empirical therapy and a better outcome of the patient, given the different antifungal susceptibility profile of some species. For these reasons, all blood cultures positive for fungi during the period from June 2015 to October 2019 were tested by means of a multiplex Real-Time PCR for rapid identification.

**Materials/methods:** All blood cultures positive for fungi by microscopic examination after Gram staining underwent FilmArray blood culture identification panel, standard culture, identification by means of Vitek 2 and antifungal susceptibility testing by broth microdilution. Only blood cultures positive for single Candida species were included in the study. Median values of C-reactive protein and complete blood count from samples drawn concurrently with blood cultures were also evaluated.

**Results:** A total of 71 blood cultures were included in the study. The frequency of isolates was: *Candida albicans*: 34 (47.9%); *Candida glabrata*: 17 (23.9%); *Candida parapsilosis*: 16 (22.6%); *Candida tropicalis*: 4 (5.6%). The agreement between FilmArray and Vitek 2 was of 100%. Respectively for *C. albicans*, *C. glabrata*, *C. parapsilosis* and *C. tropicalis*, a significant difference was found among median values of age: 69 vs 80 vs 61 vs 61 years (*p*<0.05); C-reactive protein: 9.9 vs 21.3 vs 8.3 vs 11.9 mg/dl (*p*<0.05); neutrophils: 7840 vs 10480 vs 4920 vs 4950 cells/microliter (*p*<0.012); neutrophil/lymphocyte ratio: 6.9 vs 18.1 vs 4.3 vs 5.0 (*p*<0.02). We found a significant greater proportion of *C. glabrata* isolates resistant to fluconazole: 8/17 (47.1%; chi square: 29.6; *p*<0.0001) and of *C. parapsilosis* isolates resistant to both anidulafungin: 11/16 (68.8%; chi square: 49.7; *p*<0.0001) and micafungin: 6/16 (37.5%; chi square: 26.6; *p*<0.0001).

**Conclusions:** In this study we found a greater inflammatory state associated with *C. glabrata* fungemia, possibly due to older age and underlying disease.

Abstract third-party references: NHS Scotland

Background: For whole genome sequencing (WGS) to transform pathogen typing, outbreak detection, resistance calling, and source attribution, its high-resolution discrimination must be applied appropriately to the clinical and public health questions being addressed. We have developed a fully integrated “end-to-end” process that is defined from the selection and transmission of samples to the reference laboratory, through the technical and bioinformatic pipelines, to the epidemiological actions implemented as a result of this activity. Chosen exemplars organisms include species with different molecular biology and clinical time lines, and with a diversity of clinical questions to be addressed.

Materials/methods: Pathogen sequencing is being implemented in Scotland in a collaboration between the Microbiology Reference laboratories, Health Protection Scotland (HPS), and the National Services Division (NSD). We describe the service through a total of 32 documents covering all aspects for the process including a service objective, sampling, laboratory protocols, data analysis, turnaround time, data sharing, operational capacity and quality control standards. This approach has now been applied to Neisseria meningitidis, with Mycobacteria spp. and Streptococcus pneumoniae following closely behind.

Results: The service has already yielded data used to track and trace outbreaks, as well as inform public health actions. Examples of these are common for STEC, Salmonella spp. and Shigella spp., for which the WGS service is fully established. The insights gained from working with these examples are used to supplement and improve the service for other organisms (such as current work attempting to determine the best use and results of WGS clustering for Neisseria meningitidis).

Conclusions: The ambition is to provide a seamless pathogen sequencing service from patient to clinical and public health action. We have found this approach to be effective in generating a sense of direction and focus on patient and public health deliverables. We believe this will be of value to others contemplating the introduction of pathogen sequencing service for public health benefit.

The difference in mortality between adult patients with laboratory-confirmed influenza A and B, a single centre observational study

Diana Ayoola Mabayoje*, Teresa Cutino-Moguel1, John Haigh1, Mark Wilks1, Catherine Welch2, Mark Melzer1

1Barts Health NHS Trust, London, United Kingdom, 2University of Leicester, Leicester, United Kingdom

Background: Seasonal influenza is an annual occurrence that leads to large community outbreaks and increased hospitalisation with significant morbidity and mortality due to complications such as secondary bacterial pneumonia. A number of studies have suggested that influenza A (IFA) is associated with increased rates of hospitalization and mortality compared to influenza B (IFB). Whipps’ Cross Hospital serves an ethnically diverse population of approximately 350,000 people in East London. During the 2017 to 2018 influenza season, moderate to high levels of influenza activity were observed in the United Kingdom with a high proportion of IFB circulating. The aim of this study was to compare demographic and clinical variables, including severity of infection and mortality, in patients diagnosed with IFA or IFB during the 2017 to 2018 UK influenza season.

Materials/methods: Patient demographic and clinical information were obtained by accessing electronic and paper medical records of patients testing IFA or IFB positive using the Cepheid GXP. We used $\chi^2$ test to compare these variables in patients with laboratory confirmed IFA and IFB.

Results: 127 adult patients had confirmed influenza, 71 (55.9%) had IFA and 56 (44.1%) IFB. 93 (73.2%) of patients diagnosed were over 60. 104 (81.9%) patients had underlying medical co-morbidities. 23 (32.4%) patients with IFA and 17 (30.4%) patients with IFB had a documented complication, most commonly bacterial pneumonia. There was no significant difference between severity at presentation, need for supplementary O2, admission to HDU/ITU or median length of stay. The overall mortality rate was 4.7% (6/127 patients) and 7.1% (9/127 patients) at 7 and 30 days respectively. There was a statistically significant difference in 7-day mortality between patients with IFA (1/71 patients, 1.4%) compared with IFB (5/56 patients, 8.9%) ($p = 0.047$) although this became non-significant at 30 days.

Conclusions: We did not observe significant differences in severity, length of stay, rates of hospitalization or rates of complication between patients with IFA and IFB. There was a statistically significant higher 7-day mortality in patients with IFB which was not apparent at 30 days.

Evaluation of targeted antifungal prophylaxis after liver transplantation: are echinocandins the optimal choice?

Matteo Rinaldi*, Michele Bartoletti¹, Alberto Ferrarese², Erica Franceschini³, Caterina Campoli¹, Simona Coladonato¹, Simone Ambretti³, Antonio Siniscalchi³, Maria Cristina Morelli³, Matteo Cescon¹, Patrizia Burra¹, Cristina Mussini³, Russell E. Lewis¹, Pierluigi Viale¹, Maddalena Giannella³

¹Policlinico Sant’Orsola-Malpighi, University of Bologna, Bologna, Italy, ²Padua Hospital, Padova, Italy, ³Policlinico of Modena University Hospital of Modena, Modena, Italy

**Background:** Targeted antifungal prophylaxis (TAP) is considered the optimal strategy for prevention of invasive fungal infection (IFI) in patients undergoing liver transplant (LT). However, feasibility and efficacy of such an approach has been scarcely investigated.

**Materials/methods:** Prospective cohort study of consecutive adult patients undergoing LT at three Italian hospitals, from January 2015 to December 2018. During the study period, a common TAP protocol was followed in the participating centers. Patient were classified as having no risk (NR), low risk (LR) and high risk (HR) for IFI with indication to receive no prophylaxis, fluconazole (7-14 days) and anti-mold drug (21 days), respectively. Endpoint variable was IFI diagnosis, defined according to EORTC criteria, within 1-year after LT. IFI breakthrough (IFI-B) was defined as IFI occurring within ≤1 dosing interval after drug discontinuation.

**Results:** We included 485 LT patients: median age 56 (IQR 49.61) years, median MELD at LT 17 (IQR 12.25). IFI-risk class distribution was NR, LR and HR in 31.8%, 20.8% and 47.4% of cases, respectively. Antifungal prophylaxis was administered to 220 patients, with an overall compliance to TAP protocol of 64.1%, which raised to 71.7% among HR patients. The drugs used for TAP were echinocandins (110, 50%), liposomal amphotericin-B (88, 40%) and fluconazole (22, 10%). TAP median duration was 13 (IQR 7-20) days. IFI was diagnosed in 29 patients (6%), comprising 17 invasive candidiasis (IC) and 12 invasive aspergillosis (IA). Median time to IC and to IA was 12 (IQR 3.5-34.5) and 28.5 (IQR 12.5-81.3) days after LT, respectively. Eleven patients presented with an IFI-B, 9 of them during echinocandin TAP. Multivariate analysis adjusted for HR class, adherence to TAP, and echinocandin use, showed that only HR class was independently associated with IFI development (HR 3.02, 95%CI 1.2-7.5, p=0.017). However, there was a trend toward higher IFI risk in patients receiving echinocandins (see Figure).

**Conclusions:** We confirm TAP as a feasible and effective strategy to prevent IFI in LT recipients. Concerns about the use of echinocandins for TAP is rising due to their trend toward higher cumulative risk of IFI, mostly IFI-B.

**Presenter email address:** mat.rinaldi1989@gmail.com
Head-to-head comparison of analytical sensitivities of BD MAX MDR-TB, Xpert MTB/Rif Ultra and FluoroType MTB using human and artificial sputum

Markus Beutler1, Sara Plesnik1, Marina Mihalic1, Laura Olbrich2, Norbert Heinrich2, Samuel Schumacher1, Michael Lindner4, Ina Koch1, Wolfgang Grasse6, Christoph Metzger-Boddien1, Sabine Hofmann-Thiel1, Harald Hoffmann2

1Institute of Microbiology and Laboratory Medicine, Department IML red GmbH, WHO-Supranational Reference Laboratory of Tuberculosis, Gauting, Germany, 2Ludwig Maximilian University, Division of Infectious Diseases and Tropical Medicine, Munich, Germany, 3Foundation for Innovative New Diagnostics, Geneva, Switzerland, 4Asklepios Fachkliniken, Gauting, Germany, 5gerbion GmbH & Co. KG, Kornwestheim, Germany

Background: A new generation of fully automated molecular tests for pulmonary tuberculosis (TB) has been recently launched with Xpert MTB/Rif Ultra [XP-Ultra] and BD-MAX MDR-TB [BD-MAX]. However, data regarding the performance of BD-MAX and the comparability of both assays based on experiments using the same defined test matrix are scarce. For the sake of comparability, it is indispensable for such studies to use the same test matrix. Since larger pools of human sputum are not easily obtainable and expensive to check for Mycobacterium tuberculosis complex (MTBC) negativity, artificial sputum highly resembling human sputum would be a valuable alternative.

Materials/methods: We have investigated the analytical sensitivities [LoD95] of BD-MAX and XP-Ultra in comparison to the well-established FluoroType MTB (FT-MTB). We have further introduced a novel, human-sputum like, mucin-based artificial sputum (MUCAS) that was used as test matrix and compared to human sputum as well as physiological saline solution each spiked with MTB in declining culture- and qPCR-controlled concentrations.

Results: With BD-MAX, XP-Ultra, and FT-MTB, we measured LoD95 values of 2.1 cfu/ml [CI95%: 0.9 – 23.3], 3.1 cfu/ml [CI95%: 1.2 – 88.9], and 52.1 cfu/ml [CI95%: 16.7 – 664.4] in human sputum; of 6.3 cfu/ml [CI95%: 2.9 – 31.8], 1.5 cfu/ml [CI95%: 0.7 – 5.0], and 30.4 cfu/ml [CI95%: 17.4 – 60.7] in MUCAS; and of 2.3 cfu/ml [CI95%: 1.1 – 12.0], 11.5 cfu/ml [CI95%: 5.6 – 47.3], and 129.1 cfu/ml [CI95%: 82.8 – 273.8] in saline solution, respectively. LoD95 of resistance markers were 9 to 48 times higher compared to LoD95 TB.

Conclusions: BD-MAX and XP-Ultra performed equally and had a significantly increased analytical sensitivity compared to the FT-MTB. MUCAS showed characteristics like human sputum while normal saline differed significantly. MUCAS would be an excellent standardized sputum-like test matrix for quality control of TB-PCR assays.

Abstract 2614

**In vitro synergy of isavuconazole in combination with colistin against Candida auris**

Patrick Schwarz*1,2, Anne-Laure Bidaud3, Eric Dannaoui3,4

1University Hospital Marburg, Department of Internal Medicine, Respiratory and Critical Care Medicine, Marburg, Germany,
2Philipps University Marburg, Center for Invasive Mycoses and Antifungals, Marburg, Germany, 3Hôpital Européen Georges Pompidou, Unité de Parasitologie-Mycologie, Paris, France, 4Hôpital Henri Mondor, Faculté de Médecine, Working Group Dynamyc, Créteil, France

**Background:** *Candida auris* is an emerging, multidrug-resistant, pathogenic yeast, associated with invasive infections, hospital outbreaks and a high mortality rate. Colistin is a polypeptide antibiotic from the class of polymyxins with activity against gram-negative bacteria. Colistin has also shown *in vitro* activity against some fungi. The aim of the present study was to assess the *in vitro* interaction of the broad-spectrum azole isavuconazole with colistin against clinical *C. auris* isolates.

**Materials/methods:** A panel of 14 clinical *C. auris* isolates from the culture collection of the Westerdijk Fungal Biodiversity Institute were used for the experiments. Combinations of isavuconazole with colistin were tested by a broth microdilution checkerboard technique based on the EUCAST reference methodology. Plates were read spectrophotometrically, and fifty percent of inhibition was used as an endpoint for both, the drugs alone and in combination. Results were interpreted with the fractional inhibitory concentration index (FICI). Drug interactions were defined as synergistic (FICI≤0.5), indifferent (FICI>0.5≤4) or antagonistic (FICI>4). Results were also interpreted by the Bliss interaction model for visualization of the interaction. A reference surface was evaluated from the dose-response curves of each of the two agents, and eventually, the synergy levels were mapped on the experimental combination dose-response surface.

**Results:** By EUCAST methodology, isavuconazole MICs ranged from 0.004 to 1 µg/ml (geometric mean MIC of 0.21 µg/ml). When tested alone, colistin exhibited no antifungal activity with MICs of 1 28 µg/ml for all isolates. Combination of isavuconazole with colistin was synergistic for all isolates with FICIs ranging from 0.31 25 to 0.5. Interpretation by the Bliss interaction model led to synergy for 10/1 4 (7 1%) of the isolates. All other interactions were indifferent. Antagonism was never seen whatever interpretation model used.

**Conclusions:** Combination of isavuconazole with colistin interpreted by the FICI showed strong synergy against all tested isolates and for the majority of isolates interpreted by the Bliss model. Confirmation of the *in vitro* synergistic interaction of isavuconazole with colistin by another technique (e.g. gradient concentration strips) and *in vivo* is warranted.

**Presenter email address:** patrick.schwarz@med.uni-marburg.de
Abstract 2616

Challenges in investigation and control of invasive group A Streptococcus outbreaks associated with community health services delivered at home

Laura Nabarro*1, Colin Brown1, Derren Ready1, Rachel Mearkle1, Esther Robinson1, Sooria Balasegaram1, Valerie Decraene1, James Elston1, Ashley Popay1, Peter Hoffman1, Bharat Patel1, Pauline Harrington1, Susan Hopkins1, Ashley Popay1, Peter Hoffman1, Bharat Patel1, Pauline Harrington1, Susan Hopkins1, Theresa Lamagni1

1Public Health England, London, United Kingdom

Abstract third-party references: Public Health England

Background: In England, a substantial proportion of healthcare, particularly wound management, is delivered by community health services delivered in the patient’s home (CHSDH). This presents unique infection control challenges. Since 2010, Public Health England has identified 16 outbreaks of invasive group A Streptococcus infection (iGAS) associated with CHSDH. This study describes these outbreaks to inform future public health actions.

Materials/methods: We included outbreaks detected between 1st January 2018 and 30th September 2019 involving ≥2 cases of iGAS infection of same emm type, linked to the same CHSDH service. We excluded outbreaks where other exposures offered a more plausible route of transmission. We interviewed the chair of each outbreak control team, with data collected through transcribed recordings using a standardized semi-structured questionnaire.

Results: We identified nine outbreaks involving 87 cases and 27 deaths (31%). Patients’ median age was 82y; 91% had received wound care. Outbreaks varied in size from 2-39 cases (median 6) and lasted from 3 to 487d (median 179d), with significant intervals between identified cases (range 0-163d). Six outbreaks identified cases through retrospective investigation (median 2.5, range 2-7). Investigations included enhanced questionnaires (7/9), network analysis (7/9), whole genome sequencing (WGS, 6/9) and screening of equipment (2/9), staff (9/9) and patients (2/9). Of 8 outbreaks with data available, 296 (median 19, 1 positive, 0.35%) staff were screened (throat and skin lesions). Specific routes of transmission were not identified.

Multiple interventions were utilised including enhanced infection control (9/9), equipment change (3/9) and penicillin V prophylaxis to HCW (7/9). Difficulties obtaining information from CHSDH services, screening and treating staff together with inadequate occupational health support, resulted in delays to investigation and implementation of control measures. Investigating teams emphasized the importance of asking about CHSDH involvement in all community iGAS cases together with role of emm type monitoring and WGS in investigation of possible outbreaks.

Conclusions: CHSDH associated iGAS outbreaks are increasingly identified in the UK with high mortality rates in vulnerable populations. Further work is needed to establish the optimal investigation and management of these outbreaks.

Biofilm production by Gram-negative bacilli isolated from periprosthetic joint infections

Alicia Macías-Valcayo*, John-Jairo Aguilara-Correa1, Jaime Esteban-Moreno1

1Fundacón Jiménez Díaz University Hospital, Madrid, Spain

Abstract third-party references: Funded by SEIMC (Project COLBETA)

Background: Prosthetic joint infection (PJI) occurs in 1-2% of arthroplasties and is a leading cause of prosthetic failure. Most PJI are caused by staphylococci, but there is a significant increase in the proportion of PJI caused by aerobic Gram-negative bacilli (GNB) during the last years. Our aim was to determine the ability of GNB isolated from PJI to develop biofilm.

Materials/methods: Sixty-six strains isolated from consecutive patients with PJI were used. All PJI were diagnosed according to internationally accepted criteria. The samples came from hip (53.03%), knee (34.84%), shoulder (3.03%) and elbow (3.03%) infection, osteosynthesis-associated infection (4.54%) and vertebral abscess infection secondary to vertebral surgery (1.51%). The biofilm formation was evaluated using a modified method of Stepanovic et al. static biofilm assay (APMIS 2007, 115 (8): 891-9), using TSB + 1% glucose with a bacterial inoculum of 10⁶ CFU/mL at 37ºC for 24 h under static and aerobic conditions and safranin for staining. Biofilm formation of isolates was based on the optical density (OD) of each strain and the optical density control (ODc) measured at 570 nm, and classified into weak (ODc<OD<2xODc), moderate (2xODc<OD<4xODc), and strong (OD>4xODc) biofilm-former.

Results: The obtained results are shown in Table 1.

Conclusions: All of the studied strains were biofilm producer, mostly moderate-strong ones. Noteworthy, P. aeruginosa was the strongest non-fermentating GNB biofilm producer and M. morgnii was the strongest fermentating GNB biofilm producer.

Genomic characterisation of *Kerstersia gyiorum*, an isolate from a patient with acute otitis media

Alexander Kruglov¹, Vladimir Gostev²,³, Daria Likholetova²,³, Olesya Generalova⁴, Sergey Sidorenko²,³

¹City Hospital No 24, Moscow, Russian Federation, ²Pediatric Research and Clinical Center for Infectious Diseases, Saint Petersburg, Russian Federation, ³North-Western State Medical University named after I.I Mechnikov, Saint Petersburg, Russian Federation, ⁴Saint-Petersburg State University, Saint Petersburg, Russian Federation, ⁵National Agency for Clinical Pharmacology and Pharmacy, Moscow, Russian Federation

**Background:** *Kerstersia gyiorum* is a Gram-negative aerobic motile bacillus of *Alcaligenaceae* family. There are about 16 reports on *K. gyiorum* isolation and most of them associated with infectious diseases in human.

**Materials/methods:** The *K. gyiorum* strain Kg_1_17 was recovered from an adult male with acute otitis media (AOM) in Moscow in 2017. Patient was successfully treated with levofloxacin and 3rd generation cephalosporin. The culture was identified with MAL-DI-TOF MS (Bruker Daltonics). MICs of antibiotics were determined by broth microdilution. MiSeq (illumina) and MinION (Oxford Nanopore) were used for complete genome sequencing. Genome was assembled using Unicycler, followed by RAST annotation.

**Results:** The isolate Kg_1_17 was identified by Biotyper software with score 2.3. The MICs of amikacin, gentamicin, ceftazidime, cefotaxime, meropenem, imipenem, doripenem, tigecycline and polymyxin B were below EUCAST epidemiological cut-off for *Pseudomonas aeruginosa*. Evaluated ciprofloxacin MIC [4 mg/L] correlated with substitutions in *gyrA* and *gyrB*. 3,574 coding sequences were annotated in genome of *K. gyiorum* (length 3,879,169 and GC% - 62.5), including nine rRNA genes, 55 tRNA, 97 1 hypothetical genes and one intact bacteriophage (76% identity with *Burkholderia* phage phi644-2). Annotated operons grouped by function and marked on legend are shown in the Figure. Extrachromosomal elements were not identified. Mobilome consisted of two transposons and 87 IS elements of 20 types. A number of potential resistance mechanisms were identified: CatB (phenicol resistance) and several efflux systems. Four putative beta-lactamases [PBL] of A- and C-like classes [two genes] and metallo-beta-lactamase were found. Analysis of protein sequence of A-like class PBL demonstrated 44-48% amino acids similarity with *Fusarium* spp. Structural comparison of all PBL show high similarities with *Methanothermobacter thermautotrophicus*, *Caulobacter crescentus*, *Veillonella parvula*, and *Burkholderia gladioli* lactamases. Putative virulence genes included: phospholipase C (*plcH*) which suppresses neutrophil respiratory burst, motility- and chemotaxis – associated genes (*cheA*, *cheB*, *cheW*, *cheY*, *flaN*). Genome comparison of isolate Kg_1_17 with public available *K. gyiorum* sequences shown high nucleotide similarity.

**Conclusions:** Identified genome markers along with previous studies allows to consider *K. gyiorum* as potential human pathogen and causative agent of AOM. Further study is needed for understanding biology and pathogenicity of this microorganism.
Ten years of antimicrobial stewardship in a tertiary care hospital in northern Italy

\(^1\)Bolzano, Antimicrobial Stewardship Program, Bolzano, Italy

**Background:** Antimicrobial Resistance (AMR) is a global threat, due to overuse or misuse of antibiotics, among other causes. We summarize the results of the first 10 years of the antimicrobial stewardship program (ASP) implemented in our 750-bed tertiary care hospital in Northern Italy.

**Materials/methods:** The ASP started being implemented in 2007 and from 2009 data were regularly analyzed and fed back to all stakeholders. This approach still encompasses daily ID consultation, microbiological surveillance, front- or back-end antibiotic provision by the pharmacy service, and constant activity by the Infection Control and Prevention staff. Susceptibility data are from first blood culture isolates per patient per year and results were interpreted according to CLSI until 2010 and EUCAST from 2011. Due to low numbers, isolates were pooled on a 2-year basis; statistical significance was calculated by MedCalc.

**Results:** Table shows the most relevant pathogens with respective resistance patterns in the first and last biennium. Significant decreases in resistance were observed; only resistance to cefotaxime and ciprofloxacin in *K. pneumoniae* increased significantly. These results are paralleled by the lowest antibiotic consumption over time in our Autonomous Province, compared to all other Italian regions.

Abstract 2624

**Clostridioides difficile** burden of disease in adults: early experiences of a prospective population-based surveillance study of hospitalised CDI cases in the inpatient module of the City of Louisville Diarrhoea (CLOUD) study

Senen Pena-Oliva¹, Stephen Furmanek¹, Ruth Carrico¹, Joann Zamparo², Elisa Gonzalez*², Julio Ramirez¹

¹University of Louisville, Division of Infectious Diseases, Louisville, United States, ²Pfizer Vaccines, Medical Development and Scientific/Clinical Affairs, Pfizer Vaccines, Collegeville, United States

Abstract third-party references: This study was sponsored by Pfizer, Inc. On behalf of the CLOUD Louisville Study Group.

**Background:** Laboratory diagnosis of **Clostridioides difficile** infection (CDI) relies on stool specimen collection from patients with diarrhea. Since many patients with diarrhea do not have a stool specimen collected, the incidence of laboratory-confirmed CDI cases may be underestimated. To understand the extent of CDI underdiagnosis among inpatients, we implemented a prospective population-based surveillance study of hospitalized patients with new-onset diarrhea in all nine adult hospitals in Louisville, Kentucky. Our objective is to present early experiences of surveillance from the inpatient module of the City of Louisville Diarrhea (CLOUD) study.

**Materials/methods:** Surveillance officers in each hospital identify all cases of new-onset diarrhea (≥3 loose stools within 24 hours, Bristol stool form scale 5-7) among eligible inpatients (Louisville resident >50 years of age) and obtain informed consent. Stool samples from consenting patients are tested at the University of Louisville reference laboratory for 1) glutamate dehydrogenase (GDH) and 2) **Clostridioides difficile** toxins A and B using C. DIFF QUIK CHEK COMPLETE®, Techlab. Here we report laboratory results from the first sixty days of surveillance.

**Results:** Surveillance for the study period was a total of 26,356 eligible patient-days (Figure 1). A total of 573 eligible patients had new-onset diarrhea, corresponding to 2.2 cases of new-onset diarrhea per 100 eligible patient-days. We enrolled 74% (425/573) of eligible patients with new-onset diarrhea and tested stool samples for **C. difficile** from 90% (382/425) of enrolled patients, for a testing density of 1.45 per 10,000 patient-days. Of the 382 tested stool specimens, 30 (8%) were GDH positive/toxin positive, 65 (17%) were GDH positive/toxin negative.

**Conclusions:** New-onset diarrhea was common among inpatients >50 years of age. Stool specimens collected from eligible inpatients with new-onset diarrhea found that 8% had CDI (GDH positive/toxin positive) and **C. difficile** was identified in the stool specimens of an additional 17% inpatients. Further analysis of these data, and the continuation of the CLOUD Study in Louisville will contribute to a better understanding of the frequency of CDI underdiagnosis and the burden of CDI in the United States.

**NDM-1 emerging on distinct plasmid backbones from the IncL/M family**

Maria Lopez*1,2, Nicholas Ellaby1, Neil Woodford1, Maria Tomas2, Matthew Ellington1

1Public Health England, London, United Kingdom, 2INIBIC, A Coruña, Spain

*Background:* The global pandemic of the OXA-48 carbapenemase among genetically diverse Enterobacterales has been associated with the dispersal of IncL/M based plasmids. The emergence of other carbapenemases on IncL/M plasmids raises concerns that these plasmids could facilitate further pandemics of carbapenemases. Here we describe the emergence of NDM-1 on distinct IncL/M plasmid backbones and compare the emergent plasmids with the pandemic OXA-48 encoding plasmids.

*Materials/methods:* Reference sequences for complete IncL/M plasmids (23) from NCBI were compared against long-read sequences (11) from carbapenemase-producing Enterobacterales (CPE) isolates referred to PHE’s AMRHAI Reference Unit (2015-19). Bioinformatic tools were used to annotate resistance genes and compare plasmids.

*Results:* IncL/M plasmid and long-read sequences lengths ranged between 60,145bp and 98,533bp, there were 41 core-genes (at 95% similarity), reflecting between 50% and 34,45% of the plasmid lengths. Plasmid backbone areas were contiguous and highly conserved whilst the resistance regions were highly variable and confounded whole plasmid sequence comparisons. A widely divergent phylogenetic tree was reconstructed from the plasmid core-genes which allowed the visualization of the NDM-1 gene on plasmids from distinct clades, indicating the gene has been acquired by IncL/M plasmids more than once. Both NDM-1 IncL/M plasmid clades were distinct from the OXA-48 plasmid clade, but the NDM-1 encoding plasmids from both clades have been found isolated from clusters in diverse Enterobacterales in different locations in the UK.

Comparison of the resistance regions around the NDM-1 gene indicate that it is contained inside a Tn3-like transposon based complex class-I integron, and that variants of the same resistance integron have been acquired by the plasmids in the different branches of the IncL/M plasmid family.

*Conclusions:* The inclusion of long-read sequences in the analysis of IncL/M family has provided the data necessary to determine a constructed core genome with which to better understand the emergence of the NDM-1 gene in distinct plasmids which might otherwise have been considered related. For the IncL/M family of plasmids, separate analysis of core-genes and resistance regions enables a greater understanding about the dispersion and success of these plasmids.

Abstract 2627

**Antimicrobial susceptibility of non-pigmented rapidly growing mycobacteria**

1Fundacion Jimenez Diaz University Hospital, Madrid, Spain

**Background:** Non-pigmented rapidly-growing mycobacteria (NPRGM) can cause human infection. Susceptibility testing is recommended because patterns variability.

**Materials/methods:** Susceptibility data collected from NPRGM isolated between 2011 and 2019 were included. Isolates were recovered from different body locations. Species identification was performed using GenoType CM, AS and NTM-DR, kits (Hain Lifescience GmbH, Germany). Susceptibility testing was performed by broth microdilution method according to the CLSI standards (Sensititre microtiter trays, Thermo Scientific, USA).

**Results:** 149 strains were included: *Mycobacterium fortuitum* complex [72], *M. mucogenicum* complex [24], *M. chelonae* [22], *M. abscessus* complex [11], *M. abscessus* ssp. *abscessus* [11], *M. abscessus* ssp. *massiliense* [7], *M. peregrinum* [1] and *M. phocaicum* [1]. Results are shown in Table 1. Amikacin, tigecycline and linezolid were the most effective antimicrobial agents.

**Background:** Gram-negative bacteremia is associated with increased morbidity and mortality in hospitalized patients. The worldwide incidence of Gram-negative bacteremia has increased over the last decades. The main focus of current management guidelines is interventions dealing with the reduction of short term mortality. Data regarding functional capacity among survivors are limited. We aimed to determine risk factors for functional decline at 90 days among survivors of Gram-negative bacteremia and to evaluate the rate of functional decline in these patients.

**Materials/methods:** This was an observational prospective cohort study based on recently published randomized controlled trial (RCT) conducted in 3 centers in Israel and Italy between 2013 and 2017. Hospitalized patients with Gram-negative bacteremia who survived until day 90 and were not bedridden at baseline were included. The primary end point was functional decline at 90 days.

**Results:** Five hundred and nine patients were included. The median age of the cohort was 71 years [interquartile range [IQR], 60–80 years], 46.4% [236/509] were male and 352 of 509 (69%) patients were independent at baseline. Functional decline at 90 days occurred in 24.4% of patients (124/509). In multivariable analysis; older age [OR, 1.03; for an one-year increment, 95% CI 1.01-1.05], functional dependence in instrumental activities of daily living (IADL) at baseline [OR, 4.64; 95% CI 2.5-8.6], low Norton score [OR, 0.87; 95% CI 0.79-0.96] and underlying comorbidities as cancer [OR, 2.01; 95% CI 1.14-3.55], chronic pulmonary disease [OR, 2.23 95% CI 1.12-4.42] and longer length of hospital stay [OR 1.09; for one-day increment, 95% CI 1.04-1.15] were associated with functional decline. Appropriate empirical antibiotic treatment was associated with lower rates of functional decline within 90 days [OR, 0.4; 95% CI 0.21-0.78].

**Conclusions:** We have examined the degree of functional decline and its risk factors in patients surviving bloodstream infections. These patients have poor long term trajectories after clinical recovery and hospital discharge. This has vast implications for patients, their family members and health policy makers.

**Presenter email address:** aditur88@gmail.com
Abstract 2630

**Efficacy of ceftobiprole for Pseudomonas aeruginosa hospital-acquired pneumonia in critically ill patients: a pharmacokinetic-pharmacodynamic evaluation**

Camille Mane*1, Véronique Duhalde2, Guillaume Martin-Blondel1,2,3, Didier Concordet1, Peggy Gandia1,2

1INTHERES, Université de Toulouse, INRA, ENVT, Toulouse, France, 2Toulouse University Hospital, Toulouse, France, 3U1043, INSERM, Toulouse, France

**Background:** Ceftobiprole is a new generation antibiotic indicated as a 2-hour infusion of 500 mg q8h in the treatment of community-acquired and hospital-acquired pneumonia (excluding ventilator-acquired pneumonia). This indication includes Gram-positive and Gram-negative pneumonia such as Methicillin-Resistant Staphylococcus aureus (MRSA) and *Pseudomonas aeruginosa* pneumonia. In critically ill patients, no further dose adjustment than a 4-hour infusion in patients with high glomerular filtration rate is recommended despite pharmacokinetic modification in those patients.

The objective of this study was to determine the efficacy of different ceftobiprole dosing regimens for *Pseudomonas aeruginosa* pneumonia, based on a pharmacokinetic-pharmacodynamic (PK-PD) criterion.

**Materials/methods:** Published ceftobiprole population pharmacokinetic models were screened and the most relevant model based on available construction and validation parameters selected. Simulations of kinetic profiles were performed using this model for different situations: 4 doses (500, 1 000, 1 500 and 2 000 mg), 4 infusion times (2, 4, 6 and 8h) and different renal functions (normal Glomerular Filtration Rate (GFR), high GFR (160 mL/min) and low GFR (10 mL/min).

For each situation, the percentage of simulated PK profiles meeting the PK-PD target applied in the intensive care unit was calculated (i.e. probability of target attainment). The PK-PD target is an unbound plasma concentration over 4 times the Minimal Inhibitory Concentration (MIC) of the causative bacteria for 100% of the dosing interval (100% fT> 4 MIC). In the absence of a validated ceftobiprole breakpoint for *P. aeruginosa*, the EUCAST breakpoint for non-defined species (4 mg/L) was applied.

**Results:** Simulations were performed using the Muller et al. model [AAC,2013]. With the usual dosing regimen (2-hour infusion of 500 mg q8h), 1%, 0.6% and 25% of simulated profiles reached the PK-PD target for patients with normal, high or low GFR, respectively. With a normal GFR, the PK-PD target is reached for at least 90% of simulated profiles when an 8-hour infusion (i.e. continuous infusion) of 1 500 mg q8h ceftobiprole is applied.

**Conclusions:** These results challenge the efficacy of the currently recommended dosage of ceftobiprole administered to critically ill patients treated for pneumonia.

**Presenter email address:** mane.c@chu-toulouse.fr
Validation and exploration of HldE: a promising target for antibiotic potentiation in Gram-negative bacteria

Sandra Silve1, Yassine Cherrak1, Jon Hansen1, Thierry Vermat1, Michael Mourez1, Eric Bacqué1, Frédéric Jeannot1, Sébastien Coyne2*

1Evotec Id (Lyon) Sas, Marcy-l’Étoile, France, 2Aix-Marseille University, Marseille, France, 3Statens Serum Institut, København, Denmark

Background: Heptose residues are the first non-essential constituents of the inner core LPS of most Gram-negative bacteria. Deep rough mutants, devoid of heptose therefore exhibiting a short LPS, were shown highly susceptible to antibiotics. HldE is a cytoplasmic enzyme participating in the biosynthesis of ADP-glycero-manno-heptose, the active form of heptose incorporated into nascent LPS. HldE inhibitors were reported. As part of our collaboration with GSK within the IMI ENABLE consortium, we have evaluated HldE as a potential target to develop antibiotic potentiators. This study presents (i) the full validation of HldE; (ii) the characterization of an optimized HldE inhibitor; (iii) investigations of tolC-hldE synthetic lethality.

Materials/methods: Lambda-red hldE-inactivated E. coli and its trans-complemented strain were generated. Genetic mutants and HldE inhibitors were characterized in standard microbiology and LPS gel assays. Spontaneous resistant mutants were studied by (q)RT-PCR and their genome sequenced. The ΔhldE mutant was inoculated to mice in a thigh infection model. Synthetic lethality was investigated using CRISPR-Cas9 system.

Results: Extended antibiotics susceptibility was confirmed in ΔhldE E. coli and by chemical HldE inhibition using a reference compound in a ΔtolC strain. Potentiation occurred at low HldE inhibition level. No resistance was selected at high concentration of the reference compound while a moderate frequency of resistance, mediated by hldE-overexpression, was observed at lower concentration. In a thigh infection model, ΔhldE displayed decreased virulence and 6-fold increased susceptibility to erythromycin.

An optimized HldE inhibitor, obtained by medicinal chemistry, exhibited increased potentiation on E. coli, although still limited to a ΔtolC background. In the latter, stand-alone antibacterial activity was observed. The inability to generate a double tolC-hldE inactivated mutant together with growth arrest when both genes were repressed suggested a synthetic lethality between tolC and hldE.

Conclusions: We have validated HldE both in vitro and in vivo as a valuable target for potentiating antibiotics and showed an intriguing synthetic lethality with tolC. In vivo decreased virulence of a ΔhldE mutant suggests that HldE inhibition could in addition reduce the bacterial virulence. Our results warrant further efforts to design HldE inhibitors.

Abstract 2632

Rapid detection of ciprofloxacin susceptible strains of *Neisseria gonorrhoeae*; an important guide for treatment

Ciara Cox¹, James Mckenna²

¹Queen’s University Belfast, Belfast, United Kingdom, ²Royal Victoria Hospital, Belfast, United Kingdom

Background: *Neisseria gonorrhoeae* (NG) is the aetiological agent of the sexually transmitted infection, Gonorrhoea, and is associated with urethritis in males and cervicitis in females. Antimicrobial resistant (AMR) NG is a major global threat due to the emergence of multi-drug resistant strains. The World Health Organisation (WHO) proposed that molecular tests capable of detecting resistant strains could control AMR spread. In most routine laboratories, NG antibiotic sensitivities are determined by minimum inhibitory concentration (MIC) testing however, this requires growth of the organism and can take up to 72 hours for results. The *ResistancePlus*® GC kit (SpeeDx Pty Ltd) can rapidly detect *gyrA* gene mutations associated with ciprofloxacin resistance. Absence of mutations would enable precision treatment as an alternative to empirical intramuscular ceftriaxone 1g. This study compares genotypic and phenotypic data in samples from patients attending GenitourINARY Medicine clinic in Northern Ireland.

Materials/methods: Specimen extracts identified as NG positive using Cobas® CT/NG (Roche Diagnostics) and confirmed on an in-house TaqMan assay and/or Cepheid GeneXpert assay as per standard care testing, were anonymised and re-tested using *ResistancePlus*® GC kit. The rate of ciprofloxacin susceptible strains was determined. A subset of patients had a separate sample sent for MIC sensitivities, which enabled a comparison between genotypic and phenotypic results.

Results: A total of 75 NG positive samples were included in the study which tested positive on both Cobas® and *ResistancePlus*® GC test (100% agreement of NG detection between assays). Amongst 75 positive samples; 43 (57.3%) had no *gyrA* mutation; 17 (39.5%) of these were confirmed by culture, 24 (55.8%) had no additional sample sent for culture and 2 were not isolated. 26 (34.6%) positives had a *gyrA* mutation detected; 7 (26.9%) were confirmed on culture, 2 were not isolated and the remaining 17 (65.4%) had no MIC sensitivities performed.

Conclusions: *ResistancePlus*® GC can rapidly detect NG and associated ciprofloxacin resistance mutations directly from a single clinical sample, guiding treatment and preserving ceftriaxone. Here, 43 samples had no *gyrA* gene mutation detected indicating susceptibility to ciprofloxacin, yet less than half generated phenotypic data, demonstrating that *ResistancePlus* GC could facilitate individualised medicine.

Deaths from bloodstream infections caused by antibiotic-resistant bacteria in Japan between 2015 and 2017: a population-level estimation

Shinya Tsuzuki1,2, Nobuaki Matsunaga1, Koji Yahara3, Aki Hirabayashi1, Toshiki Kajihara1, Motoyuki Sugai3, Keigo Shibayama3, Norio Ohmagari1

1National Center for Global Health and Medicine, Shinjuku City, Japan, 2University of Antwerp, Antwerpen, Belgium, 31-chome-23-1 Toyama, National Institute of Infectious Diseases, Shinjuku City, Japan

Background: Bloodstream infections (BSIs) are a major cause of infectious disease-related morbidity and mortality in modern global health. However, estimating the number of deaths attributed to BSIs is challenging. The objective of this study was to understand the epidemiology of BSI-associated death caused by antibiotic-resistant bacterial species that are frequently isolated from patients in Japan.

Materials/methods: We included methicillin-resistant Staphylococcus aureus (MRSA), third-generation cephalosporin-resistant Escherichia coli (3REC), fluoroquinolone-resistant Escherichia coli (FOREC), third-generation cephalosporin-resistant Klebsiella pneumoniae (3RKP), multidrug-resistant Pseudomonas aeruginosa (MDRP), and penicillin-resistant Streptococcus pneumoniae (PRSP) in our analyses. We estimated the number of deaths from BSIs caused by these organisms in 2015, 2016, and 2017 in hospitals using the Japan Nosocomial Infection Surveillance (JANIS) database. The number of deaths was estimated using BSI mortality data obtained from previous studies. We adjusted the total number of BSIs by year and prefecture according to the proportion of the number of beds participating in JANIS. We included only beds for acute care and infectious diseases and excluded psychiatric beds and long-term care beds. We calculated 95% confidence intervals (CIs) in consideration of both bed coverage and mortality.

Results: We estimated that, on average, 5.2 (95% CI: 3.6–7.2) deaths per 100,000 population per year were attributed to BSIs caused by these major antibiotic-resistant organisms. MRSA accounted for 2.5 (95% CI: 2.0–3.1), 3REC accounted for 1.7 (95% CI: 0.9–2.7), and FOREC accounted for 2.4 (95% CI: 1.3–3.7) deaths per 100,000 population per year, respectively. MRSA and FOREC accounted for 93.3 % of the BSI deaths caused by these six major antibiotic-resistant organisms.

Conclusions: MRSA, 3REC, and FOREC account for the majority of BSI-associated deaths caused by antibiotic resistant organisms in Japan. The focus of antimicrobial resistance countermeasures should target S. aureus and E. coli as the primary organisms of concern.

BSI; bloodstream infection, MRSA; methicillin-resistant Staphylococcus aureus, 3REC, third-generation cephalosporin-resistant Escherichia coli, FOREC; fluoroquinolone-resistant Escherichia coli, 3RKP; third-generation cephalosporin-resistant Klebsiella pneumoniae, MDRP; multidrug-resistant Pseudomonas aeruginosa, PRSP; penicillin-resistant Streptococcus pneumoniae.

Prospective genomic surveillance of multidrug-resistant organisms in Vietnamese intensive care units

Leah Roberts*1;2, Fahad Khokhar2, Nguyen Van Kinh3, Nguyen Vu Trung3, Gia Binh Nguyen4, Dao Xuan Co4, Le Thi Hoi3, Hoa Nguyen1, Tran Giang2, Cuong Bui2, Hai Ninh Tran1, James Bryan1, Archie Herrick2, Behzad Nadim3, Hindrik Rogier Van Doorn4, Julian Parkhill4, Zamin Iqbal1, Estee Torok2

1EMBL-EBI, Cambridge, United Kingdom, 2University of Cambridge, Department of Medicine, Cambridge, United Kingdom, 3National Hospital Of Tropical Diseases, Hanoi, Vietnam, 4Bach Mai Hospital, Hanoi, Vietnam, 5Wellcome Trust Major Overseas Programme, Hanoi, Vietnam, 6University of Cambridge, School of Veterinary Medicine, Cambridge, United Kingdom

Background: Vietnam has a high burden of infectious diseases and rising rates of antimicrobial resistance (AMR). Multi-drug-resistant organisms (MDROs) are common in healthcare settings and may contribute to healthcare-associated infections. This prospective surveillance study aimed to determine the prevalence and transmission of MDRO in two hospitals in Hanoi, Vietnam, using bacterial whole-genome sequencing (WGS).

Materials/methods: All patients admitted to two ICUs at the National Hospital of Tropical Diseases (NHTD) and Bach Mai Hospital (BMH) were included. 4142 clinical and environmental samples were collected between June 2017 and January 2018, and characterised using MALDI-TOF MS, Vitek2 and WGS (HiSeq). Raw reads were de novo assembled using SPAdes. Sequencing typing (ST) and AMR gene detection was carried out using mlst and Abricate (respectively). Phylogenies of the main species were constructed using MashTree.

Results: 406 patients were included in the study (median age 53 years, 63.5% male). Three species accounted for the majority of isolates (79%): Escherichia coli (735/3890, 18.8%), Klebsiella pneumoniae (1334/3890, 34.1%) and Acinetobacter baumannii (1131/3890, 28.9%). The main STs found in A. baumannii were ST804 (17.1%) and ST195 (15.7%). The blaoxa-23 gene (83%) was the most prevalent, where 74% also carried blaoxa-66. 34 A. baumannii were identified with blondm1, of which 15 (44%) were ST355. The major K. pneumoniae STs were ST15 (32.6%) and ST16 (19.5%). 82% of all K. pneumoniae carried either KPC or NDM genes, with blapkpc (44%) and blondm1 (25%) the most common. The blonaegase gene was present in 95% of ST16 isolates and was not identified in any other ST. 202 (77%) ST16 isolates also carried a blondm4 gene. The E. coli isolates were highly variable; the main ST was ST648 (11.8%), however no other ST accounted for more than 10% of the dataset.

Conclusions: This study represents the largest prospective surveillance study of AMR in Vietnamese ICUs. The observation of similar lineages within both hospital ICUs despite no inter-hospital patient transfers could suggest community acquisition and transmission prior to hospitalisation. This presents significant challenge for AMR control in Vietnam requiring an integrated approach to antimicrobial stewardship and infection control both in hospital and community settings.

Abstract 2635

Evolution of tuberculosis in children under five in our healthcare area
Eva Lozano Mochón1*, Josebe Unzaga1, Mikel Urrutikoetxea-Gutierrez2, Maria BeGoña Larrauri1, Maria BeGoña Amezua1, Elisa Garrote Llanos1, José Luis Díaz De Tuesta1

1Hospital Universitario Basurto, Bilbao, Spain, 2Basurto University Hospital [Microbiology Department], Osakidetza, Bilbao, Spain

Background: Historical series of tuberculosis (TBC) amongst children in the Basque Country showed a higher incidence of TBC-meningitis as in other regions. This was the main reason for keeping BCG-vaccine on the immunization schedule until 2013. With the withdrawal of the vaccine a rebound of the incidence of the TBC-meningitis was feared. The aim of this study was to review the TBC cases in children under 5 years at Bilbao-Basurto Health Area [2003-2019].

Materials/methods: Medical records of children under 5 years with diagnosis of tuberculosis by culture and/or molecular techniques in our area during the study period were reviewed.

Results: The pediatric population was stable around 55,000 inhabitants and there were 8 diagnosed cases of tuberculosis, with an annual incidence rate of 0.9 per 100,000 patients. The average age was 30 months. The distribution was as follows:

- In 2007, a vaccinated child of Moroccan parents with a bacilliferous uncle, with both positive culture and PCR. Treated with Rifampicin, Isoniacid and Pyrazinamide initially but replacing rifampicin with ethambutol because of an Idiopathic Thrombocytopenic Purpura.

- In 2013, three vaccinated children related to a school outbreak. The source was a bacilliferous teacher. Two of them were diagnosed in gastric aspiration by culture and the other one only by PCR. The three patients had little clinical expression and received standard treatment with good response.

- In 2014, an unvaccinated one-year-old, whose mother was bacilliferous, developed pneumonia and hiliar adenopathies. The culture and PCR were positive and was treated with standard therapy with adequate response.

- In 2019 three unvaccinated one-year-old Spanish children developed a pulmonary TBC. One of them, whose grandfather (from Cameroon) was bacilliferous, also developed tuberculous meningitis diagnosed by PCR. The molecular assay showed a mutation at the rpoB and inhA gene that confers resistance to isoniazid and rifampicin and was treated with isoniazid, pyrazinamide, ethambutol, linezolid and levofloxacin.

Conclusions: Tuberculosis in children under 5 years of age in our environment is fundamentally sporadic and outbreak related. There is only one case of multidrug-resistant M tuberculosis in relation to immigration. There was only one case of tuberculous meningitis after the vaccine withdrawal.

Abstract 2640

Pertussis among ≤ 3 months old in Finland, 2015-2018: should we refine our adult immunisation schedule or switch to maternal immunisation?

Timothee Dub*, Mika Gissler2,3, Teemu Möttönen1, Jussi Sane1, Hanna M. Nohynek1

1Department of Health Security, Finnish Institute for Health and Welfare, Helsinki, Finland, 2Information Services Department, Finnish Institute for Health and Welfare, Helsinki, Finland, 3Department of Neurobiology, Care Sciences and Society, Karolinska Institute, Stockholm, Sweden

Background: In Finland, universal pertussis immunisation schedule consists of DTaP-IPV-Hib vaccines at 3, 5 and 12 months of age followed by 3 boosters at 4 (DTaP-IPV), 14–15 (dtap) and 25 (dtap) years. During 2015-2018, a total 45 laboratory confirmed pertussis cases ≤ 3 months of age, too young to have received effective immunisation, was notified to the National Infectious Diseases Register (NIDR). We described cases’ mothers’ age at delivery, compared it to mothers’ age at delivery for nationwide 2015-2017 birth cohorts to evaluate possible changes to the Finnish immunisation programme to maximize protection against pertussis in the very young. We aimed to study whether postponing the 25 years of age dtap booster would increase immunity in pregnant women as an alternative to maternal vaccination.

Materials/methods: We linked NIDR pertussis cases ≤ 3 months old records to births documented in the Medical Birth Register (MBR) to get information on mothers’ age at delivery. Additionally, we extracted Statistics Finland national data to assess distribution of mothers’ ages at delivery of livebirth. We then estimated at what age pertussis immunisation should be offered to still provide protection to the highest number of livebirths, assuming a protective duration of 4 years after aP containing vaccine.

Results: All 45 pertussis cases ≤ 3 months old were linked to MBR. Cases’ mothers’ age at delivery ranged from 19 to 44 years. For comparison with available nationwide data, we restricted our analysis to cases born in 2015-2017 [n=36], where 11 [31%] mothers were aged 25-29 years and 11 [31%] aged 30-34 years. In the nationwide 2015-2017 birth cohort, age distribution of delivering mothers differed with 29% [n=46542] among 25-29 years and 34% [N=53570] among 30-34 years. Finally, we calculated that dtap given at the age 25 years provides immunity to 23% [n=35760] of livebirths while postponing it to 29 years of age could provide protection to 28% [44948] of livebirths.

Conclusions: When deciding on the age of adult aP-containing dt-vaccine boosting, an additional point to consider is to maximize the protection of a newborn in absence of or as a complement to active maternal vaccination.

Spallanzani, Rome, Italy, 20Imagin Institute, Paris, France

Background: Leishmaniasis is endemic in the Mediterranean European countries, but is also imported in the whole of Europe from across the globe. Several specialized hospitals and medical centres diagnose and treat both visceral and cutaneous leishmaniasis caused by various species, but currently up-to-date surveillance of the species diagnosed and their presumed geographic origin is lacking.

Materials/methods: Fourteen specialized diagnostic and treatment centres from 11 European countries pooled their diagnostic data from the period 2014-2019, in order to get more insight into the presumed geographic origin of infection and species diagnosed. These 14 centres are all affiliated to the European LeishMan consortium.

Results: In total 1174 cases were diagnosed, originating from 68 different countries where leishmaniasis is endemic. Almost all species were found, both from the L. [Leishmania] and L. [Viannia] subgenus. Cutaneous leishmaniasis (n=887) was caused by all species, while mucocutaneous disease (n=37) was caused by L. braziliensis in the new world, and primarily by the L. donovani complex in the old world. Visceral leishmaniasis (n=227) was caused by either L. infantum or L. donovani, and in 1 case by the enigmatic L. enriettii complex. Almost 670 cases were imported from countries other than where they were diagnosed, either from an endemic European region, or from outside Europe (n = ca. 540). Further stratification based on year and type of traveller is ongoing, pending data collection for the entire year 2019.

Conclusions: In most European countries, notification of leishmaniasis is not mandatory. Surveillance is therefore largely dependent on initiatives from reference centres. The LeishMan network aims to further follow-up the imported and autochthonous cases in the European territory by continued data collection, for monitoring the origin of, and the diseases caused by the Leishmania parasites.

Abstract 2642

Unexpectedly high false positive *Haemophilus influenzae* rates using a meningoencephalitis syndromic PCR panel in two tertiary centres

Marie-Céline Zanella¹;², Vladimira Hícic³, Abdessalam Cherkaoui¹, Daniel Goldenberger⁴, Gesuele Renz⁵, Adrian Egli⁴;⁵, Jacques Schrenzel¹;²

¹Geneva University Hospitals, Bacteriology Laboratory, Division of Laboratory Medicine, Geneva, Switzerland, ²University of Geneva Medical School, Geneva, Switzerland, ³Geneva University Hospitals, Division of Infectious Diseases, Department of Medical specialities, Geneva, Switzerland, ⁴University Hospital Basel, Clinical Bacteriology and Mycology, Basel, Switzerland, ⁵University of Basel, Applied Microbiology Research, Department of Biomedicine, Basel, Switzerland

**Background:** PCR panel assays are increasingly used in routine diagnostic laboratories for meningitis and (meningo-)encephalitis diagnosis. Since the implementation of the Biofire® Filmarray® Meningitis/Encephalitis (ME) panel, several cases of false-positive (FP) results for *H. influenzae* have been reported.

**Materials/methods:** Retrospective case review conducted at Geneva and Basel University Hospitals on all *H. influenzae* positive results determined by Biofire® Filmarray® ME panel on cerebrospinal fluid (CSF) samples sequentially analysed from June 2016 to October 2019. The panel was performed in strict accordance with the manufacturer’s instructions. Clinical and laboratory data were collected. Cases were defined as a true positive (TP) when confirmed by a positive *H. influenzae* specific qPCR on the same sample and/or CSF cultures, in addition to clinical manifestations and CSF analysis. Other cases were considered as a FP. Both laboratories are accredited (ISO/IEC17025) and participate in external quality control.

**Results:** A total of 3082 ME panels corresponding to 2895 patients (2252 adult, 643 paediatric) were performed: results for *H. influenzae* were negative in 99.4% (3064/3082) (95% CI 99.1–99.6%) and positive in 0.6% (18/3082) (95% CI 0.4–0.9%) CSF samples. CSF white blood cell count was determined in 1 3 samples (median 7M/L [range 1 -4031M/L]). Culture and specific qPCR were performed on 1 7/18 and 3/18 CSF samples, respectively. Among 1 7 samples sent for culture, 10 concerned patients not treated with antibiotics prior to lumbar puncture and one only was *H. influenzae*-positive. Clinical manifestations and CSF analysis were barely compatible with *H. influenzae* ME and/or an alternative diagnosis was made in 72.2% (1 3/18) cases. A total of 2 TP (one case, positive blood and CSF cultures; one case, positive blood culture), and 16 FP (three culture and qPCR negative; 1 4 culture-negative without qPCR performed) cases were retained. Nine patients received specific antibiotics for ME.

**Conclusions:** False-positive results for *H. influenzae* with the Biofire® Filmarray® ME panel were surprisingly frequent. ME panel results should always be interpreted together with clinical presentation and CSF analysis. Special caution should be paid to *H. influenzae*-positive results and a *H. influenzae* specific qPCR should be considered to mitigate the consequences of FP results.

**Presenter email address:** marie-celine.zanella@hcuge.ch
Pharmacodynamic analysis of meropenem in combination with a novel ß-lactamase inhibitor ANT2681 against New Delhi metallo ß-lactamase-producing *Escherichia coli*

Adam Johnson*1, Laura Mcente1, Nikki Farrington1, Adam Kirby1, Ruwanthi Kolamunnage-Dona1, Martin Everett2, Magdalena Zalacain2, Carole Sable2, Laethitia Alibaud2, Nicholas Harper1, Shampa Das1, William Hope1

1University of Liverpool, Liverpool, United Kingdom, 2ANTABIO, Labège, France

Background: Antabio is developing a novel metallo-ß-lactamase inhibitor with activity against NDM. ANT2681 has been shown to potentiate the MIC of meropenem against a broad range of MBL-containing clinical isolates. Preclinical pharmacokinetic and pharmacodynamic (PK-PD) studies are needed to identify the appropriate dynamically linked index.

Materials/methods: A well characterised murine neutropenic thigh infection model with a challenge strain NDM-producing *E. coli* NTBC 121 was used to perform dose range-finding and dose fractionation studies. Initial dose range-finding studies were conducted with meropenem alone to select a dose of meropenem with limited (sub-maximal) activity, to be used as a backbone in combination experiments. A dose range of 5-150 mg/kg ANT2681 q4h IV was evaluated in combination with a fixed dose of meropenem 50 mg/kg q4h SC meropenem and the EC$_{50}$ of ANT2681 was calculated. Subsequent dose fractionation experiments were performed by administering a total daily dose of 480 mg/kg ANT2681 split over q4, q8 or q12 hours and combined with a backbone of meropenem 50 mg/kg q4h SC. The plasma PK of meropenem and ANT2681 were assessed using dosages of meropenem/ANT2681 of 25/5, 100/75 and 500/240 mg/kg q24h.

Results: Linear mixed effect models were used to compare the dosing regimens. There were significant differences in log$_{-10}$CFU/g change over time [p<0.05] between meropenem alone and each MEM/ANT2681 combination regimens; however, there were no significant differences between each fractionated dose regimen of MEM/ANT2681 [i.e. 50/80 mg/kg q4h, 50/160mg/kg q8h and 50/240mg/kg q12h] demonstrating that pharmacodynamics were unlikely to be peak or time driven. Meropenem pharmacokinetics in mice were consistent with previously published estimates. ANT2681 has linear pharmacokinetics in mice.

Conclusions: Statistical analysis from dose fractionation studies demonstrate that AUC is the relevant dynamically linked index. PK-PD bridging studies to define the magnitude of the pharmacodynamic index of ANT2681 are currently being performed.

Abstract 2646

Compatibility of the new NTM Elite agar with MALDI-TOF for direct isolation and identification of non-tuberculous mycobacteria

Marjorie Vrignaud*, Eugénie Déléage¹, Laurence Devigne¹

¹R&D Microbiology, bioMérieux, La Balme les Grottes, France

Background: Pulmonary nontuberculous mycobacteria (NTM) represent an increasing threat as NTM infection can become chronic in susceptible patients and require heavy antibiotic treatments. Their diagnosis remains difficult due to fastidious sample preparation involving prior decontamination, slow growth and pulmonary flora that can be abundant, especially in the case of cystic fibrosis (CF) patients.

RGM medium has been designed at the Freeman Hospital (Newcastle Upon Tyne, UK). This medium shows increased specificity and sensitivity compared to reference methods.

NTM Elite agar (bioMérieux) is the industrial version derived from RGM medium dedicated to the isolation of nontuberculous mycobacteria from respiratory specimen without prior decontamination.

Materials/methods: 50 well-characterized nontuberculous mycobacteria strains were subcultured on both the reference medium (Colestos) and on NTM Elite Agar. Colonies were processed in duplicate with the VITEK® MS MYCOB/NOCARDIA KIT and were analyzed by MALDI-TOF with the VITEK®MS system (KB IVD V3.2.0.). Duplicates were considered as individual tests for analysis, thus representing 100 results per tested media.

Results: The strains were identified at species or complex level at 94% on NTM Elite agar and 85% on Coletsos. The rates of no identification were 4% on NTM Elite agar and 13% on Coletsos. Duplicate spots resulted in a no identification results in only four cases for Coletso, and only one case for NTM Elite agar. This could be explained by an easier picking of the colonies on the NTM Elite agar plates compared to the Colestos tubes, especially in the case of rough colonies. The rate of misidentification was 2% for both media and concerned only one strain.

Conclusions: Isolation of nontuberculous mycobacteria from specimen without prior decontamination with NTM Elite agar, associated with a direct identification by MALDI-TOF VITEK®MS, enables a simplified streamlined screening of nontuberculous mycobacteria, thus improving patient care.

Abstract 2647

Adherence to an admission screening for multidrug-resistant organisms in a tertiary care hospital in Switzerland

Frederike Waldeck*, Philipp Patrick Kohler1, Matthias Schlegel1, Eva Lemmenmeier1

1Cantonal Hospital St. Gallen, Department of infectious diseases and hospital epidemiology, St. Gallen, Switzerland

Background: Targeted admission screening for multi-drug resistant organisms (MDRO) is a recognized measure to prevent transmission and outbreaks. The aim of this study was to evaluate adherence to our screening algorithm in patients transferred from hospitals of high prevalence areas and identify factors associated with omitted screening.

Materials/methods: We included patients transferred from abroad or from high-risk regions within Switzerland from 2013 – 2018, according to the patient administration system. These patients were cross-checked with the infection control database regarding screening for MDRO. Sex, date of birth, origin of transferal, ward at admission, date and realization of screening and screened organisms were noted. Univariable and multivariable logistic regression were performed.

Results: We included 835 patients (41.8% female). Median age was 60 years (interquartile range 45 – 71 years). Screening was done in 389 (46.6%) patients and in 333/389 (85.6%) patients all indicated organisms were screened. The following characteristics were associated with poorly performed screening in univariable analysis: female sex (40.7 vs. 50.8% in males; odds ratio [OR] 0.66 [95% confidence interval [CI] 0.50 – 0.88]), transferral from high prevalence areas in Switzerland (25.2% vs. 49.1% from abroad; OR 0.32 [CI 0.21 – 0.49]) and admission directly to the ward (12.9% vs. 56.6% in patients admitted to the emergency department; OR 0.11 [CI 0.07 – 0.17]). Adherence to the screening algorithm improved over time (28.1% in 2013 vs. 54.9% in 2018, OR 0.32 [0.19 – 0.54]). In multivariable analysis direct admission to the ward (OR 0.11 [CI 0.07 – 0.19]) and year of screening (OR 1.24 per year [1.13 – 1.35]) remained significantly associated with adherence to screening.

Conclusions: Adherence to our MDRO screening algorithm was surprisingly low but improved over time. Direct admission to the ward was a predictor of omitted screening. Strategies to evaluate and improve adherence are essential to increase detection of MDRO colonisation and to prevent their spread.

Presenter email address: frederike.waldeck@kssg.ch
Novel putative AHL-lactonases widely distributed across diverse carbapenemase-producing Enterobacteriaceae

Maria Lopez1,2*, Nicholas Ellaby1, Neil Woodford1, Matthew Ellington1, Maria Tomas2

1Public Health England, London, United Kingdom, 2INIBIC, A Coruña, Spain

Background: Bacterial quorum signalling via acyl-homoserine lactones influences the production of virulence factors depending on bacterial population density. Quorum signal inhibition (quorum-quenching) by AHL-lactonases may provide an adjunct or alternative that could be harnessed for the treatment of bacterial infections. In Proteobacteria, AHL-lactonases are mainly classified into the metallo-β-lactamase superfamily (MBL), the phosphotriesterase family or the alpha/beta hydrolase family, each with distinct yet conserved catalytic domains. We identified multiple MBL-like proteins and alpha/beta hydrolase family lactonases in four major species of carbapenemase-producing Enterobacterales (CPE).

Materials/methods: From long-read whole genome sequences (Oxford Nanopore Technology MinIon) of eight clinical K. pneumoniae, E. coli, E. cloacae and Citrobacter freundii isolates, conserved AHL-lactonase domains were detected (Motif search, GenomeNet, Japan). Alignment of the protein sequences (Clustal) with those already described as lactonases was performed and domains confirmed via CD search (NCBI/HMMscan). BLASTp was used to assess the novelty of the detected lactonases. Sequences were uploaded to PredictProtein.org for protein structure prediction and sub-cellular localization.

Results: From a total of 18 putative AHL-lactonases from the MBL superfamily found, all possessed the characteristic Zn2+-binding motif (HXHXDH-H-D). CPE isolates from four species had a putative novel conserved Zn2+ binding motif (HGHLDH-H-D) that was not previously described as AHL-lactonase.

This highly conserved putative lactonase (87.91% amino-acid identity) had a predicted cytoplasmic location but lacked a signal peptide in all four species examined. Moreover, it was distinct to other known lactonases (~16.5% amino acid similarity), further supporting the status of this type as a novel candidate AHL-lactonase.

Alpha/beta hydrolase family proteins showed a catalytic triad associated with AHL-lactonase activity [GXSXG-E/D-H], amongst the CPE isolates, which was conserved as a GYSLG-E/D-H motif. Domains unique within each species were also found.

Conclusions: The presence and conservation of AHL lactonase domains across the four most important CPE species highlights the ubiquity of this potentially useful factor for anti-bacterial or anti-virulence strategies amongst some of the most resistant Enterobacterales we face.

Epidemiology and management of pneumonia based on data entry in a computerised decision support system for antimicrobial prescriptions: a retrospective study

Gaud Catho*1, Alice Ranzani1, Jerome Stirnemann2, Virginie Prendki3, Benedikt Huttner1

1Geneva University Hospitals and Faculty of Medicine, Division of Infectious Diseases, Geneva, Switzerland, 2Geneva University Hospitals and Faculty of Medicine, Division of Internal Medicine, Geneva, Switzerland, 3Geneva University Hospitals and Faculty of Medicine, Division of Internal Medicine and Rehabilitation, Geneva, Switzerland

Background: Computerized decision support systems (CDSS) are promising tools for antimicrobial stewardship (AMS). Pneumonia, one of the leading causes of antimicrobial prescriptions, is a “natural target” for AMS programs.

Materials/methods: Through the ongoing COMPASS trial [NCT03120975], we implemented a CDSS. When prescribing antimicrobials on inpatient wards, physicians must choose the indication for each antimicrobial; thereafter they are provided indication-specific treatment recommendations based on local guidelines. We extracted data for inpatients from whom the antibiotic indication contained the term “pneumonia” between January 1, 2019 and October 31, 2019. Of note, a patient could have >1 indication for the same episode. A prescription was defined as the prescription of a specific drug independent of route or dosage.

Results: Over the study period, 638 patients were treated for 669 episodes of any pneumonia diagnosis, representing 48.8% of 1371 episodes treated with antimicrobials with an indication. Median age was 77 years (IQR 65-86). Community-acquired pneumonia was the most frequent indication [413/807 indications, 51%] followed by health care associated pneumonia [179/807, 22%] (Figure 1). For 9% [53/594] of episodes with an initial pneumonia indication, the indication changed to a non-pneumonia indication during hospitalization, the inverse occurred for 10% [75/777] of episodes with an initial non-pneumonia indication. Amoxicillin-clavulanate was the most commonly prescribed antibiotic [43%, 393/906 prescriptions], followed by piperacillin-tazobactam [18%, 167/906]. Combination therapy was started for 17% [115/669] of episodes. Treatment was initiated intravenously (IV) ≥1 antibiotic IV for 64% [431/669] of episodes and oral switch (all antibiotics PO) was performed for 44% [191] after a median of 3 days (IQR 2-4). Treatment was concordant with local guidelines for 75% [672/893] of prescriptions for which recommendations were available. Median inpatient treatment duration and median length of stay for episodes for which a pneumonia indication was selected [and not changed to a non-pneumonia indication] were respectively 5 days (IQR 2-7) and 8 days (IQR 5-13).

Conclusions: A CDSS requiring physicians to provide indications for antimicrobial prescriptions enables rapid assessment of syndrome-specific indicators and thereby facilitates the development of targeted interventions promoting optimal antimicrobial therapy, such as IV PO switch, which our data show to be suboptimal.

![Figure 1. Frequency of pneumonia indications (with recommendations available) and guidelines concordance](image_url)

Safety characterisation of ART24, a novel live bio-therapeutic product, in development for the prevention of *Clostridioides difficile* infection, by *in silico* and *in vitro* testing

Michelle O’Donnell¹, Calum Walsh², Rodrigo E. Mendes³, Colin Hill⁴, Paul Ross⁴, Mary Rea¹, Ronald Farquhar¹, Laurent Chesnel⁵

¹Artugen therapeutics, Teagasc Food Research Centre, Fermoy, Ireland, ²University College Cork, Teagasc Food Research Centre, Fermoy, Ireland, ³JMI Laboratories, North Liberty, United States, ⁴University College Cork, APC Microbiome Institute, Cork, Ireland, ⁵Artugen therapeutics USA, Inc, Concord, United States

**Background:** ART24 is being investigated as a live biotherapeutic product (LBP) treatment to prevent recurrence of *Clostridioides difficile* infection (CDI) following successful antibacterial therapy. ART24 was isolated from a human fecal sample, identified, and purified. ART24 is a member of the *B. amyloliquefaciens*/*B. velezensis* group. Further, ART24 is considered a member of the “operational group *B. amyloliquefaciens*”, which consists of the soil borne *B. amyloliquefaciens*, and plant associated *B. siamensis* and *B. velezensis*, which is synonymous with *B. amyloliquefaciens* subsp. *plantarum*. The human carriage of *B. amyloliquefaciens* as well as the genome of ART24 itself were investigated as a mean to identify potential safety and toxicity concerns prior to animal and human testing.

**Materials/methods:** The whole closed, assembled and annotated ART24 genome was investigated for functional operons that contain known antimicrobial gene content, plasmid, phage content, and virulence factors using Anti-SMASH, Bagel4, plasmid-SPAdes, PHASTER, IslandViewer4 and RAST SEED viewer. In addition, standard susceptibility testing of ART24 against 16 antibiotics was determined using CLSI recommended broth microdilution and results interpreted using current CLSI and EUCAST breakpoints. Finally, available metagenomic datasets from human fecal samples were mined for the presence of *B. amyloliquefaciens* and *B. velezensis* using Kraken2, Bracken and curatedmetagenomicData to better understand the presence of the “operational group *B. amyloliquefaciens*” in the general population.

**Results:** *In silico* analysis indicates that the ART24 genome displays expected genetic properties related to *Bacillus* subspecies, and that off-target activities of virulence and antibiotic resistance mechanisms are unlikely. ART24 is susceptible to all drugs tested for which interpretative criteria are available. *In silico* analysis to identify *B. amyloliquefaciens* and *B. velezensis* gene content in metagenomic datasets showed that the operational group is present in human fecal samples analyzed at an overall low percentage relative abundance, variable between geographic regions, and was not linked with any disease state in the datasets tested.

**Conclusions:** The series of *in silico* and *in vitro* testing analyses performed on ART24 did not reveal any obvious safety concerns. ART24 is a promising LBP clinical candidate in Phase 1 clinical development for prevention of recurrent CDI.

Use of therapeutic drug monitoring to optimise cefazolin dosing in the treatment of methicillin-susceptible Staphylococcus aureus bacteraemia

Veena Venugopalan1, Savine Hernandez2, Kathryn Desear3, Charles Peloquin2, Kartikeya Cherabuddi4, Anthony Casapao*5

1University of Florida/UF Health Shands Hospital, University of Florida, College of Pharmacy, Gainesville, United States, 2University of Florida, University of Florida, College of Pharmacy, Gainesville, United States, 3University of Florida/UF Health Shands Hospital, Gainesville, United States, 4University of Florida/UF Health Shands Hospital, University of Florida, College of Medicine, Gainesville, United States, 5University of Florida, University of Florida, College of Pharmacy, Jacksonville, United States

Background: The impact of cefazolin exposure on treatment outcomes in high inoculum infections is unknown. Clinical data suggests that for β-lactams, a higher threshold of 50% ft>MIC up to 100% ft:MIC≥4 MIC is associated with positive clinical outcomes. The objectives of this study were to evaluate the achievement of cefazolin PK target attainment and to further assess clinical and microbiological outcomes in hospitalized patients with MSSA bacteremia.

Materials/methods: We conducted a single-center, retrospective review between Dec 2017 and May 2019, of adult patients receiving cefazolin for MSSA bacteremia with serum concentrations obtained at steady state. Total cefazolin plasma concentrations were adjusted for 80% protein binding to estimate unbound drug. PK targets assessed in this study were free drug concentration maintained above the MIC of the pathogen (100% ft>MIC) or 4-fold higher than the MIC of the pathogen throughout the entire dosing interval (100% ft:MIC≥4). Clinical success at the end of therapy was defined as resolution of presenting signs and symptoms of infection. Microbiological success was defined as absence of MSSA in repeat blood cultures. The MIC90 for MSSA to cefazolin is 2 mcg/ml, which was used as the MIC threshold for PK analysis.

Results: Twenty-two patients were included in the analysis. The median age was 53 (IQR, 49-65). The most common sources of the bacteremia were musculoskeletal (32%), endocarditis (18%), and SSTIs (18%). Fifty-nine percent (n=13) of patients were on continuous infusion cefazolin. The mean dose of cefazolin was 6 grams/day. The median cefazolin serum concentration was 7.1 mcg/ml (IQR, 5.6-12.3). All patients achieved 100% ft>MIC and 55% (12/22) achieved 100% ft:MIC≥4. Dose adjustments to optimize PK were performed in 27% (n=6) of patients (dose increased in 4 cases). Clinical success was achieved in all but one case (21/22). Microbiological success was achieved in all patients.

Conclusions: A PK target of 100% ft:MIC≥4 was not achieved in 45% of patients, which highlights the need for cefazolin TDM. The ability to obtain cefazolin concentrations provided the opportunity to optimize exposure in 27% of patients in this cohort. Clinical and microbiological success were achieved in the majority of patients evaluated.

Abstract 2658

Multidrug-resistant organisms (MDRO) colonisation pattern, prevalence and acquisition in a neonatal intensive care unit, evidence for guiding active surveillance cultures: a 2-year experience active surveillance process at Saint Joseph Hospital, Jerusalem

Ali Sabateen*1

1Saint Joseph Hospital Jerusalem, Saint Joseph Hospital Jerusalem, Jerusalem, Palestine

Background: Healthcare-associated Infections (HAIs) at neonatal intensive care units (NICU) reduce the rate of clinical and microbiological responses and increase the cost of care and hospital stays. Most HAIs are caused by 3rd generation-resistant members of the Enterobacteriaceae family (3GCREB). Proper surveillance and appropriate infection control practices can rigorously reduce the incidence of HAIs, however, overutilization of health institute resources through repetitive surveillance and microbiological investigations may not positively influence patient outcomes, but increases financial burden, and demands on staff and time. This study evaluated the value of repetitive active screening (twice weekly) for MDRO detection.

Materials/methods: The infection control committee carried out a systematic retrospective review of a 22-months experience (January 2017 to October 2018) questioning evidence for worthiness of the frequency of active screening (twice weekly) for MDROs at NICU. Overall, 740 babies screened at the NICU were included in the study, from which 2955 rectal and throat swabs’ results were reviewed, together with results of repeated active screening at the first 3, 7, 10, 20, and 30 days.

Results: Of the 2955 swabs results reviewed, 2257 swabs were negative (76.3%), while 207 (7.0%) cases had at least one colonized microorganism (negative for 3GCREB), and 45 cases (1.52%) were positive for 3GCREB. The data showed that the first 2 swabs obtained from neonates at day 3 and day 7 carried the highest number of conversions to 3GCREB compared to the 10, 20, and 30 days swabs. Only two cases of 3GCREB caused bacteremia during a 22-months period.

Conclusions: The incidence rate of total positive swabs for a single isolate was 8.52% and the 3GCREB rate was 1.52%, which is lower than rates reported by previous studies. None of the 3GCREB cases converted to CRE, likely due to appropriate infection prevention strategies, proper surveillance, and antibiotic use. Our findings showed that once weekly screening swabs is optimal and sufficient. Repetitive active screening of rectal and throat swabs twice weekly is costly and is not advisable in terms of the 3GCREB rate, rather it is preferable to repeat active screening once weekly.

**Genomic analysis of VIM-2-encoding conjugative megaplasmids in Pseudomonas spp. spread interregionally in Poland**

Paweł Urbanowicz*, Radosław Izdebski, Anna Baraniak, Ibrahim Bitar, Jaroslav Hrabak, Dorota Żabicka, Waleria Hryniewicz, Marek Gniadkowski

1National Medicines Institute, Department of Molecular Microbiology, Warsaw, Poland, 2Charles University, Biomedical Center, Plzeň, Czech Republic, 3National Medicines Institute, Department of Epidemiology and Clinical Microbiology, Warsaw, Poland

**Background:** Metallo-β-lactamases (MBLs) are one of the major AMR mechanisms specified by mobile genes. In *Pseudomonas* spp., MBL genes, encoding IMP and VIM types mainly, are usually located in the chromosome, and only few reports described *bla* VIM-carrying plasmids to date. Here we show complete sequences of VIM-2-encoding megaplasmids spread in pseudomonads in Poland, following our previous ECCMID presentation based on epidemiological observations.

**Materials/methods:** Over 500 non-duplicate MBL-producing *Pseudomonas* spp. isolates were submitted from all over Poland to the National Reference Centre for Susceptibility Testing in 2003-15. According to our early study, the isolates carrying In46 1 (aadB- *bla* VIM-2-aadA6) were suspected for the plasmidic location of the *bla* VIM integron, and analysed by PFGE, MLST, S1-PFGE and mating (ECCMID 2019). In this work selected strains were fully sequenced using PacBio Sequel and assembled with HGAP4, followed by manual annotation and detection of AMR and virulence genes.

**Results:** In 2003-15, 95 isolates harbored In46 1, the most common MBL-encoding integron in *Pseudomonas* spp. in Poland, having been collected in 54 hospitals in 36 cities in 10/16 administrative regions. The group comprised 33 STs of *P. aeruginosa* and four of *P. putida*, and 77 isolates had *bla* VIM-2-carrying megaplasmids (~190–~550kb) of usually high conjugative efficiency. Twenty-eight diverse isolates were selected for WGS; so far plasmids from 11 isolates from an early period (2003-2008) have been completed. All but one of the plasmids sized from 413 to 489kb, and showed remarkable identity to each other and to several other pseudomonadal plasmids, including IncP-2 VIM-2-encoding molecule from Portugal (GenBank KY494864). Interestingly, plasmid pPUV-1 (471kb) was found to be integrated into the chromosome in one of the isolates (locus PAO0069), flanked by identical clusters of recombinase/integrase genes of putative phage origin. The remaining pPUV-7 (343kb) had different backbone and belonged to another and so far unique lineage.

**Conclusions:** The WGS analysis confirmed close relatedness of VIM-2-encoding megaplasmids expanding in the Polish *Pseudomonas* population on an unprecedented scale. These seem to represent a specific variant of more broadly spread molecules, differing at least by the *bla* VIM-2 integron. Apart from functioning autonomously, the plasmids are able to integrate into the pseudomonadal chromosome.

Metagenomics next-generation sequencing for the identification of undiagnosed DNA and RNA viruses in adult allogeneic haematopoietic cell transplant recipients with steroid refractory graft-versus-host disease

Marie-Céline Zanella1,2,3, Samuel Cordey2,3, Florian Laubscher2,3, Mylène Docquier4,5, Gael Vieille2,3, Christian Van Delden1,2, Dionyssios Neofytos1,2, Vincent Braunersreuther4, Thomas Mckee6, Johannes Lobrinus6, Stavroula Masouridi Levrat2,7, Yves Chalandon2, Laurent Kaiser1,2,3, Diem-Lan Vu Cantero1,2,3

1Geneva University Hospitals, Division of Infectious Diseases, Department of Medical specialities, Geneva, Switzerland, 2University of Geneva Medical School, Geneva, Switzerland, 3Geneva University Hospitals, Virology Laboratory, Division of Laboratory Medicine, Geneva, Switzerland, 4University of Geneva, iGE3 Genomics Platform, Geneva, Switzerland, 5University of Geneva, Department of Genetics and Evolution, Geneva, Switzerland, 6Geneva University Hospitals, Division of Clinical Pathology, Geneva, Switzerland, 7Geneva University Hospitals, Division of Hematology, Department of Oncology, Geneva, Switzerland

Background: Allogeneic hematopoietic cell transplant (allo-HCT) recipients with steroid refractory/dependent graft-versus-host disease (GvHD) are highly immunosuppressed and may be more vulnerable to infections with weakly pathogenic viruses, commensal viruses, or unexpected variants overlooked by routine assays.

Materials/methods: We included 25 adult allo-HCT recipients with acute or chronic steroid refractory/dependent GvHD who were transplanted from 2016 to 2019 at Geneva University Hospitals. Plasma samples were collected throughout the period of intensive steroid treatment or second-line GvHD therapy including ruxolitinib. Metagenomics next-generation sequencing (mNGS) analysis was performed on pooled plasma samples, using a validated viral pipeline and de novo analysis. Specific real-time r(RT)-PCR was performed to confirm mNGS findings.

Results: Median duration of intensive immunosuppression was 5 months (range 1.5 to 21.6 months); 23/25 (92%) patients received ruxolitinib. GvHD-related mortality rate was 36%. In 16/25 (64%) patients, sequences of ≥3 distinct viral species were detected by mNGS; Anelloviridae and human pegivirus-1 were the most prevalent (26% and 36% patients, respectively). In 7/25 (28%) patients, all with fatal outcome, unexpected viral sequences that are not part of routine investigations were identified with mNGS. These included usutu virus (one case), rubella virus (one vaccine- and one wild-strain case), novel human astrovirus [HAstV] MLB2 (one case), classic HAstV (one case), human polyomavirus 6 and 7 (two cases), and two protoparvoviruses (one cutavirus, one bufavirus). All mNGS results were confirmed with r(RT)-PCR in unpooled plasma samples, additional available specimens and tissue biopsies over a median period of 7.1 weeks (range 0.4 to 35.4 weeks).

Conclusions: Unexpected, opportunistic and protracted viral infections were identified in 28% of highly immunocompromised allo-HCT recipients with steroid refractory/dependent GvHD. The identified viruses in the present analysis had all been previously described in humans but rarely reported as a cause of disease in allo-HCT patients or with unknown or debated pathogenicity. Rubella virus identification raises the possibility of persistence and re-emergence from past infection or vaccination. Further investigations are needed to understand the clinical significance of these viral infections.

Baloxavir drug exposure after single-dose baloxavir marboxil is similar between children aged 1 to <12 years and adults: analysis of the miniSTONE-2 trial

Jeffrey Baker¹, Stefan De Buck*², Vincent Duval², Laura Burleigh Macutkiewicz³, Sophie Dimonaco³, Steffen Wildum², Neil Collinson³, Barry Clinch³, Balpreet Matharu¹

¹Clinical Research Prime, Idaho Falls, United States, ²F. Hoffmann-La Roche, Basel, Switzerland, ³Roche Products Ltd, Welwyn Garden City, United Kingdom

Background: miniSTONE-2 investigated the safety, pharmacokinetics (PK) and efficacy of single-dose baloxavir marboxil (BXM) in otherwise-healthy (OwH) children aged 1 to <12 years with influenza. Here, systemic exposure to BXM and its active metabolite, baloxavir, are reported.

Materials/methods: miniSTONE-2 was a global, multicenter, double-blind, active-controlled study in OwH paediatric patients with influenza, conducted during the 2018/19 season. Patients were randomised 2:1 to receive either a single oral dose of BXM (2 mg/kg for patients weighing <20 kg or 40 mg for patients ≥20 kg) or oseltamivir. Optimal paediatric doses were determined by systematic synthesis of all available PK data of baloxavir, including modelling and simulation to bridge PK in a quantitative manner between adults and paediatrics. The PK strategy for this study used a combination of sparse (107 patients) and intensive (19 patients) PK sampling. Concentrations were analysed using a non-compartmental approach.

Results: As expected, BXM (pro-drug) was rapidly hydrolysed to baloxavir, therefore systemic BXM concentrations were low or below lower limit of quantification in most patients. In the intensive PK cohort, baloxavir reached maximum concentration (Cmax) about 4 hours after administration. The observed Cmax [mean [min–max] = 73.1 [18.10–137.00] ng/mL] was in a similar range to that observed in the non-Asian adult population treated with a 40 mg dose [mean [min–max] = 63.9 [11.1–133] and 60.6 [12.2–158] ng/mL in OwH and HR patients, respectively]. In the sparse sampling cohort, the mean concentration at 24 hours (C24) was 57.1 [min–max: 0.00–217] ng/mL. The central tendency and overall range of exposure data was similar to that observed in OwH [37.2 ng/mL [7.35–81.4]] and HR non-Asian patients [35.9 ng/mL [5.77–90.2]] treated with a single 40 mg dose. Mean C24 in non-Asian adults (OwH) was 57.9 ng/mL [21.4–155], also in close agreement with C24 values observed in this study. When stratified according to body weight, plasma concentrations were similar across body weight groups.

Conclusions: When administered as a weight-based single oral dose in children, baloxavir exposure (Cmax and C24) was similar to those in adult populations receiving a single dose of 40 mg.

**Background:** Schizophrenia is a serious mental illness characterized by many symptoms including abnormal behavior, false beliefs, decreased social interaction, strange speech and a decreased ability to understand reality. The condition may lower the life expectancy even by 20 years, occurring with a frequency of 0.5% in the general population. There have been many reports on the association of some infectious agents including parasites on the pathogenesis of mental disorders including schizophrenia with a recent review by Xiao et al. where the authors mention numerous studies linking *Toxoplasma gondii* exposure to schizophrenia. *T. gondii* general population prevalence varies globally from approximately 8% in Norway to over 60% in Africa and Latin America. Recently, France which had a high prevalence in 1965 (83%) has seen a decline to 37% in 2005. We set out to examine the frequency of *T. gondii* infection in schizophrenic patients in Southern Poland (Lesser Poland region).

**Materials/methods:** The study was performed on a schizophrenic patient group cared for by one of the largest mental health hospitals in Poland, i.e. Babiński Clinical Hospital in Cracow. The number of persons included in the study was 111 (M=39, F=72) aged 20-65. The study group included 75 patients with schizophrenia according to ICD-10 vs. 36 mentally healthy persons in the control group. Study participants' blood was tested serologically for IgM, IgG antibodies as well as *T. gondii* avidity. The studies were performed using a commercially available ELISA kit. Numerous other parameters were collected during the study, including other diseases, animal ownership, etc.

**Results:** 30 patients (40%) from the schizophrenic study group tested positive for *T. gondii* using serological methods (IgG positive). Only 10 persons (28%) from the healthy subjects control group tested positive for this parasite. More detailed analysis of the results will be shown on the poster.

**Conclusions:** The results show that patients in southern Poland (Lesser Poland region) with schizophrenia were infected with *T. gondii* in much greater number than the healthy control group. This pilot study may be a good framework for setting up a large national study in Poland.

Abstract third-party references: School of Medicine, University of Barcelona, Spain, CibeRes (Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, 06/06/0028), Pneumology Department, Hospital Clinic, Barcelona, Spain, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS)

**Background:** *Streptococcus pneumoniae* is the leading cause of Community-Acquired Pneumonia (CAP). Excessive inflammatory response during pneumonia could lead to macrophage impaired function increasing bacterial survival. **Aim:** To develop a model of activated THP-1 macrophages derived cells infected with *S. pneumoniae*.

**Materials/methods:** Macrophages derived from THP-1 cells differentiated with phorbol 12-myristate 13-acetate (PMA), were activated for 5 hours with different doses of lipopolysaccharide (LPS) [0, 2, 5, or 10 µg/ml]. Afterwards, we analysed proinflammatory cytokines levels by RT-qPCR (IL-1β, IL-6, IL-8, IL-10, COX2, NF-KB and TNFα). In parallel, macrophages were infected with *S. pneumoniae* (Multiplicity of infection, 20:1) using different infection times: 1, 2 or 3 hours (fig. 1). Then, bacterial intracellular colonies forming units (Log10 iCFU/ml) were determined to infer macrophages’ bactericidal activity.

**Results:** The highest expression of IL-6, IL-8, IL-10, COX2, NF-KB and TNFα was with 5 µg/ml of LPS, while IL-1β and IL-10 reached it with 10 µg/ml dose. The interaction between time of infection and LPS doses gave significant differences at 2 µg/ml of LPS comparing 1 vs 3 hours of infection [3.16(2.90-3.52) vs. 2.76(2.6-2.9), p-value=0.009], and at 5 µg/ml comparing 1 vs 2 hours of infection [2.78(2.51-3.08) vs. 2.79(2.63-3.12), (p=0.030)]; in contrast, no differences were found at 10 and 0 µg/ml of LPS.

**Conclusions:** High LPS doses are associated with increased proinflammatory cytokines levels and decreased macrophages’ bactericidal activity. This model will be useful to evaluate the cellular response to immunomodulatory therapies during pneumonia or sepsis caused by *S. pneumoniae*.

Potentiation of quinolones activity against *Escherichia coli* by suppression of SOS response and oxidative detoxification systems

Sara Díaz Díaz*1,2,3,4, Esther Recacha1,3,4, Jesús Machuca Bárcena1,2,3,5, Ana García-Duque1, Jesús Blazquez4, Alvaro Pascual Hernandez1,2,3,4, Fernando Docobo Perez2,3,4, Jose Manuel Rodriguez Martinez1,2,3,4

1Hospital Universitario Virgen Macarena, Sevilla, Spain, 2University of Seville, Sevilla, Spain, 3Ibis-Biomedicine Institute of Seville, Sevilla, Spain, 4Red Española de Investigación en Patología Infecciosa (REIPI), Sevilla, Spain, 5Hospital universitario virgen macarena, Sevilla, Spain, 6Centro Nacional de Biotecnología, Madrid, Spain

**Background:** Enhancement of *in vitro* activity of quinolones has been shown when SOS response is suppressed and reactive oxygen species (ROS) are overproduced, separately. Herein, we investigate the effect of these two processes, alone or in combination, using a genetic strategy creating doubles or triple knockouts mutants for SOS response (*recA*), detoxification effectors (*katG, katE, sodA, sodB, ahpC*), and regulator of the stress response (*oxyR and rpoS*) in an isogenic model in *Escherichia coli*.

**Materials/methods:** *E. coli* BW25113 (wild-type) single-gene deletion mutants (Δ*recA*, Δ*katG*, Δ*katE*, Δ*sodA*, Δ*sodB*, Δ*ahpC*, Δ*oxyR* and Δ*rpoS*) were selected from the KEIO collection. Double-gene deletion mutants (Δ*recA*Δ*katG*, Δ*recA*Δ*katE*, Δ*recA*Δ*sodA*, Δ*recA*Δ*sodB*, Δ*recA*Δ*ahpC*, Δ*recA*Δ*oxyR*, Δ*recA*Δ*rpoS*, Δ*katG*Δ*katE*, Δ*sodB*Δ*sodA*) and triple-gene deletion mutant (Δ*recA*Δ*katG*Δ*katE*) was generated by phage P1vir transduction. Susceptibility testing to ciprofloxacin was determined by gradient strips in aerobiosis and anaerobiosis. Antimicrobial activity was evaluated by time-kill curve assays with ciprofloxacin concentration of 1xMIC relative to Δ*recA* during 24h and spot test with different inoculum (10^2-10^7 CFU/ml) and ciprofloxacin concentration of 0.125xMIC relative to Δ*recA* (0.0005mg/L) in aerobiosis.

**Results:** Suppression of SOS response together with detoxification systems reduced ciprofloxacin MICs values up to 16-fold and 4-fold compared to wild-type strain and Δ*recA* mutant, respectively in aerobiosis. However, this effect was not observed under anaerobic conditions. Time-kill curves assays [Figure 1a] showed a significant reduction in CFU/mL of double knockout (Δ*katG*-Δ*recA*, Δ*sodA*-Δ*recA* and Δ*ahpC*-Δ*recA*) compared to Δ*recA* in short times (2h: 2-2,5Log and 4h: 2,5-4Log). Spot test [Figure 1b] showed a greater susceptibility of double (Δ*katG*Δ*recA* and Δ*katE*Δ*recA*) and triple knockout (Δ*katG*Δ*katE*Δ*recA*) respect to Δ*recA*. Also, Δ*recA* mutant increased susceptibility compared to *E. coli* BW25113 and simple (Δ*katG*, Δ*katE*) and double knockout (Δ*katG*Δ*katE*).

**Conclusions:** Suppression of SOS response and detoxification systems enhanced sensitization of *E. coli* to quinolones so that the search of inhibitors of both systems would be useful to combat resistance.

---

**Figure 1.** Results of a) time-kill assays (ciprofloxacin concentration 1xMIC relative to Δ*recA*) at 2h and 4h, ***p<0.001, **p<0.005; b) spot test (ciprofloxacin concentration 0.125xMIC relative to Δ*recA*) at 24h.

**Abstract 2674**

**Antimicrobial resistance monitoring through the ATLAS global surveillance programme 2004-2018**

Meredith Hackel*1, Sam Bouchillon1, Michael Dowzicky2, Dan Sahm1

1IHMA, Schaumburg, United States, 2Pfizer, Inc., Collegeville, United States

**Background:** The ongoing problem of antibiotic resistance, including multidrug resistance is a global health issue. In order to determine the extent of the problem and to identify changes in the resistance patterns of global, regional and local pathogens, world-wide antibiotic surveillance programs are essential. The Antimicrobial Testing Leadership and Surveillance (ATLAS) program has provided reliable, global, regional and local in vitro susceptibility data, including mechanisms of resistance, since 2004. As it is important to monitor the emergence of new species and new resistance mechanisms over time, in this analysis we present a longitudinal analysis of resistance to commonly prescribed antimicrobials for isolates collected globally for ATLAS 2004-2018.

**Materials/methods:** A total of 284,808 non-duplicate, clinically isolated Enterobacterales were collected in 2004-2018 in the ATLAS program. Susceptibility testing was performed by broth microdilution and interpreted using 2019 EUCAST breakpoints. For tigecycline, only *Escherichia coli* and *Citrobacter koseri* are analyzed following the EUCAST 2019 guidelines. Avibactam was tested at a fixed concentration of 4 mg/L.

**Results:** The proportion of Enterobacterales isolates resistant to commonly used antimicrobials has fluctuated over the 15 years compared in this analysis, with significant increases in resistance for cefepime (9.9% to 20.1%), meropenem (1.5% to 3.0%), and piperacillin-tazobactam (12.5% to 15.4%) between 2004-2006 and 2016-2018, and ceftazidime-avibactam (0.5% to 1.6%) between 2010-2012 and 2019-2018 (p<0.05). Amikacin and tigecycline showed no significant increase in resistance over 15 years of study.

Percent resistant based on EUCAST 2019 breakpoint; tigecycline data includes *E. coli* and *C. koseri*, only; NT, not tested

**Conclusions:** This longitudinal analysis of a 15-year surveillance study confirms rising rates of antimicrobial resistance to commonly used antibiotics. Continued monitoring is essential to understand the scope of this global public health issue, and to aid in the development of new strategies and treatments for these key pathogens.

Abstract 2675

**Predictors of worse outcome in patients with West Nile virus infection: a multi-centre study**

Giulio Virgili*1, Luciano Attard2, Michele Bartoletti1, Luigi Raumer4, Giada Rossini3, Roberto D'Angelo4, Luca Spinardi5, Valentina Geatti6, Lorenzo Massoli7, Mariachiara Di Nuzzo7, Enrico Biagi8, Carlo Contini7, Marco Libanore9, Elisa Fallica9, Valeria Tugnoli9, Erica Franceschini9, Cristina Mussini10, Martina Lancellotti10, Giulia Martelli11, Francesco Cristini11, Sergio Venturini12, Massimo Crapis12, Keivan Kaveh Moghadam13, Pierluigi Viale1

1Alma Mater Studiorum - Università di Bologna, Infectious Disease Unit – Department of Medical and Surgical Sciences, Bologna, Italy, 2Policlinico Sant’Orsola-Malpighi, Infectious Disease Unit, Bologna, Italy, 3S. Orsola-Malpighi University Hospital, Operative Unit of Clinical Microbiology, Bologna, Italy, 4Policlinico Sant’Orsola-Malpighi, Operative Unit of Neurology, Bologna, Italy, 5Policlinico Sant’Orsola-Malpighi, Neuroradiology, Bologna, Italy, 6Alma Mater Studiorum - Università di Bologna, Operative Unit of Radiology, Bologna, Italy, 7University of Ferrara, Infectious Disease Unit, Ferrara, Italy, 8Ospedale Sant’Anna, Infectious Disease Unit, Ferrara, Italy, 9Ospedale Sant’Anna, Operative Unit of Neurology, Ferrara, Italy, 10University of Modena and Reggio Emilia, Infectious Disease Unit, Modena, Italy, 11Ospedale “Infermi” di Rimini, Infectious Disease Unit, Rimini, Italy, 12Hospital “Santa Maria degli Angeli” - Pordenone, Infectious Disease, Pordenone, Italy, 13Ospedale Maggiore Carlo Alberto Pizzardi, Neurology and Stroke Unit, Bologna, Italy

**Background:** Although West Nile virus (WNV) infection has established itself as a real epidemiological emergency, there is still a lack of knowledge regarding its clinical connotations. The primary objective of this study is to identify negative prognostic factors (clinical, electro-encephalographic, radiological, biohumoral or microbiological) in patients with West Nile virus infection(WNI).

**Materials/methods:** This was a retrospective, observational, multicenter study conducted in five centres during the WNI outbreak occurred in Northern Italy in the 2018

All adult patients with diagnosis of West Nile infection virus were included. The diagnosis of WNI was defined by specific nucleic acid in blood, CSF, or urine, or Virus-specific IgM antibodies in CSF or serum.

The primary endpoint was worse outcome, defined by the following composite variable: 30-day mortality or presence of neurological sequelae after six months of follow-up.

**Results:** A total of 130 patients were enrolled. Median (IQR) age was 70 (49-79) years and 43% of the patients were females. The median (IQR) Charlson Index score was 4 (0.75 – 5). Patients were managed in regular wards or intensive care units in 93.1% and 6.9% of cases, respectively.

Worse outcome was observed in 33% of the cases. More specifically, we found 30-day mortality in 13.8% of cases and neurological sequelae at six months follow-up in 25% of cases. These were represented by cognitive-mnestic or motor impairment (44.8%), cranial nerve deficiency (6.8%), persistent headache (24%), neuropsychiatric disorders(17.2%).

Multivariate analysis according to logistic regression demonstrated the factors independently associated with worse outcome were: detectable viraemia at infection diagnosis [OR 2.535 [95% CI 1.00-4.437] p 0.050], leukopenia [WBC <4000/mm] [OR 3.591 [95% CI 1.147-11.240] p 0.028], fever≥38 °C [OR 3.471 [95% CI 1.165-10.347] p 0.026], diarrhea/abdominal pain [OR 3.043 [95% CI 1.106-8.374] p 0.031], onset phenotype with meningitis/encephalitis [OR 2.496 [95% CI 1.026-6.072] p 0.044].

**Conclusions:** Simple variables such as leukopenia, presence of diarrhea/abdominal pain and fever over 38 °C, together with the type of clinical onset and detectable viraemia are able to predict the outcome of WNV infection.

**Presenter email address:** giulio.virgili@studio.unibo.it
**Evaluation of the RIDA QUICK Helicobacter and RIDASCREEN Helicobacter kits on stool samples for *Helicobacter pylori* diagnosis**

Alice Buissonniere¹, Lucie Benejat¹, Emilie Bessède¹, Francis Megraud², Philippe Lehours*¹

¹Chu Pellegrin Bordeaux, CNR Campylobacters-Helicobacters, Bordeaux, France

**Background:** The diagnosis of *Helicobacter pylori* infection can be made by non-invasive tests. The detection of bacterial antigens in stool samples is a technique proposed by some suppliers. The objective of this study was to evaluate retrospectively the performance of the commercial RIDA®QUICK *Helicobacter* and RIDASCREEN® *Helicobacter* (r-biopharm) kits on stool samples.

**Materials/methods:** A collection of 132 stools was used in this study: 94 stools obtained from *H. pylori* negative patients (negative culture and PCR on gastric biopsy) and 38 stools from *H. pylori* positive patients (5 patients negative culture /PCR + and 33 patients culture + /PCR +). The performances (sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV)) were evaluated for the RIDA®QUICK *Helicobacter* and RIDASCREEN® *Helicobacter* kits in comparison to the real-time PCR results performed on gastric biopsies (Oleastro et al., J Clin Microbiol 2003). Discordants with respect to the *H. pylori* status, were checked on the same day of the test by repeating the test. The RIDA®QUICK *Helicobacter* tests were read by the naked eye by 3 independent users. RIDASCREEN® *Helicobacter* tests were analyzed on an ELISA Etimax (Diasorin) according to the supplier’s recommendations.

**Results:** All of the readings concerning the RIDA®QUICK *Helicobacter* tests were concordant between the 3 users, ie 94/94 negative tests and 34/38 positive tests. RIDASCREEN® *Helicobacter* tests were negative in all 94 *H. pylori* negative and positive in 35/38 positive stools (see table). Reading of the RIDA®QUICK *Helicobacter* tests was not a problem in routine practice. The migration of the stool suspensions within the strip did not pose a technical problem.

**Conclusions:** The RIDA®QUICK *Helicobacter* and RIDASCREEN® *Helicobacter* kits have excellent performances and can be included in the armamentarium of diagnostic tests for *H. pylori* infection.

Abstract 2678

**Epidemiology of the Staphylococcus aureus CA-MRSA USA300 in Belgium**

Maria Angeles Argudín*, Delphine Martiny¹, Nicolas Yin¹, Ariane Deplano¹, Claire Nonhoff¹, Alaeddine Meghraoui¹, Charlotte Michel¹, Marie Hallin¹

¹Laboratoire Hospitalier Universitaire de Bruxelles (LHUB-ULB), CNR Staphylocoques, Brussels, Belgium

Abstract third-party references: This study has been financed by the LHUB-ULB.

**Background:** Methicillin resistant Staphylococcus aureus (MRSA) is a major concern for public health. Since the 90s, community acquired (CA) MRSA lineages have been increasingly reported as cause of skin and soft tissue infections, necrotizing pneumonia and endocarditis. Within CA-MRSA only the USA300 North American (NA) variant has a worldwide distribution. Some studies established that its epidemiology in Europe is the result of multiple introductions with limited spread in the general population. However, data from the Belgian National Reference Center (NRC) of Staphylococci suggest that this clone is frequent (nearly endemic) in our country. Our data also suggest that the USA300 Latin American (LV) variant is emerging in Belgium. In this study, we have used whole genome sequencing (WGS) to analyze a collection of CA-MRSA USA300 and related isolates recovered in Belgium from 2005 to 2018.

**Materials/methods:** 119 isolates previously characterized by classical molecular typing methods (PCR detecting mecA, PVL and ACME; spa-typing) were selected from the NRC collection for WGS. BioNumerics v.7.6 (Applied Maths) was used for phylogenetic analysis (wgSNPs). Center for Genomic Epidemiology tools have been used to establish STs, spa-types, and SCCmec, from WGS data as well as to determine the presence/absence of ACME (related to USA300-NA), COMER (related to USA300-LV), virulence, antimicrobial, biocide and metal resistance genes.

**Results:** The wgSNPs showed the presence of three main clusters, corresponding to USA-300-NA, USA300-LV and “other” CCB CA-MRSA [Figure 1]. Some USA300-NA strains were directly related to the reference strain, suggesting multiple non-related introductions. Other strains were closely related (≤20 SNPs) implying outbreaks. In fact, two big clusters of closely related USA300-NA strains were found: (a) fluoroquinolone resistant isolates recovered between 2008 and 2017; (b) fluoroquinolone susceptible isolates recovered between 2008 and 2017; (b) fluoroquinolone susceptible isolates recovered between 2010 and 2018. Five out of 8 USA300-LV isolates were related to trips to South America. Regarding other CC8 CA-MRSA, we confirmed the introduction in Belgium of the clone ST923 previously found in Colombia and Venezuela producing pediatric infections or colonizing healthy youths and children.

**Conclusions:** In this study we elucidated the epidemiology of USA300-NA in Belgium, and confirmed the recent introduction of USA300-LV and ST923 in the country.

**Acknowledgments:** This study has been financed by the LHUB-ULB.

**Figure 1.** wgSNP minimum spanning tree of CC8 CA-MRSA isolates.

Each circle represents a strain colored on the basis of the populations found. The genome of the USA300-NA TCH1516 (accession number: NC_010070) strain (in red) was used as reference genome for mapping to determine SNP differences. Two main groups of closely related USA300 isolates were found: (a) fluoroquinolone resistant isolates recovered between 2008 and 2017 in four Belgian regions (but mainly from Brussels); (b) fluoroquinolone susceptible isolates recovered between 2010 and 2018 in four Belgian regions (but mainly from Antwerp and East Flanders). Few strains without PVL and/or ACME clustered within USA300 NA isolates, suggesting that they have lost these virulence traits. Numbers indicated n° of SNPs differences.

ART24, a novel live biotherapeutic product, in development for the prevention of Clostridioides difficile infection spares gut commensal species in vitro and allows for expansion of beneficial bacteria

Michelle O’donnell¹, Bran Healy¹, Colin Hill², Paul Ross³, Mary Rea¹, Ronald Farquhar¹, Laurent Chesnel*³

¹Artugen therapeutics, Teagasc Food Research Centre, Fermoy, Ireland, ²University College Cork, APC Microbiome Institute, Cork, Ireland, ³Artugen therapeutics USA, Inc, Concord, United States

**Background:** ART24 is being investigated as a live biotherapeutic product (LBP) treatment to prevent recurrence of *Clostridioides difficile* infection (CDI) following successful antibacterial treatment. ART24 was isolated from a human fecal sample, purified and identified as a member of the “operational group *B. amyloliquefaciens*”. We have determined that the strain has potent *C. difficile* killing activity and sought to determine the spectrum of activity of ART24.

**Materials/methods:** To investigate the effects of ART24 on gut microbiota, three approaches were undertaken. First, ART24 cell-free pH-neutralized supernatants were prepared from 24-hour cultures and assessed for antibacterial activity using a well diffusion assay against *C. difficile* and gut commensals. Additionally, a human colonic model with frozen fecal slurry (n=6 subjects) was inoculated with 6x10⁸ CFU of vegetative ART24 and incubated for 24 hours. Lastly, minipigs were dosed with 1.06x10¹⁰ CFU/dose QD for 28 days and fecal samples were collected. DNA was extracted from the colonic model and minipig fecal samples and analyzed using qPCR and MiSeq compositional sequencing and bioinformatics along with statistical analyses.

**Results:** ART24 was found to have a relatively narrow spectrum of activity primarily against *Clostridium* and *Bacillus* species. Little to no activity against *Lactobacillus* and *Bifidobacterium* was observed indicating very weak activity against gut commensal bacteria. By qPCR and 16S analysis from the in vitro colonic model ART24 demonstrated little to no impact on other components of the gut microbiota (*Enterobacteriaceae, Firmicutes, Bacteroidetes, Verrucomicrobia, and Lactobacillus*) after 24 hours of incubation. The ART24 treated wells showed an increase in the *Bifidobacterium* genus relative to T0 where the relative abundance went from 3.95% to 16.02%. No changes in alpha and beta diversity in vitro, in the colonic model, and in the animals were observed and correlate with the qPCR and agar-based results, indicating that ART24 does not have a deleterious effect on the human colonic microbiota.

**Conclusions:** These studies suggest that ART24 has little effect on the human and minipig colonic microbiota and suggest that it supports the expansion of *Bifidobacterium*. ART24 is a promising LBP clinical candidate undergoing Phase 1 clinical development for the prevention of CDI recurrence.

**Presenter email address:** lchesnel@artugentherapeutics.com
Evaluation of the expanded-coverage Staphylococcus species assays and improved methicillin resistance detection algorithms of the BioFire FilmArray Blood Culture Identification 2 (BCID2) panel

Tanner Robinson1, Jeremiah Antosch1, Kerrin Koch1, Iryna Kavetska1, Jessica Stone1, Briana Flaherty1, Maggie Buccambuso1, Kristen Holmberg1, Yang Lu1, Benedicte Pons2, Margarita Rogatcheva*1, Usha Spaulding1

BioFire Diagnostics, LLC, Salt Lake City, United States, 2BioMerieux, Grenoble, France

Background: Staphylococci are opportunistic pathogens and a major cause of both nosocomial and community-acquired bloodstream infections (BSI). Compared to the existing BioFire® FilmArray® Blood Culture Identification (BCID) Panel, the updated BioFire BCID2 Panel contains an assay with expanded coverage for Staphylococcus species. Also, alongside an updated Staphylococcus aureus assay, the BCID2 Panel includes assays for key coagulase-negative staphylococci (CoNS) like Staphylococcus epidermidis, and Staphylococcus lugdunensis. Revised algorithms, facilitated by a new assay that identifies the insertion site of the staphylococcal cassette chromosome mec in S. aureus, aid accurate reporting of methicillin-resistant S. aureus (MRSA). Here, we evaluate the coverage and performance of these assays and associated algorithms.

Materials/methods: Coverage and performance were evaluated using sequence data available for 72/77 species/subspecies, 107 Staphylococcus isolates and 107 residual positive blood cultures (PBC) collected prospectively from 9 clinical sites. For pathogen identification from residual PBC, the reference method was microbial culture performed at clinical sites. The Xpert MRSA/SA BC test (Cepheid, Inc.) and phenotypic susceptibility testing were used as reference methods for MRSA.

Results: In silico assessment predicts reactivity for 66/72 staphylococci compared to ~40 species by the BCID Panel. During analytical testing, the Staphylococcus species assay also detected 103/107 isolates. Specific assays for S. aureus, S. epidermidis, and S. lugdunensis were reactive to all relevant isolates. At least one Staphylococcus species was reported in 472/1074 (44%) samples enrolled in the prospective clinical study; the BioFire BCID2 Panel accurately identified 99.8% of these. The BioFire BCID2 Panel MRSA results were 100% concordant with phenotypic results and 95.4% concordant with Xpert MRSA/SA BC test. In addition, the algorithm accurately identified the absence of MRSA in 3/3 cases where methicillin-susceptible S. aureus was present with methicillin-resistant S. epidermidis (MRSE) in the PBC.

Conclusions: The BioFire BCID2 Panel assays for S. aureus, S. epidermidis, S. lugdunensis, and Staphylococcus spp. are highly inclusive of clinically relevant staphylococci. The high accuracy of the MRSA detection algorithms are anticipated to assist in implementation of effective treatment plans and antibiotic stewardship.

Data presented are from assays that have not been cleared or approved for diagnostic use.

Abstract 2681

Targeting membrane transporters and energy metabolism in *Mycobacterium tuberculosis* through in silico drug repurposing

Liliana Rodrigues*, Pedro Cravo1, Miguel Viveiros1

1Global Health and Tropical Medicine [GHTM], Instituto de Higiene e Medicina Tropical [IHMT] - Universidade NOVA de Lisboa, Lisboa, Portugal

**Background:** Energy metabolism, particularly the oxidative phosphorylation pathway, has emerged as a novel target pathway in tuberculosis (TB) drug discovery. Inhibitors of bacterial energy metabolism may interfere with several physiological processes, including the activity of efflux pumps involved in drug resistance. A way to accelerate drug discovery is to find new uses for existing approved drugs, a strategy known as drug repurposing. A repurposed drug can follow directly to preclinical testing and clinical trials, reducing time, cost and risk. We used such strategy to find drugs that target energy metabolism and membrane transporters in *Mycobacterium tuberculosis*.

**Materials/methods:** A list of *M. tuberculosis* proteins involved in energy metabolism and membrane transport was compiled using the TDR Targets and Mycobrowser databases. Each of these proteins was considered a potential drug target and its amino acid sequence used to interrogate two web-based databases [DrugBank and STITCH 5.0] that provide information on drugs and their targets. From the targets obtained from both databases only the ones predicted to interact with approved drugs were selected. The functional regions of the approved drug targets and *M. tuberculosis* targets were compared using The ConSurf Server.

**Results:** TDR Targets and Mycobrowser identified 668 genes that encode proteins involved in energy metabolism and membrane transport. Sequence similarity screenings predicted 69 targets associated with 245 approved drugs. Functional regions comparison between approved drug targets and predicted *M. tuberculosis* targets resulted in 18 potential *M. tuberculosis* targets that are expected to interact with 23 approved drugs. These drugs are predicted to target succinate dehydrogenases, sodium-potassium ATPases, NADH-dehydrogenases, among others. Some examples are thiabendazole, deslanoside and doxorubicin.

**Conclusions:** Most of the identified drugs are approved for a variety of indications, such as arrhythmia, epilepsy, chronic immune thrombocytopenia, and cancer and may serve as lead compounds for the development of new anti-TB drugs. This work has the potential to greatly benefit TB drug discovery by finding new drugs for a largely unexplored pathway and by introducing a new approach that can increase the probability of identifying effective drugs and decrease the bottlenecks of conventional drug discovery.

Abstract 2684

(In)stability of female urinary microbiota: who’s resident and who’s passing by

Magdalena Ksiezarek*, Svetlana Ugarcina Perovic1, Joana Rocha1, Filipa Grosso1, Luisa Maria Vieira Peixe1

1UCIBIO-REQUIMTE. Laboratory of Microbiology, Faculty of Pharmacy, University of Porto, Porto, Portugal

Background: The recent recognition of the female urinary microbiota (FUM) has challenged the current assumptions of the etiology, diagnosis and treatment of urinary tract diseases. Still, we have incomplete knowledge on healthy community profiles and their stability over time. Using extended culturomic approach, we aimed to evaluate FUM composition and stability of healthy women.

Materials/methods: Ten healthy reproductive-age women provided midstream urine samples (n=20) at two time points within 2,5 years interval, that were subjected to extended culturomics (100 ul urine; blood agar and supplemented chromogenic agar; 48h of incubation; different atmospheric conditions) with isolate identification to the species level by MALDI-TOF/MS and/or suitable genotypic biomarkers (16S rRNA, pheS, rpoB, recN).

Results: Over 2000 isolates (range of 17-321 isolates/sample) were assigned to 5 phyla, 45 genera and 111 species (average of 19 species/sample). The stability of phyla between 1st and 2nd sampling was observed, comprising Firmicutes (51% of species in both samples), Actinobacteria (38%, 33%), Proteobacteria (6%, 11%), Bacteroidetes (3%, 3%) and Fusobacteria (1%, 2%). A high bacterial load was observed (10^4- 10^8 CFU/ml) – in 70% samples varied up to 10^2 CFU/ml between paired samples. The Staphylococcus and Lactobacillus were the most prevalent genera present in 18 out of 20 (18/20) and 17/20 samples, respectively. The stability at species level was observed for 35 bacterial species, most being previously identified as highly prevalent e.g., Staphylococcus epidermidis (8 out of 10 individuals, 8/10) and Streptococcus anginosus (6/7) mostly in low relative abundance (RA). Notably, opportunistic pathogens associated with urogenital tract health were detected e.g., Gardnerella vaginalis (3/5), maintaining high RA at both sampling points (up to 91% RA). Additionally, one individual presented highly abundant Enterobacteriaceae member (10^7-10^8 CFU/ml) in both samples (1st sample: Citrobacter koseri [99.98% RA]; 2nd sample: Escherichia coli [90.76% RA]) together with Lactobacillus jensenii.

Conclusions: For the first time, we described that healthy FUM undergoes bacterial species shifts over time, that further complicates the establishment of a healthy FUM pattern. Despite those fluctuations, certain species are more persistent and less susceptible to changes e.g., Gardnerella vaginalis and Lactobacillus crispatus, which needs to be further explored.

Abstract 2685

Evaluation of the Novodiag Bacterial GE+ kit for the diagnosis of intestinal bacterial infections

Charly Roy1, David Robert2, Delphine Boraud2, Alice Buissonniere1, Lucie Benejat1, Astrid Ducournau1, Francis Megraud1, Emilie Bessède1, Philippe Lehours*1

1Chu Pellegrin Bordeaux, CNR Campylobacters-Helicobacters, Bordeaux, France, 2Laboratoire Exalab, Laboratoire Exalab, Le Haillan, France

Background: The bacteriological diagnosis of intestinal bacterial infections has historically been based on culture on agar plates. However, culture lacks sensitivity and some enteropathogens such as pathovars of Escherichia coli escape routine diagnosis. Our goal was to evaluate the analytical performance of the Novodiag® Bacterial GE + kit, for the detection of enteropathogenic bacteria in acute community diarrhea.

Materials/methods: 252 stools were included in this study (198 retrospective and 54 prospective). The results were compared to stool culture in first intention. In the case of negative culture, the performances were evaluated in relation to the results obtained on BD Max Enteric Bacterial Panel (retrospective stools) or by other real-time PCR formats (in-house or commercial).

Results: Of the 252 samples, 207 were positive and 45 were negative. In the prospective samples (January-March 2019), 6 stools were positive by culture (prevalence: 11.1%) and 18 with the Novodiag® Bacterial GE+ kit (prevalence: 33.3%). All enteropathogens combined, the Novodiag® Bacterial GE + kit had a sensitivity of 99.03% and a specificity of 95.65%. Only 3 discrepancies were identified: an EHEC detected by BDMax but negative by Novodiag®, culture and in-house PCR; a Campylobacter coli detected by Novodiag® but negative by PCR RidaGene Bacterial Stool Panel (r-biopharm), culture and in-house Campylobacter PCR; and 1 Campylobacter jejuni positive by PCR RidaGene and BDMax but undetected by Novodiag®. Overall sensitivities for Campylobacter, Salmonella, Shigella, Yersinia, EHEC and ETEC ranged from 99 to 100%, and specificities from 99 to 100%, PPV from 94.1 to 100% and NVP from 99 to 100%.

Conclusions: The analytical performances of the Novodiag® Bacterial GE + kit are excellent. It can be used as a routine tool in the rapid diagnosis of bacterial gastroenteritis. Despite the eNAT tube dilution of the primary sample, the detection of Salmonella sp. and EHEC was perfect. The kit has the advantage of only detecting pathogenic Yersinia sp. The performances for Campylobacters are very satisfactory.

Abstract 2688

**Toll like receptors, IFN-lambdas and IFN-stimulated genes expression in cystic fibrosis patients with rhinovirus infection**

Federica Frasca*, Camilla Bitossi, Agnese Viscido, Giuseppe Oliveto, Mirko Scordio, Maria Trancassini, Valeria Pietropaolo, Fabio Midulla, Giuseppe Cimino, Paolo Palange, Alessandra Pierangeli, Carolina Scagnolari, Guido Antonelli

*Sapienza University of Rome, Roma, Italy

**Background:** Since an inappropriate and sustained activation of toll like receptors (TLRs) and interferon (IFN) response may contribute to a chronic inflammatory outcome resulting in detrimental effects in CF patients, our aim is to evaluate whether human rhinovirus (HRV) infection might alter the respiratory gene expression of TLRs and type III IFN pathways compared to HRV-negative patients.

**Materials/methods:** Respiratory samples (n=515) were collected from the respiratory tract of CF patients (n=294) over a period of 12 months. HRV-RNA was tested by RT-PCR. Amplified fragments of HRV-positive samples were sequenced for HRV species characterization. Levels of TLRs (TLR2, TLR4, TLR8), type III IFNs (λ1 and λ3), IL28RA, and IFN stimulated genes (ISGs: MxA, ISG15, and ISG56)-mRNAs and HRV viral load were measured by quantitative RT/TagMan assay.

**Results:** HRV-RNA was detected in 80 out of 515 respiratory samples (15.5%) with a similar rate in all age groups (0-10 years, 11-24 years, ≥25 years). Increased transcript levels of TLRs (TLR2, TLR4, TLR8), type III IFNs (λ1 and λ3), IL28RA and ISGs (MxA, ISG15, and ISG56) were observed in HRV A-C positive patients compared to those with non-HRV infection (p<0.05 for all genes, Mann-Whitney U Test). By contrast no differences in the expression of TLRs and type III IFN pathways were found between HRV-B positive patients and those without HRV infection. Moreover, transcript levels of TLR2 (r=0.3924), TLR8 (r=0.4222), IFNA3 (r=0.4548), IL28RA (r=0.4587), MxA (r=0.4455) and ISG15 (r=0.3778) positively correlated with HRV viral load (p<0.05 for all genes, Spearman's rho coefficient).

**Conclusions:** Our results indicated that TLRs, IFNλ1/3, IL28RA and ISGs transcripts are highly expressed in the respiratory tract of HRV A-C positive CF patients and correlate with viral load.

**Abstract 2689**

**In vitro activity of ceftolozane/tazobactam and comparators against *Pseudomonas aeruginosa* isolates collected in the United States: SMART 2018**

Krystyna Kazmierczak*1, Janet Raddatz1, Katherine Young2, Mary Motyl1, Dan Sahm1

1IHMA, Schaumburg, United States; 2Merck & Co., Inc., Kenilworth, United States

**Background:** Ceftolozane is an antipseudomonal cephalosporin with improved activity compared to ceftazidime. The combination of ceftolozane and tazobactam, a β-lactamase inhibitor, is approved for treatment of complicated urinary tract and complicated intra-abdominal infections in the US and more than 60 countries, and for treatment of hospital-acquired and ventilator-associated bacterial pneumonia in the US and Europe. We evaluated the activity of ceftolozane/tazobactam (C/T) and comparators against β-lactam non-susceptible (NS) *P. aeruginosa* isolates collected in the US as part of the SMART surveillance program in 2018.

**Materials/methods:** Twenty-four medical laboratories each collected up to 250 consecutive aerobic or facultative gram-negative pathogens from various infection sources, including 895 *P. aeruginosa*. MICs were determined by CLSI broth microdilution and interpreted using CLSI 2019 breakpoints. Avibactam was obtained from BioChemPartner (www.biocompartner.com) and tested at a fixed concentration of 4 mg/L. A multidrug-resistant phenotype (MDR) was defined as non-susceptibility to three or more sentinel agents (aztreonam, cefepime, piperacillin/tazobactam, imipenem, amikacin, ciprofloxacin, colistin). Pan-β-lactam-NS was defined as non-susceptibility to all tested β-lactams (aztreonam, ceftazidime, cefepime, piperacillin/tazobactam, imipenem, meropenem).

**Results:** C/T demonstrated potent *in vitro* activity against *P. aeruginosa* collected in the US (MIC₉₀ 2 mg/L; 96.4% susceptible), with similar percentages of susceptibility observed across US census regions (Table). 30.6%, 26.8%, 23.1%, 21.6%, 25.5%, and 8.7% of collected isolates were imipenem-NS, piperacillin/tazobactam-NS, meropenem-NS, ceftazidime-NS, MDR, and pan-β-lactam-NS, respectively. Susceptibility to C/T ranged from 74.4%-92.0% among these resistant subsets of isolates, 6-19 percentage points higher than susceptibility to ceftazidime/avibactam (CZA). *In vitro* susceptibility to C/T was consistently higher among β-lactam-NS and MDR *P. aeruginosa* collected in different regions. C/T retained activity against 56.9% of all CZA-resistant *P. aeruginosa* (5.7% of collected isolates), while only 31.3% of C/T-NS isolates (3.5% of collected) were susceptible to CZA. Four metallo-β-lactamase-producing isolates were collected in 2018, in the West (n=2), Midwest (n=1) and South (n=1), and these isolates tested as resistant to both C/T and CZA.

**West:** California, Colorado, Utah; **Midwest:** Illinois, Indiana, Iowa, Michigan, Minnesota, Nebraska, Ohio, Wisconsin; **Northeast:** New York, Pennsylvania; **South:** Florida, Georgia, Kentucky, North Carolina, Texas. CAZ, ceftazidime; CZA, ceftazidime/avibactam; C/T, ceftolozane/tazobactam; TZP, piperacillin/tazobactam; IMI, imipenem; MEM, meropenem; NS, non-susceptible; R, resistant; pan-β-lactam-NS, non-susceptible to all tested β-lactams; MDR, multidrug resistant: NS to three or more sentinel agents.

**Conclusions:** C/T could provide an important treatment option for patients in the US with infections caused by drug-resistant *P. aeruginosa*, including ceftazidime/avibactam-resistant isolates and those non-susceptible to one or multiple antimicrobial agents.

**Presenter email address:** kkazmierczak@ihmainc.com
ART24, a novel live biotherapeutic product, in development for the prevention of *Clostridioides difficile* infection is bactericidal against *C. difficile* and degrades toxins A and B in vitro

Michelle O’donnell¹, James Hegarty*¹, Sarah Schulz¹, Rachael Jacobson¹, Colin Hill¹, Paul Ross², Mary Rea¹, Ronald Farquhar⁴, Laurent Chesnèl⁴

¹Artugen therapeutics, Teagasc Food Research Centre, Fermoy, Ireland, ²Albany Molecular Research, Inc, Buffalo, United States, ³University College Cork, APC Microbiome Institute, Cork, Ireland, ⁴Artugen therapeutics USA, Inc, Concord, United States

**Background:** ART24 is being investigated as a live biotherapeutic product (LBP) treatment to prevent recurrence of *Clostridioides difficile* infection (CDI) following successful antibacterial treatment. ART24 was identified from a screening effort from stool samples detecting bacteria with direct anti-*C. difficile* activity and proteolytic capability. ART24 was identified as a member of the *B. amyloliquefaciens/B. velezensis* group. We sought to determine if both of these activities translated in vitro in *C. difficile* toxin degradation and *C. difficile* killing.

**Materials/methods:** The anti-*C. difficile* activity of ART24 was investigated using a 12-well plate liquid co-culture method incubating different ratios of ART24 to *C. difficile* for 24 hours. ART24 was tested against different starting levels of *C. difficile* (10²-10⁵ CFU/ml). *C. difficile* was enumerated pre and post-incubation to assess the effect of each ratio of ART24. Extracellular protease activity from ART24 was tested for its ability to cleave purified *C. difficile* toxins A and B. Toxin cleavage experiments were run in duplicate using pH-neutralized and IPA-extracted supernatants from freshly grown ART24, prepared from 2 independent cultures. The aliquots were incubated for 2 hours at 37°C. Western blot analysis was conducted, using standardized toxin A and B antibodies. ART24 was also tested as a lyophilized powder after reconstitution and serial dilution in PBS.

**Results:** ART24 is bactericidal against *C. difficile*. The lowest ratio [ART24:*C. difficile* CFU] that supports *C. difficile* killing (>3 log reduction in 24 hours) was 300:1, with lower ratios inhibiting the growth rate of *C. difficile*. A reconstituted preparation of lyophilized ART24 caused complete cleavage of *C. difficile* toxins A and B. The amount of toxin cleavage was dependent upon the amount of lyophilized ART24 CFUs reconstituted, with lower dilutions (i.e. 10⁻² and 10⁻³ dilutions) showing more cleavage than higher dilutions (range of 10⁻⁴ to 10⁻⁷ serial dilutions).

**Conclusions:** At projected clinically-relevant concentrations, ART24 is bactericidal against *C. difficile* in liquid co-cultures and completely cleaves toxins A and B. ART24 is a promising LBP candidate in Phase 1 clinical development for the prevention of recurrent CDI.

Background: Influenza viruses cause seasonal outbreaks and pose a continuous pandemic threat. Although vaccines are available for influenza control, their efficacy varies each season and a vaccine for a novel pandemic virus manufactured using current technology will not be available fast enough to mitigate the effect of the first pandemic wave. Antivirals can be effective against many different influenza viruses but have not been used extensively for outbreak control. Baloxavir, a new antiviral which targets the influenza virus endonuclease, has been shown to reduce virus shedding more effectively than oseltamivir, a widely used neuraminidase inhibitor drug. This raises the possibility that baloxavir could limit spread of influenza by reducing virus transmission from an infected individual to healthy contacts. To investigate this potential, we used the ferret model, which is the most widely used animal model for influenza virus transmission.

Materials/methods: We conducted studies in two different locations with different experimental setups to compare the onward transmission of A[H1N1]pdm09 virus from infected ferrets treated with baloxavir, oseltamivir or placebo, to naive sentinel ferrets exposed either indirectly in adjacent cages or directly by co-housing.

Results: Baloxavir treatment of infected ferrets significantly reduced infectious virus shedding compared to oseltamivir- or placebo-treated ferrets. The frequency of virus transmission from baloxavir-treated ferrets to untreated sentinels was reduced compared to either oseltamivir or placebo group in both experimental setups, even when treatment was delayed until 2 days post-infection. Oseltamivir had no effect on reducing transmission compared to placebo. We did not detect the emergence of drug resistant variants in baloxavir-treated animals or in untreated sentinels.

Conclusions: Using the ferret model, we showed that treatment of influenza-infected individuals with the novel antiviral baloxavir reduces the likelihood of virus transmission to untreated contacts. Our results support the concept that antiviral treatment which significantly decreases influenza virus shedding during infection can translate into reduced influenza transmission.

**In vitro activity of imipenem/relebactam against *Pseudomonas aeruginosa* isolates collected from patients in Europe: SMART 2018**

Nimmi Kothari¹, Stephen Hawser*¹, Sibylle Lob², Krystyna Kazmierczak³, Katherine Young², Pamela Moise³, Mary Motyl³, Fakhar Siddiqui³, Dan Sahm²

¹IHMA, Monthey, Switzerland, ²IHMA, Schaumburg, United States, ³Merck & Co., Inc., Kenilworth, United States

**Background:** Relebactam (REL) is an inhibitor of class A and C β-lactamases that was approved in the USA in combination with imipenem (IMI) for the treatment of complicated intraabdominal and urinary infections. We evaluated the activity of IMI/REL against recent *Pseudomonas aeruginosa* (*Psa*) isolates collected from patients in Western and Eastern Europe as part of the global Study for Monitoring Antimicrobial Resistance Trends (SMART) surveillance program.

**Materials/methods:** In 2018, 54 hospitals from 23 European countries collected up to 250 consecutive aerobic or facultative gram-negative pathogens from various infection sources. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints. US FDA breakpoints were applied to IMI/REL.

**Results:** A total of 1952 *Psa* isolates were collected from patients with lower respiratory tract (64.7%), bloodstream (11.9%), urinary tract (11.8%), and intraabdominal infections (11.6%). Among the 1952 isolates, 5.7% were metallo-β-lactamase (MBL)-positive and were removed from subsequent analyses because REL is not active against class B MBLs. Among the remaining 1840 MBL-negative isolates, 90.8% were susceptible to IMI/REL (MIC₅₀, 0.5 mg/L; MIC₉₀, 2 mg/L; MIC range ≤0.12->32 mg/L), and 71.4% were susceptible to IMI (MIC₅₀, 2 mg/L; MIC₉₀, 16 mg/L; MIC range ≤0.12->32 mg/L). In the presence of REL, imipenem MICs decreased by 2 dilutions for 41.4% of MBL-negative isolates, by 3 dilutions for 21.3% of isolates, and by ≥4 dilutions for 8.9% of isolates. The in vitro susceptibility to IMI/REL and comparators of all MBL-negative *Psa* and subsets of isolates with IMI-resistant phenotypes is shown, stratified by Western and Eastern Europe and for Europe overall (Table).

Overall, IMI/REL was active in vitro against >90% of MBL-negative *Psa* isolates collected in 2018, 13-18 percentage points higher than the activity of the tested comparator β-lactams. IMI/REL activity for overall *Psa* and IMI-resistant *Psa* was exceeded only by colistin; IMI/REL susceptibility was slightly higher in Western than Eastern Europe. In both regions, IMI/REL maintained activity against >67% of MBL-negative *Psa* isolates that were resistant to IMI.

**Conclusions:** IMI/REL could provide an important alternative treatment option for patients in Europe with infections caused by MBL-negative isolates of *Psa*, including IMI-resistant subsets.

Impact of a restrictive antibiotic policy on the emergence of extended-spectrum β-lactamase producing Enterobacteriaceae in the intensive care unit: a quasi-experimental observational study

Christophe Le Terrier1,2, Marco Vinetti2,3, Régine Richard2, Bruno Jarrige4, Sébastien Breurec5, Michel Carles2, Guillaume Thiéry6

1University Hospital Geneva, Intensive care unit, Geneva, Switzerland, 2University Hospital Guadeloupe, Intensive care unit, Pointe-a-Pitre, Guadeloupe, 3Clinical Saint-Pierre Ottignies, Intensive Care Unit, Ottignies-Louvain-la-Neuve, Belgium, 4University Hospital Guadeloupe, Hospital Infection Control Department, Pointe-a-Pitre, Guadeloupe, 5University Hospital Guadeloupe, Department of Microbiology, Pointe-a-Pitre, Guadeloupe, 6University Hospital of Saint-Etienne, Intensive care unit, Saint-Priest-en-Jarez, France

Background: Massive consumption of antibiotics in the intensive care unit (ICU) is a major determinant of extended-spectrum beta-lactamase–producing Enterobacteriaceae (ESBL-E) spreading. We evaluated whether a stewardship program including restrictive antibiotic policy in the ICU would reduce ESBL-E emergence without worsening patient’s outcomes.

Materials/methods: We conducted an observational quasi-experimental pre-post intervention study of all consecutive patients with length of stay (LOS) superior to 48h to the medical-surgical ICU of University Hospital of Guadeloupe. From Jan 1, 2014 to Dec 31, 2014, a liberal strategy was used including a broad-spectrum antibiotic as initial empirical treatment in case of sepsis or suspected infection, followed by de-escalation after 48-72h. From Jan 1, 2015 to Dec 31, 2015, a restrictive strategy was adopted which consisted of limitation of broad-spectrum antibiotics, avoidance of antibiotics targeting anaerobic microbiota and shortening of antibiotic duration. In addition, antibiotic therapy was initiated only after microbiological identification, except in cases of septic shock, acute respiratory distress syndrome and meningitis. Our primary outcome was the incidence of ICU-acquired ESBL-E and the main secondary outcome were all-cause ICU mortality and the rate of ESBL-E infections.

Results: 767 and 826 patients were respectively enrolled in the liberal and in the restrictive strategy period study. During the restrictive strategy period, less patients were treated with antibiotic therapy (41 vs 52%; p<0.001), treatment duration was shorter (5 vs 6 days; p=0.01) and antibiotics targeting anaerobic pathogens were significantly less administrated (87.1% vs 37.5%; p<0.0001). The rate of ICU-acquired ESBL-E carriage was significantly lower during the restrictive strategy period (18.9% vs 11.1%; p<0.0001). Similarly, ICU-acquired ESBL-E infection rate and ICU mortality were lower during the restrictive strategy period. In multivariate analysis, the length of stay in the ICU, the number of antibiotic administrated and the restrictive strategy period were independently associated with a lower rate of ESBL-E acquisition.

Conclusions: In a large cohort of ICU patients, a stewardship program including a restrictive antibiotic strategy showed effective in terms of reduction of antibiotic consumption, especially broad-spectrum antibiotics and antibiotics targeting anaerobic microbiota. This strategy was associated with a lower rate of ESBL-E acquisition without worsening patient’s outcomes.

Genome-based analyses of *Klebsiella pneumoniae* to detect possible host-associations, host-adaptation and effects on virulence

Kathleen Klaper*,1, Lena Heinrich1, Roman Gerlach1, Stephan Fuchs1, Yvonne Pfeifer2, Guido Werner2

1Robert Koch Institut, Wernigerode, Germany, 2Robert Koch Institut, Wernigerode, Germany

**Background:** The increase of “classical” drug-susceptible *K. pneumoniae* (cKP) with extended-spectrum-β-lactamase production (ESBL-cKP) poses a serious threat to health care. In the last 10 years a new “hypervirulent” but mainly drug-susceptible pathotype of *K. pneumoniae* (hvKP) emerged, associated with community acquired infections. Nowadays, there are more and more reports on antibiotic-resistant hvKP, affecting treatment options in ambulatory care and causing nosocomial outbreaks. Traditionally, hvKP have been defined as invasive strains of capsular serotypes K1 and K2 that are string test and rmpA/A2 positive. However, a consensus definition is still missing. Furthermore, there is less knowledge on how and why hvKP colonizes and transits to infection. We investigated genetic characteristics associated with host colonisation or invasion, in order to better understand the pathogenicity of hvKP strains.

**Materials/methods:** A collection of *K. pneumoniae* isolates from German hospitals, including susceptible cKP, ESBL-cKP and hvKP isolates were subjected to whole genome sequencing (WGS). Growth experiments and antibiotic susceptibility assays were performed and cell morphology was assessed microscopically. To analyse macrophage-mediated phagocytosis, RAW264.7 cells were infected with *K. pneumoniae* isolates and intracellular bacteria were quantified. Furthermore, the impact of hypoxia on hvKP pathogenesis was analysed.

**Results:** The majority of K1 isolates belonged to the clonal complex CC23, whereas non-K1 isolates were clonally diverse. ESBL and carbapenemases genes were present regardless of the *K. pneumoniae* multilocus sequence type and several multidrug-resistant hvKP were detected. Interestingly, microscopic analysis of cell length distribution of hvKP cultures revealed filamentous bacteria cells, whereas cKP and ESBL-cKP cultures display heterogeneous rode shaped cells. The elongation into filaments was even more pronounced under hypoxia conditions. In *vitro* phagocytosis assays revealed a lower phagocytosis rate for hvKP than for cKP and ESBL-cKP that is not altered by hypoxia.

**Conclusions:** Our analyses revealed the emergence of ESBL and carbapenemases-producing hvKP isolates in German hospitals. Furthermore, the occurrence filamentous morphotypes in hvKP cultures indicates that filamentation of hvKP bacteria cells provides a survival advantage when hvKP encounter host immune response and phagocytosis.

Abstract 2697

**Genomic adaptation of *Staphylococcus aureus* in a diabetic foot environment**

Cassandra Pouget*, Michel Hosny*, Alix Pantel, Bernard La Scola, Frédéric Laurent, Albert Sotto, Catherine Dunyach-Remy, Jean Philippe Lavigne

1Université de Montpellier, INSERM U1047, Nîmes, France, 2AP HM, IHU, Marseille, France, 3CHU Nîmes, Service de Microbiologie, Nîmes, France, 4HCL, CNR staphylocoques, Lyon, France

**Background:** *Staphylococcus aureus* is the most prevalent pathogen isolated in diabetic foot ulcers (DFU). Few publications have studied the virulence and the adaptation of this pathogen in this chronic wound conditions. The purpose of this study was to evaluate the adaptation of *S. aureus* in an *in vitro* model miming the conditions encountered in DFU.

**Materials/methods:** The *in vitro* experiments consisted to cultivate during 16 weeks four clinical *S. aureus* strains (three with infecting profiles: PVL - Edin-, PVL+ Edin-, PVL+ Edin+; and one with a colonizing profile) by successive inoculations in a specific environment based on the Lubbock biofilm model (composed by Bolton broth, human plasma, human hemolyzed blood, epithelial cells with a fixed basic pH). Before and after exposition in the medium, the four isolates were evaluated: 1) phenotypically; 2) by qRT-PCRs (to evaluate expressions of the main virulence (e.g., lukFS-PV, edinB, edinC, hla, spa, eap, fnbAB, cna) and the global regulator (agr) genes); 3) by crystal violet (to assess the biofilm formation); 4) by *Caenorhabditis elegans* model (to evaluate their virulence); and 5) by whole-genome sequencing (WGS) (to detect potential modifications of genomes).

**Results:** After 16 weeks, we observed the development of small colony variants (SCVs) and the loss of beta-hemolysin production in the 4 studied strains. qRT-PCRs showed a significant decrease of expression of the main virulence genes tested (*lukFS-PV, edinB, edinC, hla, spa*) but the increase of genes involved in adhesion and biofilm (*eap, fnb, icaA, agr*). Crystal violet confirmed the increase of biofilm formation of the isolates after exposition and a decrease of virulence was also noted (LT50: 4.2 days ±0.5 before vs 6.7 ±0.3 after exposition). WGS demonstrated a reduction (~2 Kb) of the genome of the 4 isolates after exposition and same mutations in virulence and metabolisms encoding genes (*splB, splF, sarD*) that could explain the adaptation of the bacteria.

**Conclusions:** Our *in vitro* model confirms the impact of environment on the adaptation of *S. aureus* to prolonged stress environmental conditions. These results contribute to a best comprehension of the role of *S. aureus* to limit its virulence in the chronic wounds.

Abstract 2698

Impact of a national antimicrobial stewardship programme to switch from trimethoprim to nitrofurantoin for treatment of urinary tract infections on the incidence of Escherichia coli bloodstream infection in England, 2015–2019

Amelia Au-Yeung1*, Ayoub Saei1, Andre Charlett1, Olisaeloka George Nsonwu1, Russell Hope1, Berit Muller-Pebody1, Susan Hopkins1, Rachel Freeman1

1Public Health England, London, United Kingdom

Background: Escherichia coli is the commonest cause of urinary tract infections (UTI) in England. Unsuccessful treatment of UTI may allow progression to an invasive bloodstream infection (BSI).

An increase in trimethoprim resistance detected in E. coli UTI informed the recommendation to use nitrofurantoin as first-line treatment for uncomplicated UTI in national guidelines. To encourage behavioural change consistent with this recommendation, a national antimicrobial stewardship program, Quality Premium (QP), was introduced in 2017/18 to measure trimethoprim-to-nitrofurantoin prescribing from April 2017 and trimethoprim prescribing in patients over the age of 70 years from April 2018. The QP was associated with a financial incentive for primary care coordinating bodies for meeting targets.

The aim of the study was to investigate the impact of the QP on the incidence of E. coli community-onset BSI (COBSI) and trimethoprim-resistant COBSI.

Materials/methods: The ratio of trimethoprim-to-nitrofurantoin items prescribed was calculated from dispensed public prescriptions [via National Health Service Business Services Authority].

E. coli COBSI were defined as infection episodes occurring within 48 hours of admission to a hospital in England. Data were extracted from the national mandatory surveillance system and linked to blood culture susceptibility data where available.

Interrupted time-series analysis was performed, adjusting for secular trend. The pre-intervention and post-intervention periods were defined as April 2015 to March 2017 and April 2017 to March 2019, respectively. Mean number of cases per month and associated confidence intervals (CI) were estimated using linear regression.

Results: The mean trimethoprim-to-nitrofurantoin ratio pre-intervention was 1.4, and reduced to 0.6 post-intervention. The observed number of E. coli COBSI increased by 9.0%, but the number of trimethoprim-resistant E. coli COBSI decreased by 30.1% pre- and post-intervention.

After adjustments, there were average reductions of 130 cases of E. coli COBSI (95% CI: reduction of 38 to 221, p=0.007) and 109 fewer cases of trimethoprim-resistant COBSI (95% CI: reduction of 74 to 144, p<0.001) per month.

Conclusions: The results demonstrate that the implementation of the national antimicrobial stewardship program was associated with decreased trimethoprim prescribing and increased nitrofurantoin prescribing in England. This was associated with a significant decrease in trimethoprim-resistant E. coli COBSI.

Abstract 2700

Study of the in vitro activity of cefiderocol in comparison to other antimicrobial agents against a collection of Acinetobacter baumannii clinical isolates from different geographical locations

Laura Muñoz\(^1\), Clara Ballesté\(^*1\), Ignasi Roca\(^1\), Jordi Vila Estape\(^2\)

\(^1\)Hospital Clinic - Universitat de Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, \(^2\)Hospital Clinic University of Barcelona, Department of Clinical Microbiology-CDB, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

**Background:** Cefiderocol, a catechol-substituted siderophore cephalosporin currently in late stage clinical development, combines rapid penetration into the periplasmic space via iron transport and increased stability to hydrolysis by all β-lactamase Ambler classes. This study provides additional data on the in vitro antimicrobial activity of cefiderocol and that of commercially available antibiotics against a defined collection of clinical multidrug and carbapenem-resistant Acinetobacter baumannii isolates.

**Materials/methods:** Antimicrobial susceptibility was tested using pre-prepared frozen 96-well microtiter plates containing twofold serial dilutions of: cefepime, ceftazidime-avibactam, imipenem-relebactam, ampicillin-sulbactam, meropenem, meropenem-vaborbactam, ciprofloxacin, minocycline, tigecycline, trimethoprim-sulfamethoxazole and colistin using standard broth microdilution procedure in cation-adjusted Mueller-Hinton broth (CAMHB). For cefiderocol iron-depleted CAMHB was used and prepared following CLSI-approved methodology. A collection of 114 clinical strains of A. baumannii from Argentina, Azerbaijan, Croatia, Greece, Italy, Morocco, Mozambique, Peru and Spain were selected.

**Results:** Minimum inhibitory concentration (MIC, mg/L) for cefiderocol and comparators against Acinetobacter baumannii are represented in this table:

</table>

\*MIC\(_{50}\) and MIC\(_{90}\): MIC to inhibit growth of 50% and 90% of isolates, respectively.

Not included: ciprofloxacin and trimethoprim-sulfamethoxazole = MIC\(_{50}\) and MIC\(_{90}\) >8.

Available CLSI breakpoints were applied to determine categories (susceptible, intermediate and resistant).
Conclusions: Almost 80% of isolates showed susceptibility to cefiderocol suggesting it as a good alternative to treat infections caused by *A. baumannii*, including carbapenem-resistant strains, as 76% of meropenem-resistant isolates were susceptible to the new drug.

Concordance of early and late endpoints for community-acquired bacterial pneumonia (CABP) trials

Stephen Bart*,1, Sumathi Nambiar1, Ramya Gopinath1, Daniel Rubin1, John Farley1

1Food and Drug Administration, Silver Spring, Maryland, United States

Background: While there are ongoing efforts to align regulatory requirements for antibacterial drug development, differences in recommendations for CABP trial endpoints remain. The US Food and Drug Administration recommends an early clinical endpoint (3-5 days), when historical data suggests the difference between treated and untreated subjects is greatest. The European Medicines Agency recommends assessment of overall clinical response at a test-of-cure visit after the end of therapy.

Materials/methods: We analyzed subject-level data from six recent CABP trials submitted to the FDA [n=4,645 subjects] to compare concordance between clinical outcomes at the early and late endpoints and to evaluate reasons for discordance.

Results: Clinical outcomes from early and late endpoints were concordant for 85.5% of subjects. The fraction of early responders that ultimately failed was similar to the fraction of early non-responders that ultimately succeeded (6.0% vs 8.5%, respectively). The early endpoint had a high positive predictive value (92.9%) of success at the late endpoint, with a negative predictive value of 46.2%. Multivariate logistic regression modeling found early endpoint responders/late endpoint failures were more likely to be obese, be infected with Chlamyphila pneumoniae or Staphylococcus aureus, have received antibacterial drug therapy prior to randomization, and have severe chest pain at baseline, while less likely to be North American or have sputum production at baseline. Worsening chest pain was highly associated with failure among early endpoint responders (adjusted odds ratio 22.1). Reasons for failure differed among early responders and non-responders: early responders were more likely to fail later due to non-study antibacterial drug therapy or loss to follow-up, while early non-responders had higher odds of failure due to death or discontinuation after an adverse event.

Conclusions: Overall, clinical outcomes at early and late endpoints were highly concordant. Factors associated with failure among subjects exhibiting early improvement were identified. These data will help in the continuing efforts to align CABP clinical trial requirements to better support global antibacterial drug development.

Activity of imipenem/relebactam against non-Morganellaceae Enterobacterales and *Pseudomonas aeruginosa* isolates from 6 countries in western Europe: SMART 2016-2018

Nimmi Kothari¹, Stephen Hawser*¹, Sibylle Lob², Krystyna Kazmierczak³, Marcela González-Del Vecchio⁴, Katherine Young⁵, Mary Motyl⁴, Fakhar Siddiqui⁴, Dan Sahm⁶

¹IHMA, Monthey, Switzerland, ²IHMA, Schaumburg, United States, ³MSD, Madrid, Tres Cantos, Spain, ⁴Merck & Co., Inc., Kenilworth, United States

**Background:** Relebactam (REL) is an inhibitor of class A and C β-lactamas, including KPC, that was approved in the US in combination with imipenem (IMI) for treatment of complicated intraabdominal and urinary infections. We evaluated the activity of IMI/REL against non-Morganellaceae Enterobacterales (NME) and *Pseudomonas aeruginosa* (Psa) isolates collected in France, Germany, Italy, Portugal, Spain and the United Kingdom for the global SMART surveillance program.

**Materials/methods:** In 2016-2018, 36 hospitals in the indicated countries collected up to 250 consecutive gram-negative pathogens each year from various infection sources. For this analysis, only bloodstream (BSI) and respiratory tract infections (RTI) were studied. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints. US FDA breakpoints were applied to IMI/REL. Multidrug-resistance (MDR) was defined as nonsusceptibility (intermediate or resistant MIC using CLSI breakpoints) to ≥3 sentinel drugs: amikacin, aztreonam, cefepime, ceftazidime (NME only), ciprofloxacin, colistin, imipenem, and piperacillin-tazobactam. Isolates testing with IMI MIC ≥2 mg/L (NME) or ≥4 mg/L (Psa) were screened for β-lactamase genes.

**Results:** Because REL is not active against class B metallo-β-lactamas (MBLs), MBL-positive isolates were removed from susceptibility analyses. These isolates made up 0.3% (3/1024) and 0.4% (19/4417) of NME and 3.6% (4/111) and 1.5% (31/2004) of Psa isolates from BSI and RTI, respectively. KPC-positive isolates were detected in 2.1% of BSI and RTI isolates, ranging from 0% of isolates collected in France and Germany to 11.1% in Italy. The in vitro susceptibility to IMI/REL and comparators of MBL-negative NME, MBL-negative Psa, and resistant subsets are shown for isolates collected from patients with BSI and RTI (Table).

*US FDA breakpoints for IMI/REL: ≤1/4 mg/L, susceptible; 2/4 mg/L, intermediate; ≥24/4 mg/L, resistant (Enterobacteriales); ≤2/4 mg/L, susceptible; 4/4 mg/L, intermediate; ≥28/4 mg/L, resistant (Psa). EUCAST breakpoints for IMI/REL are currently under discussion.

**Conclusions:** IMI/REL was active against >96% of MBL-negative NME and >92% of MBL-negative *Psa*. Among KPC+ NME, susceptibility to IMI increased from ≤5% to >90% upon addition of REL, and among IMI-resistant *Psa* from 0% to ≥74%. For all MBL-negative NME and *Psa*, IMI/REL activity was exceeded only by amikacin or colistin; for KPC+ NME, IMI/REL showed the highest activity.

Abstract 2707

Biofilm formation of methicillin-resistant Staphylococcus aureus: does it vary with the type of infection?
Vanessa Silva*1, Luciana Almeida2, Sara Hermenegildo1, Nuno Cerca2, Jose Luis Capelo1, Gilberto Igrejas1, Patricia Poeta1

1University of Trás-os-Montes and Alto Douro, Vila Real, Portugal, 2University of Minho - Campus of Gualtar, Braga, Portugal, 3Universidade NOVA de Lisboa, Lisbon, Portugal

Background: Methicillin-resistant S. aureus (MRSA) has been recognized as a major health problem, in particular in hospital settings. MRSA infections are often associated with the emergence of biofilms and the risk of developing chronic infections. The biofilm phenotype has been identified in up to 80% of all non-acute infections and one of their most critical features is their considerably higher resistance to environmental stress, antimicrobials, disinfectants and host immune defenses. Therefore, we aimed to characterize MRSA strains recovered from different types of human infections and to evaluate their ability to form biofilm.

Materials/methods: Eighty-three MRSA strains were recovered from bacteremia episodes (n=13), osteomyelitis (n=42) and diabetic foot ulcers (n=28). The antimicrobial susceptibility testing was performed against 14 antimicrobial agents and according to EUCAST (2018) criteria. The capacity of biofilm formation of these strains was evaluated by the microtiter dish biofilm formation assay and, according to their level of biomass, they were classified as low, moderate or high biofilm-formers.

Results: Most of the strains were classified as multidrug resistant since they were resistance to 3 or more classes of antibiotics. The isolates were categorized as low, moderate or high biofilm-formers according to the cut-off values of ≤0.6, 0.6 to 1, and >1, respectively. Strains recovered from osteomyelitis had the higher biofilm forming ability. The majority of the strains (51.8%) were classified as moderate formers, followed by low (27.7%) and high biofilm-formers (22.9%).

Conclusions: Moderate biofilm formation was observed among MRSA strains recovered from different human infections which is alarming since biofilm formation is an important cause of treatment failure. The high prevalence of high biofilm-former strains implicated in osteomyelitis is a concern since surgical interventions are the most efficient way to treat biofilm-associated infections in bone.

Detection of Enterobacterales and associated antimicrobial resistance genes with the BIOFIRE FILMARAY Blood Culture Identification 2 (BCID2) panel

Jeremiah Antosch*1, David Judd1, Jessica Stone1, Kerrin Koch1, Tanner Robinson1, Iryna Kavetska1, Briana Flaherty1, Maggie Buccambuso1, Kristen Holmberg1, Yang Lu1, Margarita Rogatcheva1, Usha Spaulding1

1BioFire Diagnostics LLC, Salt Lake City, United States

Background: Enterobacterales are a common cause of bloodstream infections (BSI), and the dissemination of extended-spectrum beta-lactamases (primarily CTX-M) and important carbapenemases (IMP, KPC, NDM, OXA-48, and VIM) among the Enterobacterales is associated with increased morbidity and mortality. The BioFire® FilmArray® Blood Culture Identification 2 (BCID2) Panel builds upon the existing BioFire® FilmArray® Blood Culture (BCID) Panel by addition/modification of assays for the rapid detection of bacteria, yeast, and select antimicrobial resistance (AMR) genes in positive blood culture (PBC). This study evaluated the expanded coverage of the updated assays for Enterobacterales (7 species-level and 2 pan-reactive) and 6 associated AMR genes.

Materials/methods: Reactivity and specificity of these assays were evaluated using in silico sequence data and pure-culture isolates. Concordance with reference methods was examined for 1,074 residual PBC samples collected from US and European clinical laboratories, with pathogen detections compared to routine culture and AMR gene detections compared to routine antimicrobial susceptibility testing (AST) in conjunction with molecular assays.

Results: The in silico assessment indicated reactivity with 207 species, representing 46 genera from 7 families of Enterobacterales as well as nearly all known alleles of AMR genes. Analytical testing confirmed reactivity with 108/108 available species, representing 31 genera from 5 families, as well as the detection of CTX-M (16 types, 12 hosts), IMP (6 types, 3 hosts) KPC (7 types, 9 hosts), NDM (4 types, 4 hosts), OXA-48 (5 types, 4 hosts), and VIM (3 types, 3 hosts) genes. Prospective testing detected 27 species of Enterobacterales in 269/1,074 PBC, with associated detections of CTX-M (46, 3 hosts), KPC (4, 1 host), NDM (1, 1 host), and VIM (4, 2 hosts) genes and demonstrated excellent concordance with reference methods. 2/2 false positive results were resolved with sequencing, and 1/1 false negative result is currently under investigation. No cross-reactivity was observed in analytical or prospective testing.

Conclusions: The BioFire BCID2 Panel will detect a wide variety of clinically relevant Enterobacterales, indicate the carriage of select AMR gene(s) when present, and is expected to aid timely and effective antimicrobial therapy.

Data presented are from assays that have not been cleared or approved for diagnostic use.

ART24, a novel live biotherapeutic product, in development for the prevention of Clostridioides difficile infection is active against a broad range of C. difficile ribotypes in vitro

James Hegarty*,1, Michelle O’donnell1, Bran Healy1, Colin Hill1, Paul Ross2, Mary Rea1, Ronald Farquhar1, Laurent Chesnel3

1Artugen therapeutics, Teagasc Food Research Centre, Fermoy, Ireland, 2University College Cork, APC Microbiome Institute, Cork, Ireland, 3Artugen therapeutics USA, Inc, Concord, United States

Background: ART24 is being investigated as a live biotherapeutic product (LBP) treatment to prevent recurrence of Clostridioides difficile infection (CDI) following successful antibacterial therapy. ART24 was isolated from a human fecal sample, identified, and purified. ART24 is a member of the B. amyloliquefaciens/B. velezensis group. ART24 was found from a screening effort aimed at identifying bacteria from stool samples with direct C. difficile killing activity. The data presented here sought to investigate the broad range of activity against contemporary clinical isolates of various ribotypes.

Materials/methods: The ART24 strain was assayed for anti-C. difficile activity against a panel of 42 contemporary C. difficile isolates (25 distinct ribotypes) using an agar well diffusion method. Cell-free supernatants from fresh cultures and isopropanol extracts from lyophilized cells were tested for direct C. difficile growth inhibition. To further characterize ART24 and its anti-C. difficile activity, the effect of 20mg/ml proteinase K and gastrointestinal enzymes (chymotrypsin, trypsin) was investigated using cell-free supernatants. C. difficile agar plates were incubated in the anaerobic chamber overnight (18-24 hours) and analyzed for the presence of zones of clearing and measurement of the zones around the application of ART24 samples.

Results: Cell-free pH-neutralized supernatants from freshly grown ART24 as well as isopropanol extracts from resuspended lyophilized ART24 inhibited all 25 ribotypes of C. difficile tested. There was no difference in the zone size/activity of pH-neutralized supernatants from freshly grown ART24 and the IPA extracts from reconstituted lyophilized ART24 capsule content.

The antimicrobial activity from cell-free pH-neutralized supernatants from freshly grown ART24 was found to be resistant to the high level of gastrointestinal enzymes tested. The levels used were 20x greater than the average normal used [1mg/ml] for testing bacteriocins. Specific re-testing with proteinase K using dilutions of ART24 cell-free supernatant also showed resistance suggesting that the anti-C. difficile activity is not related to peptides.

Conclusions: In conclusion, ART24 exhibits protease-resistant anti-C. difficile activity against a broad range of contemporary C. difficile isolates including clinically relevant isolates of various and clinically relevant ribotypes. ART24 is a promising LBP candidate in Phase 1 clinical development for the prevention of CDI recurrence.

In vitro activity of ceftolozane-tazobactam against Enterobacterales and Pseudomonas aeruginosa from patients with bloodstream infections in the Asia/Pacific region: SMART 2018

Sibylle Lob1, Krystyna Kazmierczak4*, Wei-Ting Chen2, Tsz Kin Khan3, Katherine Young4, Mary Motyl4, Dan Sahm1

1IHMA, Schaumburg, United States, 2MSD, Taiwan, Taipei, Taiwan, 3MSD, Hong Kong, Hong Kong, Hong Kong, 4Merck & Co., Inc., Kenilworth, United States

Background: Ceftolozane/tazobactam (C/T) is an antipseudomonal cephalosporin combined with a β-lactamase inhibitor. C/T has been approved by the FDA and EMA for complicated urinary tract infections, complicated intraabdominal infections, and hospital-acquired and ventilator-associated bacterial pneumonia. Using isolates collected in Asia/Pacific as part of the global SMART surveillance program, we evaluated the activity of C/T and comparators against Enterobacterales and P. aeruginosa (PA) from patients with bloodstream infections (BSI).

Materials/methods: In 2018, 42 clinical laboratories in Australia, Hong Kong, India, South Korea, Malaysia, New Zealand, Philippines, Taiwan, Thailand, and Vietnam each collected up to 50 consecutive aerobic or facultative gram-negative pathogens from BSI for a total of 1898 isolates. MICs were determined using CLSI broth microdilution and interpreted with EUCAST breakpoints. Isolates testing with C/T MIC ≥4 mg/L [Enterobacterales] or ≥8 mg/L [PA] (excluding all isolates from India and Enterobacterales from one site in Taiwan) were screened by PCR and sequencing for genes encoding β-lactamases.

Results: The 5 most common species collected were E. coli (n=880, 46.4%), K. pneumoniae (n=397, 20.9%), P. aeruginosa (n=127, 6.7%), A. baumannii (n=99, 5.2%), and E. cloacae (n=53, 2.8%). The activity of C/T and comparators against Enterobacterales and PA is shown in the table.

Among 121 molecularly characterized Enterobacterales isolates with C/T MIC ≥4 mg/L, 24.0% carried metallo-β-lactamases (MBL), 4.1% carried OXA-48-like carbapenemases, 1.7% carried KPC, and 52.9% carried only extended-spectrum β-lactamases (ESBL) and/or acquired AmpC. No acquired β-lactamases were detected in 17.4% of characterized isolates, of which 85.7% were species with intrinsic AmpC. Among 10 molecularly characterized C/T-resistant PA, 9 characterized MBL and in one no acquired β-lactamases were detected.

Conclusions: In Asia/Pacific, C/T was active against >87% of Enterobacterales from BSI (activity only exceeded by carbapenems, amikacin, and colistin) and against 99% of PA isolates [activity only exceeded by colistin]. C/T could provide an important treatment option for patients with BSI in the Asia/Pacific region.

Abstract 2714

Crimean–Congo haemorrhagic fever in pregnancy: a systematic review and meta-analysis of clinical presentation and maternal and foetal outcomes

Nzelle Kayem*, Christina Aye‡, Charlotte Benson‡, Sarah Baker‡, Mariana Tome‡, Stephen Kennedy‡, Proochista Ariana*, Peter Horby‡

*University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, ‡University of Oxford, Nuffield Department of Women’s & Reproductive Health, Oxford, United Kingdom, †John Radcliffe Hospital, Women’s Centre, Headington, United Kingdom, £Stoke Mandeville Hospital, Aylesbury, United Kingdom

Background: Crimean–Congo haemorrhagic fever (CCHF) is an arboviral infection with an extensive geographic distribution. It is known to cause severe and often fatal infection in man. While there are several reviews narratively summarizing evidence on CCHF in pregnancy, the evidence is often aggregated, failing to account for differences in sample sizes. Here, we critically appraise and synthesize evidence on the effects of CCHF in pregnancy.

Materials/methods: A search of clinical trial registries and bibliographic databases from their respective dates of inception to September 30, 2019, was conducted using a combination of MeSH terms and keywords. There were no language restrictions. Individual patient data were extracted to generate proportions and statistical analyses using the Freeman-Tuckey double arc-sine transformation were conducted in R.

Results: Our comprehensive review yielded 20 studies, which reported 48 pregnant women with CCHF. All of the studies were descriptive and most of these studies were methodologically robust with an overall fair or good quality rating. Key clinical features for CCHF in pregnancy were fever 98·0% (95% CI 82·2 – 100·0%, I²=0%, P=0.4) and vaginal bleeding 25·0% (95%CI 5·9-49·5%, I²=3%, P=0.36). These estimates were precise with no evidence of between-study heterogeneity. The absolute risk of foetal loss due to maternal CCHF was estimated at 47·03% (95% CI= 22·80 to 71·88%, I²= 3·81%, P=0·35, see figure) and maternal death was 16·75% (95% CI 2·00 to 44·36%, I²=30·05%, P=0·239). However, only three studies were included in the proportional meta-analysis with very small sample sizes ranging from five to eight pregnant women and the estimates are imprecise due to the wide confidence intervals.

Conclusions: While this evidence suggests that CCHF in pregnancy is characterized by vaginal bleeding and is associated with high rates of maternal and foetal death, the data is completely descriptive. Additionally, the estimates are unreliable due to the small sample sizes and may be further confounded by the inclusion of more severe cases; underscoring the need for large prospective studies to obtain a more precise estimate on the burden of CCHF in pregnancy.

PROSPERO protocol number CRD42018097022

Figure: Proportional meta-analysis forest plot for foetal loss from maternal CCHF

Evaluation of omadacycline alone and in combination with rifampin against biofilm-producing Staphylococcus aureus and Staphylococcus epidermidis

Taylor Morrisette1*, Katherine Lev1, Razieh Kebriaei2, Jacinda Abdul-Mutakabbir1, Michael J. Rybak1

1Wayne State University, Anti-Infective Research Laboratory, Detroit, United States

Background: Indwelling medical devices with associated infections represent a substantial cause of morbidity. Two common pathogens associated with these infections include Staphylococcus aureus and Staphylococcus epidermidis (common biofilm-producing bacteria). Owing to treatment failures with biofilm-associated infections, novel therapeutic approaches are urgently needed. Omadacycline (OMC), an aminomethylcycline, is highly active against S. aureus and S. epidermidis. However, there is little information on OMC activity against common biofilm-producing organisms associated with infections of implants. The objective of this study was to evaluate OMC alone and in combination with rifampin (RIF) against biofilm-producing strains of S. aureus and S. epidermidis.

Materials/methods: Eight randomly selected strains of S. aureus (five strains, three MRSA) and S. epidermidis (three strains) with variations in susceptibility to OMC and RIF were evaluated. Synergy was assessed by evaluating fold-reduction change in OMC minimum inhibitory concentration (MIC) with combination MIC and combination biofilm MIC (bMIC) testing for all strains in the presence of 0.5x MIC of RIF and 24-hour biofilm time-kill analyses (TKA) for one strain of S. aureus (N315) and S. epidermidis (NRS101) at 0.5x and 1x bMIC. In TKAs, synergy (≥ 2-log10 CFU/mL kill compared to the most effective agent alone at 24 hours) and bactericidal activity (≥ 3-log10 CFU/mL reduction at 24 hours compared to the starting inoculum) were evaluated.

Results: OMC demonstrated potent activity with low MICs against the evaluated strains (0.125-0.5 mg/L), with a slight increase of MICs in the presence of biofilm (0.25-2 mg/L). In the planktonic state, RIF reduced OMC MICs in 60% of S. aureus strains (1- to 2-fold) and 33% of S. epidermidis strains (1-fold), while RIF reduced OMC bMICs in 100% of S. aureus strains (2- to 3-fold). RIF did not impact OMC bMICs for the evaluated S. epidermidis strains. However, at 0.5x and 1x bMIC, synergy (>2.3 log10 CFU/mL reduction compared to RIF) and bactericidal activity (>4 log10 CFU/mL reduction), respectively, were observed against NRS101 with OMC and RIF combination. Furthermore, synergy was demonstrated at 1x bMIC against N315.

Conclusions: Based on these results, further research is needed to evaluate the combination of OMC and RIF for biofilm-associated infections.

Abstract 2716

**Antibiotic prescription practices in primary care in low- and middle-income countries: a systematic review and meta-analysis**

Giorgia Sulis*1,2, Pierrick Adam1,2, Vaidehi Nafade1,2, Genevieve Gore1, Benjamin Daniels3, Amrita Daftary2,3,5, Jishnu Das4, Sumanth Gandra6, Madhukar Pai1,2,7

1McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, 2McGill University, McGill International TB Centre, Montreal, Canada, 3McGill University, Schulich Library of Physical Sciences, Life Sciences and Engineering, Montreal, Canada, 4Georgetown University, McCourt School of Public Policy, Washington, D.C., United States, 5York University, School of Health Policy and Management, Toronto, Canada, 6Washington University School of Medicine, Division of Infectious Diseases - Department of Medicine, St. Louis, MO, United States, 7Manipal Academy of Higher Education, Manipal McGill Program for Infectious Diseases, Manipal Centre for Infectious Diseases, Manipal, India

**Background:** Despite the well-known role of antibiotics in the development of antimicrobial resistance, important knowledge gaps still exist regarding the extent of their use in low- and middle-income countries (LMICs), particularly at the community level.
